In this paper we focus on human delegation where a user delegates a part of his responsibilities to another user. This can be done directly or through membership to roles. These issues of delegation were informally discussed previously in [10]. We identified three main kinds of delegation: actor-to-actor, actor-to-role and role-to-role delegation. Each of them can be based on roles, functions and/or operational goals. In this paper, we study in depth these issues. To the original work, we add some extensions which enhance the effectiveness and the totality of our approach.

In summary, our research provides the following contributions:

- Delegation addressed in this paper can be based not only on functions, roles and operational goals as proposed in [10], but also on more coarse-grained

responsibilities (business processes and business goals) as required. This kind of delegation requires more confidence and autonomy of the delegatee.
- Current approaches focus only on Who, What and Whom facets of the delegation and omit the Why and How ones. In this paper, we discuss also the latter ones. The Why facet controls and justifies the delegation activities.
- We provide a meta-model including all concepts useful to define delegation capabilities, and we formalize their semantics by the means of formal logic.

This paper is the first attempt to model delegation of multi-level responsibilities in the context of business process flexibility.

3. MULTI-LEVEL DELEGATION MODEL

In order to satisfy the flexibility requirements related to business process modeling, we introduce in this section a new delegation model based on multi-level responsibilities. The proposed model reuses basic concepts introduced in [10] and extends them with new concepts. We will first present a summary of the basic concepts; then, we introduce the new concepts related to delegation. Examples used throughout the paper for illustrating concepts concern the loan handling process in a bank.

3.1. Overview of the Role-Based Approach for Modelling Flexible Business Processes

The central concepts in our approach are the role and the function. A role can represent competency to realize particular functions, e.g. "an engineer", and can embody authority and responsibility, e.g., "a project supervisor". A role can be responsible for the achievement of a business_process (BP) or a business goal. A function (i) is a collection of operational goals satisfied by performing operations, (ii) is hold by one role, and is a part of a BP. An organization is structured as a network of BPs in order to achieve business_goals. A business_goal is achieved by performing a BP which comprises many functions. An actor belongs to organizational_units, can play several roles based on his responsibilities and qualifications and performs functions specifying work steps in a BP. Organizational_units can be firm's branches or describe firms collaborating to achieve common processes.

$ACTORS,\ ROLES,\ FUNCTIONS,\ O\_GOALS,\ OPERATIONS,\ BPS,\ B\_GOALS,\ ORG\_UNITS$

define sets of actors, roles, functions, operational goals, operations, business processes, business goals and organizational units, respectively.

Let

$a \in ACTORS,\ r,\ r_1,\ r_2 \in ROLES,\ f \in FUNCTIONS,\ op \in O\_GOALS, o \in OPERATIONS,\ bp \in BPS,$
$bg \in B\_GOALS,\ ou \in ORG\_UNITS$

$Can\_play(a,r)$ means that a can play r.
$Comprises(f, op)$ means that f comprises op
$Satisfies(op, o)$ means that op is satisfied by achieving o.
$is\_responsible(r, bg)$ means that r is responsible for the achievement of bg.
$is\_responsible(r, f)$ means that r is responsible for the performance of f.
$Participates(r, f)$ means that r participates in the achievement of f by performing some operations satisfying operational goals of f.
$Comprises(bp, f)$ means that bp comprises f.

3.2. Facets of the Multi-level Delegation Model

We now introduce the supplementary components related to delegation. As mentioned in Section 2, we define five facets of the delegation capturing these questions:

- Who delegate the responsibility?
- To Whom the responsibility is delegated?
- What is the delegated responsibility?
- Why delegation takes place?
- How delegated work should be performed?

These facets are represented respectively by the entities: *Delegator, Delegatee, Responsibility, Context, Instructions.*

An actor can delegate parts of his responsibilities to another actor which performs these responsibility parts; this can be done directly or through membership to roles. Delegation is controlled by the means of the relation Can_delegate: a 5-tuple with five attributes representing the five facets. $Can\_delegate(dtor, dte, resp, c, i)$, means that dtor (or the members of dtor if dtor is a role) can delegate the responsibility resp to dtee (or the members of dtee if dtee is a role) in the context c, forcing the achievement instructions i. Throughout the paper we will use the terms dtor, dte, resp, c and i to denote the actors/roles involved in the delegation (delegator and delegatee respectively), the responsibility to delegate, the context of the delegation, and recommendations or directives to be provided by the delegator to the delegatee.

An actor can take part in more than one delegation in different roles. In addition we extend the relation Can_hold [10] by two new relations between the entities Role and Function, which are Is_responsible and Participates. Similarly, two new relations are defined: Is_responsible, between the entities Role and Business_process, and between Role and Business_goal respectively. We will discuss these concepts.

- Who and whom facets: Our model supports individual delegation as well as role-based delegation. The delegator and the delegatee can be either actors or roles. Then, it is possible to define role-to-role, actor-to-actor and actor-to-role delegations. We assume that it is no significant to define role-to-actor delegation.
- What facet: The delegated responsibility can be at different levels of refinement (operational_goal, function, role, BP, business_goal).
- Why facet: The fourth facet is the context of delegation which answers the question "Why the responsibility is delegated". Context can be: unplanned absence, illness, leave, collaborative work, saving of time, lack of resources, decentralization of work, conflict of duties, etc. Responsibilities that an actor can delegate to another actor can differ depending of the context of delegation. For instance, a loan manager can delegate the function "Offer_validating" to his assistant in the context of "Lack_of_resources" or "Absence", but not in the context of "Conflict_ of_duties".
- How face: The last facet defines the way of specifying "How to achieve the delegated responsibility?" The delegator has to provide it to the delegatee. Confidence allowed to the delegatee depends on his/her competency, autonomy and experience. Delegation requires that the delegatee has sufficient experience and capacity to perform work. It may also give the delegatee some new responsibilities. The delegatee is responsible for performing the delegated work. The delegator is responsible for ensuring that the work was well carried out.

There are several ways of delegating a work. The delegatee may have no autonomy; he/she has to precisely follow delegator directives for achieving the delegated work. The delegator can give some recommendations but it is in the responsibility of the delegatee to decide how the delegated work is fulfilled. The delegator can also delegate a work without any recommendation, this requires a high level of confidence and analysis on behalf of the delegatee which has total autonomy, and he/she decides and acts without contacting the delegator.

For example, if the "Loan_manager" delegates the function "Loan_handling" to the "Loan_assistant", he/she can precise some recommendations for its achievement.

Recommendations and directives are defined by the delegator. They can be fine or coarse-grained, planned or ad-hoc. If they are coarse-grained, the delegatee has to enforce and refine them.

3.3. The Meta-Model of Delegation

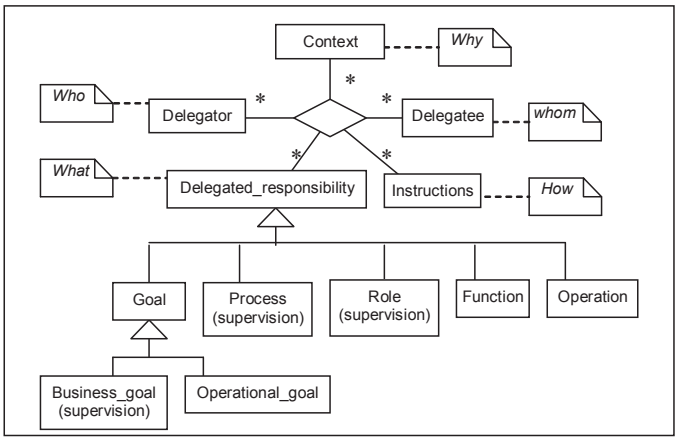
The meta-model of our delegation framework is represented by an UML diagram in Figure 1.

We represent now the delegation formally:

$DELEGATORS, DELEGATEES, D\_RESPONSIBILITIES, CONTEXTS, INSTRUCTIONS$

are set of delegators, delegatees, delegated responsibilities, contexts and ways.

Figure 1. Meta-model of delegation



$DELEGATORS \subseteq ACTORS \cup ROLES$, $DELEGATEES \subseteq ACTORS \cup ROLES$,

$D\_RESPONSIBILITIES \subseteq B\_GOALS \cup B\_GOALS \cup ROLES \cup FUNCTIONS \cup B\_GOALS \cup OPERATIONS$

$INSTRUCTIONS = \{$, *"Recommendations", "Directives"*$\}$

We now represent formally rules expressed by our model:

$\forall r, r_1, r_2 \in ROLES, f \in FUNCTIONS, p \in B\_GOALS, o \in OPERATIONS, \forall dtor \in DELEGATORS,$
$dtee \in DELEGATEES, resp \in D\_RESPONSIBILITIES, \forall c \in CONTEXTS, w \in WAYS, i \in INST$

Hypothesis 1
If dtor can delegate f to dtee, then dtor can delegate any operational_goal comprised in f to dtor, he/she can also delegate any operation associated with that operational_ goal to dtee.

$Can-delegate(dtor, dte, f, c, i) \wedge Comprises(f, p) \rightarrow Can-delegate(dtor, dte, p, c, i)$
$Can-delegate(dtor, dte, f, c, i) \wedge Comprises(f, p) \wedge satisfies(o, p) \rightarrow Can-delegate(dtor, dte, o, c, i)$

Hypothesis 2
If dtor can delegate his/her responsibility of achieving bp to dtee, then dtor can delegate any function f comprised in BP to dtee. He/she can thus, according to hypothesis 1, delegate to dtee any operation and any operational_ goal associated to f.

$Can-delegate(dtor, dtee, bp, c, i) \wedge comprises(bp, f) \rightarrow Can-delegate(dtor, dtee, f, c, i)$

Hypothesis 3
If dtor can delegate bg to dtee, then dtor can delegate to dtee any bp reaching bg. He/she can thus, according to hypothesis 2, delegate to dtee any function associated to bp.

$Can-delegate(dtor, dte, bg, c, i) \wedge reachs(bg, bp) \rightarrow Can-delegate(dtor, dte, bp, c, i)$

Hypothesis 4
We suppose that role-to-actor delegation is not possible and express this rule as follows:

$\neg Can-delegate(dtor, dte, resp, c, i) \wedge dtor \in ROLES \wedge dte \in ACTORS$

Examples of instantiation of the model:

$Can-delegate($" $loan\_manager$","$loan\_assistent$","$loan\_handling$",
$saving\_of\_time$","$recommendations$")

means that any actor who is member of the role "Loan_manager" can delegate the function "Loan_handling" to any actor who is member the role "Loan_ assistant" in the context of "saving of time" and the delegator has to provide recommendations to the delegatee.

3.4. The Delegation Process

In this section, we specify the different steps of a delegation. The delegator has to specify with respect to the predicate can-delegate (i) the responsibility to be delegated, (ii) the context of the delegation, (iii) a list of delegatees being able to receive the delegation in the determined context. The choice of the most appropriate delegatee is in the discretion of the delegator; it depends on the importance of the delegated responsibility and the delegatee competency. The selected delegatee should agree to receive the delegation. Once the delegatee is selected, both the delegator and the delegatee will agree on control and coordination methods which depend on the delegatee confidence, competency and autonomy.

Then, the delegator defines the directives or recommendations required for the enactment of the delegated responsibility. The refinement level of these recommendations or directives depends on the kind of the responsibility and the delegatee competency. Particular responsibilities should be carefully delegated. The delegatee has to refine the delegated responsibility following the delegator recommendations or directives. Some responsibilities require to be refined by the delegatee because each individual has his specific method to realize given tasks.

Supervising the delegation : in some cases, the delegator has to supervise the progress states of the delegated parts of the responsibility. In other cases, the delegatee does not have to return to the delegator the intermediary inputs and outputs associated with the delegated responsibility. Thus the delegatee has to contact the delegator when the delegated responsibility is achieved.

In all cases, once the delegated responsibility is achieved, the delegator can revoke the delegation and have to measure the quality of the achieved work. We represent in Figure 2 the algorithm capturing the main phases of the delegation process. Metrics can be used to measure the variance between the required results and the obtained ones. Then, the delegator can decide to improve the obtained results. These aspects are out of the scope of this paper and will be discussed in a future work.

3.5. Illustration

For illustrating the semantics of our model, we use the case of a loan handling process in a bank.

Figure 2. Algorithm of delegation

Algorithm1. The delegation process

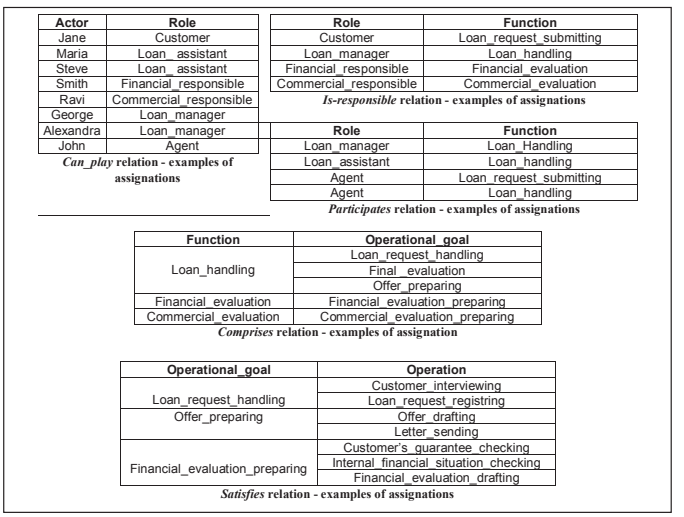
INPUT: $dtor_i \in DELEGATORS, resp_j \in D\_RESPONSIBILITIES, c_k \in CONTEXTS$

Let *Establish-dtee* a function which, for a given 3-tuple $(dtor_i, resp_j, c_k)$ return a sorted list $\{(dte_l, inst_m)\}$ such that $dte_l \in DTE, inst_m \in INST$ and $can-delegate(dtor_i, dte_l, resp_j, c_k, inst_m)$.

BEGIN
$List-dte \leftarrow Establish-dte(dtor_i, resp_j, c_k)$
if $List-dte \neq \emptyset$
  $path \leftarrow 1$
  while $path \neq 0$ **do**
    If $agree(List-dtee[path])$
    $path \leftarrow 0$
    endif
  endwhile
endif

if $List-dte = \emptyset$ or $path = length(List-dte)$
$Success-delegation \leftarrow false$

Figure 3. Examples of assignations



Actor	Role
Jane	Customer
Maria	Loan_ assistant
Steve	Loan_ assistant
Smith	Financial_responsible
Ravi	Commercial_responsible
George	Loan_manager
Alexandra	Loan_manager
John	Agent

***Can_play* relation - examples of assignations**

Role	Function
Customer	Loan_request_submitting
Loan_manager	Loan_handling
Financial_responsible	Financial_evaluation
Commercial_responsible	Commercial_evaluation

***Is-responsible* relation - examples of assignations**

Role	Function
Loan_manager	Loan_Handling
Loan_assistant	Loan_handling
Agent	Loan_request_submitting
Agent	Loan_handling

***Participates* relation - examples of assignations**

Function	Operational_goal
Loan_handling	Loan_request_handling
	Final _evaluation
	Offer_preparing
Financial_evaluation	Financial_evaluation_preparing
Commercial_evaluation	Commercial_evaluation_preparing

***Comprises* relation - examples of assignation**

Operational_goal	Operation
Loan_request_handling	Customer_interviewing
	Loan_request_registring
Offer_preparing	Offer_drafting
	Letter_sending
Financial_evaluation_preparing	Customer's_guarantee_checking
	Internal_financial_situation_checking
	Financial_evaluation_drafting

***Satisfies* relation - examples of assignations**

A customer's loan request is accepted only if its features are compatible with the financial and commercial strategies and interests of the bank.

The process starts by a customer loan request, then, an agent registers this request, which will be next evaluated by both the financial and commercial departments. The first evaluation is performed by the financial person responsible and involves financial aspects related to both the customer and the bank, for instance, the guarantees provided for refunding the loan. The commercial evaluation is performed by the commercial responsible and involves commercial aspects like the possibility to acquire new regular customers and is performed by a loan manager.

Basing on the commercial and the financial evaluation, the loan manager performs the final evaluation and he may reject the request; in this case an agent writes the refusal letter. He/she may also propose a counterproposal which will be prepared by the loan manager's assistant. He/she may as well accept the request, then the loan manager's assistant establishes a complete proposition including the duration, the amount, the interest rate, the refunding instructions, etc. We provide some assignation examples in Figure 3.

Roles involved in this process are:

$$"Customer",\ "Financial\_responsible",\ "Commercial\_responsible",$$
$$"Loan\_manager",\ "Loan\_assistent",\ "Agent"$$

In the following, we present a possible instantiation of the delegation model.

$$BUSINESS\_PROCESSES = \{"Loan\_handling"\}$$

$$ACTORS = \{"Jane","John","Maria","Steve","Smith","Georges","Alexandra","Ravi"\}$$

$$ROLES = \begin{Bmatrix} "Customer","Agent","Loan\_manager","Loan\_assistent","Financial\_responsible", \\ "Commercial\_responsible" \end{Bmatrix}$$

$$FUNCTIONS = \begin{Bmatrix} "Loan\_request\_submitting","Loan\_handling", \\ "Financial\_evaluation","Commercial\_evaluation" \end{Bmatrix}$$

$$\theta\_GOALS = \begin{Bmatrix} "Loan\_request\_handling","Commercial\_evaluation\_preparing", \\ "Financial\_evaluation\_preparing","Commercial\_evaluation\_preparing" \end{Bmatrix}$$

$$OPERATIONS = \begin{Bmatrix} "Customer\_interviewing","Loan\_request\_registring", \\ "Customer's\_garantee\_checking","Internal\_financia\_situation\_checking", \\ "Financial\_evaluation\_drafting","Condition\_evaluating", \\ "Couterproposal\_drafting","refusal\_letter\_drafting","Offer\_drafting" \\ "Letter\_sending" \end{Bmatrix}$$

$$Can\_play("Jane","Customer"),$$
$$Can\_play("Smith","Customer"),$$
$$Can\_play("John","Agent"),$$
$$Can\_play("Maria","Loan\_assistent")$$
$$Can\_play("Steve","Loan\_assistent")$$
$$Can\_play("Smith","Financial\_responsible")$$
$$Can\_play("Georges","Loan\_manager")$$
$$Can\_play("Alexandra","Loan\_manager")$$
$$Can\_play("Ravi","Commercial\_responsible")$$

$$Is\_responsible\_for("Customer","Loan\_request\_submitting")$$
$$Is\_responsible\_for("Loan\_manager","Loan\_handling")$$
$$Is\_responsible\_for("Financial-responsible","Financial\_evaluation")$$
$$Is\_responsible\_for("Commercial-responsible","Commercial\_evaluation")$$

$$Participates("Loan\_manager","Loan\_handling")$$
$$Participates("Loan\_assistent","Loan\_handling")$$
$$Participates("Agent","Loan\_handling")$$
$$Participates("Agent","Loan\_request\_submitting")$$

$$Comprises("Loan\_handling","Loan\_request\_handling")$$
$$Comprises("Loan\_handling","Final\_evaluation")$$
$$Comprises("Loan\_handling","Offer\_preparing")$$

$$Satisfies("Loan\_request\_handling","Customer\_interviewing")$$
$$Satisfies("Loan\_request\_handling","Loan\_request\_registring")$$
$$Satisfies("Offer\_preparing","Offer\_drafting")$$
$$Satisfies("Offer\_preparing","Letter\_sending")$$
$$Satisfies("Financial\_evaluation\_preparing","Internal\_financial\_situation\_evaluating")$$
$$Satisfies("Financial\_evaluation\_preparing","Financial\_evaluation\_drafting")$$
$$Satisfies("Financial\_evaluation\_preparing","Customer's\_garantee\_checking")$$

We identify in the following some examples illustrating delegation.

Example 1.

$$Can-delegate("George","Maria","Loan\_manager","saving\_time","Rrecommendations")$$

This is an actor-to-actor delegation which means that "George" can delegate his role "Loan manager" to "Maria" in the context of "time_ saving", he has to give her recommendations.

This means also that "George" can delegate to "Maria" all functions, operational_ goals and operations associated with this role. Thus, "Maria" can perform these responsibilities as well as delegate some of them to other roles/actors participating in the functions of delegated role.

Example 2.

$$Can-delegate("George","Maria","Loan\_handling","Lack\_resources","Directives")$$

This is an actor-to-actor delegation which means that "George" can delegate the function "Loan_handling" to "Maria" in the context of "Lack_of_resources", he has to give her directives.

This means also that "George" can delegate to "Maria" all operational_goals and operations associated with this function.

Example 3.

Can – delegate(" *Loan _ manager*","*Loan _ assistent*","*Laoan _ manager*", "*Urgent _ situation*","*Directives*")

This is a role-to-role delegation which means that any actor member of the role "Loan_manager" can delegate this role to any actor member of the role "Loan_assistant", in the context of "Urgent_situation" and with directives

DISCUSSION

In our example, the "loan_manager" can create new operational_goals or functions if needed. For instance, with reference to his experience, he may judge that throughout the year, in particular periods, instead of delegating all the operations of the operational goal "Loan_request_handling" to an agent, he performs him-self the operation "Customer_interviewing" and only delegate the operation "Loan-request_registring" to an agent. Thus, after interviewing the customer, he may stop the process even before "loan_request_registering" if he judges that it is useless to continue the process and to perform the operation "Loan_request_registring" followed by the operational goal "Financial_evaluation_preparing", etc. knowing that in any way (even if the financial evaluation is positive), the loan request will be rejected. An agent can not take the decision of stopping the loan handling process in a beginning stage; the loan handler can do it. Stopping the process saves the time of the actors participating in the rest of the process including the financial responsible, the decision of the loan manager avoids him to perform a useless financial evaluation knowing that the commercial evaluation will stop the process later.

In other circumstances, the loan manager may prefer that the loan request handling be performed by his assistant rather than an agent, he may judge that the loan manager's assistant may, in the stage of loan request handling, be able to propose a counterproposal if needed, rather than taking this decision later, this is also time saving.

Furthermore, in this example, the business manager has only to specify the process phases on a coarse-grained level (as level process, goal and functions). The "Loan_manager" is responsible for the function "Loan_handling" has to enforce and refine the manager's specification in a lower level using operational_goals and operations.

For instance, the manager can only specify the steps of a process as top-level functions, the role holding each function of the process has to specify its achievement using operational goals and operations. However, if the manager identifies only processes allowing the achievement of a business goal, actors holding the role which is responsible for each business process have to define exhaustively functions representing the process steps. Nevertheless, he can delegate parts of this responsibility to other roles (for instance, specifying the steps as top-level operational goals and operations or the achievement of some function fragments consisting of a number of operational goals including their relationships).

4. CONCLUSION

In this paper we discussed the importance of delegation in flexibility and effectiveness of business processes, and we proposed a multi-level delegation model which supports three types of delegation (actor-to-actor, actor-to-role and role-to-role delegation), and five levels of delegated responsibility (role, function and operational_goal, business_goal and process). The ability to delegate responsibilities greatly simplifies the process management and control by decentralising management and decision-making.

The multi-level delegation proposed in this paper responds to actual requirements related to the decentralisation of decision-making by allowing actors to be more autonomous. Our approach meets also requirements of collaborative work. It resolves problems related to conflict of duties, lack of resources (e.g. time, equipment), unforeseen circumstances, such as unplanned absence (illness, leave) and actors' substitution.

The work presented in this paper is the first attempt to model delegation based on roles, functions, goals and processes.

Delegation mechanisms raise many issues which need further research such as:

- Controlling that delegation is not ill-advisedly used.
- Revocation of delegation.
- Management of delegation.
- delegation in the context of inter-organisational collaborative work
- Tool support.

An Optimal Query Execution Plan for Database Systems

Hassan Pournaghshband, Southern Polytechnic State University, USA; E-mail: hpournag@spsu.edu

Shahriar Movafaghi, Southern New Hampshire University, USA; E-mail: s.movafaghi@snhu.edu

ABSTRACT

A major decision for the query processor of the database management system in centralized as well as distributed environments is how a query can produce the result as efficiently as possible. The typical query optimizer will not necessarily produce an optimal query plan. It simply tries to find the best possible plan within a minimum amount of time using mostly semi-accurate statistical information. In this paper, we discuss major issues regarding query optimization for relational database management systems, and expand the optimization issues for distributed database systems (DDBSs) to show how the query optimizer can choose an optimal plan for efficient execution of those queries that require multiple-site participations for producing the result. An algorithm that can be used toward more efficient query processing is presented. Our algorithm examines frequently used queries, and identifies two categories of groups of queries. First, a group of queries requiring the same procedures (including operations used), and second, a group of queries requiring data from the same site (or set of sites) for producing the result

1. INTRODUCTION

Query processing in a database environment refers to a series of activities involved in updating and retrieving data from database and it can be divided into four major phases: decomposition phase (consisting of scanning, parsing and validation), optimization phase, code generation phase, and execution phase [1]. Even though in this paper, we are mainly concerned about optimization and related issues regarding this phase of query processing, we believe a brief examination of all phases can be valuable [also see references 2, 3, 4, and 5].

Decomposition (Scanning, Parsing, and Validation) – The job of the *scanner* is to identify the language tokens found in the query, whereas the *parser* checks the query syntax. *Validation* is done to make sure that all relations and their attributes are valid and meaningful.

Optimization –There are generally many different methods that can be used to process a query and compute the result. *Query optimization* is the process of choosing the most efficient strategy for computing the result.

Query Code Generation – Once an "optimal" execution plan is produced by the query optimizer, it is the job of the *code generator* to generate the code for executing the plan.

Query Execution – The runtime database processor is responsible for executing the code (generated by the query code generator), whether in compiled mode or interpreted mode, to produce the response to the query.

We now return our attention on query optimization which is the focal point of this paper. Query optimization sub-module of the query processing module in centralized as well as distributed environment has been a subject for significant research and development. The term *optimization* is in a sense a misnomer (as claimed in [4]) because in some cases the efficient execution plan selected by the query optimizer is not necessarily the optimal strategy, but it is in fact just a *reasonably efficient* strategy for executing the query [4]. Hence, when dealing with query optimization, it would necessary to examine plans for different execution strategies. The process of selecting the execution plan for a given query can be divided into several detailed plans such as designing an efficient algorithm for executing an operation, the order of executing relational algebra operations, choosing the specific indices to use, and so on. In addition, there are other issues that are of particular interest for a distributed environment that are discussed in the next section.

2. DISTRIBUTED QUERY PROCESSING

The query optimizer chooses the most efficient query execution plan at the relational algebra level. In other words, the query optimizer attempts to find a relational algebra expression that is equivalent to the given expression, but it is more efficient to execute. This issue of finding *equivalent expression* needs to be discussed in great details and it is beyond the scope of this paper. Interested readers are encouraged to see [5]. In a distributed environment there are essential aspects of the query processor that have to be considered alongside those for centralized databases [6]. While distributing data across different sites allows those data to reside where they are most needed, but it also makes them accessible from other sites. Therefore, to process a query initiated at one site, we might need to make some data movements among several sites. And since transmission of data and messages across communications lines has a tendency to slow down the whole process, the order of data movement (that is, what data from which site should be moved first, what data should be moved next, and so on) among sites must be considered as an essential aspect of query processing for distributed database systems. One other essential aspect, worthy to consider, regarding query optimization for distributed database systems is the existence of multiple processor in the network. This allows for parallel processing of queries (and sub-queries) and data transmission which could lead to a faster response [6]. In our approach, as we will see in Section 3, these issues play a vital role in producing the optimal execution plan.

3. "OPTIMAL" EXECUTION PLAN

In both, centralized and distributed database systems, it is the responsibility of the query optimizer to transform the query as submitted by the user into an equivalent query that can be executed more efficiently. To do this, the query optimizer estimates the evaluation cost of each strategy and decides if the chosen strategy has the least cost. One process in estimating the execution cost of a query is to estimate the result size of each operation in each possible execution sequence. This is of prime interest because the size of the intermediate relations plays a significant role in the performance of an execution strategy. Unfortunately, there is no general consensus on the method of estimating the size of intermediate results. Among different techniques that have been proposed in the literature the one that is given in [7] is based on the Discrete Fourier Transformation. Their algorithms present tradeoffs between accuracy of the approximation and memory requirements. The estimation of size of the intermediate relations is based on statistical information about the relations, their attributes, and indexes. One problem regarding this approach is that most systems do not update the statistics on every change. This could lead to inaccurate estimates, and thus selection of strategies far from optimal. An alternative approach has been examined in {8 and 9] and others. Discussion of their approach, which in fact is dynamic query execution, is beyond the scope of this study.

The selection of a good strategy statically can be made effectively by the prediction of execution costs of the alternative plans prior to actually the executing the query. The execution cost is basically expressed as the combination cost of CPU, I/O and the communication costs (for distributed systems). In centralized systems, many cost functions ignore the CPU factor and emphasize on I/O cost. They compare different evaluation plans in terms of the number of block transfers between secondary storage and main memory. This (i.e., efficient memory management) has attracted the interest of many researchers such as [10, 11, and 12]. Whatever the cost factor (CPU or I/O, or both, plus communications for DDBSs), to estimate the cost for a given plan, the query optimizer estimates the cost of individual procedures making up the plan, and adds them together to get the total cost of

executing the query. The process of cost estimation for individual procedures is repeated for those procedures used in different execution plans, and thus, it could become a very time consuming task. To overcome this problem, authors in [13] suggest the design of a query optimizer that examines current queries and generates a master plan for each group of queries requiring the same set (or subset) of individual procedures. The task of identifying similar queries that can be grouped together can in turn become cumbersome if not done efficiently. The fact that in the distributed database system the data reside in different locations can be a cause of many difficulties in query processing and optimization. In a DDBS each site may initiate a query, and may access data at that site and/or at several other sites on the network. In fact, the query may be broken into a set of sub queries that must be executed in order to produce the result of the query. In our approach, for an efficient process, we design an optimizer which examines frequently used queries, and identifies the following two categories of groups of queries: 1) Groups of queries requiring the same procedures (including operations used), and 2) groups of queries requiring data from the same site (or set of sites) for producing the result. Each of these two categories of queries is explained below and an algorithm that generates these groups from a set of queries is given in Section 4.

1. Groups of queries requiring the same procedures (including operations used) - For these groups, the query optimizer generates a super-query execution plan for each group before breaking it into a set of sub queries for execution. Of course, as mentioned earlier, the task of grouping queries can become costly if not done efficiently. Since Join operation is one of the most time consuming and costly operations in query processing, we take into account the Join operation as the first criterion for grouping queries in this category. That is, the query optimizer must begin this process by grouping queries that have Join operation in common (i.e., Joining the same relations as their operand.) Next, the query optimizer identifies those queries that have in common, binary operations (other than the join) such as the Cartesian Product. Finally, it reviews the remaining queries to identify and group those queries that share the same predicates (or part of them for compound predicates) for Selection operation. For each of the above groups, the query optimizer combines participating queries into a super-query before breaking it into a set of sub-queries for efficient execution of each query member of the set.
2. Groups of queries requiring data from the same site (or set of sites) for producing the result - For these groups, the query optimizer generates a super query execution plan according to data being used, and then breaks it into a set of sub-queries (one sub-query for each site participating in the plan) for efficient execution of sub-queries. This minimizes the amount of data movement among sites. In addition, the nature of DDBSs and the existence of multiple processors in the network allows for parallel processing of these sub-queries and simultaneous data transmission between sites. This could significantly speed up the process of producing the result. Furthermore, the query optimizer can follow the same process discussed earlier for the first category of groups for even more efficient execution of these sub-queries. That is, each sub-query of a group in second category, can be treated as a *base* query of the first category. In other words, each sub-query of the second category becomes a super-query discussed for the first category of groups of queries.

4. THE ALGORITHM

This algorithm generates two groups of queries. A group of queries requiring the same procedures (including operations used) and a group of queries requiring data from the same site (or set of sites) for producing the result. It also generates a group of queries belonging to both of the above groups

The algorithm reads as its input a set of queries and generates as its output the sets of "groups" of queries discussed above.

Algorithm:

Input: A set of queries Q = {q1, q2, …, qn}.

Output: Three sets of groups of queries G_1, G_2 and G_3.

Step 1: Scan queries in Q to identify

a. those queries requiring the same relations that must be JOINed for producing the results. Call this set P (P is a subset of Q) and
b. those queries requiring data from the same site(s) for producing the results. Call this set T (T is also a subset of Q).

Step 2: Scan queries in (Q – P) to identify queries requiring the same relations that are operands for *binary* operations (other than JOIN) for producing results. Call this set R (R is a subset of (Q – P))

Step 3: Scan queries in (Q – P – R) to identify queries requiring the same relations that must use the SELECT operation with common set (or subset, if compound predicate) of predicates. Call this set S (S is a subset of (Q – P – R))

$G_1 = \{P, R, S\}$

$G_2 = \{T\}$

$G_3 = \{G_1 \Omega G_2)$

End Algorithm

5. CONCLUSIONS

There are different techniques used by the DBMSs in processing and optimizing high-level queries submitted by users. In this paper, we first discussed the major issues regarding query plan evaluation for query processing and showed how the query optimizer can choose an optimal plan for efficient execution of queries. We then discussed an efficient process for designing an optimizer which examines frequently used queries, and identifies two categories of groups of queries. One groups of queries requiring the same procedures (including operations used), and one groups of queries requiring data from the same site (or set of sites) for producing the result. Finally, we presented an algorithm which examines frequently used queries, and identifies those two groups of queries.

A Prescriptive Approach to Business Process Modelling

Yishu Ding, University of Manchester, P.O. Box 88, Manchester M60 1QD, UK; E-mail: yishu.ding@postgrad.manchester.ac.uk

ABSTRACT

Business process modelling approaches are expected to describe business processes and prescribe advices for decision makers to implement changes to business processes for improvement or reengineering projects. Being prescriptive means that predictive advice becomes outputs to facilitate the construction of a "to-be" situation with the inputs including proposed changes and the "as-is" situation. Much effort has been made both on the descriptive ability to give a precise and close description of existing business processes and on the analysis of potential problems and changes impact. However, little work has been done to prioritise the prescriptive ability, therefore reducing stakeholders' involvements and slowing down the transition from the "as-is" situation to the "to-be" situation through change. This research proposes a prescriptive approach to business process modelling comprising a variable-oriented meta-model and an associated methodology. This approach utilizes concepts from quantitative modelling and feedback control theory to impose a systematic transformation process. A case study of an electricity distribution division illustrates the applicability of the developed approach.

1. INTRODUCTION

Business process modelling is an essential step of Business Process Improvement (BPI) and Business Process Reengineering (BPR), both of which targeting existing business processes. Given the complexity of an organization and the hefty cost incurred by the implementation of business processes, the possibility of experimenting with proposed changes to real systems is difficult to attain. This suggests research on business process modelling may be achieved from two aspects: the descriptive modelling, and the prescriptive modelling. Descriptive modelling focuses on the elicitation and the representation of business processes so that related knowledge can be understood and shared. The intention of prescriptive modelling is to provide process analytical support through modelling and facilitate process evaluation and alternative selections by giving predictive advice. Descriptive modelling approaches are favoured at the early stage of business process improvements and in reengineering projects, and at the moment proposed changes are evaluated, a prescriptive model grows more desirable, because knowing and sharing the effect a change will induce on an overall organization with stakeholders and justifying whether this effect is expected become primordial.

Recent modelling approaches offer the prescriptive ability through the addition of organizational concepts, eg. goals, and non-linear causal relationships. The use of these prescriptive elements helps to elicit the rationale of existing business processes and estimate the potential effect of a change. However, because of the qualitative expression of information, the preciseness of the analyzed results and the usefulness of justifying decisions are limited. Also, a systematic process support is missing when dealing with increased complexity.

Focusing on prescriptive ability, this research proposes a quantitative business process modelling approach comprising a variable-oriented meta-model and an associated methodology. This approach complements descriptive modelling approaches and is suitable to be applied at the stage where changes to existing business processes are to be evaluated for the construction of a "to-be" situation.

This paper gives an analytical summary of the existing business process modelling approaches in terms of their prescriptive and descriptive dimensions. The discussion is then directed to the desired properties of a business processes modelling approach owning the prescriptive ability. The variable-oriented meta-model is presented in the fourth section, followed by a description of the methodology in the fifth section. A case study is conducted with the presence of the methodology to illustrate the applicability of the proposed approach.

2. BACKGROUND

A business process is a main component of an organization. In a business process, a sequence of atomic activities is conducted to deliver a service to customers for the achievement of a goal.

Business process modelling approaches fall into three classes, descriptive, semi-prescriptive and prescriptive.

A number of modelling approaches have been developed to represent an organizational view of a business process, each one emphasizing on a given aspect. Activity-oriented approaches, eg. IDEF0 (Mayer, Benjamin et al. 1995), (IBM, 2002) highlight a specific ordering of activities in a business process. Role-oriented approaches (Ould, 1995) go beyond the mechanistic thinking in activity-oriented approaches and embrace the consideration of responsibilities undertaken by an organizational unit. A role involves a collection of responsibilities which are carried out by a set of activities (Ould, 1995). This approach brings a business process into the social context of an organization and highlights that business process redesign is not only an effort to optimise the order of activities, but also a restructuring of the organization's resources, eg. physical and human resources, and organizational hierarchies. Actor-oriented approaches make another organization concept, the actor, explicit, and introduce an aspect of implementation of a business process into process modelling. An actor is "the physical entity that personifies an instance of the role at any given moment" (Prekas and Loucopoulos, 2000). Additionally, object-oriented modelling (Wang, 1994) considers business processes as a set of objects interrelated with each other.

Some semi-prescriptive organization-oriented approaches (Yu, 1996), incorporate intentional elements into the description of a business process and provide a certain degree of analysis by offering a rationale of business processes.

One proposed methodology (Gong, Li et al., 2004) has a prescriptive ability by building cause and effect relationships among business process variables using the facility of causal loop diagrams, from system dynamics research (Forrester, 1961). This methodology emphasizes the significance and efficiency of utilizing cause and effect relationships in the analysis of business processes. However, its applicability is limited to guidelines, and a lack of a formalized mechanism reduces its applicability for nontrivial projects.

3. THE EXPECTED PROPERTIES OF A PRESCRIPTIVE MODELLING APPROACH

The quality of a prescriptive modelling approach depends on the quantity of trustworthy analyzed results and the degree of the controllability on a real system, gained from these results.

3.1 Quantitative Modelling

Whether a constructed model is scientific and is a close enough representation of a real system is critical to determine the degree of trust in the results. Quantitative modelling is "based on a set of variables that vary over a specific domain while quantitative and causal relationships have been defined over these variables" and its quantification is considered as a way to build a scientific model. (Bertrand, 2002).

The existence of variables is a precondition to construct a quantitative model. Research into quantitative management (Anderson, 1994) has considered that an organization is an amalgamation of variables. Furthermore, the business process level is the location of conducted activities, and data collected from this level can

be used as a feed into variables in a constructed quantitative model. This ensures the model is a close representation of the organization in reality.

Generated quantitative results from the model are numerical and allow closer scrutiny than qualitative results. This helps decision makers conduct evaluations and make their decisions.

3.2 Controllability

The controllability of a prescriptive modelling approach embodies itself from two aspects.

Firstly, in models developed with this approach, the controllability is demonstrated by the ease of the traceability of the impact that a change may cause when this change is applied to such developed model. The concept of feedback loop originates from the servomechanism control theory (Porter, 1950) in the field of engineering, and is developed as a component in the research of system dynamics (Forrester, 1961) to model and analyze social systems. The use of feedback loops facilitates making both this traceability and the effect caused by changes clear. A control mechanism is built in whenever a loop is formed.

Secondly, the controllability on a real system can be secured from analyzed results. Measurements, as a quantitative utility, are recognized as an efficient management tool. The ability to measure something is a precondition to control it (Kaplan &Norton, 1992). A number of performance management frameworks based on measurements (Platts and Tan 2002), (Keegan, Eiler et al. 1989), (Cross and Lynch, 1988), (Kaplan and Norton, 1992) have been developed to enable an efficient use of data. Incorporating variables representing common characteristics of data, that are measurements collected from the business process level, into a model, enables relating analyzed results with the measurements, and corresponding variables of a model with activities that can be conducted for the implementation of changes.

4. A PROPOSED PRESCRIPTIVE BUSINESS PROCESS MODELLING APPROACH

This prescriptive business process modelling approach is developed to achieve these expected properties. This approach consists of two components, a variable-oriented meta-model and a methodology.

4.1 A Variable-Oriented Meta-Model

The developed meta-model is an abstraction over quantitative aspects of business processes and a set of developed concepts is to be used with the proposed methodology. Additionally, this meta-model also serves as a reference for the later formalization and automation of organizational knowledge management.

The concepts developed in this variable-oriented meta-model are defined here.

Variable: a symbol containing different values under different circumstances. Each variable may be refined into a strategy variable, a process variable or an operational variable.

Strategy variable: a symbol that represents a property of an organizational strategy.

Operational variable: a symbol that represents a common characteristic from a set of data which are derived from measurements of actual activities of an organization. Operational variables have actual measurements as values.

Process variable: a symbol that serves as a bridge between operational variables and strategy variables.

Value: a numerical quantity associated with a variable. A "Value" entity has two sub-entities, measured value and deferred value. These two sub-entities are, respectively, the numerical quantity obtained from organization data and the numerical quantity obtained from the transformation of a set of variables' values according to a mathematical formula.

Relationship: a quantified causal relationship between two variables. A change on a variable' value results in a change of another variable's value. This relationship is either implicit or explicit.

Mathematical functions: a mathematical function defines how a change on a variable's value will affect other variables' values.

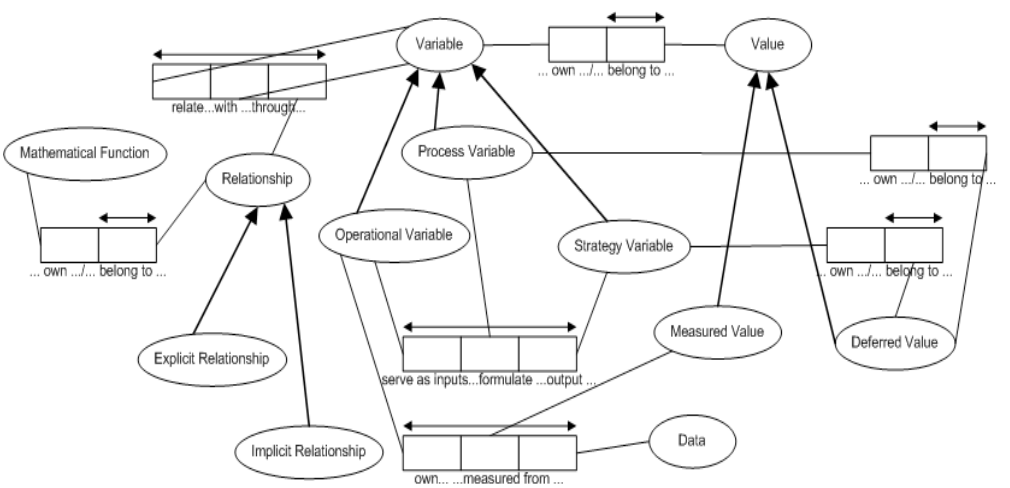
Explicit relationship: when a relationship between two variables is deferred from available knowledge, this relationship is explicit.

Implicit relationship: when two variables relate with each other in a way which cannot be derived from available knowledge, this relationship is implicit.

Operational variables have measured values while strategy variables and process variables have deferred values. The values of operational variables serve as inputs to calculate values of process variables, which themselves are used as inputs into strategy variables.

This meta-model presents the quantitative aspects of business processes and yet it is not purely mathematical as these variables are classified in an organizational context. By integrating concepts from organization management (Loucopoulos, 2003), variables, scattered in an organization, are shelved at three levels: the operational level, the service level, and the strategy level. Operational variables belong to the operational level, where business processes are conducted as sequences of atomic activities. Process variables belong to the service level, at which business processes deliver services. These two levels contribute to the achievement of organizational strategies at the strategy level which accommodates strategy variables. It is prescriptive in that variables at the three levels are interrelated in a logical "input-process-output" order (Platt &Tan, 2002). The achievement of organizational strategies is justified by the values of strategy variables outputted

Figure 1. Variable oriented meta-model



from the transformation of values of operational variables through process variables. Values of operational variables are collected from data gathered from real happenings of business processes, as this ensures the validity of the justifications and enhances the efficiency of control.

4.2 A Methodology

This methodology provides process support to instantiate concepts developed in the meta-model and presents the way in which the prescriptive ability is achieved in four steps. This methodology complements qualitative modelling approaches and is applied at the later stage of business process analysis when changes are proposed and evaluated.

The presentation of this methodology is accompanied with the conduction of a case study to illustrate its applicability. The background of this case study is set in the distribution division in an electricity group. This division is responsible for the transportation and delivery of electricity to consumers. With the opening of the European electricity market, the monopoly position of this division is challenged by future competitors. The distribution division responds to these challenges by a redesign of its business processes through a customer-oriented perspective. Research work (Kavakli & Loucopoulos, 1999), (Prekas & Loucopoulos, 2000), has been done to describe existing business processes, analyze the factors which have led to changes, and propose changes to these existing processes. This current research builds on this previous work and plans to apply the proposed approach as a further step in the transition to a "to-be" situation.

Step 1: Represent an Organization with a Generic Set of System Variables

The generation of a set of system variables is the process of representing a quantitative view of a whole organization. This step is necessary in that having a set of system variables is a precondition to fit variables, introduced by changes, into a global view of an organization and thus observe the changes effect in the context of the organization rather than within the limits of local areas where these changes occur.

The varieties of organizations and the complexity of variables result in the difficulty of generating a method with which such a set of variables can be developed. The concept of system variables is a reminder that a high level view should be taken in the extraction of these variables, as plunging too early into specifics risks missing a global view. The developed four levels view helps to discriminate system variables and to serve as a guidance to extract the proper ones. These four levels are business process implementation dependent, business process design dependent, organization dependent, application domain dependent. At the business process implementation dependent level, each atomic activity of a business process is conducted and thus variables from this level are the most specific. System variables should be elicited from a unique level, this level being higher than the business processes implementation dependent level. It is recommended to extract variables by starting from the highest level and going down to the suitable level of interest. This top to bottom method has the advantage of building a global but simplified view at the beginning and gives the possibility of zooming into a specific picture later. Figure 2 gives examples of variables at each level.

In this case study, system variables from a distribution division are elicited as listed in Figure 3 at the organization dependent level. These variables represent main states of main objects in this division.

Figure 2. Variables in the four levels view

Application domain dependent level	Eg. the number of customers
Organization dependent level	Eg. the number of customers who contact with PPC office
Business process design dependent level	Eg. the number of customers who visit PPC office personally
Business process implementation dependent level	Eg. the number of customers who visit PPC office personally during January 2006

Figure 3. Elicited system variables from the electricity distribution division

System Variables at the organization dependent level	
Object: Customers	The number of potential customers
	The number of customers who apply for connections
	The number of customers who sign contracts
	The number of customers who get connected
	The number of customers who get disconnected
Object: Electricity	Electricity in demand
	Electricity available to be distributed (network capacity)
	Electricity ready to be used
	Electricity measured
	Network capacity used
	Network capacity unused
Object: Material	Material in use
	Material in inventory
	Material in construction
	Material idling
Object: Payment	Payments billed
	Payments made
	Payments recorded

Step 2: Transform Changes to Variables

The second step consists in transforming changes into variables. Changes are proposed and expressed in the format of goal hierarchies which consist of strategy goals, sub-goals and operational goals (Kavakli & Loucopoulos, 1999). Changes might be limited to the operational level in order to improve existing business processes; alternatively, changes might occur across the operational level, the service level and the strategy level, because organizational strategies are shifted to new ones. Updated strategy goals usually underlie expected states of objects. Because these states are observable and quantifiable, they are used as labels of variables to represent the changed strategies. Sub-goals bridge strategy goals with operational goals and they achieve strategies by relating to a business process or to a service. Process variables are elicited from these sub-goals. The labels given to these process variables vary with the characteristics of these sub-goals. They might be strategy variables associated with a business process or a service. They also might be properties of the transition between two states of an object. When a sub-goal refers to a service, its variables can be extracted from possible criteria to justify this service. Operational variables are elicited from these operational goals and they represent either properties of an atomic activity or common properties of several atomic activities. When an operational goal involves more than one atomic activity, the use of process variables at the business process design-dependent level narrows the gap between process variables from sub-goals and operational variables, and also eases the communication and understanding of the relationships among variables, although using these intermediary process variables is not necessary.

Changes in this distribution division not only take place at the operational level but also reach the strategy level; therefore, the transformation is conducted at the three levels of the organization. The figure 4 shows examples of each used heuristics including elicited variables and their corresponding goals. When operational variables are elicited from the operational level, corresponding atomic activities are identified for the later specification of relationships among variables.

Step 3: Specify Cause and Effect Relationships Among Variables

This step involves two tasks. The first task is to locate variables causally related and the second task is to quantify these relationships with mathematical functions.

There are three ways to trace the causal relationships among variables. Firstly, deduced goal hierarchy from qualitative analysis (Kavakli & Loucopoulos, 1999), (Yu, 1996) is a resource to relate operational variables with strategy variables

Figure 4. The transformation of changes to variables

The level where changes take place	The classes of goals where changes occur	Heuristics used in the transformation	Examples
Strategy Level	Strategy goals	Expected states of an object	Goal: improve customer satisfaction Variable: customer satisfaction
Service Level	Sub-goals	Expected states of an object	Goal: improve load forecasting methods Variable: the preciseness of forecasted load
		Expected states of an object and related business processes	Goal: improve customer satisfaction for new installation requests Variable: customer satisfaction for new installations
		Properties of a transition between two states of an object	Goal: improve load increase satisfaction Variable: load increase satisfaction
Operational Level	Operational goals	Properties of an atomic activity	Goal: Minimise the waiting period for new installations Variable: the time of installation construction when customers ask for new installations
		Common properties of several atomic activities	Goal: Minimise the waiting period for new installations Variable: the waiting time for a new installation which involves the atomic activities, "installation construction", "service order creation", "the communication between service Dept. and studies. Dept."

through process variables. This resource offers an initial sketch of relationships among variables. Secondly, the identification of atomic activities that operational variables share enables building possible links among the related variables. The third way is to fit system variables into a network of elicited variables, ensuring that all system variables are embedded into such a variable network and that this network is a comprehensive view of the organization. In this network, system variables play the role of process variables or strategy variables.

The relationships among variables should be quantified. Explicit relationships are quantified by using available knowledge. Implicit relationships, often appearing with the introduction of new variables, exist because of common sense, intuition and experience. The transformation of implicit relationships to explicit relationships is a process of proving them scientific. The feasibility of the transformation resides in the presence of data, either gathered from history or collected from experiments.

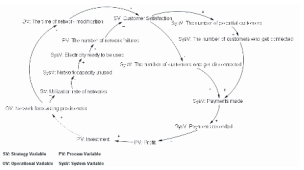
Figure 5 gives a partial view of the identified causal relationships.

Step 4: Causal Loop Analysis

A loop is a set of variables linked together by a circular dependency chain. This step consists of highlighting loops and checking whether variables expected to be controlled belong to a loop or relate themselves with variables belonging to a loop. As a loop is a control mechanism on system behaviours, this step, in essence, is a way to identify or introduce control mechanisms. The observation of the loops helps to check the effect of changes and impose control to adjust unexpected effects. When a loop contains variables linked by decision information flow, the control is enabled through decisions from human beings and thus requires human beings' interventions. Variables linked by decision information flow are only causally related when a decision is made. When options exist for making a decision, multiple decision information flows can be built to form loops. These related variables, as controllable variables, should be emphasized because they are the places where human beings have the ability to affect system behaviours.

In the case study, causal loops are identified to analyze the effect of changes and where controls are imposed to limit unexpected effect. The distribution division expects to obtain information of which proposed changes will bring most benefit

Figure 5. Causal relationships among elicited variables



and also be compatible with investment capabilities. The "investment" variable is therefore considered as a decision variable, and decision information links connect "investment" with other variables representing proposed changes. The observation of these loops shows the way each proposed change affects the achievements of organizational strategies, but also how each proposed change affects each other. For example, when the investment is made to improve "network forecasting preciseness", the chance of network modification will be reduced when customers apply for new installations. Consequently, customer satisfaction will be improved because of the reduction of the waiting time for network modification, and this will lead to the increase of the number of customers who get connected, and thus increase the revenue. However, this investment also improves the utilization rate of electricity networks and thus the reduced available electricity load could be a cause to network failures at peak time. This will negatively affect customer satisfaction and eventually reduce revenue. These two loops, as shown in figure 5, will therefore balance each other and likely lead to a stable situation.

This methodology takes qualitative results from qualitative modelling approaches as inputs, processes them through four steps, and outputs a model containing variables representing a quantitative view of business processes. Data collected from the implementation level is fed into the model to output the values of the variables of interest. This enables a quantitative observation of system behaviours and paves the road toward the evaluation of proposed changes.

This case study illustrates the applicability of the proposed approach. In this case applied with the developed approach, the effect of changes on an organization is observed quantitatively and the trace of implemented changes at the operational level affecting organizational strategies becomes explicit.

6. CONCLUSION

The developed prescriptive approach to business process modelling, incorporating concepts from quantitative modelling and control theory, enables a quantitative modelling of business processes with variables, and provides a systematic process of taking qualitative inputs to outputting quantitative outputs. In contrast with current modelling approaches, it represents a complete shift from the emphasis on the descriptions of business processes to the prescription and facilitates the transformation from a situation with proposed changes to a "to-be" situation; it takes a quantitative view and represents organization-oriented concepts with variables; it provides a systematic process to support the quantitative transformation from qualitative knowledge of business processes; it has a certain formalism that increases the possibility of automated analysis to tackle complicated applications.

Future work will focus on the evaluation of change effects and the construction of a "to-be" situation. Also, the development of automated support tools is planned in order to increase the applicability of this approach.

ACKNOWLEDGMENT

I would like to thank my colleague, Daniel Dresner, for helping me polish this paper.

ABSTRACT

In this article the authors develop a decision support system for the selection of facilities location using a modification of the Brown Gibson model. The decision process of selecting an area in urban and rural environments is using objective factors considered by Gibson model and subjective factors which were determined using empirical data. The selected approach is built around a multi-criteria methodology with reference to objective and subjective criteria, which constitute the quantitative and qualitative parameters of the system, respectively. The model excludes any critical factors that may distort its usefulness, by choosing among pre-selected areas that fulfil certain minimum pre-requirements. Research findings provide useful indications that can improve the body of knowledge of location-theory. In addition, they can contribute to the development of policy proposals for the Greek state regarding the issues of: selection of location and residence, regional development, decentralisation as well as the study of the non-homogeneous and in-balanced development of areas in urban and rural environments.

Keywords: Brown-Gibson, location, multi-criteria, urban, rural

1. INTRODUCTION

Decisions on site investments are usually based on a number of parameters, with particular hierarchies or combinations of factors considered for particular circumstances. An enormous deal of attention in the literature has been given to optimal location factors in industrial location decision (Jungthrapanich and Benjamin, 1995), but not so much in residential location. It would not be wrong to say that not every factor in the literature is appropriate for every industry or location. Moreover, these factors are likely to differ over time, type of business or area specific features.

To date, in the literature, there has not been a well-defined linkage between all these factors and location selection. In addition, most research do not investigate whether all these factors are still recognised and well documented in practice or not. The intent of this study is to develop a multi criteria evaluation method for area selection in rural and urban environments. Its specific objectives are to:

- review previous models and identify their strengths and weaknesses;
- investigate dominating factors for people or companies deciding to locate their residence or office, respectively, using particular geographical areas with emphasis on rural and urban environments;
- develop a new model that overcomes the weaknesses of the previous models by combining all the necessary subjective and objective factors that influence area selection;
- provide a more efficient and effective framework on which to base decisions;
- apply the model to an example decision involving the selection of two facilities

Its strength is that for the first time all subjective criteria are not determined with the aid of subjective quantification techniques or assigned from personal preferences but their estimation is based on a large scale questionnaire. The model excludes, the use of critical factors, as it considers that choosing an area for residence means that certain minimum (or critical) requirements are already well fulfilled by these areas.

The article starts with a list of quantitative and qualitative factors that influence area selection. It tries to identify the optimal location factors that fit most advantageously with the residence internal environment. Then the model is developed based on Brown-Gibson's work and with reference to the selected optimal location factors. In section 3, an application of the model is conducted, through a five step process, by selecting two residential sites, one in urban and another one in rural (natural) environment with the objective in mind to determine which site offers the best environment for residence. Finally, in section 4, conclusions are highlighted.

2. DEVELOPMENT OF THEORETICAL MODEL

Although location decisions have theoretically developed quite well for a long time now, an analysis of the literature shows that there still exists a gap between theory and practice, particularly with respect to the residential location question. The approaches summoned in location theory are found to be narrowed in application in actual decisions from the fact that they involve a large number of qualitative and quantitative factors (Juthrapanich and Benjamin, 1995; Badri et al, 1995; Atthirawong and MacCarthy, 2001).

Past research on location decisions often deals with a single objective; while the criteria involved in proposed models are mainly related to cost or to dimensions that are translated into numerical values. However, location selection is a multiple criteria decision making analysis (MCDM) by nature, as the decisions depend on a number of factors (Yang and Lee, 1997). Therefore, there is a need to expand the methods used in order to take into consideration a broad range of factors including objective and subjective aspects. (Keen and Scott-Morton, 1978; Roy and Vincke, 1981; Jacquet-Lagreze and Shakun, 1984; Roy 1988; Zopounidis, 1990, 1995a, 1995b; Hurson and Zopounidis, 1995).

There are four basic categories that deal with the problems of the above nature (Siskos, 1984): (a) multi-criteria mathematical programming, (b) theory of multi-criteria usefulness, (c) theory of superiority relations, and (d) theory of multi-criteria monotonous regression. However, the most common methods in selecting residence sites among alternative solutions are the Electre method (Huylenbroeck, 1995; Dias and Mousseau, 2006), the Promethee method (De Keyser and Peeters, 1996; Le Téno and Mareschal, 1998, Macharis et al, 2004) and the Analytical Hierarchical Process –AHP (Saaty, 1986, 2000), which has been found to be an effective and practical approach that can consider complex and unstructured decisions (Partovi, 1994). For example, the AHP method was adopted for the location and development of a hospital unit according to the following four steps: a) hierarchical definition of building goals, characteristics and

criteria, b) collection of data and comparison by pairs based on selection priorities, c) use of the eigenvector method for the hierarchy of decisions, d) synthesis of priorities in general axis and rating of alternative decisions (Sinuany et al, 1995). The same method has been used for the selection of the location area of a restaurant unit in Taipei (Tzeng et al, 2002). In that problem five main characteristics are involved: transport, site, marketability, financial factors, competition and environment, and eleven criteria such as cost of rent, delivery cost, transportation network, parking places, number of passing-by persons, number of competitors, intensity of competition, size of the commercial area, infrastructure of the area, refuse disposal and sewage capacity.

According to Kahraman et al (2003), the selection of residence site is generally regarded as multi- multiple criteria decision making problem that involves quantitative and qualitative criteria and it is not advisable to use conventional methods (Kioxos et al, 2002). Chau et al, (2000) asses the cost effectiveness of an environmental assessment scheme based on economic benefit-cost ratios developed for various criteria. However, such approaches of the cost-benefit nature require that all factors have to be expressed in monetary values, which may lead to wrong conclusions due to: (a) possible errors that occur from the estimation of the monetary flow under uncertainty conditions (existence of probability of alternative values in the future monetary flows), (b) the expected inflation rate (Kyriazopoulos, 2002) and (c) the difficulty in quantifying and eventually use of the qualitative factors through the use of multidimensional statistical models (Srinivasan and Kim, 1988).

For our purpose, the Brown-Gibson model (Brown and Gibson, 1972; Lipovatz-Kremezi, 2003) has been selected. It is a technique for integrating qualitative and quantitative criteria in decision making. We utilize the Brown-Gibson model to cope with both the objective and subjective parameters of the system which describe the ecological behavior of buildings with respect to multiple criteria. We first define the objective criteria for each site (urban and rural) based on the total costs. Then, define the subjective criteria and establish its value. Identify the weighting coefficients pertaining to the importance/weight of the objective and subjective criteria. Finally, calculate the total priority grade for each site (urban and rural) through the combined objective and subjective criteria. Both the weighting coefficients and the priority order of each site regarding each criterion have been found through a survey, based on a questionnaire developed for this purpose. The questionnaire was administered to a number of students' families from academic institutions all over Greece. Based on the above, the site that concentrates the highest grade is selected and the final conclusions are extracted

As an assumption, we accept that the examined buildings are of similar characteristics in terms of properties, mechanical systems, construction materials, etc that can be defined accurately. This will eliminate any biased in air quality (Djukanovic et al, 2002; Tse et al, 2004), thermal or acoustical comfort, so any differences will be contributed to the urban or rural environment rather than the different building characteristics. However, any technical interventions or possible new installations that will be required to improve indoor air quality and/or thermal and acoustical comfort - so that the final measurements will be inside the allowable limits - will be parameterized.

3. THE AREA SELECTION MODEL

One of the most challenging activities deals with the process of matching the organization with its environment in the most beneficial way. This means selecting the external environment itself, via a selection process, to fit the organization.

The area selection model uses several strategic factors to fit the residence with the specific area that best meets its requirements and needs. It has two stages. The purpose of stage one is to determine what factors an area should have to fit most advantageously with the residence internal environment. These factors are referred to as the area Optimal Location Factors (OLFs). The purpose of stage two of the model is to develop the model itself based upon a combination of the Optimal Location Factors (OLFs).

3.1 Determination of Optimal Location Factors

The area selection model recognises the need of some Optimal Location Factors (OLFs) which are identified as belonging to the following two categories: (1) the subjective factors (AK_i) and (2) the objective factors (YK_i).

The *first category*, subjective factors, is characterised by qualitative type criteria such as quality of education, quality of healthcare, quality of entertainment and recreation, quality of natural and material goods, accessibility and availability of transportation, potential growth of the area and employment conditions, pollution problems and ecosystem, crime rate-security, traffic problems-parking areas, companionship-solidarity-sociality. The nature of these factors is of qualitative character as they cannot be given monetary values.

The *second category*, objective factors, is characterised by quantitative type criteria including amongst others, construction cost, cost of preventing pollution, cost for thermal comfort and acoustical comfort, energy cost, and residence cost

A possible third category could also be included, named critical factors. A location factor is considered as critical if it prevents the location of a residence at a specific area despite of the other, possible preferred conditions that occur. For example, an area that lacks schools could not be considered as a potential site for residence in spite of the other subjective or objective factors that may be attractive. In other words, there can not be any trade-off with respect to these factors

3.2 Model Formulation

A modified Brown-Gibson's method was used where for each site i, a location measure, called "total priority mark, B_i" is calculated (Brown and Gibson, 1972; Lipovatz-Kremezi, 2003), based on:

$$B_i = n(AK_i) + (1-n)YK_i \quad (1)$$

Where:

v is the objective factor decision weight with values $0 \le v \le 1$

AK_i is the objective factor measure for area i with values $0 \le AK_i \le 1$ and $\sum_i AK_i = AK_{urban} + AK_{rural} = 1$

AK_{urban} is the objective factor measure for urban environment i

AK_{rural} is the objective factor measure for rural environment i.

YK_i is the subjective factor measure for residence i with values $0 \le YK_i \le 1$, and

$\sum_i YK_i = YK_{urban} + YK_{rural} = 1$

YK_{urban} is the subjective factor measure for urban environment i

YK_{rural} is the subjective factor measure for rural environment i.

The development of the model was based on the following three assumptions:

Assumption 1 (Critical Factors):
There already has been made a pre-selection of specific areas that fulfil certain minimum pre-requirements and this minimizes the usefulness of the critical factors. Therefore the only optimal Location Factors (OLFs) that will be used are the subjective and objective factors. At this stage, one should appreciate the importance of critical factor, because their inclusion may even exclude an area from considering it, as it doesn't fulfills the minimum requirements imposed by them.

Assumption 2 (Objective Factors, AK_i)
Basically all objective factors are measured in monetary units. However, for the sake of the model, they all are converted into dimensionless indices. Therefore, the objective factor measure Ak_i for area i is determined mathematically by the expression:

$$AK_i = \left[c_i \sum \frac{1}{c_i} \right]^{-1} \quad (2)$$

where c_i is the total objectivity factor cost for area i.

There are three restrictions imposed by formulae [2]

a. the area with the minimum cost must have the maximum measure
b. the relationship of the total objective factor, AK_i, for each area as compared to all other areas must be preserved, and
c. the sum of the objective factor measures must equal one, i.e. $\sum_i AK_i = AK_{urban} + AK_{rural} = 1$

Assumption 3 (Subjective Factors, YK_j)
All subjective factors are mathematically expressed for an area i, as:

$$YK_i = \sum_{j=1}^{n} W_j R_{ij} \quad (3)$$

where: W_j is the weight of subjective factor i relative to all subjective factors (pair-comparison), and R_{ij} is the weight of site i relative to all potential sites for subjective criterion j.

Both subjective factor weight, W_j, and site weight, R_{ij}, are determined based on the use of a special questionnaire which has been distributed in a representative sample of students' families. In fact, this is one of the modifications made in Brown-Gibson's method, which determined these two factors with the aid of a subjective quantification technique known as preference theory (Fascal, 1965).

The questionnaire was given to 400 families of students from various Greek educational institutes, with a covering letter explaining the purpose of the survey. The sample was random selected as in the academic institutions the families of the students come from all the social, economic and professional ranks and from all the geographical and administrative areas of the country (urban, semi-urban, rural, etc.), thus having all these demographic, cultural, and other characteristics that makes the sample as representative of the Greek population as possible. The development of the questionnaire was based on three pre-requisites: a) the questions take into account the ability and willingness of the interviewee to participate, b) the answers is short-easy and with a logical sequence and clarity, c) the data processing and the final investigation of the real volition and trend of the sample are feasible.There were 150 replies, which represented 37.5% of the responses. A follow-up of the survey was conducted in July 2006. An additional 54 completed responses were returned, yielding a total of 204 replies, which represented 50.75% of the responses. The pre-test of the questionnaire was conducted with 3 lecturers and 5 students' families in order to ensure that there were no items with multiple interpretations or that were biased, inappropriate or unclear. Furthermore, the measurement items were based on a comprehensive review of relevant literature. Therefore, it can be concluded that the measure developed in this study has content validity.

4. APPLICATION OF THE AREA SELECTION MODEL

To illustrate how the area selection model works, two residential sites have been selected, one in urban environment and another one in rural (natural) environment. The objective was to determine which site offers the best environment for residence.

Patission area which belongs to the municipality of Athens was selected as characteristic urban area, located in a rather small distance from the city centre. It has good accessibility for the provision of goods and services (education, healthcare, recreation areas, markets, etc), the same quality of transport means and infrastructure as Athens, it is highly populated with a wide range of people-income, the cost of living is relatively low, and it has highly environmental (pollution) problems.

For the rural environment, the municipality of Psachna in the Evia island was selected. Psachna is the capital of a small municipality located at a distance of about 16km from the city of Chalkida (the capital of Evia island). Seated at the edge of Dirfis' mountain, it has good quality of transport infrastructure. Being close to the main road connecting Chalkida and Athens makes it quite accessible for the provision of goods and services. Its location characteristics, being next to the mountains in a natural environment makes it a low polluted area, thus fulfilling the minimum requirements and characteristics of the present research.

With the application of the area selection model to the problem of choosing between the above two residential areas, an exercise is carried out below, which briefly contains the following steps.

Step 1
A Table is constructed that shows both the technical data as well as the calculation of the objective criteria expressed by formulae [2]. The aim is to translate each areas objective factors expressed in monetary figures to dimensionless information. A total of five selection criteria are used, including: construction cost, cost of technical interventions for improvement of indoor air quality, cost for thermal comfort, cost for acoustical comfort and residence cost

Step 2
Next the preference frequency of each subjective criterion is calculated by processing the data selected with the questionnaires using SPSS-11 software. Then the weighting coefficients, W_j, for each subjective criterion are determined. A total of ten criteria was used, such as quality of education, quality of healthcare, potential growth of the area and employment conditions, pollution problems and ecosystem, quality of entertainment and recreation, crime rate-security, traffic problems-parking areas, companionship-solidarity-sociality, accessibility and availability of transportation, and quality of natural and material goods,

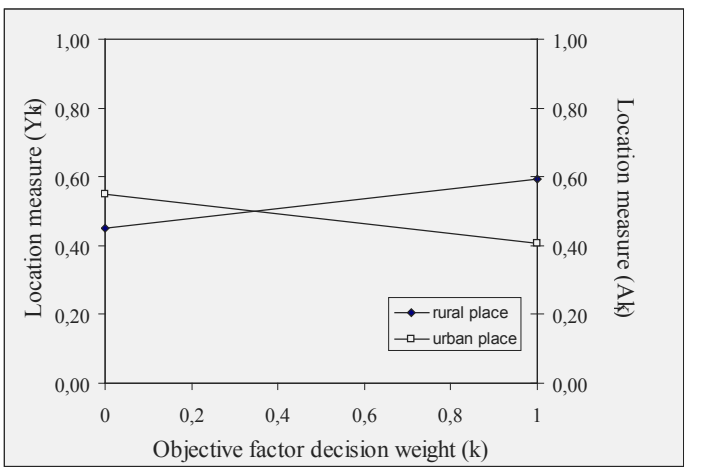
Once this information is identified the next step of the model is to prioritise each area i with respect to each subjective criterion j selected according to the preferences frequency of the interviewees. Finally the value of the subjective criterion (YK_i) for each site i is determined using equation [3] with the pre-condition, that $\sum_{j=1}^{n} YK_j = 1$. This results that $YK_{urban} = 0.548$ and $YK_{rural} = 0.452$.

Step 3
The weighting coefficient v was calculated to be v=0.415 and 1-v=0.585. It results from the weighting mean and according to the frequency of appearance of each value. It should be mentioned that the weighting coefficient v shows the weightiness according to the willingness of the interviewees between objective and subjective criteria.

Step 4
Having calculated, all the independent variables of equation [1] for each site, i, its "total priority mark, B_i" can be estimated but always assuming that $\sum_{i=1}^{n} B_i = 1$. This gives that:

B_{urban}=0.415*0.4052+0.585*0.548=0.4888
B_{rural}=0.415*0.5948+0.585*0,452=0.5112

Figure 1. Sensitivity of location measures to changes in objective factor decision weight, v



Step 5
Finally a sensitivity analysis is performed to examine the influence of the change in ν value on the final decision, see Figure 1. However, the research is possible to turn to more analytical results regarding the preferences and the selection of the people (regarding e.g. age of gender).

In our specific example, the results of the sensitivity analysis, indicating that for values of $\nu<0.34$, the urban residence site is preferred; otherwise the rural residence site should be selected.

5. CONCLUSIONS

The selection of a residential site involves the consideration of a large number of quantitative and qualitative criteria that have to be taken into account. Inevitably, this involves multiple and conflicting objectives which although are quite well recognized, their consideration have not been adequately addressed in analysis, yet.

Therefore, one of the most challenging activities is to match the organization with its environment in the most beneficial way, involving all these factors. Its significance has increased recently, due to economic downtimes and the people's environmental consciences. However, existing theories do not provide satisfactory solutions in selecting such sites. One reason for this appears to be the complicated and multidimensional nature of the problem itself. Another reason is that the proposed models suffer from the lack of a procedure that combines objective and subjective factors in an concise manner. Also many of the factors that should be considered in determining the problem cannot confine monetary values thus creating an aching void in location theory.

This article has presented a numerical model for area evaluation. It incorporates a procedure that derives a location measure, for both an urban and rural areas based upon subjective and objective considerations. Moreover, it facilititates sensitivity analyses, thus ascertaining the accuracy of the input data. It offers several advantages over previous models, which among others include:

1. Use of a two-stage model for evaluating alternative quantitative and qualitative factors first, and then evaluating specific areas between the chosen ones. Here the critical factor has not taken into consideration and the sites chosen for comparison have already been pre-selected, so the importance of the critical factors as such is negligible.
2. Incorporates the use of a questionnaire to provide solutions for the selection of subjective criteria, thus deviating from the original Brown-Gibson model which determines these factors with the aid of a subjective quantification technique known as preference theory.
3. Simultaneously considers all decision-making criteria (i.e. subjective and objective factors) to derive an optimal selection.
4. Permits ordinary ranked prioritization of decision-making criteria. For example, the assessment of the subjective criteria shows the following preferences in descending order: quality of the healthcare (17.0 %), quality of education (16.7%), potential growth of the area (13.3%), environmental pollution (12.9%), quality of security and criminality (11.9%) with the rest criteria following with lower percentage.
5. Easy to change objective factor estimates (i.e. model parameters) and solve for a new solution with little effort.

While the model presented in this article provides a powerful decision-making tool for area selection, the information it generates with sensitivity analysis possesses some limitations. One of these is that changes beyond the boundaries defined by sensitivity analysis cannot be interpreted. Such changes can be determined by using the model as a simulation tool. That is, the change can be observed by making a parameter change in the model and resolving the problem to see the simulated effect of the change in the new solution.

There are many other techniques that could be used for location analysis, such as the Analytic Hierarchy Process (AHP) process, but the present method offers some appealing advantages. One of the most important issues of AHP is what criteria should be set as the core evaluation criteria, who will select them and how. This is because using evaluation criteria that are not valued to begin with will risk that the analysis itself becomes meaningless. Another thing is that AHP assumes the system elements are uncorrelated and are unidirectionally influenced by a hierarchical relationship, thus introducing the assumption of independency among the various criteria of decision-making. There is a great deal of subjectivity as the user is asked to subjectively evaluate pairs of attributes on a point scale. However, when it comes to modified Brown-Gibson method, all criteria are set by a large group of people with different demographic characteristics through a questionnaire, thus removing the problems with criteria, hierarchy and subjectivity, as things are seen from different angles

Conclusively, we consider that this article has improved the body of knowledge of location-theory and has aided the decision process involved in residence site selection by guiding management to make better and more objective decisions. This was achieved by modifying and improving the Brown-Gibson's method, where instead of using the preference theory to determine the subjective factors, a questionnaire was designed. This is very importance for the Greek state as it contributes to the development of policy proposals, regional development, and decentralization; while prevents the deteriorate phenomenon that causes the non-homogeneous and in-balanced development of areas in urban and rural environments.

Scenarios for Mobile Virtual Communities of Students

Christo El Morr, York University, 4700 Keele Street, HNES Bldg. #412, Toronto ON M3J 1P3, Canada; E-mail: elmorr@yorku.ca

ABSTRACT

Virtual communities have emerged in the 1990s since the creation of the Web as a tool that made the internet accessible for the citizens at large. Mobile Virtual Communities (MVCs), which have been recently gaining more momentum in research and industry, are expected to be the next step in the development of virtual communities. Tools to enhance the students' experience in the campus environment can play an important role in education. This paper suggests several new ways in which MVCs can be utilized to enhance the students' life experience on campus at the educational, organizational, and communal levels.

INTRODUCTION

Virtual Communities

Humans gather and form groups in order to accomplish tasks that cannot be accomplished otherwise. Cities, schools, and workplaces are the classical meeting places where communities form. The Internet provided the infrastructure for the formation of other forms, but nonetheless similar, communities. Virtual communities meet in virtual places, such as the Internet. In virtual communities, we meet to discuss different issues and collaborate on many different projects, from politics to shopping. Chat rooms, bulletin boards, and email groups are some of they ways that we use to team up and form virtual communities.

Preece suggests a working definition for virtual community (what she calls online communities) that is broad enough to cover a wide range of communities but precise enough to fit into social science definitions (Preece, 2000). According to Preece, an online community consists of:

- Socially interacting *people*, performing special roles or satisfying their needs.
- A *purpose*, which is the reason behind the community.
- *Policies* to govern people interaction.
- *Computer Systems* that support social interaction.

Virtual communities are social systems that allow individuals to bond without completely depending on physical interaction rituals. Such physical rituals can still be present in virtual communities, but they are not the only mean by which interaction takes place. Interaction is enhanced and augmented by the virtual dimension.

Mobile Virtual communities

With the proliferation of wireless technologies and mobile devices, users are expected to practice their roles in virtual communities while they are on the move. New virtual meeting places are being created, with no clear sight of an end. Therefore, a new form of virtual communities with mobile users can only be a natural result of the mobile and wireless technology advancement and embracement. Such communities are called *Mobile Virtual Communities* (MVCs) and they continue to form a very promising research field. At the same time, telecom operators continue to look for the kind of applications that will increase revenues from 3G mobile subscribers (Ahonen & Barrett, 2002).

Different aspects of mobility have been researched during the last few years, dealing with the vision of MVCs, the appropriate technologies, the appropriate user interfaces, the intelligent mobile agents' usefulness, as well as a myriad of applications ranging from leisure to health. Research has been also trying to find a solution to security, privacy and trust issues, in addition to profitable business models.

El Morr and Kawash (El Morr & Kawash, 2007) have Classified MVCs into three categories based on the degree of virtualization they permit, their degree of mobility they embrace, and the degree of cooperation they allow. According to this classification, communities can be purely *physical*, at one end, where members meet in physical places in order to participate in community activities; or at the other end they can be purely *virtual* where they only meet online. In addition, community members can be *immobile*, tied to one place, or can be *mobile*, on the move. Finally, cooperation can take the shape of a simple *notification* which is a limited form of cooperation, or a full *collaboration* through a coordinated activity such as project building (Turban, King, Viehland, & Lee, 2002).

Researchers are proposing new mobile collaborative models based on mobile technologies (El Morr, 2007; El Morr & Kawash, 2007; Kawash, El Morr, & Itani, 2007). Education is one of the prominent potent fields that can profit form MVCs. In this paper, we will propose several scenarios where MVCs can create new opportunities for students' life on campus, enhancing several aspects of their experience: the educational, organizational or communal aspects. These scenarios help us pinpoint some of the challenges that need to be addressed to make these communities a reality. In addition to technological feasibility, these challenges include security and privacy, usability, and personalization.

MOBILE VIRTUAL COMMUNITIES SCENARIOS ON CAMPUS

In what follows, we will show the utility and importance that an MVC can play on campus to enhance the student experience. We will follow a scenario based approach that gives tangible examples on how an MVC can enable new communication channels among students in terms of notification and cooperation.

Scenario 1: Communal MVC: Mobile Club

The Human Rights Club has been active on York Campus for many years. Club members were very active in organizing debates, distributing flyers, publishing news releases, motivating students for upcoming demonstrations in town, and managing human rights awareness campaigns.

This year the Human Rights Club has launched a new service "MVC-Rights" that is intended to exploit the massive student use of mobile phones. The club members launched a marketing campaign for their new service, students interested with the service have been told to subscribe to MVC-Rights, signing up with their mobile phone numbers and subscribing to pre-set communities of interests: Middle East, Haiti, Afghanistan, Sri Lanka, Canada, etc. When the MVC-Rights was launched, the categories were pre-set by the MVC-Rights administrator in order to try the concept, but the club was planning to enable the members create their own communities at a later stage.

Each member was able to send and receive news to other community members about issues related to the life of the community and to the club in general. Members could receive the messages on their mobile phones through SMS (Short Messaging Service) or via email, and could also send the information via either of these two means of communication. In addition, members could collaborate to reply to questions coming from each other about a particular topic; in the latest Middle East crisis they were able send latest breaking news, notifications about

TV debates, and community meetings, demonstrations and other activities. Finally, the community has made use massively of the mobile technology in two major aspects: conducting polls on the fly, and call for immediate action, or urgent meetings; this immediacy enabled the club members to conduct a vibrant community life during human rights crises.

Scenario 2: Organizational MVC: Bus Schedule on the Spot

Valentina lives in downtown Toronto; it takes her about one and a half hour to reach York University. Her trip consists of a bus, subway, and another bus ride to reach the university. It is very important for her to accurately know the bus schedule, but the problem is that the printed bus schedules consist of time estimates; bus delays due to traffic, weather, and breakdown conditions are very common. The situation that bothers her most is when she is going back home from her 7:00-10:00 p.m. class and she has to wait for the bus to arrive, unaware of the exact arrival time. So many times she was hungry and wished she could buy a snack form a nearby store but she didn't want to risk leaving, fearing that she might miss the next bus.

Valentina is happy tonight, she has subscribed to the on-campus new MVC, "MVC-Bus". She entered into a Web-based system her phone number and the time and days she would like to be notified, the bus routes she is interested in receiving notification for, the bus stops she is interested in, and few other parameters. The MVC-Bus Website stated that it is able to notify Valentina for bus arrivals on the designated bus stops for the designated bus routes on the dates and times that she has chosen. Besides, the MVC-Bus allows Valentina to pull on her mobile, at any moment, the list of buses that are arriving to the bus stop nearest to her position; the MVC-Bus is able to track the exact bus locations using GPS and Valentina's location using her GPS-enabled phone. Valentina felt relieved tonight; before standing in the queue she took a look at her mobile phone and has seen the exact arrival time of Bus route number 196B going to Sheppard Avenue, the bus still needs at least 15 minutes. She went to a nearby store bought a snack and came back on time, she felt less frustrated and was glad to manage her time more efficiently.

Scenario 3: Educational MVC: Assignments on the Move

Ning is a very hard working student; he takes his work seriously. Since he entered York University he quickly realized that work in the university is different than in high-school, and that he cannot continue working alone because some assignments are required to be done in groups and some courses are project-based and hence they should be completed in teams. Even though he enjoyed working in a group, one of the major difficulties he and his group members encountered was how to setup meeting times for the assignments.

Last week, he was so happy to know that a new MVC called "MVC-Assignment" has been launched on Campus. MVC-Assignment allows interested students to organize in communities that can be created on demand and then destroyed when there is no more need for them. He decided to establish a *usability community* for his usability project team members in order to facilitate collaboration among the team members during the Fall term. Members use a Web-based application to enter their mobile phone numbers and some notification criteria such as the day and time the student would not like to receive notifications. During the following week, Ning needed to organize a meeting on-the-fly with all or some of the team members. He sent a meeting request notification to all other members, some of whom received meeting inquiry notifications on their mobile phones and responded to it. Ning could easily use his mobile phone to consult a campus map that shows the locations and availability of the team members. He notifies whoever is available to meet in 30 minutes in the student center to have a quick Q&A session in order to clarify few issues related to the project or to discuss new ideas.

Few weeks later, Ning and his team colleagues found that this MVC was also useful to do fun stuff and to enhance their social ties. In so many instances during the semester, Ning and his colleagues searched for each other in order to have a cup of coffee and a chat. Occasionally, Ning received jokes form other team members and invitations to parties. Slowly, some of the team members became close friend and at the end of the semester they were debating if they want to keep this MVC on or to create another permanent one and possibly invite new colleagues to join the community.

DISCUSSION

Although virtual communities have been developed to support learning(Liebregt, 2005; Miao & Haake, 2001; Prasolova-F, rland, & Divitini, 2003; Sourin, Sourina, & Prasolova-Førland, 2006), none to our knowledge has ventured in mobile virtual communities. Mobile Virtual Communities are still emerging, and their application could cover a wide spectrum, from mobile games to education. The previous scenarios suggest that MVC can be suitable to enhance campus life experience including educational, organizational and communal aspects. The scenarios are presented in order of increasing challenges to the feasibility, adoption, and maintenance of the suggested MVCs. The feasibility of these MVCs is correlated with the availability of the required technologies for the services. Adoption and maintenance require these MVCs to provide for sociability and usability. Some of the concerns relate to the policies that should regulate these MVCs, the user interface used, privacy of the members, and security of the data gathered from the communities.

Technological Feasibility

A service providing MVC-Rights does not require more than email and SMS distribution lists, making the implementation and deployment of such a service an easy task. MVC-Bus heavily depends on location determination technologies (LDT), such GPS. In order to generate accurate live bus schedules, it is important that the exact locations of the buses are determined in real time. However, some "diluted" implementations are possible, which require the cooperation of bus operators. In one implementation of such a service, called TraVcom, the bus operators update the bus schedule regularly, using specialized mobile devices or even mobile phones (Kawash et al., 2006). Valentina in Scenario 2 can still make use of the service even if her phone is not GPS-enabled. She can simply key-in the bus stop number and the bus route number to get an accurate arrival time. MVC-Assignment also requires the use of LDT. Cheaper alternatives to GPS can be deployed on campus. Tracking members and generating live maps with the indication of member's locations is an important factor.

All of the three MVCs can be sustained with basic forms of interaction, such as SMS. Since it may not be always possible to support advanced features (such as LDT), these services must be implemented allowing the broadest possible base to users to participate, and at the same time allowing any interested user to take full advantage of the provided features.

Adoption and Maintenance

Assuming that the interest in joining a community already exists, adoption of these communities requires usability, trust, and privacy.

A determinant factor of usability is user interface requirements, an issue that originates from the limited mobile device processing power, screen and keypad/keyboard size. Mobility also enforces constraints on the interaction so that new interaction styles should be created (Kristoffersen & Ljungberg, 1999). The right interface design should be investigated in order to enable a friendly and enjoyable experience. The collaboration tools should be studied in close partnership with the students (the end users); their satisfaction is the key success factor for such MVCs. For instance in MVC-Bus, a member should be able to pull the real-time bus schedule with little interaction with the device. A map that shows the proximity of a user in MVC-Assignment, indicating the positions of other near-by members, should be carefully designed.

The willingness of students to adopt an MVC service also highly depends on their trust of it. For instance, MVC-Assignment requires members to be willing to expose some of their private information, particularly their location. The MVC-Assignment service must be secure enough so that this information is not compromised to unauthorized parties, and also must be capable of giving the user's the option of being "non-trackable". Privacy and security policies should be developed, communicated and enforced.

Finally, personalization is a factor that can drive adoption since users will be able to tailor the service to their own needs; the service's ability to provide different levels of privacy is essential for some MVC adoption. Examples of personalization could be seen in a user choosing the bus route number, the bus stops of interest, the notification method desired (SMS, mail or both), the time, etc. For instance, it is important that Ning to be able to choose to be invisible to other members of the community.

CONCLUSION

While telecom companies are in quest for "killer" applications that can drive traffic and improve their revenue, we contend that Mobile Virtual Community services are the future such applications. We foresee these services may induce a similar social and business impact similar to the Web and email impacts.

The recent technological advancements in wireless and mobile computing have made Mobile Virtual Communities possible. The scenarios presented in this paper can be implemented using existing technologies. For instance, Kawash et al. (Kawash, El Morr, Charaf, & Taha, 2005) present a computer system that can support MVC-Bus, mentioned in Scenario #2. However, the full advantage of these services may not be realized without further deployment of advanced services, such as location determination, and without the constant enhancement of others, such as security.

Improving Organizational Systems: Incorporating General Systems Theory and Design Principles

Edward Garrity, Canisius College, 2001 Main Street, Buffalo, NY 14208, USA; E-mail: garrity@canisius.edu

ABSTRACT

A crucial factor for understanding system behavior is observing how the parts interact (Atwater & Pittman, 2006). However, the very act of analysis (defined as studying the parts in isolation) makes it impossible to understand a system and its underlying dynamics (Ackoff, 1981). This paper highlights the need to revamp our current approach to systems analysis and design and incorporate more systems thinking and system modeling into the development of organizational systems.

INTRODUCTION

The design of organizations and organizational information systems has been guided by the use of several underlying principles. These design principles are a result of an over-reliance on one mode of thinking – the application of analysis and functional decomposition, based on the *scientific method*. While the scientific method has been the cornerstone of the majority of advancements in our knowledge and the development of new technologies, an over-application and over-reliance on some of the modes of scientific thinking can actually be detrimental for the design of organizational systems.

Another mode of thinking – *systems thinking* or general systems theory, when used in combination with principles from the scientific method, may actually lead to greater insights, expanded viewpoints, and better designed organizational systems.

THE SCIENTIFIC METHOD AND ORGANIZATIONAL DESIGN

The industrial revolution ushered in the use of machines to increase worker productivity. Since machines could only be designed for very specific, repetitive tasks, it became necessary to redesign work and workflow in order to take advantage of specialized machines. Workers went from having multiple skills and general, wide-encompassing tasks to narrow, repetitive or specialized tasks. Adam Smith published the famous *Wealth of Nations* in 1776, where he described this new concept – *the division of labor*. The development of the machines that led to the industrial revolution could be directly linked to the accumulating scientific and engineering knowledge resulting from increased understanding provided by the application of the scientific method.

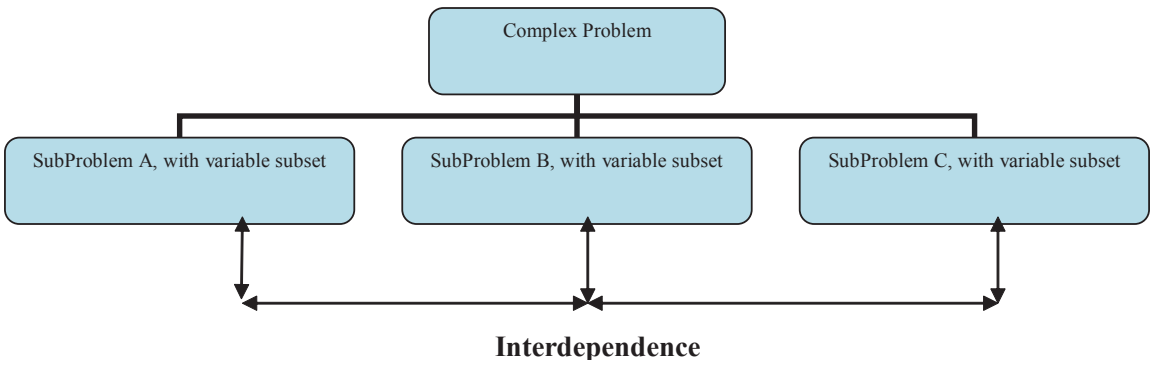
A basic principle from the scientific method is the notion of seeking truth and developing an understanding of nature or natural phenomena by breaking-down or decomposing complex systems into their elemental components. Thus, biologists are able to understand organisms by focusing on the parts (or subsystems) that make-up or compose them. An understanding of the parts helps in understanding the functioning of the whole.

The notions of understanding complex phenomena using this approach were then applied to the design of artificial, man-made systems, and organizational design. The primary organizing (design) principle from the scientific method is *functional decomposition*. Functional decomposition is a design principle whereby a complex problem is solved by breaking it down into smaller, more manageable and simpler sub-problems. This design principle, together with the use of machines and specialization of labor, led to the development of mechanistic or bureaucratic organization designs.

SIDE EFFECTS OF THE SINGLE PARADIGM

Problem solving based on the scientific paradigm can be thought of as composed of two primary parts: (1) Analysis and (2) Design. The analysis step of problem solving relies on understanding problems and phenomena by examining the individual parts in order to understand the functioning of the whole. After problems and phenomena are understood, the design step then seeks to design a solution by simplification via functional decomposition, or identification of sub-problems and specialization. This method limits the variables and complexity of the problem and, in the case where mathematical models may be applied, reduces the computational space. This has been the dominant, meta-model for isolating and solving management and organizational problems.

Figure 1. Detail complexity and dynamic complexity



However, this problem solving orientation reduces one type of complexity only to produce more of a different kind of complexity. Senge (1990) defines two types of complexity: *detail complexity and dynamic complexity*. Detail complexity involves situations where there are numerous variables, data, and although the relationships may be complex, they can often be modeled mathematically to achieve optimal solutions. Problems involving detail complexity are the focus of management science techniques and or techniques that require the use of computer-based solution. Dynamic complexity involves the interaction of the decision variables through time. While detail complexity is reduced through the application of functional decomposition and specialization or partitioning of the problem space, the very act of partitioning will result in an increase in the number of interacting components (partitions), and creates a complex web of interdependent components that share inputs and outputs (see Figure 1).

Thus, over-reliance on the problem solving methods based on the scientific approach has resulted in one type of complexity being traded-off for another. The problem-solving mindset of the scientific approach when decoupled from an understanding of system thinking, results in a limited understanding of organizational problems and problem solving. Specifically, managers often fail to realize: (1) cause and effect are often separated by time and space, (2) problem solutions that fix a problem in the short-run often create or exacerbate problems in the long-run, and (3) because of system effects (inter-dependent components) and system dynamics (multiple, non-linear feedback loops) short-term results may differ strongly from long-term results which then affects one's ability to learn from and correct past mistakes or decisions (Forrester (1971); Atwater & Pittman, (2006).

In order to understand these issues and understand how to deal with the two types of complexity, the next section discusses systems theory and systems thinking.

SYSTEMS THEORY AND ORGANIZATIONAL DESIGN

General Systems Theory (GST, or systems theory) was originally conceived by von Bertalanffy (1969) in 1945, and has been expanded, clarified, and applied to many different areas of science and thought. The concept of *systems thinking* refers to the set of cognitive strategies or systems related thinking strategies that may be applied to solve problems and or understand complex phenomena. Systems thinking behaviors are based on the original notion of general systems theory. An important area of study that arose out of general system theory (well to some extent, but mostly from engineering and computer technology) to aid in the understanding of complex systems is - *system dynamics*.

SYSTEMS DEFINED

A system may be defined as a set of interdependent components which is unified by design to accomplish one or more objectives (Kast & Rosenzweig, 1972). A system is thus an artificial creation, a way of thinking about and organizing complex phenomena. When defining or creating a system, a boundary is defined. The boundary separates the internal components from the system's external environment. A closed system does not interact with the environment, whereas an open system is one that shares information, energy or physical flows with the outer environment.

Although the system concept is very simple, its power as a problem-solving and design paradigm originates from its elegant simplicity, and this gives rise to the ability to create abstraction tools which then provide insight into problem structure and problem resolution. The systems approach thus provides a structure from which several modes of thinking are derived. *System thinking* is holistic thinking and includes notions of feedback, time delays, and dynamic interplay between components.

In essence systems thinking may be described as a paradigm or a "world view," where phenomena are viewed holistically and interconnected (Manni & Maharaj, 2004). Systems thinking may also be viewed from a more detailed and cognitive processing perspective. Richmond (1997) delineates the following cognitive processing or thinking skills or tracks that fully-define systems thinking: (1) Dynamic thinking, or examining or framing a problem or pattern of behavior over time, (2) System-as-cause thinking, or viewing the system's behavior as a result of the system itself, and thus under the control of decision makers. In essence, one must define the system boundaries in a meaningful way. (3) Forest thinking, or viewing the "big picture." This is the ability and skill to effectively see above the functional areas or silos and perceive the system of interrelationships and interdependencies that connect the component parts. This is a central feature of systems thinking and serves to strongly differentiate this mode of thinking from scientific thinking, which views and seeks to understand phenomena by understanding the parts first. (4) Operational thinking, or examining, in detail, the structure and nature of relationships; at *how* the variables affect one another, not simply that they affect one another. (5) Closed-loop thinking, is realizing that causality tends to follow a feedback loop whereby causality does not run in just one direction, but loops-back to change one or more causes and that causes can affect one another.

SYSTEM DYNAMICS

The area of system dynamics incorporates the systems thinking skills into a modeling framework that allows the problem solver to apply a systems approach to understand the complex system interactions.

Forrester (1961) first articulated notions of system dynamics and their proper modeling. Underlying the need for systems dynamics is the realization that many of today's problems in business, policy and human affairs are not only complex and difficult to solve but that many of our efforts aimed at solving these difficult problems result in "unintended side-effects." In fact, in many cases our solutions and decisions result in causing our problems. In other words, today's solutions become tomorrow's problems (Sterman, 2002).

The notion of "unintended side-effects," may actually be viewed from the standpoint of incomplete modeling. In other words, in an effort to apply scientific problem-solving methods, many problems are analyzed, decomposed to smaller subsets, and then solved by means of decision modeling, optimization, and other techniques. However, as stated previously, analysis and design of the problem domain may reduce detail complexity but when modeled from a system dynamic perspective, isolated subsystems and systems beyond the problem boundary may still interact – in other words, dynamic complexity has not been accounted for properly. Thus, notions of "unintended side-effects," may be viewed as "un-modeled interactions" from a system perspective.

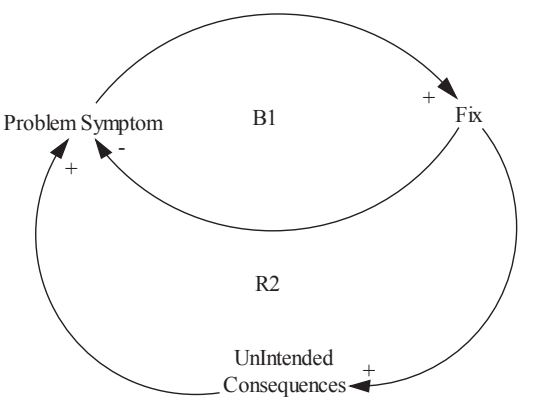
A primary tool used in system dynamics is the Causal Loop Diagram (CLD, shown in Figure 2). The CLD is an important modeling tool to help understand system dynamics, to facilitate holistic thinking, time delays, feedback loops, and all of the cognitive processing and systems thinking strategies.

System thinking is not always intuitive, commonly performed or easily understood, even by intelligent managers or educated individuals (Sterman, 2000). A number of empirical studies have confirmed this assertion (Sterman & Sweeney, 2000; Pala & Vennix, 2005). Many common mistakes by managers may be traced to incomplete understanding of system dynamics, and Senge (1990) has documented these common pitfalls using system archetypes, documented using CLDs, as in Figure 2.

BUILDING EFFECTIVE ORGANIZATIONAL SYSTEMS

A basic premise of this paper is that both paradigms are necessary to build effective organizational systems: System Thinking and Scientific Thinking. Organizational systems may be thought of as being composed of operational and decision

Figure 2. Causal loop diagram (CLD), "Fixes that Backfire"



making tasks performed by humans and machines (computers), within defined organizational structures, and that may interface across organizational boundaries and interact with other systems. Essentially, organizational systems may be designed in a myriad of ways, but are generically defined by tasks, structures, people, and machines.

Traditional information systems development techniques and methodologies have stressed functional decomposition. Thus, traditional analysis and design tools have tended to model information requirements, processes and tasks from a functionalist (scientific) viewpoint. As a result, two primary "un-anticipated side effects" have resulted: (1) information systems (that support the basic business system) have failed because of a failure to understand the human component of systems – the socio-technical system viewpoint, and (2) business systems have failed because an overemphasis on functional decomposition has led to business processes that are too fragmented, with too many information interfaces and "hand-offs" required to coordinate the entire business process (defined as the ability to provide a requisite value to an end customer). Both of these major failures are the result of a lack of system thinking, modeling and design.

THE SOCIO-TECHNICAL SYSTEM FAILURE

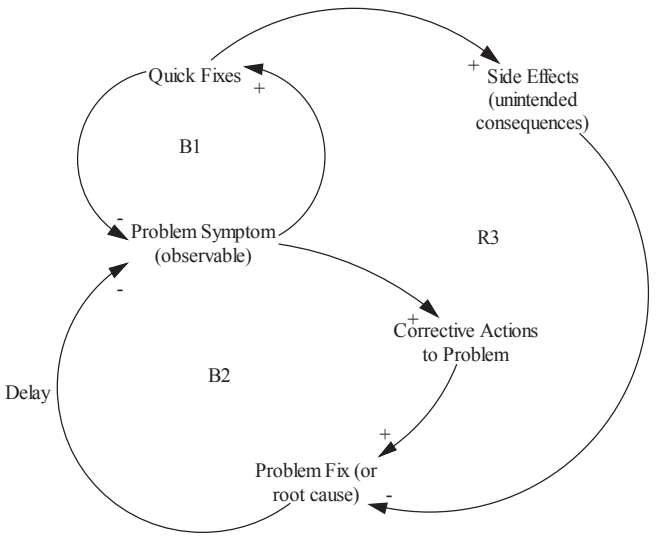
A hypothetical company is faced with the problem of making better product positioning and advertising decisions based on market research data. The hypothetical company scenario involves a product manager (who reports to the division manager), a market analyst (market research department) and a division manager (responsible for budgeting, deploying a sales force, etc.). The major problem symptom is that the product manager does not always have the best information on which to base his decisions. Based on an incomplete understanding of the situation, management decides to build a decision support system to help supply important sales, market, and demand information. The new DSS employs built-in decision models that more than provides advice, but actually "restricts" the range of possible outcome or decisions that are possible. This is done to reduce variability in product positioning decisions across the corporation, thereby providing a way for more centralized control. The DSS provides normative models based on complex mathematical principles to optimize certain relationships and outcome variables.

The result: the product managers feel completely constrained by the new system. Basically, the product managers feel: (1) a *loss of control* over their decisions, which increases their stress level since they are still held responsible for their decisions; (2) they feel their jobs have reduced their ability to have a *creative intellectual outlet*; (3) because of the use of the new system their jobs have become more *routine and repetitive*, (4) they now have *fewer interactions* with market analysts because the data collected has been standardized across the corporation for increased consistency and to aid in market comparisons at the corporate level, (5) they also have *fewer interactions and communications* with the actual sales personnel (which used to be an important and *informal way of gathering rich data*) because the DSS demands greater amounts of their time and because the inputs required by the DSS do not allow for considering their old, informal, rules of thumb that typically went into their positioning decisions. Figure 3 shows a Causal Loop Diagram of the new situation.

Basically, a lack of system thinking at the start caused management to focus on a problem symptom – the lack of good information for product managers. If a more systemic approach had been used, for example, use of *forest thinking* would have enabled management to see the bigger picture and include the human component in their view of this system (i.e., this is basically the socio-technical system viewpoint that considers the human component of the system, including humans personal goals). A more in-depth consideration of the human component would reveal that product managers did not have enough information because they also did not have enough *control* in their jobs. Lack of control meant that they did not have the ability to alter or influence the data gathered by the market research department, they did not have the bargaining power to influence the division managers to elicit time and cooperation from the sales force to gather important, rich and meaningful information.

The management decision to implement the DSS was a quick fix based on an inadequate understanding of the system dynamics. An unintended side effect of this approach was an increase in the lack of control by the product managers. This effect actually looped back and added to the underlying problem (Figure 3). In addition, all of the side effects, including a *loss of control*, reduced *creative intellectual outlets,* their jobs have become more *routine and repetitive, and fewer interactions and communications* all resulted in a lower Quality of Work Life of the product managers. A lower Quality of Work Life can have even more, long-term effects on the company as personnel may have greater turnover, higher absenteeism, and lower productivity.

Figure 3. Causal loop diagram of the STS situation (Shifting the burden archetype)



Proper systems thinking would also have highlighted that good product management decision making depends on both access to the proper information (via databases, models, informal information gathered by interactions with employees and salesmen), and a motivated product manager (human component of the system). Reducing product managers' Quality of Work Life also reduces this last factor.

The actual problem or root cause in this system situation was that the *business system* was improperly designed. The next section explains the failure from the business system or business process perspective.

BUSINESS PROCESS DESIGN FAILURE

Business process design failures may be thought of as the over-application of reductionism or functional decomposition (stemming from the scientific viewpoint). In an effort to reduce detail complexity and to define work in its most basic form, managers have created work environments with many sub-processes, organizational units, and subsequently, narrowly defined jobs. The result of defining too many sub-processes is that the sub-processes require a great deal of coordination and information flow because the sub-processes are part of a set of interdependent tasks that make up the larger process or larger system. In essence, over-design leads to a reduction in detail complexity but an increase in system or dynamic complexity. Lack of coordination between sub-processes is often described as "increasing the hand-offs" or information flows required to "piece back the fragmented processes" (Hammer & Champy, 1993). The end result is less efficient organizations and decreased customer responsiveness.

HUMANS ARE NOT MACHINES

A secondary effect of poorly-defined or over-designed processes is less satisfied workers (Hammer, 1996). When designing computer-based systems, researchers from the socio-technical design perspective stress the importance of including an assessment of the human component of systems since workers attitudes and well-being can strongly influence successful organizations. Sherman, Garrity, & Sanders (2002) developed an IS success instrument, based on Garrity & Sanders (1998) model, to measure workers' quality of work life (QWL). The measure examines items such as: (1) control over work, (2) a worker's ability to schedule or manage tasks, (3) degree of autonomy, and (4) the amount of routine in work.

As work is defined and processes and work systems designed, it is vital to take the human component into account. However, a differing amount of functional decomposition is necessary for the application of management science models and computer software than is necessary for human defined work. Hammer & Champy (1993) provide a number of examples where work can be performed more effectively by a single worker with the aid of information provided by computer support (DSS and database technology for example), than by the over-design of processes into many fragmented, sub-processes. Over-design of work leads to over-specialization and lower quality of work life. Thus, a critical task is to design systems effectively that match the quality of work life needs of the human component of systems with the design considerations and reduction in detail complexity required for software systems.

RETHINKING SYSTEMS ANALYSIS AND DESIGN

Current systems analysis and design methods fail to produce system designs that account for the wider system view which includes consideration of the business process design (i.e., tasks, structures, and processes), the human element (with corresponding socio-technical concerns), and the technical design. We recommend the following changes to produce better system designs: (1) Emphasize the co-design of business process, socio-technical and information systems; (2) Emphasize modeling of both detail complexity and dynamic complexity by incorporating the use of system dynamic modeling using causal loop diagramming (CLD) in addition to traditional analysis and design tools (e.g., data flow diagrams, hierarchy charts and decomposition diagrams); (3) Emphasize the use of prototyping and multi-dimensional measurement to obtain feedback on the impacts of designs on the human and business process components of systems (Garrity, 2001); (4) Educate systems analysts and managers on systems thinking and system dynamics.

CO-DESIGN OF BUSINESS SYSTEM AND INFORMATION SYSTEM

A critical emphasis must be placed on the *co-design* of business systems (e.g., work design, organizational structures, and task definitions) and information technology systems. This is critical because the needs of the human component, as is often stressed by the socio-technical school of thought, are vital for the success of the entire system.

A balance must be forged between the needs of the human element and the requirements of the technical system component. This is because the two components are interdependent parts of a dynamic system. The nature of the interdependence (and conflict) is best understood by modeling the two types of complexity that must be accounted for in the overall system design. The use of analytical tools and modeling (e.g., data flow diagrams) is necessary to understand the detail complexity and to design aspects of the technical design. However, the use of systems thinking and dynamic modeling is also necessary to understand and design the entire business process and socio-technical system. Thus, a fundamental shift in thinking must take place in order to achieve the level of design sophistication necessary to achieve success in this wider system context.

SYSTEMS EDUCATION

System researchers have been advocating teaching system concepts and system dynamics in business schools (Atwater & Pittman, 2006; Sterman, 2000), and while this is necessary it may not be sufficient for the design of effective organizational systems. Traditional textbooks and courses on systems analysis and design continue to stress the importance of considering users and their socio-technical concerns, but these textbooks have not included tools for the modeling of interdependent components and system dynamics.

Although organizations are complex systems, the scientific viewpoint and scientific methods have dominated research and education in business schools. This can be viewed as problematic since a crucial factor for understanding system behavior is observing how the parts interact (Atwater & Pittman, 2006). However, the very act of analysis (defined as studying the parts in isolation) makes it impossible to understand a system and its underlying dynamics (Ackoff, 1981).

SUMMARY AND CONCLUSIONS

An over-reliance on the use of analysis and design techniques such as functional decomposition or reductionism strategies, have resulted in overly complex, interdependent organizational systems. Interdependent subsystems and systems often interact with each other using multiple, non-linear, feedback loops. The complex flow of interactions often creates counterintuitive behavior resulting in unintended consequences or sub-optimal results (Sterman, 2002). This paper advocates a fundamental re-thinking of systems analysis and design that incorporates a general systems theory orientation, system dynamics modeling and the use of prototyping to produce a better understanding of and to aid in the design of organizational systems.

ABSTRACT

Specific security technologies for mobile applications and services – such as SIM/USIM/PKI SIM cards, hash chain generated security tokens for secure Mobile IP registration and mobile agent authorization, personal and public signature servers for mobile devices, and Identity based Public Key Cryptography (IdPKC) - are surveyed. Security solution examples and needed R&D are presented. A test environment for Mobile IP security solutions using IdPKC is also proposed.

1. INTRODUCTION

Mobile networking includes both network node mobility (notebook computers, handheld PDA computers, and mobile smart phones) and network software mobility (mobile agents). Mobility also puts specific technological requirements on basic security services like authentication, authorization, and digital signing.

2. SMARTCARDS

Specific security components in user devices in mobile cellular networks are smartcards such as SIM, USIM, and PKI SIM. A SIM is a smartcard securely storing an authentication key identifying a GSM network user. A PKI SIM is a SIM with an integrated RSA co-processor and storage space for private keys. A USIM is a SIM used in 3G mobile telephony networks, such as UMTS. Apart from authenticating users to cellular networks, these smartcards also are used in other security services.

2.1 SIM Card Based Authentication to Internet Services

Authentication to Internet services mostly occurs with the vulnerable username/password method. SIM based authentication is more secure and also convenient because of the widespread use of mobile phones with SIMs. In (Schuba et al., 2004) is proposed a SIM based approach with authentication protocols using an Identity Provider (IDP) Server operated by a mobile network operator. The SIM is accessed directly from the mobile phone, through a Bluetooth link to the phone, or through a WAP Proxy Gateway.

2.2 Secure Mobile IP Registration Protocol

In (Haverinen et al., 2001) GSM authentication based on the secret key in the SIM is proposed for a secure version of the Mobile IP Registration Protocol (Perkins, 2002). The AAA protocol (Glass et al., 2000) is used to access the GSM network through a proxy server, the GSM Authentication Gateway (GAGW), which translates between the Internet AAA protocol and GSM protocols. Two Mobile IP registration round trips are required. The RANDs of the subscriber are obtained and the GSM algorithm is executed on the SIM card. Finally, the actual authentication occurs. The system has been successfully tested with

- the GAGW implemented on Windows NT
- the GAGW connected to a GSM test network
- Windows 2000 and Linux based mobile nodes.

This Mobile IP Registration Protocol is also a standardization proposal in an IETF draft (Haverinen, 2001).

2.3 SSL Integration with SIM/USIM Cards

An Over-The-Air (OTA) connection to a SIM uses Application Protocol Data Unit (APDU) commands/responses (ISO/IEC 7816-4, 2005) encapsulated in protected SMS messages. APDU communication occurs in a SSL protected GPRS/TCP channel in the communication architecture described in (Badra and Urien, 2004). The Bearer Independent Protocol (BIP), defined in the European Telecommunication Standards Institute (ETSI) specifications TS 102 223 and TS 102 124 (ETSI, 2007), is required in the mobile device with the SIM. A modified SSL Handshake Protocol, in which certificate authentication is replaced by pre-shared secret based authentication, is proposed. BIP implements conversion from APDU commands/responses to SSL Handshake Protocol messages and to data sent over the SSL channel. An EAP-TLS based Authentication and Key Agreement Procedure (AKA) is proposed for a mixed WLAN-3G environment (Kambourakis et al., 2004). The SSL Handshake Protocol uses the AAA server certificate in the home network of the mobile device.

2.4 SIM Based Mobile PC Access

In (Mäkinen et al., 2001) architectures are proposed, where mobile phone SIMs and PKI SIMs are used for access to a mobile PC, which communicates with a remote server using the SSL protocol. A remote loader (RL) applet has been developed for SIMs implemented on Java cards. The RL applet supports communication to and from the SIM over an infrared link or over GSM.

2.5 Mobile Electronic Identity

Mobile FINEID, an electronic ID for inhabitants in Finland, is based on a Mobile Signature Service (MSS) and PKI SIMs allowing users to authenticate to online services and create digital signatures with private PKI SIM keys (Finnish, 2006). Currently, PKI SIMs are issued by two Finnish operators. PKI SIM owner identities are verified by mobile citizen certificates issued by the Finnish Population Register Centre (PRC) and attached to the private PKI SIM keys.

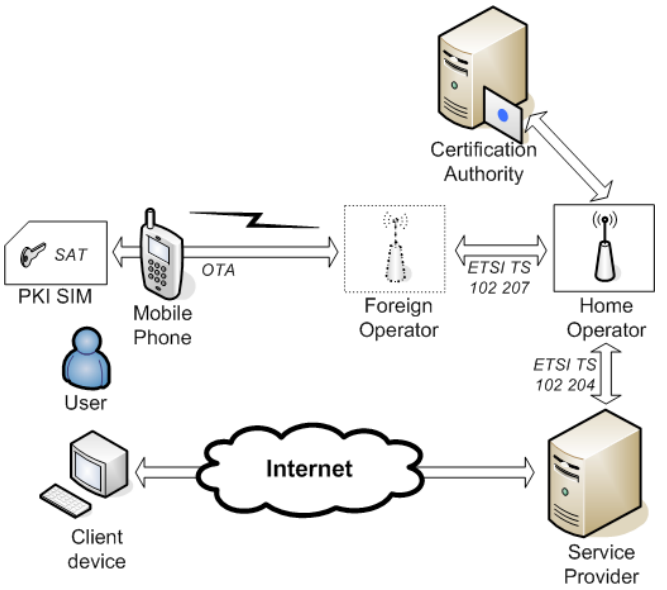
2.5.1 Technical Features of a FINEID PKI SIM Card

A FINEID PKI SIM contains a crypto processor and two PIN code protected private keys: an authentication/encryption key and a signature key. The corresponding certified public keys are stored in a directory administered by the PRC. Hashes of both public keys are stored in a PKI SIM for retrieval of correct certificates from this directory. The PKI SIMs are SIM Application Toolkit (SAT) enabled (3GPP, 2004) and contain a SAT application known as Wireless Internet Browser (WIB) (SmartTrust Case Studies, 2006). A PKI plug-in, PKCS#7 Signature Plug-In, executes cryptographic operations with the private keys through function calls executed by the WIB (SmartTrust White Papers, 2006). Function calls to and retrieval of return data from the PKCS#7 Signature Plug-In are encapsulated in SMS messages transmitted over an OTA connection.

2.5.2 MSS Architecture

The architecture of a Mobile Signature Service (MSS) is shown in Figure 1. Routing and roaming are based on public European standards. Thus, the Finnish mobile citizen certificate can in theory use any European MSS. Roaming and collaboration

Figure 1. MSS architecture



is ETSI TS 102.207 standardized, communication between the service provider and the mobile operator is based on an ETSI TS 102.207 standardized web service interface (ETSI, 2007). The interface is mainly based on SOAP (Simple Object Access Protocol), XML, and HTTP/HTTPS.

A workgroup of Finnish Federation for Communications and Teleinformatics (FiCom) has published a recommendation defining the rules for services using mobile citizen certificates and prescribing the technical interfaces for operators and service providers (FiCom, 2005). This recommendation is an application instruction for the ETSI standards TS 102 204 and TS 102 207. Extensions and adjustments to these standards are defined for limiting misuse. The purpose is to use electronic signature services independently of service providers and operators.

Example: User Authentication to a Protected WEB Service

1. The user tries to access the web service using HTTP and the web service informs the user that authentication is required and asks for the user's phone number
2. After receiving the phone number the service provider (in this case the web service) sends a signature request message, containing the user's phone number, to the mobile operator.
3. The mobile operator sends a signature request to the user's mobile phone PKI SIM, where a PKCS#1 signature is generated with the private key.
4. The PKCS#1 signature and the public key hash is sent back to the mobile operator and the user's citizen certificate is retrieved from the PRC directory based on the hash.
5. The signature is embedded into a PKCS#7 package, containing the user certificate, and sent to the service provider.
6. After successful signature verification, the user can access the protected WEB service

2.5.3 Evaluation

Currently, there are no public services for mobile FINEIDs. The architecture of current MSS systems is complex because of required SMS communication with the PKI SIM. An agreement between the service provider and the mobile operator is required for implementation services for mobile certificates. The technical specifications of operator specific PKI SIMs are confidential. Application and service development is thus mostly operator dependent.

Figure 2. Mobile signature and authentication service based on local PKI SIM access using OTA over Bluetooth

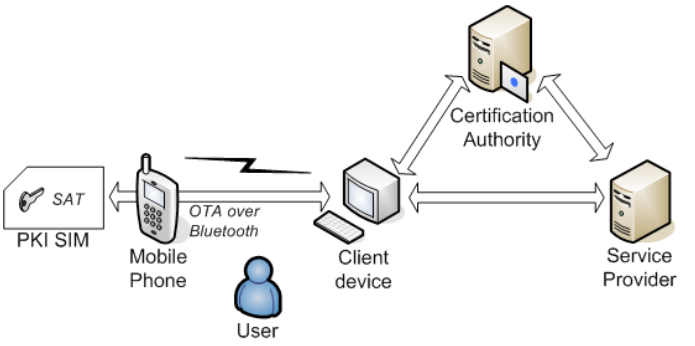


Figure 3. Bluetooth based Local PKI SIM access using the JCRMI protocol

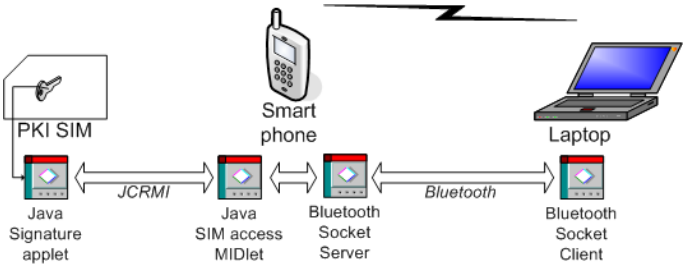

2.6 Local PKI SIM Access

The purpose of research in Arcada Polytechnic is to develop a convenient and secure PKI SIM based signature and authentication service based on local PKI SIM access. A PKI SIM and mobile phone would then be equivalent to a smartcard in a smartcard reader. The user's client device would have PKI client functionality and the service would be operator independent. Two local PKI SIM access approaches are explored.

2.6.1 Approach for Current PKI SIM Cards

An approach is based on a proposal in (Mäkinen et al., 2001). An application residing on the user's client device (e.g. notebook computer) accesses the PKI SIM over an OTA connection using a short-link such as Bluetooth as data bearer, see Figure 2.

2.6.2 Prototype PKI SIM Supporting Access from a Java MIDlet.

A prototype PKI SIM supporting local access to PKI functionality from a smart phone application is proposed, see Figure 3.

An applet in a Java PKI SIM provides a method for signing with the private key. This method can be called remotely from a Java MIDlet installed in the smart phone using the Java Card Remote Method Invocation (JCRMI) protocol (JSR 177 Expert Group, 2004). This proposal supports the use of both the smart phone as well as a PC as a client device. When a PC is used as client device, authentication and signature data are transmitted between the smart phone and the PC over a Bluetooth channel.

3. HASH CHAIN GENERATED SECURITY TOKENS

Current network security standards propose X.509 certified PKI tokens for authentication and authorization services. However, security services based on such tokens are computationally heavy and require reliable real-time connectivity to updated Certificate Revocation Lists (CRLs). More lightweight security tokens are therefore needed by mobile network nodes and mobile agents, which usually

have limited computational and power capabilities. Lightweight tokens can be generated with one-way functions, for example as hash chains with Lamport's one-time password protocol (Lamport, 1981). Hash chain security depends on the used hash functions. Collision attack resistant hash functions are SHA-256, SHA-384, and SHA-512 with message digests of 256, 384, and 512 bits respectively (Stallings, 2006, p. 353).

3.1 Secure Mobile IP Registration

The Mobile IP registration protocol (Perkins, 2002) is in (Choi et al., 2004) protected from replay and man-in-the-middle attacks by Certificate Authority (CA) certified one-time public key authentication. The Mobile Node (MN) is authenticated by the Foreign Agent (FA) of the visited network and the FA by the Home Agent (HA) in the home network of MN. One-time public keys for MN and for each FA are generated with a one-way function from nonces chosen by HA combined with shared secrets between {MN, HA} and {each FA, CA}. The CA issues certificates for these public keys. From the CA, FA receives the public MN key certificate and HA the public FA key certificate. HA chooses and sends to the CA a new nonce during this message exchange. Both public keys and their corresponding certificates are updated by the CA after each iteration. A one-time public key (K_p) is in (Choi et al., 2004) calculated by

$$K_p = f^t(h(K_s, N_{HA})) \quad (1)$$

where K_p is the public key, K_s is a shared secret between {MN, HA} or {a FA, CA), N_{HA} is a nonce chosen by HA, h is a public hash function, and $f^t(x)$ means t successive applications of a public one-way function f to x, for example $f^5(x) = f(f(f(f(f(x)))))$.

The owner of a shared secret K_s (MN and each FA) publishes for authentication purposes a random i and $w_i = f^t(h(K_s, N_{HA}))$, where $0<i<t$. The owner is authenticated if

$$K_p = f^{t-i}(w_i) \quad (2)$$

where K_p is the corresponding public key (Choi et al., 2004).

3.2 Authorization Tokens for Mobile Agents

Authorization tokens implemented by hash chain values are proposed in a methodology called CADAT (Chained and Delegable Authorization Tokens) for mobile agent applications. Access rights are defined by issued *authorization certificates* and published hash chain values. An *authorization authority,* a controller of a set of n permissions, generates from a initial seed message m a hash chain of length n $\{h^0(m), h^1(m), h^2(m), \ldots, h^n(m)\}$, where h is a hash function, $h^0(m) = m$, and $h^i(m) = h(h^{i-1}(m))$ for $i = 1,2,\ldots,n$. Each hash value represents a permission. The authorization authority and users are assumed to have {public, private} key pairs and are represented by their public keys. An authorization authority issues a *chain contract certificate* to user A, who controls a mobile agent. User A issues for the needs of the mobile agent a *token contract certificate* to a remote host. User A then publishes the tokens to grant permissions for the mobile agent to be installed on the remote host and to access resources or services on the remote host. A hash of the mobile agent code can be included in the initial seed message of the hash chain and used to authenticate the mobile agent on the foreign host platform. The mobile agent requires no cryptographic operations to access remote host platform resources. A significant advantage of CADAT is, that mobile agents must not carry sensitive information such as cryptographic keys or even access tokens. (Navarro et al, 2004)

4. SIGNATURE SERVERS FOR MOBILE DEVICES

A signature server is often necessary for digital signing with a mobile device with limited computational and power capabilities. Two signature server solutions have been proposed, Personal Signature Server (PSS) and Public Signature Server. A PSS must require strong user authentication before a signature is created and the user of a Public Signature Server must be unambiguously identified in digital signature verification.

4.1 PSS

In (Campbell, 2003) is described a PSS installed on the personal workstation of a user. The private signing key is stored and used in a USB connected computer chip. The PSS is contacted using the HTTPS protocol. The PSS authenticates the user and sends a Java applet to the remote device. With the applet the user

- selects the document to be signed
- computes a hash of the document
- sends the hash to the PSS.

The PSS asks the user to validate the signature request with an encrypted message containing a unique token and a fingerprint of the document to be signed. After reception of a reply message with confirmed validation, the PSS creates the digital signature, stores a copy of it, and returns it to the remote device. Signatures are verified by a separate applet, which doesn't need the PSS if the public signing key is available. Revoking an existing signature key pair and generation of a new signing key pair is done at the console of the workstation with the PSS. The PSS keeps track of signed documents, stores and makes available older public keys for signature verification purposes. PSS vulnerabilities are evaluated in (Campbell, 2003).

4.2 Public Signature Server

A non-repudiation technique, called Server-Supported Signatures or S^3, based on one-way hash functions and traditional RSA digital signatures, is introduced in (Asokan et al., 1997). If h is a hash function, then a hash chain of length $n>0$ is expressed as n successive applications of h to x, $h^n(x)$, for example $h^5(x) = h(h(h(h(h(x)))))$. A hash function is "personalized" by including a user identity in x. Then h(x) actually means h(ID_user,x). If $x = K_s$ is chosen to be a private user key, then $h^n(K_s)$ is the public key. If a hash value $h^i(K_s)$, $0<i<n$, is published when a signature is created, then the signer can be identified by checking that a hash chain of the published value gives the public key. Thus n represents the maximum number of signatures, which can be created with a hash chain.

A CA is needed to define unambiguously which Signature Server (S) creates a S^3 signature. S and CA create own private/public key pairs. A user of an S must send his/her user_ID, public key K_p, maximum number of signatures n, and the address of S to the CA, which creates a public signed certificate for the delivered information. A server-aided PKI infrastructure service (SaPKI) to create S^3 signatures for mobile clients in GSM and UMTS networks has been used in a "cell phone banking" application. (Cai et al., 2005).

The Public Signature Server in (Lei et al., 2004), using RSA key pairs with an exponent e=3, creates/verifies signatures more efficiently than the S^3 technique in (Asokan et al., 1997).

The security of creating/verifying signatures is thus based on

- uncompromised private keys
- the use of secure hash functions like SHA-256
- sufficient RSA key lengths.

5. MOBILE SECURITY SOLUTIONS BASED ON IDPKC

In Identity based Public Key Cryptography (IdPKC) any string representing a user or device identity can be used as a public key from which a private key can be derived with a secret master key. Thus public key use requires no certification by a trusted third party and no CRLs are needed. Security services based on IdPKC rather than on X.509 certified PKI are therefore suitable for mobile devices with limited computational and power capabilities – especially since efficient IdPKC based encryption/decryption algorithms exist (Hwu et al., 2006).

5.1 IdPKC Basics

IdPKC was first introduced in (Shamir, 1984). The basic IdPKC operation is *pairing* e(P,Q), which is defined for a pair of discrete points, P,Q, on an elliptic curve. Elliptic Curve Cryptography (ECC) is described in detail for example in (Menenez, 1994). This pairing operation is proved to be *bilinear* with respect to discrete point addition:

$$e(P1+P2,Q) = e(P1,Q)*e(P2,Q), e(P,Q1+Q2) = e(P,Q1)*e(P,Q2) \quad (3)$$

Thus $e(2*P,Q) = e(P,Q)^2 = e(P,2*Q)$ and $e(a*P,b*Q) = e(b*P,a*Q) = e(P,Q)^{a*b}$. Two types of pairing operations, Weil Pairing and Tate Pairing, exist (Maas, 2004).

The first IdPKC scheme with satisfactory security is proposed in (Boneh and Franklin, 2002), Encryption/decryption operations are Weil Pairing based. The security level of these operations is the same as for ECC based encryption/decryption operations.

$Q_{ID} = s*H_1(ID)$ is the public key of a user or a network node and the corresponding private key is $d_{ID} = s*Q_{ID}$, where

- ID is a public identity string, for example a mobile phone number or a Network Access Identifier (NAI) with the format username@domainname or devicename@domainname
- H_1 is a hash function converting an ID to a discrete point Q_{ID} on a chosen elliptic curve.
- s is a secret master key, randomly chosen by a trusted third party called *Private Key Generator (PKG)*, which securely distributes d_{ID} to a user or to a network node.

IdPKC based encryption/decryption and signing/signature verification algorithms are described in detail for example in (Lee et. al., 2003). IdPKC security is evaluated in (Maas, 2004).

5.2 IdPKC Based Mobile Security Solutions

In (Lee et. al., 2003) is proposed a secure version of the Mobile IP registration protocol in (Perkins, 2002). An AAA server authenticates the MN and the MN authenticates the HA by signature verification. In (Hwu et al., 2006) Weil Pairing algorithms presented in (Boneh and Franklin, 2001) are tuned for some elliptic curves over the binary fields $GF(2^{163})$, $GF(2^{233})$, and $GF(2^{409})$. The evaluated performance improvement is about 30%. An IdPKC scheme based on the tuned algorithms is proposed for protected end-to-end data communication between mobile smart phone users.

A test environment for mobile security solutions using IdPKC and standard AAA protocols has been built in Arcada Polytechnic, see Figure 4. Solutions proposed in (Lee et al., 2003; Hwu et al. 2006) will be implemented, tested and evaluated for existing open source and commercial Mobile IP software. The security protocols in these solutions will also be formally verified.

6. CONCLUSIONS

The SIM/USIM/PKI SIM cards in mobile devices in GSM/UMTS networks constitute a key technology for authentication services and digital signing in mobile networking. Other current security technology trends for mobile networking are

- the use of hash chains and IdPKC as lightweight alternatives to X.509 certification based PKI technology
- the use of signature servers for digital signing with mobile devices.

An essential mobile security service is secure Mobile IP registration for which still not standardized solutions based on SIM cards, on hash chains and on IdPKC are proposed.

More research on security requirements of mobile networking is needed, since current standardization of security solutions for mobile networking is quite insufficient for the needs of present and future mobile applications and services.

ABSTRACT

Variability proved to be a central concept in different domains, manufacturing, software development etc. in order to develop solutions that can be easily adapted to different organisational settings and different sets of customers at a low price. We argue that families of business process models can facilitate the installation of situated models in different organisations. We propose a representation system called MAP to capture variability in process models expressed in an intentional manner through business goals and strategies. The paper presents MAP and illustrates its use in an excerpt of a real case in the Electricity Supply Industry.

1. INTRODUCTION

Variability as a concept has proved to be useful in various engineering domains in which companies are not anymore faced to the development of a single product but to engineering product lines and families. The former represent the evolution of a given product, for example, a DVD player, whereas the latter integrates different product lines having commonality, such as DVD and MP3 player lines. Variability has been introduced to explicitly differentiate between the common and different parts in a set of similar but different product lines of a product family. Managing commonalities and variability leads to two major advantages:

a. reuse of common parts (Ommering, 2002; Tomphson, 2001) and,
b. adaptation of products to different customers and various organisational settings (Svahnberg, 2001).

Seeing the duality that exists between products and processes, our position is that business process families do exist today in companies and could beneficially be handled by introducing the concept of variability. Indeed, since the process wave initiated by Hammer and Champy (Hammer, 1994), large portfolios of business process models have been created and continue to develop as business process models are recognised as indispensable artefacts to driving business management and evolution. Besides, these portfolios evolve due to internal factors leading to business process evolution and/or external factors or mergers and acquisitions where different processes, perhaps having common parts, have to be integrated. Further, business process change is not just the replacement of one process by another. Rather process change management involves the reuse of parts of the process to be discarded, inclusion of parts of other processes, co-existence of different versions of the same process etc. As a matter of fact, one can recognize business process lines and families in current organizations today.

The foregoing suggests a move away from management of individual process to managing a set of similar processes considered as a whole, a family. Our proposal is to organize business processes as business process families and to manage variability and commonalities within the family in order to promote reuse and adaptability of business process models. We understand a business process family to be a collection of processes meeting a common goal but in different ways. For example, the goal 'admit students' can be achieved through a business process family comprising three processes that select students on the basis of a national entrance examination, a university test, or school performance respectively. The variability across the three processes is obvious. However, there is a commonality between these three processes as well: all these processes have to accept fees from the admitted student.

In this paper, we propose a modeling formalism called MAP to capture variability across business processes of a family in an intentional manner. The map is a directed, labeled, non-deterministic graph with goals as nodes, and strategies to achieve goals, as edges. Its nature allows the capture of different forms of variability through multi-edges between a pair of nodes thereby enabling many different traversals of the graph from beginning to end. Besides, using the refinement mechanism of the map, it is possible to represent variability at different levels of detail, in a hierarchy of maps. We show that this hierarchical nature permits us to represent process families as maps. We also show the power of a map to represent variability and, as an illustration, model the variations of an electricity supply process family as a hierarchy of maps.

The paper is organized in three sections. The next section introduces the MAP formalism and shows how it captures business feature variability. Section 3 presents an example and section 4 considers the adaptation of a business process model within a family.

2. CAPTURING BUSINESS VARIABILITY IN MAPS

We use the MAP formalism (Rolland, 2000) to capture variability of business processes modelled in an intentional manner.

2.1 Business Intentionality in Maps

A map is a process model expressed in a goal driven perspective. Map provides a process representation system based on a non-deterministic ordering of goals and strategies. A map is represented as a labeled directed graph (see an example in Fig. 6) with goals as nodes and strategies as edges between goals. The directed nature of the graph shows which goals can follow which one.

A *Goal* can be achieved by the performance of a process. Each map has two special goals, *Start* and *Stop* to start and end the process respectively.

A *Strategy* is an approach, a manner to achieve a goal. A strategy S_{ij} between the couple of goals G_i and G_j represents the way G_j can be achieved once G_i has been satisfied.

A *Section* is a triplet $<G_i, G_j, S_{ij}>$ and represents a way to achieve the target goal G_j from the source goal G_i following the strategy S_{ij}. Each section of the map captures the situation needed to achieve a goal and a specific manner in which the process associated with the target goal can be performed.

A section in a map can be *refined* as a map (see Fig.7). This leads to intentional process modeling as a hierarchy of maps.

As process models, maps can be compared to the various types of process modelling languages and formalisms that have emerged supporting a variety of purposes. The existing formalisms can be roughly classified according to their orientation to activity-sequence oriented languages (e.g., UML Activity Diagram), agent-oriented languages (e.g., Role-Activity Diagram (Ould, 1995)), state-based languages (e.g. UML state charts), an intention-oriented languages (e.g. Maps). The concept of goal is central in business process modelling and design. It is included in many definitions of business processes (e.g. "a business process is a set of partially ordered activities aimed at reaching a goal" (Hammer, 1994). However, most process modelling languages do not employ a goal construct as an integral part of the model. This is sometimes justified by viewing these models

as an "internal" view of a process, focusing on *how* the process is performed and externalising *what* the process is intended to accomplish in the goal (Dietz, 2004). In contrast, intention-oriented process modelling focuses on what the process is intended to achieve, thus providing the rationale of the process, i.e. *why* the process is performed. Intention-oriented process modelling such as MAP, follows the human intention of achieving a goal as a force, which drives the process. As a consequence, goals to be accomplished are explicitly represented in the process model together with the alternative ways for achieving them, thus facilitating the selection of the appropriate alternative for achieving the goal.

2.2 Modeling Business Variability in Maps

For the sake of conciseness, we use a textual notation in which goals are named by letters of the alphabet, strategies are numbers and therefore, a section named ab_i designates a way to achieve a target goal *b* from a source one *a* following a strategy *i*. Thus, the section <G_i, G_j, S_{ij}> is named ab_1 where *a* is the code of the goal G_i, *b* is the code of the goal G_j and *1* is the code of the strategy S_{ij} (see Fig. 1).

We advocate that sections are at the right abstraction level to capture business variability. We consider a section as an important process characteristic that business agents (managers, decision makers, actors…) want the business to provide and also an abstraction of a business flow. By analogy with software variability, a section can be related to the notion of a feature In FODA (Kang, 1990) for example, a feature is defined as *"A prominent or distinctive user-visible aspect, quality or characteristic of a software system or systems"*. In (Bosch, 2001), a feature is *"a logical unit of behavior that is specified by a set of functional and quality requirements"*. The point of view taken in this paper is that a *business feature* is a representation of a visible process characteristic and an abstraction of a cohesive business flow of activities expressed in an intentional manner.

Features represented in a map are related to each others by four kinds of relationships namely *multi-thread*, *bundle*, *path* and *multi-path* relationships. The relationships show the possible combination of features from which a business agent can select the appropriate ones according to the situation at hand. Let us now see how these relationships are used to express variability in business models.

The multi-thread relationship: when there are various ways to achieve the same goal starting from a source, features are related by a multi-thread relationship.

A multi-thread relationship is represented in a map by several strategies between a pair of goals as represented in Fig. 2. It shows through the strategies the different flows of activities provided to obtain the same result.

A multi-thread relationship expresses business feature variability by grouping optional features from which one or many features can be selected.

The Bundle relationship: In the case where the several ways to satisfy the same goal are exclusive, we relate them with a bundle relationship. It implies that only one way can be selected to achieve the target goal. Fig. 3 shows an example of a bundle relationship.

Figure 1. A section

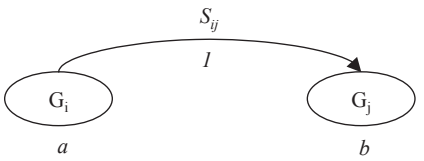

Figure 2. A multi-thread relationship

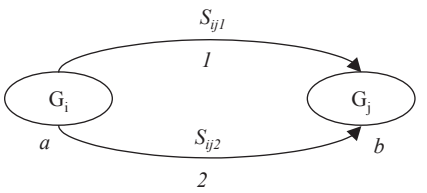

Figure 3. A bundle relationship

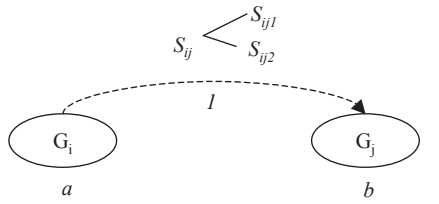

Figure 4. A path relationship

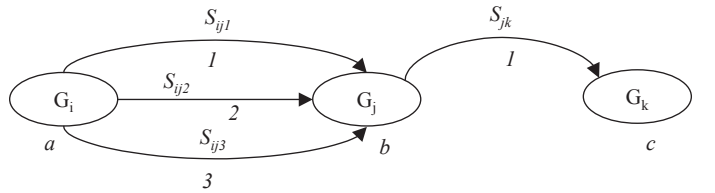


The bundle relationship expresses feature variability by grouping alternative features that are mutually exclusive.

The Path relationship: when the achievement of a target goal *b* from a source goal *a* requires the satisfaction of intermediary goals, we introduce a path relationship. It establishes a precedence/succession relationship between features expressing that in order to trigger a business flow, some other business flow must be executed first. In general, a path relationship is a composition of features, features related by multi-thread or bundle relationships or other paths. Some paths can be iterative.

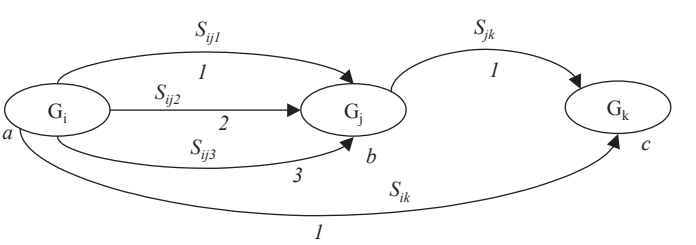
Fig. 4 represents a path relationship between the goals G_i and G_k, denoted respectively by a and c, which is composed of the multi-thread relationship containing the features ab_1, ab_2, ab_3 and the feature denoted bc_1. It expresses that in order to achieve the goal G_k, we must first select and execute one or many features among ab_1, ab_2 or ab_3 and then execute the feature bc1.

Multi-path relationship: given the multi-thread, bundle and path relationships, a goal can be achieved by several combinations of strategies. This is represented in the map by a pair of goals connected by several sections. Such a relationship is called a multi-path relationship. For example, we show in Fig. two alternative paths to satisfying the goal G_k (denoted *c*) starting from the goal G_i (denoted *a*). The first path achieves G_k through the intermediary goal G_j whereas the second path achieves G_k directly from G_i.

A multi-path relationship identifies the several combinations of business flows (represented by paths of sections) that can be executed to satisfy the same goal.

Thus, *a multi-path relationship is a means to express business feature variability by grouping the alternative paths satisfying the same goal.*

Figure 5. A multi-path relationship



In general, a map from its *Start* to its *Stop* goals represents all possible combinations of features expressed by multi-thread, multi-path and bundle relationships. Each particular combination of features is a path, from the *Start* goal to the *Stop* one, that describes a way to reach the final goal *Stop*.

2.3 Generating Variants Embedded in a Map

We notice that the bundle and multi-thread relationships are easily visible in the map. However, it is more difficult to identify all the combinations of features in a map (based on multi-path and path relationships). We propose to apply MacNaughton and Yamada's algorithm (MacNaughton, 1960) in order to discover systematically all the paths embedded in a map. The algorithm is based on the two following formula:

Let s and t be the source and target goals, Q the set of intermediary goals including *s* and *t* and *P* the set of intermediate goals excluding *s* and *t*.

The initial formula $Y_{s,\,Q,\,t}$ used to discover the set of all possible paths using the three operators that are the union (" "), the composition operator (".") and the iteration operator ("*") is :

$$Y_{s,\,Q,\,t}=(X_{s,\,Q\setminus\{s\},\,s})^*.\ X_{s,\,Q\setminus\{s,t\},\,t}.\ X^*_{t,\,Q\setminus\{s,t\},\,t}$$

And given a particular goal q of P, the formula $X_{s,P,t}$ applied to discover the set of possible paths is :

$$X_{s,P,t}=X_{s,\,P\setminus\{q\},\,t}\quad X_{s,\,P\setminus\{q\},\,q}.\ (X_{q,\,P\setminus\{q\},\,q})^*.\ X_{q,\,P\setminus\{q\},\,t}$$

In this paper we specialize the $X_{s,P,t}$ into paths, multi-paths, multi-threads and bundle relationships that we note as follows :

Multi-thread relationship between two goals k and l is denoted: $MT_{kl}=\{kl_1\ \ kl_2\ \ ...kl_n\}$ where the kl_i are the features related by the multi-thread relationship. Thus, the multi-thread represented in Fig. 2 is: $MT_{ab}=\{ab_1\ \ ab_2\}$.

Bundle relationship between two goals k and l is denoted:$B_{kl}=\{kl_1 \otimes kl_2 \otimes ...kl_n\}$ where the kl_i are the exclusive features related by the bundle relationship. In Fig. 3, the bundle relationship is: $B_{ab}=\{ab_1 \otimes ab_2\}$.

Path relationship between two goals k and l is denoted $P_{k,Q,l}$ where *Q* designates the set of intermediary goals used to achieve the target goal *l* from the source goal *k*. A path relationship is based on the sequential composition operator "**.**" between features and relationships of any kind. As an example, the path relationship of Fig. 4 is denoted: $P_{a,\{b\},c}=MT_{ab}.\ bc_1$.

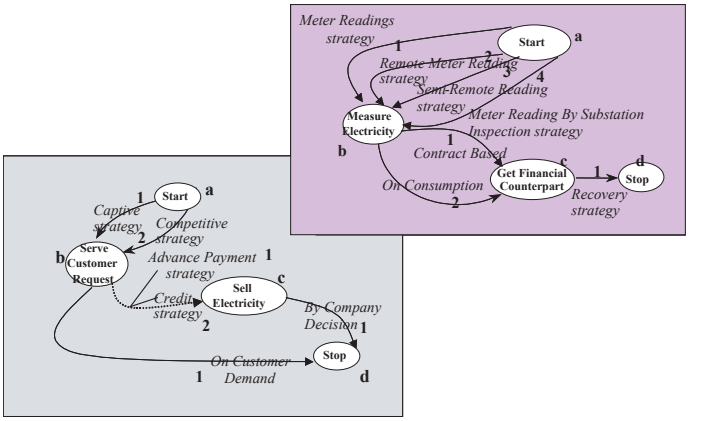
Multi-path relationship between two goals k and l is denoted $MP_{k,Q,l}$ where *Q* designates the set of intermediary goals used to achieve the target goal *l* from the source one *k*. A Multi-path relationship is based on the union operator "$\cup$" between alternative paths. Thus, the multi-path of Fig. 5 is denoted: $MP_{a,\{b\},c}=P_{ac}\quad MT_{ab}.P_{bc}$

In section 3, we illustrate the variability approach with an excerpt of a real case example and show the application of the MacNaughton-Yamada's algorithm. However, due to paper length limit, we present only the results obtained after applying the algorithm.

It can be seen that the goal of the business process family is captured in a *hierarchy of maps*. The goal associated to the root map is the high level statement about the purpose of the family. Using the refinement mechanism each section of the root map can be refined as a map and the recursive application of this mechanism results in a map hierarchy. At successive levels of the hierarchy the goal stated initially as the goal of the root map is further refined. At any given level of the hierarchy, a map describes the business process family as a set of business features and feature variability through four types of feature relationships, namely *multi-path, path, thread* and *bundle* relationships. Multi-thread and bundle introduce local variability in the sense that they allow to represent the different ways for achieving a goal directly. Path and multi-path introduce global variability by representing different combinations of business features to achieve a given map goal. Any path from Start to Stop represents one way of achieving the map goal, therefore the purpose represented in this map.

Figure 6. The ESM map sample

Figure 7 shows a refined view of the section bc_2 of this map itself expressed as a map



3. AN EXAMPLE

To illustrate our approach, we consider a business example from the ESI (Electricity Supply Industry) sector. The example is simplified to meet the paper size requirement but extracted from a real three-years project involving three large European Electricity companies and our research group (Grosz, 1998). The map of Fig. 6 provides the top level intentional view of the electricity supply business family to support Electricity Supply Management (ESM).

The map shown in Fig. 6 is organized around two key goals, "Serve Customer Request" and "Sell Electricity" that represent generic goals in the sense that they exist in any electricity distribution process. Furthermore, the map indicates an ordering constraint: in order to sell electricity to a customer, his/her request for electricity provision has to be fulfilled first.

In the ESM map, it shall be noticed that there are two different strategies to achieve each of these two goals. For example, the "Advance Payment strategy", and the "Credit strategy", are two alternative strategies to achieve the business goal "Sell Electricity". These map strategies identify two rather different business strategies to get the customer to pay for his electricity consumption. Indeed the "Advance Payment strategy" refers to a solution based on the use of payment cards to energise the customer meter whereas the "Credit strategy" refers to the more conventional solution where the electricity company provides electricity to its customer and gets paid after consumption.

Each section in the map represents a *feature* that the business process family can provide. Further, this example demonstrates the *feature variability* in the ESM family that is captured by the map. We distinguish two kinds of variability that are:

i. a variability in strategies provided to satisfy the same goal and,
ii. a variability in the combinations of strategies to fulfil the same goal.

The first kind (i) is expressed by the multi-thread or the bundle relationship. In our example, we depict a bundle relationship between the couple of goals "*Serve Customer Request*" and "*Sell Electricity*" respectively denoted *b* and *c* and composed of the two exclusive features *bc1* and *bc2* corresponding to the sections <*Serve Customer Request, Sell Electricity, Advance payment strategy*> and < *Serve Customer Request, Sell Electricity, Credit strategy* >. We also identify a multi-thread relationship composed of the features ab_1 and ab_2 corresponding to the sections <*Start, Serve Customer Request, Captive strategy*> and < *Start, Serve Customer Request, Competitive strategy* >.

The second kind (ii) is expressed by the multi-path relationship. It shows the different combinations of business flows that can be executed to satisfy the same goal. For example, given an electricity connection obtained after achieving the goal "*Serve Customer Request*", we can follow two alternative paths to stop the process. We can either respond to the customer demand applying the "*On customer request strategy*" or we can proceed with consumed electricity billing and payment

Table 1. List business features and their composition

Business features	$ab_1, ab_2, bc_1, bc_2, cd_1, bd_1$
Feature composition kind	Identified compositions
Path	$P_{a,\{b,c\},d} = MT_{ab}.\ MP_{b\{c\}d}$ $P_{b,\{c\},d} = B^*_{bc}.\ cd_1$
Multi-Path	$MP_{b\{c\}d} = bd_1 \cup P_{b,\{c\},d}$
Bundle	$B_{bc} = bc_1 \otimes bc_2$
Multi-thread	$MT_{ab} = ab_1 \vee ab_2$

through either the *"Advance payment strategy"* or the *"Credit strategy"* then stop *"By company decision"* if payment is not made after a given delay.

In order to identify all the combinations of features, we apply the MacNaughton-Yamada's algorithm introduced in Section 2. The initial formula generating all the paths between the goals *a* and *d* is: $Y_{a\{a,\ b,\ c,,\ d\},d} = (X_{a,\ \{b,c,d\},\ a})^*.\ X_{a,\{b,c\},d}.\ X^*_{d,\{b,c\},d}$. The identified paths (and therefore composition of features) are summarized in Table 1.

In the next section we will discuss how the map representation can help in customizing a business process to specific needs.

4. ADAPTING A BUSINESS PROCESS

Since a map captures a full range of features permitted in a family, the adaptation issue is of determining which features and which combination of features are relevant to the business process under design. There are two kinds to adaptation

- *Design time adaptation* permits a selection of a combination of features that results in only one path from Start to Stop.
- *Run time adaptation* allows to leave a large degree of variability in the adapted map and the desired features can then be selected dynamically at enactment time of the process.

It is possible for business people to perform this adaptation. This is because a knowledge of the business characteristics and an analysis based on these is enough to make the adaptation decision. To illustrate this aspect, we perform pay-off analysis on the map of Fig. 7. The features that form part of the adapted map are determined by an analysis of the benefits that accrue from features standing alone and in combination with other related features.

To adapt section bc_2 of the map of Fig. 6, one has to decide on how electricity should be measured and how the financial counterpart should be obtained. This leads to selecting the appropriate features and feature combinations of the map presented in Fig. 7. Each feature selection has however a payoff that can be analysed in the view of its combination to another one. The pay-off analysis for bc_2 features is summarized in the Table 2 below.

Let us consider the case where it is necessary to get financial counterparts both contract based and on consumption. The table shows that remote readings are a cost effective way to handle electricity measurement in both cases. Indeed, it is real time and therefore adapted to payment on consumption. Besides, the cost of installing remote readers can be included in the contract prices and recovered in the long term. However, the payoff table also says that remote reading, as it is automated, is not fully reliable and should be double-checked, e.g. by using substation inspection.

One possible adaptation of section bc_2 is then to keep the features ab_2 and ab_4 along with bc_1 and bc_2.

5. CONCLUSION

The notion of variability in business process families introduced here brings together a set of similar but different processes to facilitate reuse and adaptation. We use a goal driven formalism that is the MAP, to represent business process families as a set of business features and feature variability through four types of feature relationships. Once the process family has been expressed with maps, the task of building the adapted business process model to a given setting can be simply done by deciding which combinations of features are the most suited to the situation at hand. We think that expressing the variability with the map formalism is particularly useful at the adaptation phase. It exposes the business process leader to the choices that are relevant to the satisfaction of her goals in terms of the properties of the business and there is no need to deal with technical configuration details.

This paper has reported the current status of on-going work. Future work consists of (a) implementing a configuration tool to adapt a business process model of a family using the map formalism and (b) developing a software tool to support navigation in a map to select dynamically the feature most appropriate to the situation at hand.

Geeks and Gods: ICT's Debt to the Arts

Karen Simpson Nikakis, Deakin University – Waurn Ponds, Geelong, 3217, Australia; E-mail: karen.simpsonnikakis@deakin.edu.au

ABSTRACT

With each new object and phenomena humankind discovers, develops or invents, a new set of words must be coined or adopted to describe them. Words are not neutral, carrying with them associations and connotations based on their previous applications and alliances, and augmented by their shapes, sounds, rhymes and rhythms. Many words which are now embedded in ICT's, retain and continue to be colored by these earlier meanings, some of which are drawn from myths. The method of vocabulary-building utilized by ICT's reflects its openness to new ideas and users.

Keywords: connotation, nomenclature, lexis, coining, portmanteau, neologism, phoneme. alliteration

INTRODUCTION

In *A short history of the Web* (1995), Robert Cailliau describes how he and Tim Berners-Lee attempted to coin a 'catching' name for the system that they and others had been developing. Cailliau is 'determined' that the name should not 'again be taken from Greek mythology' and when Berners-Lee suggests the term *World-Wide Web,* Cailliau admits to liking it 'very much', (with the proviso that it was 'difficult to pronounce in French'). Cailliau's anecdote illustrates many of the influences affecting the coining of names and terms by ICT practitioners.

NAMING CONVENTIONS

O'Grady, Dobrovolsky and Katamba suggest that '….human language must be creative – allowing novelty and innovation in response to new thoughts, experiences, and situations' (1996:1). As young men engaged in a new enterprise, and given the prevalence of Greek gods and goddesses (and their Roman equivalents) in the nomenclature of many existing (and less flexible) scientific disciplines, Cailliau's and Berners-Lee's reluctance to draw on classical Greek mythology is understandable. Cailliau and Berners-Lee also had the advantage, enjoyed by others working in ICT's, of functioning in an enterprise which was relatively unstructured and unconstrained by generations of practice. This is illustrated by comparing the development of ICT's lexis with the lexis of astronomy. For instance, an examination of the nomenclature of our solar system, reveals the Earth to be the only planet not named after either Roman or Greek gods/goddesses. The planet names of Venus, Mars, Mercury, Jupiter and Saturn were assigned by the citizens of ancient Greece and Rome for their perceived likenesses to the deities, the beautiful goddess Venus giving her name to the bright planet, and the god of war Mars, to the red planet and so on (Carter, 2002). Once this convention was established, the naming of celestial bodies discovered later (such as the planets Uranus and Neptune, and the [now] dwarf planet Pluto) was constrained by notions of consistency and enforced by bodies such as the International Astronomical Union (IAU) which continues to regulate the lexis assigned to significant new heavenly objects.

Thus, when James Christy discovered Pluto's moon in 1978 and wanted to name it after his wife Charlene, he was refused permission by the IAU. The closest he was able to come was by choosing *Charon*, the Greek mythological ferryman of the dead, whose name, when given an English pronunciation, is phonemically similar to the first syllable of his wife's name. Charon is also appropriate (in IAU terms) in that Charon served as ferryman to Pluto, the god of the Underworld. (Carter, 2002). Even objects identified and named more recently, such as Sedna - the most distant known object in the solar system (discovered in 2004) (Brown, undated) and Quaoar, a Kuiper Belt object found in 2002 (Trujillo,undated) retain the mythological theme, being named after gods from an Innuit and an indigenous north American culture respectively.

In contrast to astronomy, the absence in ICT's of organizations functioning in a similar way to the IAU has allowed ICT practitioners to immortalise themselves and/or their loved ones. Debian – a linux distribution, is a portmanteau of the names of its creator - Ian Murdock and his then girl friend, (now wife) (Debra). Likewise, awk – a computer pattern /action language, is an acronym of its developers' last names: Aho, Weinberger and Kernighan. (http://en.wikipedia.org/wiki/List_of_computer_term_etymologies) O'Grady et al. point out that some 'systematic constraints' are essential in language creation if meaning is to be maintained, noting that 'If well-established words were constantly being replaced by new creations, the vocabulary of English would be so unstable that communication could be jeopardised' (1996:3). While this is a consideration in a new discipline, as long as neologisms remain relatively small in number, they are no more difficult to assimilate by practitioners than other discipline-specific words – be they classed as meta-language or jargon. The randomness in the terminology of ICT's however, does have the potential to affect the understanding of users expecting consistency and coherence.

Despite Cailliau's and Berners-Lee's antipathy, the lure of the lexis of the Greek myth remains strong in ICT's, especially where the function of the task is reflected semantically in the name, such as in the operating systems of Oracle and Delphi. It was to the prescient Greek Oracle living in a cave in Delphi that the troubled turned for guidance, just as the operating systems are intended to smooth the path ahead. Similarly, a Trojan horse (a malicious program designed to look like legitimate software) effectively carries with it the original mythic notion of an unsuspected and deadly attack. Users must share this cultural knowledge in order to gain this depth of understanding.

There is a further dimension to this Greek mythic nomenclature. In discussing news media, Veronika Koller notes that, 'By favouring particular metaphors in discourse, journalists can reinforce, or even create, particular mental models in their readers' cognition' (2004:3). Ancient Greek and Roman civilizations have long served as metaphors for high learning in both the rational and creative arts in the West, and when lexis from these eras is assigned elsewhere, it carries this metaphorical dimension with it. In disciplines like astronomy, which has a long and venerable history, such metaphorical transference serves to reinforce its status, but in new disciplines, such as the ICT's, such transference has the potential to *build* status.

The comparatively unstructured environments that ICT software and hardware developers work in, gives them greater freedom to coin or adopt a lexis with a humorous or larrikin edge. The founders of Yahoo! took the name from Swift's *Gulliver's Travels* (1969:260) where it referred to a repulsive, barely human creature, and a quick scan of the Web's wikipedia reveals others: Google beginning as 'googol', a tongue-in-cheek boast about the quantity the search engine would be able to search (a googol is 1 followed by 100 zeros); Sosumi (so-sue-me) – a system sound in Apple Computer's System 7 operating system, dryly reflecting the company's long history of litigation with Apple Records, and the web browser Mozilla, being a portmanteau of Mosaic-Killer (it replaced the Mosaic browser) and Godzilla (a cinematic monster). Wikipedia even cites itself as being named for the 'wiki wiki' or fast shuttle buses at Honolulu Airport (http:en.wikipedia.org/org/wiki/List_of_computer_term_etymologies), and the fact that it's one of the few places where information on computer terminology origins is readily accessible, underscores the lack of focus by ICT's on naming conventions. In addition, it suggests a certain playfulness and lack of seriousness both by the coiners of names and their recorders.

A characteristic of many of these newly coined ICT terms is their catchiness, a quality which Cailliau was also keen to see in the nomenclature of the World-Wide Web.

LOVING THE LEXIS

What is catchiness? What makes one word or term more attractive, or lovable than another? Little analysis of the term World-Wide Web is necessary to identify its most salient feature of alliteration. Alliteration, in its simplest form the 'repetition of the same sounds – usually initial consonants of words or of stressed syllables – in any sequence of neighbouring words' (Baldick, 1991:5), is achieved in this term by the identical initial sounds or phonemes (graphically represented by 'w') in all three words, and by the identical final phonemes (represented by 'd') of the first two words. In addition, the phonemes represented by 'd' and 'b' in the final two words, are similar.

While alliteration aids pronunciation, so too does the consistent consonant-vowel order across all three words. Consider the alliterative qualities of 'frosts and fogs', a word combination liable to trick the tongue into saying 'frosts and frogs'. The repetition of the same sounds in words is easier to pronounce than changes in patterns, a preference illustrated by the coining of nonsensical reduplicatives such as easy-peasy and teeny-weeny.

The denotation and connotations of a word or term are also important. Denotations do not remain constant over time or space, 'queer' and 'gay' being contemporary examples of words which have enlarged their meanings to the point where earlier meanings have been largely subsumed. While the denotation of 'World-Wide' has remained constant, 'web' now links strongly (it could be argued *more* strongly with particular generations) to a computational *denotation*, rather than to its earlier meanings. The *connotations* of 'web', at the time of Berners-Lee's adoption of it, were charming and organic (spiders' webs, the webby feet of ducks), and may have contributed to the 'catching(ness)' Cailliau describes. As far as we know, Berners-Lee didn't engage in these analytical processes consciously, and its not possible to say whether he did so unconsciously, though the attractiveness of alliteration suggests it.

SOUNDS AND SEMANTICS

The sound of a word is important in deciding on its 'rightness' for the new phenomenon it seeks to describe. Onomatopoeic words mimic the phenomena they describe closely (chicks *cheep*; dogs *woof)* and non-onomatopoeic words can also carry a sound match which seems 'right'. Widget (an interface component) was a word adopted from the 1924 play, *Beggar on Horseback*, where it describes a mass-produced object (which was never identified) but which represented a 'purely mercantile commodity that has no artistic or spiritual value' [http://en.wikipedia.org/wiki/Widget_(computing)]. The second syllable represented by 'get', echoes the more common word 'gadget', and so carries with it the semantic connotations of that word. It is likely that widget is more generally known now as an ICT term than as the undefined but soulless object in the 1924 play, and the same might be true of portals, although portals carry with them a rich heritage.

THE POWER OF PORTALS

The idea of a gateway or portal to another world is common in myth and fantasy, and far older than the use of the same notion in ICT's. While ICT portals take researchers to other domains of data, the use of portals in myths is more complex. In creation myths, the passing of portals has immense consequences for humankind – as in Adam and Eve's expulsion from their carefree existence in the Garden of Eden (unleashing the world's woes upon their descendants), and in the carrying away of Persephone by Pluto into the Underworld (leaving a legacy of cold and sunless months each year). While in its most general sense a portal is just a gate (from the Latin *porta*) (Skeat, 1983:403), when heroes pass through literal or metaphorical portals in works of myth and fantasy, they enter strange and dangerous landscapes of physical and psychological testing, or as the mythologer Joseph Campbell describes it , the 'fateful region of both treasure and danger' (1993:58). Their journeys are very different to those of researchers who enter portals knowingly in search of information relevant to their purposes, for heroes are commonly unaware of the imperative that drives them, or of the profound (usually psychological) changes to come.

In *The Hobbit*, (Tolkien:1974) Bilbo's route to psychological growth takes the form of a quest (to win back the dwarves' gold from the dragon Smaug). When Bilbo sets off alone down the tunnel to the fearsome dragon Smaug, and hears the dragon snoring, he stops at first, frozen with fear, but then forces himself on. As the narrator (Tolkien) says: 'Going on from there was the bravest thing he ever did … He fought the real battle in that tunnel alone, before he ever saw the vast danger that lay in wait.' (1974:197). Bilbo's physical journey *down* into the earth, is metaphorically a journey *down* into the unconscious, where he struggles to overcome the limitations of self (legitimate fears for his own safety), and gains the wisdom and mental strength which he later uses to end the disastrous stand-off between the dwarves and Lake men. In Henderson's words: 'the essential function of the heroic myth is the development of the individual's ego-consciousness – his awareness of his own strengths and weaknesses – in a manner that will equip him for the arduous tasks with which life confronts him' (1978:101). While computing portals can't be described as dangerous, they continue the connotations of 'newness' and 'otherness' from their mythic origins, which in turn alert the ICT user to their function.

CONCLUSION

As ICT's continue to evolve, so too does the lexis. Web logs have become blogs, which in turn have coined blogging and blogsters, while using Google has resulted in googling, having googled or having been googled. Rules of engagement or netiquette (a portmanteau - net plus etiquette) have emerged, and perhaps soon even netiquettic googsters will accept Spamsters. Presently the nomenclature of ICT's is dominated by the West, but the emerging powers of India and China are likely to add to the language and cultural mix in the future, either through their official languages or through the portmanteaux of Hinglish and Chinglish.

TIM TAM: A Teaching Initiated Modification of the Technology Acceptance Model

Con Nikakis, Victoria University - Footscray Park, Footscray 3011, Australia; E-mail: con.nikakis@vu.edu.au
Linda Hill; E-mail: linda.hill@web.de

ABSTRACT

The Technology Acceptance Model (TAM) and its variants have proven to be a useful tool in explaining user uptake intentions. With the drive to use new eLearning environments, cost-benefit analyses have been given little attention with the consequent 'Has there been a commensurate improvement in learning?' question largely unanswered. Analysis of technology uptake issues relating to learners informs teachers and educational administrators of the most efficient use of new learning technologies. This paper proposes the need for an educational, context-sensitive variant of the TAM as a basis for grappling with the educational value question, whilst maintaining learning quality.

Keywords: Technology Acceptance Model, TAM, EduTAM, technology uptake, educational technology acceptance.

INTRODUCTION

Recent research undertaken within the Information Systems arena, has related to the modelling of technology uptake in the Technology Acceptance Model (TAM). TAM has shown promise in defining the underpinning behavioural reasons why users embrace new computer technology. Much of this research has culminated in the pulling together of TAM-related research within a seminal article presented in Information Systems' Management Information Systems Quarterly (MISQ): *"User Acceptance of Information Technology: Toward a Unified View"* (Venkatesh, Morris, Davis, & Davis, 2003). The purpose of this paper is to review the development of TAM-related research that culminated in the Venkatesh paper, to identify the key factors and issues most relevant in "porting" this research practice into ICT education technology research, and in particular, the factors important in the adoption of new eLearning programs.

NEW TECHNOLOGIES IN EDUCATION – THE NEED FOR COST BENEFIT?

During the past twenty to thirty years, there has been a development of technologies at the forefront of the communication revolution. These have centred on the development of sophisticated communication channels championed by the telephone, the PABX (Private Automatic Branch eXchange), the FAX (facsimile) and recently, the internet and mobile telephone (Yi-Shun, Hsin-Hui, & Pin, 2006). A communication revolution involving the merger of three global industries: the telephone, computer and entertainment industries (Sanayei & Sadeghi, 2004); (Crafts, 2005). A revolution manifested in sales pitches that focus on consumer experiences underpinned by access to content-rich information in a form that only broadband, multimedia can deliver ("Telstra - Product & Services: 3G Mobile Phones,").

Whilst similar cutting-edge technologies aren't widely used in education, educators have shown that they aren't backward in taking on-board new technologies. The advocates of automated teaching methods used enabling technologies such as teaching machines and early computers in innovative ways, but mainly as adjuncts to traditional "face-to-face" methods (Niemiec & Walberg, 1989). In all these cases, the mooted replacement of the traditional teacher didn't eventuate.

The communication revolution encompassing cheap, highly accessible, multimedia technologies has resurrected the idea of replacing the teacher, with "learning from home" (Jared, 2005); (van Schaik, Barker, & Moukadem, 2005). Much is now possible with these technologies with interaction, instant response, extensive research capacity and simulation, available to the teacher. These technologies are no longer content delivery vehicles, but increasingly a way of providing student-centred, self-paced, eLearning programs (Turker, Gorgun, & Conlan, 2006). Government and education administrations see the rapid rise in these eLearning programs as a way of cutting delivery costs (particularly labour costs) without decreasing quality. Consequently, education administrations are funding these types of programs (Solomon, 2005).

But with the increased expenditure, 'Has there been a commensurate improvement in learning?' A TAM analysis could be part of the attempt to answer this question.

Beastall suggests that current spending on these technologies hasn't seen the improvement in learning to the extent it might have (Beastall, 2006), with Harris and Weller advocating the need to evaluate these programs using cost benefit analyses (Harris, 2003);(Weller, 2004). Cost benefit analyses should have significant currency amongst local educational administrations who must ensure their scarce funds are being used to achieve the richer eLearning environments promised (Solomon, 2005). However, analyses able to determine the degree of success of eLearning programs are often not included within the cost benefit assessments educational administrations undertake. The subsequent scepticism this can generate will drive the need for the eLearning dollar to be stretched further. The extent of student acceptance of these programs is therefore fundamental to their ultimate success (Flynn, Concannon, & Bheachain, 2005).

Thus, research into the decisive factors involved in the uptake of eLearning technologies, will have significant value for education administrations in their eLearning investment decision-making (Ndubisi & Chukwunonso, 2004).

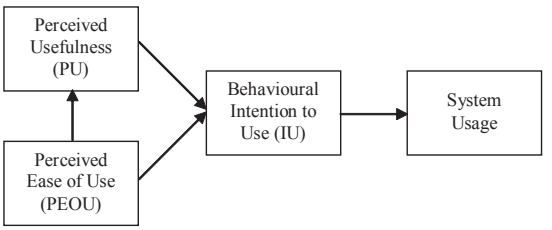
Much can be made of the experience the business world has had in technology uptake research issues. Perceptions of information technology have taken on new meaning in the business world where it's crucial the "right" choices be made to lead to the successful adoption of information technology and the monetary benefits such adoptions bring.

In ICT education, the success factors aren't as clearly defined in pure "dollar" terms, but technology uptake modelling is just as relevant (Chang, 2002). The benefits aren't immediately realized but are longer term and less tangible, leading to monetary and non-monetary benefits (Conlon, 2000). To this end, understanding the determining factors that drive a successful acceptance of an information technology education program should be an imperative. Deriving the factors thus becomes crucial to designing relevant educative programs (Ellis, 2001) for modern, apparently technologically literate students, who appears to have little time or patience in utilising courseware that they see as irrelevant.

TAM AND TAM-LIKE MODELS

In the information systems research field, the TAM (F. D. Davis, 1989) has been used to explain the key behavioural factors involved in the uptake of computer technology. This model was adapted from behavioural science's Theory of

Figure 1. Technology acceptance model



Source: (Money & Turner, 2004)

Reasoned Action (TRA) (Fishbein & Ajzen, 1975), with the underlying principal being that individuals adopt a specific behaviour if they perceive it leading to positive outcomes.

The TAM adaptation identifies Perceived Usefulness (PU) and Perceived Ease of Use (PEOU) as the principal behavioural constructs influencing users' Intention to Use (IU) (F. D. Davis, 1989).

The model has had wide acceptance as a reasonable predictor of information technology uptake. Studies since, (Taylor & Todd, 1995); (Szajna, 1996); (Gefen & Straub, 1997) and (Doll, Hendrickson, & Deng, 1998), confirm it as a useful instrument for investigating and forecasting user information technology acceptance. Many of these studies support the moderate explanatory limitations of the two factors (PU and PEOU), with the model accounting for 40%-50% of the variance in computer technology usage (Ifinedo, 2006).

Recent efforts have been undertaken to improve TAM by including factors that account for a greater part of the variance (Venkatesh & Davis, 2000); (Venkatesh & Morris, 2000); (Gefen & Straub, 1997); (McFarland, 2001); (Wright & Granger, 2001). One positive advance is the inclusion of characteristics of the Theory of Planned Behaviour (TPB). (Ajzen, 1991); (Pavlou & Fygenson, 2006) particularly in predicting the adoption of computer-related technologies for specific computing environments. Examples include the take-up of e-commerce within small business communities, and the evolution of TAM to include Wireless Internet via Mobile Device (WIMD) specific factors (J. Lu, Chun-Sheng, Chang, & Yao, 2003) with the latter study describing extra social factors such as individual differences, technology complexity, facilitation and trust.

The explanatory power of these modified models is further enhanced by structural equation modelling (Alshare, Miller, & Wenger, 2005) that combines TAM and TPB factors.

The original generality and simplicity of applications attributed to TAM have been supplanted by targeted technology-specific variations with superior explanatory power (Venkatesh et al., 2003). TAM and modified TAM models are also beginning to be described in educational contexts, particularly in relation to tertiary student attitudes to technology uptake (Drennan, Kennedy, & Pisarki, 2005), (Wolski & Jackson, 1999b).

TAM IN AN EDUCATION CONTEXT

It isn't unusual in the research world to take activities from one set of research endeavours and migrate these to another, throwing new light on research within the latter (Day & Jorgensen, 1995). Migrating the ideas espoused by Venkatesh and others into an educational technology uptake setting would seems valuable. In an educational context, TAM could be used to describe the effectiveness of new technologies introduced into classrooms (Welsh, Wanberg, Brown, & Simmering, 2003) or to evaluate the effectiveness of new teaching programs (Cheung & Huang, 2005) with a technology focus. eLearning programs would seem to be suitable (Liaw, 2001). Educational administrations might be able to use a TAM evaluation of pilot eLearning programs to determine the effectiveness of these programs before committing to full roll-outs (Ifinedo, 2006).

So, is the use of TAM in an educational context possible? If so, how? To answer these questions, it would be useful to review the literature for successful use of TAM in educative environments and determine whether there is a need for modification, adaptation, or complete rejection of the approach. The modification of TAM as described by Venkatesh that used meta-analysis in the formulation of the Unified Theory of Acceptance and Use of Technology (UTAUT) (Venkatesh et al., 2003), is a useful starting point. In this meta-analysis, there were two key issues in developing the UTAUT: the degree of robustness or the explanatory power of the model, and the degree of applicability in specific contexts (Venkatesh et al., 2003). This seminal work reflected thoughts of others (Rose & Straub, 1998) and (Szajna, 1994) in relation to these issues. So, to what extent have these two issues been raised within the information systems field of research?

Robustness of the Davis general TAM model had been tested many times (F. Davis, 1986), Straub's study verified the effectiveness of TAM in information technology but sought to recommend the development of a cultural dimension (Straub, Keil, & Brenner, 1997), McFarland's testing of TAM in relation to technology used for mail surveys (McFarland & Hamilton, 2006). Horton et al. considered the application of the technology acceptance model in explaining intranet usage in two organizations: a bank and engineering firm (Horton, Buck, Waterson, & Clegg, 2001). Lu & Gustafson verified PEOU and PU as factors when they determined there was an intermediatory exploring stage in the technology uptake process (H. P. Lu & Gustafson, 1994). Finally, Wober & Gretzel verified the TAM in their survey conducted among tourism operators (Wober & Gretzel, 2000).

The degree of applicability into specific contexts has necessitated modifications to TAM. Wu and Chen extended TAM with the antecedent variable of trust and elements of the Theory of Planned Behavior (TPB), to better understand behavioural intention in using on-line tax products (Wu & Chen, 2005), Whetton & Walker compared TPB (Ajzen, 1991), TAM and Diffusion of Innovation Theory (Rogers, 1995) in the uptake of health informatics systems and moderated TAM with a Diffusion Innovation effect (Whetton & Walker, 2002). Gurajan reinforced Whetton et al. when they identified health-care informatics literature describing the inappropriateness of TAM, and that specific adaptations were necessary for health-care (Gururajan, Toleman, & Soar, 2004). Finally, Venkatesh & Ramesh illustrated the Microsoft Usability Guidelines (MUG) (Agarwal & Venkatesh, 2002) outperform TAM in a wireless usability study (Venkatesh & Ramesh, 2006).

It is clear that TAM modelling is a useful instrument with significant robustness, in determining technology acceptance in many general applications. On the other hand, for greater applicability, TAM applied to specific environments has been shown to need either modification or adaptation. In the attempt to use a generalised TAM within specific contexts some of its explanatory power and usefulness can be lost. How does a generalised TAM lose its usefulness in an educational context?

THE CASE FOR AN EDUTAM?

There have been studies in the application of TAM or TAM-like models within educational settings. Wolski is concerned about TAM failing to include normative factors relevant in an education setting (Wolski & Jackson, 1999a). Drennan et al. conducted a study of first year management students with results that suggest student satisfaction is influenced by positive perceptions toward technology, and an autonomous learning mode – a significant adaptation of TAM (Drennan et al., 2005).

Cheung & Huang propose a partial use of TAM with modification – the addition of IT Diffusion Model factors - in their study of how the internet is used in university learning from a student's perspective (Cheung & Huang, 2005). Selim evaluates the use of the World Wide Web as a teaching and research tool amongst students and proposes a Course Webs Acceptance Model (CWAM) adaptation of TAM (Selim, 2003) which essentially validates TAM with a course website usage variation. Similarly, McFarland adds an age factor to TAM to better explain eLearning program uptake (McFarland, 2001). Legris et al. suggest that TAM is useful if human and social processes are included (Legris, Ingham, & Collerette, 2003). They describe a simple student environment which TAM is good at explaining but suggest more complex environments should include supplementary Innovation Model factors.

The limited literature suggests there are aspects of TAM that are useful in analysing educational technology acceptance and more broadly, technology-orientated educational programs such as eLearning programs. So, while TAM has wider usage and usefulness in the business community, to be a greater predictor of program success in an educational setting would require modifications with factors that aren't included in a generalised TAM.

In the technology world, the need to understand technology acceptance has been driven by the savings that can be made by an effective technology implementation.

In an educational setting, a similar impetus should also be clear but is undervalued (Finkelstein & Scholz, 2000). This maybe because of the lack of solid research undertaken over recent years into the concepts of technology acceptance in education. The little research that has been completed indicates that TAM and TAM-like models are showing some robustness in their explanatory power as predictors of technology acceptance and the consequent success of technology-based education programs. In particular, with proposed eLearning programs it would be consistent to apply TAM methodologies to evaluate degrees of success. What is also clear is that using a broad, general model is not sufficient. The application of TAM in specific educational settings necessitates the substantial modification of the model, usually by adding humanistic factors described by other models (Wright & Granger, 2001); (Wolski & Jackson, 1999a), (Ma, Andersson, & Streith, 2005).

CONCLUSION

What is needed now? Firstly, work can be undertaken in testing a generalised TAM within different educational environments to confirm the need for setting education specific modifications. Secondly, use can be made of a meta-analysis similar to Venkatesh's with applications of TAM that are education specific (Venkatesh et al., 2003). Thirdly, the education specific criteria so gleaned could then be used to propose an education specific modified TAM (Pan, Gunter, Sivo, & Cornell, 2005), that is, an EduTAM. Finally, an EduTAM should be verified and tested by applying it to existing education programs and maybe new and emerging learning environments, such as podcasting and mobile technology-based learning. In relation to the original proposition (looking for factors that modify TAM for the specific eLearning context), it is clear that TAM, in a modified form, could be a significant tool for predicting the success of new technology-based environments, such as the latest eLearning programs, within an educational setting. For an eLearning strategy this would mean that an EduTAM could be used to identify the important criteria. These criteria can then be used to set up specific educational administrative practices that bring technology uptake issues into the forefront of planning considerations, and to create strategies that are "student-centric" in relation to eLearning program acceptance. Finally these strategies could be used to address EduTAM issues within eLearning training programs delivered to teachers.

Hence, education administrations would be able to predict with greater confidence that funded eLearning programs would deliver commensurate improvements in learning.

ABSTRACT
This paper proposes an enterprise architecture framework that allows modeling organizational components for reuse and co-development, emphasizing their traceability and alignment at both design and execution time. It focuses on describing how entities interact in the context of business processes and relate to goals, actors and supporting systems. To facilitate the analysis of the architecture models, a set of five views that separate multiple organizational concerns is also introduced.

1. INTRODUCTION

Representing knowledge about an organization proves to be a challenging task since it requires several of its aspects to be represented in a coherent and integrated way. Failing to deliver such representation hinders the assessment of the organization, as well as the detection of problems and areas of improvement. For an organization to change it must be self-aware, meaning that if the knowledge on the organizational components is not shared and understood there will be a gap between the actual state of affairs and the state as perceived by the different stakeholders. In addition, information systems accentuate these issues as they facilitate information sharing and process automation, regardless of the quality of the information and how processes are aligned with the organization goals. Despite investments on systems and technology, organizations often do not have the adequate methods that enable the management and coordination of these systems to support planning, decision making, controlling and, especially, to leverage competitive advantage.

Enterprise architecture results from the process of representing and aligning the components that are required for the management of the organization. It is the set of representations required to describe a system or enterprise regarding its construction, maintenance and evolution (Zachman, 1987). It concerns the structure of the things of relevance in the enterprise, their components, and how these components fit and work together to fulfill a specific purpose within the organization. Identifying the architecture of the enterprise should therefore be considered as a fundamental step to understand and align the organizational components.

Extensive related work can be found on the literature. ANSA was likely the first project to propose views, claimed to provide complete coverage of information processing systems (ANSA, 1989; Herbert, 1994). The views on enterprise, information, computation, engineering and technology were later taken up in open distributed processing standards. The concept of view enables separating the multiple concerns of a system in such a way that they can be individually addressed and later composed in a global representation. Thus, this concept shares a common goal with other approaches to enterprise architecture.

RM-ODP (Farooqi, 1995; ISO, 1995; Schurmann, 1995) aimed at integrating and maintaining consistency between multiple distributed-systems standards. It includes descriptive elements that provide a common vocabulary and prescriptive elements, known as viewpoints, which constrain what can be built. Specifically, it defines the enterprise viewpoint for system boundaries, policies, and purpose; the information viewpoint to represent distributed information; the computational viewpoint for decomposition of system into distributable units; the engineering viewpoint for description of components needed and, finally, the technology viewpoint for describing the implementation details of components.

The Zachman Framework (O'Rourke, 2003; Zachman, 1987) is used both from modeling and management perspectives. It describes the subjects needed for developing and documenting the enterprise architecture in a matrix. The vertical axis defines multiple perspectives on the architecture while the horizontal axis offers a classification of its artifacts. Its rows are structured around the perspectives related to user roles, namely Scope, Enterprise Model, System Model, Technology Model and Detailed Representations, while the six columns focus on separating Data (who), Function (how), Network (where), People (who), Time (when) and Motivation (why). The framework is independent of specific methodologies, but does not define how to integrate the information within each cell, nor how to describe how to trace such information neither how to specify the artifacts within each cell (Frankel, 2003).

This paper proposes an enterprise architecture framework that emphasizes the traceability and alignment between organizational components, facilitating their reuse and co-development. It focuses on describing how entities interact in the context of business processes and relate to organizational goals, actors and supporting systems. The components of the proposed framework and its underlying UML representation (OMG, 2004) are presented in section 2. In order to facilitate the analysis of the architecture, section 3 describes a set of five views that separate organizational, business, information, application and technological concerns. Section 4 introduces the concept of context to enable aligning the designed components with their corresponding execution so that organizational self-awareness can be maintained. Finally, section 5 provides concluding remarks.

2. THE FRAMEWORK

The architecture defines and relates the fundamental concepts required to describe the enterprise in a set of blueprints. The current section describes these concepts as packaged UML classes. Section 3 describes the five views that encompass these packages.

An organization can be abstracted as a collection of business nouns that interact as described by verbs. The nouns represent the concepts within the organization that are of interest regarding the purpose of the model. The verbs are enterprise activities that define how work is done and how value is added, thus describing its business processes. These abstractions are modeled as entities, roles and activities. Entities (business nouns) display behavior by playing a number of roles. Activities (business verbs) specify how roles collaborate in order to achieve a given purpose.

2.1 Entity

An organization is composed of entities. An entity can be a person, place, machine, resource, event that has meaning in the context of the business and about which some information can be stored because it is relevant for the purpose of the model.

Entities can be classified, in the object-oriented sense, according to its attributes and methods. These features can be either intrinsic or extrinsic. Intrinsic features describe the entity in isolation, while extrinsic features arise from its relationships. For example, the entity "person" has intrinsic features such as age and sex, and

extrinsic features such as job position and salary, which derive from a relationship between the person and its employer. The state of the intrinsic features may change over time but always characterize the object, whereas extrinsic features are only meaningful while a relationship is valid.

Entities may also relate structurally to other entities, as in the case when an entity is composed by other entities. An entity class may also be specialized. Entities may interact with other entities only by playing roles in the context of a specific business activity. An entity is represented as a UML Class.

2.2 Role

A role is the observable behavior of an entity in the scope of a specific collaboration context, representing its features when it collaborates with other entities in the context of an activity. An entity relates to zero or more role classes through the stereotyped «play» relationship. Each role represents a subset of its external or extrinsic features in the context of a specific collaboration as defined in a role model.

Roles aim at separating the different concerns that arise from the collaborations between the entities fulfilling an activity. A role may be bound to multiple entities. Binding a role to an entity means that a specific instance of that entity is able to express the behavior defined by the role. It also means that the attributes and method of the role will be part of the entity's feature set. A role is also a type and may be classified according to its features, so it can be generalized and aggregated as a class. Roles are described in role models that describe how roles are structured and how they collaborate in order to fulfill a task. The role model may also specify constraints. Roles are described as UML Classes.

The structural relationships between roles are shown on class diagrams. Role models are packages that comprise a class diagram to describe the role structure and a UML dynamic diagram to describe its collaborations. The class diagram depicts the roles and the role associations required to fulfill a task. It also describes any constraints or business rules that govern the role associations.

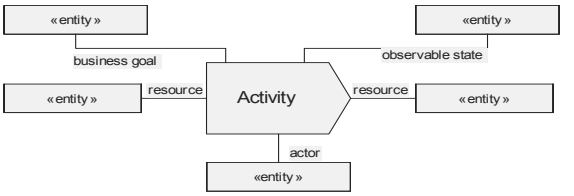
Figure 1 shows the structural dependencies between two roles, Employee and Employer, both defined in the "Works For" role model. It also depicts the binding between two entities, Person and Organization, and the two roles Employee and Employer. An activity is described by a number of role collaborations as seen on Figure 1 (right). This notation is closer to that of UML (OMG, 2004) and BPMN (BPMI, 2004).

The diagram in Figure 1 uses roles to separate the Person's external attributes from its intrinsic attributes. It can be observed that the job position and salary are extrinsic attributes and are dependent of the specific role Employee. Moreover, the role model makes clear that the Employee role relates with the Employer role, in the context of the "Works For" collaboration. Separating the intrinsic from extrinsic features allows entities to be designed independently of the activities that use them. This not only improves the reusability of the entities but also the ability to understand why a specific feature is expressed.

2.3 Activity

An activity is an abstraction describing how entities collaborate in order to produce a specific outcome. It aims accomplishing some task which, given an initial state, will always end in finite time and in a recognizable end-state. An activity may also be functionally decomposed into further activities. An activity specifies what entities are required to realize a task. As seen earlier, roles are used to separate the description of the actual entity features from the features required by the collaboration in context of the activity. In this way, activities and entities are described separately, and roles may be reused in different activities.

Figure 2. Common roles played by entities in the course of an activity



An activity often results from a number of interacting entities playing a set of roles specialized from four generic roles: resource, actor, observable state and goal (v. Figure 2). The resource role is played by the entities that are used as input to the activity. Resource entities are handled by a number of actors to generate output resources. An entity plays an actor role whenever is performing active behavior, such as entities modeling people, mechanical devices or information systems. During these operations, actors may contribute to the achievement of business goals.

From a methodological viewpoint, activities must relate to at least one entity playing the role of observable state. An observable state models a state of affairs that is of interest to a stakeholder. It can be seen as an indicator that results from performing the activity. This criterion can be used to decide if an activity can be further decomposed: decomposition is only meaning if all of its sub-activities produce at least one observable state. It is worth mentioning that the observable state set depends on the purpose of the architecture. For instance, the set of states in an architecture that will be used to identify information system requirements will likely be more fine grained detailed than the set used to describe the core activities of an organization from a strategic perspective. Observable states are detached from how activities are coordinated.

2.4 Activity Coordination

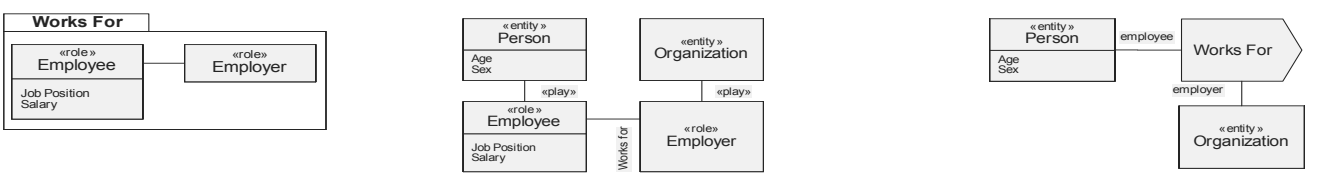
Coordination means linking together different parts of a system to accomplish a collective set of tasks. In the case of activity coordination, it means describing how activities are linked together so that they define a business process. The common definition of business process found in the literature defines it as a coherent collection of activities that takes one or more kinds of inputs and creates an output that is of value for an internal or external customer (Hammer, 2001; Verharen, 1997).

A process is coordinated and goal-driven. In this sense, a business process is a coordinated set of activities, but the converse may not be true. It is possible to describe activity coordination in different ways, such as using explicit control or data flow between activities or using events or pre-conditions. Activity coordination is represented using any of UML's dynamic diagrams, such as an activity diagram.

2.5 Role Types

The roles entities are able to play depend on the purpose of the model and on the specific organization. However, a number of basic roles are fundamental for organizational modeling:

Figure 1. The Works For role model showing the dependencies between two related roles (left); binding roles to entities (center); activity classifier (right)

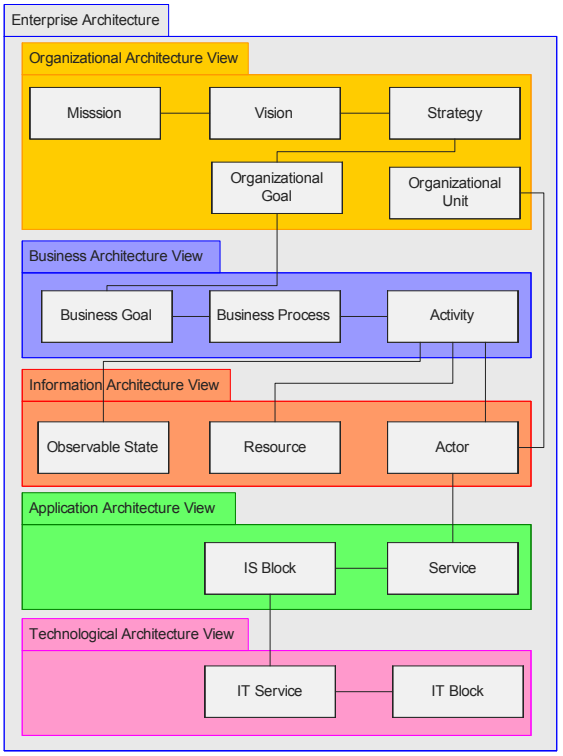


- **Mission**. A statement of enterprise's purpose.
- **Vision**. A statement on how to transform the mission into action.
- **Strategy**. A business process describing how to accomplish the vision.
- **Organizational Goal**. The goals achieved by the strategic process.
- **Business Goal.** A measurable state that the organization intends to achieve. Goals are achieved by entities involved in activity execution.
- **Resource**. The capacity of an entity to be managed by business process activities, including the ability of being consumed, incorporated, monopolized, or accessed.
- **Observable State.** A state of affairs that is of interest to a stakeholder in the context of the enterprise architecture. Observable states can guide the task of activity functional decomposing.
- **Actor**. An animate entity capable of active behavior. Actors model people, computer systems, mechanical tools or any other devices used to perform the operations required by an activity. Since entities only collaborate through roles, classifying an entity as an actor depends on the roles the entity is able to play, i.e., on the type of collaborations it participates in. This means that some entities may be potential actors but in a specific organizational case, they are just inanimate entities. The status of actor is transient and context dependent, meaning that the same entity could be an actor in the context of a process and a resource in the context of other. Actors are able to perform the set of services required to play a role. This means an actor is then responsible for providing such services. In case of people, these services are correlated to the skills, capabilities and other attributes pertaining to the person that are relevant to assign her to a role in the scope of an activity. In case of computerized systems or machines, the services represent the operations and functions that these devices put into play during the role assignment.

3. ARCHITECTURAL VIEWS

The architectural views aggregate and relate the fundamental roles played by the entities. They are defined to facilitate the analysis and development of the entities' roles through the separation of its different organizational concerns. Each view is individually represented and organized as a UML package that owns its model elements (v. Figure 3).

Figure 3. The enterprise architecture framework



3.1 Organizational Architecture View

This view deals with the aspects related with the organization but not to the specific business it conducts nor with the mechanisms used to accomplish the creation of value. It therefore includes concepts such as the enterprise mission, vision and strategy and the definition of organizational units.

3.2 Business Architecture View

The business architecture view synthesizes how business strategy is implemented and how processes are defined. The functional requirements of the business process support systems can be extracted from this view.

An activity describes the roles required for its operation. These roles are played by the organization entities and include actor role, resource role and observable state role. An activity requires one actor or a combination or team of actors to be executed. The actor represents a person, a machine or device, or an information system. An actor provides the services require for fulfilling the business role required by the activity. A resource is used as input or output of an activity during its operation. A resource is usually created, used, transformed or consumed during the operation of the activity. An observable state is specific resource role that is used as a means to observe the status of an activity. An activity is performed during a specific period. As a precondition for its enactment, all of the business roles must be fulfilled by specific entities. These entities will be engaged in playing their roles for the duration of the activity. The activity post condition is that all of the roles will have finished playing their part.

3.3 Information Architecture View

The information architecture describes what the organization needs to know to run its processes and operations as described in the business architecture. It defines a view on the business information that is system and technology independent. It is an abstraction of the information requirements of the organization and provides a high-level logical representation of all the key information elements that are used in the business as well as the relationship between them (Gilchrist, 2003; Inmon, 1999).

3.4 Application Architecture View

The application architecture view fulfills two goals: making explicit how business requirements are supported and allowing efficient management of the organization's entities. To satisfy these goals, the application architecture should be derived top-down from the analysis of the business and information architectures.

The application architecture defines the applications needed for data management and business support, regardless of the actual software used to implement the systems (Gilchrist, 2003). It functionally defines what application services are required to ensure processes and entities are supported in acceptable time, format and cost (Spewak, 1992). It describes the characteristics, styles and interactions among multiple applications. The architecture of a business process support system is described as a structure of Information System Blocks, each representing an organized collection of Services designed to handle organization information.

3.5 Technological Architecture View

The technological architecture view represents the technologies behind application implementation as well as the infrastructure and environment required for the deployment of the business process support systems. These concepts are abstracted as an Information Technology Block. An IT block realizes or implements IS blocks through number of technological Services.

4. ALIGNING DESIGN WITH EXECUTION

The concepts previously described enable capturing design-time aspects and assessing the static alignment between these aspects. Whereas this enhances the organization's self-awareness, it does not make explicit how to continuously and dynamically maintain this self-awareness. Aligning the organizational design with its execution entails capturing the current state of its active entities, i.e. actors and the particular interactions between them that change the state of resources, actors or activities. Actors interact using specific roles. Because of these interactions, actors continually change their own state, the state of activities and the state of resources.

A collaboration of resources and actors within an activity defines an interaction context that reflects the observable state of the activity, its actors and other resources. Actors are capable of engaging in multiple activities and to switch between them, potentially playing a different role on each. Several interaction contexts result from the different states of affairs related to the particular activities or roles where the actor is participates. When resuming a suspended activity the actors must be aware of the current state of affairs of the corresponding interaction context.

Figure 4 depicts the relationship between interaction contexts, actors, resources and activities. At design-time, the focus is on capturing goal, resource and actor roles related to an activity. However, during activity execution the observable features are actor interactions, which first create and then modify interaction contexts. These changes may trigger further changes on additional entities. In summary, modeling activity execution entails capturing (1) how actors interact, (2) how these interactions modify interaction contexts and (3) how interaction contexts trigger changes on the state of activities and other resources and actors. Defining models and modeling concepts to capture actual execution facilitates comparing the actual interactions of actors with activities and resources and the detection of errors or the discovery of emergent behaviors that improve the organization's effectiveness.

Figure 5 illustrates the interaction contexts and the relationship to design-time modeling concepts. The interactions captured are related to the collection of cards information for a mail application. These interactions resulted in two interaction contexts, the former shared by actors Peter and Maria and the latter, between Peter and the integration team. In the first context, Peter plays the role of task performer, Maria and the integration team provide resources for Peter. Successive interactions change the interaction context state, reflected by pending commitments. This interaction context modifies state of three activities.

Figure 4. Actors, resource, activities and interaction contexts

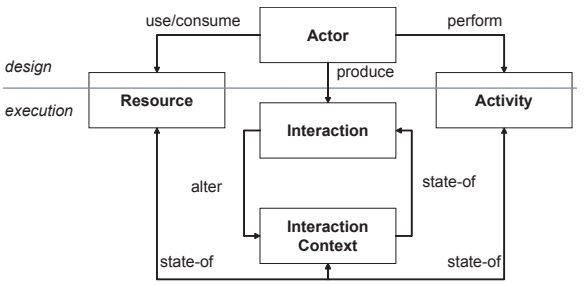


Figure 5. The "mail application data collection" interaction context

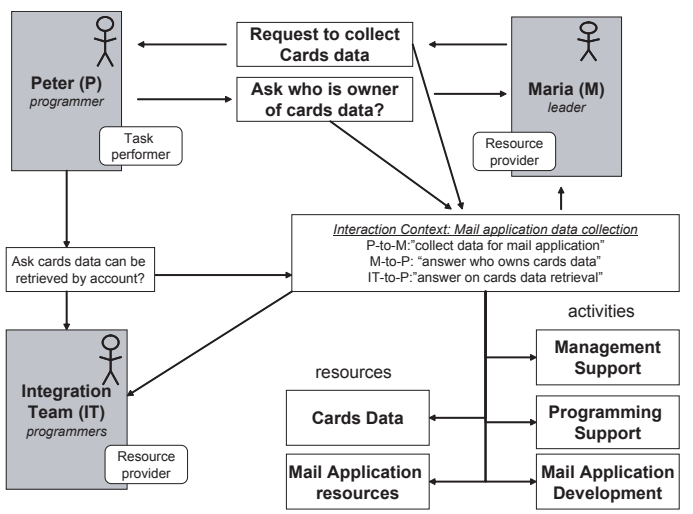

Interaction contexts are defined to capture execution. Identification and modeling of interactions contexts provides groupings of interactions exhibiting higher similarity with actual execution than other abstractions, such as activities. Interaction contexts relate to several activities and resources. Conversely, activities and resources relate to several interaction contexts. This means that interaction contexts are not part of activities or resources. Rather, they are a different concept. Moreover, actors activate their tasks according not only to task factors, but also to time, location, personal or inter-personal factors. Regarding interaction contexts as entities allows identifying interaction context emergent properties such as its priority and activation rules. This enables the discovery of actor scheduling heuristics and interaction rules. Analyzing interaction history makes also possible to find usage patterns and to discover tasks in a bottom-up fashion, facilitating the alignment between organizational models and actual execution (Zacarias, 2006).

5. CONCLUSIONS

Enterprise architecture consists of defining and understanding the different elements that shape an organization and how those elements are inter-related. This paper presents a framework for expressing the components of an architectural model for process-oriented organizations using five separate views that are integrated with the enterprise architecture model to facilitate its evolution. In this way, alignment becomes the process of continuously guiding the enterprise resources to exploit opportunities and cope with environmental changes.

The framework defines the fundamental concepts and their relationships. It also makes use of the object-oriented paradigm, exploiting mechanisms such as specialization and aggregation, with the goal of maximizing reusability and facilitating the discussion and communication of the models, thus promoting understandability.

Case Study: Overcoming the Headache of the E-Mail Inbox Through Training

Thomas W. Jackson, Loughborough University, Loughborough, Leicestershire, UK, LE11 3TU; E-mail: t.w.jackson@lboro.ac.uk

ABSTRACT

How do we overcome the nightmare of the email inbox? This paper details a two-phase research programme to demonstrate the need to give employees training regarding email communication, and conduct both seminar based training and computer-based training. Detailed results show that email training can lead to significant improvements in the way employees use email within the workplace with computer-based training showing a greater improvement. While email is a powerful information system tool, it can be optimised to further maximise its benefits and to make the email inbox more manageable.

INTRODUCTION

Nowadays employees are overwhelmed by the volume of email communication (Levitt, 2004), lose important items (Whittaker and Sidner, 2004), and feel pressured to respond quickly (often within seconds Jackson et al., 2003), among may other concerns. The major research stream in this field is trying to reduce such "email defects" by designing and building improved email systems designed from an understanding of email usage (Rohall et al., 2004). Although such systems aim to improve email communication, could providing simple education to email users provide, at worst, an interim solution to reduce email defects?

The major source of the email issues within an organisation is likely to be the end-user, as he or she creates and receives the email that periodically causes problems. The 'back to education' approach is based on identifying the *major* problems that users face with email and administering training (both seminar and computer-based to determine which has the more enduring effect) to help users to become more effective email communicators. Although the approach sounds simple and has been successfully applied in many other arenas, will it be successful for improving email communication?

To date, there is very little literature on the role of seminar and computer-based training in improving email communication. This paper is a subset of a paper published by Jackson and Culjak's in 2006. It aims to explore organisational email defects and their management by employee email training in seminars or computer-based modes. The research was conducted in two phases. In the first phase, an interpretive case study was conducted within a department to discover how email was used and viewed by employees. The second phase of the research involved an evaluation process that determined the effectiveness of two training approaches (seminar based and a combined approach of computer-based and seminar based training created by Jackson) to reduce the email defects identified from the first phase and improve the way employees use email.

OPTIMISING EMAIL COMMUNICATION

There are several approaches to improving organisational email use for everyday communication. Some authors suggest that organisations need to implement policies on how individuals use email within the workplace (Cushing, 2002; Duane and Finnegan, 2004). For example, Dudman (2005) suggests that organisations have policies on the retention and deletion of email, while Watson (2001) states that organisations should monitor employee email use to ensure that policies are followed.

Some organisations have taken a stand by banning email communication at certain times in an attempt to encourage employees to work without email (Cushing, 2002; Best, 2003; Wray, 2003). While this approach will force employees to communicate without email for one day a week (or, in the case of Phones 4U, stop employees using email for internal communication (Best, 2003)), it does not address the issues associated with ineffective email use, but rather, simply avoids them.

Email education within organisations tends to focus on hardware and software issues without taking into account the requisite communication skills (Hallewell, 2000). Most employees are not taught how to become effective electronic communicators (Nantz and Drexel, 1995). There is a tacit assumption that because employees can read and write, they can use email effectively. However, Hallewell (2000) suggested that employees need training on the 'human side' of email rather than just how to use email. He argued that email training focuses on how to send and receive email messages, without being taught when it is appropriate to do so (Hallewell, 2000). Indeed, even the most educated of employees can lack basic skills for expressing themselves effectively (Davenport, 1997).

Several issues relating to the quality of written email messages have been identified. In order to achieve both fast and understandable communication, elements associated with quality content and format must be considered when writing email messages (Brandenburg et al., 1999). Factors that contribute to the quality of the content of email messages include (Brandenburg et al., 1999):

- Tone, Courtesy, Conciseness, Clarity and Correctness

Factors that contribute to the quality of format include (Brandenburg et al., 1999):

- Personalisation; Paragraph and sentence length and layout

The above quality-oriented factors contribute to well written email messages. Several earlier studies have identified instances in which these factors have not been present, leading to ineffective email use. Frazee (1996) reported that 65% of all email messages fail to give the recipient enough information to act upon. Participants in the Whittaker and Sidner (1996) study commented that some employees failed to take into account the context of their message before they sent it. Participants stated that they would often receive one line replies to messages without knowing the context. Messages of poor written quality are likely to be difficult to read and may take longer to read and understand (Brandenburg et al., 1999). Poorly written emails containing misspelled words and typing errors are also likely to create a negative impression on the reader (Lea and Spears, 1992). The socially detached nature of email also means that individuals may include content they would not normally communicate verbally (Alonzo and Aiken, 2004). Brandenburg et al (1999) suggest that email is often abused because it is easy to use.

Much of the recent literature that focuses on improving email use within organisations looks at the development of new software tools that are embedded within or replace existing email applications. These tools are designed primarily to aid the user in managing their mailbox, by providing additional functions such as search facilities, enhanced user interfaces and the ability to track conversations. While these tools may be aiding users to manage their email on the recipient side, they do not help users to write effective emails, nor cover the most appropriate methods to do this. Missing from the literature on e-mail management are solutions and theories based on employee email training. One of the key questions in this emerging stream that needs to be determined is the effectiveness of both computer-based and traditional seminar based training in enabling employees to write more effective emails and reduce the problems often associated with email communication.

For the training of employees in effective email communication, many training methods are available and the method selected depends on a number of different factors. Such factors include the organisation size and set-up, the nature of the organisation and its trade/business, and the systems and processes that are used.

Seminar based training (SBT) refers to traditional classroom training, taught by one trained in the skills required. Computer-Based Training (CBT) (also known as computer aided instruction and computer assisted learning) is the use of the computer for training and instruction, and is commonly used for acquiring skills in the use of computer packages or acquiring specific knowledge (Whalley, 1998). Henke (1996) stated in 1996 that computer-based training was a fast growing field. Even earlier, Filipczak noted that 43 percent of all U.S. organisations with more than 100 employees were using CBT as part of their training programmes (Filipczak, 1993). However, around the same time Russ-Eft, stated that only 40 percent of companies surveyed used CBT (Russ-Eft, 1994). Considering that this statistic was noted more than ten years ago, 40% is quite a high figure.

While the use of CBT has been documented and discussed, what is lacking from the literature is evidence of whether computer-based training has more enduring effects compared to seminar based training, and whether computer-based training is more effective for training employees in the use of email.

METHOD

The research seeks to improve workplace communications by investigating the way email communication is used and exploring the role of employee training in managing the issues identified. The research adopts an interpretivist approach, as the research takes place within an organisational environment, and although the research conducted was both qualitative and quantitative the research focuses on capturing information within a social environment in an organisation, rather than a laboratory (Walsham, 1995). Two stage research involved a the Professional Development (PD) Department at Loughborough University. Professional Development is a central support unit within Loughborough University that offers staff and students services to help develop their full potential. The PD department consists of 23 staff.

The first phase of the study highlighted problem areas with the way email is used within organisations. The problem areas (email defects) relate to the inefficient and ineffective uses of email within an organisation. They pertain to all aspects of email use, including the quantity and quality of emails generated within organisations, as well as the configuration of the email application itself. In order to identify the potential problem areas with email use a web-hosted internal survey was conducted and a questionnaire was developed. This method was selected because the ability to distribute the questionnaires to a wide geographical area was vital due to a number of employees being based at different locations throughout the United Kingdom. Several open-ended questions were used to capture how many emails were received by employees and how employees categorised the importance and relevance of each email. A series of closed attitudinal questions were used to gauge how email was used and how the employees viewed organisational email use. Each questionnaire was live for a period of two weeks. Sixteen responses were received from PD, giving a response rate 70%.

The second stage determined the effectiveness of both seminar-based and a combined seminar/computer-based training approach to reducing email deficiencies as will be described below. The research aims to establish which training approach is the most effective at reducing email defects and if certain defects are more receptive to the training than others. The long term impact of the two training approaches were analysed, to determine if any improvements in email use could be sustained. Further details help explain the evaluation approach used, below.

Computer-Based Software Development

The software was designed to work with Microsoft Outlook as it recognised as the defacto corporate email standard. The computer-based email training application has been built so that it flags potential defects within an email by parsing each email and highlighting the defects to the sender before the email is sent. The software can identify certain defects within the recipient field, the subject line, message body and with attachments, providing the user with the opportunity to change the email before it is sent. Details of the parsing algorithm used are published elsewhere (Jackson et al., 2005).

If an email has been previously parsed and still contained deficiencies when the user tries to resend the message, the potential defects will still be shown to the user in the 'Mail Report' window. Any remaining potential defects will be shown to the user regardless of the number of times that a user has edited the message. The user also has the option to ignore the defects identified by the software and to send the email once it has been parsed. It was important that the user had full control over sending an email as this gave them confidence in using the system and being able to override it. If the real time trainer did not identify any potential defects within an email, then the email would be sent to the users outbox, ready to be sent to the server.

Developing the Seminar Based Email Training Programme

The SBT summarised the common problems with email use that can exist within the workplace. Training was tailored for PD by focusing on the problems highlighted from the questionnaire results together with examples from other research. It was important to highlight the common problems with email communication in order to enable participants to understand the magnitude of some of the issues.

The training programme identified defects that individual employees can help reduce, by improving the way they use email. Employees were given training on how to manage their inbox, including the use of folders and filters. Defects that related to the configuration of an organisations email system would also be brought to the attention of management in a report covering the questionnaire results.

The main section of the training focused on areas of email use that individual employees could improve. This included asking employees to consider whether it is necessary to send an email, or whether another medium such as such as the telephone would be more appropriate. The employees were also asked to consider to whom they were sending their email message, and whether all recipients needed to be copied in (cc-ed). The participants were given advice on how to write effective subject lines and emails that contain clear concise messages. The training also covered other aspects of email best practice, such as managing the inbox. This was considered important, as it will enable participants to better manage and prioritise their incoming email.

Measuring Improvement

Both SBT and CBT were conducted using sender and recipient pairs in order to measure the effectiveness of both SBT and CBT. The senders had an established email communication relationship with their recipients, in that they made regular contact with each other via email. Steps consisted of:

1. Once the sender / recipient pairs were established, the recipients would receive training on how to evaluate the emails they receive from their pair(s).
2. The recipients evaluated up to 20 emails that they received from their paired sender(s) over a specified timeframe.
3. After the senders' email had been evaluated, the senders would then receive SBT on the best practices of email, even if they were going to use CBT.
4. Once the senders had received training the recipients were asked to evaluate up to a further 20 emails they received from their paired sender over a specified timeframe.

The recipients were asked to mark each email against a set of nine criterions derived from the email defects identified in the questionnaires. The difference in the scores before and after the sender received training would indicate the success or failure of the training. The recipients would be asked to date and evaluate the emails that they received after the senders had their training. This would enable the author to determine if any improvement could be sustained, or if the effect of the training was limited.

To determine the effectiveness of the SBT, the scores both before and after training were averaged for each sender / recipient pair. The average for all participating pairs was calculated to determine the overall effect of the training for each of the criterion. The t-test statistic was used to determine the significance of the SBT at reducing each of the defects represented by each criterion. The results indicate which aspects of email use are most receptive to SBT.

RESULTS

Following SBT the t-test analysis shows that four out of the nine criteria showed significant initial improvements. The four significant improvements were:

- Better written emails that were easier to read. (at the 90% level)
- Better written emails that were more concise and to the point (significant at the 95% level)
- Better use of the subject line which made it easier to assess the importance of the message (significant at the 90% level)

- Better use of the subject line which made it easier to know what the message is about (significant at the 95% level)

The t-test analysis also showed a significant (at the 90% level) initial improvement in the PD senders' ability to choose the most effective communication medium for a message as shown by table 1.

The initial effect of the SBT can diminish over time. The results showed that seven of the criteria had higher average overall scores after one month than during the first two weeks after the SBT, indicating a reduction of the impact of the SBT across these criteria. The only criteria where the effect of the SBT did not diminish after four weeks was the senders' ability to specify clear deadlines and the senders' ability to write subject lines that enabled the recipient to gauge the importance of the message.

Table 1. Mean effect of SBT on how emails were evaluated within PD

Criterion	Before Training	After Training Weeks 3&4	Diff	Significance from (2 tailed) t test
The suitability of email as the communication medium	1.55	1.18	-0.38	0.057
The email is easy to read	1.56	1.46	-0.10	0.696
The email is straight to the point	1.59	1.29	-0.30	0.184
The relevance of the message to me	1.60	1.71	+0.11	0.741
If it is an actionable email:				
It tells me what is expected of me	1.83	1.65	-0.19	0.341
It states when action is required	2.36	1.87	-0.49	0.221
The subject line contains sufficient detail for:				
Me to assess the importance of the message	2.26	1.70	-0.56	0.006
Me to understand what the message is about	2.08	1.65	-0.43	0.073
Approx how long did it take to read and understand this message? (Seconds)	49.92	47.78	-2.14	0.491

Table 2. Mean effect of CBT on how emails were evaluated within PD

Criterion	Before Training	After Training (4 weeks)	Diff	Significance from (2 tailed) t test
The suitability of email as the communication medium	1.34	1.05	-0.29	0.157
The email is easy to read	1.48	1.15	-0.33	0.081
The email is straight to the point	1.30	1.10	-0.20	0.101
The relevance of the message to me	1.48	1.35	-0.13	0.525
If it is an actionable email:				
It tells me what is expected of me	2.05	1.00	-1.05	0.034
It states when action is required	2.40	1.30	-1.10	0.028
The subject line contains sufficient detail for:				
Me to assess the importance of the message	1.79	1.93	+0.15	0.660
Me to understand what the message is about	1.81	1.63	-0.18	0.067
Approx how long did it take to read and understand this message? (Seconds)	43.49	27.00	-16.49	0.102

Table 3. Average for SBT and CBT within PD four weeks after training

Criterion	4 weeks after SBT Training	4 weeks after combined training	Difference
The suitability of email as the communication medium	1.18	1.05	0.13
The email is easy to read	1.46	1.15	0.31
The email is straight to the point	1.29	1.10	0.19
The relevance of the message to me	1.71	1.35	0.36
If it is an actionable email:			
It tells me what is expected of me	1.65	1.00	0.65
It states when action is required	1.87	1.30	0.57
The subject line contains sufficient detail for:			
Me to assess the importance of the message	1.70	1.93	(0.23)
Me to understand what the message is about	1.65	1.63	0.02
Approx how long did it take to read and understand this message? (Seconds)	47.78	27.00	20.78

The initial impact of the combined training (SBT and CBT) resulted in improvements across eight of the nine evaluation criterions as shown by table 2. The only criterion not to show an initial overall improvement was the senders' ability to write emails that are easy to read, despite this criterion showing significant initial improvements for the SBT at PD. Only one of the criteria showed a significant (at the 90% level) initial improvement. This was in the senders' ability to write effective subject lines that enable the recipient to know what the message is about.

Six of these initial improvements in CBT had been sustained or had shown further improvement. The only criteria where the overall initial impact of the training had diminished were in the senders' ability to choose the most suitable communication medium and their ability to write effective subject lines that convey the importance of the message and enable the recipient to know what the message is about.

The t-test analysis showed that four of the nine evaluation criterions showed significant improvements four weeks later for the CBT. The four significant improvements were:

- Better written emails that were easier to read (significant at the 90% level)
- Better written actionable emails that state what action is required of the recipient (significant at the 95% level)
- Better written actionable emails that clearly state any when action is required (significant at the 95% level)
- Better use of the subject line, which made it easier to know what the message is about (significant at the 90% level)

The significant finding from this research is that when comparing the impact of the combined training approach with a single SBT approach, the results from the PD study suggest that the impact of the combined approach is more sustainable than the SBT on its own as shown by Table 3.

CONCLUSION

While existing studies identified a number of problems with email use, this project sought to research the specific email problems within the PD organisation with the intention of reducing the highlighted defects. While the generalisability of this research is impossible due to the study being of one organisation, in the UK context, the findings are indicative, and suggest that there are many deficiencies with the way email is used within today's organisations. Such defects relate to both the written quality and quantity of email received and the ineffective configuration of an organisations email systems and can increase the amount of time spent dealing with email and can lead to tasks being carried out incorrectly or not at all. Several important implications arise from the study, as outlined below.

First, the study has added to current theory on email management in organisations by providing numerous insights relating to email defects in companies, and their management by various types of training. Second, the findings demonstrate that SBT can improve employee use of email, although the initial impact of the training can diminish over time. The results highlight that the impact of SBT can vary on the specific areas of email use that are improved, with some criteria showing greater improvement than others. However interestingly, the combined training approach (seminar based and computer-based training) did produce improvements that were sustained. Further research is needed to better understand this finding.

Second, the findings from this paper may help similar organisations to PD to become more effective in managing their email communication systems. It is recommended that organisations examine their current email communication policies and develop a "snapshot" of how their employees use email. Such information will provide an organisation with a useful foundation from which to build their training in order to increase their employee effectiveness by email education. If an organisation decides to deploy an email training programme, it is recommended that it not only focus on the sender side of how to write more effective emails, but also on the recipient side, for example training can be given on how a recipient can manage their inbox. It is also recommended that any training programme aimed at improving email use should also take into account other communication media used within the organisation, so that the effectiveness of communication in general can be improved.

How the Application of Management Information System (MIS) Affects Business Value (BV) in the Airline Industry

Jerzy A. Kisielnicki, Warsaw University, Szturmowa str.3, Warsaw, 02-678, Poland; E-mail: kis@mail.wz.uw.edu.pl, kis@wspiz.edu.pl
Ewa Gwiazda, PM Consulting Inc., Canada; E-mail: Ewa.Gwiazda@worksafber.com

ABSTRACT

This article is based on the utilization of the MIS and Decision Support Systems (DSS) as significant factors influencing the BV of an airline. Authors state that a contemporary airline company needs to increase its investments in IT, specifically MIS and DSS applications. This hypothesis is based on the analysis of business needs of passenger airline pricing for such airlines as British Airlines, KLM, LOT (Polish Airlines), Svet Aero as well as on the research carried out with airline executives and their clients. The included examples illustrate that the payback period for investments in MIS/DSS – even during unfavorable economic environment - is less than a year.

INTRODUCTION

This article is based on a utilization of the MIS and DSS as significant factors influencing the BV of an airline. There is a significant difference between N.G. Carr [2004] and P.A. Strassmann [2004] in this regard. Carr states that the industries are saturated with IT applications, incremental investments in IT do not give an enterprise a strategic advantage, and strategic importance of IT has significantly decreased in recent years. Strassmann, who also advocates reduction in investments in IT, states in his book Squandered Computer [2004] that the differentiator is in *how* the IT investments are spent. Strassmann's position, rather than Carr's, is closer to ours.

Based on our research in pricing of passenger airfares, we state that today's enterprise needs constant development of the IT, MIS, and DSS applications. This development in turn drives up the enterprise's BV: both tangible and intangible assets of an enterprise. Our results can be extrapolated to the tourist, transit, and telecommunication sectors.

SCOPE AND HYPOTHESIS

In this article, we prove that the role of IT has not diminished. On the contrary, its strategic importance has changed from automation of repetitive processes to process management and management control. Based on our research, enterprises dealing with services distribution – specifically airlines – experience the growth of their IT role and along with it, the growth of their BV. The growing role of IT is caused by the volume and complexity of creating and distributing passengers' airfares. These factors drive the need of using a special class of MIS systems called the IV Generation systems.

In this article we use the following research approach:

- The first part includes the results of heuristic decision support procedures analysis
- The second part includes a CASE study of a practical example of the Generation IV MIS and the corresponding BV calculation

Since airlines do not release their operational effectiveness "hard data", we were not able to provide detailed research on BV calculation methods. However, we managed to apply our BV calculation method to the real production data.

Any airline, to be competitive, needs to implement coherent strategies to lower its costs and operating risks. The key element of operating risks is maintaining effective pricing strategy (prices too high will deter potential customers while prices too low will unnecessarily lower the profit margin). These simple on the surface requirements need a lot of data, complex transactions, and effective distribution to satisfy both the airlines and their customers. Consequently, the IT solutions need to be more sophisticated that the ones currently dominating the airline pricing market.

This article also includes the implementation procedures and IT roles in this implementation. It is based on our experience and research in analysis, design and implementation of IT solution in organizations like BA (British Airways), KLM (Royal Dutch Airlines), LOT (Polish Airlines), Malev (Hungarian airlines) and SvietAero (Ukrainian Airlines). Within the scope of our research, we issued questionnaires to:

- Airline managers and executives; to seek their opinions about the pricing decision support systems
- Clients; to seek their opinions about their experiences buying airline tickets

The research is based on the requirements of effective pricing strategy and its implementation evaluated from the pricing analyst (PA) point of view. The PA's role within an organization is to prepare and justify pricing decisions for pricing managers (PM). Based on PA's recommendations, PMs decide on price changes. The key criterion for this decision is profit optimization; the key success factor is a flexible pricing strategy.

In this article, we will prove the following two hypotheses:

H.1 The complexity of airfare pricing and distribution systems requires the use of IV Generation MIS systems.

H.2 The use of IV Generation of MIS system increases airlines' BV.

The hypothesis H1 is proved based on the research of pricing procedures in presented airlines. Hypothesis H2 will be illustrated by a specific example of a BV calculation in the context of Generation IV MIS.

In summary, we can say that the main thrust of this article is the analysis of decision-making processes and their control in the airline pricing industry as well as the role of MIS. As mentioned earlier, these findings can be applied to a wide spectrum of service distribution and their pricing strategies.

SELECTED THEORETICAL FOUNDATIONS OF MIS USED FOR DECISION-MAKING PROCESS IN AIRLINE PRICING

In order to achieve significant benefits from this class of systems, the design has to support flexible pricing strategy: pricing analysts need to have the capacity to easily access relevant information, have tools that support their analysis and

decision making processes, and allow for effective distribution of price changes through many sales channels. This implies that the MIS system needs to provide a complex set of tools and techniques ranging from typical transactional applications to simulation models and DSS functionality.

We can categorize the various MIS application based on their complexity using the concept of the MIS generation [D. J. Power - 2002]. The industry uses various methods to classify MIS; the most common are classifications presented by: E. Turban, J.E. Aronson, Ting-Peng Liang [2004], and K.C Loundan J. Loundan, [2006].

To classify MIS systems used to support the implementation of pricing strategy in airline industry, we applied a classification method that includes both hardware and software criteria and well as business functions [J.Kisielnicki, -2005].

Generation I – A database-supported transactional system used for reservations, sale of airline tickets, and inventory management.

Generation II – A database-supported on-line transactional system used for reservations, airline tickets sales, and inventory management. Also includes sales monitoring functionality and revenue management for each individual flight in a given time period.

Generation III –A Generation II system that also includes modules allowing for benchmarking an airline against the competition. This system would include a statistical modeling tool allowing for trend analysis, forecasting, etc.

Generation IV –A Generation III system that also includes modules allowing for the implementation of a pricing strategy based on probability, knowledge database, and heuristic methods to obtain an optimal profit from each sale.

Recommended MIS is a Generation IV system that includes the following elements:

Data warehouse, as an element of Generation IV MIS system, would incorporate historical, current, and future airfare information such as price, rules, flight information, fare class, where the sale originates, etc.

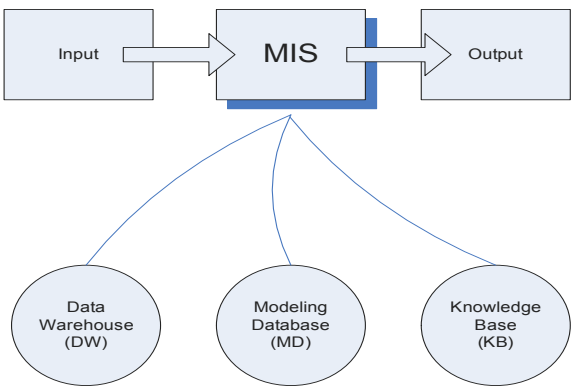
Modeling database would include yield management algorithms helping with the following decisions:

1. What price should be set for the next sold ticket; using marginal calculus models
2. What combination of prices will bring an optimal profit/revenue for each flight; using optimization and simulation models

In addition, the models would include the elements of risk assessment (for example: how many group tickets could be sold on each flight; the probability of groups returning their tickets; could the returned tickets be resold, etc.).

Knowledge base would include information about the competition, financial results of earlier promotions, etc.

Figure 1. Elements of generation IV MIS system used for pricing decision support in an airline industry



Source: Personal research

MIS itself uses all price changes as in input, and converts them – using all three supporting elements (DW, MD, and KB) – into new airfares.

Where a sophisticated MIS does not support pricing decisions, airlines are not able to establish a competitive price. Thus:

1. The airline is loosing revenue if its price is higher than the competition; plane flies empty
2. The airline is loosing profit if its prices are too low

A well-designed MIS allows for fast access to relevant data, correct pricing decisions, and effective distribution of pricing changes to travel agents, web sites, local airline offices, etc. All three elements are critical to a successful pricing strategy and its implementation.

Our hypothesis that the Generation IV MIS are required for the effective management of pricing policy was confirmed by the results of 20 interviews carried out amongst managers and executives (of airline companies) who attended the MBA program at Warsaw University. 16 interviewees, when asked for the characteristics of the adequate pricing decision support MIS, described the Generation IV MIS. Two of them described the Generation III and two described the Generation II.

Also of interest are customers' opinions about the quality of information available from the airlines. The questionnaire issued to the research sample of 80 graduate MBA students[1] of Warsaw University and the University of Trade and Law in Warsaw indicated that 80% were unsatisfied with the service provided by the travel agents and airline local sales offices. The key reasons were partial and unconvincing information about the tariffs and all associated rules (cancellation, changing dates, upgrades, etc.). While not all the blame can be put on the IT, airlines with complete and trustworthy information about their flights available through all sales channels will have better financial results than their competition. Without sophisticated calculations, we further state that this would lead to an increased BV.

ROLE OF A PRICING ANALYST AND MIS IN AIRFARE PRICING PROCESS

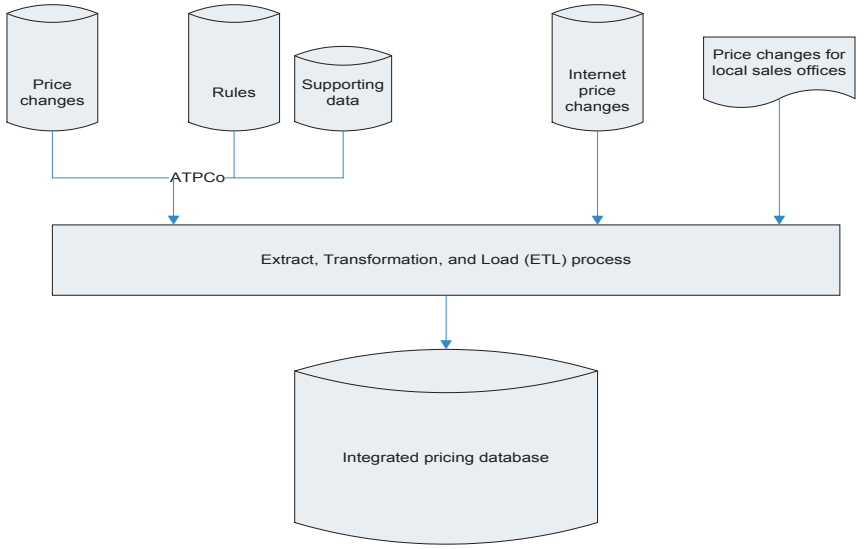
Pricing information in the airfare pricing process is both an input and an output. The output decides if an airline's pricing strategy is effective.

Is my price competitive? This is the key question that pricing managers as well as airline executives ask themselves every day. The Internet created a price transparency unheard of in the past. Every client, even if he buys his ticket from a travel agent in the end, checks the Internet first. Moreover, the competition is only a mouse-click away. This environment punishes uncompetitive airlines very quickly. In our context, uncompetitive airlines are those that do not react (i.e., analyze changes, decide on pricing changes, distribute the new price) to market changes quickly and accurately. Without a decision support system airlines would have to employ a high number of pricing analysts at a high cost and without a guarantee that they would find all the relevant pricing changes, recommend the right decision, and distribute price changes to all sales channels. Effectively, most airlines accept a compromise between costs and benefits; they employ fewer pricing analysts and in return have delayed and imperfect reactions to the competitors' pricing changes.

Generally, it is understood that designing a pricing strategy (for both products and services) requires creativity. Changes in consumer market trends, macroeconomic changes, market segmentation, airline revenue, and profit force pricing analysts to constantly monitor the effectiveness of current pricing strategy and make (timely) adjustments. Consistent maintenance of effective pricing strategy is not a simple task – the most common trap is a straight pricing competition that not only hurts the individual airline but the industry as a whole.

In addition, pricing analysts need to review several hundred daily price changes using very primitive transactional applications just to find out what is happening on the market. Currently, applications available in the researched airlines do not have mechanisms to tailor all price changes to the needs of individual analysts, do not provide decision support functionality, and are not connected to the price changes distribution systems. Hence, the necessity of employing an army of pricing analysts who sift daily price changes, make decisions (or recommendations) based on their own knowledge and experience, and pass it to another department for distribution. To mitigate the costs, airlines outsource data entry tasks (required for distribution) to countries like India where salaries are much lower, almost

Figure 2. Key element of the IV generation MIS specialized in pricing changes analysis



Legend:

ATPCo – Airline Tariff Publishing Company is the key source of market changes; it distributes all airline tariffs to all companies that buy their subscription. ATPCo distributes prices, rules, and various supporting data (code tables for countries, cities, airports etc.) ATPCo sends all changes five times a day during a week and twice a day during weekends.

The Internet price changes can be automated using screen-scraping techniques. Most airlines however are still using manual processes to monitor the Internet price changes.

Price changes originating from local sales offices (LSO) can also be automated using the workflow management process techniques. Most airlines however are still using manual processes to submit price change proposals and issue approvals.

The ETL process accesses source data, formats them, and updates the integrated database used by pricing analysts to monitor changes.

Source: Personal research

everybody speaks English, and the relatively high percentage of workforce has been educated in the UK. The time difference is also an advantage to European airlines: when their working day comes to a close and all their pricing changes are ready for distribution, staff in India begin their working day and initiate the distribution process.

In most airlines the entire process is supported by IT, but only on a transactional level (Generation I and II). To provide fast sometimes instantaneous - reactions to the market changes, airlines need a Generation IV MIS. The application of MIS would significantly help with pricing analysis, decision making, and distribution, allowing for a precise and fast response to pricing changes. MIS would integrate all sources of price changes; tailor the price changes to pricing analyst markets, and aid in decision-making processes. Figure 2 presents the key elements of such a subsystem.

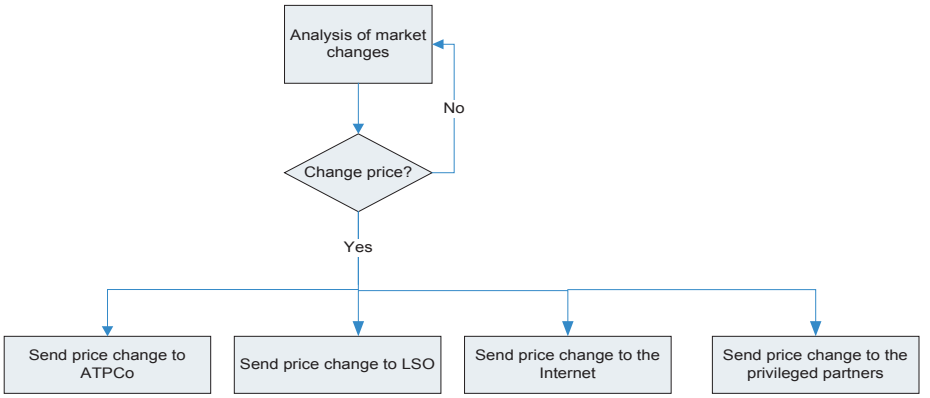
One of the key reasons to use the Generation IV MIS is the sheer volume of fares stored in the integrated database. Our research indicates that in any given moment there are approximately 200 million tariffs (this includes ATPCo distribution and SITA distribution directly to the Global Distribution Systems). Loew [2004]. The number of changes made each year is estimated at 1 billion. Loew [2004].

In addition to airfare price changes, there are also airfare rule changes that influence customers' buying decisions: ticket return policy, length of stay, travel dates and travel dates changes, etc. The number of rule changes is estimated at 1.5 million a year.

The decision making and distribution of the Generation IV MIS supporting the pricing management in airline industry is presented below:

To illustrate the challenges facing airlines, a hypothetical airline company MyAir will be used (the need to use a hypothetical airline is due to the fact that the researched company did not agree to release its data as it would provide a competition insight into its operations). Let us assume that MyAir owns 50 aircrafts, has an annual revenue of $1 billion, and operates on 10 000 markets (where a market is defined as an individual flight, for example London-NYC; the flight NYC-London would be a separate market). Let us further assume that MyAir makes approximately 1 million price changes a year and analyses approximately 5 million price changes issued by other airlines. This translates into reviewing 13 700 prices and rule changes every day (assuming normal distribution). Every delay in MyAir response would mean either revenue loss (if prices are too high) or profit loss (if prices are too low) Loew [2004].

Figure 3. Decision support and distribution of price changes processes in generation IV MIS



Source: Personal research

Table 1. Sample set of prices and rules associated with a booking class. This information is sent for each airline, market, travel date, purchase place etc.

Class	Price	Rules
Business Class	pP-(1) P-(N)	R1 Rs
Economy Class	P (N+1) RmP (M)	R1 Rw
Economy Plus	P(M+!) Rk P(K)	R1 Rp

Legend:

P – price of a ticket in a given booking class

R – rules associated with a booking class and ticket price

Source: Personal research

Every airline can change prices and rules five times a day for every market and any future dates. Additionally, normal distribution does not really happen: airlines can change 30% of their prices in a single filing, make only minor adjustments for quite some time or suddenly make drastic changes. Since there is no legislation on how far in advance the price or rule changes can occur, there is no way to predict when the high volume of these changes might arise.

It is also important to understand that not all price changes are equally important. It is estimated that each airline has 90% of revenue from 1% of its markets. Therefore prioritizing markets and price changes is critical to the effectiveness and efficiency of price changes monitoring.

An additional challenge that airlines face is monitoring rule changes. Every airfare is a combination of its price and associated rules. Table 1 presents the illustration of airfares and relationships between prices and rules.

The pricing process is completed in four stages:

Stage 1: Monitoring Competitors' Pricing

The monitoring of competitor's pricing is an ongoing task. Pricing analysts have to check the price changes of competing airlines at least twice a day on each market. They use the integrated pricing databases presented in Figure 2. While market changes could trigger a potential price change, the evaluation of current pricing does not happen in isolation of internal influences. Every price change needs to go through analysis in three internal systems:

1. Revenue accounting
2. Reservation system
3. Yield Management

Stage 2: Monitoring Competitors' Airfare Rules

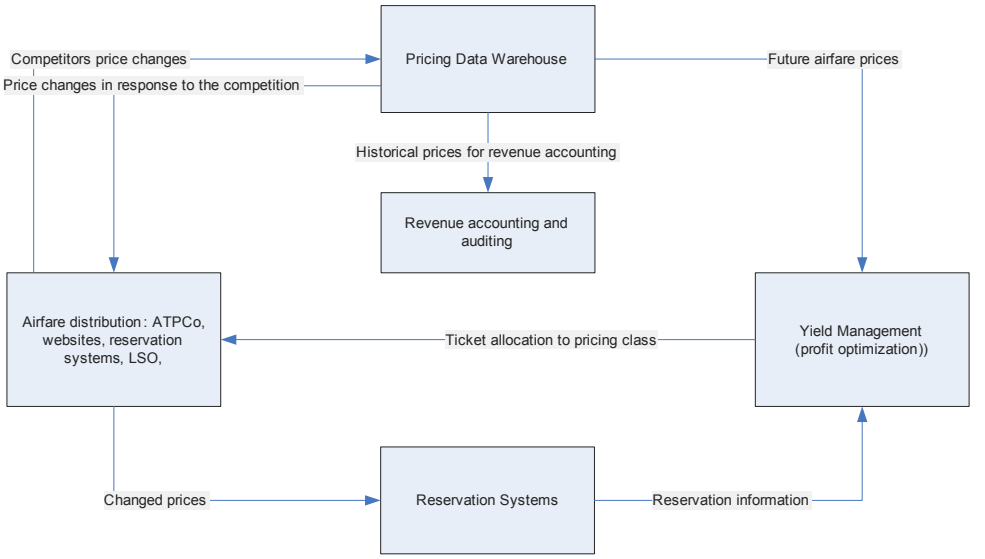
Since airfare pricing is influenced not only by the dollar amount but by rules as well, every pricing analyst has to review the changes in rules. The relationship between airfare and rules is complex: each airfare has multiple rules and each rule is linked to multiple airfares. The analysis of this relationship is not straightforward. As an example, let us use an airfare from London to NYC offered for $1,050 with a condition that a passenger will not stay in NYC on Saturday. The same airfare from London to NYC is offered for $850 with a condition that a passenger will stay in NYC on Saturday. At a first glance, this pricing difference does not seem logical; after all, the cost of the flight is the same regardless where a passenger will be on Saturday. However, this particular rule has been used for market segmentation: most business travelers want to come home before the weekend, while people who go for vacation typically want to spend a weekend at their destination. Therefore, a change in a rule saying that airfare from London to NYC is the same regardless of the length of stay in NYC means that the price for business travels has dropped by $300. Since the rule might affect more that one market, pricing analyst needs to carefully review all rule changes, associate them with all airfares, and then review the impact of the changes.

Changes in rules are as important as changes in prices; with one rule change such as in the example given above, competitors can change thousands of airfares in one filing. Table 1 presents that the relationship between airfares, prices, and rules is further augmented by the risk assessment as well as revenue/profit simulation to predict financial results of price changes.

Stage 3: Pricing Decision

An airline typically has many pricing managers, each responsible for a set of markets or market segments. The pricing manager receives recommendations for all of them on a daily basis, assesses each change in tactical and strategic context, and approves or rejects the change.

Figure 4. Data flow between internal systems using current and proposed prices



Source: Personal research

Stage 4: Price Change Distribution

Once a new set of prices is approved, it has to be distributed to all sales channels. Each airline has several distribution channels (refer to Figure 3): ATPCO or SITA (the main ones), LSOs, airlines' websites, travel agencies throughout the world, their websites, various privileged partners, etc. The importance of sales through an airline's own web site grows since the overall cost of such sale is much lower: there are no intermediate costs and all tickets sold by the Internet are e-tickets (less expensive than traditional paper tickets).

Worldwide distribution adds extra complexity to airfare pricing: the price is different depending on where the sale is taking place. For example, the return ticket Johannesburg-NYC-Johannesburg bought in Johannesburg will be less expensive than the same return ticket NYC-Johannesburg-NYC bought in NYC, because tickets bought through the Internet are priced based on the place of departure. In addition to the base price, pricing analysts need to take into account local taxes, airport fees, agents' commissions, etc. Moreover, all price changes have to reach all sales channels at the same time.

Price changes to the LSO are typically distributed via email, fax, or a telephone. While it is a fast and effective solution it is a short-term one. In the long term, airlines struggle with controlling this process and ensuring that price changes requested by the LSO are properly analyzed, evaluated, and decided upon.

Theoretically, yield management can mitigate pricing errors. Let us use the MyAir example: MyAir has a plane with 100 seats and these seats are divided into five pricing classes: very expensive, expensive, average, cheap, very cheap. Each of these pricing classes has allocated 20% of all seats. The yield manager monitors daily reservations and depending on the progress and various risk factors changes the seat allocation in each class. If very expensive airfares are selling well, the yield manager will increase the allocation in this class to 25% and will decrease the allocations in other pricing classes. If the very cheap tickets are selling fast, the yield manager might close this class altogether and allocate remaining tickets to the other classes. One of the risk factors that the yield manager also takes into account is group tickets: these should be less expensive if it was not for the risk of return. Typically, yield managers do not advise to have more that one group in each flight. Regardless of how well yield managers optimize the pricing of remaining seats, they act after the sales/reservations have been made – the lost revenue and lost profit due to inadequate original pricing cannot be recovered. It can only be adjusted for the future.

Yield managers rely heavily on IT support; to arrive at the best balance of prices in each class, they use a combination of marginal economical models, simulation, and optimization techniques.

An example of a costly pricing error made by a low-cost carrier was setting a promotional price for Warsaw-London market at Euro 1. The intent was to start at a very low price and then raise it. At the same time, BA started its promotion and was selling its tickets at a price lower than the low-cost carrier. The low-cost carrier was not able to recover the losses incurred during the Euro 1 promotion and effectively could not compete with BA. As a result, during the July-August vacation season, the low cost carrier lost Euro 100K in this market alone.

THE INFLUENCE OF PRICING DECISION SUPPORT SYSTEMS ON COMPANY'S BV

There are many different approaches in evaluating BV: how each department contributes to the company BV, what the reasons of growth or decline of BV are, etc. In this section we will present how IT, and specifically Generation IV MIS, influences BV. Even though our research indicated that IT significantly influences the BV, we can not derive precise and scientific function that defines this dependency. Therefore this part of the article is a CASE study; we will identify the influence of the Generation IV MIS on the passenger airline company's BV. The term BV, as mentioned earlier, represents both tangible and intangible assets of a company. It is also an important indicator of its market value. Since the assessment of a BV is complex, there are many methods of defining and calculating it E. Brynjolfesson, L.M. Hitt, [2003], Remenyi, D., A. H. Money, et al. [2000] P.A.Strassmann, [1990, 1999]. In literature, in addition to the BV, the use of "goodwill" of a company quite common G. Jones, N.J. Morgan, [1994] A.H. Millichamp, [1997]. Generally, we understand the BV of a company is a difference between the company's assets and its liabilities. The analysis and evaluation of different approaches to defining and calculating BV is not in scope of this article.

The results of using Generation IV MIS and its effect on a company's BV are presented in the Figure 5. The relationships between the investment in such MIS and BV benefits is defined based on the analysis of the Generation IV MIS for our hypothetical airline company MyAir.

Let us assume that MyAir has annual sales of $140 million (daily sales of approximately 4 million). The investment in IT in 2004-2005 was approximately 25 million (infrastructure and operational costs are not included). 80% (16-18 million) of this cost was spent on the new Generation IV MIS.

In this article, we used the estimates of future revenues as an indicator of BV. From this potential revenue we subtract labor costs (including professional development of pricing analysts), marketing, research and development costs required to maintain competitive edge in IT, and higher taxes incurred as a results of increased sales. We state that a company can generate additional sales due to effective and efficient IT including the Generation IV MIS.

The influence of Generation IV MIS is calculated according to the following formula:

$$BV = (P\text{-}aP) – W.$$

Where:

- BV – annual increase of company's value due to the use of IV Generation MIS ($).
- P – annual increase of company's revenue achieved due the improved pricing processes (S).
- a – indicator of the effectiveness of pricing analysts using lower generation MIS.
- W –implementation costs of IV Generation MIS ($).

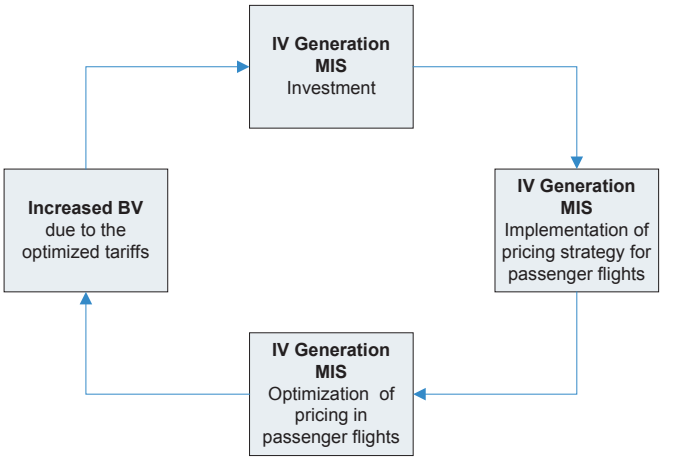
Let us assume that MyAir looses approximately $100 000 daily ($30 million annually) due to an ineffective pricing policy. In addition, MyAir looses between 2%-5% revenue ($20-50 million) due to the late responses to competitors' price changes. Using the above equation, we have:

- P=$50-80 million annually
- a is estimated at 0.7 –0.8
- W = $16-18 million

Year 1: BV is between 0 to 6 million; Generation IV MIS will pay for itself.
Year 2: BV is between $16-25 million

Based on the estimated cost of MIS and revenue, we see that the costs of the IV generation MIS will be paid off during the first year of its operations.

Figure 5. Dependency between the investment in MIS and BV



Source: Personal research

AMR research estimates that airline companies that consider pricing management as a key element of its strategy have 10% increase of revenue [Scott 2003]. Based on our research, the revenue increase depends 70% on the qualification of pricing analysts and 30% on the IV Generation MIS.

CONCLUSION

In this article we presented the complexity of airfare pricing and pricing distribution, included estimated volume of transactions and data, and indicated how investment on IV Generation MIS increases airline BV. We estimated that at any given moment, there are approximately 200 million airfares and the annual number of price changes is 1 billion. Therefore, in order to maintain effective, efficient, and flexible pricing strategy, airlines need to use sophisticated IT solutions. Based on our research (questionnaires, interviews, analysis of several airlines, and literature), we state that the Generation IV MIS meets these requirements. In addition, the Generation IV MIS directly influences airline BV, and even the significant cost of the IV generation MIS implementation is returned within one year. Paraphrasing Mark Twain, we can say that Carr's forecasting of the diminishing role of IT is highly exaggerated and certainly does not apply to the passenger airline industry.

ABSTRACT

As the highly improved Internet and information technology has led to the diversification of users' demands, personalization service attract lots of attention as a means to meet highly diversified demands of users. However, personalization service costs a lot. Also concerns over a possible violation of privacy have been raised since the service uses technology to find out the users' profiles. This research studies the advantages individuals acquire from personalization service and how privacy concern influences service acceptance. Research on related documents and information gathering from e-commerce sites derived six representative types of service. Questionnaires were utilized to research privacy concern according to services, service usefulness, and service acceptance. As expected, privacy concern has a negative relation to acceptance while service usefulness has a positive relation to it, thereby resulting in an offset between two variables. Moreover, they play a different role depending on what kinds of service or information should be provided. The results derived from this paper will help the e-commerce sites provide personalization service by collecting personal information while protecting users' privacy.

Keywords: Personalization, Personal Information, Privacy Concern, Service Usefulness, Service Acceptance

1. BACKGROUND AND OBJECTIVES

During a recent decade, the development and wide spread of Internet has made that technology be part of our everyday life. Such advance has also led to a diversification of users' demands and an increase of their buying power. Thus, to gain more customers, a wide range of service should be provided. Toward the ends, most companies are striving to utilize Internet more effectively.

Considering further developed e-commerce and Internet, the businesses' dependency on the Internet must have increased as well.

Lately, personalization has been under the spotlight as an effective way to attract more customers by satisfying their various needs. Among them, personalized websites by engaging in a one-on-one marketing have been proved successful in eliciting customer loyalty(Kim Myung-Hee, 2003).

However, there are some barriers to personalized Internet service through websites, such as, technological problems or possible privacy violation.

So, the potential of that service has not been fully realized except few cases, like My Yahoo.

This paper primarily addresses a possible balance between personalization and privacy since personalization service requires gathering of users' private information. Also it seeks to document the specific services of personalization and how privacy concern responds to each.

2. THEORETICAL BACKGROUND

2.1 Definition and Characteristics of Personalization

According to Allen , Kania and Yaeckel, personalization means providing goods and services personalized to the users' specific needs(Allen, Kania and Yaeckel, 1998). To do this, finding out users' particular requirements is essential, which is the same with collecting their profiles. In the past, information was derived from personal data provided by the user himself.

Recently, however, more specified and various personal profiles can be obtained through more sophisticated frameworks, such as, search engines, site transaction logs, cookies, shopping carts, and forms. Search engines can profile the opinions stated by a user in the news, chatting groups or other official online forums, thereby compiling his social and political standpoints. Site transaction logs collect and analyze specific information on the pages that the user visits. Of the most popular use are cookies, which track down personal information over a single websites or thousands of ones, and of which technology is advancing each day.

2.2 Effectiveness of Personalization

Peppers and Rogers(1994), and Rogers stated that personalization is an important factor in a success in a newly structured e-commerce market. Personalization is also an effective means to elicit customer loyalty, thereby, obtaining a competitive. Merits of personalization do not stop there. From a user's standpoint, he can save time to search the information and also has a wide array of options available to him(Allen, Kania and Yaeckel, 1998).

Despite some negative opinions on the personalization, a survey conducted by one American research firm revealed that American Internet users are willing to provide their private information as long as the website does not use it for other purposes or disclose it without his explicit consent(Kevin Mabley, 2001).

According to the survey by Intelliquest, more than a half responded that personalized service is the very reason for visiting a certain website. 56% said that the service is interesting while 54% said it attracts their attention. 53% said that the service is very useful, and 45% responded it provides the needed information.

As such, personalization draws users' attention as well as saves time and cost in exploring information, thus, is of much value to users. To sum up, the wide spread use of personalization is expected.

2.3 Definition of Privacy and Private Information

The concept of privacy first came up in a book, *"The Right to Privacy,"* by Samuel D. Warren and Louis Brandeis(Samuel Warren and Louise Brandeis, 1890). They defined privacy as 'a right to be alone, not disturbed by anyone.' Since then, with the development of Internet, there have been worries over a possible disclosure of private information to a third party, and a subsequent violation of privacy. Accordingly, the concept itself has been evolved to 'an active right to prevent others from acquiring personal information.'(Bang Seok-ho, Kim Eun-

Ki, Kim Jin, 2001). Currently, the concept, privacy is defined in a legal term as follows; supremacy of private life and inviolability of freedom is a right not to be disclosed of personal life; a right to protect and control personal information; a right whose protection is in an urgent need as informationization of the society is rapidly progressing.

Usually information contained in privacy is the information about a living person, and its contents would include personalized symbols, words, sound, or multimedia approached by a name or a social security number(Kim Jung-woo, 2001).

3. HYPOTHESES, FRAMEWORKS AND METHODS

3.1 Hypotheses and Frameworks

The most difficult obstacle in realizing personalized service is the problem s related to privacy(Allen, Kania and Yaeckel, 1998). Such problems are arisen because while personal information makes possible personalized goods and service, depending on the purposes of its usage, it can also pose a threat to the user himself.

Kenneth claimed that the main issues concerning privacy are: what kinds of personal information is being collected for what purposes; who did the gathering?; whose information is being subjected?; how much the collected information is being utilized(Kenneth C. Laudon & Carol Guercio Traver, 2002). These issues have been spawn a variety of opinions since sellers and buyers of personal information are taking a different view. Kenneth said that sellers claim that collecting personal information leads to target ads for specific users, thereby helping them explore goods and service that they would find interesting. In addition, businesses can save expenses since they can narrow down the target customers. Then, the industry, as a whole, can increase the effectiveness of advertisements, and the increased profits will go to service improvement in the form of free-of-charge online contents. Also, businesses can predict demands on new goods and services by surveying profiles and history of online activities of users.

On the other hand, some people claim that gathering private information of users not only damages their expectations for privacy during they are on-line but also discourages them from searching sensitive or controversial issues or websites. Most important, users do not know that they are being profiled, and companies are reluctant to let them know. In fact, it is so easy to collect information anonymously and to change information about collection policies without any notices to users.

The most problematic issue over privacy protection is a virtual absence of users' control over their private information. As a countermeasure, some countries are setting up a number of protection mechanisms. In many countries, for instance, e-commerce law stipulates that individual consent be required to gather personalized information.

A study which hypothesized that the lower control over information would lead to highly violated privacy showed that people who think they have power over the usage of their information perceive less requiring privacy. Another study showed that the less power over their information led to more negative attitudes towards the secondary usage of the information (Kim Eun-kyung, 2003).

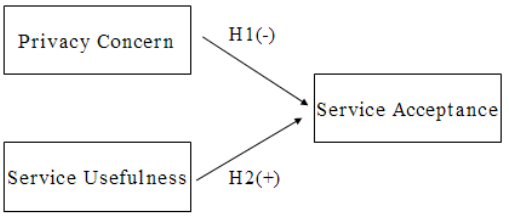
When information is being utilized for secondary purposes without a consent, privacy is being violated (Culnan M.J. and Bies, R.J., 1999). And privacy concern is alleviated when information is being collected for the first purpose, when users retain control over the future usage of their information, when the utilized information is related to the e-commerce that she engages and when information is used in appropriate survey on users.

Adding all these previous results, we can derive our first hypothesis.

H1. Concern for privacy of personal information will have a negative effect on service acceptance.

Laufer and Wolfe concluded that individuals do not willingly disclose their information unless it will be utilized in a fair and positive way to promote their economic and social benefits (Laufer, R. S., & Wolfe, M., 1977). Moreover, previous studies have indicated that two seemingly contradicting sides of information disclosure, gains and potential threats, are balanced (Delega, V.J., Metts, S., Petronio, S., & Margulis, S. T., 1993). That is, people would disclosure their information as long as such act would be reciprocated, which is when gains would surpass potential dangers (Thibaut, J., & Kelley, H. H., 1959).

Figure 1. Framework



Such information exchange in the society also applies especially when users believe in an analysis of cost-benefit. Under that principle, people will give up privacy of their private information when such act would give them benefits, especially when the potential value exceeds potential dangers. However, this presupposition has not been empirically proved under different scenarios of privacy-benefit trade-off cases (Culnan, M.J. and Bies, R.J., 1999). So, the following hypothesis is drawn.

H2. Service usefulness of personalized service will have a positive effect on service acceptance.

3.2 Methods

To confirm the aforementioned hypotheses, previous studies were used to find different types of online personalized services. In Allen et al.'s study, it is divided into 5 types of personalization: Personalized Experience, Personalized Information, Personalized Care, Cross & Up-Selling, Personalized Community. Another studies suggested 4 different types of personalized services: visiting and inquiring after someone´s health, differentiation of web pages and auto-updating about interest contents, and personalized information into providing information reflected user's inclination and providing recommended information and so on(Kim Jonh-won, 2001). Based on the previous research, we restructured the services into six personalized services: greetings, customized pages, notices for credit card payments, customized according to users' tastes, introducing goods in tune with users' past purchases, service in need of a wide range of personal information.

Date is collected through questionnaires surveying 139 persons of whom males are 86(56.6%), females 53(43.3%). For the age, below 24 are 14(10.1%), 25 through 34 are 107(77%), and above 35 are 18(12.9%). Occupations are divided into four groups; college students 73(52.5%), administrative positions 37(26.6%), specialists 25(17.8%), and none of the above 5(3.1%). Questionnaires have a scale of one to seven with 12 questions which are divided into five sub-questions. From question number 1 to 6, privacy concern is measured, while from number 7 to 12, service usefulness and service acceptance are surveyed. For each personalized service, required personal information for service is derived. Then privacy concern for the service was asked for the most private information for the service. For instance, the service 2 is about the personalized web front showing current stock prices of interest. To service this, information such as log-in and Favorite stock information is required. Then the privacy concern question was asked for the favorite stock information.

4. RESULTS AND IMPLICATIONS FOR FUTURE STUDIES

4.1 Results

To analyze the results, the average points of six types of service are drawn first. Through this, how the respondents rate each service on privacy concern, service usefulness, and service acceptance is derived. As a result, among six kinds of service, the highest one in privacy concern turns out to be the one which requires monthly income, social security number, and workplace contact number.

On service usefulness and service acceptance, service that provides information about favorite stocks is rated the most useful one.

To analyze a casual relationship among two independent variables, privacy concern, service usefulness and service acceptance. Table 2 shows that the results of multiple linear regression. The following. R square for greeting service is 0.496, indicating that privacy concern is not much related to service usefulness and acceptance.

Table 1. Average points for each service

Information	Service (1~7 points)	Privacy Concern	Service Usefulness	Service Acceptance
Log-in, Name	[Greetings] On your website, "Hello, 000. Good morning" Such service requires your name on the page.	5.15	3.17	2.95
Log-in, Favorite stock information	[Customized web page] On your website, Samsung Electronics 493,000(from yesterday 2,000▼), SKT 180,500(from yesterday 1,000▼) This service provides you with favorite stock information. Such service requires an input of your favorite stock (company name).	5.14	4.91	4.56
Log-in , Credit Card Number, Credit Card Payment Day	[Notice for credit card payments] On your website, "Mr./Ms. OOO, two days are left for OO card monthly payment. Do you want to do it now? Such service requires you to give your credit card number and payment date to an website.	5.56	4.06	3.58
Log-in, Favorite Sports Team	[Customized service according to users' tastes] On your website, "News for today's match between FC Seoul and LG Twins" This service gives you latest information on your favorite sports team. Such service requires you to provide your favorite sports team information with the website.	4.59	4.40	4.16
Purchase History (Name , price, date of purchase)	[Introducing goods in tune with users' past purchases] 'Mr./Ms. OOO, A new book on Toeic by OOO has just released. Do you want to find out more information? This service analyzes your past purchasing pattern and recommends you other goods. Information of your purchasing history, price and date is required for such service.	4.85	3.99	3.68
Monthly Income, Social Security Number, Workplace Contact Number	[Service in need of various personal information)] "Mr./Ms. OOO. We will compare your current monthly insurance payment with a new insurance without dividends for singles." This service recommends goods in accordance with your information. Such service demands an input of social security number, monthly income and workplace contact number.	5.68	3.10	2.47

For the customized web page service, R square is .668, however, privacy concern, which is -0.95, does not affect much on service acceptance.

As in the case of the notice service for credit card payment, R square is .646; privacy concern -.170; service acceptance .884. This implies that privacy concern has a negative relationship with service acceptance while service usefulness has a positive one with it. Similar probability is also .000 for service usefulness, .047 for privacy concern, implying a highly reliable result.

For the customized service according to users' tastes, R square is .695; privacy concern, -.168; service usefulness, .970. This means that privacy concern has a negative effect on service acceptance while service usefulness has a positive effect on it. Similar probability is also .000 for service usefulness, .009 for privacy concern, indicating a highly reliable result.

Service introducing goods in tune with users' past purchases has .670 R square, -.077 privacy concern, and .929 privacy usefulness. Such result means that service usefulness is positively related to service acceptance while privacy concern is negatively related to it.

For service in need of various personal information, R square is .618; privacy concern -.139, service usefulness .839. This says that while privacy concern has a negative effect on service acceptance, service usefulness has a positive effect on it. Similar probability is .000 for service usefulness, indicating reliability, however, privacy concern records .056, a much less reliability.

Lastly, a result analyzing a relationship between the average for privacy concern and service usefulness and service acceptance on each six types of service is followed as: R square .694, privacy concern -.153, and service usefulness .932.

As such, for all the service and its subsequent collection of information, privacy concerns have a negative effect on service acceptance while service usefulness has a positive effect on it. In sum, in the remaining service except the ones for greetings, favorite stock information, and introducing goods in tune with users' past purchases, privacy concern is negatively related to service acceptance. Moreover, service usefulness is positively related to service acceptance in all above six types of service.

4.2 Implications for Future Studies

This paper is limited in a number of ways: the samples are not representative in a matter of age, restricting only in 20s and 30s; they are also highly educated people with college degrees, at the very least; a sample of 139 persons is also unrepresentative; only six types of online services are surveyed while there are countless numbers of available service on the Internet; the implication of this research is limited only on the current e-commerce. There is no guarantees for the coming online trades, such as, m-commerce or u-commerce.

Thus, studies on various markets (e-commerce, m-commerce, and u-commerce) as well as on a wide variety of people, age groups, and education, for the sake of much improved data reliability, are needed.

Table 2. Results of multiple linear regression coefficient

Information / Service	R Square	Non-standardized coefficent B		T	Similar probability
Log-in, Name [Greetings]	.496	(Constant)	1.03	2.18	0.31
		usefulness	.747	11.4	.000

E-Commerce Adoption Factors for SMMEs: Supporting Cases from South Africa

S. C. Warden, Cape Peninsula University of Technology, Cape Town, South Africa; E-mail: wardens@cput.ac.za
I. M. Motjolopane, Cape Peninsula University of Technology, Cape Town, South Africa; E-mail: motjolopanei@cput.ac.za

ABSTRACT

The emergence of e-commerce (electronic commerce) and the impact of this new technological innovation changed the approach to business, transactions and processes. E-commerce adoption definitions generally refer to the process of conducting business online, spanning both Business-to-Business (B2B) and Business-to-Consumer (B2C) markets to reach global players, gaining market share for competitive advantage, utilising telecommunication networks. However, a number of unanswered questions pertaining to e-commerce adoption highlight issues such as; legal matters, political issues, telecommunication regulatory issues, security and trust aspects, customer relations and product selection. Many of these issues are essential ingredients to enable successful online trading, however, some uncertainties may inhibit the implementation of e-commerce initiatives such as; e-loyalty, marketing, customer experience, bandwidth issues and online customer maintenance. This paper develops a theoretical framework for e-commerce adoption based on literature, verified by case study research conducted in South Africa and proposes ten e-commerce adoption factors for SMMEs.

Keywords: e-commerce, adoption, online, case study, SMME[2].

1. INTRODUCTION

E-commerce adoption is not merely signing up an Internet Service Provider (ISP). Potential barriers such as risks, security fraud and marketing issues associated with e-commerce adoption need to be considered. Technical, business and external factors including cultural, political, legislative and environmental issues have been identified as inhibiting e-commerce adoption issues (Reichheld & Schefter, 2000:105-106; Klopper, 2002; Mohammed, Fisher, Jaworski & Cahill, 2002:204; Hoffman & Novak, 2000:179-180; Boschma & Weltevreden, 2005:2; Braga, 2005:544). These potential pitfalls could be mitigated by providing guidelines to reduce the risk of failure at the outset (or even after adoption) of e-commerce initiatives. Developing countries, including those in Africa, have become detached from the global economy mainly due to a lack of sustainable and appropriate ICT strategies and poor telecommunications infrastructure. As the focus of this paper is on small business, Rashid and Al-Qirim (2001:64) found that small businesses in New Zealand for example, are flexible and quick to react and generally rush to connect and participate in Web-based business.

2. E-COMMERCE IN AFRICAN COUNTRIES

According to Kah (2004:273), "…the fading of the industrial revolution into the dawn of the information revolution has transformed the world economy into a truly global one". Unfortunately, the emergence of this new phenomenon has created a wider gap between *information-rich* and *information-poor* countries, pulling apart *developing* and more *developed* economies. Although the initial e-commerce adoption trends were slow in Africa compared to other countries, the South African e-commerce sector, especially small businesses, has shown promising growth, albeit at a low Internet penetration level (Cloete, Courtney & Fintz, 2002:9).

Furthermore, Bhatnagar (2000:1-3) points out that telecommunications infrastructure forms an essential part in any future economic and social development of African economies. Spiegel (2004) finds factors linked to an education system – companies in India for example, compete in ICT and e-commerce as global players whereas China is often chosen for manufacturing resulting from the Chinese government's intention to encourage a culture of manufacturing. Some of these issues also emerged in the literature review.

The selection of African developing countries used in this research study was based on the e-Readiness rankings (2005) comprising of Egypt, South Africa, Morocco, Nigeria and Botswana. The Internet usage of these countries are depicted in Table 1, ranked according to estimated Internet users.

Although Internet connections are available in many African capitals, e-commerce infrastructure gaps exists between developed and developing countries and is the largest in Africa where only one in about 118 people use the Internet.

3. OBJECTIVE OF THE RESEARCH

The researchers explored the underlying issues pertaining to e-commerce adoption, specifically in a developing country to provide e-commerce adoption guidelines to SMMEs. In addition, the extent and conditions under which e-commerce is adopted

Table 1. Population and Internet usage statistics: Comparison of African countries by 'Usage % in Africa' (Source: International Internet Usage Statistics, 2005).

POPULATION AND INTERNET USAGE PERCENTAGE COMPARISON OF AFRICAN REGIONS					
Region	Total estimated population in 2006	Population as % of African (%)	Estimated Internet users	Usage % of Africa (%)	Usage % growth (2000-2005)
Egypt	71,236,631	7.0	5,000,000	21.1	1,011.1
South Africa	48,861,805	7.4	3,600,000	15.8	50.0
Morocco	30,182,038	11.6	3,500,000	15.4	3,400.0
Nigeria	159,404,137	1.1	1,769,700	7.8	784.9
Botswana	1,856,800	3.2	60,000	0.3	300.0

Table 2. E-commerce adoption definitions (Source: Literature, keywords or descriptive phrases in bold text).

Category	Author	E-commerce adoption
Causes	MacGregor and Vrazalic (2005:514)	E-commerce adoption is **a cost effective way to reach global customers and to compete on even terms with larger counterparts.**
	Castleman (2004:34) refers to a report produced by APEC(1999:12)	"Adoption of e-commerce has been advocated as a way of **reducing transaction costs**, gaining market share, streamlining business processes, achieving **competitive advantage,** and **improving relationships** with business partners for improved business performance".
	O'Keefe, O'Connor & Kung (1998:630) citing Lambkin, 1988)[1]	**Early adopters** of IT (e-commerce) can gain an **advantage** in the same way that early entrants into a market can gain an advantage.
	Fillis,Johannson & Wagner (2004:182)	The implications for non-adoption of e-business may vary where **product opportunities** may be lost due to late market entry when firms eventually decide to embrace the new technology, where often new types of products and services would already have entered the market.
Effects	Damanpour (2001:16)	Adopting the Internet's connectivity aspect for business has **changed the way companies communicate internally and externally**. **Internally**, how they buy and sell on the Web and share information. **External** communication activity increases efforts to understand **customers, suppliers, business partners and competitors**.
	Ratnasingam (2003)	Businesses are often too small and therefore unable to provide the financial resources **to retain the appropriate skill levels of staff** needed to implement or oversee e-commerce initiatives.
	Quaddus and Achjari (2005:127-129)	E-commerce adoption encompasses a **wide spectrum of business processes** and **configuration of technology resources** to facilitate how business managers perform their tasks, **interact with customers** and conduct their business.

was also examined. The development of an e-commerce adoption definition was needed to serve as a terms of reference for the research and to scope the e-commerce adoption study. Furthermore, proposing an e-commerce adoption theoretical framework requires verification from evidence obtained from local case studies. This would culminate in proposing ten e-commerce adoption factors.

4. DEFINING E-COMMERCE ADOPTION

The researchers firstly created a working definition for e-commerce adoption by selecting seven of the most descriptive and appropriate definitions found in literature. The definitions were then divided into two categories according to the frequency of keywords or overriding descriptive phrases appearing in the e-commerce adoption definitions. The categories are *causes* and *effects*, depicted in Table 2.

Using the information in Table 2, a definition for e-commerce adoption was created, reading as follows:

e-Commerce adoption *is a cost effective way to reach global players, gaining market share, streamlining a wide spectrum of business processes and technology for competitive advantage utilising telecommunication networks, improving relationships, advantageous to early adopters, willing to change and improve communication - internally and externally, ensuring sufficient resources and skilled-staff.*

5. THEORETICAL FRAMEWORK

A cause/effect view of e-commerce adoption emanated as the most feasible categorisation from literature to serve as a theoretical framework. Kah (2004:274) suggests government and industry intervention in developing countries are considered suitable drivers pertaining to causes for e-commerce adoption. The authors expanded the drivers to include SME business activity for their research. However, on the basis of Usage % of Africa (%) appearing in Table 1, Botswana (0.3%) was eliminated from this study. These causes and effects are summarised in Tables 3 and 4 respectively. For ease of use and completeness, four bibliographies are provided serving as the primary source for each of the specific countries explored.

In Table 4 the effects of e-commerce adoption of the selected African countries are depicted, summarised using impact, advantages and disadvantages as drivers.

6. SOUTH AFRICAN E-COMMERCE EXPANSION

- Eight online retailers are currently dominating the online consumer and apparel market and account for approximately 80% of all online retail sales. Motjolopane (2006:20) reports that "… Retail sales at the end of 2003 increased by 35% and grew by 25% in 2004".
- E-commerce adoption has expanded rapidly in the airline industry in South Africa. According to Hartley and Worthington-Smith (2003:151-152), the volume of online travel sales compared to Europe. The 'no frills' airline, Kulula.com is considered to be South Africa's largest revenue-generating B2C business. 1time Airline, another successful *no-frills* airline in South Africa, is claiming more than 75% of online travel transactions (Warden & Remenyi, 2005).

7. RESEARCH METHOD

According to Strauss and Corbin (1998:11), qualitative research is a research mechanism to assist researchers finding evidence not arrived at by statistical procedures or other means of quantification. In such cases, hermeneutic approaches are preferable to analyse findings (Remenyi, Williams, Money & Swartz, 1998:288). Hussey and Hussey (1997:66) suggest that case studies are often described as explanatory research used in areas where there are few theories or a deficient body of knowledge. Furthermore, Yin (1994:20-27) states that a case study is an empirical enquiry that investigates a contemporary phenomenon within its real-life context, especially when the boundaries between phenomenon and context are not evident. Tellis (1997) alludes to the interactive nature of case studies and states the need to use multi-perspectival analysis, where the researcher is able to consider the relevant groups of participants. Evidence from multiple cases is often considered more compelling and the "… overall study is therefore regarded as being more robust" (Herriott & Firestone, 1983:14 in Yin, 2003:46).

7.1 Number of Cases

According to Yin (2003:47) the underlying logic of multiple-case studies indicates that the researcher should select each case with care in order for it either, to predict similar results (a literal replication) or predict contrasting results for predictable reasons (a theoretical replication). Five SMMEs were used to gather evidence. The SMMEs used were Case A (international travel business), Case B (mail order and electronic component store), Case C (pre-paid electricity

Table 3. Causes of e-commerce adoption: African developing countries

Government or Industry intervention to enable ICT	SMEs sector activities
Egypt - Bibliography 1	
Initiatives launched by the Egyptian government and private sector to promote ICT and e-commerce adoption. Egyptian banks lag and lack support for SET (Secure Electronics Transaction). Low usage of credit cards poses inhibiting factor for adopting e-commerce. Low e-readiness affects e-commerce adoption.	SMEs represent almost 99% of the number of companies in the private non-farm agricultural sector. Slow uptake in e-leadership and information security, connectivity, human capital and e-business.
Morocco – Bibliography 2	
Awarding of fixed-line license aimed to provide stimulation to the telecommunication sector. Fixed-line telecommunication network declined from 1999 but recovered in 2003 due to demand for Internet access and ADSL broadband services. The telecommunication operator Maroc Telecom listed on the Paris and Casablanca stock exchanges in 2004. Telecommunication market has experienced consistent growth mainly mobile sector where competition was introduced in 2000.	Due to large-scale emigration of males to France over the years has introduced an ethnic factor of not starting many small businesses. Tourism is strengthening Morocco's small business links with the West causing awareness.
Note: No suitable literature on e-commerce adoption by SMEs in Morocco was available	
Nigeria - Bibliography 3	
Government has been the sole provider of telephony and communication systems.	Current government promoting e-business among SMEs in its National IT Policy. SMEs have been made are aware of the advantages offered by the Internet and how it could assist them reach global markets and a source of information.
South Africa – Bibliography 4	
Telkom has been the sole supplier of communication links. Government promoting great support for SMMEs. Western Cape Provincial Government allocated R50 million for small business development in 2004. Electronic banking (e-banking) is being rapidly established and mobile banking (m-banking) was introduced in 2006.	SME and e-commerce sector experienced rapid growth over the last five years and Internet penetration is more evident in small business and upper income households. Common online purchases are groceries, apparel and books, By number of Websites, flowers and gifts followed by apparel, food, beverage and groceries are most popular. Online airline ticket sales have increased rapidly in South Africa.

provider), Case D (luggage store) and Case E (low cost airline) – these were all e-commerce start-up SMMEs.

7.1 Case Study Protocol

This instrument (interview schedule) as well as the procedures involved in conducting the research was developed by the authors and adapted mainly from Lubbe (2003:9) and Remenyi, Williams, Money & Swartz (1998:172-173) respectively. The interview structure consisted of three sections; Information about the interviewee/business, Demographic information and an Interview topic guide.

Only the interview topic guide is summarised below:

- **Organisation -** Strategic objectives, Reasons for adopting e-commerce in business
- **Internal -** Human resource, Impact of e-commerce, Customer demand & service, Reduced transaction costs, Critical success factors.
- **External –** Competition, Partnerships, Networks.
- **E-commerce adoption -** Operational issues of e-commerce, Adoption of ICT systems.
- **Environment –** Technical, Market, Brand.

8. CONDUCTING THE RESEARCH

In-depth open ended interviews were conducted over a period of about 12 months focussing mainly on causes and effects of e-commerce adoption within the ambit of the interview topic guide. Information was also collected to verify the theoretical framework developed in Paragraph 6. At least two, and in some

Table 4. Effects of e-commerce adoption: African developing countries

Impact	Advantages	Disadvantages
Egypt		
The e-commerce adoption process has highlighted a number of issues: e-Readiness is low. Improvements needed in e-leadership and information security, connectivity, human capital and e-business.	SMEs were offered opportunities for innovation and the emergence of new products and services. Small entrepreneurs were assisted to overcome information poverty. Entrepreneurs become more connected, more confident, less risk-averse, and more capable of making well-informed decisions. Empowering small entrepreneurs, e-commerce offered the potential for increasing exports, promoting growth and human development.	Large firms could get 'locked in' to technologies – high switching costs is a concern - Few PCs in management. Medium sizes firms have higher degree of awareness of ICTs in management and production - Few PCs in management. Small firms not aware of the role of ICT, e-infrastructure and human capital - Few PC in management. Mainly dial-up access for Internet connectivity.
Morocco		
Telecommunication services expansion - Two, Third Generation (3G) mobile licenses planned to be awarded in 2006 and the sale of a further 25% of Maroc Telecom in 2007. The economy has been subject to considerable liberalization in recent years and foreign investment is encouraged.	New ICT related career opportunities have arisen for especially women such as telecentres, call centres, Internet cafes and telephone booths. At the same time B2C business transaction opportunities are emerging and becoming feasible for selling of manufactured hand-made products in Morocco by woman. These new directions could lead to a global economy.	Small SME sector of mainly hand-made products not ideal for e-commerce.
Nigeria		
The best-performing SSA country in terms of ICT use and product diffusion can be exploited to benefit the ICT sector. Receipt of direct foreign investment. Teledensity rate has improved following deregulation of the telecoms industry - more government policy and support may be required to provide an enabling environment for wide e-commerce adoption.	The spread of cyber cafés in the country is assisting to popularize the Internet, which in turn will enhance e-business adoption.	Lack of knowledge about e-commerce benefits, finance IT skills & infrastructural support.
South Africa		
Only small sections of businesses and sectors adopted e-commerce. 18 % of businesses out of a possible 4 500 businesses listed on the Cape Town Regional Chamber of Commerce and Industry had e-commerce related Websites Internet sales account for less than 1 % of the volume of all airline ticket sales in South Africa, 'no-frills' airlines in South Africa report up to 75% of online travel transactions.	Online air travel business has expanded and become extremely competitive. Eight online retailers are currently dominating the online market and account for approximately 80% of all online retail sales.	Business organisational e-commerce adoption barriers identified: Negative attitudes, Lack of knowledge, Resistance to change, Lack of management commitment. Gaps remain between online shopping and the physical experience: Ability to judge quality, Ease of buying locally, Privacy & Security.

cases, three interviews were conducted, tape recorded, transcribed and case study reports compiled.

9. FINDINGS

In Table 5, the causes of e-commerce adoption in South African SMMEs are summarised using categories intervention to enable ICT and small business activities.

Similarly, in Table 6 the effects of e-commerce adoption are depicted using categories impacts, advantages and disadvantages.

The effects of e-commerce adoption in Table 6, indicates various aspects and some similarities between the five cases. Revisiting the case study reports and eliminating irrelevant and non-applicable information, thirteen adoption factors were developed as common phrases from the respective case evidence. Each of the adoption factors were again verified against the evidence obtained from the five cases, depicted in Table 7.

Some discrepancies and isolated factors appeared mainly due to the particular business sector. Therefore, only factors featuring in more than four cases were deemed to be representative, thereby reducing the adoption factors to ten, depicted in Table 8.

Table 5. Causes of e-commerce adoption trends: Cases of South African SMMEs

Intervention to enable ICT	SMME business activities
Case A	
Initially only telephone and facsimile considered sufficient Guests started demanding more ICT services – Internet & PCs Outsourced ICT & Website No internal IT expertise	Owner managed – 2 Partners Less than 20 employees
Case B	
Moved from manual mail order to online order system Outsourced ICT & Website Website content management system Limited internal IT expertise	Owner managed Less than 20 employees
Case C	
Cape Town city council (CCC) required services CCC collection of account arrears Internal ICT expertise	Management owned – CEO & 5 Partners/Directors Less than 100 employees
Case D	
Purchased ICT System Outsourced ICT & Website No internal IT expertise	Owner managed Less than 20 employees
Case E	
Utilising ICT to effect cost saving Bought in ICT partner company Quick to market – competition looming	Management owned – CEO & 4 Partners/Directors Less than 200 employees

Table 6. Effects of e-commerce adoption trends: Cases of South African SMMEs

Impact	Advantages	Disadvantages
Case A		
Expanded market share Website serves as online brochure & e-commerce site	Partial funds deposited before providing service International network Online booking & virtual markets Manage business from anywhere, anyplace	None detected Slow Internet access into South Africa
Case B		
First to market in SA in electronic component sector Utilising ICT to automate systems Global market	Funds deposited before providing service (pre-paid) Extensive catalogue combined with e-commerce site	Users not e-ready Online competition Slow internet access - Broadband needed to scan Website
Case C		
Utilising ICT to effect cost saving & system automation	Predictable cash flow- low and high seasons Funds deposited before providing service (pre-paid) Long contracts with municipalities, now nationally	Business expansion determined by rate of installation of e-dispensers Users not e-ready
Case D		
Same ICT system to automate entire business First to market in Cape Town in Bag sector	Entire e-commerce system and operation cheaper than new warehouse Extensive catalogue combined with e-commerce site Transaction finalised by credit card before delivering	Users not e-ready Product not ideally suited to online trading Slow internet access - Broadband needed to scan Website
Case E		
Market shake-up Utilising ICT to effect cost saving & system automation Leading LCA sector	Funds deposited before providing service (pre-paid) Automated systems No legacy systems to maintain, no royalties	Business expansion determined by external factors- fuel, interest rates & legislation Competition, new entrants to market Slow internet access - Broadband needed to spend sufficient time on Website

Table 7. e-Commerce adoption factors: Cases of South African SMMEs

#	Factor Description	Cases				
		A	B	C	D	E
1	User-friendly Web interface	√	√	√	√	√
2	Top management support	√	√	√	√	√
3	Maintaining strong links with customers	√	√	√	√	√
4	Ensuring customer acceptance	√	√	√	√	√

11	Evidence of maintaining good trading partner relationships	√	√			
12	Powerful Web site with strong search engine		√			
13	When using a shopping cart, users can store its contents for later use		√	√		

Table 8. e-Commerce adoption factors for SMMEs

1	User-friendly Web interface
2	Top management support
3	Maintaining strong links with customers
4	Ensuring customer acceptance
5	Providing up-to-date information, including prices
6	Regular promotions
7	Customers ability to track orders via Ref. number
8	Providing support service from Web site
9	Good technical infrastructure to enable fast processing
10	Open system, anyone may access to conduct business

10. CONCLUSION

From the results of the research reported in this paper, it is evident that Internet usage is increasing and that e-commerce adoption in African countries tend to follow similar trends. The e-commerce adoption factors listed in Table 8 provides a guideline for e-commerce adoption for SMMEs. These factors were found to be applicable to SMMEs in South Africa, competing in the global economy - evident from the findings of the case studies. Although certain assumptions had to be made, for example the particular definitions chosen to develop the e-commerce working definition, case selection and assumptions made regarding the adoption factors. Table 8 represents the outcome based on the research activity conducted and reflects the essential e-commerce adoption factors. Furthermore, the authors are aware that the ten factors are not necessarily fixed in the given ranking and may differ in the context of other studies, applications or different market sectors. Finally, the list of ten e-commerce adoption factors could be used by SMMEs, consultants or web developers to serve as a guideline in an e-commerce SMME environment.

ABSTRACT

Online auctions are a very popular method to buy and sell items on the Internet. However, it is very dynamic in that it is very difficult to predict the winning bid of a given auction. There have been numerous studies to design a bidding strategy that can be utilized by bidders to ensure that they always win an auction. The closing price of an auction is not known and is dependent on several factors such as the number of auctions selling the same item, the number of bidders participating in that auction as well as the behaviour of every individual bidder. To top it up, there can be multiple auctions running concurrently at the same time. To participate in an online auction, one has to decide which auction to participate, how much to bid and when to bid. In most cases, this process is time consuming and does not always guarantee a winning bid. Knowing the closing price would definitely solve part of the problem. If the closing price of an auction is known, then bidder could then decide which auction to participate and at what price. This paper describes one technique to predict the closing price of an auction. This technique is called the Grey System Theory which has been known to be able to accurately predict values in areas where the information is insufficient. This paper also investigates the effectiveness and the accuracy of this theory when applied to online auctions. Some preliminary evaluations will be discussed.

1. INTRODUCTION

Auction is a market institution with an explicit set of rules determining resource allocation and price on the basic of bid from the market participants (McAfee & McMillan, 1987). Nowadays online auction is one of the most popular and effective ways of trading by participants bidding for products and services over the Internet (Bapna, Goes, & Gupta, 2001). Online auction has given consumers a "virtual" flea market with all the new and used merchandises from around the world. They also give sellers a global storefront from which to market their goods.

Online auction allows clients to buy and sell items by means of auctions anytime and anywhere they like. Moreover, online auctions generally last for days and weeks giving the bidders more flexibility about when to submit bids. Compared with the traditional business type, internet auctions can be a co-effective way to test-market products in an online sales environment and to liquidate dated or overstocked merchandise especially for small business owners. Besides that, by using online auction, there is no geographical limitation since both sellers and buyers do their trading in a "virtual" environment and any transaction can be made through the online banking. Moreover, due to the relatively low price and wider scope of products and services, the online auctions have attracted many bidders in the trading process. At the same time, many sellers will be attracted to the online auction as it has attracted many potential consumers. Online auctions also allow sellers to sell their goods efficiently and with little action or effort required.

There are four main types of single-sided auctions that are commonly used in traditional auctions (Klemperer, 1999) namely ascending-bid auction (also called the open, oral, or English auction), descending-bid auction (also called Dutch auction), first-price sealed bid auction and second-price sealed bid auction (also called Vickrey auction). The English begins with the lowest price and bidders are free to raise their bid successively until there are no more offers to raise the bid. Bidder with the highest bid is the winner. A Dutch auction is the opposite of an English auction, in which auctioneer begins with an initial high price and then progressively lowered until there is an offer from a bidder to claim the item. In the first price sealed bid, each bidder submits their offer for an item privately. The highest bidder gets the item and payment is based on their own bid. The Vickrey auction is similar to the first-price sealed bid auction, where the item goes to the highest bidder but he only pays a price equal to the second highest bid. Online auctions are somewhat similar to the traditional auctions but most auctions are constrained by the time. Auctions usually last for days and week depending on the seller's requirement.

Due to the proliferation of these online auctions, consumers are faced with the problem of monitoring multiple auction houses, picking which auction to participate in, and making the right bid to ensure that they get the item under conditions that are consistent with their preferences (Anthony & Jennings, 2003). These processes of monitoring, selecting and making bids are time consuming. The task becomes even more challenging when the individual auctions have different start and end times. Moreover, auctions can last for a few days or even weeks. Besides that, every bidder has his own reservation price or maximum amount that he is willing to bid for each item. If bidders are able to predict the closing price for each auction then they can make better decision on when and where or even how much they can bid for an item. In a situation where a bidder has to decide among the many auctions that are currently ongoing, this knowledge on closing price for an auction would be useful for the bidder to decide on which auction to participate, when to participate and at what price. There are other considerations that need to be taken into account to ensure that the bidder wins in a given auction. However, knowing the closing price of a given auction would definitely be an advantage because the bidder can decide where to bid and how much to bid. Unfortunately, predicting a closing price for an auction is not easy since it is dependent on many factors such as the behavior of the bidders and the number of bidders participating in that auction.

For these reasons, many investors have been trying to find a better way to predict auction closing price accurately. Neural Network, Fuzzy Logic, Evolutionary Computation, Probability Function and Genetic Algorithm, are integrated to become more commendable practical model for prediction purpose. However one particular method is to apply the Grey System Theory to predict online auction. It is a new theory and method which applies to the study of unascertained problems with few or poor incoming information (Liu & Lin, 2004). In online auction, the number of available information is limited and it is often very difficult to predict the outcome of an auction since bidders have different behavior. It is quite possible to predict the closing price of an auction using Grey Theory method and this will be elaborated in Section 4.

In this paper, we will investigate the effectiveness of the grey system theory in predicting the closing price of online auction. In Section 2, the design of grey theory system is explained. Section 3 discusses the prediction algorithm by using the grey system theory. The preliminary result is shown in Section 4. In section 5 some related works using grey theory are discussed and finally the conclusion and future work is discussed in Section 6.

2. GREY SYSTEM THEORY DESIGN

The grey system theory was first proposed by Deng Julong (1982). Grey system theory works on unascertained systems with partially known and partially unknown information by drawing out valuable information, by generating and developing the partially known information. It can describe correctly and moni-

Table 1. Attributes of traditional forecasting model

Mathematical model	Minimum observation	Type of sample	Sample interval	Mathematical requirements
Simple exponential function	5-10	Interval	Short	Basic
Regression analysis	10-20	Trend	Short	Middle
Casual regression	10	Any type	Long	Advanced
Box-Jenkins	50	Interval	Long	Advanced
Neural network	Large number	Interval or not	Short	Advanced
Grey prediction model	4	Interval	Long	Basic

tor effectively the systemic operational behaviour (Lin & Liu, 2004). Basically, the Grey system theory was chosen based on color. For instance, "black" is used to represent unknown information and "white" is the color used for complete information. Those partially know and partially unknown information is called the "Grey System Theory".

The grey system theory has been successfully applied to economical, management, social systems, industrial systems, ecological systems, education, traffic, environmental sciences, and geography (Lin & Liu, 2004). It is used successfully to analyse uncertain systems that have multi-data inputs, discrete data, and insufficient data. Grey systems theory explores the law of subject's motivation using functions of sequence operators according to information coverage. It is different from fuzzy logic since it emphasizes on objects with definite external extensions and vague internal meanings. Table 1 shows the Grey prediction model compared to other traditional forecasting models (Chiang, Wu, Chiang, Chang & Wen, 1998). It can be seen that this model only requires short-term, current and limited data in order to predict a given value.

Grey prediction is a quantitative prediction based on grey generating function, GM (1, l) model, which uses the variation within the system to find the relations between sequential data and then establish the prediction model. The grey forecasting model is derived from the grey system, in which one examines changes within a system to discover a relation between sequence and data. After that, a valid prediction is made to the system. Grey prediction model has the following advantages: (a) It can be used in situations with relatively limited data down to as little as four observations, as stated in Table 1. (b) A few discrete data are sufficient to characterize an unknown system. (c) It is suitable for forecasting in competitive environments where decision-makers have only accessed to limited historical data (Chiou, Tzeeng, Cheng & Liu., 2003).

3. GREY SYSTEM THEORY PREDICTION ALGORITHM

In this section we focus on the grey generating function, GM (1,1) which are being used in grey prediction (Deng & David, 1995). The algorithm of GM (1,1) can be summarized as follows.

Step 1. Establish the initial sequence from observation data

$F^{(0)} = \{f^{(0)}(1), f^{(0)}(2), \ldots, f^{(0)}(n)\}$.

Step 2. Generate the first-order accumulated generating operation (AGO) sequence

$F^{(1)} = \{f^{(1)}(1), f^{(1)}(2), \ldots, f^{(1)}(n)\}$.

where $f^{(1)}(k) = \sum_{i=1}^{k} f^{(0)}(i)$.

Step 3. The grey model GM (1,1)

$$F_{t+1}^{0} = a\left[-\frac{1}{2}\left(F_{t=1}^{1} + F_{t}^{1}\right)\right] + b, \qquad \forall t \geq 1.$$

Step 4. Rewrite into matrix form

$$\begin{bmatrix} F_2^0 \\ F_3^0 \\ \vdots \\ F_x^0 \end{bmatrix} = \begin{bmatrix} -\frac{1}{2}\left(F_2^1 + F_1^1\right) & 1 \\ -\frac{1}{2}\left(F_3^1 + F_2^1\right) & 1 \\ \vdots & \vdots \\ -\frac{1}{2}\left(F_x^1 + F_{x-1}^1\right) & 1 \end{bmatrix} \begin{bmatrix} a \\ b \end{bmatrix}.$$

Step 5. Solve the parameter a and b

$$\hat{a} \text{ or } \begin{bmatrix} a \\ b \end{bmatrix} = \left(B^T B\right)^{-1} B^T F.$$

Step 6. Estimate AGO value

$$\hat{f}_{T+1}^{1} = \left[f_1^0 - \left(\frac{b}{a}\right)\right] e^{-at} + \left(\frac{b}{a}\right), \qquad \forall t \geq 1.$$

Step 7. Get the estimate IAGO value

$$\hat{f}_t^0 = \hat{f}_t^1 - \hat{f}_{t-1}^1, \qquad \forall t \geq 2$$

We use the average residual error for each set of data to calculate the accuracy of the predicted data. The formula for the average residual error is given as

$$\frac{1}{n}\left(\sum_{t=1}^{n} \frac{\left|f_t^0 - \hat{f}_t\right|}{f_t^0}\right).$$

Where f_t^0 = Original data at time t

$\hat{f}$ = Predicted data at time t

n = The total number of data has been predicted

In order to test the effectiveness of grey system theory, we set up an electronic simulated marketplace. The simulated electronic marketplace consists of a number of auctions that run concurrently. There are three types of auctions running in the environment: English, Dutch and Vickrey. The English and Vickrey auctions have a finite start time and duration generated randomly from a standard probability distribution, the Dutch auction has a start time but no pre-determined end time. At the start of each auction (irrespective of the type), a group of random bidders are generated to simulate other auction participants. These participants operate in a single auction and have the intention of buying the target item and possessing certain behaviour. They maintain information about the item they wish to purchase, their private valuation of the item (reservation price), the starting bid value and their bid increment. These values are generated randomly from a standard probability distribution. Their bidding behaviour is determined based on the type of auction that they are participating in. The auction starts with a predefined starting value; a small value for an English auction and a high value for a Dutch auction. There is obviously no start value for a Vickrey auction. The marketplace is flexible and can be configured to take up any number of auctions and any value of discrete time. We assume that all the auctions in the marketplace are auctioning the item that the consumers are interested in. Our bidder agent is allowed to bid in any of the auctions at any time when the marketplace is active. It is also assumed that all auctions are selling the same item.

4. PRELIMINARY EXPERIMENTAL EVALUATION

The purpose of this experimental evaluation is to determine the efficiency and accuracy of the grey system theory in predicting the closing price of an online auction. However, to calculate the prediction accuracy of this model, we worked on the original data taken from eBay financial result (eBay, 2006), the GAAP

Diluted EPS and pro-forma Diluted EPS data between the first quarters of 2005 until the second quarter of 2006. We used four historical data to calculate the predicted value. To test the accuracy of the grey theory, the accuracy is calculated based on the residual error. It was found that the average residual error for the GAAP predicted data is 3.91% (96% accuracy) and the non GAAP or Pro-forma is 2.99% (97% accuracy). This is very promising considering the fact that only four historical data are used in the prediction.

The next step however is to investigate whether we will get similar result when we apply this theory to predict the closing price of an online auction. Using the simulated marketplace, we ran the auction from t = 1 until t = 30. We have also set most of auctions to close after t = 15. In one particular run, the closing price history for all auction running in a marketplace are shown from t = 18 until t = 25. Our first experiment is to calculate the predicted auction closing price based on three, four, five, six, seven and eight historical closing price data which is shown in Table 3. The result of the prediction is shown as below. In can be seen that the average residual error falls between 3.58% to 29.12% and the highest accuracy is using 5 historical data.

At the same time, we also calculated the predicted closing price for five more data from t = 19 to t = 30 which is shown in Table 4. It was found that the average residual error increased to a range between 4.95% to 23.88%. This result is still acceptable since the average residual error is 9.09% (or 90% accuracy). In this case, the highest accuracy is using 4 historical data. It can also be seen in both experiment that the accuracy at the highest between 5 and 6 historical data.

In the following experiment, six moving historical data were used to predict the auction closing price. That means, to predict the auction closing price at t = 24, we will use data from the last five closing (t = 18 until t = 23). We used six historical data because of its performance in the previous experiment. Table 5 shows the predicted values based on the given range. In this particular experiment, the average residual error is between 4.30% to 26.11% and the average residual error for the 5 readings is 9.85% (90%). This experiment also shows that using moving historical data, grey theory is able to predict the auction closing price more accurately by just making use of six previous data. The result of these experiments shows that grey system theory can be used to predict the auction price of an auction. The difference between actual data and original data may be contributed by other factors such as bidder's emotion, the priority of the items, and so on, which are not taken into the consideration at this point.

5. RELATED WORK

There are many researches that have been engaging in the prediction and forecasting of real world phenomenon. Chiou et al. (2003) introduced Grey Prediction Model (GPM) to plan material of spare parts equipment in Taiwan. They took three types of weapon system periodic items of planning material from 1999 to 2002, and applied GM (1,1) model to predict the planning requirement of impenitent spare parts of 2003. Through this study, they demonstrated that the GM (1,1) produced a high level of accuracy in prediction of spare parts. Lin and Lin (2004) used grey prediction to improve the efficiency of achieving accurate and speedy inspection when a coordinate measuring machine (CMM) is used to measure circularity geometric tolerance. Grey theory was applied in developing the heuristic algorithm for predicting the number of measuring points required for measuring circularity geometric tolerance. The heuristic algorithm was used to plan the number of measuring points of the next work piece and to predict the circularity geometric tolerance dimensions. This step provides a better foundation for on-line inspection to determine the number of measuring points required for measurement inspection of the next work piece. It can also predict whether the circularity geometric tolerance of the next work piece will conform to the circularity geometric tolerance dimension on the design drawing. This heuristic algorithm could also be used to

Table 2. Result performed by using Grey prediction model compared with original data collected from eBay financial result

Year and Quarter	GAAP Original Data (Million)	GAAP Predicted Data (Million)	Pro Forma (non GAAP) Original Data (Million)	Pro Forma (non GAAP) Predicted Data (Million)
2005 Q1	256.3	-	275.5	-

determine whether the manufacturing process requires modification, in order to save human and material resources and reduce failure rate.

Wang (2002) used the fuzzy grey prediction system to predict the stock price instantly at any given time. Wang combined fuzzification techniques with grey theory to develop a fuzzy grey prediction and plugged it into a system to predict the possible answer immediately. He used the prediction system to analyze stock data and to predict the stock price promptly at a specific time. Wang, Chang, Belkasim and Sunderraman (2002) designed the real time fuzzy personalized stock information agent based on fuzzy logic. The smart agent enables the users to create their own portfolios that contain the real time watch list of personalized stocks. This application enables the user to get accurate, real time information of a pre-selected list of favourite stocks. Using fuzzy reasoning, the Web stock agent is capable of ranking the "top 10 stocks" based on their real time stock information. Since output values are calculated with the consideration of degree of uncertainty, results of the data process are precise and reliable. It saves time for user to search for stock information, and good stocks from thousands of stocks.

Hassan, Nath and Kirley (2006) proposed and implemented a fusion model by combining the Hidden Markov Model (HMM), Artificial Neural Networks (ANN) and Genetic Algorithms (GA) to forecast financial market behaviour. The tool can be used for in depth analysis of the stock market. Using ANN, the daily stock prices are transformed to independent sets of values that become the input to HMM. They drew on GA to optimize the initial parameters of HMM. The trained HMM is used to identify and locate similar patterns in the historical data. The price differences between the matched days and the respective next day are

Table 5. Result performed by using Grey prediction model compared with original data generated by agent auction

Time (t)	Original Data	Using 1-6 Historical Data	Using 2-7 Historical Data	Using 3-8 Historical Data	Using 4-9 Historical Data	Using 5-10 Historical Data
18	83	-	-	-	-	-
19	85	83.085	-	-	-	-

24	69	69.425	68.9995	71.956	74.117	72.695
25	81	75.478	72.946	80.931	84.61	82.905
26	83	62.125	63.353	78.1	82.996	82.384
27	81	55.391	50.255	73.466	79.276	81.153
28	76	44.303	37.682	71.027	77.449	83.231
29	83	36.888	28.665	91.785	80.517	91.634
30	70	21.169	11.235	69.741	76.478	94.4

The average residual error of using 1-6 historical data is 4.94%
The average residual error of using 2-7 historical data is 26.11%
The average residual error of using 3-8 historical data is 5.21%
The average residual error of using 4-9 historical data is 4.30%
The average residual error of using 5-10 historical data is 8.73%

calculated. Finally, a weighted average of the price differences of similar patterns is obtained to prepare a forecast for the next day.

6. CONCLUSION AND FUTURE WORK

This paper elaborated on the used of grey theory system to predict the closing price of an online auction. It has been shown that using this method, the accuracy rate always exceed 90%. This closing price knowledge can then be used by the bidder to decide which auction to participate, when and how much to bid. This information will also allow the bidder to maximize his chances of winning in an online auction. For future work, we will continue to investigate the effectiveness of grey theory in multiple auctions. Work need to be done to incorporate more than six historical data for prediction. It would be desirable if we can take into account all the historical data to produce an even more accurate prediction. Apart from that, we would also look into combining the grey method with other AI techniques.

In a larger context, this information about the closing price will be made use to support the development of bidder's strategies in online auction (Anthony & Jennings, 2003). Given a situation in which there are more than one potential auctions that the agent can participate, it would need to decide which auction it should participate in order to guarantee that it gets the item at the best price. In this case, the best price is the bid value that is less than the agent's reservation price. If the agent can predict the closing price accurately for each potential auction, then it would be able to make a quick decision on which of these potential auctions it should participate to maximize its gain.

ABSTRACT

In this paper, we present the E-collaboration system that has been designed and developed during the first year of the NHLBI-PEN Government Funded Project. We start by presenting the design phase that led to the implementation of the E-collaboration tools of the project. Then, we describe the function of each e-tool, we discuss the impact on the project that they have produced and we present open issues for further implementations of the system. Even if a specific information technology expertise was needed in order to make our system operational, we believe that it can be easily replicated and used by investigators of other government funded projects who do not already have access to an E-collaboration system.

INTRODUCTION

In order to successfully manage a research project, keep it on track and fulfill its goals, it is essential for the team to frequently discuss plans, objectives, achievements and challenges. It is also important to have the ability to share large data sets while maintaining a high level of security and privacy. Meeting and exchanging results regularly are also essential for the success of the project.

Face-to-face communications have been considered as the most appropriate medium to share ideas, comments, and opinions and to reduce misunderstanding [1]. However, large government funded projects often involve researchers from different institutions and/or departments. Therefore it is not always possible to implement this direct mode of communication due to the challenges of distance and the increasing needs of time and cost savings.

Recent developments in information and communication technologies have enabled and facilitated new forms of inter-organizational collaboration [2]. The use of E-collaboration tools introduces a new concept of time and distance, modifies human interactions, creates a novel environment for decision making and changes the classic network of face-to-face relationships into a network of virtual relationships.

E-collaboration has been defined in many ways. For the purposes of this article, we adopt the definition proposed by the guest editors of the first special issue on E-collaboration, published in 2001 in the *Journal of Systems and Information Technology by Kock et al.* They describe E-collaboration as "collaboration among individuals engaged in a common task using electronic technologies" [3]. Our system includes not only computer based technologies but also simple telecommunication devices such as the telephone. We agree with Kock [4] and we believe our system should still be considered an E-collaboration system.

In the following sections we briefly introduce the NHLBI-PEN project and describe the context that brought us to the implementation of a set of E-collaboration tools. Then, we present the hardware and software platform, a detailed description of the function of each E-collaboration tool, and the reasons for their development. We discuss the issues and challenges we experienced during development and implementation along with the limitations of our study, results achieved, and concluding comments.

THE NHLBI-PEN PROJECT

The central mission of the NHLBI-PEN project is to develop a group of well-characterized and versatile nanoscale agents that can be assembled, labeled, targeted, filled, and activated as needed for the diagnosis and treatment of various diseases of relevance to the National Heart Lung and Blood Institute (NHLBI). The project started in May 2005 and it has been funded for five years. The research activities of this project are carried out at three different institutions: Washington University in Saint Louis, University of California - Santa Barbara, and University of California – Berkeley. The teams include researchers from different cultures and scientific backgrounds where about 80% are chemists.

NEEDS ANALYSIS

Remote collaboration initiatives are not common in chemistry departments where Information Technology resources are often limited. The departments usually provide only emails as form of communication, common Internet access and occasionally the possibility to share central equipments.

E-Collaboration requires a synergistic framework based on four components: strategy, organization, process and technology [5]. We believe that a system embodying this synergy is advisable and necessary in order to be successful. Following this assumption, the senior investigators of the NHLBI-PEN project designed a roadmap with the goal of developing a set of E-collaboration tools that could overcome the potential barriers to collaboration and information sharing created by the physical separation and schedule differences between the three Universities.

The road map was based on four stages: 1) requirement gathering, to understand and identify the needs of the users, 2) requirement specifications, to identify any system requirements and user goals that must be met for the system to be successful, 3) design prototype in stages, and 4) evaluating the design to assess the system, test the software and perform usability testing.

Research has shown that it is much more economical to consider user needs in the early stages of the design [6]. In our road map, the needs and limitations of the end users were first inquired and analyzed, and then assumptions were transferred into the prototypes. This approach is well recognized as an effective strategy in designing ease-of-use products and systems [7],

The senior investigators of the NHLBI-PEN project identified four inter-organizational set of tools: information, communication, coordination and collaboration (see Table 1). For each of them, they defined a list of needs that had to be fulfilled by a specific E-collaboration tool. A time frame for implementation, based on months from the starting date of the project, was defined as well. The collaborative tools were selected among the ones presented here [8].

Given monetary constraints and the need to personalize software with specific routines, proprietary software was not a feasible option. In order to increase flexibility, independence from a third party provider was required. The system had to be highly reliable yet easy to maintain, administer and update, once fully operational. Synchronous and asynchronous tools had to be designed with the goals of increasing the communications and the sharing of data and results among the researchers. Easy access to and operation of the E-tools had to be addressed since most of the researchers in the project did not have an information technology background. Focusing on ease of use has been used to advance the product's release date [9].

In summary, the E-collaboration system had to be cost-effective (low cost of implementation), independent to industry and software/hardware vendors (open),

Table 1. Classes of inter-organizational information systems

Information	Communication	Coordination	Collaboration
WEB portal for sharing progress and general information about the project (available after 2 months). WEB portal for storing/remember events and meetings (available after 3 months). WEB site for storing goals and achievements of the researchers during skill development visits to other laboratories (available after 6 months).	Affordable conferencing system (available after 1 month). Research groups mailing list (available after 1 month). WEB site for facilitating the exchange of chemical samples between laboratories (available after 6 months).	Electronic document interchange tool (available after 4 months). System for monitoring the budget (available after 6 months).	Collaborative Planning (available after 10 months).

easy to integrate with the existing procedure/process and fast to deploy on a simple technology. [5]

NHLBI-PEN E-COLLABORATION SYSTEM

Following the plan provided in the road map, an E-collaboration system was designed and implemented. Initial use of the E-collaboration system was restricted to peripheral or uncritical activities and then implemented in full scale. This approach had many advantages: users learned to handle the new E-collaboration approach gradually without detracting from efficiency in their daily activities; technical implementation investment risks were minimized while the possibility of standardization was increased; and the E-collaboration system was tested adequately before going to full scale production.

HARDWARE AND SOFTWARE

The hardware and software platform used for providing the E-collaboration tools described in this paper, is based on a 2U rack Pentium III server class A by Ironsystems [10]. It runs Linux Debian with Apache as web server [11], PHP as scripting language [12], MySql as relational database [13], Webalizer for web statistics [14], and Postfix [15] as SMTP server. Telnet, FTP, DNS and other services have been uninstalled for security reasons. High levels of stability, fault tolerance, and availability are addressed by the use of RAID (Level 1) technology, daily backup policy on different supports (tape, external USB drive, and data storage devices), and redundant and uninterruptible power supply. Security policies are addressed by disabling physical and remote access to the server. Only a secret username has the privilege to log-in through a SSH connection from a subnet inside the Washington University in Saint Louis network. The SMTP server uses a mail relay provided by the department for spam filtering and virus protection. Specific firewall policies, directly controlled and managed by the IT office of the department of Chemistry at Washington University in Saint Louis, block access to the server except for port 80 (HTTP) and port 25 (SMTP). A daily report of the Internet traffic through these two ports is automatically created and checked regularly.

E-CONFERENCE TOOLS

The meetings of the NHLBI-PEN project are usually held in a conference room located at the School of Medicine of Washington University in Saint Louis. In order to reach a high level of participation and to increase the effectiveness of the meeting, a hybrid system, composed by an audio and a virtual office component, was developed. The audio component is based on a SoundStation VTX 1000™ Polycom system that allows communication, *via* telephone line, with the researchers in California. The two extra microphones and the speakers included in the Polycom system allow the circulation of comments, questions, and answers between all the participants (usually twenty in Saint Louis and seven in the two sites in California). The telephone service is provided by the university telephone department. The virtual office component uses a desktop sharing utility, based on VNC [16] that allows each site to be engaged in the meeting by following the PowerPoint presentations in real time. While one site actively initiates and controls their presentations, the other site can passively view. This virtual office component overcomes the limitation in following a distant presentation where the slide under discussion and the highlighted area of the slides by the presenter's laser pointer are unknown. The movements of the laser pointer are subsequently replaced by the movements of the mouse. This desktop sharing utility uses TCP/IP and it is available through a web site that works as proxy. A dedicated computer with Windows 2000 and VNC has port TCP 5900 open through the firewall. Two levels of password authentication are required to have access to the utility: one provided by VNC and the other by Windows.

E-DOCUMENTS TOOL

The E-Documents Tool is based upon PHP Advanced Transfer Manager [17], a free web content management software. It allows the researchers involved in the project to collaboratively create, publish, share and retrieve data when needed. The main features available are: upload, download, delete or modify (users can only manipulate their own files). A super-user creates folders, has full control over all the files, and manages user accounts. In order to fulfill the requirements and the needs of the researchers, the main software package was upgraded. Specific routines were designed, developed, tested and finally added to the basic package in order to have an E-Documents Tool that can provide each user with 300 Mbytes of restricted space (Personal folder) and each research unit (identified as a senior investigator plus his/her researchers) with 2 Gbytes of restricted space. The new version also has a shared folder accessible by everyone that is used for transferring files among units. Finally, a special area has been created for the exclusive use of the Internal Operating Committee members. At the end of July 2006, the E-Documents Tool had 304 files uploaded, 270 Mbyte of data stored, and 44 active users (Figure 1).

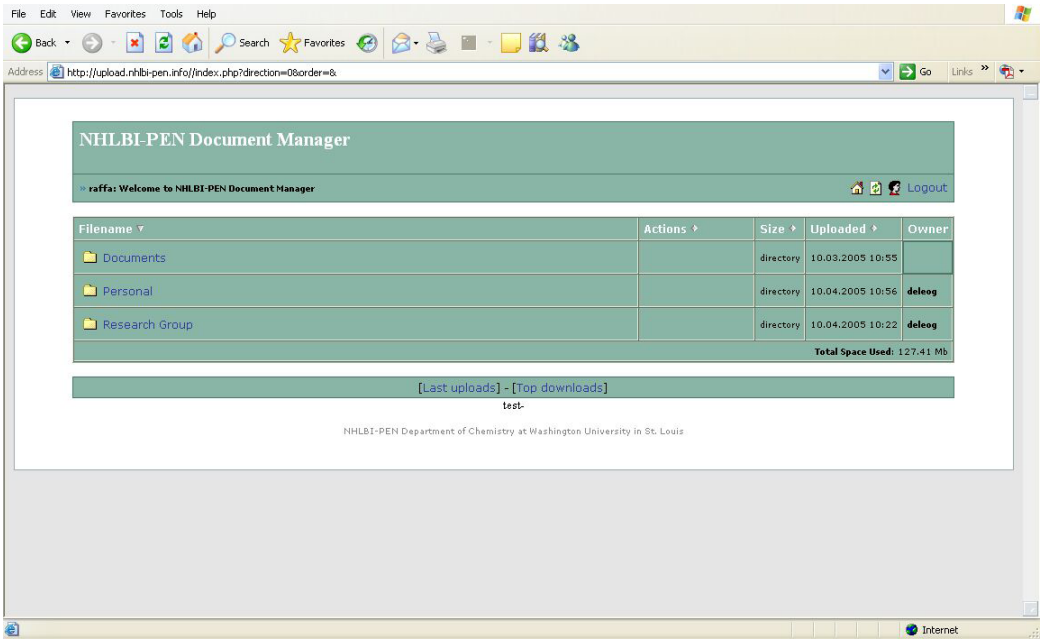
MAILING LIST TOOL

The researchers of the NHLBI-PEN project can utilize several mailing lists for easily contacting the members of each team. The mailing lists are both horizontal (for each of the 12 research teams) and vertical (for each of the 4 component: Materials Synthesis, Imaging, Animal Models, and Skills Development). The Internal Operating Committee has its own mailing list. In addition, a global mailing list that contains all the members is available.

E-RESEARCHER VISITS TOOL

The researchers of three universities are encouraged to schedule frequent short visits to other laboratories involved in the project. Throughout the year, post-doc and graduate students spend a few intensive days in other research groups to learn about additional procedures and methodologies that they have not yet experienced. The E-Researcher Visits Tool stores the researcher's name and email, information

Figure 1. The e-document tool (home folder view)

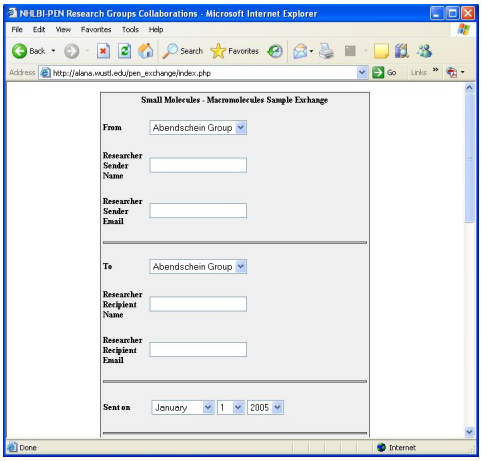


about the research group where he/she belongs, the group that he/she is visiting, and the goals and accomplishments of the visit. At the end of July 2006, the E-Researcher Visits Tool had 17 visits stored. A web site, password protected through the Apache htaccess policy, allows anyone in the project to have access to the E-Researcher Visits Tool.

E-SAMPLE EXCHANGE TOOL

The E-Sample Exchange Tool stores the information and the data of the chemical samples that have been transferred between research groups. There are two different sample exchange tools: one for Small Molecules-Macromolecules and one for Nanoparticles. A user-friendly web interface was developed in order to

Figure 2. E-sample exchange tool (insert a new record view)



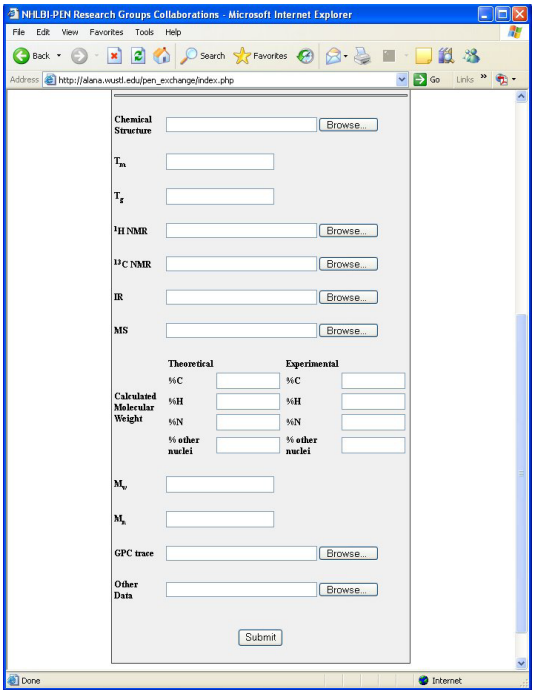


Figure 3. E-budget tool (monthly progress view)

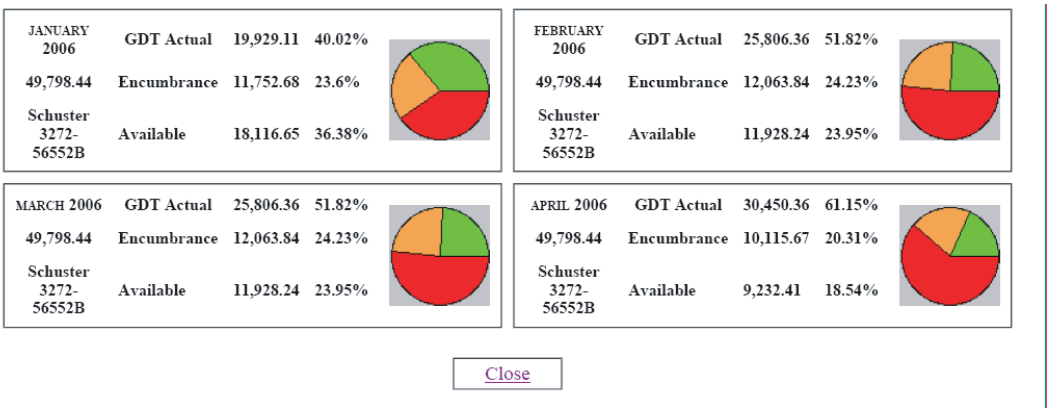
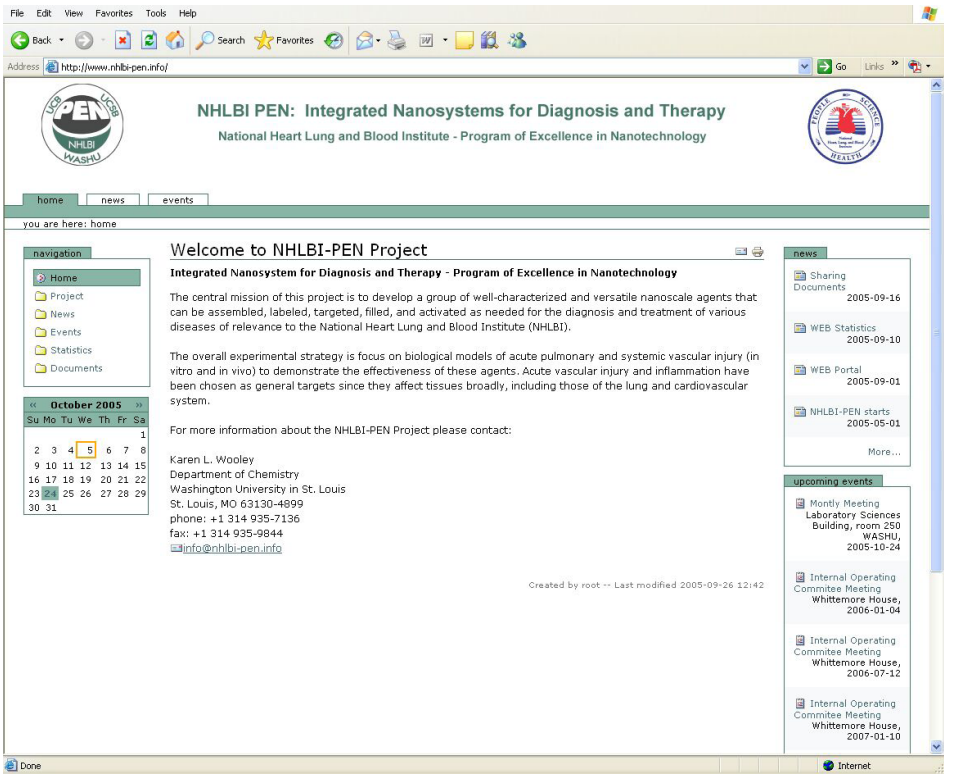


guide the researchers in creating a new record that contains general information and detailed data about the sample. General information includes the names and email addresses of the researchers who sent and received the sample, the date of sending, and an identification code. Detailed data consists of the chemical structure, the calculated molecular weight, the GPC trace, and other chemical properties. As in the case of the E-Researcher Visits tool, a web site allows anyone in the project to have access to the data. At the end of July 2006, the Sample Exchange E-Database contained 19 entries for Small Molecules – Macromolecules and 14 entries for Nanoparticles (Figure 2).

E-BUDGET TOOL

The E-Budget Tool keeps track of all the expenditures of each research group. This tool is available only to the Principal Investigator and her administration office. The budget of each research group is updated on a monthly basis and it shows the spent, the encumbrance and the available amounts. A color pie chart simplifies the visualization of the status of the budget and it is available in two formats. The first chart visualizes the research group budget situation by months, and it is used for monitoring the expenses over a long period of time. The second format gives an overview of all research groups by a selected month (Figure 3).

Figure 4. Web portal (home page view)



WEB PORTAL

The NHLBI-PEN web portal is available at http://www.nhlbi-pen.info (see Figure 4). Since the beginning of the project, the NHLBI-PEN team has been using the web portal for informing the community on new events and news. The status of the project, its progress and future plans are updated regularly. The web portal was developed using Zope [18] and Plone [19] and it provides a common interface and a single entry point to the other NHLBI-PEN E-Collaboration tools and services. The web portal contents can be easily updated by anyone, even without training in Hyper Text Markup Language (HTML).

DISCUSSION

The roadmap described in this paper is related to the first year of the NHLBI-PEN project. All the E-collaboration tools, except the collaborative planning, have been implemented and are fully operational.

The need for developing the E-collaboration tools presented in this article comes from the absence of collaborative systems at the three universities involved in the project. It is true that a teleconference system was available at each site but it was not free of charge, was difficult to reserve and the telecommunication standards used were not the same. Moreover the cost of using such systems cannot be billed directly to the grant and is not usually covered by the indirect costs of the departments. The possibility that the government agency that provides the grant would provide such E-collaboration tools free of charge does not seem realistic too.

Moreover, specific budgets for supporting IT personnel are not usually included in grant proposals. Thus, costs related to the initial investment in hardware should be considered when E-collaboration tools are planned. However, these costs would be a small percentage of the total budget of the project.

We believe the interface to our E-collaborations tools is easy to use. The researchers of the NHLBI-PEN project only need an e-mail account and a browser to have access to all the tools. Our monthly meetings have been attended often by researchers traveling in other countries or away from their offices. A wireless access point was enough for giving them the opportunity to participate. However, in order to increase the user-friendliness of our entire system, we are planning to develop a central log-in management system that stores the user's information. This would allow the user to log into each tool with the same id and password.

Bulletin boards for extended conversation and chat, where real-time text messages appear on both users screens, have not been implemented because they were not considered beneficial to the project. However, the development of a web based task list including a set of actions to be performed, pending activities, and unresolved problems is in progress. The E-Sample Exchange tools will have a "store room" section where researchers can look at the samples that are available in each group, place an order and receive the chemical at their labs. The implementation of a web based free educational tool to fulfill the skills developments component goals has been planned. Initial investigations suggested the use of Moodle [8].

Linux has been preferred to Windows as the operative system platform because more open source software is available under Linux. It is also easier to maintain once installed. We believe that the knowledge required to run a Linux server is equivalent to the one needed to administer a Windows 2000 Server.

Although the system is easy to maintain, we believe that a maintenance service (hardware and software) should be in place in order to guarantee availability of the E-tools to the researchers.

CONCLUSION

With the development of new technologies, and information communication technologies, in particular, teams have evolved to encompass new forms of interaction and collaboration. This paper demonstrates that E-collaboration tools can be used in a research funded project and that the implementation is not difficult to achieve.

The NHLBI-PEN E-collaboration system brings geographically dispersed research partners together, and supports the communication, coordination, cooperation, and sharing of data between the distant locations. We have described a system that allows the researchers of government funded projects to adopt the use of low-cost E-collaboration tools for increasing productivity and team work.

This study does not present any data about user's evaluation of the E-tools because a survey for collecting user feedbacks has not yet been developed. We only know that each E-tool has been extensively used. We are also aware that the number of the users in the NHLBI-PEN project would not have been enough statistically to make any definitive statements about the quality of our E-collaboration system.

However, we have acknowledged a transformation process from traditional (offline) communications toward hybrid services that combine elements of traditional collaboration and E-collaboration. Our E-collaboration solution is presented to improve the existing processes and provide the vehicle to establish new forms of collaboration.

Finally, we believe that a set of E-collaboration tools such the ones described, should be provided by the Universities using indirect cost budgets.

Web Quality Model: An Application to Business Domain

Gordan Gledec, University of Zagreb, Croatia; E-mail: gordan.gledec@fer.hr

ABSTRACT

Internet Economy allows businesses to move to the virtual market and establish their online presence on the Web. In order to strive, they have to keep their customers satisfied. Customer satisfaction depends on site usability, as only usable and good-quality sites can meet users' expectations. This paper describes the Web quality model and describes the methodology used for quality evaluation in the domain of business. The model is applied to the quality evaluation of two business-oriented Web site. The paper presents the results.

1. INTRODUCTION

The notion of Networked Economy, also called the Internet Economy or the Information Economy, has dramatically changed the way in which business is being conducted: it has allowed businesses to communicate electronically and run the entire supply chain through information highways. Virtual corporations, teleworking and telecooperation have become common practice worldwide [1]. The World Wide Web has become the cornerstone of such an economy.

The ease with which businesses can reach millions of potential customers in the global audience has prompted them to establish their presence on the Web. Current Internet usage statistics estimate that almost 1.1 billion people have Internet access [2]. Surely, businesses cannot and must not ignore the opportunity to profit by moving online to the virtual market.

With the fierce competition between online businesses, it is essential to identify the factors that enable them to get the competitive edge and advance in the business world. The customer satisfaction is the bare minimum that businesses have to meet in order to succeed.

Online customer satisfaction is rooted in the usability of the Web site – if the customer experiences difficulties while using the site, cannot find the information s/he is seeking or the information doesn't meet his/her expectations, s/he may turn to one of the competitors. Only good-quality sites can fulfill customer's expectations.

Quality is always prone to subjective interpretations unless it is quantified. In order to quantify the quality of a Web site, one needs to define requirements that the Web site has to meet and for each of the requirements identify a set of measurable attributes and measure them according to the specified procedure. In other words, to evaluate the quality of the Web site, the appropriate metrics have to be defined [3].

This paper describes the general Web site quality model and applies it to the world of business. It describes the methodology that can enable qualitative analysis of Web site's measurable attributes which affect the users' perception of the site's quality.

The remainder of this paper is organized as follows. Section II describes related work in the area of Web quality evaluation and quality models used in the evaluation processes. Section III describes the Web quality model while Section IV briefly describes the evaluation process. Section V explains how the model can be used to evaluate the quality of the business-related site. Section VI describes the results of quality assessment based on the quality model. Section VII concludes the paper.

2. RELATED WORK

The elements which define the quality of a software product and relationships between them were identified in the first quality models in mid 1970s. Two well known models that emerged at that time were McCall's model [4] and Boëhm's model [5]. In the 1990s, the International Organization for Standardization (ISO) in cooperation with the International Electrotechnical Commission (IEC) established two series of standards: series ISO 9126, which defined the quality model, and series ISO 14598 which described quality evaluation process. ISO standard regards quality as "the totality of characteristics of the entity that bear on its ability to satisfy stated and implied needs" [6]. Given the similarities in lifecycle and usage patterns between Web sites and software products, the ISO model can, with some modifications, also be applied to Web sites.

Many authors have defined Web site quality models based on McCall's or Boëhm's [7][8], while others base their work on ISO standards [9] [10][11].

Generally, all of them define a set of quality factors, which usually include (in one form or the other) suitability, installability, functionality, adaptability, ease-of-use, learnability, interoperability, reliability, safety, security, correctness, efficiency, maintainability, testability, flexibility, reusability, portability, visibility, intelligibility, credibility, engagibility and differentiation.

Those Web quality models lack structure and clarity of the ISO standards. Some of them provide the list of characteristics that should be taken into account during quality assessment, but none specify the methodology to be used in the process of evaluation.

To the best of author's knowledge, a comprehensive research in the area of quantitative measurement of Web site quality in the business domain has not been conducted as yet.

3. WEB QUALITY MODEL

In order to evaluate whether the specific Web site satisfies a certain quality requirement, the Web Quality Model (WQM) is defined [3]. Based on the ISO 9126 standard, it is represented by hierarchical three-level tree structure, with the six top-level characteristics:

- functionality,
- usability,
- reliability,
- efficiency,
- maintainability, and
- portability.

Each characteristic can be decomposed into a set of subcharacteristics. A set of measurable indicators is defined for each subcharacteristic.

Figure 1 depicts the hierarchy of the WQM [3]. In the top-down view, the quality of a given characteristic depends on the quality of its subcharacteristics, which

Figure 1. Quality model hierarchy

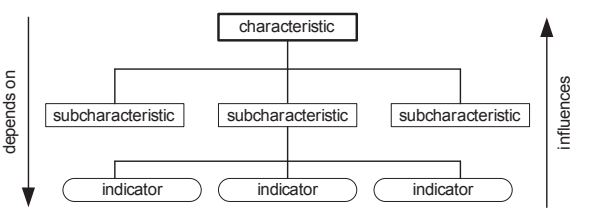

Figure 2. Characteristics, subcharacteristics and indicators of the Web quality model

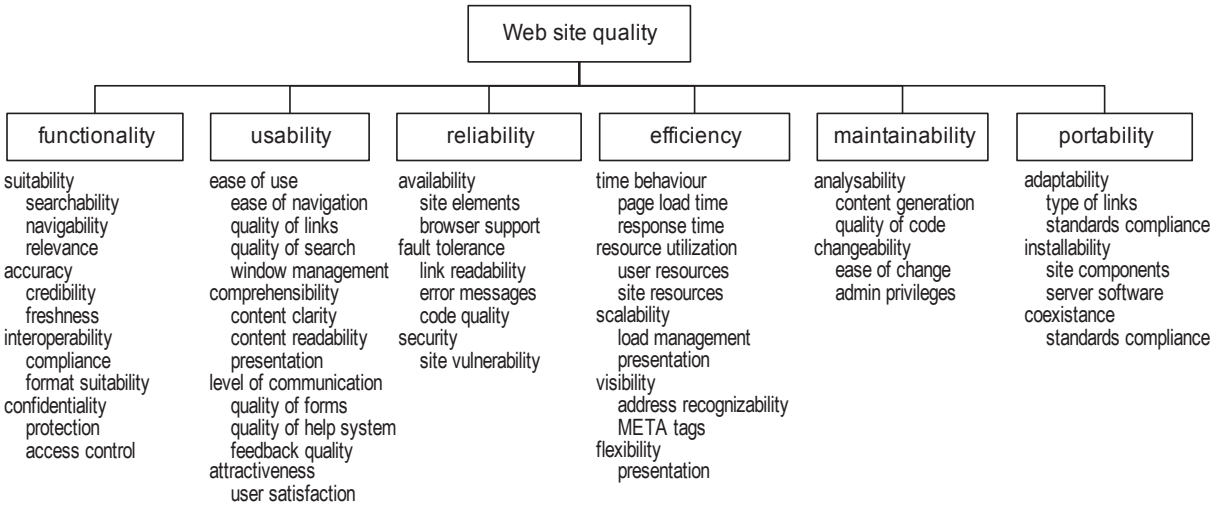


in turn depend on the quality of their indicators. However, the bottom-up view starts with the indicators: the quality of each indicator affects the quality of the appropriate subcharacteristic, which in turn influences the quality of the appropriate characteristic in the WQM.

Figure 2 describes the characteristics, subcharacteristics and indicators of the WQM [3].

A. Functionality

Functionality is defined as the capability of the Web site to provide functions and properties which meet stated and implied needs when the site is used under specified conditions. The needs can be defined with respect to the type and purpose of the site and users' expectations. Functionality is decomposed into suitability, accuracy, interoperability and confidentiality. Their importance and scope depend on the purpose of the site.

B. Usability

Usability is defined as the capability of the Web site to be understood, learned and liked by the user, when used under specified conditions. Subcharacteristics are ease of use, content comprehensibility, level of communication and attractiveness.

C. Reliability

Reliability is defined as the capability of the site to maintain a specified level of performance when used under specified conditions. This doesn't involve solely the reliability of server software or network infrastructure, but the whole site from users' perspective. The subcharacteristics are availability, fault tolerance and security.

D. Efficiency

Efficiency is defined as the capability of the site to provide appropriate performance, relative to the amount of resources used, under stated conditions. Resources on the Web site may include hardware (discs, memory, CPU), bandwidth, etc. On user side, resources may include connection costs, time, bandwidth, etc. Subcharacteristics are time behavior, resource utilization, scalability, visibility and flexibility.

E. Maintainability

Maintainability is defined as the capability of the site to be modified. Modifications may include corrections, improvements or adaptation of the site to changes in environment. This characteristic is visible to developers and administrators. The users see its effects indirectly, through other characteristics. Subcharacteristics are analysability and changeability.

F. Portability

Portability is defined as the capability of the site to be transferred from one environment to another. Like maintainability, this characteristic is not directly visible to the user, but is important to site administrators, who occasionally have to transfer the site from one platform to another, or even to a completely new working environment. This characteristic is decomposed into adaptability, installability and coexistence.

For a thorough description of all the components of the quality model, the reader is referred to [3]. From user's perspective, only four characteristics contribute to the overall quality of the site: functionality, usability, reliability and efficiency. The other two characteristics influence administrator's perception of site's quality. In the remainder of this paper, the user's perception of quality is being considered.

4. EVALUATION PROCESS

Evaluation process can be applied at any stage of the Web site lifecycle. The design of a Web site typically comprises five stages:

a. requirements analysis,
b. site planning,
c. design,
d. development and
e. usage.

The process that accompanies the WQM stems from the ISO 14598 standard series and distinguishes four stages:

a. definition of quality requirements,
b. definition of metrics,
c. evaluation planning and preparation, and
d. evaluation execution.

They are described in more detail next.

A. Definition of Quality Requirements

The cornerstone of every evaluation is the clear definition of its purpose. Without clear goals, it is impossible to expect the evaluation to succeed.

Even though the evaluation process can be executed at any stage of site's lifecycle, the quality model must include relevant and measurable components and exclude those that have no meaning or relevance at the given stage. This is particularly important when site's functionality is concerned, because the functionality indicators can be defined only after site's purpose is known. An example of functionality indicators is described later in the paper.

B. Definition of Metrics

The term *metrics* is defined as "measurement method and its measurement scale which is used in measurement process to assign numerical values from the measurement scale to the measured attributes" [6].

The metrics that enable the evaluation of each indicator are selected based on the site lifecycle stage in which the evaluation is being conducted. Various metrics can be applied in different stages:

- in the development stage, the metrics is based on measurable internal attributes of the site (code quality, file size…),
- during the usage stage the metrics is related to users and their behavior and interaction with the site (user satisfaction, task execution…).

For that reason, the metrics are not the part of the proposed model, but have to be defined based on the purpose of each particular evaluation and available data. Although metrics may be reused, they have to be adapted to the function, purpose and type of site. The metrics used in this paper are derived using the *Goal-Question-Metric* (GQM) model [12].

C. Evaluation planning and preparation

Evaluation of the indicators through the use of GQM model is based on data gathering. This data can be derived from various sources, but not all sources are applicable in each stage of site development. It is important to determine what is to be measured and how and to devise the measurement and evaluation plan accordingly. Some of the sources include:

- HTML, JavaScript and CSS source code,
- visual site inspection,
- access log analysis,
- comparison with competitors' sites,
- user comments on site guestbooks,
- heuristic evaluation,
- usability testing,
- user surveys.

D. Evaluation Execution

Each metrics defines the data collection method, the attributes that are going to be measured and the criteria to be used in assessing the degree in which the measured value satisfies the stated requirements. During evaluation execution, the measure is assigned to each measured attribute. This measure reflects the relationship between the measured value and the rating scale.

When the measurement process is over, the final ratings of each indicator, subcharacteristic, characteristic and overall site quality are determined, based on their mutual relationships, using appropriate scoring techniques.

5. METRICS FOR BUSINESS WEBSITES

In order to evaluate the quality of a business website, the model has to be adjusted to suit the intricacies of the business domain. Metrics for usability, reliability and efficiency are generally domain-independent. Those metrics must be based on the available usability and accessibility guidelines and standards [13], [14], [15].

A. Functionality

Functionality metrics have to be carefully adjusted to suit the needs of the business domain. Figure 2 gives an overview of the WQM and defines subcharacteristics and indicators for functionality: it is decomposed into four subcharacteristics: suitability, accuracy, interoperability and confidentiality.

Suitability reflects the capability of the site to provide an appropriate set of functions to accomplish specified tasks. It can be decomposed into a set of measurable indicators:

- searchability – what search options are given to the user from the functional point of view? Can s/he search the entire site or also its sections? Here, care should be taken not to confuse functionality of search with its usability – functionality refers to the given set of options, while usability deals with the ease of using them.
- navigability – what kind of navigational system is at user's disposal? Is the content properly arranged into logical sections, taking into account user's perception of the company? Does the navigational system reflect internal organization of the site?
- relevance – does the online shop have a built-in shopping cart? Does it allow users to post comments about products?

Accuracy reflects the capability of the site to provide the right or agreed results or effects. It can be decomposed into two measurable indicators:

- credibility – can the information be trusted? Is the source of the information clearly stated on the page? Does the information come from credible sources? Are unregistered visitors allowed to post content (in forums, guestbooks, etc.)? Who links to the site? Where does the site link to? Does the site provide terms of usage?
- freshness – how old is the information on the site? Is there a date of publication visible on the page? Is outdated information available online?

Interoperability reflects the capability of the site to interact with user's browser and other software. Without proper rendering of the code in the browser, the user can't use the functionality provided by the site. The indicators are:

- compliance to standards – are HTML and CSS valid? Can all browsers accurately present the site? Is the visual design tailored to one specific browser?
- format suitability – are proper data formats used to convey the content?

Confidentiality reflects the capability of the site to prevent accidental or deliberate unauthorized access and allow access to authorized persons or systems. Breach of confidentiality may result in severe loss of data on the server side and loss of credibility. The measurable indicators are:

- protection suitability – is the communication secured?
- access control – is it provided? How can users be tracked? How do they log into the site? Do they use login/password or tokens?

In order to define the metrics for the indicators, various existing business-related usability and accessibility standards and guidelines may be used: Nielsen's Alertbox [16] is an excellent source. Other sources may include competitors' sites and user surveys.

B. Metrics, Measurement and Evaluation

Using the GQM model, a set of questions and metrics which are going to be used to measure the indicators is defined. Figure 3a gives an example of the questions and metrics used to evaluate searchability indicator of suitability.

Each metrics results in a rating on the measurement scale between 0 and 1. This rating defines the extent to which the measured property satisfies the requirements. The measurement gives no indication whether the property satisfies the stated requirements, so each metric has to define rating levels that relate the measured value to the level of satisfaction of the initial requirements. The measurement scale can be divided into several categories (e.g. acceptable, partially acceptable and unacceptable), but care should be taken not to use too many categories – 3 to 5 should suffice.

Each metric must define which Web site properties are relevant for the metric (e.g. number of menu items, text and background colors, layout style, number of embedded images, etc.), specify how the data should be collected (visual inspection, automatic tools and code analysis, monitoring user behavior, etc.) and define assessment criteria and appropriate rating levels. Figure 3b shows the definition of metric M4.3 from the previous example, which helps to evaluate the *searchability*. The *elementary priority* is the rating to which the level of acceptance maps and is a part of the scoring technique [17].

Metrics add up to the rating of an indicator in different ways. Some metrics are critical and must have a satisfactory rating for the overall quality to be satisfactory. Some are desirable, but not crucial for the overall quality. If the measure of

Figure 3a. Questions and metrics for "searchability" indicator

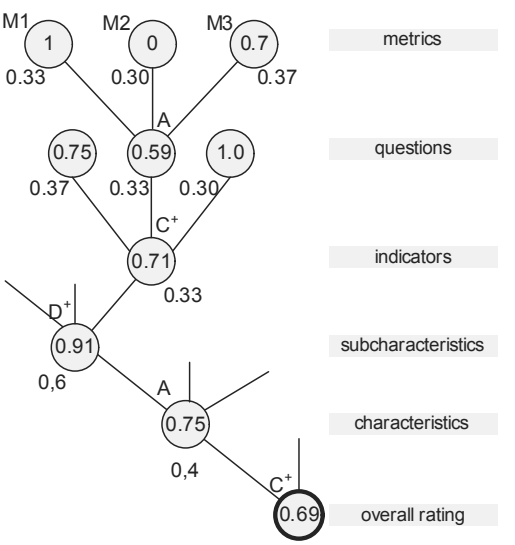
Characteristic: Functionality
Subcharacteristic: suitability
Indicator: searchability
Questions:

1. **What is the scope of search mechanism?**
   Metrics:
   M1.1. whole site can be searched
   M1.2. search can be restricted to sections
   M1.3. search can be restricted to products
   M1.4. search can be restricted to general information
   M1.5. search doesn't cover whole Internet
2. **Is advanced searching possible?**
   M2.1. search by sections
   M2.2. search by dates
   M2.3. search by locations
   M2.4. search by store subsidiaries
3. **How are the queries handled?**
   M3.1. misspelled query terms are considered
   M3.2. query term synonyms are also used in search
   M3.3. related query terms are also used in search
4. **How can search results be managed?**
   M4.1. indication of relevance
   M4.2. indication of approximate matches
   M4.3. filtering of results enabled
   M4.4. re-sorting of results enabled
   M4.5. tips are provided if no results are returned

Figure 3b. Metrics example

M 4.3. filtering of results enabled
data collection method: visual inspection
reason: Search mechanisms frequently return many matches. It is usually a good idea to provide users with the opportunity to narrow or filter the search results using additional criteria or constraints (e.g. site which sells products could enable the customers to further narrow the result set by product attributes, such as the desired size, color, manufacturer, price, etc.)
measured value: The presence of the mechanism that enables filtering of search results is being checked. It is acceptable if such a mechanism is available on every page with search results where it would be appropriate (generally where queries return too many matches), it is partly acceptable if it is enabled on a portion of pages. It is not acceptable if such a mechanism is not enabled.
elementary priority: E=1 for acceptable values, E=0 for unacceptable values, E=0.6 partly acceptable values.
sources: [11][12]

Figure 4. Example of the evaluation ratings



the critical metric is not satisfactory, the final rating is also not satisfactory. The importance of the metrics is derived from the existing usability guidelines and standards [13], [14], [15].

The same relationship maps to the upper levels of the quality model: each of the indicators affects the subcharacteristic differently, and each subcharacterstic affects characteristics differently. Finally, not all characteristics have the same impact on the final quality rating.

In order to evaluate the indicators, this paper uses the Logic Scoring of Preferences (LSP) approach, which serves as a mathematical tool to evaluate the characteristics of Web site quality. The LSP method is a general quantitative decision method for evaluation, comparison and selection of complex hardware and software systems [17]. Using LSP operators in the process of evaluation, it is possible to model different relationships between indicators: neutrality and different degrees of simultaneity (various levels of conjunction between the factors) and replaceability (various levels of disjunction between the factors). If the complexity of relationships between the metrics and indicators is less important of an issue, other models may be used. For example, in Figure 3a, in order to answer Question 1, the metrics M4.1. - M4.5. which affect the rating of the Question 1 share a certain degree of simultaneity; their relationship can be modeled by quasi-conjunction in the LSP model and is expressed as C^+ in LSP.

Ratings of one level have different impact on the upper level of the model, the evaluation criteria needs to be defined and weight factors of all metrics, indicators, subcharacteristics and characteristics determined. Various mathematical models can be applied to set the weight factors (such as SWING, AHP, etc.).

The rating process is depicted in Figure 4. At the first stage, metrics M1 - M3 are being evaluated, and ratings 1, 0 and 0.7, respectively, are given to each of the 3 metrics. Each metrics has a weighting factor (0.33, 0.3 and 0.37, respectively). The rating for the question is composed as the arithmetic middle of the metrics, taking into account their weights (indicated by A near the rating of the question). Other questions are rated in a similar manner. The ratings of those questions comprise the rating for the indicator, this time using the strong quasi-conjunction relationship (marked by C^+). The final rating of the indicator is 0.71. Next, the weighted indicators add up to the rating of subcharacteristic using strong quasi-disjunction (D^+), yielding the score 0.91. Arithmetic middle of the ratings for weighted subcharacteristic (A) is used to calculate the rating for the characteristic (0.75). Overall quality (0.69) is determined as the strong quasi-conjunction of all the weighted characteristics (C^+).

6. CASE STUDY: QUALITY ASSESSMENT OF TWO CORPORATE WEB SITES

During the study, two corporate sites were analyzed. They belong to the corporation whose core businesses are the production and distribution of food and

Table 1. Ratings of the main corporate site and the retail site

Characteristic	Main site	Retail site
Functionality	0.95	0.40
Usability	0.66	0.39
Reliability	0.86	0.83
Efficiency	0.83	0.31
Overall quality	**0.75**	**0.42**

drinks and retail. The evaluation of Web sites was conducted in May and June 2006 on the public sites, as a part of the redesign process. Two different sites were analyzed:

- main corporate site of the group, and
- retail sales site.

The WQM included 21 subcharacteristics and 44 indicators. In particular, the subcharacteristics and indicators of the functionality for the business domain were defined from scratch, as explained in Chapter V; others were adapted from previous research [3].

The data was gathered by visual inspection (menu locations, content clarity and comprehensibility, search functionality, navigation, etc.) and automated tools were used for the inspection of HTML and CSS code (length of links, number of words in the link, link availability, page length, presence of META and TITLE tags, spelling, etc.).

The indicators were evaluated by using GQM model: 56 questions were defined along with 164 metrics and relationships among them. The metrics were based on the existing usability standards, comparison with the competitors' sites and author's previous experience. The example of the metric definition is shown on Figure 3b.

In the evaluation process, each metric was assigned a rating between 0 and 1 and the LSP method was applied to evaluate the ratings of each indicator, subcharacteristic, characteristic and the final rating, depicted by Figure 4.

The final quality ratings for both sites are summarized in Table 1.

The overall rating of the main corporate site (0.75) is a fairly good one, indicating that minor improvements in site usability are needed to further enhance the user's experience. Indeed, the final summary report indicated 25 minor improvements which will be addressed in the forthcoming redesign process.

The retail sales site scored poorly (overall rating of 0.42), indicating several weaknesses that contribute to very low ratings for functionality, usability and efficiency, and consequently, overall quality rating. The final report indicates 28 major improvements that need to be addressed in the forthcoming complete redesign of the site.

7. CONCLUSION

The paper describes the Web quality model which enables qualitative evaluation of Web sites. The model is based on ISO 9126 standard. It decomposes the overall site quality into a set of six quality characteristics: functionality, usability, reliability, efficiency, maintainability and portability. The evaluation process is described and the quality model applied to two corporate business Web sites. In order to measure the indicators, the methodology uses the GQM approach to define a set of questions, which make the indicators more concrete. Each question is rated using one or more metrics by applying LSP method as the scoring technique throughout the process.

The application of the model on two business sites identified a set of weaknesses which are being addressed in the forthcoming redesign. The most notable weaknesses identified in the evaluation were related to structure and clarity of the content, page layout, navigation, searchability and categorization of items in the online store.

Internal company's user based usability survey on the same sites was performed after the WQM-based evaluation. It revealed most of the problems that were discovered using WQM. However, it required twice the time for preparation and execution, as well as more staff. These findings are in accordance with the previous research [3].

The redesign of the retail sales site is now in progress: it follows all the typical lifecycle stages and quality is being measured in each stage by applying the WQM and the metrics available at that stage.

ACKNOWLEDGMENT

This research was partially funded by the Ministry of science, education and sports of the Republic of Croatia and the Agrokor Group. The author would also like to thank Mrs. Marina Šimunić for the encouragement and support.

ABSTRACT

This paper provides a literature review and analysis of the impact of information technology in a global business environment on relational ethics. These three variables interact in a dynamic field that supports and challenges global managers in entrepreneurial endeavors. While information and communication technology (ICT) is rapidly expanding, the opportunities for global business and relational ethics are affected by the interconnections. Drawing on current literature and insights gained from a relational approach to ethics, readers are invited to reflect on the ways that relationships influence ethical actions—and outcomes—and how they can be improved. This analysis exposes the critical issues, develops a general framework and makes recommendations for ways to work with and further develop the interconnections between global business, ICT and relational ethics.

Keywords: Relational ethics, Entrepreneur, Globalization, Privacy, Information and Communication Technology (ICT)

WHAT IS RELATIONAL ETHICS AND ITS IMPERATIVE FOR GLOBAL BUSINESS?

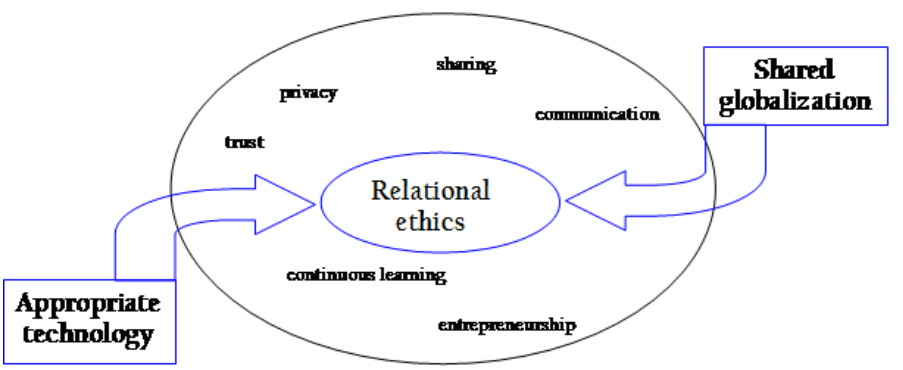
The aim of the paper is to explore the connections between global business and information and communication technology (ICT) with concern for the ways relational ethics direct stakeholder actions. The term 'relational' includes the relationships between organizational and individual stakeholders of an organization. We identify the role of appropriate technology in building and maintaining trust between individuals within and outside an organizational boundary, especially as this relates to the entrepreneurial role and mindset, and extend our view to the global business environment as the overarching context.

For Bergum (1998), "relational ethics [imply] initiating and maintaining conversation, and means that ethics is found in the day-to-day interactions of one another". Relational ethics looks at people's roles: as practitioner, administrator, team member, teacher, client, student, friend, and global 'neighbour'. This focuses on who one is, as well as what one does. Bergum and Dossetor (2005), when examining in the health sector why some kinds of relationships are better than others, provide the basic qualities of an ethical relationship; nurtured and sustained by reliance on communication and mutual concern. It is the relationship itself that supports and informs ethical interaction, activity, decision making and exchange of commodities. Philosophers have often asserted the central place that relational issues have in society and learning (Blenkinsop, 2005 and Jones, 2003). Theories of relationship have played a role in some aspects of organizational management (Tyler and Blader, 2003). Now the social and technological changes happening globally may be precipitating stronger relational imperatives.

Use of communication technology in most fields has altered the medium and pace of conversation between stakeholders around the globe. Even though the issues of privacy, trust, confidentiality and anonymity are common within the health care sector (Bergum, 1998; FPC, 2001), it is the authors' contention that caring and respecting all the parties involved in business relationships is essential regardless of the sector (Adams et al, 2005), or area of global operation. The obligations to address the above-mentioned issues remain, (for organizations as legal entities as well as for individual managers), and, in some cases, are magnified given the ability of technology to track and disseminate sensitive information. Within and across borders, the responses occurring in business relationships set the tone or atmosphere in which a relational ethic must be defined and acted upon.

The efficiency of technology enhances the ability of organizations to track customers. This parallel ability of technology to, first, identify customer needs and, secondly, to exploit this information for profits has received plenty of attention (Pham & Jordan, 2006). Using ICT to gather and disseminate product and service information can result in new business opportunities. As mature domestic markets reduce in profit potential, individuals as well as organizations seek beyond their

Figure 1. Commercial interconnections and influences revealed



geographical borders for new growth opportunities. Technology assists in this process by providing new ways of relating to existing and potential customers. This process is accompanied by the challenge of addressing the global convergence of cultures. New levels of good faith and trust may be needed to promote an atmosphere of peace and goodwill. People meet (physically and in cyberspace) and mingle in milieux which are constantly changing. Ethical relationships become central in this environment in the absence of enforceable cross-border laws and physical controls. Some dissenting voices can be found, such as Harmon (2005), who warns against a moralist approach, however, still affirms that affective and relational issues are important, although in need of balanced perspective.

The question then becomes: What kind of ethics is needed for the complexity of entrepreneurship in our times? According to Bergum and Dossetor (2005), it is recognizing that ethics is grounded in relationships. The context of these relationships can vary, but the fact remains that relationships need to be nurtured and sustained by reliance on communication and mutual concern. In Relational Ethics, the right and good relationships ultimately must concern every authentic ethical theory and impact on the relationship one has with customers (Pellegrino in Bergum and Dossetor, 2005).

Figure 1 presents the three key variables addressed in this paper. The framework reveals relational ethics impacted by the forces of technology and globalization in an atmosphere of diverse influences. The remaining discussion proceeds to address the factors in this developed framework.

THE VIEW AS (E-) ENTREPRENEUR OR INTRAPRENEUR

Working in global markets presents many challenges for management; especially in trying to create flexible solutions. Corporations have to shift their mindset to think like entrepreneurs and capitalize on growth opportunities in certain niches (Overholt, 2005).

Our definition of entrepreneur includes classical, independent innovators (individuals and/or teams), prepared for risk and a love of high returns, but also the intrapreneurs (individuals and/or teams), who are plying similar innovative skills but within and on the perimeters of larger organizations. ICT creates enhanced opportunities for entrepreneurial (networking) behaviors regardless of organizational size (Pinchot and Pinchot, 1997). In this technology-enhanced environment we cannot overlook the e-entrepreneurs. Zutshi et al (2006, p.63) define e-entrepreneurs as, "those who use the World Wide Web to interact and complete virtual transactions both with other businesses (B2B) and their consumer/customers (B2C)". The terms e-entrepreneur, intrapreneur and entrepreneur are used interchangeably in this paper.

Entrepreneurial opportunities emerge from myriad sources including stock market swings, online auctions, e-business, and unanticipated niches emerging in the global economy. Wherever commerce is found, McMillan (2003) shows the importance of markets as neither magical nor immoral but as powerful tools for improving trade and living standards. There is a challenge for managers who are unaccustomed to thinking about commerce as an instrument of social change. It is not a case of whether commerce-as-social-change should happen, but how to work with this ubiquitous global trend. Social change has occurred by market forces, so we now must navigate the new socio-economic environment with tools aligned to the changed context.

In this climate we may ask, How can entrepreneurship be improved? As organizations continue to be increasingly market driven, relational ethics must be embodied in the features needed for a market to function well to ensure that (McMillan, 2003):

- information flows smoothly
- property rights are protected
- people can be trusted to live up to their promises,
- side effects on third parties are curtailed, and
- the benefits of competition are fostered.

McMillan (2003) makes a distinction between *a* marketplace and *the* market. *A* marketplace, physical or cyberspace, is a specific venue where exchanges take place – where trade occurs. *The* market, on the other hand, is an abstraction, an overall system composed of many interdependent markets. Most transactions in society have little to do with markets. Rather, they occur among members of like minded people, mediated by different rules and relationships. McMillan (2003) sees the tradition of individual decision-making and voluntary exchange as key to the marketplace and it includes and shapes:

- reputations (costly to create and defend)
- patent policy
- intellectual property (must be protected), and
- property rights (which as the Licensing Executives Society has observed - 1997; 2006 - are found to shift as the locus of operations changes from local, hard assets to global, digital and less visible ones).

Relational issues become more central than peripheral when one enters the global marketplace. Fundamentally, Vandenberg (1999) asserts that human infants are hard-wired for relatedness. This affirms that as macro influences shape human society, micro factors between individuals will continue to set the undertone. It is human to work within a field of relational ethics.

INFORMATION TECHNOLOGY: IMPACT OF GLOBALIZATION AND THE NEED FOR RELATIONAL ETHICS

Technology can have a depersonalizing effect. The cold wall of a technology interface -- for example, a recorded phone message, or an automated teller at a bank -- can be greeted with distrust. To compete, many companies are tending to re-emphasize personalized approaches in an attempt at promoting trust. As cultural clashes are experienced, as backlashes (in the form of customer grievances) are confronted, the need to harmonize grows.

Professional institutions are recognizing the importance of issues of ethics and community responsibility. For example, the Australian Computer Society requires its members to conform to its various rules and regulations, including Ethics/Social Implications/Professional Practice (ACS, 1997). Similar guidelines are also implemented in other economic sectors. The emergence of codes of conduct, ethical standards, and at least the debate at national and international levels, are essentially evolutionary cycles, or responses to changing relational dynamics. The central position of ICT in propagating the impetus for change, as well as being the medium through which adjustment to change can occur is somewhat paradoxical. While the activities promoted are right and good, they are of little effect in themselves if action and improved ethical relationships do not occur.

ETHICS, THE (E-)ENTREPRENEUR, AND CHANGING GLOBAL CULTURE

The principles of trade and capitalism are rooted in economics and relationship, and in comparative advantage that is part of the human survival mechanism. When the human desire for creativity is considered, we are more directly in the realm of the entrepreneur and, ultimately, of relational concern and 'good' (civil) behavior if commercialization is to occur. McMillan's (2003) notion of *a* marketplace is reinforced. The classical idea that business activity need not include a social conscience is rooted less in reality in today's interconnected economies.

Ross et al (1994) in their work on continuous quality improvement show the important role good manners play for successful global business and provide a framework for export readiness with international protocol as a key step on that journey. In another view that challenges the persistent 'me-centered' mentality, Kaplan and Koval (2006) explain, 'nice' companies have lower employee turnover, lower recruitment costs, and higher productivity. Companies and people with a reputation for cooperation and fair play forge the kind of relationships that lead to improved opportunities. *Taking the long term vision*, relational ethics qualities such as caring for other people, having honor, working with honesty, competing with dignity, sharing knowledge and behaving with kindness, are important for successful global entrepreneurship.

An example of relational issues emerging in a business context has been noted by Blenkhorn and Mackenzie (1996) in the form of relationship marketing. The concept of 'mutual interdependence' as a power-control factor is present. This elevates the need to act in ways that are balanced and considerate, for instance, opening up communication, being cooperative, and demonstrating a degree of sacrifice in the relationship. Evoking relationships in commerce, at its core, is best practiced by elevating concern for the customer, a sense of ethical practice which is not only good for the customer in the short term but may also improve company performance in the longer term (Dunham, 2006). A cynical application

is noted, in that profits come from serving customers. However, from the perspective of care and concern for customers, an increased sense of responsibility is seen to emerge. Anytime customers receive good service tends to build trust and exemplifies the reciprocity at the core of economic theory.

Drake and Ross (2005) discuss customs change, bribery, child labor, human rights abuses, and integrity as the categories proposed in which deep questioning and continuous reflection are recommended, even required, if the (e)entrepreneur is to succeed in different cultures. de Geus (1998) adds to this perspective by regarding business longevity with the view that, "the corporate equivalent of pain is a crisis, which lasts long enough for most people in the organization to feel and to become convinced that something should be done". Solutions to the scenarios above represent time spent learning. Time, however, is not always abundant in the minds of entrepreneurs today. In this atmosphere, relational ethics ought to be approached so as to contribute to time management and become a time saving approach. For instance, a commercial relationship in which there is a high degree of trust will more quickly facilitate a successful transaction.

Bennett (2005) and Hladik (2006) insist it is hard to trade with those who you do not trust, or have different cultural and ethical expectations. Emerging value-sharing communities accelerate innovation in new realms of entrepreneurship and economics. The imperative to embrace relational approaches to cooperation and collaboration develops in many sectors, from traditional manufacturing through to services, including education. For example, Backhaus et al (2005) propose a dynamic collaboration model for business education that aligns with theories of knowledge and understanding attributed to Heidegger and Gadamer (Radnor 2002), and with relationship dynamics originally posited by Schutz (1966). This and other models emerging suggest continued impetus for relational approaches.

TRUST, LEARNING AND RELATIONSHIPS

Burgeoning information technology is attracting entrepreneurs in increasing numbers. The wireless and mobile revolution is proceeding and entrepreneurs are engaging in the enhanced connectivity that networking with ICT offers. This is a setting in which disruptiveness of emerging technologies (such as the Internet and nanotechnology, Horner, 2005) applies in current economic and education systems alike (Moor, 2006). Such a milieu tends to attract the global business entrepreneur, and creates opportunities in the associated market of educating the entrepreneur 'on the go.'

Bennett (2005) emphasizes identifying and addressing aspects of accountability, trust, openness, and continuous improvement. There is every reason to apply these ethics to the education of global business managers. The task becomes one not just of learning about the relational approach, but of teaching managers how to learn, as well as teaching teachers how to teach. This brings the discussion back to the continuous learning loop that is necessary for sustained relational ethics. It is not enough to rest on laurels, instead one must be poised to learn more, to stay alert to the changing needs of the people, organizations and cultures with which transactions and trade are occurring.

INFORMATION AND COMMUNICATION TECHNOLOGIES: PRIVACY AND TRUST

Technology delivers conveniences and changes the way we undertake day-to-day activities, including shopping and banking. There persists cautiousness of Internet usage by some, due to privacy and security issues. Brey (2005) notes the rise of surveillance as precipitated by bureaucratization, burgeoning capitalism, and the actions of nation states. Successful competition appears founded on information gleaned from surveillance. Large organizations are increasingly enabled through technology to manipulate personal information. In this context Brey (2005) posits that privacy is a right as well as a condition.

A number of companies are strategically reassessing Internet strategies and offering new choices to their customers. In Australia, the financial sector reveals examples of efforts at attracting increasing market share through competitive advantage opportunities overlooked by bigger players. For instance, Bendigo and St. George Banks have taken to offering more personalized customer service. This is not to say that these institutions have left the technology bandwagon behind, instead they have adopted the technology to offer choice to their customers and to reach them in rural areas, where major banks have either closed or restricted their business for efficiency purposes. In addition to rural communities, Bendigo and St. George Banks have established relationships with urban populations by offering timely, faster and personalized service and steadily increasing customer satisfaction (Owen, 2002; Lekakis, 2001; Power, 2001; Derkley, 2003).

There is a need for (e)entrepreneurs to address the fear associated with illegal or unethical access to personal information. The recent Hewlett Packard spying scandal is a case in point (Chapman, 2006). Governments across the globe are taking a strong stand against exploitation of personal information gained by companies (see Adam, 2005). Increased security and privacy measures undertaken by governments also attract controversy. The Australian government, for instance, proposed a 'Smart Card' for its citizens that would incorporate a computer chip with personal information. Questions were raised about the integrity and extent of access to information to various stakeholders (Kay, 2006; Lewis, 2006; Dearne, 2006). The same government also introduced new "smart" passports designed to improve cross border security, but is challenged as a measure that may, in fact, assist identity fraudsters by pooling sensitive personal information in a single readable source (Epstein, 2006).

CRITICAL ISSUES AND RECOMMENDATIONS

Literature review and analysis has revealed a number of critical issues for managers in a technically evolving, global environment, especially in the area of relational ethics:

- Technology, if managed well, can play a part in building and maintaining trust between individuals within and outside an organizational boundary.
- The responses occurring in business relationships set the tone or atmosphere in which a relational ethic must defined and acted upon.
- Organizations increasingly need to engage in cycles of continuous learning and applications that will confront and overcome relationship challenges.
- The central position of ICT as an impetus for change, as well as being the medium through which adjustment to change can occur is somewhat paradoxical.
- Deep questioning, continuous reflection and diligent attention to relational skills development are required if the entrepreneur is to succeed in different cultures, and
- Relational ethics attends primarily to issues of, trust, openness, understanding and engagement.

These critical issues lead to the following recommendations that may assist (e-) entrepreneurs to forge and maintain relationships as they engage in business activities:

- Leverage ICT to capitalize on communication and collaboration improvement mechanisms.
- Do not allow business relational ethics to be neglected directly or indirectly, nationally or internationally.
- Accept that relationship challenges require a continuous learning mentality at the group and individual levels.
- Understand the confounding but enlightening features of ICT in the context of relational changes in global business.
- Global business managers should engage in deep questioning, continuous reflection and diligent commitment to practical improvement of accountability, trust, and openness in the context of business and its relationship with the supply chain and beyond.

The research has suggested the juxtaposing roles of Relational Ethics, Global Business and ICT may continue to fuel research and practitioner activities into at least the medium term future.

Electronic Commerce Adoption Approaches by SMMEs Western Cape, South Africa

I. M. Motjolopane, Cape Peninsula University of Technology, Cape Town, South Africa; E-mail: motjolopanei@cput.ac.za
S. C. Warden, Cape Peninsula University of Technology, Cape Town, South Africa; E-mail: wardens@cput.ac.za

ABSTRACT

E-commerce improves value chain integration, enables customisation and also provides smaller companies opportunity to reach customers worldwide. However the approach to e-commerce adoption poses small businesses management with many challenges, one of which is the choice of an approach to adopt e-commerce. One option is an "adoption ladder" approach proposed by a number of researchers depicting e-commerce adoption as a "step-by-step" process, from simple email to a virtual integrated business. The other option is a "managed strategic adoption" approach where proponents of this approach argue that reaching e-commerce is a result of a management decision to move directly to e-commerce, based on business goals and requirements. This approach does not follow a stepped approach. Although the literature reports on a number of aspects of e-commerce adoption, no clear guidelines are apparent to determine how Small Medium Micro Enterprises(SMMEs) should progress, or move into e-commerce. This paper investigates two e-commerce adoption approaches and reports on the approaches followed by a sample of SMMEs in the Western Cape of South Africa. In addition a conceptual model on e-commerce adoption approaches is proposed and theoretical guidelines explored to assist SMMEs to choose between the two approaches.

Keywords: E-commerce adoption, adoption ladder, managed strategic adoption, SMME

1. INTRODUCTION

A significant opportunity and challenge for businesses in the next few years will be how to deploy e-commerce initiatives. E-commerce activity improves value chain integration, enables customisation and also provides smaller companies opportunity to reach customers worldwide (Da Silveira 2003:201). An increasing number of businesses are using the Internet to trade online but not many are generating profits. This poses management with challenges to identify where e-commerce profitability lies, how it is reached and how it could be sustained (Willcocks & Sauer, 2000:7). Despite these challenges Jones, Hecker and Holland (2003:287) argue that there is limited research available on how to effectively, implement e-commerce into SMME operations. Many of these challenges could either be resolved, or at least be identified, in order to follow the most appropriate e-commerce adoption path. This needs to be done at the outset of the e-commerce adoption initiatives. Although a number of local and International studies report on e-commerce adoption paths, these do not provide clear guidelines to determine how SMMEs should progress or move into e-commerce.

Several e-commerce definitions exist but no consensus has been reached on the extent or essential parameters (Kowtha & Choon, 2001:238). In this paper, e-commerce is referred to as digitally enabled commercial transactions between organisations and individuals. Commercial transactions involve the exchange of value, for example, funds across organisational or individual boundaries in return for products and services (Laudon & Traver, 2003).

The definition of a Small Medium Enterprise (SME) varies from country to country. Da Costa (2001:3-4) finds that in the United states of America (USA) SMEs are defined as firms having fewer than 500 employees, whereas in Europe SMEs are firms with fewer than 250 employees. In Japan SMEs are firms with fewer than 100 employees. In South Africa Small Medium Micro Enterprises (SMMEs) are defined as companies having the number of employees ranging between 5 and 2000. In addition, SMMEs are classified as companies with a total turnover between 0.2 million and 64 million Rand and a gross asset value ranging from 0.1 million to 23 million Rand(South Africa, 1996; South Africa, 2003). In this paper, SMME refers to the South African definition whereas SME refers to the international definitions.

The aim of this paper is to investigate e-commerce adoption approaches and to present findings of the approaches followed by some SMMEs in the Western Cape. In addition propose a conceptual model on e-commerce adoption approaches and theoretical guidelines explored to assist SMMES to choose between the approaches.

2. BACKGROUND

The focus of this investigation is confined to the Western Cape of South Africa that accounts for 15% of the country's GDP and where 10% of the South African population resides (Wesgro 2005). In addition the Western Cape is the second most productive province, after the Gauteng province. The Western Cape's strong economy can be attributed to its unique balance of economic activities that range from agriculture, fishing and forestry in the primary sector to clothing and textiles in the secondary sector. Other sectors include automotive components, marine services and manufacture, agri-business, vibrant tourism and an increasing array of future-orientated service industries (Wesgro 2005).

Small business play a vital role in most economies throughout the world and their ability to adopt and utilise the Internet and conduct e-commerce is of prime importance to ensure that SMEs are included in the new economy (Quayle, 2002;1158-1159, Stansfield & Grant, 2003:15). For example, SMEs in the USA accounted for 51% of the private gross domestic product during the period 1990-1995. However, less than 20% were selling products and services online (Reimenschneider, Harrison & Mykytyn, 2003:270). A similar view is expressed in Grandon and Pearson (2004:82) who state that although SMEs in the USA employ more than half of the work force, few had adopted e-commerce by the end of 2003. In Australia approximately 65% of SMEs have access to the Internet, with only 15% of these actually supporting websites (Pease & Rowe 2003:2). According to Viviers and Soontiens (1998:2), South African SMMEs contributed 46% to the total economic activity. Current estimates are that businesses with less than 50 employees contribute between 39% and 45% of the GDP (South Africa, 2004a), Whilst SMMEs are reported to contribute 30% to GDP (South Africa, 2004b). Despite these contributions, the use of the Internet and related technologies has not been deployed to the extent that would be necessary for survival in a rapidly changing environment (Cloete, Courtney and Fintz, 2002:1).

2.1 E-Commerce Adoption Approaches

From the literature, it is evident that there are two possible approaches for a business to adopt e-commerce. The one approach is an "adoption ladder" proposed by a number of researchers and is a "step-by-step" process. These steps start at email and then follow to a static website, e-commerce, e-business and finally e-enterprise (Van Akkeren and Cavaye 1999; Hoque 2000; Willcocks & Sauer 2000; Parish, Kibblewhite, Woodley & Richardson 2002; Jones *et al.* 2003; Vosloo 2003; and Teo and Pian 2004).

An alternative approach is a "managed strategic adoption" where these proponents argue that reaching the e-commerce adoption stage is a result of management decisions. In this case, a business would prefer to directly adopt email, a static website, e-commerce, e-business or an e-enterprise and not follow a stepped approach. This would depend on the strategic requirements of the business (Angehrn, 1997; Blackburn & Athayde 2000; Southern & Tilley 2000; Martin & Matlay, 2001; Foley and Ram 2002; Chau & Turner, 2003; Levy and Powell 2003; Rao, Metts & Monge 2003).

2.2.1 Adoption Ladder Approach to E-Commerce

An "Adoption ladder" approach requires that businesses start on the bottom rung of the ladder and progresses upwards. Van Akkren and Cavaye (1999:4) state that e-commerce adoption is a progression and sophisticated technologies are unlikely to be implemented before entry-level activities are used more readily. An example of the e-commerce "adoption ladder" is Cisco's adoption ladder model given in Figure 1. This model is selected from other possibilities due its clarity in illustrating the "step-by-step" stages of e-commerce adoption

E-mail acts as a starting point from which more sophisticated e-commerce activities flows. Tagliavini *et al*. (2001:215-220) state that effective use of e-mail could assist SMEs to gain new customers, establish relationships and create brand loyalty by enhancing information interchange with current and potential customers as well as to carry out market research. At the second level an effective website widens the market by increasing company visibility, promoting company image, improving the quality of customer service and carrying out market research based on customer needs thus differentiating SMEs. Leong, Stanners and Huang (1998:1257) add that the three most important website objectives are to enhance the corporate image, increase brand or product awareness and to provide better customer service. A website that offers online processing facilities allows orders to be automatically forwarded and processed more quickly. Since customers are demanding more speedy service, reduction of waiting times represents a competitive advantage. Online payment processing optimizes business resources whilst increasing customer satisfaction is achieved by allowing the customer to conclude the transaction online (Tagliavani, *et al*. 2001:220). Kowtha and Choon (2001:239) confer that a website with online processing facilities requires significant dedicated investments, skill acquisition and management commitment. However, Chau and Turner (2003:4) argue that an "adoption ladder" approach is less advantageous as the potential benefit of using e-commerce increases as SMEs embark on later stages on the e-commerce adoption path, therefore suggest a non-stepped "managed strategic approach".

2.2.2 "Managed Strategic" Approach to E-Commerce Adoption

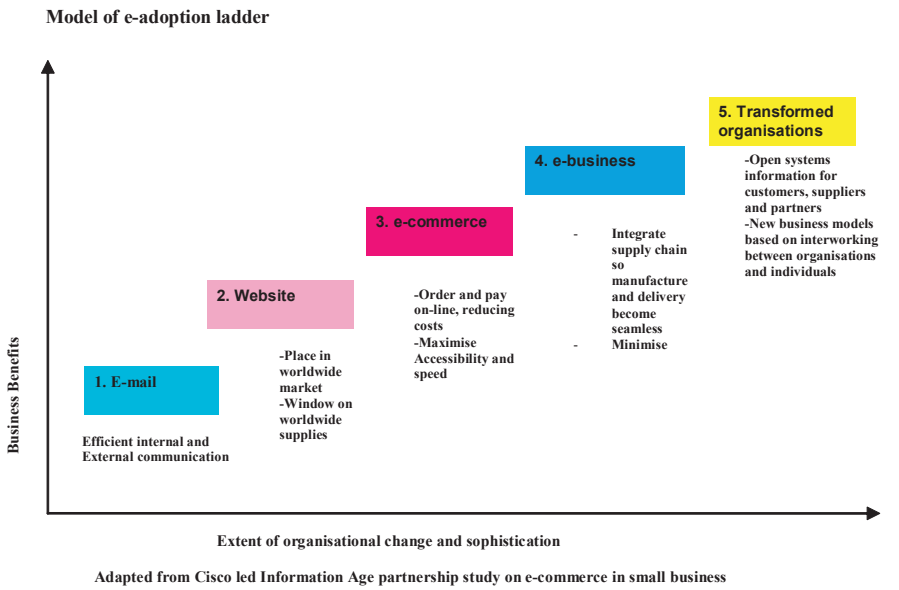
Hackbarth and Kettinger (2004: 273) argue that whilst some companies follow the "adoption ladder" approach with gradual business process improvements, others aspire to rapidly achieve business innovation with a leapfrogging strategy. According to Hackbarth and Kettinger (2004:273,281) companies adopt leapfrogging strategies when faced with more severe external competitive pressures. Businesses should scan their environment to evaluate barriers to entry, customer power, supplier power and new entrants to the market. To adopt this kind of strategy businesses must ensure internal user involvement. This includes to assess the availability of in-house IT expertise (or appreciation of IT expertise in cases of deciding when and what to outsource) and a cultural capacity to change. In addition, they should exhibit a level of comfort with new technologies and availability of resources to adopt e-commerce related technologies. Such businesses exhibit leadership in terms of senior management commitment and willingness to make an impact on people. The businesses demonstrate an accommodating business structure that accepts paradigm shifts and allows cross-functional decision making.

The two diverging approaches discussed above may lead to a point where management of SMMEs may need to pre-select an e-commerce adoption approach before embarking on the e-commerce adoption initiatives. To shed light on this problem, knowledge is required to answer some questions by learning from successful businesses that adopted e-commerce. This includes what approaches they followed, what they did right and what lessons were learned. Furthermore, propose a simple model that would assist SMMEs to choose between the "adoption ladder" and "managed strategic adoption" approach to e-commerce adoption.

3. RESEARCH METHOD

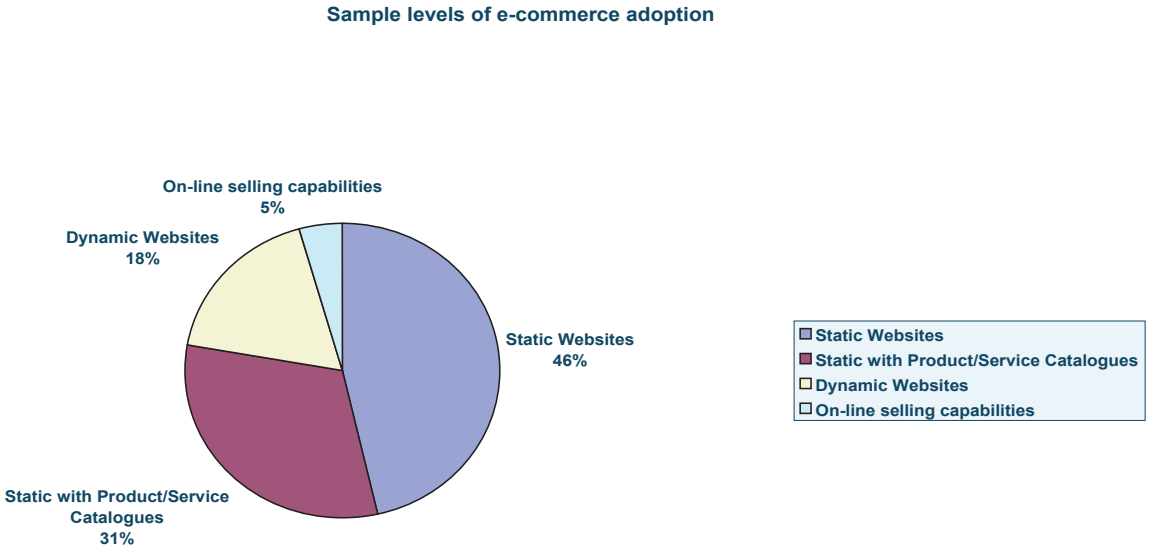
Qualitative analysis using in-depth interviews and double sampling techniques was used to gather information to determine e-commerce adoption stages and which path SMMEs used for e-commerce adoption. To determine the e-commerce adoption stage of companies, a period of three months was required, from April to June 2005. A list of 4,500 businesses registered with the Cape Town Regional Chamber of Commerce and Industry's (Chamber) website was downloaded and stored in a Microsoft Word document. There were approximately 1 000 companies that had websites. The next step was to find the Universal Resource Locator (URL) of each business to determine which of these had an active e-commerce website. Not all websites could be viewed as some websites could not be accessed. Reasons for failure ranged from File Server error, Unified Resource Locator not found, suspended websites, gateway timeouts or permission was required to access the website. The companies with more than 250 employees were deleted from the sample as well as websites with domains for sale and websites that loaded incor-

Figure 1. Cisco "adoption ladder" Parish et al. (2002)



Adapted from Cisco led Information Age partnership study on e-commerce in small business

Figure 2. Websites e-commerce stages SMMEs Western Cape



rect company profiles. The analysis resulted in a list of SMMEs selling online consisting of a sample size of 38 businesses selling online, spread across 14 different Chamber's business sectors. In some cases, only one online business was found in a sector. It would have been possible to select one business from each sector, but for richness in data analysis that allows comparison two industry sectors were selected for the study. Of the 4,500 SMMEs registered at the Chamber, 18% had websites ranging from static to dynamic interactive, where the websites offered the facility to receive payment online. Of these, only 5% had interactive websites offering facilities to receive payments online. This would qualify them being e-commerce websites. These results are depicted in figure 2.

From these results the industries selected for further analysis were the Tourism industry and Information and Communication Technology (ICT) sectors respectively. The tourism industry was selected on the basis that the tourism industry historically has been an early adopter of technology supporting inherent features making it suitable for e-commerce adoption (Wynne, Berthon,Pitt, Ewing & Napoli, 2001:421). In contrast, the ICT sector was selected as both Poon and Swartman (1999:4) and Al-Qirim and Corbitt (2002:346) found that IT related businesses were more likely to adopt e-commerce than businesses in other sectors. From these industries, SMMEs were selected for in-depth interviews from sample. The analysis would later reveal the path each SMME followed when adopting e-commerce, why they choose this approach and the benefits these companies were realizing from adopting e-commerce. The selected SMMEs owners or managers in the two industries were contacted and after numerous attempts, five SMMEs agreed to participate in the research study.

4. RESEARCH RESULTS AND DISCUSSION

Analysing the in-depth interviews indicated that SMMEs in the Western Cape are realizing benefits from e-commerce and in some cases; e-commerce was playing a strategic role depending on the owner or manager's strategic orientation for growth. Quoting one of the participants: "…if you take away the Internet we are out of business". This is an example of the importance of their e-commerce adoption commitment.

At first the researchers were concerned that these findings may be considered being biased as all five SMMEs had followed an "adoption ladder" path. Instead of going back to select more businesses from other sectors, it was decided to explore the literature again to ascertain what type of businesses would most probably have used the "managed strategic adoption" approach.

According to Warden and Remenyi (2005), 1time Airline operating in the LCA (Low Cost Airline) industry in South Africa followed a "managed strategic adoption" approach as their website was designed for e-commerce at inception. As far as could be determined, 1time Airline exhibited the necessary conditions to adopt this approach and 1time Airline may be classified as a large business as its asset value exceeds 23 million Rand and also had more than 200 employees by 2005. 1time Airline started trading in 2004 with a few staff members and from day-one, the airline management required that the Internet be the main channel for their ticket sales while selling only a small percentage via a call centre and at airports. Accordingly, 70% of airline tickets are purchased online, 20% via the call centre and 10% at airport kiosks. According to Weaver (2005:231,234) booking online air travel tickets is increasing in South Africa. Furthermore, South African Airways reported an annual increase of 200% for online sales, whilst Kulula.com (another LCA) reported that 75% of its sales are done online and the website processes over 3 million Rand in sales each day.

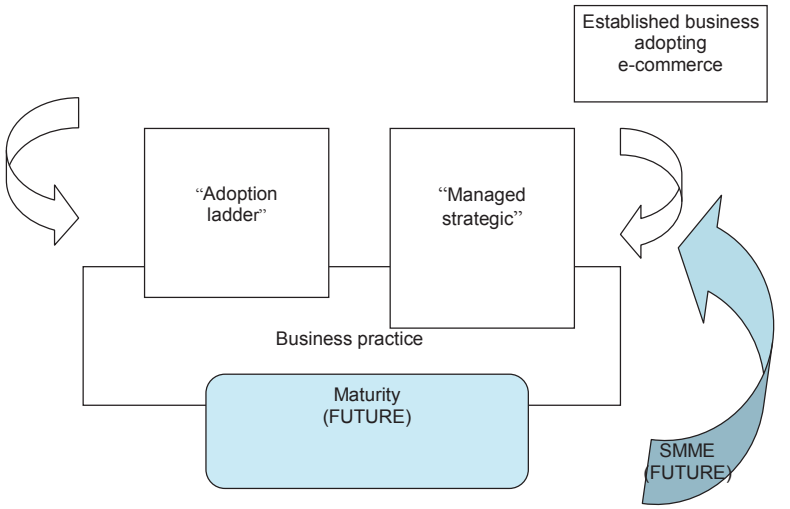
Considering the results from the 1time Airline case study, and reports from other successful airlines, provides an insight and evidence tthat larger businesses adopt a "managed strategic adoption" approach in preference to following an "adoption ladder" approach.

5. GUIDELINES FOR SELECTING AN E-COMMERCE ADOPTION APPROACH

Potential e-commerce adopters need to choose between an "adoption ladder" and "managed strategic adoption" and using the results reported in Hackback & kettinger (2002:280) obtained forty firms in the United states that had recently completed an e-business strategy the following guidelines are suggested to assist SMMEs to choose between the "adoption ladder" and "managed strategic adoption";

- The severity of external pressures evaluated by accessing the SMME market share risk, and the SMMEs customers demand for e-commerce services, If the external pressures are a high a "managed strategic adoption" would be a more suitable approach.
- Internal user involvement may be evaluated by determining the availability of In-house Information technology expertise related to e-commerce and SMME cultural capacity to change which can be assessed by the SMME' determining if they support maintaining the status quo or actively seeks participatory change. If Internal user involvement is low and the SMME does not have cultural capacity to change an "adoption ladder" approach would be a more appropriate approach to enable the SMME to gradually change and build-in expertise.
- Comfort level with new technologies maybe assessed by examining if the SMME is historically slow to respond or quick to implement new technology. Furthermore determining if IT resources are minimal or abundant to support e-commerce. Comfort level with new technologies is a key requirement for

Figure 3. Proposed model to assist SMME to adopt e-commerce



"managed strategic adoption" hence if such comfort level is non-existent an "adoption ladder" would be a more suited approach.

- Leadership in terms of Senior Management commitment to e-commerce adoption and being actively involved in the e-commerce adoption process. To follow "managed strategic adoption" Senior Management need to be committed to e-commerce adoption and willing to deal with extreme impacts. An "adoption ladder" approach on the other hand entails a modest and gradual impact.
- Accommodating and mature organisational structure, whereby there are cross functional decision making teams. SMME can assess this by examining historical approach to decision making as to whether it is interdepartmentally or cross functionally. In order to adopt "managed strategic adoption" SMMEs need to have an capability to work with cross functional decision making teams.

Figure 3 is a conceptual model showing the two approaches and SMMEs may use the provided theoretical guidelines to select an approach that best suits their organizational needs.

In conclusion, e-commerce is a process that involves various stages, namely e-mail, a static website, e-commerce, e-business and e-enterprise. E-commerce adoption in SMMEs registered with the Chamber in the Western Cape is at an early stage. Awareness campaigns would benefit those SMMEs that have not yet adopted e-commerce. By using the proposed model to explain and walk-through the various e-commerce stages potential SMME e-commerce adopters would be able to decide what the best approach would be to follow. Future empirical research is recommended to expand and add to the conceptual model and provide practical relevance for the guidelines to SMMES in the Western Cape. This would also track the severity of external pressures for e-commerce adoption in the SMMEs in the various industries.

Trouble in Computing: Taking "Positions" in the Discipline of Computing

Sheila French, Manchester Metropolitan University, England; E-mail: s.french@mmu.ac.uk

"The Connection between masculinity and technology, reflected in women's under-representation in engineering, and indeed in all scientific and technical institutions, remains strong as we enter a new era of technological change."

Judy Wajcman, TechnoFeminism, 2004

ABSTRACT

This paper explores the 'identities', and 'self positioning' of female academics working in a technical discipline. Narrative enquiry and discourse analysis are used to offer a deeper understanding of our gendered identities in relation to the dominant discourses of the computing discipline. The paper uses examples to demonstrate how the women in the study 'position' themselves, or come to be 'positioned' within the complex and contradictory discourses in the discipline. The women in the study work in the discipline of Computing where the dominant discourses around technical skills, and technical ability, along with positivist research methods are held in high esteem. In this paper I raise issues regarding the 'feminist' discourse as raised by women in the study. Some claim to work in a gender-neutral territory, and resist the feminist discourse. Others position themselves as 'feminists'. Those who claim to be 'non-feminist' have found a way to blend into the dominant technical discourse. As such they do not threaten to the status quo of their organisational setting. Conversely, those who hold the position of 'feminist' have found themselves subject to bullying, and sexist behaviour, which has led them to being constructed as the 'other' or as 'outsiders'.

INTRODUCTION AND BACKGROUND

This paper is a sub-set of work which, looks at the experiences of female academics working in the disciplines of 'computing[a] in the UK. The literature is drawn from current work about women in the academy, which is situated both in the field of 'gendered organisations', (Martin and Collinson, 2002) and the social studies of science and technology (SST). Some of the most interesting work from feminists looks closely at the relationship between technology and gender (Wajcman, 2000). Several writers such as Cockburn (1983,1985), Cockburn and Omerod (1993), Kanter (1977), Bagilhole (2002), Henwood (1996, 1998), and Wajcman (1991, 1995, 2000, 2004), have demonstrated these fields are not mutually exclusive, and that when the issues are discussed in both contexts broader analysis can take place.

Gender segregation is prevalent in the British academy where it has been argued that academic work 'is an occupation geared to and kept almost exclusively for men' (Bagilhole, 2002 pg 5). A dominant discourse of masculine values and ideals in which women are more often constructed as the 'other' or as 'outsiders' prevails. Most often the academic career path is structured according to male perceptions of what it means to be a 'successful academic' (Knights and Richards 2003). These 'masculine' values are reflected in academic outputs and in the technical rational way knowledge is debated (ibid). In the 1996 RAE[b] exercise men were almost twice as likely as women to be entered (AUT, 2004). Women's representation in the disciplines associated with technology and computer science is lower than other disciplines in British universities[c]. In subject specialisms where technology is a major feature, women's contribution to the RAE is significantly lower than women's representation in academia as a whole. Occupational segregation is both vertical and horizontal in computing (Bagilhole, 2002).

The under representation of women working in the academic disciplines of computing in the academy, is reflected further in wider British society where males dominate the design and use of technologies (DFEE 2001, Hellawell, 2001, Wilkinson, 2001). At school fewer girls are taking up computing at an advanced level, and British universities are finding that women continue to show a lack of interest in computing degrees. British industry continues to experience a major skills shortages of computer technicians and ICT professionals, (DFEE, 2001, EOC 2004) at the same time women shun careers in these fields (EOC, 2004).

GENDER SEGREGATION

Gender segregation is often explained using frameworks based on equality issues or human capital theory (Probert 2003). These frameworks are underpinned by issues concerning male power, assumptions about the division of labour in the labour market, and the relationship between paid and unpaid work in the home (Bagilhole 2002). Research within these frameworks has tended to focus on the structural and cultural influences that lead to continued employment segregation. The SST literature and much of the IS literature in gender and technology has examined the social construction of technology as a masculine domain (see Cockburn 1983, Wajcman 1991). Recently there has been a move in this research to reject an essentialist understanding of women, to focus on the experiences of the individual, recognising that 'women' are a diverse group (see Trauth 2002, Adam et al 2001, Bagilhole 2002 and Knights and Richards 2003). Theories of post modernism have focused on issues of identity, using the concepts of discourse and subjectivity, (see Henwood 1998, Hughes and Kerfoot 2002, Jorgensen 2002, Radden 2002 Whitehead 2002).

THE POTENTIAL OF DISCOURSE

This paper uses discourse as a theoretical approach, issues of identity and subjectivity are central to the narratives and discussion. Meaning is taken to be dependent on a person's subjectivity, and are situated within a historical discourse, which is constantly changing. The concept of discourse is taken from the work of Michel Foucault. Feminists have found the concepts useful in their analysis. Henwood (1998) sums up what we mean by 'discourse':

"They are not merely people's assumptions, ideas and definitions expressed through language but also the practices, formations and subject positions which follow from these". (p.39).

In these terms identity is not fixed within an individual, rather it is open to change dependent on experiences in the social world. Experiences at school, such as expectations of the way girls and boys, should behave as females or males in a heterosexual society, shape subjectivity. Subjectivity is therefore a site of dissension and conflict. The theory rejects the idea of women as a homogenous group, and places emphasis on 'difference'. The idea of a common experience of oppression of all women as a group is rejected.

In these terms, there are then a number of discourses in society, some of which are more dominant than others. The theory argues that there are 'struggles' between discourses where the dominant discourse becomes established, and that this (dominant discourse) gives meaning to the social world in which it is applied. It is argued that the dominant discourse holds the 'power' and that analysis of the 'dominant discourse' and our reaction to it can tell us about the power relations within an occupational setting. Foucault (1981) suggests that there are those in any social setting who may have a vested interest in maintaining the dominant discourse that becomes to be constituted as the norm. This does not mean that others do not contest the discourse but that they are perhaps marginalised by what is considered to be the norm or dominant discourse in that field (be it law,

education or technology). Research into discourse focuses on the way a person perceives themselves in the social world and how they 'position' themselves or come to be 'positioned' whilst working within complex and often contradictory discourses in their organisational setting. This is particularly useful to us in gaining a greater understanding of women's experiences when they are working in non-traditional subject areas such as computing, where, as we will discuss the dominant discourses may be associated with masculine values.

DISCOURSES AROUND TECHNOLOGY AND GENDER

Cockburn (1983a, 1983b, 1985) and Wajcman's (1991, 1995,) seminal work are acknowledged as the foundations of feminist technology studies (Faulkner, 2000). Cockburn's early work (1983, 1985) demonstrated how men positioned themselves in key technological roles, to the detriment of some women. Wajcman showed us how historically certain technical artefacts became symbolic of men's leisure pursuits and hence (the computer) came to be ascribed with the male identity (Wajcman, 1991). Such work has discussed technology's association with masculinity and power, which as Cockburn (1985) argued reproduced gender relations, which she described as 'hard' and 'soft' in the workplace. Much of the work in this area has focused on women's alienation and exclusion from this 'hard' culture using a structural framework. If we apply this to the academy, the pure sciences and technical disciplines can be identified as 'hard', whereas the social sciences or humanities disciplines are described as 'soft' in character. As Knights and Richards (2003) point out when terms such as 'hard' and 'soft' are used in binary oppositions, as in the case with technology, they are rarely innocent or neutral constructions. What they do is reinforce the current power and knowledge relations, thus they have the ability to sustain or transform particular identities and interests (ibid, p. 222). Both the fields of organisational gender and SST describe computing as a 'hard' discipline. The 'hard' and 'soft' distinction tends to pre-determine what is recognised as competence within the discipline, and what is considered to be of value or importance in teaching, student support, and research in the discipline.

Feminist writers have successfully applied theories of discourse to studies of gender and technology in the academy to determine why, and how women and men actively maintain or reject the dominant discourses (Clegg et al 1999, Jorgensen, 2002, Henwood, 1998). It has been argued for some time that a 'masculine discourse' surrounds the design and use of technologies in many western societies. That males from an early age consider that 'computers, like cars and others forms of hardware, constitute a naturalised part of (their) male heterosexual identity' (Clegg 2001,p.314). The male domination of computing and thus the masculine values assigned to the discourses around computing and technology, extend to the work place, where gendered relations exist in our relationship to technology just as much as they might do in the home and in education (Wajcman, 1991).

THE STUDY AND METHOD

I present here a sub-set (this is still a work in progress) of the findings of the narratives of ten women. Each of the women were interviewed for between two and four hours. The interviews were often followed up in further discussions for clarification. The women work in different educational institutions in the UK. They all work in Computing Departments in either colleges or universities. The ages of the women in this paper range from 45 – 56. Several of the women have worked in the Computing Industry, before working in the field of education. They hold positions as lecturers, senior lecturers or professor. Each of them has worked in education for a minimum of ten years.

I have taken a narrative approach allowing the women to develop their stories themselves, rather than trying to elicit direct explanations using question and answer methods (Hollway et al 2000). Using the concepts of 'discursive positioning' (Davies & Harre, 1990, 1999) I am particularly interested in how these women's self-positioning affirm or challenge the dominant discourses in computing.

FINDINGS AND DISCUSSION

The women in this study are understood as negotiating their way through complex interconnecting discourses concerning their relationship with their gender identity, sexuality and their work as academics in a technical discipline. Several themes or positions in relation to the women's identities emerged in the study. The themes resided around technical work, research paradigms, the conflict between work and family and their mothering work; both at work and at home. Whilst some represented themselves as 'different', or 'unique' because they worked in a predominately male field, others rejected issues of gender difference in their workplace. In this paper I discuss the feminist discourse and the position of 'feminist' or 'non-feminist'.

The word 'feminism' can have different connotations to it. The meaning of the term is dependant on the context and the given moment in which it is applied (Beasley, 1999). In popular culture most of us are aware of the term 'feminism', but we add our own subjectivities to make meaning of it. For myself feminism is about politics and about challenging the inequalities many women face in areas of their lives. In popular culture the term 'feminism' may have different meanings and connotations associated with it than my own interpretation.

TAKING A NON-FEMINIST POSITION

Paula and Margaret both stated that they enjoyed their work immensely. After several years teaching, both are still enthusiastic about their subject. They both enjoy teaching the technical subjects of the discipline. They work at different educational institutions where their colleagues are predominantly male.

Paula is in her late fifties; she began work in the computing industry in the early 60's. She is a senior lecturer who has worked in the computing discipline in a university for over twenty years. She has never considered, or concerned herself about working in a 'male dominated environment'; she resists any suggestion that her gender makes any difference to her workplace experiences.

"I have never, ever seen people (in work) as male or female" (Paula)

She holds strong views about feminism.

"I'm not a feminist. I've always thought that people would take me on my own abilities…… I hate the droning on of people who are victims. And I will never be a victim." (Paula)

She resists the feminist discourse. To be a feminist in her view is to be a 'victim'. She talks about being taken on her 'own abilities'; suggesting she should be employed on her own merit, regardless of her gender. When talking about her own career in computing in the university, she discusses how when her children were ill she didn't tell her head of department of any difficulties she was experiencing. Instead, she struggled to complete her work and find care for her children.

"They'd taken me on and they knew I had two young children, and I didn't want to let down the women's cause in a way". (Paula)

Although Paula clearly positions herself as a 'non-feminist', I suggest her comments about 'the women's cause' contradict her self-positioning. She as an individual does not align these comments with feminism or position herself as a feminist.

Margaret is in her early fifties, she too started her career in the computing industry. She had been head of the computing department in her institution for a number of years before taking a more senior management role. She denies there are any issues regarding gender or sexism in her workplace. She does not position herself as a 'feminist'.

"I think it (a person's behaviour) has a lot to do with that person 'character, rather than the fact that she is a woman or a man". (Margaret)

However, when talking about her career in terms of progression she stated *"there was no doubt that women had to work harder to get where they were going than the men in the (computing) industry"* and as an academic.

"I have always had to prove myself as women" (Margaret).

Here again there are some contradictions but she remains firm about her 'non-feminist' position.

Paula and Margaret resist any association with feminism, and publicly reject the feminist discourse. My analysis of their narratives and actions contradict these public statements. Both of them deny any difference from their male colleagues associated with gender and claim to work in gender-neutral territory. They reject any notions of themselves as a marginalised group.

Both women have a long history of working in computing, I suggest they have adapted and assimilated their workplace identities over time. I suggest they enjoy the high status given to the technical skills they possess, and identify with the dominant technical discourse. Taking the position of 'non-feminist', has allowed them to blend into their discipline. Allowing them to comfortably position themselves along side the dominant masculine discourse in relation to their professional identities and their work.

TAKING A FEMINIST POSITION

Hannah, and Amanda both position themselves as 'feminists'. Both work in universities in computing departments, both of them have research interests related to SST.

Hannah is in her late forties and is a senior lecture in computing. She began teaching in the discipline of computing after completing an MSc in Computing in the early 90's. Before this she had taught subjects in Literature. In her department there are thirty academics, of which five are female.

She discussed how the attitude in her department was openly hostile to women.

"I think it's, erm, there's an underlying current of misogyny, discrimination and sexism in my view. A male professor said that erm that women don't make reliable workers in the department, because they go off and have children…….he was talking about women lecturers". (Hannah).

Hannah had publicly challenged this statement in a department meeting, the male academic in question had not spoken to her since, and she felt her relationship with the majority of the male staff in the department had become somewhat tenuous.

A male member of staff had told her that other male members of staff had given the females in the department the nickname,' the hens'. This was applied to herself and the other women in the department in a derogatory way.

"If we had lunch together it was, what are you lot (the hens) up to, what are you conspiring at, and things. Actually most of the time we were discussing our children, where we could buy a good bargain, nothing related to work". (Hannah)

Amanda in her early fifties started her work in computing in the early 60's, she has worked in academia for twenty years and is a professor in her computing department. As some of her research resides in the feminist literature, her colleagues know of her feminist position. During the narrative she gave many examples of what she described as 'confrontations' about her research and her beliefs in the department. At the time of the interview she said that over the previous year there had been many times that she had thought '*to throw the towel in*' or *'just give up'* and work elsewhere. She discussed how she was concerned about the consequences for other women in department who might be associated with her and be labelled alongside her as one of the 'feminists' in the department.

" In some cases I can see that people who are my friends, are not given a job by somebody else, maybe in authority to the research director, because they're part of this Amanda (me) , soft research, feminist, colleagues, friends stuff". (Amanda)

Amanda went on to explain that this not only included the females in the department but also some of the males she closely associated with, which she described as 'pro-feminist'. She explained that the technical 'hard' research, and the teaching of technical subjects, was highly valued in her department.

"There's definitely a lot of old fashioned, 'blokiness', which is critical.

It's very hard to put your finger on it……. The technical stuff is in the hands of the men, and that's the real stuff, and so on……they are protecting some kind of, they're very protective of their own status as researchers (sic)". (Amanda)

Hannah and Amanda reject ideas of gender neutrality and challenge issues of inequality between men and women working in their departments as they arise. Both position themselves as 'feminist'. Although technically competent they have both chosen to teach and research in areas labelled by colleagues as 'soft'. Consequently, as Amanda's statements demonstrate their type of work and research may be challenged and undervalued in a department where the technical discourse is highly valued and protected.

Hannah and Amanda by their actions and nature of their teaching and research position themselves as 'feminists'. I suggest this does not allow them to blend into their workplace setting. Instead their position places them in opposition to the dominant discourse, where some of their colleagues may view them as a threat to the status quo.

CONCLUSION

In this paper it is not my intention to make any collective claims about the experiences of women working in Computing. This paper is about highlighting the complexities of our work place identities as we as individuals construct them.

In this study those women who held a position of 'non-feminist', withdrew from any discussion around issues relating to gender, and refused to acknowledge any 'difference' between men and women's attitudes to technology or technical ability. Those who positioned themselves as 'feminist', questioned the dominant technical discourse and the values attributed to positivist research methods. They are not afraid to challenge sexist behaviour or inequalities they experience in their departments.

Those who hold the position of 'non-feminist', holding a belief of gender equality or neutrality in their workplace appear to have a more satisfying work experience. I suggest that their self identities do not challenge the status quo. In contrast those positioned as 'feminists' found themselves at odds with the norms and values of the discipline leaving them open to harassment and sexism.

Issues of how we come to construct our 'self position' and 'identity' add more complexity to gender relations in the discipline. In the findings of this research there are several contradictions in the statements. As Paula's narrative demonstrates, we may interpret the word feminism from a number of perspectives, and add our own connotations to it. I suggest that for these women and their colleagues the terms 'feminist' or 'non-feminist' do not have innocent or neutral meanings attached to them.

If we wish to tackle women's under representation, or seek to understand how some women become 'marginalised', or situated as the 'other' in the discipline of computing then I suggest that in future work we need to tease out, how our self positioning and 'self identities' as women and men work to resist, or reinforce the dominant discourses of the discipline.

ABSTRACT

This article gives an overview on how military planners in multinational environments can be supported by Knowledge Bases based on Semantic Web Technologies. It reflects parts of results generated during a project for the German Center for Transformation of the Federal Armed Forces from 2005 to 2007. Focus of this project was Knowledge Representation and Knowledge Processing to support EBAO-Planners. For this, firstly context-specific problems are introduced, followed by a brief description of latest enabling Technologies for Knowledge-Modelling and Knowledge-Processing. In particular problems of instance-modeling and abstraction as well as some downsides of inference engines based on First-Order-Logic (FOL) compared to Second-Order-Logic are briefly outlined. An SOL based approach for the analysis of objective-systems is conceptually shown finalized by an example from the Effects Based Approach to Operations (EBAO) context. The conclusion identifies upsides as well as problems and subjects to improvement.

1. THE EFFECTS BASED APPROACH TO OPERATIONS

The Effects Based Approach to Operations (EBAO) introduced a new way of strategic planning not only in correlating Actions and Objectives but in holistically considering Actions, Effects and different Objectives [1]. Effects can be here described as the sum of all results which are caused by actions taken within an Area of Interest, the so called *Focus Area*. The aspect of integrating different Agencies involved with different interests, such as Department of Defence, State Department etc., is emphasized within the EBAO[2]. This approach can not be considered really new [3], but last decade's information technologies enabled efficient network communication as well as Knowledge Representation (KR). These laid the cornerstone for a sufficiently effective dealing with the complexity within fields of modern military operations [4]. Amongst others these are standards in network communication, data bases and XML with its derived modelling languages including Ontology-Languages.

Ontologies allows experts to built and maintain domain specific knowledge [5, 6]. Results from NATO's Multi National Experiment 4 (MNE4) which ended in 2005 have shown that centralized and static Knowledgebase- structure as known from classical databases have crucial drawbacks in giving an situation awareness needed by planners within the EBAO [7]. The focus of this paper is to depict the potentials of Ontology technologies in the field of Multi-Agency and Multi-National Knowledge Representation (KR). As a prerequisite for all planning-work, the formalization of objectives and a mechanism to infer dependencies between those (Reasoning) represent the Knowledge Processing part. We focus on the Web Ontology Language (OWL) here, because it is an implementation of Description Logics, a W3C Standard, and well supported by an Open Source Community. In addition to this there are hardly any competitive technologies at the market [39, 40].

2. OWL: A W3C STANDARD FOR KNOWLEDGE REPRESENTATION

Ontology languages such as OWL are usually attributed to Knowledge Processing not so much as to pure Knowledge Representation [8]. OWL provides no executable methods, but requires inference engines [9], rule systems [10] or wrappers to make structure and data accessible for applications [11]. Encapsulating knowledge structure in own language systems leads to more semantically powerful structures. Amongst others property-centric modelling [12] or a dynamic and logic-based inference [13] of class structures introduce new features in Knowledge Representation. Especially the latter feature, which is missing in executable environments such as Object Oriented (OO) Programming Languages [14], can not be transferred to these without loss of expressivity [15]. Besides this flexible mechanism to create structure by descriptions, OWL offers an fully URI-based referencing mechanism for elements on class level and instance level, which leads to an native implementation of distributed – but seemingly local – KBs [16]. This feature is shown in section 2.1. New applications called Alignment and Mapping tools make use of the graph-based [17] structure of OWL Ontologies and apply distance measure methods, developed from the 70'ies on, in order to support (next to others) a semi automated similarity comparison [18] of different structures. A short overview on this topic can be found in 2.2.

2.1 Ontologies: An Distributed and Modular Approach

For decades organisations have been working on Knowledge Base Models to represent the "whole world" within one single Ontology. This central approach leads to inconsistency, redundancy, unintentionally outdated information and other strongly unwanted effects. Technically Gödel proved in 1931 that a formal system suffers from too little expressivity or from contradictious elements [19]. So seemingly the hope for a "world-system" which contains each an every concept in every perspective has maybe not died but at least suffered a severe set-back then. And this took place even long before technology came even close to a level powerful enough to handle an amount of information this large. Individual perspectives or views – in the sense of an understanding of a subject and its properties (as shown in [20]) – can be seen as reason for why a "common sense modelling" can be considered a permanent point of failure [21, 22]. Simply too many partially contradictious views exist, each with different structures, classes and properties.

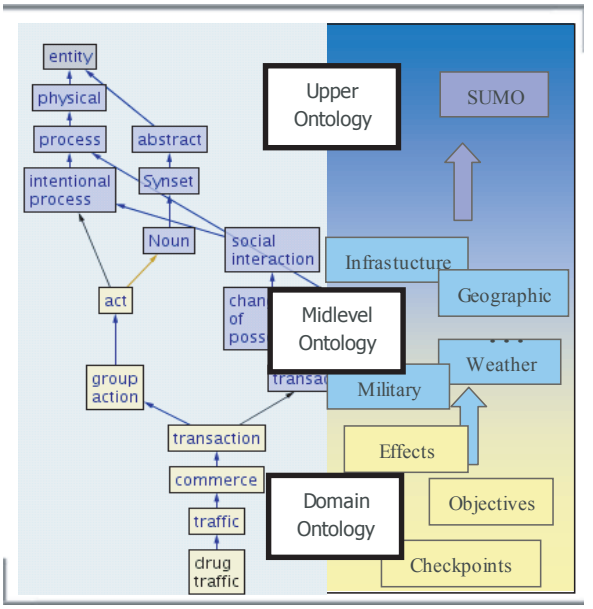
Taking this into consideration, a new way of Knowledge-modelling has been defined. The architecture of ontologies follow a three layer approach, which combines so called upper-level, midlevel and domainlevel ontologies. Once Domain-Knowledge has been made explicit it can be integrated (by means of inheritance) under more general upper Ontologies in order to assemble a KB for special purposes [23]. Figure 1 shows an example Ontology which models Drug Traffic on structure-level. Rectangles depicted in the upper part are more general concepts such as *physical*, *abstract,* or *process* and belong to the upper level of the Standard Upper and Midlevel Ontology (SUMO)-Standard [24].

Rectangles in the centre are of Midlevel, and would not be part of all ontologies, since they contain fairly common but not general concepts. The most specific level, the domain level (lower part), then represents the actual intent of the model [25]. All relations shown in the picture are inheritance relations and therefore enable a switching of different domain level Ontologies since they are of same type by definition (if they inherit from the same midlevel concepts) [26].

2.2 Comparison of Similarity Using Alignment-Tools

In order to participate in a distributed system all elements need to "know" about data structures they are working on [27]. Structures which are of no interest can be neglected but when it comes to data exchange with other participants the meaning

Figure 1. Three-level architecture of an ontology (Source: [25])

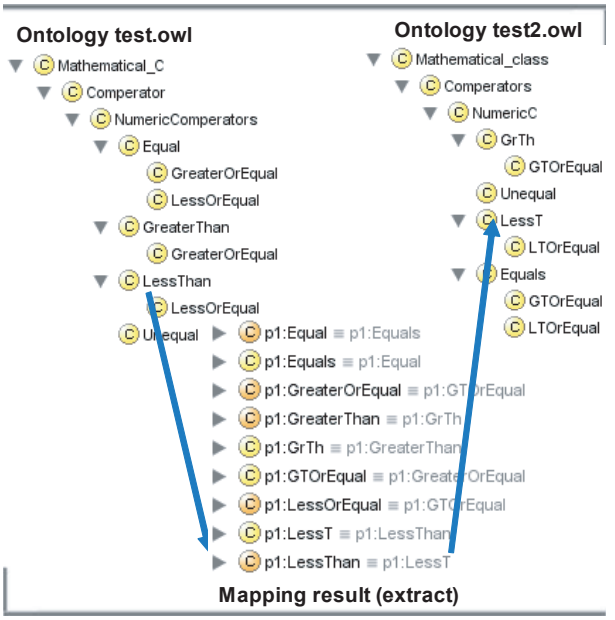


of structures and data have to be underpinned by a common understanding. Given the decentralized thought in section 2.1 it becomes highly probable for different actors to work on identical subjects but using different structures. A necessity for bridging these differences appears, if queries are to be used in different environments, class structures are to be aligned or instance-class relations are to be checked (e.g. which class does a given instance belongs to) [28].

Generally speaking differences in models can arise at two conceptual levels: Ether the modelled subject itself (Conceptualisation mismatch), or the way of modelling this subject (Explication mismatch) can differ [28]. While the first challenge is of pure semantic nature, and nearly no support but the recognition of differences can be provided, the latter situation is generally supportable by alignment tools [31]. "The way of modelling" in this context means, that a subject can be related to different other subjects on structure level (class definition). Alternatively different modelling-languages can be used. The first case can be solved by a union of all properties, if all concepts' meanings are at least comparable or equal at best [28]. If different languages have been used, a comparison depends on syntax, semantics of primitives, logical representation and the languages' expressivity [32].

Alignment helps integrate the results of different ways of modelling an identical subject under different perspectives using comparable languages. Technically the output of an alignment process is again an ontology which defines relations between classes [29]. In case OWL, specific language-elements such as *owl:sameAs* or *owl:equivalentClass* [12] are used. As an example Figure 2 shows two Ontologies about mathematical comparators and their generated mapping ontology (test.owl and test2.owl).

Figure 2. Example for tool enabled ontology-alignment



The result of this process is depicted in the middle and defines equal classes. The limits of alignment are reached, when elements within the compared ontologies are not on semantically comparable levels. In such case some properties would be match one atomic property or class in test2.owl. Integration of this kind can be done syntactically via XSLT processors. Nevertheless this approach seems very promising, since it provides – compared to manual comparison – reasonably support in analysing class dependencies [30].

3. SUPPORTING PLANNERS BY OBJECTIVE-SYSTEMS

All plans try to achieve certain objectives. The definition of objectives, which is depending on time restriction and planning scope, is often done implicitly by planners. This implicit approach seems valid, as long as the planning organization is of limited size. In case of EBAO, several Agencies and Departments are thought to plan and execute as if (at best) they were one single organisation [33]. Strictly formalized information-flows try to limit uncontrolled information exchange among planners of different departments. Hence it is by no means the case that necessary communication between information provider and consumer takes place directly [34]. Needless to say, different departments take a lot of effort to coordinate their planning processes.

But this does not imply persons involved in the planning process to be informed at all times about other-parties' intentions and plans. In order to increase the value of defined and mutually exchanged objectives, one option is to shift these objectives from paper bound media to formalized ontologies. By this, analysis methods can become (partially) IT-enabled – a process highly time consuming, if conducted manually. Of course only a portion of the objective analysis can be done by computers, but areas of high data volumes combined with relatively simple and formalizable relations can be targeted by computers very effectively. One of these areas is the detection of contradictious or depending objectives. The basic question to be answered in this section is in which way a detection of these relations can be achieved. It is not planned to give a detailed introduction into the technical questions of the mechanism itself but more an overview on the idea behind it. The basic assumption for the added value of this mechanisms is, that if planners knew that their actions and effects influence other agencies during planning time they would be able to avoid unwanted (mostly competitive) effects during execution.

3.1 An OWL- Objective Ontology

A single Objective describes, speaking abstractly in the context of this work, an (internal) state of a set of concepts at a certain point in time. For this an objective needs means to define its target concepts, the desired values to be connected with these and a mechanism to determine if the objective is to be taken into consideration in current planning. The mentioned Ontology counts about 70 classes and 60 properties which are not to be introduced here completely. We focus on core-concepts which are connected to numerous other concepts defining mathematical expressions, actions, user-interaction, or reference constructs.

Figure 3 shows concepts formalized as Unified Modelling Languages (UML) classes.

At the lower left hand side, the Objective-class carries information about EBAO specific categories (*DIME_Category* Diplomatic, Information, Military, Economic), a textual description and Instances for predefined user-interaction. The description of which concept to be changed by which values, is given by references to *ObjectiveTargetChange*-Objects.

Figure 3. Core-concepts of the objective-ontology

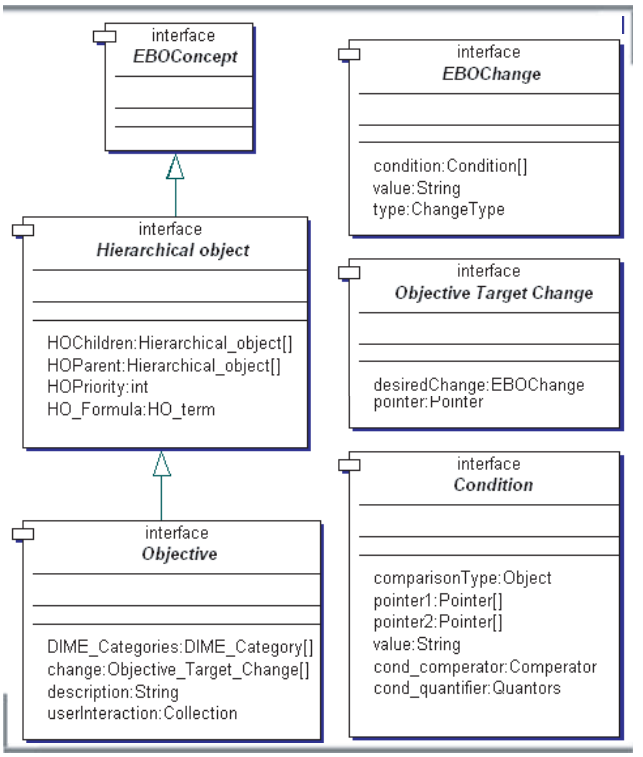


Figure 4. Abstract addressing-mechanism: The pointer-class

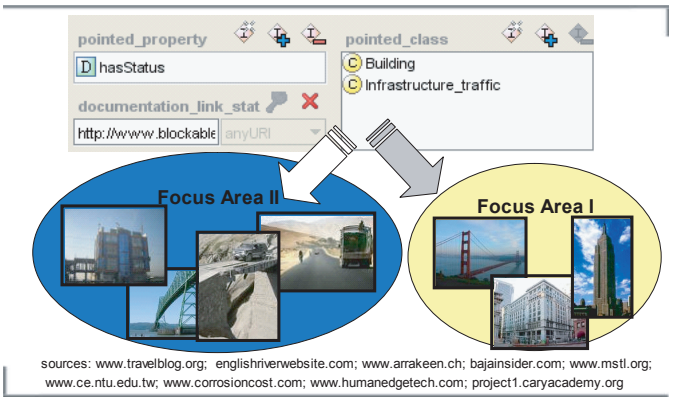


ObjectiveTargetChange addresses concepts by *Pointer* Objects (see 3.2). References to *EBOChange*-Objects define desired status and sets of addressed concepts. *EBOChange* itself changes a value in a relative or absolute way (defined by *ChangeType*) to (or by) a certain value. This change is executed, if all conditions are met, while a *Condition*-Object compares two sets of addressed values (see 3.2) or values.

Objectives exit within networked systems of objectives depending on each other [35]. In addition to this it is not a trivial task to define numerically defined end states or to set up references as desired values [36]. Objectives sometimes purely depend on their child-objectives in a sense that if a defined combination of child-objectives is fulfilled then the parent-objective is fulfilled itself. An example for this is given in the following table that defines A as parent-objective for B, C and D (left hand side). The requires-relation on the right hand side determines the conditions under which A is fulfilled (simplified with non-quantified relations only).

childElement(A, B)	requires(A, [B,C])
childElement(A, C)	requires(A, [C])
childElement(A, D)	requires(A, [B,D])

In order to embed single *Objectives* within such systems but keeping the structure encapsulated, the *Objective* class inherits form a class *Hierarchical_object* (see Figure 3). This class provides a special linking mechanism for its subclasses, which defines parent and child-relations as well as priority and *Formulae*. A *Formula* defines the dependencies for all child-elements in a logical expression.

The mechanisms described above are a domain-independent, and therefore exchangeable, way to formalize objectives with flexible addressing mechanism and primitive value or object-comparison mechanism.

3.2 The Advantages of Structural Definitions

One aspect to be outlined more detailed here is the addressing concept used within objective systems. The basic idea behind it is to avoid pure instance reference but instead use class references, in order to benefit from the Description Logic (DL) features within OWL. DL allows the definition of so called asserted class-structures enriched by logic statements. These statements can then, after applying reasoning tools, be resolved to new inferred class-structures [13]. Hence a Pointer-instance carries (as shown in Figure 4) a set of classes, one property, a recursive set of pointers and a set of instances to be able to refer to very important instances as well.

In the example shown above all militarily blockable concepts are addressed, which include classes of buildings and traffic- infrastructure. This mechanism is of descriptive nature only and requires an inference engine to determine results of these descriptions. As shown in [37] a class is substituted by all its direct instances and direct instances of its subclasses**.** Exclusive usage of class level concepts supports transferability and reuse of pointers within different Focus Areas.

3.3 Ontologies, Structures and Second Order Logic

If pointers use structure level concepts to address their concepts then First Order Logic does not natively suffice to do the resolution. Technically FOL can query for named predicates. What can not be solved is the question, if any predicate (with variable name) exists which fulfils a goal [38]. Assumed that each instance is transferred to a predicate named after its class and all relations are named after the relations' names and combine domain and range instances, then the predicates' names explicitly carry information about their content.

FOL Representation	SOL option
warlord(X)	concept('warlord', X)
hasInfluence(X, Y)	relation(X, 'hasInfluence', Y)

If OWL-ontologies are transformed as described in [37] all ontology-internal names become variable of a limited set of predicates. This enables SOL-like inferences including reachability analysis and reflection mechanisms based on FOL inference engines.

3.4 Example Results

The following example shows some options how the objective ontology described above can be analysed under conditions of distributed knowledge bases. One of the most important things for a planner setting up objectives is to know, if any other party within his own system has an interest in the concepts addressed by his objectives. If such situation is given, he would also like to know, what kind of dependencies between this two objectives exist. Especially competitive and complementary relations are of interest here, since conducted actions could turn out to be an – seen from the system's point of view – inefficient usage of resources.

In our example the subject to investigation is drug traffic in the Focus Area of northern Afghanistan. Two System-of-a-System-Analysis analysts [33], one on

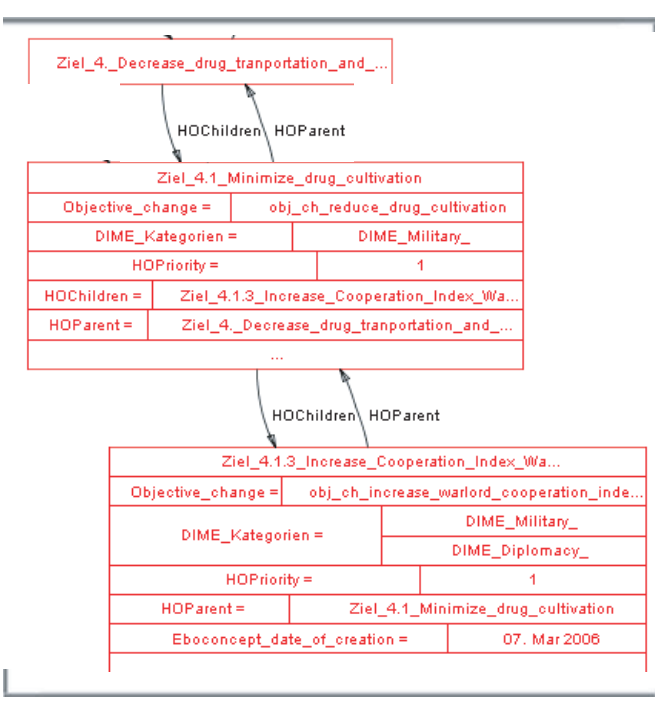
military, one on diplomatic mission are working on the effects of drug traffic on their afghan scenario. The military planner discovers some warlords' income to be generated in large portions form poppy-cultivation and opium trade. So he creates a rule to make this relation explicit, but due to lack of reliable data she/he does not quantify this information. In addition to this the analyst knows, that some warlords spend quiet a large proportion of their income on running their private militia in order to maintain control over "their" region and to stabilize or exceed their powers. Warlords of great power are considered a threat for the democratically elected afghan government since they tend to subjectively interpret state laws or decisions made by the judicative to their favour.

The diplomatic analyst objective is to increase powerful warlords' will for cooperation with the afghan government. He assumes that without the active participation of these persons, a stable government and prospering economy is far off reach. And she/he knows about the relation between actions taken about the power of warlords and their behaviour connected to the acting parties. Since warlords try to maintain their powers, their willingness to cooperate with anybody trying to weaken their influence decreases. So from the diplomatic perspective (which might be – compared to the military point of view – more far sighted in this case) it seems not recommendable to weaken warlords by aggressive means.

Both analysts now start to develop a formalized objective system to ether (in military case) decrease the income of warlords, or (in diplomatic case) to conserve the current status of the warlords. As a base for their objectives they use the Focus Area Afghanistan 2006 (distributed) KB, which offers a linked system of a large number of (mostly) compatible domain Ontologies. After loading all warlord-relevant parts of this KB to their local computers they discover after some time – indicated by a check for dependencies between their objective-system – that it seems as if somebody else addressed the warlords' income too. Figure 5 depicts a prototype for an objective analyze tool based on Stanford's Protégé-tool. Amongst other features it infers dependencies and contradictions between objectives by comparing addressed sets of concepts and their desired value. Relations such as the dependency between poppy cultivation and a warlord's income can then be inferred. Within a concrete KB these structural descriptions are then projected onto all instances collected by analysts.

Querying details about the discovered references both of them can determine the owner of these relating concepts other objective systems as their source. Now it is apparent, that their objectives are indirectly related to each other, since M wants to prevent poppy cultivation, which is a prerequisite for drug traffic – the basis for warlords' income – and D wants to keep exactly these income at a constant level. After this IT-enabled support, the procedure to resolve this conflict of interests can then be carried out on human to human level.

Figure 5. Determination of contradictious objectives



4. CONCLUSION AND OUTLOOK

The paper presented a conceptual idea on how Ontologies – here implemented in OWL in particular, can be used to mediate KB-models between different agencies. By using the decentralized approach of Ontologies at Upperlevel, Midlevel and Domainlevel dynamic KBs containing detailed expert knowledge can be assembled within a much shorter period of time. Here, alignment tools can provide great help to human analysts. Means of Second Order Logic into play enable a more powerful mechanism for querying and manipulation. Based on SOL domain independent predicates provide a framework for analyzing objective systems on dependencies and contradictions. Although this work has been implemented it has not been tested for scalability and the dynamic loading of instances from different Ontologies. While the first aspect is subject to further research, the latter one will surely be covered by Ontology editors within the near future.

ABSTRACT

This paper discusses the gender pay gap in the ICT sector 30 years after Equal Pay legislation came into force in the UK. Taking a critical and feminist approach our research has highlighted contributory factors of confidence and negotiation, salary secrets, penalties for 'time-out' and issues of part-time working. We conclude with some strategies to overcome the gender pay gap and suggest that the current situation is unacceptable in the 21st century in terms of social justice and for the economy and society as a whole.

INTRODUCTION

This study explores the gender pay gap in the ICT industry throughout England. The UK labour market is dramatically changing with rapid technological innovations alongside globalisation and more than ever organisations are required to place a premium on human and intellectual capital. The demand for labour in ICT is outstripping supply. However, a recent comparative report of the IT workforce in Holland, Germany and the UK indicates women are haemorrhaging out of the IT sector (Platman and Taylor 2004). Given that presently in the UK there is an IT specialist's skills shortage of 18.4% (IER/IFF 2003) and female IT workers represent a mere 15% of ICT managers, 30% of IT operations technicians and 11% of IT strategy planning professionals (Miller et al 2004), this suggests that the ICT industry is not equipped for equality and diversity at work.

When the Equal Pat Act (1970) was enforced in 1975 the gender pay gap stood at 36% for full time and 40% for part-time. By 1981 this had decreased to 28% (Richardson 1984) and 1990 saw a further reduction to 23% (EIRO 2002). Although this data indicates a gradual reduction of the gender pay gap, in 2007 women still receive on average 18% less than that of their male counterparts in the UK and shockingly the part-time gap of 40% has remained unchanged.

Pay inequalities is an issue for all – it is unjust, unlawful and impacts on social justice, equality and economic performance (EOC 2001). Distribution and levels of pay and benefits impact on efficiency of organizations, workforce morale and productivity (ACAS 2005). In this paper we highlight some of the key issues, which contribute towards pay inequality experienced by female ICT professionals namely confidence and negotiation, salary secrets, penalties for 'time-out' and issues of part-time working. Taking a critical and feminist approach our research concludes with some strategies to tackle the gender pay gap and we suggest that gendered pay inequality is no longer acceptable in the 21st century.

THEORETICAL UNDERPINNING FOR THE PROJECT

The economic, social and political root of women's inequality in the labour market is a contested theoretical area. This section discusses theories that have informed this field and the critical and feminist approach that has shaped our research.

Neo-classical economic theory explains women's pay discrimination in two main ways. Firstly there is an 'individual' explanation suggesting that the wage paid to an individual relates to the value of the output that the individual produces. If women are paid less than men this must be because the value of what they produce is less, that is, they are less productive (Richardson 1984). Human capital theorists on the other hand, try to link women's supposedly lower human capital to their role in the family. This view suggests that women have a' free choice' and indeed choose to obtain less education and training, choosing instead the role of child rearing. If women enter the labour market this choice therefore has an impact on pay rewards.

Of course these views can be criticised for suggesting an innate and rational economic view of the labour market and family relations divorced from actual experience. The state is involved in much of the organisation of the labour market and society through education and welfare policy for example. Not all women share the same experience and choice of education and training and such theories are attributing experiences to all women regardless of whether they work or not or have children or not.

However such approaches are now finding resonance in theories of the 'information society' or 'knowledge economy' Giddens (1984) for example concurring with Beck's individual and risk society' thesis (Beck 1992), suggests that the changing situation of men and women in the family and at work must be seen in terms of individual choice: 'we live in a world in which social order of the nation state, class, ethnicity and traditional family is in decline. The ethics of individual self-fulfilment and achievement is the most powerful in modern society' (ibid 1992).

Critical approaches to women's inequality largely are rooted in Marxist or Feminist theory. Feminist theories often locate women's inequality in patriarchal gender relations within capitalist relations. Women are thus divided along class lines but share the oppression of male domination. Capitalism and patriarchy in this way continually interacts affecting women's position in the economy and family. This leads to the 'economics of male advantage' (Cockburn 1983). In Marxist analysis, women's position in the labour market depends not on market principles but arises from the organisation of production with roots in class exploitation. Inequality in the labour market is linked to women's oppression in the family. German (2003) for example explains that the family is both broken down by the effects of capitalism but also maintained and reinforced by capital as the cheapest, most convenient and most socially stable way of caring for the existing generation of workers and reproducing the next generation. The family fulfils too precious a role to be left to 'free market' individualism. In reality, three-quarters of households in the UK are still headed by two-parent families and men and women are moving closer together in terms of work and domestic life but not in circumstances of their choosing. They do so 'against a backdrop of continuing women's oppression and intensified exploitation for both men and women' (German 2003). Fitting into these roles is hard work – for women it means working for less than equal wages and for men increased unpaid childcare in the home.

Yet the family is a gendered institution and is often taken-for granted. Wharton (2005) describes how the family is viewed as 'somehow functional for society rather than a social construction and changing in relation to history and culture' and she continues to observe that though family diversity is a social fact yet this is 'obscured by a set of taken-for-granted beliefs about the family as a social institution' (Wharton 2005). These include myths of the nuclear family, the heterosexual family, women as mothers and caretakers and men as fathers and breadwinners. However it is these myths that inform the choices made including government and employment policies. As Huws (2003) suggests:

'..more than this, women's role in the domestic sphere is used to confirm and legitimate their marginal status in the labour market. The gendering of jobs cannot be reduced to a discussion of women in the domestic sphere, but must be seen as

arising from the interplay between their socially ascribed, and therefore shifting, roles in both the public and private domains' (2003:28).

So it is in this context we discuss the experiences of women in the UK ICT sector.

METHODOLOGY

The severe under-representation of women in the ICT field has received attention from academics, industry and government agencies alike. However, there has been little attention from qualitative researchers to the gender pay gap in the UK ICT industry. Existing studies are generally of a quantitative nature (e.g. ONS 2005; e-skills 2005) and provides us with overview data of ICT professionals' salary dispersions compared by gender, age, qualifications and the gender pay gap by region.

The empirical material used in this paper is drawn from data generated by the Directing Equal Pay in ICT (DEPICT) project partly funded by the European Social Fund (ESF) and completed in December 2006 The DEPICT project focussed on women in the ICT industry in England, or those working in ICT in non-ICT organisations[1]. The issue of defining the ICT[2] sector is an ongoing complexity within the Information Systems (IS) community. We used Duerden Comeau's (2003) work on defining ICT to construct the research rationale for the DEPICT project. This goes beyond a narrow view of IT as technical departments and includes for example the creative and media sectors. In framing gender within the ICT sector the research team made the assumption that the skills and expertise required from the industry are multi-disciplinary and that the work force is generated from within a diverse boundary of disciplines (Cukier et al 2002). Although we cannot solve the issue of definition, we enabled interviewees and on-line respondents to self select and define their ICT role, occupation and sector.

Our two key means of data generation were an on-line questionnaire from which we had 236 respondents and a series of 14 case study interviews. In this paper we offer a sample from both approaches. The case studies involved interviews with women from public and private organisations of all sizes and self-defined 'entrepreneurs' and the group was self selective with women contacting the research team directly if they wanted to become further involved with the study beyond completing a questionnaire. The women represent a broad spectrum of career backgrounds, unique family units and life experiences, each woman a 'pioneer in their own right' (Czarnaiwska 2005). Such an approach builds on a long tradition of feminist research which aims to take women's stories and accounts of their gendered experiences seriously, using predominately qualitative and ethnographic methods to explore their thoughts and actions (McRobbie 1997).

PROJECT FINDINGS

In these preliminary findings we highlight some of the key factors which contribute towards the continuing gender pay gap in the ICT industry.

Confidence and Negotiation

Individualized pay packages are common in the ICT industry and requires strong individual negotiation skills and a high level of confidence. Women have reported being uncomfortable with this method of pay and reward and find that masculine and aggressive organizational culture mitigates against success in such negotiation (Tattersall et al 2004). Moreover the ICT skills that women possess are often undervalued, marginalized or unrecognized regardless of achievement (Tattersall et al 2004, Woodfield 2000).

One example comes from Ann who is in her early career stage and started working for company X after graduating;

'I was happy when they offered me £23K because a lot of people I knew from uni were on starting salaries of about £20K, I have since found out that based on tests at the interview I started on £500 less than the blokes who started at the same time…….I am comfortable with my manager that I could raise it; I am not sure that I would push it. I am not sure I would say I want a pay rise or I'm walking.

This experience could be a factor behind the report from the Equal Opportunities Commission (EOC) highlighting that female graduates earn on average 15% less than their male counterparts by the age of 24 (Purcell 2002).

Many of our interviewees expressed how they were satisfied with the pay package they were offered at interview, displaying a kind of gratitude. However, by accepting initial wage offers and not negotiating a higher starting salary contributes to the gender pay gap:

'They offered me £70K and as I was on £58K in my previous job I was more than happy to accept, then when I started work I found out that the other managers (all men) were getting £80K ….. I just think they will pay what people ask for and men ask for more'.

From a total of 210 respondents 76% answered yes they found it hard to ask for a pay rise. One manager noted how everyone in her team was on £35K salaries however she said:

'Come the pay reviews in March, they are based on performance, those who perform better, I would want to pay them more….so basically it's down to whether you have got good negotiating skills and the confidence to sell yourself'.

Salary Secrets

There is a culture of 'salary secrets' in the UK IT industry and women have reported that they only find out about pay inequalities once they reach management level and have access to financial or personnel information (Tattersall 2004). In research analysing gender equality in organisational pay structures and pay practices (Neathey et al 2003), data revealed that more than 1 in 5 employers did not allow their employees to share information about pay with colleagues. Employers often demand pay levels are kept confidential and disclosing this information to colleagues can lead to disciplinary action. Our questionnaire concurs highlighting that from a total of 204 respondents, 66% identified a confidentiality culture about pay in their organisation and in the same vein from a total of 205 responses 60% were unaware of how much their colleagues earn. Delia told us how she discovered she was paid less than all other managers:

'I earned £58K and I know I was the lowest paid manager there and I was the only women manager there, I did establish that and that's one of the reason's why I went contracting because under my current contract I actually earn…well I am closer to £90 to £100K on the current rate……how I found out I was being paid lower than the other managers was, well I did some research and went to the other managers who I knew well and I said 'If you don't mind can you tell me how much you earn?' all of them with one exception told me…it was significantly more'.

In a bid to make pay systems totally transparent the EOC have introduced the Equal Pay Review, which is a toolkit to enable employers to highlight overt and covert inequality and discrimination within pay and rewards. Additionally the EOC have introduced an Equal Pay Questionnaire which allows individuals to uncover information about colleagues pay packages if they feel they are being paid less for a similar role. (Women and Equality Unit 2006)

Paying the Penalty for Time Out

According to a report by the Women and Work Commission (2006), taking time out of the labour market to have children is one of the main reasons that women earn less than men. Career breaks are set against the years of work experience that a women builds up and reduces one of the factors valued through pay by employers. The women in our study experienced discrimination in pay and promotion during and after a period of maternity leave. An on-line respondent commented that after returning from maternity leave:

'Although they say there is no change there isn't much emphasis on my career development from them'

Moreover, from a total of 50 on-line respondents 26% said that they did not return to the same status (e.g. responsibilities, working conditions) after a period of maternity leave. Another on-line respondent commented with regards to progression:

' employers are always dubious about your commitment once you have had children'.

This account highlights that direct and indirect discrimination is evident in the ICT sector penalising women for their gender 'difference'.

Part-Time Working

Many employers are failing to tap into the available talent of a part-time work force. People with or without caring responsibilities need or want to work part-time, yet this can be considered as incompatible with working in the ICT sector. Part-time working is rarely an option and part-time workers are often under-valued and lack support from inside and outside of the organisation (EOC 2005). Men perceive that part-time work can affect their career chances (Crown 2004) which may go some way to explain the low take-up of part-time work in ICT. In our study the number of women respondents who work part-time/part-time flexi-time, equates to a mere 9% (from a total of 222 respondents). Additionally, 51% (from a total 201 respondents) said that they did not feel that it would be possible to do their job working part-time hours. A report by the DTI (2004) 'Flexible Working in the IT Industry' notes that 74% of senior managers felt that conducting their job on a flexible basis would attract lower pay, diminished promotional opportunities and less interesting project work and activities. These factors are exemplified by Rose who explains how her career was put on hold whilst she worked part-time hours:

'Basically I was made P.O.1[grade] before I had my first child and 10 years later I was still on P.O.1. It was because I went part-time. It wasn't even in question with my boss, it was 'yes you can go part-time that's fine but what you will be doing will be menial, low level programming, it's your decision', so I traded, I traded for flexibility'.

Carly, a senior IT manager describes her feelings about part-time workers:

'Most people who have joined our department are aware of what it takes to get on and this is not just about women its about men too; I think a company this big can offer a number of working choices. I think the difficulty is when you have 4 or 5 women who all want to work part-time and then you have got one man left, I am in the situation where I don't have children; I will be totally honest, I want to support those women and I think its great but I don't want to work with 4 of them…I know that I am doing more work than them.'

The introduction of flexible working legislation in the UK in April 2003 has gone some way to address the rights of parents with young children under the age of six, to work part-time hours. The Maternity Alliance Group[3] conducted a survey one year after the legislation was introduced. They found that 25% of requests for flexible working are turned down. In addition many of those who were actually 'allowed' to work flexibly had to take pay cuts or have lost status within their companies. Also men are less likely to ask for flexible working hours than women. This frames the 'problem' of balancing work and family commitments as a 'female' dilemma rather than a familial and societal one.

DISCUSSION

In this paper we have established that the ICT sector in the UK is ill equipped to deal with a diverse workforce where (often blatant) pay inequality and discrimination remains a continuing problem more than three decades after the Equal Pay Act came into force. This is unacceptable in the 21st century when fairness and social inclusion are high on the political agenda - governments and organizations alike have a social responsibility to eradicate its existence. Gender difference is penalised not only in general and cultural terms but also in financial terms. Within this paper we have highlighted the gendered factors that reinforce the pay gap. These include issues relating to women's confidence and negotiation skills, the embedded culture of salary secrets, time taken out of the industry for (e.g.) a period of maternity leave and part-time working. We suggest that there needs to be a major cultural shift within the ICT industry in order to address these issues. Strategies could include the adoption of transparent pay systems with no hiding place for inequality or discrimination. In this vein we suggest legislation to enforce Equal Pay Reviews would be a positive step and in turn will contribute to removing the embedded culture of salary secrets that exists within the ICT industry. The ability of an individual to do a job should solely determine their associated pay and reward not their gender or gender difference. Flexibility is a requirement of today's ICT workforce, women (and men) want to have a career and a family. We suggest that in order to change an industry that predominantly values and rewards those who work full-time with traditional career trajectories, flexible working options and career breaks should be offered to all. Furthermore, these issues need to be taken seriously by senior management with 'buy in' to cultural change. By not utilising women's ICT talents and abilities it is not just the women themselves that lose out in terms of unequal treatment but also the economy and society as a whole.

Internet Adoption Decisions in Small Businesses: The Impacts of a Local Web Portal

ABSTRACT

This article demonstrates the role played by the establishment of a UK village community web portal on the Internet adoption decisions of small businesses. The article reports on some of the findings of an ongoing study of this local community web portal, focusing specifically on those small businesses that had, prior to the launch of the web portal, made a decision not to adopt the Internet into their business operations. The barriers these non-adopting small businesses perceived to Internet adoption are identified, and the impacts their portal presence had on their subsequent choice of Internet adoption pathway are discussed.

Keywords: small business; Internet; Internet adoption; web portal; non-adoption

1. BACKGROUND

Discussions in the diffusion of innovations literature suggest that the advent of any given innovation is likely to be met by a variety of responses: some individuals and / or organisations will readily embrace and adopt the innovation, while others will probably prove less enthusiastic and thus be slower to adopt it; and still others will decide not to adopt that innovation at all (for a comprehensive discussion of innovation adoption behaviour, see Rogers 1995). The Internet adoption behaviour of enterprises in the small business sector is no exception to this: within it, there is typically a mix of rapid and enthusiastic Internet adopters, more cautious or slower Internet adopters, and those who decline to adopt the Internet altogether.

The factors that might influence small businesses' Internet adoption or non-adoption decisions are many and varied. Fillis, Johannson and Wagner (2004), in their proposed conceptual framework for Internet adoption identify factors focussed largely on the characteristics of the CEO. These include the CEO's attitudes to e-business, his/ her approach to change (or resistance to it), his / her attitude to technology, and his / her attitude towards acquiring new skills. They further suggest that financial and resource constraints within a small firm may pose barriers to Internet adoption. Elsewhere, it has been noted that Internet adoption is likely to be industry-sector dependent (see for example Poon and Swatman, 1997; Martin and Matlay, 2001). Teo and Ranganathan (2004) discuss attitudes to risk and how these influence Internet adoption decisions.

Adoption of the Internet is arguably more complex than the adoption of many other innovations. The essence of this complexity lies in the fact that the Internet comprises not simply one single application or technology, but rather a collection of applications (e.g. email, static web site, transactional web site, and so on). A small business' decision to adopt the Internet might entail simply deciding to use email for communication purposes; on the other hand, it might involve transforming the firm into a fully integrated e-business. Research to date suggests that many small firms approach Internet adoption in a series of steps, moving from the adoption of non-complex applications (such as email), through to more complex applications (such as transactional and integrated web sites) as their confidence in, and familiarity with, Internet technology grows (see for example Daniel, Wilson and Myers, 2002). It is increasingly acknowledged that such progression may include 'leapfrogging' of individual applications, rather than being a strict linear progression taking in each application in turn (see for example Rao, Metts and Monge, 2003).

Typical Internet adoption progressions discussed in the literature tend to begin with either email adoption or adoption of a basic informational web site. Some authors have, however, suggested that the first adoption level might entail having a 'basic web presence', by which they mean the company 'places an entry in a web site listing company names' (Chaffey, 2002), but does not have its own web site. The rationale for such an entry, as Chaffey goes on to explain, is essentially to 'make people aware of the existence of a company or its products'.

This 'basic web presence' stage of adoption has, to date, received little attention in empirical studies of Internet adoption by small firms. The present study was set up in order to help address that gap in the research literature by determining the role played by a local community web portal in the Internet adoption decisions and progressions of a number of small firms in a UK village. It is anticipated that the findings of the study will make a timely and relevant contribution to existing understanding of small business Internet adoption decisions and processes.

2. LOCAL COMMUNITY WEB PORTAL: OVERVIEW

The local community web portal under investigation in this study was launched towards the end of the 1990s as part of a wider community initiative in a UK village. This web portal was designed to provide a forum for community groups and charitable organisations located in the village to communicate details of their activities and / or services to the local population. In addition, through the provision of an online business directory, the portal gave businesses based in the village the opportunity to promote their products and / or services. It is this online business directory component of the local community portal that forms the focus of the study discussed in this article.

The online business directory was, it seems, included in the portal without any prior consultation or discussion with local SMEs to ascertain demand for such a facility or to determine specific requirements. It was offered to local SMEs as a marketing and promotional tool, partly in the anticipation that those SMEs that found it fruitful would be prepared to contribute to the ongoing funding and sponsorship of the portal it in the future.

The online business directory is organised thematically, including for example, sections for retail organisations, building and property maintenance enterprises, and private health and welfare providers. Each entry in the directory includes the name of the business, its postal address, other contact details (e.g. e-mail address, where available), a link to the business' own web site (if it has one), and a brief summary of what the enterprise offers by way of products and / or services. No charge is levied for local businesses to have an entry placed in the online business directory. However, local businesses, together with the local council, are encouraged to participate in providing sponsorship to cover the costs of maintaining the local community portal. Costs are kept to a minimum as the portal is managed, maintained and updated by a small team of local unpaid volunteers, with web content being supplied, as appropriate, by local individuals, community organisations and businesses.

Table 1. Small businesses participating in the study

Case	Type	Enterprise size (employees)
Case A	Plumber	4
Case B	Electrician	3
Case C	Manufacturer & distributor of electrical components	7
Case D	Manufacturer & distributor of ceramic tiles	8
Case E	Food importer & retailer	5
Case F	Outdoor/expedition equipment suppliers	8

3. RESEARCH METHOD

The investigation of the small businesses participating in the online business directory component of the local community web portal was undertaken by means of semi-structured interviews with the owner managers. Each of the 77 small businesses listed in the online business directory was contacted by telephone and invited to participate. In this article, the findings of the interviews conducted with six of these small businesses are presented. These six have been selected for discussion because the local community web portal acted as the catalyst for each of them to become Internet adopters. A summary of the participating enterprises is given in Table I below.

Interviews were conducted during 2004-05. In order to provide a framework for the interviews, an interview guide was prepared. The core topics covered in this guide were as follows:

- Background data about the small business and the owner / manager;
- Rationale for not adopting the Internet (prior to involvement with the portal);
- Motivations for portal participation;
- Benefits derived from portal participation;
- Problems encountered with portal participation;
- Impacts of portal participation on further Internet adoption;
- Future plans regarding Internet adoption.

4. SUMMARY OF FINDINGS

The enterprises participating in the study can be categorised as micro businesses, that is to say, they each have under 10 employees (Storey, 1994; Curran and Blackburn, 2001). In this section, the core findings of the study are presented, beginning with those findings relating to the CEOs' decision not to adopt the Internet.

The Non-Adoption Decision

During the interviews with the CEOs of the participating enterprises, a number of reasons were identified regarding why they had, prior to the launch of the local community web portal, decided not to adopt the Internet into their business operations. For example, Cases A and B indicated that the limited (i.e. local) geographical reach of their enterprises represented the dominant barrier to Internet adoption. These two enterprises had no plans to expand their customer bases to a wider catchment area, and were instead focusing on growing their customer base within the immediate locality of the village and surroundings. They believed the Internet to be an important medium for firms covering a wide geographical area, but not for enterprises like theirs which had only a local focus. Another reason discussed for non-adoption was the lack of external pressure to adopt, notably the lack of pressure from customers (highlighted particularly by Case C). Cases D and E felt that their existing methods of doing business, and particularly of marketing their products and / or services, were working well, and so they did not believe that any additional benefit would be gained from Internet adoption. Other reasons discussed in the interviews concerned the perceived risk of Internet adoption, particularly a concern about costs and potential for wasted investments (both financial and otherwise). Organisational readiness was also mentioned (particularly by Case F), with a dominant issue here being the enterprise's perceived lack of the necessary in-house ICT skills to handle Internet adoption.

Motivations for Involvement in the Portal Project

For each of the enterprises participating in the study, the key reason for getting involved in the online business directory component of the community web portal project was that the CEOs believed the portal presented a low-risk opportunity to experiment with having a very basic presence on the World Wide Web. This opportunity enabled them to assess whether any value could be derived from such a presence, and was made more attractive by the fact that it was available at no cost to their enterprises.

Impacts of Portal Participation

Participants in the study were asked to indicate the impacts their involvement in the online business directory component of the local community web portal had made on their Internet adoption decisions and behaviour. Two major types of impacts emerged from this part of the ongoing study, and these can be summarised as follows:

Pathway I: Portal Presence Consolidation

The CEOs of Cases A and B found their involvement with the portal project to have been a positive experience. Specifically, they noted that because the portal was focussed on the village in which their enterprises were based, the client enquiries they received via the portal tended to be from people located in that village. This helped to eliminate the problem of travelling large distances between client visits. It also, they maintained, represented a considerable advantage over existing paper-based directories in which their firms were already listed, as these more traditional resources tended to cover a much wider geographical area and so attracted a number of irrelevant and unsuitable customer enquiries which led to wasted time and effort.

Apart from exploring the possibility of setting up email accounts, these two CEOs indicated that they had no immediate plans for further Internet adoption, such as the creation of their own company web site. They both believed that their portal presence was sufficient for their needs. Particularly in view of its strong local links, which fitted well with their need to maintain a local client base.

With regard to their existing portal presence and the design of the online business directory component of the community web portal, the CEO of Case A commented that he would like to see the scope of the individual directory entries expanded. He specifically suggested that it would be useful if each firm could have capacity within its directory entry to include more detailed information about the firm's products and / or services, as well as more details about the firm itself, in order to be able to promote it better to the inhabitants of the village community.

Pathway II: Portal Presence and Beyond

Cases C, D, E and F indicated that their participation in the local community web portal project had proved a useful means for them to determine whether they could derive any value from Internet adoption. As a result of participating in the online business directory component of the community web site project, each of them believed that the Internet did, despite their earlier reservations, have something to offer them. Consequently, a number of specific actions had been taken by them. For example, Case C, D and E had each employed the services of an external organisation to design and create a basic informational web site for their respective small firms. For Case D, the motivation for this had primarily been to cut the costs of marketing and reduce the time spent on marketing activities (such as trade fairs). For Cases C and E, the motivation was related more to a desire to try a new marketing avenue. When probed about ongoing site maintenance and updating, as well as further development of their web sites beyond their initial design and creation, it was clear that some embryonic development plans were in place, with indications being given that transactional web sites might be considered in the future. In particular, Case D had some quite advanced plans for future development of the company web site.

With regard to responsibility for site development, Case F took a rather different stance from Cases C, D and E. He had seen the value of the online directory and recognised now that some form of web site was likely to be useful to his firm (at the very least, an informational web site). However, he was determined to maintain control of all his business operations and not rely on the services of outside consultants for site design and development. Therefore, he had decided to embark on some IT training courses at a local community educational establishment in order that he might develop and run his own web site.

For Case C, D, E, and F, the local community web portal proved to act as an important starting point for the development of these micro businesses towards becoming more Internet-enabled enterprises.

It is evident from the findings that involvement in the online business directory component of the local community web portal provided a means for each of the small businesses participating in the study to begin to overcome their barriers to Internet adoption and to begin to plot Internet adoption pathways appropriate to the needs of the individual businesses. The implications of these findings are discussed in the next section.

5. CONCLUDING REMARKS AND EMERGING ISSUES

This study sought to explore the role played by a local community web portal on the Internet adoption decisions and behaviour of a number of UK small businesses. The study focussed specifically on small businesses that had not adopted the Internet prior to their involvement with the local community web portal project. The findings of the study highlight the importance of such portals for small businesses. For two of the small businesses participating in the study, the web portal was important in its own right as a marketing and promotional tool for their firm's products and / or services. These two businesses had a local reach, which they wished to preserve. Typical efforts to promote the Internet and electronic commerce focus on opportunities for expanding geographical reach, and consequently these firms had ignored the Internet up until the launch of the community portal. Having participated in the portal project, they deemed the portal to be sufficient for their needs, and did not believe that further Internet adoption was warranted for their enterprises. This suggests that an initial portal presence stage of adoption constitutes an important component of Internet adoption models for small businesses. This finding was further confirmed by investigation of the other four enterprises participating in the study: for these small businesses, the portal represented an important means of setting them on a progressive Internet adoption pathway. Their initial portal presence provided a low-cost and low-risk opportunity to determine what value (if any) could be derived for them from Internet adoption.

In summary then, the key implications of this study are twofold. From a theoretical perspective, the study suggests that models of small business Internet adoption should include an early stage comprising portal presence. From a practitioner perspective, the study suggests that when considering Internet adoption, small businesses should not ignore the portal presence stage of adoption as representing a useful experimental opportunity. Equally, those advising small businesses about Internet adoption should not neglect the portal presence stage as a means of encouraging small businesses into Internet involvement. Local community web portals could be used by small business advisers and government agencies for demonstrating to small firms the value of the Internet even to those firms which traditionally see no need for the Internet in their operations, most particularly those with only a local geographical reach. In particular, there is scope here for local government initiatives to provide community portals, as a means of supporting national governments wider e-business agendas and aspirations.

As indicated at the beginning of this article, the study presented here is ongoing. In a future phase, it will be important to confirm these findings further with a larger sample of small businesses, to test their generalisability, and to provide additional evidence for the small business Internet adoption issues raised in this initial exploratory investigation.

Recognition of Factors Affecting Students Trust in Virtual Universities Using Delphi Method

Mohammad Ali Sarlak, Payame noor University, Arvand Free Zone, 2nd Floor, #143, 29 Alley, Khaled Eslamboli Street, Tehran, Iran; E-mail: sarlak1@yahoo.com

ABSTRACT

At the present time in Islamic republic of Iran the virtual universities are operating beside the Non- virtual universities. The problem that virtual universities now confront is low level of students trust to these universities. The current research tries to recognition factors affecting students trust in Virtual Universities using Delphi Method. This qualitative study examined the opinions of a diverse group of participating experts in the area of information technology and virtual universities. Data were collected through a Delphi methodology during which four rounds of Delphi were administered to determine the Factors affecting students Trust in Virtual Universities.

Keywords: Virtual Universities, Information and Communication Technologies, Trust, Trust Key Factors, Delphi Method, Delphi Rounds.

INTRODUCTION

The emergence of information and communication technologies (ICTs) and their use in training of people has resulted in formation of virtual universities. Most countries with more or less similar goals have acted to establish such universities. Islamic republic of Iran too, as a developing country in Asia has taken such steps. The result of this effort up to time of writing this essay has been designing of ten virtual universities in order to satisfy the educational needs of the great number of people requesting to benefit from higher education in Iran (Sarlak and abedi jafari, 2006). At the present time virtual universities are operating beside the Non-virtual universities. The problem that virtual universities confront is low level of student trust to these universities. The current research tries to recognition factors affecting students trust in Virtual Universities using Delphi Method.

DELPHI METHOD

Delphi method (Delphi Technique) is a group decision-making process that involves circulating questionnaires on a specific problem among group members, sharing the questionnaires results with them, and then continuing to recirculate and refine individual responds until a consensus regarding the problem is reached. The formal steps followed in the Delphi method are:

Step 1- A problem is identified.
Step 2 – Group members are asked to offer solutions to the problem by providing anonymous responses to a carefully designed questionnaire.
Step 3 – Responses of all group members compiled and sent out to all group members.
Step 4 – Individual group members are asked to generate a new individual solution to the problem after they have studied the individual responses of all other group members compiled in step 3.
Step 5 – Steps 3 and 4 are repeated until a consensus problem solution is reached.

The advantages of Delphi method is that ideas can be gathered from group members who are too geographically separated or busy to meet face to face. Its disadvantages are that members are unable to ask questions of one another (Daft, 2006).

The following key characteristics of the Delphi method help the participants to focus on the issues at hand and separate Delphi from other methodologies (www.wikapedia.com):

1. Structuring of information flow
2. Regular feedback
3. Anonymity of the participants

Structuring of Information Flow

The initial contributions from the experts are collected in the form of answers to questionnaires and their comments to these answers. The panel director controls the interactions among the participants by processing the information and filtering out irrelevant content. This avoids the negative effects of face-to-face panel discussions and solves the usual problems of group dynamics.

Regular Feedback

Participants comment on their own forecasts, the responses of others and on the progress of the panel as a whole. At any moment they can revise their earlier statements. While in regular group meetings participants tend to stick to previously stated opinions and often conform too much to group leader, the Delphi method prevents it.

Table 1. Interpretation of Kendall's coefficient amounts

Kendall's Coefficient Amount	interpretation	Assuredness of Arrangement Factors
0.1	Very weak consensus	Not existing
0.3	Weak consensus	Minimal
0.5	Medium consensus	Average
0.7	Strong consensus	High
0.9	Very strong consensus	Very high

Anonymity of the Participants
Usually all participants maintain anonymity. Their identity is not revealed even after the completion of the final report. This stops them from dominating others in the process using their authority or personality, frees them to some extent from their personal biases, minimizes the "bandwagon effect" or "halo effect" allows them to freely express their opinions, encourages open critique and admitting errors by revising earlier judgments.

CONSENSUS CRITERION IN DELPHI METHOD

In this research, Kendall's Coefficient of Concordance was applied to indicate the level of consensus amongst the panel members. Table 1 explains different amounts of this coefficient (Schmidt, 1997).

RESEARCH METHODOLOGY

The present research methodology is shown in figure 1.

Research Problem
The main problem that Iran's virtual universities now confront is low level of student trust to these universities. The study sought to answer the question:

What are the effecting factors on students trust towards virtual universities?

Delphi Panel Members Selection
Delphi method uses a panel of carefully selected experts who answer a series of questionnaires.The notion is that well-informed individuals, calling on their insights and experience, are better equipped to predict the future than theoretical approaches or extrapolation of trends. In current Research 25 Experts in area of information technology and virtual universities were selected as Delphi panel members.

Literature Review
The following section provides an overview of the results of 11 empirical studies on trust in the electronic and virtual entities ranging from the year 1999 to the year 2003 (Grabner-Krauter & Kaluscha, 2003). In table 2, a brief result of eleven stated studies is shown.

According to the studies above and incorporate and eliminate same cases, factors such as Perceived Size, Perceived reputation, Disposition to trust, Social presence, Perceived ease of use, trust in e-service provider, Organizational reputation, perceived risk, Trust in e- services, Trustworthiness Of internet shopping and internet merchant, contextual factors, Perceived privacy, perceived security, satisfaction with past outcomes, Familiarity with firm, structural assurances, Enjoyment, perceived usefulness, Trust in e – retailer, are the Factors Effecting people Trust to electronic and virtual institutions.

DELPHI METHOD IMPLEMENTATION

After panel member's selection, four rounds of Delphi method were performed.

First Round Results
In round one, the questions were structured as fixed-alternative options. However, the panelists were provided the opportunity to introduce 6 new factors that not mentioned in pervious studies. In other words, in first round, the ideas of panelist about importance of trust old factors as well as trust new factors that not mentioned in pervious studies were collected. It must be noted that in the first round of Delphi method, 24 experts from 25 members of panel did participate. A Likert-type scale of 1 to 5 which includes "minimal effect: 1", "little effect: 2", "average effect: 3", "higher effect: 4" and "far higher effect: 5" made it possible to score the final list of specific first round rankings. A total score for each response ranking emerged from the statistical analysis performed.

In table 3, the panelist ideas regarding importance of trust factors mentioned in 11 pervious studies is shown. Table4 includes aspects such as number of answers for each question, average of answers, their benchmark deviation, arrangement and importance of each answer according to the average base answer, and the

Figure 1. Research methodology

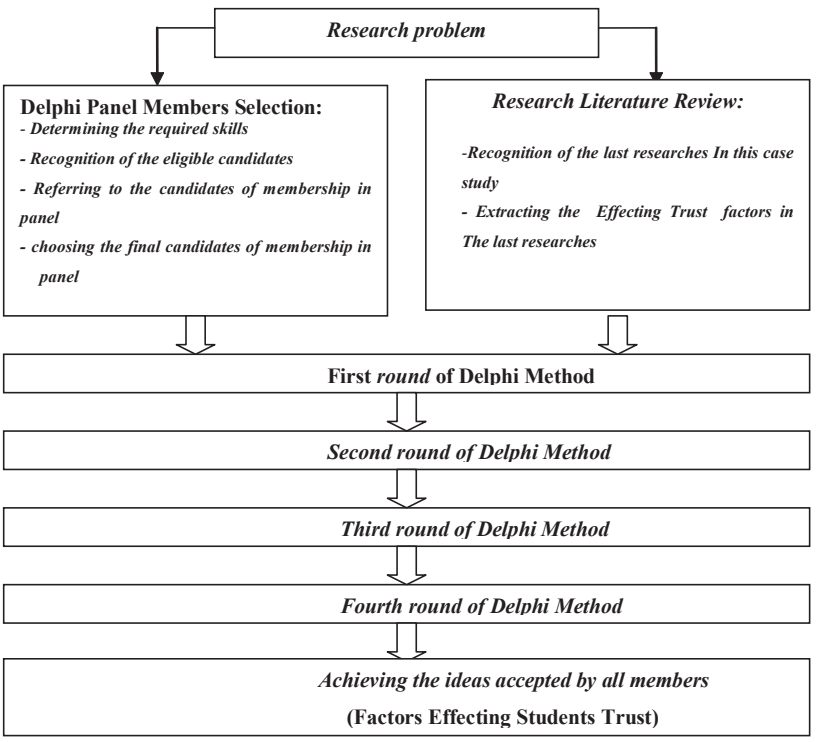

Table 2. The results of literature review

Researcher	Context	Sample Size	Theoretical Framework	Methodology	Analytic Techniques	Trust key Factors
Jarvenpaa et al. (1999, 2000)	Exploring initial trust in an Internet store and cross-cultural investigation, using online book stores and travel sites	184 students (Australia), 198 students (Israel), 115 subjects of an offline panel(Finland)	Exchange theory, balance theory, theories of reasoned action and planned behavior	Experiential survey approach, participants performed four shopping activities at on-line book-stores and on-line travel-sites; offline panel survey; cross-cultural validation of the study	Factor analyses (structural Equation modeling) and regression analyses	Perceived Size , Perceived reputation
Gefen (2000)	Exploring trust in an ecom-merce vendor, using an on-line book-store	217 students (USA)	—	Experiential survey ap-proach, participants performed product search at an on-line bookstore	Confirmatory analysis (structural equation modeling) with LISREL8	Disposition to trust
Gefen and Straub (2000)	Exploring trust in an ecom-merce vendor, using an on-line travel agency	161 students (USA)	Technology acceptance model, theory of rea-soned action	Experiential survey (free simulation experiment), participants performed search for round trip at an on-line travel agency	Confirmatory analysis with PLS, post-hoc analysis with PLS	Social presence, Perceived ease of use, trust in e-ser-vice provider
De Ruyter et al. (2001)	Exploring the antecedents of trust, relative advantage and perceived risk in the adoption of eservices	202 participants (Netherlands)	Adoption process theory, signaling theory	Experimental study, participants were presented with offline role-playing scenarios	ANOVAs (analyses of variance) and MANOVA	Organizational reputation, perceived risk, Trust in e- services
Lee and Turban (2001)	Exploring the antecedents of consumer trust in Internet shopping	405 students (China)	—	Survey	Multiple linear regression	Trustworthiness Of internet shop-ping and internet merchant, contextual factors
Pavlou and Chellappa (2001)	Exploring the antecedents of trust in electronic commerce transactions	276 students (three studies) (USA)	—	Field study with on-line questionnaire, regular survey, experimental study using manipulated Web-sites	Least-squares multiple regression analysis	Perceived privacy, perceived security, satisfaction with past outcomes
Bhattacherjee (2002)	Developing a new scale for measuring trust and testing it for the antecedents of willingness to transact with an ecom-merce company, using a bookstore	147 students, 122 online banking users (USA)	—	Experiential survey after a tour at an online bookstore, on-line survey	Confirmatory factor analyses (structural equation Modeling)	Familiarity with firm
Kim and Prabhakar (2002)	Exploring initial trust in the adoption of on-line banking	266 Internet users (196 used on-line banking) (USA)	Social network theory	On-line survey	Multiple logistic regression analysis	structural assur-ances
Koufaris and Hampton-Sosa (2002)	Exploring the antecedents of initial trust in an online company, using severable-vendors	111 students (USA)	Technology acceptance model, theory of planned behavior	Experiential survey with on-line questionnaire, participants visited an unfamiliar Web-site and performed a product search	Confirmatory factor analyses (structural equation modeling)	, Enjoyment, perceived useful-ness
Pavlou (2003)	Exploring the effect of trust in e-commerce on several factors including consumers' intention to transact	102 students, 155 Internet users (USA)	Theory of planned behavior, theory of reasoned ac-tion, technology acceptance model	Three exploratory surveys (first on predefined on-line book store, second on self-selected familiar on-line vendor, third on on-line companies in general)	Partial least squares regression analysis	Trust in e - retailer

Table 3. First round results: panelist ideas regarding importance of trust factors

Description	Numberof answers	Average of answers	Standard deviation of answers	Order of importance	Percentage of members who have determined the arrangement of factors like the arrangement of group
Perceived Reputation	24	4.88	0.33	1	87.5
Perceived Size	24	4.58	0.7	2	66.7
Previous familiarity with firm	23	3.91	0.83	3	43.4
Reliability of e- services	24	3.88	1.01	4	50
Structural assurance	23	3.83	0.87	5	39.1
Social and cyberspace presence	23	3.78	0.98	6	56.5
Satisfaction with past outcomes	23	3.78	1.1	7	47.8
Perceived risk	22	3.77	0.95	8	36.3
Easy to use	23	3.74	1.07	9	52.1
Perceived quality	24	3.21	1.12	10	70.8
Perceived security	21	2.52	1.05	11	76.1
Perceived privacy	21	2.43	0.9	12	71.4

percentage of members which arranged each factor like arrangement of group have been indicated and shown.

The second part of the questionnaire of Delphi method in first round was assigned to trust influential factors, which didn't exist in the first list. But from the point of view of those who answered, this was an important key factor. In this part, it was requested from each those who were answering to give six successful factors along with brief explanation.. In the Table4, panelist's new ideas regarding the Factors affecting Students Trust in Virtual universities are shown.

Table 4. Panelist's new ideas' regarding the factors effecting students trust to virtual universities

No.	Title	Number of iteration
1	Honesty	1
2	Sense of accepting critics	1
3	Virtue of intention	1
4	Eligibility	1
5	Stability	1
6	Loyalty	1
7	Administrative efficacy	7
8	openness	1
9	Confidentiality	1
10	Accomplishing commitments	1
11	Economical nature of studies	6
12	Predictability	1
13	Suitable environmental conditions for activities of virtual universities	5
14	Fairness& Justice	1
15	Flexibility	1

Second Round Results

In round two, the questions were structured as fixed-alternative options. It must be noted that in the second round of Delphi method, 23 experts from 25 members of panel did participate. All those who answered in this round did participate in the previous round. A Likert-type scale of 1 to 5 which includes "minimal effect: 1", "little effect: 2", "average effect: 3", "higher effect: 4" and "far higher effect: 5" made it possible to score the final list of specific first round rankings.

In second rounds questionnaires, a new list was introduced in which participants in the first round mentioned the influential factors of students' trust towards virtual universities in Iran. In this section, the respondent had to declare his/her opinion on the level of influence of each of them and the students' trust towards the virtual universities in Iran, with choosing from the existing selection. These selections are in the form of LIKRET Scale and contain " very little influence 1", " little influence 2", " average influence 3", " great influence 4", " greater influence 5". In the Table 5 results of the second round of Delphi method contains aspects such as number of answer for each question, average response, deviation of their benchmark, importance of each factor according to the average response and percentage of member who indicated, issued and arranged each factor like a continuous group is shown.

Third Round Results

In round three, the questions were structured as fixed-alternative options. It must be noted that in the third round of Delphi method, 22 experts from 25 members of panel did participate. All those who answered in this round did participate in the previous round. A Likert-type scale of 1 to 5 which includes "minimal effect: 1", "little effect: 2", "average effect: 3", "higher effect: 4" and "far higher effect: 5" made it possible to score the final list of specific first round rankings.

In the first part of the questionnaire of the third round of Delphi method, ensemble of factors were introduced which participants in the first and the second rounds did recognize those as a key and influential factor of students' trust upon the virtual universities in Iran. Only those responses receiving a median score of 4 or higher remained for the third round (Linstone & Turoff, 1975). In table6 the results of third round is shown.

In this round, Kendal's Coefficient of Concordance is 0.711.

Table 5. Second round results

Description	Number of answers	Average of answers	Standard deviation of answers	Order of importance	Percentage of members who have determined the arrangement of factors like the arrangement of group
Universities Administrative efficacy	23	3.43	0.73	1	60.8
Economical nature of studies	22	4.23	0.92	3	50
Suitable environmental conditions for activities of virtual universities	23	4.17	0.65	5	43.4
Accomplishing commitment	23	3.96	0.71	10	43.4
Fairness& Justice	23	3.91	1.20	11	65.2
Flexibility	23	3.87	0.92	12	47.8
Predictability	23	3.87	0.97	13	52.1
openness	23	3.74	0.81	14	39.1
Confidentiality	22	3.73	0.88	15	31.8
Honesty	22	3.64	0.95	16	40.9
Sense of accepting critics	23	3.52	0.95	17	47.8
Virtue of intention	21	3.48	1.03	18	57.1
Eligibility	22	3.32	0.78	19	63.6
Stability	23	2.96	0.77	20	78.2
Loyalty	21	2.90	1.04	21	100

Table 6. Third round results

Description	Number of answers	Average of answers	Standard deviation of answers	Order of importance	Percentage of members who have determined the arrangement of factors like the arrangement of group
Academic perceived Reputation	22	4.86	0.35	1	86.3
Administrative efficacy	22	4.69	0.48	2	68.1
university Perceived Size	21	4.50	0.91	3	69.4
Suitable environmental conditions for activities of virtual universities	22	4.23	0.69	4	52.3
Economical nature of studies	22	4.18	0.66	5	63.6

Fourth Round Results

In round four, the questions were structured as fixed-alternative options. It must be noted that in the fourth round of Delphi method, only 20 experts from 25 members of panel did participate. All those who answered in this round did participate in the previous round. A Likert-type scale of 1 to 5 which includes "minimal effect: 1", "little effect: 2", "average effect: 3", "higher effect: 4" and "far higher effect: 5" made it possible to score the final list of specific first round rankings.

In fourth round questionnaire, a number of factors were introduced which the participants in the first and second rounds did recognize as an influential key factor on student' trust towards virtual universities. The median scores of this factors was 4 or higher("a lot" and "a lot more)". In this round, the respondent must again give his/her opinion by choosing one of the existing items about the influential level of each factor, which influence on students trust towards virtual universities. In table 7 the results of fourth round is shown.

The brief results of Delphi fourth round are shown in Table 8.

In fourth round, Kendal's Coefficient of Concordance is 0.734, compared to the third round coefficient (0.711) was increased up to 2.3 percent.

CONCLUSION

The results of four rounds of Delphi shows that according to the following reasons, consensus amongst the panel members was obtained and can terminate the repetition of rounds:

Table 7. Fourth round results

Description	Number of answers	Average of answers	Standard deviation of answers	Order of importance	Percentage of members who have determined the arrangement of factors like the arrangement of group
Academic perceived Reputation	20	4.88	0.32	1	85.00
Administrative efficacy	20	4.65	0.50	2	65.00
University perceived Size	19	4.62	0.84	3	70.00
Economical nature of studies	20	4.26	0.73	4	63.10
Suitable environmental conditions for activities of virtual universities	20	4.20	0.60	5	70.00

Table 8. The brief results of Delphi fourth round

Description	Arrangement of factors importance based on the fourth round answers
Academic perceived Reputation	1
Administrative efficacy	2
University perceived Size	3
Economical nature of studies	4
Suitable environmental conditions for activities of virtual universities	5

Table 9. The standard deviation of panelist answers

Description	First and second rounds k1=24 , k2=23		Third round k3=22		Forth round k4=20	
	Average	Standard Deviation	Average	Standard Deviation	Average	Standard Deviation
Academic perceived Reputation	4.88	0.33	4.86	0.35	4.88	0.32
Administrative efficacy	4.58	0.70	4.50	0.91	4.52	0.84
University perceived Size	4.43	0.73	4.69	0.48	4.65	0.50
Economical nature of studies	4.23	0.92	4.18	0.66	4.26	0.73
Suitable environmental conditions for activities of virtual universities	4.17	0.65	4.23	0.69	4.20	0.60
Average of Standard Deviations		**0.666**		**0.618**		**0.598**

1. According to Table7, More than 50 Percentage of members have determined the arrangement of factors like the arrangement of group.
2. According to the Table 9, the standard deviation of panelist answers regarding the importance of trust factors has decreased from 0.666 in the first and second round to 0.598 in the fourth round.
3. The Kendal's Coefficient of Concordance for the panelist answers regarding the arrangement and importance of student trust factors in the fourth round is 0.734. With attention to the number of panelist, which is more than 10 people, this level of Kendal's Coefficient is significantly meaningful (Schmitt 1997). The Kendal's Coefficient of Concordance for the arrangement of success factors in the fourth round (0.734) in comparison to the third round (0.711) is just increased up to 0.023. This coefficient or the level of unanimity amongst the panel members did not grow much between two continuous rounds (Schmitt 1997).

STUDY IMPLICATIONS

The study findings indicate that factors effecting students trust in virtual universities are Academic perceived Reputation, Administrative efficacy of virtual university, virtual University perceived Size, Economical nature of Study in virtual university and Suitable environmental conditions for activities of virtual universities**.**

The implication for virtual and on– line universities is that the trust building to these universities requires recognition factors effecting student trust.

ABSTRACT

Collaborative software development spanning national, language and cultural boundaries, raises new challenges and risks, which interfere with the success of software projects even when all traditional risk factors are being controlled. Software project management for such collaborative projects must address these concerns. In this paper, we outline a collaborative risk management approach and recommend policies and management processes for its support.

Keywords: Collaborative risk management, Software project management, Collaborative Risk Management Plan (CRMP), Risk Monitoring, Mitigation and Management (RMMM), inter-organizational collaboration, management contingency processes.

1. INTRODUCTION

The globalization of markets, business relationships and technology has given rise to an increasing number of less centralized, collaborative efforts and partnerships for inter-organizational software development. Collaborative relationships, including third party development, outsourcing, off-shoring, and peer-to-peer alliances, require changes to management, technical and support activities, processes, and policies. In particular the following should be considered: (1) appropriate modifications of internal organizational practices to support collaborative relationships and communication, (2) enhancements and integration of project management activities including risk monitoring, mitigation and management (RMMM), and (3) creation or adaptation of management policies and processes to guide and support the above activities.

The complexity of collaborative software development and the need for extensive cooperation and clear technical and management communication intensify the demand for steady flow of information, enhanced handling of risk, and better coordination among partners. These, together with the need to coordinate management policies between participating organizations, implies that collaborative software project management requires more flexibility, yet simultaneously more thorough process and project monitoring (Mohtashami 2006).

Risk management is an essential project management activity. It deals with anticipating, preventing, and mitigating problems related to software products, projects or processes, including difficulties in personnel, communication, and coordination. Traditional risk management has been defined and practiced with varying success in the context of a single organization and its relationships with clients and subcontractors. Risk management in a collaborative setting becomes more complex and critical as issues such as differences in organizational cultures and goals, software development and documentation practices, intellectual property, security, and management conflicts, become more prominent. Detection and mitigation are also complicated by the distributed nature of the problems, and often by the lack of a central business authority[4].

The problems faced in "traditional" project management settings[5] and these additional Collaborative Software Development (CSD) challenges necessitate a broader and more comprehensive approach to project management in general and to risk management in particular. In response, this paper outlines a collaborative risk management framework in which early and ongoing planning, clear policies, and mature collaboration-aware management contingency processes play a critical role.

The rest of this paper is organized as follows. Section 2 briefly outlines critical attributes of collaborative software development. Section 3 discusses risk management in traditional and collaborative software development. Section 4 highlights new principles for collaborative risk management, and Section 5 offers a layered framework for effective risk management in CSD derived from the attributes of CSD and those principles. Section 6 then introduces important aspects of management contingency processes required to support the framework. Finally, Section 7 briefly discusses related work, and Section 8 provides conclusions and suggests future directions.

2. COLLABORATIVE SOFTWARE DEVELOPMENT

Collaborative software development is of ever increasing importance due to the globalization of business, markets and enterprises, cost reduction and expertise utilization efforts, and more. Some significant differences between traditional software development and CSD are highlighted in Table 1[6]. CSD projects are typically characterized with no clear central authority, multiple teams, locations, and management structures, often crossing national, cultural, and language boundaries. A CSD project requires a common product vision and architecture, extensive idea and knowledge exchange, continuous communication, and active use of consultation, approval and consensus [(Higuera 1994), (Gorton, Motwani 1996), (Crampton 2002), (Niederman, Beise 1999)], although limited by intellectual property, privacy, and security considerations. This in turn mandates a detailed early analysis of technological, business and social issues and early planning for risk management. To accommodate all of the above CSD initiatives have to establish and exploit extensive channels of communication and an integrated operational environment.

While not all collaborative development projects will exhibit all of the characteristics displayed in Table 1, each will share some of these attributes and challenges, and can benefit from the proposed risk management framework, suitably adapted to individual project needs.

3. RISK MANAGEMENT IN TRADITIONAL AND COLLABORATIVE SOFTWARE DEVELOPMENT ENVIRONMENTS

Traditional software engineering practices were developed to support project teams formed by functional sub-teams or cross-functional teams operating under a single business authority. Traditional risk management is defined and used in this context.

Major risk management activities include identification and categorization of risk types, and planning for how to avoid risks where possible, and otherwise how

Table 1. Differences between traditional SD and inter-organizational collaborative SD

Perspective	Traditional SD	Inter-organizational Collaborative SD
Organizational culture		
Stakeholders	Stakeholders standard & well-known	Heterogeneous stakeholders with varying roles
Organizational culture and business practices	Homogeneous organizational culture Single set of business practices	Diverse organizational cultures Multiple sets of business practices
Organizational goal	Single organizational goal	Differing organizational goals
Peer support	Internal support and corporate loyalty	Power struggle among participants, Possible lack of support by some individuals or teams
Trust and awareness	Higher degree of trust More sure of procedures and people	Lower level of trust Higher degree of uncertainty
Management		
Management cohesiveness	Unified management	Autonomous organizations, distributed management Multiple management models
Management structure	Clear management hierarchy	No clear central authority
Communication structure	Management communication follows established business practices	Communication between peers across new channels Requires high level of cooperation & communication
Technical platform & development team		
SD practices	One set of SD methodologies	Multiple heterogeneous systems, SD standards, tools and libraries
Technological Communication	Technical communication across established and trusted channels	High volume of technical communication across new & untrusted channels
SD/technical Resources	Single set of resources	One set of resources per partner plus shared resources
Risk Management plan	Single risk management plan with clear management	Multiple risk management plans No central authority for risk mitigation
Work Practices	Known set of organizational and professional standards	Some variation in organizational and professional standards
Social and cultural issues		
Social Culture	Uniform and known social practices, norms and standards	Heterogeneous social practices, norms, and standards partly unknown to other partners
Language and idiom	A single language and idiom	Multiple languages and idioms
Cultural related work norms	Uniform cultural standard for work performance	Differing standards for work performance

to detect, mitigate and recover from problems as they occur. The key risk management functions are outlined in Table 2 below. The last two functions—Risk Communication and RMMM Review—are Supporting Activities integrated throughout the process.

Most of the activities in Table 2 are broadly discussed and applicable to more traditional as well as to CSD projects. Risk Identification and Analysis function warrants some further discussion as its scope and complexity change in CSD. Traditional risk analysis categorizes each risk along several dimensions, using historical data, industry experience, and organizational theory [(Barki, Rivard, Talbot 2001), (Boehm 1989), (Nidumolu 1996)]. The dimensions reflect the origin of the risk (nature and cause), the definiteness (from near-certain to highly unlikely), the anticipated consequences (degree of risk), and the aspects affected. Following the literature (Pressman 2005) and based on our studies (Mohtashami 2006), risk dimensions have been grouped and summarized as shown in Table 3. The last group–Collaborative Impact–is specific to collaborative software development, and is discussed in more detail below.

Collaborative software development entails a comprehensive change in the software engineering practices, from business case and product vision through development processes to management policies. Cooperation and communication issues are significantly different, both in level and kind. CSD depends on shared understanding of product vision, architecture, and implementation strategy, and hence requires extensive and continues exchange of ideas, design decisions and change information. The distributed nature of CSD teams and the diversity of work practices, cultures and regulations, skills and training levels make cooperation and communication more critical yet simultaneously more challenging. Risk management in such an environment must therefore address these new challenges. Detection and mitigation are complicated by the distributed nature of problems, and by the lack of central authority. More importantly, risk management must guard ongoing relationships between partners, rather than just the success of a single product or project.

This overarching concern for collaboration and ongoing relationships led to the introduction of the two new risk dimensions (and a new dimension group)—the degree to which the effects of a risk extend beyond organizational/team boundaries (contagion), and the degree to which the ongoing relationship between partners may be affected (trust). For our extended classification structure see Table 3.

Collaborative software development affects all aspects of risk management, and introduces changes to the traditional dimensions of Table 3, including:

Table 2. Risk management functions

Risk Management Phases	**Risk Identification and Analysis**	Elicit, identify, and classify (as below) major project and process risks. Process risk data into decision-making information. Determine the values of impact, likelihood, and timeframe [SEI/team].
	Risk Planning	Translate risk information into decisions and actions (both present and future) and implement those actions.
	Risk Avoidance	Where possible, modify to minimize likelihood/impact of particular risk type.
	Risk Monitoring	Track risk indicators and mitigation actions. Anticipate increasing likelihood of particular risks. Detect (impending/actual) occurrence where possible.
	Risk Mitigation	If a problem occurs, take steps to limit its scope and impact. In particular, try to prevent cascade of related problems.
	Risk Management, Recovery and Control	Once problem has occurred, take steps to get project/ product back on track. Correct for deviations from the planned risk actions.
Support Activities	**Risk Communication**	Provide information and feedback internal and external to the project on the risk activities, current risks, and emerging risks.
	RMMM Review	Review and update risk management strategies, plans, and activities, based on current and past feedback and environmental changes.

- **Form, View, and Source:** Additional perspectives, reflecting the CSD specifics (e.g., language barriers) must be considered; also resources to mitigate associated problems must be allocated
- **Level, Impact, and Scope:** Change in likelihood and effect can be observed—certain kinds of risks and effects become more likely and significant; others less significant.
- **Source, Driver, and Type**: Risks are likely to arise at interfaces between collaborating partners, rather than entirely within a single organization, and these new problems must be identified and classified.
- **Definiteness**: An advantage in collaboration-aware risk management is that some previously predictable risks become known risks, and can be avoided. Likewise, some previously unpredictable/unknown risks become predictable and a specific strategy for addressing them can be developed (Mohtashami, et al. 2006a).

The new dimensions must also be considered carefully:

- **Contagion and risk confinement**: Many risks, even within a single organization, may have wider effects. A risk that cannot be confined to a single organization must be addressed collaboratively.

Table 3. Dimensions for classifying risk

	Dimension Group	Dimension	Key question	Categories
Classical Dimensions	Nature and cause of risk	Form	What factor is stressed?	Resource, technical, business, environmental, platform
		View	In which aspect of the process will the problem occur?	Project[1], technical/product[2], business[3]
		Source	Which activities or constraints causes the problem?	Product definition, business impact/environment, process definition, development environment, innovation, staff skills/training, legal/regulatory
	Definiteness	Definiteness	Known in advance?	Known, predictable, unpredictable, unknowable
	Degree of risk	Level	How likely to arise?	Estimated probability range
		Impact	How serious if occurs?	Negligible to significant to catastrophic
		Scope	How much affected?	Isolated component to subsystem to entire system
	Location of effects	Driver	What business aspects are most affected?	Market, performance, support environment, cost, schedule, deployment, relationships
		Type	How does it manifest?	Functional specification/ expectation Performance or other extra-functional requirements Schedule, budget, process compliance
New Dimension	Collaborative impact	Contagion	Where are the effects?	Intra-organizational, interface, global
		Trust	How is ongoing cooperation/trust affected?	Unaffected, recoverable, damaged, unrecoverable

- **Trust**: Once collaboration has deteriorated, it is difficult or impossible to restore a good working relationship. Each risk must be examined for its potential effects on existing relationships.

In addition, collaborative software development further stresses the support activities in Table 2 that is, Risk Communication and Risk Planning, and RMMM Review. Appropriate planning, risk management strategy, and well-structured comprehensive risk plans are needed to address each of the above problems effectively. A collaboration-aware risk management plan thus becomes a critical binding and facilitation tool supporting collaboration and project management activities. Monitoring, mitigation, and recovery are specialized for an individual risk or a *risk class*, depending on the probability and potential effects of that risk (Table 3). Serious risks with high likelihood receive a dedicated specialized "*risk control plan"* (SPMN 2005) for monitoring, mitigation, and control, while less likely, less catastrophic, or more generic groups of similar risks can be handled together (Mohtashami, Marlowe, Kirova, Deek 2006a).

4. PRINCIPLES OF COLLABORATIVE RISK MANAGEMENT

Successful collaboration requires collaboration-aware management, intra- and inter-organizationally, and collaboration-aware risk management, which must extend traditional risk management [(Higuera1994), (Higuera1994a)] with means for handling the specifics of collaborative software development efforts—although standard risks, and existing management policies and practices, must still be addressed and considered.

The importance of communication, both generally and as specifically related to risk management, has long been recognized: "In the continuing application of the risk management process to large software development programs, the most dramatic effect has been in opening the communication channels for dialogues within organizations relating to risk and risk management" (Higuera 1994a). Collaborative risk management extends this need across institutional boundaries, calling for new management approaches to inter-organizational information exchange and to risk management activities themselves. This has an additional benefit in establishing trust and handling cultural and language problems. (Cultural familiarity and trust are consistently identified among the top four important success factors for collaboration (Powell, Piccoli, Ives 2004).) In CSD, project management and its risk management function must be supplemented and enhanced with new communication protocols, standards, policies and strategy, in order to:

- Help with establishment and growth of trust
- Evaluate the suitability and adequacy of management and IT processes for support of technical and social aspects of inter-organizational communication
- Address organizational, social, cultural, linguistic, and legal/regulatory differences
- Manage or at least monitor disagreements over power and responsibility among organizations
- Decrease conflict and define norms
- Let information flow effortlessly, precisely, and in a timely way
- Select metrics and tools for monitoring and measuring the success of collaborative communication and risk management

These considerations have led us to extend existing risk management principles with new principles for CSD, see (Mohtashami et al. 2006a). They augment the traditional and team-based risk management principles (SEI 2005) with collaboration-aware guidelines focused on:

- Building effective collaboration through establishment of trust, cultural sensitivity, and open communication channels, and
- Institutionalization of effective management processes, including aligned management support and responsibility for risk management–building trust, shared product vision, and consensus among partners.

Collaborative risk management provides support for addressing risk in CSD, including risks triggered by CSD-specific or intensified risk drivers and sources: cultural differences (both social and organizational), the quality of trust, communication, and IT support, and difficulties with project and risk management themselves. These principles form the basis for the layered risk-management framework sketched in the next section.

5. A LAYERED APPROACH TO RISK MANAGEMENT FOR CSD

An effective Risk Management framework for CSD should be based on collaborative-risk management principles, discussed above, and provide clear definition of decisions, actions, and responsibilities related to risk management functions. A key means in implementing the framework is a collaboration-aware RM plan, which must (1) address traditional intra-organization risk identification and management in collaborating agencies, (2) handle risks identified as introduced or intensified by CSD, including single-organization risks, resulting from interfaces, communication and collaboration, (3) handle collaborative risks not well-managed intra-organizationally, (4) drive incremental modification of policies, processes, and activities as needed, and (5) support negotiation to resolve conflicts and to assign responsibilities for risk management, while still addressing traditional concerns.

In (Mohtashami, et al. 2006a), we introduced a layered structure partitioning risk classes with minimal overlap into those best monitored and managed internally, and those requiring inter-organizational, collaborative oversight. The resulting layered Collaborative Risk Management Plan (CRMP) has three components:

1. Modified and enhanced individual, intra-organizational risk management plans incorporating collaborative risks.
2. A shared inter-organizational plan to address risks likely to be missed inside individual organizations, or which affect multiple organizations in different ways, or seriously affect cooperation and collaboration.
3. Establishment of a structure for administration and management of the shared plan, and (perhaps separately) for conflict resolution, to mediate/arbitrate conflicting organizational interests.

Thus, our collaborative RM framework has three major components: modified internal plans—one per partner, a shared inter-organizational plan (with both traditional and collaboration-specific features), and a structure for mediation and resolution. This layered approach can only be successful if accompanied by effective project management practices, including a collaboration-aware RMMM Review process.

It is not sufficient, however, to simply change the risk management functions. Changes in management contingency processes and policies are necessary, to support collaborative risk management, to reduce risk, and otherwise to conduct effective collaboration-aware management and development.

6. CONTINGENCY PROCESSES FOR CSD

To support CSD and collaborative RM effectively, project management depends on management contingency processes and policies, constituting a collaboration-aware management contingency profile (MCP). The MCP, the continuous, iterative, and interactive communication, particularly across organizational boundaries, and the creation of shared knowledge and awareness are the keys to effective collaborative project management. In addition to the typical objectives of a management contingency profile [(Piccoli, Ives 2000), (Powell, et al. 2004)], a collaboration-aware MCP must guide and support management efforts in addressing the CSD challenges discussed earlier.

CSD projects require more management involvement, plus management processes that permit a higher level of dynamic behavior than may be customary (Piccoli, et al. 2000). Moreover, the nature of the development process, and the required level of formality, must be determined with care. Although high-risk complex (but non-safety-critical) projects ordinarily benefit from a more dynamic, less formal management profile, Cohen (Cohen, Levinthal 1990) and Piccoli (Piccoli, et al. 2000) suggest that management intervention may nonetheless be beneficial. Barki (Barki et al. 2001) in fact argues that formal planning is important, particularly when cost management is at least as important as system quality. Not only management profile, but also the development process must allow for some flexibility, particularly at boundaries between collaborators.

The major risks, and thus the major focus of management processes and policies, fall into four primary categories: (1) technical risks, (2) risks arising from com-

munication, trust, and culture, (3) integration and planning risks, and finally (4) risks arising from risk management itself (risk reflection).

Technical risks–tools, product and process: Technical risks arise from difficulties with development platforms and tools, challenges with process coordination and design methodology alignment, or from problems with product compatibility, functionality and dependability (performance, reliability, scalability, etc.). These risks are exacerbated by strong process interdependence or complexity, by high rates of changes in requirements or development environment, and by lack of availability or clarity of information (Barki, et al. 2001).

Problems such as poor inter-institutional planning, or lack of effective inter-institutional risk management strategy, further increase these risks. CSD is also vulnerable to management resistance to cross-institutional technical integration, or to unification of protocols and communication modes/standards, and also to poorly specified inter-institutional technical interfaces.

Inter-organizational and inter-cultural communication and trust: The key factors in this category—trust, cultural differences and miscommunication—are mutually reinforcing. Our studies (Mohtashami 2006) indicate that, with risk management and management contingency profile, these factors contribute significantly to CSD product and process success.

Toffolon (Toffolon, Dakhili 2000) emphasizes the importance of management of communication and coordination for effective collaborative software development. Social communication at both management and technical levels is also important in building familiarity, trust, and employee morale. Policies for promoting communication and trust are discussed in (Mohtashami et al. 2006a).

Cross-organizational integration and planning: Cross-organizational integration of functions, as well as platform and information, should be defined and managed from both organizational and software development perspectives. Organizational integration deals with linking resources across physical boundaries, so that scattered organizations and teams can share and exchange information seamlessly. Two important aspects are (1) sharing and broadcasting information, and (2) collective decision making, planning and scheduling. Software development integration relies on compatibility of tools and methodology. Finally, technical platform integration is important primarily insofar as it supports these activities.

In general, CSD calls for formal planning activities, management intervention, and integration [(Barki et al 2001), (Bogia, Tolone, Kaplan, de la Tribouille 1993)]. Because of the scope, impact and contagion of many risk factors, formal planning must nonetheless support dynamic management of collaborative activities. Therefore, CSD requires a project management profile that supports high levels of planning, adaptability and integration of management approaches. Formal control effectively contains the complexity of CSD, while adaptability controls unexpected variation—the challenge is remaining flexible enough to adapt to CSD's chaotic nature.

Risk reflection: The increased complexity of risk identification, classification, and management, as well as complexities introduced by cooperative decision-making for risk mitigation, may lead to additional complications. New risks can arise from bad, inappropriate, or overly constrictive RMMM plans and policies. While this paper does not address the issue further, RMMM planning, review and evolution is an essential requirement for a successful collaborative project management.

The contingency processes, required to address the above added complexity and challenges, include behavioral control management policy (rules and procedures), collaborative management policies, and management of differences in institutional practices; risk management overlaps each of these categories. These aspects of management profile are responsible for initiating or effectively controlling the following activities: management of organizational behavior, management of processes, policies for integration, policies for IT support, and policies for risk identification and management.

Management of organizational behavior deals primarily with social and technical training, and with establishment of a cooperative culture. It includes creation of inter-organizational trust, recognition of and adaptation to cultural differences, establishment of training programs, and demonstration of senior management support for the collaborative effort.

Management of processes includes establishment of a proper fit between project risk and management profile, enhancing task clarity (clear specification of global requirements, partner responsibilities, and interfaces), and establishment of communication protocols and standards, as well as tool and development process standardization.

Policies for IT support need to respond to the high uncertainty of CSD. They should address provision of tools to support and manage non-routine activities (such as event-driven group conferencing). They must deal with increased needs for security and integrity, as well as protection of privacy and intellectual property. In addition, they must support tool and process integration, and sharing of a wide variety of software and management artifacts.

Policies related to risk identification and management require definition and institutionalization of a collaborative RM framework, institutionalization of collaboration-aware risk identification and analysis, monitoring of risk arising from inter-organizational communication and interfaces, and cross-organizational sharing of risk-related information, events, and changes. These activities are essential to CSD, and are discussed in detail in (Mohtashami et al. 2006a).

7. RELATED WORK

Related work falls primarily into the following areas: risk management and software project management, distributed software development (SD) and software teams, collaborative software development and cultural differences and sensitivity.

Extended discussions of project management, traditional risk management, and RMMM planning, can be found, for example, in [(Pressman 2005), (Sommerville 2006)], in publications focused on software project management [(Tsui 2004), (Royce 1998)], or in the publications of the Software Engineering Institute (SEI 2005) and the Project Management Institutes (PMI 2006). Ranky (Ranky 2006) offers a practical introduction to collaborative project management, and Fang (Fang, Nunamaker, Romano, Briggs 2003) examines the problems associated with traditional project management approaches given business globalization and information technology advances, and highlights the benefits of collaborative project management.

Distributed software development and its risk management are addressed in [(Barki et al. 2001), (Gotterbarn 2005), (Higuera 1994), (Lee, DeLone, Espinosa 2006)]. Good analysis of virtual teams management and collaborative software development issues can be found in [(Chopra, Meindl 2001), (Beranek, Broder, Romano, Reinig 2005), (Cantu 1997)]. Selection of software process models for distributed and collaborative software development is also a subject of ongoing discussion (see for example (Ramesh, **Cao, Mohan., Xu** 2006)).

Risk management for distributed SD, particularly focused on customer-supplier relationships and team-work (Team RM) is addressed in [(Beranek, et al. 2005), (Higuera 1994), (Higuera 1994a), (SEI 2005)]. The Team RM approach emphasizes collaboration, teamwork, as well as negotiation and use of shared team risk management plans. However, it does not consider such issues as lack of a single authoritative decision-making entity or cultural differences, which are specific to CSD and are addressed in the collaborative risk management framework presented in this paper.

8. CONCLUSIONS, IMPLICATIONS AND FUTURE WORK

We have introduced an enhancement of current risk management practices and policies to handle complications arising in large, multi-organizational/multi-enterprise, collaborative software development projects.

In support of collaborative project management and collaborative RM, in particular, we have introduced the concept of a layered risk management plan as a critical means of collaborative risk management. The effective execution of such a layered plan requires appropriate management and mediation policies and processes. Understanding the role these play in CSD, and augmenting the CRMPs with effective collaboration-aware management contingency profiles, further adds the dynamic control and flexibility needed for successful CSD projects.

As a preliminary study, this work leaves many open questions, which we (and we hope others) will explore in the future. Important areas of future work include:

- Further exploration of risk classification and risk management issues for collaborative software development (Mohtashami et al. 2006a).
- Exploration of approaches to develop specific recommendations for management contingency processes and policies
- Investigation of strategies for reconciling mitigation actions taken by different authorities (e.g., in multi-company CSD projects) and the changes needed in MCPs to support these strategies

- Consideration of the impact of Software Development Lifecycle process models on the success of CSD projects and their management
- Investigation of the interactions between collaborative risk management, management contingency processes and policies, and overall software project management activities.

The range of open questions, and the difficulty in collecting solid statistics on the experience of on-going collaborative efforts, makes full validation of this proposal challenging. Nonetheless, we expect that practitioners will be able to use the preliminary results and ideas presented in this and prior papers in developing more effective, collaboration-aware risk management plans and management contingency policies for their specific efforts, resulting in improved CSD project management practices.

ENDNOTES

1. Project includes process, resources (including personnel), communication, and systems analysis.
2. Product requirements and technical environment.
3. Corporate health, business case, senior management support, etc.
4. Clear project management structure does not necessarily entail authority to make process changes across organizational boundaries required to reduce or handle risk. Such changes depend on organizational decisions and require the involvement and support of business management, whose span of control is restricted by the organizational boundaries.
5. The failure rates of contemporary projects (Standish 2004-2005), indicate problems even with in-house project development despite the existence of developmental methodologies, frameworks and risk management practices. Given such problems – with time, cost, functionality and quality—development in a dispersed or virtual setting is even more challenging.
6. The comparison is based on extremes – a simple case of traditional software development is compared with a complex CSD effort – in order to identify as many potential areas of new or intensified risk as possible. There is a spectrum from "fully local" to "fully distributed/fully collaborative" efforts, and many of the factors we identify affect single-enterprise projects in the middle of this spectrum.

Pull and Push Business Functions in an Experimental Text Processing System

ABSTRACT

We observe an unprecedented growth in the volume of unstructured data. Active use of business information contained in large volumes of unstructured data is becoming one of the biggest challenges now. In this paper, we examine an automated mechanism for pull and push functions for business documents. The pull function allows users to access the information contained in documents. The push function alerts users to the presence of information contained in new documents which is consistent or inconsistent with the background information. To implement these functions, documents are annotated using XML tags, and then, XML query processing techniques are used. Our approach is to use a limited context defined by an ontology or set of well established background documents for the guidance in identification and annotation of basic concepts and relationships in new business documents. The described text mining system is a highly modular and parametric, giving the human a tool to adjust quickly in a dynamically changing environment. The indirect goal of this paper is to provide a foundation for a new self-tunable text mining system that can adjust to new environment by itself.

1. INTRODUCTION

The abundance of business documents makes it increasingly likely that the precise information the user needs or wants is available. At the same time, however, retrieval of this information is much more challenging. Fortunately, this trend has been accompanied by unprecedented progress in technologies for content-based access to text documents. Using these technologies is crucial for achieving competitive advantage for our businesses.

Current information extraction techniques are either keyword/category based, such as Google, AltaVista [1] or Yahoo [8, 13], or structure dependent such as Rapper [10] and XWrap [9]. Our approach to text mining is to use the combination of qualitative and quantitative techniques for identification of relevant concepts and relationships. The selected concepts and relationships are extracted in the process guided by ontologies and by background documents for the domain of interest.

In this paper we address the problem of simultaneous text mining of two distinct groups of documents, background documents and new documents, as shown in Fig.1. The documents will be also referred as text corpora. We examine an automated mechanism for pull and push functions for business documents. The pull function allows users to access the information contained in the documents. The push function alerts users to the presence of information contained in new documents which is consistent or inconsistent with the background information. To implement these functions, documents are annotated using XML tags, and then, XML query processing techniques are used.

The described system is highly modular and parametric giving the human a tool to adjust quickly to text mining in a dynamically changing environment. The indirect goal of this paper is to provide a foundation for a new self-tunable text mining system that can adjust to new environment by itself.

Our approach assumes multi-stage document processing. These stages include ontology processing, background document annotations, queries for ontology and background documents, new document annotations, comparative queries for new and background documents, and generation of alerts when the information in new documents does not match information the background documents.

XML was chosen as a language for our annotations [4, 12] for several reasons: (1) XML provides a simple, standard, self-describing way of storing and exchanging text and data, (2) XML-based retrieval systems are relatively simple and can retrieve XML information quickly without linguistic analysis of text documents during the query time, (3) XML notation is very convenient as an internal representation because it allows for incremental annotations that represent explicitly the various phases of information extraction (knowledge discovery process), (4) XML can provide many annotation types and XML-based query systems can retrieve only those types of information that are requested, (5) XML annotations can be inserted/deleted/modified in the future responding to dynamically changing needs, (6) XML annotated text is open to further processing beyond annotations, and (7) XML texts can be integrated with other structured data.

The results of our project represent an integration of various text processing technologies and have immediate application for pull and push functions as shown in Fig.1. These results generalize beyond our application and will be important wherever concept-based information retrieval through XML-capable search engines or query systems is desirable.

The "Pull" functional requirement is the ability of the system to answer queries for new or background documents. The "Push" functional requirement needs more discussion. In the business world we often have to deal with new events described in new documents that need to be reflected directly in the "knowledge base" of our corporation. The text processing system can help us identify such documents to be included in the set of background documents. We refer to such function of text processing system as a push function.

The system described in this report is being designed to support military medical documents; however, such a system, because of its general nature, can be successfully used in other business environments. It provides integrated concept-based access and awareness of unstructured data. The system is capable of querying unstructured data sources and continuous monitoring of event patterns in new documents.

2. FLEXIBLE ARCHITECTURE OF EXPERIMENTAL TEXT PROCESSING SYSTEM

Our experimental text processing system is flexible in the sense that it can be constructed from various available modules. Each module is highly parametric allowing the human to adjust parameters for the existing needs.

The architecture of our experimental text processing system is shown in Fig 2. It is constructed from relatively independent modules: Ontology Processing Module, Text Annotation Module, and Pull and Push Modules.

Figure 1. An overview of pull and push functions

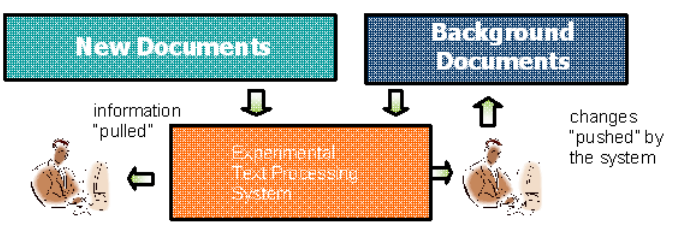

Figure 2. An overview of a flexible system architecture of an experimental text processing system

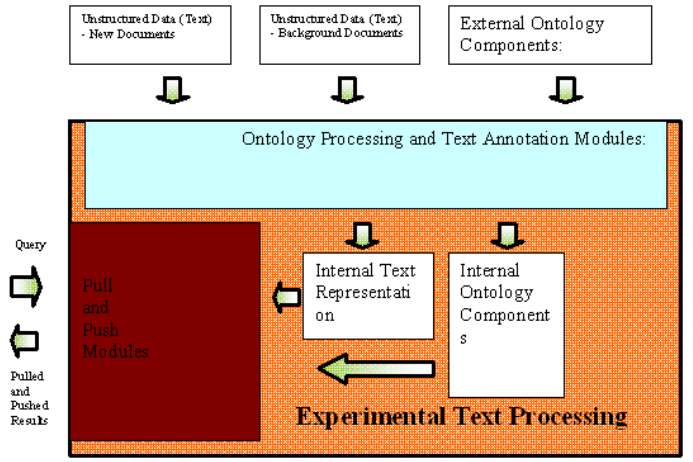

Text annotation can involve concepts hierarchy of concepts and concepts relationships. For each annotation level we can apply various statistical processing types, for example frequencies of words, direct collocations, and distant collocations. For each pair of annotation level and processing type, we can use various ontology components: simple and compound concepts, relationships, word stems, synonyms, antonyms, stop words, stop modifiers, etc. Not all combinations of system parameter values are important to consider. Some combinations of parameter values are useful in specific situations only, and some combinations of parameter values can result in either contradicting functionality of the modules.

Based on internal representation, the query can be issued or alerts generated. The query can be:(a) keyword search, (b) hierarchy and relationship search, or (c) comparative.

The internal text annotation is done using XML. XML allows us to annotate important concepts, hierarchy of concepts and relationships between them. These annotations are done using tags ***<concept>*** and ***<relationship>*** and various tag properties e.g. ***type, source,*** etc.

Document processing is done in several stages. In the first stage, the internal ontology is created by using components of external ontology (if available) and statistical processing of primary background but also new documents as shown in Fig. 3. In the second stage, relevant concepts, hierarchy of concepts and relationships between concepts are identified in background documents and annotated using XML as shown in Fig.4. In the third stage, the query is processed to verify the consistency of knowledge contained in ontology and background documents. In the fourth stage, the relevant concepts, hierarchy of concepts and relationships between concepts are identified in new documents and annotated using XML as shown in Fig.5. In the fifth stage, the alerts are generated if the consistency of knowledge contained in new documents and background documents is violated.

The flexibility of the architecture of the text processing system is of crucial importance for success in business automatic information extraction from text. So

Figure 3. Stage 1of text processing

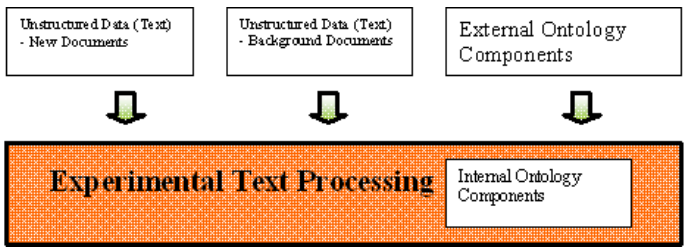

Figure 4. Stages 2 and 3 of text processing

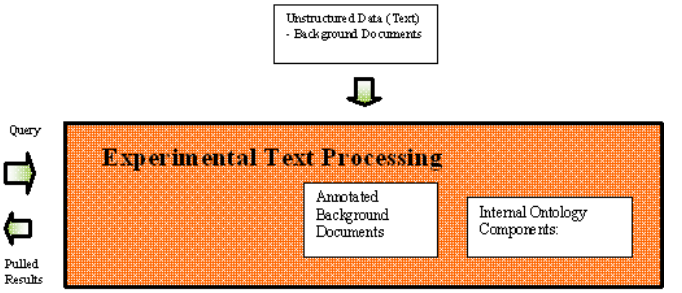

Figure 5. Stages 4 and 5 of text processing

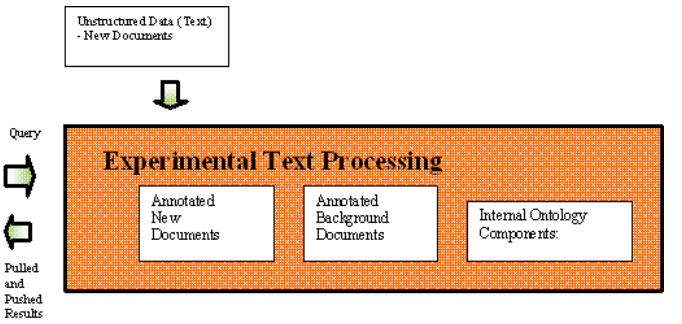


far there are no black box solutions that are good for text processing for a broad range of styles of business documents. Our experience suggests that in order to succeed in a complex business environment with a text processing system it is necessary to use an iterative approach in terms of both domain and complexity of analysis to tailor the system to business needs. We suggest proceeding concurrently with experiments in these two directions.

3. ONTOLOGY PROCESSING

Whenever we humans process an individual document (text) we view it in a broad context of facts and rules acquired throughout our life. Let us refer to this context as a background knowledge. The background knowledge can be in various forms. It can be in the form of background documents that we remember or studied and can recall quickly. In can be also in the form of more digested information such as dictionaries. Let us refer to "digested" knowledge as an ontology. In general, the ontology can contain not only the list of concepts as in simple dictionary but also explicit concept hierarchy and relationships between concepts.

Our understanding of a new document very much depends on the "scope" of our background knowledge. Obviously, there are various scopes of background knowledge and "quality" of background knowledge can be different for different areas. Let us, in this section, concentrate on a "digested" knowledge – ontology. When we refer to an ontology, we can mean a general ontology or more often, an ontology for the specific area of interest e.g. medical, technical.

One of the measures of ontology "quality" is ontology completeness levels. To compute a concept completeness level for an ontology with respect to a set of documents, we first compute the number of all concepts in ontology that are found in a set of documents and divide it by a number of all concepts in a set of documents. Similarly, we can define concept hierarchy completeness level and relationship completeness level. By completeness level, we can mean overall completeness level or completeness level with respect to a subset of documents or even a completeness level with respect to single document or its fragment. This is an important measure how "good" ontology is for the specific set of documents. When several distinct sets are processed e.g. new and background documents the completeness measure for each subset may need to be calculated.

3.1 Concepts in Ontology

There are different requirement for ontologies depending on text recognition levels. For the lexical text recognition level, the ontology should contain the list of concepts, their possible representations and the methods to identify them. Specifically, an ontology for lexical recognition can contain: (a) list of concepts represented by primary names, alternative names, stem words, and synonyms, (b) list of stop words, and if applicable (c) list of misspellings. For the list of concepts, we assume that each concept is represented by a unique primary name, e.g. "**organization",** that we call *name*. Each concept *name* is associated with a list of alternative names, e.g. "**organizations,"** to allow for alternative forms, singular and plural, etc. The list of alternative words can be also generated from the stem words, e.g. assuming a stem word "**organization,"** the alternative name "**organizations"** can be generated by appending the "s" to the stem word. In general, both generated and stored alternative words can be used. Each concept has a list of synonyms, e.g. "**corporation"** for the concept "**organization."** Each concept can have a list of misspelled words, e.g. "**corporation."** The list of misspelling words can be also generated from the alternative names by using some rule e.g. removing one character, replacing one letter by another letter. In general, both generated and stored misspelled words can be used.

3.2 Creating Ontology with Concepts

Internal ontology can be built from a variety of external resources. In the medical area, there are many existing external ontologies e.g. Mesh, UMLS, SNOWMED. Some of the external ontologies are very large e.g. UMLS, so that they need to be appropriately processed (restricted in size) to be useful for text recognition purposes. Sometimes, for a narrow area of interest, the internal ontology can be created from the specific set of documents (text corpora). This process is called ontology extraction from text corpora. For our project text corpora can contain both background documents and new documents.

Ontology extraction is based on finding statistically important words in documents. The words in the document are also referred as tokens. It is easy to see that ontology extraction, guided only by global statistical computations, may not be reliable, especially when we deal with a small number of documents or groups of documents with significantly different presentation features. Therefore, statistical techniques should take into consideration a diversity of documents. In summary, when an ontology is not available, there is a potential increase in the number of generated errors, in terms of false positives, but human interaction can make this process much more reliable.

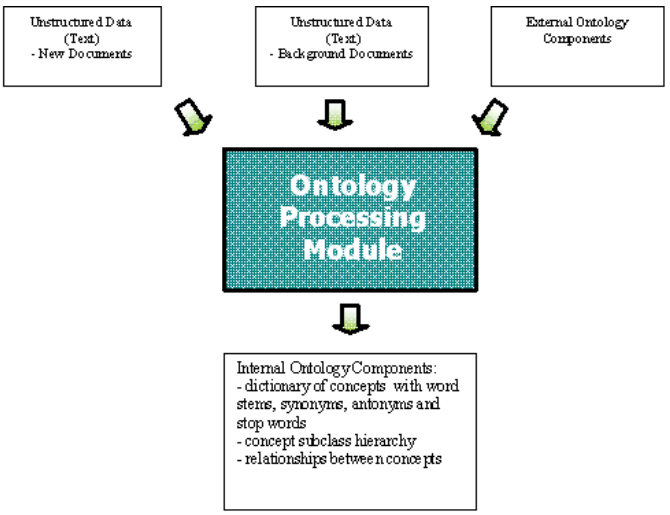
In general, the external ontology components can be used together with internally created ontology for lexical text recognition. More specifically, the optimal use of ontology might require appropriate combining of external and internal components so that they will provide both effective and efficient support for the text recognition.

Let us discuss briefly the process of creating the internal ontology from the documents (text corpora) as shown in Fig. 6. As we discussed before, there is need to construct such internal ontology when the external ontology does not exist for a given area, or when external ontology needs to be enhanced by knowledge from the given area (an external ontology has a low completeness level with respect to text corpora). The process of constructing internal ontology is multi-phased. First, it involves finding the frequency of all tokens in text corpora. Second, we eliminate some tokens of no semantic value e.g. "a", "the", and create a stop list from them. Third, we choose mainly nouns that can be potentially relevant concepts. Next, we need to group tokens representing the same concept together and assign to the group a unique identifier i.e. typically *primary name*. Last, we choose some frequency threshold to eliminate irrelevant concepts. An enhanced version of this multi-phase process will also involve computing frequencies for collocated tokens.

Let us also discuss some specifics about combining of external and internal components so that they will provide both effective and efficient support of text recognition. We can enhance the multi-phase process of creating internal ontology, described above, by investigating frequency of co-occurrence of external ontology concepts with text corpora concepts to identify new concepts with multi-component names.

In summary, the ontology processing module creates internal ontology components from modified external ontologies and from components obtained by ontology extraction process from text corpora. Actually, this process is much more complicated than described above. Let us mention the aspect of ontology

Figure 6. Ontology processing



self-modification. After the internal ontology is used for text recognition, it should self-adjust automatically e.g. re-arrange, expand and possibly shrink. This self-adjusting mechanism, together with zooming techniques, will allow ontology to respond to dynamically changing text environment.

At this stage let us assume that the example internal ontology is available and it contains the following concepts: "**organization,"** "**disease**," "**rate**," and "**study**." The concept "**organizations,**" has an alternative name "**organizations**" and the synonym "**corporation."** Similarly, alternative name for **"rate"** is **"rates,"** and for **"injury"** is **"injuries"** etc**.**

3.3 Multi-Component, Compound, and Derived Concepts

So far we were discussing simple concepts whose primary name or its equivalent textual representations contain one word. There are also concepts whose primary name or one of its equivalent textual representations contain several words (components). We will refer to such concepts as *multi-component* concepts. If at least one of the components corresponds to another concept, then the *multi-component* concept becomes *compound* concept. If all components of *multi-component* concept match some other ontology concepts we will call it a *derived* concept.

Let us consider a sample ontology from Section 3.2. If is enhanced by a new concept, "injury rate," that concept would be classified as *compound* since "rate" is already a valid concept. If we add another new concept "injury," then the *compound* concept "injury rate" would become also *derived*. It is important to notice that as ontology changes the properties of concepts can also change. In a well designed system all changes need to propagate appropriately.

The *multi-component* concepts can be stored and processed in the ontology as simple concepts. The *compound* and *derived* concepts can be also stored as *simple* concepts but then some additional ontology processing is necessary to discover relationships between then. Alternative notations are described in the next subsections.

3.4 Hierarchy of Concepts

Multi-component concepts are candidates for building traditional type hierarchy for concepts. For example, "injury rate" is a subtype of the concept, "rate." This classification can be explicitly specified in the ontology or can be computed.

In general, there are also other candidates for building traditional type hierarchy e.g. "flu" is a subtype of "disease." Such a hierarchy can not be simply discovered by collocation of words but need to be extracted using more sophisticated analysis.

3.5 Relationships Between Concepts

An ontology can also contain relationships between concepts. The relationship can be unique for some concepts but very often they are classified into some classes called relationship types. For example, let us consider two important types of relationships: "***is-a,***" and "***has.***" The first relationship type represents an alternative notation for a hierarchy of concepts as described in the previous section. In our example instead of concept hierarchy can be described by the following relationships: "injury rate ***is_a*** rate" and "flu ***is_a*** disease." The second relationship type "***has***" is used to describe a strong association between concepts including ownership, main activity or components. Let us assume that for our ontology example, we have a relationship "CASS ***has*** study." From the existing relationships new concepts and relationships can be derived. They will be also called derived concepts or derived relationships. From the "***has***" relationship, we can create a derived concept such as "CASS study". There are also derived relationships obtained by so called inheritance operation.

4. TEXT ANNOTATION

Typical documents include a wide variety of concepts from physical objects to events and states of affairs. The text recognition process will extract this information. The first step in identifying and annotating all important information in documents is to recognize basic concepts. This process can be extended to identify and annotate the concept hierarchy and relationships between concepts as shown in Fig. 7. This process establishes the mapping between words in the text, also referred as tokens, and concepts (i.e. ontology concepts), concept hierarchies, and relationships. Once a word is mapped to the ontology concept, it is called a text corpora concept or simply text concept. The same applies to concept hierarchy and relationships between concepts. There are many ways to describe this mapping. One very convenient, technique is to annotate such words inside the text e.g. using appropriate XML tags. This annotation technique is used in our paper.

4.1 Annotation of Concepts Using Ontology

The concept text annotation sub-module is based on lexical analysis of text, i.e. it scans the text, extracts each word, and annotates the words matching the concepts in ontology with appropriate tags. The annotated words become text concepts. In the initial phase, a set of text concepts is simply a subset of ontology concepts.

Let us consider an example of a sample fragment of a document:

Our CASS organization is involved in a variety of studies. Disease rates are CASS main study.

The system can process the text with concepts properly annotated shown below. The lines without tags are not annotated. The characters in bold constitute the original text. The annotated text fragment is shown in Fig. 8.

Figure 7. Text annotation

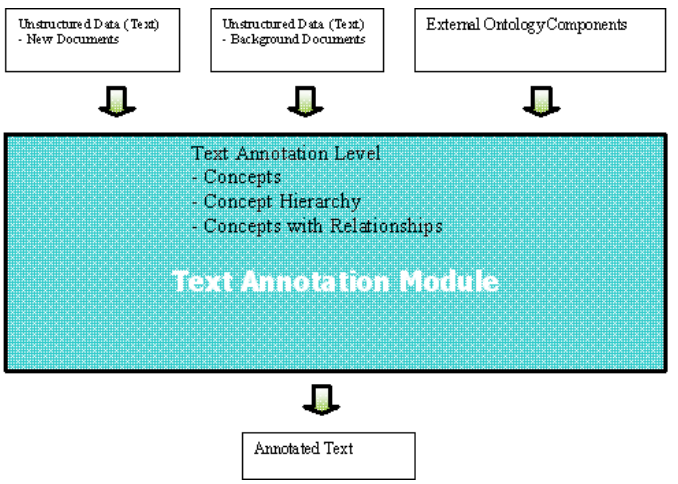


Figure 8. Document fragment with concepts annotated

```
1.  Our CASS
2.   <concept name="organization" >Organization </concept>
3.  is involved in a variety of
4.  <concept name="study"> studies </concept>
5.  .
6.  <concept name=" disease" > Disease </concept>
7.  <concept name=" rate" > rates </concept>
8.  are CASS main
9.  < concept name="study""> studies </concept>
10. .
```

Let us discuss annotations in Fig. 4 resulting from lexical text recognition process. In this process all words (tokens) matching an ontology concept are annotated as "concept" as shown in line 2, 4, 6, 7, 9 and 11. We assume that ontology contains all information necessary for an extended matching sub-process. Such a sub-process needs to take into consideration synonyms, misspellings, and alternative forms (e.g. singular and plural) resulting in a unique assignment of a word (token) to the concept. In actual implementation, the concept primary name can be a word stem but for the readability purposes we will use a meaningful name.

4.2 Annotation of Compound Concepts Using Statistical Computations

In the case the when ontology completeness level is low the process described in Section 4.1 can be augmented by finding words (tokens) with high frequency and treating them as concepts (text concepts) even though they are not present in ontology. We want include these concepts especially if they are collocated with the discovered ontology concepts.

The text annotation process for compound concepts can be performed together or after annotation of simple concepts in text. In the currently described process, all non-matching words are considered. First, we treat all existing ontology concepts in the text as a "hook." A word in the text with statistically supported collocations with the ontology concept is grouped together with the ontology concept itself to establish a new compound concept as shown in line 2-3 of Fig. 9. Such compound concepts are annotated as "compound". It is important to note that statistically supported collocations can return false positives in the sense that some unneeded components are attached to the beginning or to the end of the concept from the ontology.

In this process we want to make a more precise determination about concepts including compound concepts. We explicitly specify each concept property with the values: "simple," "compound," or "derived." Also, we can annotate the concepts by stating their source: they can be located in "ontology," or only in the "text" as shown in Fig. 9.

In our example, the concepts in text are annotated as the "simple" concept as shown in line 3 and 4 and as the "compound" concept as shown in line 2. The source of concept can be "ontology" as shown in line 2 and 4, and "text" as shown in line 3.

4.3 Annotation of Concept Hierarchy Using Ontology

In the case when ontology contains concept hierarchy, that information can be used in the annotation process of a document. Let us assume that "CASS organization" is recorded in the ontology as a sub-concept of "organization." Then the process of annotation can include this information as shown in Fig. 10.

In our example, the concept "organization" has the property *hierarchy* with the value "super-concept" indicating that "CASS organization" is recorded in ontology as a sub-concept of "organization."

Figure 9. Annotations of compound concepts

```
1.  Our
2.  <concept name="CASS organization" type=" compound "  source= " text ">

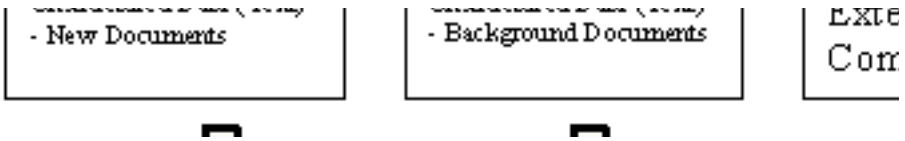
4.          < concept name=" organization"  type="simple" source= " ontology " >organization </concept></concept>
```

Figure 10. Annotations of concept hierarchy



4.4 Annotation of Concept Hierarchy Using Statistical Computation

If an ontology with concept hierarchy is available, then concept hierarchies in documents can be identified and matched with ontology concept hierarchy. The problem is that many hierarchies in the document can be very complicated and they are only partially reflected in the ontology. There are different methods to deal with this problem. One method is to use syntactical text recognition by applying Parts of Speech (POS) analysis. If the document is written using strictly grammatical use POS analysis can be very helpful. In the document, however, that is not well structured, there may be an excessive number of modifiers since the parser could mistakenly cluster some other words together. In any case, POS can give us only some guidance but not precise results. Therefore, statistical computation (quantitative analysis) is required to obtain the relevant hierarchies. Typically, such annotation process is based on elimination rather than expansion. Statistically supported collocations are investigated as they serve the purpose of eliminating some irrelevant noun modifiers. In our case, for example, the modifier "our" is eliminated but the modifier "main" is included in the concept hierarchy as shown in Fig. 11.

4.5 Annotation of Relationships Based on Ontology

If an ontology with concept relationships is available, then the relationships can be identified and matched with ontology relationships. This process can be improved if a phrase structure parser is also available. Structure rules can refer directly to concept annotations. Let us discuss one of the rules: if the verb is 'is,' 'are,' etc., then name is 'is_a'; if the verb is 'announces,' 'has introduced,' etc. then name = 'has'; if it is 'includes,' exhibits,', etc., then type = 'capability,' and so on. In our example the verb 'are' is classified as 'is_a' type.

A relationship in the document can relate to the ontology in numerous ways giving several patterns for relationship identification. These patterns correspond to different sets of matching rules. There are many of these patterns. Let us discuss some of them. The first pattern is when the exact relationship type and concepts already exist in the ontology. For our example, the first pattern would be applicable if the relationship "disease rate ***is_a*** main study" exists in ontology. Another pattern would identify relationship type in the document if only one concept of relationship type can be matched.

4.6 Annotation of Relationships Based on Statistical Computations

There are many relationships used in different contexts and, therefore, the strict ontology structure may not be sufficient to retrieve the relevant relationships. The statistical matching rules can be used in such situations. If the statistical rule indicates a close association of concepts, then the relationship between the concepts is identified and annotated as generic "association" as shown in Fig. 13.

5. PULL FUNCTION

It is important to notice that our system allows the user to get the information directly without referring to any text. Practically, it means that we have several modes for results: text referring results and data returning results. The latter mode works like data retrieval in a database system. The user can specify a concept or a concept with relationships. Our system can return several types of results: text, text fragment(s) containing the concept or frequency of occurrence of the concept in the text.

Figure 11. Another example of annotations of concept hierarchy

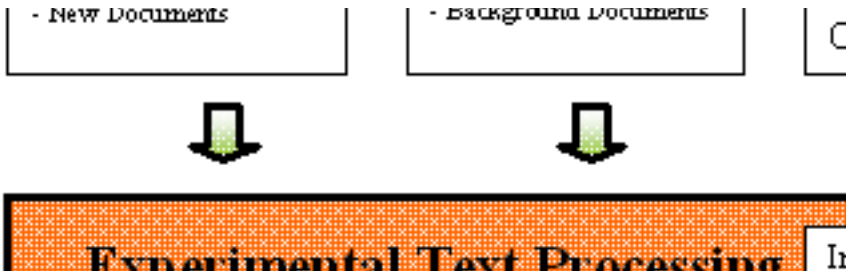


Figure 12. Annotation of relationships

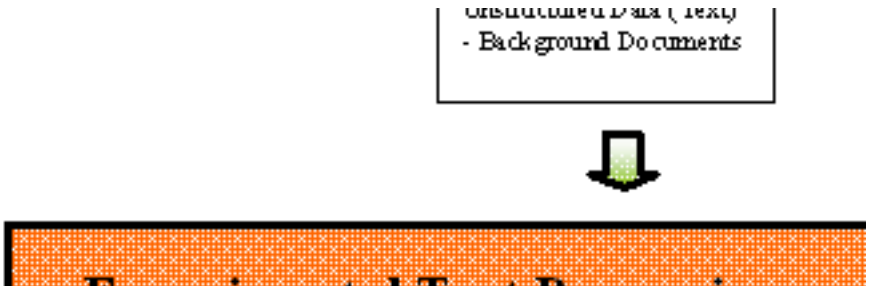

Figure 13. Document with relationships annotated

1. **Our**
2. <concept name="CASS organization" type=" compound " source= " ontology ">
3. < concept name="CASS" type="simple" source=" text"> > **CASS** </concept>
4. < concept name=" organization" type="simple" source= " ontology " hierarchy=" super-concept" >**Organization** </concept></concept>
5. < relationship name="association" type="simple" source="text" > **is involved in a variety of** </ relationship>
6. < concept name="study" source="ontology" type="simple"" source= " ontology " > **studies** </concept>
7. **.**

5.1 Keyword Search

Most of the existing text retrieval system have this feature implemented. Here the queries are based on simple keywords or any logical combinations using OR, AND, and NOT operators. Typically the documents are ranked based on these keywords and the most relevant documents are returned. Some text processing system also contain a text mining module that can cluster documents based on concepts.

5.2 Queries Involving Concept Hierarchy and Concept Relationships

Concept hierarchy and relationship annotations allow the user to issue specific data queries e.g. "Give me the names for the projects done by CASS" for a set of documents. For our example, the result would be "disease rates". A document fragment also could be displayed to show this information. Some statistical ranking and clustering can be improved when text is annotated with concept hierarchies and relationships.

6. PUSH FUNCTION

After the new document is processed, there are three types of information that can be "pushed" by the system: (a) "new document is consistent with background document," (b) "new document is inconsistent with background document," or (c) "new document is disjointed with the background document".

For the military medical documents, the most important situation is to identify the case when "new document is inconsistent with background document." Therefore, our experimental system should trigger some action, in this case, e.g.: alert subject matter expert, about the situation who make the makes the final decision such as review and updates the background document. For other business applications, when "new document disjoint with the background document," it may also be important to trigger some action.

The push function requires comparison of documents: the new document with background documents. The background documents indirectly provide the list of concepts of interest. There are many levels of operation for the Push module. At the first level, it compares concepts. This is very similar to the pull function operated at the simplest mode.

6.1 Push Function Based on Concepts

There are many levels of operation for the Push module. At the first level, it compares concepts. This is very similar to the pull function operated at the simplest mode. In this case, our system returns several types of results, e.g. pairs of text fragment(s) containing the same concept or pairs of frequencies of occurrence of the concept in the new and background text. It is possible to add keyword restriction if necessary. There is a need to experiment with the system and to tune it to satisfy the requirements. For example, it is possible by specifying the general constraints between concept frequency matrices (including collocated concept matrices). In general, however, that level may be appropriate to find disjointed documents but may be insufficient for "similar" documents. It typically would cluster together both "consistent" and "inconsistent" documents. Therefore, for our purpose, we need to include concept hierarchy and/or relationships in document comparison.

6.2 Push Function Based on Hierarchies and Relationships

Let us consider the following document fragment as a new document.

Battle injury (BI) rates are the main topic of CASS studies.

Figure 14. Pull and push module

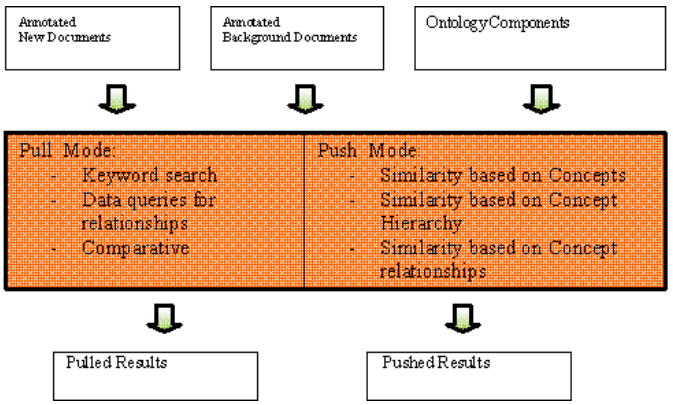

Figure 15. New document with concepts and relationships annotated

1. < concept name=" BI rate" type="compound" source="text" >
2. < concept name="BI" " type="compound" source="text" >
3. < concept name=" battle" " type="simple" source="text" > **Battle** </concept>
4. < concept name=" injury" " type="simple" source="ontology" " hierarchy=" super-concept" > **injury** </concept> **(BI)** </concept>
5. < concept name=" rate" " type="simple" source="ontology" " hierarchy=" super-concept" > **rates** </concept></concept>
6. < relationship name="association" type="simple" source="text" > **are the main topic of** </ relationship>
7. <concept name="CASS study" type=" compound " source= " ontology ">
8. < concept name="CASS" type="simple" source=" text"> > **CASS** </concept>
9. < concept name=" study" type="simple" source= " ontology " hierarchy=" super-concept" > **studies** </concept></concept>**.**

Let us also assume that the previous text fragment given in Section 4.1 constitutes the background document. The provided above new document fragment can be processed by Text Annotation Module resulting in the document annotations as shown in Fig. 15.

Comparison of the concept hierarchies in new and background document would reveal the semantic differences much more precisely. We can automatically discover inconsistencies between the background information that claims that "CASS main study is disease rates" and the new document that claims that "CASS main study is battle injury rate" (please note the role of word *main* in the analysis).

There are many parameters that can be specified for hierarchy comparison functions that are used in the Push Module. For example, a comparison function can take into account the inheritance of relationships, e.g. if the background document contains "CASS main study is injury rates," then the new document "CASS main study is battle injury rates," would be accepted as "consistent" with the background document. The same comparison function can perform matching at various hierarchy levels.

In addition, hierarchy comparison functions or relationship comparison function can use equivalence transformation between "is_a" relationship and "super-concept."

In general, the use of a combination of matching functions may be required. Then we either need to define their priority, or establish some global measure of "inconsistency" based on measures of individual functions.

7. SUMMARY

The goal of this project is to provide an experimental processing system for unstructured data in the dynamically changing environment of new and background documents. The project allows for automatic generation of XML annotations and their use in retrieval systems. Our approach in this project is to use a combination of qualitative and quantitative technique of identification of basic concepts and relationships with respect to the domain of interest represented by a well established ontology. The immediate use of these techniques are for pull and push business functions.

ABSTRACT

There has been a revolution in marketing, especially using new media, such as blogs. The purpose of this study is to determine how different types of information on the Internet can affect customers' motivation to take a vacation in a particular place. The analysis suggests that information provided in blogs can help customers experience a feeling about a particular place and influence their choice of vacation. The analysis also confirms two moderating relationships: (1) customers who browse travel information from blogs will have stronger purchase intentions than if they browse information about travel packages provide by tour operators; and (2) customers who browse travel information in blogs experience stronger feelings than if they browse information in travel packages.

1. INTRODUCTION

E-commerce web-site owners hope customers will become locked into on-line shopping malls [1][4]. Unfortunately, they do not really understand customers' needs, especially psychological factors, like their feelings, thoughts, and senses, or how customers choose an unfamiliar product or service. Traditional marketing research assumes that a consumer acts as a rational decision-maker. According to this concept, if consumers buy products or services from suppliers, they focus on the products' functions and effects that maximize their value. E-commerce researchers also follow this assumption, and their research results suggest that the owners of web sites should provide many kinds of products and services for customers.

The 1998-2000 marketing research priorities of the Marketing Science Institute set the goal of understanding customer experience as one of two important research topics [32]. Reber [22] defines experience, as any feelings that people have while they encounter events and activities in their daily lives. Holbrook & Hirschman [19] consider consumption as a primarily subjective state of consciousness with various symbolic meanings, hedonic responses, and esthetic criteria. Consumption experience, for example, could be behavior like pursuing fantasies and feelings and having fun. Experience is considered as a service and companies can create or even customize experiences to meet customers' individual needs. Although many studies in the literature focus on the real world, few focus on the virtual world.

In the list of 2006~2008 marketing research priorities [31], measurement of the impact of new media is one of top tier topics. A blog is the most famous new medium on the Web. Clyde [10] defines a blog as a web page that has brief and chronologically arranged items of information. Since a blog often combines text, photographs, videos and/or audio, and links to other blogs, it is a fluid and dynamic medium. Vuorinen [27] lists five features of a blog: it is written fairly frequently; it is free form and brief; it follows a reverse-chronological order; it is personal; and it links to other blogs. To date, very little research has been conducted on blogs. In fact, most of the literature consists of reports and essays on concepts and user behavior, and does not address the use of blogs for business purposes.

Schmitt [26] suggested that there has been a revolution in marketing, which he calls experiential marketing. According to Schmitt, we must change our deeply ingrained marketing ideas in favor of providing valuable experiences for customers. Experiential Marketing can satisfy customers' needs and desires and encourage them to become immersed in on-line shopping malls.

Can a blog be for an experiential web application? According to Gartner Research's [30] report about blog users' behavior, 52% of users are able to express themselves creatively, 37% can document personal experiences or share them with others, and 29% can motivate other people to action. Thus, a blog can be as an experiential application.

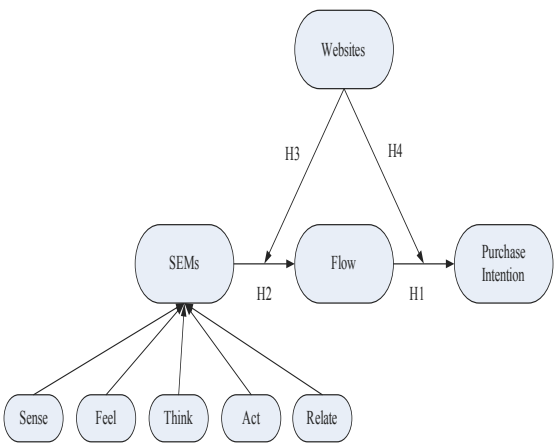
The blog has become an important experience for users for two reasons. First, an increasing number of people are writing blogs [24]. The Hong Kong Blogger Survey Report [18] found that bloggers want to express and even share their feelings and creativeness, so blogs are rich in content. Second, since blogs allow users to explain their feelings willingly and freely, people are attracted to this new medium.

In this paper, our purpose to investigate how blogs can be used as experiential web applications. We select two travel web sites: Realtravel in the U.S and ezTravel in Taiwan. The main difference between the web sites is that Realtravel has a lot of travel blogs written by tourists, whereas ezTravel only provides on-line ticketing and travel packages.

2. CONCEPTUAL FRAMEWORK AND HYPOTHESIS DEVELOPMENT

Based on experiential marketing and consumer behavior literature, we develop a conceptual framework of experiential marketing, as shown in Figure 1. We believe

Figure 1. Our research model



that consumer purchase intentions with respect to travel services are guided by a flow experience, such that users become immersed in playfulness and involvement, which triggers a new exploratory experience [17].

2.1. Flow Theory

According to Flow Theory, flow is a process of optimal experiences that are intrinsically enjoyable [11][7]. Flow is a temporary and subjective experience, and it is also the reason that people want to participate in particular activities [11].

Webster et al.'s [28] study of human-computer interaction established that flow is a subjective experience of human-computer interaction that is characterized by playfulness and exploratory behavior. When people interact with computers, they feel playful and involved, which triggers a new exploratory experience for them.

Hoffman & Novak [17] proposed a model of network navigation for hypermedia that involves two kinds of browsing experience: goal-directed behavior and experiential behavior. When users' behavior is goal-directed, they have a specific goal and make an optimal decision about browsing for information. On the other hand, when users' behavior is experiential, they focus on processes, not on a specific goal. According to Hoffman & Novak's model, four consequences flow from network navigation, namely, increased learning, increased perceived behavioral control, increased exploratory and participatory behavior, and positive subjective experiences. Hoffman & Novak also posited that increased exploration can derive better information, especially when making purchasing decisions. We believe that the same concept can be applied to the use of blogs because they motivate people to search for more information. Thus, we propose the following hypothesis:

H1: Flow experiences positively influence purchase intentions.

2.2. Experiential Marketing

Pine and Gilmore [25] advanced the concept of experience economy, and divided the progression of economic value into four stages: commodities, goods, services, and experience. Experience economy means that enterprises must regard service as a stage and create an attractive consumption situation that immerses the consumer in a consumption experience. Traditional marketing and business concepts offer hardly any guidance on how to capitalize on the emerging experiential economy, because such concepts were developed in response to the industrial age, not today's information, branding, and communications revolution [26].

Schmitt [26] takes issue with the features and benefits approach of traditional marketing. In the traditional model, consumers are thought to go through a considered decision-making process, where each feature or characteristic of a particular product or service is seen to convey certain benefits, and these are all assessed by the potential purchaser (either consciously or unconsciously). However, for Schmitt, this is far too limited a way of viewing purchase decisions, with its excessive emphasis on the rational and logical elements of the decision, and not enough (or any) on the emotional and irrational aspects involved in the purchase. The alternative framework that Schmitt proposes is based on two elements: strategic experience modules (SEMs), which are different types of experiences, and ExPros (short for experience producers), which are the various agencies that deliver these experiences. Experiential marketing is the discipline of creating products and services that consider all elements of this framework.

Since blogs aggregate people who have similar interests, blogging portals give readers the opportunity to interact with other bloggers [27]. Schmitt [26] identifies five different types of experience, which we use to describe the features of blogging behavior. Here, we briefly consider Schmitt's five SEMs in terms of blogging.

(1) SENSE: Sense experiences help motivate potential consumers and immediately creating a sense of value in their minds. In addition to the sense of sight aroused by travel pictures, bloggers can also set regional music to touch off the readers' sense of hearing.
(2) FEEL: When trying to influence the purchase intentions of consumers, their feelings toward a product should not be ignored. By considering the abundant pictures usually shown in travel blogs and the accompanying literary compositions, it is possible to understand the feelings of the travelers more easily.
(3) THINK: Thinking experiences can persuade consumers to engage in creative thinking, which may prompt them to re-evaluate a product. The mechanisms of blogs, such as blog scroll, backtracking, and comments, help users search for more innovative and diversified travel information outside their own small, closed social network [13][14][5].
(4) ACT: Active experiences focus on changing the long-term behavior and habits of consumers toward a particular product. When influenced by other bloggers' travel ideas, an individual may decide he/she wants to travel to the same place.
(5) RELATE: People tend to relate to a broader social or cultural context. In reality, social ties in blogs are shown by hyperlinks, which can help an individual get in touch with numerous travelers and join an extensive community of like-minded people who are interested in traveling.

Furthermore, Hoffman & Novak [17] suggested that focused attention is one of the four primary antecedents that motivate users so that the flow experience can occur. Schmitt's five types of experience can motivate users to focus their attention. Therefore, we advance the following hypothesis:

H2: The experiences defined by Schmitt's SEMs positively influence flow experiences.

2.3. The Difference Between Travel Websites

We consider two travel websites, Realtravel and ezTravel. Realtravel is actually a blog website that provides information to people who wish to travel, so people can compose some travel journals, share experiences, communicate via blogs with people who have common interests all over the world, and even form a community. On the strength of tourist blogs in Realtravel, people can search for more information about traveling, including the descriptions of places and photographs. In addition, Realtravel offers information about tickets, hotels, and transportation so that a consumer can arrange a trip that correlates with a blog immediately.

EzTravel is the leading on-line travel service provider in Taiwan with 1.7 million members. The company offers package trips, including group trips, backpacker trips, and train, bus and flight bookings. Consumers can just browse the webpage of EzTravel when they want to plan a trip.

It is claimed that the presentation format of information display boards affects decision-making [6][23]. A recent study by Widing and Talarzyk [29] tested these theories in the on-line environment. The results support their hypotheses that the information display capabilities of these new services alter users' decision-making processes. Given this conclusion, we put forward the following hypotheses:

H3: The relationship between Schmitt's SEMs and flow experience is stronger in travel blogs than in travel packages.

H4: The relationship between flow experience and purchase intention is stronger in travel blogs than in travel packages.

3. METHODOLOGY

We designed our study to gather information about two kinds of travel decisions. Our focus is on students who want to arrange a package for their graduation trip. In this section, we describe sample and data collection, and instrument development.

3.1. Sample & Data Collection

The study was conducted at a large public university in Taiwan. Students of two classes volunteered to choose a journey for their graduation trip. They chose a trip to Phuket, and browsed for information about the trip in two ways: one was a travel package provided by ezTravel and the other was Realtravel, which contained blogs provided by people who had traveled to Phuket. To avoid browsing bias, we provided three travel blogs and one trip, which were selected by six graduate students. After the students had browsed the travel websites, they answered two questionnaires on the differences between the two travel website providers. A total of 52 surveys were distributed, and we received 50 useable responses (96 percent).

3.2. Variable Measurement

The dependent variable of intention to purchase has been employed in previous TAM research (e.g., [12]) and in marketing studies of user behavior (e.g., [3]).

Each experience under Schmitt's SEMs was developed and validated as part of this research. Schmitt's five experiential activities were consistent with perceived intrinsic motivation [26]. We adopt the Flow scale developed by Luna et al. [20] and Hoffman & Novak [17]. To ensure that the English and Chinese versions of the questionnaires were consistent in meaning, all the scales used in this study were examined by experts to ensure that the items were comprehensible and unambivalent to Chinese respondents. The respondents assessed all the items via a 7-point scale ranging from strongly disagree to strongly agree.

4. DATA ANALYSIS AND RESULTS

We used PLS (partial least squares), which is considered an appropriate analytical approach, to (1) model latent constructs as either formative or reflective, and (2) assess the psychometric properties of the constructs (the measurement model) within a theoretical context (the structural model) [21]. Unlike other structural equation modeling techniques, PLS uses a relatively lean sample size to validate a model [8][9]. A sample size of 30 would be a reasonable starting point for the three-construct model [9]. Following Anderson and Gerbing [2] and Hair et al. [16], the models were tested with a two-stage structural equation model. First, we conducted Confirmatory Factor Analysis (CFA) to assess the constructs' validity in terms of convergent and discriminant validity. Second, we performed structural equation model analysis to test the research hypotheses empirically.

4.1. Measurement Model

The model contains one second-order variable (SEMs). We also created a second-order construct using the factor scores from the first-order construct.

With respect to the quality of the measurement model for the full sample, three types of validity were assessed: content validity, convergent validity, and discriminant validity. We assessed the convergent validity by examining the average variance extracted (AVE), since each construct has an AVE of at least 0.7 [8]. Finally, we verified the discriminant validity by examining the value of the square root of the AVE to determine whether it was consistently greater than the off-diagonal correlations [15]. As shown in Table 1, the composite reliability values range from 0.928 to 0.972, which are above the acceptability value; the average variance extracted by our measure ranges from 0.722 to 0.896, which is also above the acceptability value of convergent validity; and the square root of the average variance extracted for each construct is greater than the off-diagonal correlations. All our multi-item constructs meet these criteria, thus confirming the constructs' validity.

4.2. Assessing the Structural Model

To test the moderating effect of the type of travel website, we used three structural models in the PLS-Graph: the full sample, the sub-sample of the Realtravel website, and the sup-sample of the ezTravel website. We also tested for differences between all three models by using a bootstrapping technique to derive the path estimates and t-value, which were used to test the hypotheses. The results of the structural model test are shown in Table 2.

Hypothesis 1 suggests that flow experiences positively influence purchase intention. From the structural equation modeling results and standardized path coefficient (SPC) of 0.67 ($p < 0.001$), this contention is strongly supported. Our analysis of the results also shows that SEMs positively influence flow experience (SPC = 0.734, $p<0.001$), providing support for H2. Hypotheses 3 and 4 propose that travel blogs and travel packages moderate the relationship between flow experience and purchase intention and between SEMs and flow experience. The result shows that the standardized path coefficient of the Realtravel website is greater than that of the ezTravel website, thus proving that proving that travel blogs can strengthen the intention to purchase.

5. DISCUSSION AND CONCLUSION

The objectives of the study are twofold: (1) to verify that customers' experiences strengthen purchase intentions; and (2) to examine two types of travel website to determine how they affect users' purchase intentions.

Our results suggest that users who obtain information about travel packages from blogs may have positive experiences so that they become immersed in the flow scenario. This results in increased purchase intentions, no matter whether the sample is a full sample or one of the two sub-samples, which is the same as the result based on information search theory. In the travel industry, travel websites should provide more information and combine more types of media about trips, which would increase customers' intention to purchase.

The analysis also confirms two moderating relationships: (1) customers who browse travel information in blogs will have stronger purchase intentions than if they browse travel packages provided by tour operator; and (2) customers who browse travel information in blogs have deeper experiences than those who browse travel packages. Therefore, customers who browse information in blogs have more experiences and stronger purchase intentions.

Our study has two potential limitations. First, the sampling was limited to students of an undergraduate class. Hence, there exists the possibility of sampling bias. Second, the sample sizes were about 50, which may be considered small; however, as noted earlier, PLS uses a sample size of 30 as a reasonable starting point [9].

In summary, blogs represent a fundamentally different on-line environment for marketing activities compared to travel package websites. The results of this study suggests that consumers can obtain richer information from blogs. The opportunity for customers to browse for information on the Internet can be realized in numerous ways and website owners should therefore provide new media to lock in their customers.

ACKNOWLEDGMENT

This research was supported by the e-Application Innovation Four-year Project (3/4) of Institute for Information Industry and sponsored by MOEA , ROC.

(IT) Management in the Organization of the Developing Countries

Azim Sahatimehr, Bonab Islamic Azad University, Iran; E-mail: sahatimehr_a@yahoo.com

1. ABSTRACT

At the present century (IT) plays major role in the international development programs. Those countries which have been well educated or specialized in this subject have taken the best advantage in every aspect of today's human kind activities. Information is the lifeblood of any system. It is the essential ingredient for a successful business. if the resources of the information are not reliable or the mismanagement of the technological information exists in the organization, it is clear that the destructive decisions will lead the organization towards the bankruptcy or dark end .in most of the developing countries the organizational activities are not goal oriented and communication system, and also circulation of the information are not well organized. In this paper difficulties encountered whit the management of (IT) in the developing countries are discussed and for effective use of (IT) in this countries constructive suggestions are made.

Keywords: Management – Technology – E. Collaboration – Development.

2. (IT) STRATEGY IN DEVELOPING COUNTRIES:

At the present time it can be noticed that, from telecommunications to super computers, from semiconductors to multimedia technology is probably the single most important factor driving the evolution global competition. Where are developing countries in this global market? The debate about the competitive need of these countries technological growth – and local government's role in improving it is increasingly becoming the focus of the debate of formulating technology policy. This debate centers on the question of whether government can or should play an active role in stimulating commercial technological innovation. For example in Iran at a time when companies are steadily gaining ground in the industrial sector because of the privatization and the formation of the capital market , government support for R&D on critical technologies is absolutely essential . However , not by owning and controlling the industry but by being an active partner with the private sector , linking industry with universities , by providing generous funding of basic research at universities and major investment on the part of related ministries such as heavy industry , oil , and energy in technology development . Critics may counter – argue that however painful the formation of private industry and loss of business might be any government remedy would be worth than the disease. There is the question of whether, on general developing countries need technology policy? If so, what is the role of local governments in shaping this policy and what are the appropriate domestic technologies for these countries for producing? Learning from other countries like Japan, U.S, and Singapore in forming their technologies is the matter which could be focused upon it.

3. HOW THE PROGRESS SHOULD BE MADE?

In order to have a society capable of growth, there are other issues to be resolved. If one believes that the foundation of society have been established for growth, then the next question becomes who makes progress happens? Is it people or government, or, combination of both? Is it external forces or is it the internal need of a country that makes progress happens. If we consider, the U.S. and Singapore, one could ask, what was the role of people in making these countries the way they are presently? For example In the case of Iran as a developing country, also Iranian government, by virtue of its nature which is Islamic, has been making efforts to create an atmosphere for progress. Nevertheless, in many areas, the progress is not adequate to create an environment that promotes citizens to participate in building the country to its potential. Perhaps a fundamental question is how the government can integrate the power people and the institutional systems that bring civil justice and at the same time provide principles for growth. Many Arab countries are moving in this direction.

Much as they fear the fundamentalists, the Arab governments are still under pressure to reform. They know that they have to manage the process carefully, but they can not stop it. The challenge for the governments, there fore, is to maintain some momentum towards greater freedom and democracy, enough to give their people a feeling of gradual improvement. (1)

Iran is also moving toward democracy. However the collaboration between government and the people is not enough. There fore, the next step is to integrate efforts of the government and the people conceivably, another major revelation in Iranian thinking is quintessential to take the country many steps farther than where it presently is.

This revelation lays on collaboration between people and government. A type of magical unity that a nation craves to take that quantum leap in terms of progress

Looking to this subject from different angles, reveals that, what need the nation of a developing country to achieve in order to create the condition for technology policy to mold itself in a meaningful direction? However , in general if there is infrastructure for progress and the society share justice , people and government are flexible , then the governments of developing countries can look at people as it resources not as an adversarial camp that requires support on a constant basis. In the case of Iran, majority of people look at their government as source of their income. However, if these vision changes, which means, Iranians become skilled resources for their government or their country, then Iranian government can focus on creating technology policy, however, before technology policy can succeed, the privatization of major industry has to be completed. The reason is because government can not be in direct competition with citizens. The first step towards allowing a government of facilitate growth is to privatize. However, privatization is not without its problems. Some studies indicated that , the privatization and liberalization programs either failed outright in the so called market economics of Saudi Arabia and the United Arab Emirates or were blocked in the so called socialist countries of Syria , Libya , and Algeria through the concerted efforts of labor , party members , and bureaucrats (2) .

Considering that most of these issues are some what the same for Iran, then Iran presently is experiencing some the same problems shared with its Arab neighbor. There has been no study about the process of privatization conducted in Iran yet. There fore, many of the questions can not be answered yet. Under the privatization plan of the Islamic republic of Iran, a number of companies have been privatized.

Iran has suffered tremendously for lack of an infrastructure. As a nation, Iranians have to think twice when they demand modernization, state of the art technologies, and the latest and greatest of the western products. They have to stop and think about what makes them deserve to have the best but contribute very little in building their country. There fore, once they become honest in their thinking, then as a nation, thinking about how to build the economy, is possible. So they have to participate in building the infrastructure and then will start to appreciate what it takes to have a technologically advanced country. The participation process takes times but if and only if this participation happens, the formation of a technology policy is possible (3).

4. (IT) MANAGEMENT IN THE ORGANIZATIONS OF THE DEVELOPING COUNTRIES:

Information technology is the fastest – growing industry in the world. In a way Iran has to absorb the technologies from other countries just like what Japan did after war II. In the process of strengthening ability to borrow and adapt U.S. technology, Japan has also created the intellectual talent to generate new technology on

its own. Iran and also other developing countries should focus on the absorption and application of existing ideas. The most important task currently facing the policy community is not how to create a new series of recommendations but how to systematically implement an existing set of ideas.

Because of the dynamics of technology fusion , established technologies in any industry constantly run the risk of being displaced by radically different technologies coming from outside . As a result, traditional distinctions between High – tech and Low – tech industries are fast disappearing. In effect, every business is, or should be, High – tech. Thinking in Global scale nations should create an international research and education network (IREN) that could expand internet to serve universities, governments, and industries. (IREN) could be important because it will greatly increase the capacity for collaboration by many geographically dispersed companies and institutions.

Now a days knowledge has proven so vital to organizational success that a new organizational form – knowledge based firms has emerged. With a slow down in the world economy, the bursting of the technology bubble and tighter budgets, the importance of leveraging existing knowledge and expertise has reached new highs. Knowledge management will remain in a critical success factor for organizations as the economy recovers. In most of the developing countries knowledge management is a critical issue and especial attention should be focused upon it. In the organizations there are formal knowledge and informal knowledge networks so management of both should be taken in to consideration. Effective use of information for economy and technological development is needed. For sustainable development and protection of environment and saving of our planet for future generations, transfer of knowledge, information and experience among all nations is an essential factor, which it should be considered seriously. In this paper especial attention has been focused on e-collaboration. Collaboration is a process by which individuals and/or groups work together on a practical endeavor. Collaborative work is a fundamental feature of organizations and is increasingly being supported by technology. The advent of (ICT) or information and communication technologies in network for nation and support has enabled collaboration to take place on a virtual dimension regardless of time and location. This form of working relationship through the electronic network is known as electronic collaboration. The development of these technological capabilities and e – collaboration initiatives is changing the way individuals and groups perform and interact. As well as the scope of traditional processes and work flow. E-collaboration offers an unprecedented way for organizations to share information and knowledge, and to better integrate business, work or learning processes.

For solving the existing problems of the developing countries and for the best management of (IT), for above mentioned reasons e-collaboration could be the right choice. If we believe that for the better future and comfort of all nations, we need to share in resources and technological achievements, in this case we have to help each other in order to achieve the mutual targets. Hence to achieve sustainable development, close cooperation between organizations in international scale is needed. It has been shown 4, 5, 6, 7, 8 due to the lack of proper circulation of scientific information between developed and developing countries accelerated depletion of energy resources and un repairable environmental damages have been occurred. It is believed that through e-collaboration and exchange of knowledge and technical achievements the human being can solve most of existing problems and create better life for future generations.

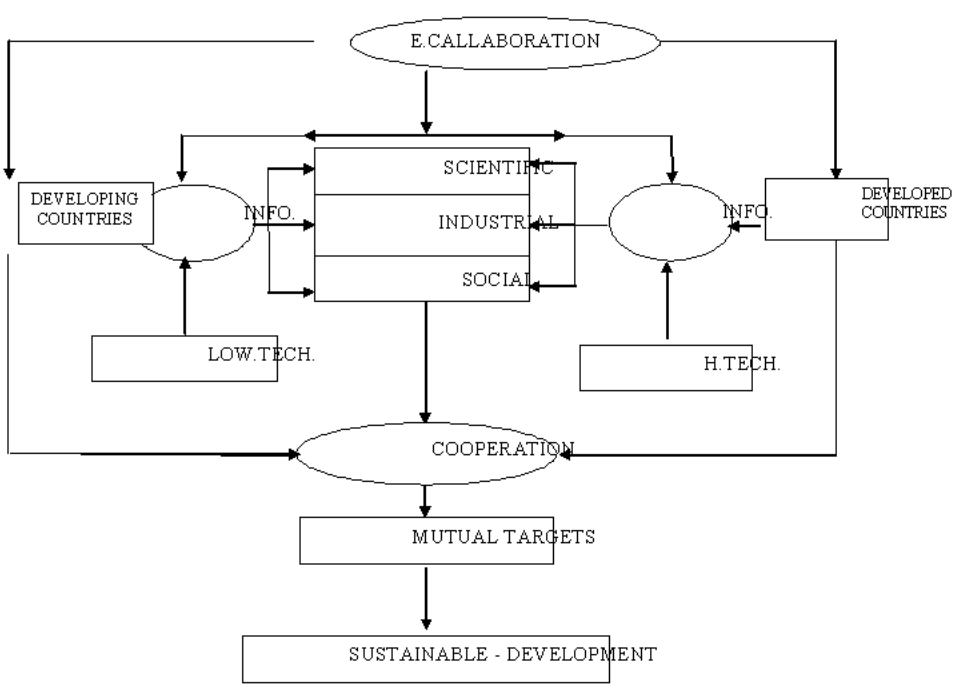
In Fig1with e-collaboration the High – tech and Low tech. information's flows in both directions from developed and undeveloped countries in different fields of scientific , industrial and social fields in order to exchange ideas, knowledge and experiences to solve existing problems and for gaining the mutual targets and benefits.

As could be seen from fig 1 the e – collaboration could have essential role in achieving targets which finally could end to the sustainable development.

5. CONCLUSIONS AND RECOMMENDATIONS:

- Information technology increasingly gaining importance in the world today. Information and Communications technologies are pervading all aspects of life at work, university, and home.
- In order to succeed in our complex world, a variety of people require (IT) education.
- Management of (IT) in developing countries is an essential factor which should be taken into consideration.
- For solving scientific, industrial and social problems of developing countries, e. collaboration could have major role which in Fig 1 has been shown.

Figure 1.



- In order to have better life for whole nations and to protect environment and planet for the future generations , the transfer of ideas , experience , knowledge in the, international scale is necessary and gaining benefit from (IT) in whole aspects should have the first priority .
- Paying especial attention to the international research and education network (IREN) is highly recommended.

ABSTRACT

Business activities are performed by human or automated actors. For the organization to adapt to changes it must be able to understand how and why actors are related to and assigned to processes. This requires a consistent representation of the services required by the organization's processes and those provided by its actors. This paper focuses on defining the concepts that allow to structurally align human actors and business processes through the description of the organizational competencies required to perform processes' activities. These structures are used within a marketplace-based model, supporting the management of actors and activities according to the supply and demand of competencies.

1. INTRODUCTION

Competency-based management is becoming an object of growing interest as its importance is recognized from a strategic perspective. It aims leveraging the competitive advantage of knowledge-based organizations by observing individuals as strategic assets and explicitly integrating them into the organization's business strategy and processes. This approach has led to the development of several methods and systems (Woodruffe, 1993; Stone, 1995; Hamel & Prahalad, 1990; Fletcher, 1995).

Competency-based management provides individuals with a set of task definitions and objectives, linking organizational and personal objectives. It facilitates process analysis and standardization inside and outside the organization's boundaries, making recruitment and compensation systems fairer and more open. However, competency related information is prone to become obsolete due to organizational changes, so it can become expensive and time consuming to keep this information updated (Chartered Institute of Personnel and Development UK, 1995). Competency management support systems play a role in different organizational activities, such as expert finding, personnel recruitment and project management. These activities customarily involve human judgment to classify the skills held by workers, to evaluate the degree of competency and keeping up-to-date profiles. To facilitate the management of competencies and to minimize the subjectivity of human evaluation, several approaches put forward the use of information technologies to facilitate tasks such as contextualizing the communication between actors (Yimam, 2000), managing skills and activities within teams (Gronau & Uslar, 1994) and using groupware to support information sharing (Johansen et al, 1991).

Nevertheless, these solutions focus on supporting the operational phases of a business process and few assist the identification and selection of actors before the actual commitment to carry out its activities. This operational focus also means that skill management systems often do not relate the skill information pertaining to the actors to the activities' requirements as derived from the organization's process models. Consequently, information on the organization's competencies cannot be directly traced to its business processes. This hinders skill management from a process perspective and promotes the existence of mismatches within the enterprise architecture description.

This paper outlines a framework to overcome these issues by extending previous work on business process and actor modeling (Caetano, Zacarias, Rito Silva, & Tribolet, 2005; Neves, Caetano, Vasconcelos, & Tribolet, 2001; Spencer, Spencer, & Signe, 1993; Zacarias, Caetano, Pinto, & Tribolet, 2005) with a set of concepts that allow representing and evaluating actors and competencies in the context of a business process. The remainder of this paper is structured as follows: section 3 describes our proposal on competency modeling, section 4 describes how to integrate this model into an organization using the concept of competency marketplace and section 5 sets out the conclusions and describes future work.

2. RELATED WORK

Despite the research on competency-based management, representation of competencies is not fully addressed in nearly all business process modeling standards. IDEFØ (Scheer, 1999) is a method of modeling organizational decisions and activities through functions, inputs and outputs but it does not provide the means to represent how activities are performed by actors. BPMN (Business Process Management Initiative, 2004) is a notation that focuses on describing business process flows. Participation in a process is represented through swimlanes that relate activities to its performer, thus mapping responsibilities at a high level of abstraction. There is no means to specify the requirements an actor must fulfill to execute an activity. Other approaches, such as IDEF3 (Mayer et al, 1995) and RADs (Ould, 1995) focus on describing process flow but overlook the specification of actor competencies as well as activity requirements.

There is a large amount of research on competency modeling outside the scope of business process modeling. The "competency movement", credited to McClelland (1973), uses the concept of competency to classify human actors and to relate them with the ability of performing a task. Spencer (1993) defines competency as a characteristic of an individual that is causally related to effective and/or superior performance in a situation. *Underlying characteristic* means the competency is part of a person and can be used to deduce behavior, being part of what Davenport (1997) classifies as tacit knowledge. *Causally related* means that a competency causes or predicts behavior. *Criterion referenced* means it is possible to quantify the performance of a competency and implies a causal relation between purpose and result.

Defining the granularity of competency representation is equally important as a high-level representation will not provide enough information, while if it is too detailed, the entire representation process may become compromised, as it is effort and time-consuming (CIPD UK, 2005). Competencies are usually represented as hierarchical structures or competency trees. An example is the "body of knowledge", in which competencies are classified according to specific areas of knowledge, such as IEEE's Software Engineering Body of Knowledge (Abran & Moore, 2004). Lang and Pigneur (1999) also propose using a hierarchical structure to represent competencies since it simplifies processing when compared to the mining of textual descriptions. It is also easier for people to identify competencies, the expectations of the organization and possible gaps. Pigneur proposes four competency categories as starting points: Enabling Technologies, Field Experience, Knowledge and Personal Traits. However, the semantics associated with these hierarchies is static by design, relying on a specific functional domain classification to describe the competencies.

A pragmatic approach is found at CommOnCV (Harzallah & Lecrère, 2002), which models *curricula vitae* during the recruitment process. Competencies are represented as annotations derived from each *curriculum* and are represented using RDF (Brickley et al, 2000) or DAML+OIL (Euzenat, 2002). The annotations are based on a particular competency model, created within a specific knowledge area.

Competency trees present problems related to flexibility and reusability. These trees are usually deep, with the functional categorization specified in its upper levels; the description of a competency is not easily decomposable, leading to the dispersion of concepts between nodes. As a result, inference is limited as the concepts are not structured and connected to each competency as individual components. Reusing competencies in different contexts is hindered as functional categorization is embedded at the tree's upper levels.

3. COMPETENCY MODELING

The approach relies on defining the structure of competencies so they can be aggregated or composed at design time. This structure can be instantiated at run time enabling inference and analysis. These three phases separate the definition of individual competencies from their hierarchy as well as from the runtime information that will instantiate the structures.

The rationale behind separating the definition of a competency from its hierarchy is that it is not possible to anticipate the needs of an organization in terms of its competency categorization. If the definition and the corresponding hierarchy were entwined, then the competency would be defined in the scope of a single organizational context, making difficult specifying the same competency across multiple contexts. This is often the case where different organizational units use different classification schemes for the same competency. Thus, this separation aims at maximizing the reusability and flexibility of the structure.

3.1 Competency Definition

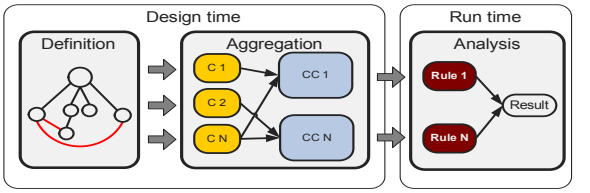
Defining a competency requires specifying or reusing the concepts that are necessary for its description and, second, specifying the structure that will hold these concepts and their relationships. Creating a structure to relate competencies is complex since it not straightforward to model a potential large set of disparate individual features that influence the performance of a given task, such as knowledge, practical experience, psychological and social factors, context and motivation.

Before detailing how competencies are defined, it is important to disambiguate some fundamental concepts. A *skill* is the ability to perform a particular activity, while *knowledge* is related to the information needed for enabling the skill. As an example, while there are skills needed to carry out network troubleshooting, there must be knowledge about physical media and network protocols for that skill to be available. The improvement of skills and knowledge through experience, training or education leads to *occupational competency* (Jones & Bearly 2006). This means a single competency may encompass multiple skills. A *competency* relates to the behavior that individuals must perform as input into a situation while achieving some level of performance. It represents the association of knowledge and action. This means, on the one hand, that competencies are based on knowledge, and, on the other, that for a competency to be recognized as such, it is necessary to demonstrate the capability of giving use to that knowledge through an action that brings value to the task.

A competency is an expression defined through the aggregation of elementary *nouns* and *verbs* (e.g. "coding a search algorithm in Lisp", "coding a web service in C#"). The concepts may be related or dependent (e.g. Lisp and C# are programming languages with different programming paradigms). To deal with the representation of such features, we define a set of layered hierarchic structures that specify the competency's concepts regardless of their usage context. This type of structure allows concepts to be reused while defining isolated competencies.

Actors and activities relate to competencies whose meaning depends on their usage context. These competencies may also be structurally related. To cope with this, competencies are aggregated as coherent groups comprising individual competencies. Separating the aggregation of competencies from their definition enables their rearrangement according to usage context without disrupting the corresponding definition. Groups of aggregated competencies can be bound to actors and activities, specifying supply and demand of competencies.

Figure 1. Design-time and run-time modeling phases



3.2 Structuring Competencies

Competencies are often structured hierarchically. As previously discussed, such an approach offsets representation simplicity and expressiveness. However, most approaches rely on static classification schemes that prove difficult to adjust to the organization dynamics and its environment. Furthermore, hierarchical representations are defined in the scope of some functional context, so it is not straightforward to detach a structure from its context and keep its semantics. Therefore, as it is not reasonable to assume that functional contexts are shared throughout the organization, the representation structure must be able to separate competency definition from its categorization.

To overcome these issues and those identified in section 2, we propose using a multi-dimensional tree structure, where each dimension relates the element with its usage context. This allows multiple views on the same object while keeping its uniqueness. Such structure can be perceived as a regular hierarchical tree where a number of contextual layers can be superimposed.

Nodes in the same dimension or layer are connected using intra-level links allowing relating elementary concepts. Inter-level links associate nodes from different dimensions allowing the specification of complex concepts. The semantics of this type of link is defined by ontological relations, such as "belong-to", "uses" or "enables".

The diagram in Fig. 2 depicts three layers (A, B, C), each defining elementary concepts in a given context. Using inter-level links (depicted as dotted arcs) to associate a number of elementary concept nodes in different contexts enables a competency defined as {⟨A1, B1⟩, ⟨A1, C1⟩, ⟨B2, C1⟩} to be specified.

As an example, Fig. 3 shows a number of elementary competencies related to software development.

Fig. 3 specifies the following set of competencies:

- Develop Software in the Banking Business Domain
- Software Design using both Imperative and Object Oriented Paradigms
- Code Software both in C# and Lisp Programming Languages
- Know Java Programming Language
- Administer Linux Operating System
- Use any Operating System
- Use the Visual Studio IDE

3.3 Competency Aggregation

Competency aggregation allows specifying multiple contexts through the specification of viewpoints. After being defined, competencies can be composed so they can be handled as a unit. The meaning of the competency "programming" can change according to the perspective. One definition could be the knowledge of a given programming language. Nevertheless, it can also mean the knowledge

Figure 2. Elementary concept structure (left). Competency definition (right)

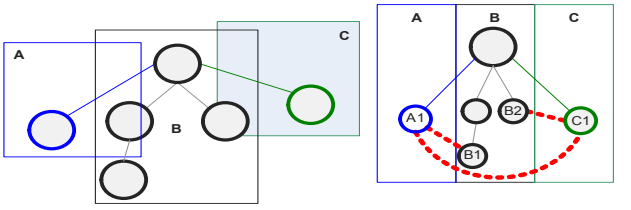


Figure 3. Elementary concepts and competency definition

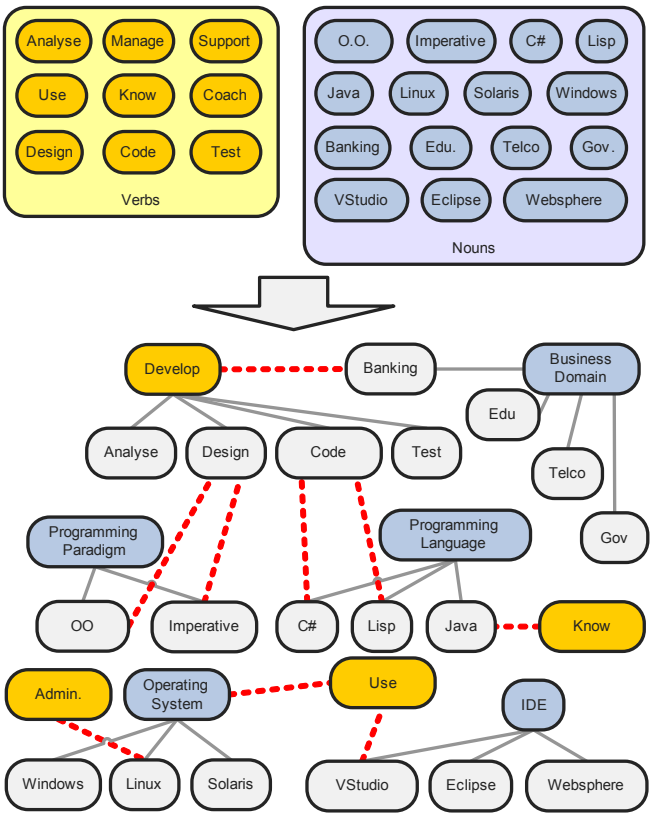

in programming paradigms and programming languages. These two contexts can be specified as distinct viewpoints.

Different observations can be taken from the value of a competency element by changing the hierarchy while using the same inputs. It becomes necessary to ensure the independence between the viewpoint and the competencies themselves. The latter cannot be dependent on the categorization chosen by the organizational unit: they are part of the individual and exist regardless of context. Therefore, we propose using two layers: one featuring objective information on the competencies and other with their classification and context information. Thus, the upper level hierarchy corresponds to categorization and views, allowing the creation of structures that can reuse previously defined components. This approach is flexible since it enables the creation of a semantic level above elementary competencies by separating both and making individual's competencies context invariant.

Other aspect has to do with granularity: a monolithic structure is inadequate to representing competencies, so it is useful to create smaller trees, particularly in the case of relationships between nodes that arise from their own definition as concepts. As an example, take imperative, object-oriented and functional while programming paradigms. This classification can be considered context insensitive. These smaller trees are also known as "concept islands" (Lau & Sure, 2002), self-contained concept groups from sub-domains of a larger domain. Since these islands are interlaced, it makes sense to include them into multiple trees, which implies a complex network of node relationships. One approach is combining the concept islands into a single tree. This introduces complexity at ontology design time. Worse, it limits the expressiveness and flexibility of the structure. Therefore, we propose representing the concept island as multiple trees and keeping them separately in a repository. This approach enables these structures to be used as modular building blocks when composing larger trees. It also supports the flexible rearrangement of blocks, without breaking existing connections, i.e., maintaining the connections traceable from runtime back to the atomic elements that form a competency.

To illustrate the competency aggregation step, Fig.4 shows the result of competency composition. The original structure does not require revision. Aggregated competencies defined in this step may also be used to map roles to competencies.

3.4 Competency Analysis

The main goal of this phase is instantiating the competency structures according to the competencies provided by the organization's human actors. While the first two phases are enacted during design time, this phase relates activities and actors at run time, allowing the assessment of competency supply and demand.

Competency analysis requires a set of propagation rules to be defined between different hierarchy levels. Both the rules and the hierarchy itself are part of the classification scheme used by an organizational unit and should not be mistaken for the definition of the competencies. The latter should be independent of the analysis phase as otherwise competencies will not be able to cross-organizational boundaries.

Propagation rules describe how a node's information can be computed from its child nodes. They are defined bottom-up and are related to non-leaf nodes. Leaf nodes are instantiated with values that are propagated up to the root node using the rules on each intermediate node. A rule can include operations, such as logical expressions, weighted averages and threshold definitions. This enables real-time propagation of values, as opposed to static assignment where the connection to the original structure is lost from the moment that the first values are obtained.

When matching competency supply and demand there are important questions about the abstraction level or granularity used on both sides of the negotiation. If the supply is specified in more detail than the demand, simple bottom-up derivation is sufficient to match both sides. However, in the opposite case, it is necessary to request a further specification to the entity responsible for the offer. The updated specification will be included in the existing model as a supplementary layer.

While the most visible aspect of inference is performed at competency level, its application in that case is straightforward. The following example focuses on the application of rules to the relationships between elementary competency concepts. Fig. 5 depicts a scenario where a programming competency depends 60% on programming language knowledge and 40% on programming paradigms. As the programming paradigm is not a leaf node, another rule must specify how

Figure 4. Competency aggregation

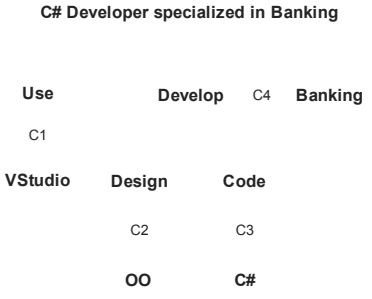

Figure 5. Example of propagation rules

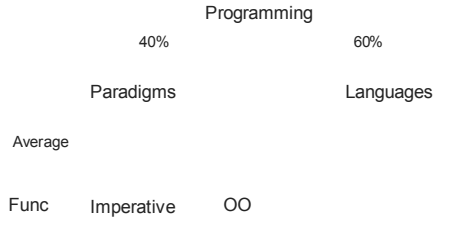

to compute its value. In this case, a non-weighted average of its descendents has been used.

A fundamental aspect of the proposed framework is the traceability across the three phases. It enables the identification of a specific atomic element that composes an aggregate competency instantiated at runtime. In turn, low-level syntactic translation mechanisms create the conditions to analyze competency elements that would otherwise be obscured by their macro description. The competencies are expandable down to leaf-level, therefore representing the most objective information possible about the organization's human actors. So, competencies can become as independent as desirable from their organizational classification and activity-specific arrangements. As a result, competency movement across different units implies ontological agreement only at the lowest hierarchical level.

4. THE COMPETENCY MARKETPLACE

The primary goal of representing competency supply and demand is allowing an organization to find, schedule and manage suitable teams of actors to perform activities. Our approach follows the paradigm of a marketplace transaction. This facilitates the management and tracking of competencies from an organizational perspective while promoting actors to develop their own competencies. It also facilitates correcting the gaps between the actual requirements of an activity and those specified in the process models through market rules. It is important that all parties in the marketplace share a common vocabulary and semantic model to make the negotiation possible. Such shared knowledge should be iteratively built and continuously updated. The market dynamics enables the runtime evaluation of the negotiated work, thus offering feedback for process improvement.

The implementation of a competency marketplace involves a specific process, which goes through the stages of Information, Negotiation and Settlement (Lang & Pigneur, 1999). The Information stage consists in representing actual supply and demand. This is specified at design time during the Definition and Aggregation phases of the framework. The next step is finding the best candidate that fulfills the requirement of an activity. This is accomplished by searching the supply-side representations using inference and propagation mechanisms on the hierarchical structures, instantiated with the proficiency values associated with each actor. The result is a set of actors and the corresponding evaluations computed from the similarity level between the required and provided competencies.

After identifying a potential group of actors able to perform the task, the results must be categorized according to existing work scheduling plans that limit their availability. The results also need to consider business rules that may constrain the process (e.g. actor B and C can not participate in the same activity instance) and the type of results (e.g. the result must be a team of two people). The information resulting from this step can be used to facilitate team formation.

Team formation corresponds to the negotiation between the transaction participants. Each individual actor, the team as a whole and the activity owner settle the contract details, making explicit the assignment and scheduling terms. A contract is defined after the negotiation phase is complete, specifying the details, thus binding actors to an activity through their competencies along the settlement step.

Implementing the contract means performing the activity's tasks. The execution phase can be evaluated during its performance or *a posteriori* using metrics whose goals are measuring how the contract was carried out.

This approach promotes an actor to be actively involved in the management of her own competencies. This influences her evaluation criteria and, as a result, how management observes her performance. It is in the best interest of the actor to be properly represented in the model, since an accurate description will facilitate her scheduling to the tasks included on her competency pool. It will also enable the identification of gaps inhibiting good performance, calling for specific training.

5. CONCLUSIONS AND FUTURE WORK

The concept of competency is fundamental to align actors and activities within business processes. It enables an organization to understand and evaluate what is required by its processes and what is provided by its actors. It also provides a means to make competencies visible to all process stakeholders, including its performers, designers and owners, allowing mismatches to be identified and continually adjusted. Provided the different stakeholders see the benefit of accurately representing the competencies they are responsible for, the marketplace will converge to a state that represents the actual supply and demand of competencies within the organization.

To validate this approach, we have developed a web-based system that implements the concepts outlined in this paper, which is currently being evaluated in real organizations. It allows employees advertise their competencies and process owners and designers to specify activity requirements and evaluate the performance of actors. The system supports the dynamic aspects of actor scheduling, allowing the search of competencies, assisting the process of team formation and evaluating the scheduling results.

The establishment of trust relationships is crucial and the integration into the Semantic Web will enable the creation of shared repositories of services. The unification between competencies and technological services is subject of our future work. We are currently extending the framework to include the representation of the services provided by information systems and other business process support systems. This will enable defining alignment metrics between the organization's service providers and its processes.

ABSTRACT

Mobile commerce or m-commerce, defined as the exchange or buying and selling of commodities, services, or information on the Internet through the use of Internet-enabled mobile handheld devices, is a coming milestone after electronic commerce blossoming in the late 1990's. Mobile handheld devices provide convenience and portable access to the huge information on the Internet for mobile users from anywhere and at anytime. However, most software engineers are not familiar with programming for handheld devices. Handheld computing is the programming for handheld devices such as smart cellular phones and PDAs (Personal Digital Assistants). It consists of two kinds of programming: client- and server- side programming. This paper introduces handheld computing and gives a detailed description of Palm OS programming, client-side handheld programming. Other related issues such as mobile commerce systems and handheld devices will be discussed also.

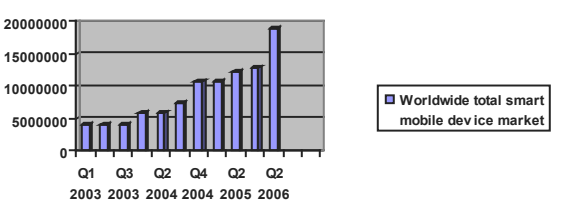
INTRODUCTION

Mobile commerce is a coming milestone after electronic commerce blossoming in the late 1990's. Figure 1 shows the growth in demand for smart mobile devices including handhelds, wireless handhelds, and smart cellular phones through 2006, as estimated by the research firm Canalys (2006). However, it is also commonly admitted that the development in this field is constrained. There are still considerable barriers waiting to be overcome. One of the barriers is most software engineers are not familiar with handheld programming. Handheld computing is the programming for handheld devices such as smart cellular phones and PDAs. This paper gives a study of handheld computing to help software engineers better understand this subject. It includes three major topics:

- *Mobile commerce systems*: The system structure includes six components: (i) mobile commerce applications, (ii) mobile handheld devices, (iii) mobile middleware, (iv) wireless networks, (v) wired networks, and (vi) host computers.
- *Handheld computing*: It consists of two kinds of programming: client- and server- side programming.
- *Palm OS and programming*: The Palm OS Developer Suite is used to develop applications for Palm devices by handheld programmers.

This paper focuses on Palm OS programming by giving a step-by-step procedure of a Palm application development. Other client-side handheld computing is also discussed.

Figure 1. Worldwide total smart mobile device market

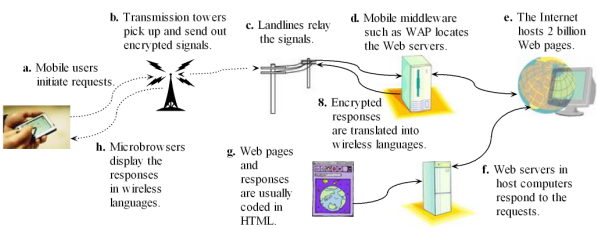


BACKGROUND

With the introduction of the World Wide Web, electronic commerce has revolutionized traditional commerce and boosted sales and exchanges of merchandise and information. Recently, the emergence of wireless and mobile networks has made possible the extension of electronic commerce to a new application and research area: mobile commerce, which is defined as the exchange or buying and selling of commodities, services, or information on the Internet through the use of mobile handheld devices. In just a few years, mobile commerce has emerged from nowhere to become the hottest new trend in business transactions. To explain how the mobile commerce components work together, Figure 2 shows a flowchart of how a user request is processed by the components in a mobile commerce system, along with brief descriptions of how each component processes the request (Hu, et al, 2004):

1. *Mobile commerce applications*: Electronic commerce applications are numerous, including auctions, banking, marketplaces and exchanges, news, recruiting, and retailing, to name but a few. Mobile commerce applications not only cover the electronic commerce applications, but also include new applications, which can be performed at any time and from anywhere by using mobile computing technology, for example, mobile inventory tracking.
2. *Mobile handheld devices*: An Internet-enabled mobile handheld device is a small general-purpose, programmable, battery-powered computer that is capable of handling the front end of mobile commerce applications and can be operated comfortably while being held in one hand. It is the device with which mobile users interact directly with mobile commerce applications.
3. *Mobile middleware*: The term middleware refers to the software layer between the operating system and the distributed applications that interact via the networks. The primary mission of a middleware layer is to hide the underlying networked environment's complexity by insulating applications from explicit protocols that handle disjoint memories, data replication, network faults, and parallelism (Geihs, 2001). The major task of mobile middleware is to seamlessly and transparently map Internet contents to mobile stations that support a wide variety of operating systems, markup languages, microbrowsers, and protocols. WAP and i-mode are the two major kinds of mobile middleware.
4. *Wireless and wired networks*: Wireless communication capability supports mobility for end users in mobile commerce systems. Wireless LAN, MAN,

Figure 2. A flowchart of a user request processed in a mobile commerce system



and WAN are the major components used to provide radio communication channels so that mobile service is possible. In the WLAN category, the Wi-Fi standard with 11 Mbps throughput dominates the current market. However, it is expected that standards with much higher transmission speeds, such as IEEE 802.11a and 802.11g, will replace Wi-Fi in the near future. Compared to WLANs, cellular systems can provide longer transmission distances and greater radio coverage, but suffer from the drawback of much lower bandwidth (less than 1 Mbps). In the latest trend for cellular systems, 3G standards supporting wireless multimedia and high-bandwidth services are beginning to be deployed.

5. *Host computers*: A user request such as database access or updating is actually processed at a host computer, which contains three major kinds of software: (i) web servers, (ii) database servers, and (iii) application programs and support software.

HANDHELD COMPUTING

Handheld computing is a fairly new computing area and a formal definition of it is not found yet. Nevertheless, the author defines it as follows:

Handheld computing is to use handheld devices such as smart cellular phones and PDAs (Personal Digital Assistants) to perform wireless, mobile, handheld operations such as personal data management and making phone calls.

Again, handheld computing includes two kinds of computing: server- and client-side handheld computing, which are defined as follows:

- *Server-side handheld computing*: It is to use handheld devices to perform wireless, mobile, handheld operations, which require the supports of server-side computing. Examples of its applications include (a) instant messages, (b) mobile Web contents, (c) online video games, and (d) wireless telephony.
- *Client-side handheld computing*: It is to use handheld devices to perform handheld operations, which do not need the supports of server-side computing. Examples of its applications include (a) address books, (b) standalone video games, (c) note pads, and (d) to-do-list.

The terms of computing and programming are sometimes confusing and misused. The handheld programming, defined as programming for handheld devices, is different from handheld computing and includes two kinds of programming too:

- *Server-side handheld programming*: It is design and development of handheld software such as CGI programs that reside on the servers.
- *Client-side handheld programming*: It is design and development of handheld software such as J2ME programs that reside on the handheld devices.

Client-Side Handheld Computing

Some popular mobile environments/languages for client-side handheld programming are listed below:

- *BREW (Binary Runtime Environment for Wireless)*: It is an application development platform created by Qualcomm Inc. for CDMA-based mobile phones (Qualcomm Inc., 2003).
- *J2ME (Java 2 Platform, Micro Edition)*: J2ME, developed by Sun Microsystems Inc., provides an environment for applications running on consumer devices, such as mobile phones, PDAs, and TV set-top boxes, as well as a broad range of embedded devices (Sun Microsystem Inc., 2002).
- *Palm OS*: Palm OS, developed by Palm Source Inc., is a fully ARM-native, 32-bit operating system running on handheld devices. Using Palm OS to build handheld applications will be introduced later.
- *Symbian*: Symbian Ltd. is a software licensing company that develops and supplies the advanced, open, standard operating system—Symbian OS—for data-enabled mobile phones (Symbian Ltd., 2005).
- *Windows Mobile*: Windows Mobile is a compact operating system for mobile devices based on the Microsoft Win32 API. It is designed to be similar to desktop versions of Windows (Microsoft Corp., 2005).

Figure 3. A generalized client-side handheld computing development cycle

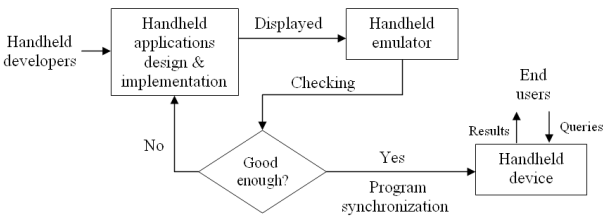


Table 1. A comparison among five handheld-computing languages/environments

	BREW	J2ME	Palm OS	Symbian OS	Windows Mobile
Creator	Qualcomm	Sun Microsystems	PalmSource	Symbian	Microsoft
Language/ Environment	Envir.	Language	Envir.	Envir.	Envir.
Market Share (PDA) as of 2005	N/A	N/A	3rd	4th	1st
Market Share (Smartphone) as of 2006	?	N/A	4th	1st	5th
Primary Host Language	C/C++	Java	C/C++	C++	C/C++
Target Devices	Phones	PDAs & phones	PDAs	Phones	PDAs & phones

They apply different approaches to accomplishing the development of mobile applications. Figure 3 shows a generalized development cycle applied by them and Table 1 gives a comparison among the five languages/environments. The second half of this article is devoted to the details of Palm OS and programming.

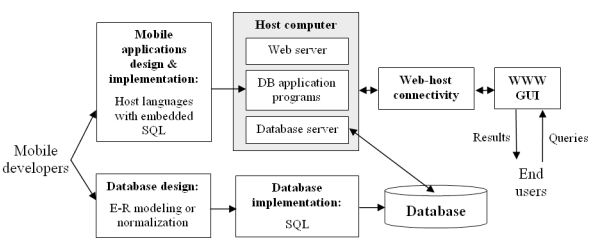
Server-Side Handheld Computing

Most applications created by this kind of programming such as instant messaging require network programming such as TCP/IP programming, which will not be covered in this paper. The most popular application of server-side handheld computing is database-driven mobile web sites, whose structure is shown in Figure 4. A database-driven mobile web site is often implemented by using a `three-tiered client/server architecture` consisting of three layers:

A database-driven mobile web site is often implemented by using a `three-tiered client/server architecture` consisting of three layers:

1. *User interface*: It runs on a handheld device (the client) and uses a standard graphical user interface (GUI).
2. *Functional module*: This level actually processes data. It may consist of one or more separate modules running on a workstation or application server. This tier may be multi-tiered itself.

Figure 4. A generalized system structure of a database-driven mobile web site



3. *Database management system (DBMS)*: A DBMS on a host computer stores the data required by the middle tier.

The three-tier design has many advantages over traditional two-tier or single-tier designs, the chief one being: The added modularity makes it easier to modify or replace one tier without affecting the other tiers.

PALM OS AND PROGRAMMING

Palm OS is a fully ARM-native, 32-bit operating system designed for used on Palm handhelds and other third-party devices. Palm OS runs on almost two out of every three PDAs. Its popularity can be attributed to its many advantages, such as its long battery life, support for a wide variety of wireless standards, and the abundant software available. The plain design of the Palm OS has resulted in a long battery life, approximately twice that of its rivals. It supports many important wireless standards, including Bluetooth and 802.11b local wireless and GSM, Mo-bitex, and CDMA wide-area wireless networks (PalmSource Inc., 2002). Two major versions of Palm OS are currently under development:

- *Palm OS Garnet*: It is an enhanced version of Palm OS 5 and provides features such as dynamic input area, improved network communication, and support for a broad range of screen resolutions including QVGA.
- *Palm OS Cobalt*: It is Palm OS 6, which focuses on enabling faster and more efficient development of smartphones and integrated wireless (WiFi/Bluetooth) handhelds.

Palm OS Programming

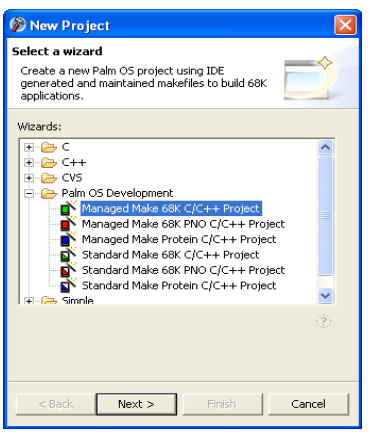
The Palm OS Developer Suite, which is the official development environment and tool chain from PalmSource, is intended for software developers at all levels. It is a complete IDE (Integrated Development Environment) for

- Protein applications (all ARM-native code) for Palm OS Cobalt and
- 68K applications for all shipping versions of the Palm OS.

The following steps show how to develop a Palm OS application, a simple "Hello, Mobile world!" program, under Microsoft Windows XP:

Figure 5. A screenshot of the Palm OS Developer Suite

Figure 6: A screenshot showing Palm OS application and make types



1. Download *Palm OS Developer Suite* at http://www.palmos.com/dev/tools/dev_suite.html .
2. Activate the Eclipse Workbench IDE as shown in Figure 5 under the Windows environment by selecting the following commands

```
Start ► All Programs ► PalmSource ►
     Palm OS Developer Suite
```

   May select a default workspace at "C:\Program Files\PalmSource\Palm OS Developer Suite\workspace."
3. Create a new project by selecting a wizard: There are three Palm OS application types as shown in Figure 6:
   - *Palm OS 68K Application*,
   - *Palm OS 68K Application with PACE Native Objects*, and
   - *Palm OS Protein Application*.

   There are also two kinds of *make files*:
   - *Standard make*: It provides a generic set of makefiles that you can modify and tailor for your specific application build.
   - *Managed make*: It dynamically generates your makefile based on the contents of your project folders.
4. Create a Palm OS C/C++ program and put it in the directory "C:\Program Files\PalmSource\Palm OS Developer Suite\workspace\Hello\." Program 1 gives a Palm example, which displays the text "Hello, Mobile world!," an image, and a button "OK."

Program 1. An example of a Palm OS program HelloWorld.c

C:\Program Files\PalmSource\Palm OS Developer Suite\workspace\Hello\HelloWorld.c

```
#include  <PalmOS.h>
#define   Form1  1000
#define   OK     1003

UInt32  PilotMain( UInt16 cmd, void *cmdPBP, UInt16 launchFlags ) {
 short      err;
 EventType  e;
 FormType   *pfrm;

 if ( cmd == sysAppLaunchCmdNormalLaunch ) {
  FrmGotoForm( Form1 );
  while( 1 ) {
   EvtGetEvent( &e, 100 );
   if ( SysHandleEvent( &e ) )  continue;
   if ( MenuHandleEvent( (void *) 0, &e, &err ) )  continue;
    switch ( e.eType ) {
     case ctlSelectEvent:
      if ( e.data.ctlSelect.controlID == OK )
       goto  _quit;
       break;
     case frmLoadEvent:
      FrmSetActiveForm( FrmInitForm( e.data.frmLoad.formID ) );
      break;
     case frmOpenEvent:
      pfrm = FrmGetActiveForm( );
      FrmDrawForm( pfrm );
      break;
     case menuEvent:
      break;
     case appStopEvent:
      goto  _quit;
      break;
     default:
      if ( FrmGetActiveForm( ) )
       FrmHandleEvent( FrmGetActiveForm( ), &e );
      break;
    }
   }
_quit:
  FrmCloseAllForms( );
 }
 return 0;
}
```

Figure 7. A screenshot of the Palm OS Developer Suite after the project Hellow-World is created

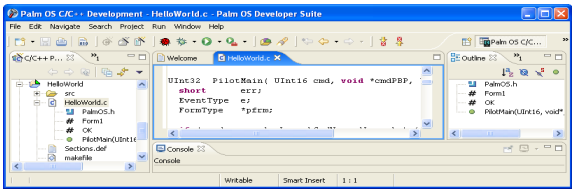


Figure 8. A screenshot of the Palm OS Resource Editor

For how to create Palm OS applications, check Palm OS Developer Documentation at http://www.palmos.com/dev/support/docs/. In order to display the current status on the Eclipse, may need to constantly `refresh` the project *`HelloWorld`* by right clicking on the mouse on the project name as shown in Figure 7.

If the project includes resources (`.xrd`) such as buttons and images, the Palm OS Resource Editor at

```
Start ▶ All Programs ▶ PalmSource ▶
  Tools ▶ Palm OS Resource Editor
```

could be used to create the resources as shown in Figure 8.

5. Build the project *HelloWorld*.
6. Activate a Palm OS emulator by selecting

```
Start ▶ All Programs ▶ PalmSource ▶
   Tools ▶ Palm OS Emulator
```

7. Drag the icon of *`Hello.prc`* (Palm Application file) at "`C:\Program Files\PalmSource\Palm OS Developer Suite\workspace\Hello5\Debug\Hello.prc`" to the Palm OS emulator. Figure 9 shows the execution result of the project *`HelloWorld`*.

Figure 9. A screenshot of the execution results of the project HelloWorld

Table 2. Palm OS programmer's API reference

Function	Descriptions
User Interface	User interface APIs include events, notifications, attention, control, dialogs, forms, lists, menus, scroll bars, etc.
System Management	Provides largest number of functions such as alarm, debug, file streaming, graffiti, I/O, memory, pen, sound, time, windows, etc. for system management.
System Management	Provides largest number of functions such as alarm, debug, file streaming, graffiti, I/O, memory, pen, sound, time, windows, etc. for system management.
Libraries	Include miscellaneous libraries such as Internet, Bluetooth, cryptography, etc.

8. If the application is finalized, synchronize the application to handheld devices by selecting

```
Start ▶ All Programs ▶ Palm Desktop ▶
    Palm Desktop
```

after downloading the Palm Desktop at http://www.palmos.com/dev/tools/desktop/.

Palm OS Programmer's API Reference

Table 2 gives the Palm OS programmer's API reference of Palm OS 68K SDK (PalmSource Inc., n.d.). It includes four major sections (i) user interface, (ii) system management, (iii) communications, and (iv) libraries.

CONCLUSION

Using Internet-enabled mobile handheld devices to access the World Wide Web is a promising addition to the Web and traditional e-commerce. Mobile handheld devices provide convenience and portable access to the huge information on the Internet for mobile users from anywhere and at anytime. However, most software engineers are not familiar with programming for handheld devices. Handheld computing is the programming for handheld devices such as smart cellular phones and PDAs. This paper gives a study of handheld computing and includes three major topics:

1. *Mobile commerce systems*: Mobile commerce is defined as the exchange or buying and selling of commodities, services, or information on the Internet through the use of mobile handheld devices. The system structure includes six components: (i) mobile commerce applications, (ii) mobile handheld devices, (iii) mobile middleware, (iv) wireless networks, (v) wired networks, and (vi) host computers.
2. *Handheld computing*: It consists of two kinds of programming:
   - Client-side programming: It is the programming for handheld devices and it does not need the supports from server-side programs.
   - Server-side programming: It is the programming for wireless mobile handheld devices and it needs the supports from server-side programs.
3. *Palm OS programming*: Two major versions of Palm OS are currently under development:
   - *Palm OS Garnet*: It is an enhanced version of Palm OS.
   - *Palm OS Cobalt*: It is the Palm OS 6.

This article focuses on Palm OS programming by giving a step-by-step procedure of a Palm application development. The Palm OS Developer Suite is used to develop applications for Palm devices by handheld programmers.

Integrating Formal Methods with Reuse Techniques

Laura Felice, INTIA, Universidad Nacional del Centro de la Provincia de Buenos Aires, Argentina; E-mail: lfelice@exa.unicen.edu.ar
Carmen Leonardi, INTIA, Universidad Nacional del Centro de la Provincia de Buenos Aires, Argentina; E-mail: cleonard@exa.unicen.edu.ar

ABSTRACT

It is widely accepted by software community that formal methods increase software quality and reliability, and even though their industrial use is still limited it has steadily been growing. A well-known formal method is the RAISE Method [4,5] based on the idea that software development is a stepwise. Originally designed to be applied at different levels of abstraction as well as stages of development, RAISE is successfully applied to different domains obtaining high precise specifications of components. However, there is no explicit reference to the specification reusability in the process. Feature models have received much attention in the software engineering community who see the Domain Analysis [7] as a prerequisite in a successful reuse, for example FODA [8], FORM [9] and Featured Reuse-driven Software Engineering Business (FeatuRSEB) [6]. This paper presents a brief overview of feature modeling and the integration into RAISE. Some key relations between features are formalized using RAISE specification language [3]. Such integration allows to take advantage of formal methods in the context of software reuse.

INTRODUCTION

Formal methods have come into use for the construction of real systems, as they help to increase software quality and reliability, and even though their industrial use is still limited it has steadily been growing. A well-known formal method is the RAISE Method, which has been used on several real developments. By using formal methods early in the software development process, ambiguities, incompleteness, inconsistencies, errors or misunderstandings can be detected, avoiding their discovery during costly testing and debugging phases.

In particular, there are two main activities in the RAISE method: writing an initial specification, and developing it towards something that can be implemented in a programming language. Writing the initial specification is the most critical task in software development. If it is wrong, i.e. if it fails to meet the requirements, the following work will be largely wasted. It is well known that mistakes made in the life-cycle are considerably more expensive to fix than those made later.

Our goal is to work with reuse in the confines of the domain engineering, where there is no reference in RAISE process. Therefore, the introduction of a Domain Analysis method into RAISE is a crucial task considering the possibility of reusing the specifications in the future.

Examples of more relevant Domain Analysis methods include FODA, FORM and Featured Reuse-driven Software Engineering Business (FeatuRSEB). They support the notion of feature-oriented. This is a concept based on the emphasis this method places on finding the features or functionalities usually expected in applications for a given domain.

In a reuse strategy, domain analysis must be maintained over many systems, and the repository should contain domain models that form the basis of subsequent development activities. Domain analysis is essential to formalize reuse. However, it is missing from most software development methods. Reuse engineering extends information engineering by adding this new stage, to provide a place in the life cycle where the most valuable reusable components for the domains of the enterprise can be identified and a library containing these components can be created. At this stage of the software development, working with formal methods (or formal specification languages, specifically) implies to provide a means of unambiguously stating the requirements of a system, or of a system component. In this way, formally specified system components that meet the requirements of components of the new system can be easily identified. Thus, components that have been formally specified and sufficiently well documented can be identified, reused and combined to form components of the new system.

Nevertheless, the main problem is that we may not understand the requirements. Specially, when the requirements are written in a natural language the result is likely to be ambiguous. The aim of the initial specification is to capture the requirements in a precise way applying a reusability model.

Based on this paradigm, our work consists in the incorporation of the feature model into a RAISE formal method, filling the gap between requirements and the RSL (RAISE specification language) specifications. In this work we suggest introduce the phase -reusable domain analysis- using a feature model and expressing the relationships among them in RSL language. Thus, we can combine domain analysis notions with a formal language in early phases of development process. Particularly, we use the feature model proposed by FORM method, briefly described in section 2.

The remainder of the paper is organized as follows. In section 3, we briefly introduce the Raise method. Section 4 presents the integration of Domain analysis into RAISE. In section 5 we give a formalization of the relation in a feature model in RSL language. Section 6 concludes the paper and describes future work.

2. THE FORM METHOD

FORM product line engineering consists of two major processes: asset development and product development. Asset development consists of analyzing a product line (domain analysis, feature modeling) and developing architectures and reusable components based on analysis results. Product development includes analyzing requirements, selecting features, selecting and adopting architecture, and adapting components and generating code for the product.

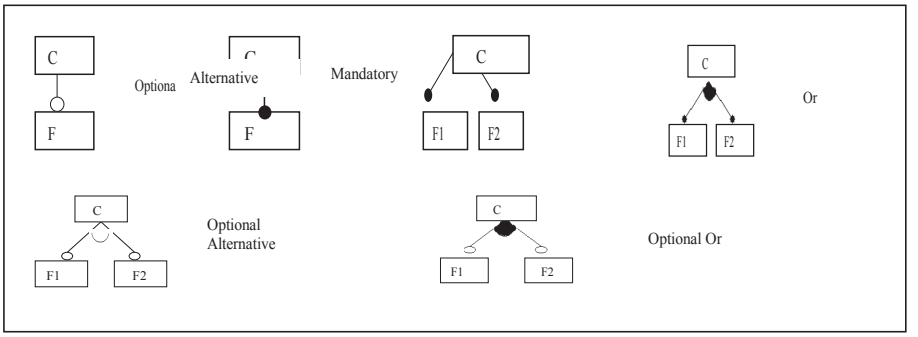
The FORM (Feature-Oriented Reuse Method) method comes as a concretization of the FODA (Feature-Oriented Domain Analysis) processes and has been recently extended by Feature Oriented Product Line Software Engineering (FOPLE) [10,11]. It provides guidelines for the creation of the feature model, design and implementation phases. FORM performs an analysis of domain´s features and attempts to provide a mapping between features and architectural components. This method follows all principles of modern software, being flexible, extendible and maintainable.

The use of features is motivated by the fact that users and developers often speak of product characteristics in terms of "features the product has and/or delivers". That is, services provided, and techniques used in applications are abstracted as features, and they are used by domain experts to communicate their ideas, needs, and problems.

To create coherent models, feature analysis involves tasks for identifying, classifying, and organizing product features as models. Feature models are a well accepted means for expressing requirements in a domain on an abstract level, and it resides between the requirements model and the system design model.

As potential features are identified, they are classified according to the types of information they represent. For example, users are concerned with functions provided by the systems (i.e. service features); analysts and designers are concerned about domain technologies, and developers are concerned about implementation techniques.

Figure 1. Types of features



FORM separates features into four different feature categories:

- *Capability features* are distinct services, operations, or non-functional aspects. Features of this category are end-user visible and are selected by the customer to specify the desired system.
- *Operating environment features* address the hardware and software components used by the family. All the components of a system with their interfaces and protocols are part of this category.
- *Domain technology features* are domain specific technologies and problem solutions, used by domain experts.
- *Implementation technique features* are general problem solutions, which may be used in different domains.

A feature model should cover all four categories of features for a domain. To make it possible, FORM uses the following constructs:

A *feature diagram*: a graphical AND/OR hierarchy of features, capturing the logical relationships (composition / generalization) among features. Three types of relationships are represented in this diagram: "composed-of", "generalization/ specialization", and "implemented-by". Features themselves may be "mandatory" (unless specified otherwise), "optional" (denoted with a circle), or "alternative" (denoted with an arc) [Figure 1]. A mandatory feature is neccesary for general users, and an optional feature is neccesary for partial users. Czarnecki [1] introduced the notion of sets of features.

Using the optional, mandatory and alternative criteria for features, it is possible to define subsets with constraints for minimum and maximum number of features to be taken out of this set.

Composition rules that supplement the feature diagram with mutual dependency and mutual exclusion relationships.

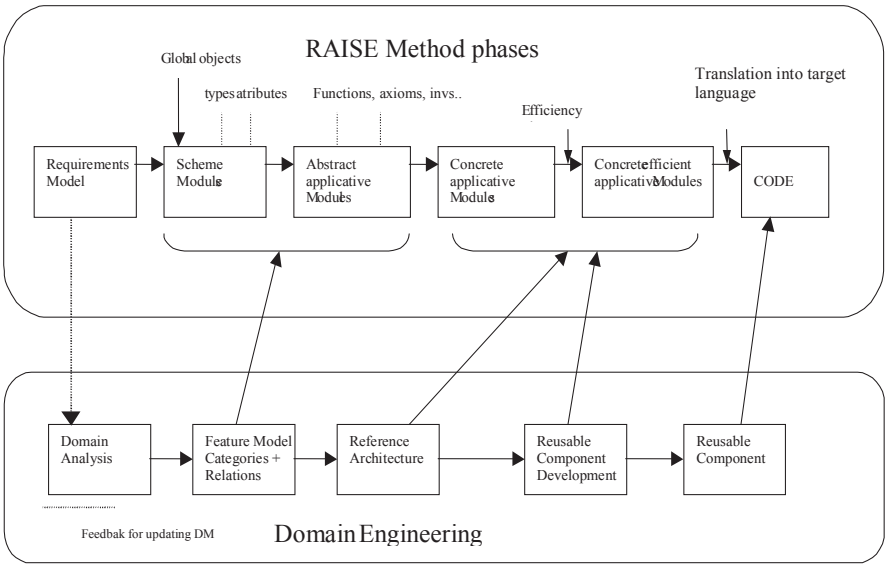
Depending on the domain, it is possible that AND/OR diagram tends to become complex. The AND/OR diagram was used to show the relationships among selected features.

Features are considered following the four level feature hierarchy, since the hierarchy reflects step-wise refinement in the reference architecture. These concepts are strongly connected with the style of development in RAISE, where the separate and step-wise are the basis to build a solid specification of an infrastructure.

3. RAISE OVERVIEW

RAISE method provides guidelines to hierarchically structure a specification, aiming at encouraging separate development and step-wise development. A development in RAISE begins with an abstract specification and gradually evolves into concrete

Figure 2. RAISE phases and DE



implementations. RAISE proposes to structure modules hierarchically in order to get a particular component over by reference only to it and its suppliers, to limit the effects of changes of a module to it and its clients, and to limit the properties of a module to it and its suppliers. It is an object-oriented method and covers a large portion of systems development phases.

Moreover, the RAISE method permits the abstract specification of sequential as well as concurrent systems, modular operations for decomposing large systems into subsystems and composing subsystems into a more complex system.

4. INTEGRATING DOMAIN ANALYSIS INTO RAISE

In this section we present the integration of domain analysis into RAISE method. The underlying idea is to specify and design a family of systems to produce qualitative application in a domain, as we can see in the lower part of figure 2, promoting early reuse and reducing development costs.

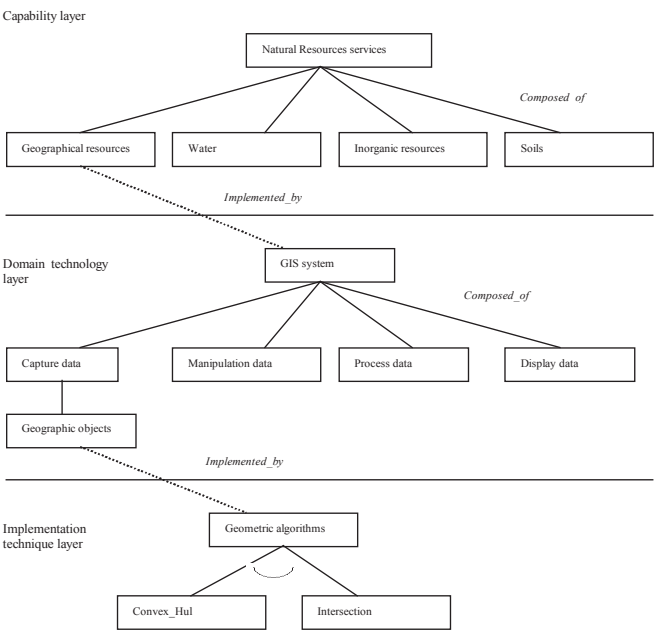
Domain engineering gives a set of guidelines that can be used to derive domain products from the feature model. The objective of domain engineering is to establish a mapping between the decision space (Feature model) and the artifact space (Reference Architecture). Each feature with the corresponding relations in the decision space somehow constrains the selection of the final reference model considering differences in types of features following the four level hierarchy. Feature model gives a set of guidelines that can be used to derive domain products from it and it is considered as an intermediate step between analysis and design models.

4.1 The Feature Model and RSL Modules

The objective of a feature model is to capture commonalities and variabilities of a family. There is a trace from the requirements to the feature model, and there are relations within the feature model. Categories help to elaborate features, but feature relations do not have a rigorous definition and we need the precise usage of relations for modeling.

Given the example of [12] in Figure 3 (Feature Model of Agriculture system domain), next section deals with some relations among features, and we show them described in a way we can automatically check the feature model for consistency. "Agriculture system" is an information system whose objective is a model which will help deciders to identify problems with the management and the access to resources for several purposes. Following, we discuss how the feature model serves as a guideline to identify RSL reusable modules.

Figure 3. Agriculture System partial feature model



In the partial example illustrated in Figure 3, Natural Resources service can be mapped respectively, into Natural Resources RSL module, performing a set of operations with its specific role. Once a feature is mapped into a module, the sub-features of the feature such as Geographical Resources, Water, Inorganic resources, Soils can be modules that are part of Natural Resources following the same type of relationships in the feature model (e.g., generalization, aggregation).

Moreover, operations can be mapped as internal functions to provide services, and they are a collection of types and values without type of interest. On the other hand, non-functional features include end-user visible application characteristics that cannot be identified in terms of services or operations, like quality attribute, cost, etc. So, they can not be mapped into any RSL constructions.

With respect to the model operating environment features, the RSL specifications are independent from the operating environment. These features can be mapped into the subsidiary RSL modules, which are less important from the point of view of development.

Model domain technology features such as GIS systems will be considered by the RSL system modules and they will be expected to be finally implemented as software modules. In object-oriented terms they will form the objects of the software system.

Modules derived from implementation technique features are generally used to implement or to derive concrete applicative specifications derived from capability or domain technology features. Geometric Algorithms would be part of a module called "Algorithms". This module will be defined as a generic module, i.e. a module we expect to instantiate more than once with different parameter, being the sub-features (Convex_Hull or Intersection) the possible instantiations. Each RSL module derived would be later refined and completed with the definition of functions. Once the RSL modules are derived from the feature model, they need to be organized into a model in order to represent how they are related to each other and what the contexts for their use are.

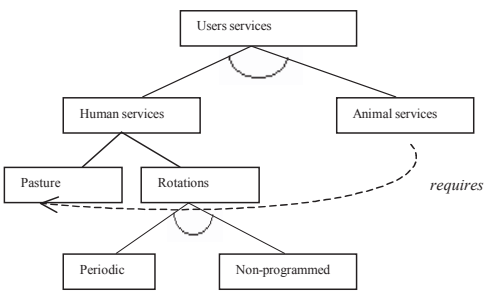
This simple heuristic is very useful in providing a good first reference architecture that will be the basis to specify the Concrete applicative RSL modules.

4.2 Dependencies in a Feature Model

To complete the feature model, we give an overview of dependencies used not only in FORM but also in FOPLE and FeatureRSEB. "Composed of" relation is used when a parent feature consists of a set of child features. "Generalization/specialization" relation connects very general features with concrete ones. "Implemented by" relation represents a connection between user-visible features and their implementation strategy, used in the specific domain. In Figure 3 we have taken a subset out of all the features of the Agriculture system. We show features of Natural Resources services: the features "Geographical resources", "Water", "Inorganic resources" and "Soils" are so-called mandatory features, and are part of the instance by definition.

The Capability layer is used to represent the details of the family required to further develop the system design, while Domain technology layer are specific technologies and problem solutions linked with the sub-feature Geographical resources. The Implementation technique layer are the 'solutions' used by domain experts (Example: Geographic objects are "implemented by" Geometric algorithms). "Requires" dependency (uni-directional) is used to describe if one feature needs another (e.g. Animal services "requires" Pasture, figure 4). "Exclude" depen-

Figure 4. "Requires" relation



dency (bi-directional) is used when one feature conflicts with another. “Hints” dependency is used to express that the choice of another feature increases the system usage. “Mathematical” dependency describes the relative impact from one feature to another.

5. FORMALIZING THE RELATIONS OF THE FEATURE MODEL IN RSL

RSL is one of the most versatile and comprehensive languages for formal specification, design and development of software. A significant advantage of using RSL is that it combines both algebraic and coalgebraic specification techniques in one specification language.

Different features in a feature model are related by different kinds of relations. Generalization, requires, excludes and implemented_by are considered binary relationships. Each relation in a feature model must be well formed. Next, the structure for each type of relation is defined as follows:

```
type
  Rel={|r:Rel1 • well_formed (r ) |},
  Rel1=
     Generalization | Implemented_by | Composed_of | Requires |
     Excludes ….
type
  Generalization::
       subfeature: Feature
       superfeature: Feature,
  Composed_of::
         has-part: Feature
         Part-of: Feature-set,
  Implemented_by::
       source: Feature
       target: Feature,
  Requires::
       source: Feature
       target: Feature,
  Excludes::
       source: Feature
       target: Feature,
   ……..
```

Below, we give the boolean function “well_formed” used to define well-formed relationships. Each relation has different properties. For example, the “generalization” relation must satisfy the following: a subfeature can not be root; the superfeature can not be leaf and the subfeature can not redefine the attributes of their superclasses. The “requires” relation describes that the binding of one variant implies the need of another variant (required variant). “Excludes” defines a feature relation that the selection of one feature excludes the selection of the other (see below).

Also, as relations are described in RSL language, all the concepts involved in the feature model can be specified in RSL. Multiplicity for features and parameters for features [1] in a graphical notation way may result ambiguous. It is neccesary to give clear semantics. The need to consider the complete set of relations has been identified by the feature modelling community, and approaches to formalizing them are defined in several formal languages [2, 14].

6. CONCLUSIONS

The use of formal methods in system development can help to overcome inconsistencies, and should aid the promotion of software reuse in early stages of software development. In this paper we present a first approach to integrate a feature model into RAISE methods to be used in the context of software reuse. The feature model enables to work with the identification of commonalties and variabilities among related applications creating a feature model of a specific domain. More precisely, a feature model has been developed for the “Agriculture system” being the basis to the specifications of the RAISE reusable component. In this work we identified basic features relations, i.e. Generalization, Requires and Exclude, among the features in a domain context. Our contribution is not only to define features, categories and relations in RSL; but also to give an approach to a rigorous reasoning of feature models. We are currently extending the work by taking feature interaction [13]. Feature interaction occurs when one feature modifies the operations of another. Also, we are working towards a reference architecture in the RAISE method framework.

The Value of Communities of Practice (CoPs) Within Knowledge Management (KM)

Micky Kerr, University of Leeds, UK; E-mail: m.p.kerr@sheffield.ac.uk

ABSTRACT

This paper focuses on Communities of Practice (CoPs) as one vehicle for managing knowledge in an international organisation, with core business areas in civil and defence aerospace, as well as industrial and marine power. The study aims to characterise the nature of CoPs in terms of the value they provide. 21 CoPs were sampled using a range of data collection methods, and thematic analysis resulted in the following four categories of value: re-use and transfer of knowledge; connecting and strengthening of networks; motives and rewards for participation; and gaining management support and organisational credibility. It is argued that the multi-dimensional value of CoPs implementations can be conceptualised as reducing costs, and/or adding benefits at various levels. Effective CoPs operate like a lens to draw in disconnected people, practices and knowledge, and then focus on relevant issues at personal, community and organisational levels. CoPs can be a powerful component of a holistic KM strategy, when the strengths of people's tendency to seek social interaction and share informal knowledge are balanced with addressing formal, business needs and demonstrating organisational value.

INTRODUCTION

This paper focuses on Communities of Practice (CoPs) as one vehicle for managing knowledge in the workplace. The research investigates 21 CoPs operating in an international organisation, with core business areas in civil and defence aerospace, as well as industrial and marine power. A review of the relevant literature on CoPs is used to inform the rationale and objectives for the present study. The research context and methods are then described, before presenting and discussing the main findings, and drawing preliminary conclusions.

LITERATURE REVIEW

Despite claims made by theorists and practitioners that Knowledge Management (KM) can be a primary opportunity for improved organisational effectiveness and gains in competitive advantage, the empirical evidence remains sparse (Scarborough, 2003). A consideration of the literature reveals a polarization between what may be classified as technology-based approaches and more social/people orientations to KM (McDermott, 1999; Wenger et al, 2002). Both technological and social solutions should be accommodated if an organisation is to manage knowledge resources effectively (Bhatt, 2001).

Bechy (2003) highlights the transfer of knowledge across boundaries as a major KM challenge, and the potential role of occupational CoPs. Indeed, CoPs have been forwarded as central to many KM strategies, particularly those aimed at facilitating knowledge sharing and exchange between geographically, socially and organisationally distributed workgroups (Brown & Duguid, 1991; Lave & Wenger, 1991; Orr, 1990). Ali (2001) further supports the importance of cultivating CoPs to promote the more creative and implicit features of knowledge activities. There is a significant interest in how to effectively capitalise on the organic, informal and resilient nature of CoPs, in order to cultivate and nuture them as more formal organisational knowledge assets (McDermott, 2000). From this standpoint, CoPs can help span boundaries created by typical hierarchical and bureaucratic organisational structures (Scarbrough, 2003). The emphasis is on encouraging the free and open sharing of experiences among CoP members about work, and facilitating this through trust and reciprocity with little direct management (Swan & Newell, 2000). However, the notion of cultivating CoPs and increasing the level of management and control means that some return on investment becomes a priority.

For CoPs, like many KM activities, this goal of demonstrating value is difficult to meet. Essentially, there is a recognition that it is easier for organisations to adopt, accept and justify technological KM solutions. However, guidance on nurturing these often fragile organisational units has been recently outlined (Gonglo & Rizzuto, 2001; Wenger et al, 2002.). Typically, this advice describes ideal lifecycle models of development, and offers suggestions on how to facilitate the CoPs through various stages to reach maturity and demonstrate value at the organisational level (Skyrme, 2002). Despite these advances, there is scope for empirical work on what the value of CoPs means in organisational reality.

Research Objectives

The reported successes of CoPs are limited to a relatively few number of organisations and small-scale case studies (Breu & Hemingway, 2002). With this in mind, the current study has the following objectives:

- to characterise the nature of the CoPs
- to categorise the value that CoPs can provide

Research Context

The research was carried out in a large global company providing power for land, sea and air, which has core business areas in civil and defence aerospace, as well as industrial and marine power. At this time, CoPs were being promoted and supported as one element of a company-wide KM initiative. Within this investigation, 21 CoPs were sampled using a range of data collection and analysis methods, which served to triangulate the findings and strengthen the overall claims. The CoPs covered a wide range of issues and topics including: parts and components (e.g. bearings, compressors, and control systems); analysis techniques (e.g. automatic and thermo-mechanical); engineering design (e.g. computational fluid dynamics and whole engine modelling); IT (e.g. computer-aided design and intranet development); and organisational strategy (e.g. business intelligence and knowledge management).

METHODOLOGY

The multi-method case study approach provided a comprehensive account of CoPs, and permitted the perspectives of the main stakeholders (i.e. facilitators, members and researcher) to be acknowledged and investigated. Both planned and opportunistic methods of data collection were used, with each technique offering particular insights. A qualitative survey and semi-structured interviews constituted the main methods of data collection, while the researcher also participated in workshops, meetings, and informal discussions. All data were analysed for qualitative themes.

Questionnaire

Initially, a short self-assessment questionnaire was developed collaboratively by the researcher and key contacts within the host organisation. This instrument was designed to elicit the views and opinions members had of their CoP, together with any future aspirations. It can be seen as a health-check mechanism or a method of

taking the temperature of a CoP (Adams & Freeman, 2000). The survey focused attention on CoP issues such as; objectives, activities, problems and successes, and was either administered at meetings or circulated electronically to the appropriate distribution lists. Anonymity was guaranteed and 52 responses were received.

Interviews

Ten interviews with facilitators and members of various CoPs were also conducted in the early stages of the case study. These allowed the researcher to become familiar with the specific groups under investigation, and started the process of gathering data about indicators of value. Subsequently a further 15 interviews were undertaken with facilitators and members. All interviews were audio-recorded and in order to retain a degree of informality and flexibility, a semi-structured interview guide was used to cover a set of issues (e.g. goals and objectives; roles and activities; problems and obstacles; successes and achievements)

Meetings and Workshops

The researcher also participated in meetings and workshops (n=15), which were centred on providing feedback to, and eliciting further views from CoP members. Several of these face-to-face events were used for more specific purposes, such as, gathering and documenting success stories and failures as useful lessons. In conjunction with the more formal methods of collecting data, informal discussions were also held with several of the CoP facilitators (n=5).

Thematic Data Analysis

The recorded interviews were fully transcribed, while detailed field-notes from meetings, workshops and informal discussions were also written up. As the survey responses were also in written format, the analysis was mainly qualitative and focused on developing themes to address each of the research objectives.

RESULTS

Key features of the CoPs are briefly described before outlining the main findings from overall analyses of value (see Table 1 for representative examples of the CoPs investigated).

Nature of CoPs

Although the CoPs initiative formed part of a larger KM programme within the organisation, two clear patterns of emergence can be distinguished. Most of the CoPs were initially informal interest groups, while a minority were set up in the wake of a disbanding project team. Typical objectives for these groups are to facilitate different types of KM processes, namely; solve problems (know-what), share good practices (know-how), and link people (know-who). Face-to-face meetings and workshops were common at start-up and then to review progress and plan next steps at regular intervals. Email, discussion lists and intranet websites allow on-going updates and news provision for members. In terms of organisation, some CoPs have become hierarchical and evolved sub-units with dedicated functions. There are also examples of CoP roles being distributed by company site location or across key individuals.

Value of CoPs

The study reveals the following four categories of value attributable to the CoPs initiative: re-use and transfer of knowledge; connecting and strengthening of networks; motives and rewards for participation; and gaining management support and organisational credibility. These factors are inter-related and within each there are several sub-components and characteristics of interest.

Re-Use and Transfer of Knowledge

A prominent aspect of this value indicator is re-using up-to-date knowledge to solve similar problems. This process was demonstrated within the Thermo Mechanical Analysis CoP, where a request for information on windage in oil dominated sumps was raised by an analyst based in Canada. Another expert in this type of analysis was able to provide an answer, because a similar problem had been encountered and successfully solved at his own UK site. Specifically, the solution was contained in test rig data, which were located and transferred between these individual members of the CoP. Within the same CoP, a second instance saw an enquiry for carbon seals information posed by a German member. This led to the name of a colleague based in USA being suggested by a UK member of the CoP. Overall, the international links within the CoP facilitated the feedback of advice and test data, about heat generation, and wear and tear on carbon seals, to the original questioner in Germany.

The development of good working practices is assessed as another valuable knowledge transfer contribution made by CoPs. The Facilitators CoP is a key player in co-ordinating efforts to learn lessons from both positive and negative experiences, and to draw upon wider KM resources and experts where appropriate. One tangible outcome is the documentation of this knowledge, which is shared among all the CoPs, through both electronic and face-to-face forums. This collaboratively developed material also serves to promote the CoPs initiative to the rest of the organisation. A member of the Computer Aided Design CoP articulates one part of a vision about how this KM system might function, in which for example, relevant knowledge concerning the rationale for design modifications could be incorporated into a website as an entry on a prompt list, a lesson learnt or a working practice.

Lastly, knowledge transfer can increase efficiency and reduce unnecessary repetition. For instance, the Manufacturing Laboratories Managers CoP conducts up-front work to obtain opinions on any proposed amendments to specifications, so that they are correct when formally issued. Such time and cost savings are also shown within the Computational Fluid Dynamics CoP, where requests from an out-lying group resulted in the retrieval of test data. The general consensus is that without the CoP, this data either would not have been found (i.e. cost of re-doing the test) or would have taken a long time and effort to discover (i.e. cost of individuals time). Subsequently, this episode influenced when and why expensive testing procedures should be conducted in the future.

Table 1. Example communities of practice

Nature of CoP	Core objectives	Main functions	Key activities	Example value
Group of CoP Facilitators	Help members to cultivate their own CoPs	Sharing similar experiences	Meetings aimed at picking up successful lessons	Agreed set of guidelines for setting up a CoP
Topic of Knowledge Management	Sharing latest ideas on KM – strategies, practices and technologies	Linking people with KM interests and pointing to new opportunities for collaboration	Themed/focused meetings rotating around company locations	Shift from focus on technology to holistic view of KM. Assist with internal innovative KM applications
Engineering Analysis Technique	Inter-project sharing	Problem solving across boundaries	Moderated discussion group	Time and money savings
Computer Aided Design Tool	Sharing best practice about this package	Learning	Website with hints, tips and Frequently Asked Questions	Faster lead user group (experts) development

Connecting and Strengthening Networks

CoPs in this study combat the disconnectedness of both geographically remote, and those less experienced members of the company. UK-based members of Whole Engine Modelling CoP admitted a lack of knowledge about what their US counterparts were doing. This has now improved to such an extent that they can locate and identify who, for example, has previous experience with specific measurement techniques and instruments. Likewise, the Combustion Cost Reduction CoP actively encouraged a *'know-who'* functionality by inviting nominations for membership, so providing access to the people who are judged favourably by their peers and managers. Other CoPs, such as the Bearings, also see expert identification and location as a key feature, especially for inexperienced members and those further away from the core activity. To launch the Bearings CoP, all group members provided a mini CV, which was then published as a who's who on their website. As a result, members have direct communication links to experts who are located in different domains, such as in-service and product-support.

The development and enhancement of such networks through boundary spanning also plays a critical role in the formation and development of a CoP identity. Within the Computational Fluid Dynamics CoP for example, membership has widened to include sub-contractors, who had previously reported a sense of isolation. These new members of the CoP now feel part of user group, and are excited at being invited to the quarterly meetings, where problems are addressed and best practice shared. Furthermore, spanning boundaries through sabbatical visits between Canadian and UK members of the Whole Engine Modelling CoP have been used to encourage a two-way exchange of experience between sites with strengths in different modelling methods.

Motives and Rewards for Participation

For many members, participation in a CoP is internally motivated to some degree, as the communal activity was seen as inherently valuable. It is also clear that ensuring participants get positive feedback from their investments of time, effort and knowledge is critical. This form of outcome is encouraged through a feedback cycle of making the experience useful (e.g. learning something new or seeing the outcomes of a contribution), so that members became more likely to participate in the future. Likewise, a more vibrant and active CoP also tends to increase the chances that participants would enjoy a positive and valuable experience. Findings from several CoPs, most notably the KM, indicate the importance of a non-judgmental arena and the development of trust to motivate and encourage involvement.

Gaining Management Support and Organisational Credibility

The final mode of value exhibited in this study concerns the challenge faced by CoPs to acquire a sufficient level of organisational support while retaining a degree of self-ownership and direction. Several of the CoPs were able to help projects and other formal groups accomplish their tasks more efficiently. This greatly enhanced their credibility and focused their efforts on relevant issues for the organisation. Generally, management support and recognition helps to give credibility to the CoP and indicates that it is seen as valuable. A reciprocal relationship, which requires on-going negotiation between CoP members and the organisation as a business, is also regarded as another feature helping survival. In the Web Editors case, retaining sufficient organisational support, while adhering to a self-management philosophy helped to manage the transition from a project team to a CoP. To date, most value for the company has been delivered through knowledge exchange between business units and in cultivating innovative and holistic KM practices and thinking.

DISCUSSION

The foremost value indicator comprises the core elements of knowledge management espoused in much of the literature, namely building on and re-using previous experience, while also generating new systems for creating, sharing and transferring knowledge (Kakabadse et al, 2003). CoPs not only provide contexts for sharing expertise (Breu & Hemingway, 2002), but also help develop expertise quicker by giving members the opportunity to become recognised as experts in a particular topic or domain (Archichvili et al, 2003). The Web Editors CoP is a good example of a "learning CoP", where novices gain knowledge about building and publishing intranet sites from experienced members.

Findings are consistent with Archichvili et al (2003), who report that CoPs can help reduce the duplication of activities, through timeliness and efficiency in acquiring information. In line with the existing investigation, they also found that CoPs could operate as a general encyclopaedic problem-solving tool, as an expertise identifier, and as a way of keeping informed and up-to-date about developments in their profession (Archichvili et al, 2003). Having access to best practices and lessons learnt via the CoPs was key to bringing about this multi-functionality.

The current research supports earlier work by Scarbrough (2003), who concludes that one major benefit of CoPs is integrating previously weakly or non-related individuals and professional groups within any organisation. On a related theme, Boland and Tenkasi (1995) highlight the role played by information and communication technologies in fostering a shared or community identity across dispersed employees. It can be argued that as members become connected to people they would not have had a chance to without the CoP, the social capital of the organisation is strengthened (Archichvili et al, 2003). Furthermore, the capability of the CoPs in this study to moderate the fragmentation of people and knowledge may be very useful in providing continuity during times of change and uncertainty (Breu & Hemingway, 2002).

In terms of encouraging CoP participation, Breu & Hemingway (2002) present a similar "success breeds success" argument, in which members can test out their ideas in a risk-free environment without many negative consequences. Motivating factors highlighted within the current investigation include; the role of relevant professional interests, together with satisfactory prior experiences, the integrity of the organisation, and the competence of members to encourage active engagement in CoPs (also see Archichvili et al, 2003).

Although the shift from informal interest groups to CoPs can be seen as part of the company's wider KM initiative, it also exhibits a sense of legitimisation (Wenger, 1998) and an element of sponsorship (Nickols, 2000). Previous studies tend to position CoPs as pre-cursors to generating value at the organisational level. For instance, the creative and innovative nature of CoPs can be cultivated to focus on formal project work with unambiguous and observable organisational deliverables (Breu & Hemingway, 2002). Similarly, Von Krogh et al (2001) emphasise the role of CoPs in making knowledge explicit, with subsequent strategic application towards business goals, both within the organisation and to external partners. They offer a phased description of how these should be managed and outline a raft of organisational benefits, including better decisions on investments and collaboration across geographical and functional company boundaries. Similar findings are exhibited in the current study, although the Web Editors evolution from a project team to a CoP is an interesting exception to the typical pattern of development.

CONCLUSIONS

This paper has explored Communities of Practice (CoPs) as one form of Knowledge Management (KM) enacted within the engineering context of two aerospace organisations. The current research argues that the value of CoPs implementations are multi-dimensional and can be usefully conceptualised as reducing costs, and/or adding benefits at various levels. CoPs should be inherently rewarding at the personal level in order to capitalise on individual motivations. At the group level, the value is in connecting people and their expertise. The re-use and transfer of both explicit and implicit knowledge through social and technical mechanisms is a defining feature of this form of value. While it is advocated that members should control and negotiate what they do and how they do things in the CoP, there should also be some clarity about the benefits offered to the organisation.

Successful and effective CoPs can best be depicted as operating like a lens to draw in disconnected people, practices and knowledge, and then focussing on problems and issues of relevance at personal, community and organisational levels. Accommodating these multiple requirements pose questions for managers, researchers, and practitioners alike. In terms of recommended ways forward, sub-groups could be used to consolidate the depth of core knowledge within the CoP, while recruiting new members may help to widen its scope. Overall, combining the strengths of people's tendency to seek social interaction and share informal knowledge, with the organisational benefit of addressing more formal, business needs, CoPs can be a powerful component of a holistic KM strategy.

ABSTRACT

Software development is a complex business, whether maintaining or extending existing legacy systems, or whether developing new systems. Another challenge faced by programmers, is determining whether sufficiently rigorous unit- and integration-testing is employed to give confidence that a system is behaving as intended. One approach to help address such challenges is to use automated program analysis tools and techniques, where the programmer will use a software tool to gain an insight into some aspect of the system they're working on. One particular type of static program analysis technique, call-graph analysis, focuses on the calling relationships that exist in a program. One of the common problems with this and other static analysis techniques is that they tend to be source language based and are therefore often limited in terms of applicability, especially in multi-language/module systems. In this research we investigate call-graph analysis on the .Net platform that sidesteps these common limitations and allows analysis of programs regardless of source language, and regardless of the number of modules/assemblies in the program. We demonstrate the soundness and usefulness of the approach by demonstrating the analysis of a multi-module application that is written in several different source languages from 2 different vendors.

Keywords: Call-graph analysis, .Net, Program analysis, Integration testing

1. INTRODUCTION

Key challenges faced by programmers today include the difficulty of understanding complex codebases while performing maintenance and ensuring that test-suites sufficiently cover the code in question. Software maintenance particularly often involves many difficulties, including gaining an understanding of the system being modified or analyzing an existing system as a whole. Understanding a system is often complicated by documentation which is either out of date, limited or in some cases even non-existent, and analyzing a system is complicated when it spans over several languages, implementation modules, and/or process boundaries. By 1990, the amount of legacy code being maintained was already estimated at 120 billion lines of code (Sommerville 2001, p. 623.) Today, this is estimated to be in excess of 250 billion lines of code! (Losch 2005) With a legacy codebase of this size being maintained, the argument for re-engineering systems instead of outright replacement becomes quite compelling.

These challenges are typically addressed through suitable program comprehension and -coverage analysis tools. A key data structure used by both these types of program analysis tools is the program call-graph. Call-graph analysis focuses on the particular calling relationships that exist in a program, and the results of such a tool are very useful in determining the call relationships used to track errors and design suitable test data for unit and integration testing. However, conventional program call-graph analysis often relies on program source code parsing techniques, which limit it to that particular source language. Thus, if the system consists of multiple modules written in multiple languages then it follows that it would be extremely difficult at best to do a full-program analysis, unless you have analysis tool(s) that can read all the source languages and can inter-operate when generating the call graph. An alternative approach that addresses both these limitations is to perform analysis on .NET Common Intermediate Language (CIL) instead of the program source language. In this research we develop a simple software framework and a prototype call-graph analysis tool using CIL, thus in principle demonstrating the feasibility of this approach in practice.

The contribution of this paper is in the development of the prototype model mentioned which provides a usable foundation from which further work may be conducted, on the .Net platform and CIL. Details of the model are given in Section 3, followed by a short discussion and outline for future work.

2. BRIEF LITERATURE REVIEW

While we've had program development, there seems to be renewed interest in many types of such tools. This interest is driven by several factors, including the increased capacity for analysis on today's machines, the increasing ability for analysis as a result of software platform advances, and the changing focus of the industry with respect to software development and maintenance. Ultimately however all of these things can be largely drawn back to the problem of software maintenance and software change. If a system was not that well designed to begin with, or if it's been modified in less than ideal ways and accumulated a substantial so called "code debt" (Fowler 2000, pg. 66), gaining an understanding of the codebase, clarifying its original design intentions and developing meaningful test suites are crucial (for which such tools are very useful.)

Call Graph Analysis

Olin Shivers' provides a succinct description of the call graph analysis problem: "*For each call site c in program P, what is the set F(c), that c could be a call to?*" (Shivers 1988):

Call Graph analysis is the process of generating a program call multi-graph (call-graph) for a program. It's a directed graph where nodes represent procedure, function or method names, and edges represent calling relationships (Aiken 2005). A program call graph is therefore a control flow representational construct at the inter-procedural level (therefore not showing detail inside procedures/methods.) A call graph may also be described in textual form by enumerating all the nodes) together with the set of edges between them. Note however that this description actually encompasses several possible meanings, for example:

method m_i invokes method m_j

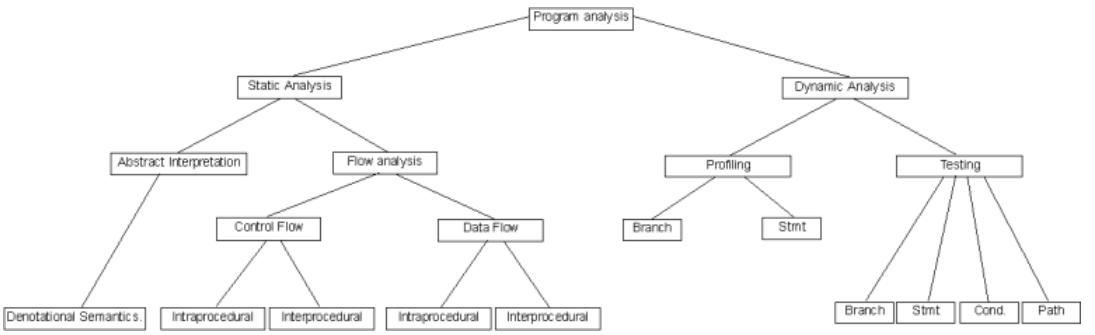
call site c_k inside mi invokes m_j

call site c_k inside mi invokes m_j on an instance of X (Rountev, Kagan & Gibas 2004)

Figure 1 below shows a taxonomic breakdown of program analysis in general, serving to place call-graph analysis into the broader program analysis context:

Call graphs are central to various types of compiler optimizations, including both inter-procedural optimization (where the effects of callers and callee's are summarized into the call graph) as well as intra-procedural optimization (for example where the included receiver class sets may allow method invocation to be bound statically instead of dynamically). Call graphs are also central to several other types of analysis such as call-chain analysis and call-tree coverage analysis, and is also useful in various types of developer tools, such as test tools, debug tools and program understanding tools.

Figure 1. Taxonomic breakdown of program analysis (Losch 2005)



Call graph generation in first order languages such as FORTRAN is very easy: It can be performed by firstly generating the nodes by finding all functions in the program, followed by insertion of edges for each function call that exists in the program. That is, for each call to function *b()* in arbitrary method *a()*, you insert an edge (a,b) (Lakhotia 1993, pg. 273).

In higher order languages things are unfortunately substantially less simple, due to the requirement to estimate the receiver classes at call-sites prior to call-graph construction. The problem is more or less as follows: In order to perform Inter-procedural data flow analysis (a process whereby you compute summaries of the effects of callers and callee's at function/procedure entry points and call-sites respectively, which may be consulted during optimization (Grove 2001, pg. 686)), you need to have already constructed a call graph that may be traversed during this analysis. As mentioned, in first-order languages there is no problem as the the target function is directly and unambiguously evident from the call site. However, with object-oriented languages with dynamic dispatch mechanisms, the actual target of a call site is usually dependent on the data flow(s) to that point in the program (in particular, the actual class type of the object variable on which the method call is performed), which implies that you need to have already performed some form of data flow analysis in order to discover the actual receiver classes for a call site (ibid)! Thus there occurs a seemingly paradoxical situation.

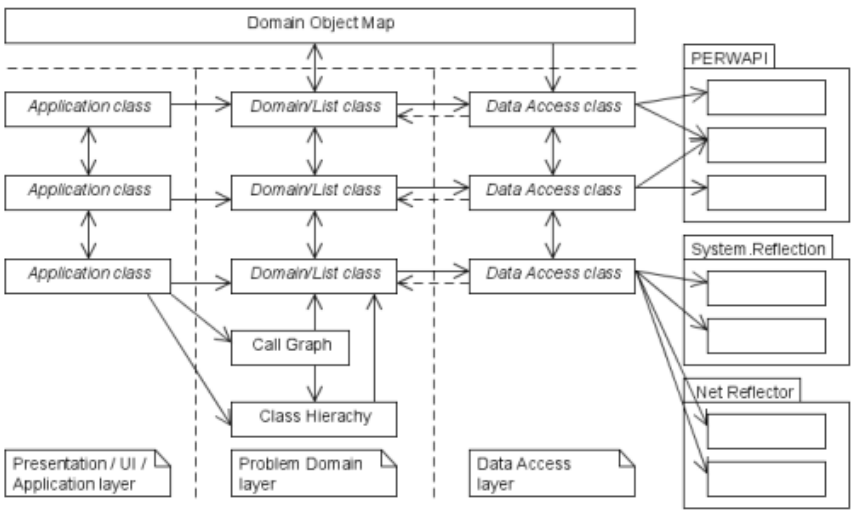
Typical solutions include performing the two steps in parallel (to be precise to interleave them), or to make suitable assumptions (whether optimistic or pessimistic) for one of the three entities involved (call-graph, receiver class sets or inter-procedural analysis) in order to break the deadlock and then iterating the solution to a suitable solution point (ibid). Dean compares and contrasts several techniques for the construction of call-graphs in the presence of "higher-order" functions and goes on to evaluate them in terms of three properties, namely: Precision; Time complexity; Supported Language features (Dean 1997, pg. 2).

Grove & Chambers present a fairly comprehensive evaluation of existing call-graph construction algorithms in (Grove 2001). They implement the evaluation via a generic parameterized call-graph construction algorithm implemented in the context of an optimizing compiler infrastructure. This approach allows them to validly compare different call-graph algorithms on a "level playing field."

Call Graph Analysis at Intermediate Code Level

While some research has been done with respect to program analysis in general and call-graph construction in particular using VM's and intermediate languages, most of this work is Java based. For example, Lance presents work where the unmodified bytecode output by a Java compiler was analyzed to produce "end-product program analysis information" and utilized a prototype to prove the concept (Lance 1999). Another work by Maggi & Sisto demonstrates the feasibility of performing data flow analysis against Java bytecode to infer type information (Maggi 2001). On the other hand, Zhao demonstrates the viability of performing intra-procedural dependence analysis using Java bytecodes in their work (Zhao 2000). Other work such as that by Arnold (2005) examines the idea of using dynamically collected profiling information, collected via the virtual machine itself to generate high-accuracy call-graphs.

Figure 2. Analyzer architecture layout



Finally, Searle presents a tool called "DUCT" (for Define Use Chain Tool) which focuses on "relative debugging" and the following of "define-use" chains in program code. DUCT, unlike most other research focusing at the intermediate level (and very much like this research) leverages .Net CIL to allow it to operate on "a wide variety of languages without modification." (Searle 2003) Additionally, it should be noted that DUCT uses an incremental approach and mostly avoids traditional global program analysis (although like other incremental algorithms it also does require an initial full analysis to start with). DUCT's implementation uses essentially 3 analysis data structures, namely a Control Flow Graph, a Class Hierarchy Graph, and a Call Graph.

3. CALL GRAPH ANALYZER IMPLEMENTATION

A layered architecture, typical of many systems and particularly 3-tier business systems was used, as initially there was some uncertainty with respect to exactly how the .Net files would be interacted with (i.e. it was uncertain which back-end library or combination of libraries would be used to read the IL assemblies.) The analysis framework along with all algorithms and logic it contained was therefore to be well separated from the mechanics of actually retrieving the information, thus making it possible to easily change the data-access aspect without affecting the rest of the analyzer too much (hence the similarity to how a tiered business app might use an object persistence framework to insulate itself from database platform changes.) The particular architecture was inspired by an example object-persistence framework by Philip Brown (2000). The original architectural layout is shown in Figure 2 below. The idea was to contain the "analysis domain" logic in the middle layer, keeping separate all assembly data access concerns in data access classes in the right-had layer. These in turn delegate to one or more underlying reflection libraries to get their work done. Lastly, user interface and other application logic are kept in the application layer on the left.

Since most domain classes would have a common need/requirement in terms of having to be populated/loaded from the back-end API's by the data access classes, having this functionality common to a base domain class seemed sensible. Similarly, common data access behavior could be put in a base class for all data access classes.

The implementation used C# as primary implementation language, but also used all of the other languages available in Visual Studio 2005 (Beta 2) namely C++, VB.Net and J#, as well as Borland Delphi, as an alternative vendor's language. Small test libraries or assemblies were constructed in each of these languages, some with multiple links, as test cases for the analysis. For example, there's a C# test application that calls on a J# library, that in turn calls on a C++ library.

Other tools used include the Nunit unit testing framework for .Net as well as TestDriven.Net (a plug-in for Visual Studio that make Nunit testing available from within the VS IDE.) Note that Visual Studio 2005 (however, only the high end Team Suite edition) now has built-in Unit testing support (which is clearly closely modeled on Nunit's approach). It also includes other code analysis support functions, such as unit-test coverage analysis. For version control Subversion was used, together with the TortoiseSVN plug-in for Windows Explorer.

4. PRELIMINARY RESULTS

We now demonstrate and evaluates the .Net CIL based analyzer in actual use, firstly using an "Animal Taxonomy" example inspired by a somewhat similar example using the usual Shape/ Square/ Rectangle hierarchy in the Java language, by Rayside (2001). The main assembly listing is shown in Table 1 below. The components were compiled into .Net executables files and then run through the analyzer. Then the analyzer is evaluated and demonstrated to operate on a multi-assembly application where one assembly was constructed using a compiler from another vendor.

Firstly, the analyzer was run without Class Hierarchy Analysis, and as would be expected, this was processed extremely quickly, but also incorrectly includes an edge between AnimalInheritance.doATrick(Mamal) and Mamal.rollOverAndPlayDead(). Class Hierarchy Analysis (CHA) can be described as the process of the calculation of a program's inheritance hierarchy (Dean et al. 1995, pg. 1). Performing Class Hierarchy Analysis produces some form of Class Hierarchy Graph (whether explicit or implicit). This structure describes all the inheritance relationships between the classes in the program, as well as the methods that each class contains, particularly virtual and overridden methods and which ones are abstract (Bairagi 1997, pg. 2). In this case, the runtime was on the order of 47ms

Table 1. Animal taxonomy main listing (written in C#)

```
 1: namespace AnimalInheritance {
 2:   abstract class Mamal { public abstract void rollOverAndPlayDead (); }
 3:
 4:   class Cat     : Mamal { public override void rollOverAndPlayDead() { } }
 5:   class Hamster : Mamal { public override void rollOverAndPlayDead () { } }
 6:   class Dog     : Mamal { public override void rollOverAndPlayDead () { } }
 7:   class Terrier : Dog { }
 8:
 9:   class AnimalInheritance {
10:     static void doATrick ( Mamal m ) {
11:       m.rollOverAndPlayDead();
12:     }
13:
14:     static void Main ( string[] args ) {
15:       doATrick( new Terrier() );
16:     }
17:   }
18: }
```

in this case. This value appeared quite stable and repeated runs did not alter this value appreciably. The results of a particular run can be viewed in Figure 3.

Following these experiments, the analyzer was run with the aid of Class Hierarchy Analysis, but using a conventional full-program scan to build the class hierarchy. The results for this can be seen in Figure 4. As expected this was several orders

Figure 3. Execution of call graph analyzer without class hierarchy analysis

     [TFact.Fact(Int32) : Int32] ------->[TFact.Fact(Int32) : Int32]
     [CSAppRefDelphiLib.Main(String[]) : Void] ------->[Environment.Exit(Int32) : Void]
     [Environment.Exit(Int32) : Void] ------->[Environment.ExitNative(Int32) : Void]

Time taken: 187 ms.
```

of magnitude slower, both in space and time required, comparing the number of classes and methods processed and the time taken to the previous run. Time taken was approximately 7593ms (with an estimated variance of about 200ms based on observing repeated runs). This is at least 2 orders of magnitude larger than before. The discrepancy between the storage requirements here and previously is even more staggering: approximately 2,000 classes processed versus just 5 before and about 20,000 methods seen versus just 6 before.

Here we can see the analyzer now being very conservative, by now including all three of Cat, Hamster and Dog classes as being receiver classes of the rollOverAndPlayDead method call (together with also including for safety, all visible types in all referenced assemblies. Finally, we show an example where the analyzer was run to strictly include only the reachable types when building the *Class Hierarchy Graph* (CHG). (This is in terms of processing result much like that of the *RTA* algorithm by Bacon and Sweeney (1996), however the actual algorithm is rather different.): The output was as follows:

The performance is markedly improved, evidently back to where it was in the beginning in terms of time, with the class count also being the same as the first experiment and the method count being marginally higher. More importantly, the result is also a lot more accurate, thanks to the extra intelligence employed. Clearly the cost of blindly traversing all of the "visible" program code, without analyzing whether it is in fact reachable from the main entry point is enormous.

One of the key goals of this research was to prove that it was possible to do multi-language/multi-module full-program analysis. We therefore also tested the analyzer with several multi-language scenarios, including this one where a C# application calls on a Borland Delphi library. The source for the both functions are given in Table 2.

Table 2. Call graph analyzer multi-module example: Program code

C# Main Program Code

```
using System;
using System.Collections.Generic;
using System.Text;
using DelphiLib;

namespace CSAppRefDelphiLib {
  class CSAppRefDelphiLib {
    static void Main ( string[] args ) {
      TFact fact = new TFact();
      System.Environment.Exit( fact.Fact( 5 ) );
    }
  }
}
```

Delphi Library Code

```
library DelphiLib;
 type
   TFact = class
   public
     function Fact (n : integer) : Integer;
   end;

function TFact.Fact( n : Integer) : Integer;
begin
  if n = 0 then
    result := 1
  else
    result := n * Fact(n -1 );
end;

begin
end.
```

These two programs were compiled by completely different compilers written by completely different vendors. The main program was fed into the analyzer as input. The output is shown below in Figure 6.

As can be seen, the analyzer had no problem with the fact that the library was originally written in another source language, as should be expected. It can be inferred that a different language was used through visual inspection from the type names, but that is all. There are no other obvious differences. It would be interesting to re-run some of these tests against/on the Mono platform.

5. BRIEF DISCUSSION

Most conventional program analysis approaches employ source based approaches, either simple text I/O or actual scanning and parsing techniques. In some cases byte-code analysis is also used, although this (with a few exceptions) focuses on Java bytecode rather than .Net CIL. While a detailed quantitative comparison of techniques is outside the scope of this research, it is nevertheless useful to try and establish qualitatively the relative strengths of the various approaches, so as to establish whether the .Net CIL based approach is comparable, better or poorer than conventional techniques. There does not appear to exist any comparative study in the literature that compares both source and bytecode based approaches as part of the one study. Murphy (1998) presents an empirical study of static call-graph constructors and states that "four choices of input format are available for the developer of an extractor for a system implemented in C: unprocessed source, preprocessed source, object code with symbol table information, and executable code with symbol table information." Unfortunately they also state that their focus was on source based processing in their study and that object-code based analysis was thus out of scope.

The first observation to make is that .Net CIL files tend to be very compact. The IL assembler language is actually quite simple, and while op-code's can be multiple bytes, most of them (90%) are in fact single bytes. To be precise, there is at present only 250 op-codes, 225 of which occupy a single byte, the remainder occupying 2 bytes (Lidin 2002, pp 422 - 428). Roughly speaking, based on estimates observing the ratios of source code to binary size of the Analyzer code, test case libraries and example libraries produced as part of this research, it would appear that the ratio of IL binary size vs. Original Source code size would be about 2:3. More investigation would be needed to establish whether this observation is borne out in larger systems. But in any case, in terms of I/O overheads, it can therefore be argued that IL will probably be as easy or easier to deal with than text based source code.

Of course, on today's machines, I/O throughput is unlikely to be a significant bottleneck during program analysis. However, as can be observed by trying to analyze even trivial programs with the analyzer while employing a naive approach to what is read as "potentially callable," it is quite possible to have the analyzer consume several hundred megabytes of memory and take several minutes of processing time. So the real problem lies with managing the intermediate in memory representation, and with the algorithms employed during analysis. Here the IL

based approach will suffer the same challenges faced by text based approaches – there is essentially no advantage to either approach from this point of view.

Comparing Java bytecode based analysis to .Net bytecode based analysis, it appears that some of the Java bytecode approaches suffer somewhat partly because of weaker reflection support (whether third party libraries or in the platform.) Lance (1999, pg. 5) presents their "JAristotle" bytecode based Java program analyzer. He remarks that the development of the bytecode based prototype required the writing of (only) 13,700 lines of Java code, and contrast this with the prior "Aristotle" based front-end (which was source based) and required modification to some 30,000 lines of an existing C parser to implement. While probably not directly comparable (since that analyzer computes intra-procedural flow-graphs, not call-graphs) it is nevertheless instructive to note that the .Net CGAnalyzer source code consist of approximately only 1500 lines of C# code, and this includes more than one approach to the analysis as well. This appears to be due in part to to the stronger reflection and introspection support in the .Net platform which enabled us to avoid writing code to directly deal with IL bytecode. This advantage is in addition to and apart from the implied advantages of being able to analyze whatever language target the .Net platform.

6. CONCLUSION AND FUTURE WORK

This research project investigated the possibility of leveraging .Net's CIL bytecode together with reflection support as a vehicle for static program analysis, in particular call-graph analysis, and successfully implemented a prototype to prove the concept. Like Lance (1999) this approach has the benefit of sidestepping the usual lexical and syntax analysis that is associated with conventional source based analyzers, with a consequent lowering of the amount of effort required to get a working analyzer going. Unlike Lance (1999) our approach focuses on .Net, a platform that is deliberately multi-language, and one that is likely to be increasingly used as a platform for legacy migration. In this way, this work therefore will ultimately contribute towards easing the maintenance burden for legacy systems.

The focus on .Net has also made the entry to program analysis easier in other ways. There are a number of API's and libraries available to choose from that can shield one from having to even deal with the bytecode oneself. All of this is reflected in the number of lines of code that was required to effectively implement a protoype analyzer with several analysis features, including a form of Class Hierarchy Analysis and an RTA-like call-graph generation algorithm (that uses a "reachable types only" approach to limit the amount of analysis work done.)

There are clearly many potentially interesting areas for future work: This research project was originally started with a view to call-chain analysis. Having now developed a basic call-graph one could now go directly forward and add some form of call-chain analysis. Call-chain analysis is sometimes used in the context of integration test coverage analysis (see for example (Rountev 2004b)), which requires dynamic analysis support as well to measure the actual chains occurring at runtime. As such, another avenue of work may be to investigate dynamic analysis support on the .Net platform with a view to fully supporting call-chain analysis as part of integration test coverage.

ACKNOWLEDGMENT

This research project was undertaken as part of a Master of Science degree with University of Liverpool and Laureate Online Education.

ABSTRACT

The concept of the domestication of media technologies has been developed to describe and analyse the processes of technology's acceptance, rejection and use. The concept is both theoretical and conceptual but proves to be valuable when applied to everyday life scenarios. This paper employs the Silverstone model of domestication (1989, 1992) as a structural and analytical framework to achieve an empirical understanding of domestication from the viewpoint of the domestic user of the internet. A model of re-domestication is offered to comprehend the process of domestication through the eyes of everyday users.

INTRODUCTION AND BACKGROUND

The field of technology acceptance and adoption has its roots in information systems and in systems of innovation disciplines. Everett Rogers' S curve adoption model (1995) and the TAM are widely used by researchers wishing to predict user acceptance of information technologies. With such technology focused treatments of the process of adoption and use very little is known about how the user experiences the social processes through which technologies undergo in order to become accepted and used in everyday life. In order to bridge this knowledge gap, this paper will present findings from a study of domestic internet users on their personal experiences of how internet technologies become part of their everyday life – in other words, how technologies are domesticated.

The dominant technology-led models (Negroponte, 1996, Kelly 1999) provide an inadequate explanation of how ICTs are incorporated into the household. In fact, these technological determinist accounts completely ignore the role of the user in the process. Such models suggest that ICTs come into the household as completed or self-contained artefacts, with fixed interpretations and meanings. This ignores the role of users in shaping or reshaping technologies in many important respects. Users of technology are generally (and too easily) conceptualised as relatively passive end users and are thus overlooked or taken for granted. Technological artefacts are treated as 'black boxes', and users are denied agency to choose, use and experience them in different and varying ways. This, in turn, denies them a role in the active construction of meaning.

This paper will focus on the human side of the relationship between users and computers/internet. The domestication process is essentially about how relationships between humans and technologies are constructed, maintained and modified. Domestication is, above all, sensitive to the social factors (age, gender, class to name but a few) that are central to how both the user and the technology are mutually shaped in this process. Domestication is one of the more accepted conceptual frameworks used to analyse ICT users and their relationship to technologies they use. Domestication was deemed more suitable than alternative adoption of technology models (for instance, Rogers 1995) as it signifies the ability of individuals, families, households and other institutions to make new technologies and services their own; to integrate them into everyday lives. In a dialectical process, skills and practices interact with and underpin the construction of meaning around the use of ICTs.

The concept of domestication was first formulated to deal with the appropriation and use of mature media technologies, such as television (Silverstone *et al*., 1992). This produced a 4-stage model of domestication aimed at making sense of the process whereby people come into possession of a new technology, for whatever reason, and where they subject the technology to social processes in order to 'tame' or 'integrate' the technology into their lives, and into the moral economy of the household.

The domestication concept, as expressed and employed here, is very much a European construct. First developed in the UK by researchers at Brunel University to explore the relationship between media and households (Silverstone *et al*., 1989, 1992), it was later applied by Norwegian researchers and other technologies such as cars and smart houses (Lie & Sørensen 1996, Berg 1999). Domestication more recently has been extended and applied to organisational contexts (Pierson, 2006) and to educational contexts (Hynes & Rommes, 2006) where humans seek to eke out a place for technology in their daily routines of both learning and work.

In this paper, domestication will be applied as a tool which helps in analyzing the process through which the user makes the technology 'one's own', a process in which both the technology and its user are changed. This process takes place through various phases or dimensions in which the artefact is fitted into the routines and practices of the everyday life of its user (Silverstone et al., 1992; Lie and Sørensen, 1996; Aune, 1996; Mansell and Silverstone, 1996; Frissen, 1997; Mackay, 1997). The product of the application of domestication in this way provides an ethnography of how users themselves experienced the process of how the internet became a part of their everyday lives.

THE FOUR PHASES OF DOMESTICATION

n the **appropriation** phase, possession and ownership are central. The acquisition of the technology is the main activity or concern. A technology gets appropriated as it is sold and then owned or possessed by a household. That is the point at which a commodity crosses the threshold between public and private, beginning its new life as a domestic object. **Objectification** tries to capture how values, tastes or styles are expressed through the display of the new technology. It involves both a spatial aspect (where it is placed in the house), and a temporal aspect (how it is fitted in the time structure). However, the spatial aspect is more central in this phase, '…physical artefacts, in their arrangement and display, as well as…in the creation of the environment for their display, provide an objectification of the values, the aesthetic and…cognitive universe, of those who feel comfortable or identify with them' (Silverstone *et al*., 1992:22–23). The **incorporation** phase emphasises how ICTs are used, and the temporal aspect is more central in this phase. Silverstone *et al*. (1992) suggest that for an artefact to be incorporated it has to be actively used, such as in the performance of a task. The **conversion** phase is concerned with the relations between the households' internal affairs and the public domain or outside world. This phase is also concerned with how users speak and articulate their relationship with technology.

This model, however, is posited as a paradigmatic process with abstract phases relating to user experiences. The Silverstone approach, in some ways, lacks a real sense of *user* experiences. In some respects, it can also appear rigid in the ways phases are entered into – these become blurred when applied to new media technologies (especially the computer and internet). The challenge of this paper, then, is to empirically apply the Silverstone domestication model and assess whether this process can be transferable to new ICTs.

METHODS AND APPLICATION

The empirical dataset is drawn from small-scale qualitative study of 16 households as part of a wider doctoral research analysing the use and consumption of new media technologies in the household setting in Dublin, Ireland (Hynes, 2005). The households were drawn from middle class and working class suburban areas and were of varied composition. Instead of a survey of a representative sample of the population to provide a package of easily managed figures and statistics,

this paper will strive to eliminate objectivity in order to achieve subjectivity. Subjectivity, in this case, represents individual domestication experiences and narratives of user's internet consumption.

A number of research techniques were carried out to provide a rich picture of the nature of internet consumption. In-depth interviewing formed the main research instrument. To complement the interviews, the respondents were asked to complete a time-use diary describing their overall media use in order to gain a complete picture of how the internet fitted into their portfolio of media use. A small amount of participant observation was also employed.

To understand the domestication process from the viewpoint of the user, I shall present a version of domestication gained through an analysis of the empirical data. The 4-stage approach proposed by Silverstone *et al.* (1989) underpinned my study, providing a theoretical framework and a tool by which to analyse the process of domestication. However, it became apparent that the user's *own* interpretation of how and why they consumed the technologies was not adequately described by the Silverstone approach. In fact, the results and findings from my study might be understood as the *product* of the application of Silverstone's model which evolved into an alternative 3-stage model. This alternative model aims to advance the concept of domestication, in order to portray the lived realities of domestic users as they experience domestication of internet technologies in their own homes.

RESULTS

In carrying out this research, I have applied the domestication process as offered and developed by Silverstone *et al.* (1989, 1992). In a sense, I have used Silverstone's concept as an 'ideal model', through which the findings were filtered about the domestic consumption practices and experiences of the users. Silverstone's model has both informed the way I gathered the data and the way I have interpreted the data, essentially meaning that the domestication concept has provided me with an analytical tool. The Silverstone version proved to be more appropriate than the competing, alternative theories and concepts of ICT integration into everyday life (Lie & Sørensen, 1996) or even diffusion models of uptake (Rogers, 1995). The Silverstone model proved useful in the ways it highlighted certain phases or aspects of the social processes through which domestic users experience a level of meaning and significance, embedding the artefact into 'everyday life' and the household.

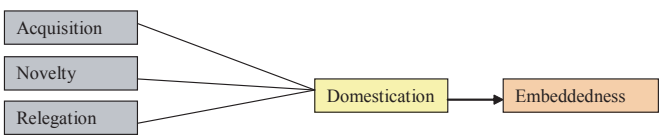
However, despite my extensive use of Silverstone's domestication concept, it should only be thought of as a theoretical apparatus, or empirical check-list employed to make sense of the experiences of users. While I have retained the terminology offered by the Silverstone's approach to domestication, my analysis of domestic use suggests that the process of domestication can be understood in another way, one which stems from my rich, in-depth research of domestic users.

I propose a user-based model which makes sense of users' experiences. These processes are not fixed or linear, but can be experienced at different stages during use. The 3-stage model below describes the processes that occur *before* the actual acquisition of the technology to the changes the user and technology undergo during subsequent social processes (Figure 1). Although this schema begins with 'acquisition', I propose that the processes that occur before the technology actually enters the home form a crucial element of the acquisition phase.

ACQUISITION PHASE: THE HOME'S NEW ARRIVAL

The Silverstone 4-stage model suggests domestication begins when the technology enters the home; however, my empirical analysis suggests that users experience earlier stages/aspects *before* the technology even reaches the home or even before it is used in any real meaningful way in the domestic domain.

Figure 1. 3-stage model



The findings indicate the following phases of acquisition:

- First/previous encounter(s) sets the scene/shape of use
- Interest, motivation and skills
- Justification for purchase
- Research
- Actual purchase experience
- Entrance of the technology
- Location in the household
- Early use
- Learning, training, and teaching skills to other family members.

My findings suggest that what goes on before the entrance of the technologies to the home is just as important as what goes on once they have entered the domestic space. In this study, the users or 'informed' non-users shape their experiences typically on their first encounters with the technology – such as in a school, university and college or work – and this shapes the way users approach the acquisition of the technology.

Interest, motivation and skills also prove to be crucial factors in the ways respondents shape their experiences when coming into possession of the technology. Respondents see skills and abilities to operate the technology as crucial to the type of machine acquired, how they perceive the technology, and where this technology is to be located. If the technology is seen as another part of the entertainment network and used mainly for entertainment or communication purposes, it tended to be located in the communal living space. When the technology is seen as an information resource, in the same way as a set of encyclopaedias, it tended to be located in a bedroom or study location.

The justification for purchase, and the research that the respondents conducted prior to the purchase of the actual equipment, was associated with a high level of significance for respondents. This sub-phase of acquisition was important in that it informed what kind of technology was best suited to their needs and financial status.

The technology then enters the home and remains in the acquisition stage whilst the user realises the actuality of consumption. Once the technology achieves a level of familiarity, and the user overcomes the difficult stage of becoming acquainted with it and its functions, the process enters the next stage.

NOVELTY PHASE: 'I COULDN'T TURN IT OFF!'

The second phase, which I have termed the novelty phase, is experienced after the early stages of meaning association and value attribution have assigned a certain level of significance to the technology. This phase is concerned with meaning and use. All respondents testify to experiencing this stage during their domestic use. For example, a female respondent explains how she experienced the 'novelty phase':

It took a couple of nights, when we had it first, we had it on all the time - the novelty of it - just surfing through it, finding out how things worked, what goes where, and what you can do with it. It was a bit of a buzz at first, but it soon wears off. (Female, 38)

This phase has an unfixed timeframe and is entirely dependent on the individual user. The time it takes for the 'freshness' or novelty to abate is determined by what functions the users themselves have discovered. Significantly, it is also possible to re-experience this phase, along with the acquisition phase, throughout the process as a whole, as new uses and functions are constantly discovered and the technology is reshaped, and as new items of hardware and software are added. Once this happens, the user will undergo the process again and experience yet another novelty phase.

RELEGATION PHASE: HOW THE TECHNOLOGY LOST ITS CHARM

The third phase in this empirical model is the relegation phase. Once the period of novelty has abated users' patterns of use change as the technology fits into the everyday routines of their lifestyles. After the initial acquisition and novelty periods, the attraction of the technology begins to dissipate and the technology

slowly begins to achieve a level of embeddedness and integration. The technology comes to be regarded as just 'being there', relegated to just 'another machine for the home', in the same sense as the television, radio or telephone. The testimonies below illustrate how the technology loses its charm:

Even though when you buy something, within weeks – because you have worked for it and you have bought it and are delighted with it. Suddenly it loses its novelty like everything does. I found the computer still lost the novelty of being a wonderful thing (Female 33).

When I first got it, I would have considered it a special type of machine. I was very much careful because it was so expensive, so it was packaged and only taken out if I wanted to do something specific. But now, because I have it for so long, it is part of the home. I'd come in and put on the television and computer (internet) automatically (Female 24).

No, to us it is part and parcel of the household like the television (Female 48).

However, as stated before, even though the technology may appear to be in the relegation phase, if new functions or uses are discovered, the user re-enters the two initial phases. The model I propose should not be considered as a linear process, because overlapping and entwining of all stages is possible, unlike the Silverstone model.

CONCLUSIONS

This paper argues that when the Silverstone model is applied to the domestication of the internet, several issues become problematic. First, the process needs to become more fluid and dynamic than the initial conception of the model, due to the increased functionality of new media technologies. It is rarely the case that new media technologies are dedicated to one purpose or function; instead they can converge with or assume the role of mature media uses. Closure of meaning becomes problematic because of the increased functionality and utility of new media, in the ways that the internet can mean different things to different users, sometimes simultaneously (as an information resource, communication medium, or entertainment station).

Transfer of meaning and interest across the different functions of new media may also occur. This multiplicity of functions brings with it an added problem of new skills and practices required to operate the technology and make use of it to its fullest capacity. Renegotiations of meanings and uses are possible and common in relation to new media technologies. For instance, meanings are renegotiated when novel aspects of new technologies are discovered by users. This ensures the process of domestication of new media technologies is not harmonious, linear, or complete, but is in constant flux and transformation, resulting in heterogeneous and unfixed outcomes of domestication. Some of the factors making domestication problematic when applied to new media technologies are:

New Technologies

Users experience the domestication process, more often than not, when the technology is newly acquired, or when it is first encountered in external environments. However, in the case of new media technologies, peripheral devices are often bought to complement the existing artefact (printers, scanners, digital cameras etc). This brings about a new domestication experience, and sometimes a relocation of the artefact, which further enhances the user's experience of the technology. New technologies and peripheral devices open new negotiations in ways not possible with mature or traditional media.

Software

Users can explore and discover new aspects to the technology brought about by new software. New software also carries baggage in the shape of new skills required to negotiate and navigate the new experience.

Shift of Focus

When users discover alternative uses and functions of the technology, their experience is again enhanced. For instance, if the primary function of the internet was to surf for information, but the user discovers email, chat-rooms and/or message boards, their interest, skills and conception of the artefact is developed and extended. This brings about a re-negotiation of meaning and significance of the technology in their everyday life.

While the model I propose gives an understanding of the lived reality and user experience of the domestication process, it is essential to place it within the context of my sample, as a working application of Silverstone's model. It must be viewed as an empirical, rather than a theoretical model. It is only through practical application that such a model can further our understanding of the complex processes of domestication, that is the ways users acquire, use and consume and make sense of the technologies within their own 'everyday' reality.

ABSTRACT

Knowledge integration is one of the keys to e-business which have more competitive advantage than traditional organizations. However, building knowledge management system from technology-oriented and user viewpoint is insufficient. Because of the effect of free-riding, the benefit of knowledge integration can't be linked to group size in direct proportion. This paper examines how the total effective level of effort persons exert vary with individual belief about knowledge level, group size, and their cost-knowledge level ratios. This study discusses the relation among these factors and proposes solutions to vanish the effect of free-riding under asymmetric information.

Keywords: Knowledge integration, public goods, asymmetric information

1. INTRODUCTION

In the past few years, knowledge management had mushroomed all over the industrials. According to the framework addressed by Alavi et al. (2001), "knowledge process" is classified into four fundamental elements: (1) construction, (2) storage/retrieval, (3) transfer, and (4) application. One research question they proposed is how to implement effectively knowledge transfer. In recent work, Lin et al. (2005) have proposed a sender-receiver framework for investigating knowledge transfer under asymmetric information. They view knowledge as goods traded in a knowledge market and one of their most significant research contributions is to apply a signaling mechanism to overcome 'adverse selection problem', which is a common phenomenon arising in knowledge sharing that means inability manager is unable to differentiate between the qualities of knowledge under incomplete-information.

Successful knowledge management can be attributed to ability, motivation, and opportunity (Argote et al. 2003). Ability is a talent but can be enhanced by training (Nadler et al. 2003). The position of ability should be identified so as to make it more valuable. Thus, opportunity, such as an organization or informal networks, establishes an invisible multidirectional channel to save acquiring and search cost by reducing distance (Borgatti and Cross 2003, Hansen 1999, McEvily and Zaheer 1999, Reagans and Zuckerman 2001, Uzzi and Lancaster 2003). However, knowledge transfer will be inefficient if members of the organization utilize internal knowledge without any reward. (Menon and Pfeffer 2003). Hence, in addition to ability and opportunity, the organization should provide members with motivation to take part in the knowledge management process (Argote et al. 2003).

Another major research question is what incentive makes persons contribute and share their knowledge truthfully. Although organizational knowledge can be conveniently stored in various component forms, including electronic documentation, database, and even expert system (Tan et al. 1998), many factors limit the success of knowledge storage. One of the barriers is that employees lack time to transform their knowledge into reusable component forms (Cranfield University 1998; KPMG 1998b; Glazer 1998). Another barrier is their organizational culture without a rewarded mechanism for exerting such effort (Brown and Duguid 1998; Cranfield University 1998; KPMG 1998b).

Because knowledge sharing is one of the most important aims in most knowledge management projects, many managers seek an efficient way to make their employees contribute their knowledge without reservation, not hiding what they had learned. In d'Aspremont et al. (1998), knowledge is treated as public goods for studying sharing knowledge and development efforts on R&D agreements and research joint ventures. They have considered a situation where one cannot identify a 'most knowledgeable' partner and proposed a balanced contract arrangement based on a two stage game which leads the cooperative activities to a first best solution.

"Free-riding" is a common effect when a group carries out knowledge sharing and all participants could consume the public benefit. This is because the provision of public goods generates an externality that all participants benefit from others who provide public goods. Hence, individuals' behaviors may tend to reserve their effort, resulting in the decrease of the level of the public good. The concept of public goods is also conveniently applied to other disciplines characterized by non-rivalness and non-excludability, such as peer-to-peer system, information security, and so on. Varian (2004) examined how system reliability varied with three prototypical cases: total effort, weakest link, and best shot. In the case of total effort under complete-information, his research result shows that system reliability is determined by the agent with the highest benefit-cost ratio. This result is similar to the work of Bhattacharya et al. (1992) which suggests that the most intelligent agent's knowledge is the only useful input for efficient development effort when individual knowledge levels are revealed.

To help employees share their best findings and management experiences, a large number of companies put themselves to the great expense of hiring consultants to set up IT-based applications, gathering and retrieving their useful knowledge. Ba et al. (2001), however, point out that building knowledge management system from software engineering and user acceptance perspectives is insufficient. Under circumstances without incentive, a manager is difficult to entice her peers and subordinates to contribute their individual knowledge into the knowledge management system.

As in Antoniadis et al (2004), we consider knowledge a cumulative public goods like files their work handles. Because our model treats in this paper the case where there are only two types of knowledge, this distinction makes ours less complicated to yield analytical solution under incomplete-information. The heart of this study is to establish an incentive mechanism depended on different knowledge types under incomplete-information, also known as screening, or truth telling. We present the model in section 2 and enhance this model by adding incomplete-information in section 3. A screening mechanism is introduced and detailed in section 4. Finally, we give a numerical example and conclude this paper in section 5 and 6.

2. A MODEL OF KNOWLEDGE INTEGRATION

Consider a knowledge integration model for n participants. These participants want to cooperate to get certain epistemic work done efficiently and share the public benefit, such as product development, technology innovation, or knowledge sharing. In order to simplify analysis process, Lin et al. (2005) denote the expected value of a participant's knowledge as either K_H (high level) or K_L (low level), where $K_H > K_L > 0$. We follow the same notations and call a person with high knowledge level a high type participant, and one with low knowledge level a low type participant. Similarly, we define C_H and C_L as the cost of exerting effort to a high type participant and low type one, respectively. We assume $C_H < C_L$ for a high type participant is efficient than low type one. This assumption means that the cost is an increasing linear function, the argument of which is the level of effort, and knowledge of higher level can reduce more expenses than that of inferior level under exerting the same effort.

In this model of complete-information version, each participant decides on x_i, the quantity of effort she exerts, where $x_i \geq 0$. In this paper we assume that each participant is risk neutral and effort is an observable variable, such as work hours, the frequency of proposals, or the cited rate of individual submitted report. The total effective level of effort and cooperative benefit is respectively defined as $Q = \sum K_i x_i$ and $f(Q)$, where the cooperative benefit function $f(.) \geq 0$ is assumed to be continuously differentiable, increasing, and concave in its argument. Then, the payoff of participant i is $f(Q) - c_i x_i$. For participant i, solving the first-order condition for participant i's payoff and defining $G(.)$ as an inverse function of $f'(.)$ yields:

$$x_i^* = \max\left\{\frac{1}{K_i} G\left(\frac{c_i}{K_i}\right) - \frac{1}{K_i}\sum_{j\neq i} K_j x_j^*, 0\right\}. \quad (1)$$

Each participant's strategy shows that when marginal public benefit is not greater than marginal private cost, they will free ride on the others. Thus, participants with highest knowledge-cost ratio determine a Nash equilibrium and the others free ride on the participants. This also means that when the number of participants with highest knowledge-cost ratio is greater than one, the number of Nash equilibrium outcomes will be infinite. Because concentrating on the total effective effort, we use asymmetric Nash equilibrium outcome directly for convenient.

$$\frac{1}{mK_H} G\left(\frac{c_H}{K_H}\right),$$

therefore, is the symmetric Nash equilibrium outcome we derive from (1) if there exists at least one high type participant in the group, where m is the number of high type participants. By considering a situation where all participants are low type ones, we have

total effective effort

$$Q^* = \begin{cases} G\left(\frac{c_H}{K_H}\right) & \text{if } \exists K_i \neq K_L \\ G\left(\frac{c_L}{K_L}\right) & \text{if } K_i = K_L, \forall i \end{cases}. \quad (2)$$

Our first proposition summarizes the above observations.

Proposition 1. In complete-information case (the knowledge type of each participant is public information),

(a) the low type participants always free ride on the high type participants, and
(b) for any group size, overall knowledge integration level, i.e., Q^*, is the same except that all participants are low type ones.

If nature determines the probability that $K_i = K_H$ is θ, in complete-information case the expected total effective level of effort they exert under given condition is

$$E\left[Q^*\right] = (1-\theta)^n G\left(\frac{c_L}{K_L}\right) + \left(1-(1-\theta)^n\right) G\left(\frac{c_H}{K_H}\right). \quad (3)$$

We now consider a scenario where knowledge integration is initiated by an all-powerful leader who has complete and perfect information about all participants' parameters. The leader, therefore, can stipulate the effort each participant should exert to maximize the social welfare:

$$\underset{x_1, x_2, \ldots, x_n}{Maximize} \quad W = \sum_{i=1}^{n} f(Q) - c_i x_i. \quad (4)$$

By first-order condition, this program would be optimal allocation if $\frac{\partial W}{\partial x_i} = nK_i f'(Q) - c_i \leq 0$ holds for each participant i. These inequalities mean that individual contribution levels have to maximize the total value of the group less the total cost incurred by the participants. Thus, from $f'(Q) \leq \frac{c_i}{nK_i}$ and $\frac{K_H}{c_H} > \frac{K_L}{c_L}$, we derive the socially optimal total effective level of effort:

$$Q_s^* = \begin{cases} G\left(\frac{c_H}{nK_H}\right) & \text{if } \exists K_i \neq K_L \\ G\left(\frac{c_L}{nK_L}\right) & \text{if } K_i = K_L, \forall i \end{cases}. \quad (5)$$

The above observations suggest that based on the viewpoint of arbitrary, a compulsive policy should force participants carry out $x^*(K_H) = \frac{1}{mK_H} G\left(\frac{c_H}{nK_H}\right)$ and $x^*(K_L) = 0$ if given m high type participants, where $m \geq 1$; otherwise, $x^*(K_L) = \frac{1}{nK_L} G\left(\frac{c_L}{nK_L}\right)$.

Proposition 2. In complete-information, the achievement of social welfare implies that

(a) socially total effort is absorbed by all high type participants if there exists at least one high type participant in the group, and
(b) low type participants' selfish shirking behaviors are allowable due to lacking of competitive advantage, unless all persons are low type participants.

Furthermore, we consider a situation where each participant can determine whether to join the group or not. In fact, a high type participant might receive a negative payoff under the arrangement of social welfare. If a high type participant's payoff is negative and the cooperative activity is devoid of a reasonable compensation mechanism, she will leave the group. Hence, the compensation mechanism is necessary for the achievement of social welfare if all participants have liberty to determine whether to join or leave.

Because social welfare, $W = \sum_{i=1}^{n}\left(f(Q) - c_i x_i\right)$, can be decomposed into $f(Q) - c_i x_i$ and $\sum_{j\neq i}^{n}\left(f(Q) - c_j x_j\right)$, we could derive $\frac{\partial}{\partial x_i}\left(f(Q) - c_i x_i\right)$ and $\frac{\partial}{\partial x_i}\sum_{j\neq i}^{n}\left(f(Q) - c_j x_j\right)$ after differentiating both expressions with respect to x_i. Hence, differentiating social welfare with respect to x_i yields:

$$\frac{\partial W}{\partial x_i} = \frac{\partial}{\partial x_i}\left(f(Q) - c_i x_i\right) + \frac{\partial}{\partial x_i}\sum_{j\neq i}^{n}\left(f(Q)\right) \quad (6)$$

Because each participant's individual payoff is to maximize $f(Q) - c_i x_i$, $\frac{\partial}{\partial x_i}\left(f(Q) - c_i x_i\right) = 0$ is the first-order condition to this problem which is the same as the former part of $\frac{\partial W}{\partial x_i}$. Hence, the externalities can be measured by $\frac{\partial}{\partial x_i}\sum_{j\neq i}^{n}\left(f(Q)\right)$ for participant i. Solving it yields:

$$\frac{\partial}{\partial x_i}\sum_{j\neq i}^{n}\left(f(Q)\right) = (n-1) f'(Q) K_i \quad (7)$$

Thus, the appropriate socially optimal compensation paid for a high type participant is:

$$p_H = (n-1) f'\left(Q_s^*\right) K_H = \left(\frac{n-1}{n}\right) c_H. \quad (8)$$

Since low type participants free ride on social welfare unless all persons are low type participants, the appropriate socially optimal compensation for them is:

$$p_L = \begin{cases} 0 & \text{if } \exists K_i \neq K_L \\ \left(\frac{n-1}{n}\right)c_L & \text{if } K_i = K_L, \forall i \end{cases} \quad (9)$$

Because in social welfare the externalities increase with the group size, the subsidy paid to participants also increases with the number of attendants.

Proposition 3. In the complete-information case, if all participants are paid p_H or p_L based on their types, Nash equilibrium outcomes achieve the socially optimal level of effort.

3. KNOWLEDGE INTEGRATION UNDER ASYMMETRIC INFORMATION

In this section we consider this model of incomplete-information version. Assuming each participant has private information about her knowledge type and all participants' knowledge types are independent. Let $x_i^*(K_H)$ and $x_i^*(K_L)$ denote participant *i*'s effort as a function of her knowledge level. Each participant knows that her coworkers' knowledge level is high with probability θ and anticipates that their effort would be $x_i^*(K_H)$ or $x_i^*(K_L)$, depending on their knowledge level. This implies that each participant's expected effective level of effort is:

$$\theta K_H x_j^*(K_H) + (1-\theta) K_L x_j^*(K_L). \quad (10)$$

Thus, based on individual knowledge level, participant *i* chooses $x_i^*(K_i)$ to maximize her payoff as follows:

$$\max_{x_i(K_i)} U_i(K_i) = f\left(K_i x_i + \sum_{j\neq i} \theta K_H x_j^*(K_H) + (1-\theta) K_L x_j^*(K_L)\right) - c_i x_i. \quad (11)$$

Solving the first-order condition for (10) yields:

$$x_i^*(K_H) = \frac{1}{K_H} G\left(\frac{c_H}{K_H}\right) - \sum_{j\neq i} \theta x_j^*(K_H) - (1-\theta)\frac{K_L}{K_H} x_j^*(K_L) \quad (12)$$

and

$$x_i^*(K_L) = \frac{1}{K_L} G\left(\frac{c_L}{K_L}\right) - \sum_{j\neq i} \theta \frac{K_H}{K_L} x_j^*(K_H) - (1-\theta) x_j^*(K_L). \quad (13)$$

In a separating strategy, we let $x_i^*(K_H) = x_j^*(K_H)$ and $x_i^*(K_L) = x_j^*(K_L)$ where $i \neq j$; it yields:

$$x_i^*(K_H) = \frac{\frac{1}{K_H} G\left(\frac{c_H}{K_H}\right) - (n-1)(1-\theta)\frac{K_L}{K_H} x_j^*(K_L)}{1+(n-1)\theta} \quad (14)$$

and

$$x_i^*(K_L) = \frac{\frac{1}{K_L} G\left(\frac{c_L}{K_L}\right) - (n-1)\theta \frac{K_H}{K_L} x_j^*(K_H)}{1+(n-1)(1-\theta)}. \quad (15)$$

Since a high type participant's work efficiency is higher than low type one's, i.e., $\frac{K_H}{c_H} > \frac{K_L}{c_L}$, persons with higher knowledge level always contribute their effort in this model. On the other hand, assuming that all low type participants don't work at all, i.e., $x_i^*(K_L) = 0$, the necessary and sufficient condition for a low type participant to free ride on the others is $G\left(\frac{c_L}{K_L}\right) \leq \frac{(n-1)\theta}{1+(n-1)\theta} G\left(\frac{c_H}{K_H}\right)$. This also implies that when information is rife that most of persons are low type participants, i.e., $\theta < G\left(\frac{c_L}{K_L}\right) \Big/ \left((n-1)\left(G\left(\frac{c_H}{K_H}\right) - G\left(\frac{c_L}{K_L}\right)\right)\right)$, low type participants prefer to contribute their effort rather than shrinking. $G\left(\frac{c_L}{K_L}\right) \Big/ \left((n-1)\left(G\left(\frac{c_H}{K_H}\right) - G\left(\frac{c_L}{K_L}\right)\right)\right)$ is denoted as $\hat{\theta}$ for conciseness. Each participant based her private type has two strategies relying on whether θ is less than $\hat{\theta}$ or not. Hence, given $\theta < \hat{\theta}$, solving (14) and (15) simultaneously yields $x_i^*(K_H)$ and $x_i^*(K_L)$. Given $\theta \geq \hat{\theta}$, plugging $x_i^*(K_L) = 0$ into (14) yields new $x_i^*(K_H)$. We list the results as follows:

$$x_i^*(K_H) = \begin{cases} \frac{1}{nK_H}\left(G\left(\frac{c_H}{K_H}\right) + (n-1)(1-\theta)\left(G\left(\frac{c_H}{K_H}\right) - G\left(\frac{c_L}{K_L}\right)\right)\right) & \text{if } \theta < \hat{\theta} \\ G\left(\frac{c_H}{K_H}\right)\left((1+(n-1)\theta)K_H\right)^{-1}. & \text{if } \theta \geq \hat{\theta} \end{cases} \quad (16)$$

and

$$x_i^*(K_L) = \begin{cases} \frac{1}{nK_L}\left(G\left(\frac{c_L}{K_L}\right) - (n-1)\theta\left(G\left(\frac{c_H}{K_H}\right) - G\left(\frac{c_L}{K_L}\right)\right)\right) & \text{if } \theta < \hat{\theta} \\ 0 & \text{if } \theta \geq \hat{\theta}. \end{cases} \quad (17)$$

Thus, the expected total effective level of effort under asymmetric information is

$$E[Q] = \sum_{i=0}^{n} \binom{n}{i} \theta^i (1-\theta)^{n-i} \left(i \cdot K_H x_i^*(K_H) + (n-i)\cdot K_L x_i^*(K_L)\right) = n\left(\theta K_H x_i^*(K_H) + (1-\theta) K_L x_i^*(K_L)\right)$$

which implies

$$E[Q] = \begin{cases} \frac{n\theta}{1+(n-1)\theta} G\left(\frac{c_H}{K_H}\right) & , \text{if } \theta \geq \hat{\theta} \\ \theta G\left(\frac{c_H}{K_H}\right) + (1-\theta) G\left(\frac{c_L}{K_L}\right) & , \text{if } \theta < \hat{\theta}. \end{cases} \quad (18)$$

Although low type participants free ride on high type ones when $\theta \geq \hat{\theta}$, the expected total effective level of effort increases with θ. Low type participants prefer to shrink rather than exert effort when the expected total effective level of effort is greater than $\frac{n}{n-1} G\left(\frac{c_L}{K_L}\right)$.

Proposition 4 In the incomplete-information case (the knowledge type of each participant is private information),

(a) although high type participants are still pivotal contributors, the expected total effective level of effort under incomplete-information is less than that under complete- information unless θ approaches one,
(b) the more the number of attendants, the more the motivation for low type participants to free ride, and
(c) when the number of attendants is 'mild' and knowledge-cost ratio of high type participants is close to that of low type participants, participants of both types would exert the effort.

4. INCENTIVE-COMPATIBLE INCENTIVE MECHANISM (SCREENING, TRUTH REVELATION)

Since participants' types are unknown, in this section we consider whether there exists a payment mechanism, or a contract, such that each participant, based on maximizing individual benefit, truthfully reveals her type to achieve social optimum. This contract can be described as $[P_H, x_H]$ and $[P_L, x_L]$; that is, each

participant feels free to pick one of the two options, and then achieves the stated workload and receives the deserved subsidy. Under this architecture, P_H and P_L is the subsidy paid to participants who report their ability for high type or low type, respectively.

Hence, under this mechanism we must have two incentive-rationality (*IR*) constraints; that is; no matter what contract each participant signs, she earns a nonnegative payoff after ending the activity. We denote these two constraints as (*IRH*) and (*IRL*) where '*H*' and '*L*' represent a participant's type. In order to let each participant all truthfully reveal her type, we must have another two incentive-compatibility (*IC*) constraints; that is; because each participant can't earn more payoff by mimicking the behavior of the other type, they sign contracts based on their individual type. These two constraints are denoted as (*ICH*) and (*ICL*). Thus, this framework can be described as

$$\max_{x_H, x_L} \quad W = nf\left(n\bar{K}\right) - n\bar{c}$$

subject to

$$f\left(K_H x_H + (n-1)\bar{K}\right) - c_H x_H + P_H \geq f\left(K_H x_L + (n-1)\bar{K}\right) - c_H x_L + P_L \qquad (ICH)$$

$$f\left(K_L x_L + (n-1)\bar{K}\right) - c_L x_L + P_L \geq f\left(K_L x_H + (n-1)\bar{K}\right) - c_L x_H + P_H \qquad (ICL)$$

$$f\left(K_H x_H + (n-1)\bar{K}\right) - c_H x_H + P_H \geq 0 \qquad (IRH)$$

$$f\left(K_L x_L + (n-1)\bar{K}\right) - c_L x_L + P_L \geq 0 \qquad (IRL)$$

where $\bar{K} = \theta K_H x_H + (1-\theta) K_L x_L$, and $\bar{c} = \theta c_H x_H + (1-\theta) c_L x_L$.

Our approach to this problem is to relax it by delete all constraints, solve the relaxed problem, and check whether there exists P_H and P_L to satisfy these omitted incentive constraints. The following proposition shows that there exists a payment mechanism based on the expected number of high type participants, i.e., $n\theta$, to maximize the program.

Proposition 5 Assume $\theta > 0$. Let the contracts be:

$$\left[P_H = c_H x_H^*, x_H^* = \frac{1}{n\theta K_H} G\left(\frac{c_H}{nK_H}\right)\right],$$

$$\left[P_L = f\left(K_H x_H^* + (n-1)\bar{K}\right) - f\left((n-1)\bar{K}\right), x_L^* = 0\right].$$

Then, all participants truthfully reveal their type and exert the assigned effort. (See Appendix A)

Thus, the expected total effective level of effort under screening is $E[Q] = G\left(\frac{c_H}{nK_H}\right)$, which is the same as the socially optimal total effective level of effort under complete information in a situation where there exists at least one high type participant in the group. The proposition 5 suggests two things: first, to make high type participants act as pivotal contributors, the function of P_H is to exempt high type participants from the cost of exerting effort. Because the cost of exerting effort to a low type participant is higher than that to high type one, a low type participant has no incentive to deviate from accepting P_H if P_L is 'large enough'. Second, to make low type participants truthfully report their ability, a fixed fee based on the number of attendants is necessary to entice low type participants to be honest. However, the price of P_L must be commonplace so as to prevent high type participants from envying low type ones, even if they not only free ride on the high type participants but also earn extra payments.

5. NUMERICAL EXAMPLE

We apply a specific form, $f(x) = x^{\alpha}$ (where $0 < \alpha < 1$), to examine the behavior of participants under asymmetric information without incentive mechanisms. Given $\alpha = \{0.45, 0.5, 0.55\}$, $n = 10$, $c_H = 5$, $K_H = 55$, $c_L = 5.5$, and $K_L = 50$, the expected total effective level of effort, $E[f(Q)]$, varies depending on θ and α as shown in

Figure 1

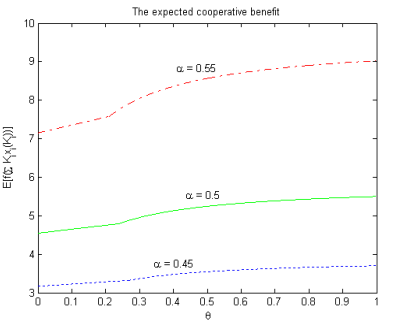

Figure 2

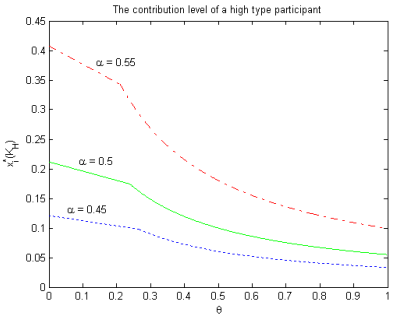

Figure 3

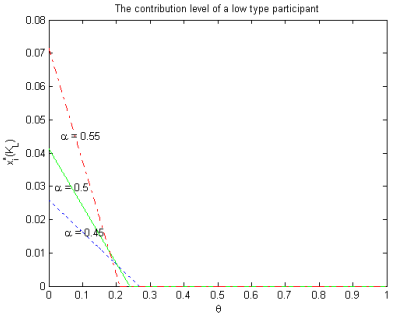

Figure 1. The contribution level of a high type participant and one of a low type participant are shown in Figure 2 and Figure 3, respectively.

First, these figures reveal that although the efforts of participants are decreasing with θ, the expected knowledge integration level still increases as θ. Second, when knowledge value is greater than production cost, the effort exerted by high and low type participants will increase as α, the degree of concavity (see figure 2 and figure 3).

Second, the cooperative benefit under complete-information is always greater than the expected one under incomplete-information. However, unlike the complete-information case, low type participants exert their effort when θ and n are sufficient small. All observations suggest that an incentive mechanism is an essential dimension to knowledge integration, especially in the society full of uncertain contingency.

6. CONCLUSION

Knowledge integration is one of the keys to e-business which has more competitive advantage than traditional organizations. However, under a situation without incentive, everyone treats this issue from her personal viewpoint, such that technology fails to operate well. Thus, if we develop a knowledge management system only based on software engineering and user acceptance perspectives, the benefit of establishing the application is hard to achieve an anticipative level. Because of the effect of free-riding, the real value of a research team can't be measured only by the group size. Hence, to maximize the benefit of human resources, our belief is to make the best possible use of men/women. That is, we allocate high ability persons to core departments, and free or lighten their cost. For low ability persons, we should support a smaller reward to compensate their behavior for telling the truth. This research can be further extended to a multiple stages game to analysis the long-time performance of knowledge integration.

APPENDIX A. PROOF OF PROPOSITION 5

Given the unconstrained mathematical program, by first-order condition, the following inequalities must be satisfied:

$$nf'\left(n\bar{K}\right)n\mathrm{q}K_H \le n\mathrm{q}c_H \qquad (A1)$$

$$nf'\left(n\bar{K}\right)n\left(1-\mathrm{q}\right)K_L \le n\left(1-\mathrm{q}\right)c_L \qquad (A2)$$

Because of $\frac{K_H}{c_H} > \frac{K_L}{c_L}$, $(A1)$ will bind at the optimum so as to $\bar{K} = \frac{1}{n}G\left(\frac{c_H}{nK_H}\right)$. Thus, $x_H^* = \frac{1}{n\mathrm{q}K_H}G\left(\frac{c_H}{nK_H}\right)$ and $x_L^* = 0$ will satisfy $\bar{K} = \frac{1}{n}G\left(\frac{c_H}{nK_H}\right)$ if given $\mathrm{q} > 0$. Furthermore, let $P_H = c_H x_H^*$, $P_L = f\left(K_H x_H^* + (n-1)\bar{K}\right) - f\left((n-1)\bar{K}\right)$ and check all incentive constraints as follows:

$$f\left(K_H x_H^* + (n-1)\bar{K}\right) - c_H x_H^* + P_H = f\left(K_H x_H^* + (n-1)\bar{K}\right) \ge 0 \qquad \text{(IRH)}$$

$$f\left(K_L x_L^* + (n-1)\bar{K}\right) - c_L x_L^* + P_L = f\left(K_H x_H^* + (n-1)\bar{K}\right) \ge 0 \qquad \text{(IRL)}$$

$$f\left(K_H x_L^* + (n-1)\bar{K}\right) - c_H x_L^* + P_L = f\left(K_H x_H^* + (n-1)\bar{K}\right) = f\left(K_H x_H^* + (n-1)\bar{K}\right) - c_H x_H^* + P_H \qquad \text{(ICH)}$$

$$f\left(K_L x_H^* + (n-1)\bar{K}\right) - c_L x_H^* + P_H = f\left(K_L x_H^* + (n-1)\bar{K}\right) + x_H^*\left(c_H - c_L\right) \le f\left(K_L x_L^* + (n-1)\bar{K}\right) - c_L x_L^* + P_L \qquad \text{(ICL)}$$

Teaching Online: Using Moodle for a Blended Course

Yukiko Inoue, University of Guam, UOG Station, Mangilao, Guam 96923; E-mail: yukiinoue2005@yahoo.com

ABSTRACT

The purpose of this paper is to articulate the use of a server-based software package designed to allow educators to provide collaborative activities and learning resources to online students, as well as supporting face-to-face learning. After providing a discussion on the course management systems and Moodle, the author describes the rationale why Moodle has been selected to be integrated into a blended research course at an American Pacific island university. This is a pilot implementation of mixing e-learning with face-to-face classroom learning in the graduate education program. Based on the qualitative data (self-reported perceptions of students about online experience), the author discusses the use of Moodle mainly from students' point of view, and concludes by setting future directions for design research in the online course based on constructivist perspectives.

INTRODUCTION

In 1993, there was no World Wide Web. Today, it seems as if it is everywhere…. Is it any wonder that so many instructors are both anxious and apprehensive as they try to make sense of this new phenomenon? There are so many questions to answer: What is the difference between teaching "on the ground" and teaching online? What are the fundamental techniques? What kind of equipment or software do you use? How do you assess how effective you are? (Ko & Rossen, 2004, p. xv)

"Teaching online" means conducting a course—partially or entirely—through the Internet; what makes teaching online unique is that it uses the Internet, especially the World Wide Web, as the primary means of communication (Ko & Rossen, 2004). Using new media technology and the Internet offers possibilities to enhance Web-based learning (also known as "e-learning"), which is currently one of the major applications of the Internet. Due to the rapid development of Web-based technologies, increasing bandwidth, decreasing costs, and widening access, online versions of education programs are becoming increasingly popular teaching strategies for universities to adopt (Townsend & Wheeler, 2004). In classroom learning, face-to-face contact can help motivate and involve students in active learning, but in online learning via the new teaching and learning technologies makes materials available anytime and anywhere; in practice, both face-to-face and online programs often rely on transmissionist, teacher-centered provision of information rather than on student-centered construction of knowledge (Wonacott, 2002): "Students may end up receiving passively both online and in the classroom. Two themes, nevertheless, clearly emerge as the most frequently cited strengths—thus the *personal contact* allowed by face-to-face classroom learning and the *flexibility* allowed by online learning" (¶ 2).

The new educational technologies can be classified in two broad categories: (1) communication technologies are broken down into synchronous (online chat, audio-graphics, whiteboard, online video-conferencing, and live Web-casting) and asynchronous (e-mail, bulletin board, listserv, and computer conferencing) technologies, whereas (2) resources technologies are divided into four levels (Fox, 2005): Level 1 (Web sites, online databases, and online journals); Level 2 (online materials created by teachers, such as notes, syllabi and references); Level 3 (online multimedia courseware packages that include text, graphics, animation, audio, and video); and Level 4 (intelligent tutoring systems, expert systems, online simulations, and virtual reality environment). Fox further notes that because of their prevalence, it is useful to examine where virtual learning environments (WebCT, Blackboard, and Moodle) fit into the above classification.

This paper purports to articulate the use of a server-based software package designed to allow educators to provide collaborative activities, critical reflection, and learning resources to online students, as well as supplementing face-to-face learning. After providing a discussion on the course management systems (CMSs) and the CMS Moodle (Modular Object-Oriented Dynamic Learning Environment), the author describes the rationale why Moodle has been selected to be integrated into a "blended" course. One frequent question asked when one hears about blended learning (BL) is "What is being blended? Therefore, BL is clearly defined. Based on the student reflection papers on their online experience and their perception about BL, the author discusses the use of Moodle mainly from students' point of view, and concludes by setting future directions for design research in the online course based on constructivist perspectives.

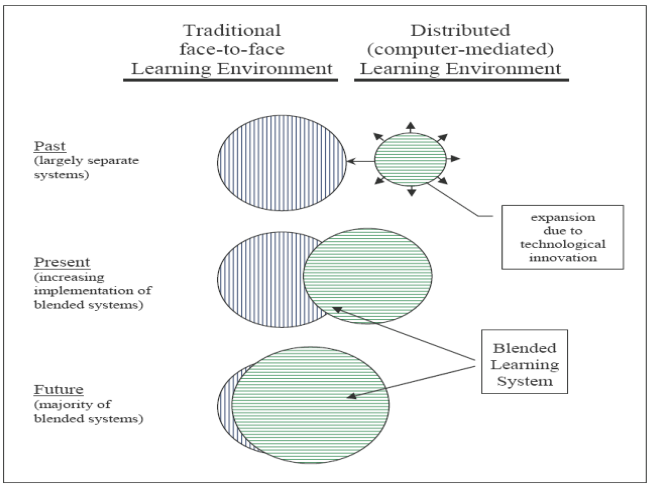
WHAT IS BEING BLENDED?

The term BL is being used with increased frequency in both academic and corporate circles (Graham, 2004): "In 2003, the American Society for Training and Development identified BL as one of the top ten trends to emerge in the knowledge delivery industry (cited by Rooney, 2003)" (p. 1). While there are a variety of responses to this question ("What is being blended?"), Graham has identified three most commonly documented definitions: (1) combining instructional modalities (or delivery media); (2) combining instructional methods; and (3) combining online and face-to-face instruction. The first two positions above reflect the debate on the influences of media versus method on learning, whereas the third position more accurately reflects the historical emergence of BL systems. BL emphasizes the central role of computer-based technologies in BL as depicted in Figure 1.

COURSE MANAGEMENT SYSTEMS

Learning software systems, such as CMSs or learning management systems (LMSs), provide the platform for online learning by enabling the management, delivery, and tracking of learning. CMSs, which are often viewed as being the

Figure 1. Progressive convergence of traditional face-to-face and distributed environments allowing development of blended learning systems (Source: Graham, 2004, p. 28)



starting point of any online learning program (Cavus, Uzunboylu, & Ibrahim, 2005), have the unique capacity to capture significant amounts of information about *how* students use the system, *how* they access online activities, and *how* they interact with other students in synchronous and asynchronous modes (Ullman, Peters, & Reimann, 2005).

The rising costs of education often lead to the call for a change from the traditional, space-and-time bound institutions to ones that offer increasingly cost-effective, technologically enhanced programs; as institutions of higher education turn to technology, primarily Internet-based, to address these challenges, the use of "open source" CMSs is dramatically increasing (Minielli & Ferris, 2005). Open source is "viable and significant in the commercial Internet and enterprise …[but] this new development is less than ten years old and may face significant legal and/or business challenges ahead" (Abel, 2005, pp. 3-4). Some of the best known commercially available CMS systems are Blackboard, WebCT, and Desire2Learn; there are also many open source software and free CMS systems, such as Moodle, Segue, Interact, CourseWork, Atutor, and KEWL (Cavus, et al., 2005). Additionally, "The terms 'free software' and 'open-source software' are sometimes used interchangeably in the discussion of software.…but free software is not 'free' as 'free' in the monetary sense, but users of the software should have the *freedom* to run, modify, adapt, customize and share without charge" (Kennedy, 2005, p. 327).

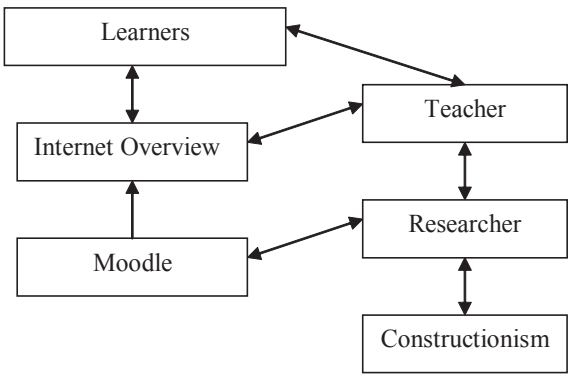
Blackboard—a commercial product produced by Blackboard Inc.—is a mature CMS with a large number of features that support learning and the most dominant CMS provider, whereas Moodle was first released in 2002 and was developed as an educationally sound alternative to Blackboard by Martin Dougiamas of Curtin University (Corich, 2005). Moodle provides many of the tools available within Blackboard, but the user interface is more primitive and the online help is minimal in comparison. According to Corich, the majority of early e-learning adopters in New Zealand decided to use mature CMSs like Blackboard and WebCT but, more recently, many institutes have been looking to the open source community to provide a less expensive and there are a growing number of the institutes looking towards Moodle. Compared with Blackboard, in Corich's research, students found Moodle easy to use and appreciated the way that Moodle presented materials week by week. In fact, Moodle is one of the popular CMSs, and it has a very large user base with 12,165 registered sites in 155 countries with 4,021,531 users in 376,565 courses as of May 30, 2006 ("Moolde," 2006).

THE CMS MOODLE

Dougiamas (2000) implemented using a prototype of a new Web course (titled "Internet Overview") development tool called "Moodle" that used constructionist referents to model engagement of the participants with course content and each other. Dougiamas notes:

I was inspired to create a new Web-based tool I could use to implement, modify, and experiment with an interactive internet-based course as easily and as flexibly as possible. I called this tool Moodle…. As a researcher using constructionism as a referent, I needed to develop Moodle to a usable state, then use Moodle itself to develop Internet Overview from a teacher's perspective. Through interaction with students and the course, I intended to develop new insights as a researcher and perhaps the nature of constructionism (see Figure 2). (¶ 24)

Figure 2. Diagram of affective relationships between the instructor's roles as teacher and researcher, course software, the course and students (Source: Dougiamas, 2000)



The system of Moodle is grounded in situated cognition and cognitive flexibility theory that provide the opportunity for an instructor to create a constructivist and constructionist environment to enhance teaching and learning; the abilities to design "student-centered" learning are embedded in Moodle and its modules, but it is ultimately the responsibility of the instructor to make good use of them (Antonenko, Toy, & Niederhauser, 2004). A constructivist perspective, as Dougiamas (1998) describes, does view learners as actively engaged in making meaning, and teaching with that approach looks for what students can *analyse*, *investigate*, *collaborate*, *share*, *build,* and *generate* based on what they already know, rather than what facts, skills, and processes they can parrot. As seen in Figure 2, to do this effectively, a teacher needs to be a learner and a researcher, and at the same time to strive for greater awareness of the environments and the participants in a given teaching situation in order to continually adjust their actions to engage students in learning, using constructivism as a referent.

Free open-source is becoming a serious competition to the CMS vendors, but the advantage of open-source solutions goes beyond cost savings as listed below (Yordanova, et al., 2003):

- Moodle allows to be adapted for many operating systems (Windows, Linux, Sun, and UNIX) and software environment (Mysql, Postgresql, MS-SQL Server, Oracle, and Access).
- Moodle can be installed at an institutional server and allows establishment and maintaining of courses from different categories kept in a catalog at a portal page.
- Moodle supports more services than others concerning course activities; the teacher arranges the activity modules in order the students will use them; and editing is possible in any time.
- Course formats give the templates for course settings facilitating the teacher design work.
- There are opportunities for uploading files of various formats that allow usage of materials from previous ordinary courses and easy extension of existing courses.
- Moodle supports many different languages with opportunities to add extra ones.

Moodle provides a range of functionality using such 'building blocks' as *Forums*, *Journals*, *Resources*, *Choices*, *Surveys*, and *Assignments*. Students can upload their assignments (any file format) to the server, which are then date-stamped. Instructors can keep track of student involvement as well as monitor and get reports on the aspects of the student's learning. Focusing on how Moodle has been implemented in a hybrid business English course at Kyoto Sangyo University, Baskerville and Robb (2005) describe the following unique components of Moodle:

- *Submission and retrieval system*: There is a common area for students to submit files ('To Teacher') in the administration block, and to retrieve files from the teacher ('From Teacher').
- *Attendance*: This feature logs the time of initial access to a course area; the instructor can view the attendance for the entire semester and download the results as an Excel file.
- *Class resources*: This feature provides data that students need to complete an assignment.
- *Class quizzes*: Moodle allows the teacher to set when students may begin a quiz and how long they have to complete the quiz.
- *Class activities*: Activities are to reinforce what students have been learning and to help them with current assignments.
- *Calendar*: Notes can be posted to the calendar to remind students of assignment due dates.
- *Participants*: Students and teachers in the course are shown on this page along with how much time has elapsed since they last accessed this page.
- *Forums*: This area allows communication among students or between students and teachers.
- *Logs*: The feature is flexible enough to report the results of all activities for all students down to checking one particular activity of an individual student.

Table 1. Moodle features and activities in the blended research course

Categories	Learning activities	Moodle 'building blocks'
Instructor Presentation	This includes lectures, simulations, charts, and graphs, as well as computer assisted presentations using tools like PowerPoint.	*News Forum* – Instructor's welcome message *Resources* -- PowerPoint slides for each week's lecture
Discussion	Guided discussion sections are common format for discussion. In seminars, instructor presentation and discussion are often combined.	*Forum* – Students participate in a weekly online discussion and a weekly online exercise
Group-oriented and individual projects	Collaborative activities are included here, in addition to group and independent projects presented to the entire class.	*Assignment*: Students upload weekly assignments, and submit online
Research	Research may be conducted either by individuals or in groups (e.g., practical applications, fieldwork and interviews).	Students develop their research proposal and submit online (but present it orally in class)
Assessment	This involves exams, essays, and projects; portfolios that combine different types of work; and evaluation for participation.	Scoring guidelines and rubrics are used, in addition to student participation in Moodle activities

Adapted from Ko & Rossen, 2004, p. 48

USING MOODLE FOR A BLENDED COURSE

The School of Education at an American Pacific island university has been the early adopter of Moodle, and training has been offered with small-groups assistance to provide faculty the skills needed to prepare course materials for online learning. The author of the present paper is one of those trained and has taught a blended graduate research course (titled "Introduction to Research Methods") using Moodle in the fall of 2006. This is the first implementation of mixing e-learning with face-to-face classroom learning in the teacher education program. The course is scheduled to teach entirely online in the future. Moodle has been selected for the implementation because of its *flexibility*, *efficiency*, and *cost-effectiveness*, as previously discussed in this paper.

This research course provides an overview of the concepts and applications used in educational research, with a focus on knowledge of research methods necessary to obtain valid and reliable outcomes as solutions to educational problems. The detailed course syllabus indicates the instructor's planned learning outcomes, and student practice, as well as how mastery is assessed. Student work is evaluated based on scoring guidelines and scoring rubrics. Incorporating an active learner model ('constructivist' approach), it is hoped that the instructor sends the message effectively so that students feel satisfied with their online experience. It is also hoped that the likelihood of faculty-student interactions may increase by timely feedback. Eventually, various strategies will be experimented to enhance content interaction, including animations, short video segments and interactive activities embedded right into the lecture material. Student surveys (or reflection papers) are conducted at the end of the semester to improve the course constantly.

The activities in most college courses can probably be divided into a few large categories (Ko & Rossen, 2004); the building blocks of Moodle are used in the course as summarized in Table 1.

HOW DOES STUDENT LEARNING EXPERIENCE BENEFIT FROM BL?

The aforementioned course was offered in a blended modality (up to 50% online)—thus in-class meetings (50%), and online activities (50%). A total of 19 students enrolled in the course and all of them completed the course. Students submitted all the assignments electronically creating 'files.' Students also participated in a weekly online discussion and a weekly online exercise. At the end of the semester, students developed a one-page reflection paper (their perceptions about BL, including their online experience). Typical reflection statements are as follows:

- BL is convenient for the full-time graduate student who is also a full-time employee, simply because it provides a great opportunity for students to work at their own pace.
- Online learning encourages student interaction and electronic contact with the professor beyond the confines of the classroom.
- This virtual platform provides students with the flexibility to complete and submit assignments virtually anywhere.
- Incorporating technology with traditional lecture formats has a positive, synergistic effect on the learning environment for graduate students.
- BL teaches students how to manage time and to be more responsible by setting proper due dates of assignments and other learning activities.

Several students expressed as follows: "the best part of BL is that students not only attend classes, meeting face-to-face with each other and their instructors, but they also can communicate electronically outside of class meetings using Moodle," supporting the characteristic of blended instruction (thus the *personal contact* allowed by face-to-face classroom learning and the *flexibility* by e-learning) pointed out by Wonacott (2002). Regarding communication, face-to face communication seems to be better for tasks for which students need immediate clarification and explanation, but face-to-face communication appears to be preferable when students need to generate new ideas.

Many of the students in the course are full-time school teachers or administrators. It also should be emphasized that students at the graduate level are responsible enough to study on their own. In this situation, the BL system works very well; accordingly, student reflection papers show that students have satisfied with their online experience. Furthermore, students in the course found that Moodle easy to use and appreciated the way that Moodle presented materials week by week, just as found in the research study by Corich (2005).

Nevertheless, several students pointed out the inconveniences, including inaccessibility to the website, the occasional power outage, and network downtime. The power surges, brownouts, and blackouts people experience in this Pacific island promote more than the usual amount of wear and tear than equipment normally receives, even with proper protection. In addition, lack of adequate air conditioning can allow damage due to moisture, heat, mold, and even insects. Maintenance and replacement parts can be difficult to come by and are expensive.

CONCLUSION AND FUTURE RESEARCH

The widespread adoption and availability of digital learning technologies has led to increased levels of integration of computer-mediated instructional elements into the traditional face-to-face learning experience. Students' perceptions of using the CMS Moodle are important, however:

Our focus should be teaching and learning….We must remember that our goals as educators include engaging students in higher order learning, facilitating the exercise of critical thinking skills, and ensuring students' mastery of conceptual, analytical, and theoretical knowledge as well as rather than solely developing students' ability and comfort with the use of technologies. (Minielli & Ferris, 2004, p. 17)

To effectively utilize open-source CMSs, educators not only need to be aware of terminology, functions, and uses of the most popular types of electronic

courseware, but also they need to develop and critique pedagogically based on research; therefore, "design research" is very important to maximize student learning (Reeves, Herington, & Oliver, 2005). "Design" really means the *shape* and *direction* the instructor wants the course to take, and the instructor has to keep in mind two design principles (Ko & Rossen, 2004): "to make sure that (1) your course objectives are defined in terms of the learning outcomes that you want students to be able to demonstrate and that (2) you align all activities, assignments, and assessments with those expected learning outcomes" (p. 46). Course designs are also very important to maximize student *online* learning; design research "has grown in importance since it was first conceptualized in the early 1990s…but many researchers continue to conduct studies that principally seek to determine the effectiveness of the delivery medium, rather than the instructional strategies and tasks" (Reeves et al., 2005, p. 96). Design research requires that faculty members should:

- define pedagogical outcomes and create learning environments that address them;
- emphasize content and pedagogy rather than technology;
- give special attention to supporting human interactions and nurturing learning communities;
- modify the learning environments until the pedagogical outcomes are reached; and
- reflect on the process to reveal design principles that can inform other instructors and researchers, and future development projects. (Reeves et al., 2005, pp. 109-110)

Blended instruction is becoming more commonplace in higher education. Through the pilot implementation described in the present paper, it is clear that the requirements noted by Reeves et al. are the necessary steps to enhance the quality and usefulness of design research in the use of the CMS Moodle for a blended course: apply theory to course design, put design into practice, collect and analyse data, and use the results to revise and modify the design. In order to enhance and maintain high quality *blended* or *online* instructional practices, it is essential for instructors to develop and implement specific assessments to evaluate the effectiveness of the teaching-learning process. That is, future studies should examine actual student performance with concrete learning tasks—not perceptions or preferences—in order to see whether these are consistent with teaching and learning effectiveness in the use of course management tools such as Moodle.

1. ABSTRACT

This paper has taken the key concepts taken from Andreas Riege's (Riege 2005) work to construct a questionnaire that was used within the drug development department of a large multi-national pharmaceutical organisation. The questionnaire assesses the department's culture to sharing knowledge which will aid in the development and deployment of a new Knowledge Management Decision Capturing Tool. The overall aim of the research is to increase the chance of the tool succeeding within the organisation by better understanding the cultural issues. This paper details how the questionnaire was formulated, analyses the results and draws conclusions form what can be learnt from such research projects.

2. INTRODUCTION

Nowadays we live in a knowledge economy that relies on the knowledge of employees. This is particularly relevant to the Pharmaceutical industry that develops and sells drugs and medications. Yet what they are really purveying is the knowledge and creativity of the researchers who develop these products, obtain approval, and get them to market. Knowledge Management has emerged as a popular and important area of academic and practitioner research, the principal reason behind the rise in popularity, is that authors such as (Drucker 1993)have assigned a value to the knowledge within an organisation. The sharing of knowledge between employees in an organisation has been shown to be of great benefit and provide competitive advantage (Argote, Ingram 2000). Argot and Ingram (Argote, Ingram 2000) stated that 'The ability to transfer knowledge from one unit to another has been found to contribute to the organizational performance of firms in both the manufacturing and service sectors'. Due to these factors, organisations are becoming increasingly aware of the need to actively manage the knowledge of their employees and knowledge repositories, as their operating strategies are driven into distributed models by the advent of modern cross functional and cross team working practices (Argote, McEvily & Reagans 2003). For example, typically, only one out of 30 new projects results in marketable medication in the pharmaceutical industry (Myers 1991) and the knowledge the researchers carry from project to project therefore has a direct bearing on profits. A company that can improve the ratio to one in 28 through more rapid and efficient development has a competitive advantage (Myers 1991)

Attempts to address the issues of information and knowledge extraction within the initial discovery stages of drug development have met with mixed results. Scarce Knowledge Management based literature exists on the subject, indeed Schweizer (Schweizer 2005) questions the ability of the acquiring pharmaceutical company to 'absorb' the knowledge of the biotech company, concluding that in many cases the pharmaceutical company may prefer to outsource its R&D activities to these companies and instead concentrate upon its core competencies of late stage clinical trials, regulatory affairs and marketing activities.

The research detailed within this paper is part of a larger three year research programme into how the multi-national pharmaceutical company can increase their competitive advantage through the careful development, education, deployment and training of staff around a specific Knowledge Management and Decision Capturing Tool (KM-DCT) that will aid their employees to:

- Record and structure their knowledge and decisions.
- Make informed decisions through interrogating the stored knowledge and decisions.
- Provide considered and concise strategic options for internal customers, thus saving them time and above all providing a higher level of scientific accuracy.
- Use a tool that is seamlessly part of their working habitat, integrated with their everyday process.

This paper details the results of stage one of the research which involves assessing the environment (employees and culture) within the drug development department of the pharmaceutical company with regards to knowledge sharing and capturing.

This research has been based on the paper "Three-dozen knowledge-sharing barriers managers must consider" (Riege 2005) which presents a number of barriers and problems that must be considered. The key concepts of that paper have been used to develop a questionnaire that was used within the drug development department of the multi-national pharmaceutical to assess the department's culture to sharing knowledge and determine how the suggestions fit this organisation. The results of the questionnaire will be used to feed into the development of the KM-DCT, with the overall aim of the research to increase the chance of KM-DCT succeeding.

A practitioner aims to create an environment conducive to knowledge sharing and is largely reliant upon the implementation of technology to support such knowledge interaction (Richardson 2001). On the other hand, the academic arena approaches Knowledge Management from a conceptual angle, seeking to analyse the underlying basis of knowledge and create an environment conducive to knowledge sharing without the emphasis upon technology (Sullivan 2000)(Nomura 2002).

In order to gain a competitive advantage through the development, education, deployment and training of staff on the KM-DCT, three main areas will be addressed to ensure that the three year research programme is successful. Research will address the following three main areas as a holistic approach:

- Employees (culture)
- Process integration
- Technology

Employees, because only human beings can generate knowledge from information and re-use it in a different context. Processes, because the transmission of knowledge from person to person requires rules and procedures in order to make use of knowledge or take action on it. Technology is necessary to store, retrieve, and organise vast quantities of information and make it digestible by human beings so that new knowledge can be discovered. Note that technology was not first on this list. Without detailed consideration of the employees and processes technological systems will undoubtedly fail.

3. METHODOLOGY

3.1. Research Methods

It was decided that the most efficient way to capture the information required would be to use a questionnaire. The ability to distribute the questionnaires to a wide geographical area was vital as a number of employees were based at different locations throughout the United Kingdom. Surveys also allow a greater number of variables to be studied than some other experimental methods (Galliers 1992).

It was also important to be aware of some of the pitfalls related to using questionnaires. Using a questionnaire takes a snapshot of the persons view at a particular point in time. They may also allow bias to be introduced because the person completing the survey chooses the answer they give. This may of course not reflect their true belief or their true state. Questions are also open to interpretation of the respondent. They may also not show the full picture as to why the respondent gives the answer they do. These are all issues to bear in mind whilst analysing and interpreting the results.

3.2. Questionnaire Sections

Three key areas of knowledge management have been addressed within the questionnaire and are namely:

- Technology
- Culture
- Process

Whilst technology and culture can be addressed by questions in the questionnaire, the daily process of an employee must also be taken into consideration. For this reason a number of questions were asked surrounding the user's daily process. It was important to see if we could establish a way of introducing the toolset into their work whilst minimising disruption to their daily process and causing unnecessary stress or complication.

In addition to these widely recognised areas another section was created. This focused on reward. In preliminary discussions it was apparent that many employees felt that they couldn't make time to focus on knowledge sharing because of the lack of reward that would be received and perhaps even the negative impact it would have on their job. They felt that there was no system to reward them for knowledge sharing or encourage them to share. Any knowledge sharing was being done 'off their own backs' in the hope that it would improve their skills and job performance. There was also no way to record the fact they had spent time sharing knowledge in their time-sheets leading to unexplainable holes in their work schedule. Given the preliminary discussions it was important to discover if these feelings were shared throughout the organisation.

3.3. Question Types

A number of questions where presented as multiple choice answers. In the majority of these scenarios they were in answer to a question that asked about the frequency something occurred. Most of these multiple choice questions were presented with an even scale, meaning that they had and even number of possible answers. There were generally 4 or 6 options. This was done to prevent employees from giving just a neutral answer and forced them to make a clear decision about the side of the argument they agreed with.

There were also a number of open text fields available. It was felt that although no statistical analysis can be easily achieved with these fields they would provide and excellent insight into the views of those questioned and enables them to expand on the answers that they give. This allows a greater view into their thoughts and hopefully leads to less interpretation being required to alleviate some of the issues mentioned previously.

3.4. Deployment

The questionnaire was delivered as an online survey within the target organisation. This was done for a number of reasons.

The first and foremost reason was that anonymity was required. The questionnaire asks a number of questions which may be considered quite sensitive and their answers may be perceived by the employees as a threat to their job security should they offend anyone. It is also obviously important that truthful answers were received. In order to ensure that a unique reference to the employee was available without compromising their privacy, windows login id's were first encrypted using a cryptographic hashing algorithm which is very difficult to reverse (the system actually uses the SHA-1 algorithm).

Secondly, to ensure that recipients answered within their normal working environments to minimise the disruption caused and maximise the probability that responses would be received. It also increased the benefits of the questionnaire technique for obtaining results from highly geographically dispersed recipients.

The questionnaire contained many questions that related to IT and systems that the IT department delivers, thus it was important to get their agreement. The Human Resources department also ensured that they were acceptable to the members of staff.

The survey contained 60 questions divided into the previously discussed categories and was distributed to employees in one geographically dispersed department. Employees were asked to participate via and email and of the 100 asked to participate, at the time of writing, 65 responses had been received.

4. RESULTS AND ANALYSIS

Like the questionnaire the results have been divided into four sections, Technology, Culture, Daily Process and Reward and Recognition Schemes.

4.1. Technology

The first key indicator area has been used to determine the ability of the employees to use technology and to understand their current concerns with the existing systems that they use.

It is interesting to note that two thirds of the participants stated they were experienced as a computer user. Whilst 20% said that they had some experience and 12% said that they were experts. Only one person rated themselves as a novice. The employees' opinions of their experience with technology in general, followed a similar pattern. However slightly more employees felt they only had some experience.

Reluctance to use IT systems due to a lack of familiarity or experience with them is an issue for some employers, however, in a company where the majority of employees feel that they have experience with computers one might expect that this would not be a problem. What is quite positive is that 50% of the participants actually became excited about the prospect of something new.

Employees were also generally happy with the amount of training they had received to perform tasks associated with their daily work. However, over 50% felt training is inadequate. What this may indicate is that a system of clear communication is necessary to allow those who are perhaps slower at picking up the new technology or do not feel comfortable with the training, to obtain more references or training, whilst allowing those who are content to bypass this.

Another key issue mentioned by Riege (Riege 2005) is that not demonstrating all of the advantages of a new system over an old can cause negativity towards a system. This has also been identified as a problem within the target organization with 6% saying that benefits are rarely explained and 66% saying that they are only sometimes made clear.

Almost two-thirds of employees felt that sufficient technical support was available which is a positive outcome. It is worth investigating the reasons behind why one-third did not feel that technical support is available.

There was also a feeling that IS tools and business processes are not very well integrated with 61% saying that only sometimes are they well integrated. This lack of perceived integration will obviously impair sharing and coupled with the previous point shows an area that must be investigated.

4.2. Daily Process

As mentioned earlier in the paper, for a new system to be a success it needs to be embedded within current daily processes, which includes the systems they use on a regular basis. The second key indicator determines the applications the employees use on a daily basis and what activities they undertake. Through understanding these it will be possible to determine the most suitable place for the KM-DCT to be embedded.

One of the most obvious options is to make the tool a web based system on the company intranet. When asked how often employees made use of the internet for work, 30% said all the time and 17% said hourly, this left 39% saying they

used it once or twice per day. Only seven employees said they used it just once or twice per week. This reinforces the fact that the web is a great location for a new system.

Several questions were asked about the sites that were frequently visited. When asked how often employees read the company portal, 47% said sometimes and 27% often, this indicates a logical place to put the tool. However, this may not signify a prominent enough position and more questions may need to be asked in order to determine how the tool could be promoted more successfully than simply making it available from the corporate portal.

It is also interesting to note that 81% of employees said that they received 25 or more emails per day and 92% stated that they left Microsoft Outlook running all the time. This represents a definite option for further investigation and research into possibilities of integrating the tool into emails will be worthwhile. Being able to automatically advise based on the outcome of previous decisions whilst working within Outlook could be a positive step.

Microsoft Word and Excel were also often used with 26% of employees stating they used Word always and 60% stating they used it often. Excel was used slightly less but still had over 60% saying they used it always, often or sometimes.

4.3. Culture

It has been said (Riege 2005) employees can take 'ownership of intellectual property because they do not feel they are given sufficient credit when sharing knowledge'. This will obviously cause employees to be reluctant to share knowledge in future and cause them to keep knowledge to themselves, and only sharing what is truly necessary. Almost 50% of employees said they sometimes receive credit and 25% said that they rarely receive credit. This is obviously a very negative thing. Methods for giving credit are often difficult. It is important that employees still feel an emotional attachment to their information even though it is being used by the team. What is quite surprising is although there was a lack of credit for knowledge sharing, 85% of participants stated this did not make them reluctant to share knowledge in the future.

A lack of time to share knowledge is also an issue, 12% of employees said that they rarely received enough time to share knowledge and 56% said that only sometimes did they get enough time to share knowledge. Only two employees felt that they always had enough time to share knowledge.

Actually identifying employees to share knowledge with and employees who need your knowledge is also important. Fifty-three percent of employees said that they did not have time to identify employees who have knowledge that they require. A slightly higher 61% said that they did not have time to identify employees who may require their knowledge.

Being able to actually record knowledge sharing in their time sheets presents an issue for most employees as 76% of the respondents felt that they couldn't record their knowledge sharing activities. While this should not be an issue for the use of the tool, as the tool will mostly be used within meetings where the activity can be recorded without problems, this is still an interesting finding.

Twenty-five percent of those questioned said they always benefit from sharing knowledge and 50% often do, with 21% saying that they benefit sometimes. This demonstrates there is a culture that realises the benefits of knowledge sharing.

Questions were also asked relating more to the organisational culture and encouragement and availability of knowledge sharing practices. When asked if knowledge was shared outside a participant's team 81% said that it was and over half felt that sharing knowledge outside their team was part of their work process. Only 47% were aware of the company wide goals for knowledge sharing. Often the 'Integration of km strategy and sharing initiatives into the company's goals and strategic approach is missing or unclear' (Riege 2005).With almost half of the employees unaware of the company's knowledge sharing goals and objectives, it may be difficult for a unified approach to succeed.

Whilst 40% of employees stated that they are often encouraged to share knowledge by their superiors and 13% always encouraged, this still leaves 32% who are only sometimes encouraged and 14% who felt that they rarely received encouragement to share knowledge.

Sixty-five percent said that they found sharing knowledge easy. Almost 60% felt that there were an adequate number of places to interact formally and informally to share knowledge with colleagues, for example within meetings and coffee rooms respectively. Only one-third of respondents felt that they were given the opportunity to interact with colleagues outside their immediate job, for example at conferences.

4.4. Reward Schemes and Recognition

The final key indicator area has been used to determine the mindset of employees within the department to whether they require a reward and recognition system, or if they currently use one how it affects their work. It is clear that the majority (90%) of employees do not know of any reward schemes that currently run within the organisation, yet the small minority that do (10%) feel that the scheme offers sufficient reward for knowledge sharing.

Interestingly only a small percentage of employees (35%) felt that they were in competition with employees both within and outside their department. This indicates that 65% do not feel they are in competition which is a good factor for knowledge sharing, although competition can be useful to motivate employees.

Also only Nine employees felt that their organisational structure prevented them from knowledge sharing. For example they felt that knowledge was only shared between themselves and their direct manager. Whilst this is not necessarily a real problem for the company as a whole, for those individuals the sharing of knowledge is being suppressed.

Finally, almost 50% of employees stated they would be encouraged to share knowledge if it were incorporated into their yearly review process.

5. CONCLUSIONS

This paper has detailed the results of stage one of the research which involved assessing the environment (employees and culture) within the drug development department of the pharmaceutical company with regards to knowledge sharing and capturing.

In the Technology section of the questionnaire the results indicate that the majority of employees are comfortable with using IT, but what was clear is that the benefits of any new system need to be made explicit to the employees. In the Process section, the majority of employees use Microsoft tools on a daily basis followed by the organisations intranet. When a new tool is developed it is important that it can be embedded into existing frequently used tools to aid in its use. In the Culture section employees indicated that knowledge sharing should be recognised as bonafide activity and to aid this they should be allowed to list it on their timesheets. Finally in the Reward and Recognition section, employees indicated that they would be encouraged to share knowledge if it was incorporated into their annual review process.

The four key findings from this research are listed below:

1. Enable knowledge sharing to be recorded in its own right and as a valued activity (timesheets).
2. Benefits of the new system need to be explicit.
3. Build new tools into existing applications.
4. Make knowledge sharing part of the employee's job by including it in their yearly review process.

The results from the cultural side of this study show that employees are willing to share knowledge if it is made explicit that it is part of their job and that they can record their knowledge sharing activities to projects. From a technological viewpoint any new system should be embedded within frequently used existing systems, and the benefits must be made clear to employees.

The sorts of problems highlighted in this study are not thought to be unique to this organisation and other organisations could benefit from repeating such a study before introducing new tools to aid in decision capturing and knowledge sharing.

Blending Synchronous and Asynchronous Learning Approaches for Teaching Knowledge Management Courses

Shaheen Majid, Nanyang Technological University, Singapore; E-mail: asmajid@ntu.edu.sg
Intan Azura Mokhtar, Nanyang Technological University, Singapore; E-mail: iam@pmail.ntu.edu.sg

ABSTRACT

Knowledge management (KM) has been one of the core operations of most companies and organizations since the early 1990s. As a consequence, KM education is experiencing exponential growth around the globe. In recent years, development in info-communication technologies (ICTs), increase in digital content, and the escalating use of the Internet and wireless capabilities have reformed the way learning is carried out. Many academic institutions are trying to fully exploit the potential of online learning tools and offer a variety of innovative pedagogical approaches that utilize information technologies in order to make the learning process more effective, interesting, meaningful, and engaging for students. However, face-to-face communication in a traditional classroom setting has its own advantages as it provides immediate feedback and answers to students' queries. This in turn, brings about increased student motivation, involvement, information and knowledge sharing, and development. The blend of these two approaches enhances their benefits and at the same time minimizes their limitations. This paper reviews the approaches adopted by the Division of Information Studies, Nanyang Technological University, Singapore, for teaching various modules in its Master's of Science in Knowledge Management (KM) program. This paper also explains the various ways in which the NTU online learning system, edveNTUre, is used for collaboration and content delivery for teaching the KM program, which helped improve the level of communication, collaboration, and interaction between students and lecturers.

1. INTRODUCTION

The global knowledge-based economy and growth of technologies have made it inevitable for online learning environments to spawn, in order to keep up with the demand for updated information and new knowledge, within the constraints of time and distance. Online learning, with its open access and independent learning environment (Stansfield, McLellan & Connolly, 2004), transcends physical and geographical boundaries to allow students to exchange ideas and share experiences cross-culturally. These characteristics of online learning make it an ideal learning mode that can effectively complement the traditional learning mode in meeting challenges posed by the digital age.

2. ISSUES CONCERNING ONLINE LEARNING

With the popularity and acceptance of online learning as a valid and effective learning method, there is a gradual change from lecturer-centered to student-centered learning approaches (Stansfield, McLellan & Connolly, 2004). As a result, the lecturer's role is becoming more of a facilitator in the learning process, while students actively participate and contribute to their own learning (Lee & Tan, 2004). It encourages students to view things differently, more critically and creatively (Pan, 1999). DeRienzo (2000) claims that in online learning, interaction is the key factor. She argues that the role of the lecturer is transforming from a broadcaster of knowledge to that of a mentor.

Kumar (2004) claims that online teaching and learning would become more effective through incorporating multimodality in content delivery which involves dissemination of knowledge in different modes of representation (eg. visual, textual, audio). Multimodal presentations are believed to stimulate and fully utilize all the abilities of human brain (Thomas, Kellogg & Erickson, 2001), allowing more opportunities for erudition, creativity and the generation of ideas.

In the traditional classroom, the synchronous or face-to-face social interaction with immediate feedback to learning queries by the teacher, facilitate student learning (McInnerney & Roberts, 2004) and help to allay doubts that may arise in the course of learning. This immediate feedback to questions helps students to quickly evaluate and guide their learning (Galusha, 1997). However, in the online learning environment, the lack of face-to-face interactions with their teachers can be exasperating for students and even hinder their learning process (Dzakiria, 2005). In addition, teachers may not be able to assess the learning situation immediately through students' facial expressions or signs of doubt (Stansfield, McLellan & Connolly, 2004). Nonetheless, the lack of face-to-face interaction with the teacher and other students are not necessarily barriers to learning. Students have indicated that asynchronous communication, such as emails and listservs, provide sufficient opportunities for collaboration with other students and feedback from the teacher (Daugherty & Funke, 1998).

Therefore, a balanced approach, using various learning methods and tools, and incorporating both synchronous (real-time) and asynchronous (delayed time) learning approaches, is more appropriate in overcoming barriers to online learning.

3. EDUCATING KNOWLEDGE MANAGEMENT PROFESSIONALS

The emergence of the knowledge-based economy and the popularity of e-business initiatives have made KM an essential area of activity in organizations. KM is a systematic process of taking advantage of the intellectual capital and knowledge assets for organizational success. In the current complex, dynamic, and volatile business environment, proper knowledge management can provide a competitive edge to an organization over its competitors.

Other than providing a competitive edge over rivals, good KM practices also allow information and knowledge sharing to take place. Many studies have claimed that information and knowledge sharing plays an important role in the learning and development of individuals (Rafaeli & Ravid, 2003). However, Majid and Yuen (2006) found that a barrier to information and knowledge sharing includes limited socializing opportunities. Hence, proper KM practices that utilize online capabilities would effectively improve the sharing of information and knowledge amongst people who frequently complain of a lack of time or social opportunities to do so. In the Division of Information Studies, School of Communication and Information, Nanyang Technological University, Singapore, various approaches are used to teach KM, which includes the innovative use of various features of an online learning system deployed by the University.

4. ONLINE LEARNING AT NANYANG TECHNOLOGICAL UNIVERSITY (NTU)

Nanyang Technological University is considered as one of the most prestigious and leading academic institutions in Asia, known for providing high quality education by using innovative pedagogical approaches. The university has a strong engineering college ranked among the best in the Commonwealth, a prestigious business school, an internationally acclaimed National Institute of Education, and one of the best Schools of Communication and Information in Asia. Recently several new schools such as the School of Biological Sciences, the School of Humanities and Social Sciences, the School of Physical and Mathematical Sciences and the School of Art, Design and Media, have been established.

The faculty at NTU extensively uses IT for instruction and delivering course content. All lecture theaters are equipped with state-of-the-art technology such as the latest computers, projectors, visualizers, VCR/ DVD players, wireless communication hubs and other gadgets. The campus is equipped with broadband high-speed telecommunication capabilities and all classroom computers are linked to the campus network as well as the Internet. Although currently NTU offers only selected academic modules online, it is considering using online modules extensively in the near future. As the physical size of Singapore is very small, students are expected to physically attend most of their classes. However, digital content is significantly used in all courses and the NTU online learning system plays a central role in instant communication between the instructor and students, student-to-student and other concerned parties.

4.1. The *edveNTUre* System

edveNTUre is the university online learning management system which was established in 2000 and within a short span of about 6 years, over 95% of all courses taught in NTU makes use of it. The *edveNTUre* (the letter 'e' stands for electronic; 'ed' for education, with the name of the university 'NTU' embedded in it) is powered by the Blackboard e-education system. The Blackboard system was preferred as it was used by over 3,300 institutions worldwide (Lee & Tan, 2004). It was also expected that a large user-base would ensure that the system continues evolving, and providing new tools and enhanced features. Several enhancements helped customize the Blackboard system into *edveNTUre* to meet specific needs of the NTU teaching community.

The use of *edveNTUre* has resulted in a paradigm shift in teaching and learning at NTU which was difficult to achieve by only using traditional classroom approaches. The e-learning platform has allowed dynamic content to be delivered digitally through the University through both wired and wireless networks to all students anytime and anywhere on a variety of devices (Lee & Tan, 2004). It complements traditional lectures through several online learning tools including discussion forums for collaborative knowledge sharing, personalized learning, dynamic content delivery and other automated teaching tools. The University is celebrating an e-learning week in October 2006 where all lectures and tutorial sessions will be conducted by using different online tools such as streaming of recorded lectures, virtual classes, online discussion board, short video presentations, and weblogs. This exercise is part of the University's initiative on "Pandemic Flu Response Planning for Business Continuity", to test the capabilities of the e-learning system to continue the teaching and learning process during a natural disaster or health epidemic.

5. KNOWLEDGE MANAGEMENT PROGRAM AT NTU

Recognizing the importance of knowledge management in the new economy, the Division of Information Studies introduced a specialization in Knowledge Management in 2000, as part of its MSc. in Information Studies programme. Soon it was realized that a more comprehensive and in-depth treatment is needed to prepare such professionals who can appreciate the complexities of this fast emerging discipline and be ready to provide leadership for implementing knowledge management initiatives in their organizations. In 2002, in collaboration with the Civil Service College, an MSc. degree in Knowledge Management was launched. NTU was among the pioneer to offer this degree in the Asia Pacific region.

The MSc. (KM) program provides a balanced coverage of management, technology, and information related topics, which are considered essential for preparing well-rounded knowledge professionals. In order to provide core competencies to all students and at the same time offer adequate flexibility for acquiring specialized skills, a three-tier programme was designed. As students in this programme come from diverse disciplines and backgrounds, three core courses, namely, *Foundation of Knowledge Management*; *Knowledge Management Tools*; and the *Professional Seminar*, were introduced to expose students to basic concepts, issues and the complexities of knowledge management.

At the second-tier level, Elective 'A' courses were structured to allow students to choose two out of four courses to focus on in the areas of human capital, knowledge tools, organizational behavior, and knowledge resources. These second tier courses provide basic competencies and prepare students for more advanced courses in the intended areas of specialization.

At the third-tier level, Elective 'B' courses provide an opportunity for students to select courses in their areas of interest. Moreover, students can either opt for the coursework only option where they take 11 modules (3 core, 2 Elective 'A' and 6 Elective 'B' courses) or a combination of coursework and dissertation (3 core, 2 Elective 'A', 4 Elective 'B' courses and a short dissertation). Currently, the programme is offered on a part-time basis and classes are held in the evening. However, from August 2007 this programme will also be available on a full-time basis, and as a result, overseas students will also be allowed to join this programme.

6. SYNCHRONOUS AND ASYNCHRONOUS APPROACHES FOR TEACHING KM

It is evident that where face-to-face instruction has its own merits, online learning and collaboration tools can bring students and lecturers together to discuss ideas and share opinions on a 24/7 basis, thus making the learning process more pragmatic, interesting, and unique. It is obvious that using a combination of approaches such as class lectures and online learning tools can supplement each other's strengths and at the same time help overcome their weaknesses. As a result, a dual approach comprising face-to-face instruction and the extensive use of online learning tools for content delivery and collaboration, has been adopted in NTU. As described in the next section, the combined approaches facilitated NTU's enhanced knowledge sharing through socialization and collaboration.

6.1. Face-to-Face Instruction to Facilitate Socialization

Considering the nature of the KM programme, which itself advocates the effective use of human capital and 'rich' communication channels in organizations, the face-to-face interaction between students and lecturers, and among fellow students was considered desirable. It provides an avenue for students to socialize as well as share their ideas and experiences, followed by active participation in online discussion forums. Moreover, the traditional classroom learning approach is considered more feasible in the Singapore context where students live in close geographical proximity. As all classes are held in the evening, even working students can easily visit the campus to attend classes.

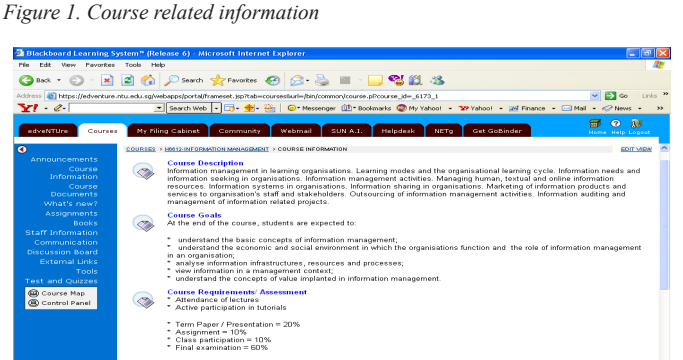
In addition to IT-supported lectures, ample emphasis is given on other interactive learning activities such as small group discussions, student presentations, case study analyses, group projects, hands-on sessions, and so on. The physical presence of students allows them to network and develop various interest groups. A study conducted at NTU to understand knowledge sharing patterns of graduate students in the School of Communication and Information also showed that other than e-mail, respondents preferred sharing their knowledge with their peers through face-to-face interactions (Majid & Yuen, 2006). The NTU experience also shows that longer tea breaks of half an hour have immensely contributed to increased informal interaction among students and developing alliances. It has been observed that this approach was helpful in providing an opportunity for students to carry out peer-to-peer learning.

6.2. Online System to Facilitate Collaborative Learning

In addition to taking full advantage of classroom learning, all KM courses extensively use IT, particularly the *edveNTUre* e-learning system, for delivering course content as well as a collaboration tool. At the start of a new semester, a new folder is created for each course offered during that semester. The course coordinator populates various areas in the folder such as course information, course documents, staff information, assignments, announcements, and tests and quizzes. Some important and frequently used areas in the course folder are described below:

a. **Course Information:** This section provides some basic information about

Figure 1. Course related information



the course such as the course description, course goals, course requirements, student assessment scheme, and recommended readings (Figure 1). In addition, it also provides details about the lecture and tutorial schedule.

b. **Staff Information:** This link provides contact information about the course coordinator, and all lecturers and tutors associated with that particular course. It often includes information about the names, email addresses, office telephone numbers and office locations of all the staff involved in teaching the course.

c. **Assignments:** In this section, information about assignment topics, recommended format and style for written assignments, assessment criteria, due dates, and so on are provided to the students (Figure 2). Almost all KM courses require students to submit written assignments, prepare individual or group term reports, and make presentations.

Often students are expected to submit a hardcopy of their written assignments for receiving the lecturer's feedback and grades as well as upload a softcopy through the *digital dropbox*. Many course instructors also upload the softcopies of student assignments and term reports in this area for reference by other students (Figure 3).

d. **Course Documents:** This is one of the most heavily used areas of the course folder. Most lecturers use PowerPoint slides with appropriate animations and they are expected to upload their lecture slides and other materials at least 2-3 days before the actual lecture day (Figure 4). It allows students to go through these materials before coming for class and bring a printout of these slides to class for taking additional notes. With the presence of wireless broadband Internet connection, students can also easily access the slides on their laptops in class and type in additional information discussed by the lecturer. In addition, instructors often use this area to either make available softcopies of additional readings or provide links to other electronic resources. The tracking feature of the system provides information about the use statistics of various course objects.

This area can also be used for providing access to other course materials. For example, in certain courses, various topics are given to the students during tutorial sessions for small group discussions. Each group picks, on a rotation basis, its leader to moderate the group discussion. Thereafter, all groups assemble and their leaders make brief presentations to the whole class, followed by a question-and-answer session. These group leaders are also expected to prepare a summary of the points raised during the class discussion and make them available online to all students.

e. **Collaboration Tools:** The edveNTUre system provides several collaboration tools that are available for easy and instant communication between the instructor and students as well as among the students. E-mail addresses of the

Figure 2. Description of student assignments

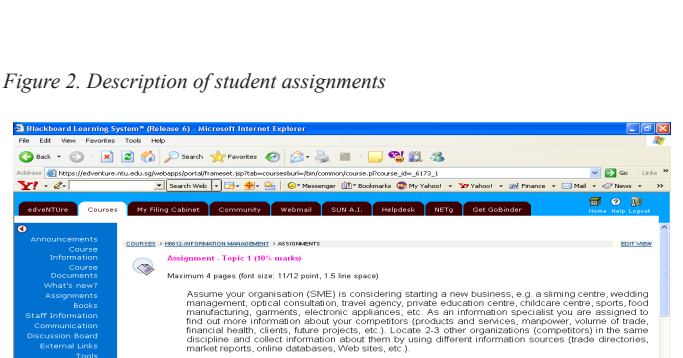


Figure 4. Lecture slides and discussion summaries

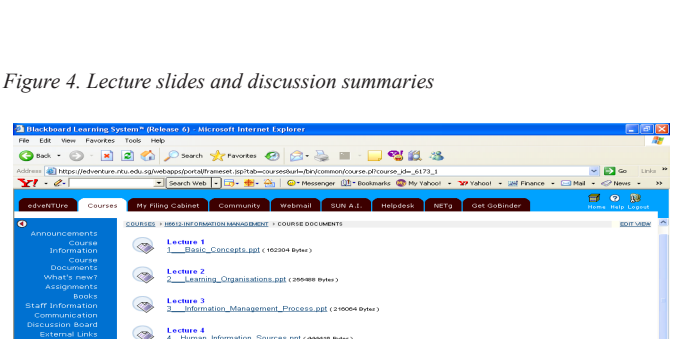

Figure 3. Softcopies of students' term reports and class presentations

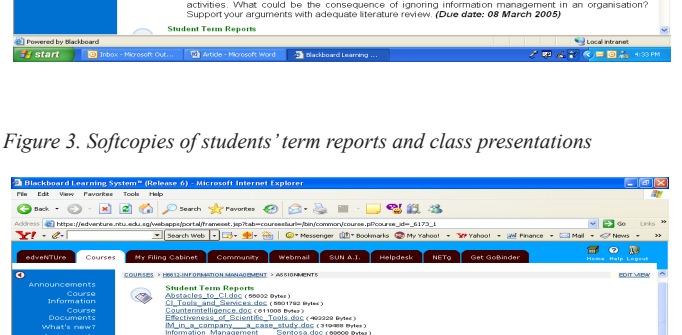

Figure 5. Summary report generated by the anti-plagiarism software

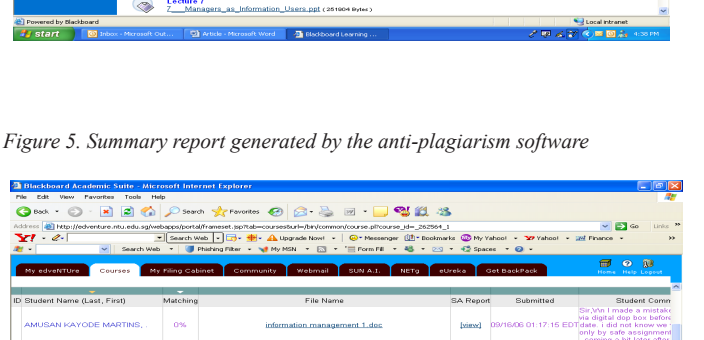

students registered for a particular course are available in the course folder for sending mass or individual e-mails to students within a class. Another very powerful and heavily used feature of the *edveNTUre* is the discussion board. Here, the instructor creates separate 'forums' for each discussion topic and students express their opinions on that topic. Students can read opinions of other students or add a new thread of discussion. Even shy students, who often do not actively participate in class discussions, feel comfortable expressing their opinions in these online forums where they can choose to remain anonymous. Threaded discussions can be reviewed and archived for future reference – an accumulation and documentation of real life scenarios, lessons learnt and shared, and best practices of doing things. Often, instructors become facilitators in such interactions so that students would not go astray in their discussions.

Staff and students can also join various university wide online interest groups created by different societies and professional associations, and participate in their discussions and other interactive activities.

f. **Safe Assignments:** Earlier, many lecturers have been experiencing and complaining about the widespread problem of student plagiarism. In most situations, they were unable to effectively control this problem due to the lack of time and difficulty in identifying the source documents. With the installation of this anti-plagiarism tool, it is much easier, faster, and less time consuming to get a complete report about the level of copying, sources used, and the copied text (Figure 5). Now, many course instructors require students to submit a softcopy of their assignments, term reports, and other materials through the safe assignment option. Students, at the time of submitting their work, can also see a plagiarism report and, in many cases, try to remove the plagiarized text before the final submission.

g. **Other Useful Features:** Certain other useful features available through *edveNTUre* include online announcements such as information about the availability of course materials, changes in class schedule, due dates for student assignments and other course related matters. Some other features available through *edveNTUre* are *Course Glossary*; *Digital Dropbox* where students can submit softcopies of their assignments and term reports, *Online tests and quizzes*, and external links to Web resources.

7. NEW E-LEARNING INITIATIVES AT NTU

In order to make online learning more interesting, interactive and engaging for students, certain new features are being introduced to 'humanize' the *edveNTUre*. The main objective is to add more human elements for effective "high tech – high touch" delivery of online contents (Lee, Tan & Goh, 2005). Some of the recent online learning initiatives introduced by the NTU are:

a. **Distance Education:** NTU is considering implementing distance education in certain academic programmes. Recently, a highly interactive and state-of-the-art distance learning facility, called the *Smart Classroom*, has been established. Currently, this facility has been successfully used for a distance learning programme with the Massachusetts Institute of Technology (MIT).

b. **PresseNTUr:** This tool enables lecturers to quickly and easily create their teaching contents either by using a talking head or their own face through using a digital camera. Through this technology, an instructor can synchronize his lecture with his PowerPoint slides or a video. Pace of the presentation can be changed by the students according to their learning speed. The recorded lecture can be delivered via PDAs as well as through Podcast.

c. **Breeze:** This Macromedia content creation tool allows converting PowerPoint slides into a low bandwidth format of the Macromedia Flash animation. It also allows voice narration to be synchronized with the PowerPoint slide delivery.

d. **Reusable Learning Objects:** The Centre for Educational Development in collaboration with the School of Communication and Information is in the process of implementing a taxonomy system aimed at building a better course management system. This system will enable staff to deposit learning objects in a repository organized to facilitate use and reuse for constructing lessons, presentations, and other documents. This system is expected to improve the use, reuse, and profuse of learning objects**.**

8. CONCLUSION

In recent years, advancements in online learning tools have encouraged many academic institutions to embrace this platform for dynamic content creation and delivery which is expected to make learning more interesting, effective, meaningful, and engaging. Although online learning has many notable advantages, it cannot entirely replace the need for a lecturer imparting knowledge in a face-to-face mode. Therefore, it is desirable that academic institutions, deploying online learning initiatives, should come up with a strategy that suits their local environment and teaching philosophy. Similarly, the success of the online learning initiatives would also depend on the technical competence, preparedness, and motivation of the academic staff and students. Lecturers need to learn creative and innovate ways of developing content which might need learning new skills, thus resulting in increased workload. Students also need to be more disciplined, organized, responsible and willing to share their ideas and opinions by using available collaboration tools. A major change in mindset is needed where both parties are ready and motivated to effectively play their roles. In this context, appropriate awareness strategies and training, both for the lecturers and students, can play a critical role in the success of the new initiatives. The use of a combination of approaches in teaching KM courses through active physical and virtual discussions emphasizing socialization and collaboration will enhance learning.

Project Scheduling Under Uncertainty

Tarun Bhaskar, GE Global Research, Bangalore, India; E-mail: tarun.bhaskar@ge.com
Manabendra Nath Pal, Indian Institute of Management Calcutta, Kolkata, India; E-mail: mnp@iimcal.ac.in

ABSTRACT
Scheduling is a very important part of the planning phase of project management. But the fact that it is a planning phase process makes it susceptible to uncertainty. This paper discusses uncertainty at different phases in project scheduling and then provides a method for handling uncertainty at the planning phase. We consider the project-scheduling problem with multiple resource constraints, discuss the uncertainty involved in the activity duration and its effect on the schedule. We propose a priority rule for a new schedule generation scheme, which takes care of the criticality of the activities and the randomness involved in the current and future activities. The method is demonstrated on a problem taken from the literature.

Keywords: Project Scheduling, Uncertainty, Robustness, Resource, Heuristic

1. INTRODUCTION

Scheduling is a decision-making process, which plays a crucial role in manufacturing as well as service industry. Scheduling mainly concerns the allocation of limited resources to jobs over time. This decision problem exists in lots of manufacturing and production systems as well as most of the information-processing units. According to the *Project Management Institute (PMI)* scheduling software is a "run-the-business workhorse" in many companies and it may improve success rates for them by up to 20% (Essex, 2005).

Several methods have been proposed for solving scheduling problems. These methods take the values of some parameters (such as resource and time required to complete each activity, available resources etc.) of the problem as the input and generate a schedule for the problem. In most of the cases, the parameters of the projects are estimated based on the domain knowledge and past experience of the manager. So there is some amount of uncertainty embedded in these estimates. The uncertainty can be at two levels:

1. At the planning level when the manager may not be very sure about the estimates of the parameter itself and
2. At the implementation level, when the manager gives a deterministic estimate of the parameter, but they change while executing the schedule.

In the first case the nature of the manager defines the type of input to the problem to a large extent. For example when the manager is risk averse, she would not be willing to give a deterministic estimates for the parameters. Therefore, she can either chose to give a vague estimate (for example a fuzzy number) or a random estimate or she may use some other measure, which represents uncertainty. In the second case the schedule, which was developed using the estimated values, becomes inefficient which leads to rescheduling the project several times. So a schedule, which is robust enough to take care of these changes to some extent, should be a preferred schedule. This paper is focused around the first aspect of uncertainty discussed above and discusses it for project scheduling problem.

The *Resource Constrained Project Scheduling Problem (RCPSP)* has been extensively studied in the literature. There can be different objectives of a project-scheduling problem, but minimization of project completion time is one of the most important objectives of a project-scheduling problem (Schonberger, 1981; Willis, 1985; Ulusoy and Ozdamar 1995). If we solve the problem considering this objective, time required by each activity becomes a very important input that is estimated based on past data and the experience of the project manager. So, activity duration estimates are susceptible to uncertainty.

The project-scheduling problem under resource constraints has been studied to a large extent but the literature is the field of scheduling with uncertainty is scarce (Demeulemeester and Herroelen, 2002). The research in this field can be classified into three main sections: criticality indices of activities and paths, probability distributions related to activity times and scheduling of activities. The criticality index (CI) of an activity is defined as the probability that the activity will be on the longest path (Dobin and Elmaghraby, 1985; Bowman 1995; Cho and Yum, 1997; Elmaghraby *et al.*, 1999). A detailed discussion on this topic has been provided in the review paper (Elmaghraby, 2000). The second topic of discussion in this area is the probability distribution of the activity and project completion time. The basic assumption of PERT network is that the activity time follows a beta distribution (Malcom *et al.*, 1959). Ginzburg (1988) suggested a new measure for the mean and variance of the distribution for activity duration

The third area is scheduling of activities under uncertainty (Malcom *et al.*, 1959; Schmidt and Grossmann, 2000; Pontrandolfo 2000). But very few studies considered resource constraint. Ginzburg and Gonik (1997) have proposed a simulation-based heuristic to solve the problem. At every decision point, they run the simulation to find out the criticality of each activity and then use a heuristic to allocate resources to activities. Their main concern was that the decision taken at a point is not only dependent on the past decisions taken, but also are dependent on the future decisions. So, at each decision point they run the simulation to find out the probability of a particular activity lying on the critical path. This repetitive process makes the method cumbersome and time consuming.

In this paper, we propose a heuristic method to solve the project-scheduling problem with multiple resource constraints, which has random activity duration. This method takes care of the concern of Ginzburg and Gonik (1997) without getting into a time consuming and cumbersome job of repetitive simulation. The heuristic proposed in this paper is a non-recursive method and gives an efficient solution to the problem. We use three different distributions (uniform, normal and beta) to model the uncertainty in the activity duration. We use a problem from the literature (Ginzburg and Gonik, 1997) to demonstrate our method.

The rest of the paper is structured as follows. In the next section we introduce the notations used in this paper and then we explain the problem in section 3. We discuss the proposed heuristic in section 4 and use that to solve a problem taken from the literature in section 5. Finally, we discuss the results, future research directions and then we conclude.

2. NOTATIONS

- a_j Optimistic time required for activity j.
- b_j Pessimistic time required for activity j.
- σ_j The standard deviation of time for activity j.
- j Activity number of the project. $j = 0, 1, 2, 3, ..., N+1$, where 0 and N+1 are dummy start and dummy end nodes respectively
- t_j Duration of activity j, a random variable
- M_j Maximum remaining path length of activity j, a random variable.
- A_j Set of activities on the path of maximum length starting from j
- A_0 Set of activities on the critical path
- S_j Net standard deviation of the path associated to M_j. $S_j = \sqrt{\sum_{k \in A_j} s_k^2}$ for all activities on that path.
- r_{jk} Renewable resource of type k required to perform activity j. $k = 1, 2, 3, ..., K$.
- R_k Total available resource of type k.
- T Project completion time without resource constraint. This is the critical path length of the project based on the expected value of the time taken by each activity.
- S Standard deviation of the critical path. $S = \sqrt{\sum_{k \in A_0} s_k^2}$ for all activities on the critical path.

$\overline{R_k}$ Minimum resource of type k required to complete the project in time T assuming no other $(K-1)$ resource constraints.

T_k Time taken (based on the expected value of the activity time) to complete the project considering only the k^{th} resource constraint and no other $(K-1)$ resource constraints.

i Cycle number of a decision point. A decision point occurs either at the beginning of the project or when at least one of the running activities is completed.

R_{ik} Resource of type k available at cycle i.

C_i The set of activities which are ready to be scheduled in cycle i. This is the set of activities, which satisfies the precedence relationship.

C_{im} The subset m of the set C_i that can be formed taking as many activities as possible without violating any resource constraint. m = 1, 2, 3, ..., M. So, $C_i = \bigcup_{m=1}^{M} C_{im}$.

l_{im} Number of activities in the subset C_{im}.

Z_{im} The value of SPI (as explained in section 4) of subset m in cycle i

3. PROBLEM DESCRIPTION

The problem discussed in this paper is of scheduling the project under multiple resource constraints with ill-defined activity duration. Most of the time it is convenient to estimate the upper and lower bound of the activity duration. Based on these estimates, the problem is to find the expected completion time of the project. So the problem has the following properties:

- A set of activities
- Random activity duration, which is generated based on the lower and upper bounds
- Fixed resource requirement and availability. We consider only renewable resources.
- A fixed precedence relationship
- Preemption not allowed
- Objective of minimization of expected project completion time.

A mathematical formulation of the problem, as given in Ginzburg and Gonik (1997), formulates it as a stochastic optimization problem, which is a hard problem to solve. We propose a heuristic method to solve the problem.

4. THE PROPOSED HEURISTIC

Now we introduce the heuristic to solve the problem discussed above. This heuristic is based on a priority rule, which gives a priority list of set of activities at each decision point. A decision point occurs either at the beginning of the project, or when at least one of the running activities is completed, till the last activity is scheduled. At every decision point, a set of all activities (C_i) whose predecessors have been completed is formed. All possible subsets of this set are formed which satisfies the resource constraints. So, at every decision point, several subsets of activities compete for the same resource. We decide on the winning subset based on the priority rule. A deterministic version of the priority rule has been discussed (Bhaskar *et al.*, 2004), but the need of similar measure for probabilistic network is evident. We call this priority rule as Schedule Performance Index (SPI). The SPI is based on the following important points:

- The objective is to minimise the expected project completion time. So we need to take care of the most critical activities. So, we should schedule that subset of activities whose criticality factor is highest among all competing subsets.
- As discussed earlier, we agree with the concern of Ginzberg and Gonik (1997) that at every decision point we need to take care of the randomness of the duration of activities that has not yet been scheduled.
- The scarcity of the resources should be minimised. This can be done by scheduling, if possible, the subset of activities with maximum resource requirement at the earliest. By doing this we try to avoid any resource crunch in the future.

As discussed in the first two points above, we need to incorporate the criticality of the activities in SPI. The criticality factor in our work represents, for each subset of activities, its distance from the critical path taking care of the randomness in the activity duration. We use the concept of *Maximum Remaining Path Length* (MRPL) (Moder *et al.*, 1983) to take care of criticality. MRPL of a particular activity is defined as the length of the longest remaining path starting from that activity. This represents, at every decision point, how critical is a particular activity. If we add the net variance of the remaining path, it takes care of the randomness of the future activities. So, a factor that represents the proximity of subset of activities to the critical path, taking care of the randomness of future activities, can be given by:

$$\frac{M_j + nS_j}{T + nS}$$

Where n is a number representing the weightage given to the randomness of future activities. We discuss the effect of n on the final results in the later section. We divide the expression by $(T+nS)$ to make the parameter less than 1, as $(T+nS)$ is at least as much as the numerator and it remains constant throughout the project.

Now we consider the last point, i.e. regarding the utilization of the resources, discussed above. We schedule the subset that requires maximum amount of resources compared to other subsets. By doing this we minimise the probability of any resource crunch in future. This can be measured by the ratio of resource required to resource available. So we introduce the following factor in our priority rule:

$$\prod_{k=1}^{K} \left(\frac{\sum_{j \in C_{im}} r_{jk}}{R_k} \right)$$

It is now a known fact that the complexity of the project scheduling under multiple resource constraints is not a linear function of the types of resources we use. So, we take the product over the types of resources in the problem.

The factors defined above are the measure of the criticality and the resource management of the subsets respectively. These measures are calculated at all decision points. So, this gives the local perspective of the problem at the decision point. We now introduce some global measures of the problem which remains constant throughout the problem and which represents the overall perspective of the problem. We have calculated the weight of each resource type in the problem, which represent the criticality of that type of resource. This can be given by the probability of a resource crunch of that type of resource during the whole time span of the project. This can be measured by the ratio of the resource available and the resource required to complete the project in the minimum possible time. This ratio gives us the criticality of that project. So we use this ratio as the power to represent the weight of a particular type of resource. This can be represented as:

$$p_k = \frac{\overline{R_k}}{R_k}$$

Similarly, to measure the overall probability of time overrun as the weight of the time factor explained above can be given as follows:

$$q = \frac{\max_k(T_k)}{T}$$

The value of T and T_k in the above expression is based on the expected value of the time taken by each activity.

So, the final expression for SPI, which is used in finding the winning subset, can be obtained by combining all these factors and it is represented as:

$$Z_{im} = \prod_{k=1}^{K} \left(\frac{\sum_{j \in C_{im}} r_{jk}}{R_{ik}} \right)^{p_k} \cdot \frac{1}{l_{im}} \sum_{j \in C_{im}} \left(\frac{M_j + nS_j}{T + nS} \right)^{q}$$

$\overline{R_k}$ and T_k can be calculated using Burgess and Killewbrew Algorithm (Burgess and Killebrew, 1962) and Brook's Algorithm (Bedworth, 1973) respectively. It is evident from the expression of SPI that the whole expression becomes zero if the resource of one or more type required by the activities in a particular subset C_{im} at any decision point is zero. To take care of these situations, we introduce some remedies for this. For any subset of activities, C_{im}, at a decision point i, if one or more resource type (but not all) are not required, then we can postpone the activities as discussed above. So in this case where the value of

$$\left(\frac{\sum_{j \in c_{in}} r_{jk}}{R_k} \right)$$

goes to zero, we replace the value by a very small positive real number ∂ (say 0.001). Where as in the case where there is no requirement of any type of resource

Now we use the above priority rule (SPI) to develop the heuristic algorithm for scheduling the project with uncertain activity times. To find the final schedule, we follow the following steps:

- Find the critical path length and the standard deviation of the critical path based on the mean of the distribution considered for random activity time.
- Use the Burgess and Killewbrew Algorithm to calculate $\overline{R_k}$
- Use the Brook's Algorithm to find T_k.
- Calculate the values of p_k and q.
- At each decision point:
  - Generate the random variate based on the parameters of the assumed distribution. The distributions considered in this paper and its parameters have been discussed in section 5.
  - Find the activities whose predecessor activities have been completed and populate the set C_i
  - Make the subsets C_{im} from the elements of the set C_i, which satisfies the resource constraints.
  - Calculate Z_{im} for each of these subsets
  - Schedule the subset with maximum value of Z_{im}.

This algorithm takes care of the uncertainties of the activities, which have not been scheduled at a particular point in time. Using this algorithm we schedule the activities till all the activities are completed and find out the completion time.

5. EXPERIMENT AND RESULTS

In this section we test our heuristic algorithm using an example taken from Ginzburg and Gonik (1997). The project under consideration has 36 normal and two dummy (start and end nodes) activities. These activities require renewable resource of only one type. The number of resources available is 50. The details of time required to complete an activity, the precedence relationship and the resource requirements are given in Table 1. The time required to complete an activity is not well known, therefore the optimistic and pessimistic time estimates are provided in the data.

For this experiment, we use three different standard probability distributions to generate the project activity duration. The justification of a particular distribution for PERT type of network is outside the scope of this paper. The distributions used in this study are:

1. A beta distribution in the interval $[a_j, b_j]$;
2. A uniform distribution with the range $[a_j, b_j]$
3. A normal distribution with mean as $(a_j + b_j)/2$ and variance as $[(b_j - a_j)/6]^2$

We generate random variates based on the above distributions and use them as the activity durations. To take care of the randomness and to get the average characteristic of the solution, we run the algorithm for 1000 times for each distribution and take the average of those 1000 runs as the project completion time. The results for different n are given in Table 2. The average project completion time for each run is rounded off to the just higher integer in case of non-integer completion time. But the average completion time, which is stated below, is the exact average of those integer completion times.

Table 1. Initial data of the test project

Activity no. (j)	r_j	a_j	b_j	Successors
0	0	0	0	1, 2, 3, 4, 5
1	16	40	60	6, 7
2	15	35	70	10, 11
3	18	25	35	12
4	19	30	45	13
5	10	26	33	14
6	18	9	15	8, 9
7	24	38	50	27, 28
8	25	10	18	26
9	16	16	24	27, 28
10	19	30	38	17, 18
11	20	18	22	26
12	18	25	32	24, 25
13	15	31	45	17, 18
14	16	58	78	15, 16
15	17	35	45	20, 21, 22
16	19	25	35	23
17	21	35	60	19
18	24	30	50	20, 21, 22
19	13	35	42	35
20	16	20	30	33
21	12	14	21	34
22	14	15	20	35
23	16	30	42	33
24	15	28	40	30, 31
25	13	22	28	32
26	14	20	35	29
27	18	16	24	29
28	22	15	22	30, 31
29	10	13	18	36
30	18	27	38	36
31	16	35	55	37
32	17	20	30	34
33	19	25	27	37
34	20	17	38	36
35	15	38	55	37
36	24	12	22	37
37	0	0	0	-

The results stated above gives the expected completion time of the project and they reveal lots of interesting facts. The expected completion time in case of beta distribution is less than that of other distributions. So, the assumption of a beta distribution gives an optimistic estimate of the completion time compared to other distributions. As we increase the value of n, the completion time increases in most of the cases because the value of n represents the weightage we give to the randomness of the future activities. So, higher the weightage given to the randomness of the future activities, higher is the time of completion.

The result gives an indication that for higher value of n, the chance of completion of the project within the estimated time should be higher. We try to analyze this observation by doing one more experiment. For each distribution we calculate the project completion time by taking the $\mu_j + n\sigma_j$ as the deterministic activity duration of each activity and used the proposed method for scheduling. We calculate the number of instances of project (in case of random activity times) where project completion time lies within the time estimated by the deterministic

Table 2. Project completion time for different distributions

n	Uniform	Beta	Normal
0	422.22	410.25	421.53
1	436.86	412.62	438.21
2	433.69	424.82	437.56
3	453.11	418.56	448.58
4	468.73	432.56	462.86

case with $\mu_j + n\sigma_j$. This would give us an indication of chance of completion of project within the time estimated by taking $\mu_j + n\sigma_j$ as the activity duration. The preliminary results show that around 50% of the instances lie within the calculated time estimate in case of $n = 0$ for almost all the distributions (in case of beta distribution this value was 43%). As we increased the value of n, the chance of completion increases. For $n = 4$, the chance of completion of project was 97.1%, 97.5% and 95% for uniform, normal and beta distributions respectively. These are only indicative results, which show that there may be a relationship between the value of n and the probability of completion of project within some time. A theoretical study in this regard needs to be done and we consider it as an interesting area for future research.

6. CONCLUSIONS

In this paper we have discussed uncertainty involved in project scheduling under resource constraints. We have discussed uncertainty involved in the planning as well as the implementation phase of the problem and have proposed a method to take care of uncertainty in the planning phase. We have proposed a new efficient heuristic for project scheduling under multiple resource constraints and random activity duration. The heuristic is non-recursive and does not require simulation at each decision point. It also takes care of the concern of the researchers that the decision taken at any decision point should also be a function of the randomness associated with the future activities. The method is tested on a problem taken from the literature. The results also show that beta distribution, compared to the other two distributions, gives an optimistic measure of project completion time. In this work we have considered randomness only in activity duration.

This work can be extended in two directions. The result shows that the project completion time increases with increase in the value of n. It would be interesting to find out the exact value of the probability of completion of project as a function of n. Finding the most appropriate probability distribution or even a bound on the probability would be of interesting. The second extension can be considering uncertainty in the resource requirement and the resource availability as well. This study becomes more interesting as it is clear that the uncertainties in resource and activity duration are correlated.

ABSTRACT

How can customers get trust from Internet-based companies? Among many activities to get trust, this study focuses on mobile CRM-related activities. Mobile CRM-related activities are efforts of companies to manage customer relationships using mobile technologies such as SMS (Short Message Service). This study analyzes if mobile CRM-related activities are effective to obtain customers' trust, considering moderate effect of commitment. Many CRM studies have focused on company's point of view. But, this study evaluates CRM-related activities from customers' side. The perceived evaluation of mobile CRM-related activities influences customers' commitment. The commitment explains customers' trust. Mobile CRM-related activities have three dimensions: content differentiation, contact frequency, and contents repetition. Also, commitment consists of three constructs such as affective commitment, continuance commitment, and normative commitment. In order to verify a research model, questionnaire surveys were conducted to collect data. The collected data were used to test hypotheses using structural equation modeling (SEM). The result shows that the customers' evaluation of mobile CRM-related activities contributes to build customers' trust through commitment (affective commitment, continuance commitment, and normative commitment).

Keywords: Trust, Mobile CRM, Commitment, Contact Frequency, Content Differentiation, Content repetition

INTRODUCTION

As Internet-based companies have more competition in the market, trust became a critical factor to survive in markets. Once customers trust the Internet-based company, they will visit the website more frequently and make more transactions. During the process of the transactions, the Internet-based company makes efforts to instill trust to customers' mind. For example, the Internet-based company sends s short message for the status of transactions with mobile technology, which is SMS (Short Message Service) using cellular phone. Once the customer gets the message, he/she may feel more comfortable for the transaction. This is one of methods to provide trust. However, some customers may have negative feelings of privacy intrusion when the Internet-based company contacts them using personal information, while others may feel comfortable, especially when the company provides coupon or promotion information. This kind of negative feelings could play as the barriers to build customer trust in the long term. When the company uses customer information, the company uses CRM (Customer Relationship Management). Thus, it may need to check if the mobile CRM-related activities can be helpful to build trust for the Internet-based company. If customers have negative feelings, the mobile CRM-related activities must be abandoned. Until today, many academicians and managers have stressed CRM-related activities to obtain competitive advantage and coped with changeable business environments. Since they think that using information from CRM can maintain the relationship between existing customers and companies (Kim, 2003), they have tried to expand CRM-related activities. But, it is necessary to evaluate whether or not CRM-related activities can really contribute to build customers' trust in Internet markets.

Most of previous literature has studied effects of CRM-related activities from company's viewpoint, not on customer's viewpoint (Kim, 2003; Hwang and Park, 2004). Even though Suh and Park (2005) studied evaluation and improvement of CRM-related activities from customers' side, they did not link CRM-related activities to customers' trust. Also, they did not consider mobile environments.

This study focuses on building customers' trust through mobile CRM-related activities from customers' viewpoint. The ultimate purpose of this study is to explain how to achieve customers' trust through Mobile CRM-related activities. Thus, this study tries to answer the following research question; "Is mobile CRM-related activities effective to build customers' trust with considering commitment?" Practically, the result of this study may suggest important guidelines to build successful mobile CRM strategies to obtain customers' trust for Internet-based companies.

Next sections review previous studies of CRM-related activities and commitment and develop hypothesizes. The following section explains data collection and analyzes the collected data. Finally, this study concludes with some comments and limitations.

LITERATURE REVIEW

Many scholars have defined trust in their own ways. According to Moorman et al. (1992), trust is "a willingness to rely on an exchange partner in whom one has confidence", while Morgan and Hunt (1994) explain that trust exists when one party has confidence in an exchange partner's reliability and integrity. Dwyer and Lagace (1986) state that trust is a belief, confidence, or expectation about an exchange partner's trustworthiness evaluated the partner's expertise, reliability, or intentionality. Also, they said that trust is a behavioral intention or behavior of "willingness" that reflects partner's reliance (Moorman et al., 1992; Moorman et al., 1993; Morgan and Hunt, 1994). Reviewing literature, trust is better to understand as confidence in the relationship.

Meanwhile, Gruen et al. (2000) analyzed trust building processes: calculative, prediction, capability, intentionality, and transference. *Calculative* refers that "trustor calculates the costs and/or rewards of target acting in an untrustworthy manner." *Prediction* means to develop confidence for behaviors to be predicted. *Capability* indicates to assess the target's ability to fulfill its promise. *Intentionality* is understood as evaluating the target's motivations. Finally, *transference* means that trustor draws on "proof sources," from which trust is transferred to the target. If this study applies mobile CRM-related activities to five processes to explain trust building processes, customers may calculate the costs/rewards, develop confidence, assess promise of the company, evaluate motivations, and transfer when they faced mobile CRM-related activities.

CRM (Customer Relationship Management) addresses all aspects of identifying customers, creating customer knowledge, building customer relationship, and

shaping their perceptions of the organization and products (Srivastava et al., 1999). Most existing literature focused on the effects of CRM system installment for customer performance (Kim, 2003), the relationship between CRM system and Marketing Performance (Hwang and Park, 2004), and the impact of customer partnership on CRM success (Lee et al., 2004). These studies were focused mostly on company's point of view, not on customers' point of view.

This study focuses on customer side's CRM evaluation under mobile environments. Thus, this study analyzes three mobile CRM evaluation criteria. The first criterion is *Contents Differentiation*, which means how different the contents are, compared with contents offered from other companies in the same industry. The second criterion is *Contact Frequency* defined as how frequent customers face CRM-related activities from the company. The last criterion is *Contents Repetition*. This indicates whether or not customers face repetitive contents from the company.

In order to build trust, commitment may play a mediating role between trust and mobile CRM-related activities. According to Dwyer et al. (1987), commitment is understood as a pledge of relational continuity between exchange partners. Moorman et al. (1992) explained commitment as a reflection of a positive valuation of a relationship. These definitions commonly mean an enduring desire to maintain a valued relationship. If people are committed to the product or the company, they feel that keeping relationship is valuable and do not frequently switch the product or the company. Finally, they may have trust for the company.

Some studies have taken a uni-dimensional approach to explain commitment (Dwyer et al, 1987; Morgan and Hunt, 1994). But, commitment is better to understand by multi-dimensional constructs such as affective commitment, continuance commitment, and normative commitment (Anderson and Gerbing, 1988; Gruen et al., 2000). The affective commitment is a positive emotional attachment, which means how favorable customer feels about product, service, or company. If customers psychologically feel drawn to the company, they maintain a relationship (Gruen et al., 2000). The continuance commitment is based on the sunk cost in a relationship. It indicates when customers give up the relationship they consider the cost and perceive lack of alternatives. Thereby, customers continue to have the relationship (Gruen et al., 2000). The normative commitment is a moral obligation derived from existing relationship. According to the normative commitment, customers keep the relationship because they feel a sense of belonging to the organization or the community. In brief, customers with affective commitment remain because they want to. Customers with continuance commitment remain because they need to. Customers with normative commitment remain because they feel they ought to do so (Anderson and Gerbing, 1988).

RESEARCH MODEL AND HYPOTHESES

The research model for this study is shown at the following figure 1. Three dimensions of mobile CRM-related activity evaluation positively influence to each dimension of commitment. And three commitment constructs affect customer trust. Three commitment constructs are affective commitment, continuance commitment, and normative commitment. Trust can be accounted for by mobile CRM-related activity evaluation through commitment. Thus, according to this research model, customer can build trust by mobile CRM-related activities through customer commitment. Customer can evaluate mobile CRM-related activities by content differentiation, contact frequency, and content repetition. These criteria can work with each dimension of commitment to build trust. Finally, customer has trust through each dimension of commitment.

Commitment is the key mediating variable in the field of relationship marketing. Since customers maintain relationship with companies, expect long-term benefits of staying with them, and have the faith that the companies will not act opportunistically, customers can consider potentially high-risk investments with awareness (Garbarino and Johnson, 1999; Morgan and Hunt, 1994). If company's mobile CRM-related activities offer customers a magnitude and numbers of benefits, customers will maintain the relationship (Becker, 1960). Thus, this study suggests three mobile CRM-related activity evaluation criteria (Contents Differentiation, Contact Frequency, and Contents Repetition) are positively related to commitment to build trust. The flowing hypotheses are suggested.

H1a: Contents Differentiation positively explains Affective Commitment.
H1b: Contents Differentiation positively explains Continuance Commitment.
H1c: Contents Differentiation positively explains Normative Commitment.
H2a: Contact Frequency positively explains Affective Commitment.
H2b: Contact Frequency positively explains Continuance Commitment.
H2c: Contact Frequency positively explains Normative Commitment.
H3a: Contents Repetition positively explains Affective Commitment.
H3b: Contents Repetition positively explains Continuance Commitment.
H3c: Contents Repetition positively explains Normative Commitment.

Once customers have commitment, they may continue to use the web site and make transactions with the Internet-based company. Since trust generally is regarded as a critical component for successful relationship (Dwyer et al., 1987; Moorman et al., 1993; Morgan and Hunt, 1994), positive relationship of each dimension of commitment is essential to build trust. The following hypotheses are proposed regarding the relationship between commitment and trust.

H4a: Affective Commitment positively explains Customer Trust.
H4b: Continuance Commitment positively explains Customer Trust.
H4c: Normative Commitment positively explains Customer Trust.

RESEARCH METHODOLOGY AND RESULTS

This study collected the data through questionnaire survey. Before the formal survey, two rounds of pre-tests were conducted to confirm face validity and

content validity. First round involved sixteen undergraduate students who use cellular phones. Second round of pre-tests involved two doctoral students through face to face contacts. Based on their feedback, certain items in the questionnaire were re-worded and layout changes were made in order to improve clarity and readability. After two rounds of pre-tests, this study conducted survey.

Each item in the questionnaire was extracted from existing literature. The Table 1 summarizes items and sources. The seven point Likert type scales (1 is "extremely little" and 7 is "extremely much") are used to measure the impact of mobile CRM-related activity evaluation, commitment, and trust.

Population for this study is cellular phone users who have experience to have received any CRM-related service. Sample was selected from four major universities located in Seoul, Korea. The questionnaire double checked whether or not they have any experience to have received mobile CRM-related services, mainly SMS (Short Message Service), when they use cellular phones. The survey was conducted at the classroom setting. The 300 students were participated and 254 responses were usable.

Figure 2. Result of CFA

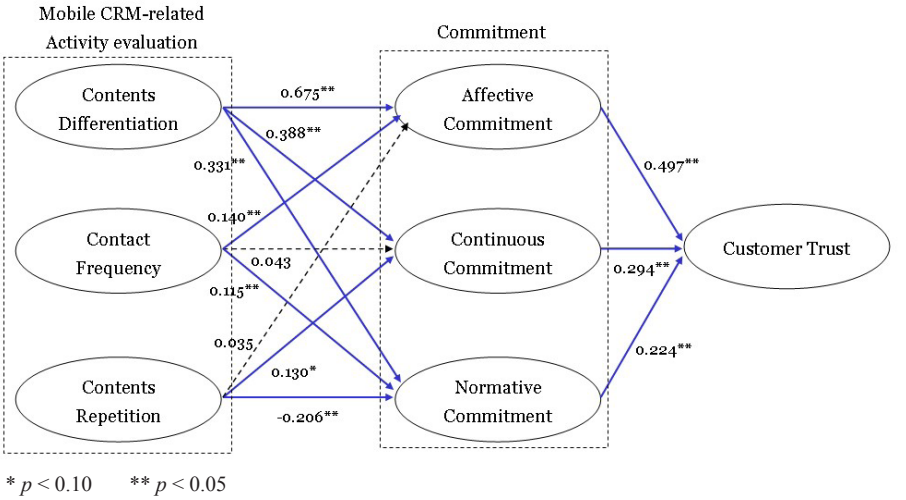
Figure 3. Standard estimation results for proposed model



Before testing hypotheses, this study conducted exploratory factor analysis (EFA) to cull out items that did not load on appropriate high-level constructs (Churchill Jr., 1979). EFA used principal component analysis and VARIMAX rotation method. After EFA, this study dropped four items because two items estimated under 0.4 factor loadings and other two items stretched over two constructs (Table 2). Cronbach's alpha values in Table 2 indicate that measures are reliable, even though Normative Commitment is relatively low. Thus, the result of EFA confirms that measures have construct validity after dropping four items.

In order to check convergent and discriminant validity, this study conducted confirmatory factor analyses (CFA) using Structural Equation Modeling (SEM) method (Figure 2). Convergent validity is the extent to which measures for a variable act as if they are measuring underlying theoretical constructs because they share variance (Schwab, 1980). Discriminant validity means the degree to which measures of two or more constructs are empirically distinct (Bagozzi et al., 1991). Most of model fit measures are acceptable (GFI=0.919, AGFI=0.883, NFI=0.904, RMSEA=0.048, CFI=0.962). For convergent validity, all factor loadings are significant, while for discriminant validity all the correlations pass the criteria that estimated correlation between any constructs±2S.E. should not include unity (Anderson and Gerbing, 1988). Thus, the result indicates that constructs are valid measurements.

The result of path analysis is at the figure 3. Most fit measure values are acceptable (GFI=0.911, AGFI=0.879, NFI=0.899, RMSEA=0.038, CFI=0.971). Thus, this study could check twelve hypotheses. The solid lines in the Figure 3 indicate significant coefficients, while dotted lines do insignificant coefficients. The data revealed that most hypotheses are significant except H2b and H3a.

The first hypothesis (H1) is regarding the relationship between contents differentiation and commitment. The results show that Contents Differentiation is positively related to three dimensions of commitment, respectively (H1a: 0.675, p=0.000; H1b: 0.388, p=0.007; H1c: 0.331, p=0.018). The second hypothesis (H2) involves the relationship between Contact Frequency and Commitment. H2a (the relationship between Contact Frequency and Affective Commitment) is supported at the 5% significance level, while H2c (the relationship between Contact Frequency and Normative Commitment) is supported at the 10 % significance level (H2a: 0.140, p=0.016; H2c: 0.115, p=0.056). But H2b (the relationship between Contact Frequency and Continuous Commitment) is not supported even at the 10% significance level (H2b: 0.043, p=0.463). The result of the third hypothesis (H3) testing shows that Contents Repetition affects Continuous Commitment positively (H3b: 0.130, p=0.040) and Normative Commitment negatively (H3c: -0.206, p=0.009). However, it is difficult to say that Contents Repetition can explain affective commitment (H3a: 0.035, p=0.559). At first, in the case of H3c, this study expected to have positive relationship between Contents Repetition and Normative Commitment. But, on the contrary, the result shows negative relationship even though the coefficient is statistically significant. At the next section, this study discusses this result in detail. The result of last hypothesis (H4) is confirmed positive relationship between Commitment and Trust. All of three hypotheses are supported at the 5% significance level (H4a: 0.497, P=0.000; H4b: 0.294, P=0.001; H4c: 0.224, P=0.040).

DISCUSSION

The purpose of this study is to analyze trust building processes as the effect of mobile CRM-related activities. In order to explain the processes, this study adopted the concept of commitment. Commitment plays a role of mediator between trust building processes and mobile CRM-related activities. Customers who have experienced mobile CRM-related activities from Internet-based companies become to have commitment with the companies and finally have trust for the companies.

Scrutinizing the results, this study raises several issues to be discussed. First, Contents Differentiation is the critical component for customers to have trust through commitment. As shown at the figure 3, Contents Differentiation positively influences three dimensions of commitment. Considering the coefficients, the values are much higher than other relationship with 0.675, 0.388, and 0.331, respectively. This indicates Contents Differentiation is the most important factor to make customers feel commitment to the company. Generally, customers prefer various and useful information. If Internet-based companies provide valuable information for customers, customers cannot help using the service from the Internet-based company.

Second, the hypothesis regarding Contact Frequency and Continuous Commitment (H2b) is not supported. It may imply that customers do not like too frequent contacts from Internet-based companies. Thus, the Internet-based company needs to realize the fact that if the company contacts customers so frequently the company may lose the customers because customers do not like too frequent contacts. However, frequent contact makes customers feel that the company is making efforts to have good relationship with them (H2a) and that customers feel belonging to the kind of community that the company made (H2c). Despite the result of H2a, customers do not like repeated contents (H3a), which may make customers lose affirmative feelings for the company.

Third, Contents Repetition and Normative Commitment (H3c) show statistically significant result, even though it shows negative relationship. This study initially expected to have positive relationship between two dimensions, but the results proved to be negative relationship. These results indicate the customers harbor ill feeling against excessive frequency and repetition. Subsequently, customers do not have feelings that they belong to the part of community for the company.

Finally, three dimensions of commitment affect positively customers' trust. In particular, Affective Commitment has larger effect on Trust compared with other commitment. Considering the result, the best way to build trust is making commitment through content differentiation. In other words, content differentiation as one of the mobile CRM-related activities can trigger to have commitment (affective, continuous, and normative), which influences to build trust. Therefore, Internet-based companies need to focus more on Contents Differentiation, along with Contact Frequency and Content Repetition.

CONCLUSION

This study highlights trust building processes through evaluating mobile CRM-related activities in the perspectives of customers. Despite the wide adaptation of cellular phone technology in the communication between the company and customers, the nature of information exchange in mobile technology is yet little known. In order to build trust, Internet-based companies have to make efforts for customers to have commitment to the company. When the company uses mobile CRM-related activities as a tool to provide commitment, the company needs to emphasize content differentiation, along with mobile contact frequency and contents repetition.

This study suggests two essential implications for managers. First, this study confirms contents differentiation is a very important factor for Internet-based company's mobile CRM-related activities rather than the other two factors. And customers have negative affection about frequency of mobile CRM-related activities. In addition, repetitive information makes customer distrustful to the company. Second, all of three commitments are positively related to trust. Most of all, affective commitment is the most powerful factor to build customer's trust.

ABSTRACT

In the field of spatial information systems, and especially in particular of geographical databases, many authors have studied how to formulate queries using pictorial configurations. The constraints deriving from topological relationships between pairs of symbolic graphical objects (the classic shapes point, polyline, and polygon) can be relaxed when a query search condition finds no match in the database, so that users can receive approximate answers rather than null information. In this paper a computational model for the similarity of the spatial relations is proposed. An operator conceptual similarity (OCS) graph describes the model, and links the more similar relations, defining the weight of each relaxation. The polygon-polygon, polyline-polyline, and polygon-polyline cases are discussed and matrices, which enlarge the known 9-Intersection model matrix are also considered.

1. INTRODUCTION

Many researchers have recently focused their attention on different approaches to expressing geographical data queries. The evolution of visual query languages has led to the proposal of pictorial query representation. Furthermore, computer networks and distributed computing technology have transformed many computer-based applications from the traditional stand-alone mode to the networked mode.

Geographical databases have received considerable attention due to the emergence of new applications. These databases too, some research efforts have focused on the problem of human-computer interaction and the representation of visual queries for geographical data.

In the field of spatial databases, many authors have studied how to formulate queries using pictorial configurations. In a geographical database these enable the configuration of geographical objects to be described, thus expressing the user's "mental model" of the query [4, 13].

The user's mental model corresponds to the semantics of the query (in the user's mind). It may show some mismatching with the Visual Sentence for the query. Let us suppose the user wishes to express the query that has the following textual description:

"Find all the regions passed through by a river and partially overlapping a forest"

The user is not interested in the relationship between the river and the forest; however the absence, in natural language formulation, of any explicit relationship between them produces ambiguity. In fact, the user implicitly thinks that no relationship exists between any river and any forest, but the correct query expression without any ambiguity using natural language is:

"Find all the regions passed through by a river and partially overlapping a forest, irrespective of the topological relationships between the river and the forest".

To represent this query graphically some authors use the classic shapes "point, polyline, and polygon". In [4, 12] the authors propose a pictorial query language called GeoPQL (Geographical Pictorial Query Language) to express any queries, and call these shapes Symbolic Graphical Objects (SGO) [4, 12]. The topological relationships between pairs of SGO use operators based on the Object-Calculus proposed in [14, 15], where a set of topological, metric and logical operators are defined. When a query search condition finds no match in the database, it would be useful for the system to produce not only configurations with an exact correspondence with the drawing representing the pictorial query, but also similar configurations obtained by relaxing some of the constraints. The most common approach to relax constraints is to measure the distance from the drawn query using criteria defined for the specific domain. In the case of pictorial queries of a geographical database, the constraints can be classified as three main types: spatial, structural and semantic constraints.

In this paper we discuss spatial constraints [5, 6], in order to decide which constraints must be relaxed and which maintained. To do this, we define a computational model for the similarity of the spatial relations by which to transform the pictorial query.

The similarity between topological relations is described by the ***Operator Conceptual Similarity graph*** (OCS graph), which links the most similar operators (in the sense explained in the following section), defining the weight of each relaxation. The query answers are produced by assigning a total score computed by this computational model.

In recent years, various papers have discussed the problems with topological relations between pairs of objects in a 2-dimensional space. Two models for binary topological relations - the 4-Intersection model and the 9-Intersection model - have been proposed [1, 2, 3] and compared [7]. In the 9-intersection model, as described in [8], the interior (A°), boundary (∂A), and exterior (A^-) of a 2-dimensional point set embedded in IR^2 are defined as usual and will be referred to as the topological parts of an object. The definition of binary topological relationships between a polyline L and a polygon R is based on the nine intersections of L's interior, boundary, and exterior with the interior, boundary, and exterior of R. A 3 x 3 matrix M, called the 9-intersection, concisely represents these criteria.

$$M = \begin{pmatrix} L^o \cap R^o & L^o \cap \partial R & L^o \cap R^- \\ \partial L \cap R^o & \partial L \cap \partial R & \partial L \cap R^- \\ L^- \cap R^o & L^- \cap \partial R & L^- \cap R^- \end{pmatrix}$$

Starting from these studies, two other models of conceptual similarity among topological relations between a polyline and a region were developed [8]. A further study of spatial similarity and a computational method to evaluate the similarity of spatial scenes based on the ordering of spatial relations is discussed in [9]. More recently, two papers have studied the spatial neighbourhoods between objects [11, 12]. In [11] the authors studied topological relationships between two regions, comparing two strategies for minimizing topological constraints in a query expressed by a visual example, and giving search results in terms of number and similarity values. In [12] the authors present an idea on how qualitative spatial reasoning can be exploited in reasoning on action and change. They investigate how its conceptual neighbourhood structure can be applied to the situation calculus for qualitative reasoning on relative positional information.

The paper is structured as follows: in Section 2 the GeoPQL operators are briefly introduced and two query examples are also shown. Section 3 proposes a computational model to determine the most conceptually similar relationships for each configuration, and the three cases polygon-polygon, polyline-polygon and polyline-polyline are studied. Section 4 gives an example of transformation to an approximate query, and finally Section 5 concludes.

2. THE GEOPQL OPERATORS

The GeoPQL algebra consists of 12 operators: Geo-union (UNI), Geo-difference (DIF), Geo-disjunction (DSJ), Geo-touching (TCH), Geo-inclusion (INC), Geo-crossing (CRS), Geo-pass-through (PTH), Geo-overlapping (OVL), Geo-equality (EQL), Geo-distance (DIS), Geo-any (ANY), and Geo-alias (ALS). Geo-touching refers to a pair of touching graphical objects, Geo-crossing refers to the cross-over between two polylines, Geo-pass-through refers to a polyline which passes through a polygon, Geo-alias allows an SGO to be duplicated in order to express the OR operator, and Geo-any allows any relationship between a pair of SGO to be considered valid, i.e., no constraint exists between them. This last operator allows an unambiguous visual query to be obtained, as explained in [4].

3. THE COMPUTATIONAL MODEL

The answer to a query may sometimes be "zero elements". In this situation, it would be useful if the system automatically relaxed one or more topological constraints until a positive result is achieved. To do this, we need to define the *operator conceptual similarity* (**OCS**) *graph*. This is obtained from the configuration of two disjointed (DSJ) objects through three operations: object shifting, rotation, and size change (smaller, larger). If we consider two disjointed polygons as our initial configuration, as shown in Figure 1(a), their relative positions can be modified by shifting and/or rotating one of them. By shifting (or rotating and shifting) polygon B towards A, we obtain the second situation, in which they are touching (Figures 1(b) and 1(c)). Note that polygon B can touch polygon A in two different ways: at one point or along a line.

If we continue to shift polygon B we obtain the third situation, which presents in reality two sub-situations. The former (Figures 1(d) and 1(f)) produces only an overlap between the two objects, while the latter (Figure 1(e)) produces an overlap and a touch. Still shifting polygon B, we pass from Figure 1(e) (OVL + TCH) to Figure 1(f) (OVL), or to Figure 1(h) (INC + TCH).

From Figure 1(h) we pass to Figure 1(i) (INC), or, with a shift towards the outside), to Figure 1(f) (OVL).

The enlargement of SGO B as shown in Figure 1(j) causes it to coincide with SGO A (Figure 1(k)). But it is also possible to move from the condition "TCH + INC", shown in Figures 1(g) and 1(h), to the condition "EQL", shown in Figure 1(k). In contrast, by shifting SGO B as shown in Figure 1(h), we obtain the condition shown in Figure 1(i) (INC). Finally, from Figure 1(g) we can also obtain the condition shown in Figure 1(j) (INC).

We have six possible conceptual similarity graphs which refer to all the combinations between two features (point-point, point-polyline, etc.). However, the three cases in which one point is one of the two SGO are sub-cases of the others. We will therefore study only three cases: polyline-polyline, polygon-polygon and polygon-polyline.

Not all the operators defined in GeoPQL are considered in each case. For example, in the polyline-polyline graph, the operator Pass-through (PTH) does not need to be considered, as it is valid only in the case of polygon-polyline. In the polygon-polyline graph, the operator Cross (CRS) need not be considered as it is valid only in the polyline-polyline case. Similarly, Overlap (OVL) is valid only in the case of polygon-polygon. We now consider and discuss the three cases separately.

3.1 Case of Two Polygons

The graph shown in Figure 2(a) represents the *OCS graph* for the pair "polygon-polygon". It begins from the condition of two disjointed SGOs (row of the graph). Using one of the three operations described above to modify the configuration, we arrive, step by step, at the leaf of the graph, i.e. the operator EQL. The 4x4 matrix structure that enlarges the classic 9-intersection matrix [8] is shown in Figure 2(b). In the 9-intersection matrix the authors consider an object's internal, boundary and external points and their position with respect to the other object (without distinguishing if the boundary contact points consist of one or more points or lines and without considering the number of times that each condition is verified). In contrast, in the 4x4 matrix of Figure 2(b) we distinguish the kind of boundary between the two SGO (point and/or line), as well as the number of times which each condition can arise (expressed as a whole, positive number inside the crossover point in the matrix of the points considered for each SGO). Each side, representing in this case one polygon, has three rows, which refer to the points of each polygon: i (interior), b (boundary), and e (exterior). The boundary points are subdivided into p (point) and l (polyline). The values inside the matrix represent the number of times that a given configuration appears in the sketch representing the pictorial query. In Figure 2(b), for example, the symbol " – " represents an impossible case and n is a generic natural number.

Figure 1

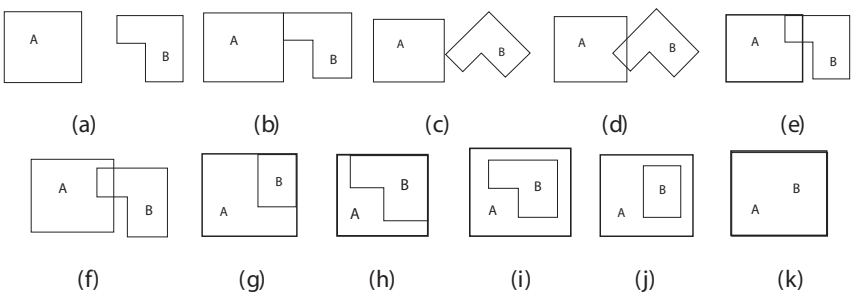

Figure 2

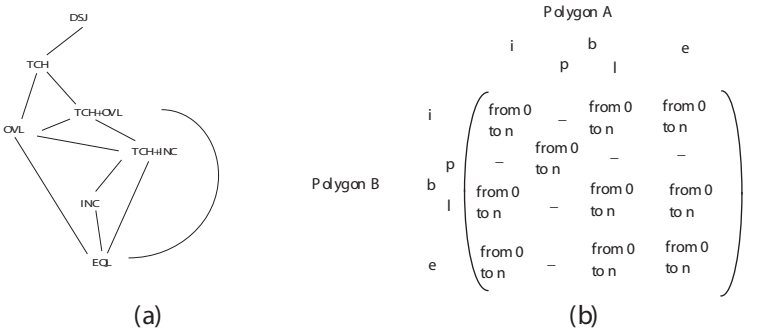

3.2 Case of Polygon-Polyline

The *OCS graph* of the operators valid for the polygon-polyline case is shown in Figure 3(a). The graph was obtained from the configuration of two disjointed (DSJ) objects. The three operations described above are applied to the polyline (or polygon) to obtain all other possible configurations (from touching to pass-through, etc.). The 4x4 matrix structure, which enlarges the classic 9-intersection matrix, is shown in figure 3(b).

3.3 Case of Two Polylines

The *OCS graph* of the operators valid for the polyline-polyline case is shown in Figure 4(a). Again, the graph was obtained from the disjointed polyline-polyline configuration (DSJ), by shifting, rotation, and extending/shortening.

The matrix structure for this case (a 5 x 5 matrix), which enlarges the classic 9-intersection matrix, is shown in Figure 4(b), while the part within the two lines is explained (in its different configurations) in Figure 4(c).

Here too, we can obtain the three different configurations TCH, EQL, and INC from two disjointed polylines, as shown in Figure 5(1(a)), 5(1(b)), and 5(1(c)).

Continuing this procedure, we can obtain four other configurations from the configuration of Figure 5(2(a)).

With a rotation of B_1 we obtain Figure 5(2(b)) (EQL, equal) if $B_1 = A$ in length, or Figure 5(2(c)) (INC) if B_1 is shorter than A; if the two lines touch (TCH) as in Figure 5(3(a)), shifting B results in the crossover (CRS) configuration of Figure 5(3(b)). Finally, if the starting configuration is that shown in Figure 5(3(c)), by lengthening B we obtain Figure 5(3(d)) (CRS + TCH).

In Figure 5(2(c)), lengthening B results in Figure 5(2(b)) (EQL), while, from Figure 5(3(b)) we obtain Figure 5(2(c)) (INC), if B is shorter than A, or Figure 5(2(b)) (EQL) if B = A.

From the configuration of Figure 5(2(d)) we can then obtain Figure 5(2(e)) (CRS), similar to Figure 5(2(b)).

If A = B in length, rotating B in Figure 5(2(b)) results in Figure 5(1(b)) (EQL).

The exterior points are subdivided into two: x and $\bar{x}$, which represent the two semi-planes obtained by extending one polyline from the two points of boundary. The terms X_1, X_2, Y_1 and Y_2 assume the numeric value 0 or 1 or 2 depending on the value of b / b (boundary of the Line A and boundary of the Line B), as shown in Figure 4(c).

If the boundary of line A is not in common with that of line B_2 they (two points) may be all in the semi-plane x of B, or all in the semi-plane $\bar{x}$ of B, or one in x and one in $\bar{x}$. So, in correspondence with "0" of b (A) cross b (B) we have 0 and 2, 2 and 0 or 1 and 1, in correspondence with B (e (x and $\bar{x}$)), as shown in Figure 4(c).

If the line A boundary has a point in common with a point of the line B boundary, the other boundary point is in either the semi-plane x of B or the semi-plane $\bar{x}$ of B. So, in correspondence with "1" of b (A) cross b (B) we have either 1 and 0 or 0 and 1, in correspondence with B (e (x and $\bar{x}$)), as shown in Figure 5(4). Finally, if both points of the line A boundary are in common with both points of the line B boundary then in correspondence with "2" of b (A) cross b (B) we have 0 and 0, in correspondence with B (e (x and $\bar{x}$)), as shown in Figure 5(5).

Figure 3

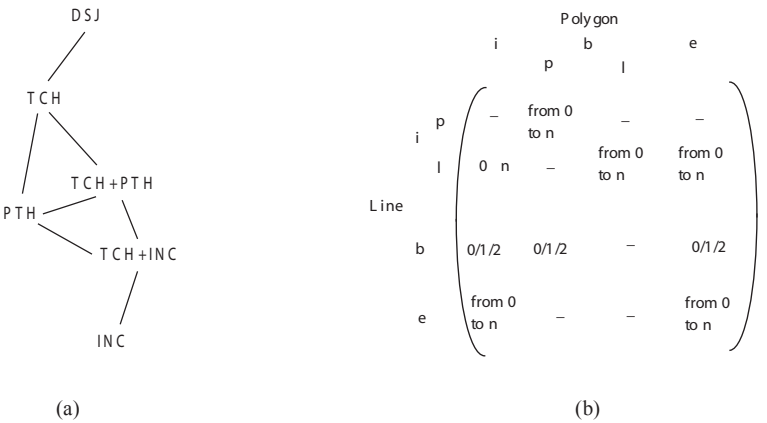

Figure 4

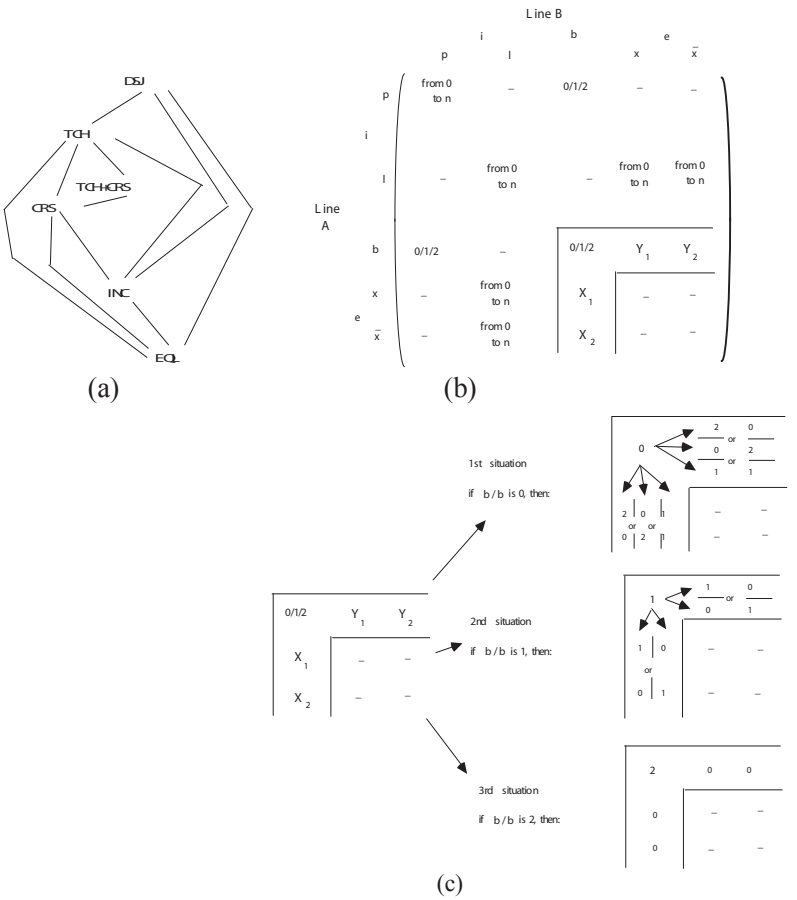

Figure 5

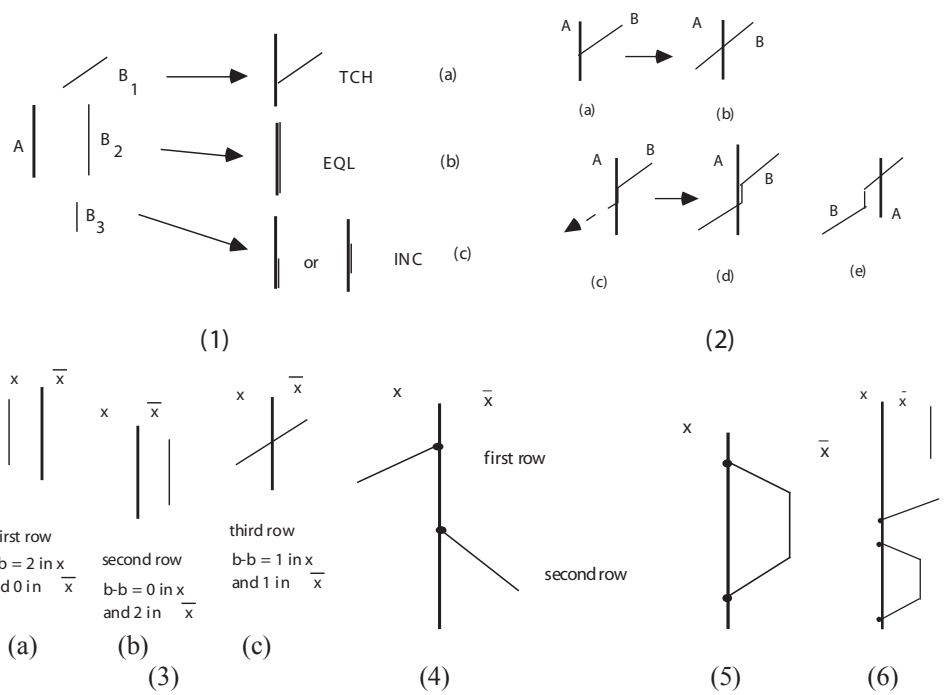

Figure 6

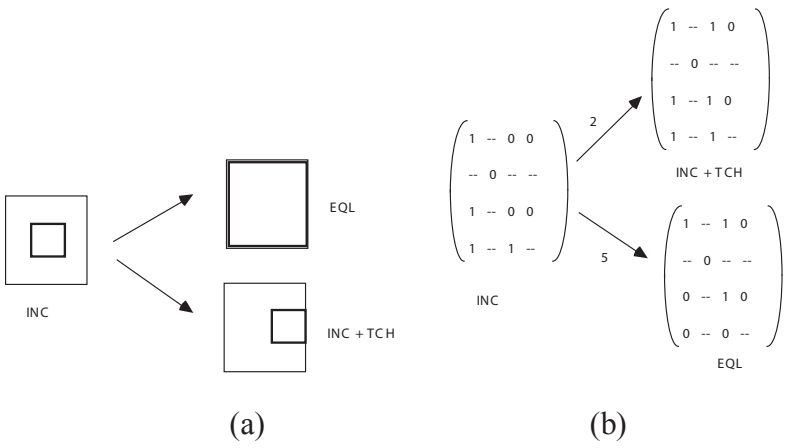

Obviously, the boundary points of one line can be 0, 1 or 2 internal points of the other, as shown in Figure 5(6).

4. APPROXIMATE QUERIES RELAXING OPERATORS

Suppose that the user formulates the query:

"Find all the lakes which are Inside a Province"

Using GeoPQL, the pictorial query drawn is shown in Figure 6(a). Suppose also that the query gives "zero elements" as the answer.

The system then asks if the user wishes to relax the topological constraint "INC" and, if "yes", it goes to the neighbourhoods relative to "two polygons", selects the operator INC and determines the nearest configurations: in this case, INC+TCH (by a shift) and EQL (by an extending), as shown in Figure 6(b). For each of these pairs the *degree of neighbourhoods*, obtained from the matrix of Figure, is evaluated. By "degree of neighbourhoods" we mean the number of changes in the new matrix compared with the original (from the INC to the INC+TCH matrix and from the INC to the EQL matrix).

In the first case, we have "2" (the third value of the first row, and the third value of the third row). We leave the reader to evaluate the second case.

The minor degree of neighbourhoods (also called *weight*) between the two relaxations allows the system to automatically select the relative operator(s) (in our case, INC+TCH) by which the original operator (in our case, INC) is relaxed. Following the original, unsuccessful query, the system therefore automatically processes the query "Find all the lakes which are **Inside Or Touch** a Province". The new result is still evaluated.

The procedure stops when a result is found.

5. DISCUSSION AND CONCLUSION

In this paper we proposed a complex matrix for each of the three configurations polygon-polygon, polygon–polyline, and polyline-polyline and a computational model for the similarity of their spatial relationships. This is described by an *operator conceptual similarity (OCS) graph*, linking the most similar relationships and defining the weight of each relaxation.

A large number of different configurations exist between a polyline and a polygon, two polylines and two polygons - more than the 19 binary topological relationships presented in [1, 2]. We have defined a correspondence between these configurations and said 19 topological relationships and have considered the number of contact points (whether touching or crossing) between the two objects, i.e. the cardinality (points number) of the intersection between the polyline interior and the polygon boundary. These considerations led us to consider a more complex matrix and the relative OCS *graph* for each pair of objects in order to design a computational model to determine more conceptually similar relationships for each configuration. We discussed the three different configurations and gave an example of query relaxation.

ABSTRACT

Enterprise Architecture (EA) is an ill-understood concept, especially in the context of e-business. The aim of this paper is to explore the elements that make up EA and to classify the kinds of purposes EA could serve for the realization of e-business. Using literature research, we derive three elements of EA frameworks. We applied the EA elements on a running case at a large multinational firm, which is currently migrating towards an e-business platform. In the case study, EA was only useable for descriptive purposes, making EA a valuable instrument for communication and analysis. EA was not useable for prescriptive purposes such as the design or redesign of information systems in relation to changing business processes. The main cause of this is the lack of comprehensive tooling support, something that will hamper using EA for developing and deploying e-business solutions in the future.

1. INTRODUCTION

Businesses are constantly facing the need to adapt to new international legislation, technological innovations, increasing competition and changing customer demands. Adaptability is a multidimensional concept [8], requiring comprehensive alignment between the strategy of a company, its business processes and the supporting information technology (IT). Achieving alignment between business processes and IT requires an integrated approach to all aspects of the enterprise [20]. Various consultancy and research institutes [10][21][24][28][34] suggest using the concept of enterprise architecture (EA) as an integrated approach towards business-IT alignment. Veasy [30] states that one of the key objectives for using architectural concepts is to achieve organizational flexibility and adaptability for complex organizations to manage the increasing rate of change. In addition, EA proponents advocate that the use of EA will leverage strategic adaptability, increased organizational performance and technology integration resulting in significant cost reduction and growth potential [1], [6], [12], [30].

Many EA frameworks e.g. Zachman, TOGAF, DODAF and GERAM were developed [4], [5]. Usually, such EA frameworks are offered with design approaches, modeling notations and principles aimed at guiding architects during the business-IT alignment process.

Although there are many whitepapers on EA presented by consultancy firms and governmental agencies, scientific contributions on EA and its practical value is scarce [2][7]. Moreover, it is unclear what constitutes an EA, as EA is an ill-defined [23] and still evolving concept [14]. In this paper, we derive the main elements of EA by analyzing existing EA frameworks in order to obtain better understanding of what constitutes EA. We endeavor to identify what purposes enterprise architecture should serve in the transition to e-business platforms.

This paper is structured as follows. In the following section, we present the state of the art in EA. Section three presents the research approach. In section four, elements which constitute EA are derived from literature. Next we identify the business needs for EA using a single case study. In section six we develop an EA reference framework. Then we evaluate the purposes of the devised framework in a case study environment. Finally, section eight presents the main conclusions and some directions for further research.

2. STATE OF THE ART IN ENTERPRISE ARCHITECTURE

With the original article published in 1987, Zachman [33] was the first to discuss architectural concepts in relation to IT. Zachman's article was his response to the needs of his IBM clients that had requirements for data standards and information sharing strategies across several systems, which called for an overarching architecture [4].

The idea of enterprise architecture is that it can be used to guide design decisions and limit the solution space by setting constraints [16]. Architecture aims at creating some kind of structure in a chaotic environment using systematic approaches [1]. In general, the architecture concept intends to establish standards for the employment of information technologies in ways that responded to strategic and business requirements, and that helps an enterprise to manage the ongoing transition from its current processes and systems to a desired future architecture [27].

Since Zachman's pioneering work [33], IT architects and managers used numerous proverbs in conjunction with the term 'architecture'. The term "enterprise" refers to the scope of the architecture, dealing with the organization as a whole or in case of EA, dealing with multiple departments and organizations rather than with a certain organizational part [7]. Other proverbs (e.g. business, process, application, service, network etc.) usually suggest a certain aspect or technical component that the architecture is meant to depict. Due to the use of the proverbs, it has become evermore complicated to clarify enterprise architecture. Moreover, Khoury & Simoff [18] underline that scarce attention has been paid to the theoretical basis of EA methods and frameworks until now.

3. RESEARCH APPROACH

In order to study the concept of EA in a business environment, we adapted the Information Systems Research Framework (ISRF) [9]. The ISRF suggests an interactive cycle of four main steps including: 1) literature review, 2) analysis of the business needs, 3) framework development, and 4) evaluation of the developed framework.

To analyse the business needs, we use the case study instrument. This approach allows us to investigate EA in a real-life setting [31]. As a case study, we used a multi-national company that is in a transformation process to become an e-business company in some of its operations. We conducted a single case study by analyzing multiple sources of information, including semi-structured interviews with two head architects (one responsible for business and the other for IT), archival analysis and participatory observation.

4. ELEMENTS IN ENTERPRISE ARCHITECTURE FRAMEWORKS

Generally EA frameworks embody a constellation of elements which architects consider relevant for modelling both business and IT systems. We found five common elements of EA in the reviewed literature (see table 1).

As first element, we found that most EA frameworks make use of layers [12], which are distinguished using various proverbs (e.g. business, process, organiza-

Table 1. Some elements of enterprise architecture found in literature

Zachman [32]	x				
Zee et al [34]	x	x			

Alongside the modeling notations, IT architects are more consciously starting to use architectural principles [12],[20]. Architectural principles are

modeling the relationship between different architecture layers [2][20]. Gartner [14] predicts significant growth for the EA tool market and

tion, application, information and infrastructure). These proverbs represent the functionality within an enterprise system [21].

As second common element, we found that EA frameworks often suggest some predefined views. The notion of views is so basic that some researchers consider the Zachman Framework merely as a table consisting of 36 different views on an IT system [24]. In the IEEE1471 Standard for Architectural Descriptions [10], the derivation and definition of views is a crucial step for architectural design. EAs are disclosed by means of views; typically, stakeholders of an enterprise access and use the architecture through views presenting the information they need in a user-friendly format and supported by useful analysis techniques [20]. It is agreed upon that the use of views reduces the size and complexity of architecture layers [10][20][33].

The third common element in EA frameworks is the modeling notation. The modeling notation refers to a language allowing for description of the components and the relationships in the architectural layers. While the most frequently used notations for modeling EA are languages originating from the software engineering field such as the Unified Modeling Language (UML) and IDEF, some languages are emerging specifically for the description of business processes such as the Business Process Modeling Notation (BPMN) [5]. We emphasize that the EA modeling notations found in literature are not only different in their syntax and semantics; they also differ in the objectives they aim to achieve. Consequently, there is currently no single modeling notation suitable for modeling multiple distinguished architecture layers.

As a fourth element, we found architectural development approaches. Spewak [27] was amongst the first to discuss the EA planning process, considering the fact that the original Zachman framework does not propose an EA design approach. The design approaches constitute a way of working or a prescriptive process model, which specifies the activities, required for migrating from the current situation to a target situation. Hence, the design approaches provide a process-oriented view of information system development. Examples of EA development approaches are TOGAF-ADM [28] and GERAM [5].

Usually, the third and fourth element some architectural principles [12],[20]. Architectural principles are considered guidelines that describe the constraints imposed upon the organization, and/or the decisions taken in support of realizing the business strategies [15]. In this way, principles restrict the design freedom of designers and set the direction for the future.

Finally, tools are necessary to support EA frameworks. By nature, EA requires the interconnection and accumulation of large amounts of information from different sources [20]. Modeling the content and relationships of enterprise elements can only be successful if supported by adequate tooling [2][14]. Most of the EA tools currently on the market have started as CASE (Computer Aided Software Engineering) tools [5] and are not yet capable of modeling the relationship between different architecture layers [2][20]. Gartner [14] predicted significant growth for the EA tool market and predicts current tools will evolve into more comprehensive and customizable tools capable to model all layers of the enterprise.

In order to create some clarity, we classified the elements mentioned according to the terms used by Sol [25]. This framework has proven to be useful in similar research [15] on working with information systems. This framework compromises a way of thinking, controlling, working, viewing, modeling and supporting as six interrelated aspects to capture a problem area and has proved to be helpful in similar research [15].

We relate the way of thinking to the concept of layers in architectural development. The way of controlling refers to the overall management (e.g. financial, risk) of EA and is left out of table 1. The way of working refers to the steps taking to develop an EA. The way of modeling relates to modeling notations for EA. Finally, the way of supporting refers to repository tools for electronically documenting and relating the current processes, information flows and applications. We illustrate the elements after a brief discussion of the business needs.

5. THE BUSINESS NEEDS: A CASE STUDY

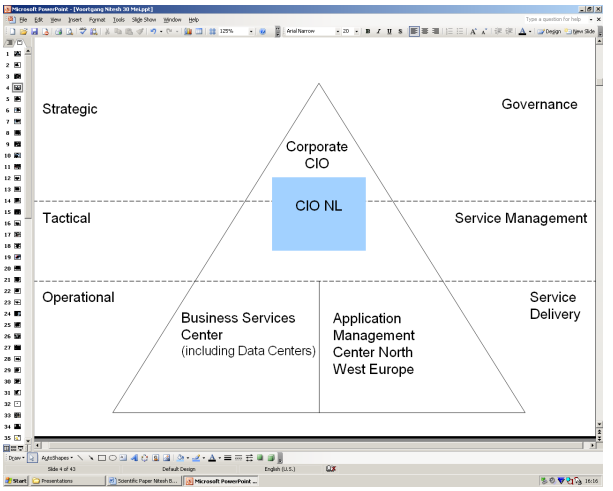
We conducted a case study at a major multinational company operating in over two hundred countries. The goals of the case study are to 1) understand the need for EA for e-business and 2) describe an environment in which an EA framework can be applied.

Within the multinational, the various country-oriented units are using their own customer relationship management (CRM) system. Consequently, there are more than hundred different systems throughout the entire firm. As these systems were developed separately, it is difficult to gather customer information on the global level. In order to attain synergy and reduce cost, the companies Corporate CIO (Corporate Information Office) plans to deploy a common SAPCRM landscape. The objective is to move from separate systems towards a shared CRM architecture, designed to support information exchange for cross-country sales.

We conducted the case study at the CIO in the Netherlands. In collaboration with the CIO's of nine other west European countries, the Dutch CIO is planning and anticipating the roll out of the global SAPCRM. In doing so, the Dutch CIO is devising a future CRM architecture for the Netherlands in collaboration with the Business Services department (BS) and the Application Management Center (AMC). The following figure depicts the relationships between the stakeholders involved.

In this figure, both Corporate CIO and the Dutch CIO (CIO NL) operate on a strategic level, respectively looking at the global environment and the local situ-

Figure 1. The layered governance structure



ation within a country. For each country, the migration from the existing CRM architecture to the CRM target architecture must be specified individually.

However, developing such a comprehensive architecture for the SAPCRM rollout requires a detailed description of the current sales processes, information flows, application services provided by AMC and infrastructure services provided by BS. As the role of some application, meant to support some specific process at any given department, may change in the future, the relations between the processes, information flows and applications needs to be described as well. Therefore, the main problem the Dutch CIO faces is the development of a comprehensive architecture describing the current and future relations between the processes, information flows and applications.

6. REFERENCE FRAMEWORK

In order to analyze the alignment of the CRM processes and the supporting IT, we developed a reference framework. The reference framework should enable both business and IT designs to focus specific layers and the establishment of the link to corresponding elements [10]. The term 'reference' also indicates that the framework is generic and can be used in similar companies.

The reference framework we propose contains three main parts: aspects, layers and five ways of Sol [25].

The top level of the cube shows some essential aspects of EA for the stakeholders. These aspects are adapted from a multi-client study by the Nolan Norton Institute [34], mainly because their study showed that the five aspects (governance, objectives, cost, capabilities and change-processes) are the primary IT concerns of 17 large companies.

The side level of the framework represents the five 'ways of information systems' suggested by Sol [25]. We believe that an explicit description of the ways of controlling, working, viewing, modeling and supporting are essential for architectural development.

Figure 2. The reference framework

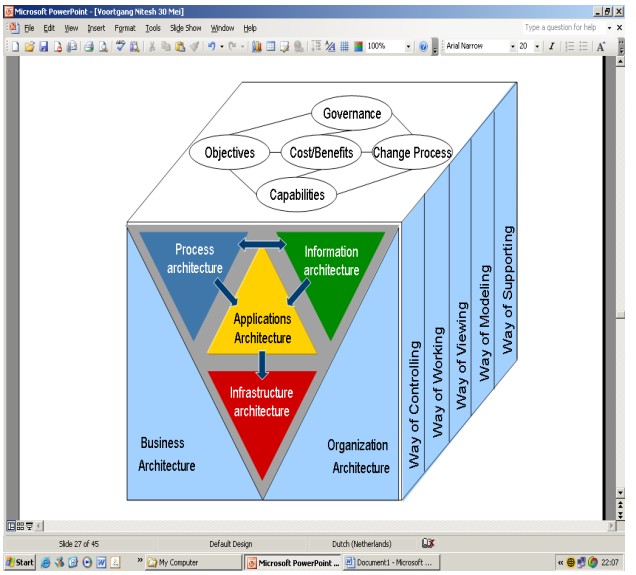


Table 2. Application of the framework elements

	Elements	Findings
Aspects	Governance	The governance structure is left implicit, some planning and control mechanisms are in place steering the e-business projects on a global level.
	Objectives	The objectives for the SAPCRM project are clearly documented and well communicated throughout all countries. The objectives were formulated using a top-down approach.
	Cost-benefits	The costs of the project are estimated on a global level, the benefits and risk (e.g. data migration and versioning) are not yet agreed upon.
	Change process	The change processes required for the migration from the current CRM platform to the future SAPCRM are not prescribed.
	Capability	The required capabilities for the project are not stated in the project documents.
Layers	Business Architecture	Stakeholder representatives are working on various business plans during the implementation of SAPCRM.
	Organization Architecture	The roles of the actors are explicit while the responsibilities of the actors and their relationships with the other layers are vague.
	Process Architecture	The CRM process architecture are well documented and communicated.
	Information Architecture	The information objects and their relationships are not modeled.
	Application Architecture	There is a static list of all the applications in the enterprise, however not in relation to the other layers.
	Infrastructure Architecture	The infrastructure services required for CRM applications are clear, however, not in relation to the other layers.
Ways	Way of controlling	There are some generic cost, quality and security mechanisms defined and used.
	Way of working	Architectural development is still intuitive and unstructured, except for the process layer.
	Way of viewing	Generally, the three-tier view (presentation, logic and data) is used for the categorization of (e-) business solutions. Other views are not standardized.
	Way of modeling	No common modeling language is defined or used in the firm, except for process modeling.
	Way of supporting	ARIS and maybe Casewise, however, there is no tool for modeling all layers in relationship to each other (there is no integrated tooling support).

Table 3. Possible purposes of EA

Timeline / Purposes	Ex-ante	Ex-post
Descriptive	Communication instrument	Analysis instrument
Prescriptive	Design instrument	Redesign Instrument

The cube front depicts the architecture layers as these four layers are already widely used for IT modeling throughout the firm.

In the following section, we illustrate the application of this framework and discuss the purposes of EA.

7. EVALUATION OF EA PURPOSES

Using a tabular structure, we present the application of the framework elements on the CRM case of the multinational. A comprehensive description of the case study can be found in [2]. The following table summarizes the main case study results.

Using the proposed framework as an analysis instrument, we found that the firm, more specifically the Dutch establishment, does not cover all of the elements for architectural development. Especially elements such as an enterprise wide way of working, modeling and supporting are still lacking. This means that for CRM processes there is no complete documentation of the information flows, supporting applications and infrastructure services. Moreover, there is no description of the relations between these layers, making it difficult to determine which processes and information flows will be affected by introducing SAPCRM. Therefore, we cannot say that the firm has an integrated approach for aligning business with IT.

However, application of the framework showed that the EA elements in the framework do have purposes when planning for the deployment of SAPCRM. We summarized the possible purposes in the following table.

First, we distinguish two types of elements: descriptive and prescriptive. An EA element is prescriptive when it limits the freedom of the architect and systems engineers, for example when specifying particular ways of working, viewing or modeling. When an element does not suggest any guidelines or specific approaches such as the aspects and layers, the element is descriptive.

A descriptive element allows for documentation and analysis of for instance the business processes in the company. On the other hand, a prescriptive element should help in setting a common way of designing, redesigning and supporting the architecture layers.

When an EA framework (set of elements) is used prior to the actual implementation of an e-business solution (e.g. SAP CRM), the major roles it could play are those of a communication instrument or a design instrument. On the other hand, when a framework is used to look at the functioning of a specific service or application, the framework functions as an analysis instrument or a redesign instrument.

In the case study, we found that not all of the elements of EA (proposed in our framework) are in place. The elements in place are the aspects and layers, which were management used mainly for communication and analysis, limiting the use of EA to descriptive purposes.

8. CONCLUSIONS

In the paper, we explored the ill-defined concept of Enterprise Architecture (EA) using literature research by identifying its main elements and purposes. We illustrated the elements and potential purposes for e-business using a case study. We reviewed a variety of academic and practitioner contributions to gain insight in what constitutes an EA. As a result, we found that EA is an organization specific constellation of three main elements: aspects, layers and ways for architectural development.

While the aspects (e.g. governance, capabilities) represent the more high-level managerial side to EA, the layers depict a vertical decomposition of processes, information flows, applications and infrastructure services.

Application of the developed EA framework on the case study allowed us to identify four possible instrumental purposes of EA frameworks. The purposes are communication, evaluation, design and redesign instrument. The case study showed that without a repository-based tool containing descriptions of the enterprise's processes, information objects and applications, EA is only useful as a communication and evaluation instrument. Considering the number of business processes and the underlying IT applications, a repository tool is essential in order for EA to be used as a design or redesign instrument.

Our findings are based on a single case, therefore we suggest further research on the purpose of EA for firms in the transition towards an e-business platform. We underline the need for more comprehensive repository based tooling support, supposedly with a modeling notation that is suitable to describe and relate both business (processes, structures and actors) and IT (information objects, applications and services).

Potential Consumer Responses to RFID Product Item Tagging and Emergent Privacy Issues

Rebecca Angeles, University of New Brunswick Fredericton, P.O. Box 4400, Singer Hall, Macauley Lane, Fredericton, New Brunswick E3B 5A3, Canada; E-mail: rangeles@unb.ca

ABSTRACT

Using the theories of procedural justice/fairness, expected utility, and literature on consumer privacy, this study uses the survey method to measure consumer willingness to purchase radio frequency identification (RFID)-tagged product items within the Canadian context. Procedural justice/fairness is operationalized using the implementation of the Personal Information Protection and Electronic Documents Act (PIPEDA) enacted in Canada on January 1, 2004.

1. INTRODUCTION

This empirical study seeks to understand how consumers will react to radio frequency identification (RFID) tagging at the product item level before this becomes standard practice when major retailers like Walmart mandates its implementation. This study uses the concepts behind procedural justice/fairness, expected utility theory, and consumer privacy protection to anticipate the public consumer reaction to product item tagging at the retail store and answer the following questions:

1. What impact will the implementation of procedural fairness have on the willingness of consumers to purchase RFID-tagged product items?
2. How will consumers respond to RFID tagging initiatives at the product item level?
3. Will there be differences in consumer responses?
4. How can retailers use the findings to design and plan RFID product item initiatives at the retail store level?

2. CONSUMER PRIVACY AND EXPECTED UTILITY THEORY CONCEPTS

Privacy has been defined as "…the ability of the individual to *control* the terms under which personal information is acquired and used…." (Westin, 1967, p. 7). Information privacy, in turn, has been clarified as "…the claim of individuals, groups, or institutions to determine for themselves when, how, and to what extent information about them is communicated to others…." (Westin, 1967, p. 7). On the basis of social science literature, Goodwin (1991) defines consumer privacy based on two dimensions of control: (1) control of information disclosure which pertains to capture and storage of shopper information in databases, and (2) control of unwanted intrusions into the shoppers' environment which pertains to receiving unsolicited promotional or advertising material. Research on consumer privacy has also shown that there are different consumer segments representing varying levels of information privacy sensitivity. In an earlier body of work, Westin (1967) considered "privacy fundamentalists" as those consumers who were very concerned about the use of their personal information so much so that they would not participate in online data collection efforts despite privacy protection measures that web sites might offer. Cranor et al. (1999) also describe this group and found that its members are twice as likely as other consumers to report having been a victim of invasion of privacy acts on the Internet. The polar opposite of this group are those who are "privacy unconcerned" or those who easily share personal information as they do not care about personal privacy. The "middle-of-the-roaders" are the "privacy pragmatists" who selectively share personal information depending on the expected perceived benefits they hope to gain in the exchange.

3. EXPECTED UTILITY THEORY

The expected utility theory or utility maximization theory presents the idea that consumers conduct a quick cost-benefit analysis procedure in their minds within the limits of the information presented to them before deciding to trade off some of their personal information in the marketplace (Rust et al., 2002). If the net expectation is positive or beneficial to them, they will engage in the information exchange transaction.

4. PROCEDURAL FAIRNESS/JUSTICE

The concept of "procedural fairness or justice" refers to the notion that the individual perceives a particular activity in which they are participating as being conducted fairly (Lind and Tyler,1988). Providing the consumer or shopper with voice and control over outcomes appears to lead to their perceptions of procedural fairness (Lind and Tyler, 1988; Folger and Greenberg, 1985; Awad and Krishnan, 2006; Malhotra et al., 2004; Gunther and Spiekermann, 2005). Culnan and Armstrong (1999) point out that in the field of marketing, the principles behind "notice" and "consent," which are the hallmarks of the Fair Information Practices Act, operationalize procedural fairness. "Notice" means that when shoppers provide personal information to retailers or vendors, they have the right to know why the information is being collected, what will be done with the information, the measures taken to protect its confidentiality, the consequences of providing or withholding information, and mechanisms for addressing shopper complaints involving personal privacy should these arise (Culnan and Armstrong, 1999). "Consent" means that shoppers could control how the information they share will be used and be able to voice their dissent and stop the use of their personal information when the retailer collects the information for one purpose but uses it for another.

5. THE PERSONAL INFORMATION PROTECTION AND ELECTRONIC DOCUMENTS ACT (PIPEDA): THE CANADIAN CONTEXT

This study also makes reference to the Personal Information Protection and Electronic Documents Act (PIPEDA) passed in Canada last January 2004, as the legislation that seeks to protect consumer privacy in that country. Critical provisions in PIPEDA also embody the principles supporting the Fair Information Practices Act. Thus, compliance of retailers will PIPEDA will be a surrogate for the implementation of procedural fairness within a retailing shopping environment.

6. VARIABLES USED IN THE STUDY

This study focuses on whether or not there are significant differences between groups A (those who would purchase RFID-tagged items given the procedural item provision and B (those who would not purchase RFID-tagged items given the procedural item provision) across a number of variables.

6.1 Basis for Grouping Respondents (Groups A and B): Response to Procedural Fairness/Justice item

The following conditions, which also represent key directives of PIPEDA, were hypothesized in this questionnaire item to operationalize the concept of "procedural

fairness/justice": 1) the retailer/firm informs shoppers fully about the collection of customer purchasing and profile information via RFID tags and how the collected information would be used; 2) the retailer/firm posts notices in areas of the store notifying shoppers of the use of RFID tags with certain products; 3) the retailer/firm allows shoppers to 'opt-in' or agree to cooperate with their data collection effort or 'opt-out' or choose not to participate in the data collection effort involving RFID tags; 4) the retailer/firm uses 'deactivation kiosks' in the store so that shoppers can deactivate RFID tags attached to products they purchased; 5) the retailer/firm distributes brochures clearly explaining how RFID tags work in the store, how tag readers work with the tags, what information is stored in the tags, what information about you will be collected from the tags, and what will be done with the information downloaded from the tags; 6) the retailer/firm posts notices in the store indicating that it is in compliance with the Personal Information Protection and Electronic Documents Act passed by the Canadian government in January 2004; 7) shoppers could control the types of products and services advertised to them as well as when and for how long advertising messages would be displayed on the screen; 8) shoppers could indicate what information in their customer profile could be used for marketing; and 9) shoppers could review the information in their customer profile and correct any errors. Study participants were asked to respond with a "yes" or "no" to this item called the "decision" variable: "If the rules and safeguards I've just mentioned [i.e., pertaining to the conditions previously listed] were adopted by companies offering (RFID-tagged products), how interested would you be in purchasing RFID-tagged products from those companies?" For the purposes of the rest of this study's discussion, the respondents who decided they would purchase RFID-tagged product items given the procedural fairness/justice conditions are referred to as "group A"; those who decided they would not purchase these items, in any case, are referred to as belonging to "group B."

6.2 Other Variables Used

T-tests and chi-square tests were used to see if there are significant differences between groups A and B across the following other variables used in the study. The first variable refers to the following specific conditions that respondents require, reflecting measures that they would want the retail store management collecting RFID tag information at the product item level to put into effect before they decide to purchase the RFID-tagged item: a) the retail store would inform respondents of the collection of their purchasing information through RFID tags and how it would be used; b) the respondents could control the types of products and services eventually advertised to them as well as when and for how long advertising messages would be displayed on the screen; c) respondents could indicate what information in their profiles could be used for marketing and what could not; and d) respondents could review the information in their customer profiles and correct any errors. Respondents were asked to indicate the importance of these requirements using a seven-point Likert scale, with "1" anchoring on "Not important at all" and "7" anchoring on "Very important."

The second variable refers to the following nine different retail shop scenarios described to the survey respondents that are expected to affect their decision to buy or not buy RFID-tagged items. In these scenarios, the retail store: (1) captures shoppers' purchasing behavior using RFID tags prior to, during, and after a sales purchase; (2) captures shoppers' purchasing behavior via RFID tags and stores the information in a database, which they will later sell to another firm; (3) captures shoppers' purchasing activities via RFID tags, stores the information in a database, and later uses the information to send shoppers more targeted advertising; (4) captures shoppers' movements in the store via RFID tags as they pick up store product items and put these back on the shelves; (5) captures shopper information via RFID tags embedded in their clothing or other personal items like wallets or purses; (6) collects shopper information via RFID tags and later associates sales transaction information with shoppers' personally identifiable information stored in a database; (7) uses RFID tags which cannot be disabled or "killed" prior to shoppers' purchase of items or exiting the store; (8) uses an RFID system that can pickup information remotely from store products without shoppers' knowledge or consent as they carry tagged items around the store; and (9) collects shopper purchase information via RFID tags and later links this information with certain personal data items such as their name, phone number, credit card number, etc.

The third variable refers to the following specific measures that the retail management might implement in the store that may encourage respondents to purchase the RFID-tagged items: a) observance of PIPEDA by the retailer; b) allowing customers to "kill" or disable or remove the RFID tag after the purchase; c) allowing the opt-in/opt-out choice for the consumers regarding the information collected by the tag; d) allowing the customers to choose whether or not they will allow gathering of information by the RFID tag; e) manufacturers and retailers use clear, understandable labels indicating that a product is RFID-tagged; and f) manufacturers and retailers publicize using web sites, news releases, or other means, their policies concerning the use, maintenance, and protection of customer records that have information gathered by RFID tags. For each condition, respondents were asked whether or not they would be encouraged to purchase the tagged items.

The fourth variable refers to the relative intrusiveness of RFID when compared to the following other technologies used by consumers: cell phones, debit/credit cards, automated teller machines, shoppers' loyalty cards, camera phones, and access-control badges. Respondents were asked to indicate if the RFID tags violated individual privacy "more than," "less than," or as much as each of these technologies.

The fifth variable is the privacy variable the covers a number of personal situations that give some indication of the privacy threshold of the respondent. (The detailed descriptions of these personal situations are given in the "Findings" section.)

And finally, the sixth variable is the respondents' perception of the effect of RFID-tagging at the case/pallet and individual product item levels on the final selling price of the tagged item. Respondents were asked to indicate if they thought RFID tagging would raise product prices, lower product prices, or have no impact on product prices.

7. RESEARCH METHODOLOGY

Undergraduate and graduate students at the Faculty of Business Administration, University of New Brunswick Fredericton were surveyed within the period 2004-2005. A brief lecture on RFID, its uses in supply chain management, and the provisions of PIPEDA was given. Short video clips on how RFID tags are deployed at the case and pallet levels in both the manufacturing and retail environments and the use of RFID tags at the product item level within a retail shopping scenario were shown to the respondents. Data analysis techniques used in the study include standard descriptives procedures (i.e., frequencies), reliability tests, t-tests, and chi-square analysis.

8. STUDY FINDINGS

A total number of 380 respondents in the convenience sample agreed to participate in the study with the following demographics: (1) gender: 172 females (45.1 percent) and 208 males (54.6 percent); (2) age groups: 18-22 years old, 266 (69.8 percent); 23-59 years old, 110 (28.9 percent); under 18 years old, 4 (1.0 percent); (3) years in college: one year, 67 (17.6 percent); two years, 104 (27.3 percent); three years, 114 (29.9 percent); four years or more, 83 (21.8 percent); (4) educational attainment: less than a college degree, 340 (89.5 percent); college degree, 35 (9.2 percent); master's degree, 4 (1.0 percent), and doctoral degree, 1 (0.3 percent).

Differences between groups A (those who would purchase RFID-tagged items given the procedural item provision and B (those who would not purchase RFID-tagged items given the procedural item provision) across a number of variables was investigated. The t-test was used to test the differences between groups A and B in their evaluation of the importance of the different requirements they would like to see the retail store's management put in place before buying tagged items. Chi-square tests were used to test the differences between each of the remaining five categorical variables and the general willingness of the respondents to purchase the tagged item represented by the variable, "decision," which divides the sample into groups A and B as previously explained given retail store conditions where the procedural justice measures are observed.

The following are the study's findings. T-test results show that groups A and B did not differ in terms of their perceptions of the level of importance of each of the four requirements they would like the retail store's management to take into consideration (i.e., the first variable). In terms of the second variable, those respondents who expressed willingness to buy tagged items under nine specific store retailing scenarios were also more likely to purchase the tagged items under general conditions, given the procedural justice provision (Table 1).

Table 1. Differences between groups A and B on their willingness to buy RFID-tagged Items under Specific Retail Shopping Scenarios and their Decision to Buy RFID-tagged Items with the Procedural Justice Provision

Variable	N	Shopper Decision (with Procedural Justice Provision)			Chi-Square	p
		Will Purchase RFID-tagged item	Will not purchase RFID-tagged item	Missing Values		
Store scenario 1: Store captures customer purchasing behavior by RFID tags prior to, during and after a purchase					31.746	.000
Will buy RFID-tagged item given store condition 1	215					
Actual		194	21

TOTALS	380	305	75	1		

In terms of the third variable, respondents who admitted being encouraged to purchase tagged items if the retail management implements six specific measures in the store are also more likely to purchase the tagged items in, in general, given the procedural justice provision.

Regarding the fourth variable, there were no significant differences between groups A and B in their perceptions of the intrusiveness or privacy invasiveness of RFID technology compared to cell phones, debit/credit cards, automated teller machines, shoppers' loyalty cards, camera phones, and access control badges.

Concerning the fifth variable, which is the privacy variable covering a number of personal situations, selected items within the "privacy variable" construct significantly distinguished group A from group B: (1) refusal of the person to give out personal information to a firm; (2) use of an unlisted home phone number; (3) refusal of the person to be included in a mailing list put out by a firm which is later used for promoting products or services; (4) use of television to help the person purchase something from a home shopping club; (5) use of a toll free phone number to purchase a product or service. Study respondents who fit the following profile were also more likely to purchase tagged items given the procedural justice provision: (1) gave out personal information to a soliciting firm; (2) have a listed home phone number; (3) agreed to be part of a firm's mailing list for promotional purposes; (4) used the television to buy a product or service; and (5) used a toll free phone number to buy a product or service.

Finally, concerning the sixth variable, there were no significant differences between groups A and B in their perceptions of the effects of RFID-tagging at the case/pallet and individual product item levels on the final selling price of the tagged item in retail stores.

9. IMPLICATIONS OF FINDINGS

This study's findings support the concept that consumers do exercise their "privacy calculus" by anticipating costs and benefits before giving away personal information, and that the consumer population is segmented between those who are more privacy sensitive and those who are less so. One should, however, bear in mind that this study's findings cannot be extended to the wider population as they have been based on a convenience sample of fairly young and well-educated participants who are more open to the use of emerging technologies in the marketplace.

Retailers should initially address the consumer segment that will potentially be more responsive to product item tagging initiatives at the retail floor. Assuring the delivery of benefits to this segment and soliciting their "buy-in" in the use of RFID in the retail floor could pave the way towards chipping away at the resistance of the more privacy conscious group.

A Concept Map of Information Systems Research Approaches

Rafael Gonzalez, TU Delft, Jaffalaan 5, 2628BX Delft, The Netherlands; E-mail: R.Gonzalez@tudelft.nl

ABSTRACT
This paper presents a simple concept map of the wide and diverse spectrum of information system (IS) research approaches, focusing on helping researchers in having an overview of what these approaches are, what they are grounded on and what methods are available for them. It considers research philosophy, methodology, and method. It should help researchers, especially those getting started in IS research, in getting acquainted with the approaches and in justifying their choices coherently.

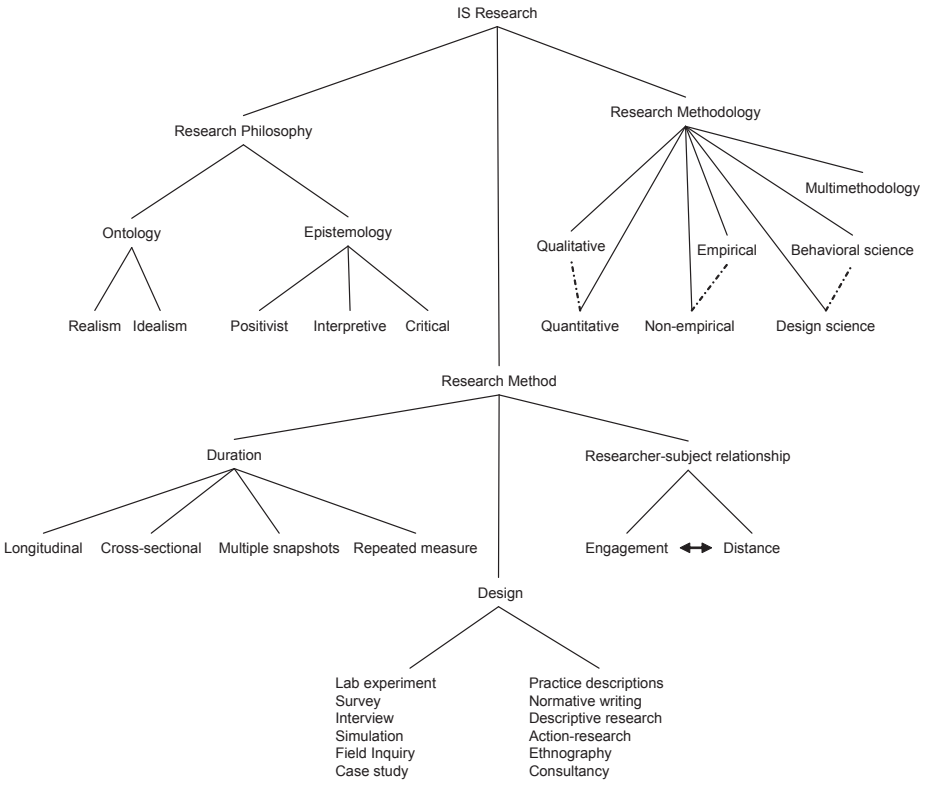
1. INTRODUCTION

Research in information systems (IS) has received much attention and many different interpretations probably because the field itself is broad and multidimensional, as noted by Mingers (2001). Most researchers see IS as a social science or a socio-technical field (Hirschheim, 1992) and many disciplines (including management, sociology, computer science, and psychology, among others) are cited as informing its research and practice (Land, 1992; Checkland & Holwell, 1998). Walsham (2005) even reminds us that information systems are social and organizationally-embedded systems that use information and communication technology (ICT) for what technology is supposed to be used: improving the lives of people. This socio-technical understanding of IS, has given rise to multiple approaches to IS research.

In this paper, we present a concept map of IS research for navigating through the different existing approaches, highlighting their differences, background and relationships. It must be noted that this paper is not about research in general, so it will omit many fundamental topics (such as variables, hypothesis, and induction versus deduction). Also, the authors' background is not in philosophy, so even though there is a lot of philosophical terminology, this paper is not about philosophy, it is about research in information systems. This paper is not about information systems development (ISD); even though similar classifications have been proposed for ISD, we will not be looking into development approaches or methods, only research. One final warning is that due to space limitations this paper takes a bird's eye view of the subject and should help as a guide, but detailed accounts of the approaches are outside the scope and as a consequence limits and definitions appear stricter than they really are.

On the next section we present the concept map itself and then go into each of its categories individually. Starting with the research philosophy in section three,

Figure 1. IS research concept map



followed by the research methodology in section four, further specified with the research methods in section five. Section six presents concluding remarks, concluding hints on how to select the research approach. The reference list in the end should also help in getting more detailed accounts and comparisons of the approaches.

2. INFORMATION SYSTEMS RESEARCH CONCEPT MAP

The following set of concepts related to IS research borrows ideas from different authors and does not provide absolute definitions, but rather a guide, especially aimed at budding researchers, of available approaches, how they differ from each other and what their philosophical grounds and available methods are. Because of its general view, it is quite possible that a concept may belong to more than one category and that some others may be left out. We will first look at the concept map in Figure 1 and then at its description on subsequent sections.

3. IS RESEARCH PHILOSOPHY

The research philosophy provides the ideological basis of a methodology. Typically, it is seen as composed of ontology and epistemology (Nandhakumar & Jones, 1997), but it may also embody ethics and axiology (Mingers, 2001), although we will not include these last two dimensions. Ontology refers to the nature of being (Nandhakumar & Jones, 1997), while epistemology refers to the theory of knowledge (how we acquire knowledge) (Hirschheim, 1992).

The dominating ontologies are realism and idealism, or more specifically:

- **External realism** – reality exists independently of individuals and their representations of it (Nandhakumar & Jones, 1997; Dobson, 2001; Hirschheim, 1992);
- **Internal realism** – reality is an intersubjective construction (Nandhakumar & Jones, 1997);
- **Critical realism** – sees science as a process of explanation and enlightenment, rather than a derivation of predictive laws, and states that structures can only be identified indirectly through their effects (Dobson, 2001); and
- **Idealism** – can be viewed in the sense of the early platonic World of Ideas, can be linked to German Idealism (Kant synthesizes concept and experience, Hegel sees consciousness as crucial for understanding and Fichte also sees consciousness as linked to the external world) (Hirschheim, 1992), or can be seen more generally as subjective idealism, in which reality is simply a construction of each individual (Nandhakumar & Jones, 1997).

We will dedicate the next subsections to epistemology. For IS research, some (Galliers, 1992; Wynn, 2001) have used a binary classification (empirical-interpretivist, quantitative-qualitative); others (Klein and Myers, 1999) offer a threefold classification of IS research (positivist, interpretive, critical), which we will use to distinguish epistemological foundations.

3.1. Positivist Approach

Positivism emphasises the role of science as the only method conducing to truth. It claims that the social world can be described by law-like generalizations stemming from collection of value-free facts (Nandhakumar & Jones, 1997; Chen & Hirschheim, 2004). It aims at verifiability or falsification of theories (*ibid.*). It believes in causality and usually takes on a quantitative-empirical methodological approach (*ibid*.; Hirschheim, 1992). Positivist research can be identified by the presence of: hypotheses, propositions, models, quantitative variables and statistic inference of "objective" data (Klein & Myers, 1999). Hirschheim (1992) describes positivism as based on five pillars: unity of the scientific method, search for causal relationships (through reductionism), empiricism, value-free science, and the logical and mathematical foundations of science. Positivism subscribes to an ontology based on realism, which sees the world as made up of immutable, observer-independent objects (*ibid*.; Chen & Hirschheim, 2004). The assumption is that the truth is out there and that it can be reached through the methods of science (Wynn, 2001). Extreme positivism in IS research sees technology as neutral, believes in rational management, ignores power relations and conflict, sees organizations as individual closed entities and focuses on the business environment (Mitev, 2000). This method may be appropriate for the natural sciences (although also under scrutiny in this domain), but not for the social ones (Checkland and Holwell, 1998; Hirschheim, 1992) and since we have established that IS are social in nature, then it seems clear why many researchers consider positivism inadequate for IS research. However, despite this criticism, it is still the dominant epistemology (Chen & Hirschheim, 2004).

3.2. Interpretive Approach

Interpretivism argues that both the researcher and the human actors in the phenomenon under study interpret the situation (Nandhakumar & Jones, 1997). Instead of generalization it aims at in-depth understanding (Chen & Hirschheim, 2004). Since researchers need to be engaged in the phenomenon, field studies are seen as most appropriate interpretive methods (*ibid*.). Interpretive research is identified with the presence of participant's perspectives as primary sources of information analyzed against cultural or contextual circumstances (*ibid*.; Klein & Myers, 1999). Many advocate interpretivism as the most appropriate for IS intervention (*ibid*., Checkland & Holwell, 1998). Interpretivism sees organisations as social (conversational) processes in which the world is interpreted in a particular way, which legitimates shared actions and establishes shared norms (*ibid*.). Interpretive approaches aim at understanding the IS context and the way in which actors draw on and interpret elements of context; furthermore, they question the utility of generalizations, emphasising on the insight obtained with descriptive efforts (Mitev, 2000). Interpretivism's main methods are action research and ethnography.

3.3. Critical Approach

According to the critical approach, there is no way to infer that a given law is true, no matter how many instances are analysed (Hirschheim, 1992). This approach denotes a critical process of inquiry seeking emancipatory social change through revealing hidden agendas, inequalities and manipulations (Klein & Myers, 1999; Cecez-Kecmanovic, 2001). It is characterized by reflexivity (self criticism) and the belief that no one has the monopoly of truth (*ibid*.). Self-conscious criticism exposes ideological and political agendas bringing the possibility of emancipation to the actors involved: only by subjecting the imperatives of the system to the needs of its members could an organization be emancipated (*ibid*.). This emancipation should be reached through public discourse which allows understanding purpose rather than simply achieving consensual action (Panagiotidis & Edwards, 2001). Seeking an "ideal-speech situation" (even if unreachable at its core) allows participants to go through a public process of discursive will-formation, rather than accepting an arbitrary political rule from established authorities (Ulrich, 1983). In practice, this means that participants are given the same chance to speak, that they are regarded as accountable (truthful) and that they are given the chance to question each other from a higher level of abstraction; meaning that they can raise criticism to the foundations of an argument, not only to the argument itself. This implies changing the search for objectivity, to a search for discursive validity. Critical research is still seen as lacking sufficient clarity and intertwining between theory and practice and thus not widely embraced (McGrath, 2005).

4. IS RESEARCH METHODOLOGY

Defining research methodology is not easy, especially when trying to distinguish it from method or approach. One understanding is to see it as a systematic approach involving guidelines, activities, techniques and tools (Wynekoop & Russo, 1997). But this notion is more readily associated to method than to methodology (Mingers, 2001). We take the view that a methodology is a more abstract concept relating either to the study of methods or to a more general and less prescriptive approach than a method (*ibid*.; Checkland, 2000). As a complete definition we adopt the following:

"Methodology is understood here in its philosophical sense as an overall strategy of conceptualizing and conducting an inquiry, and constructing scientific knowledge. Methodology, therefore, refers not only to research methods or techniques (such as case study or interview), but also to the epistemological assumptions of methods and how they are linked to a particular theory." (Cecez-Kecmanovic, 2001, p. 142)

On top of its philosophical underpinnings, a methodology can be qualitative or quantitative, empirical or non-empirical. There is another possible division between design science and behavioral science (Hevner & March, 2003) but we feel it is not general enough to be taken as the opposing poles for IS research

(technical versus social, in this case). In any case, both in practice and in theory it is quite possible to find a pluralist approach at combining methods in what is dubbed multimethodology.

4.1. Qualitative vs. Quantitative

Quantitative research has long dominated scientific inquiry through its pursuit of measurable, statistic, data-laden truths. Qualitative research has, however, emerged in IS with the recognition that it is a social field not subject to numeric measurement and that traditional approaches did not give an adequate understanding of its social nature. Qualitative research is motivated by Weberian assumptions that truths are approximate and by a shift in the use of IS to support social processes instead of just transactions (Wynn, 2001). Qualitative shouldn't be immediately associated with interpretivism or quantitative to positivism, since for example, surveys and questionnaires (quantitative in nature) can be used in interpretive research (Nandhakumar & Jones, 1997). Quantitative is the dominating tendency in IS, although qualitative research is on the rise (Chen & Hirschheim, 2004).

4.2. Empirical vs. Non-Empirical

Empirical research, based on observation or experience, is typically regarded as "scientific" because it is repeatable, refutable, objective and rigorous. Non-empirical (sometimes equated to interpretive) research has different interpretations of social phenomena, recognizes the influence of the scientists over the studied situation and highlights the difficulty in forecasting human activity (Galliers, 1992). Although some radical scientists claim that "if it can't be measured it's not real", we have seen how different approaches, from the social sciences, have increasingly been used in IS research (*ibid*.).

4.3. Multimethodology

Methodological pluralism is based on the idea that diversity (inherent in information systems) implies strength, since different methods provoke different responses, which means that complex situations benefit from different methods (Mingers, 2001). Although philosophical, cultural, psychological and practical barriers may hinder its use, Mingers (*ibid*.), a long-time advocate of pluralism, has argued it is feasible in all these issues. Pluralism has been used both as a way to transcend positivism (and its criticism) (Hirschheim, 1992) and as a way to combine behavioral and design science (Hevner & March, 2003).

5. IS RESEARCH METHOD

The research method is understood here as more specific than a methodology: it is the systematic approach to inquiry which implies skills, assumptions and practices as the bridge, so to speak, between the methodology and the actual design of the research. Thus, the method defines, informed by a methodology, the type of research in terms of duration, researcher-subject relationship and design (for lack of a better word): methodology leads to method in the form of the specific things the methodology user chooses to do in a particular situation (Checkland, 2000).

5.1. Method According to Duration

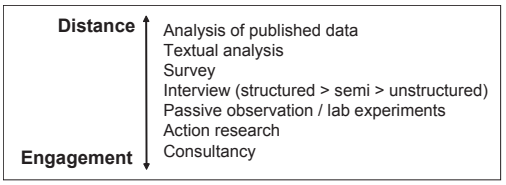
In terms of duration, a method can have different levels of time-related involvement. They can be categorized into (Chen & Hirschheim, 2004):

- Longitudinal (evolves over uninterrupted period of time and focuses on process),
- Cross-sectional (collects data through one snapshot at a particular point in time),
- Multiple snapshots (cross-sectional with more than one data collection), and
- Repeated measure design (various time periods to examine evolution of phenomenon).

5.2. Method According to Researcher-Subject Distance

The magnitude of the distance between the researcher and the subjects (or participants) can change within a single inquiry, but it helps to previously consider what that engagement might be and decide on how close we need to be to gain the most insight; a helpful range, according to distance is presented in Figure 2.

Figure 2. Distance end engagement in IS research, adapted from (Nandhakumar & Jones, 1997)



5.3. Method According to Design

Finally, the research method may be supported in different designs, although most imply a whole methodology when used. The reason they are considered method, rather than methodology is because we have already stated that methodology indicates philosophical strategy and assumptions. This means that, for instance, case study and action research can be conducted qualitatively or quantitatively, but only when making that clear does it become a full methodology. This argument is, however, debatable. The following are some of the most used methods:

- **Normative writing**: concept development not based on empiricism or theoretical grounding, but on speculation or opinion (Wynekoop & Russo, 1997).
- **Lab experiment**: studies within a designed, controlled environment, which typically include contrasting related variables (Chen & Hirschheim, 2004).
- **Field Inquiry**: generally speaking, field inquiry may involve case studies, action research or ethnography; particularly, a field experiment is an experiment which is designed in the spirit of a lab experiment but is carried out in the real world (*ibid*.).
- **Case study**: an empirical inquiry that investigates a contemporary phenomenon in real life, when boundary and context are not clearly evident or the prior knowledge of constructs and variables is inferior, differentiating it from field studies (Yin, 1994; Darke *et al*., 1998). The case study can take a positive or interpretive epistemological approach and is thought to be particularly appropriate for the study if information systems within organizations (*ibid*.).
- **Action-research**: Action research, in contrast with a case study (although it may be part of one), is concerned with actual planned change and production of theory in the process (Avison *et al*., 2001). It is assumed as a never-ending learning cycle in which informed practice improves a social system and feeds-back on theory. Baskerville and Wood-Harper (1998) point out some of action research's main characteristics: (1) multivariate social settings, (2) interpretive assumptions about observation, (3) intervention by the researcher, (4) participatory observation and (5) the study of change in the social setting.
- **Descriptive research**: Interpretive research studying literature or past research or events (Wynekoop & Russo, 1997).
- **Practice Descriptions**: descriptions of a practitioner with implicit bias and no *a priori* research intent (*ibid*.). These are of course hard to place within a rigorous scientific structure, but can still find a place within certain academic communication outlets.
- **Consultancy**: although mainly regarded as a source of income, consultancy may be strongly related to (or regarded as) research when conducted by university staff (Freestone & Wood, 2006) or indeed considered as a research method, at least for management science (Nandhakumar & Jones, 1997).
- **Simulation**: as a research method, simulation is used for prediction and explanation in numerous disciplines, helping researchers identify universal principles and processes of the real world, formalized into models, which can then offer new cognitions (Becker *et al*., 2005).
- **Ethnography**: coming from anthropology, ethnographic research requires that the researcher immerse him or herself for a longer period of time than a case study in an unfamiliar situation, seeking to place the phenomena in a social and cultural context and relying heavily on detailed first-hand observational evidence (Myers, 1999). Ethnography is increasingly being used in computer systems development as pointed out by Wynn (2001).

There are also some research instruments that usually make part of some of the above designs, but sometimes may be sufficient as methods themselves. Two common cases of such instruments are:

- **Survey**: gathering data through questionnaires (Chen & Hirschheim, 2004).
- **Interview**: an interview can be associated to other research designs (most notably case study) mainly as a data collection technique; as a qualitative method, it seeks to describe the multiple realities of the subjects (Stake, 1995).

6. CONCLUDING REMARKS

Since all approaches have advantages and disadvantages, a first conscious criterion for selecting them is the context, which limits both the choice of methods and they way they are used (Cecez-Kecmanovic, 2001); this context includes the researcher's assumptions (Olesen and Myers, 1999). According to Trauth (2001), when choosing a research method, five factors come into play: the research problem, the researcher's theoretical lens, the degree of uncertainty surrounding the phenomenon, the researcher's skills and academic politics (at an institutional, disciplinary and cultural level). Fitzpatrick *et al.* (1998) further suggest that personality traits and skills are equally important as the topic, objective and questions and the idea is to find the best fit between the situation and the way to obtain conclusions from it.

How exactly these factors determine the choice is outside the scope of this paper, but we believe that by having awareness of the possibilities and their background, the choice will be better informed. When in doubt, a researcher is probably better off following institutional tradition, supervisor preference or past experience. Also, it should be noted that even though political structures, reward systems and authorities are aware of the social or human side of things, they still favour and are guided by conservative methods (Trauth, 2001).

We believe that by using the concept map in Figure 1, a researcher can get acquainted with IS research approaches, know what decisions ought to be made, have an idea of how to justify them and employ the reference list when more detail is required. The main suggestion is to be coherent in the choices made, instead of forcing a design into an inadequate epistemology or even worse, using a design without even considering its underlying philosophy.

It is still possible to explain the concept map in much more detail and include some concepts that may have been left out. We believe that there have been several accounts of IS research, but there is a need for unifying them in order to help researchers, rather than to stimulate philosophical discussion or distinction among schools of thought (although this is also relevant).

Responsibility in User Participation in Information Systems Development

Rafael Gonzalez, TU Delft, Jaffalaan 5, 2628BX Delft, The Netherlands; E-mail: R.Gonzalez@tudelft.nl

ABSTRACT

Information systems (IS) are social in nature; they structure and use information technology within an organisation to fulfil its needs. If we are to fully understand IS development in an organisational context, those needs must come in great part from the users of the system. However, this is something that is not properly addressed by current IS research and practice. This article shows some of the reasons and consequences of this neglect. It also points at responsibilities that different actors (managers, users, developers, researchers) have on this issue.

1. INTRODUCTION

Information systems (IS) are social, rather than technical systems (Hirschheim, 1992). One of the crucial components of this social structure is the user of the IS. In principle, everybody agrees that information systems should not be developed and designed without an intense communication process with the user. Mumford has been one to acknowledge this, by saying that "people at any level in a company, if given the opportunity and some help, can successfully play a major role in designing their own work systems." (Mumford, 2001, p. 56); sentiment echoed by Omland (1999) and Schultze (2001). Kettinger and Lee (2002) also argue that if users and the IS function in a company agree on the need and characteristics of a new information technology (IT) project before its adoption, it is likely that the satisfaction of the users will be higher.

Before continuing, it is important to clarify what is understood by information systems and why they are considered to be of social nature. Checkland and Holwell (1998) describe IS broadly as the organizational need to manage IT in relation to an organisation's activities and intentions, and characterize it as a hybrid discipline, which draws from exact science, technology and social science. Land describes an information system as "a social system, which has embedded in it information technology" (Land, 1992, p. 12). IT, by the way, is defined as a collection of practices, techniques and devices concerned with collecting, storing, processing and distributing data or information (Checkland and Holwell, 1998). Thus, any inquiry regarding IS requires a grasp of both the structured and structuring influence of social action, particularly in those scenarios where technology, information and social action are inextricably intertwined (Schultze, 2001). In other words, as de Moor (2002) points out, the social and technical systems in an organization co-evolve by changing each other; methods to deal with this should focus on the interpretation of this complexity rather than its representation, preventing the generation of new specifications which do not involve the community (and are thus artificial, obsolete and alien to the group). Furthermore (*ibid*.), many specification methods assume that the initiating, coordinating and integrating roles are played by external analysts and designers, while users are assumed to have only tacit knowledge and insight.

The next section presents some background of the treatment of user participation in existing literature. Section three discusses some of the reasons why user participation is neglected in IS development, followed by some of the negative consequences of this neglect. Section four presents a list of the main actors of IS development (from the researchers to the managers) and what their responsibility or role is or might be in improving user participation. Section five presents some final remarks and suggestions.

2. BACKGROUND

User participation in IS development is by no means a new or ignored subject. At least since the early 70s it has been addressed as cooperative design, participatory design, user-centered design and even end-user development. Some of the initial input was provided by Scandinavian trade union cases (Kyng, 1991) and the topic has been present in several issues of the Communications of the ACM. The use context has not been ignored (Karat, 1997), among other things because it has been recognized that doing so ends up being more difficult in the end (Brown & Duguid, 1994).

Accordingly, users have been proposed as co-designers (Fischer *et al*., 2004; Kyng, 1991). A general argument is that all work is social and cooperative in nature (*ibid.*), which translates to the information systems domain (Brown & Duguid, 1994). Kyng (1991) sees cooperative design as a mutual learning experience with limitations because neither the user nor the designer will enter fully into each other's role. Another limitation is that in spite of cooperation, design decisions still draw lines and some users may feel that features have been left out (Brown & Duguid, 1994). One strand of cooperative design is participatory design (Kyng, 1991), justified by early arguments for user involvement, such as: combining sources of experience, creating ownership and experience, and enabling participation in decision-making by those affected. However, despite there not being any serious critique against it, participatory design has been slowly or partially implemented (*ibid*.; Karat, 1997; Mao *et al*., 2005).

Another approach is that of user-centered design, or UCD (Karat, 1997; Mao *et al*., 2005). According to a recent survey (*ibid*.), UCD improves usefulness and usability. Indeed, stemming from this approach, the ANSI/HFES 200, ISO 9241, and ISO 13407 standards for usability were developed, including design principles and evaluation measures (*ibid*.; Karat, 1997). Some of these practices focus on user analysis, which are highly context sensitive and difficult to generalize and to be agreed upon (Dillon & Watson, 1996). Other difficulties of UCD are: complexity, cost-benefit relationship, and lack of formal methods (Mao *et al*., 2005). UCD also risks focusing too much on internal user requirements at the expense of external, equally important ones (Brown & Duguid, 1994). A problem that remains for UCD and other participatory approaches is that they tend to be only partially applied, usually at the initial phases of IS development, and not in a rigorous end-to-end manner (Mao *et al*., 2005; Fischer *et al*., 2004).

An increasing trend, both more radical and risky than the previous approaches, is end-user development (EUD). At first, this may be seen as a consequence of inadequate user participation in the past, prompting users and user communities to "upgrade" their role to that of developers, aided by easier tools and access to knowledge. However, seriously treated, EUD is a viable socio-technical approach, which according to the principles of meta-design (*ibid*.) empowers users to become not just participants or co-designers, but designers in control of the continuous development of the systems they use, in a style similar to some successful open source developments (*ibid*.). For EUD to consolidate itself as a successful IS development approach, it is necessary that user motivation, effective tools, and management support create an effective balance (*ibid*.). The challenges presented in this section, prompt us to continue treating the subject.

3. NEGLECTING USERS: REASONS AND CONSEQUENCES

Some authors (Mumford, 2001; Collins *et al*., 1994; Armour, 2002) consider user involvement in IS development an ethical issue. Whatever the reasons may be for ignoring users or just calling on them partially or with false intentions, the fact is that introducing a new IS will alter the way people go about their jobs or communicate amongst each another. Ignoring this is a lack of vision that may

decrease the quality of work life. This is coupled with the fact that the success of the IS may be compromised and failures may result in economic or even human loss. We will present an incomplete, yet relevant, set of reasons and consequences for not involving users adequately in IS development.

3.1. Possible Reasons for Neglecting Users

A reason for neglecting user participation stems from the belief that this is a *soft issue***,** which pertains to other actors or disciplines. It is not uncommon to hear IS practitioners disregarding the user participation issue as one that is related with human aspects that don't concern them. This is not to say that they are unaware of its impact, they just believe it is someone else's responsibility to care for this. The hard-core technicians consider these social details as something that they shouldn't be bothered with. Besides, they might argue that it is not scientifically possible to deal with human issues: "for something to be considered scientific it must use the agreed set of conventions – the scientific method" (Hirschheim, 1992, p. 30), and since the scientific method does not offer an adequate way to handle user participation, it is regarded as an unscientific or soft issue.

A second, not often recognized, reason for not including users is an intent to *strengthen or enforce power relations*, especially within a hierarchical organization. Information technology, by changing the communication medium, may alter in a positive or negative way the meaning of a message. There is a discourse built in the system, which determines hidden meaning, and may be in fact reinforcing power structures. There might be a direct conscious manipulation of an IS to maintain power relations, as shown in (Olesen and Myers, 1999), who describe how top level assistants modified a Lotus Notes implementation, so that other employees wouldn't have access to managers' agendas and in doing so maintained their control over them. There are also more subtle ways to enforce power through IS, such as the one mentioned by Cecez-Kecmanovic (2001), in which a University President apparently calls for employee involvement in a restructuring, through the use of computer-mediated communication, but in reality takes covert strategic action by ignoring the criticism posted on the system and going ahead with his initial ideas, without the staff being able to argue that they didn't have a say in it.

Another common reason for user participation to be ignored or brought to a minimum is the desire to *build fast and cheap* systems. This is an increasingly strong objective, in part because of the dynamics of IT, which may make a long-lasting development an already obsolete product when it comes out. At least that is the assumption, and it is one which sees IT as a technical device in isolation. The downside to this is that usually, on the long run, this may not be the case and, in fact, a simplified design can produce a system that doesn't work as desired. One should keep in mind that "managing complexity requires flexibility and diversity while profit generation requires efficiency and control. These two sets of needs are difficult to combine." (Mumford, 2001, p. 49)

Now that some of the reasons for not appropriately involving users have been put forward, it seems attuned to examine some of the consequences.

3.2. Consequences of Neglecting Users

The first direct consequence of neglecting users in IS development is potential *failure of the system*. All new software can be assumed to contain errors, even after millions of executions (Collins *et al.*, 1994) and not all of them can be blamed on not involving users. The Hubble's faulty mirror, the AT&T shutdown of long-distance for hours in 1990, the USS Vincennes unreliable radar system (which ended up in shooting down an Iranian commercial flight), the Therac-25 radiation therapy machine killing people with x-ray overdoses, are all notorious examples of IT failure (*ibid*.). One can't help but wonder if user input would have avoided any of these failures. Usually the managers have an idea of what they would like to see in the new system, the developers understand this in a particular way, which may or may not be compatible, and then the users accommodate it to their daily work. Of course, a fool-proof, well documented system may be taught and put to use according to plans, but it has already been underlined that IS are coupled with organizational issues that cannot be handled by the system intrinsically, such as politics and culture. The management of this aspect necessarily must involve all the actors. Failure is not always technical failure.

Another natural negative consequence of not involving users is that they could manifest *resistance towards the system*, Collins *et al.* (1994) discusses a hospital case in which medical staff distrusts a new automated pharmaceutical process and the solution is to put it out of production. Mitev (2000) notes that, regarding IS, some actors go along with the will of others, while some resist. Resistance is in fact a common feature of any social system. Another example: a few years ago, one of the authors was involved with the help desk of a relatively large IT provider in Colombia where they managed service calls with the aid of an in-house developed database system. It was a simple, single-user database, which technicians and managers used to register and follow-up the calls. The company had recently been absorbed by a bigger one (not related to IT) and part of this deal meant switching to one particular large helpdesk software. Nobody argued that the new system would be full of best-practice features; nonetheless, during the process of adapting the tool, not once were the technicians involved; they were simply trained on using the software and forced to use it in parallel with the old tool for a complete switchover a few weeks after. There were a lot of details that the technicians were accustomed to filling in a certain way and the new tool proved to be rather tedious for this purpose, resulting in the users not including this information in the new tool and simply relying on the old one for their work. This ended up in a growing rejection of the system, which in turn caused further training (cost), a longer adaptation period (time), general dissatisfaction and a decrease in productivity for quite some time.

Strengthening of power structures was already mentioned as a reason for not involving users, but it can also be an undesired or unexpected consequence (from a user's perspective). Mitev (2000) describes the implementation of *Socrate*, a reservation system derived from the popular and successful *Sabre* (for airlines) in the SNCF (French railways). Though this system failed in many aspects, one in particular illustrates the purpose of this paragraph: the adoption of airline-like yield management was implemented to make the railways competitive at a European level. This, however, changed the practices of both railway workers and passengers, conducing to major strikes, criticism and basic chaos. Top executives were convinced that yield management would achieve a techno-commercial solution to the problems in the SNCF and make it cost-effective. However, they did not account for the fact that yield management is hardly just a techno-commercial tool, because it is linked to power relationships, mainly through pricing, that got transferred to staff and passengers, introducing a previously non-existing power structure. Someone could argue that the French are just too eager to strike at any chance they get; regardless of whether this reputation is deserved or not, it certainly means that changes at a technological level should have considered consequences at a political level.

Now that we have seen some reasons and consequences of neglecting users, we argue that someone must take responsibility for involving them effectively, this is the topic of the next section.

4. WHO IS RESPONSIBLE FOR USER PARTICIPATION?

Among the possible actors to take responsibility in user involvement, we can consider those involved in IS development and use, according to Collins *et al*. (1994): provider, buyer, user and penumbra (those affected by system, yet not part of the organisation). They propose a set of responsibilities that these actors have on each other and on themselves, which point to the fact that their interests are different and many times conflict.

Some *managers (buyers)* sometimes take on the responsibility of considering the human aspect of IS development and giving due place to users. Armour (2002), a manager himself, for instance, calls for a "spiritual life of projects" and states that "in our cold, cost-cutting pursuit of efficiency and productivity, we shouldn't forget that software is only made by people" (*ibid*., p. 14). However, it is likely that managers will answer to their functional responsibility and concentrate on profits. As Jackson (1985) puts it, they wouldn't give up their position of power for an idealized design.

One wouldn't expect *users* to be responsible for involving themselves in the development, but they have increasingly taken on this vacant responsibility, when they feel others don't. Due to delayed IT delivery, poorly prepared requirements and resistance to change – coupled with easier and widely available access to programming languages and the Internet – users have increasingly become confident enough to develop their own solutions without the IS department (Kettinger and Lee, 2002). This has even resulted in user-driven innovation, as opposed to the IS function's traditional role in this (*ibid*.). Users now consider themselves as more experts than what the IS function might expect from them. Enabling the user's recognized expertise and grasp of what the organisation needs, coupled with IS department's know-how might produce better results than any of the two separately.

Another fundamental actor is made up by the *developers (providers)*. Their job is to build an IS which complies with high quality standards, but most importantly, that does what is needed and adds value to the organisation; in order for this to happen, its users are crucial for its success and must be included in the development. On the one hand, there are ethical codes of behaviour that could be interpreted as suggesting user involvement when they recommend acting consistently with public interest (Gotterbarn, *et al*., 1999). On the other hand, their own professional and group success is tied to the success of the system, so it is short-sighted to only serve a limited set of interests or cut corners.

Lastly, we can include another actor, not necessarily involved with the development or implementation of IS, but crucial in establishing the way in which these two activities are carried out: the IS *researcher*. Being responsible for knowledge production in IS, a researcher's role in user participation is very important. Through publications, conferences, associations and, perhaps more importantly, teaching activities, they influence the way in which developers learn how to build an IS, how managers understand and use IS and, furthermore, how users themselves are seen. In a recent paper, Geoff Walsham (2005) argues that researchers should take on the responsibility of carrying out their inquiries with a critical approach that understands that knowledge is a social construct, that there are historical and cultural contingencies in its production and that power relations influence its development. Furthermore, Walsham suggests that through teaching, publishing and institution building, researchers can influence the way in which IS are understood and used, highlighting the obvious but undermined notion that IT is aimed at improving the lives of people around the world. In other words, IS should contribute towards development (in a broad sense, not a purely economic sense), particularly contributing to reducing the digital divide, questioning the ethnocentrism in existing technology and taking into account gender issues. All three contributions are related to the end-users of IS. A teaching example of this can be found in (Omland, 1999) that presents an IS development course emphasising the human (user) factor.

5. CONCLUSION

This paper offers an invitation to understanding user participation in information systems development not by looking at the benefits, but rather at the reasons and consequences of partially or totally neglecting users. This negative approach to the user participation issue is meant to raise awareness on the responsibility that different actors have on changing the situation.

We hope that by showing the reasons, consequences and responsible actors we can enhance understanding of the user participation issue with a call on each of these actors to take responsibility. We recognize that by presenting seemingly negative reasons and consequences we have left out what sometimes may be positive aspects of not involving users, such as keeping a project within budget and time constraints, allowing for decision-making not to turn into endless discussion, or innovating without user bias on comfortable tradition. But we do this in order to stress the fact that IS development has a social-nature and approaching it instrumentally (whether it be a technology or management-centred perspective) may be counterproductive for the system itself, which includes all stakeholders.

Participation doesn't start with asking the users about functionality or interfaces; it does not end with questionnaires about usability or friendliness either. It should start by discussing the problem situation with the stakeholders (users in the foreground) without the IS being already the preconceived solution; and it should also be an open-ended learning experience.

Changing Healthcare Institutions with Large Information Technology Projects

Matthew W. Guah, ESAAC – Erasmus School of Economics, Erasmus University Rotterdam, The Netherlands; E-mail: guah@few.eur.nl

ABSTRACT

This paper reviews the development of institutional theory in direct relations to historical changes within the UK's National Health Service (NHS) with an eye to contributing to the theoretical specification of social information processes. This is done partly by extending certain paradigms (see Powell & DiMaggio, 1991; Meyer & Rowan, 1977; Tolbert & Zucker, 1994) through a proposed model of causes and consequences of variations in levels of institutionalisation in the healthcare sector. It reports findings from a three-year study on the NHS implementation of the largest civil information systems worldwide at an estimated cost of $10 billion over a ten-year period. The theoretical basis for analysis is developed, using concepts drawn from "IT conversion effectiveness", "productivity increases", realization of business value", and "organisational performance improvements", as well as mixed empirical results about the lack of IT investments value in the NHS. The findings suggest that large-scale IT change imposed upon a highly institutionalised healthcare is fraught with difficulty mainly because culturally embedded norms, values and behavioural patterns serve to impede centrally imposed initiatives to automate clinical working practices. It concludes with discussion about the nature of evaluation procedures in relation to the process of institutionalizing IS in healthcare.

INTRODUCTION

An historical overview of IT projects on the UK's National Health Service (NHS) during the last five decades is presented here with the intention to both clarify the links between institutional theory and previous traditions of sociological work on organisational structure. The initial exposition of this theory by works of established institutionalists (Tolbert & Zucker, 1994; Meyer & Rowan, 1977; Scott et al, 2000) focuses on the ways of challenging dominant theoretical and empirical traditions in organizational research. While this paper clarifies some ambiguity and elaborates on the logical and empirical implications of a phenomenologically-based version of institutional theory, the primary aims are to clarify the independent theoretical contributions of institutional theory to analyses of the NHS and to develop this theoretical perspective further in order to enhance its use in empirical research in other healthcare environments (internationally and globally).

Markus (1983) claims that interaction theory draws together three principal strands of resistance: internal factors, technical problems and political context. This theory has been highly influential in IS strategy and other social sciences generally since Markus first developed the ideas over two decades ago. The focus here (see Table 1) is on how interaction theory offers a new way of looking at IS implementation in the healthcare industry.

Much has been researched in the last few decades about the major lack of a coherent implementation strategy for information systems (IS) in the healthcare industry (Stevens et al, 1993). Most of such claims have been levelled against an apparent "productivity paradox" with respect to investments in healthcare management (in general) and IS (in particular). Wanless (2002) and Committee on Quality Health Care in America (2002)—both national government's mandated investigations into the UK and USA national healthcare systems respectfully—among others, have failed to find a convincing body of evidence that investment in Healthcare IS is associated with increased output (refuting the productivity paradox), but not with healthcare value as measured by patient satisfaction.

WHAT IS INSTITUTIONALISM?

Institutionalism is continuously being used to mean different things by researchers of political science, economics and sociology. Lowndes (1996:182) presents institutionalism as informal codes of behaviour, written contracts and complex organisations with four elements:

- A middle-level concept. Institutions are devised by individuals and therefore constrain individuals' actions. Institutions here are seen as part of the broad social fabric and medium for individuals' day-to-day decisions and other activities. DiMaggio and Powell (1994) argue that institutions shape human actions, imposing constraints whilst providing opportunities for individuals.
- Having formal and informal aspects. Lowndes views institutions to involve formal rules or laws, which allows informal norms and customs to be practiced. That is because some institutions are not consciously designed nor neatly specified, yet part of habitual actions by its members. Such institutions may be expressed in organisational form and relate to the processes within.
- Having legitimacy. Legitimacy in institutions goes beyond the preferences of individual actors. Such preferences are valued in them and go beyond their immediate purpose and outputs.
- Showing stability over time. Lowndes views institutions as gaining their legitimacy due to their relative stability over time, and their links with a 'sense of place'.

Table 1. Implementation theory: Usage, fitness, relationship & sufficiency

Authors	IS Implementation	Theory Description
Lucas, 1993	Appropriate Use of IS	Process theory explaining appropriate IS use. Variance theory linking use with business value.
Grabowski & Lee, 1993	Strategic Fitness of IS	Process-type relationship between strategic fit and performance of IS.
Markus, 1983	Relationship of IS assets	How IS investment do or do not become IS assets. How IS assets do or do not yield improved organizational performance.
Sambamurthy & Zmud, 1994	Insufficient to produce impacts	Process model connecting raw material inputs to outputs. Variance theory of IS management competencies and IS impacts Variance theory linking impacts and business value.

New institutionalists generally view institutions to have "the humanly devised constraints that shape human interaction" (North, 1990: 3) what March and Olsen, (1989:162) refer to as "rules of the game" that organisations and individuals are constantly expected to play the game. Another stand taken by new institutionalists sees informal institutions (tradition, custom, culture and habit) are embedded in culture and conventions defined as behaviour structuring rules (North, 1990; March and Olsen, 1989). New institutionalists stress embodied values and power relations of institutions together with interaction between individuals and institutions (Lowndes, 1996). They attempt to distinguish between informal institutional rules and personal habits. Such distinction forms the basis for the definition of institution in this research where informal conventions and their impact upon the NHS and its partners are being explored.

RESEARCH METHODOLOGY

The research study began in 2001, with the initial interest of conducting an exploratory-descriptive study in ten NHS hospitals to explore why, 'historically, the NHS has not used or developed IT as a strategic asset in delivering and managing healthcare' (DoH, 2000). Intensive literature review unveiled few longitudinal studies, which systematically and rigorously examined how IT systems were introduced and changed over time. There were no studies that examined inter-organizational relationships between different constituents in the adoption and diffusion of IT systems (NHS directorship, hospital management systems or IT suppliers and patients). Not only were most of these studies descriptive and lacked an historical dimension, they presented IS in healthcare as largely theoretical with most contributions reporting the findings of a specific IT project implementation using simple success and failure criteria—Scott et al (2000) being amongst the most significant contributions.

Using such relevant and wide-ranging backdrop this research study recognized that it was important to extend the empirical enquiry for two reasons: (i) exploratory-descriptive case studies on a single organization (or one hospital) would not elicit in-dept and rich data to develop any meaningful analysis and conclusions on how IT was being deployed and managed; (ii) the introduction of a large-scale IT-enabled change program needed to be researched at the wider societal, organizational field and individual levels, covering an extended period of time, to understand the processes of institutionalisation (Tolbert & Zucker, 1994). The research study was therefore designed to capture the myriad of views and opinions about the NPfIT over a three-year period to build a rich picture of such processes underpinning large-scale IT change.

Three methods of data collection were adopted: (i) a range of academic, government and industry studies on the healthcare sector were assembled—both UK and healthcare services in other countries. The materials proved invaluable for understanding the societal, economic, political, cultural and technical differences in healthcare nationally and internationally; (ii) participation in trade fairs, conferences, workshops and exhibitions on healthcare—focusing on general or more specific healthcare activities. These events also generated many useful research contacts that proved invaluable for targeting interviews.

A semi-structure interview (see Table 2) schedule was used to enable interviewees to expand on their answers. While most interviews lasted for about ninety minutes, nearly all interviews were tape-recorded and transcribed. Respondents were later contacted with feedback from the interviews and where necessary errors were corrected. This method of data collection was critical for allowing interviewees to raise additional themes, issues and concerns that they felt were important to the research study. As a result of the political contention of some of the interview content, some interviewees asked that names of individuals and hospitals be anonymous.

During the first year of interviews, the scope of the study had to be extended, as it was important to elicit data and information from a wider range of respondents engaged in the implementation of NPfIT. These included IT service providers bidding for public sector IT contracts and doctors in general practices around the country. Most IT service providers offered critical insights into the political and procurement processes within the NHS and public sector more generally. General practitioners, on the other hand, offered useful insights about the communication channels underpinning the institutional processes underpinning NPfIT. Given the range of constituents involved, the resulting data was evaluated and interview schedule refined, ensuring questionnaires be more closely targeted to the professional and personal situation of the individual, as generic questions were less meaningful. The final questionnaire was ultimately divided into the following major themes involving 15 questions:

Vision for the National Programme for IT: overall vision and how it was compatible with individual hospital objectives.

Strategy for the National Programme for IT: Who was engaged with and how the strategy was being communicated within different organization.

Implementation of the National Programme for IT: What professional, managerial and technical skills or capabilities were needed to implement various elements of the National Programme for IT.

Value Delivery for the National Programme for IT: The main risks identified by each hospital and how past IT failure could be avoided, as well as looking at the cost/benefit choices and issues for each organization.

Risk Analysis for the National Programme for IT: The value being derived from the National Programme for IT?

The aim was to get the perspectives of a number of different informants using structured interviewing, by building up intensive longitudinal cases which would, nevertheless, be amenable to statistical analysis. In this method, differences of

perception of informants become part of the data, not an inconvenience to be explained away in the search for some objective truth.

DATA ANALYSIS

Content analysis was used to surface themes in the interview data that reflected participants understandings related to systems implementation. The approach suggested by Weber (1990) was used to code the interview data. A set of codes used to classify the data was developed, based on concepts from the research literature and augmented with major additional concepts discovered by the researchers during the coding. We used a content analysis form where each sentence from the interview transcripts was assigned one or more codes. Each data element was coded with an assessment of the level of agreement in code assignments, involving certain degree of recoding of data sources. As this was the first study that uses content analysis about modelling of system implementation in the NHS, certain degree of recoding was considered acceptable.

Table 3 contains a list of the most frequently cited attributes and benefits of system implementation model. The audiotapes were fully transcribed, and individual site summaries were produced before conducting a content analysis of each transcript. After a complete review of all summaries, issues describing IS implementation strategies by iterative examination were identified. Certain themes emerged which were explored using the competing values framework as an interpretive framework where appropriate (see Table 3). The trustworthiness of such analysis has been assessed by triangulation between data sources and exploring any differences in the researcher' interpretations during a couple of follow-up meetings with selected interviewees.

During the period of the field study, there was a continuing, vigorous, informal debate within NHS Information Authority as to the merits of establishing a fault proof IS implementation framework in healthcare, particular for the NHS, during this period of healthcare reform. Benefits in terms of improved quality, greater structure and more discipline were widely accepted.

THE NHS CASE STUDY

The NHS is the institution responsible for all health care and services in the UK with the goal of undertaking this responsibility at no costs to the public, at the point of delivery. The NHS was created in 1948 by a parliamentary art of the UK government of Mr. Howard Wilson, after a national healthcare review by Mr. Black immediately after World War II. Within the past 58 years, the NHS operating environment has changed radically.

The period from late 1980's to early 1990's brought in the advent of competitive bidding bringing long-term increase costs to the management of the NHS, as well as a feeling of internal market within the NHS. By the mid-90's, management of IS in the NHS was division-based. Divisions were spread across several sites and medical functions were centrally controlled. Computing services and IS development project were beginning to be contracted to external private businesses and staff at the NHS were beginning to feel disgruntled and unappreciated. The increasing influence of global communications, Internet and other new technologies demanded a response from the NHS.

In the late 1990's the government increasingly recognized the opportunity to use IT to improve the delivery of service within the NHS. After a series of reviews of NHS IT service delivery, a more integrated and seamless IT organization was recommended (DoH, 2000, Wanless, 2002). The NHS Information Authority embarked on the Integrated Care Report Service (ICRS) project to provide, among other services, a nationwide electronic patient database. The result was a document called "*Information for Health*" that specified the need for the complete automation and integration of various patient information databases in the country (DoH, 2000). The system was commissioned to selected IS service providers at a combined price of $10 billion.

In spite of its vision—to transformation IT—the NHS has a history of introducing large-scale IT development projects that has not been an overall success, with some suggesting a failure rates of between 60 to 80 percent (Brown, 2001). Though the UK public sector spent around $3.5 billion per annually on IT, the failure of major IT-enabled projects were characterized by delay, overspend, poor performance and abandonment (NAO, 2004, p.3). At the political level, it is argued that 'better IT is needed in the NHS because the demand for high-quality healthcare continues to rise and the care now provided is much more complex, both technically and organizationally (Connecting for health, 2004, p.7). About $250 million is spent on management and administration in the NHS, a controversial figure, as many believe more doctors and nurses should be recruited.

THEORETICAL ANALYSIS OF THE CASE

The NHS case study illustrates the dynamic nature of a national healthcare information system implementation, set within the context of a rapidly changing organization. As with all large IT-enabled programs, the success or otherwise of the strategic plan is in its implementation (Herzlinger, 1989; Doolin, 2004; Hendy et al, 2005). The lessons IT costs versus medical decision-making are well documented in the literature and involve the lack alignment between the business and IT strategy (Luftman, 2000); a lack of ownership and leadership of the IT project among senior decision makers (Brown, 2001); poor risk assessment skills (Heathfield et al, 1998); over-scoping of the functional and technical specification leading to IT projects becoming over-budget and late (NAO, 2004); poor communication between program/project managers and potential users of the system (Guah & Currie, 2005); inadequate resources to deliver/implement IT systems (Currie & Guah, 2006).

The empirical research found that issues of project risk were at the forefront of the minds of clinicians, GPs hospital managers and IT staff. Formal project management methods and tools were perceived as offering only part of the solution to mitigate the considerable risks from introducing the NPfIT.

The fragmentation was not just about the diversity of IT systems within the NHS, but also about the political geographical, social, organizational and financial complexity of delivering healthcare.

The overriding view was for the NPfIT to become an integrated IS across and beyond the NHS. The threats to achieving this were perceived by many clinicians to fall within the control of politicians and IT service providers rather than from NHS staff. Project risk mitigation was a complicated issue, compounded by the political and ideological considerations, such as the PFI, which facilitated the increasing use of private sector firms. Whilst the NHS is often characterised as a top-down bureaucracy (Mohan, 2002), past achievements in IT development and implementation had often been initiated at a decentralised (hospital, departmental, unit) level. Although this was now discouraged by the centrist approach of the NPfIT, staff participating in the research expressed concerns that any failures associated with IT project implementation may be labelled '*staff resistance*' rather

than the shortcomings of external constituents, such as politicians, management consultants or IT suppliers.

The success or failure of information systems is inextricably linked with the dynamics of the organization within which they exist. Miranda and Saunders (2002) have demonstrated the complex interaction of technical, social, cultural and political elements that result in a failed IS. Equally, IS success depends on more than technical competence. The cultural and political environment of the NHS is difficult to study as it depends not only on the tangible organizational structure but also on the tacit knowledge and the perceptions of the participants (Guah & Currie, 2005). This is in addition to the cultural and political environment of an organization that is not static but in a rather state of constant flux and dynamic change.

Institutionalism of IS in the NHS is concerned with processes of cultural persistence and change of healthcare processes. The survival of an organization depends as much on conforming to societal norms of acceptable practice as to achieving high levels of production efficiency and effectiveness (Covaleski et al, 1993). Prior work has shown that an organization's formal structure, policies and procedures serve to demonstrate conformity with the institutionalised rules and requirements of external constituents (Meyer & Rowan, 1977; Dimaggio & Powell, 1983). In light of these concerns healthcare in the UK showed that the NPfIT was intended to play a high profile role within the heavily institutionalised environment of hospitals (Scott et al, 2000).

The vision for NPfIT was infused with the institutional logics more commonly associated with the private sector, as an innovation that would contribute to greater productivity, efficiency, cost control and customer satisfaction in healthcare delivery. Paradoxically, this externally directed institutional logic served to under represent and simplify the vast complexities and contradictions in how it was perceived, and reacted to, by those affected by government-led IT-enabled changed. Within the NHS, staff were increasingly sceptical about the merits of private sector logics, such as the PFI initiative, as their values, norms and goals invariably placed financial considerations secondary to choices about patient care.

CONCLUSIONS

The primary contribution of this paper has been to provide a theoretical basis drawing from Institutional theory, which was used to analyse the NHS implementation of NPfIT. The theorization goes beyond the relatively simplistic types of studies which dominate the IS literature today. Much to the contrary, it has been shown that an implementation strategy can accommodate elements such as the links between culture, contradiction and conflict, an analysis of detailed work patterns, and the dynamic and emergent nature of political involvement at national level.

The theory has been illustrated using limited empirical examples only, with a focus on the NHS systems, but it could be used to analyse any case study involving healthcare systems from any parts of the developed world. Viewed from a more critical perspective, however, any theory illuminates some elements of particular case situations and is relatively silent on others. The NHS has grown within an environmental niche that arose out of a complex interaction between the national healthcare environment, business environment, the organizational environment and the people within the NHS. Changes within the organization subsequently rendered the environment hostile to the NPfIT which was affected by its changing links with organizational structure and people, the changing responses of people within the NHS to the environment around them, and the changing individual and collective mindsets and understanding of those people. While a detailed discussion of ways in which this can be achieved is beyond the scope of this paper, some broad approaches have been mentioned.

In the current environment of increasing demands for better quality of healthcare from patient and seemingly reduced amount of funding from National governments, the need for suitable institutional theory is increasingly common and the IS field must increase its understanding of the problematic issues involved and approaches to resolving them. It is hoped that this paper makes a modest contribution to these goals.

ABSTRACT

Data integration is one of the most important tasks in the data warehousing process. The use of ontologies in the mediation process allows semantic and structural integration. In this paper, we propose a new mediation system based on an hybrid architecture of ontologies modelled according to GLAV (Generalized Local As View) model. The hybrid architecture builds a local ontology for each data source and a global ontology viewed as a mediator. The integration model defines how sources, local and global ontologies are mapped. So we propose an ascending method for building ontologies, which facilitates the semantic reconciliation between data sources. Moreover, we use OWL (Ontology Web Language) for defining ontologies and mappings between data sources and ontologies. User queries are expressed in our specific language which handles global ontology concepts and local ontologies properties since we assume that the user is expert in its domain. Queries are decomposed by the rewriting algorithm to obtain a set of equivalent subqueries that are sent to the corresponding sources for execution, and after that recomposed to obtain the final result.

1. INTRODUCTION

In a data warehousing process, data integration is an important phases. Centralized data warehouse is a solution for companies that handle static data. However, when data change, this solution becomes not practical because of the refreshment cost. We think that data integration by mediation can solve this problem and allows to construct a mediation system for building analysis context on-the-fly using data from their real sources.

In this paper, we treat only the first part, which concerns the building of the mediation framework. It consists in creating a mediator based on ontologies. The use of ontologies in the integration by mediation is not recent [3, 4], it allows to implement a structural and semantic integration. There are several architectures based on ontologies in integration systems [1, 2, 16]. approaches with only one ontology as in the case of system *SIMS* [5], approaches with multiple ontologies as in *OBSERVER* [6] and hybrid architecture which associates a local ontology for each data source and a global ontology to link them [7]. The later is interesting because it is flexible for updates and there is no need to define mappings between local ontologies. Several structural models can be applied on this architecture: *GAV* (Global As View) [9, 10, 11], *LAV* (Local As View) [12, 13, 14, 6, 8]. The advantages and disadvantages of these two approaches are opposite [8]. *LAV* is flexible for updates but the construction of query's answers is complex, contrary to the construction of answers in a system adopting an approach *GAV* which simply consists in replacing the predicates of the query global concepts by their definition. *GLAV* (Global-Local As View) [15] is the combination of *GAV* and *LAV*. It inherits the query unfolding property of GAV, maintains independence between data sources and allows to indirectly computing mappings between them. It uses views in local and global levels. The query processing in this model is only feasible when the query is expressed in a language that takes into account global and local levels.

In this context, we propose an ascending method for building ontologies starting from the local ones, then we use these ontologies to build manually the global ontology and define mappings between global and local ontologies (figure 1). We use *OWL* (OntologyWeb Language) to define ontologies and their mappings. Our goal is to use the ontologies terminology to formulate user queries. To reach this goal, we propose a query language based on global ontology concepts and local ontologies properties. The problem of mediator using several ontologies according to the *GLAV* model is the query rewriting and the way how the obtained results are combined. For this end, we propose our query rewriting algorithm, which enables to reformulate user queries to queries comprehensive by the mediator.

Our work lies within the scope of a project of virtual data warehousing of banking data in LCL - Le Crédit Lyonnais (French bank). The purpose of the project is to manage and improve the decision process in LCL in the direct marketing activities domain. It contains many management applications and databases. The banking data are heterogeneous and change much, so the construction of cubes on-the-fly is pertinent. Each cube represents a specific analysis context.

The remainder of this paper is organized as follows. Section 2 presents our mediation system starting by our approach, which allows to create various ontologies applied to the case of the sources of the LCL. Next, we present our query language. After that, we present our query rewriting algorithm and give an example. The architecture and the implementation of our mediator are exposed in section 3. We finish this article by the section 4 which concludes our work and presents the prospects on new generated problems.

2. ONTOLOGY-BASED MEDIATION SYSTEM

The construction of the mediation system is decomposed into three steps:

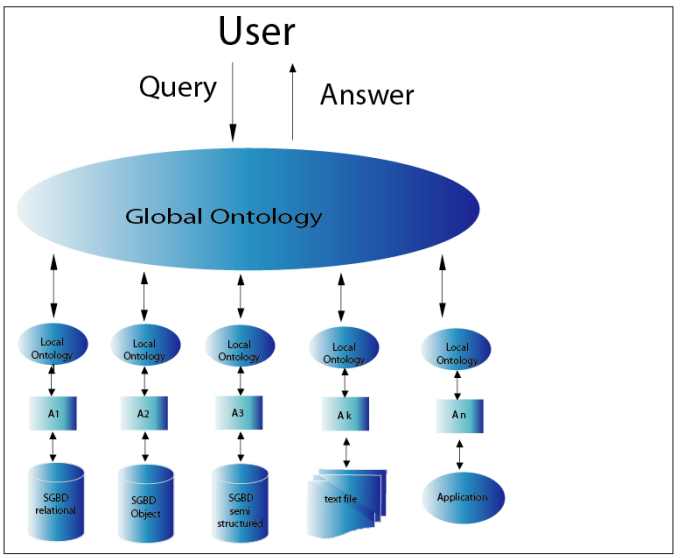
1. definition of local and global ontologies
2. definition of a query language
3. definition of the query rewriting algorithm.

2.1 Ontologies Development Approach

In this section, we present our approach of ontologies construction using the hybrid architecture modelled according to GLAV model. We also use OWL for the ontologies description. In fact, OWL is capable to describe data and metadata in order to make ontologies more powerful for the integration task. OWL is based on RDF (Ressource Description Framework), so it gathers the RDF description power and the mechanism of reasoning. The approach we propose consists in creating ontologies in an ascending way. We start from local ontologies, and extract a global ontology from the local ones in order to facilitate the semantic reconciliation between sources.

- The first phase consists in creating local ontologies. It contains two steps: (1) the analysis of sources; and (2) the definition of ontology concepts. The first step is a complete analysis of each source independently. The analysis consists in searching primitives used in sources, implicit information, its storage, its significance and its relation with other terms. After that, we define concepts which will constitute the ontology hierarchy, their relations and constraints on their use.
- The second phase is the extraction of the global ontology starting from various concepts used in local ontologies. It contains two steps: (1) local ontologies analysis; and (2) selection of all concepts and solving semantic conflicts. The first step is a complete analysis of local ontologies. Note that, ontologies analysis is easier than that of data sources. After concepts selection, the expert solves all kinds of heterogeneity (naming conflicts, confounding conflicts and/or scaling conflicts) to determine global ontology concepts.
- The third phase, which represents the core of the system, consists in defining mappings between the global and local ontologies. The global ontology is built

Figure 1. Ontology-based mediation system



from local ontologies. So, in order to identify the original ontological source of concepts, we use annotations. *OWL* enables the annotation of concepts and properties according to predefined meta data schema.

Our study is limited on relational data sources, where tables are represented by *OWL* classes. Relationships between classes are represented in *OWL* by *owl:ObjectProperty* and *owl:-DatatypeProperty. OWL* properties can represent various attributes and constraints in the relational schema. They also represent attributes by *Datatype*. If the attribute is a primary key constraint, then a functional characteristic will be added. In addition, we use *owl:ObjectProperty* to represent foreign keys attributes. Therefore, we obtain two ontologies representing the two relational data sources. The process of ontologies development must be particularly reliable for the global ontology construction. In fact, this ontology ensures the connection between various local ontologies and contains the knowledge for the query formulation and the data warehouse construction. The LCL has two relational data sources, each one contains two tables. the *OWL* schema is represented in the following table:

2.2 Query Language

The use of the global ontology as a model for query reformulation is not new. It can be more intuitive for the users. Our system allows queries to exploit concepts of the global ontology and properties of local ontologies. A basic user query is in the form:

Concept ^ Property ^ Concept or only Concept.

2.3 Query Rewriting

The *GLAV* Approach corresponds to each concept $Concept_G$ or V_G from the global ontology a concept $Concept_L$ or a view V_L from the local ontology. A query

Table 1. LCL relational tables representation in OWL

Tables	Equivalent OWL
Collaborator	owl:Class rdf:ID="Collaborator"
MarketingDemand	owl:Class rdf:ID="MarketingDemand"
Person	owl:Class rdf:ID="Person"
Profile	owl:Class rdf:ID="Profile"

expressed in terms of global ontology can not be always reformulated in a view from the local ontology only if the query is expressed in terms of the global and the local schemas. For that we propose the preceding query language (see example in section 2.3.2) and the following rewriting algorithm.

2.3.1 Rewriting Algorithm

The user query expressed in our language query will be rewritten by our algorithm to obtain a set of linked subqueries. If a concept in the user query is not linked with the preceding ones, it will be excluded. Semantically, this exclusion tends to make the query coherent. A coherent query is decomposable into subqueries, and of which its results can be recomposed. The query rewriting can be seen as a mapping between the global ontology and local ontologies.

- **Formal Algorithm**: Formally, a based-ontology mediation system *O* is a triplet *(G, S, $M_{G,S}$)* where *G* is the global ontology, *S* is the set of local ontologies and $M_{G,S}$ are mappings between the global ontology *G* and local ontologies *S* in O.
- **Global ontology**: Let C_g be the set of the hierarchic concepts of the global ontology, An_g the set of annotations, and Annotation a function defined from C_g to An_g.
- **Local ontologies**: Let *S* be a set of *n* local ontologies $S_1, S_2, ..., S_n$. We note A_{si} the set of a local ontology concepts. A_s is the union of the A_{si} of the n local ontologies. Local ontologies concepts are linked by a set Rsi of properties defined in $A_{si} * A_{sj}$. Let R_s be the union of all properties sets R_{si}. Let An_s be the set of annotations and let Wrapping be the function defined from As to An_s which associates to each concept an annotation.
- **Mappings**: the mapping $M_{G,S}$ defines how the concepts of the global ontology *G* and concepts of the local ontology S_i are linked. $M_{G,S}$ is a function from C_g to S_i.
- **Query language**: Queries are expressed in terms of a query language Q_g. In our system, queries are conjunctions of global ontology concepts and local ontologies properties, so we obtain two types of queries:

Algorithm 1 Query rewriting

Entry:
$Q : Userquery$
$G = \{C_{g1}, C_{g2}, ..., C_{gn}\}, S = \{C_{s_1}, C_{s_1}, ..., C_{sn}\}, R = \{r_{s_1}, r_{s_1}, ..., r_{sn}\}$
Result:
$Q_d[k] : The\ set\ of\ k\ queries\ deduced\ from\ Q$
$T[k] : The\ set\ of\ correspondence\ tables\ for\ the\ k\ queries$
$K \leftarrow 1, Q_d[k] \leftarrow Q, NoCorrespondent \leftarrow True$
for all $u \in \{1...Size\ Of\ (Q_d)\}$ **do**
  for all $Q_i\ (i = 1...n) \in Q_d[u]$ **do**
    if $Q_i\ is\ Q_{LAV}$ **then**
      for all $Q_j\ (j = 1...i-1)$ **do**
        Ψ : *the set of subsumed, subsuming or equivalent concepts* C_s *of* Q_i
        Ω : *the set of* C_j *concepts obtained using* C_s *concepts of* Ψ *such as* : $Annotation\ (C_s) = Annotation\ (C_j)$ *and* $C_j \in Q_j$
        for all $C_j \in Q_j$ **do**
          for all $C_h \in \Omega$ **do**
            if $CorrespondConcept(C_j, C_h) \neq \Phi$ **then**
              $HasCorrespondent \leftarrow false$
              $K++$
              $Q_i \leftarrow C_i \cup r_h \cup C_h\{r_h\ is\ the\ role\ which\ links\ C_i\ and\ C_i\}$
              $Q_d[k] \leftarrow Q_d[k] \cup Q_i$
              $T[k] \leftarrow T[k-1]$
              $Addcorrespondence\ (C_j, C_h)\ in\ T[k]$
            end if
          end for
        end for
      end for
      if $NoCorrespondent$ **then**
        $Q \leftarrow Q - Q_i$
      end if
      $Else\{Q_i\ is\ Q_{GAV}\}$
      for all $Q_j(j = 1...(i-1))do$ **do**
        if $CorrespondSubQuery(Q_i, Q_j) \neq \Phi$ **then**
          $add\ the\ correspondence\ (C_i, C_j)\ in\ T[k]$
        else
          $Q \leftarrow (Q - Q_i)$
        end if
      end for
    end if
  end for
end for
$return(Q_d, T)$

1. Either the user uses the global ontology concepts only, in this case we obtain a Q_{LAV} query.
2. Or the user uses the global ontology concepts and the local ontologies properties, and in this case we have a Q_{GAV} query.

- **Query rewriting**: the general idea is that the mediator must obtain a conjunction of Q_{GAV} subqueries and a table of correspondence between the different subqueries. In the case of a query which contains more Q_{LAV} subqueries, it is necessary to reformulate all Q_{LAV} subqueries to Q_{GAV} subqueries to allow the construction of the correspondence table. To rewrite the Q_{LAV} to Q_{GAV} we propose the algorithm (see previous page).

The reasoning mechanism of *OWL*, helps our algorithm to obtain a set of Q_{GAV} and/or Q_{LAV} subqueries, which are equivalent semantically. The goal of the user query rewriting is to eliminate Q_{GAV} subqueries, which have not any relationship with other ones in the same query. *Function2* has as parameters two concepts C_i and C_j and gives, as result the role (if it exists), which links them. *Function1* returns two equivalent concepts or two concepts linked by a role. Our algorithm uses all global ontology concepts and local ontologies roles to provide a set of equivalent subqueries. For each subquery Q_i of the user query Q.

Algorithm 2 Function1: CorrespondSubQuery(Q_i, Q_j)

Entry:
$Q_i, Q_j : TwoSubqueries$, $G = \{C_{g_1}, C_{g_1}, ..., C_{g_n}\}$, $S = \{C_{s_1}, C_{s_1}, ..., C_{s_n}\}$, $R = \{r_{s_1}, r_{s_1}, ..., r_{s_n}\}$
Result:
$(c_i, c_j) :$ *The relationships between* Q_i *and* Q_j
for all $C_k \in Q_i$ **do**
  for all $C_h \in Q_i$ **do**
    if $C_k = C_h$ **then**
      $Return\ (c_k, c_h)$
    else
      if $CorrespondConcept(C_k, C_h)$ **then**
        $Return\ (c_k, c_h)$
      else
        $Return\ \Phi$
      end if
    end if
  end for
end for

- If Q_i is Q_{LAV} subquery, that means it contains only one concept; the algorithm selects concepts C_j into all previous subqueries Q_j of Q. So, we obtain the set of all candidate concepts.
- If the algorithm finds a correspondence between C_i and concepts C_j then, for each concept $C_j \subset \Omega$, it verifies if there is a correspondence between this concept and the concept C_i. If C_i corresponds to C_j then, it will be replaced by C_j. The result is a new rewritten subquery using the corresponding concept.
- If there is no correspondence, the concept C_i is excluded.
- If Q_i is Q_{GAV} subquery, that means it contains two concepts and a role, the algorithm search in previous subqueries of Q, a corresponding subquery. If there is no one, Q_i is excluded.
- The algorithm processes all subqueries into Q. After that it processes new rewritten queries as the initial query.

Algorithm 3 Function2: CorrespondConcept(C_i, C_j)

Entry:
$C_i, C_j : Two\ Q_{GAV}\ Subqueries$, $G = \{C_{g1}, C_{g1}, ..., C_{gn}\}$
$S = \{C_{s1}, C_{s1}, ..., C_{sn}\}$, $R = \{r_{s1}, r_{s1}, ..., r_{sn}\}$
Result:
$(r :$ *The Role, which links* c_i *and* c_j
if $r(C_i, C_j) \in Rorr(C_j, C_i) \in R$ **then**
  $Return\ r$
else
  $Return\ \Phi$
end if

2.3.2 Example

Our approach is validated on LCL relational data sources. The following query concerns all collaborators having an address in .Lyon. and a certain profile:

(Collaborator(x) ^ hasAddress(x; y) ^ Address(y)) ^ (Address(z) ^ hasAsTown(z; "Lyon")) ^
(Profile(p))

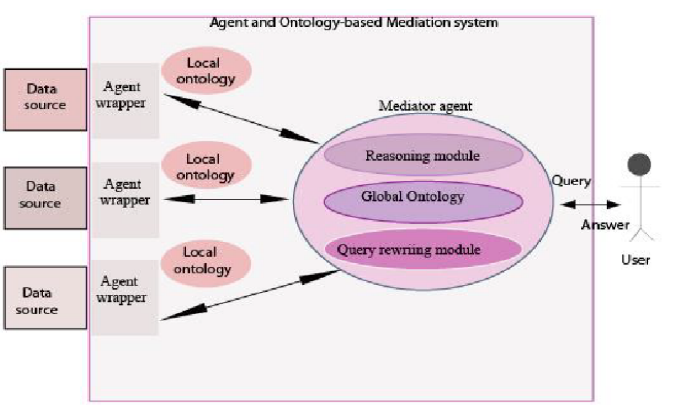
The mediator breaks up it into three subqueries. The two first are sent directly to the sources to be executed because they are linked by the concept Address and thus they can be recomposed by a classic join. However, the third subquery is not linked directly with the two previous subqueries. The mediator must find a link between Profile concept and concepts of the previous subqueries, if there is no link, it excludes this concept. In our example, the mediator must find a link between two concepts .Collaborator. and .Address., which is a property gathering directly these concepts with Profile concept. It can be also a property links Profile concept to another equivalent concept, subsumed or subsuming one of the two previous concepts: *Collaborator* or *Address*. In our case, *Person* concept is the concept subsuming *Collaborator*, and it has a link with *Profile*. The mediator must thus rewrite the third subquery *Profile(p)* into "*Person(r)* ^ *HasProfile(r,p)* ^ *Profile(p)*". It must add in his table of correspondence that *Collaborator* of the first subquery corresponds to *Persone* of the third subquery. It will join its result with the two previous one.

3. IMPLEMENTATION

To validate our approach, we develop a prototype that implements our architecture of mediation. Our system manages data sources independence and their distributivity. It manages also the interaction between global ontology and local ones during the query creation. Our prototype is based on Multi Agents Systems (*MAS*) since they are more adapted for distributed and cooperate environments. Our environment is distinguished from the existing integration systems by mediation by the fact that it enables to express descriptions of sources using the recent recommendation *W3C* for the ontologies description, which is *OWL*. It offers very interesting possibilities of descriptions and reasoning. Our objective is also to combine the power of expression and description of language *OWL* with the aspect communicating and cooperative Systems Multi Agents (*MAS*).

The mediator is an agent that communicates with other agents. It contains the global ontology and the rewriting module. The other agents are the sources agents. The process of query creation or rewriting is done by a dialogue between the agent mediator and the other agents. For the development of this environment, we used a certain number of tools: the ontology editor Protégé2000[1], the framework *JADE*[2] for agents, the framework *Jena*[3] for *OWL*-ontologies handling. Jena is a project of free source code developed by *HP* for the semantic Web. This framework offers us many advantages: it enables to have a uniform access for various ontologies because all information is stored in a *Jena* model. For the reasoning on *OWL*-ontologies, we use the free arguer *Pellet*[4], which allows to reason on the terminological part. Queries interface is presented in the form of a Java Web application based on the framework *Struts*[5].

Figure 2. Based-agent mediator architecture



4. CONCLUSION AND FUTURE WORK

In this paper, we have proposed a new approach of data sources integration based on ontologies in data warehousing environment. Our approach is based on a hybrid architecture, using a global ontology for the mediator and local ontologies for the sources. It is important to create global ontology starting from local ontologies, because this facilitates and improves the resolution of semantic heterogeneity between data sources. We defined a method of ontologies construction, a language which guarantees the correct treatment of queries , by allowing their expression in terms of global and local ontologies. We also proposed a strategy of query rewriting, which ensures the user query coherence, by eliminating concepts not linked with others of the same user query. We applied our approach of ontologies creation on the relational sources of the LCL.

These ontologies are used in our system of integration, and were useful in the phase of creation and rewriting of queries. Various perspectives are considered. Initially, completing the implementation. Then the adaptation of the system to the various sources of information. It will be necessary to automatize the ontologies conception method. To reach this goal, we think to use data mining techniques to generate concepts classes and relationships in a formal way.

The Value of Virtualization for Web Environment

Jean-Pierre Kuilboer, University of Massachusetts Boston, 100 Morrissey Blvd., Boston, MA 02125, USA
Noushin Ashrafi, University of Massachusetts Boston, 100 Morrissey Blvd., Boston, MA 02125, USA; E-mail: noushin.ashrafi@umb.edu

ABSTRACT

The success of many e-commerce applications depends on their reliability, robustness and security. Designing a web server architecture that advances these properties without compromising performance is a challenging task. Effective and efficient web applications demand a virtual operating environment which is autonomic, integrated and based on open standards. A virtualized environment makes the most efficient use of its resources by sharing resources and providing what is needed only when it is needed. This paper, examines the role of virtualization as a booster of IT utilization and as a driver of IT operational agility.

Keywords: virtual system, operational agility, web-server, integration, flexibility, operational access

1. INTRODUCTION

While the business world has recognized the need to be agile in order to survive a tumultuous and unpredictable environment, the IT industry has been busy through the 1980s and 1990s investing hundreds of billions of dollars into creating complex, underused IT environments. This costly infrastructure has not been able to cope with constantly changing needs and a perpetually evolving business climate. In 1993 Brynjolfsson (1) examined the productivity paradox and questioned the value of increasing IT investment without corresponding benefits. The debate is still ongoing and has produced inconclusive results (2) Following drastic cost cutting measures of the early 2000s, the market settled for flat budgets, increased workloads, and intense pressure to achieve more with less. Inputs have been affected by less extravagant resources requests and helped by the tumbling hardware prices while outputs are increasingly raised through better utilization of existing computing assets. For example IDC estimates that the overall server average system selling price fell by about 16% from 2001 to 2002 (3). Yet, with business increasingly conducted online and with advertising, sales, and support highly dependent on the internet technologies, high volume web servers are now subject to intense scrutiny. The upgrading of existing workstations, servers, networks, or storage by adding additional hardware to accommodate new requirements often competes with other business priorities and faces reluctance from the other business functions to fund perceived cost centers. Better integration and consolidations have been sought as a way to improve IT effectiveness and efficiency.

Moving forward involves the coordinated efforts to integrate technologies, processes, and people while satisfying business priorities. Innovative solutions are percolating through industries and reaching the end-users. One of the most discussed topics of the last two years has been virtualization. Virtualization is not a new concept; after going through a golden age in the mainframe environment in the 1970, a dark age brought by the underpowered PC era, and a long incubation period as computing power followed the Moore's law since the 1980s, it is ready for a comeback. Experts in the field prescribe a resource virtualization renaissance to address problems such as security, performance, and reliability (4).

The old utopia of integration and better utilization across departments, firms, and the business eco-system at large is now enabled, in part by a number of technologies under the umbrella of virtualization. Virtualization is a technology about workload consolidation to drive up utilization by subdividing the resources of modern Information Technology. It divides one piece of real hardware into numerous virtual ones, where each is managed separately and is more resource constrained than the original machine. The technology can be deployed as both hardware virtualizations through partitioning and through software virtualization where each application brings its own set of configurations on-demand.

2. DEFINITION

Defining a concept is always open to different interpretations. For example agility, reliability, and flexibility have many facets and are defined differently by diverse professional community. Singh (5) defines virtualization as a framework or methodology of dividing the computer resources into multiple execution environments, by applying one or more concepts or technologies such as hardware and software partitioning, time sharing, partial or complete machine simulation, emulation, quality of service, and many others.

It is easy to perceive how this definition applies equally well to the concept of time-sharing adopted on mainframe in the early years of computing and the latest trends on operating system virtualization allowing for example a single laptop/desktop to run Apple OS X, Linux or Microsoft Windows Vista.

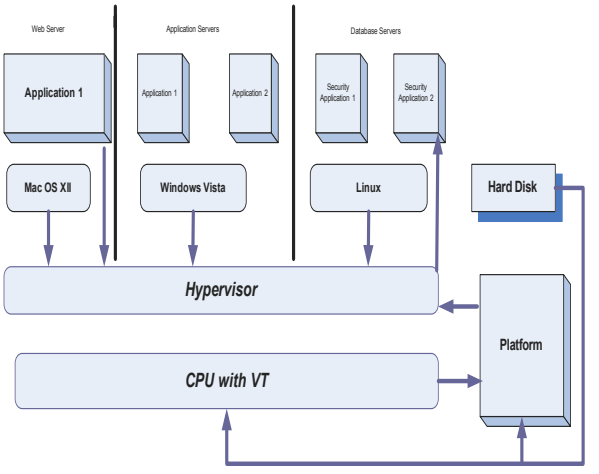
Figure 1 illustrates a generic e-business architecture with virtual servers.

3. DEPLOYMENT

While the hardware cost by itself was the main driver of virtualization in the 1960s, its recent incarnation is motivated by different factors. Standard IT budget could let both hardware and software stand at less than 10% of yearly IT expenditures. Thus the largest potential for added value is through better processes, people and utilization of existing resources. To achieve higher utilization, keep pace of changes in configuration, and maintain a high level of availability of systems (e.g. on a 24/7 e-business environment) virtualization should provide means to provision, deploy, and maintaining system using off band capabilities.

Chris Wolf (6) contends that virtualization is going mainstream. Virtualization is now considered a serious tool for production environment. The use of virtu-

Figure 1. Virtualization architecture



alization expands from its traditional use as a development platform to critical production environments.

Leading IT industry software companies are jousting to have a role in this evolution. Big players such as Microsoft, IBM, EMC, and HP are considering virtualization either as a hardware, software, or storage advantage and are acquiring smaller companies that have a head start in virtual systems. Microsoft, once reluctant to the idea has recently adopted a more flexible stance with its purchase of Connectix and the release of *virtual server.* Anticipating the market trend Microsoft acquired Softricity, a leader in virtualization and application streaming solutions, and promoted Windows Server Virtualization as a part of the new Longhorn platform using software code-named Viridian as a hypervisor by 2008. It will only be available on 64-bit versions of the server operating system, and similarly only available if the physical hardware supports either IVT (Intel's Hardware Assistance for Virtualization) or AMD-V (AMD's Hardware Assistance for Virtualization). The open source has also been working on evangelizing virtualization and the Xen project is the most widely distributed hypervisor coming through this avenue.

IBM (7) claims that today CIOs are making significant headway in *On Demand* Business and aims its virtualization to the idea of utility computing. They are leveraging their mainframe experience (i.e. They introduced the concept in the 1960s) and present virtualization and other on demand technologies to deploy services and to lower computing infrastructure and labor costs. They are supplementing their portfolio with acquisitions such as Rembo that provides the ability to maintain and deploy software images, automated installation and customization across multiple locations. The product has security features that can protect workstations used by multiple people in a virtualized environment by automatically "wiping away" operating systems and personal data after each use and re-installing clean software thereby addressing security concerns.

HP has similar ambitions. HP virtualization solutions will help an organization pool and share IT resources, lowering its costs by optimizing utilization while increasing agility, enabling the rapid response to changes in the marketplace. HP's offerings encompass three levels: element virtualization, integrated virtualization, and complete IT utility, which represent increasing business value and strategic importance to an organization.

EMC has been the major player with virtualization products it obtained from its 2004 acquisition of VMWare that provided a range of products including VMWare Workstation, GSX server software, and ESX server with its hypervisor directly installed on bare metal machine without additional host operating system (6).

In the enterprise storage domain, There is a great deal of excitement in the storage industry about the potentials of virtualization technology to reduce total cost of ownership (TCO) and increase utilization of existing enterprise storage systems. Virtualization leverages the connectivity that is provided by storage area networks (SANs), by creating an abstraction layer between the servers and the SAN. This abstraction enables the servers in the SAN to view the physical storage as a common pool of capacity. While forthcoming, this view has not yet been fulfilled for lack of complete solution across heterogeneous vendor products (9).

As the most established IT industry contenders push for its deployment, virtualization is deemed to become one of the dominant trends in the coming year and is one of the most exiting areas of IT. Virtualization is commonly quoted when associated with main aspects of IT. Primarily organizations use virtualization in conjunction with servers, operating systems, applications, storage, data center, and networks (10).

3.1 Web Server and Virtualization

Increasingly business is conducted online. With advertising, sales, and support depending on the internet technologies, high volume web server are critical to business continuity.

Efficient web applications demand a virtual operating environment which is resilient, autonomic, integrated and based on open standards.

A virtualized environment makes the most efficient use of its resources by sharing resources and providing what is needed only when it is needed. Not only are resources highly used, excess capacity can easily be used for new or unexpected needs.

Nowadays the success of many e-commerce applications, such as online banking, depends on their reliability, robustness and security. Designing a web server architecture that keeps these properties under high loads is a challenging task because they may conflict with performance.

3.1.1 Value of Virtualization for Web Server

Virtualization is directly relevant to a web server life cycle. From inception to replacement a web server (both physical and logical) is a prime candidate for virtualization. Web servers with dynamic content have particular attributes. They have an accelerated life cycle and need to be developed, provisioned, deployed, and maintained on a short timetable. In addition, in e-commerce, loads are difficult to predict and web servers located in the insecure Internet or a demilitarized zone (DMZ) are subject to intense security risks.

3.1.2 Consistent Platform

The virtual server software hides the physical hardware and creates a generic hardware platform that is consistent regardless of the physical server used to host virtual servers (11). This virtual platform makes the transition from development to deployment to operation seamless and alleviates problem of compatibility among platforms. Load testing can also be achieved by varying the resources allocated to the VMM.

For example VMware ESX allows you to control CPU time, memory space, network bandwidth, and storage bandwidth. Similarly in the Sun architecture, the Solaris Resource Manager software gives its administrators almost unlimited flexibility to assign and isolate resources to specific containers. Resource pools can be changed either manually or automatically on a rule basis.

3.1.3 Isolation of the Development Environment to the Production Environment

During development it is not rare to have systems crash unexpectedly. The partitioning of resources into secure containers will avoid side effect of the crash on the host system and concurrent VM. Virtualization will also provide almost instant recovery of an instance through a pre-staged process.

With the many generations of computer hardware reaching the market and constituting a complex mix of basically incompatible resources, virtualization in the server space hides the physical hardware from the virtual servers (12). The virtual server presents a generic consistent interface making restoring a virtual server easier.

3.1.4 Increased Automation

Manually tuning is often infeasible due to unpredictable loads and requests arrival rate. Computer systems, Web servers included, could use analytic performance models as a guide to dynamically adjust configuration parameters such as the number of active processes (13,14,15). Virtualization technology is well equipped to solve the problem by automating resources allocation initially and adjusting them based on simple rules sparing human intervention.

Automation of the provisioning, maintenance or recovery process is a problem derived from shifting cost from hardware/software to servicing systems and the unfeasibility to tend to individual server on a timely basis. For years firms such as Landesk, Softricity, and Rembo have been dedicated to such endeavors. Layering virtual solutions above the bare hardware makes the deployment of a number of virtual machines painless and will make the upgrade of virtual machine feasible with techniques such as in VMWare vmotion allowing to move a running virtual machine from one physical server to another.

3.1.5 Higher Hardware Utilization

One of the leading detriments of distributed powerful computers is their low utilization and stretched low ratio of server/administrator. Hardware costs, while not the burden it once was, still are remarkably ineffective. With rapidly advancing technology organizations wants to spare unnecessary hardware purchase, knowing that the next generation will bring more power at less cost. Running multiple virtual servers per physical host adds significant savings that can be better invested in other aspects of the systems.

While potentially using hardware resources to their limit could raise problems with power consumption, its planning is enhanced by better measurement of the existing assets.

Security. As distributed architecture and increasing dependence on the Internet has grown, security has become a critical preoccupation for most organization. Risks and threats are being addressed by virtualization by isolating environment. Before virtualization, control was often a tradeoff for agility. The only way to restrict exposure was to limit the number of applications running on a server,

which lead to reducing flexibility and increasing administrative operating costs. For example for a Internet service provider hosting traditionally was procured by either offering expensive dedicated physical servers or sharing through software running on a unified platform. In the first case customers could have managed service or simply take advantage of the co-location of a data center. In both cases administration still was difficult to control. In the second case restrictions were more stringent, limiting installation or use of customized software packages. With virtual servers this is no longer the case, allowing more freedom in a more robust environment.

4. PERFORMANCE

Performance has always been an issue in IT. In fact database, storage or network experts are quite obsessed with benchmarks and measurements. Processor manufacturers have measurements by MHz for particular architectures and recently they are moving to multi-core CPU in order to take full advantage of multithreading. In networking flows are monitored with bandwidth speed. In such competitive environment any overhead is looked at unfavorably. The concept of Virtualization may be a solution to performance problem, but while it is showcased as decreasing complexity and increasing flexibility, complaints still abound about machines running slowly when running emulation.

One solution is IBM's virtual machine model where each virtual machine is an exact copy of a real machine with limited set of resources, but often optimized by hardware support. High security is achieved through filtering by a control program of instruction potentially damaging to concurrent virtual machine (e.g. memory changes, storage modification). In the Java virtual machine the software provides an abstract layer sandboxing the real hardware from harmful access.

4.1 Sources of Overhead

With full virtualization or emulation the system is simulating a completely different computer chip. Virtual applications running on top of an emulated system incur a level of overhead which almost always lead to disappointment. Even with increasingly powerful processors and faster computer memories the interpretation of programs will be slower than running in their native form.

The additional sources of overhead include the reflection of exceptions and I/O interrupts to the virtual machines, support of virtual timers and clocks, and the translation of I/O channel programs before the VMM initiates I/O. When the application depends on time synchronization with actual time, emulation often leads to incorrect results or excruciating complex solutions (16).

The virtualization control software, called a hypervisor or virtual machine manager, imposes a performance penalty as it manages resources such as memory or input-output. Traditional CPUs were not designed to run a variety of operating systems simultaneously. With new set of processors the major CPU developers are trying to fix some of the performance penalties.

4.2 Improving Performance

Hardware facilitation of virtual machine monitors is seen as one avenue out of the performance bottleneck. Intel has recently launched its VPro line of microprocessor derived from the Vanderpool aimed at boosting both performance and security. AMD has competing line of Rev F processor with Pacifica and Presidio also emphasizing virtualization and security. IBM POWER5 systems combine enhancements to the processor architecture with greatly better firmware to increase its virtualization. The most recent microprocessors architecture with multiple cores is the response to demand for virtualization. This new approach has superseded the long time race for increase in clock speed. The first generation caught software vendors and organization by surprise and subsequently added the non-technical uncertainty in operating systems and applications licensing. Similarly to obtain full benefit from multiple core systems the operating system and applications should be multithreaded. Virtualization can also assign core to alternative operating environment, making full use of the processing capabilities. Since the market place has adopted compromises to the licensing issue ranging from a licensing per processor to reduced licensing cost per core.

5. PRACTICES

IT practitioners and researchers are by nature open to adopt latest technologies. Often burned by the initial hype of new technologies but also helped by subsequent ramping up of emerging techniques that make practice simpler or better. Although the market response to virtualization has been quite remarkable, as a practice, it is still in its infancy.

5.1 Future Trend for Virtualization

Currently processors such as IA-32 do not facilitate virtualization and the VMM has to work hard to get the benefit of full system virtualization. Without any hardware assistance virtualization running unmodified guest OS do not get the performance expected. Para-virtualization offer a remedy to performance at the detriment of requiring either special hardware or running a limited set of guest OS customized to run over the particular VMM. The most common Para-virtualization systems are Xen (17) and Denali. A side effect of the customized OS is that they support and provide a limited set of generic devices to the guest OS. This limits the use of most innovative new I/O devices for network or storage support.

The best hope in the near future is the upcoming generation of processors from Intel, AMD, or IBM. Providing the VMM with the possibility to run at ring -1 or have the necessary hardware assist for the common privileged instructions which would otherwise have to be trapped and simulated by the VMM. Similarly experience with virtualization and a healthy competition among future OS providers will lead to more robust guest operating systems, thereby alleviating some of the risks associated with potentially errand commands.

5.2 Security Impact

Virtualization is often perceived as having a positive impact on computing security. The isolation of applications within their own space, transparency, and segmentation of resources under a tight centralized control are potentially confusing to the attacker and make the system more reliable. The network fingerprinting by hacker is more difficult as real resources are opaque to a scan. In an environment with non expert end-user, open Internet access and traditionally less robust platform, virtualization add one layer of indirection which make virus or rootkit infection more difficult. As previously stated recovery from disaster is rapid.

On the other hand integration and aggregation of the pool of resources in a data center offered by virtualization(18) is attractive from an operation point of view but will makes the target more attractive to hackers. In a scenario where the Virtual Machine Monitor is infected by a rootkit, the attacker would be able to take control of a vast array of organizational resources and would go undetected by conventional methods. A VMM running on ring -1 infected by a rootkit would present a virtual virgin interface to virus/malware checker and applications file integrity would also be duped. Similarly virtualization will have to be more coordinated with security tool providers to solve real questions. For example of IDS/IPS rely on physical host data to check for traffic patterns when not relying on signature based detection. With virtualization and knowing where the data is coming from is more indeterminate. Other security issues will arise when n layer system could be based on MAC addresses or IP addresses for authorization. Example could be a Web Server talking to an Application Server talking to a Database Server for dynamic queries. Aside from performance issues of a virtual system, the transition from virtual to physical and back to virtual could become quite confusing especially if virtual machines are dynamically moved from server to server.

The scenario could either lead to consolidation in the market or lengthy alliance process making adoption of best of breed system more problematic.

6. CONCLUSION

Almost after 80 years since virtualization was introduced by IBM (19) around 1927, IT people entertain the same concern that machine utilization percentages are an important measure of data processing management competence. Virtualization across a number of information technologies has made a comeback with a transition from mainframes to distributed systems. Virtualization has rapidly been adopted by small to large organizations. Particularly when mass customization is to be applied to systems, virtualization offers the benefit of central control and the flexibility to have stakeholders have a system adapted to their needs.

Usability Analysis of Concept Maps as Knowledge Discovery Tools

Abdus Sattar Chaudhry, Nanyang Technological University, 31 Nanyang Link, SCI Building, Singapore 637718; E-mail: aschaudhry@ntu.edu.sg
Lee Yee Fuang, Nanyang Technological University, 31 Nanyang Link, SCI Building, Singapore 637718

ABSTRACT

The potential application of concept maps in knowledge discovery is examined using a framework comprising usability, learnability, and task & technology fit. An online survey and follow-up interviews indicated that teachers and administrators at the Ministry of Education in Singapore were comfortable in using concept maps. They expressed that concept maps should to be integrated with search engine tools. Usability analysis suggested that enhancements in functional design of concept maps, improvement in quality of contents, and regular updating of resources were important to attract mass usage of concept maps.

INTRODUCTION

Concept maps are one of the most notable methods for representing relationships between concepts. Using this premise as a basis for further investigations, many researchers have begun to analyse various applications of concept maps, including organising and presenting information to aid knowledge discovery. Concept maps have their roots in education. The idea was grounded in the sound learning theories of Ausubel (Novak & Gowin, 1984) who posited the importance of prior knowledge in learning new information. The fundamental idea is assimilation theory where learning takes place by the assimilation of new concepts and propositions into existing concepts and prepositional frameworks held by the learner.

Concept maps are tools for organizing and representing knowledge that include concepts; usually enclosed in circles or boxes of some type; and relationships between concepts or propositions; indicated by a connecting line between two concepts. Words on the line specify the relationship between the two concepts. The basic graphical elements are nodes and links, which are organised using common patterns, such as branches, arrows, groups, notes, lists and so on. Nodes (points, vertices, icons, and so on) represent the concepts, and links (lines or arcs) represent the relationships between concepts. Figure 1 portrays an example of a simple concept map.

Concept maps are representations of a set of concepts and their relationships and concept mapping is a technique for representing knowledge or information in graphical form by listing relevant concepts and then drawing lines between them to represent their interrelationships. When two or more concepts are connected, a meaningful statement or proposition is formed. Propositions are statements about some objects or events in the universe, either occurring naturally or constructed (Cañas et al. 2003). They are also called semantic units, or units of meaning. Typically a concept is expressed using one or a few words with labelled links. These links are lines or curves with phrases that connect concepts to form relationships. A linking phrase is used to join concepts to form a meaningful proposition, which is a basic unit of knowledge according to the theory of meaningful learning. Nodes in a map do not carry any information. Arrowheads in the links specify directions which determine the logical connection of the relationships. Curved lines can be used when straight lines cannot be used to link the nodes, thus providing the flexibility to avoid rearrangement. Another important element of concept maps is Cross-links. Cross-links make explicit relationships between or among concepts in different domains within the concept map.

Much research on users' perceptions of concept maps has been done in the context of the tool's application in education. Santhanam and Dawson (1998) investigated the effects of concept mapping to students taking subjects in genetics. Uzuntiryaki and Geban (2002) examined concept mapping instruction in the science subject by comparing it to traditional instruction. Potelle and Rouet (2003) studied the effects of concept maps on low and high knowledge students.

Figure 1. An example of a concept map

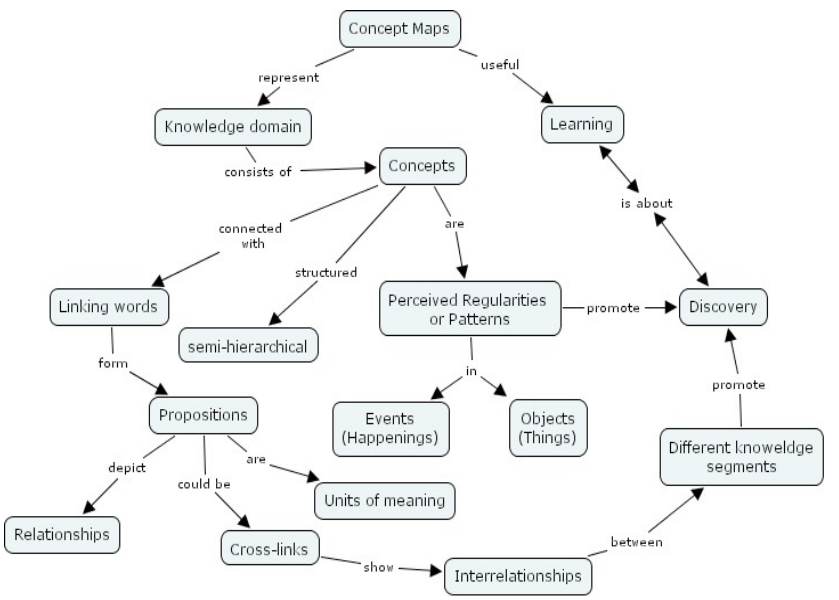

Figure 2. Concept map on teachers' professional development

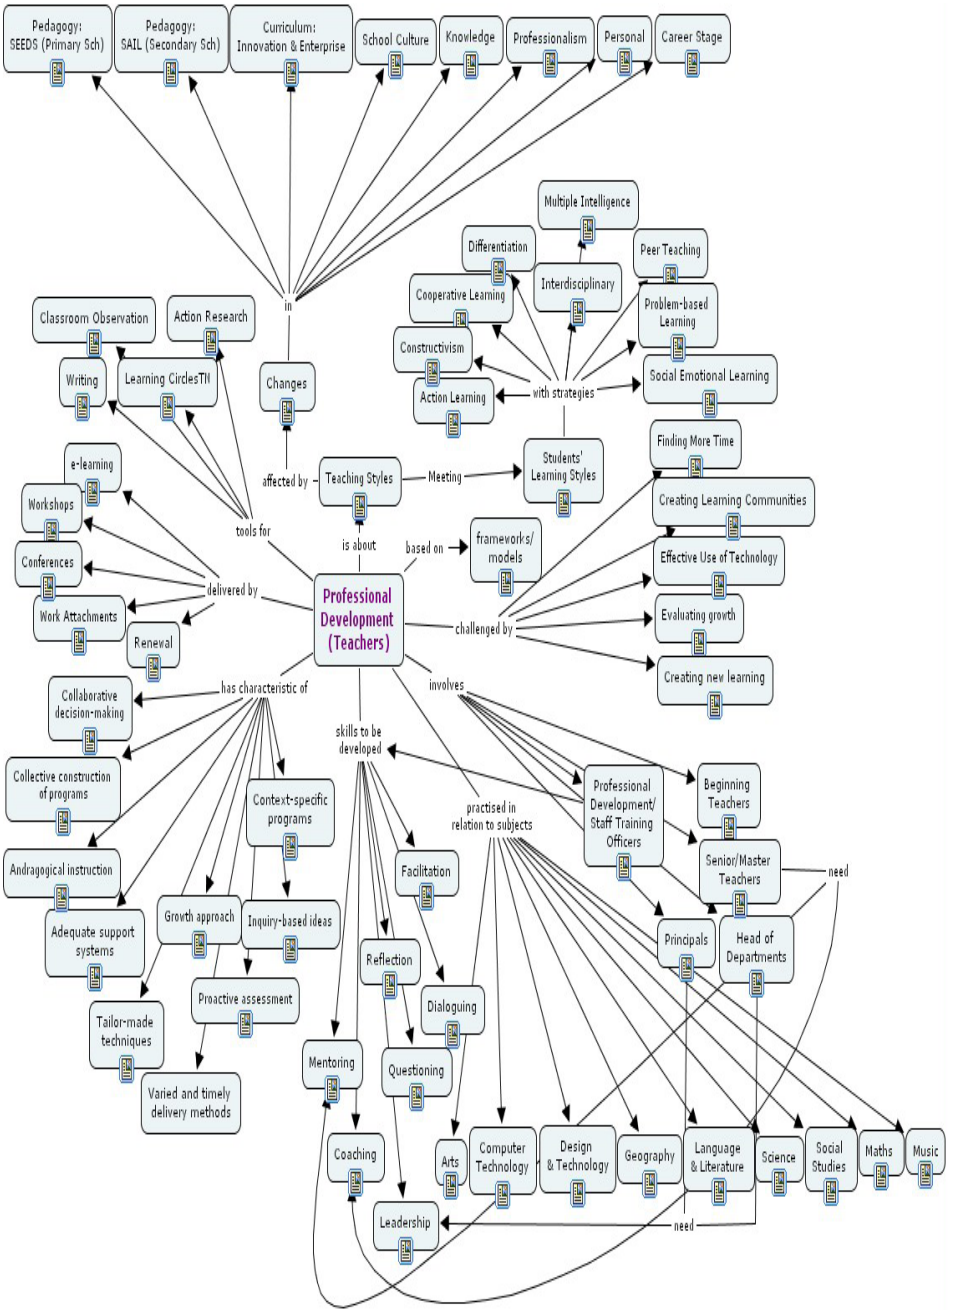


Research on users' perceptions of concept maps in the knowledge management field is not very prevalent. Much of it deals with knowledge elicitation and knowledge construction. Ford, et al. (1996) described a nuclear cardiology expert system called NUCES in which concept maps were used for knowledge elicitation and navigation. Leaker et al. (2003) described an approach to support experts as they built their own knowledge models of a domain. Mularz and Lyell (2004) explored the integration of concept maps and semantic web technologies for the capture, visualization and navigation of knowledge in support of the lifecycle of knowledge management.

This study was aimed at investigating the potential application of concept maps in knowledge discovery. Teachers' professional development was chosen as the central topic for developing a prototype concept map to be used for review. Relevant concepts were derived from selected information repositories and reference questions received by READ@TN (Teachers Network's information resource centre at the Ministry of Education in Singapore). The prototype concept map covered a set of terms and their relationships, which also took references from Educause taxonomy (http://www.educause.edu/Browse/647), ERIC Thesaurus (http://eric.ed.gov/) & Library of Congress Subject Headings (*LCSH)*. Relevant documents were categorised and linked to the established concepts and their associations. User feedback on the usefulness was of the concept map was sought from a group of teachers. This domain-specific concept map was implemented to function as a finding aid.

A framework comprising usability, learnability, usability, and task & technology fit was used for review of concept maps. Based on this framework, several parameters were identified to perform usability analysis by two main groups of stakeholders: teachers and administrators. It served as a map of the knowledge for a community-of-interest in the area of continuing professional development for teachers.

DATA COLLECTION

Original concepts for the map were derived from the writings of Diaz-Maggioli (2004) and Zmuda (2004). These concepts were subsequently presented to a team working on teachers' professional development for comments and amendments. *CmapTools, (*an open source tool by the Institute for Human Machine Cognition (IHMC), University of West Florida) was used to construct the concept map. It allowed easy publishing of knowledge models in concept map servers and enabled concept maps to be linked to related concept maps and to other types of media. Linking phrases were added to the key concepts on the preliminary concept map to express the relationships among concepts. This was followed by adding cross-links to illustrate the inter-relationships between concepts in different areas or sub-domains on the map.

A total of 157 documents housed by READ@TN were linked to the relevant concepts. These included mostly documents in Microsoft Word and PDF format. In-house web pages and quality information from external websites were also linked to the concept map. Most concepts had one or two documents attached to them to give the respondents a flavour of what they could expect on the concept maps. The concept map was subjected to several rounds of reviews by senior education officers. Changes to the structure and contents were made prior to implementing the prototype on a hosting server (http://www.100free.com) at http://leeyf.100free.com. The availability of concept map on the Internet provided ease of access for participants. They could experience the working of the concept map at their convenience. On the basis of their experience they subsequently responded to a questionnaire survey (which was also web-based). Figure 2 show the final concept map constructed.

Thirty education officers and five administrators participated in the online usability survey. The participants were invited to view the concept map after a demo was arranged to introduce the concept map to them. Eighteen participants signed up for the follow-up interview (three senior administrators, nine senior education officers and six junior education officers).

FINDINGS

Usability

Three parameters including ease of use, effect, and satisfaction were used to review the usability aspects. Feedback from participants on these parameters is reported in the following section.

Ease of Use

Ease of use of the concept map encompasses the notion of simplicity and accessibility of finding and discovering information. Seventy-seven % participants reported that the concept map presented to them was easy to use. However, a fair portion of the respondents felt that, when the map was first presented to them, they were overwhelmed by the concept map and had difficulty understanding and using the map.

Twenty-nine % indicated that navigating the concept map was easy. All respondents were able to follow the logic of the navigation. Most participants were able to appreciate the navigational logic of the concept map. A large majority was able to easily navigate the concept maps for relevant information.

Sixty-eight per cent participants supported the proposition that concept maps improve the information searching output; while 14% did not agree that concept maps added value to the information searching experience. Despite the differences in opinion, all participants acknowledged concept map as a useful tool to aid knowledge discovery. They expressed that concept maps could provide guidance and direction to the information search process.

Satisfaction

Satisfaction is derived when a user is able to perform his/her information search task successfully. About one-third participants strongly supported the acceptance of concept maps while almost two-third expressed continuing interest to use concept maps in the future. When asked which group of Internet users could effectively use concept maps to search for information, 69% felt that concept maps would be accepted in all strata of Internet users; 71% felt that concept maps could only be accepted by novice Internet users while an astonishing 94% agreed that seasoned Internet users were capable to effectively use this finding aid. Forty-nine % felt comfortable using the concept maps. A further 31% were confident; only 17% experienced some stress while using concept maps to find information. The findings revealed a moderately high level of satisfaction and acceptance to the use of concept map in the context of teachers' professional development. The fact that participants had indicated strongly their desire to use concept maps shows a high level of confidence within them in this information search tool.

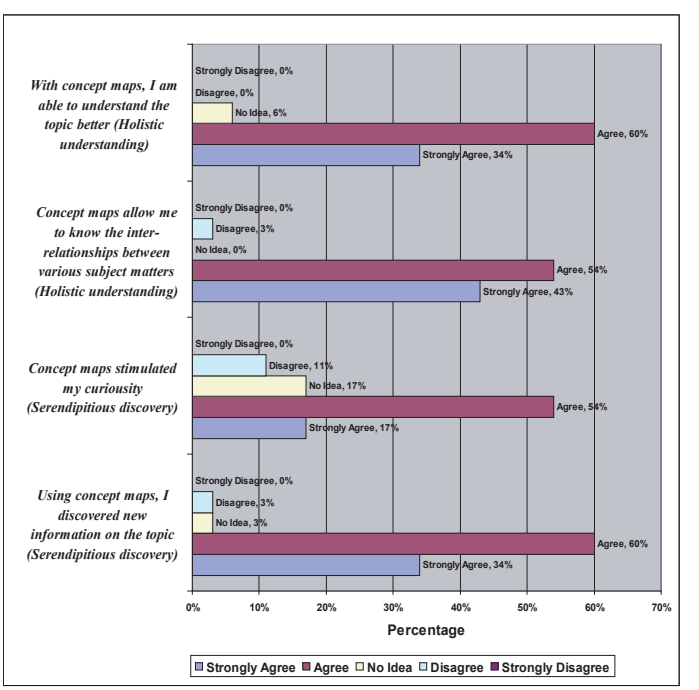
Effect

The effect of concept maps is tied to performance and outcome of the information searching exercise. There is a good spread of responses on the effectiveness of concept maps compared with other online search tools such as Internet search engines, Internet directories, library online catalogue. Forty-two % participants maintained that concept maps were more effective while 32% felt otherwise. More than three-quarter (77%) either agreed or strongly agreed that their overall experience with concept maps was successful and positive. All respondents felt that concept maps were able to guide them in their information search. They expressed full confidence in concept maps reflecting that concept maps provide a sense of purpose in finding information. However, statistical analysis suggested that concept map alone was not able to replace the role of other search tools like Internet search engines (e.g. Google, MSN Search) and search directories (e.g. Yahoo Directory), as less than half believed it could do so.

Learnability

Learnability refers to the ease of learning the system's functionality and gaining proficiency to complete the search for information. Our analysis attempted to review whether the concept map as an information search system encouraged holistic understanding and supported serendipitous discovery. We also reviewed if the concept map was able to enhance a broader understanding of concerning concepts surrounding each topic. When the concept map was developed, we expected that with the inter-relationships between various sub-topics (concepts) teachers would be able to gain breadth in their subject of interest. In the review, we wanted to

Figure 3. Learnability aspects of use of concept maps



find out whether the concept map demonstrated the ability to arouse interest on related concepts to facilitate the discovery of new information domains. Figure 3 displays the trends among participants on these learnability aspects.

Analysis of responses of participants indicated a good potential of concept maps on the various learnability aspects. In terms of holistic understanding, 94% participants agreed that concept maps provided them an overview of the topic and helped them understand the topic better. All respondents either agreed or strongly agreed that concept maps allowed them to explore the inter-relationships between various subject matters. In terms of serendipitous discovery, 71% of the respondents indicated that concept maps stimulated their curiosity. Almost all respondents asserted that they were able to discover new knowledge through the use of concept maps.

Task & Technology Fit

As the study looks into the learner's ability to interface with concept maps to find information, the issues on Task and Technology Fit (TTF) comes into play. Various elements of TTF were of concern in this study. These included the following parameters:

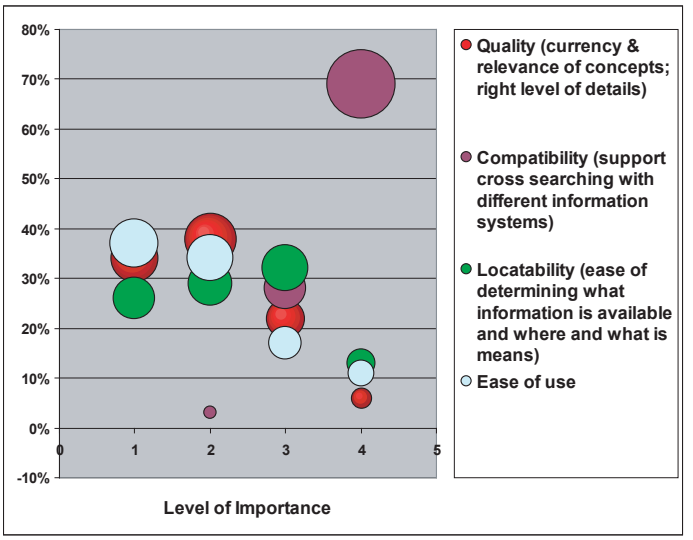
- Quality of concept maps
- Ability to locate information
- Compatibility with other information searching system
- Ease of use

The participants provided input on the importance of the various parameters. Ease of use and quality were viewed as the most critical elements, ability to locate information was ranked third, and majority viewed compatibility as least important. The issue of compatibility was not a serious concern to the respondents in their information finding. Figure 4 shows the level of importance attached to concept maps.

The study highlighted several interesting points in terms of TTF. Most participants pointed out that the quality and the ease of use of finding aids take precedence over other considerations. It is therefore vital that concept maps be designed taking these understandings in view. Despite concept maps' ability to enhance the searching experience and facilitate knowledge discovery, they are not widely used among educators in Singapore to find information, as discovered in this study.

In terms of human-computer interactivity, concept maps provided good interactivity between the system and the users. This was supported by more than half of the respondents. Again, with strong evidence from respondents that there was considerable interactivity between concept maps and the user, one could infer that concept maps are useful tool to facilitate knowledge discovery. In terms of functions, most of the respondents felt that concept maps were most suitable to search for well defined items. About one- third also recognized that concept maps were able to perform accidental discovery of useful information. Sixty-two % felt that concept maps made information finding easier, while only 6% disagree. About 45% agreed or strongly agreed that they could save time looking for information using concept maps, compared to occasions where they had to use Internet search engines and directories. About 30% disagreed with the earlier group. On the basis of these findings one can safely conclude that concept maps could complement other web-based search tools in providing users with a complete information finding abilities.

Figure 4. Task & technology fit



DISCUSSION

One of the strengths of concept maps is their facility to provide meaningful orientation and visual bearings to support information search through the use of nodes, labelled-links and cross-links. The participants of this study were able to appreciate this. An interviewee quoted *"What I liked about concept maps was that it gave me a birds' eye view of the information I was looking for. I get a good macro perspective of the topic and associated ones"*. Another said "*the links are especially helpful to let us know relationship between various subjects. I could never get such things from Google or Yahoo. The cross links added another useful dimension on the information, which is very valuable when I need to explain the subject to my course participants."*

The cross links value-add to the information finding process. They support the users in navigating the concept map. All participants agreed that the links contributed to their smooth accessing of relevant information. However, placing links on concept maps is a double-edge sword. Some interviewees have cautioned not to over-cluster and impair the smooth navigation of the concept maps by inserting excessive links.

More than 80 % participants claimed that concept maps had stimulated their curiosity; and almost all indicated that they were able to understand the topic better and discovered new information on the topic. As one interviewee cited *"Until I see your concept map, I didn't know I know so little about professional development"*. Another said *"What pleasant surprise! I learnt so much on professional development in just a few minutes."*

The source of purposeful learning is context stimulated by genuine interest and curiosity (Sylvie, Andrew & Jacques, 2001). While involving themselves in this study, many participants gained practical insights into teachers' professional development, which allowed them to view their profession in a wider perspective. A significant number of participants also pointed out that they experienced unanticipated findings of worthy information. In fact, one could see concept maps as a valuable platform for individuals to mine for concepts and ideas to further their understanding on specific topics.

When asked to rank factors most important to them in using concept maps to find information, the quality of concept maps came in second, behind ease-of-use. Users demand for prevalent and high-relevant concepts; and constantly updated information. Currently, concept maps are not able to match the vast amount of information one could access via Google or Yahoo. It is therefore advisable to look into the integration of concept maps with other common search tools to optimise the search outcomes.

Participants repeatedly stated that the noteworthy information search results were obtained through using both concept maps and search engine complementarily. For instance, they used the key words on the concept maps as search phrases on the search engines. They also used the articles available on the concept maps to trace other relevant documents on search directories. The challenge, as a result, is to establish a meaningful integration between concept maps and the various search tools to offer the best finding experience to users. It is with such an agenda that the greater potential of concept maps can be unleashed to support information discovery.

Functional design quality, or ease-of-use, was voted by the online survey participants as the most important characteristic of concept maps. This study surfaced three important areas of users' concern in the design of concept maps, namely over-crowding, interactivity and customisation. Over-crowding was flagged as a concerning issue when 37% of the online respondent felt that they were overwhelmed when first exposed to the concept map. Subsequently, the study found that a small group of individuals might need certain mental orientation to effectively comprehend the working of the map.

Some participants recommended implementing a "maps-within-maps" design concept and avoiding excessive cross-links as resolutions to avoid over-crowding.

But when discussed during the interview sessions, some interviewees warned that "maps-within-maps" would not be appealing to people who wanted fast information and it might put these users off. They added that it was good to be able to see all concepts at one glance. A suggestion was also made to technically code the concept map such that it allows scaffolding and hide details not needed. It might be appropriate for the concept maps designer to further conduct a design acceptance testing and seek feedback from intended users to arrive at an optimal design.

There is also a need to enhance the interactivity of the concept maps with users to increase the effectiveness of the map on information discovery. Many valuable suggestions were received from participants regarding this aspect. Among the suggestions are facilitating manipulation to the design by authorized users, providing templates and instructions to perform the manipulation, forwarding online comments and clarifications to concept maps designer/administrator and setting up communities of practice via online chat-room. In fact, more can be done to make concept maps even more dynamic, for example, allowing users, instead of just authorised personnel, to create concept maps. This is a "collaboration" feature which can be supported by using appropriate tools.

An important factor influencing the acceptance of concept maps is users' *competence* to handle their search. For instance, online chats may be included to enhance interactivity; font and colour setting may be made available to provide a higher level of customisation; and integration with other search tools may be developed to produce better search outcomes. There are also some concerns over who would be responsible for creating the maps, how the maps and related resources would be maintained and at what cost. These are all valid and practical concerns which are seldom dealt with in research papers.

Managing users' *expectation* is perhaps one of the most important considerations in gaining their acceptance to concept maps. An interesting feedback from a survey respondent reads *"there is a need to establish the link between what the concept maps could provide, and what each user actually needs. I feel that concept maps provided the "generally targeted" information (that caters to general needs) but not the "specifically targeted" information (that caters to each individual)."* Indeed, specific features and finding capabilities must be clearly demonstrated and communicated to users to ensure a full appreciation of what concept maps can genuinely offer.

CONCLUSION

This study has indicated that teachers are impressed with the simplicity, user-friendliness and usefulness of concept maps as an information finding tool. They seemed to be enthusiastic to adopt the tool in furthering their knowledge discovery efforts and to recommend it to their colleagues. However, concerns expressed by participants of the study did suggest that concept maps cannot be used in isolation. Drawing on their unique capabilities, there should be meaningful integration with other search tools to bring about higher search outcomes and richer resource discovery experience. The ongoing focus is therefore not to compare concept maps with other search tools but explore avenues to marry them. The study also indicated that while concept maps are generally accepted as useful information search tools, there are still many areas for improvement. To attract mass uses of concepts, the functional design needs enhancements and content quality of concept maps need to be constantly updated. Concept maps as knowledge discovery tools are desired to be promoted among different communities of practice through easy to use infrastructure support.

Implementation Differences Between DSS/BI and Other Types of Information Systems

Efrem G. Mallach, University of Massachusetts Dartmouth, North Dartmouth, MA 02747; E-mail: emallach@umassd.edu

ABSTRACT

This paper considers concerns that arise in the implementation of TPS and those that arise in the implementation of DSS/BI systems, noting differences between the two. Important management focus areas in implementing TPS include low-level user training, extensive user testing, change management and cut-over strategy. With DSS/BI, attention should focus on data quality, higher-level user training, having an executive "champion" and adapting the system to its users. Managers approaching an implementation project must be aware of these differences, as should academics who write textbooks or who teach from textbooks that do not cover them adequately.

1. INTRODUCTION

No business information system is of value unless people use it to achieve business objectives. An unused system may be an impressive monument to technology but cannot justify the use of corporate funds. Therefore, no matter how well a system was designed and developed, it must be put to use before its goals can be achieved. That is the role of *implementation*.

However, not all systems are created equal in this regard. The critical success factors for implementing one type of system are not necessarily the same as those for implementing a different one. While this may seem obvious when stated, there are two practical problems:

1. Research tends to focus on one type of system in isolation. It does not compare the conclusions of one study, for one type of system, with the conclusions of research on other types of systems.
2. Even what is known about implementation of different types of systems has yet to make its way into the textbooks used to teach future practitioners and users of IS.

2. DEFINITIONS AND DISCUSSION OF IMPLEMENTATION

Implementation, as used here, is the process of preparing an information system for use. Kwon & Zmud (1987), in their seminal paper on the subject, define it as:

...an organizational effort directed towards diffusing appropriate information technology within a user community.

A similar definition comes from a popular introductory MIS textbook (Laudon & Laudon 2004):

...all organizational activities working toward the adoption, management and routinization of ... a new information system.

Both these definitions focus on organizational aspects. By the time implementation begins, technical work is (or should be!) complete.

This is not the only possible definition. The problem arises from different views of when something is ready for use. The major dichotomy is between the user and vendor communities. Vendors see a system, or whatever system component they sell, as ready for use when it's ready to ship to customers. User organizations see it as ready for use when it has been customized as needed, its databases fully populated, and its client software installed on individual users' desks. The user's implementation starts where the vendor's ends. The vendor's view includes more technical activities than does the user's. Attempts to resolve this conflict, without offending anyone who considers a given activity to be part of implementation, result in defining it to cover virtually everything after drawing data flow and entity-relationship diagrams—a "definition" so inclusive as to be nearly meaningless.

We will use the user view here, not the vendor's. This reflects our focus. It is not a value judgment of "rightness" or "wrongness."

Accordingly, we consider areas such as database preparation, system conversion, training, and other activities that occur after programming and database development are done.

The questions this paper addresses are: Are there significant differences in these areas between (a) decision support and business intelligence (DSS/BI) systems and (b) other enterprise-level information systems? (These latter will be referred to as "transaction processing systems," TPS for short, recognizing that this term often has connotations of older technology which are not intended here.) If there are, what does this imply?

The distinction here is between systems that update the organization's operational database and those that use it to support management activities but do not update it. The former are typically used at lower levels in the organization to carry out routine activities; the latter are used by managers and knowledge workers to support decision making and related higher-level tasks. The terminology *DSS/BI* versus *TPS* is a convenient way to express this but is not meant to restrict the discussion to specific technologies. Modern integrated enterprise-level systems such as ERP, CRM and SCM increasingly include DSS/BI capabilities that would have been provided by separate packages not long ago. Even when this is the case, however, the two sets of functions have different user communities and thus different implementation requirements. Phrasing the question in terms of modules of an integrated system, rather than separate systems, would change some of the discussion but would not affect either the underlying issues or the conclusions.

3. IMPLEMENTATION OF TPS

The stages of implementation for Enterprise Resource Planning systems (ERP), a prime example of a large-scale, enterprise-level TPS, have been studied extensively. Over 15 years ago, the implementation of its Material Requirements Planning (MRP) predecessor was studied in (Cooper & Zmud 1990). Rajagopal (2002) discussed a model for ERP implementation. Lai (2006) provides guidelines for successful ERP implementation, based on experience in China.

An example of TPS implementation is given in (Mandal & Gunasekaran 2002). They discuss a large (6000-employee) Australian wine producer and exporter's implementation of SAP R/3 ERP software. The system focused on online inventory control. In addition to the customization that any SAP installation requires, a separate bar-coding system was also developed and integrated with SAP. Key aspects of implementation here included:

- The system was tested extensively by its prospective users, with formally maintained lists of open issues and timing to complete all tasks.
- Shop floor personnel, many of whom had never before used a computer, were trained on the new system before its roll-out.

- Additional on-site training and support was provided after roll-out.

Some employees, whose jobs had not previously required them to use a computer, felt their new job requirements justified additional compensation. This was handled by providing overtime payment during the learning phase, returning to normal pay levels once computers were no longer seen as anything special.

Muscatello & Parente (2006) iterate the importance of training as part of ERP implementation, noting that "future employees will have to have a significantly greater skill set than previous employees," and also noting the frequently-mentioned need to be willing to modify business processes in order to achieve a better fit to the technology in use. While this is not an implementation issue *per se,* the need to adapt to changed business processes as well as to new technology can complicate the human aspect of the implementation process.

4. IMPLEMENTATION OF DSS/BI

Implementation of DSS/BI[1] systems has been studied less than that of TPS, with (Kivijarvi & Zmud 1993) being one example with a Finnish focus. The state of research was summarized in (Mora et al. 2002). Little has been reported that provides much practical guidance or contrasts DSS/BI issues with those that arise for TPS.

Fortunately, specific DSS/BI implementation cases have been reported. We can draw meaningful conclusions from them. Summarizing a conference at which executives reflected on their BI implementation experience, Havenstein (2006) reports that the two key implementation issues in this sphere are data quality and executive buy-in. These are less critical with TPS: data quality, while not unimportant, is more of a technical and clerical issue than a managerial one. Executive sponsorship may improve the acceptance of business process changes that a TPS requires, if it requires any, but those who are to use a TPS will ultimately do so because their jobs require it—not because they are inspired by the CEO's vision. Their attitude toward using it may be important as regards morale and motivation, but the usage itself is not optional if they want to keep their jobs.

An example of a DSS implementation that raises some of the same personnel issues that typically arise in the TPS context is provided by (Botha & Atkins 2006). In that study the target users were New Zealand farmers, not corporate managers and knowledge workers. One reason for the system's poor adoption was overestimating user capability vis-à-vis system complexity. This example is, in some ways, the exception that proves the general rule. Managers and knowledge workers in an office environment will usually be more computer-literate than this user community.

5. CONCLUSIONS

There are significant differences between the implementation of TPS and of DSS/BI systems. It is important for those who manage such implementations, and for those who will teach future managers their trade, to be aware of them.

These conclusions involve *focus*. It's not that low-level computer training (to use the first bullet below as an example) is always totally unnecessary with DSS. Sometimes it is, perhaps for an unusual user community (e.g., the New Zealand farmers of (Botha & Atkins 2006)) or perhaps for a small number of users within a group that is more typical overall. However, organizations have finite resources. They must allocate those resources where they will do the most good. Our purpose here is to point out (to continue with that example) that low-level training tends to be an important focus area with TPS, but not with DSS/BI.

5.1. With TPS:

- **Low-level computer training** is mandatory. TPS users may not have used computers before, though this is changing as teenagers flock to the Web, e-mail, online chat and personal networking sites. Even if they have used computers, they often do not have the professional sophistication to adapt easily to a new information system.
- **Extensive user testing** is essential, as the system carries the operational database which drives all business activities. Errors may not be detected until they have caused havoc down the line. (Testing by developers can never be complete since they only test for situations they can foresee, and which the software was therefore designed to handle. Users create situations that developers did not foresee.) DSS/BI output is reviewed by humans before it is acted upon, providing a level of protection against erroneous outputs.
- **Change management**. Users of an existing TPS often see their value to the organization as tied to their expertise with that system. They know no more about the new system than a new hire would, perhaps less. First- and second-level user management must be careful to show them that the new system will be to their advantage, or serious negative consequences may result. This responsibility cannot be passed off to technical support staff or "bucked up the ladder."
- **Cut-over strategy**. Since it is impractical to use two TPS in parallel[2], and is likewise impractical to give users a choice as to which they will use, it is necessary to move an organization systematically from the old to the new. Conversion approaches are beyond the scope of this paper but can be found in (Palvia et al. 1991), among other places.
- **Executive sponsorship** is important, as noted above, to the extent that the new TPS imposes cultural changes (including major business process changes) on the organization. This was common when organizations moved to their first ERP system but is becoming less of an issue as more and more companies have had one for a while. New TPS may involve usage changes, such as going from "dumb terminals" to PCs or to a Web-based user interface, but increasingly leave the processes behind the interfaces alone.

5.2. With DSS/BI:

- **Data quality** is more of a concern. DSS/BI systems often use data warehouses whose inputs come from multiple systems, some of them perhaps incompatible with others. Using data developed with inconsistent assumptions, based on different time periods, structured in different ways, etc., can lead to problems even if each individual system is internally consistent and (in its own context) fully correct. This raises broad data governance issues, often for the first time.
- Training is needed, but at a higher level. Today's knowledge workers are comfortable with technology in general. They need to be brought to a comparable comfort level with the technology of DSS/BI. As a Holland America Line BI project manager was quoted in (Songini 2003), they need to "spend the time to get to know the data." This is *information* literacy, not computer literacy. "Getting to know the data" would be a waste of time for most TPS users.
- Having **an executive "champion"** is vital. Whereas an airline check-in agent cannot issue a boarding pass without the appropriate computer system, a buyer can in principle decide how many blue shirts to order by "gut feel." Such users will adopt a DSS/BI system more readily if the executive suite uses it, or at least visibly backs its use.
- For similar reasons, it is more important to **adapt a DSS/BI system to its users** than the other way around. Xu & Quaddus (2005) point this out, suggesting that a pilot project permits this without impacting the majority of users. While this may result in a roll-out procedure that resembles pilot conversion of TPS, the motivation for using the pilot approach is totally different.

6. RECOMMENDATIONS

6.1. For IS Faculty

Information systems textbooks, in discussing implementation, do not differentiate by type of system[3]. To them, implementation is implementation. However, as we have seen, this is not the case. It falls to IS faculty to make up for deficiencies of the text in use, including this one. If a faculty member thinks implementation is worth more than the briefest notice, he or she must point these differences out. (I personally think it's worth more than a brief notice, since most introductory MIS students are not MIS majors, and implementation is an area where users play a big part.)

6.2. For IS Textbook Authors

Many IS textbooks spend a great deal of time discussing alternative system development methods: SDLC, various flavors of prototyping, modern variations such as agile development, RAD and extreme programming, etc. The descriptions are followed (in the better books) by discussions of where each fits best. That's good as far as it goes, but it doesn't go far enough. Implementation methods should be treated the same way: by discussing alternatives and when to use each.

6.3. For IS Practitioners

Most experienced practitioners intuitively have a good idea of what to do in this area, as the conference report of (Havenstein 2006) shows. One danger is that, in

reading the "one size fits all" recommendations of textbooks and perhaps hearing them repeated in an MBA classroom by an instructor with little real-world experience, experienced practitioners can become convinced that their intuition is at fault when it isn't.

However, we can *and must* say more than "get 20 years' experience, then trust your gut." Professional papers are published, in part, so that practitioners will learn from them. They must recognize, in reading a paper about system implementation, that its conclusions are probably limited to the type of system being studied. They generalize in finite ways, if at all, to others. Their limitations may be even narrower than system type, as in (Lai 2006) where the author cautions about generalizing his (already ERP-focused) results beyond China, or (Kivijarvi & Zmud 1993) where the limitation of the sample to Finland may limit the validity of extrapolation beyond its borders.

ENDNOTES

1. The term *DSS* is older and more common in academic circles. The newer *BI* (often credited to Gartner's Howard Dresner in 1989) is more often found in industry. While one can argue that DSS is a broader concept that subsumes BI as well as other types of IS, that distinction is not important here. They share the characteristics—user community, nature of input data, use of output, etc.—that affect implementation.
2. Parallel conversion was an industry staple 30+ years ago. Lamentably, it persists in most MIS texts. It is impractical when both old and new systems are online and fundamentally flawed when input timing can affect output. This is discussed further in (Mallach 2006).
3. The author has examined over 25 MIS and systems analysis texts from major publishers over the past few years. Twenty are listed in (Mallach 2006). Others appeared since that paper was written. This statement applies to all, without exception. Listing them here would serve no purpose other than increasing the length of this paper's reference list.

A Proposal of Integration Between IT Governance and Business Balanced Score Card

ABSTRACT

Useful management models have to work with the most important aspects in a modern organization: environment, market analysis, innovation, learning, operation, diffusion, reengineering and added value. These terms are related in a supply demand schema under a dynamic systems based frame, because the supply demand schema is the best way to understand and simulate the real daily operation of every organization. The New Economy behavior is not possible to replicate or simulate with classical theories based on internal organization characteristics or considering modern concepts (as innovation, for example) in a more or less isolated way. These concepts (environment, market analysis, innovation, learning, operation, diffusion, reengineering and added value) cannot glue any old how, they have to be absorbed in a modern system based context. A new conception of how to measure the value added is supported by this new business dashboard. Nowadays it is impossible to further delay the preponderance of Information Economics and Information Systems as an essential frame to understanding the enclosing of our organization in a marked leaded by concepts such as: effectiveness, integration and globalization. The name of this new conception that joins the best of IT Governance proposal with the best of Business Balanced Scored Card idea is IG4 (Information Governance Four Generation Model).

1. INTRODUCTION

There are many models to analyze the companies' management and strategies (Balanced Score Cards, EVA, etc) under a business perspective. Under the system and technological point of view there are other theories to plan and manage the systems in the companies such as IT Governance, Balanced Score Card for IT, System Strategy Planning and the Cobit initiative. These two perspectives, business and systems, are glued together in the current theories throughout alignment of IT with business (strategy alignment and operational alignment). However in the Modern Economy and under the powerful Internet, the private companies and the public organizations are completely dependent on the Information Systems: With hundreds of thousands of transactions the functions that are not covered by systems are impossible to accomplish in the daily company business. In this scenario to align systems with business is not enough and it is necessary to integrate both approaches, business and technology, in only one approach: the IG4 model. The IG4 model substitutes alignment for integration.

As is depicted in figure II, the IG4 model tackles the system perspective and the business perspective under an applied orientation. The SBMII model covers the disciplines of IT Governance, Systems Strategy (and its sub-component of System Strategy Planning) and Balanced Score Card. The IG4 model has a high management and strategy orientation due to this; it does not support the level of detail of the operation level. However the IG4 model considers the best analysis characteristics of these models: the CMMI model (process oriented) [Ahern, 2004], the Software Project Dynamics (software develop oriented) [Abdel-Hamid, 1991] the reengineering theories (process oriented), activity based costing (costing oriented) and Lean thinking (quality oriented) [Womack, 2003]. There are other studies based in different variables to measure the IT effectiveness [Scott, 1995]. These variables are more focused in levels of IT expenses (training, number of PC, etc) obtained by surveys than an added-value method and a complete review of the organization throughout their systems. In conclusion, none of these studies gives a complete response to the IG4 objectives thought in giving integral answers to New Economy requirements.

In addition, in recent periods, there has been a tendency to consider innovation and change as hackneyed fashion and the solution of every organization income problem. It is impossible to attend any conference or company meeting in which innovation is not a central theme. During the last decades, there were different fashions that rocked the organization department's boat: reengineering, ERP

Figure 1. Conceptual model of the modern organizations

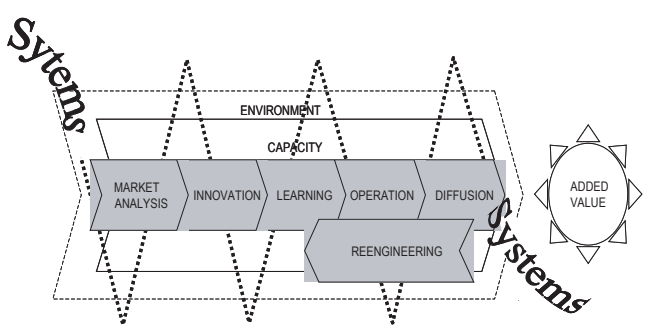

Figure 2. The fit of SIMIII between technology and business

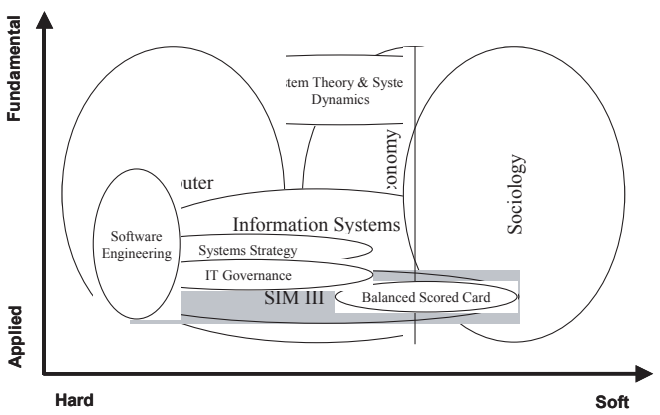

(Enterprise Resource Planning), Internet, just in time, globalization, activity based costing, etc [Davenport, 1998]. After the dot com bubble burst, there has not been a new global movement that gives opportunities for quick growth and this makes innovation a recurrent conversation topic. However, to consider innovation in plain theories or in an isolated way is not giving good results [Sull, 2000]. There are several examples that confirm this fact:

- It is difficult to find clear and convincing relations between the research capacities (innovation) and the chances to create added value [Bryjolfsson 1993, 1996] [Hitt, 1996].
- In the last years, some sectors such as telecom and banking in order to improve results have preferred mergers or purchase strategies better than innovation strategies as different studies showed [Olazabal, 2002]. When telecom applied the 3G only considering a new innovative and powerful technological opportunity, the results were not as desired.
- Some areas have reached maturity (technological maturity, functional maturity and contents maturity) and sometimes only innovation is synonymous with new niches but with very low customer margins (in Internet history several examples can be found) [Johnston, 2003].

The present outlook follows a logical evolution; the industrial based management gave way to marked centered management, after that social centered management took its place, which presents a virtual and collaborative focus [Kaplan 1996, 2006]. But social models mainly give responses to important aspects such as leisure activities (chatting, peer to peer, etc) or transmission of ideas and information (wikis, blogs, etc). However, they do not cover the complete market and do not entirely explain the supply / demand based economic market. A framework is needed which conjugates more elaborated strategic ideas under the dynamic system glue [Forrester 1961, 2003] (as depicted in figure I these concepts are not isolated).

The general formula of this proposal is based on the general business formula "Demand = f (Supply)" and with more detail:

Value Added = Value Added Systems Depended + Value Added No System Depended

This research concentrates on the Value Added System Depended, where:

Value Added System Depended = f(Value Added in the Business by Systems) + f(Value Added in the Operations by Systems).

This formula marks the three views of the model: Value View = Business by Systems View + Operations by Systems View as is depicted in the figure III. If it expands all of this terms in a formula:

Value added + Operation effectiveness + Welfare = f (Environment, Market Analysis, Innovation, Learning, Operation, Diffusion, Reengineering) + f(Systems Quality, Operation, Maintenance, IS People & Organization, Development & Acquisitions)

The IG4 model is at the same time a model, a philosophy, a tool and a method. The measure unit is always the systems or its subdivisions (subsystem, functionality, characteristic, etc).

1. The IG4 model is supported in a methodology that allows in a clear and systematic way to analyze our systems: this is because IG4 incorporates human, technological and business considerations.
2. The IG4 model is at the same time a tool. It is supported in a simulating tool that allows implementing a continuous and dynamic process (it supports added-value and time delays) following the supply demand cycle of our organization and through continuous feedbacks about our systems. Because of this dynamic simulation tool the IG4 model is supporting the functionality of Strategy System Planning.

This paper is a summary of a study supported by three complementary validations (the complete model is showed in the figure V):

Figure 3. Three interrelated views support the whole model

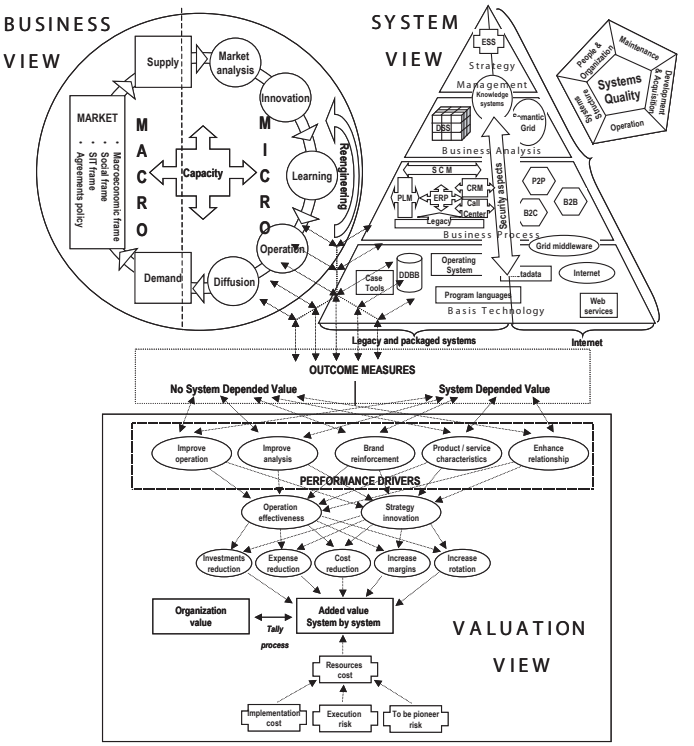

Figure 4. A comparative (benchmarking) scenario supported in four stages

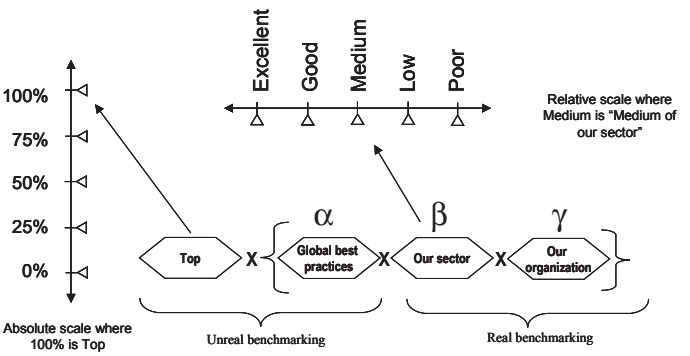
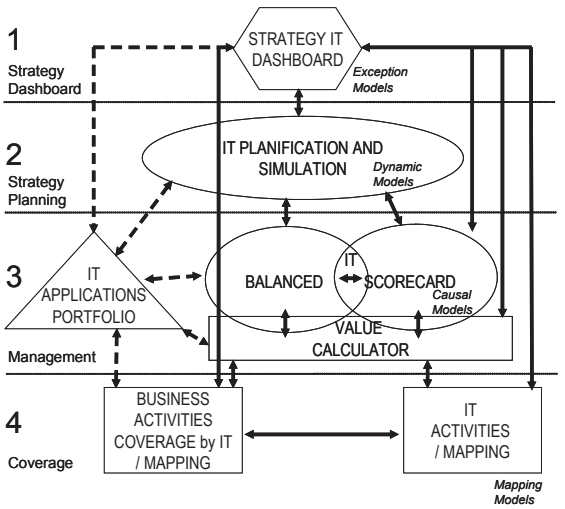


1. A review of the variables that have affected the IT industry history.
2. An empiric validation through a survey to project directors of thirty large system projects.
3. A review of the general admitted theories that mainly involve the IT frame.

2. THE MAIN CONCEPTS OF THE MODEL

In this paragraph the main conceptual points of the IG4 model are analyzed in more detail: Added value, environment, capacity, diffusion, reengineering, innovation and all of them glued with the concept of systems: Beginning analyzing added value. It is good to analyze the goal of every activity before building our balanced scorecard: Improving the **productivity**? Improving the **added value**?

Figure 5. Complete view of the information governance model (IG⁴)



Improving the organization's **profit**? It is necessary to combine the three concepts: productivity, value added and organizational profit, to analyze something as amazing as all around New Economy [Bakos, 1992] [Hitt, 1996] [Boehm, 2000]. Furthermore these concepts split the New Economy and allow us to separate and analyze concepts as different as a blog (value added disguised as journalism), a portal (productivity generated by the direct connection among different agents) and a complete solution such as MySAP.com (economic profit by manual tasks reduction and better management tools).

The productivity concept, as a relation between entry and exit economic flows, is supported in the elimination of intermediate steps (operation effectiveness). In today's Information and Knowledge Society where the communication and the knowledge are not always moved by direct economic transactions, to consider the concept of added value (it incorporates welfare) to the final users is critical. The third element is the organizational benefit that is the forgotten subject among the three concepts. This concept has to play a key role in the New Economy and by extension in the 21st dashboard [Porter 1980, 2000]. Figure II shows a more detailed approach of the three interconnected perspectives of the model: system view, supply / demand view and valuation view. The three views together are a powerful tool to analyze every 21st century organization.

What part of the company value is due to systems and what part is due to no-system causes (properly business)? When the value of a petrol company drops in the stock market it may be because the oil reserves are decreasing (no-system depended) or the management is not good (in large part system depended). In general when a telecom company is losing customers is because the quality of service is not enough good (in large part system depended). As systems are critical, the new balanced scorecard have to split the system depended added value from the no-system depended added value. For example, system analysis explains the large amount of mergers that happen nowadays when the organization cost structure is susceptible to resizing techniques. One main component of the last bank-merging wave is to save money by centralizing staff departments and sharing the costly IT systems investments. Just as a man is flesh and blood, the companies are systems and software. In this environment the role of the Information Economics (the economics of the overall information and knowledge industry) in the Economic theory is essential and has to be supported in the organization by an adequately balanced scorecard [Masuda, 1975] [Senge, 1990] [Lane, 1998].

If we want to decrease the digital divide we would make easy that public and private organizations to be catalysts of this change. The big problem is when it understands by New Economy only: to simplify the value chains, to reduce costs and where every intermediate expense or elaborated service is eliminated. With this simple format, Internet is not a useful means for the companies to expand their supply, and more than an opportunity it is a threat that destroys the entry barriers of new competitors. In contrast, what are the citizens of 21st century demanding about the New Economy? The citizens of 21st century where the life quality and the leisure are key concepts will not understand in medium and long term an Internet reduced to "single window" and they hope developed services that mix the aptitudes of traditional economy with the easiness supported by the New Economy.

21st human activity is completely influenced by the **capacity** possibilities (part of the environment variable). Hollywood movies and traditional cultures made to believe that the individual or the team effort is a decisive ingredient of success factor. In contrast, the global businesses are not a baseball game or a romantic script. The individual gave the baton to the team and in the modern organizations the team has to give the baton to the environment (where, the team and the individual are a modest part of this environment). For example the operating system market treats with products of more than 20 million lines of code (knowledge capital) where the social tendencies, the existence of clusters, the business models and the public opinion, all together, are essential to achieve the success. Because of that in the modern models, environment and capacity are not the border of our organization, are a crucial virtual part of our organization. Just as important or more important than the internal organization are the alliances, the links with the research centers or the connection with the icebreaker users (multinationals, young people, trend creators, universities, etc). The real organization edge is not the physical organization: there are no outsiders there are artificial walls.

The number of variables to value in an organization is huge (experience, sector, maturity, synergies, scale economy, technology, etc) and without a contrast method (feedback), all the benchmarking methods are worthless. In addition, the benchmarking techniques do not allow huge innovation because they are forcing the sectors to be similar and because of that, to link the organizations with the research centers is essential as is depicted in figure IV. The stock market is the only benchmarking scenario where there are contrasted rules and thousands of people assuring the data quality. As the same the stock market is a contrasted bank of value information, it is necessary to go down one step and to establish a "stock market" of contrasted ideas where a real match between the stock market value and the ideas that support this value is created.

The New Economy products are neither cars nor suits [Toffler, 1980]. The **diffusion** effect of new fashion in clothes or a new car model is easily assimilated by the market that only has to adapt to a new style or new features. In contrast, the information technologies bear important changes that affect the business models, not forgetting the user interface and finally legislation. In this situation, carefully determining the diffusion effect and the methods to accelerate it, becomes critical [Amabile, 1989]. Furthermore, it has to add two always over sighted adjustment effects to the innovation effect: reengineering and integration as part of the re-engineering. The New Market innovation produces without breaking new very complex products and services that require the essential **process reengineering** to obtain simplified solutions accepted by the marked. The adjustment process goes together with the internal learning and the external diffusion to complicate the process because it plays in the time delaying the implantation of optimized new business models. To try in a few years to deploy the third generation telecommunication wave (UMTS) over technologies not completely established and full of future (SMS, IP voice, bluetooth, 2,5G, etc) led to the failures that took place. In the real market, reengineering is not a second level concept or nineties old fashion because it interferes deeply in the actual knowledge and investment intensive organizations. Another mistake is to think only in technological language: the concept that beats the technology market is not the strategy or the functionality; the concept that beats the technology is the systems [Stewart, 2003] (systems = business + technology + human).

The New Economy as **innovation** has a part of adventure and a part of consolidated value added [DeBono, 1972] [Drucker, 2002]. In the Old West, the people who invested in gold mines assumed high risk and questionable earnings but for the people who invested in fashion jeans companies (the jeans that the miners wore), the profits were lower but have lasted to the present. The history is repeated and the balanced scorecard of the New Economy has to support both realities: adventure, innovation and risk and complement of the classic value chain contributing to new business opportunities and ways to face new business lines.

In 19th century, the companies were capital and workers. In 20th century, the companies were departments and business units. In 21st century, the companies are **systems** (more than software) [Folgueras, 2006]. Nowadays, important elements of companies are: links with other companies, business models, internal processes, analysis tools, accumulative knowledge, communications with stakeholders, etc [OECD, 2000] [Digital Planet, 2004]. In a big company with hundreds of thousands

of transactions, models that are not supported by systems are worthless. The only possible organization structure is the system structure. Aspects you cannot measure you cannot improve. But if you cannot automatically treat (systems) neither can you measure or operate them, because the concepts of balance scorecard, systems and value added are related [Forrester, 2003] [Abdel-Hamid, 1991].

3. CONCLUSIONS

There are many models to analyze the companies business and strategies (Balanced Score Cards, EVA, etc). Under the system and technological point of view there are other theories to manage the systems in the company such as IT Governance, Balanced Score Card for IT, System Strategy Planning and the Cobit initiative. These two perspectives, business and systems, are glued together in the actual theories by alignment of IT with the business (strategy alignment and operational alignment). However in the Modern Economy and under the powerful Internet, the private companies and the public organizations are dependent on the information systems: With hundreds of thousands of transactions the functions that are not covered by systems are impossible to accomplish in the company business. In this scenario aligning systems with business is not enough and it is necessary to integrate both approaches, business and technology, in only one approach: the IG4 model. The main model contributions of the IG4 model introduced in this paper are.

1. To follow the supply / demand schema as the real organizations do.
2. To use dynamic tools in a supply / demand schema facilitates the process simulation when there are several interconnections with feedback and when the value is the value of several years.
3. To control system by system the system depended value from no-system depended value (properly business).
4. To make up added value with economic concepts (profit and productivity) and no direct economic considerations (welfare and leisure).
5. To understand the virtual organization: In an intensive capacity (knowledge and investments) market, the environment and its agreements are crucial and are part of our virtual company.
6. To consider properly the innovation: Five connected terms (market analysis, innovation, learning, diffusion and reengineering) are focused in a changing environment, only one in the traditional cost vision (operation).
7. To avoid the Tower of Babel: The added value is the common language of the cause-and-effect relationships (together with other outcome measures and performance drivers). It allows tally processes.
8. To control the time is as important as control de value added, because the terms external diffusion and internal learning are critical.

This article asks if the classical management reports, which are based on many possible combinations of concepts such as strategy, human behavior, internal processes or technologies are optimum [Mintzberg, 1994]. With the balanced scorecard proposal introduced in this article, behind the glasses of environment, market analysis, innovation, learning, operation, diffusion and added value, it is not seeing the bubble burst and it is only seeing huge opportunities adequately planned in time. If the balanced scorecard incorporates these concepts, we will understand and predict the New Economy.

ABSTRACT

The purpose of this paper is to argue that communication technologies play a non-neutral rather than passive role in formulating both student and teacher identities in verbal and non-verbal social exchanges. Further research into group interaction within peer-based collaborative tools is required to determine how these cognitive tools can lead to higher levels of learning in students. For many years, educators have been exploring ways to improve teaching and learning practices with the help of technologically innovative tools. Cognitive tools used in collaborative learning environments support the interactive construction of knowledge during problem-solving processes as they promote students' adoption of an active learner mode. Increasingly, the social aspects of our e-learning environments are being used to inform how educational episodes should best be designed to take full advantage of the cognitive powers that students possess. While conceptual understandings are foremost to learning, we also need ways of expressing outwardly the representation of our concepts. Language, tools, symbols, and cues are the ways we objectify and communicate our concepts in everyday life inside and outside our classrooms. By furthering our understanding of various e-learning cultures, cues and contexts, we can ensure that the best possible educational scenarios emerge.

INTERNET COMMUNICATION TECHNOLOGIES AND NETWORKED LEARNING: IDENTITY FORMATION THROUGH SOCIAL EXCHANGE

Although instructors have always been faced with diversity in their classrooms, computer-mediated environments offer an even greater range of complex and multifaceted learning environments because of the shifts in geographic and temporal boundaries, as well as the lack of interpersonal social cues in interpersonal communication. Understanding this type of communication within networked learning environments is worthy of further research as trends toward flexible learning environments (e.g., tele-learning; m-learning; e-learning) are physically separating teachers and learners between and among each other. A physical separation affects interpersonal communication within the learning process in various ways. For example, monitoring student cues is important with respect to the provision of opportunities to gain understanding of teaching effectiveness (McAlpine, Weston, Beauchamp, Wiseman, & Beauchamp, 1999).

Building on prior knowledge, making thought processes more explicit, and developing organized knowledge structures are areas instructional psychologists have been intent on exploring for many years. Researchers have replaced a static notion of the learner with more dynamic process-oriented theories. Constructivist theories, although wide and varied, stress the social and active aspects of learning environments and advocate teachers acting more as guides than authoritarians. The learner's social and cultural interactions with the environment and the individual's self-regulation in terms of what they might attribute to their successful or unsuccessful learning experiences have become more pronounced. Weiner's attribution theory, for example, draws attention to attributions the learner makes explicit through self-monitoring, as well as the attribution cues that the teacher passes on to the students. When there is a separation between and among students and teachers, and communication technologies are used to facilitate the learning transactions, interpersonal communication processes change. These communication process changes, referred to by Moore as transactional distance, can alter expository teaching so significantly that new ways of teaching and learning are required (Kanuka, 2001; Moore & Kearsley, 2005). A good place to start in understanding these communication process changes is to begin with what we know about face-to-face interaction.

PSYCHO-SOCIAL RELATIONS TO PHYSICAL PROXIMITY

One way Burgoon, Bonito, Ramirez Jr., Dunbar, Kam, & Fischer (2002) derive an understanding of interdependent message exchange is by defining the properties of face-to-face interactions through the senses. Varying degrees of cognitive, emotional, and behavioural engagement, the ease or smoothness of the interaction, and perceptions of connection, receptivity, similarity and understanding all contribute to a rich, interactive experience. Nonverbal behaviours such as physical proximity, eye contact, touch, body orientation, and body lean enable sensory immersion and create psychological closeness as well as physical and social presence (Coker & Burgoon, 1987; Mehrabian, 1981; Short, Williams, & Christie, 1976). Two people in close proximity automatically share a heightened sense of mutual understanding, connection and common ground. In a study examining proximity, Burgoon *et al.'s* findings revealed that, "Actual or perceived distance can indeed weaken people's task engagement, their sense of connection with one another, and the credibility they ascribe to task mates" (p. 671). Further research is identified as being required to focus explicitly on what nonverbal cues might be available to augment verbal information and how such cues are actually utilized in the interaction process.

At a basic level, face-to-face interpersonal communication requires speakers and listeners to co-ordinate both content and process (Clark & Brennan, 1991; Whittaker, Brennan & Clark, 1991). Effective coordination of communication involves the construction and maintenance of shared beliefs, requiring listeners and speakers to infer and monitor each others' understandings, in addition to their attitudes and motivation. Much of our personal interaction in face-to-face classroom settings, which communicates our beliefs and intentions, requires paralinguistic and non-verbal cueing in addition to our individual utterances (Baron, 2000; Gram, Kanuka, Norris, 2004). Thus, both paralinguistic cueing and utterances infers a shared context that includes both linguistic and physical contexts (Grosz & Sidner, 1986), as well as the management of the conversation, or 'process coordination' (Whittaker, 1995). Individual utterances alone do not adequately convey beliefs and intentions (Allen & Perrault, 1986; Searle, 1990; Whittaker, 1995).

The importance of interpersonal communication on collaborative formations has been demonstrated by research. Research has revealed, for example, that people who are in close proximity to each other are more likely to communicate frequently. This, in turn, results in effective collaboration (see, for examples, Whittaker, 1995). Indeed, research has revealed that physical proximity has a significant impact on social and organizational knowledge, and we are more likely to not only be more familiar with the work of those who are close (e.g., an office next door; sitting in a chair next to us), but we are also more likely to respect the work of colleagues who are in close physical proximity (Kraut, Fish, Root, & Chalfonte, 1993).

CUEING IN COMMUNICATION AND MEDIATION

Theories on the impact of the non-verbal communication assert that paralinguistic cuing is critical to the management and coordination of the conversational content (Clark & Brennan, 1991). Non-verbal communication theories maintain that interpersonal communication requires cognitive cues (i.e., head nods and visual attention) (Clarke & Brennan, 1991; Clark & Schaefer, 1989), turn taking (i.e., head turning, posture, eye gaze) (Kendon, 1967) and social cueing (facial expression) (Argyle *et al.*, 1974). The latter, social cueing, is of particular importance in the formation of learning communities as this element of communication includes negotiations, bargaining, and conflict resolutions (Whittaker, 1995) – elements essential to higher level thinking and learning skills (Kanuka & Anderson, 1998). Further, research has shown that when we have access to visual information, our interactions are more personal, less argumentative, broader in focus, and less likely to end in deadlock (Reid, 1977; Williams, 1977).

There is also evidence that suggests text-based communication can be highly disruptive in the turn-taking process (Collett, Kanuka, Blanchette, & Goodale, 1999). Aspects fundamental to interpersonal interactions that require timely feedback, switching speakers, and clarifications are reduced, or absent; in text-based communications. Conversational turn-taking in this environment is also considerably more time consuming than face-to-face interactions making the communication system suitable for certain types of communication such as information exchanges which do not require fast, dynamic and animated exchanges. In teaching learners to learn, they become members in a community. They learn the social rules of that community, but also learn how to solve problems not just according to rules, but through good interpretations. Good interpretations involve the conceptual understanding of the roles and ways of interacting with a community. Producing and evaluating designs and policies is conceptually integrated with the person's identity as a member of the group (Clancey, 1995). Tools, activities and signs are representations which also give us more direct access to the conceptual understanding inherent within a particular group. While cognitive approaches provide analyses of the ways a learner's knowledge is structured, situative approaches provide analyses focused on the actions of individuals with material and informational systems in relation to one another. Cognitive studies which examine social interactions provide us with important clues about how communication can be used in e-learning environments to motivate students and stimulate their thought processes for deeper levels of learning and increased critical thinking skills.

COMMUNICATION BREAKDOWNS IN E-LEARNING

Garrison, Anderson, & Archer (2000) present a model of community inquiry to distance educators that acts as a guide for the optimal use of computer conferencing transactions. They identify three elements essential to an educational transaction in discourse environments: cognitive presence, social presence, and teaching presence. These authors note that group cohesion is a strong indicator of social presence and that the quality of text-based discourse is heightened when students see themselves as part of a group rather than as individuals. With regard to how social presence develops, Garrison *et al.*, assert that salient factors in participants' developing and sharing social presence through mediated discourse is created through familiarity, skills, motivation, organizational commitment activities, and length of time in having used the media (p. 95). They also note, similar to Burgoon *et al.* (2002), that participants in computer mediated communication environments develop compensating strategies in the absence or reduction of visual cues (Garrison *et al.*, 2000) and adapt technology to their communication practice (Burgoon, *et al.*, 2002).

Since simple information exchanges can be of limited benefit in student learning, distance educators remain committed to eliciting higher levels of thinking in asynchronous text-based communication environments. Jonassen (1997) proposed that cognitive tools were best used as reflection tools to amplify, extend, and even reorganize human mental powers in order to help learners construct their own realities and complete challenging tasks. Cognitive tools using asynchronous communication were thought to provide students with the opportunity to develop argument formation capabilities, increased written communication skills, greater complex problem-solving abilities, and increased opportunities for reflective deliberation (Abrami & Bures, 1996; Garrison, Anderson, & Archer, 2000; Hawkes, 2001; Winkelmann, 1995). Discourse models developed by Garrison *et al.* (2000), as well as Gunawardena, Lowe, and Anderson (1997) sought to explain how students involved in online discussion should move from lower to higher levels of learning. However, in practice, researchers such as Angeli, Valanides, and Bonk (2003), Gunawardena and Zittle (1996), Gunawardena, Carabajal, and Lowe (2001), Kanuka and Anderson (1997), and Thomas (2002) all found evidence documenting how student discussions remain primarily at lower levels of thinking due to an absence of challenging, debating and/or defending between and among students (Kanuka & Rourke, 2005). In testing Garrison *et al.'s* (2000) model of critical discourse, Kanuka and Rourke (2005) determined that students remain mostly in the exploratory phase (phase two of four phases). Similarly, in tests of Gunawardena *et al.'s* (1997) model, students remained in the lower two phases of sharing and comparing information, and discovering and exploring dissonance.

Further research into instructional strategies used in computer-mediated collaborative environments would provide even more empirical evidence of how these cognitive tools are able to promote higher order and critical thinking skills. To discover how higher levels of thinking might best be achieved in online discourse, Rourke and Kanuka (2005) conducted a study to analyze various types of instructional methods which incorporated discussion activities into their design. Specifically, within highly structured instructional methods (e.g., Webquests, Debates, and Deliberative Inquiry) findings revealed a denser concentration of discussion postings in the higher phases of critical discourse models. One explanation for these findings refers to discussion activities which explicitly require students to contend with one another's assertions. Research has also shown that with text-based computer mediated communication technologies, groups are less productive across tasks, have lower expressed satisfaction on tasks related to judgment, and lower cohesiveness than face-to-face groups (Straus, 1997). Moreover, computer mediated groups have less total communication, take more time to complete tasks than face-to-face groups (Hiltz, Johnson, & Turoff, 1986; Weisband, 1992) and experience higher rates of negative interpersonal communication (e.g., flaming). Alternatively, research has shown that face-to-face groups are more productive on all tasks and this difference becomes even greater when the number of task requirements increases (Straus, 1997). Hence, aspects of community important to higher education may be difficult to realize in text-based asynchronous computer-mediated distance education environments (Gram, *et al.,* 2004).

IMPACT OF TECHNOLOGIES ON IDENTITY FORMATION

Technology-mediated communication is a complex process. In particular, it is a complex multimodal process that involves not only speech, but also gaze, gesture, and facial expressions (Clark & Brennan, 1991, Clark, 1996). This research has given rise to the belief that multimodal technologies (such as video conferencing that provides both speech and vision) provide more effective communication than single mode technologies (such as audio conferencing or email and listservs). Somewhat surprisingly, research has not supported this assumption. A review of the research shows that speech alone can be as effective as speech plus video; under certain circumstances speech can be as effective as face-to-face communication and video is not significantly different from speech communication (Reid, 1977; Whittaker, 2003). Some research has even revealed that adding visual information may impair critical aspects of spoken communication (Anderson, *et al.*, 2000). Further, there is evidence from the research on communication media which indicates that audio systems (e.g., Elluminate, Centra), and audio and video systems (e.g., Web cams) can provide more effective interpersonal interactions than text-based communication systems alone (Collett, *et al.*, 1999). Though, this research should be interpreted with caution, as low quality video systems (e.g., discontiguous visual and audio transmissions) may provide distractions to a point where the communication process and the quality can be severely eroded (Whittaker, 1995; Whittaker, 2003). Currently, Internet networking bandwidths do not support high quality and/or stable video and audio systems.

Some research within the field of communication has also focused on aspects of media richness and/or the effects of filtered cues. Results of this research suggest that different communication media affect groups largely through differential transmission of social context cues (or paralinguistic cues). Text-based computer mediated communication is considered to be 'social cueing poor' as it limits the exchange of paralinguistic and interpersonal cues (e.g., age, sex, physical appearance) and other physical surroundings. Social cueing is an important aspect that facilitates and regulates interpersonal interaction, information and monitors feedback (Straus, 1997). Reductions in social cues through the use of reduced-channel media (e.g., text-based communication tools) disrupts the flow of communication causing difficulty in following and understanding discussions (Straus & McGrath, 1994). This can result in diminishing the intensity of interpersonal interactions and social connectedness, as well as increasing a sense of anonymity and feelings of depersonalization (Straus, 1997). In a depersonalized context, in

turn, there is reduced motivation to share personal information and/or inquire about others, as well as reduced expressive communication (Hiltz, *et al.*, 1986). Explanations for these results tend to revolve around the belief that the time and effort required to type versus speak results in considerably less communication in text-based discussions than face-to-face in addition to difficulties in following and understanding the text without supplementary social cues, adding to the cognitive workload (Straus, 1997).

Groups have access to a variety of interchanges: students of the same age interacting with their peers, younger students interacting with older students, and all students interacting with the instructor or various experts. Through this reciprocal interchange among several groups, novices adjust their perceptions and make new choices of language and activities. The computer is used as a tool to facilitate multiple interactions, since students of various ages are commonly placed in the same e-learning classroom. Younger students experience social relations differently from their instructors or older classmates, since the machines they use to mediate their communication often substitutes for face-to-face relations (e.g., Internet chats, cell phones). These technologies enable private subcultures to grow and exist in the public sphere. Hayles (2004) states that our ideas of the body change along with cultural changes, and declares that body boundaries intermingling with technology and information-rich environments leads to shifts in habits, postures, enactments, and perceptions.

DISCUSSION

While there is much we do not know about technology-mediated communication, we can glean from this literature that communication is a complex process. The purpose of this paper is to argue that communication and all its complexities in social interaction needs to be considered in terms of shaping both student and teacher identities with technology playing a non-neutral rather than passive role. Understanding how the non-neutral effects of technology affects students' experiences within the social context of distance learning could also provide distance educators with better insight into designing improved instructional environments which promote critical discourse while addressing a greater number of students' individual needs. Through social interactions in a local community-based practice, language, tools, symbols, and cues are used to objectify and communicate our concepts. Diminished social cues have also been shown to engender social apathy and foster socially undesirable behaviour. Students enter into dialogue with one another having also come from diverse ethnicities and a variety of personal experiences largely shaped by the technological devices which enable specific types of communication in the society within which they have been immersed. Important clues contained in interactive processes between humans in social networked systems may provide an increased level of adjustment by these systems to address the level of cognitive support required by learners. By furthering our understanding of various e-learning processes, we can ensure that the best possible educational scenarios emerge and are translated from theory into practice.

ABSTRACT

The National Center for Energy Management and Building Technology (NCEMBT) initiated a series of research projects related to the indoor environmental quality (IEQ) and energy performance of existing buildings. These projects have generated a vast amount of data on the operation of commercial and institutional buildings. The goal of the NCEMBT is to make these data available online via a knowledge-based resource management system (KBRMS). This paper describes the construction of the KBRMS including the data flow analysis, the data collection and assimilation process and the design, development and prototype demonstration of the KBRMS. The beta version of the KBRMS is operational. The system is divided into public and private sections with the enforcement of role-based access control (RBAC). The external public web portal displays general project information and the research-related publications while the internal web portal accesses project-related data analysis tools, analysis results and intranet communication modules. This paper shows some summary statistics that are automatically calculated through the pre-defined analysis tools using MS SQL Sever stored procedures. More field monitored building data will be put into the system resulting from future projects.

INTRODUCTION

Knowledge discovery in database (KDD) and data mining are emerging fields for extracting useful knowledge from volumes of data. As defined by Fayyad (1996a), "the KDD process is a nontrivial process of identifying valid, novel, potentially useful and ultimately understandable patterns in data". Data sets have little value unless meaningful knowledge can be extracting from the data (Fayyad, 1996b). The multi-step KDD process involves data integration, preparation and transformation, data mining and evaluation, and data visualization. A general framework for the KDD process, proposed by Ingolf (2002), identifies the relationship among management (process view), mining models (model view) and datasets (data view).

The NCEMBT initiated a series of research projects related to the IEQ and energy performance of existing buildings. Researchers from the University of Nevada, Las Vegas are major participants in these multi-year tasks. Each research project generates significant amounts of data. These data may be in form of building IEQ measurements, occupant perception questionnaire responses or underfloor air distribution (UFAD) flow simulation. NCEMBT is obtaining these data sets to transform the built environment by delivering applied research and educational information that results in sustainable building systems which are efficient, productive, secure and healthy.

The true value of the data does not lie within each set but rather in the sum of all the sets. The relationships contained between the individual building data sets are of most value not only to the NCEMBT researchers but also to other research entities, such as the American Society of Heating, Refrigerating and Air-Conditioning Engineers, Inc., the U.S. Environmental Protection Agency and private companies. Statistically significant relationships can only be developed and derived from the associations that exist among all the data sets. For example, a statistically valid correlation between ventilation rates and occupants' perception of the indoor environmental quality of their workplace can only be derived from the analysis of complete datasets of several buildings. However, to do so the existing datasets need to be upgraded to a data warehouse, which in turn will allow data mining. The development of the KBRMS is the first step towards the goal of data mining of large building sciences data sets. The concept of organizing and interpreting the discovered rules through the web as proposed by Ma (2000) will be used for this ongoing project.

Organizing such abundant, non-structured data on energy and IEQ performance of buildings using a well-designed, highly flexible internet-based management system, significantly increases the availability the inherent information resulting in greater knowledge generation. As discussed by Imielinski (1996), research on knowledge discovery scenarios can initially be achieved through the construction of performance-driven system and eventually move on to a complete knowledge and data discovery management system. The goal of this project is to create a system with KDD capability using results from multi-year research studies. This paper examines the flow of data collection and assimilation process, the design and development of the resource management system and presents the current stage of the KBRMS.

SYSTEM DESIGN

Based on its industrial experience, the NCEMBT has proposed an organizational framework to accommodate its data flow as shown in Figure 1. Because each functional area consists of various subjects, an analysis of the data flow needed to be completed prior to the implementation of the web-based resource management system. The analysis was followed by the design and development of the portal architecture.

DATA COLLECTION AND DATA FLOW

Information from NCEMBT projects was modularized and dissected into categories using the classification scheme depicted in Figure 1. Each category was further divided into (sub)levels depending on the underlying data structures (Figure 2). Such a classification approach provides strong data assimilation and reusability capabilities. Accessibility to individual modules was designed to be controlled by the user right definition. The system integrates and organizes all available information under designated repositories based on a customized user definition.

Figure 1. Requirement analysis performed based on the NCEMBT's functional areas

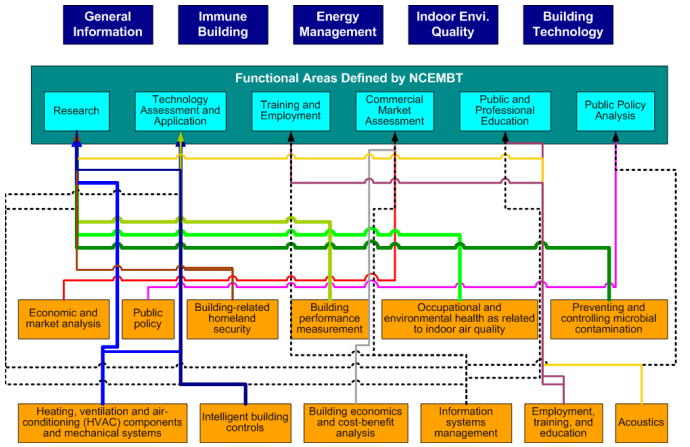

Figure 2. Hierarchy definition used for the portal system

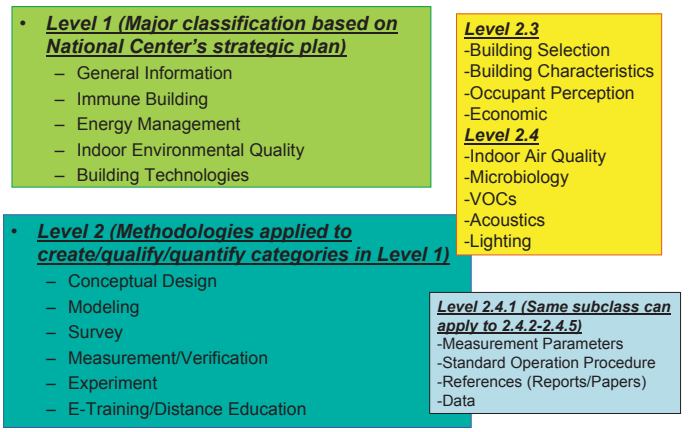

Therefore, the same resources can be accessed by various users at pre-defined data resolutions. One primary development strategy was to minimize the administration effort for content managers and maximize the utilization of analysis and knowledge retrieval tools.

DATA FLOW

Analysis of the data flow as shown in Figure 3 defined the required modules and interfaces needed for the portal system. The data flow follows the path by which public users access the general information without undergoing a registration process. This path is also followed by the content manager to log in. This system is designed to allow

- building managers who participated in the building monitoring projects to access their respective building data and compare the performance of their building to all others contained in the data set
- users to download hourly averaged data sets through the web portal; and
- project team members to access all raw data up to a 10-second resolution.

SYSTEM DESIGN AND DEVELOPMENT

The web portal covers materials from passive information, such as general project introduction and organizational summary, to data-centered information pages, such as results of building occupant surveys or IEQ measurements.

A multi-tier application architecture was employed. The portal contains two data sources. The configuration settings are stored in an xml-formatted file while the content for the application is stored in a SQL Server database. Data access is provided through a Microsoft .NET assembly using the stored procedures. The portal framework was built using of a number of components that handle both the security and portal configuration information. The presentation layer is organized by several web forms and user controls that handle the display and management of the portal data for end users.

All portal contents are stored in MS SQL Server databases. The basic approach uses an xml file which contains all the configuration settings for the portal. This method provides a simple and easy way to manipulate configuration settings. The configuration file is used to store all high level portal, tab and module definitions.

The portal development was divided into three stages: database development, portal functionality module development and portal skin development. The knowledge management portal has two level of accessibility: external public web access and internal management tools. The internal management tools provide an efficient way for the content manager to update the web information. MS SQL Server was selected as the major data repository. Portal development and cosmetic presentation use MS .NET technology, including ASP.NET, VB.NET and XML.

Role-based access control (RBAC) is a proven technology for enforcing separation of duties, administration and access for web-based system. Ahn (2000) developed models, architectures and mechanisms for examining the application of RBAC in a web-based workflow system and implied suitability to deploy such control in large-scale collaborative environments. The system developed here builds upon Ahn's models.

Figure 3. Data flow definition for the portal

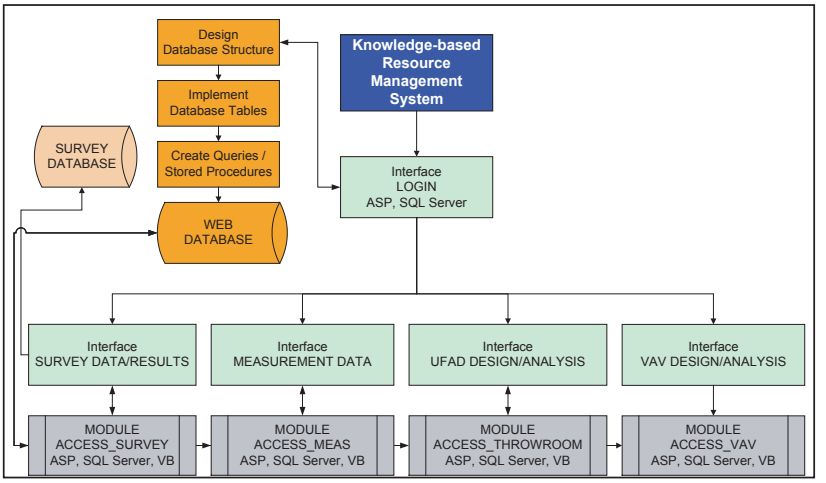

Figure 4. Public accessible web portal

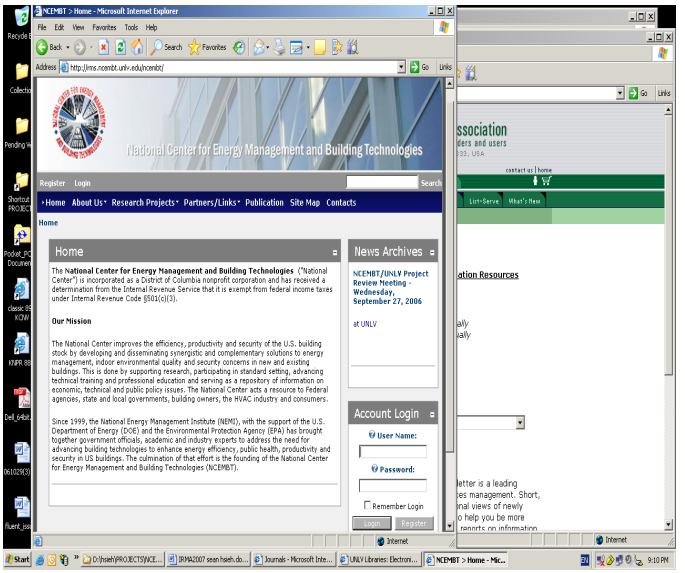
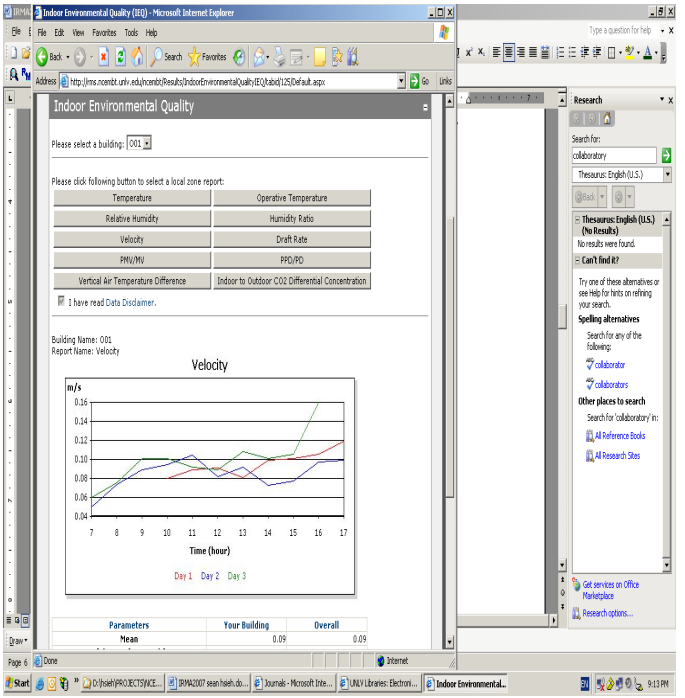


SYSTEM DESIGN

Portal Components

Nine basic portal components were implemented as shown in Figure 4. The web site can be accessed from public (seven modules) or private (nine modules) sections. General information can be viewed by all audiences without system login while private defined components/materials can only be viewed through a password-enabled mechanism.

Figure 5. Summary IEQ data reporting page



Reporting Module Example

Due to the complexity and large quantity of data collected from the first 20 buildings, a reporting module was developed to provide options for data aggregation, access to instant site-specific summary reports and download of the raw data files. Aggregated results and summary statistics of monitored building performance parameters can be accessed via pull-down menus. Figure 5 shows the screenshot of the IEQ parameters that can be displayed for each monitored building. A summary report was developed for each building and incorporates building demographics, recorded IEQ parameters including lighting, microbiological, and sound data and summary results of occupant perceptions of their respective indoor environments.

SUMMARY

An online knowledge-based resource management system to manage, organize and display large data sets of the performance of commercial and institutional buildings has been developed. Handling a large amount of data collected via various measurement techniques and approaches posed significant data storage and management challenges. It also offers a real-world experience on data cleaning, consolidation and manipulation. The knowledge-based resource management system provides pertinent stakeholders (i.e., researchers, engineers, building operators, and facilities managers) with a wealth of building performance data. The system allows users to access various aggregated monitored building parameter sets and provides results of statistical analyses of occupants' perceptions of their indoor environment questionnaire which have been compared to measured building performance parameters. The resulting knowledge is generated to further improve the built environment.

This is a continuous effort that will eventually evolve into the construction of data warehouse and data mining model of building sciences research. More energy management and building technology related knowledge from future projects will be made available along with the growth of the resource management system.

ACKNOWLEDGMENT

This research was supported by the National Center for Energy Management and Building Technology (NCEMBT) under a cooperative agreement with the U.S. Department of Energy.

Business Oriented Development of the IT Landscape: Architecture Design on a Large Scale

Michael Rohloff, MRI Management Consulting, St. Cajetan Str. 13, 81669 Munich, Germany; E-mail: michael.rohloff@mri-consult.de

ABSTRACT

The paper outlines enterprise architecture as a means of business IT alignment, the respective domains, and fundamental design techniques. It is based on three basic views on architecture. The component view describes the elements of architecture and their relationships. The communication view shows how the elements interact with one another. The distribution view describes how the elements are distributed in terms of location or organizational assignment. Key element of architecture design is to account for interdependencies among the building blocks of architecture. Blueprints are introduced as a means in planning the deployment of architecture on a large scale. Blueprints give a comprehensive view on the building blocks and how the interact. They show the effects of architecture design between business, application, and infrastructure architecture. The main stakeholders and their respective usage of the design techniques are outlined.

Keywords: business IT alignment, enterprise architecture, views, blue prints, stakeholders.

1. ENTERPRISE ARCHITECURE DEVELOPMENT AS A MEANS FOR BUSINESS IT ALIGNMENT

1.1 Enterprise Architecture Domains

Architecture is a commonly used term in the design of information systems. Yet, it is used very differently in scope ranging from the architecture of computer systems to information systems architecture. IEEE Standard 1471-2000 defines architecture as „.. the fundamental organization of a system, embodied in its components, their relationships to each other and the environment, and the principles governing its design and evolution" (IEEE 2000). We summarize the understanding of architecture in "architecture is the art and practice of designing and building structures".

Enterprise Architecture comprises the entire business with all its constituents. The alignment of the business and organizational design of the enterprise with the IT architecture is fundamental. However, understanding and structuring of the basic elements differs (see the discussion in Buhl and Heinrich 2004). The wide range of different domains and scope of enterprise architecture as well as its high complexity are characteristics of enterprise architecture.

The architecture domains introduced in this paper follow the basic structuring of the Open Group (TOGAF 2003) and details the respective domains in architecture building blocks in order to give a comprehensive overview of all constituents of enterprise architecture.

The *business architecture* describes the fundamental organisation and requirements of the business based on business strategy and objectives. It is composed of the following four building blocks:

The business model gives a high level view on the nature of the business in terms of products & services offered in the market, the value chain, business partners, market channels utilized, and the combination of resources and information for generating value add.

The organizational architecture describes the organizational design of the enterprise and the principal cooperation with customers and suppliers.

The process architecture classifies and describes all processes of the business and their respective value adds. It is the core building block of the business architecture.

The process architecture can be classified in the core business processes customer relationship management, supply chain management, product life cycle management and the management and support processes (see usage in figure 8).

The information architecture shows the logical structure of all information entities like products, business partners, logistic information etc.

The IT architecture is composed of the application - and infrastructure architecture.

The *application architecture* gives an overview on all applications supporting the processes of the business with the building blocks enterprise applications, portal & information management platform, data repositories, and EAI Services.

The *infrastructure architecture*, also referred to as technology architecture, comprises the software, hardware and network infrastructure required for operations of all applications. Infrastructure building blocks are basic services (e.g. Email, Telco), workplace services, server systems & storage, and the network. Security is integral part and described in an overlaying structure.

With this architecture definition in mind, it should be obvious that Enterprise Architecture is more than the collection of the constituent architectures. The interrelationships among these architectures, and their joint properties, are essential to the enterprise architecture.

In difference to TOGAF and META Group 2002 the Information Architecture in the above framework is not described as a separate architecture domain. It is split in a building block of the business architecture in terms of logical information structures and a building block of applications architecture in terms of implementation of data repositories. This provides for a clear distinction of the business oriented description of the enterprise architecture and the derived technological implementation (for an overview on other enterprise architecture frameworks see Lapkin 2004a and b).

This paper can only give an outline on the domains of enterprise architecture framework and sketch the main building blocks at a high level. All building blocks are detailed down to the level of modules, systems and components. The framework gives a comprehensive description of all relevant elements of enterprise architecture providing a principal structure and classification schema used as a reference for architecture development.

An Enterprise Architecture however, includes not only the three domains for the "as is" architecture (baseline architecture) and the target architecture. It contains also a strategic information base with a clear definition of business objectives and strategy.

The strategy is needed for the transitional processes in order to implement new technologies in response to the changing business needs. That means the enterprise architecture includes also the process to create, update and manage the evolution of the architecture domains in line with business strategy. The design of business architecture determines the development of the IT architecture.

The following listing sketches some objectives to be pursued with enterprise architecture (Aranow 2002, p. 9f., Masak 2005, p. 9f., Meta 2002, p. 6f., 49f., Günzel/ Rohloff 2003, p. 424, TOGAF 2003):

- Strategy and business orientation - enabling, leverage of IT, new business models
- Transparency - complexity and dependencies of architecture building blocks

- Communication between business and IT community - different people from management to IT experts involved
- Planning - target oriented, steering of I&C program with strong impact and to secure compliance to corporate standards
- Synergies - develop & implement the I&C landscape in a systematic manner and to utilize synergies
- Adaptability - dynamic development of market, business, and technology, provide for scalability and growth

Enterprise Architecture is a means to support business and IT alignment. Architecture planning is the ground for the development of the IT landscape and at the same time provides the agility to react fast to market requirements.

1.2 Overview on the Architecture Framework

An architecture description is a formal description of a system, organized in a way that supports reasoning about the structural properties of the system. It defines the building blocks and components that make up the overall system, and provides a plan from which products can be procured, and systems developed, that will work together to implement the overall system.

The IEEE-Standard "Recommended Practice for Architectural Description of Software Intensive Systems" (IEEE 2000) can be used as a basis for an architecture description: every system has an architecture, which can be recorded by an architectural description. The architectural description is organized into one or more constituents called (architectural) views. Each view addresses one or more of the concerns of the system stakeholders. The term view is used to refer to the expression of a system's architecture with respect to a particular viewpoint (Bachmann 2000, Clements et al. 2003).

In contrast to information systems architecture, which is widely discussed under the aspect of a single information system being integrated in an organization and aligned with business processes, enterprise architecture takes the entire IT landscape into focus. In comparison architecture is understood as city planning and not only as planning the architecture of a house (Gartner 2002, Burke 2003). It requires the definition of development plans for an entire area and not only the construction plan for a building. The development of the IT landscape in contrast to the information system architecture of a single system is architecture design on a large scale. It requires adequate features for architecture description.

Essential requirements for "architectures in the large" (compare Dern 2003, p. 81-83) are:

- Reduction to core entities and construction principles
- Balance of abstraction and specialization
- Representation of mutual dependencies
- Integration of architecture in the large and in the small

In the following we will show how an architecture framework and three distinct views on architecture support the reduction to core entities and construction principles. Blueprints give overview on the IT landscape and show interdependencies between the building blocks of architecture. Views and blueprints can be combined for large and small scale architecture development. The figure 1 depicts the architecture framework and the corresponding techniques for architecture description. It is based on the principal elements of the architecture framework for information systems described by Sinz (Sinz 1997, p. 3). The framework is based on the following elements:

Views: Each enterprise architecture domain can be described taking a specific view, which looks at the architecture, its structure and elements from a specific perspective.

Relationship/ dependencies between the enterprise architecture domains can be described using the concept of blueprints.

Standards are an essential element being used for all architecture building blocks which provide for inter-changeability, ease of across system communication etc.

Besides the use of standards, identification and usage of commonly recognized pattern is also an important objective for architecture design.

We focus on the introduction of three distinct views for enterprise architecture and the description of architecture dependencies with the means of blueprints. Pattern and standards are not described in this paper.

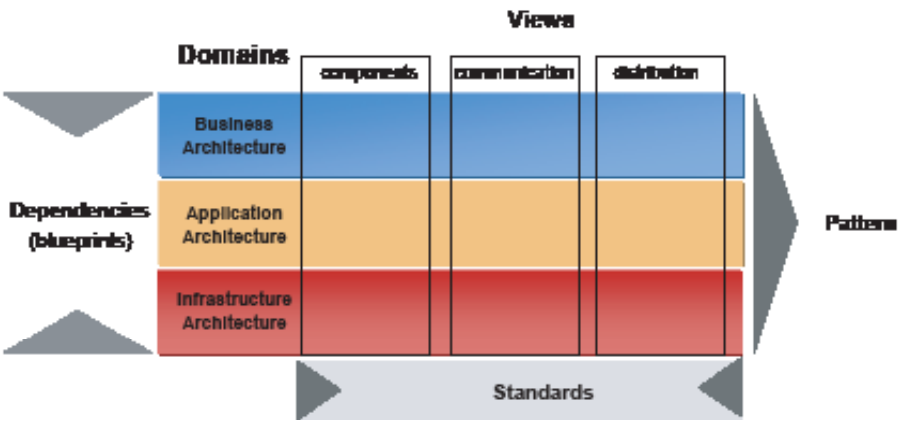
2. TECHNIQUES FOR ENTERPRISE ARCHITECTURE DESIGN

2.1 Views on Architecture

The principle of views is the basis of every reasonable architecture description and the need for multiple views in architecture descriptions is widely recognized in the literature. The IEEE standard 1471 (IEEE 2000), however, describes only the concept of views, stakeholders and concerns. Because of the wide range of opinions on selecting appropriate views, the standard does not make any statements on selecting views, the notation or name of views.

There exists a variety of views in different architecture frameworks. Data-, function-, process oriented views, and dynamic aspects are often named, sometimes supplemented by an organizational and resource view (e.g. for different views see the information system architectures discussed in Bernus et al. 1998). Zachman (1987, p. 291) was one of the first to state "There is not an information architecture but a set of them" and he introduced different views on architecture. This work was continued over the years (Sowa/ Zachmann 1992, Zachman framework). It comprises more than 30 views in a matrix with data, function, network, people, time, and motivation in scope from planning to implemented architecture. The main drawback is the fact that there are too many views included in it. The framework is a mix of views, domains of enterprise architecture, and different stakeholders.

Figure 1. Architecture framework and architectural description



Taking a close look on the diversity of views, we identified three basic views which are sufficient to describe all relevant aspects of enterprise architectures:

Component view: The view describes the logical and functional structure of the architecture in scope. All building blocks and their systems and components are described in terms of composition, structure and relationships among one another. The component view allows for different level of detail. Components, systems, subsystems, building blocks can be grouped or decomposed. The segmentation of the diagram is in building blocks based on the respective architecture in scope.

Communication view: The view describes the communication (interaction) between systems and components. The relationship among the systems is decomposed in the interaction of components within a system and to other systems. Different types of communication can be described with distinct notation for communication lines. The segmentation of the diagram is in communication areas based on the respective architecture in scope.

Distribution view: The view describes the allocation of systems or components in terms of geographical or organizational distribution. The diagram is segmented in organization or location based on the respective architecture in scope.

Figure 2 gives an overview, which illustrates the basic look of these views. An aggregated view on architecture is required which goes beyond the semantics of modelling techniques like UML, thus a notation specific for the purpose of architecture design has been developed (see figure 4 for more details).

These three views can be applied to all domains of enterprise architecture. However, the segmentation of the diagram is selected according to the appropriate context of the domain and chosen level of detail. In the following section we

Figure 2. Three views on Architecture (principal layout)

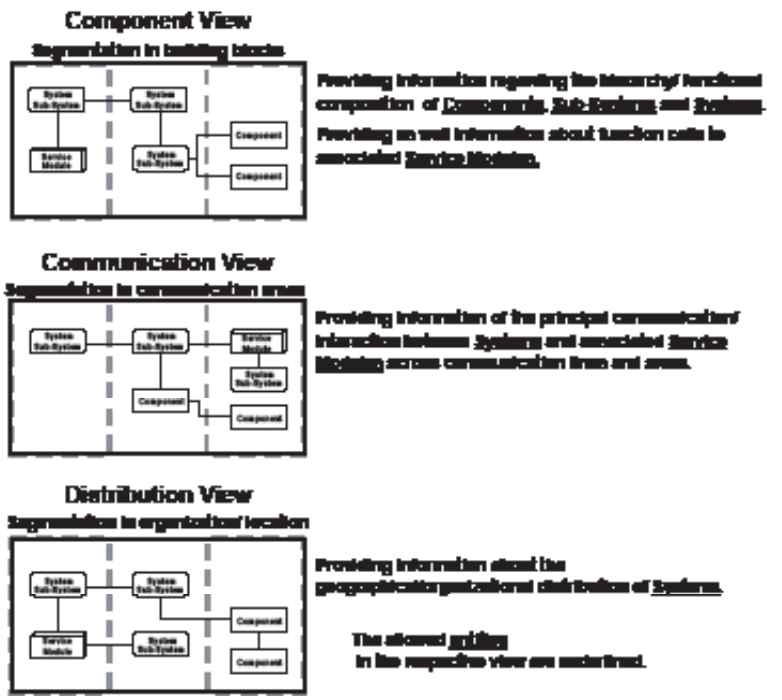


Figure 3. Notation for architecture views (extract)

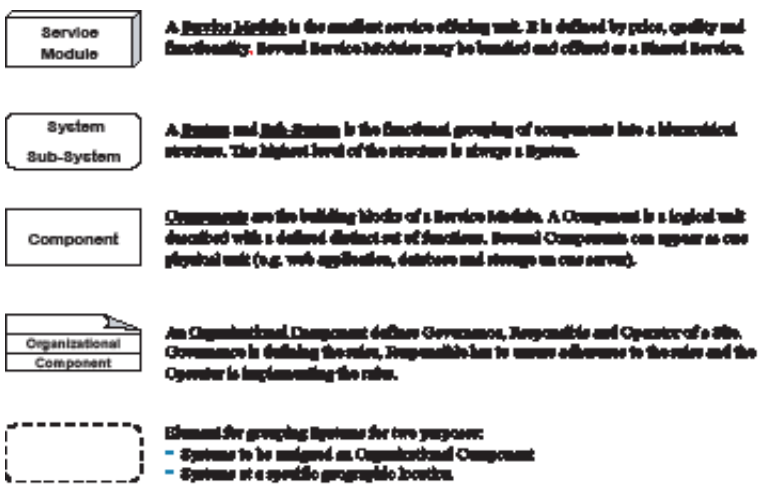

illustrate the use of the views for the domain of infrastructure architecture using the example of an Email Service.

The high complexity of enterprise architectures can be reduced by taking particular views which focus on specific aspects of architecture. The three views facilitate the reduction to core entities and construction principles as well as the understanding of their behaviour.

One objective among others in the description of architecture is to identify pattern in order to establish standards for the design of architecture (Buschmann et al. 1996). These standards can be derived from these views for components, communication or distribution.

For the design of architecture a "Service Oriented Architecture" (SOA) approach is followed. Basically, IT architecture can be always seen as providing services to the business, e.g. an application supporting a business process or office and communication services at the workplace. This perspective puts the value add of IT into the focus. Consequently the building blocks of the architecture framework are structured in service groups, core services, and service modules. The example of an Email Service is used to demonstrate the description of this service using the three views. It is not only to show how these views describe the Email Service in all its aspects but also to outline the notation and features of these views. Figure 3 gives an extract of the notation of the essential elements.

Figure 4. Component view (example Email Service)

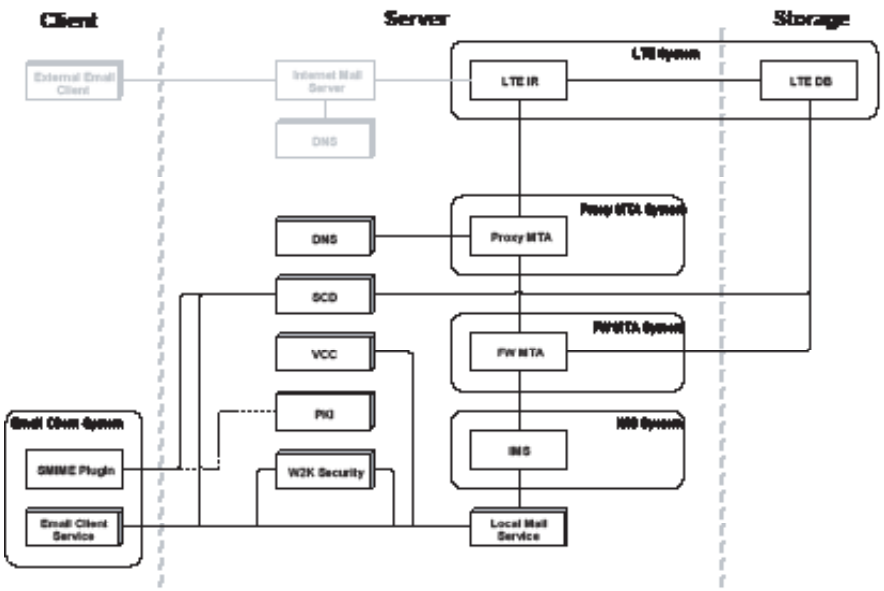

Figure 5. Communication view (example Email Service)

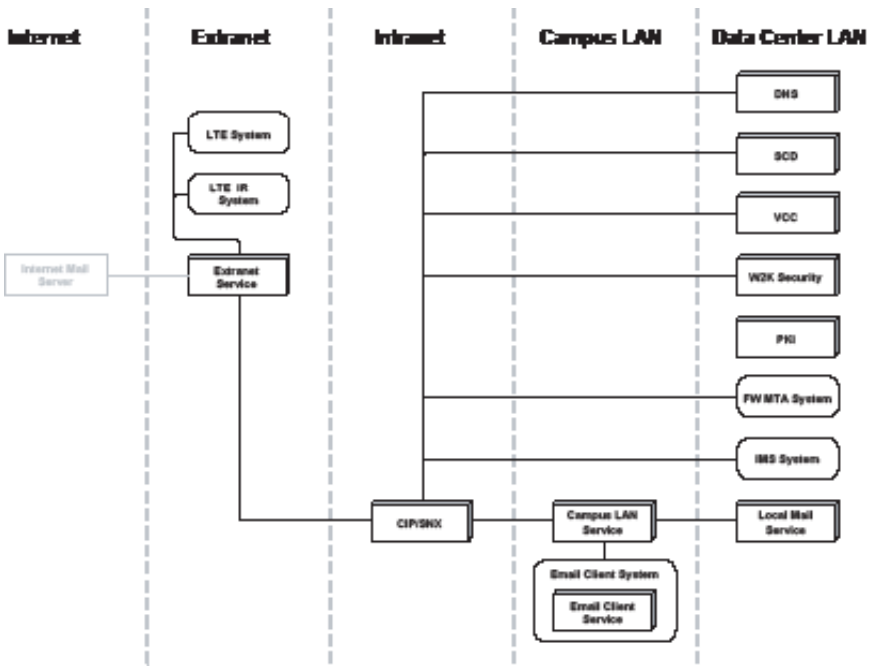

The component view is used to convey the functional and logical structure of architecture. As depicted in figure 4, the view is divided vertically into three major parts: client systems, server systems, and storage systems (infrastructure building blocks). All service modules, systems, and components are described in terms of composition, structure and relationships among one another.

The communication view describes the interaction between the service modules, systems, and components of the Email Service. The diagram is segmented in the communication areas Internet, Extranet, Intranet, Campus LAN, and Data Center LAN.

The distribution view describes the allocation of service modules, systems, or components in terms of geographical or organizational distribution. The distribution view is divided horizontally into three major parts. The segmentation of the diagram follows the company's organization in corporate, group, and region. In addition organizational responsibility is assigned which defines Governance, Responsible, and Operator of a Site. Governance is defining the rules, Responsible has to ensure adherence to the rules, and the Operator is implementing the rules.

The Email Service example illustrated the use of the three views for infrastructure architecture. The same principles for the design of the views are applied for applications architecture using the respective building blocks for the segmentation of diagrams. The views can be used at any level of detail for the decomposition of the chosen part of architecture (building block, service module, system). The combination of the architecture descriptions derived can be used for an integration of architecture in the large and in the small.

2.2 Dependencies of Architecture Building Blocks

Enterprise Architecture is more than the collection of the constituent architectures. The inter-relationships among these architectures, and their joint properties, are essential to the enterprise architecture. Thus, the architecture domains should not be approached in isolation. Key element of architecture design is to account for interdependencies among the building blocks of architecture. Blueprints are introduced as a means in planning the deployment of architecture on a large scale. Blueprints give a comprehensive view on the building blocks and how the interact.

Figure 6. Distribution view (example Email Service)

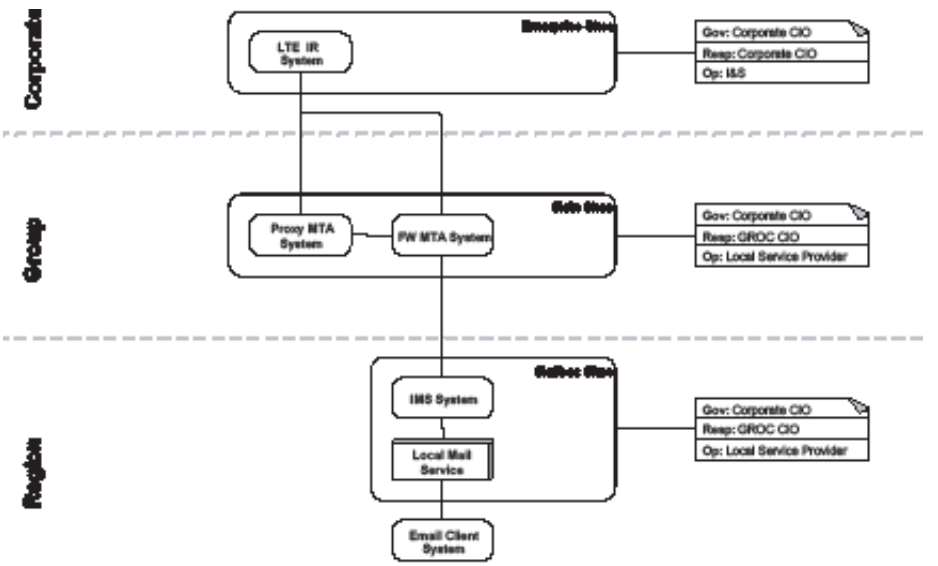

Figure 7. Main blueprints for IT architecture development

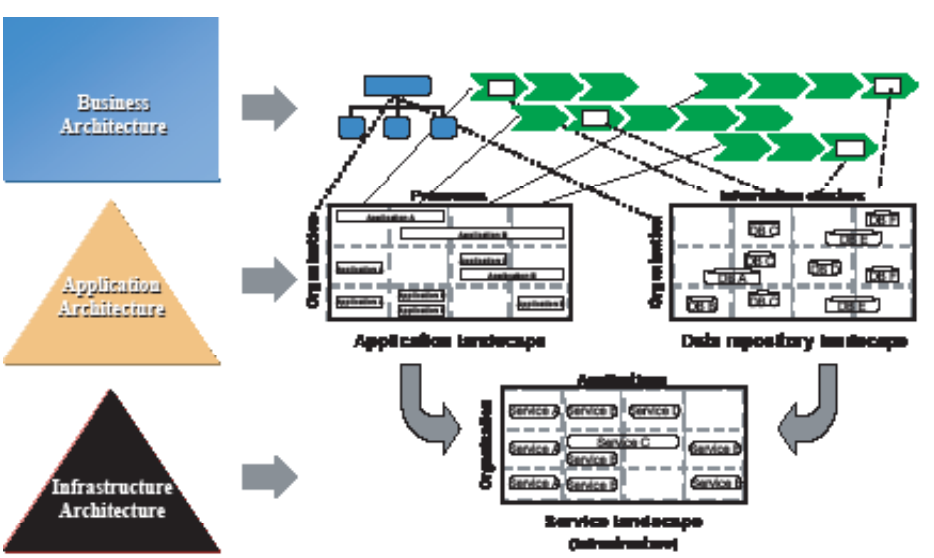

They show the effects of architecture design between business -, application -, and infrastructure architecture.

In the focus of enterprise architectures is the alignment of business and IT. In other words, the design of the business architecture determines the IT architecture which has to support and enable business. The building blocks of business architecture, with the process architecture as the core, define the frame for the design of the IT landscape. The dependencies between the different architectures can be described in blueprints. A blueprint is a plan which describes the deployment of an architecture building block across the enterprise. It pictures the landscape of this building block in a matrix of two business dimensions.

The Figure 7 illustrates the derivation of main IT blueprints from the organization and process architecture.

The application landscape describes for each business process how it is supported by applications. The second dimension shows the deployment in organizational units, like divisions, business segment etc.

The data repository landscape describes the deployment with databases and how they support defined information clusters of the information architecture. The second dimension shows the deployment of the databases in organizational units.

The service landscape shows the deployment of infrastructure services and the support of applications. The second dimension shows the deployment in organizational units.

In general, different types of blueprints can be generated depending which dependency of business -, applications -, and IT infrastructure architecture or respective building block is in focus. Also, the matrix dimensions can be chosen at different level of detail. However, the experience in architecture projects shows that a high level is sufficient in order to derive decisions for architecture development. Generating to detailed blueprints involves a lot of resources and time without enriching the decision base in the same degree. The three blueprints introduced provide a good information base for management decisions. The following section gives an example of an application landscape for Siemens Medical being worked out in a corporate architecture project.

Blueprints for application landscape are in the main focus in order to show IT support for business. The figure 9 gives an example of an "as is" application landscape of the medial solution group of Siemens AG. The applications in use are mapped to level 1 business processes of Siemens. Second dimension of the matrix are the divisions of medical solution.

In a number of projects these types of blueprint have been proven to give a transparent overview on the application landscape and are a sound basis to derive architecture decisions. At a glance one can see processes not supported by applications or redundancies where more than one application is in place for a process. Blue prints are used for presentation of "as is" as well as target architecture. The blueprint of the target architecture describes the deployment plan to implement IT strategy. From the gap analysis of "as is" and target architecture IT projects are derived. Finally, the projects are prioritized and the overall IT program is defined in order to implement the architecture.

3. ARCHITECTURE DESIGN TECHNIQUES AND STAKEHOLDERS

The scope of enterprise architecture and the architecture development process, ranging from strategic formulation to implementation, in mind it is obvious that a number of people coming from different organizational backgrounds and disciplines are involved. Figure 9 outlines the main stakeholders involved in planning, development, and implementation of enterprise architectures. It shows their basic roles and usage of architecture design techniques (see Dern 2003, p. 108f., META 2002, p 69f., 205f., 333f., TOGAF 2003). In addition to the techniques discussed in the prior chapter, methods for IT strategy definition and implementation are included in this overview due to the fact that this is the major reference for architecture development.

The stakeholders like CEO/CFO; CIO, IT strategy planer, and program manager are involved in the business/ IT strategy and decisions for direction, objectives

Figure 8. Blueprint example of "as is" application landscape medical group Siemens AG

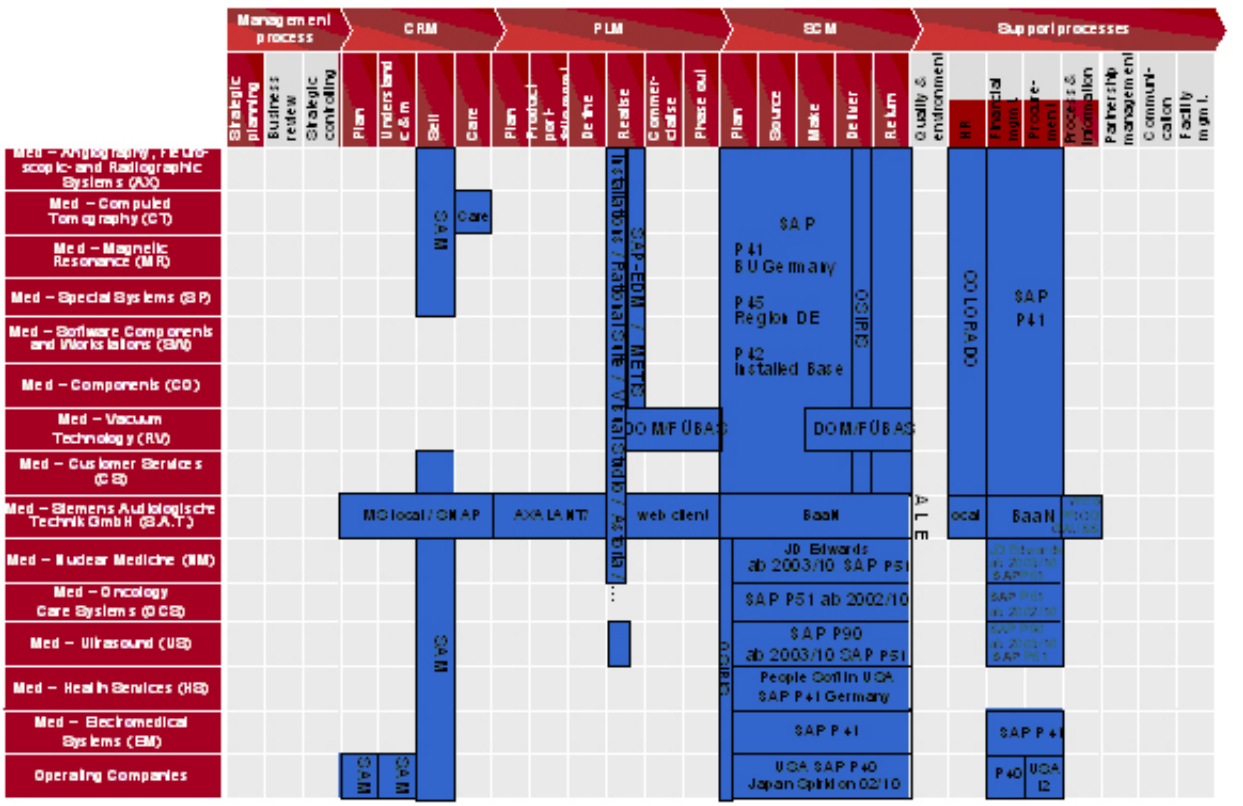

Figure 9. Architecture design techniques and stakeholders

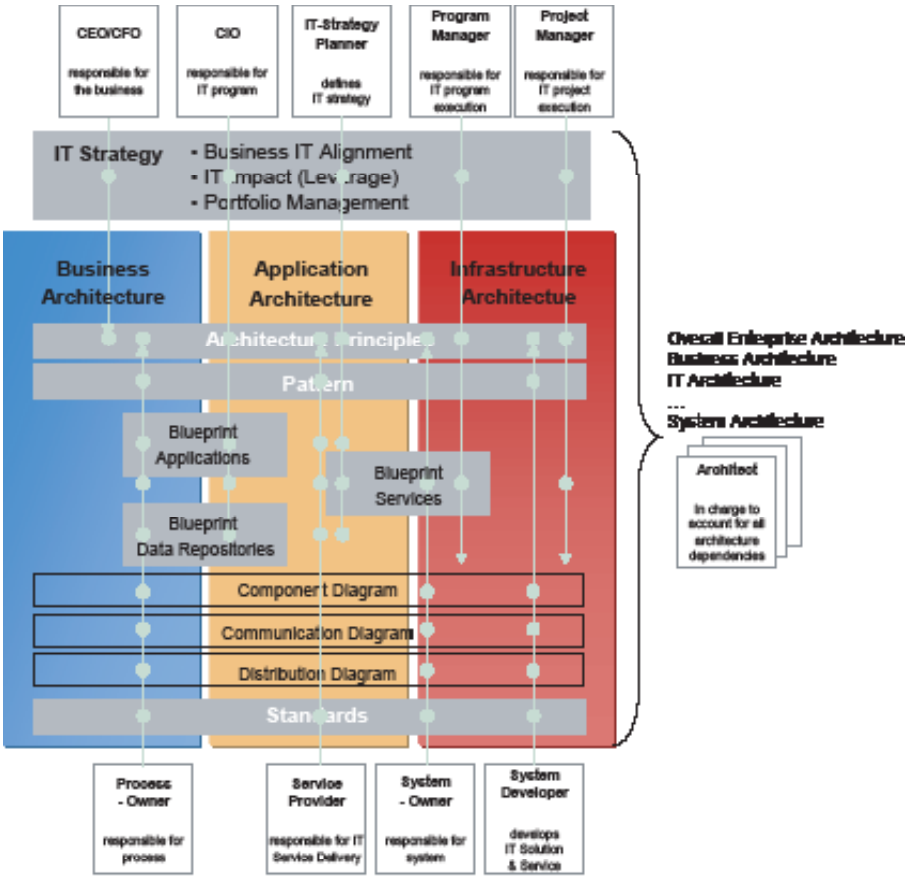

of architecture, and IT program. They merely use methods of business IT alignment, IT impact, portfolio techniques and blueprints. Architecture principle and pattern are partly used.

The central role plays the enterprise architect who leads the architecture development and coordinates all respective activities. He is responsible for as is/ target-architectures and the dependencies among architectures. In addition, there are other domain related architects involved. Responsibility of architects can be on diverse domains ranging from enterprise - to system architecture. Architects use the entire range of techniques with different levels of detail depending on their respective domain.

Process owners focus on blueprints which show how processes are supported by applications and services. Principles and patterns for business architecture are also used.

Service providers use blueprints for an overview of the IT landscape and to allocate services. Principles and patterns are also used.

System owners and system developers use component -, communication - , and distribution diagrams with focus at system level. Defined principles and pattern are basis for their work.

Thus, these techniques are used differently by the stakeholders depending on the respective scope of work. The different ways of architecture description are an important means of communication among the stakeholders involved in the architecture development process and the alignment of business and IT. In order to generate different views of architecture, all architecture documentation is stored in a repository. The Corporate modeler (Casewise 2006) is used and enhanced with additional features for architecture description. The IT Navigator (IT Navigator 2002) was developed for analysis and assessment of architecture (blueprints, IT project portfolios etc.).

However, architecture development is very much management and communication among the different parties involved and not only technical construction. The techniques introduced are embedded in a well defined architecture development process. Within the scope of this paper only an outlook on the main stakeholders could be given. Architecture management and process are fundamental for a business oriented, sustainable development of enterprise architecture. Project experiences in this area will be addressed in a separate paper.

ABSTRACT

One of the most important issues in Customer Relationship Management (CRM) is how to measure the relationship with customers. More research into quantitative approaches to this measurement is needed. To help consider this issue, the reciprocal relationship between the automobile maker Mazda and its suppliers is analyzed and the results presented in this paper. This set of interlocking business relationships is known as a keiretsu. This paper uses the influence analysis tool DEMATEL (DEcision MAking Trial and Evaluation Laboratory), to measure one kind of reciprocal relationship, the influence, of each firm in the keiretsu of Mazda Yokokai. The results of this analysis are used to identify some characteristics of effective relationships between Mazda and its suppliers.

Keywords: influence, relationship, cross-shareholdings, transactions, DEMATEL

1. INTRODUCTION

A keiretsu is a set of companies with interlocking business relationships. In the Japanese automobile manufacturing industry, these relationships include cross-company transactions and cross-shareholdings between automobile manufacturers and companies supplying their parts. A keiretsu can be considered as a type of network organization. In the automobile manufacturing industry, the competition between manufacturers is substantially the competition between the keiretsu of manufacturers. Generally speaking, from 60 percent to 70 percent of the cost of each vehicle is derived from the cost of auto-parts. The remaining costs are labor, equipment costs, and various other costs such as advertising and distribution. For different automobile manufacturers, for each vehicle with the same displacement volume, the selling price, wages of employees, and the price of raw materials, are approximately the same. Consequently almost all of the profit is generated from the reduction in costs of the parts obtained from suppliers. Hence, one kind of reciprocal relationship, the influence between the manufacturer and its suppliers, is a key competitive factor in the industry. The aim of this paper is to use the influence analysis tool DEMATEL (DEcision MAking Trial and Evaluation Laboratory), to measure the influence of each firm in the keiretsu of Mazda Yokokai and hence uncover the effective structural relationships between suppliers and the automobile manufacturer.

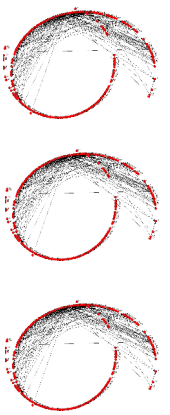
The structure of this paper is as follows: In Section 2 the authors briefly review some previous studies of relationships; Section 3 introduces and applies the DEMATEL measurement technique, showing the result of the influence of each firm in the keiretsu of Mazda; An analysis and discussion of the implications of the measurement results are presented in Section 4. The final section (Section 5) contains some concluding remarks.

2. BACKGROUND

There are many kinds of reciprocal relationships that can be considered. Dyer analyzed the relationship between firms based on distances between their locations and the frequency of face-to-face communication among engineers in the automobile industry (Dyer, 1994, 1996). Bensaou identified the successful portfolios of buyer-supplier relationships from the viewpoint of effective supply-chain management (Bensaou, 1999). Ito measured the firm's relationship in the keiretsu of Toyota from the viewpoint of centrality (Ito, 2004). Ito and Sakamoto developed a new method to calculate the importance of each individual firm in the keiretsu of Toyota and Nissan (Ito and Sakamoto, 2005). Recently, inter-organizational relationships in keiretsu have been analyzed with quantitative analysis tools such as CONCOR (Lincoln and Gerlach, 2004). Fukuoka et al reported a new trend in relationships between firms in the keiretsu of Nissan from the viewpoint of network organization (Fukuoka et al, 2006). All of these researchers focused on the relationship of each firm in the keiretsu. However, there are only a few empirical studies that analyze reciprocal relationships between the firms in the keiretsu (Nohria and Eccles, 1992; Hakansson and Waluszewski, 2002). One kind of reciprocal relationship is the level of influence between firms. Measuring this level of influence helps to identify effective relationships between firms.

3. MEASUREMENT

Influence is a term that refers to the power to indirectly control or affect the actions of other persons or things. In the social sciences, influence derives from an interpersonal relationship, and most research into influence is based on a psychological approach. Fontela and Gabus (1976) developed a tool for analyzing influence networks called DEMATEL, which is an abbreviation for DEcision MAking Trial and Evaluation Laboratory. DEMATEL is an approach for identifying the influence or the hidden or indirect power of a group of relationships, based on the principle "Friends of my friend are my friends". In this current research, DEMATEL is used as a new method to measure the influence of actors within the keiretsu of Mazda Yokokai.



3.1 Outline of DEMATEL

A brief overview of the mathematical basis of DEMATEL is as follows.

In a social network composed of n actors, the binary relation between each actor and the strength of this binary relation can be identified. Based upon the structure of this pattern of reciprocal relationships, an n×n adjacent matrix A^* can be obtained. The first step in the analysis is to normalize this matrix by multiplying each element of A^* by l , the largest row sum of A^*. The normalized matrix $A = l A^*$ is therefore obtained. The (i, j) element of a_{ij} of this matrix denotes the level of direct influence from actor i to actor j.

The reachable matrix, denoted by A^x, refers to the fact that actor i can reach actor j through the number of steps x. For instance, A^2 means that actor i can reach actor j through 2 steps. Therefore A^x measures the indirect influence from actor i to actor j. All of the levels of indirect influence can be summarized as follows, which the authors refer to as the indirect matrix.

$$A^f = A^2 + A^3 + \cdots + A^n = A^2(I - A)^{-1}$$

The total influence matrix, which includes both the direct and indirect influence matrix, can therefore be expressed as follows.

$$T = A + A^f = A + A^2 + A^3 + \cdots + A^n = A(I - A)^{-1}$$

3.2 Data Collection

In order to measure this pattern of influence, data showing the transactions and cross-shareholdings in the keiretsu of Mazda Yokokai were collected from the publications of the Japan Auto Parts Industries Association and Automotive Parts Publishing Company (JAPIA&ATJC, 2005). In 2004, the number of firms involved in transactions and cross-shareholdings was 181 and 223 respectively. This data set makes up about 42 percent of the complete set of transactions between Mazda and other firms.

The relationships between the firms in each category were identified through graph modeling. A tie shows the presence or absence of transactions or cross-shareholdings between each pair of firms. The authors collected directed 0-1

Figure 1. Relationship graph of transactions of Mazda Yokokai in 2004

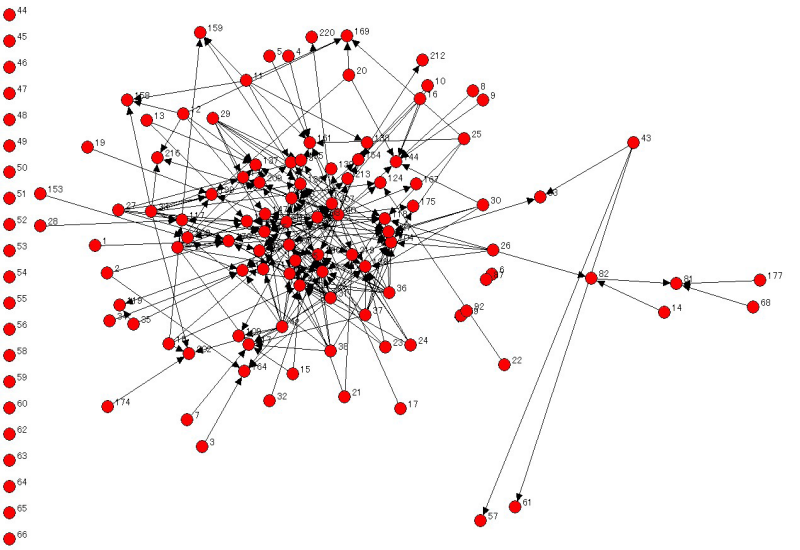


Figure 2. Relationship graph of cross-shareholdings of Mazda Yokokai in 2004

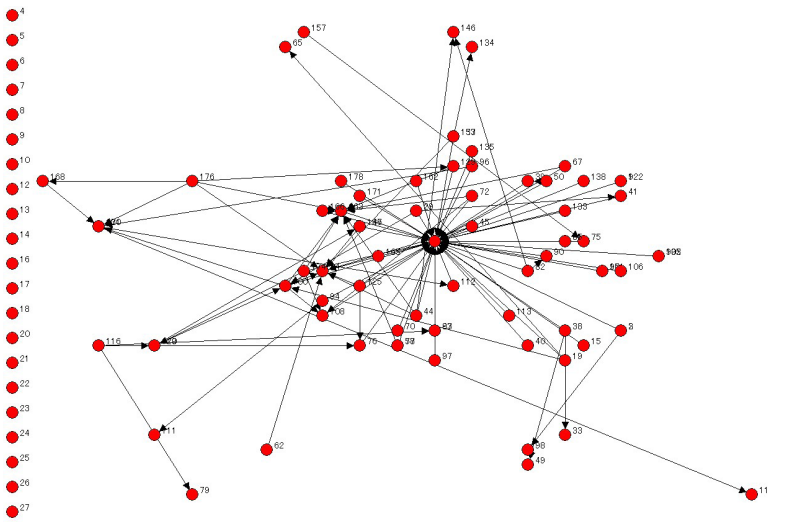

relationships to model the influence of each firm. The network of transactions in the Mazda keiretsu is shown in Figure 1, and the network of cross-shareholdings in the Mazda keiretsu is shown in Figure 2. The numbers in both Figures 1 and 2 refer to various companies in the keiretsu. The list of company names is provided in Appendix I.

3.3 Influence Measurement

Using a computer program developed by the authors, the influence of each firm in the Mazda keiretsu was calculated. The result of the influence of transactions is shown in Figure 3.

Figure 3 shows that the influence from Mazda to other suppliers is zero, but the influence from other suppliers to Mazda is quite high. Figure 4 shows the influence from other suppliers to Mazda in more detail. The total influence from other suppliers reaches 5.46. This shows Mazda received many parts from suppliers. The influence of cross-shareholdings was calculated using the same method. The influence from Mazda to other suppliers is 0.50, but the influence from other suppliers to Mazda is zero.

The results of this analysis clearly show that Mazda has investments in many of the companies that supply its parts, and consequently receives many parts from these suppliers.

4. ANALYSIS AND IMPLICATIONS

The finding that the more investment that Mazda makes in its supplier firms the more transactions Mazda will have with them, is not an unexpected result. The question that can now be asked is: "How strong is this relationship between level of investment and number of transactions?" To answer this question, the correlation coefficients between transaction and cross-shareholdings were calculated. The results of this analysis are shown in Table 1.

This analysis shows that two correlations, that between influence B of transactions and influence A of cross-shareholdings, and that between influence A of

Figure 3. Transactional relationships in the Keiretsu of Mazda Yokokai

					181

***p < 0.01*

Note: The first layer is the Pearson's correlation coefficient; the second layer is the probability (two-side test), and the third layer is the sample size. Influence A means actor i directly influences actor j; and Influence B means actor i is influenced from actor j.

transactions and influence B of cross-shareholdings, were significant ($p < 0.01$). The correlation values were 0.678 and 0.399 respectively, which shows that a strong relationship exists between the level of transactions and cross-shareholdings. In other words, the statement that "the more a firm invests in a supplier, the more the firm receives parts from that supplier" is valid. The reciprocal finding that "the higher level of investment that a firm accepts, the more parts that firm will supply" is also valid.

5. CONCLUSIONS

In this paper, the influence of each firm was measured in order to investigate the pattern of relationships in the keiretsu of Mazda. The study found that the influence of cross-shareholdings in other firms is closely related to the influence of the transactions between them. This means that the higher influence of cross-shareholdings has a strong impact on the influence of transactions. The implication of this finding for the automobile manufacturer Mazda is that an important strategy for them is to find those firms that have higher influence in the keiretsu and strengthen their reciprocal relationship with them.

One limitation of the paper is that the data of transactions and cross-shareholdings in this analysis are restricted to one fiscal year. Data from more years would be required in order to more completely study the trend of these identified influences through time series analysis. In addition, the form of influence investigated in this study is only one aspect of the reciprocal relationship between an automobile manufacturer and its supplies. Further quantitative research, such as the use of capacity analysis between two actors and clique analysis of the network structure, will be undertaken in the future, to attempt to capture the complexity of the relationships in the keiretsu of Mazda.

ACKNOWLEDGMENT

The authors would like to express their thanks to Nagaoka University of Technology for their financial support and the anonymous reviewers for their constructive comments of this research.

A Novel Method for Securing Online Databases

Stephanos Mavromoustakos, Cyprus College, 6 Diogenes Str., Engomi, P.O. Box 22006, 1516 Nicosia, Cyprus; E-mail: mstefanos@cycollege.ac.cy

ABSTRACT

In the past few years, we have experienced a rapid increase in the development and usage of Web-based systems. However, a main problem of these systems is the lack of security mechanisms to protect their data especially in cases where high security is required. In this work, we present the architecture of a secure system using voice biometrics. Among the existing security and biometric methods, voice biometrics can be an affordable technology providing high security. The proposed architecture includes a biometric server where the users' unique set of speech models (voiceprint) is stored. The authentication procedure requests from the user to pronounce a random sequence of digits and after capturing speech and extracting voice features at the client side are sent back to the biometric server. The biometric server decides whether the received features match the stored voiceprint of the user who claims to be, and accordingly grants authentication. By implementing the proposed architecture, online databases are provided with a higher degree of certainty based on the user's identity.

1. INTRODUCTION

Web-based systems, such as web-banking and e-commerce, are continuously growing and gaining a considerable part of the marketplace. Providing access to information has been handled so far by implementation of personal identification numbers (PINs), cards or tokens [1]. The problem with these is that they do not provide a robust solution for e-commence and they are vulnerable to fraud. To further increase e-commerce growth and public respect, higher security protection should be provided to users. By integrating advanced biometric authentication in an Internet application, secure, low-risk and convenient transactions can be executed. Biometric authentication means the automated use of physiological or behavioral characteristics, such as iris, face, signature, finger, or voice, to verify one's claimed identity [2].

Authentication methods using biometrics can replace or complement conventional authorization mechanisms, namely passwords and personal identification numbers (PINs), for higher security applications. The main risk of traditional authorization methods is that passwords and PINs are sensitive to be stolen, guessed or retrieved by a person. Moreover, considering the amount of Internet applications a customer uses that require a password, it is difficult for him/her to possess securely multiple and difficult to be guessed passwords. On the other hand, biometrics utilizes intrinsic characteristics of a person and is not susceptible to fraud. Another advantage of biometric methods over the traditional ones is that the authentication is not restricted to a binary decision, thus multiple levels of security can be posed.

Comparing the biometric methods mentioned above, voice biometrics could be regarded as the most promising one for being widely utilized in Internet applications for securing online databases. The increased presence of microphone devices and their low cost compared to other biometric acquisition devices makes voice biometrics the least expensive to deploy. Furthermore, voice biometrics do not invade customer's privacy and users are more willing to cooperate (voice has not been used for individual tracking and monitoring). Speaker authentication can be combined with other speech – enabled applications over the Internet, i.e. verbal passwords, speech recognition.

This paper, proposes a novel method for securing online databases using voice biometrics. The proposed method suggests the transmission of voice features instead of the whole speech signal to ensure maximum security and privacy and also to save on bandwidth. The structure of this paper is as follows: Section 2 discusses biometric authentication and its advantages and disadvantages. Section 3 provides an overview of the system. Section 4 explains the proposed voice biometric authentication including the enrolment process and the authentication process. This section also describes the tests performed to evaluate the performance of the system in real environment conditions. Finally, Section 5 sums up the findings of the paper and provides some concluding remarks.

2. BIOMETRICS

Biometrics is the science of using digital technology to identify the identity of individuals based on behavioural or physiological characteristics. By basing a security system on the physiological features rather than a few keystrokes or a password, the possibilities of fraud are drastically reduced. The terrorist attacks of September 11th 2001, and the desire to tighten security in every way possible, particularly in America, resulted enormous funds being made available to the research and development of biometric systems. As a result, the biometric industry is now emerging and is rapidly gaining acceptance from governments, companies and individuals.

Already, there are many industries employing biometrics, including the U.S. Immigration and Naturalization Service, major western countries armies, international banks, governments and healthcare organizations. The European Union also moves towards creating standards for biometric passports which will be deployed in the near future, while Britain plans to issue new identity cards which include biometrics. During the Olympic games in Athens in 2004, biometrics were also widely deployed to enhance the security of athletes and buildings.

There are many types of biometrics, but among the most common are scanning fingerprints, voices, faces, retinas or irises. Computer hardware and software programs have been developed to scan a thumb print, for example, and then compare it with a stored databank of other prints for an exact match. Or a voice is compared to a bank of voice-print samples using pattern classification algorithms. Face recognition is the measurement of certain characteristics, such as the distance between eyes. Retina scanning has the computer camera inspecting the pattern of veins in a human eye. And, finally, iris scanning takes retina scanning one step further by concentrating on the color pattern surrounding one's pupils [3].

Key features of voice biometric that differentiate it from other types of biometric procedure are that it is non-invasive and that it can be performed remotely by telephone or via Internet. Approaches such as fingerprint analysis and retina scanning are much less acceptable to users. In addition, the cost and complexity of the systems required for fingerprint or retinal scanning far exceed that of the single microphone of a voice-based system that is, in any case, already provided in typical PC systems, the telephone and the mobile handsets. Voice biometric systems generally include classical pattern recognition components; that is data acquisition (recording of speech signals), pre-processing, feature extraction and classification. These components are used in the two primary functional biometric system components, the *enrolment* and the *verification* processes discussed in section 3.

The main advantage that biometric can offer is security and convenience. Among the various types of biometric technologies available, voice recognition is one of the cheapest to implement [1]. Iris scanning provides high security and is convenient in that it allows the users to keep their glasses on throughout the scan [3]. A biometric system is not based on a standard true or false system [1] but by utilizing a threshold of acceptance closeness to the user's characteristic different levels of physical security, authenticity, integrity and confidentiality can be established [4].

While biometric authentication includes several advantages it does have some drawbacks as well. Even though it is difficult, but not impossible, fingerprints

and pictures can be copied from anywhere and voice can be recorded [4]. Another major drawback is the cost associated with these technologies with iris scanning as being more expensive [1]. Finally, users of these systems concern of their privacy data. However, educating these people will curb their misguided fears [1].

3. SYSTEM OVERVIEW

The system consists of the client, the Application Server and the Secure Voice Biometric Server (SVBS). The client could be any computer with Internet connection in which the user can access an Internet service. The role of the Application Server can be attributed to multiple, online database applications. The SVBS is a secure server that could be located away from the application server as a third party service. The SVBS generates trains and updates the user's unique set of speech models (voiceprint), stores them securely in a database, and performs the matching process to authenticate a user.

Consider the case when a user needs to purchase an expensive product from an e-commerce site utilizing the proposed voice biometric approach for enhanced security. After registering to the e-commerce service, the user is asked whether he requires biometric user authentication on his transactions. If the user selects this feature then he is redirected to the SVBS where he follows the enrolment procedure to create his voiceprint, which is stored in the secure server. Figure 1 illustrates the enrolment process while Figure 2 shows the e-commerce transaction process in an abstract form.

Every time the user wants to purchase a product, he is redirected by the application sever to the SVBS where biometric authentication is performed to verify (or not) the user's identity. If the user is the one who claims to be then authorization is granted and the user is free to proceed with the transaction.

4. VOICE BIOMETRIC AUTHENTICATION

During a speaker authentication procedure, the user provides an identity claim together with speech samples corresponding to prompts from the SVBS. The processing of the raw speech data results in distinctive and representative voice features (Feature Extraction), which contain information of the physiological characteristics of the user. The extracted features are then compared with the voiceprint of the claimed user, which was created during the enrolment phase, and a matching score is calculated (Verification). If the matching score is over a predefined threshold then the authorization is considered successful, otherwise a call back procedure is followed. The following sections describe in detail the feature extraction, enrolment and authentication processes.

4.1 Feature Extraction

Speech is produced by the flow of air through the various articulators such as the vocal tract, lips, tongue, and nose. Air is forced out of the lungs through the trachea and the glottis, where it passes through the vocal cords. The vocal cords, if tense, vibrate like an oscillator, but if relaxed, do not vibrate and simply let the air pass through. The air stream then passes through the pharynx cavity and, depending on the position of a movable flap called the velum, exits either through the oral cavity (mouth), or the nasal cavity (nostrils). In the former case, the tongue and the teeth may modify the flow of the air stream as well. Different positions of these articulators give rise to different types of sounds. The different sounds produced by human beings are strongly related to the physiological characteristics of the vocal tract of each speaker. The fact that different speakers have different vocal-tract configurations for the same utterance is the basis for using vocal-tract filter parameters (feature coefficients) to good effect for speaker identification. These unique characteristics can be identified through a parameterization procedure called feature extraction.

Feature extraction is the process of measuring certain attributes of speech needed by the voice biometric system to differentiate people from their voice. The most often used technique that we also use in our system, is the mel frequency cepstral coding (MFCC) [6] which uses the Mel scale which is based on the human ear scale. The proposed system suggests the feature extraction process to be performed locally on the client's hardware and the calculated features to be securely transmitted

Figure 1. Enrolment to the biometric server

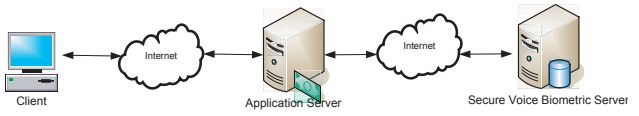

Figure 2. Voice biometric authentication for accessing an online database

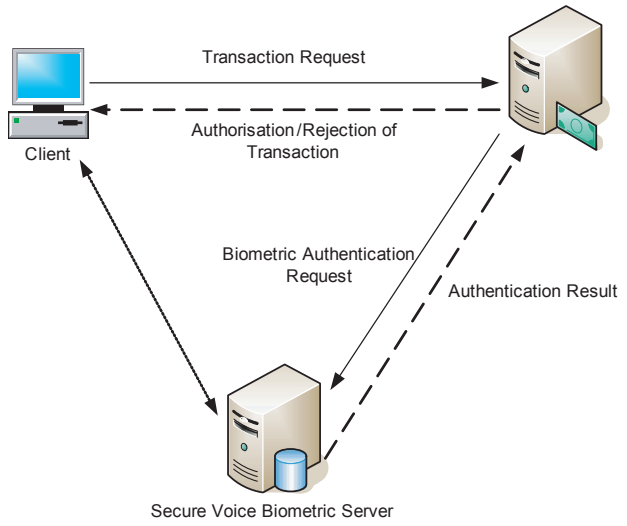

Figure 3. The enrolment process

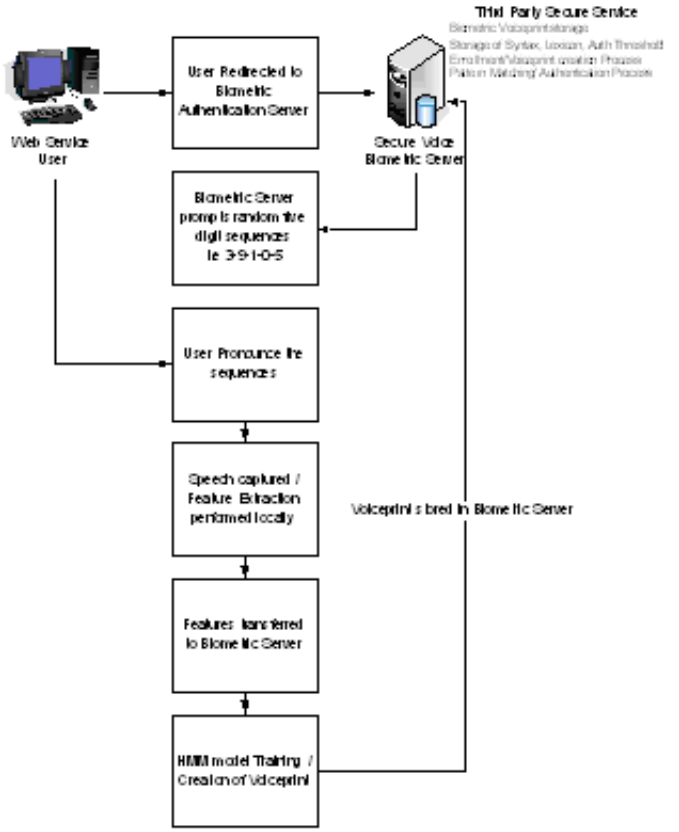


to the SVBS. The reason is that due to their size, the features take significantly less bandwidth when transmitted over the Internet making the whole interactive procedure of verification much secure and quick.

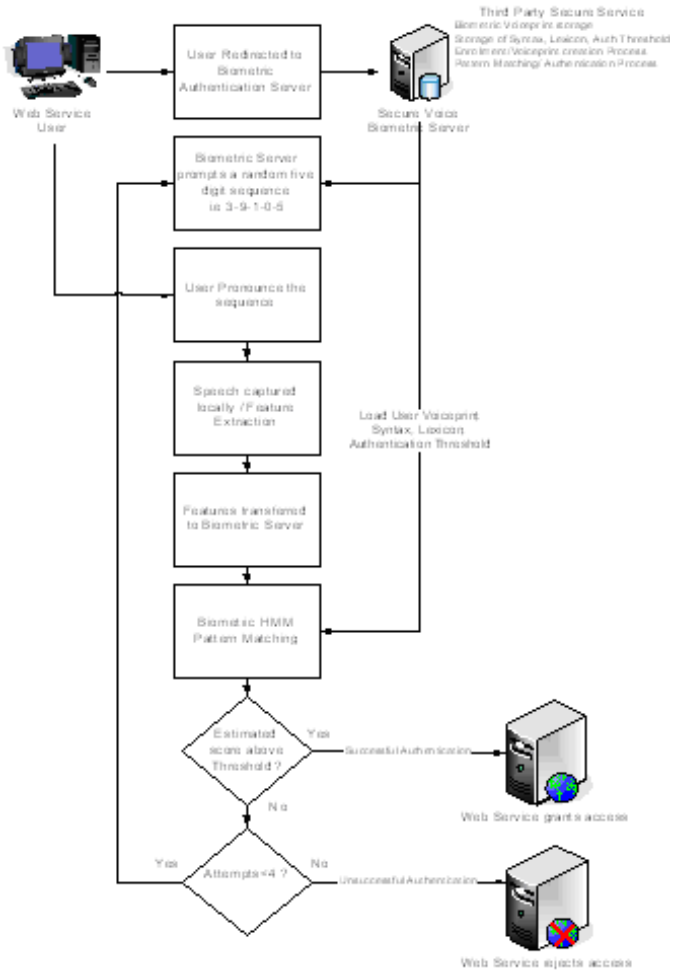
4.2 The Enrollment Process

When a biometric authentication is needed for transactions between a user and an Application Server, the interested user should enroll in the SVBS (Figure 3). Thus, the first time the user requests the service from the Application Server its client is redirected to the SVBS. To eliminate the probability of a fraudulent enrolment, SVBS sends a password to the interested user via email.

The user can log into the SVBS by using this password to establish a secure connection with the SVBS. The SVBS sends a random sequence of digits 0-9 to the client, and the client prompts it to the user. While the user is pronouncing the sequence, the speech signal is recorded and the client performs the feature extraction task. When the user has prompted the whole digit sequence (a procedure which lasts two to five minutes) and a specifically downloaded from the SVBS client's software has extracted all the appropriate speech features, these features are sent back to the SVBS. The SVBS processes the received features and trains whole-digit HMMs (Hidden Markov Models) [5] for the specific user. The user's voiceprint, which consists of all digits (0…9) HMM models, is safely stored at the SVBS database. Since the enrolment procedure is unsupervised, there is an increased risk of a low-quality but still valid enrolment. Such an enrolment can increase the probability of False Rejection (FR) as well as the probability of False Acceptance (FA) for a user. In order to avoid such a problem, after the voiceprint of the user has been created, the SVBS starts immediately an authentication process. If the authentication is successful, the user's voiceprint is considered accurate and the enrolment ends. Otherwise the SVBS deletes the problematic voiceprint from its database, terminates the enrolment process and suggests the user a second trial.

The strict protocol followed during the enrolment process is obliged by the fact that user's voiceprint is created for the first time. Early unsuccessful authentication indicates inadequate hardware, misspelled training phrases, noisy environment, or suspicious enrolment trial, and thus it should be rejected.

Figure 4. The authentication process



4.3 The Authentication Process

When the user's client starts a high-security transaction with the Application Server, it is redirected to the SVBS (Figure 4). After a secure network connection has been established between the client and the SVBS, the latter asks for an identity claim (such as a username) of the interested user. After receiving the username, the SVBS checks the user existence in its database. If such an identity exists, then the SVBS sends a sequence of five random digits to the client. The client's application prompts the user to pronounce the sequence, records the speech signal, extracts the required MFCC features, and sends them back to the SVBS. The SVBS performs the pattern matching operation between the received features and the voiceprint of the claimed user stored in its database and produces a matching score.

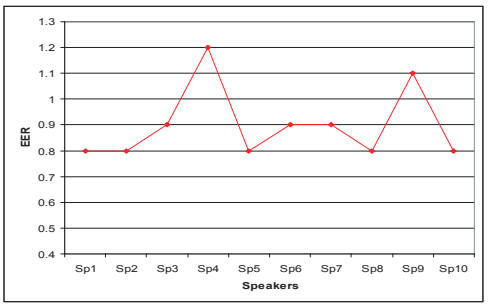
If the matching score is above the threshold obliged by the security level of the application, then authorization is granted and the result is forwarded to the Application Server to authorize the transaction. After a series of successful authorization, the SVBS updates the current voiceprint using the recently received features. In this way, the HMM models of each user are enriched to include more characteristics of the hardware configurations, and noise and emotional conditions. Such a statistical generalization increases accuracy of the system.

If the score does not meet the desired threshold, the authorization is repeated using a new digit sequence. In case the maximum number of three trials is exceeded, authorization is rejected.

4.4 Evaluation Results

Speaker authentication can be performed using various voice characteristics, while many approaches can be followed at the verification stage [3], [4]. Among the features one can extract from a speech signal for speaker authentication purposes, the proposed method utilizes Mel-Frequency Cepstrum Coefficients (MFCC) [5], [6]. Tests using an in-house single digit database recorded over the Internet were performed to evaluate the performance of the proposed system. Specifically, recorded speech (8 KHz, 16 bits, mono) from ten users, were segmented in 25msec frames overlapping with other by 60%, thus a feature vector was output every 10msec. After pre-emphasis of the speech signal, 12 MFCC were computed. To capture time dynamics of the signal, the energy and MFCC first and second time derivatives (called Delta and Delta-Delta or Acceleration Coefficients) [10] were also computed, leading to 36-dimensional feature vector. Notice that Delta and Acceleration Coefficients were not computed at the client-side and transmitted back to the SVBS, since they could be directly computed through MFCC coefficients at the SVBS. Speaker authentication is based on continuous density HMM

Figure 5. Tests with CMS



(Hidden Markov Models). More precisely, a five-state left-to-right HMM with four mixtures is used for each digit, as well as for the silence interval [11]. An additional silence model was trained so as to model the beginning and ending of an utterance and also the intermediate pauses. The HMM are trained through the Baum-Welch algorithm [8], while speaker verification is performed using the Viterbi algorithm [8]. Data from ten users were used to evaluate the speaker authentication performance against False Acceptance Rate (FAR), False Rejection Rate (FRR) and Equal Error rate (EER) [12]. Tests performed using the above conditions resulted an average EER equal to 5%.

In an Internet-based application, it is expected that different microphone configurations and/or environmental noise conditions will appear and affect the speech signal in a different way. This problem, known as the 'mismatched condition' can severely degrade a system's accuracy [6]. To maintain authentication accuracy, a technique such as Cepstral Mean Subtraction (CMS) [13] was used and identical tests were repeated.

It was found that CMS can reduce the effect of the channel appearing in the recordings over the Internet and increase authentication performance by reducing the EER just below 1% as can be seen in Figure 6. Moreover, the problem of mismatched condition can be eliminated through the dynamic update of user's voiceprint after every successful authentication.

5. CONCLUSIONS

Transaction-based Internet applications as continuously grow require higher security mechanisms to protect their data. Simple security mechanisms such as, username and password do not provide high security. Integrating advanced biometric authentication in Internet applications, secure low-risk and convenient transactions.

This paper proposed a novel method for securing online databases using voice biometrics. A system was developed and demonstrated very good verification performance based on this approach. The system consists of the client, the Application Server and the Secure Voice Biometric Server (SVBS). The SVBS generates trains and updates the user's voiceprints, stores them securely in a database, and performs the matching algorithm to authenticate a user.

The proposed architecture is advantageous since it is easily upgraded. Moreover, some heavy-duty functions (i.e. pattern matching, HMM training) have been loaded to the SVBS, and the main responsibility of the client is speech capturing and feature extraction. SVBS can apply different levels of security during the authentication procedure according to the security policy of the current application.

The Whole World at Work: Managers Around the Globe Describe Their IT Experiences – Suggesting a New Framework for Global IT Leadership Development

Patricia Shafer, Compel, Ltd., USA; E-mail: pshafer@compelconsulting.com
Barbara A. Trautlein, Compel, Ltd., USA

ABSTRACT

The foundation of this paper is research titled: "The Whole World at Work: Managers Around the Globe Tell Us What's Changed and What Still Needs to Change in Organizations," conducted from late spring 2004 through early 2006. The research included 160 interviews with managers and consultants working in multinational corporations on five continents, an extensive literature review, and client interventions. We find that the subject of technology is very much on the minds of managers across the organizational value chain. Nearly 47% of "The Whole World at Work" interviewees mentioned technology when asked what has changed most in organizations during their careers, and interview content analysis indicates that a majority of manager comments about technology were mixed or negative in tone. However, when asked to envision the ideal organization of the future, less than 15% of managers made reference to technology. In contrast, more than 90% described the best organizations of the future as ones in which "people" will be at the forefront, with organizations focusing less on mechanics (technology, process and profits) and more on communicating, collaborating, and building consensus. Based on "The Whole World at Work" findings, we propose a previously unidentified global yearning for more holistic organizations and leaders. We have coined a term – E-vergence(SM) – postulating an emerging convergence of manager experiences, views and aspirations around the world. We also propose a model of leadership necessary to foster successful future organizations - The New Hybrid Leaders - multi-dimensional managers developed to exhibit "transformational," "transnational," and "trans-cultural" competencies (Bass, 1998; Trompenaars & Woolliams, 2003). This calls for rethinking and reformulating technology management education within a framework that will achieve comprehensive IT leadership development. New competencies are required for technology managers who aspire to influence increasingly global organizations and achieve career success.

INTRODUCTION

Technology: Promises vs. Reality

Technological change has been a key influencer of organizational strategies in the late 20th and early 21st century, considered one of the five most important organizational variables in the future (Laubacher & Malone, 1997).

As globalization received increasing attention in the 1990s, it was also suggested that a dispersed enterprise is nothing but fragments without common cultural values, and technology is what makes "getting it all together" possible (O'Hara-Devereaux & Johansen, 1994). Also, for many industries, technology continues to be viewed as a competitive driver. In its identification of the top five trends determining future retail banking success, the IBM Institute for Business Value predicted movement towards IT investments focused on "improving responsiveness, resilience and enterprise-wide collaboration" (IBM, 2005).

Yet, there is also a countervailing sentiment that expectations of technology are often unrealistic. Gartner, Inc. analyses indicated that companies' estimated spending on hardware, software, IT services and telecommunications would total $2.6 trillion in 2006. Yet, managers at the vast majority of companies making such investments complain that information overload actually slows down decision-making (Gantenbein, 2006).

So, what is it that happens inside corporations between the expressed hopes of technology and manager perceptions of suboptimal results? What is yet to be done differently?

"The Whole World at Work: Managers Around the Globe Describe Their Organization and Technology Aspirations and Frustrations – Suggesting a New Framework for Global IT Leadership Development" addresses these questions from the vantage point of qualitative interviews conducted with managers in multinational corporations (MNCs). The findings point to the efficacy of a more holistic IT leadership and development framework that can be employed on a global level. The envisioned "sweet spot" is an intersection between manager definitions of the best organizations of the future and a central role that technology managers could play.

METHODS

Research Design

The foundation of "The Whole World at Work" global research was conducted from mid-2004 through early 2006 and consisted of 160 semi-structured qualitative interviews with managers working in MNCs headquartered in North America, Europe, Asia/Oceania and sub-Sahara Africa. Thirty nationalities were represented in the sample.

As Hunter (2005) notes, "in situations where relatively little is known about an area under investigation, such as global research, qualitative approaches allow the researcher to conduct investigations to identify emerging themes" (p. I). In the 1990s, only a small percentage of organizational and human resource management articles was international in outlook (Adler, 2002). A review of the literature also confirms that cross-cultural research specific to technology is sparse. We designed our multinational research to explore particular questions of interest across geography, industry and gender, as well as to see what emerged naturally from the interviews.

We relied on an open-ended narrative interview protocol of ten essential questions with optional sub-question prompts focusing on what has changed, is changing, and still needs to change in organizations. The core interviewee constituency was comprised of 107 people representing MNCs in three industries – Retail Products and Services, Financial Services, and Paper/Printing/Publishing.

The three industries all have a track record of cross-border experience and have publicly articulated "global" as a strategic priority and challenge. Their differences include internal structures, systems and cultures, as well as certain aspects of industry dynamics. Noting both similarities and differences, we speculated that it would be of interest if we discovered a common pattern across these industries.

The 107 managers included 65 men (60.7%) and 42 women (39.3%). Regional representation included 46 from North America (43%), 26 from Europe (24%), 20 from Asia/Oceania (19%), and 15 from sub-Sahara Africa (14%). In the Asian sample, Japanese represented the largest single concentration of interviewees. This was intentional, given that among Asian corporations the Japanese MNCs have the most tenured modern history of competing globally.

Manager positions ranged from one level below CEO to one level above supervisor, and spanned line and staff roles across the organizational value chain. Few interviewees were in roles directly related to or responsible for technology functions. Many, however, had been indirectly responsible for and or largely affected by innovations and change initiatives involving technology. Collectively, 29% reported active involvement in a roll-out such as Enterprise Resource Planning (ERP) or Customer Relationship Management (CRM). The same percentage described involvement in a major restructuring with a required technology implementation. Nearly all had been involved in a major change initiative such as a new product or service introduction, merger, or acquisition that involved use of a new technology.

From the results, we were able to articulate the experiences, views and aspirations of managers across regions, industry and gender regarding:

- the ideal organization of the future;
- what works and does not work in change management;
- effective organizational leadership.

Our methods also revealed internal "barriers" that may prevent organizations from achieving ideals reflected in manager responses.

Interviews generally lasted from 60 to 90 minutes and were transcribed verbatim. We analyzed interviews employing grounded theory methodology and a qualitative data analysis software package (Glaser & Straus, 1967; Weitzman, 2000). We verified the validity of early findings with a subset of original manager interviewees and also incorporated select protocol questions into interviews during client organizational development projects and interventions.

RESULTS

Overall: Presence, Impact, and Effects of Technology on Productivity and People

We did not include questions about technology in our protocol. Yet, unsolicited, 65.4% of interviewees mentioned technology in their responses. (See Table 1). About one quarter (25.2%) of managers described technology as an organizational fact of life, a confirmation that issues of adopting and adapting to new technologies are crossing geographic (e.g. East-West) and economic development (e.g. North-South) boundaries.

Conflicting views were evident in references to effects of technology on productivity (34.6%) and people (35.5%). Managers acknowledged technology-enabled enhancements to productivity and remarked that it is now possible to do business from anywhere, anytime. Conversely, many comments indicated that managers often feel "controlled" by technology and compelled to "try and gain more control" of technology.

From a female manager in North America:

We [don't] get more done because there's just more piled on. You can be efficient if you focus on it. But if you walk around with your pager and cell phone and PC, you're less efficient. You have to know when to not be available, even if you'll get 'dinged.'

Reviewing the Past: What's Changed? People and Technology

"Technology" was the second most common response when managers were asked *what has changed most* and *what is currently changing* in organizations. Just over 50% of managers mentioned "people issues" – the ways employees are treated and the degree to which they are valued. Technology was referenced by 46.7% of managers.

Manager comments regarding technology and change were replete with paradoxes and tensions. Managers often characterized technology as both empowering and encumbering, equating technology with compressing time and fueling the push-pull of:

- *freedom* to work anywhere and *pressure* to work all of the time;
- *higher customer satisfaction* matched by *relentless consumer demand*;
- *more data* that can lead to *paralysis* and *diminished creativity*;
- *faster information flow* eroding *personal relationships* and communications.

From a male manager in Europe:

Globalization [has] been great because I've been able to gain ideas and reflect on how we do the business. The flip side of that, led by technology, is the pressure for global matrix management that can add levels . . . The opportunity is to learn from our peers but not get bogged down in bureaucracy.

Table 1. Talking about technology

Technology Category	ALL %	NA %	Eur. %	Asia %	Africa %
All Comments Concerning Technology Combined	65.4	78.3	61.5	40	66.7
What's Changed/Is Changing	46.7	60.9	46.2	20	40
Opportunities Created	44.9	58.7	30.8	25	53.3

Technology as a Change Management Enabler	4.7	4.3	0	10	6.7
TOTAL Ns Per Region	107	46	26	20	15

NOTE: ALL=all respondents combined; NA=North Americans; Eur=Europeans; Asia=Asians; Africa=sub-Saharan Africans.

Concerns about technology "getting in the way" surfaced in other terms, as well, with 16.8% of managers identifying technology as something that distances us from customers and coworkers. Equal percentages of men and women articulated this view. North Americans (28.2%) expressed concerns about "distancing" more than other regions. Africans (13.3%) were less than half as likely as North Americans to convey this sentiment and Europeans (11.5%) less so. Managers in Asia-headquartered companies (0%) did not say anything that indicated such a concern.

From a female manager in North America:

We say that we're focused on customers [but] we distance ourselves from customers with technology . . . Some of these great technological advancements have created easier ways to do business, but we're not talking to customers as much anymore.

Reviewing the Past: Technology—Neither Change Enabler nor Constrainer

We asked managers to describe the most successful and least successful change projects that they had been involved in or led. Few highlighted technology as a factor either enabling successful change (4.7%) or constraining it (8.4%). Leadership, business understanding, and people factors emerged as more pivotal even in cases where technology implementation was the focal point of a change initiative.

From a male manager in Europe:

I have seen many examples of IT that are not rooted in business understanding. So, they are not as successful as they could be . . . We had to go to SAP [and] it's taken too long and hasn't gotten the results. But I think that this is because it wasn't run as a business transformation vs. a technology project . . . You have to provide the genuine business need and case, not just that you're striving for the latest technology . . . [and spend] a lot of time on stakeholder management.

Reflecting on successful organizational change, managers emphasized the importance of communications/education (70.1%), engaging people (41.1%), and integrating people/cultures (25.2%). Likewise, failures were attributed to a lack of attention to communications/behavior change (38.3%), mutual understanding/alignment (37.4%), and cultural resistance (30.8%).

From a female manager in North America:

You can't build a computer platform without knowing the business model . . . A big key to that is educating our employees. You can have all of the data in the world, but if you don't help people interpret it, and build bridges between departments, well, you don't go very far.

Collins has noted that none of the good-to-great companies began a transformation with technology, yet they all pioneered technology applications to great competitive advantage once they grasped how technology fit within their own context (Collins, 2001). Similarly, when manager interviewees recalled less-than-successful large-scale technology initiatives, they pointed to disconnects between abstract ideas and workplace realities.

From a male manager in Europe:

The least successful projects [were] thought of and executed on a very high and abstract level. For example, they had this big idea to reduce our IT costs by reducing IT infrastructure – consolidating it and getting us on common operating platforms and equipment . . . We're in more than 100 countries . . . You can't run the world with one system or solve all problems with three formulas . . .

Looking Forward: Defining the 'Ideal' Organization

We also asked managers to envision how an ideal organization of the future would look, feel, act, and be experienced by employees, customers and shareholders. In a reversal of interest, less than 15% of interviewees suggested technology would be a key aspect of the best organizations. More than 90% of interviewees described a desired future in which people would be at the forefront of organizational intentions – with leaders supporting strategies to engage, enable and even nurture employees in the face of pressure to focus on cost-savings and profits.

Managers who spoke of an important role for technology said that technology would enhance the future to the extent it builds customer relationships, fosters productivity, enhances communications, bolsters training and development, and achieves more work-life balance. We characterize this as a latent aspiration for organizations to more fully leverage the "human side of IT" (Goman, 2000; Gordon, 2003).

Technology Through a Regional Lens

It appears that MNC managers have much in common regarding experiences and views of the ideal organization of the future and technology. Nevertheless, there are intriguing regional variations. Due to the newness of "The Whole World at Work" research and small sample sizes in sub-Sahara Africa and Asia, we cannot definitively assert or explain these differences. Rather, they merit further investigations and analyses.

North Americans (60.9%) were most likely to cite technology as what *has changed* most and *is changing* in organizations. Asians (20%) were least likely. Technology was described as creating opportunities by 44.9% of managers, with North American managers (58.7%) and sub-Saharan African managers (53.3%) most likely to articulate this view in contrast with managers in Europe (30.8%) and Asia/Oceania (25%). North American managers were also most inclined to describe technology as disrupting their lives.

From a female manager in North America:

[Technology] has increased the pace and the amount that has to be done . . . It's much more of a struggle than ever. I have to consciously make an effort to balance. I do a horrible job of it. I'm struggling.

While European managers also described declines in work-life balance resulting from technology, the more prevalent theme was the detrimental effect of technology used to consolidate decision-making.

From a male manager in Europe:

IT capability has allowed for a lot of centralization capability and centralized control that from a management perspective makes sense, but from an employee standpoint undermines or undervalues the role of the employee in the field. It's compromised our organization.

Against conventional wisdom and stereotype, managers working in Asian MNCs made the fewest references to technology. This scarcity is intriguing given associations of Asian corporations with quality measures, process management, and state-of-the-art manufacturing. Asians speaking of technology focused on how it necessitates that organizations streamline and reduce costs in the spirit of fierce competition.

Sub-Saharan African managers may be divided into two subsets – those in South Africa and those in countries other than South Africa. Both can be described as "pro-technology," but each presents a unique attitudinal profile.

South African managers tended to talk about large-scale, system-wide applications of technology and be *generally* positive in their descriptions of outcomes.

Sub-Saharan African managers outside South Africa were *uniformly* positive about technology and viewed lack of access to technology (not technology itself) as problematic. Indeed, these managers described technology as a kind of Holy Grail, as well as a must-have for Africa's participation on the world stage.

From a male manager in the Ivory Coast:

I must invest in myself to make sure that I learn . . . Most of the work you are going to find incorporates technology . . . Those people [who] upscale themselves are going to succeed.

From a male manager in the Democratic Republic of Congo:

There are no more barriers [with] modern technology . . . You can't any longer say, 'No, I'm in the Congo.' There are [only] international values of performance, of quality . . . If you can't integrate into this new rhythm, you have a problem.

IMPLICATIONS AND DISCUSSION

E-Vergence and 'The New Hybrid Leaders'

Based on "The Whole World at Work" findings, we have suggested (Shafer & Trautlein, 2006) that there exists an *E-vergence*(SM) – an emerging convergence of experiences, views and aspirations for organizations that feel "whole" – where the ethos is one of people and relationships receiving ample attention in the course of managing technology, task and process.

We have also said that evolved organizations of the future will require a model of multi-dimensional leadership dubbed *The New Hybrid Leader* (Shafer & Trautlein, 2006), where the most leaderly of leaders would be equipped and eager to integrate, respond to and lead diverse groups; demonstrate situational flexibility in management style; and be effective in a variety of geographic, cultural and dual-gender settings. These are tenets of "transformational leadership," defined as: individual consideration (fostering partnerships between people, making contact with them, and active communications), intellectual stimulation (fostering learning, risk-taking and joint problem-solving), and charismatic inspiration (visioning and passion) (Bass, 1998).

Development Opportunities for Technology Professionals

"The Whole World at Work" findings indicate that organizations and therefore technology professionals face a shift in expectations. It can be argued that the time has come to develop new competencies. Managers will *value* professionals who can harness the technical aspects of technology as well as lead in new ways.

This suggests the importance of dramatically re-thinking approaches to leadership development in the 21st century, particularly in complex global organizations. A holistic global IT leadership development framework would "deal with the intensification of systemic complexity . . . [and] respond adaptively to the depth, scope and pace of change . . . " (Daloz Parks, 2005). It would be assumed that technology managers are increasingly at the center of networks of information and relationships, but they are able to influence organizations only to the extent that they think and behave as leaders.

From a male manager who heads an IT function for a European MNC that is one of the largest corporations in the world:

You have to align yourself with the business . . . You have to be in there talking about their strategies [and talking] their language . . . I make this a high priority . . . Poor or good communication is 90 percent of everything, especially in IT.

There is growing evidence of the tangible benefits of "soft capacities." Globalization is a process said to be both technological and human (Lodge, 1995). Among engineers and scientists at the top of academic IQ tests, the "stars" also rank high on emotional intelligence (EQ) (Goleman, 1995), and are adept at turning informal networks into ad hoc teams, persuading, and promoting cooperation. According to IT managers themselves, when IT leadership fails, poor interpersonal skills are a likely culprit (Caruso & Gentry, 2005).

From a male North American manager:

One of the consistent problems is mistaking technology as a leading component of the change process. In fact, it's usually the people side and the leadership that is the big challenge.

The current missing link is customized technology leadership development that goes beyond technical skills and topics to include *connectedness*. As we conceptualize it, a "Connected Technology Leaders"(SM) development framework steers clear of formulaic instruction and accounts for the human dynamics of change. Learning occurs through IT managers involved in facilitated dialogues, scenarios and simulations embedded within four foundational components:

- **Core and Context** – understanding personal strengths and weaknesses in reference to "transformational" leadership style assessments.
- **Customers and Colleagues** – appreciating viewpoints of customers and colleagues and integrating into internal and external social networks.
- **Company and Community** – comprehending the vision, strategies and goals of the organization and stakeholders.
- **Components of Continuity** – applying learning and insights through action plans related to real work issues.

Re-framing technology leadership involves increasing technology manager understanding of: 1) how managers define the ideal organization of the future; 2) what works and does not work in change management; and 3) effective organizational leadership. The desired outcome is technology professionals developed to be compelling catalysts of quality decisions in complex organizations.

Technical and Logical Issues Arising from Collaboration Across Multiple Organisations

Abbass Ghanbary, University of Western Sydney, Australia; E-mail: ghanbary@scm.uws.edu.au
Bhuvan Unhelkar, University of Western Sydney, Australia; E-mail: bhuvan@scm.uws.edu.au

ABSTRACT

This paper discusses the technical and corresponding logical modelling issues arising out of Collaborative Business Process Engineering (CBPE). These modelling issues are based on the technologies of Service Oriented Architecture (SOA) and Web Services (WS). Business Process Modelling Notation (BPMN) is applied in this paper in order to present the proposed model of collaboration across multiple organisations. The uniqueness of this research, and the ensuing discussion, is that the collaboration between multiple organizations is envisaged through a 'yellow pages' and not through the known business-to-business (B2B) interaction. As a result, the collaboration discussed in this paper requires applications to publish, locate and communicate with each other across disparate technical platforms.

Keywords: Web Services, Service Oriented Architecture, UDDI Directory, Business Processes, Trust

INTRODUCTION

This paper describes how business processes of multiple organizations can successfully collaborate with each other. The ideas presented in this paper extend the now well-known concepts of B2B (Business-to-Business) collaborations, and apply them to multiple organizations that may not be known to each other and yet may want to get together electronically to satisfy a particular business demand.

B2B integration (or Business Integration) is a secured coordination amongst two or more known businesses and their information systems. It has dramatically transformed the way business is conducted between specific business partners, suppliers, customers and buyers. According to Microsoft, business process integration enables businesses to link their multiple business processes. Such integration of business processes results in what Gates (1999) has called a 'Digital Nervous System' or DNS. Building business-to-business (B2B) e-commerce systems presents many challenges to the system architect. Each company involved, stores its data and documents in formats that are likely to be different from the formats used by the other participating companies. There is, obviously, a need for companies to integrate what tend to be vastly different systems http://www.microsoft.com/technet/prodtechnol/biztalk/biztalk2000/evaluate/biztalka.mspx.

However, with the advent of Web Services (WS) and Service Oriented Architecture (SOA), it is now possible for businesses to offer as well as locate and consume services irrespective of the physical location of awareness of these businesses with each other. According to Hao (2003) SOA is an architectural style whose goal is to achieve loose coupling among interacting software agents. The SOA achieve loose coupling among interacting by employing a small set of simple and ubiquitous interfaces to all participating software agents. The interfaces should be universally available for all providers and consumers. Also descriptive messages constrain by an extensible schema delivered through the interfaces. A schema limits the vocabulary and structure of messages. An extensible schema allows new versions of services to be introduced without breaking existing services http://webservices.xml.com/lpt/a/1292.

This technical ability of businesses to collaborate with each other has lead to some interesting challenges in terms of both the technologies and the resulting logical interactions between businesses. These challenges emanate from the fact that in CBPE, we are attempting to model services that can be offered and consumed by organizations that may be unknown to each other electronically. This ability to offer services by publishing them on the Internet, and then locating and consuming them, results from the ability of web services to 'transcend' technological boundaries and environments, as discussed later in this paper.

As a part of the development of model for successful collaborative business process engineering, many important issues and challenges were identified and studied. Based on the three-dimensional process framework developed by Unhelkar (2005), these issues and challenges could be broadly categorised into technical, methodological and social challenges. Technically, the challenge is to study the simplicity of implementation of Web Services and their corresponding security and performance issues. These technical issues, revolving around Service Oriented Architecture (SOA) further expand into identifying the availability and management of the various channels of transaction capabilities between the collaborating organizations. Methodologically, the challenge is to identify, model, evaluate and investigate the impact of collaborative business processes on the structure and dynamics of the collaborating organisations. Socially, collaborations lead to challenges in terms of privacy, trust, legal as well as cross-cultural issues between the organizations.

The paper is presented as follows: Starting with a literature review in the area of business collaboration, the discussion deals with the web services technologies and models and the integrated collaborative business processes using a standardised business process management notation (BPMN). Finally, the impact of collaborative web based system on trust is discussed, and concluded with the potential for a successful CBPE model resulting in business integration across multiple unknown businesses.

LITERATURE REVIEW

The advent of the Internet and computer mediated communication has intensified the nature of collaboration between businesses. This is so because of the ever increasing ability of the Internet to enable business applications to interact with each other quickly. The resultant electronic collaborations (e-collaborations) are also broadly defined as collaboration among individuals engaged in a common task using electronic technologies http://cits.tamiu.edu/kock/pubs/journals/2005JournalIEEETPC/KockNosek2005.pdf.

The existing literature does not explain in sufficient detail how to extend the aforementioned electronic collaboration across many organisations that would enable them to share their products and services. We believe that such an extension is possible through the application of Web Services technologies. This belief also appears to be supported by Goethals and Vandenbulcke (2006), who mention that Web Services could be used for integrating system for collaboration even amongst unknown parties.

Fong (2006) describes the main challenge of the collaboration when the involved organisations have to make the investment necessary for replacing redundant or older system as well as building a dynamic platform that incorporates multiple standards. The challenge is further increased when, in unstructured e-collaboration (without prior contract), creating or exchanging of non-standard documents takes place.

Web Services are a suit of technologies that enable web applications to 'talk' with each other independent of their technical environments. Web Services are based on XML (), WSDL () and UDDI (). Web Services is a newly emerging distributed computing model for the web. S'duk and Unhelkar (2005) define Web Services as an attractive service model able to incorporate standards and open protocols for calling services and transmitting data. Web services make software functionality available over the Internet so that programs can request a service running on another server (a web service) and use that program's response in a website, WAP service, or other application. According to Unhelkar & Deshpande (2004), Web Services based technologies enable applications to "talk" with one another even across organisational firewalls, resulting in an opportunity for a cluster or group of organisations to simultaneously transition to Web-based entities.

Tilley, et al, (2002) describes the WS as a novel approach to engineer and deploy software solutions such as cooperative information systems. Snell and Tidwell (2002) define WS as a network accessible interface to application functionality, built using standard Internet technologies. Another definition by Cerami (2002) state that any services that are available over the Internet, uses a standardised XML messaging system, and are not tied to any one operating system. Thus we see that WS tend to offer opportunities that are way beyond the business integration that is commonly discussed and that merely talks about document exchanges. For example, it is very important from this research point to note the view of Kirda, et al, (2001), who declares that Web Services hold the promise of considerable gains for many organisations by giving them the opportunity to develop techniques to effectively integrate disparate applications by leveraging computer technology. Not only do integrated systems can provide better business value by sharing data, communicating results and improving overall functionality, but the mere ability to integrate systems opens up doors to synergise between systems of disparate organizations.

The ability to promote as well as locate services, however, is provided through Universal Data Dictionary Interface (UDDI). UDDI is a platform-independent, XML-based registry for businesses worldwide to list themselves on the Internet. Enterprise UDDI Services is a key element of Web Services infrastructure that provides a standards-based solution for discovery, sharing, and reuse of Web services, helping to maximize the productivity of developers and IT professionals. The purpose of UDDI is to allow users to discover available web services and interact with them dynamically. The process can be divided into three phases: Searching (discovery), Binding, and Executing.

Roy and Ramanujan (2001) states that UDDI specifications provide a mechanism to register and locate WS. It defines an electronic business registry where businesses can describe their business and register their WS as well as discover and integrate with other businesses that offer Web Services.

Considering, Goethals and Vandenbulcke (2006) emphasis that the UDDI is currently not the best means for realising Web Services discovery since they are accessible to anyone resulting the pollution of the registries. Hence, UDDI will allow companies to publish information about the Web Services they offer in a Universal Business Registry (UBR) that will be accessible by anyone. The solution would be to use the private UDDI or WSIL (Web Services Inspection Language).

The study of the existing literature brings us to the following questions as mentioned in the report by microsft.com. As the number of companies that offer Web-based services increases exponentially into the millions, how do buyers looking for a specific service find all of the potential sellers who can meet their needs?

Considering Pollock (2002) opinion that most problems contributing to the high failure rates of integration projects are not technical in nature, but logical, the following will recommend a technical/logical model to resolve already identified problems.

THE WEB SERVICE TECHNOLOGIES

The research is facing many challenges as it investigates the issues involved within the collaboration across multiple organisations. For example, there are the issues of how to create the proper channels of collaboration, what is the confidence level of these created channels and how these organisations could trust and collaborate when they do not even know each other?

As mentioned previously, it was realised some of the challenges such as the channels and their availability are technical issues. The issue of trust can be classified as a logical issue dealing with human factor. This study needs to investigate and identify a way for technology to solve the human related factor of trust. The study further revealed the need to put in place a mechanism in for organisations to define/publish and locate/consume each other's applications specifically when they are not even aware of each other's physical existence.

Figure 1 (Unhelkar, 2003), explains how Web Services are able to define and publish at the same time locate and consume services and applications. While the XML application is defined by WSDL and published by UDDI the same application is located by UDDI and can be consumed by WSDL. Therefore the application can talk even when the organisations are using disparate platforms.

The circle on the left hand side present that the Web Services, specifically WSDL define the XML application and the UDDI publishes the application. And, on the right hand side circle, the UDDI locate the original XML application that was submitted by left hand circle and the WSDL of the right hand side circle consume the application.

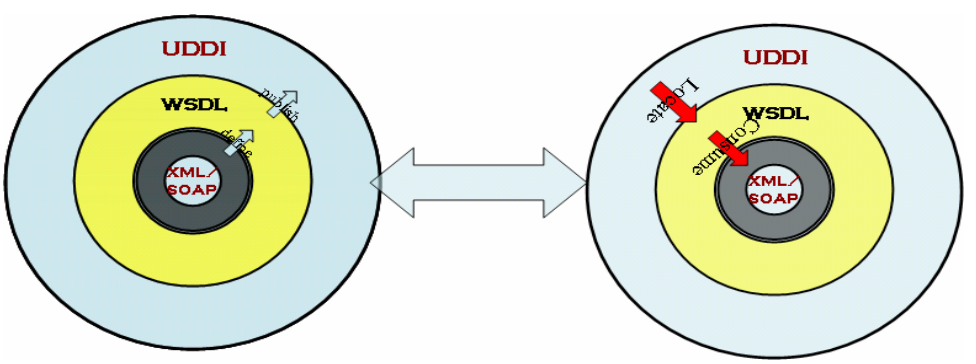
The literature review on the concept of the WS triggered the study by applying the existing technology of Web Services to propose a new model of Collaborative Web Based System (CWBS). The applications of the multiple organisations could be defined/published and located/consumed.

The literature review clearly explained how the WS specifically the UDDI could be applied to create entirely new channels of the collaboration that will not pollute the UDDI directory.

The study proposes two levels of the UDDI directories to register the organisation's information. The first level registers the industries while the second level registers organisation information such as name, address, products and services offered.

The channels of collaborations are illustrated in Figure 2, by identifying that UDDI directories can also publish and locate applications, the demonstrated model was automatically validated hence the different level of the UDDI's directories could also communicate with each other.

Figure 1. The Web services model (Extracted from Unhelkar (2003))



The level 2 directories would not be able to communicate with each other directly. The submitted applications can only published/located through level one directory for the better management of the CWBS.

Figure 2 will present the unique model of the collaboration amongst the multiple organisations that necessarily are not known to each other. These organisations might never have business agreement prior collaborations.

The red dotted line in the picture present a request entering the Collaborative Web Based System (CWBS), based on the request, the CWBS send the request to the first level to identify the industries involved. Then, the system will send it to level 2 in order to find the organisation capable of handling the request and submit the application. The proposed model will have the capability the send the application (request) to multiple organisations either in same or different industry until the process is competed and submitted back, informing the client of final result.

The system is also capable of performing another transaction by submitting the application back to the first level to find the related industry for further processing in the level 2. This classification places the industries as well as the organisations in the allocated place to make it very easy for their publication and location without polluting the directories.

The Figure 2 also illustrate how the organisations and the users not adapting the Web Services will remain outside of the model, unable to use or register in the system (Red organisations). However, if an organisation or a client using the systems facilities, but not registered, are allowed to use the system as long as they are using the Web Services. (Green organisations)

The application will return back to the client after completion, informing the finalisation of the request by supplying all the related booking and transactions numbers. The red dotted line shows existing channels of collaborations across the organisation and clearly shows how the participants could collaborate.

PROPOSED BUSINESS PROCESS MANAGEMENT NOTATION

In this section of the paper, the authors present the Business Process Management Notation (BPMN) designed for the software implementation of the proposed model in Figure 2. Business Process Modelling Notation (BPMN) will provide businesses with the capability of understanding their internal business procedures in a graphical notation and will give organizations the ability to communicate these procedures in a standard manner. Furthermore, the graphical notation will facilitate the understanding of the performance collaborations and business transactions between the organizations (http://www.bpmn.org/Documents/NWG-2001-09-01R4%20Charter.pdf).

Figure 3 depicts the process where a prospective member is ready to register in the system. It is very important to note that different prospective members such as user, person (`Doctor`, `Patient`) and organisations could connect to the Collaborative Web Based System (CWBS) to register. The CBWS does not classify them as a member until the registration is completed.

Prospective Member connects to the CWBS and requests to register in the system. The CWBS prompts the appropriate member registration form to the prospective member to enter the relevant details. If the information is insufficient or incorrect prospective member is asked to input correct details.

Then, CWBS prompts that the registrations form to be submitted and the prospective member submits the registration form. At the end, CWBS registers prospective member sending a unique registration number. The system recognises the prospective member as a member and allows the client to log out of the CWBS.

As depicted in Figure 3, the developed system is ready to accept registration of all prospective members. A prospective member could be any one of the following persons (user of the `system`, `doctor`, `Patient`) or an organisation such as police, insurance company, pharmacist, hospital, Health care system or any other organisations.

In Figure 4, the CWBS places the registration in the allocated directory in order to avoid the pollution of the directories. The CWBS identifies the relevant member industry from the registration form. The CWBS identify the industry's registration by informing the administrator for further direction if the industry does not exist. The directory level 1 will receive an identification number from that specific member and the CWBS register the member details of the member in directory level 2. Finally, the system stores the member details in the database. This is an automated process and only instance of human actor involvement will occur when the specified industry is not available in CWBS.

The Figure 4 illustrates how an automated process places the member details in the right place for the uncomplicated publish/locate process. The difference between the process shown in Figure 4, and a non-collaborative business process would be that the non-collaborative business process would *not* have the directories.

Figure 5 further illustrates the nature of CWBS. In Figure 5, channels of identifying a desired organisation are based on directories where the product and services they offer are stored. The process is triggered when a client submits a request (an inquiry) to the CWBS. It is very important that the user is using the Web Services. CWBS accept the request and identify the member's relative industry/industries based on the submitted request.

The CWBS prompts an optional form requesting details of registration if the Client is not a member. The CWBS prompts a message denying the request when there is no prior registry of the organization capable of handling the request.

The CWBS finalize the appropriate checks and submits the application to the directory level 1. The directory level 1 identifies the industry and submits the application to suitable level 2 directory to identify the organisation capable of

Figure 2. Proposed model of collaboration across multiple organisations

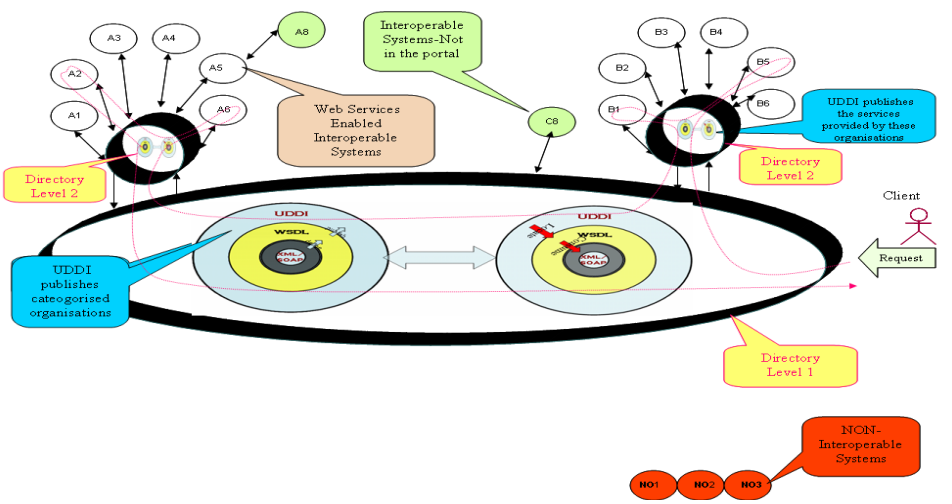


Figure 3. Registration of prospective members

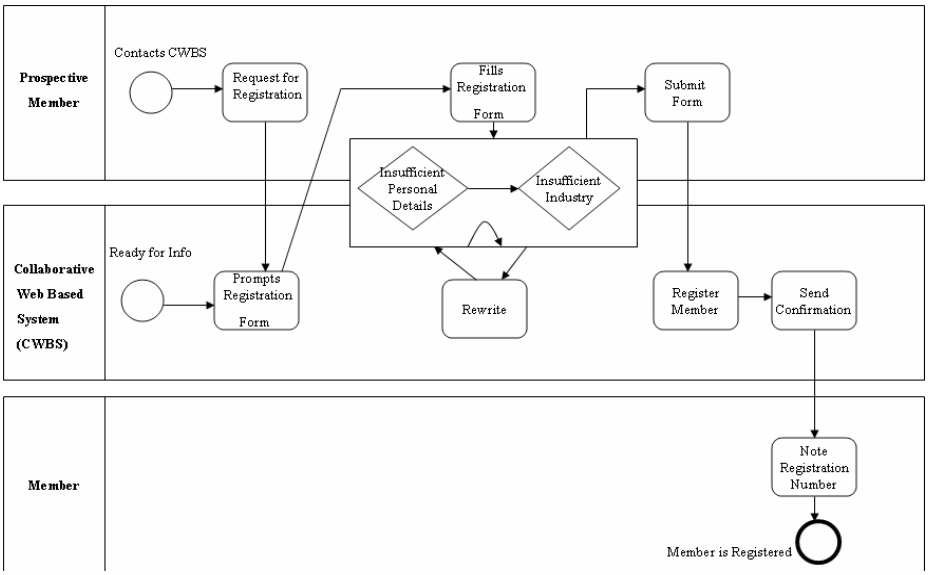

Figure 4. Place the registration in the directory

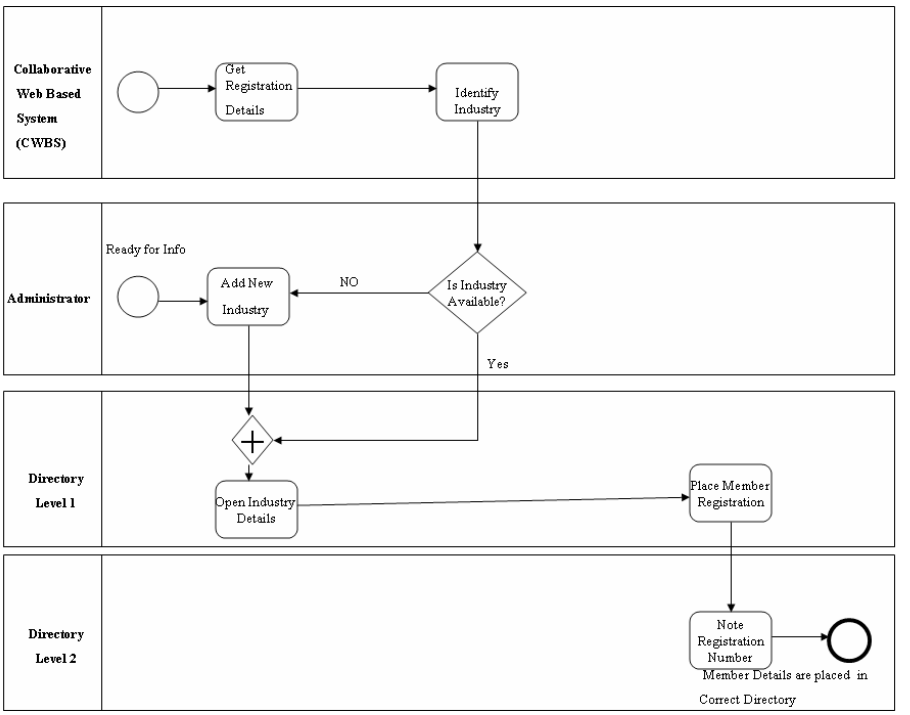


handling the requests. Then, CWBS eliminates the organisations that are not meeting the environmental boundaries (geographical, budget, member optional preferences).

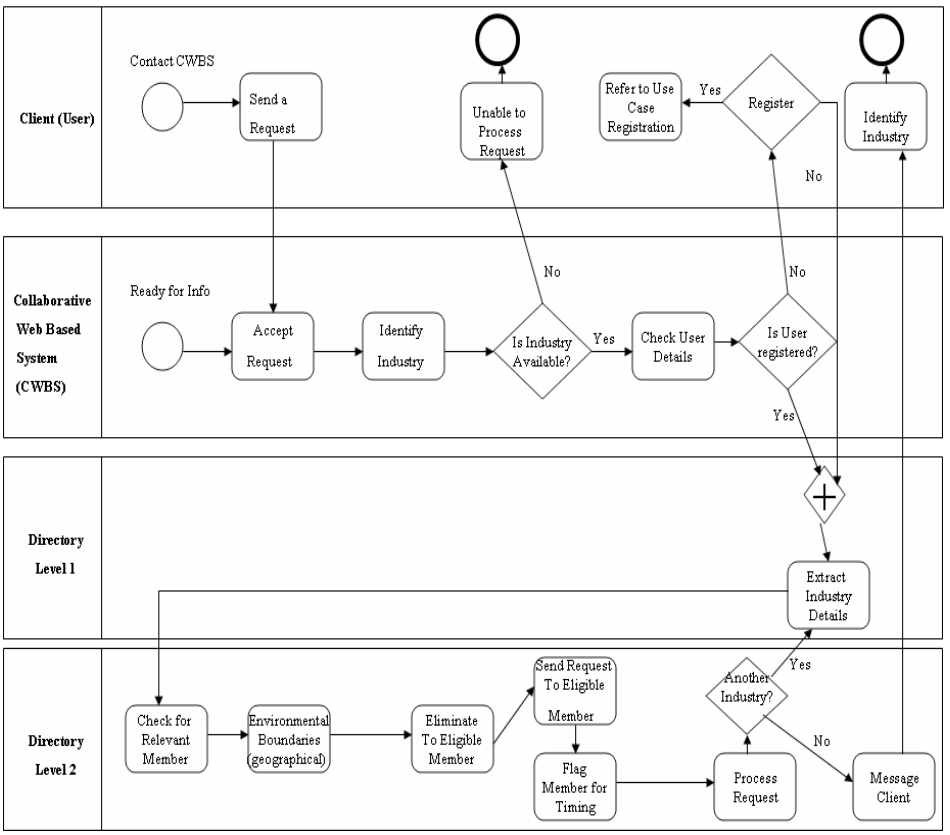
The CWBS follows eliminations of the capable parties who have received the most recent requests. In the next stage, the CWBS processes the client request and collaborates with selected members regarding request.

Right at this stage, the system flags the members involved in the process not to receive the next query. The application will return back to level 1 and if other industries should be involved in the request, the CWBS will go through the process of locating them in order to complete the request.

Finally, the CWBS prompts a message to client informing the outcome of the requested application and allows the user to log out.

Figure 5 above, illustrated the finalising of the processing a request that could be a classified as a very complex type. In this figure, the business process collaboration of multiple organisations is engineered. It is also clearly demonstrated how they collaborate without even knowing each other. The Web Services technology

Figure 5. Process service/product request



creates an opportunity for their application to process and progress regardless of the original platform used for their ordinary process.

IMPACT OF COLLABORATIVE WEB BASED SYSTEM ON TRUST ACROSS ORGANISATIONS

Having considered how the business processes of multiple organisations can be engineered in a way to collaborate, the study can focus on the trust issues amongst them. Jessup and Valacich (2006) outline three different relationships classified in the modern business world as basic, preferred and strategic. A basic relationship can be best described as buy products and services on the basis of price and convenience. Preferred relationship occurs when buyer and seller set preference and price to benefit each other and in strategic relationship both sides share risks and rewards.

The preferred relationship between the ***company*** and ***consumers*** takes place while the most influencing factor of ***trust*** is respected. Those factors are classified as positive customer service experience, length of the relationship with company, company or product reputation, brand familiarity and privacy policies. Therefore, the factors most damaging the trust could be classified as online security fears, telemarketing, company reputation by past incident, general suspicious of company and the disapprove of the company's business practice. http://www.clickz.com/stats/markets/professional/article.php/3312681#table2.

In the proposed environment, the organisations collaborate (work together) rather than compete (work against). The business processes (Applications) of the participated organisation work together to serve a customer request.

The system immediately identifies the industry/organisations involved in the process as soon as the original application is submitted. The application will be submitted to the relevant organisation in the order of priority. For example, if the client is a patient and submitting a request to appoint and see a doctor, the client is unable to purchase the medication online before the doctor submitting the prescription online.

In the given example, the application will be forwarded to the doctor for further process. The system then submits the application to the pharmacy for further processing. However, the doctor and pharmacy might not know each other, hence the system is locating the pharmacy there is really no issue of the trust involved since the client can actually carry the physical prescription to any pharmacy and purchase the medication.

This comparison shows the difference between the two processes – without and with CWBS – especially in the way in which it affects the roles played by people in the organizations and the role of the client. The application will be submitted to an organisation for further process and confidentiality of the involved organisations is indeed respected.

CONCLUSION AND DIRECTION

This research investigated the current collaboration (Business-to-Business) in order to look at possible solutions to enhance the collaboration across business processes of multiple organisations that are not necessarily known to each other. The business processes were studied in order to find the suitable channels of collaboration and evaluate the availability and the level of confidence of the proposed channels.

The paper explained how Web Services can facilitate engineer the collaborative business processes across multiple organisations. The logical challenge was also resolved by proposing a model of collaboration and the illustrated Business Process Management Notation (BPMN) illustrated the availability of the channels systematically and carefully under the guiding principles of the proposed directories.

As per Ghanbary (2006), when an organization undergoes electronic transition (e-transition), there is ample focus on the effect of the rapidly evolving technology on the dynamic environment as well as the structure of the organisation. Undoubtedly, transitions cause organizations to restructure and would introduce a new suite of business processes enabling them to remain in the market as well as grow by dealing with greater number of customers.

In the proposed model, the confidentiality of the participated organisations will be respected while the business processes will be fully collaborative. The research will need more investigation in order to study the actual impact of the collaborative business process on social (trust and legal) issues.

ABSTRACT

Perceptron learning is proposed in the context of so-called scoring systems used for assessing creditworthiness as stipulated in the Basel II central banks capital accord of the G10-states. The approximate solution of a related ranking problem using a large margin algorithm is described. Some experimental results obtained by utilizing a Java prototype are exhibited. From these it becomes apparent that combining the large margin algorithm presented here with the pocket algorithm provides an attractive alternative to the use of support vector machines. Related algorithms are briefly discussed.

1. INTRODUCTION

At least since the Basel II central banks capital accord of the G10-states, cf. e.g. [1], the individual objective rating of the creditworthiness of customers has become an important problem. To this end so-called scoring systems, cf. e.g. [12], [23], [17], [6] have been used for quite some time. Generally these systems are simple classifiers that are implemented as (linear) discriminants where customer characteristics such as income, property assets, liabilities and the likes are assigned points or grades and then a weighted average is computed, where a customer is judged "good" or "bad" according to whether the average exceeds a cut-off point or not. In an extreme case the attributes are just binary ones where 0 respectively 1 signifies that the property does not hold respectively holds. This situation frequently arises in practice. The weights can then either be computed using classical statistical methods or more recently employing artificial neural networks, cf. e.g. [19], provided that suitable bank records are available for training.

However, the use of only two classes for the classification of customers presents certain problems. The event of a credit default for example is not precisely defined, cf. [1], p. 92, so that banking records would almost certainly need at least one more class (e.g. "doubtful (?) customers"). This indicates that a finer distinction among customers could be useful. Indeed, after a computation of default probabilities (again usually based on two classes) banks divide customers into a larger number of classes. This, of course, seems rather counter-intuitive, since surely the division should (and could) be based on experience and be effected before probabilities are computed. Hence in this paper it is assumed that training data are available, where banking customers are divided into mutually disjoint risk classes $C_1, C_2, \ldots, C_k$. Here class C_i is preferred to C_j if $i<j$. It was shown in [8] how this preference relation may be learned employing a generalized version of the pocket algorithm to solve the associated ranking problem. Unfortunately this is not a large margin algorithm, cf. e.g. [11], and hence in this paper a large margin perceptron ranking algorithm based on the work of Krauth and Mezard, cf. [14], will be presented.

Note that the use of several classes has been investigated beforehand, see e.g. [2], p. 237. Moreover, the use of ranking functions has been recognized in an information retrieval context, cf, e.g. [25], for solving certain financial problems, cf. [15], and for collaborative filtering, cf. [20], [21]. However, at least in the banking business, ranking functions, as described in section 2 below, see also [7], [22], apparently have not been used before for the rating of customers. Note also that the fixed margin ranking algorithm described in [20] and [21] involves solving a quadratic and a linear programming problem successively whilst the algorithm presented below is obtained from a reduction of the ranking problem that allows a surprisingly simple albeit approximate solution using a modified perceptron learning algorithm.

2. REDUCTION OF THE RANKING PROBLEM

Suitable anonymous training data from a large German bank were available. In abstract terms then t vectors $\mathbf{x}_1, \mathbf{x}_2, \ldots, \mathbf{x}_t$ from $\Re^n$ (think of these as having grades assigned to individual customer characteristics as their entries) together with their risk classification (i.e. their risk class C_s for $1 \le s \le k$, where the risk classes were assumed to constitute a partition of pattern space) were given. Hence implicitly a preference relation (partial order) "$\rangle$" in pattern space was determined for these vectors by

$$\mathbf{x}_i \rangle \mathbf{x}_j \qquad \text{if } \mathbf{x}_i \in C_i \text{ and } \mathbf{x}_j \in C_j \text{ where } i < j.$$

It was then required to find a map $m_{\mathbf{w}}: \Re^n \to \Re$ that preserves this preference relation, where the index $\mathbf{w}$ of course denotes a weight vector. More precisely one must have

$$\mathbf{x}_i \rangle \mathbf{x}_j \qquad \Rightarrow m_{\mathbf{w}}(\mathbf{x}_i) > m_{\mathbf{w}}(\mathbf{x}_j)$$

If one now specializes by setting $m_{\mathbf{w}}(\mathbf{x}) := \langle \phi(\mathbf{x}), \mathbf{w} \rangle$, denoting the scalar product by $\langle .,. \rangle$ and an embedding of $\mathbf{x}$ in a generally higher (m-) dimensional feature space by ϕ, then the problem reduces to finding a weight vector $\mathbf{w}$ and constants ("cut-offs") $c_1 > c_2 > \ldots > c_{k-1}$ such that

$$\mathbf{x} \in C_1 \text{ if } \langle \phi(\mathbf{x}), \mathbf{w} \rangle > c_1$$
$$\mathbf{x} \in C_s \text{ if } c_{s-1} \ge \langle \phi(\mathbf{x}), \mathbf{w} \rangle > c_s$$
$$\text{for } s = 2, 3, \ldots, k\text{-}1$$
$$\mathbf{x} \in C_k \text{ if } c_{k-1} \ge \langle \phi(\mathbf{x}), \mathbf{w} \rangle.$$

The problem may then be reduced further to a standard problem:

Let $\mathbf{e}_i$ denote the i-th unit vector in $\Re^{k-1}$ considered as row vector and construct a matrix $\mathbf{B}$ of dimension $(m_1+2m_2+k-2)\times(m+k-1)$, where $m_1 := |C_1 \cup C_k|$ (here $|S|$ denotes the cardinality of set S) and $m_2 := |C_2 \cup C_3 \ldots \cup C_{k-1}|$, as follows:

$\mathbf{B} := \begin{bmatrix} \mathbf{R} \\ \mathbf{D} \end{bmatrix}$, dimension R = (k-2) ×(m+k-1), and the i-th row of $\mathbf{R}$ is given by the row vector $(0, \ldots, 0, \mathbf{e}_i - \mathbf{e}_{i+1})$ with m leading zeros. Moreover $\mathbf{D}$ is described by:

For every vector $\mathbf{x}$ in C_1 respectively C_k $\mathbf{D}$ contains a row vector $(\phi(\mathbf{x}), -\mathbf{e}_1)$

respectively $(-\phi(\mathbf{x}), \mathbf{e}_{k}-\mathbf{e}_{1})$, whilst for every vector $\mathbf{x}$ in C_s with $1 < s < k$ it contains the vectors $(\phi(\mathbf{x}), -\mathbf{e}_s)$ and $(-\phi(\mathbf{x}), \mathbf{e}_s-\mathbf{e}_1)$. The reduction of the problem to a system of inequalities is then proved by the following lemma.

Lemma 1: A weight vector $\mathbf{w}$ and constants $c_1 > c_2 > \ldots > c_{k-1}$ solving the ranking problem may (if they exist) be obtained by solving the standard system of inequalities $\mathbf{Bv} > \mathbf{0}$ where $\mathbf{v} := (\mathbf{w}, c_1, c_2, \ldots, c_{k-1})^T$.

Proof (see also [7]): Computation.

Of course, it must be admitted that the existence of a suitable weight vector $\mathbf{v}$ is by no means guaranteed. However, at least in theory, the map ϕ may be chosen such that the capacity of a suitable separating hyperplane is large enough for a solution to exist with high probability, cf. [4].

The price one has to pay for this increased separating capacity consists on the one hand of larger computation times. On the other hand, and perhaps more importantly, a loss of generalization capabilities due to a higher VC-dimension of the separating hyperplanes, cf. e.g. [24], must be taken into account. Hence it seemed advisable to employ fault tolerant perceptron learning using a generalized version of the pocket algorithm, cf. e.g. [11], [7]. In order to further improve the generalization properties here a large margin perceptron ranking algorithm based on the work of Krauth and Mezard will be presented. This may be be used to construct a separating hyperplane that has the large margin property for the vectors correctly separated by the pocket algorithm. The reader should compare this to the large margin ranking described in [20]: There the problem is solved using a (soft margin) support vector machine. Unfortunately computation of the complete set of cut-offs requires the solution of an additional linear optimization problem.

3. LARGE MARGIN PERCEPTRON RANKING

Here the minimal distance of any vector to the closest cut-off will be maximized. The reader should compare this to the fixed margin strategy in the sense of [20].

3.1 Pseudo Code for Perceptron Ranking

First note that the reduction of the ranking problem in section 2 immediately leads to an elegant perceptron ranking algorithm (where separability is assumed).

The **pseudo code** for this algorithm reads as follows.

Perceptron Ranking Algorithm

Input: Binary vectors $\mathbf{x}_1, \mathbf{x}_2, ..., \mathbf{x}_t$ (or vectors with integer entries) from Z^n with corresponding classifications $b_1, b_2, ..., b_t$ from $\{1, 2, \ldots, k\}$ (where the classes $C_1, C_2, \ldots, C_k$ for simplicity have been denoted by their indices) as training vectors, and a function ϕ: $Z^n \rightarrow Z^m$, where in general m>n.

Output: A weight vector $\mathbf{w}$ and k-1 cut-offs c_i satisfying $c_1 > c_2 > \ldots > c_{k-1}$ as vector $\mathbf{c}$ that solve the ranking problem.

Initialize $\mathbf{w}$, $\mathbf{c}$ arbitrarily.
Cycle through the t+k-2 vectors $\mathbf{e}_1-\mathbf{e}_2$, $\mathbf{e}_2-\mathbf{e}_3$, ... $\mathbf{e}_{k-2}-\mathbf{e}_{k-1}$, $\phi(\mathbf{x}_1)$, $\phi(\mathbf{x}_2)$, ..., $\phi(\mathbf{x}_t)$ and do until no further erroneous classifications occur
If $< \mathbf{e}_p-\mathbf{e}_{p+1}, \mathbf{c}> \leq 0$ then
  $c_p := c_p + 1$;
  $c_{p+1} := c_{p+1} - 1$;
End If
If $\mathbf{x}_p \in C_s$ & $<\phi(\mathbf{x}_p), \mathbf{w}> \leq c_s$ & $1 \leq s \leq k-1$ then
  $\mathbf{w} := \mathbf{w} + \phi(\mathbf{x}_p)$;
  $c_s := c_s - 1$;
End If
If $\mathbf{x}_p \in C_s$ & $<\phi(\mathbf{x}_p), \mathbf{w}> \geq c_{s-1}$ & $2 \leq s \leq k$ then
  $\mathbf{w} := \mathbf{w} - \phi(\mathbf{x}_p)$;
  $c_{s-1} := c_{s-1} + 1$;
End If
Return $\mathbf{w}$, $\mathbf{c}$

Remark: The restriction on the entries of the training vectors, which would be rather a nuisance for practical applications, can be removed fairly easily, cf. [18].

3.2 Correctness Proof for Perceptron Ranking

This follows immediately from the Perceptron Laerning Theorem, cf. [16] and [3] by observing that its application to the ranking problem as presented in section 2 leads to the update operations given in the pseudo code above. Note here that for perceptron learning under the assumed separability the monotonicity of the cut-offs is guaranteed already if the inequalities resulting from the block matrix $\mathbf{D}$ in section 2 are satisfied. Hence here the pseudo code could be shortened accordingly. However, if application of the pocket algorithm is envisaged, then the inequalities resulting from the block matrix $\mathbf{R}$ in section 2 constitute rules that must be fulfilled and hence cannot be ignored if a small number of faults is considered admissible. The reader may wish to consult [22], for a similar ranking algorithm. It is, however, given using a kernel version and its Novikoff bound will be somewhat worse in general as can fairly easily be seen.

3.3 Pseudo Code for Large Margin Perceptron Ranking

The work of Krauth and Mezard concerning large margin perceptron learning is described in [14]. Certain modifications were necessary in order to combine it with 3.1 and obtain a large margin algorithm, cf. [9]

The **pseudo code** for this algorithm reads as follows.

Input: Binary vectors $\mathbf{x}_1, \mathbf{x}_2, ..., \mathbf{x}_t$ (or vectors with integer entries) from Z^n with corresponding classifications $b_1, b_2, ..., b_t$ from $\{1, 2, \ldots, k\}$ (where the classes $C_1, C_2, \ldots, C_k$ for simplicity have been denoted by their indices) as training vectors, and a function ϕ: $Z^n \rightarrow Z^m$, where in general m>n. In addition a real number $\alpha > 0$ must be chosen.

Output: A weight vector $\mathbf{w}$ and k-1 cut-offs c_i satisfying $c_1 > c_2 > \ldots > c_{k-1}$ as vector $\mathbf{c}$ that approximate the maximal margin solution of the ranking problem. The approximation improves with increasing α.

Initialize $\mathbf{w}$, $\mathbf{c}$ with $\mathbf{0}$, $\mathbf{0}$.
Loop
For the given vectors $\phi(\mathbf{x}_1), \phi(\mathbf{x}_2), ..., \phi(\mathbf{x}_t)$ compute the minimumm of the following expressions:
  (i) $<\phi(\mathbf{x}_i), \mathbf{w}> - c_s$ if $1 \leq s \leq k-1$ for $\mathbf{x}_i \in C_s$, $1 \leq i \leq t$
  (ii) $-<\phi(\mathbf{x}_i), \mathbf{w}> + c_{s-1}$ if $2 \leq s \leq k$
Then m either has the form
  (a) $m = <\phi(\mathbf{x}_j), \mathbf{w}> - c_s$ for some j und $\mathbf{x}_j \in C_s$
  or
  (b) $m = -<\phi(\mathbf{x}_k), \mathbf{w}> + c_{s-1}$ for some k und $\mathbf{x}_k \in C_s$
If $m > \alpha$ then
  display $\mathbf{w}$, $\mathbf{c}$;
  stop;
Else
  If (a) then
    $\mathbf{w} := \mathbf{w} + \phi(\mathbf{x}_j)$;
    $c_s := c_s - 1$;
  Else
    $\mathbf{w} := \mathbf{w} - \phi(\mathbf{x}_k)$;
    $c_{s-1} := c_{s-1} + 1$;
  End If
End If

So in contrast to the ordinary perceptron ranking in the wide margin perceptron ranking the update operation is performed with the "worst" classified element as opposed to with an arbitrary misclassified element.

Note that for the case $\alpha = 0$ the original perceptron ranking as in 3.1 is obtained. Note also that a correctness proof of the algorithm follows from the correctness proof of the slightly modified Krauth/Mezard algorithm as given in [9] and the correctness proof in 3.2.

Perhaps it should also be pointed out that in analogy to ordinary perceptron learning kernel versions of both algorithms are readily deducible since in both cases only scalar products need to be computed to decide on the update operation.

3.4 Experimental Results

In order to test the large margin algorithm and with a view to further extensions a Java prototype was constructed. This was connected to an Access database via ODBC. In addition an Excel system with the Solver installed was employed for quadratic programming.

The experiments were carried out with 58 data vectors, which allowed perfect separation, provided by a German financial institution. The customers had been divided into 5 preference classes and the method by which the classes had been obtained was not disclosed (originally there were only 4 classes but six likely looking candidates were assigned to class 5 thus creating a slightly artificial situation). Each customer was characterized by 8 attributes where each attribute had been assigned a grade (from 1 to 5, where 1 is the best grade) based on evaluations by internal computer programs (again the details of this evaluation are not disclosed to outsiders). This led to an obvious reversal in some inequalities of the algorithm since the lowest weighted average grade was considered the best. The experiments were conducted on a standard laptop (1.47 GHz clock, 512 MB RAM). In order to test the quality of approximation measurements were conducted for various values of α (denoted by alpha in the Excel diagrams). For simplicity the function φ appearing in the algorithm was taken to be the identity. Moreover for comparison purposes the optimal large margin weights and cut-offs were calculated by solving the following quadratic programming problem employing the Excel Solver:

Minimize $\|\mathbf{w}\|^2$ subject to

$\langle \mathbf{x}_i, \mathbf{w} \rangle - c_{s-1} \geq 1$ for s = 2, 3, 4, 5

$\langle \mathbf{x}_i, \mathbf{w} \rangle - c_s \leq -1$ for s = 1, 2, 3, 4

where $\mathbf{x}_i \in C_s$ and i = 1, 2, 3, …, 58.

In this programming problem the entries of the vector **w** and the cut-offs were declared as variable to the Excel Solver so as to simultaneously get an optimal weight vector and optimal cut-offs

As a measure of the quality of approximation the distance of the "worst-classified" element to the nearest cut-off was computed. In diagram 1 the result for the optimal solution namely 0.0739745 is marked by a horizontal line. Note that the time measurements refer to elapsed time only and hence cannot be entirely accurate since for example cache effects have not been taken into account. However, for the puposes of the present paper this somewhat crude form of measurement was deemed adequate.

The results obtained were as follows in Diagrams 1 and 2.

As may be seen from diagram 1 the approximation to the optimal solution improves quite fast with increasing α up to about 80. Thereafter, however, only slow progress is made. Nevertheless, for practical purposes this approximation may be quite sufficient.

Clearly the time requirements increase linearly with increasing α as can be seen from diagram 2 (where times are given in milliseconds) and thus appear quite reasonable.

4. CONCLUSION AND OUTLOOK

A new large margin ranking algorithm has been presented. Encouraging experimental evidence has been obtained using "real life" data from a financial institution. The algorithm is based on a reduction of the ranking problem and a combination of the resulting ranking algorithm together with a result essentially due to Krauth and Mezard. In contrast to the wide margin ranking algorithm described in [20] it can be implemented with a surprisingly compact Java encoding. This is due to the fact that it can be seen as an extension of classical perceptron learning. On the other hand, of course, it gives only an approximate solution which may, however, as indicated by the experimental results, be quite satisfactory for practical applications. To clarify the situation additional experiments are needed and it is envisaged to perform these as soon as suitably large data sets become available.

In addition the algorithm only works for separable sets. However, it is intended to combine it with a modified version of the pocket algorithm by applying it to those data sets only that are correctly separated. This way an empirical risk minimization would be performed which is then followed by maximizing the margin. This seems attractive since that way certain approximations inherent to the soft margin support vector machine as utilized in [20] are avoided. Again it is intended to conduct suitable experiments as soon as possible.

Finally a few comments on related algorithms seem in order. The large margin algorithm in [20] has been briefly discussed already. The ranking algorithms in [5] and [13] appear inferior from the results given in [20]. In [26] large margin perceptron learning was introduced for the pocket algorithm. However, in spite of reasonable experimental evidence, the theoretical basis appears slightly shaky, for details see e.g. [10]. The ranking algorithm in [22] (soft margin version) appears to contain a gap since the monotonicity condition for the cut-offs seems to

Diagram 1

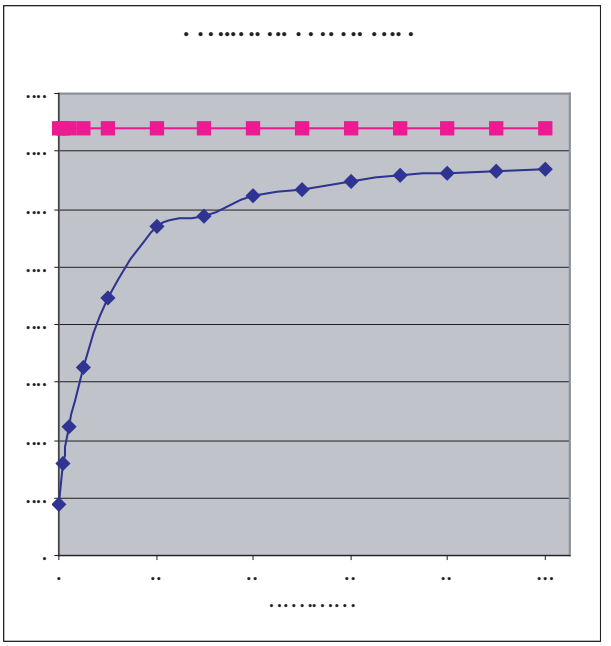

Diagram 2

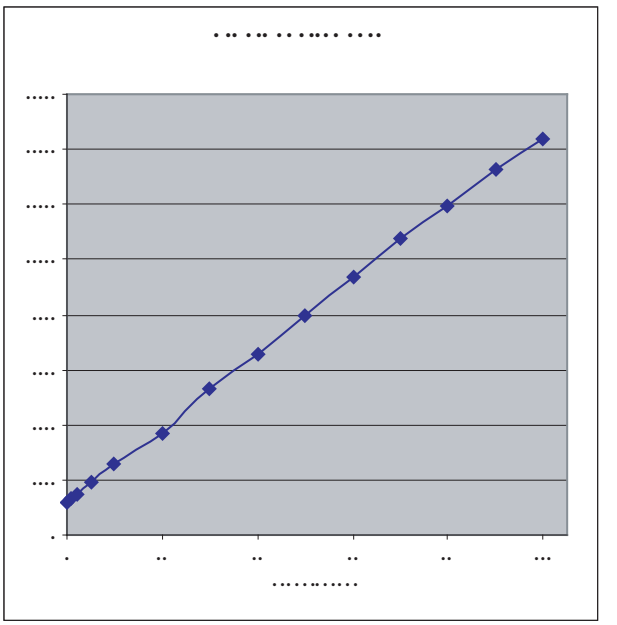

be neglected. Moreover an additional vector is ignored without explaining the consequences. In short then the algorithm closest to the one presented here seems to appear in [20]. Of course, it has been tested in a completely different context and an objective comparison concerning the banking application envisaged here is still outstanding.

Improving the Quality of Online Consumer Communities

Irene Pollach, Vienna University of Economics and Business Administration, Nordbergstrasse 15, A-1090 Vienna, Austria; E-mail: irene.pollach@wu-wien.ac.at

INTRODUCTION

Consumer-opinion websites enable consumers to voice their opinions on products, services and companies, read those others or and interact with other consumers on a website other than that of a manufacturer, retailer or auction. To consumers, these websites are sources of pre-purchase or post-purchase product information (Hennig-Thurau & Walsh, 2003). Consumers voicing their opinions on the Web are valuable sources of knowledge not only to other consumers but also to companies. They may learn about customer preferences and product defects (Nah et al., 2002), which they can translate into opportunities for product modification and development (Cho et al., 2002; Pitta & Fowler, 2005).

Previous research on consumer-to-consumer interactions on the Web has primarily focused on C2C auctions (e.g. Standifird, 2001; Dellarocas, 2003; Mollenberg, 2004), while communicative aspects of consumer interactions have not been paid much attention to. Relevant studies conducted in this area have looked at the persuasiveness of consumer-to-consumer communication on the Web (Xue & Phelps, 2004), the effect of positive and negative messages on consumers' brand evaluation (Chiou & Cheng, 2003), the use of online communities for marketing (Evans et al., 2001; Maclaran & Catterall, 2002), consumers' reasons for visiting C2C websites (Hennig-Thurau & Walsh, 2003), and their motivation to voice their opinion on C2C sites (Hennig-Thurau et al., 2004). These papers are anchored in the fields of marketing, information systems, but have not viewed consumer-to-consumer interactions as communicative exchanges. This paper is grounded in media richness theory, focusing on the interactional structures and tools available to participants in communicative exchanges on consumer-opinion websites. The goal of this paper is to identify mechanisms that render the information disseminated on consumer-opinion websites more valuable to both consumers and companies.

CONCEPTUAL FRAMEWORK

This study applies the concept of media richness to interactions on consumer-opinion websites. Media richness theory is well suited for this analysis, since there is a close link between website design, web usability and media richness (Palmer, 2002). Originally proposed as a theory in the realm of managerial communication, media richness theory suggests that media can be high or low in richness, which is defined as "the ability of information to change understanding within a time interval" (Daft & Lengel, 1986, p. 560). While leaner media suffice for unequivocal messages, task performance is expected to improve when richer media are used for complex messages (Daft & Lengel, 1986). Also, users perceive a medium as richer as they gain experience with it (Burke & Chidambaram, 1999).

Media richness theory argues that a medium's richness depends on its capacity regarding four parameters: the immediacy of feedback, the number of cues it can convey, language variety, and personal focus. Face-to-face communication is considered to be the richest medium, as its participants are able to give rapid feedback, communicate cues other than language (e.g. physical appearance, body language, tone of voice), use natural language to convey a wide range of meanings, and can communicate feelings easily. Richer media thus create a more positive affective state in the receiver, as they are capable of conveying information about the emotional state of the sender (Daft & Lengel, 1986; Daft et al., 1987; Lengel & Daft, 1988). Interactive media such as telephone or e-mail are considered to be leaner than face-to-face conversations but richer than static written communication, with telephone conversations being richer than e-mail messages (Lengel & Daft, 1988). The exact position of websites along the continuum between face-to-face and written communication is difficult to determine, since they may provide anything from mere textual information to multimedia applications (Palmer, 2002).

Examining websites in light of the four parameters of media richness, one can safely say that feedback in electronic media is always less immediate than oral communication—irrespective of whether synchronous or asynchronous—as typing a message causes a delay in transmission (Dennis & Kinney, 1998). The Web's capacity to convey social cues is lower than that of other channels, which entails that many of the social cues we are used to in the physical world are absent in online interactions (Donath, 1999). The parameter of language variety refers to how a medium serves to increase understanding among communicators by transmitting verbal and non-verbal information as well as signs and symbols (Daft & Lengel, 1986). Although in this sense written communication conveys less information than oral communication, web-mediated communication has means unavailable in conventional written communication, e.g. hyperlinks or animations, thus providing richer interactions than non-digital written formats such as letters or faxes. Ultimately, a sender who communicates feelings and emotions has greater presence in the exchange, since receivers tend to constantly monitor the sender's emotional expressions (Strongman, 1996). In the absence of nonverbal and visual cues, a writer in computer-mediated communication tends to lose in presence compared to the speaker in an oral conversation (Tanis & Postmes, 2003).

DATA COLLECTION AND ANALYSIS

Media richness theory provides a scheme for organizing and understanding the design features offered by C2C websites, which helps to identify ways of making them more suitable for the tasks they seek to perform. This study applies the techniques of content analysis to analyze features of websites (cf. Robbins & Stylianou, 2003; Zhou, 2004). The strengths of this approach lie in the unobtrusive, systematic, and replicable collection of data (Krippendorff, 1980).

The sample websites were found in the *Yahoo Directory* under "Consumer Opinion" (Yahoo Directory, 2006), which contains links to 28 sites. The *Google Directory* did not have a corresponding category containing chiefly consumer-opinion websites and was thus not considered for drawing the sample. From the 28 consumer-opinion websites found via the *Yahoo Directory*, nine had to be excluded, because they were not available at the time of data collection, contained only sponsored links, or were just alternative URLs to other sites listed in the directory. The resultant sample consisted of 19 websites (see Table 1 in "Results" section). A user account was opened with each site in order to gain access to all features offered.

A coding instrument was developed that makes for the systematic and unbiased collection of data from the sample websites by conducting a pilot study of the interactional structures of the first 9 websites from the alphabetically ordered list of sites. To develop this coding scheme, as many different features and tools as possible were identified that provide for feedback, multiple cues, language variety, and personalized messages. The scales used to measure these facts were nominal, taking into account the presence or absence of a particular feature. In content analysis, nominal scales do not require human judgment and interpretation to the same extent as, for example, ordinal scales and thus reduce coder bias. Subsequently, all 19 sites were examined for the presence or absence of the 25 features derived from the pilot coding. Since the study is exploratory in nature, the coding scheme was open for new codes that emerged throughout the coding process and sites already coded were then recoded for the presence or absence of these features (cf. Schultz, 1999; Ellison, Heino, & Gibbs, 2006). Overall, the coding scheme included 27 codes (see Appendix). All sites were revisited and re-coded as a check on intra-coder reliability (cf. Bauer, 2000; Stempel & Wesley, 1981), reaching an agreement of 99.61%.

RESULTS

As Table 1 shows, the sites enable consumers to express themselves in a variety of formats, including discussion threads (DI), complaints (CO), praises (PR), product reviews (RE), questions (QU), product ratings (RA), consumer blogs (BL), and wikis (WK). Further, Table 1 indicates how many sites require users to register (RG) in order to actively participate in such interactions. Reading contributions is possible without registration on all sites.

Feedback

The 19 C2C sites use almost exclusively asynchronous feedback mechanisms. In fact, *TCCL* and *Riffs* are the only websites facilitating synchronous feedback in the form of online chats. Asynchronous feedback on C2C websites includes comments on product reviews (n=12), e-mails (n=10), ratings of the usefulness of a product review (n=9), replies in discussion threads (n=8), company rebuttals to complaints (n=6), personal messages among registered users (n=6), replies to questions (n=4), and wiki collaborations (n=1).

Feedback facilities can also be looked at in terms of the parties involved. While only eleven sites offer one-to-one consumer communication (i.e. PM, e-mail, chat), 16 sites post one-to-many feedback from consumers (i.e. ratings, comments, replies in threads) and six sites enable companies to provide feedback on consumers' opinions in the form of rebuttals. Only one C2C website does not include any feedback mechanisms at all, confining interactions to message transmission and reception. To some extent, also the operators of the C2C sites give feedback to the contributors as well. While some of them merely claim that they reserve the right to remove inappropriate or offensive messages, two sites claim to approve all reviews before they post them online, and two websites automatically screen all messages for offensive words and censors them.

While the majority of sites rely on voluntary contributions, six sites offer financial or material incentives to contributors, which also function as a feedback mechanism. The incentives offered include cash rewards for every 100th review submitted by registered members or credit points which are redeemable for products or cash and are earned for each review or each time the review is read.

Multiplicity of Cues

Allowing members to provide information about themselves when they register is one way to remedy the Web's reduced capacity to convey social cues. Twelve sites enable users to make such information available in their member profiles, including for example location, gender, occupation, e-mail addresses, verbal biographies, hobbies, and links to personal websites. On ten sites, the user profiles also include statistics about the user's activities on the site. The data users are able to provide or the site provides about them include the number of contributions by the user, the join date, the number of credit points earned, the average rating s/he has received for his/her contributions, the number of visits, the date of the last visit, and the average response time.

C2C sites also provide cues regarding the status of individual users in C2C communities. Two sites provide rankings of their contributors either on the basis of the number of credit points they have earned or on the number of contributions they have made to the site. Six other sites award titles based on the quality (e.g. *top reviewer*) and quantity (e.g. *senior member*) of users' contributions. *ReviewCentre* does not award titles to users but to their contributions, labeling high-quality reviews as *expert reviews*. Similarly, registered members on *Dooyoo* can nominate reviews for inclusion in the site's *Hall of Fame*.

Another way of determining a user's status in a C2C community is by enabling registered members to indicate in their profiles which users in the community they trust in terms of expertise. These buddy networks people create when they add people to their list of trusted members may help others to decide whether or not to trust a reviewer. Overall, four sites offer such reputation systems. One C2C site merely lists a user's *Friends* but does not indicate how many users have added this user to their list of *Friends*.

Language Variety

All 19 C2C sites enable people to articulate their opinions publicly using natural language, e.g. discussion threads, blogs, chats, product reviews, comments, questions and answers, complaints and praises. The texts can be enhanced with active hyperlinks on six sites, e.g. to link to the sites of companies or products that writers are reviewing. Six sites also enable writers to paste pictures into their messages. Similar to hyperlinks, pictures may help people to provide evidence for their arguments for or against a company or a product. Three websites inviting verbal reviews offer a default structure that encourages readers to deal with positive and negative aspects of a product in the review.

Eight sites use categories in addition to verbal statements in the form of Likert-scale questions or closed-ended questions. These communication formats clearly

limit people's means of expression to a pre-defined set of answers and introduce a response bias as they suggest ideas and cannot account for qualifications to responses (*Blunch, 1984)*. Such ratings appear in two different formats. First, people can rate products or companies according to predefined criteria (e.g. customer service, ease of use, etc.). Second, they can rate the usefulness of other consumers' contributions, e.g. "Was this review very helpful / helpful / somewhat helpful / not helpful to you?". Although such data can be analyzed more easily than verbal product reviews, they provide only meaningful information if large numbers of users make use of these rating facilities.

Personal Focus

Six of the C2C websites enable people to use a selection of emotive icons to express sentiments such as fear, boredom or uncertainty, which sequences of ASCII characters do not convey as unequivocally as icons. Thus, such interactions are richer than those in which people can use either only ASCII-code emoticons in texts or no emoticons at all because opinions are to be expressed in the form of ratings. Another factor determining how much presence a writer has in computer-mediated communication is whether or not they post their contributions anonymously, use a screen name, or use their real names. On four sites people can voice their opinions anonymously, on three sites they are strongly encouraged to use their real names, and on twelve sites they can register any name. Consumers thus have the possibility to express feelings, emotions and attitudes when they select screen names. Avatars, which enable people to express emotions and attitudes, can only be used on five C2C sites. Thus, in the C2C interaction systems studied, interlocutors do not have much visual presence, although the medium has the capabilities to do so.

DISCUSSION AND IMPLICATIONS

Media richness theory argues that leaner media suffice to convey simple messages, while richer media should be used to convey complex messages. Messages on consumer-opinion websites have varying levels of complexity, depending on the writer's motives and on the reader's use of these messages. The tasks performed by users of consumer-opinion websites are threefold, including (1) passive information gathering (i.e. reading) before or after a purchase or as part of social interactions, (2) active information gathering (i.e. asking) before or after a purchase or as part of social interactions, and (3) information dissemination to share information after a purchase or as part of social interactions. Passive information gathering is complex, given that the relevant information has to be found first and then several or possibly many different viewpoints have to be processed. Reading stimulated by the need for social interaction is clearly less challenging, as an interactant will only respond to one message of his/her choice at a time. Writing, meanwhile, involves complex messages, if the writer seeks to produce a comprehensive and accurate product review, but uses less complex messages, if the purpose of writing is to vent emotions or interact with others. Thus, to be successful, consumer-opinion websites need to offer a high level of richness to those users producing or consuming complex messages, but at the same time they must not overwhelm those consumers exchanging less complex messages.

As the above results have shown, the websites examined have implemented a number of measures intended to render contributions to these sites more valuable. Table 2 summarizes these measures, indicating which parameter of media richness they belong to and how many sites have implemented them. Essentially, the measures listed in this table represent a non-exhaustive inventory of potential success factors for consumer-opinion websites, given that they enhance the richness of consumer-to-consumer interactions.

The quality of contributions in C2C interactions could be improved in a number of ways. Feedback mechanisms may impact quality, since writers might pay more attention to the quality of their contribution when site owners review contributions before they make them available publicly or may even decide not to post them. Similarly, people are likely to try harder when they know other people can rate them or comment on what they have written. However, readers may not be willing to provide feedback that rewards the writer but does not provide any rewards for themselves.

Quality is also closely associated with language, as opinions expressed verbally can account for both positive and negative views on a product or a company, unlike opinions expressed by answering multiple choice questions or closed-ended questions. When users rely on word-of-mouth communication, they consider negative information more helpful than positive information in distinguishing between high-quality and low-quality products (Herr, Kardes, & Kim, 1991). This suggests that website operators should encourage consumers to consider both positive and negative points when stating their opinion on a product, as is currently done by three C2C websites in the sample. When writers are guided by such a structure, their contributions may contain more valuable product evaluations rather than personal stories or venting of emotions.

Further, activated hyperlinks may enhance the quality of contributions in C2C interactions, as they enable the writer to loosely integrate information from other sources, giving a broader picture than the information posted on one C2C website can give. Ultimately, quality in C2C interactions can also be enhanced by offering emotive icons to writers, since words on a screen cannot always convey what people convey with facial expressions or intonation in face-to-face interactions. Conversely, the use of emotive icons may shorten or eliminate passages verbalizing emotions in consumers' contributions.

However, website operators wishing to enhance their sites need to be aware that not all features are valuable to all sites, in particular to those sites offering only one interaction format. For example, ratings of contributions add to the richness of general-opinion websites (e.g. product review sites) but are clearly of less value to pure complaint sites or discussion forums. Conversely, company responses would be a meaningful enrichment for complaint sites but not for discussion forums. Clearly, hybrid sites, facilitating more than one interaction format, provide richer interactions, as users can choose – depending on their experience with the medium – the format they perceive as the richest for the task they seek to perform.

The results also suggest that it is worthwhile for C2C websites to separate the tasks of information search/dissemination and social interaction. C2C websites could cater to both consumers' information and social needs but with different interaction facilities, for example by offering a discussion forum with member statistics and product-review facilities supported by trust networks. This separation would enable people to perform their information-oriented reading or writing tasks in a richer setting and social tasks involving less complex messages in a leaner setting.

Business Process Analysis, Modeling and Simulation for Geo-Political Risks and Crisis Management

Francis Rousseaux, Ecole Centrale d'Electronique, France; E-mail: Francis.Rousseaux@ircam.fr
Kévin Lhoste, Ecole Centrale d'Electronique, France; E-mail: lhoste@ece.fr

ABSTRACT

The paper aims to present a real experience of designing a Control, Command, Communication, and Intelligence system to support crisis management through a three step business process. A better understanding of what is a crisis and a model of knowledge gathering appeared within the system development. We will explain this particular business process management through the successful example of the CHEOPS Project.

PAPER TEXT

When a company wants to offer a new tender for its clients in the geopolitical crisis management domain, it has to solve a dilemma. Firstly it has to build rapidly, a functional product in order to take a place on this well discussed market but on the long term this strategy isn't sufficient. An incremental design process is required in order to organize an architecture, to bring out functional and ergonomic specifications, and to structure an ontological application such as a multi-agent cooperation model.Furthermore a reflection on what a crisis is, on the values level which helps to make the model more accurate can be added.

We will explain this three step business process through the successful example of the CHEOPS Project. Firstly, we will describe its risk management system, then we will put the emphasis on its multi-agent cooperation model, and lastly, we will present a situation analysis as a constructive modelling process and we will finish with an analysis on the CHEOPS project business management and its possibilities of evolution.

1. TECHNICAL PROCESS

The CHEOPS Project is based on a fictive crisis simulation called CHEOPS-TCHAD, where Chad is involved in a civil war opposing the government and rebels supported by Libyans. The French Army has to protect the official government against Libyan's threat.

Before the CHEOPS-TCHAD Project, success in crisis management depended mostly on the Military's Attaché (AM) experience. The system was composed of two major parts: the Chadian operation field and the Military Intelligence Direction (DRM) located in Paris. Protocol constraints regarding communication between them were too important to define a cooperation model. In the project, each actor has a CHEOPS system and they are linked together. The AM provides its CHEOPS' database with geopolitical information. The DRM's CHEOPS system has a huge image, plan, map and document database. In addition the system is connected with a lot of information sources.

The constraint in such a multi-user system is that each user has a specific need in terms of information objects. The thematic layer concept allows each user to build his own vision of the geopolitical operation field selecting objects relevant to him.

In order to model crisis, it is essential to define the event, situation and scenario concepts. An event is a pool of facts; their identification and handling is the base of crisis situation analysis. A situation is a geographical operation field in a given moment and is composed of relevant objects essential for its analysis. A model situation is a situation which has been analysed and described. A scenario is a collection of model situations. When a scenario is encapsulated in a period, it becomes a crisis.

We can define the crisis concept showing differences between permanent and crisis states. In the crisis state, the situation analysis is made harder because human discernment is wasted by stress, importance of stakes and indeed cost. The crisis generates a temporal paradox because its analysis and linked tasks, like communication or justification of choices, need time incompatible with crisis resolution. One man can not manage a whole crisis by himself like in the Marc Aurèle time [Marc Aurèle 92]. Only virtual or real human groups working together can face a dynamic and complex situation, and so it is a typical multi-participant activity.

To meet this group working requirement is one of the main stakes of this domain. Crisis management gets it sense only if it is coordinated which adds a complexity level. This complexity is due to the fact that coordination should dispatch participant productivity without limiting their efficiency. Crisis analysis should be split in time, space, speciality, actions and functional roles of participants [Brugnot 01]. The crisis management Information and communication system (ICS) anticipation is important but is not always enough to avoid crisis and so it is essential to implement a three part operational crisis management:

- Anticipated operational management: to plan emergency action, to allocate needed resources and to optimize key parameters.
- Real time operational management: to update situation and decision parameters, and to make plans matching with reality.
- Back to normal operational management: to disengage efficiently allocated resources.

Therefore rules and constraint propagation techniques based planning modules have to be realised. In crisis management ICS, information of the situation is critical but documentary information is critical too. Commented past crisis files create a database which brings a comparison point, decisional argument and a base for innovation [Boyce & Barnes 06] In addition, on request data extraction can justify decisions and brings complementary information. An electronic document management system, based on indexed full text has to be realised.

In this ICS, the emphasis is put on heterogeneous systems interoperability, but in order to build a real multi-participant system, it is essential to develop a strong collaboration between experts who can have a different point of view and to be able to organize and deploy a crisis cell very rapidly. AI can be very interesting to help the decision process, particularly with new automatic learning techniques [Kodratoff & al. 87] like the Case Based Reasoning, which uses analogy mechanisms, and other learning techniques ([Michalski 86], [Michalski 93], [Mitchell & al. 83], [Kodratoff 86], [Rousseaux & Tecuci 87], [Dejong & Mooney 86], [Barès & al. 94]) which takes benefits of experts produced explanations in order to generalize problem resolution modes.

Some other problems which represent knowledge modelling constraints have to be taken into account:

- Databases for objects modelling in space and time, and uncertainty management and management of fuzzy.

- Attention management for relevant granularity scale in space and time: phenomena can be predictable only with a certain amount of prior spatial-temporal data.
- Decision help to take pictures of interesting situations, to compare and comment on them. But also to be able to model something which no longer exists.
- Ergonomics to detect the user's intentions from basic actions, to anticipate and solve ambiguity in concordance with user's supposed goals (GEOCOOP [Zacklad & Rousseaux 95]).

2. METHODICAL PROCESS

The CHEOPS-TCHAD simulation has demonstrated that in order to solve efficiently complex collective problems, a multi-agent cooperation model has to be designed [Van Peach 02]. It is what has initiated the MadeInCoop model. This one can be divided into four main principles:

- The knowledge level cooperative human-machine activity design, which describes users and system activities considering that artificial and human agents have goals and knowledge.
- The cooperation situations positioning in global organisational context, which describe organisation, tasks and characteristics of its agents, and especially which enables identification of agent sub-groups which are usually interacting.
- Cooperation dynamic description, which is based on agent interactions.
- Actor cooperative activities description, which models one actor activities in problem resolution, coordination and communication actions.

The Collective General Activity model in MadeInCoop can be divided into three sub models. The first one is the task model, which has to provide a general schematic which models main activity aims and the means used to reach these goals. It includes a chronological dependency description between aims. In this simulation, we can find two main tasks groups according to the situation: in normal phases, it consists of imagining all possible scenarios and following answers, and in crisis phases, it consists of following situations and its evolution feeding databases, to analyse events, to define goals and plan the means to reach them. The second one is the agent model. For each agent, the know-how, the responsibilities and the availabilities are defined. Finally the organisational model defines the negotiation rules between agents and tasks in order to respect characteristics coming both from agents and tasks. The result is the definition of some interaction situation between agents and general coordination principles between inter or intra agent groups.

There are six main agents. The Military Attaché (AM) collects information and sends argued reports on the situation (it is a human agent), the event database manager (GETEV) classify each event, the map database manager (GESTCART) manages different maps, provides zoom and can put in relief thematic layers , the messenger (MESSAG) transmits messages (it is a human agent), the news report analyst (ANALYS) translates text news reports into the database format, the tactical simulator (SIMUL) makes calculations and simulations in order to estimate current strength or necessary time to move units, and the arguer(ARGU) lets the user from tactical hypothesis to search corresponding events in the database and on the opposite, to analyse a pool of events in order to find strategic hypothesis.

In MadeInCoop, the general model draws the background, where the different cooperation situations will happen which will let agents solve the problems collectively. The shift, between the general model and the cooperation, changes the way to handle the situation in two ways. It is a shift from a static view to a dynamic view focused on the interaction between agents, and it is a shift for a more detailed view where problem resolution activities and coordination are handled more precisely.

Based on most of the activities on cooperation between human agents, we will use the Maieutic approach (Maieutic is Socratic Method that induces a respondent to formulate latent concepts through a dialectic or logical sequence of questions) where the cooperation can be modelled with high level dialogues between agents. Agents try to cooperate; they share a working memory where a history of their dialogues is recorded. This record can be used on 3 different processes: The first is the problem resolution process, which is the progressive exploration of the group "problem space ". The second is the coordination process; it's a record of the agent's progressive engagement. This process controls the first. The third is a communication process which enables us to follow the steps of a collective speech.

In order to illustrate this model, we will use an artificial problem resolution dialogue between local crisis management computer agents. In this scenario, the Chad is in a civil war context opposing the official government and the rebels

Figure 1. Inference structure

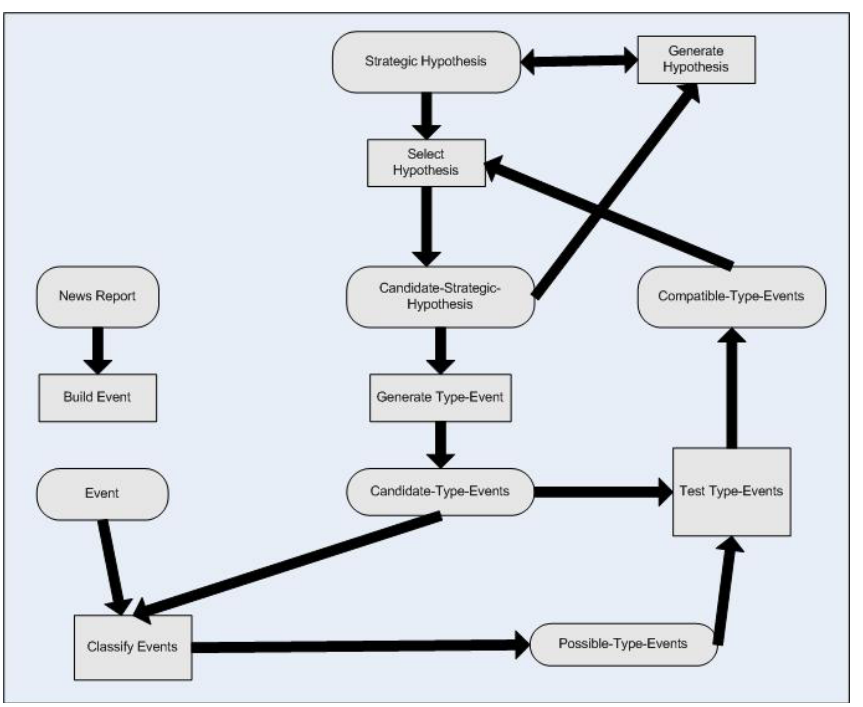

Figure 2. Virtual memory workspace of the local crisis management PC

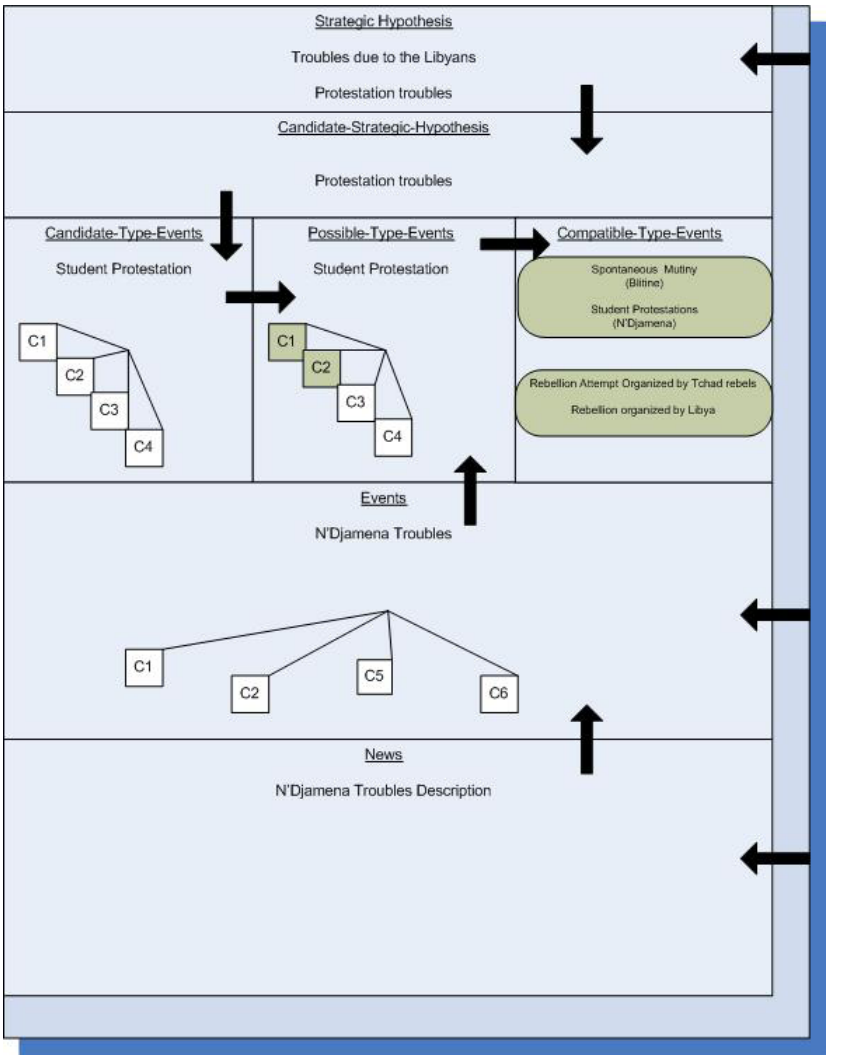

helped by Libyans. The goal of the system is to help French military direction to take decisions, identifying if movements are spontaneous civil war movements, which do not need French intervention, or if these movements are due to the Libyans trying to invade the Chad area, which would need a French intervention because it would be an international law-breaking. The last events chronologically logged are the following:

- Troubles have appeared in the Biltine's barracks, which is near the north frontier without having the possibility to know the causes of these troubles.
- Street Fights have been signalled in Chad's capital N'Djamena near the national assembly, the consequence is that governmental troops have been sent from the north area to the capital.
- The airport of the Chadian capital has been bombed but the enemy fighter planes have certainly not been identified. Experts are analysing bomb impact pictures. Rebels have old Soviet planes which would not have permitted them to commit this bombing.

In MadeInCoop, the collective problem resolution method is based on a "structure induction" method [Simon & Lea74], [Hoc 87].

An event is built from a news report before being paired with candidate type events. The quality of these pairings selects possible type-events , of which compatibility with context is selected with confrontation with possible type events precedently identified.

In the following example, two strategic hypotheses have been generated and the AM tries to select the "protestation troubles" hypothesis. The process begins with extracting some properties of the news report (C1, C2, C5, and C6). From the candidate hypothesis, the AM generates a candidate type event with the C1, C2, C3, C4 properties. Comparing it with the capital's troubles, he is concluding that "student protestation" is a possible type event to model these troubles. The following step is to test the possible type event, to verify that it defines a compatible type events pool with other candidate type events. The conclusion of the test is not favourable because another interpretation of the events exists: "spontaneous mutinies" which are associated with "student protestation" is compatible with "protestation troubles".

Table 1 presents an extract from the virtual dialog between agents:

The actions of the coordination model are the same as those for the collective problem resolution (CPR) but different memory areas have to be reserved. A common group position area has to be reserved, where are recorded all the arguments and decision validated by the group and reflecting the "official" point of view of the group. An individual area has to be reserved to put the individual group members' decisions when they differ from the group decision. The imple-

Table 1

	Interpretation based on the problem resolution process	
1	AM: Did you receive the description of the N'Djamena events? It seems to be protestations organized by students near the opposition. This confirms that Biltine events are probably just the consequence of a problem linked with the soldiers' salaries and so it is interior troubles…	Build-Event Classify-Event Test-Type-Event Select-Hypothesis
2	ARGU: I disagree, the cause of Biltine events is unknown because the M'Boutoul ethnic group implicated is with the rebels.	Classify-Event
3	AM: Can you show that is it possible that rebels can be implied in recent events?	Test-Type-Event
4	ARGU: Yes I can demonstrate it. (Demonstration following)	Classify-Event Test-Type-Event
5	AM: What are the consequences?	Generate-Strategic-Hypothesis

mentation of coordination acts is mainly determined by group members' actions on virtual memory workspace. Its structure has four type: ACTION(OBJECT, PLACE,RIGHT,SEQUENCE).

3. EPISTEMOLOGICAL PROCESS

When we talk about crisis management intention interpretation, mission preparation or battlefield intelligence with militaries or civil servants, they have clear advice on the concept of an event. For them a fire or a bombing is clearly an event. For these operational actors the world is made of objects which exist in a reduced space and time and which have behaviours [Cauvet & Rolland 92] and of events which happen and which have to handle in order to control the situation. For them a decision helper system should be a representation of the operations field with plans, maps and pictures, a representation of real objects, with their associated properties, and a model, which enables the user to translate the real situation into a simulation where he can simulate the actions to take and their consequences.

The CHEOPS system has been designed and specified with operational officers. This representation could bring to an efficient digital representation only avoiding some aporias [Chaudron 94] [Poirel & Chaudron 94]. In a first time the event concept to be clearly defined: to be considered as an event in a crisis management context, an event has to gather some properties: it has to be linked with facts and so with environment objects to be localized in space and time, to be linked with a considered environment where the event is interpreted [Sperber 92] and to be linked with an intentional context [Sieroff 92]. We can wonder if in designing crisis management systems we try to rationalize and make a situation collectively understandable. This model is based on a deterministic concept: the same fact produces the same effects and if you understand the causes of a crisis you can avoid this crisis the next time that the cause will merge.

This project, which has succeeded in a military context with strong constraints, can be easily applied in a civil context. A lot of complex systems are multi-agent because it implies different actors working separately, but the solution of one subsystem has consequences on others and so a cooperative system like MadeInCoop should be useful. In addition most of these systems are based on people knowledge which could be integrated to the system making the other agent benefit from it.

4. APPLICATIONS

These risk management systems can be applied in a lot of domains: in ecology, in order to avoid ecological disasters, to preserve natural resources or to protect the endangered. In industry, these systems could be useful to avoid risks and crisis without affecting the production. For example, in a car production chain, a production stop costs a lot of money, these failures could be predicted and avoided with a risk management system. In transportation domain, these systems can increase the quality of services because one failure happened, it affects all the transportation network and the related activities, and so the crisis risk prediction is essential. In the health domain, such systems could avoid large epidemics, predict possible diseases and propose prevention actions to take. Finally, such risks and crisis management systems which work like a closed system could be linked together to make a meta-agent network where each risk management system would be considered as an agent taking part in a more global management system.

5. CONCLUSION

As a conclusion, we can say that this project, through the design of the CHEOPS collective crisis management system has contributed to a knowledge gathering method for ICS.

The goal was to adopt a global description on the knowledge level, without neglecting industrial organisational constraints.

We can see that this business process is cyclic and each iteration helps the system to become more accurate and more competitive. The business process management was a complete success and it enabled us to increase incrementally the experimentation field to other concrete cases adding a scientific goal to the technological objectives.

A lot still has to be done but the matter is scientifically rich enough to let a great deal of researchers in multidisciplinary domains to bring their contribution. This subject is a challenge for our societies because beyond technological and scientific aspects ICS invites us to collective intelligence.

ABSTRACT

Enterprise Resource Planning II (ERP II) systems integrate external entities into an organization's ERP system, primarily through integrating supply chain partners. This integration is facilitated through web services, a loosely coupled, platform independent way of linking applications within different organizations. Though many web services security standards exist, many organizations fail to implement these standards completely, therefore leaving the company vulnerable to security threats. This research study proposes a planning model for ERP II security. Some best practices related to managing and securing an ERP II system are gathered from extensive interviews with industry experts and government officials.

INTRODUCTION

Vendors recognized the significant opportunity for IT integration across departments, and robust ERP systems were developed out of more limited material planning packages for manufacturing. These systems modified the traditional processing paradigm of aligning the IT processes with department functions and instead created systems that tracked the workflow within the organization. This required management to coordinate with IT more closely and align job functions and training to the ERP system requirements. These ERP systems were purchased from major vendors and then customized to fit the particular needs of the organization with extensive help from outside vendors.

ERP systems arguably led to significant cost savings. However, original ERP systems were unable to accommodate the competitive pressures brought on by Just-In-Time (JIT) inventory management, supply chain integration and net-centric business models. These competitive issues led to a transformation of the ERP model into what is now called ERP II systems. These include linkages across the supply chain, and integration of customer relationship management (CRM) and logistics management software. The organizational boundary become diffuse, if not non-existent from the perspective of data flows. Suppliers are able to push transactions through the system with no real-time control by the receiving organization. In fact, network perimeters become obsolete since outside organizations are exchanging data with core business applications inside the organizations' trusted computing zone.

Darwin John, the former CIO of the FBI recently stated that "Security should be number two or three on any CIO's list of priorities" (Darwin John, personal communication, January 2006). While it is true that many vendors sell security solutions by creating a sense of fear, uncertainty and doubt, there is realistic reason to be worried. Carnegie Mellon's CERT Coordination Center's 2004 Annual Report states,

"In every way, the next twenty years will bring more of everything. More threats, more attacks, more resources at risk, more interconnection, more communication, more emergencies."

This highly pessimistic view of security appears to be warranted. The FBI/CSI annual crime report estimates that malicious software cost United States companies at least 170 billion dollars in 2004. This figure does not include loses from insider attacks, theft of intellectual property, or failed IT implementations. Symantec Corporation reports an unprecedented rise in malicious botnets and that malicious software is becoming more sophisticated, stealthy and polymorphic (Rob Clyde, VP of Research for Symantec, personal communication, November 2005).

More troubling than the proliferation of malicious software is the rise of extremely sophisticated and successful attacks on major United States companies, universities and government agencies seeking to steal defense and trade secrets. Though details are closely held by the Federal Bureau of Investigations, it has been widely reported that an active investigation is underway on network intrusion by agents of the Chinese government into highly sensitive United States government agencies under the case name Titan Rain (Espiner, 2005). Individuals associated with the National Security Administration have reported to the researchers that the Chinese government has over 3,000 professional information warfare agents actively attempting to steal United States government secrets, weapons plans and corporate trade secrets.

Many companies engage in routine business practices, which if details about them were discovered, could be used in launching attacks. For example, an attacker would be interested in knowing the shipping schedule of toxic chemicals through populated areas. A foreign agent may attempt to discern the intentions of our military through gaining information about supplies going to certain defense depots or shipping ports. A potential enemy would be very interested in design documentation regarding our weapons systems, and may attempt to counter our force superiority through exploitation of weaknesses in these systems.

Also, corporate espionage is a serious threat to large corporations, and these agents often seek similar information as intelligence agents: intellectual property, trade secrets, marketing plans, R & D proposals, merger and acquisition plans, etc. (Crane, 2005). Many foreign corporations actively seek to steal United States companies' trade secrets through placement of agents inside of their IT shops who can install malicious code to circumvent security restrictions, or to allow the agent to directly access the data from the servers.

RESEARCH METHODS

The researchers conducted a literature review regarding ERP II system vulnerabilities; though there is surprisingly little in the academic literature about these issues; after the initial review the researchers reviewed hacker websites and postings regarding these vulnerabilities. These initial reviews revealed that very little information is available on the net about ERP vulnerabilities.

The researchers also conducted a series of interviews with senior executives, IT security professionals, government officials, Big-4 IT security specialists, and other experts to using s a grounded theory approach to qualitative research (Strauss, 1990) to develop an initial model of planning ERP II security based on senior IT executives understanding of IT security in ERP II systems. These interviews were also undertaken to determine what the vulnerabilities are in these systems and to investigate the process of securing organizations in ERP II linkages.

The researchers then reviewed the XML/web services security literature to document security challenges that need to be addressed in ERP II projects (Anzbock, Dustdar, & Gall, 2002; Cremonini, De Capitani di Vimercati, Damiani, & Samarati, 2003; Damiani, De Capitani di Vimercati, & Samarati, 2002; Nadele, 2003). In order to

better understand the issues facing IT staff during ERP deployments, a series of interviews with IT professionals in the process of an ERP implementation were conducted. Based on these investigations, the researchers developed an initial best practices guide and a planning model for ERP II Security.

Subjects in the Study

Given the qualitative and exploratory nature of this research, it is important to describe the subjects in some detail. Over a process of several months, telephone and face-to-face interviews were conducted with:

- The former CIO of the Federal Bureau of Investigations
- The current CIO of the Bureau of Alcohol, Tobacco and Firearms
- The Senior Security Consultant to the United States State Department and author of many NIST standards
- A State Chief Information Security Officer
- The CIO of a large multinational corporation
- Current and former federal agents/information security professionals who were/are employed by the FBI, NSA, and DIA
- Hackers
- One of the authors of original Rainbow series who was also one of the authors of the HIPAA legislation
- Two ERP vendors
- Three Big-4 accounting firm information security specialists
- Several faculty members from two of the three universities with the best reputation for IT security training
- ERP managers for two very large organizations
- Project managers for two ERP implementations

Limitations of Methods Used

A number of limitations on the methods used must be acknowledged. First, the sample of subjects was an extended convenience sample with snowballing. The researchers then approached individuals with whom they had contacts, and followed the chain of referrals for subsequent interview subjects. Second, the researchers attempted to contact a number of ERP vendors, IT consulting companies, Big-4 consultants, and companies known to the researchers to be involved with an ERP deployment. Unfortunately, corporations refused to grant access to their systems or discuss specifics about security implementation of their systems. It became apparent that vendors control dissemination of information about system vulnerabilities through Non-Disclosure Agreements and most corporations would not cooperate with this research.

Furthermore, discussions about ERP systems with hackers were not fruitful. Gaining entrance to the hacker community is essentially a "community of practice" process, where one is slowly invited to the community as one develops relationships and demonstrates competency (Wenger, 2002). Given that the subject of discussion is a felony under several provisions of the United States Code, it is understandable that the hackers approached by the researchers were less than forthcoming.

The initial model for ERP II security planning should not be considered a valid model, as it has not been empirically validated. Future work needs to be done to establish the accuracy of this model by testing its usefulness in an actual ERP II implementation.

FINDINGS

In the following section a brief overview of several ERP II security vulnerabilities is reviewed. Then a model is introduced which shows a matrix of polices and best practices which should be implemented to secure ERP II systems.

ERP II SECURITY VULNERABILITIES

Inherent Security Vulnerabilities in ERP II Systems

Vendors have done a good job creating secure ERP systems. Most have robust access control, auditing, and user authentication features. Their security architecture in general is sound. While early systems had significant weaknesses, no well-known ERP system on the market has a reputation for inherent weaknesses.

However, ERP systems are extremely complex pieces of software, and as with all code, there are going to be vulnerabilities. These systems are also vulnerable to weaknesses in the underlying databases. SAP R/3 had a known vulnerability that allowed users to gain super-user access to the ERP (Net-Security.org, 2001). With this privilege, an attacker could access or corrupt any data. In one sense, the incredible complexity of these systems facilitates security since their users will only have knowledge about a limited set of the system's functions. Their opportunities to launch attacks will necessarily be limited by their incomplete knowledge of the system architecture. This complexity also exposes the essential design flaw in these systems, and the need for custom configuration of thousands of options to ensure security. While auditing standards exist for ERP II systems, no known methodology allows enterprises to ensure that their customization conforms to the security policies of the organization (Magklaras & Furnell, 2005).

From a usability perspective one concern is that some ERP II systems still have a look and feel reminiscent of the old main-frame environment. Systems may require users to remember the names of screens for input and provide no contextual cues to guide the user. Usability research shows that users will circumvent security that they believe to be onerous or to interfere with their ability to accomplish work (Cranor, 2005). Thus, if users are not able to remember screen names or navigation sequences, they will augment their memory with reminders. These reminders become vulnerabilities themselves, as they often contain detailed guidance on accessing the systems and can include user IDs and passwords for screen access.

Vectors of Attack

Experts agree that the most likely vector of attack on ERP system will be through privilege escalation by an insider. Given that the data contained in the ERP II relates to customers, suppliers, vendors and employees, there is little data in the system of interest to a casual hacker seeking systems that can be compromised. Most professional hacking today is done for monetary gain. Much of it is related to identity theft and online fraud. Again, these forms of computer crime do not lend themselves to attacks on ERP II systems. However, an insider may attack the ERP II system through sabotage of key files, modifying passwords on accounts to halt the work flow, or by modifying DTDs or XML schemas to block the exchange of data (Polivy & Roberto, 2002).

A professional attacker will study the system for vulnerabilities and attack the system at the point where his skill, training and experience tells him that he is most likely to gain access without detection. This is one of the reasons why focusing on the security of the ERP II system alone cannot provide for effective security. For example, an attacker could access the network through a compromised web server and then install sniffing software on that machine to monitor the network for passwords. With a username and password combination, the attacker could then log directly into the ERP II system. This highlights the key roles that continual auditing and patch management play in maintaining the security of these systems.

Competitive Intelligence Threats

Inference is a well-known problem in access control (Morgenstern, 1987). Essentially, a user can submit a series of queries to a database with his access permissions. Using logic, the attacker is then able to identify specific attributes about one subject in violation of the access control policies. This issue is of paramount importance in the planning of an ERP II deployment. Most security features within ERPs are created in reference to specific screen views. An employee is granted access to particular screen, usually based on their role. While many ERP IIs use a form of RBAC, the need to customize thousands of screens leads to many unintended consequences that violate the organization's security policies.

Aggregation is the threat of unintended disclosure that arises from the combination of many items of data that allow deductions about some process or event about which the attacker has no other information (Jaeger, 2001). For example, if an attacker knew that the US Military had requisitioned air transport to Central Africa, had ordered lightweight summer clothing for 5,000 troops, and that vaccinations for malaria had been ordered for the third week of July, he could surmise that approximately 5,000 troops are being sent to Central Africa. If the attacker also had knowledge of the cargo being shipped ahead of time, one could make conclusions about the nature of the mission. This same form of intelligence gathering occurs in attacks on large corporations. In an insider is able to access many parts of the ERP II system, she may be able to determine true costs of products, discounts offered to particular vendors, marketing plans, R&D budgets, or financial issues that have not been released to the public. Many of the security experts interviewed stated that most ERP II systems have significant vulnerabilities related to unintended access control combinations, and that insider will exploit these vulnerabilities to gather specific confidential information.

Supply Chain Partnership Model Weaknesses

One threat from opening up your system to supply chain partners is that once inside your system, it is possible for partners to "explore" the rest of your corporate data (Domke, 2001). Unisys Vice-President Peter Regent cautions companies that "You'll have to reengineer your processes to align with security. Otherwise, you won't get any return on your investment [in supply chain systems]" (Paul, 2004). Unfortunately, most ERP II systems are not engineering around security. The usual model is for the supply chain partners to agree on data exchange formats and to identify their common business processes. Security features are then added onto whatever existing mechanisms allow for the exchange of data.

Another serious concern that is often ignored in the implementation of ERP II systems relates to planning for the dissolution of the supply chain partnership. Too few organizations plan how to protect their data once they decide to remove an organization from the supply chain. An explicit procedure needs to be implemented to protect the confidentiality of data once the decision is made to remove someone from the chain. This can require extensive modifications to code when using web services.

Many of the consultants interviewed for this research caution that most supply chain linkages allow access to too much data by the parties. Essentially, organization A will be granted permission to access company B's ERP II system, but company B will not invest the resources needed to ensure that the data accessible by agents of organization A is minimally sufficient. Many organizations place the outside organization into an existing role. However, this can lead to the outside partner having access to information about true prices, marketing strategies, etc. that can give them competitive advantage. Research is underway at Purdue University to address how to arrange for encrypted exchanges of pricing and cost data so that both parties can gain maximum advantage through the relationship (Clifton, 2004). Essentially, organizations in an ERP II linkage still do not entirely trust the other participants, so the data on costs, production, shipping, etc., may be altered or otherwise obfuscated to protect the party releasing the data. This leads to an erosion of the potential value for all participants in the supply chain partnership.

Lastly, from a network security perspective, the creation of linkages with supply chain partners has two significant effects. First, the organization loses its network perimeter. In effect, the IT systems are merged into a unified system and each party allows outside organization access to the internals of its IT system. Second, everyone connected in a supply chain is exposed to whatever vulnerabilities exist in every partner's systems (Bragg, Rhodes-Ousley, & Strassberg, 2004). Thus, despite an organization's best efforts at protecting its systems, if one of its partners is compromised by malicious software, that partner's system can infect other organizations' system or introduce significant vulnerabilities into their IT architecture.

A MODEL FOR ERP II SECURITY PLANNING

The researchers developed the following model for ERP II security planning based on the seminal Information Assurance Model and the results of the interviews. See Figure 1.

This model is based on three components:

1. Security Services
2. Management Considerations
3. Targets of Security Planning

Each of these components is represented by an axis in the model. There are forty-five cubes within this model, and the researchers propose that effective ERP II security planning requires organizational effort to address each of these thirty-six cubes. For example, Database Security x Audit Methodology x Integrity would require that the organization define an audit methodology to ensure the integrity of data in the database through an analysis of existing database security measures.

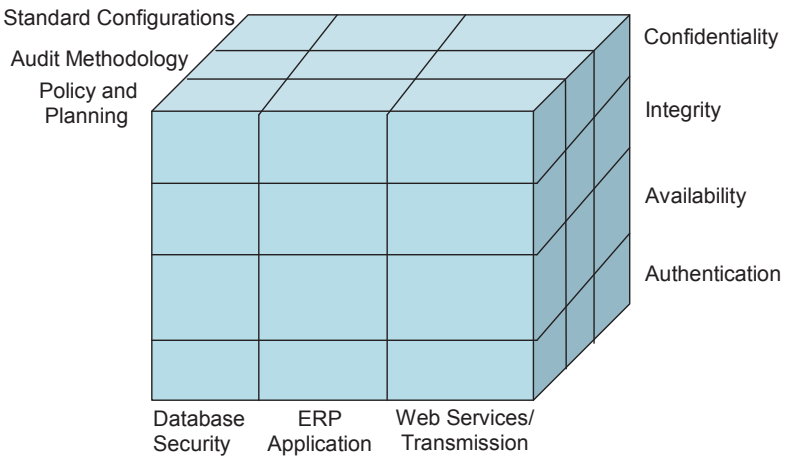
Security Services

The original IAM model proposed the well-known CIA triad for information security: confidentiality, integrity and availability. These are the security services that any system can provide. There is an inherent tension between these services, as ensuring the integrity and confidentiality of data often interferes with the availability of data. This model was later expanded to include authentication of users and non-repudiation of transactions (Schou, 2004). Accordingly, this planning model requires all participants in an ERP II enabled supply chain to address confidentiality, integrity, availability, authentication and non-repudiation of transactions. These services are provided by the ERP II system, but planning needs to ensure that the features of the systems are fully implemented.

Management Considerations

The second axis of the ERP II Security Planning Model discusses the three broad areas for management attention: standard configurations, audit methodologies, and policies and planning. The best practices portion of this paper will address specific issues related to standardized configurations which are suggested in order to reduce the complexity of the security planning process, to enable better patch and configuration management, and to reduce the overall vulnerability of the system through reducing the types of operating systems and applications. Audit methodologies will also be discussed in detail in the best practices guide. Senior executives report that reliance of the existence of third party IT audits does not guarantee the security of a system. Each firm has its own audit methods. This issue becomes even more crucial when considering international partnerships. ITIL, ISO 17799, and Control Objectives for Information and related Technology

Figure 1. The ERP II security planning model



(COBIT®) (ITIL, 2006) COBIT are three widely used IT audit frameworks, but they vary greatly in their focus, level of detail, and scope of review. Effective security demands that all partners agree ahead of time on a standardized audit methodology to ensure that vulnerabilities are discovered and addressed in all partner organizations. Lastly, there needs to be a formal process, a well-managed project to plan the policies that will guide users of the ERP II system. This process must be conducted internally, and cannot be wholly delegated to the ERP II implementation consultants.

Targets of Security Planning

Throughout this project, ERP II managers emphasized the critical interdependencies between the underlying databases and the ERP II applications. It was also discovered that all major ERP II vendors are using web services to facilitate inter-company communication. Accordingly, we have defined three areas that require management attention in planning. First, the database must be secured. In most ERP II systems, the ERP II appears to the database as a single user. However, the ability to connect to the database exists outside of the ERP architecture. An attacker may be able to sabotage the ERP II or steal data via unauthorized access to the database. The configuration of the ERP II is also a critical challenge as there are literally thousands of possible configuration options and screens to address. An effective ERP II implementation requires a minimum of 5% of the resources to be dedicated to planning access control models and searching for security policy violations that could occur (West, B., personal communication, March 2006). Lastly, there are significant weaknesses in the implementations of most web services projects. These weaknesses occur through using only a limited set of the web services standards, which results in providing only part of the CIA triad.

FUTURE RESEARCH

The researchers realize that perhaps the most important piece of this research may be missing. Currently we are working on mapping the collected qualitative data, essentially a list of best practices to the model developed in this paper. We hope to demonstrate a systematic approach to securing ERP II implementations.

ABSTRACT

In this work an evaluation of an object-relational schema implementation representing different relationships of an UML class diagram against the relational approach was made. To perform this test we have implemented both object-relational and relational schemas from a UML class diagram in a commercial database leader in the market. The main goal has been to prove the competitiveness of the object-relational technology. The methodology used for this work was to present several schema implementations of association, composition, aggregation and inheritance relationships, propose a set of representative queries to evaluate their behavior, compare the results and make an analysis based on response times. Four alternatives implementations of the schema diagram were made for a composition relationship presented in the proposed UML class diagram. The queries have been executed with no flush to the database buffer pool among runnings to simulate a real situation. In some object-relational queries several built-in functions and operations have been used. As a consequence of this work we are proposing some extensions to the relational schema diagram to add the object-relational alternatives (references, arrays, multisets, etc.) proposed by the SQL:2003 standard.

Keywords: Performance test. Object-relational schema. SQL:2003. Array. Multiset. Scoped references.

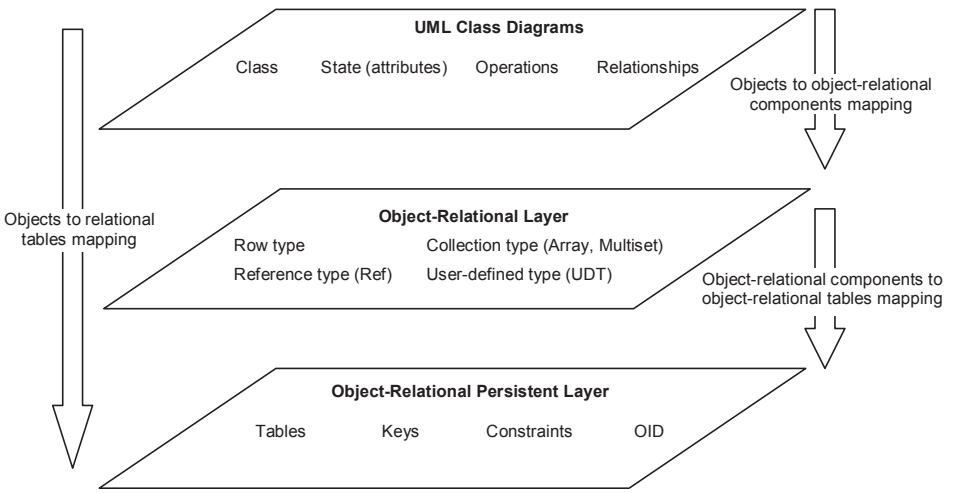
INTRODUCTION

Object-relational database management systems (ORDBMS) based on the SQL:2003 standard offer several new capabilities to implement inheritance, association, aggregation and composition relationships among objects, comparing to the relational approach based on the SQL'92 standard. These novel capabilities are based on the use of user-defined types (UDTs), references and collections. A reference is a logical pointer to a row object that is constructed from its object identifier (OID). In the object-relational (O-R) approach association and aggregation relationships can be implemented by means of single references or collection of references, depending on the relationship cardinality. Composition relationship which is a stronger whole-part relationship than aggregation can be implemented by including a single object or a collection of them into other objects, again depending on the relationship cardinality. Collections can be implemented by two different structures: array and multiset; the main difference between them is the prediction of a given maximum size (the array) or not (multiset).

In relational database management systems (RDBMS) relationships are implemented via tables, foreign and primary keys. Depending on the relationship degree and cardinality a join table is defined in order to hold it. A join table must contain at least a foreign key column for each primary key of the entities participating in the association.

In this work we evaluate the implementation of inheritance, association, aggregation and composition relationships over Oracle 10g to prove the competitiveness of the object-relational technology. We have used this ORDBMS for both object-relational and relational implementations. The reason for choosing Oracle 10g is because it is leader in the database market and includes many of the SQL:2003 features. To perform the implementation evaluations several queries have been selected considering the use of special built-in functions applied to references (REF, DEREF) and collections (TABLE). Those queries were executed and compared to their relational equivalent, which take the form of join operations.

Figure 1. Layers involved in mapping objects into ORDBMS



The results obtained in terms of the elapsed time and execution plans proposed by the optimizer are given.

Two important works are found in the literature about the study of the ORDBMS performance [1, 5]. They were done several years ago, when the O-R technology did not offer the nowadays features. At that moment arrays and multisets were not implemented and scoped references were not supported. We used them as a reference for this paper. Furthermore, [6] was taking into account in our research since it refers to the benefits and contributions of the O-R technology in the software development process and [7] where some concepts about O-R mappings are proposed.

MAPPING LAYERS OF ORDBMS

In [4] we have defined three layers involved in the transformation of UML class diagrams into ORDBMS persistent objects. The first one corresponds to the UML class diagram, the second is the object-relational layer composed of the O-R elements proposed by the SQL:2003 standard [8] -UDTs, arrays, multisets, references, row types-, and the third is the object-relational persistent layer composed of typed tables which are defined from the elements of the second layer containing keys, constraints and OIDs, among other things. Unlike the relational model the additional layer of the object-relational model adds a greater complexity.

The layers involved in the transformations and the elements composing them are presented in Figure 1. It shows that the relational transformations complying with SQL'92 standard are made in one step from UML to relational tables; while O-R transformations take two steps from UML to object-relational components and from the latter to persistent object tables.

DATA MODEL EXAMPLE

We have used a book case model of a purchase order administration in a business company whose UML class diagram for the schema implementations is shown in Figure 2. This model contains many of the relationship types needed to perform the evaluation. It should be noted that no aggregation relationships are presented, this gap was overcame by implementing the composition relationship in a "weak" manner treating it as an aggregation as will be shown later in this paper.

The UML class diagram was translated into an object-relational schema compliance with the SQL:2003 standard and into a relational schema designed under the SQL'92 standard and following the normalization rules. This was done in order to compare the performance of both technologies.

RELATIONAL SCHEMA DEFINITION

The UML class diagram mapping into a relational schema is based on the definitions made on [3].

For the inheritance hierarchy of classes, three ways are presented in the literature [2, 3]: flat, vertical and horizontal. We have implemented the three methods but in this paper it is only shown the flat model by creating one single table for all classes (super and subtypes) in the hierarchy. In the hierarchy it is assumed that Person and Company sets are disjoints and the three object types (customers, persons and companies) must be represented, then in the table where those attributes not corresponding to the type stored in a row, contains NULL values.

Figure 2. Class diagram for a purchase order application

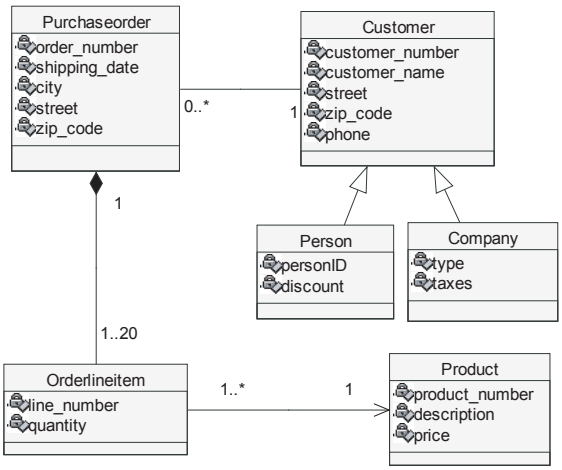


Table 1. Object-relational mapping layers

UML layer components	Object-Relational layer components	Persistent layer components
Customer class	Customer UDT	Customer type table with substitutability property
Person class	Person UDT under Customer	
Company class	Company UDT under Customer	
Purchaseorder class	Purchaseorder UDT	Purchaseorder type table
Orderlineitem class	Orderlineitem UDT	
Product class	Product UDT	Product type table
Customer - Purchaseorder association	Purchaseorder reference multiset (attribute of Customer UDT) Customer reference (attribute of Purchaseorder UDT)	
Purchaseorder - Orderlineitem composition	1. Orderlineitem object array (attribute of Purchaseorder UDT)	
	2. Orderlineitem reference array (attribute of Purchaseorder UDT)	Orderlineitem type table
	3. Orderlineitem reference multiset (attribute of Purchaseorder UDT)	Orderlineitem type table
	4. Orderlineitem object multiset (attribute of Purchaseorder UDT)	
Orderlineitem - Product association	Product reference (attribute of Orderlineitem UDT)	

Association, aggregation and composition relationships are implemented by means of primary and foreign keys.

OBJECT-RELATIONAL SCHEMA DEFINITION

The O-R schema is generated by using references, arrays and multisets and/or a combination of them according to the definitions made in [4].

In Table 1 we present the elements composing the three layers involved in the O-R schema definition. Observe that Purchaseorder-Orderlineitem composition relationship has been implemented in four different ways:

- The first one (1.) is by defining an Orderlineitem type array of dimension 20 in Purchaseorder type table, this is the most natural implementation according to the relationship defined in the UML class diagram. We included the objects of the "part" into the "whole" due to it's a strong relationship where the part life depends on the whole life. We used an Orderlineitem type array into Purchaseorder type table because the multiplicity of the part is well known having a maximal number of 20.
- The second one (2.) is by defining an array of references to Orderlineitem objects in Purchaseorder type table, implemented by the orderline_va attribute. This implementation was made in order to use references within the composition relationship so that it can be treated like an aggregation relationship. It is important to note that if the "whole" is deleted some procedure to eliminate the "parts" must be implemented in order to maintain the integrity of the references. This is not a natural implementation of a composition relationship, it is done in this case in order to evaluate this relationship type. Although for some cases and depending on the nature of the relationship this can be an alternative for a composition.
- The third (3.) and fourth (4.) alternative implementations include a multiset of references and a multiset of objects respectively. The difference between these two and the previous two is that for multiset it is not known the maximum size of the collection. The considerations made about using references or objects are the same than the previous paragraphs.

The relationship between Orderlineitem and Product is an unidirectional association, so we have included a reference to Product as an attribute in Orderlineitem UDT.

Observe that the persistent layer is composed of fewer elements than the O-R layer, depending on the way the composition is implemented three or four tables are defined.

Considering that there are no symbols proposed to represent the O-R elements in a database schema diagram we introduce a graphical notation for this purpose which is shown in Table 2.

Table 2. Object-relational extensions to the relational schema diagram

Graph	Element
→	Reference (single arrow)
⇉	Array of references (double arrow)
⇉	Multiset of references (quadruple arrow)
▭	Object array
▦	Object multiset
▭→	Object array containing references to other object
▦→	Object multiset containing references to other object

According to the graphical elements proposed, the resultant object-relational schema diagram corresponding to the first implementation of the composition relationship is shown in Figure 3. The other schemas of the remainder implementations of the composition relationship are shown in Figures 4 to 6.

In Fig. 3, the Customer class has a multiset of references to Purchaseorder class. The Purchaseorder class has a single reference to the Customer class and an array of Orderlineitem objects containing a reference to Product class.

Figure 4 shows that the Customer2 class has a multiset of references to Purchaseorder2 class. The Purchaseorder2 class has a single reference to the Customer2 class and an array of references to the Orderlineitem2 class. Orderlineitem2 class contains a single reference to Product2 class.

In Fig. 5, the Customer3 class has a multiset of references to Purchaseorder3 class. The Purchaseorder3 class has a single reference to the Customer3 class and a multiset of references to the Orderlineitem3 class. Orderlineitem3 class contains a single reference to Product3 class.

Figure 6 shows that the Customer4 class has a multiset of references to Purchaseorder4 class. The Purchaseorder4 class has a single reference to the Customer4

Figure 3. Schema diagram for the object-relational implementation. Composition relationship implemented using an array of objects

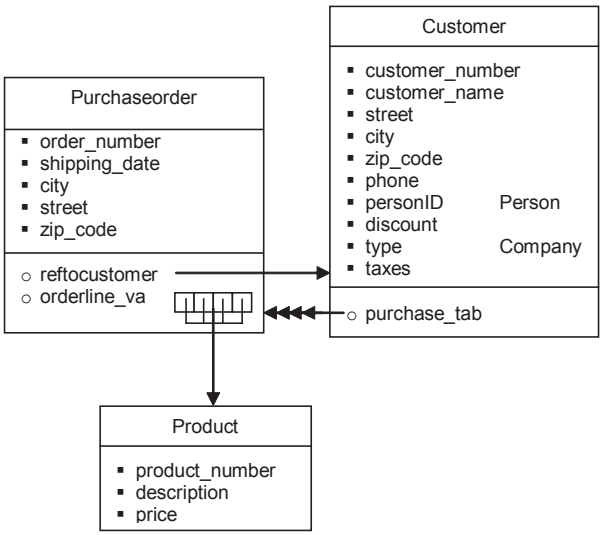

Figure 4. Composition relationship implemented by means of an array of references

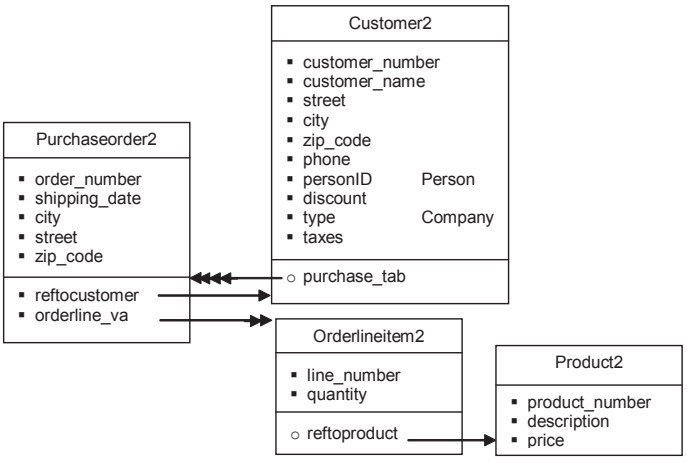

Figure 5. Composition relationship implemented by means of a multiset of references

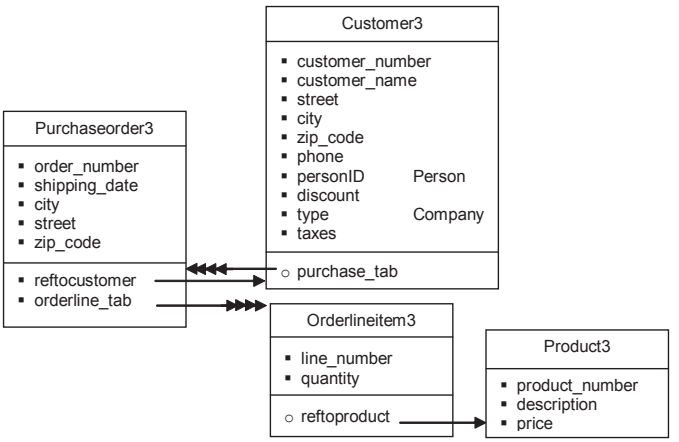

Figure 6. Composition relationship implemented by means of a multiset of objects with references to other object

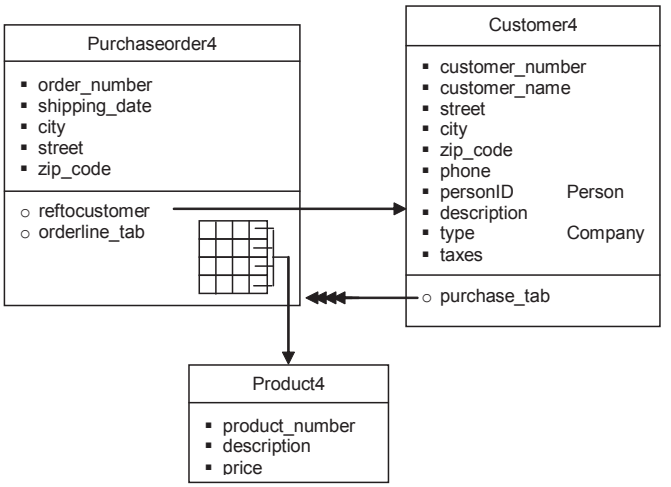

class and an embedding multiset of Orderlineitem4 objects with single reference to Product4 class.

DATABASE IMPLEMENTATION

In order to make a proper evaluation among the different implementations the tables of the database were populated with thousands of object/tuples using store procedures written in the programming language provided by the ORDBMS containing random values generation functions for the data.

In the object-relational schema every row object in an object table (type table) has an associated OID that uniquely identifies it. The OID allows the corresponding row object to be referenced by other objects. A built-in data type called REF is used for such references. We have used scoped REF to constrain that only references to a specified object table can be implemented, because they are stored more efficiently than unscoped REFs. In the relational schema every row in a table has a primary key that uniquely identifies it allowing table joins.

The number of generated instances of each class is shown in Table 3.

Table 3. Number of objects of each class in the data model

Class	Number of instances
Company	451
Customer	1,000
Orderlineitem	63,578
Purchaseorder	10,000
Person	320
Product	10,000

EVALUATION TEST BETWEEN THE SCHEMAS

We have defined several relational and object-relational queries to compare the performance of the schemas proposed. As can be seen the selected queries explore the use of collections (array and/or multiset) of objects and references, single references and inheritance hierarchy. These queries have been selected due to collections and references make the difference between the O-R approach and the relational one, and the reason of the performance comparison made.

We have executed each one 10 times in different moments and we have calculated the average elapsed time for them. We decided not to flush the database buffer pool among runnings because in real life users execute several applications at the same time all of them consuming system resources. The hardware used for the implementation and testing is an Intel Pentium IV CPU 3.00 GHz, with 1 GB of main memory, running the Microsoft Windows XP operating system.

The goal of the comparison among the queries is to make a relative evaluation of the proposed implementations and analyze the use of references, arrays and multiset of the object-relational technology against the joins of the relational approach. In this analysis we considered the response times and the execution plans defined by the optimizer.

Query 1. Find the order numbers and the detail of line numbers and quantity ordered.

In this query we are analyzing the behavior of the four implementations of the composition relationship in order to find out the most convenient alternative in terms of the response time.

1.1 Array of objects

```
SELECT p.order_number, o.line_number, o.quantity FROM purchaseorder_t p,
TABLE(p.orderline_va) o;
```

1.2 Array of references

```
SELECT p.order_number, o.column_value.line_number, o.column_value.quantity
FROM purchaseorder2_t p, TABLE(p.orderline_va) o;
```

1.3 Multiset of references

```
SELECT p.order_number, o.column_value.line_number, o.column_value.quantity
FROM purchaseorder3_t p, TABLE(p.orderline_tab) o;
```

1.4 Multiset of objects

```
SELECT p.order_number, o.line_number, o.quantity FROM purchaseorder4_t p,
TABLE(p.orderline_tab) o;
```

1.5 Relational model

```
SELECT p.order_number, o.line_number, o.quantity FROM purchaseorder p,
orderlineitem o
WHERE p.order_number = o.order_number;
```

The results obtained are shown in Table 4.

Table 4 shows that the use of a multiset of objects (query 1.4) has the same response time than the join (query 1.5) proposed for the relational query; in this case both

Table 4. Results of the query 1

Query	Rows selected	Response time (hh:mm:ss)
1.1	63578	00:00:03
1.2		00:00:07
1.3		00:00:07
1.4		00:00:02
1.5		00:00:02

technologies are competitive. The use of collections of references (queries 1.2 and 1.3) have the worst response time, the explanation for this behavior relays on the size of the references, which are more than 40 bytes long requiring an extra time to solve it. Looking at the execution plans the use of arrays requires a collection iterator operation (PICKLER FETCH) that is not present for multisets, it is traduced in a higher cost and number of bytes involved.

Query 2. Find the customers, their order numbers together the line numbers and quantity ordered.

This query is similar to query 1 but in this case we are starting from the customer typed table adding an extra multiset of references. When the composition is implemented like an aggregation two hop references are employed. For this case we are using the traversal of two collections.

2.1 Multiset of references + Array of objects

```
SELECT c.customer_number, c.customer_name, p.column_value.order_number, o.line_number, o.quantity
FROM customer_t c, TABLE(c.purchase_tab) p, TABLE(p.column_value.orderline_va) o;
```

2.2 Multiset of references + Array of references

```
SELECT c.customer_number, c.customer_name, p.column_value.order_number, o.column_value.line_number, o.column_value.quantity FROM customer2_t c, TABLE(c.purchase_tab) p, TABLE(p.column_value.orderline_va) o;
```

2.3 Multiset of references + Multiset of references

```
SELECT c.customer_number, c.customer_name, p.column_value.order_number, o.column_value.line_number, o.column_value.quantity FROM customer3_t c, TABLE(c.purchase_tab) p, TABLE(p.column_value.orderline_tab) o;
```

2.4 Multiset of references + Multiset of objects

```
SELECT c.customer_number, c.customer_name, p.column_value.order_number, o.line_number, o.quantity
FROM customer4_t c, TABLE(c.purchase_tab) p, TABLE(p. column_value.orderline_tab) o;
```

2.5 Relational model

```
SELECT c.customer_number, c.customer_name, p.order_number, o.line_number, o.quantity
FROM customer_plano c, purchaseorder p, orderlineitem o
WHERE c.customer_number = p.customer_number AND p.order_number = o.order_number;
```

The results obtained are shown in Table 5.

Looking at the results shown in Table 5 the relational approach is more efficient in terms of response time than the O-R technology. The cause is that the multiset of references implementing the association between Customer and Purchaseorder add an extra time for solving the query as was mentioned before. The multisets used for the composition relationship consumes much more time than the arrays. Looking at the execution plans the operations, cost, number of bytes and the other variables of the plans gave us no clue about this behavior. What it is clear in this case is that when two collections are involved in a query is better to implement it by means of arrays if possible.

Arrays perform much better than multisets in the case that the entire collection is manipulated as a single unit in the application because the array is stored in packed form and do not require joins to retrieve the data, unlike multiset, using Oracle 10g.

Query 3. Find the products ordered by the customers.

In this query we are using two collections plus single references to retrieve products information, that is to say it were employed three hop references.

3.1 Multiset of references + Array of objects + Single references

```
SELECT c.customer_number, c.customer_name, p.column_value.order_number, o.reftoproduct.product_number
FROM customer_t c, TABLE(c.purchase_tab) p, TABLE(p.column_value.orderline_va) o;
```

3.2 Multiset of references + Array of references + Single references

```
SELECT c.customer_number, c.customer_name, p.column_value.order_number, o.column_value.reftoproduct.product_number
FROM customer2_t c, TABLE(c.purchase_tab) p, TABLE(p.column_value.orderline_va) o;
```

Table 5. Results of the query 2

Query	Rows selected	Response time (hh:mm:ss)
2.1	63578	00:00:05
2.2		00:00:10
2.3		00:01:14
2.4		00:01:14
2.5		00:00:03

3.3 Multiset of references + Multiset of references + Single references

```
SELECT c.customer_number, c.customer_name, p.column_value.order_number, o.column_value.reftoproduct.description
FROM customer3_t c, TABLE(c.purchase_tab) p, TABLE(p.column_value.order-line_tab) o;
```

3.4 Multiset of references + Multiset of objects + Single references

```
SELECT c.customer_number, c.customer_name, p.column_value.order_number, o.reftoproduct.product_number
FROM customer4_t c, TABLE(c.purchase_tab) p, TABLE(p.column_value.order-line_tab) o;
```

3.5 Relational model

```
SELECT c.customer_number, c.customer_name, p.order_number, pr.description
FROM customer_plano c, purchaseorder p, orderlineitem o, product pr
WHERE c.customer_number = p.customer_number AND p.order_number = o.order_number
AND o.product_number = pr.product_number;
```

The results obtained are shown in Table 6.

As it can be noted queries with the third added hop have the same performance than query 2.

Query 4. Find customer information for all customers of person type.

In this query we are using the inheritance hierarchy of Customer obtaining the supertype information of person subtype. The substitutability property allows the storage of any subtype in the supertype table.

4.1 Object-relational

```
SELECT p.customer_number, p.customer_name, p.street, p.city
FROM customer_t p WHERE VALUE(p) IS OF (person_ob);
```

4.2 Relational

```
SELECT customer_number, customer_name, street, city
FROM customer_plano WHERE type = 'P';
```

The results obtained are shown in Table 7.

The response time for both queries is similar; due to the few rows involved in the query the time is very low. Analyzing the execution plans both are very similar, and no differences can be found. The advantage of the O-R approach is that the model evolution can be easily implemented, subtyes can be added to the hierarchy and can be stored in the supertype table.

Query 5. Find customer and person information for all customers of person type.

The difference between this query and query 3 is that in this case we are treating supertype instances as subtype instances.

5.1 Object-relational

```
SELECT p.customer_number, p.customer_name, p.street, p.city, TREAT(VALUE(p) AS person_ob).person_id, TREAT (VALUE(p) AS person_ob).discount FROM customer_t p WHERE VALUE(P) IS OF (person_ob);
```

5.2 Relational

```
SELECT customer_number, customer_name, street, city, person_id, discount
FROM customer_plano WHERE type = 'P';
```

The results obtained are shown in Table 8.

The result analysis made for query 4 is the same for this one. Due to in both queries (4 and 5) the flat model is used, so the optimizer makes a sweeping of the entire tables.

Table 6. Results of the query 3

Query	Rows selected	Response time (hh:mm:ss)
3.1	63578	00:00:10
3.2		00:00:12
3.3		00:01:13
3.4		00:01:11
3.5		00:00:07

Table 7. Results of the query 4

Query	Rows selected	Response time (hh:mm:ss)
4.1	320	Less than 1 second
4.2		Less than 1 second

Table 8. Results of the query 5

Query	Rows selected	Response time (hh:mm:ss)
5.1	320	Less than 1 second
5.2		Less than 1 second

CONCLUSIONS

In this work we have evaluated the implementations of relationships of different type into an object-relational schema and have made the comparison of them against a relational approach. Oracle 10g was used for the implementations. We started with a UML class diagram of a book case example. In order to define the O-R schema we have transformed the class diagram into O-R elements of an intermediate layer and then they were transformed into persistent typed tables. These tasks are more complex than the relational model which involves a more direct mapping. Several O-R schemas have been defined involving different alternatives for the implementation of composition relationship. Arrays and multiset of references and objects have been used for this purpose. We have proposed graph elements to support object-relational extensions for the relational schema diagram. Those elements are very useful for database developers since the complexity of the object-relational model can be represented graphically facilitating their interpretation.

The evaluation of the O-R implementations against the relational approach has been driven by a set of queries, their response time and execution plans. As a result of this study, comparing the use of arrays, multiset, objects and references, for the implementation of composition and aggregation relationships, no general conclusion of which one is better can be made. Each case can be analyzed according to the business rule to be implemented, several alternatives for them are open, and it is worthy to make some evaluations before making a final decision. The performance of the inheritance hierarchy is the same in both technologies analyzed, having the O-R technology more flexibility for type evolution.

Even though the relational technology threw the best results, the object-relational technology had good ones in some cases, not so far the relational behavior. In the future work our plan is to implement the mappings in an OO language such that it is possible to evaluate if the O-R technology can reduce the impedance mismatch existing between the OO programming languages and the relational approach. A priori, the expectation is to get certain advantages from the O-R technology regarding to this issue.

Knowledge Support for Software Projects

Birinder Sandhawalia, National Centre for Project Management, Middlesex University, Trent Park, Bramley Road, London N14 4YZ, UK; E-mail: b.sandhawalia@mdx.ac.uk

Darren Dalcher, National Centre for Project Management, Middlesex University, Trent Park, Bramley Road, London N14 4YZ, UK; E-mail: d.dalcher@mdx.ac.uk

ABSTRACT

The unpredictable nature of software projects and the need for effective communication within project teams requires a framework for social interaction and feedback that results in better decision-making. This paper analyses the creation and capture of knowledge within software development projects and discusses the central role of decision making in the development process. The paper views how the knowledge generated within a software project can be provided greater visibility and communicated effectively, and to achieve this, presents a framework to facilitate social interaction and feedback during the development process.

1. INTRODUCTION

The use of knowledge is expected to result in better decision-making, innovation and competitive advantage within software projects. Software development projects are life-cycle driven and are organised around teams that are assembled specifically for the limited duration of the project. The software development process relies on the knowledge and creativity of individuals and teams, and the formation of these teams requires the involvement and participation of all team members in the development process. There is also an increasing need to involve users early in the software development life-cycle since designing software requires extracting detailed knowledge of the users. Effective communication is the basis for discussion between users and developers during the requirements definition process that is essential to provide an understanding of the software requirements. However, problems of communication occur due to the diversity of professional expertise and organisational roles that confer users' different views and expectations of the system to be developed.

The unpredictable nature of software projects and the need for effective communication within project teams necessitates a framework for social interaction and feedback that results in better decision-making. This paper analyses the creation and capture of knowledge within software development projects. The paper discusses the central role of decision making in the development process and how the effective use of knowledge helps to improve decision-making during the development process. The knowledge created and decisions implemented need to be effectively communicated across the entire process. Social interaction and feedback are key factors that facilitate the effective use of knowledge within software projects. The paper views how the knowledge generated can be provided greater visibility within the projects and communicated effectively, and also presents a framework to facilitate social interaction and feedback during the development process.

2. KNOWLEDGE

Knowledge is the capacity for effective action. Alavi and Leidner (1999) define knowledge as 'a justified personal belief that increases an individual's capacity to take effective action.' While 'personal' implies the contextual nature of knowledge, action requires competencies and know-how, and implies the dynamic nature of knowledge. Knowledge is fluid and formally structured, and it exists within people, processes, structures and routines, (Davenport and Prusak 1998). Polanyi (1967) suggests that knowledge exists as tacit and explicit. Tacit knowledge comprises an individual's mental models, and while it is personal and in the mind of an individual, it is also context specific and difficult to articulate, formalise and verbalise, and is therefore hard to communicate and share. The factors that influence an individual's mental model include the individual's education, expertise, past experiences, perceptions, biases, prejudices and environment. Explicit knowledge can be easily articulated and codified and therefore transmitted and communicated. Polanyi (1967) contends that human beings acquire knowledge by actively creating and organising their own experiences and sums it up by stating that "we can know more than we can tell."

The importance of knowledge is increasing as organisations recognise that they posses knowledge and increasingly learn to view this knowledge as a valuable and strategic asset. Knowledge assets include knowledge which resides within the individuals, systems, processes, documents and structures of the organisation. Davenport and Prusak (1998) recommend that to remain competitive, organisations must efficiently and effectively create, capture, locate and share their organisations knowledge and expertise, and have the ability to bring that knowledge to bear on problems and opportunities.

2.1 Knowledge Management

The American Productivity and Quality Center (1996) defines knowledge management as "a conscious strategy of getting the right knowledge to the right people at the right time and helping people share and put information into action in ways that strive to improve organisational performance." Knowledge management, therefore, requires that it is imperative to identify what knowledge needs to be managed, how, when, where, by whom, and for whom. Consequently, the key elements of KM are collecting and organising the knowledge, making it available through knowledge infrastructure, and then using the knowledge to improve decision making and gain competitive advantage. Alavi and Leidner (1999) refer to knowledge management as a systematic and organisationally specified process for acquiring, organising and communicating both tacit and explicit knowledge of employees so that other employees may make use of it to be more effective and productive in their work and decision-making while improving product and process innovation.

3. THE NEED TO MANAGE SOFTWARE PROJECT KNOWLEDGE

Compared to organisations which are permanent structures and have routines, projects are temporary by nature and their implementation requires creative actions, practitioner's experience, and the ability to apply knowledge to development problems. Projects are designed to achieve specific objectives within a predetermined time frame, budget and resources. Projects involve planning for non-routine tasks to be conducted in several phases, and can be characterised as unique, goal-oriented and complex undertakings steeped in uncertainty, which aim to produce a meaningful product or service in order to satisfy a need, (Dalcher 2003).

Software projects are life cycle driven and follow the sequence of going from concept through definition and development, to testing and delivery. However, unlike other projects, the requirements of software projects are subject to frequent change. As a product, software can be changed, and it is therefore assumed that this change is possible at even the later stages of the development process. Such change and uncertainty make software projects more unpredictable than other projects, and are therefore organised around teams, relying upon the knowledge and creativity of the individuals and the teams. Software projects are typically implemented by teams assembled specifically for the project and often disbanded upon its completion. Requirements evolve and team members often change during the course of projects, while feedback from one phase of the project to another rarely provides team members with an opportunity to learn from their good decisions or mistakes. Team members often come together for the first time at the outset of the project and therefore it is difficult to create the right knowledge culture and locate the knowledge assets. Moreover, project implementation effort is often

focused on immediate deliverables with no emphasis on how the experience and insights gained would help and benefit future projects.

The amount of knowledge required to manage a project depends upon the novelty and uniqueness of the required outcome. Love et al (1999) argue that even though a project is unique, the processes involved in delivering the final outcome are similar in projects and, therefore, most projects do not need to start from scratch as they can utilise existing processes and learn from the experiences acquired from previous projects. Projects are required to be completed within a specific schedule and budget, which makes the reuse and harnessing of knowledge desirable. Without the reuse of existing knowledge or the ability to create new knowledge from existing solutions and experiences, project organisations have to create new solutions to every problem they encounter, potentially leading to delays and inefficiencies. With the reuse of knowledge, projects can be planned more efficiently to be delivered within budget and on time. Koskinen (2004) suggests a metaphor of a project tree to visualise the entire knowledge required by a projects, and states that the types of knowledge that a project may require are tacit, explicit, additive or substitutive. Koskinen (2004) further refers to additive and substitutive knowledge as knowledge that is new to the project and is either invented internally or acquired from external sources. This is similar to Bredillet's (2004) view that project teams need to know what knowledge is available to complete the project based on past experience, and what knowledge needs to be acquired or will emerge as a result of the unique nature of the project tasks, especially within software projects.

The implementation and outcome of projects depends upon a large extent on the knowledge of individuals, their access to local and global knowledge resources, and recognition and integration of existing knowledge. Problem solving within unique project instances generates further knowledge, and the knowledge assets thus created, combined with the experience gained by implementing the project, can benefit subsequent projects. Certain software process improvement approaches, for example the Capability Maturity Model, suggest that the development process be optimised to deliver the most of the software organisation's capability. Such approaches often suggest that knowledge be managed or leveraged, but do not bring it down to an operational level. However, the knowledge requirements make it imperative to identify what knowledge needs to be managed, how, when, where, by whom, and for whom. Consequently, the key requirements for managing knowledge within software projects are collecting and organising the knowledge, making it available through knowledge infrastructure, and then using the knowledge to improve the execution of projects.

The knowledge that is created requires a strategy or model that facilitates the cross leveling of this knowledge across the software development process, and globalises the knowledge created within the software project. Process models for software development depict sequential, incremental, prototyping or evolutionary approaches. Developmental models help simplify and reduce the complexity within software projects by providing a perspective to organise the different stages or phases of the development process. The following section presents and discusses the Dynamic Feedback Model, which underlines the relationships and interactions between the various entities and phases of the software development process.

4. THE DYNAMIC FEEDBACK MODEL

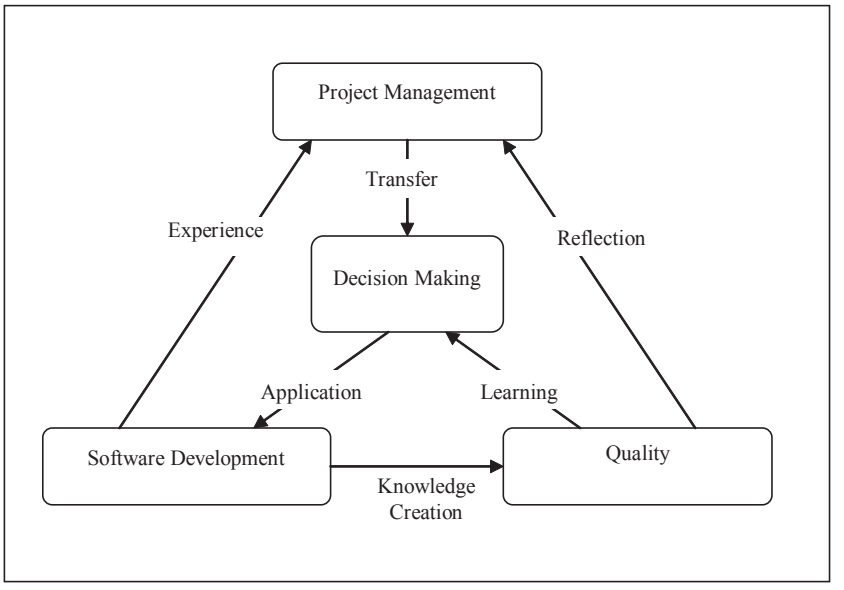
Complex and uncertain software development situations require a model that can account for the knowledge needed to plan and implement decisions within the development process. An example of such a model is the Dynamic Feedback Model (DFM) that underlines the relationships and interactions between the entities by depicting the feedback loops operating between them. The model, as depicted in Figure 1, focuses on four different functional areas that are intertwined throughout software development. The DFM models the relationships in a non-linear fashion amongst the functional areas and allows a continuous view of the development process. The four areas are management, technical, quality and decision-making.

4.1 Functional Areas

The management area involves the planning, control and management of the software development process. It also pertains to the strategy and operation of the project. Key concerns revolve around identifying performance gaps, assessing progress, and allocating resources to accomplish tasks. As technical development and knowledge creation are on going activities, the management area also takes on a continuous view. It does not limit its focus to delivering a product, but to the continuous need for generating and maintaining an on-going flow of knowledge required for continuous development.

The technical area deals with the creation and continuous improvement of the software system. The area recognises the changing needs and perceptions of the development process. The activity in this area includes evolution and maintenance of the software, while also maintaining its functionality and utility. Experimentation, learning and discovery take place as the software goes from inception to evolution. The development and design of the software form the basis for interac-

Figure 1



tion between team members, and the knowledge created through the interaction provides the raw material for decision making within the process.

The quality area is perceived as a dynamic dimension, which continuously responds to perceived mismatches and opportunities reflected in the environment. It is concerned with assuring the quality of the product developed and the process used to develop it. Being an area of assessment, it provides the basis for learning.

The decision-making area lies at the core of the model as software development is described as a decision making process (Dym and Little 2000). This area attempts to balance knowledge, uncertainty and ambiguity with a view to maximise the expected returns on an on-going basis. Knowledge acquired from implementing decisions is used within the process either as background knowledge available to support future decisions, or as a formalised part of an integral body of knowledge which can be used to optimise the decision making process. Decision-making helps manage opportunity and risk and therefore this area can also be considered the risk management area. Risk assessment and planning are key activities within this area, which also ensures the implementation of decisions and the monitoring of their execution on a continuous basis. The knowledge required for the implementation, execution and monitoring of decisions is provided by the interaction and feedback loops of the model.

4.2 Feedback Loops

The DFM is in essence a set of interactions and feedback loops governing and controlling the development of software form a continuous perspective. The decision making perspective of the DFM ensures that rational and reasoned choices are made from the alternatives available during the development process.

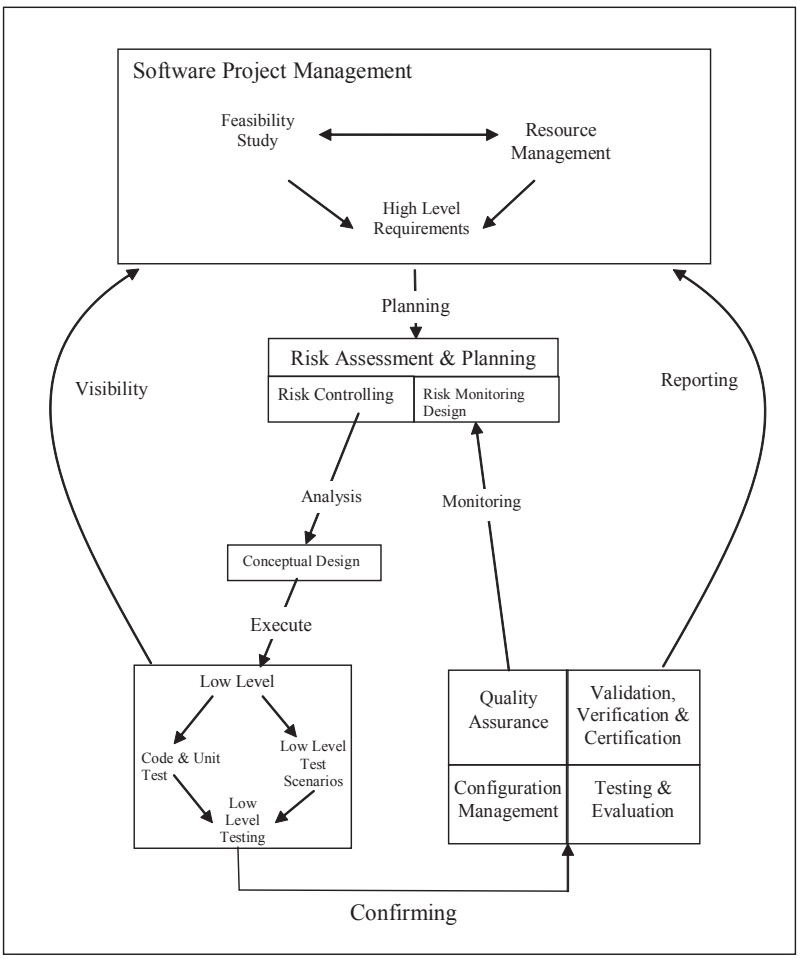
The basic loop in the dynamic system is the knowledge transfer-application-experience loop. This loop helps to plan and control the production, evolution and growth of the software in association with project management and decision making. The loop enables the continuous generation of new information as well as feedback knowledge and experience gained while executing the project. The use of this knowledge is crucial in changing plans to adapt to reality and opportunities, modifying the decisions and re-examining the assumptions. The visibility of this basic feedback loop provides a continuous process to ensure the system remains relevant with regard to its objectives.

The knowledge creation loop links the knowledge created and learning with effective application. The knowledge generated during the design process within the decision-making area is applied to help develop the software. The knowledge created in the technical area helps in quality assurance, while the learning that emerges from identifying and correcting mismatches is fed back to the decision making area for use in subsequent development.

The reflection-transfer loop provides visibility to the project management area regarding the opportunities and mismatches present in the quality area, and also those provided by the implementation and execution of the decisions made.

The above mentioned loops depict relationships between the different functional areas. The DFM can therefore be used as a framework for understanding the dynamic nature of the interactions between entities in software development, and the knowledge that flows between them. The model moves away from linear thinking and offers a continuous perspective for understanding and implementing relationships, and the role these relationships play in software development. The model achieves this through the on-going feedback and interactions of the

Figure 2



loops, which present the framework to provide the knowledge flow required for software projects. The following section examines the feedback and interactions between the different phases of software development projects.

4.3 The DFM Process

The phases of the software development process can broadly be categorised as problem definition, requirements analysis, design, implementation and maintenance. The DFM views knowledge as a key asset in the development of software and focuses on its feedback within the functional areas of development. In doing so, the DFM encourages thinking about software development in terms of the different phases and their interactions. The feedbacks within the functional areas of the DFM are depicted in Figure 2, and the use of knowledge for decision making within the various activities of software projects.

The project management area facilitates project planning and execution, and is also where the user requirements are elicited and the problem defined. Planning involves resource management where the skills and competencies required to execute the project are identified and teams are formed. Proper requirements analysis and specification are critical for the success of the project, as most defects found during testing originate in requirements. In order to understand the customer requirements, the developers require insight into the domain of the business system and the technical concepts of the system to be developed. Knowledge is created while understanding the requirements by the interaction of the different team members, and also between the users and the developers. This knowledge provides the perspective for decisions made to implement the project. The project management area is where discussion takes place between the users and developers as software development requires that users are involved in the development of the software. A clear understanding is needed between the users and developers to build the software, and this understanding is established through dialogue and communication. The formalisation of such an understanding usually results in the form of proposals and contracts. The feasibility of the project and the cost involved in executing the project are the basis for the proposals and contracts. The project management area addresses the need to assess the feasibility of the project and its cost analysis.

Based upon the decisions made and the outcome of planning within the project management area, an analysis of the impact the project will have on the business and technical environment is made along with the possible risks involved in implementing the project. The analysis views the goals, scope and functionality of the system being developed and how they fit or respond to the existing processes with which they are required to interact. Risk assessment and planning are conducted and feature the two traditional components of risk identification and prioritisation. Identification tries to envision all situations that might have a negative impact on the project, while prioritisation involves analysing the possible effects and consequences of the risk in case it actually occurs. The project also requires crucial decisions to be made in the design stage. High level design is the phase of the life cycle that provides a logical view of the development of the user requirements. Design involves a high level of abstraction of the solution, through which requirements are translated into a 'blueprint' for constructing the software, and provides the architecture of the application and its database design. Decision making at this stage of the process helps transform the requirements into a set of software functions and a physical database structure. Scenarios are developed to test the acceptability of the design with relation to the requirements.

The technical activities of design, code generation and testing are performed in the technical area. The area includes the detailed design phase where the high level design is converted into modules and programs. A unit test plan is created for the conditions for which each program is to be tested. The required programs are coded or translated into the programming language, and the programs are tested using the unit test plans. The technical area ensures that the integration plan is implemented according to the environments identified for integration. The area also ensures the maintenance, functionality and utility of the software apart from its creation and evolution. The decisions made in this area relate to the technical activities and provide confirmation of the design and suitability of the requirements. The decisions made are verified during system testing within the quality assurance area.

Pressman (1997) states that quality assurance consists of the auditing and reporting functions of management, and that its goal is to provide management with the data necessary to be informed and assured about product quality. The quality assurance area involves system testing which validates that the software developed meets the requirement specification. This phase identifies the defects that are exposed by testing the entire system. A series of tests are performed together, each with a different purpose, to verify that the system has been properly integrated and performs its functionality and satisfies the requirements. The quality assurance area thus provides verification of the decisions made and tasks performed in the technical area while confirming the decisions made during the design phase, and validating the requirements.

The different phases of the process are validated and given visibility by the feedback loops. Controlling the execution of decisions generates knowledge (Dalcher 2003a). The feedback loops globalise this knowledge within the process and ensure that knowledge is available for decision making. The decisions made in the decision making area during design and risk analysis receive confirmation during technical development and quality assurance. Technical development provides the project management area visibility of the software being developed to meet the requirements. Quality assurance further reports and validates to project management the decisions made during design and technical development. The project management area is able to assess the feedback and incorporate it in planning to help address some of the change and uncertainty inherent within the software development process.

5. CONCLUSIONS

Software projects require knowledge to implement projects effectively. Software projects are organised around teams and rely upon the knowledge, creativity and competence of the individual team members. Effective knowledge management helps provide timely and required knowledge to team members, which results in better productivity and quality of the software processes and product. The DFM adopts a long-term perspective of software development that enables it to address the issues of uncertainty and ambiguity, and therefore benefit from the decisions made and knowledge created during the development process. The long-term perspective also enables the DFM to look beyond a single project and use the knowledge generated towards improvements in future software projects. The DFM is receptive to changes in the environment and tackles them by feeding acquired knowledge back into the decision making process. As software development becomes more integrated in management practices the importance of continuous learning, knowledge, and skill acquisition as underpinned by the DFM will remain central to improved control, visibility and management. The availability of a long-term view justifies the adoption of multiple perspectives, the reuse of knowledge and the utilisation of a decision making perspective, which underpin feedback and improvement.

The DFM provides a framework that facilitates social interaction and feedback, which further enhance the use of knowledge within the software development process. The feedback loops help facilitate the flow of knowledge created and insights gained within the processes and developmental activities of the functional areas. The continuous view of software development provided by the DFM enables the knowledge, both tacit and explicit, to be globalised through-out the software project organisation. In the domain of software development, the DFM provides software project organisations with an approach that focuses on the non-technical aspects, and the knowledge required to support the developmental effort. The DFM helps identify how and where knowledge is created, shared, transferred, applied and assimilated within the software project organisation. In doing so, the DFM provides a framework and culture that views knowledge as a valuable resource, and supports the effective implementation of software projects. Future work includes validating knowledge support provided by the DFM for software development projects.

Information Security Policy: Taxonomy and Development Issues

Lech J. Janczewski, The University of Auckland, Private Bag 92019, Auckland, New Zealand; E-mail: lech@auckland.ac.nz

ABSTRACT

The content of this paper aims at defining what an Information Security Policy (ISP) is, what are the possible ISP formats, and what parts of the ISP are of particular importance. Special emphasis is put on the presentation of methods for the reduction of effort needed for the development of a good ISP.

INTRODUCTION

The answer to the question: *What is an Information Security Policy?* is not so simple. There are many opinions about this, so let's look at what some researchers have considered:

Karen Forch (1994) stated that all organizations should develop a security policy statement and train all employees on its contents. A policy statement should include main checkpoints that are directed specifically at an individual organization's operations including: Avoidance, Deterrence, Prevention, Detection, Recover, and Correction.

DPMA Model Corporate Computer Security Policy Statement (2006) concludes that it is the policy of a company to protect its proprietary information assets and allow the use, access and disclosure of such information only in accordance with corporate interests and applicable laws and regulations.

The Generally Accepted Information Security Principles (GAISP), (2006) draws upon established security guidance and standards to create comprehensive, objective guidance for information security professionals, organizations, governments, and users. The use of existing, accepted documents and standards will ensure a high level of acceptance for the final GAISP product, and will enable a number of benefits to be achieved.

Finally, Ross Anderson (2001) stated:

By security policy I mean a succinct statement of a system's protection strategy (for example, "each credit must be matched by an equal and opposite debit, and all transactions over $1,000 must be authorized by two managers"). A security target is a more detailed specification, which sets out the means by which a security policy will be implemented in a particular product-encryption and digital signature mechanisms, access controls, audit logs, and so on.

The content of this paper summarises a research aimed at defining what an Information Security Policy (ISP) is, what are the possible formats, and what parts of the ISP are of special importance. The content of the paper will therefore include the following parts:

- What is and what is not an ISP,
- What are the possible formats of an ISP,
- Possible approaches used for the development of an ISP
- Important issues regarding the content of an ISP.

The paper terminates with conclusions and suggestions for future research of these issues.

THE BASIC DIFFERENCE

To some extent the authors quoted in the introduction illustrate the basic difference in the approach to what an ISP is. ISP could be a term used for defining:

- Management's point of view about the protection of the information resources of an organization,
- Results of a project aimed on the development of facilities, procedures, and awareness to protect company's information resources,
- Implementation of a project defined above,
- A document distributed to all employees (or to their subset) informing them of information security arrangements.

In this paper we define an ISP as an internal or generally accessible document produced or endorsed by senior management. This document defines policies deployed or to be deployed within the organization to protection the information resources of the organization and that all staff should follow it.

INFORMATION SECURITY POLICY FORMATS

There are many forms of such a document ranging from a one page document, to an extended 200 page long volume. Janczewski & Colarik (2002) defined these basic differences:

- *General ISP*
  This may be a very short document (less than one page) stating that the security of information is of importance for the company, and that all staff are responsible for assuring that data will be accessible only to those authorised, and not changed without authorization. It is an ISP mission statement.
- *Practical ISP*
  This is a collection of basic rules on how to handle company documents and resources to maintain a high level of security. These rules are top level concepts of security do's and don'ts. For instance, it could contain a statement that all the company files need to have backups performed at the end of each working day, or that no staff member is allowed to disclose their password to anyone. A practical ISP is usually a few pages long. This document is presented to every employee and they are asked to sign an acknowledgement.
- *Detailed ISP*
  This document is an extension of the Practical ISP and contains details of all the procedures mentioned in the Practical ISP document plus a detailed instructional breakdown of those rules, such as how to do a proper backup. Obviously, the development of such a document can have a significant initial cost in being established. Once it is created it can provide for employee training and consistency. Detailed ISPs can be over 200 pages long.

The names of these different policies may varies from organization to organization, and may be quite different from the above, yet it is easy to classify given document to any of these three groups.

GENERAL ISP

As mentioned before the general ISP is usually very short and outlines the wish of the top management to protect information resources of the organization. Below is an example of such a policy introduced at the University of Auckland, New Zealand (2006):

By proactively managing information security, the University can reduce the likelihood and/or the impact on our information systems from a wide range of threats. These threats include:

- Theft of physical IT assets,
- Theft and exploitation of information,
- Deliberate disclosure of sensitive information by University people, agency or contract employees,

- Accidental disclosure of information by University people, agency or contract employees through careless talk (social engineering) or poor document control,
- Destruction or corruption of information stored on computers whether deliberate or accidental,
- Prosecution because of non-compliance with legislation e.g. the New Zealand Privacy Act,
- Concerted attacks on our networks and information by highly organised and computer literate groups; e.g. hacking, denial of service attacks, worms and viruses.

As it was shown in this example the objective of the General ISP is only to indicate the wish of management to protect their information resources. General ISPs does not say how to do this or what consequences would be imposed on those who do not follow it.

PRACTICAL ISP

This is a publication, which contains a number of headings with short (one or two sentence) blurbs. For instant it could be titled as "The Quick Reference Guide to Information Security" and cover issues such as:

1. Access to Information
2. Password Generation & Control
3. Notebook & Laptop Security
4. Viruses
5. Work From Home, etc

Each entry is summarised by a short instruction. For example (from an original company document) the issue of "Destruction of Computer & Telephony Hardware" was followed by: "Information Services are responsible for computer & telephony hardware assets and will determine the method of disposal for each individual item".

More extended version could be represented by a 50 page long document labelled "Information Security Policy" including such parts as:

- *Scope of the Policy*
  General introduction on what the policy covers, applicability, etc
- *Assets Classification and Control*
  This is one of the most important security policy aspects: the definition of access rights to all of the organization's assets which are not freely available and methods of managing these privileges
- *Personnel Security*
  All measures necessary to have trustworthy staff and methods of verifying this trust.
- *Physical and Environmental Security*
  Every real company uses office space and owns/uses office and ICT equipment. This space/equipment should be protected and that part of the ISP addresses these requirements.
- *Computer and Network Operation and Management*
  All protection measures related to computer hardware/ software and networks. This may include the firewall settings, protection against viruses and SPAMs.

Each chapter outlines specific group policies. For instance the "Personnel Security" chapter could contain several Objectives, followed by Policy and Guidelines like:

- *Objective*
  To minimise the damage from security incidents and malfunctions, monitor and learn from such incidents.
- *Policy*
  Channels for reporting security incidents and malfunctions shall be established and all staff made aware of them.
- *Guidelines*
  Staff should be made aware of the purpose and use of the channels for reporting security incidents

A disciplinary process should be instituted for dealing with security breaches.

The above is a quote from an anonym company document.

In many cases the Practical ISP is printed as a short document and staff are asked to read and follow it. For instance, the University of Auckland Practical ISP (2006) warns the staff and the students: "Users who do not comply with mandatory IT policy will be subject to the provisions of the appropriate statute".

DETAILED ISP

A detailed ISP is an extension of the Practical ISP. Not only does it define what needs to be protected but also states how it could be done. For instance while the practical ISP may imply that each employee should back up files, the detailed ISP would instruct the user on how this should be done. This policy may also define how often this needs to be carried out plus how to retrieve backed up data. Such a document could be well over 200 pages long.

It is obvious that an effort to produce such a document is usually significant and that only large organization can afford to do this. Janczewski and Tai (2006) stated (in relation to the practical ISP within accounting Small and Medium Enterprises, (SME)):

All respondents seem to have an information security policy in their organizations. However, a more careful analysis reveals that what they have might not be a real "information security policy" as some of the respondents said they have "IT policy" (or something to that effect). While IT policy might govern what employees can or cannot do with the IT system, an information security policy should go beyond the IT system and include policies on operational or procedural matters. So even though the respondents have policies in place, the policies might not be of good enough quality.

This implies that in practical terms none of those SMEs developed a detailed ISP.

On the top of the large costs related to producing such a document the maintenance effort spent on it could be equality prohibitive. It is clear that such a policy may only make sense if it is properly updated.

The author of this paper recalls a case of auditing a branch office of an international bank where the branch IT manager produced a copy of their detailed ISP. One of the points there was the definition of a procedure for handling of faulty computer equipment. The regulation stated how to report a fault and prepare the equipment for repair. Further, it was indicated that a specific company is authorized to service the equipment. It looked faultless. But in the meantime the bank had changed the repairer making the name in the ISP not valid. One could imagine the consequences of shipping faulty equipment containing sensitive information to an unauthorized service dealer!

IS STANDARDIZATION OF ISPS POSSIBLE?

There are several, sometime conflicting parameters:

- Companies differ in every possible aspect: domain, objectives, size, and IS technology implemented.
- The business environment is usually based on a LAN-type network spanning desk top machines, mainframes and servers with connection to the outside word. This connection may be of the many types including VPN, dial up, and WEB based.
- The application and system software used could be different, however one element is common: no application is perfectly separated from the rest of the world. Through CD ROMs and USB devices even standalone machines are able to exchange data.
- The law in each country is different and may impose different constraints on a company's information systems in terms of the security of their and other's data and software. However, there is a noticeable world trend to standardise law. A company wishing to benefit from international trade must abide with other country's regulations. This puts pressure on local law to follow other international regulations.

This means that security mechanisms & procedure descriptions must be set up to guard information assets from destruction or unauthorised modification. This forces each company to set up their own data security policies which should have

a common denominator. Is a generic ISP such a common denominator? In the author's opinion the answer is a qualified YES, due to the following reasons:

- Internationally ICT has become highly standardised. The trend is similar to the automobile industry where cars are produced by different companies that look relatively similar but:
  - o They are assembled in many countries and shipped internationally,
  - o Driving methods are practically the same,
  - o Main subassemblies work on the same or similar principles.

  The same applies to the ICT industry.
- The growth of the international trade is significant. Each supplier must be prepared to co-operate with a wide range of customers. This puts pressure to adjust their own structure to that of their customers.
- The production/trade methods around the world have become standardised. During the writing of this paper tensions between the USA and Iran are high. But despite what these two countries represent in terms of the political doctrines or culture models, it is obvious that the ICT equipment used in both countries is more or less compatible and is used in a similar way.

Despite all of these compelling reasons many companies, especially SMEs, have not developed a full ISP set (Tai, 2006). The main reason for this is due to the relatively high demand for financial and human resources to develop and maintain such a set of documents. There should be a way of reducing these costs and the next section explains how this could be possible.

APPROACHES TO ISP DEVELOPMENT

The most elaborate approach to setting up an ISP is to develop it as a part of a waterfall methodology suggested by many authors. One of the best examples of this was presented by Whitman and Mattord (2005). In this case the ISP is a part of the whole process starting at the decision to develop an information security system and concluding with system implementation, maintenance and update. If done correctly, such a procedure would lead to the best results; however the costs would be enormous.

The other approach is to take into consideration the most popular international security standard, the ISO 17799 *Code of practice for information security management* (2005) and use it as a framework to develop a company ISP. This way the quality of the resulting ISP would be very high while the effort would be significantly lower than using the fully sized risk analysis and development process. This was well proved by Tai (2003).

Probably the most robust and quickest way of developing an ISP is to use a *Toolkit*, or a *Toolbox* (von Solms, 2001) developed at the Nelson Mandela Metropolitan University, Port Elisabeth, South Africa (former Port Elisabeth Technikon). The concept of the toolbox is based on using the ISO 17799 standard as a foundation stone of the software package guiding the ISP developers though the process of constructing an ISP document.

The Toolbox is an integrated software driven tool. It is based on a very sound theoretical foundation. However its "intelligence" helps novice security officers in setting up the ISP quickly and efficiently. It also may be used as a support tool for experienced consultants.

Each of the above presented methods has advantages and drawbacks. The first method allows the development of a custom-tailored ISP, which is the best for the given conditions, but the cost would be substantial. On the other hand, the last approach allows the quick development of a basic (yet practical) ISP.

Many authors have presented examples of ISP, such as Janczewski & Colarik (2004) or comprehensive instruction how to setup an ISP (Kaon, 2006).

NEGLECTED ISP ISSUES

A well developed ISP contains sections addressing issues such as:

- Organization of Information Security
- Asset management
- Human Resources Security
- Physical and environmental security
- Communications and operations management
- Access control
- Information systems acquisition, development and maintenance
- Information security incident management
- Business continuity management
- Compliance

This list makes up the foundation of the ISO 17799 standard.

Regulations are required for the areas addressed in the list above. However, some of these issues are not receiving proper attention and may result in significant security breaches and considerable losses. The issue that will be addressed in this paper is the issue of the ownership of documents or files and authorised access to them.

Almost all security models define security levels and categories. The lattice theory is based on this (Amoroso, 1994). The introductory step in there is definition of possible security levels and categories. In a military institution such a listing may look as it is presented in the Table 1.

Table 1. Example of security levels and security categories

Security levels		Security category
Top secret		HQ
Secret		Navy
Confidential		Army
Limited circulation		Air forces
No restriction		

It is possible for the number of security levels to differ from the number of security categories. Also, it is not important (apart from the psychological point of view) what terms are used to name each of the security levels. The security categories are usually associated with different units of an organization.

Now, a number of interesting questions should be made:

- How many security levels are needed?
- How strictly should we determine the borders between these levels?
- Are the assigned levels and categories strict or can they change over time?

The number of security levels must have an optimum. One security level does not make any sense. This would imply that all the documents are available to anybody and few would follow this principle. Therefore two levels is an obvious minimum but may not provide proper protection of information. On the other extreme, many security levels, like, say 20 or 30 does not make sense as this would make it impossible to manage such a system.

All this implies is that any organization embarking on the introduction of a security classification system must decide how many levels should be generated. In saying that there are limitations:

- The initial most obvious choice is the introduction of 3 levels, which could be labelled as:
  - o No restriction (the document is accessible for anybody)
  - o Internal use (the document is accessible for employees only)
  - o Confidential (the document is accessible to a restricted number of employees)
- In military and governments usually there are at least 4 security levels: "general", "internal circulation only", "confidential", and "top secret". The "top secret" is for use by a limited number senior management.

Generally speaking the choice of the number of security levels is a function of two variables:

- The security needs of the organization (more security levels allow the better tailoring of security systems to the desired needs).
- The economy of the system (more security levels cost more to implement and maintain)

The next issue is the strictness of the division between security levels. Janczewski & Portougal (2000) studied this specific issue. They came to the conclusion that it is worth making the borders fuzzy. Sometimes shifting an item up or down the confidentiality scale could have noticeable economic effects.

Table 2. Standard security label

Security level	Security category
Secret	Human resources

Table 3. Improved format of a security label

Security level	Security category	Expire date	Owner
Secret	Human resources	12 March 2008	Smith

Starting from the Bell LaPadula security model (1973) through the Orange Book (1985) and culminating on the previously mentioned ISO standard 17799, all sources advocate the development of security labels attached to all subjects and objects. The security label is a record of the security level and security category of the object to which is attached. One should note that the security category is sometimes referred to as the "security compartment". A security label could look similar to this in the Table 2.

An obvious question must follow: is such a security label adequate for a typical business environment?

Imagine the following situation: A company is preparing a marketing plan and the plan is considered as a top secret and a *top secret* security level is attached to it. The CEO of the company then appears on national TV and announces the new marketing strategy. What would you think reading such a document later seeing the "Top security" label still attached to the document?

The other important aspect of the label is that what should be done if changes are made to the document?

The obvious solution to this problem is to nominate a person as an owner of the document and authorise only this person to introduce changes to it. These changes could relate not only to the content of the document itself but to the content of the label.

Hence, it seems sensible that a security label of any document or file should have a format presented in the Table 3.

This security label was extended to include fields describing the date of the document expiring and an indicator of who the owner is. Such a label has significant advantages especially in the case of electronics processing. A system validating all the classified documents would inform the owner of a document about it's expiry date and ask for a decision on what to do next with the content of the security labels and the document itself. As a result an appropriate change could be done such as like removing it from circulation or changing its security level.

CONCLUSION

All the above allows us to formulate the following conclusions related to the ISPs:

1. Each company should develop a set of documents relating to Information Security management that includes a brief guide, full policies and detailed procedures. Emphasis should be placed on the full policy (or the Practical ISP).
2. These documents should contain a set of major clauses regarding such issues as assets classification and control, personnel security, physical security, computer operations, network operations, system access control, and risk management.
3. The development of an ISP could be the result of a full risk analysis but without noticeable decrease of the quality of the final document other methods offer similar products with significant costs and time reduction.
4. A generic ISP documents forms the foundations stone of these methods.
5. Development of a good ISP should be preceded by establishing rules of handling sensitive information/documents, such as the establishment of the security levels and the handling limited circulation information. One can imagine the confusion resulting from the introduction of security labels within an organization which did not set before these rules before.

Hence future research should be aimed at developing a methodology of evaluation of company information systems from a security point of view. Such evaluations could include the analysis of:

- Procedures of handling company customers and suppliers,
- Structure of the telecommunication system
- Internal flow of information, etc.

Issues and Challenges Facing E-Entrepreneurship and E-Innovation

Fang Zhao, RMIT University, GPO Box 2476V, Melbourne, Victoria 3001, Australia; E-mail: fang.zhao@rmit.edu.au

ABSTRACT

This paper explores key issues and challenges facing e-entrepreneurship and e-innovation through case studies. The case studies draw mainly upon interviews with senior managers of the case companies and documentary research of the companies' publications. One of the key issues facing e-entrepreneurship and e-innovation today, as demonstrated by the case studies in this paper is that e-business needs to respond closely to market needs and gain market credibility. Another key issue is that there should be credibility built within the e-business marketplace before inception of the business. In addition, the intangibility of an online service needs to be addressed in order to build brand awareness. The discussion of the issues as such provides readers with both theoretical and practical guideline for a further study.

Keywords: E-business, entrepreneurship, innovation, case study

1. INTRODUCTION

The dotcom crash and the following three-year economic downturn saw hundreds of Internet entrepreneurial startups closed down or sold. However, many of the innovations and technologies created by them "live on and play important roles in the future either via acquisitions, in new startups, or through copycatting by the industry's giants" (Hamm, 2003, p.52). Blogger.com was a troubled startup that hosted 200,000 Weblogs, personal websites where people could share insights and web links with all comers. It was bought by Google in 2003 and has since become part of Google's information storehouse. Another example was Liquid Audio, a digital music pioneer subsequently acquired by Anderson Merchandisers, a major distributor of music CDs to help create profitable online music distribution.

Despite the many failures caused by the dotcom crash, it presented new challenges as well as new opportunities to entrepreneurs of e-business. This author argues that a combination of entrepreneurship and innovation will be a crucial factor to the long-term sustainability of e-commerce and e-businesses. For the purposes of this paper, the terms of e-entrepreneurship and e-innovation refer to broadly entrepreneurship and innovation in the context of e-business activities and operations.

This paper aims to explore key issues and challenges facing e-entrepreneurship and e-innovation through case studies. The case study draws mainly upon interviews with senior managers of the case companies and documentary research of the companies' publications. In the following sections, the paper starts with a review of the concepts of entrepreneurship and innovation in the e-business context and then moves on to discuss generally key issues and challenges facing entrepreneurial and innovative e-business companies. After that, two case studies of the business models of two dotcom companies engaged with entrepreneurship and innovation were presented to illustrate the specific issues and challenges facing them. This is followed by a discussion of future trends of e-businesses and their implications for e-entrepreneurship and e-innovation. The paper winds up with conclusions.

2. THE CONCEPTS OF E-ENTREPRENEURSHIP AND E-INNOVATION

2.1 E-Entrepreneurship

E-entrepreneurship describes entrepreneurship in e-business. The e-dimension of entrepreneurship incorporates all the key elements of entrepreneurship including risk-taking, proactivity, and innovation in building, running and managing e-business. The concept of e-entrepreneurship is not limited to small e-businesses but includes corporate e-intrapreneurship which is embedded in establishing e-infrastructure to do e-business in large organizations. E-business operates in a fast-moving, highly uncertain, unknowable and unpredictable context, and as such entrepreneurship in e-business by necessity exceeds the traditional concepts of entrepreneurship. For example, the traditional notion of entrepreneurship of being or becoming an expert or finding and protecting a unique knowledge in a niche market, clashes with the fact that e-business knowledge is often short-lived and available to everyone, anytime, and anywhere (Steinberg, 2003, 2004).

Empirical studies demonstrate that the concept of e-entrepreneurship has changed in the wake of the dotcom crash, presenting new challenges to e-entrepreneurs. In 2003, Steinberg (2003) conducted a multiple-case study on e-entrepreneurship in the Greater London business area, which provided intriguing findings about the changes in the social meaning of e-entrepreneurship since the dotcom crash. The study used a sample of 42 dotcom entrepreneurs who had started a small business in the wake of the dotcom crash in 1999/2000 or who had business which survived the crash. In the view of the entrepreneurs surveyed, entrepreneurship in e-business was different to classic entrepreneurship. In terms of skills and knowledge, e-entrepreneurship requires not only basic business skills and expert knowledge, but also the social skills necessary to be able to relate to other disciplines and sectors. In this regard, relationship and partnership with other sectors and businesses are crucial to e-entrepreneurship. The study also found that the dotcom crash had proven to be a positive turning point for a new generation of entrepreneurship which would open up e-businesses and endeavour to establish a new professional identity within e-business. E-business networks also played a central role within the new e-entrepreneurship. This e-entrepreneurship community was made up of business people who had previously been working in other sectors or in other firms and had moved into the e-business field to pursue a new personal and professional challenge. Traditionally, expertise in entrepreneurship was limited, by and large, to one specialist discipline, however, unlike the traditional entrepreneurship, the new sense of entrepreneurship in e-business was determined by the ability to creatively combine different sets of expertise to accommodate the wide range of needs of e-businesses powered by rapidly evolving and complex new digital technologies. The very character of e-business thus shaped the fundamental construct of e-entrepreneurship, that is, constantly engaging in, and developing innovative information and communication technologies in one way or another.

2.2 E-Innovation

E-innovation can be broadly defined as innovation that is related to e-business. Technological innovations in e-business have significantly changed inter-firm communications and have the great potential to revolutionize the efficiency and effectiveness of inter-firm relationships and their governance. Take Cybersettle.com for example. The company was founded in the mid-1990s by a pair of attorneys, and has not only survived the dotcom crash but attracted more customers and partners. The dotcom does what most do not and has created a thriving e-business model through e-innovation. Customers can use the website to settle a wide variety of commercial disputes online quickly and inexpensively. By August 2003, it had handled more than 75,000 transactions and over $US500 million in settlements (Winston, 2003).

The common and most important functionalities of the e-business technological innovations are standardization, centralization and formalization to facilitate inter-firm collaboration. However, technological e-innovation is only one aspect of e-innovation. It may include establishing and/or implementing innovative processes, operations, service, strategy, structure, technology, etc. in relation to e-

business. For example, e-innovation may represent an innovative strategy enabling customers to do what best serves their purpose via information communications technology (Martin, 2004). In order to implement an e-business innovation strategy and realize the commercial value of the innovation, companies often resort to partnerships which provide complementary resources and advantages in order to get things done.

3. ISSUES AND CHALLENGES FACING E-ENTREPRENEURSHIP AND E-INNOVATION

Today's e-business operates in a highly competitive marketplace where sustainable competitive advantage is almost impossible as there are minimal barriers to new entrants and competitors in the marketplace. Innovation faces constant challenges of imitation and erosion. There have been different views in the literature about the benefits of first movers in e-business marketplace. Mellahi and Johnson (2001) asked the question "does it pay to be first to market or should e-commerce firms wait for first movers to make an investment and then cannibalize the idea with lower entry cost?" The cause of the concerns are raised by a general belief that it is safer and less expensive to imitate the first mover in the e-business environment, where there is a higher level of technical uncertainties and rapid rate of technological innovation. For instance, many new dotcoms rushed to build an e-marketplace and chose imitation as a business strategy rather than innovation. This author argues that it is the lack of a combination of innovation and entrepreneurship capacity that has caused the demise of many imitators in the dotcom industry. The essence of innovation and entrepreneurship is taking a new idea to market, not imitating a new idea without taking into account the special needs of local markets, and being innovatively and proactively responsive to environmental changes by introducing a new product, process, service or implementing a distinctive business model as did the case companies studied in this paper.

In the early days of e-business, it was likely that most businesses could be applied differently online and offline. "Irrational exuberance" was prevalent within the market and venture capitalists were prepared to take on much more risk. However, since the dotcom crash, the market appears to have reverted to traditional models and methods. More attention has been given to the fundamental structural components of e-business, such as flow of revenue. E-business, to many companies, is now just seen as another channel to market (rather than signalling the demise of offline business as originally prophesized). Likewise, many senior managers interviewed for the present study indicated that there was no difference in the concepts of entrepreneurship online and offline. Traditional business models are here to stay. For new e-businesses to succeed, they need an innovative idea incorporated into a sound business model which is viable economically and which is facilitated by knowledgeable and experienced people.

As such, those entrepreneurial and innovative e-business activities which genuinely have utility for the customer (e.g. e-banking) are more likely to be successful. For example, the difference between retailing and banking is that while one is seen as an emotive and/or social activity, the other is perceived to be a chore. Therefore, offering an electronic channel to facilitate the latter is more likely to succeed than the former – people want convenience and speed when they bank but they are more likely to value other factors which an online channel may not necessarily be able to offer when they shop for goods and services. In this respect, dotcom companies should endeavour to enhance customer experience by offering tools on their Websites which enable customers to personalize the shopping process, and provide more personalized business services such as those offered by the bicycle company of the case study 2 of this paper.

3.1 Case Study 1: SpeakerDirect

SpeakerDirect (www.speakerdirect.com.au) is a young Melbourne (Australia) based dotcom, providing an online speaker portal. The online speaker portal business idea was developed in Dec 2003, and the portal was formally launched in March 2004, illustrating the fact that the founders believed that speed to market was one of the essential elements of their strategy, and a characteristic of the e-market. The Website system was developed from scratch with the premise that the company wanted a corporate friendly, and comprehensive tool for both speakers and speaker-seekers. SpeakerDirect is actually a business resource as well as a promotional platform. SpeakerDirect.com.au provides a free service for corporations to search and select corporate speakers. However, unlike their competitors, the company does not take engagement fees. The company has an ambitious goal of becoming the number one global speaker portal within five years and to connect up the entire business community. The company philosophy is one that aims to offer both speakers and seekers a personalized service alongside the electronic service, although the emphasis of their efforts is on the latter (e.g. they might meet with a major corporate and maintain communications by telephone on a frequent basis).

The founders and current directors of the company came from marketing and public relations background and also have experience in introducing an online tool in a market traditionally run by agencies. During their time within the corporate world, they identified a need and a business opportunity for a comprehensive search tool for corporate speakers. Under the traditional model, speaker-seekers were required to contact individual agencies who would provide a list of their registered speakers. The agency would then charge a fee on top of the speaker cost. However, this model is administration-heavy, for both the agency and the speaker-seeker, therefore the company's founders came up with the idea for an online speaker portal. This essentially is an online database of corporate speakers and entertainers which is free to search and provides a profile of each speaker, online show reels and indicative fees. Searchers can then contact speakers through the company's online system to arrange bookings etc. Speakers pay an annual fee to be listed on the Website, and in return, they are given their own personal Website (they can also link to their own Website), and an email inbox to receive and respond to inquiries. This is complemented by regular reporting functions (such as the number of searches the speaker has been displayed on, personal website hits received etc). The success of the model is evident, and only six months after the formal launch of the portal, SpeakerDirect.com.au has around 300 speakers, and 12,000 hits a day.

From the perspective of the Company's founders and directors interviewed for the present study, entrepreneurship and innovation mean risk (financial, emotional and personal):

"Entrepreneurship is taking control and action on a concept or a dream in the face of adversity. The tangible aspect of making that happen is where innovation comes in. For example, I want people to communicate with each other over long distances (the dream), therefore I am going to do something about it and invest time and dollars to do it even when everyone is saying it cannot be done/I am mad/it is too risky (entrepreneurship/the risk) and a phone is designed to achieve this (the innovation to achieve the dream). A combination of both is the 'big picture' that requires tenacious and passionate people to turn an idea into reality by being independent and in control" (Interview Data, 2004).

The business model that the company has developed is in itself an example of a combination of entrepreneurship and innovation – it is the first of its kind, replacing the idea of the client having to deal with many agencies separately, by creating a one-solution portal. Another example of entrepreneurship and innovation is the system behind the website. This was designed to be multi-functional (but streamlined) and very user-friendly for both speakers and seekers. One of the most innovative features is a bulletin board where companies can advertise an event for which speakers can express an interest in being engaged for – this would be a useful tool for anyone who is time-pressed or needs a speaker at short notice.

Another key e-dimension of entrepreneurship and innovation that the case company demonstrates is responsiveness to client and market needs. For example, SpeakerDirect.com.au is seeking to position itself as a media tool (e.g. by providing a service whereby speakers are available to journalists for "expert comment", gaining valuable and credible exposure, but without actually being engaged on a fee basis). In the directors' words, they have "flipped the agency concept on its head", and as a result, many seeker clients believe the free service is "too good to be true".

The company's initial success relies not only on its entrepreneurial and innovation capacities but also its active partnering program which includes developing existing relationships with corporations, and building strategic alliances with trade associations and other dotcoms. Evaluation of the partnerships is done upfront (e.g. with speakers, how to position themselves and with clients, what their needs are and how they can be met). For example, the company has developed a strategic alliance with an online talent agency located in the same premises, and has become part of the agency's network. The two directors of this agency also sit on the company's board, complementing the company's experience with their own eight years' experience in international Website development and with

actors and entertainers. The company has also engaged in developing working partnerships with corporate speakers.

According to the directors of the company, a plan has been made to develop a systematic procedure and structure for selection of speakers and monitoring of their performance. At this early stage of the process, all speakers are accepted. However, it is likely that after 12 months, those speakers who have not received engagements because, for instance, they are unsuitable, will not re-list themselves. Speakerdirect have however developed a reporting tool for speakers who want data in order to assess their relative successes, which details speakers' personal Website hits, enquiries, engagements etc.. Speakers are also encouraged to contribute to the marketing and public relations effort themselves by directing people to the Website and through self-promotion, because those who do not are likely to be less successful than those who do. Speakers do, however, have an initial consultation in which they can discuss their positioning. Subsequent evaluation by the company may include assessment of the speaker's fee, testimonials, their show reels and general credibility. On the client's side, key organizations and associations who may use the service are identified, and contacted in order to explore their needs and promote the online portal.

However, there are some issues relating to the company which may warrant attention. In terms of management of speakers, there needs to be people behind the system driving it and a commitment to the partnership between speakers and clients (seekers) on both sides. There is a corresponding need to be fluid, dynamic and responsive to needs, adapting to clients. Non-responsiveness or a slow turnaround and/or delivery of solutions are key problems which may damage the partnerships. In an online context, the intangibility of the service provided may also lead to customer dissatisfaction. The company has however tried to counter this with more tangible solutions, such as by producing company literature to give to speakers and seekers and through personal contact. The business model of SpeakerDirect is innovative in a sense that it is not an agency and takes no engagement fees, and it takes clients directly to speakers with the specific skills and areas of expertise they are looking for. However, the financial viability of the model remains a question, which inevitably reminds readers of the key lessons learned from the dotcom crash in 1999/2000.

There is also an issue of acceptance and credibility facing this young and innovative company. It has found that corporations have often been sceptical about the online speaker portal service, because they have been conditioned to think and work according to how the market worked previously: e.g. dealing with numerous agencies, or believe that they should be paying a fee for the service. In this respect, they think the online speaker portal concept may be *too* entrepreneurial. However, the company addresses these concerns with education, personalization of the service (e.g. telephone contact), and by evidencing its credibility within the corporate world. The founders also experienced difficulties in strategizing and implementing their idea, and believe that more education and funding for small businesses are required in order that e-commerce does not appear to be too elusive for startups.

3.2 Case Study 2: Bicycle Exotica

Bicycle Exotica was formed in 1999, after the owner-manager experienced frustrations while attempting to purchase a high-end bike for himself. Prior to this he had been employed by a bicycle wholesaler, and therefore had some expertise in the area. The case company imports a range of high-end ($AU5,000+) bicycles and components and sells them direct to the public in Australia, unlike the traditional supply model where wholesalers sell to bike shops. The company employs one other full-time staff member and gets part-time support from the owner-manager's partner. Specific activities such as book-keeping and web site development are outsourced. Turnover was around $AU750,000 in 2003.

The direct-selling business model is non-traditional and risky, as bikes (especially high-end models) are an emotive product and customers prefer to 'see before they buy'. However, the owner/manager's earlier experiences of trying to buy a high-end bike convinced him that not only could he improve access to the products for customers, but he could 'cut out the middle man' and so offer the bikes at a more competitive price than the traditional model of selling through shops. The Bicycle Exotica Website provides an online 'shop front', although the owner/manager encourages customers to contact him directly. He likes to offer a personalized service (he might speak to a customer five times before a sale), and in this way he overcomes the intangible element of his business. The Website specifically does not offer a 'shopping cart service', again because of the product characteristics.

The company's business model obviously has advantages and disadvantages compared to the traditional bricks-and-mortar model. Australians often buy high-end bikes from the United States, because it has a smaller number of supply steps than the Australian market and therefore bikes can be offered at a cheaper price. However, Bicycle Exotica's business model means they can compete with the global market.

Bicycle Exotica has consciously tried to maximize the advantages of their business model, and minimize its disadvantages by using innovative methods. For instance, rather than using a print catalogue, the company developed a CD which comprehensively showcases its products. In addition, the company's Website has a level of detail higher than the standard amongst bike sellers. Most important of all, the Website is a core part of the business rather than an 'add-on'. The company has also developed a 'bike fit' program whereby customers can send their body measurements to ensure they get the right size bike, which again, is a departure from the traditional method whereby it is done in person. The owner/manager frankly admitted that he had "stuck his head out" by selling direct to the public because the bike industry is traditionally quite protective. Furthermore, the owner/manager's offering of a personalized service to customers provides for the emotive element of the sale. The company can sell high-end bikes at a similar price to lower-end bikes sold through shops. However, this philosophy has not been embraced by everybody. For example, one competitor applied pressure to an Australian bike magazine in order to prevent the company advertising within the magazine. Nonetheless, the company tries to maintain good relationships in the industry by offering bike shops discounted bikes for them to resell to their customers.

It is likely that the business model would not succeed if the company did not maintain good partnerships with other bike sellers, suppliers, Website developers and other Web technology providers. To enhance customer services and minimize the disadvantage of online sale, the case company has developed a tentative 'clicks and mortar' partnership with a Sydney bike shop in relation to one of the bike brands it sells. Customers can view the range at the bike shop and purchase them through them. The company will sell the products to the bike shop at such a price that they can offer them at the company's prices (ordinarily, although shops would buy the company's products to resell to their customers at a favourable price, the resale price would still be higher than what the company would sell it for). Customers are hence getting the 'best of both worlds' whereby they can view the products they want to buy, at a favourable price, although the profit margins would be lower for both the company and the bike shop than if the bike was sold direct.

Although the e-business model is working well, there are serious challenges the company has to address. The bike industry is a typical cottage industry, where many businesses are owner/manager or run by bike riders, but not business people. To this extent, entrepreneurship and innovation are still relatively new concepts. According to the owner/manager interviewed for the present study, at present the Internet is hardly being utilized effectively by the industry in Australia and most Websites are superficial. B2B electronic supply chains hardly exist in the bike industry (although he claims, they would be welcomed!). The market is also fairly small, with many competing products, which means that no one business has a big enough share that they can invest in innovative ideas. Nevertheless, the case company has survived the worldwide dotcom crash and is profitable, thanks to its innovative and entrepreneurial business model and good working relationship with its brick-and-mortar partners.

4. FUTURE TRENDS OF E-BUSINESS AND THEIR IMPLICATIONS

As the key premise of e-entrepreneurship and e-innovation lies in a thriving e-business environment, their future development is tightly bound with, and determined by, the future of e-business. The author speculates possible development trends in e-commerce and e-business in the near future on the basis of current development patterns and discusses the implications of the trends for e-entrepreneurship and e-innovation.

E-commerce and e-business practices will continue to grow. Industry analysts and renowned research groups such as Gartner Group projected a strong growth in e-commerce and e-business, estimating that the market would be worth $US7.3

trillion worldwide in 2004, and will continue to grow in the next few years. But, unlike some of the present examples, e-business will be more mature (rather than experimental) in nature, in terms of the scope, quality and credibility of online customer services and products. Participating in e-business will be part of every executive's job in the near future. Despite its success, the recent initial public offering (IPO) of Google's shares saw them fall below the price range set by its executives, suggesting that many investors were still very cautious about e-business in the wake of the disastrous dotcom crash in which millions of shareholders around the world were badly burned. The response to Google's IPO indicated that the public expectation for high-tech e-business ROI tends to be normal now, and views e-business and e-commerce as the same as other businesses. The implication of this trend is an opportunity for growth as well as challenges of succeeding in a relatively mature market where quality and credibility of products and service count.

The collaboration of e-businesses is, and will continue to be, the key to sustained business success. An e-business strategy will be ineffective without an integrated e-partnership strategy, because the ability to leverage collaborative relationships becomes essential in today's competitive e-business world. Consumer/purchaser power will dominate the e-business world and propel smaller e-entrepreneurs to bind together to provide customers with an ever-widening array of products and services, real-time and rich information, and speedy and quality transactions. Moreover, collaborative e-partnerships help to streamline the product-to-market process through collaborative planning and design, improve efficiency from the channel network by reducing inventories, and ultimately generate profitability. However, alarmingly, many e-business alliances failed, or did not achieve their goals. How to make e-partnership work requires more than the navigation of technological hurdles and complexity. Human, organizational and cultural factors become more crucial as e-business moves towards maturity. The biggest challenges to managers include conflict in different organizational and country cultures, taxation, financial and commercial risks, and legal risks concerning on-line intellectual property, national and international on-line trade and law (Zhao, 2006).

Lee and Whang (2002) maintain that the future of e-business lies in intelligence. They believe that the next trend of e-business is intelligence at the supply chain level. Intelligence refers to the capacity for processing, accessing, controlling and managing information and knowledge. If this view holds true, the implications for future entrepreneurship and innovation are profound. To enhance the intelligence will be the main business line and the focus of e-entrepreneurial and e-innovation businesses.

In terms of e-marketplaces, it would appear that a trend has developed whereby the current highly successful mega e-marketplaces such as Amazon.com, eBay and the like increasingly drive smaller players out of markets and limit competition, thus turning e-marketplaces into oligopolies (Murtaza, et al., 2004). However, the ubiquity of the Internet is and will continue to be a strong counter force to the formation of oligopolies as there are actually no barriers to market entry in the cyber world, and the Internet provides constant opportunities to engineer new types of entrepreneurial business and innovation. Future e-marketplaces will require a whole range of quality services and innovative products, and alliances to deliver supreme value to customers. Thus, deals based only on price will be obsolete in future e-marketplaces.

Although the concept is as old as the manufacturing process, quality management will gain momentum in e-business management. The failure of many e-businesses and the dotcom crash have on the whole been caused by poor quality customer services and support, problems with Website security and technologies, and weaker change management (Janenko, 2003). The key principles of quality management will be the fundamental cornerstone to e-business success, which include:

- Customer focus;
- Continuous improvement and measurement to achieve customer satisfaction;
- Acquiring customer and market knowledge;
- Mutual respect, mutual trust and mutual benefit of all stakeholders;
- Consistent and precise performance to high standards in all areas of the organization;
- Striving for excellence through benchmarking, etc;
- Measurement of quality using data and tools;
- Improving quality and efficiency of decision-making;
- Better use of resources to achieve effectiveness and efficiency;
- Results focus;
- Management by facts and processes;
- Effective leadership and team commitment;
- Teambuilding and collaboration;
- Valuing employees & human and intellectual capital;
- Employee training/education/development;
- Empowerment and involvement; and
- Opening channels of communication.

These familiar components of quality management undoubtedly offer an essential guide for the quality operations of e-entrepreneurial and innovation businesses. It is a wide-spread fallacy that a good quality Web site design and a high volume of hits or traffic are good indicators of quality and will lead automatically to e-business success (Janenko, 2003, Ross, 2003). Indeed, it is this misconception that turned the "dotcom boom" into "dotcom doom". The primary fundamental quality management constructs therefore still have appeal in current and future e-business management.

5. CONCLUSIONS

In this frenetically changing competitive landscape, entrepreneurship and innovation enable organizations to gain competitive advantage and hold the key to their e-business success. The fast growth and business success of companies such as eBay, Amazon.com, travel.com and priceline.com, along with the bankruptcy of numerous dotcom firms worldwide in 2000 hold potent management implications for IT innovation and entrepreneurial organizations worldwide. As such, e-entrepreneurship and e-innovation have become emerging disciplines for proactively responding to changes in the e-business world.

This paper identifies and studies issues and challenges facing e-entrepreneurship and e-innovation. One of the key issues facing e-entrepreneurship and e-innovation today, as demonstrated by the case studies in this paper is that e-business needs to respond closely to market needs and gain market credibility. Another key issue is that there should be credibility built within the e-business marketplace before inception of the business. In addition, the intangibility of an online service needs to be addressed in order to build brand awareness. The discussion of the issues as such provides readers with both theoretical and practical guideline for a further study.

Dimensions of Autotelic Personality in the Context of Mobile Information and Entertainment Services

Jacky P. C. Chou, Centre for Research on Information Systems Management, AUT University, Private Bag 92006, Auckland, New Zealand; E-mail: ggyy@xtra.co.nz

ABSTRACT

Autotelic Personality represents an important individual construct in flow theory yet little is known about its underlying dimensions. Csikszentmihalyi (1988) suggested that the higher the autotelic nature of an individual, the more likely for him/her to experience flow. This study explores autotelic personality, its underlying dimensions and its relationship with perceived playfulness in the context of Mobile Information and Entertainment Services (MIES). This study found Autotelic Personality to be an important quality in order for users to experience perceived playfulness in the MIES context. Several underlying dimensions of Autotelic Personality were identified, including personal innovativeness, self efficacy and control.

INTRODUCTION

Autotelic Personality characterizes a person "who is able to enjoy what he is doing regardless of whether he will get external rewards from it and who thus is more likely to experience flow for a given activity" (Hoffman & Novak, 1996). Csikszentmihalyi (1988) in his study of happiness identified what an 'autotelic' personality is – a person who sets their own goals, whether short-term or long-term, and then has great fun in achieving them. As Csikszentmihalyi stated:

"...the complexity of a flow activity is limited by the degree of challenge it can provide, and by the willingness and "creativity" of the person to create challenges in an activity. A person who can do this well, or who has the ability to enter a flow state relatively easy, is said to have an "autotelic personality"

Although Autotelic Personality is identified as an essential part of the Flow model by Csikszentmihalyi, very little research explored the underlying dimensions of Autotelic Personality (Finneran and Zhang, 2005; Nakamura and Csikszentmihalyi, 2002).

The convergence of mobile commerce and internet technologies has promised users unprecedented convenience and greater enjoyment. In recent years, mobile information and entertainment services (MIES) has been gradually gaining popularity among mobile phone users (Garcia-Macias, 2003; Baldi and Thaung, 2002; Van de Kar et al. 2003). Research into mobile internet to date has by and large focused on extrinsic use of these services, for example, productivity and usefulness and has largely ignored important end-user characteristics. To better understand users' acceptance of MIES, we argue that it is equally important to examine an intrinsic motivator "Perceived Playfulness", defined as:

"The extent to which the individual perceives that his or her attention is focused on the interaction with the World-Wide-Web; is curious during the interaction; and finds the interaction intrinsically enjoyable or interesting" (Moon and Kim, 2001)

This construct was proposed by Moon and Kim (2001) based on the theory of flow and its importance verified by Chung and Tan (2004). However, some researchers have recently pointed out that individual differences have been ignored in many flow related studies (Finneran and Zhang, 2005; Nakamura and Csikszentmihalyi, 2002).

Therefore to gain a better understanding of the role of Autotelic Personality in MIES, it is important to identify those individual differences likely to make up Autotelic Personality and which contribute to the emergence of Perceived Playfulness.

INDIVIDUAL DIFFERENCES AND PERCEIVED PLAYFULNESS

Individual differences refer to factors such as personality, situational, and demographic variables that influence user's beliefs about and use of information technology. In the context of Flow, Webster and Martocchio (1992) studied microcomputer playfulness and suggest microcomputer playfulness act as an individual' tendency to interact spontaneously, inventively and imaginatively with microcomputers. It is a situation specific individual characteristics represents a type of cognitive playfulness. Moon and Kim (2001) considered Perceived Playfulness as an intrinsic belief or motive, which is formed by an individual's subjective experience with IS/IT. Hence, identifying those individual characteristics that lead to Perceived Playfulness may provide insight into this (stable) individual belief construct.

This study examines the pattern of relationships between Perceived Playfulness and those individual differences that lead to its occurrence. We are also keen to know whether these individual differences are likely to be the dimensions of Autotelic Personality. This study draws upon previous research on Flow as Perceived Playfulness is fundamentally based on Flow. Prior work related to the state of flow with information technologies has adopted alternative conceptualizations, often with different terminology of the major dimensions related to Flow construct (Siekpe, 2005; Finneran and Zhang, 2005). Most research tends to use these individual differences (except Focused Attention) as antecedents of flow instead of underlying dimensions as shown in Table 1.

Personal Innovativeness and Flow

The flow experience usually occurs in structured activities such as games, ritual events, sports, artistic performances, etc. (Csikszentmihalyi 1988). It does not normally occur in everyday life because challenges and skills are rarely balanced. However, even if skills and challenges are balanced, it does not guarantee a flow experience occurring. This is due to the fact that activities only provide the challenges; it is still up to the individual to recognize the challenge, provide the skills, and extract enjoyment from the activity. Therefore, challenge is more related to the perceived complexities *provoked by* the activity rather than the individual per se. As Csikszentmihalyi (1988) stated; the complexity of a flow activity is limited by the degree of challenge it can provide, and by the willingness and "creativity" of the person to create challenges in an activity. Because of this reason, Personal Innovativeness introduced by Agarwal and Prasad (1998) was deemed important in the context of our study. Personal Innovativeness in the domain of information technology is conceptualized as an individual trait reflecting a willingness to try out any new technology. Furthermore, Agarwal and Karahanna (2000) provide

Table 1. Different conceptualizations of personal innovativeness, self efficacy, control and focused attention

Individual Difference	Construct	Dimensions	Antecedents
Personal Innovativeness	Cognitive absorption; Flow	Flow-Finneran and Zhang (2003)	Cognitive absorption-Agarwal and Karahanna (2000)
Self Efficacy/Skills	Flow		Koufaris (2002); Ghani et al. (1991); Hoffman and Novak (1996); Novak et al. (2000)
Control	Flow; Perceived Playfulness	Trevino and Webster (1992); Webster et al. (1993); Koufaris (2002)	Chung and Tan (2004); Ghani and Despande (1994); Ghani et al. (1991); Webster and Ho (1997); Chen (2000);
Focused Attention	Flow; Perceived Playfulness	Trevino and Webster (1992); Webster et al. (1993); Koufaris (2002)	Hoffman and Novak (1996); Novak et al. (2000); Chung and Tan (2004);

empirical support of its influence on cognitive absorption, which is a construct similar to flow. In this regard, Pagani (2004) suggests individual innovativeness can be seen as willingness to adopt 3G multi-media services.

Self Efficacy and Flow

Self Efficacy is similar to Skill which has been well studied in research on Flow (Koufaris, 2002; Ghani et al. 1991; Hoffman and Novak, 1996; Novak et al. 2000). Recall that the most important condition for a Flow state to occur is when the challenges of a situation match the skills of the participant. Past researches have drawn distinction between general self-efficacy and computer self-efficacy (CSE). While the former being an overall judgement of an individual on efficacy across multiple computer application domains, the later represents the judgement on specific task in the domain of general computing. Agarwal et al. (2000) pointed out that there is a significant support for a relationship between self efficacy and individual beliefs about IT. Their result suggests software specific self-efficacy will have a stronger effect than the initial general self-efficacy due to the "carryover" effect, i.e. the accumulated application specific self-efficacy will eventually displace the effects of initial belief with the passage of time. Because of this reason, Computer Self Efficacy (CSE) is preferred over Skill as the latter may convey the meaning of general competency on everyday tasks.

Control, Focused Attention and Flow

Hoffman and Novak (1996) developed a theoretical mode of Flow within the hypermedia context. In this model, Challenges, Skills and Focused Attention have been modeled as the primary antecedents of flow. Other secondary antecedents (Interactivity and Telepresence) were also added in accordance to the literature of hypermedia. The consequence of flow leads to increased learning, perceived control, exploratory behavior and positive experience. However, their earlier work is exploratory in nature therefore all the hypothesized relationships were not empirically tested. Novak et al. (2000) later revised the original model and changed Control as a primary antecedent of flow. The revised model was then tested and results showing all these four antecedents exert positive and significant on flow. A somewhat interesting finding is that they model Control and Skill together as a higher order construct (i.e. Skill/Control) However, a distinction should be made between these two, control capturing an individual's perception that he/she exercises control over the interaction with environment (Webster et al.. 1993) whereas Self Efficacy (Skill) is the judgement on specific task in a specific domain prior to that interaction. Chung and Tan (2004) in their study also proposed Focused Attention and Control as two individual cognitive aspects that lead to Perceived Playfulness.

DEVELOPMENT OF THE RESEARCH HYPOTHESES

From the literature review, several limitations were identified. It was noted that there was a lack of focus on the individual side in the literature on intrinsic motivation. It has also been found autotelic personality as an important personality construct has not been well examined in previous studies. The hypotheses to be explored in this paper therefore are:

H1: Personal Innovativeness, Focused Attention, Self Efficacy and Control are positively related to Perceived Playfulness
H2: Autotelic Personality is a second order reflective structure formed by Personal Innovativeness, Self efficacy, Control and Focused attention
H3: Autotelic Personality is positively related to Perceived Playfulness

RESEARCH METHODOLOGY

Sampling

The sample consisted of university students who attend information system and business lectures at Auckland University of Technology. Participants were a total of 149, who volunteered to participate in the study. The participants were 99 males and 55 females. In terms of phone categories, about 60% of all the respondents specified they have WAP-enabled mobile phone or GPRS phone. Respondents holding a 3G mobile phone came second in the list, with a significant proportion of 12% among the respondents. Users of the CDMA mobile phone are relatively few, only 7% compared to other phone categories. At the same time, 21% of all the respondents are not sure about the phones they are using. When asked whether their phone provides a feature with which to access MIES services, 83% of the respondents answered "Yes" to this question. This indicates the wide availability of mobile internet capable phones in the New Zealand market.

Research Design

Data was collected via personally-administered questionnaires in class. This study aims to explore the antecedents of Perceived Playfulness in the context of mobile information and entertainment services (MIES). It explains the relationships among variables and constructs in a theoretical model and examines the differences between two groups. Therefore, the purpose of this research is hypothesis testing, based on our extensive knowledge of the variables and their relationships in the theoretical framework. A questionnaire was used to collect the data. A participant information sheet was also given to each respondent. The data collection was conducted in November 2005 at Auckland University of Technology. Students from six classes were invited to do the questionnaires. A total of

Table 2. Measurements items

Variable	Source
Personal Innovativeness	*Agarwal and Prasad (1998)*
Self Efficacy	*Hung et al. (2003)*
Control	*Agarwal and Karahanna (2000)*
Focused Attention	*Webster et al. (1993)*
Perceived Playfulness	*Moon and Kim (2001)*

186 questionnaires were returned. Incomplete questionnaires were discarded, leaving 149 usable samples.

In terms of measurement, all items were constructed as agree-disagree statements on a seven-point Likert scale. Since the variables in interest have been previously validated under different contexts, mirroring the same items in a new context is straightforward. To ensure measurement reliability, items validated in previous research have been used (see Table 2). The measures for Personal Innovativeness, Self Efficacy, Control, Focused Attention and Perceived Playfulness were taken from or based on previous IS research and were modified to suit the MIES context. Adopting the same measures as others instead of creating new measures may enhance the comparability of the paper with others, specifically when existing measures already become a field standard (Churchill et al. 1999).

DATA ANALYSIS AND RESULTS

The data analysis technique employed in this study is Partial Least Squares (PLS). PLS is a recent technique that generalizes and combines features from principal component analysis and multiple regressions (Thompson et al. 1995). The PLS approach provides a means for directly estimating latent variable component scores. It is a technique comprised of measurement and structural models (Gefen et al. 2000). The aim of testing the measurement model is to specify how the latent variables are measured in terms of the observed variables, and how these are used to describe the measurement properties (validity and reliability) of the observed variables. The structural model investigates the strength and direction of the relationships among theoretical latent variables. Autotelic Personality as a second order factor can be approximated using various procedures. One of the easiest to implement is the approach of repeated indicators known as the hierarchical component model suggested by Lohmöller (1989, pp. 130-133). In essence, a second order factor is directly measured by observed variables for all the first order factors. This procedure works best with equal numbers of indicators for each construct.

Measurement Validation

To measure internal consistency of a given block of indicators, internal composite reliability (ICR) scores were obtained through PLS-GRAPH to assess the reliabilities of each latent variable. Where the internal consistency of any latent variable exceeds 0.70, this indicates tolerable reliability (Fornell and Larcker, 1981). All latent variables in our model have internal consistencies greater than 0.7, this indicates all constructs have high reliabilities. Two validities need to be captured in the measurement model: convergent validity and discriminant validity. Essentially, they estimate how well the measurement items relate to the constructs. PLS performs confirmatory factor analysis to establish factorial validity regarding these two validities (Gefen and Straub, 2005). To test convergent validity of the measures associated with each construct, the loadings and cross loadings of each indicator on the latent variables must also be examined. Convergent validity is shown when the *t-values* of these loadings are above 1.96 (Gefen and Straub, 2005). The results (Table 3) indicate almost all measurement items exhibit very high convergent validity on their measured latent variables.

However, it has been noticed that the first measure of Focused Attention (FoA1) and the second measure of Perceived Playfulness (PP2) exhibit very low loadings. The way to establish discriminant validity is to examine the square root of the AVE of each construct to the correlations of this construct to all other constructs.

Table 3. Convergent validities

	PI	SE	FoA	Ctrl	*PP*
PI1	**0.774**	0.257	0.190	0.331	*0.177*
PI2	**0.869**	0.410	0.261	0.417	*0.438*
PI3	**0.816**	0.492	0.104	0.412	*0.443*
PI4	**0.826**	0.372	0.213	0.357	*0.364*
SE1	0.410	**0.880**	0.041	0.443	*0.468*
SE2	0.408	**0.877**	0.012	0.443	*0.477*
SE3	0.475	**0.959**	0.045	0.470	*0.488*
FoA1	-0.021	0.017	**0.456**	0.123	*0.025*
FoA2	0.067	-0.058	**0.698**	0.168	*0.088*
FoA3	0.225	0.052	**0.866**	0.379	*0.281*
Ctrl1	0.401	0.430	0.304	**0.846**	*0.459*
Ctrl2	0.281	0.344	0.256	**0.769**	*0.329*
Ctrl3	0.442	0.415	0.369	**0.818**	*0.532*
PP1	0.152	0.076	0.300	0.226	***0.434***
PP2	0.107	-0.063	0.218	0.093	***0.105***
PP3	0.432	0.357	0.290	0.453	***0.779***
PP4	0.316	0.418	0.278	0.404	***0.775***
PP5	0.291	0.483	0.208	0.404	***0.768***
PP6	*0.379*	*0.488*	*0.230*	*0.498*	***0.846***

Table 4. Discriminant validities

	PI	SE	Ctrl	FoA	*PP*
PI	**0.824**				
SE	0.496	**0.934**			
Ctrl	0.468	0.498	**0.822**		
FoA	0.267	0.074	0.412	**0.808**	
PP	*0.486*	*0.534*	*0.557*	*0.316*	**0.739**

In the PLS-GRAPH, the AVEs can be easily obtained by performing a bootstrap re-sampling. Fornell and Larcker (1981) suggest that the square root of AVE should be greater than the corresponding correlations among the latent variables. The results shown in Table 4 demonstrate all latent variables exhibit high discriminant validities. The diagonal cells in the correlation matrix shown in Table 3 are the square root value of AVE for each latent variable.

The initial test of the measurement model using confirmatory factor analysis indicated that some construct revisions were needed. The loadings and cross-loadings of indicator FoA1 and PP2 in Table 3 showed relatively low correlations on the latent constructs they were meant to describe. Essentially this result presents a need to re-specify the instruments. The approach described in Churchill (1979) is to purify the measures. Items that do not share equally in the common core should be eliminated. As suggested by Straub et al. (2004), this approach can be applied to PCA, PLS and covariance-based SEM. As a result, FoA1 and PP2 were eliminated in the revised model.

The Structural Model

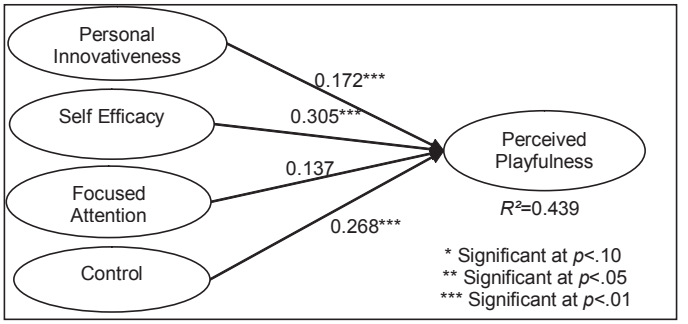
Testing Individual Differences on Perceived Playfulness

We first test the proposed four individual differences and their influences on Perceived Playfulness in the context of MIES. The results indicate all factors except Focused Attention exert significant influence on Perceived Playfulness as shown in Fig 1.

Testing Second Order Factor

When testing second order constructs, the percentage of the paths should be at 0.70 or above to establish the convergent validities of the first order factors (Chin, 1998). As shown in Fig 2, the correlations between Personal Innovativeness, Self Efficacy, Control and Autotelic Personality are highly correlated because the 0.70 threshold has been met. Since a reflective model would assume the first and

Figure 1. Individual differences as antecedents of perceived playfulness



second constructs are extremely highly correlated, a formative model seems less likely for Autotelic Personality. The low loading from Autotelic Personality on Focused Attention (after measurement revision) casts further doubt on its role in reflecting Autotelic Personality. Next, a mediation test was performed to see if the second order construct fully mediates the relationship between the first order factors and the theorized dependent variable (Chin, 1998). Autotelic Personality is used as a more parsimonious second order factor and it shows significant correlation its first order factors. As a surrogate of its first order factors, Autotelic Personality strongly influences Perceived Playfulness and is highly significant (β=0.647, t=11.2900). This aggregate measure is the only significant predictor of Perceived Playfulness when all first order factors are controlled for.

All items have large and significant loadings on their corresponding factors indicating evidence of good construct validities (Doll et al. 1994). For the latent variables, with *t-values* above 2.0 being considered significant, all factors except Focused Attention have large and significant structural coefficients, indicating good construct validity. The *R-square* values (0.627~0.672) showing three of the four first order factors (Personal Innovativeness, Self Efficacy and Control) can be reliably explained by Autotelic Personality. Based on these results, Hypotheses 1, 2 and 3 were supported.

DISCUSSION AND CONCLUSION

Chin and Gopal (1995) suggest the relative importance of the reflective model is established by contrasting the loadings from the overall latent belief with each of the individual beliefs. Each belief represents a separate attitudinal dimension which reflects an existing overall attitude. Our findings suggest all underlying factors (Personal Innovativeness, Self- Efficacy, Control and Focused Attention) significantly correlated with Autotelic Personality. The loading of Focused Attention indicate it is not an important underlying belief in reflecting Autotelic Personality compared to other factors. According to Buchanan et al. (2001), navigate the mobile internet via mobile phones can be a daunting experience given the constraints of small screen display and cumbersome input mechanisms. A common criticism of early WAP sites was that they involved too many selections and moves between menus and submenus, for the user to achieve their desired contents. Therefore, user's Focused Attention is likely to be affected by the screen size of mobile phones (Buchanan et al. 2001; Sweeney and Crestani, 2006).

Our findings suggest all underlying factors (Personal Innovativeness, Self- Efficacy, Control and Focused Attention) significantly correlated with Autotelic Personality. On the other hand, only Personal Innovativeness, Self Efficacy and Control significantly determine Perceived Playfulness. High correlations were also identified between these three factors and Autotelic Personality. This is consistent with Asakawa (2004) that autotelic students are those felt more in control of the situation and positive about challenges as compared to their non-autotelic counterparts. Acknowledging that an autotelic person perceived challenge situation differently from non-autotelic person, this study integrated Personal Innovativeness as one of the underlying dimension of Autotelic Personality (Agarwal and Karahanna, 2000). The higher loading of Autotelic Personality on Personal Innovativeness and Control indicates both constructs are important dimensions of Autotelic Personality. This study also provides empirical evidence that Self Efficacy is a significant dimension of Autotelic Personality in the context of MIES.

In summary, the important dimensions of Autotelic Personality are: Personal Innovativeness, Self-Efficay and Control. These dimensions are positively related to Perceived Playfulness. This study thus empirically proves the existence of this important construct and the predisposition of its core dimensions to lead to the occurrence of Perceived Playfulness in the context of MIES. Our findings suggest individuals with Autotelic Personality are more likely to experience Perceived Playfulness in relation to these services. In terms of practice, it is possible to use these dimensions to address the unique needs of different user groups. For example, it might be a possibility to categorize MIES users according to the importance of Personal Innovativeness, Self Efficacy and Control when designing marketing strategies for service offerings. As Hoffman and Novak (1996) suggest, this has crucial implications for market segmentation of the mobile marketplace.

ABSTRACT

Business process management is established for improving business processes within an enterprise. However, the concept could also be applied to enhance collaborative business processes spanning over multiple enterprises. In contrast to the intra-organizational case, management of cross-organizational collaborative processes imposes several organizational and technological challenges that result from the variety of independent actors in the environment of collaborations. This paper focuses on these challenges, presents a conceptual solution for the different management tasks, and demonstrates how a realized concept which supports networked enterprises in the management of collaborative business processes could look like.

1. INTRODUCTION

Nowadays, economic organizations are dramatically changing towards networked structures [ÖsFl00]. These are characterized by core competence specialized value units [PrHa90] that intensively interact along the added value in order to together generate the intended product. This intensification of exchanges leads to strong collaborative relationships (also called collaborative business, cf. [RöSc01], [Cama02]). So the ground is prepared for enterprise networks and virtual organizations [DaMa92]. Such collaborations are mainly driven by the intention to generate added value, which is achieved through synchronized execution of associated business tasks. This sequencing of activities constitutes a collaborative business process and implies special properties that strongly differ from the regular case [Wert06]. First, the activities are spanning over multiple organizations, because the generation of added value is performed through cross-organizational division of labour. Second, each of the individual business activities that compose the process clearly belongs to a unique organization. The collaborative business process can be partitioned in several parts, each of which contains one or more activities, distinctly associated with an organization and fully controlled by her. Therefore those parts of cross-organizational business processes, which strongly differ from intra-organizational ones, can be characterized as autonomous fragments. Consequently concepts and solutions developed for the intra-organizational case are mostly not suitable for cross-organizational purposes. This article investigates the Business Process Management concept in such collaborative environments. After explaining the intention of the concept, we propose a platform which is apt to support the idea for cross-organizational business processes. In the following sections the conceptual and technical basics of this platform are presented. In contrast to other approaches, e.g. [GrAb01], not only bilateral processing of business processes is focused, but end-to-end processes. Therefore, we will step through the three phases of the cross-organizational Business Process Management and show the concepts we developed for every phase. Afterwards we will show how the concept is realized so far and finish with a short outlook.

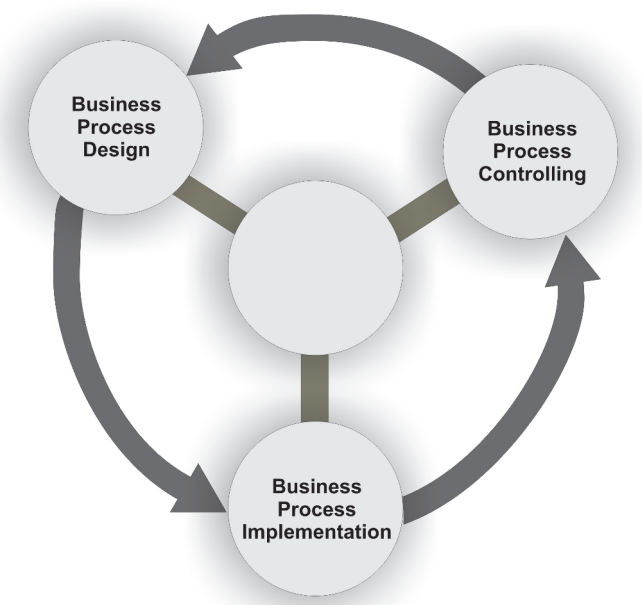
2. BUSINESS PROCESS MANAGEMENT IN COLLABORATIONS

A continuous and successful business strategy must not simply cover the design of business processes, since the design solely results in static models of the considered processes which do not allow for process changes. However, execution of these static models usually yields improvement potential over time, e.g., because the execution context changed or certain execution aspects were not reflected in the model. To realize and quantify these improvement potentials, it is necessary to measure execution of the models, i.e., perform controlling of them, which allows for identifying weaknesses and changing the models accordingly.

These three steps are integrated in the Business Process Management concept: business process design, business process implementation and business process controlling [ScJos02]. The basic lifecycle concept can be found in the House of Business Engineering [ScNü95; Sche96]. Business process design refers to modelling of existing as-is or intended to-be processes. This can be accomplished using modelling languages (e.g., EPC [KeNü92], BPML [Arki02]) and the respective modelling tools. Business process implementation summarizes all operative steps that are necessary to execute a process which was modelled before, including IT systems for execution as well as human interaction. Research effort is currently put into the exploration of mechanisms to minimize the need for human interaction in business process implementation. Business process controlling denotes all actions that aim towards measurement and examination of running and finished processes with the goal of discovering optimization potentials. Once found, such a potential can be realized by changing the process model in the next modelling phase.

This lifecycle is conceived for a single organization. In the design phase, each process model is changed by a single modeller at a time. During the execution phase, the process is handled by a single execution system within a single organi-

Figure 1. Business process lifecycle



zation. Consequentially all controlling information can be gathered "indoor", i.e., within the organization. However, in environments with multiple organizations acting cooperatively, collaborative processes cannot be regarded as monolithic anymore, since different parts of them are designed, executed and controlled by multiple different organizations [LuBu99]. Consequently the lifecycle abruptly gets very complex and difficult to handle:

The *design (respectively modelling)* task comprises multiple autonomous modellers that act independently and follow different goals. This results in self-contained parts of the collaborative business process. Therefore the process design can rather be characterized as an assembly task of autonomous process parts.

The *execution* is distributed over different enterprises. Consequently there is no central processing engine. Instead each autonomous process part has its own independent processing engine, so classic workflow concepts and technologies have to be extended to match the new cross-organizational requirements [Schu02].

Controlling means monitoring of running and finished processes and comparing them with set values. However, monitoring in the sense of determining unique process states is impossible for collaborative workflows, because their state is hidden in the autonomous workflow engines. They only disclose virtual state information that clouds the real procedures. Moreover, the controlling comprises the aggregation and calculation of valuation functions. However, these functions contain information on business structures (esp. cost factors). Such information is considered business-critical and inaccessible to third parties, even if they are partners.

Having revealed these gaps, we will step through these three phases and show the concepts for collaborative business processes in the next section.

3. CONCEIVING A CROSS-ORGANIZATIONAL BUSINESS PROCESS MANAGEMENT

Transferring the concept of business process management for single organizations to cross-organizational environments characterized by the involvement of multiple actors in the different phases requires the shift from a centralized paradigm to a support for distributed environments. For these actors a collective behaviour cannot be supposed. Thus each phase requires new techniques that are different to those of the classical business process management and that incorporate the split activities. Therefore we do not focus on bilateral processing of business processes, but on end-to-end processes with potentially a huge number of contributors.

Distributed Business Process Modelling

The design of business processes is considered one of the fundamental management tasks. In order to document the design, a specification medium is needed. On the conceptual level models have raised as the primary medium for business process specifications (e.g. EPC, BPML, BPEL, etc.). Thus the design task can be summarized as the creation of business process models. With regard to cross-organizational business processes, this actually comprises the model generation for an original that spans over multiple organizations. In principle this can be performed in a centralized and a decentralized way:

Supposing a centralized model creation, a single actor (that may also be incorporated by a group of collectively acting individuals) is in charge of the whole process model. This implies detailed knowledge and unrestricted access to all aspects of the process through all organizations. Due to the individual demand of protection, real-world organizations usually do not agree to fully expose their knowledge and their processes to a third party. So this case can be considered implausible.

Assuming a decentralized model creation, this implies the existence of different modelling individuals, each of which generates only parts of the process. Within this procedure they may follow different modelling paradigms, methods and languages. Therefore this approach requires both a technique for assuring the consistent individual model creation and a technique for the integration of the partial models.

Another dimension to cope with is the direction of the model creation procedure. In this sense, the differentiations are if a model is created in more and more detailing an abstract description of the model object or if the model builds up by adding more and more aspects to it and aggregate it afterwards.

Although from a theoretical perspective, such an approach has to cope with all potential permutations of modelling techniques, our approach is limited to a homogeneous approach, i.e., we presume the use of a single modelling language. Even in this scenario there are sufficient degrees of freedom for the modelling subject. In our implementation we use the event-driven process chain (EPC) language, which is one of the most common process model languages in Europe.

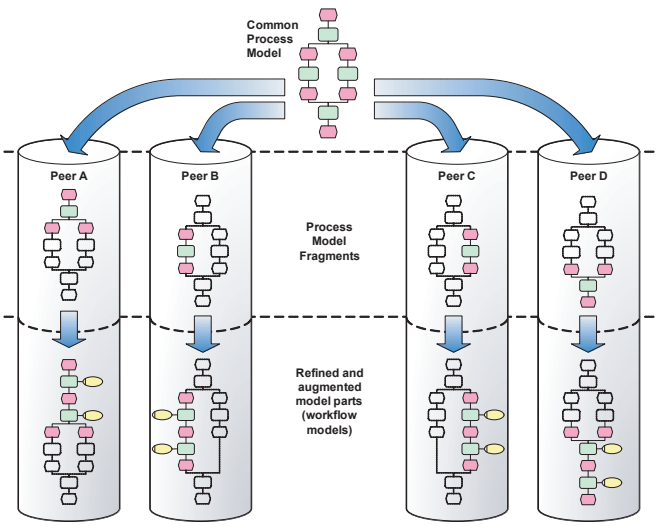
More precisely, our design procedure comprises four steps:

1. *Definition of process modules:* We start with the assessment of the status quo of the different organizations involved by specifying their capabilities. In our case they have to express their ability to produce output using process models that describe their possible processing sequences. The results are component-like models that can be assembled together and that incorporate process interface descriptions specifying interaction points.
2. *Definition of process intentions:* The composition of the process modules has to follow certain business objectives. In order to construct an objective-adequate process model, the intention of this process must be defined. This especially addresses the output the process has to deliver as well as the organizational constraints (e.g., the whole process has to be performed within the EU).
3. *Process module composition:* The composition itself is performed by analyzing compatibility of process interface pairs. That yields pairs of matching interfaces through which process modules can be connected. Based on those modules which are able to produce the intended outcome, a network of modules is successively constructed and generates the final product. Thus the composition is directed by the matching assignments of the process interfaces. The set is filtered by the organizational constraints of step 2 and rated by a common target function. The best rated result is the final one and describes a common cross-organizational business process model for all participants.
4. *Process model consistency analysis:* To avoid contradictions within the overall process model, the composition phase closes with a consistency analysis during which the model is analyzed with respect to flow logic consistency. Such a test is described for example in [SaOr99]. Having passed this test, the cross-organizational business process model can be realized within all involved organizations.

Distributed Business Process Execution

The distributed execution of a business process starts with a common process model that all participants share and that is business oriented, i.e., its content is mainly conceptual and its purpose is organizational management. From this model every participant extracts those parts that he has to execute and augments them with arbitrary information he needs for execution, e.g., refinements of process sub-parts or execution context parameters (cf. Figure 2). Thus the business model is transformed into an IT-oriented workflow model, the main purpose of which is the execution of the contained process. The following section introduces the steps from the common process model to the execution of the workflow model:

Figure 2. Distributed business process execution



1. *Splitting Up the Common Process Model:* All activities in the common process model are annotated with the executing organization unit ("Company X"), or with an organization unit role ("Customer") that can be mapped onto a concrete actor within the execution context. So the common model disaggregates in disjoint process model fragments that are executed by exactly one actor each. As the process modules were composed to the common process model during the modelling phase they have interface descriptions. So it is possible to define exactly which goods and which information must be transferred from one actor to another.
2. Apart from goods and information, the execution of the whole process devolves from one actor to another at an interface. Therefore it is necessary to define how the control of the process is transferred. At process junctions it may be even possible to split up process control or join multiple execution threads again.
3. *Augmenting the Process Fragments:* Execution of a process fragment usually requires considerable prearrangements on the part of the executing actor. Therefore the process fragment is first transformed from the modelling language into an executable language. Since the business process model is business oriented, it usually does not contain information about execution parameters, e.g., an IP address of an interface or authentication credentials for an ERP system. So it must be augmented with these missing execution parameters during or after transformation to the executable language. After that, the process fragment is contained in an executable workflow model.
4. Usually the common business process model disaggregates into multiple process fragments, each of which is transformed into a single workflow model. These workflow models are deployed to the respective IT systems then, which are finally configured with the contained information.
5. *Executing the Process:* Figure 2 shows how the whole top-level process is implemented by executing the workflow models of the process fragments which it consists of. After configuration of all involved systems this happens automatically, i.e., without interaction with individual process instances.

Since the whole process is executed fragment-wise by multiple separate systems, there must be transition points from one system to another where execution is finished or suspended at the source system and perpetuated at the target system. This transition has two different aspects: data flow and control flow. Data transfer between separate IT systems is widely used already, e.g., between departments within a single organization. However, the transfer of process execution control and context via push and pull mechanisms is not common. Especially in split and join situations, e.g., when a simultaneous execution of multiple process parts on multiple systems begins or finishes, the process context must be duplicated and merged accordingly. During execution, performance data is gathered as a means for the next step: the controlling phase.

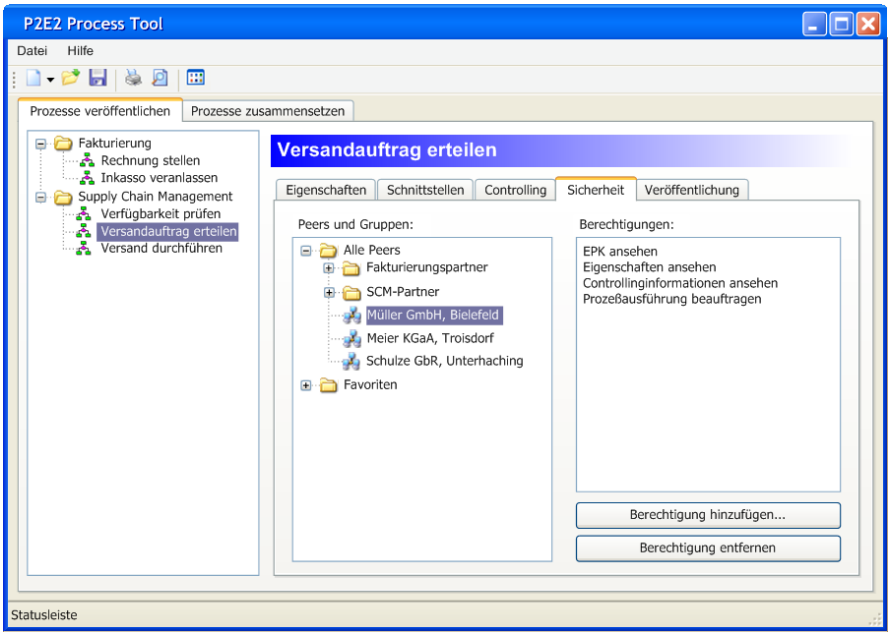
Distributed Business Process Controlling

From the management perspective, the ability to execute a business process is not sufficient. In order to improve the design and the way of execution it is essential to measure the target object, i.e., to reveal performance indicators of the cross-organizational business process. In the intra-organizational case, this means to extract historical execution information from a single process execution system and to calculate the performance indicators from them. In contrast to that, the cross-organizational case is rather complicated. On the one hand there are multiple execution systems, each of which holds only partial information about the execution of a single cross-organizational business process. Thus the challenge is not only to compose performance data from multiple sources, but also to identify linked process chunks and to reconstruct the complete structures of historical cross-organizational business processes under the side condition of heterogeneous keeping of data and system ownership. On the other hand this information on the reconstructed process not necessarily leads to performance indicators for the whole process, because their calculation requires the valuation of process execution data. However this valuation (e.g., the cost function) is usually considered a business secret, so an overall indicator processing cannot be performed without exposing individual business knowledge. Therefore we propose to calculate distributed performance indicators in a way equivalent to the execution data processing: each organization transforms the process information gathered from the execution systems into its individual (partial) performance indicators. These figures will then be used to compute the overall indicators. Following this procedure, the organizations are not obliged to publish their calculation scheme and only communicate the resulting values.

4. TECHNICAL REALIZATION

In this section the realization of the concepts described above will be presented. Within the research project P2E2 – Peer-to-Peer Enterprise Environment[1], a platform has been developed that prototypically implements the distributed Business Process Management principles.

Figure 3. Screenshot of PDDT



The basic idea is to form a network of actors ("peers") which are all equal with respect to rights and what they are able to do [ScFi02]. The network is dynamic, i.e., peers may enter and leave the network at any time. The peer-to-peer principle guarantees equal opportunities for all participating parties. Every party distributes models of the processes that it offers to perform. A customer peer can reassemble these process fragments to the model of a complete process and buy the execution of it (or parts of it) from other peers. Thus the P2E2 network structurally corresponds to the organizational network of the collaborating organizations and therefore provides a wide set of advantages as a technological base for enterprise networks [KuWe04].

Distributed Business Process Modelling

First, the processes offered in the network must be modelled, aggregated, assembled and so on. The top-level modelling language used in the P2E2 prototype is the event-driven process chain (EPC). Modelling is performed using the ARIS Toolset by IDS Scheer AG. However, the P2E2 meta-model explicitly supports other modelling languages, too.

In the first step, every peer designs his own processes in any desired detail, thus obtaining a "private" model which can contain arbitrary (even secret) information about the process and therefore is not shared with other peers. Then he generates a "public" view to the model by reducing the contents of the private model to the minimum that is necessary for other peers to comprehend the modelled process and its interfaces.

In the next step, all public models by all actors are distributed among the network. For this purpose we developed the Process Distribution and Discovery Tool (PDDT), a peer-to-peer software which is based on the JXTA peer-to-peer framework and supports distributing, versioning, searching and transferring models (see Figure 3). With the shared information about the available process fragments, any peer can construct a complete process from the fragments. Using the PDDT again, this common process model is shared with all peers that participate in its execution.

Distributed Business Process Execution

Figure 4 shows the architecture of a P2E2 peer along with the controlling and configuration applications which are not an integral part of the peer itself. This subsection about execution starts with the output of the modelling tool in the lower left corner of the figure.

In P2E2, the execution part of the Management concept is simplified compared to the scenario outlined in Section 2, because the common process model is composed from several process fragments. So the responsibilities for the execution of the process parts are ex ante established and partitioning. Besides, the augmentation of the process fragments with execution information benefits from the fact that the private model with all execution details already exists. Therefore the common process can be omitted. So it is sufficient that every peer augments its process fragments once and reuses this information in every execution.

Another part of the augmentation phase is the conversion of all models into a common execution model language, i.e., XPDL in our case: finally, all P2E2 process fragments exist as executable XPDL models. To obtain them, a multi-stage conversion and augmentation is performed. First, the EPC models are automatically converted into XPDL format using the modelling tool. Then the attributes of all XPDL model elements are filled in with data necessary for execution using another tool developed within the project, which is named "augmentation tool" in Figure 4.

Execution in P2E2 is finally performed using workflow engines by Carnot AG and abaXX Technology AG ("WFMS" in Figure 4). Whenever necessary, communication between executing peers is performed by calling BAPI methods using Wf-XML.

Distributed Business Process Controlling

During execution, every engine records performance data and stores it for the third phase: controlling. The most basic performance data gathered during execution is stored in the audit trails of the workflow management systems (see Figure 4). However, mainly due to business secrecy, their content is not exposed directly. Instead, every peer processes its performance data to its liking and exposes the results or parts of the results over a specific web service interface exclusively. Of course, this information only refers to the execution of a process fragment, not the process as a whole.

The reassembly from fragments to the whole process is achieved using a specific controlling tool (see Figure 4). It first fetches performance information about process fragments from all participating peers using the web service described above. Then the information how the whole process is composed from process fragments is used to aggregate per-process information from per-fragment data.

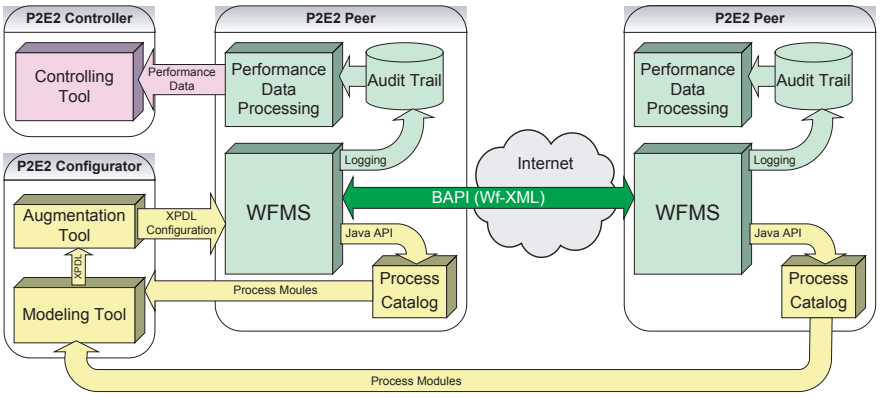
5. CONCLUSION AND OUTLOOK

In this paper, we have presented a concept for the cross-organizational business process management, including distributed modelling, execution and controlling, that is already widely-implemented. In particular we addressed and ensured the continuous IT support of all three phases, the decision autonomy and secrecy demand of the participating organizations during the process, and the technical and conceptual feasibility of our approach (which will be finally verified when the entire prototype is completed).

Currently, two business scenarios are evaluated with our concept. One of them is taken from the financial services sector and deals with factoring, the other one deals with supply chain management in international and national product distribution.

This concept was developed at the Competence Centre Business Integration (CCBI), Institute for Information Systems (IWi) at the German Research Centre for Artificial Intelligence (DFKI), Saarbruecken. It addresses current research problems in the area of process integration and networked businesses by bring-

Figure 4. P2E2 technical architecture



ing together the business-oriented and the IT-views. The work is performed by clustering national and international funded research projects (esp. ArKoS, ATHENA, INTEROP, P2E2), intending the development of solutions for a better interoperability in business networks.

Complexity and Dynamism in the Information Systems Domain

Yasmin Merali, Warwick Business School, The University of Warwick, Coventry, CV4 7AL, UK; E-mail: Yasmin.Merali@warwick.ac.uk

ABSTRACT

This paper argues that the emergence of the network economy and network society extends the boundary of the Information Systems (IS) domain, and that complexity science offers the apposite concepts and tools for incorporation into a General Conceptual Framework (GCF) and Methodological Base (MB) for IS. The paper is structured in the following way. The next section outlines the imperative for a paradigm shift –from dealing with IS as discrete systems to dealing with IS as components of the interconnected world. Section 2 outlines the complexity science concepts for articulating the dynamism, adaptation and co-evolution observed in the interconnected world, and Section 3 discusses the way in which the complexity science concepts connect with existing philosophical movements in the IS domain, and reflects on how they may contribute to the development of a GCF and MB for IS.

1. INTRODUCTION

The IS and IT landscape is characterised by network dominance and increasing complexity. As shown elsewhere (Merali and McKelvey, 2006), the network motif is one that we can see at play at many different levels in the evolution of the IS field, for example,

- the potency of discrete advances in hardware and software capabilities to generate significant change in business and society is realised through the mobilisation of network effects;
- technological advances escalate the potency of network effects by continually enhancing the connectivity and bandwidth of networks;
- the growth of IT-enabled socio-economic networks is accompanied by globalisation and an increase in the number and heterogeneity of players who can affect the dynamics of networks.

Recent work on small world and scale-free networks (Newman, Barabási & Watts, 2006) shows that small changes in network connectivity can bring about major, almost costless changes in the characteristics and behaviour of the socio-economic players and milieu. The net effect of this is a perception that individuals and organisations have to deal with a world that is increasingly dynamical, complex, and uncertain, and that their actions may have unintended consequences that impact on other parts of the world.

The network form of organising is the signature of the internet-enabled transformation of economics and society. Management literature has shifted from focusing solely on the firm as a unit of organisation to focusing on networks of firms, from considerations of industry-specific value systems to considerations of networks of value systems, and from the concept of discrete industry structures to the concept of ecologies. The labels "network economy" and "network society" (Castells, 1996) have become integrated into the management lexicon. In the strategy literature the network economy is characterised by competition in high-velocity environments, speed of technological change and uncertainty (Eisenhardt, 1990. Organisations, needing to shape and redefine their own competitive arena are confronted with the need to continually innovate (Hayton, 2005). This brings with it the challenges of working towards radical and incremental innovation, whilst dealing with resource constraints to achieve an efficacious balance of risk and return. From the IS perspective, an interconnected world that is comprised of technologically mediated networks of networks can be conceptualised as

- a complex multidimensional network which
- connects a diversity of agents (individuals, groups, institutions, nations, computers, software components etc.) through
- multiple and diverse communication channels

IS and IT underpin the realisation of this networked world. Strategy, OD and IS research have converged on issues of connectivity, co-ordination, competition and collaboration, learning and transformation at multiple levels of analysis in the networked world.

These developments have two important consequences for IS scholarship and methodology development: IS methodologies need to offer the requisite ontological and epistemological constructs for enabling us to

- deal explicitly with dynamism, complexity and continuous change, and
- engage with the trans-disciplinary discourse

characteristic of the emergent networked world, in which many heterogeneous components (social, institutional, technological and informational) are connected in a dynamic fashion.

Complexity science is viewed as a source of concepts for enabling the trans-disciplinary exploration of complex organisation in the networked world, and for explaining the dynamics of networked systems at different levels of description ranging from the micro- to the macro. It offers a powerful set of methods for explaining non-linear, emergent behaviour in complex systems (Anderson, 1996, Merali, 2004 have overviews for OD and IS). There are three special issues dedicated to applications of complexity theory[1], [2], [3] in the IS domain.

The systemic level IS capabilities underpinned by the network form of organisation that are of particular interest in the "New Economy" include:

- intelligence (sensing internal and external contextual characteristics, developing representations of the environment and formulating and implementing appropriate strategies and responses).
- coordination (particularly dynamic co-ordination and recombination of distributed resources, processes and capacity to act),
- robustness (the ability to reconfigure, self-repair and renew, and to maintain integrity in the face of changes in and attacks from the environment),
- efficiency (of co-ordination, transaction and resource development within and across organisational boundaries, and
- flexibility (adaptive capability and transformational capacity).

The next section highlights concepts from complexity theory for articulating IS phenomenology and dynamics of the networked world.

2. COMPLEXITY CONCEPTS

2.1 Complex Systems and the Network Form of Organising

Complex systems are non-linear systems, composed of many (often heterogeneous) partially connected components that interact with each other through a diversity of feedback loops. Their complexity derives from the partially connected nature and the nonlinear dynamics which make the behaviour of these systems difficult to predict (Casti, 1997). The non-linearity of these systems means that small changes in inputs can have dramatic and unexpected effects on outputs, affording possibilities ***both***, *for maintaining the steady state* ***and*** *for transformation*: small changes in topology can make a big difference to what is possible and what is not. The particular network dynamics and possibilities for adaptation and transformation of the network at any given time are emergent manifestations of the non-linear interactions in the particular network context. The context may support a heterogeneous combination of:

- types of links
- properties of the nodes
- types of information and knowledge flows through the links
- types of information and knowledge content and processes of nodes
- degree of connectivity and density of connections in the network
- patterns of connectivity.

The language of complexity science allows us to use network dynamics as the explanatory mechanism for linking micro-level diversity with the emergence of coherent macro-level phenomenology of the networked world.

2.2 Complexity Concepts and Networks

Complex adaptive systems (CAS), *emergence, self-organisation* and *co-evolution* in complex systems are complexity concepts developed the most in organisational literature, and are of particular interest to us in our project of developing a GCF for extending the IS domain into the management field.

The concept of CAS (open, dynamical systems that adapt and evolve in the process of interacting with their environments) serves to characterise the phenomenology of IS in the networked world (Merali, 2004). CAS are non-linear systems embodying self-organisation and emergence and have the potential (capacity) for adaptation *and* transformation.

The pattern of interactions that underpins the dynamics of CAS is explained in terms of the network of interconnections. A CAS is made up of multiple, interconnected components ("agents"). The resulting network connectivity allows for the generation of feedback loops.

A system regulated by negative feedback loops would characteristically display stability, whilst a system dominated by positive feedback loops would be subject to the "runaway" escalation of a particular trajectory. CAS embody the potential for simultaneous existence of *both* negative *and* positive feedback loops. Hence a diversity of feedback cycles may be interlinked in a variety of ways, with different consequences. – The interlinked cycles may maintain a homeostatic organisation (as in the Maturana and Varela's 1973 account of autopoietic organisation of stable living organisms) or they may spontaneously generate new, more complex forms of organisation under certain critical conditions (Prigogine, 1987; Langton, 1991; Kauffman, 1993).

Emergence refers to the phenomenon whereby the macroscopic properties of the system arise from the microscopic properties (interactions, relationships, structures and behaviours) and heterogeneity of its constituents. The emergent macroscopic "whole" displays a set of properties that is distinct from those displayed by any subset of its individual constituents and their interactions.

At the microscopic level, the behaviour of an individual constituent is contingent on the precise state of that constituent and conditions in its local environment *at that instant*. For constituents on the boundary of the system, the local environment will constitute "internal" and "external" components. The collective behaviour of the individual constituents at the microscopic level will manifest itself as the behaviour of the "whole system" visible at the macroscopic level.

Self-organisation is the ability of complex systems to spontaneously generate new internal structures and forms of behaviour. This *generative* aspect takes the complex systems concept of self-organisation beyond the early cybernetics concept of self-organisation which focused on the self-regulatory and control aspects of organisation. In the self-organisation process, the components *spontaneously* re-orientate and restructure their relationships with neighbouring components giving rise to the emergence of structures that embody an increased level of internal complexity. The constituents are partially connected: the behaviour of each one depends on the behaviour or state of some subset of all the others in the system. Each acts on local information only derived from the others with which it is connected. Thus the *system* self organises: no single component dictates the collective behaviour of the system. Network connectivity is critical in defining and maintaining the ordered state, with most components receiving inputs from only a few of the other components so that change can be isolated to local neighbourhoods. Self-organisation is not the result of a priori design, it surfaces from the interaction of system and the environment and the local interactions between the systems components.

The existence and persistence of the system is thus a relational phenomenon, predicated on the relationship of the constituents of the system to each other and to constituents of the environment in continuous time. Local, contingent, neighbourhood interactions and adjustments at the micro-level are at the same time detectable as a coherent pattern of properties constituting the "whole" system.

The classical separation of *"becoming"* from *"being"* does not advance our understanding of complex systems. In order to identify how emergent properties are produced we need to be able to access descriptions of the system at multiple scales from the micro to the macro *at the same time*. This presents us with a problem of representation in the classical mode of top-down refinement. Typically, complex systems representations are either developed as mathematical models or as computer simulations.

At the micro-level, system and environment components interact in a contiguous space, and, depending on the nature of particular relationships, can to a lesser or greater degree be considered to be mutually effective. Thus the dynamic definition of a system is contingent on the dynamic definition of its environment, and system constituents are an integral part of the landscape in which they exist. The concepts of systems adaptation and evolution are thus extended to the dynamics of the ecosystem within which systems are situated and thus to *co-evolution* of system and environment.

These characteristics require us to redefine the way that boundaries are conceptualized: from the classical view of fixed boundaries, towards a more dynamic view of boundaries as relative and relational phenomena, linking system and environmental elements through differential coupling.

The emergence of the macro level phenomenology from micro level interactions and the mutually defining relationship between the system and its environment are defining characteristics of our information network dynamics. The question of how to deal with boundaries in this context remains a non-trivial one.

To summarise, CAS are sensitive to initial conditions and hence embody path dependency, in the sense that history matters. However the heterogeneity of network nodes (i.e. we can have nodes that are defined by different sets of characteristics) and their connectedness (i.e. not all nodes are connected to the same number of other nodes) coupled with the possibility of dynamically reconfiguring network topology (by activating/deactivating links, and/or adding/removing nodes) affords a level of micro-diversity and a combinatorial potential that makes it impossible to predict with any certainty the future state of the macro-level system.

In face of this escalating computational complexity and mathematical intractability, complexity science offers agent-based modelling as a way to explore the possibilities and characteristics of the unfolding dynamics of complex adaptive systems. The next paragraphs highlight the characteristics of the agent-based approach that are useful for looking at the network dynamics of the interconnected world, suggesting the need to develop conceptual frameworks for defining the parameters to be modelled.

2.3 Agent Based Modeling and Multi-Scale Descriptions

Agent-based computational modeling has features that are particularly relevant when studying socially embedded systems, and it is displacing conventional mathematical theorizing approaches (Carley, 1995, Axtell, 2000).

It is possible to model diverse agents, capable of acting with local information and noisy pay-offs (Axtell 2000). Genetic algorithms (Holland, 1998) provide the means to explore adaptive behaviour, learning, evolution and fitness in dynamic landscapes. Running such models furnishes us with an *entire* dynamical history of the process under study. This is important when exploring processes of emergence and self-organisation in complex adaptive systems. Complex systems have many degrees of freedom, with many elements that are partially but not completely independent, with ambiguous system-environment relationships. There is a greater diversity of local behaviours than there is of global outcomes. In order to achieve an effective representation of the dynamics of the processes connecting the local (micro-level) and global (macro-level) characteristics we need to develop a multi-scale description of complex systems, and agent-based modeling provides a mechanism for doing so.

For social systems the specification of the components (agents) for the construction of agent based models is itself often a challenging prospect. With the escalation of available computational power it will be possible to build models with a million agents of reasonable complexity.

The diversity of social relationships and the idiosyncrasy of individuals makes it difficult to develop models that are both, sophisticated enough to capture the essential features of the social interactions and characteristics, and simple enough

to make visible the dynamics of the system. The difficulty lies in identifying what constitutes the requisite set of attributes for defining social systems – and *this* is a matter that necessitates a discourse with the sciences of sociology, philosophy and psychology amongst others (Merali 2004).

From a methodological perspective, we need ontological and epistemological frameworks to guide the utilisation of complexity concepts in studying and dealing with social systems. However the science of complexity does not offer the requisite frameworks, nor do the social sciences. Turning to philosophy and the social sciences we find that there are a number of existing philosophical perspectives that we may be able to draw on in order to explore the possibility of developing the requisite frameworks

3. PHILOSOPHICAL OPENINGS

Our exploration of complexity concepts brings us to some openings that invite a further investigation of several philosophical positions, and these are highlighted below for future speculation.

To assimilate and accommodate the phenomenology of emergence and CAS we need to identify a philosophical position that enables us to deal with

- inseparability of *being* from *becoming*
- "fluidity" between system and context,
- *potentiality* of the emergent system and its constituents given that emergent phenomena are non-deterministic, path-dependent and context sensitive, and
- assimilation of the present and persistent with the possible and transient.

Heidegger's *Being in Time* (Heidegger, 1962) offers us a number of enabling concepts for this endeavour. Heidegger's *Dasein* (*being-there*, or *being-in-the-world)* gives us the articulation of individual and collective *being* and its relationship with past, present and future time.

Dasein (*being-there* or *being-in-the-world)* is the wholeness of being that includes the context and assimilates objects of the world into itself. This is an affirmation of *Dasein* in the present. However *Dasein* in the present is in, and open to, a space of *possibilities* of the (collective) world (this is articulated in Heidegger's concept of *clearing*) and it is pressing *forward* into the possibilities (of the future). This pressing forward has a general direction (Heidegger's *towards-which* or *for-the-sake-of-which*), but no specific conscious goal – as Dreyfus (1987) puts it,

Dasein is simply oriented toward the future, doing something now in order to be in a position to do something else later on, and all this makes sense as oriented towards something that the person is finally up to but need not have, probably cannot have, in mind.

So, *Dasein* embodies the past, present and future: The "pressing into the future" of *Dasein* in the *past* is the passage into *Dasein* in the *present* which is already pressing into *Dasein* in the *future*.

In attempting to locate complexity concepts in relation to the map of established philosophical positions, Heidegger's existential phenomenology offers a promising starting point for our ontological framework: the notion of *Dasein* articulates the qualities of emergence (in the unfolding of *Dasein*), the contiguity of *being* with *becoming,* and the spontaneous organisation of *being* (incorporating the context, assimilating objects in the environment into dynamics of being).

Turning to the social sciences, we find that Critical Realism (Bhaskar, 1986) also articulates path dependency, emergence and transformation in social systems: it does so in terms of *causal mechanisms*, tracing the emergence of the experienced world from the existence of possibilities in the actual world, realised through generative mechanisms of the real world. In *Complexity theory and the social sciences* David Byrne develops the proposition (Reed and Harvey, 1992), that Critical Realism constitutes the philosophical ontology complementing complexity as the scientific ontology.

With regard to the epistemological dimension, defining and studying the being of particular complex systems-in-the-world, presents us with another problem. The moment we speak of being, it is interpreted (Eco, 1997). Interpretations are grounded in the system of interpretation or perspective of those who generate them. It is therefore possible to generate a diversity of interpretations from the observation or experience of any particular event or state of affairs. Similarly, the possibilities of being are transcendental, extending beyond articulated experience existence and imagination of any person. We are thus confronted with the problem of appreciating the potential (of being) beyond articulated accounts, representations or speculations about the past, present or future.

The problem of exposing that which lies behind and beyond language-based interpretations and descriptions of the world constitutes an opening for the exploration of Derrida's deconstructionist (Derrida, 1978) philosophy. This opening is explored in Paul Cilliers' Complexity and Postmodernism. Cilliers draws on Derrida to develop an excellent exposition of the parallels between the complexity of language systems (and the possibilities of meaning emerging from the relationship between language-based descriptions of the world and the world itself) and connectionist accounts of the complexity of social systems.

To summarise, whilst the science of complexity does not directly offer us ontological and epistemological frameworks for the application of complexity to social systems, complexity concepts resonate very strongly with several existing philosophical movements, highlighting a number of openings for future investigation in the development of GCF and MB for IS.

4. POSITIONING IS IN THE MANAGEMENT FIELD

The exposition of the information network-in-use in this paper accentuates the existence of the information network as an integral, constitutive element of the network society and economy. The information network both, serves, and shapes the networked world.

As illustrated above, conceptualising the networked world as a CAS transcends the traditional boundaries between disciplines in the management field. This has two important implications for future IS research:

- the travail of IS in the interconnected world is a trans-disciplinary one, and demands the active development of a discourse with the other disciplines. The adoption of complexity science concepts would speak for a discourse not only across the management field, but also across the natural and human sciences
- the centrality of IS in the network economy and society places the IS domain at the heart of the management field, and we should, as a discipline, re-cognise our responsibilities for informing the discourse pertaining to information networks-in-use in other management disciplines.

5. CONCLUSION

To summarise, this paper has shown that the complexity and dynamics of systems are not readily treated with traditional research approaches that simplify the world with high level generalisations predicated on macro-level observations of structural persistence and assumptions of Gaussian statistics. Complexity science furnishes us with the concepts and tools for building multi-level representations of the world and for making sense of the dynamics of emergence. The dynamics of emergence is predicated on micro-diversity, and fine grained representations are essentially descriptive models of the detailed complexity of the world and its dynamics. Thus it is through exploratory modelling that we discover how the complex world works, and how macro-level properties and behaviours of systems emerge from micro-level diversity and dynamics. Consequently, modelling is the principal research tool for complex systems, and sensemaking is a legitimate research goal. This implies a significant shift in the established thinking about what constitutes knowledge and how it is best obtained. This is the challenge for traditional research and in particular for the hypothetico-deductive school.

Evaluation of Web Services Resource Framework for Virtual Organization

Asif Akram, CCLRC Daresbury Laboratory, Daresbury, UK; E-mail: a.akram@dl.ac.uk
Rob Allan, CCLRC Daresbury Laboratory, Daresbury, UK

ABSTRACT

The organization of resources in communities is an efficient way for resource discovery. The effectiveness of proposed communities depends on the technologies selected, their interoperability, platform independence and compliance with standards. This paper outlines the role of different available technologies to sustain the effective working of the community and to provide the general middleware for the community formation. Main focus of this paper is to evaluate the Web Services related specifications particularly Web Services Resource Framework and Web Services Distributed Management; and their effectiveness in the community formation.

1. INTRODUCTION

Emerging distributed computing paradigms, such as Grid Computing [4] and Virtual Research Environments [7] comprise of services/peers which collaborate in one way or another to improve their effectiveness – this cooperation leads to the formation of a "Virtual Organization". Virtual Organizations already exist in e-commerce, science, research and engineering projects – whereby a collection of organizations or scientists come together to solve a single large problem. Enormous development in Information and Communication Technology (ICT) has changed the requirements and expectations of consumer/user leading to tense competition (economically), composite and complicated services (scientific), and demand for diverse and dispersed resources (Grid environment). Extensive collaboration in every aspect in every possible way is required to meet these high user expectations. A Virtual Organization is one such strategic approach to building strong but flexible links to partner organizations with similar interests [6].

The effectiveness of a Virtual Organization relies on the technology selected for the middleware, adherence to standards, and built in support for managing the diverse resources. In our understanding, the middleware provides basic features for community formation; defines protocols for coordination among resources and peers; the mechanism to advertise the capabilities of the resources, the discovery of suitable services and the management of these dynamic resources.

The community formation process and different types of communities are discussed previously and can be found in [1], [2] and [3]. The 'Section 2' discusses the requirements of the VO and suitability of emerging specifications in the Web Services. The 'Section 3' evaluates Web Services Resource Framework (WS-RF) [5, 13] and Web Services Distributed Management (WSDM) [14] for Virtual Organizations and different collaborative environments. The last section explains the existing and proposed implementation details for the community.

2. REQUIREMENTS OF VIRTUAL ORGANIZATION

A Virtual Organization "VO" defines a logical group of members within the grid, which can be geographical distributed. Usually all members have a common interest, for example one institute, a group of scientist or a commercial enterprise. Within these VO's all resources are shared and the use is strictly defined by policies. Selection of any technology to simulate VO requires thorough consideration and analysis of its built in support not only for the formation of VO but its management and functionality. In the following section we will discuss different requirements of VOs in the context of features available WS-ServiceGroup and WSDM. Technical details of WS-ServiceGroup and WSDM are based on the GT4 [8] implementation of WS-RF and Apache implementation of WSDM [9].

2.1 Bootstrapping Service

Virtual Environment provides essential information to a peer on joining the network to discover enough network-based and other resources to sustain itself. Each container hosting Web Services manage

ContainerRegistryService and DefaultIndexService which collects data from various sources and provides a query/subscription interface to that data. Resources are added in the ContainerRegistryService and DefaultIndexService at the time of initialization.

2.2 Maintaining Membership Policy

Each community needs to keep appropriate membership criteria, thus members of community should have resources, capabilities and competencies compatible with the rest of the members. VO manages the membership requirement of community by restricting membership according to a set "Membership Policy". Membership Policy is constrained in the ServiceGroup as MembershipContentRule below is the example:

```
<wssg:MembershipContentRule MemberInterface="ns2:X" ContentElements=""/>
<wssg:MembershipContentRule MemberInterfaces="ns3:Y" ContentElements="ns3:RP1 ns3:RP2" />
```

MembershipContentRule in the first statement expects members to implement "ns2:X" portType; where as second MembershipContentRule expects not only implementation of "ns3:Y" but also exposing two ResourceProperties.

2.3 Lease Time

The membership of any ServiceGroup is for specific duration set at the joining time. After membership duration ceases, peers can apply to renew their membership, the outcome of which can be linked to the effectiveness of a peer and its historical effectiveness within the community. VO makes strategic alliances to achieve set goals and there is no need for long term contract which is contrary to the purpose of Virtual Organizations.

2.4 Access Control

Different members enjoy different access rights for different resources available within the community. Nature of access rights depends on the effectiveness and activeness of specific member within the community and relevance of resources to a particular member. Access rights granted to different peers depends on their role within the community and nature of resources; Each Resource has its own access and security policies which are controlled in the form of Grid Map file in GT4.

2.5 Resource Monitoring Service

Optimized usage of resources means maximum productivity of the resources; which boosts overall performance of the community. Overloading resources or minimum usage of resources with respect to their capacity results in declined standards, which can be achieved by better governance and scheduling. ServiceGroup implementation provides QueryResourceProperties operation which can be used to search members matching certain criteria i.e. CPU with 50% load, resource with 1 GB memory etc. Resource monitoring leads to fault detection, performance analysis, performance tunneling, performance prediction and scheduling.

2.6 Performance Controller Service
The WSDM-MUWS describes the manageability of the resources. The manageability capability is best thought of as an interface to the internal workings of the Service. The role of the manageability capability is to list the available operations on a resource so that management software can get a list of the available operations. These capabilities are defined using XML and can be aligned with ServiceGroup membership content rules by including ResourceProperties essential for monitoring and management in the membership content rules.

2.7 Scheduling Manager Service
The combination of WS-ServiceGroup and WSDM-MUWS provides best Resource Querying and Monitoring mechanisms; on top of which any level of complex scheduling service can be implemented. Scheduling of tasks involves co-ordination between member peers and co-operation with other communities, which leads to complex and demanding workflows. Both WS-ServiceGroup and WSDM-MUWS subscribe to the changes in the Resource Properties of the members through Web Services Notification (WSN) and effective use of WSN provides real time monitoring capabilities to schedule tasks to member peers either in parallel or series.

2.8 Security Manager Service
The Community provides a secure environment to its members for co-ordination. The community as a whole ensures the protection of data through its unique ability to adapt, resist and protect data by scattering the multiple copies within the community boundary. Members can access local resources and communicate with other members without any additional authorization and authentication once they are known to the local authentication authority. Most of WS-RF implementation provides different level of security, message level and transport level security along with delegations of credentials.

2.9 Community of Communities
In WS-ServiceGroup each VO itself is a stateful Web Services with ResourceProperties encapsulating the member's details. WS-ServiceGroup can be arranged in hierarchical manners to create communities within community as long they all full membership criteria. Community of Communities is essential to pool similar services within the community and group different communities to from super VO according to the requirement of workflow.

3. WS-RF AND COMMUNITY FORMATION

The community formation is to achieve the relevance of resources and services with respect to each other or according to the business requirements. The suitability of resources and services is the basis of different type of communities, which is crucial for the collaboration among participants from business, commercial or academic domains can be achieved. The services are units of work that map closely to the activities in a business or scientific process, such services are immediately relevant to analysts who can readily participate in their creation and use them to define complicated new processes thus enabling Service Driven Environment. The architectural implementation of the community based on WS-RF ServiceGroup has many advantages and some are listed below:

3.1. Governance
Sharing of services/resources offered by participating Peers is central to our Community approach and is fundamental of VO. The ability to rapidly assemble the applications or orchestrate the processes based upon the availability of services from participating members. The sharing of different resources, by definition requires efficient governance. Monitoring and Discovery System (MDS) in Globus Toolkit 4, is a suite of Web Services to monitor and discover resources and services on the Grid. The implementation of MDS allows resource discovery and monitoring in the standard way. The query and subscription interfaces in MDS to arbitrarily detailed resource data can be configured with trigger interface for appropriate actions under specific conditions.

3.2. Reusability
Conventionally developers are geared to tackle each application as an independent problem to be solved, with little possibility of the code reuse. Web Services based communities are all about application development with reuse in the mind, both in term of the existing code and in terms of planning new code to be used in future applications. Different service/s provided by different members, can be reused by other members to support their services or to develop composite services i.e. workflow.

3.3. Rapid Application Development
Peers are categorized in Communities based on the service/s they tend to share; these services are reusable fragment of code, which can be assembled in many different ways to develop bigger and sophisticated applications. The community focus on each activity as a service, which can be useable in different applications and applications are no more isolated code with limited applicability outside their problem domain. These services are orchestrated through a "workflow" based on the available resources, competencies, strengths/weaknesses of members; which may require collaboration among communities to "buy in" services missing within the community.

3.4. Manageability
Sharing of service/services offered from different resources even when these resources are in different Communities leads to endless possibilities. Thus development of any complicated applications is more or less orchestration of independent services, resulting in more manageable application development process with respect to time and development cost. Modular software is designed to avoid failures in large systems, especially where there are complex user requirements. The possibility to replace similar services particularly at run time under un-predictable circumstances gives new dimension to the management of final goal according to the user requirements.

3.6. Improved Quality
MDS monitors the status of different registered resources and service/s with "self-cleaning", each resource has a lifetime and is removed from the Index of available resources if it is not refreshed before it expires. Monitoring capability can be coupled with set of conditions to control the Quality of Service (QoS) [17] of individual resource i.e. advertise only those resources with processor load less than 50%, resources with memory size of at least I Gig. Tools can discover similar type of services and select any service from the pool of similar services according to the Quality of Service (QoS) constraints and the requirements of final goal. The module design of services means they can be replaced at run time without compromising the quality. The replacement of semantically equivalent services can be automatically initiated by the community (in case of Co-Operating community) or can be manually done by the client.

3.7. Diversity
Very few applications can survive in the isolation. Most often applications have to be integrated with other applications inside and outside the enterprise. This integration is usually achieved using some form of "middleware". Middleware provides the "plumbing" for data transport, data transformation, routing etc. [15]. No sizeable IT organization operates with a single programming standard, and with emergence of Web Services as the de-facto standard the architecture of the applications is changing with no reliance on single programming modal. Modular applications developed by integration of different of services deployed on variety of platforms and environments can exploit the specialization of individual programming language to achieve maximum quality. This Technology-to-Technology" (T2T) gives new dimension to integration of application development, which requires changes in programming style and our understanding to the problem.

4. SEMANTIC AND COMMUNITY MANAGEMENT

The recent trends in industry connected with enterprise integration demand solid technology to provide effective Knowledge Management within and across industrial enterprises [16]. Combination of Semantic Web and Peer-to-Peer technologies provides many attractive and powerful features for this domain, but these great possibilities are not yet fully explored. There is a strong interest in the development of reliable platform for support of cooperative knowledge management and flexible integration of various applications, Web Services and industrial resources in the Grid Environment.

WS-RF is described as a set of protocols for manipulating WS-Resources, and deals with application data (resource properties) in the form of the XML. Additional data is defined within WS-RF itself –e.g. TerminationTime in WS-ResourceLifetime and service group entry WS-Resources in WS-ServiceGroup. It is easy to attach semantic information with the service through optional resource. Any service can work on multiple resources and one resource can be managed by multiple services, adding additional resource declaring the semantic information related to the service, data types and operation is more feasible. Tools can query the semantic resource of the service, if it exists before integrating the service in the workflow. WS-Resources can have reference to other WS-Resources in the form of EPR, which gives an alternative possibility of keeping the semantic information separate from the WSDL and integrating it with the service as a WS-ResourceProperty. WS-RF mandates the use of XML Schema for the application specific data and use of languages like XPath or XQuery for querying purposes. The application data can be anything in XML format and WS-RF doesn't constrain the XML Schemas used to describe the data which make it possible to annotate the data with semantics.

Different implementations have different mechanism to collect the information which can be from different sources. GT4 has three different possibilities to populate Index Service (i) to get information from resources, (ii) through subscription/notification mechanism and (iii) through any external program. WS-RF is described as a set of protocols for manipulating WS-Resources, and deals with application data (resource properties) in the form of the XML. Additional data is defined within WS-RF itself –e.g. TerminationTime in WS-ResourceLifetime and service group entry WS-Resources in WS-ServiceGroup. External program provides maximum flexibility to collect the data and apply local Knowledge Base to extend the WS-ResourceProperties. This approach requires the flexibility in the data set with attached semantic, to organize the services based on the semantic nature of the data consumed by the service and semantic information related to the operations in the form of pre and post-conditions.

The WS-ServiceGroup specification can express group, membership rules, membership constraints and classifications using the resource property model from the WS-ResourceProperties. Groups can be defined as a collection of members that meet some constraints as expressed through resource properties. Membership Policy is constrained in the WS-ServiceGroup as MembershipContentRule defined either in the form of WSDL portType or WS-ResourceProperties. The use of XML Schema and WS-ResourceProperties facilitates further elaboration the membership policy by coupling semantics with MembershipContentRule. Thus WS-RF communities can be formed on the basis of semantic defining the application data, application operations or both of them without any additional support from the WS-RF engines. The default reliance of WS-RF on XPath as query language and adding the semantic in the form of WS-ResourceProperties make it easier to query the semantic information and relate it to the local knowledge base.

5. PROTOTYPE

Currently available P2P systems tend to use protocols which are proprietary and independent of other networks, incapable of leveraging their services. For example, Gnutella [20] defines a generic file sharing protocol and Jabber [21] defines an instant messaging protocol, but none of these protocols are interoperable. Each system creates its own P2P community, duplicating efforts in creating software primitives required by P2P systems, such as managing underlying physical network. Initial prototype for community formation [3] is developed in JXTA [23]. Details and result of our initial prototype are discussed in [3].

For later release we have re-designed the architecture to accommodate Web Services due to broader acceptance of Web Services and WS-* supporting specifications in the Grid Community. WS-RF was the automatic selection for the community formation due to its build in support for VO in the form of WS-ServiceGroup and WS-Resources. The Globus Toolkits has Monitoring and Discovery System (MDS), which defines and implements mechanisms for service and resource discovery and monitoring in distributed environments. MDS extensively uses interfaces and behavoiors defined in the WS-RF and WSN specifications and can be easily integrated with other standard implementations. MDS architecture and the relevant Web Services interfaces allow users to discover resources and services, monitor their states, receive changes in the status and visualize monitoring results. MDS can be used to implement large-scale distributed monitoring and distributed systems. MDS manages ContainerRegistryService and DefaultIndexService; and when new instance of Resource is created through Factory/Instance pattern it is added in the DefaultIndexService. Each Resource itself decides the amount of information it wants to expose; and this information is usually the subset of ResourceProperties in the WS-Resource.

The key issue in selecting the ResourceProperties to be advertised in the VO; is the one which are aligned with the WSDM-MUSE requirements. WSDM-MUSE provides uniform interface for similar WS-Resources; to query their properties and management operations. Each member within the community fulfills the membership requirement and exposes identical ResourceProperties therefore they all can be managed by single WSDM-MUSE interface which is the case with Competing Community. It is also possible that within the community their can be different type of Resources; this is the case when VO has multiple membership criteria in the form MembershipContentRule for Co-operative Community and multiple WSDM-MUSE interfaces are required for each type of resource/service.

WSDM-MUSE operations are specific to the nature of resource; due to varying nature of the resources it was not possible to have generic operations for every resource/service; although it is possible to have single WSDM-MUSE monitoring other management interfaces in a limited fashion. Standard manageable resource definitions create an integration layer between resources (Resources may be using different protocols and programming languages) and users/administrators. WSDM creates a free agent Web services proxy capable of communicating with multiple resources, breaking the classic model of the proxy being a wholly dedicated to single resource/service.

The main benefit of using WSDM is its "Co-relatable Properties" which defines the properties that together determine if two manageable resources with different identities are still the same resource. Concept of "Co-relatable Properties" helps to manage same resource/service which can be in different VO's and is managed by multiple independent policies. Each ResourceProperty itself is the Notification Topic; and VO and management interface subscribe for notification for any update in the state. In case of Community of Communities top level VO gathers information from constituting VOs at regular intervals (retrieving information from its local index); it also subscribes to the changes in the local index. In MDS and WSDM information related to each resource/service is kept as ResourceProperties; which makes it possible to utilize notification mechanism for dynamic discovery and monitoring leading to soft state nature of registration, indexing and monitoring. The extensive use of XML Schema to declare data makes WS-ResourceProperties as the ideal candidate for attaching the semantic to the resource and service. Semantic information is coupled with the service as WS-ResourceProperties means possibility to manage/update the semantic at run time through general purpose WS-ResourceProperties operation life add, update and delete. In the prototype flexibility in the WS-ResourceProperties is achieved by heavy use of data type "xsd:any", to bind any type of data with the WS-ResourceProperties for semantic information.

6. CONCLUSION

In this paper we have presented the concept of categorizing peers in communities on the basis of their expertise and interests. We have suggested Web Services based Community formation due to its broader acceptance, platform independence and interoperability. Vanilla Web Services lack the notion of state and stateful interactions, resource lifecycle management, notification of state changes, and support for sharing and coordinated use of diverse resources in dynamic 'virtual organizations' [4]. WS-RF specifications are designed on top of Web Services specifications to provide missing components. WS-RF along with the WSDM makes the best combination not only for community creation but for community management. Community creation and community discovery is addressed by WS-ServiceGroup Specifications and WSDM provides the missing bit of monitoring and management. WS-ServiceGroup and WSDM is powerful tool to manage dispersed resources; but their effectiveness relies on the other WS-RF specifications and Web Service Notification.

Host Based Intrusion Detection Architecture for Mobile Ad Hoc Networks

Prabhudutta Ray, Center for Development of Advanced Computing, Noida, India; E-mail: mtechray@yahoo.com

ABSTRACT

Mobile ad hoc network is a collection of mobile hosts, which can communicate with each other using wireless interfaces and can also dynamically form a network topology where each node can act as router to forwarding the packets to other nodes. These networks are in high demand due to the ease and speed in setting up such networks. Due to the inherent vulnerabilities of wireless medium and node mobility make such network highly susceptible to malicious attacks. Things are getting worst when some nodes getting hijacked or compromised and make this network to stop from the smooth workings. This paper proposes the host based intrusion detection architecture to identify the malicious node and provide security support to continue the smooth workings of this network.

Keywords: HAR, ACM, ARP, CM, ADM, MDM, HDD, SCM etc.

1. INTRODUCTION

Mobile ad hoc network (MANET) has become an exciting and important technology in recent years because of the rapid development of wireless devices. MANETs are highly vulnerable to attacks due to the open medium, dynamically changing network topology, lack of centralized monitoring and management point and lack of clear line of defense. Since mobile nodes are autonomous devices that are ready to capable of roaming independently and due to roaming, network topology changes dynamically. The nature of the mobile nodes makes the network very vulnerable to an adversary's malicious attacks. First of all the use of wireless links renders this network susceptible to attacks ranging from passive eavesdropping to active interfering. Second, the nodes with inadequate physical protection are receptive to being captured, compromised and hijacked. Since identifying a particular mobile node in a large scale network cannot be done easily, and attacks by a compromised node from inside the network are far more damaging and much harder to detect. Therefore, all the nodes in this network must be prepared to provide its own security to operate in a mode that does not have any centralized administration and trust no peer. Due to decentralized nature of decision-making, many network algorithms rely on the cooperative participation of all the other nodes in the network, which creates a great problem for this network. Since any adversaries can capture any node to exploit this vulnerability for new types of attacks designed to break the cooperative algorithms. Further packet routing creates vulnerability in the ad hoc network, because most of the ad hoc routing protocols are also co-operative in nature. Since the nodes are acting as router, unlike with a wired network, where firewall and extra protection can be placed on routers and gateways to provide extra security. So an adversary who hijacks an ad hoc mobile node could paralyze the entire wireless network by injecting false routing information and intentionally dropping the packet so that false routing information conclude in messages from all the nodes being fed to the compromised node and it can dropping the packet to waste the valuable resource of this network. In summary, history of security research for mobile ad hoc network provide intrusion prevention measures, such as encryption and authentication, can be used to minimize the intrusion, but cannot eliminate them. For example, above measures cannot defend against compromised mobile nodes, which act as master for several slaves in a clustered network architecture, which carry the private keys of other slaves in that cluster. The dynamic nature of the ad hoc network also means that trust between the nodes in the network is virtually non-existent. Without trust, preventive measures are unproductive and measures that rely on a certain level of trust between nodes are susceptible attacks themselves. Further no matter how many intrusions prevention measurers are inserted in a network there are always some weak links that one could exploit to break in. Intrusion detection presents a second wall of defense and it is a necessity in any high-survivability of this type of network.

2. SURVEY OF INTRUSION DETECTION ARCHITECTURE

Since fixed network based computer system there are several points where the monitoring activity can be performed to protect the devices which becomes the target of an intruder. An intrusion can be defined as "any set of actions that attempt to compromise the integrity, confidentiality, or availability of a resource", when it takes place, intrusion prevention techniques, such as encryption and authentication are usually the first line of defense. But the scalability and complexity of the ad hoc network address exploitable weakness in the system due to design and programming practice of various autonomous nodes. Such as vulnerabilities like buffer overflow, static buffer flows and memory leakages can waste significant amount of electrical power and intensive processing drains. So we have to avoid the situation whereby the device has to do more routing in the ad hoc network. The primary assumptions of intrusion detection are the node activity in terms of user and program activities are observable via system auditing mechanism during a particular session of the node activity and differentiate between normal and intrusion activities. So intrusion detection therefore involves capturing audit data of the session and reasoning about the evidence in the data to determine whether the system is under attack. Based on the session audit data of the host, which supplied by the operating system or maintaining the audit data by special mechanism, IDS can analyze and monitor the events to find that whether the activity is belonging to any normal behavior or not. Though each node in the network act as router but this paper does not consider any network level examination of the packet.

3. CATEGORIZATION OF IDS MODEL

intrusion detection model can be categorized into misuse detection and anomaly detection. Misuse detection model: - detection is performed by looking for the exploitation of known weak points in the system, which can be described by a specific pattern or sequence of events or data (the" signature" of the intrusion).

Anomaly detection model: - detection is performed by detecting changes in the patterns of utilization or behavior of the system. This is the type of intrusion detection described in [1]. It is performed by building a statistical model that contains metrics derived from system operation and flagging as intrusive, if any observed metrics that have a significant statistical deviation from the model. Conceptually, an intrusion detection model, i.e., a misuse detection rule or a normal profile, has major two components:

- The features extraction (or attributes, measures), e.g. "the number of failed login attempts", "the number of opening of Vi editor", the manipulation of bash_profile file ", etc, that altogether describe a logical event, e.g. user manipulation of system files and environment variables.
- The modeling algorithm, e.g. rule –based pattern matching, that uses the features to identify intrusion.

The main advantage of misuse detection is that it can accurately and efficiently detect instances of known attack that is already specified in the system but unable to detect newly (truly innovative) attacks. Anomaly detection systems, for example, IDES [2], flag observed activities that deviate significantly from the established normal usage profiles as anomalies, i.e. possible intrusions. The main advantage of anomaly detection is that it does not require prior knowledge of intrusion and can thus detect new intrusion, but it may not be able to describe what the attack is and may have high false positive rate. Since defining a set of

predictive features that accurately capture the representative behaviors of intrusive or normal activities and extracting abnormal features from the data that quickly identify the intrusive activity in the system is the most important step in building an effective intrusion detection model which can be independent of the design of modeling algorithms.

4. PROBLEMS OF THE EXISTING IDS TECHNIQUES AND ITS LIMITATION

Since ad hoc networks neither have any centralized administration, nor have any traffic concentration points where the IDS can collect audit data for the entire network. Therefore, at any one time, the only available audit trace will be limited to communication activities taking place within the radio range, and the intrusion detection algorithms must be made to work on this partial and localized information [3].

A scenario of this problem can be seen in the following. Suppose IDS on a mobile ad hoc network are communicating with a certain encryption algorithm. Once an attacker compromises the security of one node in the network, it can send a message to all of the neighboring nodes conveying the need to change the encryption algorithm because due to an attack the attacker gain control of the network. Since the compromised node is communicating with the authorized encryption algorithm, the other nodes in the network trust the compromised nodes decision, and change the encryption algorithm for the network. This could lead to a type of availability attacks on the network. Since the nodes are busy trying to change the encryption keys by using intensive processing power, the IDS takes up a lot of the communication bandwidth between nodes, making the other, regular communication between nodes very slow. Further scalability is limited because distributed data collection can also cause problems with excessive data traffic in the network. Further it is also difficult to reconfigure or add capabilities to the IDS when network is fully operational. In summary, it must be needed to answer the following research questions in developing an ideal intrusion detection system for the mobile ad hoc networks

1. What architecture of the system is necessary for developing intrusion detection and response systems that fits in the mobile nodes and run continually with minimal supervision?
2. What are the suitable appropriate points to collect audit data of the nodes?
3. How to find out anomalies which depends on the partial, local audit traces –if they are the only acceptable audit sources?
4. How do we impose a minimal overhead on the system where it is running, so as to not interfere with its normal operation and run independently?
5. What is a good model of activities in a wireless communication environment that can separate anomaly when the nodes under attacks from the normalcy?
6. Finally due to resources constraints on the mobile nodes, IDS should not consume too much resource including power, processing time; therefore IDS should increase the run-time efficiency?

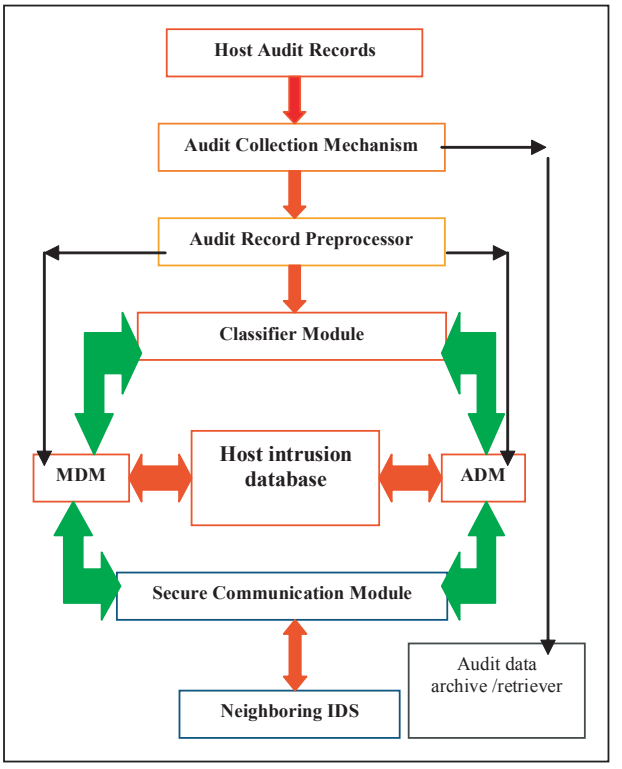
Considering the above all issues it can be found that if the design of IDS architecture are standalone for each host then they can detect attacks independently to decrease the co-operation between nodes and also takes the major decision locally. In order to provide protection to the individual nodes in the ad hoc networks it is required to constantly monitor the activity performed on the individual host so that unnecessary communication with other nodes can be minimized.

5. PROPOSED ARCHITECTURE

Host based system architecture are concerned with what activity is happening on each host. This architecture is ideal if it is able to detect actions and other activities with high confidence. In order to function properly, IDS has to be installed on every node in the network to processes and perform analysis on the audit data gathered locally, at the expense of the already limited resources on the hosts. The below architecture takes care to ensure that the IDS running on each host does not drain resources more than necessary. Here all the modules work collectively at the same time to provide the necessary support for the intrusion detection in the network.

The proposed architecture has eight parts, a) Host Audit Records (HAR), b) Audit Collection Mechanism (ACM), c) Audit Record Preprocessor (ARP), d) Classifier Module (CM), e) Anomaly Detection Module (ADM), f) Misuse Detection Module (MDM), g) Host Intrusion Database (HID) and h) Secure Communication module (SCM).

Figure 1. Graphical representation of a proposed host based IDS



a) Host Audit Records (HAR)

each operation of a host should be recorded to check that whether an intrusion is taking place. The local host audit record will consist of specific items out of the network traffic as well as user commands of the node. HAR is responsible for collecting useful information to minimize the volume of the audit data, responsible for gathering and storing not to processing it.

b) Audit Collection Mechanism (ACM)

This module usually passes the audit records to both the modules, one is Audit data archive/retriever, for the session duration storage, and to the Audit Record Preprocessor. The audit data archive /retriever can support as a simple buffer that writes the session oriented raw audit data into audit files or as sophisticated as a custom database management system used to store and retrieve audit data.

c) Audit Record Preprocessor (ARP)

This refers to one or more individual preprocessors used by IDS to isolate and format certain audit records prior to inputs into the other modules. Some records of the ongoing activity of the users must be maintained to provide as input to the intrusion detection system. In this module detection specific audit records are created from the host audit records. Each record contains the fields like subject, actions, object, exception-condition, resource-usage, time-stamp etc. This formatted audit records are providing structured and system specific useful information, which are passed below to the three individual module (MDM, CM, ADM) of the IDS. These individual modules are independently process the each audit records to determine any new intrusion has occurred or any malicious activity is performed by the host or not [4].

d) Classifier Module (CM)
Classification algorithms have attracted considerable interest both in the machine learning and data mining research areas [5]. In this architecture the classifier module basically concentrates on the decision tree approach. Objective is to use learning algorithm such that it is good if it produces hypotheses that do a good job of predicting the classification of unseen attacks. Audit record preprocessor (ARP) module provides structured and system specific set of records. Each record has the structure, consisting of a number of attribute value pairs. One of these attributes represents the category of the record. Basic approach is to determine a decision tree that on the basis of answers to questions about the non category attributes predicts correctly the value of the category attributes which takes only the values {attack, Don't attack}. From the tree construction, this module in the IDS properly does classification and finding new attacks. The use of the decision tree-learning algorithm is to test the "most important" attribute first, which makes the most difference to the classification of an example. That way, it can be hoped to get to the correct classification with a small number of tests, meaning that all paths in the tree will be short and the tree as a whole will be small so that it will provide faster approach to detect attacks on the node.

e) Anomaly Detection Module (ADM)
Each ADM is responsible for detecting a different type of anomaly. There can be many ADM modules based on the complexity of the IDS architecture. Each working separately or co-operatively with other ADM modules based on the processing load, e.g. .one is looking for file access frequency, while another might watch user input speed. In this architecture ADM will analyze data, compare with known profile which already defined, run the statistical analysis to determine if any deviation is significant, and flag the events as a true attack state, false attack state, or normal state. If it finds a false positive, then profile must be updated to reflect the results. Since in that case it making bridge with the classifier module (CM) to identify new types of attack occurred in the node. ADM's activity is to update profiles and checks for anomalous behavior whenever an audit record is generated or a session terminates. If abnormal behavior is detected, an anomaly record is generated having three components <Event, Time-stamp, and Profile>[6]. These generated records are compared with the audit record preprocessor input to conclude for an attack and then matches with the classifier module. If an ADM can identify an anomaly based on the data in the Host intrusion database, then it can initiate a local and global response to the intrusion. An example of a local response could be to stop communication to the identified node, rendering it useless to an attacker. A possible global response would be to use the secure communication module to alert other nodes in same cluster or in the other cluster, allowing them to configure a new network topology by excluding the designated compromised node. If the amount of data in the HID and CM is not sufficient to determine if the present activity should be as an intrusion, then it is possible for ADM to use the secure communication module to query the other nodes in the network to get help in identifying an intrusion [7].

f) Misuse Detection Module (MDM)
Detection is performed by looking for the exploitation of known weak points in the system, which can be described by a specific pattern or sequences of events or the data (the "signature" of the intrusion). Here the collections of signatures (representative patterns) define the known attacks [8]. The primary purpose of MDM is only to identify the known patterns of attacks that are specified in the local intrusion database. It also gathering sufficient information from the CM module about the specification of new attacks, accordingly it can update the rule sets. MDM takes the audit data for analysis and compares the data to HID for attack signatures. The attack signatures are normally specified as rules with respect to timing information and are also referred to as known attack patterns. If any comparison made between ADM and MDM, then it can be find that MDM'S job is to only identify known patterns of attacks that are specified in the host intrusion database. If MDM needs more information from the other neighboring nodes then it should use the Secure Communication Module to interact with them. Using the information provided by neighboring nodes IDS, then MDM might be able to predict an intrusion with more accuracy.

g) Host Intrusion Database (HID)
HID is a database maintaining in the nodes that warehouses all the information necessary for the IDS, such as the signatures of known attacks, the established patterns of users and resource usage and the normal volume of data flow in the network. The ADM and MDM communicate directly with the HID to determine if an intrusion is taking place.

h) Secure Communication Module (SCM)
SCM is providing necessary communication with other IDS on the network. It will allow the MDM and ADM to use co-operative algorithms to detect intrusion [9]. This module initiates a global response when an IDS of a node or a group of IDS of several nodes detects an intrusion. Basically, to provide security in a wireless medium it is required any communication that must be occurred from one node to another will use the SCM. Since Buttyan et.al. [10] discuss the problems regarding any public-key based security system to make each user's public key available to others in such a way that its authenticity is verifiable. In ad hoc networks, this problem becomes even more difficult to solve because of the absence of centralized services and possible network partitions [11]. Since data communication via SCM will need to be encrypted in order to ensure the data received by another IDS is accurate and has not been modified in any way. This module is only used by the IDS to exchange security related information between nodes and also share the necessary bandwidth that mobile devices uses for normal data transmission. So it is required to be efficient and fast, and can only use the amount of bandwidth it needs when transmission required. Efficiently managing the bandwidth for normal data transmission for mobile devices is another issue for IDS design also [12].

6. CONCLUSION
This paper has discussed several new issues and ideas that must be addressed when designing intrusion detection systems for mobile ad hoc networks. Even if the prevention schemes are perfect and implemented correctly, there are still internal and insider attacks that utilizes software vulnerability. A compromised node is an insider, with all the necessary cryptographic keys, and if it elected as a cluster head then it can launch many attacks. Thus, intrusion detection system should be designed in such a way that it can provide a necessary level of protection to the node and network and work independently without minimum human supervision. Through continuing investigation, it can be shown that this architecture is well suited for better intrusion detection in wireless ad hoc network that are distributed and co-operative in nature. Furthermore, the modular characteristics of the architecture allow it to be easily extended, configured and modified, either by adding new components, or by replacing components when they need to be updated. Such as it is possible to modify the audit record preprocessor module to provide more structured format of output. Application of this architecture might prove helpful in networks that are dynamic in nature, such as a group of tanks roaming in the desert, emergency response teams, and law enforcement etc.

7. FUTURE WORK
Future work includes implementation of such IDS architecture and testing its effectiveness in mobile ad hoc networks environments. Further enhance the capability of classifier module, so that it detect the attacks with minimal amount of time and provide useful information to the ADM and MDM module, to increase the effectiveness and scalability of this proposed architecture.

ABSTRACT

Educational development and reform for any nation have always been characterized by the government's efforts to adapt education to national development needs. The heart of educational development and reformation, as in for developed and developing countries, has always been basic and technical education development with an aim to provide quality education for human resource development to meet the needs of the social, economic and political development of the country. The first section will conceptualize the role of ICT in developing economy and the global trends in ICT Practices, while the second section will give a brief of country profile, economic profile along with the impact of the peace agreement in Sudan, and will also highlight the present education system in Sudan stressing on the state of higher level education.

Keywords: ICT, Higher Education, Developing Countries & Education System.

INTRODUCTION

Information and communication technology (ICT) has become, within a very short time, one of the basic building blocks of modern society. Many countries now regard understanding ICT and mastering the basic skills and concepts of ICT as part of the core of education process, alongside reading and writing. Within the past decade, the new ICT tools have fundamentally produced significant transformations in industry, agriculture, medicine, business, engineering and other fields. They also have the potential to transform the nature of education-where and how learning takes place and the roles of students and teachers in the learning process.

ICTs have changed the nature of work and the types of skills needed in most fields and professions. While they have, on the one hand, created a wide array of new jobs, many of which did not even exist ten years ago, they have also replaced the need for many types of unskilled or low-skilled workers. These trends pose new challenges to educational systems to prepare students with the knowledge and skills needed to thrive in a new and dynamic environment of continuous technological change and accelerating growth in knowledge production.

ROLE OF ICT IN DEVELOPING SOCIETY

Information technology presents tremendous challenges and opportunities to society. The manner in which the country meets the challenge of information technology will largely shape its economic and social future into this century. A spectacular array of knowledge and information interchanges and processes lies at the heart of the information age. The capability of peoples and communities to be educated and trained in these new technologies is central to the appreciation and mastery of this new age.

The role of education and training aspects of ICT in capacity building & developing economy:

The challenges of the information age are not confined to any one sector but pervade all sections of society. Technological changes are leading to pressures on politics, work, education and social organizations. And these changes are going to force change as profound as that shaped by the industrial revolution, but at a much far faster pace. The question is not whether profound change will happen, but how our existing social structures will adapt themselves to these inevitable changes. The use of training and education will largely determine how these structures can deal with today's rapidly changing society.

Third World Nations need to develop an effective science, technology and innovation policy to spearhead this drive. Such a policy must be directed at specific actions such as research and the transfer, diffusion, rapid absorption and application of technology, with particular emphasis on the greater use of information technologies. In addition to the broad, societal needs outlined above, there are a number of specific sectoral needs of the information age.

Education it is clear that any society wishing to capitalize on information technology must invest heavily in education. Educational institutions must not only gear their efforts towards enabling people to master the complex and rapidly changing technologies themselves but also need to explore how such advances can be linked to, and influence, the wider business and commercial world. Degree, Diploma and specialized certificates programs, in particular, have a vital role to play in meeting the challenge ahead.

Training is a fundamental requirement of the information age. Countries coming to grips with competition and change in a dynamic and external environment should emphasize on more training. New entrants to the labor market must be trained in the skills and technologies associated with information technology, and existing public and private sector staff must be moulded to perform different tasks in a more flexible and innovative manner.

EDUCATION AND TRAINING FOR TECHNOLOGY

It has been argued by educationists and reformists that in striving to meet the wide ranging needs of IT, country's higher education system must maintain a strong diversity. Even vocational higher education is not that far inferior to university education. Society needs a broad continuum of graduates with different mixtures of knowledge and skills. It is required to have variety and flexibility in form, context, length, access and output. In this context, many students are taking the Private Technical College route specializing in areas of ICT and computers, which commands a very strong job opportunities in this sector.

Tertiary education can play a vital role in helping Third world Nations to exploit new opportunities in the information technology sector. Innovation, based on the application of science and technology, is now the mainspring of international economic competitiveness for any developing economy of the world.

Training should be seen as an investment rather than a cost and should be the focus of strategic planning like in most of the competitive economies. Training initiatives undertaken by developed nations bring many spin-off benefits to the wider economy, those having abundant natural resources and scope for development. The information age also requires emphasis on technical training to ensure that the labor force has the right skills balance.

GLOBAL TRENDS IN EDUCATIONAL ICT PRACTICES

As mentioned clearly by Middlehurst (2003) in his study on challenges and choices for Higher Education Institutions that increasing faith in the power of technology has seen an enormous increase in the use of ICT in education institutions world wide. This trend has further led the emergence of a number of non-traditional

HE providers competing for the student population among themselves, and with the traditional university.

Nowadays, the traditional university no longer has hegemony over the provision of higher education. In rising to the new challenge, it is turning to ICT to improve the quality of its operations, and also to reach for students in destinations beyond the traditional physical boundaries. At the same time the increasing use of ICT in higher education institutions is set within a context of wider economic, social, and political changes affecting countries worldwide.

Thus, the rationales and choices made by institutions for their ICT applications are influenced by a variety of macro and micro environments, and consequent perceptions of competition and the need for collaboration. Issues such as the digital divides, literacy limitations, financial constraints (largely developing countries), changes (increases) in student enrolment numbers (which is a global phenomenon), global technological developments, and competition between and among HE institutions and the emergent providers of higher education (global phenomena), are examples of the forces that drive change contexts (Middlehurst, 2003).

We can give examples from some countries that are also in process of implementing ICT in the higher education system for nation's growth:

AFGHANISTAN

Currently undergoing a large scale restructuring effort, Afghanistan has neglected its educational system because of recent wars and political instability. In this effort of gaining a centralized educational system, television sets are being sent to various villages across the country, and the aim is reaching students with educational broadcasting.

NEPAL

Nepal is an agricultural country that has an income per capita of less than US$ 250. More than four fifths of the population depends on agriculture as the main economic activity. The major ICT investment is the scholarships granted by the Ministry of Science and Technology to the unemployed youths

SUDAN: COUNTRY PROFILE

With an area of 2.5 million km^2, Sudan is the largest of African countries. Its vast size permits considerable variations in relief and vegetation: the north is a rainless desert; in the center there are wooded Savannah lands receiving monsoon rains ranging between 500 and 1500 mms annually; thick equatorial forests cover southern parts where precipitation reaches 1800 mms.

With strategic position in Africa, neighboring nine countries, and huge natural resources including the new discovered oil and gold and with the settlement of the southern Sudan conflict and the signing of peace agreement, the country became viable to receive financial and technical support from various donors.

ECONOMY OF SUDAN

Sudan's primary resources are agricultural, but oil production and export are taking on greater importance since October 2000. Although the country is trying to diversify its cash crops, cotton and gum Arabic remain its major agricultural exports. In recent years, the GIAD industrial complex introduced the assembly of small autos and trucks, and some heavy military equipment such as armored personnel carriers.

Extensive petroleum exploration began in the mid-1970s and might produce all of Sudan's needs. Significant finds were made in the Upper Nile region and commercial quantities of oil began to be exported from October 2000, reducing Sudan's outflow of foreign exchange for imported petroleum products. There are positive indications of significant potential reserves of oil and natural gas in southern Sudan, the Kordofan region and the Red Sea province.

In recent times, the government has worked with foreign partners to develop the oil sector, as a result of increased oil export, Sudan earnings from this sector have gone up from $500 million in 2000–01 to $1500 million at the end of 2005.

Some of the economic indicators of Sudan in recent years are presented in Table 1.

It can be observed from the above table that the economy of Sudan has improved over the years and with the recent peace agreement it will continue to stride in the areas of development.

SUDAN PEACE AGREEMENT

The government of Sudan and the Sudanese People's Liberation Movement (SPLM) in the South has signed a permanent peace accord, ending Sudan's 21-year civil war. This is a final comprehensive peace agreement. It is the culmination of a more than two years of intensive negotiations which was mediated by the regional Intergovernmental Authority on Development (IGAD). This peace agreement marked the end to 21 years of civil conflict that has claimed the lives of more than two million people and displaced four million more from their homes. A peaceful Sudan would serve as an engine for growth and breadbasket for East Africa once oil revenues and other resources are used for rebuilding infrastructure, economic development, and education.

EDUCATION IN SUDAN

Education is envisaged to equip recipients with knowledge and skills and assist to constitute human capital that empowers them to promote new values and to bring about change in their lives and in their communities. The educational system in the country therefore exercises a determining influence on the socio-economic and cultural development in the country.

On the other hand education promotes labor productivity growth and social development and spreads value and solidarity, tolerance social justice and environmental awareness for women, education in addition to its high private rates

Table 1. Sudan economic indicators

Indicators	1995	2000	2003	2004	2005
Current account balance (Billion US$)	-1.475	-1.84	-1.457	-1.366	-1.089
GDP based on (Purchasing Power Parity) per capita GDP (US$)	1295.69	1779.91	2025.334	2127.666	2220.681
GDP per Capita, current price (US$)	257.192	391.978	529.726	586.46	643.31
GDP current prices (Billion US$)	7.189	12.191	17.793	20.211	22.747
Inflation (Index, 1995=100)	100	501.05	613.142	652.996	692.176

of return, is found to be inversely connected with fertility and to increase child survival rates and better health.

The provision of basic education for all depends on political commitment and political will backed by appropriate fiscal measures public, private and voluntary.

As for higher education in a development setting:

As the nature and dimension of socio-economic and cultural factors have significant bearing on the quality of life of people, the search for solution for bringing about desirable improvement has been a continuing process in which the role of human resources development through education is duly emphasized.

The impact of development of human resources is intense and pervasive on all sectors of growth and is closely associated with the system of providing education and training. The effectiveness of the educational system is, however, primarily dependant on the availability of adequate finance to meet the requisite costs of the provision for the development of higher education and research.

The system of higher education, being chiefly responsible for preservation, generation and dissemination of knowledge and skills of the highest order, exercises a determining influence on the socio-economic and cultural development in the country. A World Bank report identified universities in developing countries as having three major roles:

a. Producing high level manpower to fill scientific technical, managerial and teaching job.
b. Carrying out research to generate knowledge and innovation relevant to the country's development.
c. Providing advisory services to assist development.

Noting that the principal output of higher education, are high level manpower, knowledge and innovation (research) and development advisory services, the World Bank identified number of hypotheses which can be reformulated in the context of Sudan. Higher education in Sudan had mirrored the different phases of economic and social change in the country.

The institutions of higher learning in the country, particularly specialized universities and colleges, have to use non traditional higher education infrastructures with a view of availing more efficient modes of learning. The installation of adequate infrastructures and intensive training of and the setting of knowledge information storage servers and date bases and e-learning platforms are mechanisms to serve that purpose.

HIGHER EDUCATION SYSTEM IN SUDAN

Higher education plays an important role in providing the generation with the necessary knowledge, values and skills to shoulder the responsibility of the overall development and to play their roles in different walks of life. Higher education provides the society with the intellectual, professional, scientific, educational, political, cultural and administrative personnel for development. It is considered the main tool for development and the more vivid source for scientific research.

Higher education is provided by universities, both public and private, and institutes and colleges of technical and professional education. The National Council of Higher Education is the government body responsible for higher education. Since 1990, many government universities have been created, mostly in the provinces. A few private tertiary institutions have also opened.

  b) University level second stage: Master's Degree.
  c) University level third stage: Doctor of Philosophy.
  d) University level fourth stage: Higher Doctorate.

The National Comprehensive Strategy in the education domain:

In the field of higher education, the National Comprehensive Strategy has got concerned with realizing the resolutions of Education Revolution with the objective of achieving the following:

1. Revising higher education legislation and laws.
2. Increasing the number of higher educational institutions.
3. Qualifying of teaching staff.
4. Authentication of knowledge.
5. Encouraging scientific research related to the solution of the country's development, economic and social problems and linking the higher education with the environment and society.

EXPANSION OF HIGHER EDUCATION

The first half of the decade of the nineties witnessed the expansion of higher education through out the Sudan. The number of universities has increased from 10 in 1990 to 54 universities in 2005. Also public higher Institutions have increased from 7 in 1990 to 27 in the year 2005. The government of Sudan believe in the necessity of expanding higher education to meet the community demands and to reach international rates which in some countries reach 60 % of those in the age group 18 - 24.

ICT FOR HUMAN DEVELOPMENT & EDUCATION IN SUDAN

Despite the high tide of expansion in the field of ICT that shaped the international relations in today's economic and social life, resulting in unprecedented human advancement though out history of mankind, yet the benefits of putting to use ICT is not evenly realized by developing countries especially in Africa. This is attributed to a number of reasons, to mention a few, the non-preparedness of most of the countries in terms of institutional and operational capacities for running ICT system.

Sudan experience of the last two decades in building and capitalizing on ICT as a gateway for sustainable development is a landmark in Sudanese history. The experience tells how the institutional, legal and regulatory frameworks were reformed to advance ICT as tools for integrating the economy into the global market spheres. Moreover, staging a country, long been isolated and burdened by foreign debt, to new development horizons.

It is worth mentioning here that still the roles and functions of teachers in the standard classroom setting has not changed due to the traditional instruction methods used. The students are still taught through verbal instruction, and do not have the chance of autonomous hands-on execution of ICT possibilities. Moreover, as the curriculum undergoes frequent changes, the available software becomes insufficient, and the teachers are limited in terms of exploration possibilities.

Development in ICT in Sudan is represented by a gallant expansion of infrastructure and capital investment including management systems and human capital. Still areas pertaining to expanding the ICT markets in terms of product, distribution, quality of ICT products measured by their suitability to broader use, and affordability of the services.

Importantly establishing the link and measures with the economic and employment opportunities for individuals as well as society at large. These poses stubborn challenges to ICT advancement that would really support its expansions and reduce the risks of unguided competition that would probably lead to diminishing returns on investments and ultimately lead to crowding out effect of the actors adopting supply led strategy rather than demand pull strategies.

In view of the above, the UNDP is intervening to assist the government through its ICT institutions to collectively part sharing the interventions that promote ICT for human development and education. A process, which will assist formulating national strategy involving all stakeholders within the UN ICTD programme framework.

DEVELOPMENT STRATEGY TO NARROW THE DIGITAL GAP

ICT investment requires a tremendous amount of resources, particularly in the current period after the oil exploration in 2000. The program to narrow the digital gap should, therefore, carefully design and implemented. At least two primary concepts should be taken into account in developing the strategy.

Table 2

Program	Projects
Informatics Polices & Legislations	1- Drafting & ratifying Informatics & related Financial Legislations.
Establishment of a National Information Network	1- Drafting & ratifying National Information Network Law. 2- Design of Database and its Operating System. 3- The Interconnection of Local Networks. 4- Training.

Informatics Services	1- The program of the Digital Library. 2- Assessment of size of the present Information Services.

Source: Ministry of Higher Education and Scientific Research, January 2004

The first basic strategy is to make use as much as possible the existing domestic capacity, human resources as well as hardware infrastructure. For domestic connectivity, the strategy should be designed to capitalize from the existing communication infrastructure (fiber optic, copper, satellite, and microwave). Such concept will protect the higher education sector, as one of the social sector, from the technology's high obsolescence rate.

The higher education sector, collectively, is a large market for any domestic providers. Although the population who can afford using the ICT infrastructure is mostly between 40-50 years old, a substantial proportion of it does not possess adequate IT skill. Investing in younger generation, as a potential customer for the future is, therefore, imperative for ICT service providers. The future is not too distant either, since within 3 to 5 years they will be graduates and become an individual user, or even representing their employer to become institutional users.

The second basic strategy is to rely on the new paradigm concept, which has been chosen as the strategy for the national higher education development. The concept that rely on merit based tiered competition, user participation through proposal based competition, and higher accountability, is considered as the best suited strategy for higher education.

CURRENT DEVELOPMENT PROGRAMS

Knowing the fact that ICT capacity is an essential part of the future knowledge economy [World Bank, 2001], the Ministry of Higher Education considers ICT development at high priority. Within the auspices of the Ministry of Higher Education there are a few ongoing programs being carried out.

CONCLUSION

The Information and Communication Technologies (ICT) provide very forceful instruments to bring higher education to the Third World. However, as has been pointed out in several of the studies reviewed, "technology by itself is not a solution to any development problem; it only provides an opportunity." Further, "a thorough and wide-spread development in Third World countries requires "not only electronic communication policies and regulation but also social aspects.

In order to avoid being marginalized in the future knowledge economy, human development has to be a top priority for the nation [World Bank, 2001]. The ICT could significantly contribute to the nation in providing opportunity to conduct efficient, and yet quality, higher education. Although the peace agreement and the economic development has a tremendous impact to the national capacity to reduce the digital division, a careful, selective, and well-targeted ICT investment program for higher education is well justified.

The ICT could play an important role in higher education sector, particularly by providing the necessary infrastructure for improving quality in the institutions in the country. In addition to the domestic collaboration, collaborative activities among the neighboring countries could also boost efficiency. The higher education sector in these countries has many similar problems that collaboration in solving common problems is strongly recommended. The ICT could play an important role in providing support for the collaboration to happen.

One important and general conclusion is therefore that in order to get a sustainable impact upon the development process of Third World societies, the development of ICT in these countries must be supported both by technical and non-technical applications of relevance to the situation in which people in the country concerned live. Only then will the ICT structures created, contribute towards a development that will benefit the people of the countries in which the ICT is implemented.

The Interface Design for Learning Environments via Web Using the Multiple Intelligences Theory and the Ergonomic and Usability Criteria

Simone de Paula Silva, CECIERJ Foundation/CEDERJ Consortium, Brazil; E-mail: simonepaulas@gmail.com
Cristina Pfeiffer, CECIERJ Foundation/CEDERJ Consortium, Brazil; E-mail: pfeiffer@cederj.rj.gov.br
Andre Vinicius Moraes de Costa, CECIERJ Foundation/CEDERJ Consortium, Brazil

ABSTRACT

Nowadays, the success of distance learning environments via web depends mainly on a well-designed interface for the user because teachers and learners are physically in different places and time. So, the instructional interface development process is a great challenge for distance education courses offered in these environments. The goal of this paper is to propose planning and methodology strategies to develop interfaces using the Multiple Intelligences Theory according to ergonomic recommendations and usability. It is also presented an application of the proposed methodology in the Natural Sciences in Education I course-discipline of the Pedagogy Undergraduate, Program, one of the six bimodal undergraduate courses offered by CECIERJ Foundation/CEDERJ Consortium. This Consortium is a partnership between the government of Rio de Janeiro State, Brazil, and six Public Universities located at Rio de Janeiro city.

INTRODUCTION

In a computer-based training environment, instructional interface elements should be those that are specifically designed to facilitate the learners´ access and participation. Fundamentally, their learning process once teachers and learners are physically in different places and time. This means that the success of the learning process in these environments depends on a well-designed user interface to help learners to guide themselves through instruction (Lohr, 2000). For this reason, ergonomic recommendations and usability in a design project should be considered.

On the other hand, the Information and Communication Technologies (ICT) progress are helping teachers to follow individually the learning process of their students. The ICT can also make possible to elaborate interfaces for web environments which can provide the student comprehension throughout symbol systems (linguistic, numerical, musician, graphic etc.), facilitating learning process for different cognitive styles. So, ICT are perfect to apply the Multiple Intelligences (MI) Theory approach defended by Howard Gardner (2001).

The goal of this paper is to propose a methodology to develop distance education interfaces for courses offered via web using the MI Theory according to the ergonomic recommendations and usability. It is also presented an application of the proposed methodology in the *Natural Sciences in Education I* course-discipline of the Pedagogy Undergraduate Program offered by CECIERJ Foundation/CEDERJ Consortium.

THEORETICAL FOUNDATION

Some important concerns (as ergonomic recommendations, usability of instructional interfaces) and the MI Theory that were fundamental to elaborate the methodology proposed in this paper will be developed now.

Ergonomic Recommendations and Usability of Instructional Interfaces

Hackos et al (*apud* 1998) and Marchionini et al (1995 *apud* Lohr 2000) showed that:

"The user interface is formally defined as the communication link between an environment (a product or system) and an user. It consists of objects or elements designed to communicate the function of the environment. An instructional interface by this definition can be thought as the elements that assist the user, a learner, in the task of learning. In a computer-based training environment, instructional interface elements are those that are specially designed to facilitate access to, and participation in, instruction and instructional support."

In agreement with Lohr (2003), the project of an educational interface is a challenging effort that requires instructional design and educational project knowledge as long as human and psychological factors, ergonomic research, computer sciences and publishing project. Many recommendations are available to attend the designer professional, but many among them do not fulfill with the specific necessities for educational environment. Nilsen (2000) says that "*many of the existing environment interfaces present problems in the information architecture, visual elements organization, interactivity and functioning"*.

Hall (2000 *apud* Silva , 2006) detaches that education based on web depend on the target public, the communication context and the virtual environment. Although designers must face these questions, a web-based course should consider the learning objectives which are the most important factors in guiding the entire creation process of the project development.

In this way, Fleming (1998) proposes to observe how people study in the internet and how are their expectations when using the learning environment. The interface should provide the knowledge of how a student should answer questions related to the browsing and to the learning.

Finally, it is important to understand that the interface design project for learning environments via web have to consider the target public identification (user), his/her objectives and tasks. Then, when the ergonomic and usability criteria are applied the quality of the interaction is guaranteed due to the teach-learning process.

The Multiple Intelligences Theory

The MI Theory (Gardner, 2001) can help a teacher to organize his work and to know well his students. This fact will be possible through a set of categories used to describe strong and weak characteristics of the students, within a special recommendation to avoid prejudices and/or stereotyping them [p.185, 186]. Using the MI Theory is easier to assign subjects, teaching methods, hardware, software and ways of evaluation in order to considerate the most strong intelligences that are revealed by the students.

At the beginning of the Eighties, Gardner has initially identified seven different human intelligences: the *linguistic intelligence* (sensitivity to spoken and written language, the ability to learn languages, and the capacity to use language to accomplish certain goals); the *logical-mathematical intelligence* (capacity to analyze problems logically, carry out mathematical operations, and investigate issues scientifically); the *musical intelligence* (skill in the performance, composition,

and appreciation of musical patterns)*;* the *bodily-kinesthetic intelligence* (potential of using one's whole body or parts of the body to solve problems); the *spatial intelligence* (potential to recognize and use the patterns of wide space and more confined areas); the *interpersonal intelligence* (capacity to understand the intentions, motivations and desires of other people)*;* the *intrapersonal intelligence* (capacity to understand oneself, to appreciate one's feelings, fears and motivations).

From 1997 and on, Gardner (2001, p. 63-79) has been identifying more three "new" possible *intelligences:* the *naturalistic intelligence* (applied to people who demonstrate great recognition and the classification of its environment); the *spiritual intelligence* (spiritual human predispositions) and the *existential intelligence* (capacity of pointing out the meaning of the life, the direction of the death, the final destination of the physical and psychological worlds).

There are some meaningful works in Education using the MI Theory. The SUMIT (Schools Using Multiple Intelligence Theory) Project, for example, was a 3-year national investigation which has involved 41 schools in the United States. It sought to identify, document, and promote effective implementations of MI. After this study, 78% of the schools have declared positive results in standardized tests; 63% have associated this success to the pedagogical practices used and based on the MI Theory; 78% have declared that there was an improvement in the learning process of the students with learning problems; 80% have declared an improvement in the participation of the parents and 75% of them have attributed the improvement to the MI Theory; 81% have declared that the students were more disciplined, and 67% of them have attributed this improvement on the students' behaviour to the MI Theory. Although these numbers can reflect an emphasis positive, it is also important to say that they were based on empirical data, that cannot be refuted by anyone.

Vicari (2005) has developed an experiment at Paulista University in São Paulo State, Brazil, which involved the application of learning activities with undergraduate students of Production Engineering. The MI Theory was applied as a pedagogical strategy on the learning process. The experiments have the intention to verify whether learning contents presented, according to the student profile, could facilitate the learning process, and whether learning contents not adjusted to the student profile could make the learning process more difficult. 92 experiments were taken: 41 according to the student profile and 51 in contrast. The percentage of consonant contents was higher than the percentage of conflicting contents. The conclusion of this case study was that in distance learning, when there is a previous knowledge of the student profile and individual learning styles based on the MI Theory, it is possible to present an adequated way in order to obtain better results in learning process.

The VLSM is an adapted model aligned with the philosophy of Saskatchewan Education University (Boulton, 2002). The virtual teacher´s task is to scaffold learning to support the learner in the use of VLSM design elements: layer 1- Instructional Strategies; layer 2- Multiple Intelligences, layer 3- The Organization Models; layer 4- ICT Genre. The layers of VLSM demand online instruction to utilize many different combinations of the four layers in order to meet different intelligences and learning styles (Witfelt, 2000 apud Boulton 2002). In the second layer (Multiple Intelligences), teachers will need to examinate their pedagogical beliefs and take into consideration the theory of Multiple Intelligences (Witflet, 2000; Bisho et al, 2001 *apud* Boulton 2002). The MI Theory suggests several other ways in which the subject material may be presented to facilitate effective learning. Meeting individual learning needs can be accomplished through the use of eight potential individualized instruction pathways.

CONTEXT OF THE CASE STUDY

CEDERJ Consortium (Distance Undergraduate Education Centre of Rio de Janeiro State, Brazil) is connected to SECTI (Innovation, Technology and Science State's Secretary of Rio de Janeiro) and associated to six Public Universities located at Rio de Janeiro city (UENF, UERJ, UFF, UFRJ, UFRRJ and UniRio). Since 2001, some bimodal undergraduate courses are offered: Computer Science, Biological Sciences, Mathematics, Pedagogy (Initial series of K12), Physics and Administration. The main goal of these courses were to socially include the students who can not study in a local University. In 2007, it will be offered some other courses: Chemistry, Geography, Pedagogy (complete course) and Modern Languages. Actually there are 14.000 registered students and 20 (twenty) regional centres spread all over Rio de Janeiro State prepared to assist the students during the course. The contents of these courses are developed by teachers who work at the associated Public Universities and edited by the CEDERJ staff to adapt the written pedagogical material to be presented in two ways: publishing and web-based material. Specifically for the web-based instruction, there are four multidisciplinary departments and each one responds for Biological Sciences, Mathematics, Physics and Pedagogy developing material (Silva, 2006).

The Pedagogy Program of CEDERJ was created to be completed in 3 years learning period, along 30 and 60 hours course-disciplines. There are mandatory courses-disciplines and others which are eligible by the student, according to the teaching methodology. The course-disciplines are offered to the learner through didactical printed material, digital material and web classes at CEDERJ e-Learning platform (http://www.cederj.edu.br). The students have presential and also long distance tutors to help them on the learning process. Long distance tutorial can be accessed through a public telephone, fax or at CEDERJ plataform. The tutors can use didactical printed material and web classes during tutorial meetings.

THE DESIGN OF WEB-BASED INTERFACES USING THE MI THEORY

This item describes planning and methodology strategies to develop distance education interfaces for web courses using the MI Theory accounting as also ergonomic recommendations for usability. It is also presented an application of the proposed methodology in *Natural Sciences in Education I* course-discipline of the Pedagogy Undergraduate Program of CEDERJ Consortium.

Planning Strategies to Design Web-Based Interfaces Using the MI Theory

In traditional "face-to-face" classrooms the teacher conducts, helps and promotes educational and learning process. On web classes, however, the interface should transmit the idea of being in an environment built especially for the student with an appropriated design. Moreover, the instructional interface design should offer a rich learning context minimizing the loneliness feeling, a frequent complain of distance education learners. Thus, a distance education interface via web should offer several resources in order to accomplish the learners-target needs, according to their individuality, their real life environment and also the aims of the learning activities. For planning and using learning strategies in the interface's design of a course-discipline, it must be considered (Silva, 2006):

- Target public (learners): identification of the system's user;
- Contents: what is accosted by each discipline/course and its pre-requisites?;
- Strategies: the relation between the course-discipline aims and daily matters;
- Concepts: which concepts have to be given to the target public (learners)?;
- Function: the course-discipline function related to the program;
- Mission (goals): course-discipline goals related to the program;
- Tasks: activities which have to be accomplished by students using the interface;
- Cognitive styles.

These eight elements above should be considered in order to create a metaphor conception that will be used in the hole interface design to construct the course-discipline environment for the web. The web designer should concern about the text language of each screen, so that the interface will not function only as a background. In this way, it is important to create a context and a visual identity that enables the discipline contents' organization and the insertion of learning activities inside the designed interface.

Resources or situations such as, for example, a video sample, are organized or included in the interface to promote the learning of a content / subject / theme. The function of this survey for the metaphor creation is to enrich or to propose an interface with interesting learning situations that help the student to attend a video, read a text, to participate on a debate about some subject with his classmates. These situations should be associated to different learning styles of the students and should contemplate all the multiple intelligences.

For Fleming (1998), it should be given opportunities for visual learners to view pictures or diagrams, for verbal/textual learners to hear and read explanations, and for active learners to learn through discovery or experience. It sounds quite daunting, but it's not as hard as it seems. Providing these different opportunities will make learners feel more at ease right from the start and will help ensure that they are not turned away by an approach that does not address their needs.

The ICT progress was made to become real the MI approach defended by Gardner. It is already possible to create computer programs or software directed toward different intelligences, programs that offer a variety of entry points allowing the students to demonstrate their understanding in various symbols systems (linguistic, numerical, musical, graphical etc.) (Gardner, 2001).

Applying the Strategies to the Interface Design of the Pedagogy Program of CEDERJ Consortium

The Education web staff is a multi-disciplinary team, composed by a coordinator and an instructional designer, both undergraduated in Education. There are also web designers, animators, illustrators and programmers.

The coordinator assembles the printed educational material of a particular course-discipline of the Pedagogy Program and selects a group composed by an instructional designer, a web designer and an animator/illustrator to work on the contents. Then the work starts in order to implement 15, 20 or 30 course-discipline classes, according to the hours required on the program. These groups are selected considering the qualification and individual features of the components.

After the planning stage described above, it is necessary to create a script to be followed by the workgroup, guided by the steps to elaborate and to implement the interface design or the web classes of a course-discipline as seen next:

Step 1. Workgroup meeting to define the discipline's web design;
Step 2. Meeting with the instructional designer, responsible for writing the texts of the web classes;
Step 3. Elaboration and implementation of the course-discipline design/environment;
Step 4. Teacher's approval;
Step 5. Applying usability tests for the evaluation of the course-discipline interface by the students and tutors (Silva, 2006);
Step 6. Final design and course-discipline implementation;
Step 7. Upload of the web classes on CEDERJ platform allowing the students´ access.

IMPLEMENTED INTERFACES

The interfaces are elaborated/designed by the illustrator/animator responsible for the discipline using Adobe Flash software. Each layout corresponds to a .fla file. The instructional designer is responsible for the content elaboration of the web classes which are based on the text of the published material. Therefore, he/she has to select videos, internet sites, games etc., to include them in the interfaces. When the instructional designer has finished the content elaboration of the web classes, the web designer will implement them by producing .swf files. Finally, these .swf files will be published in a .php page at CEDERJ platform. This platform is a framework which corresponds a distance education environment known as a CLMS – Content Learning Management System.

The implemented interfaces of the course-discipline *Natural Sciences in Education I* are static due to the specifications of CEDERJ platform. It does not allow a frequent interface update because it has been attended by a great and crescent number of users. However, in the second semester of this year, a new version of the platform will be implemented and it will be possible to receive dynamic interfaces.

It will be showed now some implemented interfaces using the planning and the script already described for web classes elaboration related to the course-discipline entitled *Natural Sciences in Education I* of the Pedagogy Program. The TV interface has been designed to associate each channel to an special intelligence proposed by Gardner. Then, each channel tries to show the discipline content in a way that stimulates the cognitive style of the individual student that is associated to an intelligence type.

As long as the design and the implementation of interfaces stimulate many intelligences types, it allows the student to access pedagogical activities that are more related with their cognitive style facilitating the learning process.

The dynamic of this course-discipline in the web is a TV program with two characters: "Gil Terra" and "Ana Soe". The content of the lesson is presented in a TV screen inviting the student to guide him/herself by choosing TV channels.

Figure 1 presents the text with questions regarding the subject presented in the lesson, and guides the student towards TV channels where he/she may access videos, published didactical material, linkage, suggestion of activities etc., all intended to be carried throughout their professional career as teachers.

To Access the complementary video of the classroom, the student should click the video channel (Figure 2), where is possible to attend interviews, news, and documentaries related to the subject presented in class. This type of Learning Activities (LA) is for verbal and textual learners to listen and read explanations (Fleming 1998). For Gardner, this LA stimulates the *linguistic intelligence.* For the practical activities it is necessary to click on the channel entitled "practicing in the classroom" (Figure 3). For Gardner, this LA stimulates the *bodily-kinesthetic intelligence* because it invites the student to use his/her body (as the hand or the mouth) to solve problems or to create products. This LA also stimulates the

naturalist intelligence as the student can build some instruments to study Nature. To access the internet sites that are recommended in the class, the student should click in the channel entitled "complementary reading" which, in agreement with Gardner, should stimulates the *linguistic intelligence*, the *musical* and the *logical-mathematical intelligences* too.

At the "stop and think" channel (Figure 4) active learners will learn through discoveries or activities (Fleming 1998) by accessing animations, videos, texts or games, synchronized to the *logical-mathematical and the intrapersonal intelligences* (Gardener 2001). Finally at the "Comments" channel (Figure 5) the learners can discuss the themes presented in the course-discipline to improve their *interpersonal intelligence* (Gardner 2001).

CONCLUSIONS

The educational interfaces should be developed to enhance a new knowledge acquisition, academic abilities and attitudes which are necessary for their career. In consonance to this, it is fundamental to know the learners´ cognitive style because from this stage it is possible to decide about the curricula, the pedagogy and the evaluation methods. Another important aspect is that the educational decisions will be taken based on a up to date student profile. The application of the MI Theory and the ergonomic and usability criteria during the planning and design of the interfaces for learning environments based on the web can facilitate the settlement of an enriched environment that: 1) present learning situations where the information organization will reach the interests and the preferences; 2) minimize learners´ troubles; 3) identify the experiences and the objectives of each learner; 4) reach the educational objectives established at the beginning.

Why Analysts Draw: The Effect of Diagrams Supporting UML Use Cases

ABSTRACT

An experiment was undertaken to compare effectiveness of use cases with and without supporting use case diagrams. The Cognitive Theory of Multimedia Learning is used to hypothesize diagrams improve the effectiveness of use cases by providing visual cues aiding model viewers in selecting and integrating relevant information. The level of understanding developed by participants viewing either uses cases or use cases with a use case diagram was measured using comprehension, retention and problem solving tasks. Results support the hypothesis that participants developed a significantly higher level of understanding when viewing UML use cases with the support of a use case diagram. This suggests practitioners should consider combining a visual representation with use cases to achieve higher levels of understanding in persons viewing these descriptions.

Keywords: UML, Use Case Modeling, Conceptual Modeling, System Analysis

1. INTRODUCTION

Use cases in the unified modeling language (UML) are a popular modeling technique for system analysis and design (Burton Jones and Meso, 2006; Siau and Loo, 2006). The application of use cases by practitioners varies (Dobing and Parsons, 2006). However, use cases remain primarily text-based descriptions that provide a structured sequence of processes within a system (Jacobsen et. al., 1994). While text is a rich, familiar and expressive modeling language, text can also be ambiguous and difficult to conceptualize. It seems reasonable, given the popularity of use cases, to consider whether use case diagrams provide a significantly more effective method for communicating system analysis information than text-based use cases alone.

An experiment was undertaken to compare the effectiveness of use cases with and without supporting use case diagrams. The Cognitive Theory of Multimedia Learning (Mayer, 2001) is used to hypothesize that diagrams improve the effectiveness of use case delivery by providing visual cues aiding model viewers in selecting and integrating relevant domain information into effective cognitive representations. We take the view that techniques should be compared on how well they support the development of an understanding of the domain they represent (Gemino and Wand, 2003). To test understanding, we use a problem solving task (Bodart et. al., 2001; Gemino, 1999) that requires reasoning about the domain and focuses attention on higher levels of understanding.

2. BACKGROUND

Use Case Modeling

A Use Case is a description of a sequence of events in a system that produces a result as understood from a user's perspective. A use case presents the actions associated with a person's "use" of the system (Jacobson et. al., 1994). The use case is often an important part of object-oriented analysis methods (Dobing and Parsons, 2006; Siau and Cao, 2001).

Researchers that support the UML suggest the simplicity of the use case method is an asset. Kobryn (1999) suggests that use cases are simple and natural notations that are easy to understand for stakeholders, analysts and designers. While the use case is primarily text, the UML has developed an assortment of diagramming techniques that can potentially integrate with use case information. A key for the use case remains the lack of formalism (Jacobson et. al., 1999).
