British Cataloguing in Publication Data
A Cataloguing in Publication record for this book is available from the British Library.

All work contributed to this book is new, previously-unpublished material. The views expressed in this book are those of the authors, but not necessarily of the publisher.

The manuscripts published in these proceedings were subject to a blind, peer review by at least three reviewers.Manuscripts are assigned to reviewers with specific expertise in the area of the paper. IRMA 2005 InternationalConference utilized 500+ expert reviewers, external to the conference organizing committee to complete the blindpeer/expert review. Each manuscript is assigned to at least three expert reviewers and is subject to a blind, peer reviewby these reviewers. A final decision is made based upon the recommendations of the reviewers.

Managing Worldwide Operations and Communications with Information Technology (ISBN 978-1-59904-929-8) is printed in two volumes. Volume 1 covers pages 1-822. Volume 2 covers pages 823-1652.

Reducing the Size of Auxiliary Data Needed to Support Materialized View Maintenance in a Data Warehouse Environment

Lubomir Stanchev, Indiana University – Purdue University Fort Wayne, 2101 E. Coliseum Blvd., Fort Wayne, IN 46805, USA; E-mail: stanchel@ipfw.edu

ABSTRACT

A data warehouse consists of a set of materialized views that contain derived data from several data sources. Materialized views are beneficial because they allow efficient retrieval of summary data. However, materialized views need to be refreshed periodically in order to avoid staleness. During a materialized view refresh only changes to the base tables are transmitted from the data sources to the data warehouse, where the data warehouse should contain the data from the base tables that is relevant to the refresh. In this paper we explore how this additional data, which is commonly referred to as auxiliary views, can be reduced in size. Novel algorithms that exploit non-trivial integrity constraints and that can handle materialized views defined over queries with grouping and aggregation are presented.

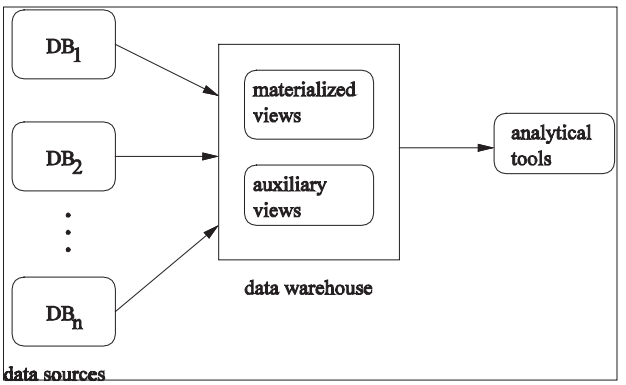
1. INTRODUCTION

A data warehouse contains aggregated data derived from a number of data sources and is usually used by OnLine Analytical Processing (OLAP) tools and data mining tools for the purpose of decision making (see Figure 1 and [GM95]).

The data sources consist of several databases, which usually contain huge amounts of data (e.g., the day-to-day transactions of a store chain). Conversely, *materialized views* (MVs) contain summary data compiled from several data sources. The main challenge in implementing the data warehouse architecture is keeping the materialized views up-to-date.

We will refer to the one time synchronization of a MV with the content of its underlying tables as a *view refresh* and to the continuous process of synchronization as *view maintenance*. In order to demonstrate how a MV can be refreshed, consider a MV V that is defined as the inner join of the base tables T_1 and T_2. If the changes ΔT_1 are applied to the table T_1, then the changes that need to be applied to V can be expressed as $\Delta T_1 \bowtie T_2$ [1]. However, in general it is impossible to calculate the value of T_2 knowing only the old value of V. Therefore, all the tuples in T_2 that can potentially join with ΔT_1 need to be stored in an *auxiliary view* on the data warehouse site.

Figure 1. The data warehouse model



In this paper we extend previous research on the subject (e.g., [QGMW96]) and explain how integrity constraints can be exploited to reduce the size of the created auxiliary views. In particular, our contributions include considering novel types of integrity constraints that can further reduce the size of the auxiliary views and algorithms for handling MVs defined over queries with grouping and aggregation.

2. RELATED RESEARCH

The problem of MV maintenance has been studied for over twenty years (see [BLT86]). The papers [GJM96] and [H96a] are excellent references on the problem of making MVs self-maintainable. MV maintenance over object-relational database schemas, similar to the one used in this paper, is presented in [ZM98], while [AHRVW98] describes how to maintain MVs over semi-structured data.

The paper [QGMW96] is an excellent source on exploiting integrity constraints to reduce the size of auxiliary views. However, it covers only candidate and foreign key integrity constraints and considers only conjunctive queries without grouping and aggregation. The paper [H96b] presents an algorithm for testing the self-maintainability of a MV in the presence of arbitrary functional dependencies.

3. PROBLEM DESCRIPTION

Our database schema consists of base tables and MVs, where only base tables can be updated by the users of the system. Each base table has the system attribute `ID`, which is a unique tuple identifier (and therefore a key for each table). The other attributes of a table are either *standard*, that is, from one of the predefined types (e.g., integer, string, etc.), or *reference* and contain the `ID` value of a tuple that is in the database (In other words, we require that all reference attribute define a referential non-null foreign key constraint). In addition, we impose the acyclicity requirement that there cannot exist reference attributes A_1, ..., A_n on tables T_1, ..., T_n, respectively, such that attribute A_i references table T_{i+1} for i = 1 to n-1 and attribute A_n references table T_1.

Given a MV V stored on the data warehouse, a database schema, and the type of changes that are allowed to the view's underlying tables, our goal is to find the smallest set of auxiliary views for V, where the precise definition of an auxiliary view follows. Note that we require that both the old and new values of updated tuples to be sent to the data warehouse.

Definition 1 (self-maintainable set of materialized views) The set of MVs $\overline{V}$ is self-maintainable iff every MV in the set can be refreshed using only the old values of $\overline{V}$ and the changes to the underlying base tables.

Definition 2 (auxiliary materialized views) The set of MVs $\overline{V}_1$ is an auxiliary set of MVs for the MV V iff $V \cup \overline{V}_1$ is a self-maintainable set of materialized views.

We will refer to the query that defines a MV as the *underlying query* for the view. In this paper we only consider MVs with underlying queries that are select-project-join queries (no self-joins allowed) with possible grouping and aggregation. We require that the selection condition of the underlying query is a conjunction of atomic predicates of the form "$T_1.Pf_1?P_1$" or "$T_1.Pf_1?T_2.Pf_2$", where *Pf* is used to denote a *path function* (precise definition follows), T - a base table, P - an atomic value, and "?" - an element of the set $\{>,\geq,=,<,\leq\}$.

Definition 3 (path function) A path function *Pf* has the general syntax $A_1^{a_1}.\ldots.A_n^{a_n}.A_{n+1}$, where $\{A_i\}_{i=1}^n$ are derived attributes and $\{a_i\}_{i=1}^n$ are elements of the set {1,-1}. Given a tuple t, we define $t.Pf$ to be equal to $((\ldots(t \Rightarrow A_1^{a_1}) \Rightarrow \ldots) \Rightarrow A_n^{a_n}).A_{n+1}$. Note that $\bar{t} \Rightarrow A$ is used to denote the set of tuples with `ID` $t.A$ for $t \in \bar{t}$. Similarly, $\bar{t}.A^{-1}$ is used to denote all tuples t' for which $t' \Rightarrow A$ is in the set $\bar{t}$. (We have used $t \Rightarrow A$ as a shorthand for $\{t\} \Rightarrow A$ and A as a shorthand for A^1.) The expression $t.Pf$ is *well defined* when it represents a set that contains a single value, where we will use $t.Pf$ to denote this value.

In addition to the key constraints defined by the ID attributes and the referential constraints defined by the reference attributes, our algorithms can take advantage of the following two integrity constraints:

(def $T.Pf$) $\Leftrightarrow$ ($\forall t \in T$) ($t.Pf$ is well defined) and

($T.Pf_1$=$T.Pf_2$) $\Leftrightarrow$ (def $T.Pf_1$) $\wedge$ (def $T.Pf_2$) $\wedge$ ($\forall t \in T$)($t.Pf_1 = t.Pf_2$).

The first constraint denotes that a path function is well defined and the second constraint states that we will reach the same value if we follow either of the two paths.

Our running example is based on the database schema shown in Figure 2. We have used ellipses around base table names and round rectangles around primitive types. Also, we have used dashed lines to denote standard attributes, solid lines to denote reference attributes, and the ID attributes of the tables are not shown. We assume that the following integrity constraints hold for the schema (in addition to the described key and foreign key constraints): (*SECT.dep = SECT.class.dep*) and (def *PROF*.*prof*$^{-1}$.*dep.group*).

Example 1 Suppose that only additions and deletions that are consistent (i.e., do not violate the integrity constraints) and primitive (i.e., single tuple) are allowed to the base tables of our example schema and consider a MV V defined using the following underlying query: $\pi^d_{S.number,C.code,P.name,D.name}\sigma_{D.group='ARTS' \text{and} C.number>300 \text{and} P.age>30}(S \bowtie C \bowtie D \bowtie P)$, where π^d is used to denote duplicate preserving projection, the first letters are used to denote the corresponding base tables, and the join conditions are on the respective reference attributes. The auxiliary views that are created by our algorithm are shown in Table 1.

Figure 2. The example database schema

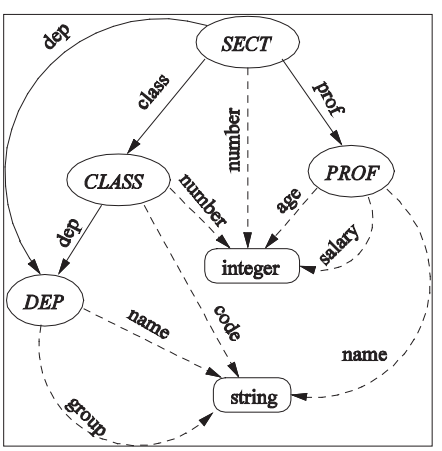


Table 1. Auxiliary views for motivating example

auxiliary view	underlying query
V_P	$\pi^d_{\text{ID, name}}(\sigma_{age>30 \wedge prof^{-1}.dep.group='ARTS'}(P))$
V_D	$\pi^d_{\text{ID, name}}(\sigma_{group='ARTS'}(D))$
V_C	$\pi^d_{\text{ID, code, dep}}(\sigma_{dep.group='ARTS' \wedge number>300}(C))$

In the paper we will show that V can be incrementally refreshed using the following formula:

$$V^{new}=V^{old}+\pi^d_{S.number,\ C.code,\ P.name,\ D.name}(V_P^{new} \bowtie V_D^{new} \bowtie V_C^{new} \bowtie \Delta S),$$

where "+" is used to denote the application of changes (bag version) and the superscripts *old* and *new* are used to denote the content of the table before and after an update, respectively.

We next demonstrate the potential benefit of our algorithm. Consider the four example base tables and suppose they contain the number of tuples shown in Table 2. Suppose that 2 of the departments are in the 'ARTS' group, 10% of the classes pass the predicate "*number*>300", and 80% of the professors pass the predicate "age>30". Also, suppose that 5% of the classes for which "*number*>300" are in a department that is part of the 'ARTS' group and 2% of the profs teach classes in a departments that is part of the 'ARTS' group.

The third column in Table 2 shows the sizes of the auxiliary views if only predicates from the underlying query of the MV are applied to the auxiliary views (i.e., the algorithm from [HZ96] is applied). The forth column shows the sizes of the auxiliary views if the algorithm from [QGMW96] is applied. It extends [HZ96] by removing the auxiliary view for the *SECT* table and storing only classes that are in a department that belongs to the 'ARTS' group. The last column shows the sizes of the auxiliary views when our algorithm is applied. It improves on the previous algorithm by storing only professors who teach courses in a department from the 'ARTS' group.

4. PROPOSED SOLUTION

Consider a MV V with the following underlying query: $\pi^d_{A_1,\ldots,A_o}(\sigma_{E_1 \wedge \ldots \wedge E_e}(T_1 \text{ x } \ldots \text{x } T_t))$ (x is used to denote a cross product), a database schema Σ, and suppose that only consistent primitive insertions and deletions to the tables $\{T_i\}_{i=1}^t$ are allowed. Then the following algorithm produces a set of auxiliary views for V.

Algorithm 1

Step 1. Create an undirected graph with vertices corresponding to the elements of the set $\{T_i\}_{i=1}^t$. For each condition in the set $\{E_i\}_{i=1}^e$, draw an edge between the tables involved in the condition. (In particular, if only a single table is involved in the condition, then draw a loop edge around it.) Next, delete

Table 2. Comparison on the number of tuples for our example

Base Relation	Tuples in Base Relation	Tuples in Auxiliary views ([HZ96])	Tuples in Auxiliary Views ([QGMW96])	Tuples in Auxiliary Views (our algorithm)
SECT	100 000	100 000	0	0
CLASS	50 000	5 000	250	250
DEP	30	2	2	2
PROF	2 000	1600	1600	32
	152 030	61 602	1852	284

all vertices that have no edges connected to them and no attributes in the set $\{A_i\}_{i=1}^{a}$. Then examine the subgraph induced by the edges labeled with equality predicates. If there is a vertex in this subgraph with the properties: (1) all its edges are in the subgraph, (2) removing the vertex will not change the number of connected components in the subgraph, and (3) the vertex's table does not contain attributes in the set $\{A_i\}_{i=1}^{a}$, then remove the vertex and repeat the procedure until possible. Finally, rewrite the underlying query Q of the MV V by deleting the tables that correspond to deleted vertices. (This also involves deleting from Q any predicates on the deleted tables.)

Step 2. For each table T_i in Q (i=1 to t), create an auxiliary view V_i that contains all the tuples of T_i. We will use Q_i to refer to the underlying query for V_i.

Step 3. Consider a table T_i in Q and the corresponds auxiliary view V_i created in the previous step. If the selection condition of Q contains one or more atomic predicates on the table T_i, then add these predicates to the selection condition of Q_i via conjunction. Similarly, add to Q_i a duplicate preserving projection on the attributes of T_i that are projected out in Q union the attributes of T_i that appear in an atomic selection predicate of Q that involves attributes from other tables. The described procedure is applied for i=1 to t.

Step 4. If there is a table T_i in Q that has the property that every table in Q can be reached starting from the table T_i and following reference attributes, then remove V_i from the set of auxiliary views.

Step 5. If there exist a table T_i and a path function $Pf = A_1^{a_1}. \ldots .A_n^{a_n}.A_{n+1}$ such that: (1) Step 4 was not applied to T_i, (2) (`def` $T_i.Pf$) and (3) The table reached by following the path $A_1^{a_1}. \ldots .A_n^{a_n}$ from the table T_i contains an atomic predicate $p(A_{n+1})$ in Q, then add $p(Pf)$, via conjunction, to the selection condition of Q_i.

Going back to Example 1, Step 1 was not applied. Step 2 was applied to create the auxiliary views: V_P, V_D, V_C, and V_S, which initially contain the respective base tables. Step 3 was applied to add the predicate "*age*>30" to V_P, the predicate "*group*='ARTS' " to V_D, and the predicate "number>300" to V_C. The step also applies the projections shown in Table 1. For example, the `ID` attributes are projected for all four tables because they appear in the join conditions. Step 4 was applied to remove the auxiliary view V_S. Finally, Step 5 added the predicate "$prof^{-1}.dep.group$='ARTS'" and "$dep.group$='ARTS' " to V_P and V_C, respectively.

The following theorem addresses the correctness of Algorithm 1.

Theorem 1: Algorithm 1 produces a set of auxiliary views that make V self-maintainable relative to the defined assumptions.

Proof: Step 1 uses the available integrity constraints to rewrite Q into an equivalent query that references fewer tables and therefore does not affect the correctness of the algorithm.

The created auxiliary views in Step 2 make V self-maintainable. In particular, since $\pi^{d}_{A_1,\ldots,A_n}\sigma_{g}(T+\Delta T) = \pi^{d}_{A_1,\ldots,A_n}\sigma_{g}(T)+\pi^{d}_{A_1,\ldots,A_n}\sigma_{g}(\Delta T)$, the changes to each auxiliary view can be calculated by applying the selection condition of its underlying query followed by the duplicate preserving projection operation of its underlying query to the changes of its underlying table. Then the new value of V can be calculated as $Q(V_1,\ldots,V_t)$ (we use $Q(R_1,\ldots,R_t)$ to denote the result of Q when the table T_i is substituted with table R_i for i=1 to t).

We will next examine two cases: when Step 4 was not applied and when it was applied.

Case 1 (*Step 4 was not applied*) We will use $V_{i,r}$ to denote the auxiliary view for V_i after Step r. Note that $V^{new}=Q(T_1^{new},\ldots,T_t^{new})=\pi^{d}\sigma(T_1^{new}\bowtie\ldots\bowtie T_t^{new})$. We will show that $\pi^{d}\sigma(T_1^{new}\bowtie\ldots\bowtie T_t^{new})=\pi^{d}\sigma(V_{1,j}^{new}\bowtie\ldots\bowtie T_{t,j}^{new})$ for j={2,3,5}, which proves that $V^{new}=\pi^{d}\sigma(V_{1,5}^{new}\bowtie\ldots\bowtie T_{t,5}^{new})=Q(V_1^{new},\ldots,V_t^{new})$ and therefore the selected auxiliary views make V self-maintainable.

First, note that $\pi^{d}\sigma(T_1^{new}\bowtie\ldots\bowtie T_t^{new})=\pi^{d}\sigma(V_{1,3}^{new}\bowtie\ldots\bowtie V_{t,3}^{new})$. The reason is that $\pi^{d}\sigma(T_1^{new}\bowtie\ldots\bowtie T_t^{new})=\pi^{d}\sigma(V_{1,2}^{new}\bowtie\ldots\bowtie V_{t,2}^{new})$ (direct consequence of Step 2) and applying Step 3 to $V_{i,2}$ for i = 1 to t does not change the value of the expression $\pi^{d}\sigma(V_{1,2}^{new}\bowtie\ldots\bowtie V_{t,2}^{new})$. In particular, Step 3 first applies to $V_{i,2}$ the single table predicates of Q. This will not change the above expression because $\sigma_E(R_1\bowtie R_2)=\sigma_E(\sigma_E(R_1)\bowtie R_2)$ if E is a predicate only on the attributes of R_1. Next, Step 3 removes from $V_{i,2}$ attributes that do not participate in the join condition and that are not projected in Q. This rule will not affect the expression because $\pi_{\bar{A}}(R_1\bowtie R_2)=\pi_{\bar{A}}(\pi_{\bar{B}}(R_1)\bowtie R_2)$ when $\bar{A}\subseteq\bar{B}$ and $\bar{B}$ are attributes of R_1 that do not participate in the join condition.

Next, consider what happens when step 5 is applied to the auxiliary views of the expression: $\pi^{d}\sigma(V_{1,3}^{new}\bowtie\ldots\bowtie V_{t,3}^{new})$. In particular, this step substitutes auxiliary views with more restrictive auxiliary views that contain only tuples that can join with the other auxiliary views. Therefore, since $R_1\bowtie R_2=\sigma_E(R_1)\bowtie R_2$ when E is a predicate that selects tuples of R_1 that join with R_2, our expression will not change after the application of Step 5 to its auxiliary views.

Case 2 (*Step 4 was applied to table* T_1). Note that

$$\begin{aligned}
&V^{new}=Q(T_1^{new},\ldots,T_t^{new})\\
&=\pi^{d}\sigma((T_1^{old}+\Delta T_1)\bowtie T_2^{new}\bowtie\ldots\bowtie T_t^{new})\\
&=\pi^{d}\sigma(T_1^{old}\bowtie(T_2^{old}+\Delta T_2)\bowtie\ldots\bowtie(T_t^{old}+\Delta T_t))+\pi^{d}\sigma(\Delta T_1^{old}\bowtie T_2^{new}\bowtie\ldots\bowtie T_t^{new})\\
&=V^{old}+\pi^{d}\sigma(T_1^{old}\bowtie\ldots\bowtie T_{n-1}^{old}\bowtie\Delta T_n+\ldots+T_1^{old}\bowtie\Delta T_2\bowtie\ldots\bowtie\Delta T_t)+Q(\Delta T_1, T_2^{new},\ldots,T_t^{new})
\end{aligned}$$

We will next show that the second expression in the above formula empty and therefore $V^{new}=V^{old}+Q(\Delta T_1, T_2^{new},\ldots,T_t^{new})$. Indeed, consider the join of T_1^{old} with an insertion or deletion to the table T_2. The fact that T_2 can be reached from T_1 following reference attributes guarantees that the result of this join will be empty.

It remains to show that $\pi^{d}\sigma(\Delta T_1, T_2^{new},\ldots,T_t^{new})=\pi^{d}\sigma(\Delta T_1, V_2^{new},\ldots, V_t^{new})$, which will prove the theorem. However, this can be proven the same way we proved that applying Steps 2, 3, and 5 to the auxiliary views in Case 1 do not change the value of the expression.

Note that the above theorem only shows that the selected by Algorithm 1 auxiliary views make the input MV V self maintainable, but does not explain how V can be incrementally refreshed. However, when Step 4 was applied, $V^{new}=V^{old}+Q(\Delta T_1, V_2^{new},\ldots,V_t^{new})$ and therefore $\Delta V = Q(\Delta T_1, V_2^{new},\ldots,V_t^{new})$. Of course, before ΔV can be calculated, the auxiliary views need to be refreshed.

When Step 4 was not applied, the formula for calculating ΔV is:

$$V^{new}=Q(V_1^{new}, V_2^{new},\ldots,V_t^{new})=V^{old}+\pi^{d}\sigma(V_1^{old}\bowtie\ldots\bowtie V_{t-1}^{old}\bowtie\Delta V_t+\ldots+\Delta V_1\bowtie\ldots\bowtie\Delta V_t),$$

where the brackets contain 2^n-1 expressions covering the cases where V_i is represented as V_i^{old} and as ΔV_i.

Before describing our algorithm for selecting auxiliary views for a MV with aggregation, we present an example.

Example 2 Consider the MV V with the underlying query:

$$_{D.name}\mathcal{F}_{\text{count(S.ID) as } sect\_count}(D\bowtie C\bowtie S)$$

and suppose that only consistent insertions and deletions are allowed to the underlying tables. We will first rewrite the query as the equivalent query:

$$_{D.name}\mathcal{F}_{\text{count(S.ID) as } sect\_count}(D\bowtie S).$$

Then we will create the auxiliary view $V_D=\pi^{d}_{name,\mathtt{ID}}(D)$. If a section is inserted/deleted, then we will use V_D to find the department's section and then add/subtract 1 to the value of the attribute *sect_count* of the corresponding tuple in V. If such a tuple does not exist in V, then one should be created with *sect_count*=1 (a tuple should exist when deletion is performed). Of course, if the *sect_count* of a tuple in V becomes 0, then the tuple should be deleted from the MV. If a department is inserted or deleted, then only V_D needs to be updated because a new or deleted department can not join with an existing section.

Next, consider a MV V defined with the following underlying query:

$$_{B_1,...,B_b}\mathcal{F}_{agg_1(C_1),\ ...,\ agg_s(C_e)}\ \pi^{d}_{A_1,...,A_a}\ (\sigma_{E_1\wedge...\wedge E_e}\ (T_1 \times ... \times T_t)),$$

where $agg \in \{\texttt{min}, \texttt{max}, \texttt{sum}, \texttt{count}, \texttt{avg}\}$. Suppose the MV is defined over a schema allowing only consistent insertions and deletions to the tables $\{T_i\}_{i=1}^{t}$, where we add the requirement that at most one operation can be performed on each tuple to disallow tuple updates. Then the following algorithm can be used to create the set of auxiliary views for V.

Algorithm 2

Step 1. Suppose that the MV V is defined using the query $Q(T_1,...,T_t)$ and let Q_C by the conjunctive query formed from Q by stripping its grouping and aggregation. Apply Step 1 from Algorithm 1 to rewrite Q_C and then rewrite Q accordingly.

Step 2. Modify Q and add a `count`(A) aggregation (if one does not already exists) if there exists the aggregation `sum`(A) or `avg`(A) for some attribute A and Q does not contain a *min* or *max* aggregation. (This step adopts the mechanism of managing views with aggregation from [MQM97].)

Step 3. If Q contains a *min* or *max* aggregation, then apply Steps 2, 3, and 5 from Algorithm 1 to Q_C to create the set of auxiliary views for V. Otherwise, apply to Q_C Steps 2, 3, 4, and 5 from Algorithm 1 to create the set of auxiliary views for V.

Going back to Example 2, Step 1 was applied to rewrite the query and Step 4 from Algorithm 1 was applied to remove the auxiliary view for the *SECT* table. Step 2 of Algorithm 2 was not applied.

Theorem 2. Algorithm 2 produces a set of auxiliary views that make V self maintainable relative to the defined assumptions.

Proof(Sketch): Note that Step 1 rewrites the original query. Step 2 just adds additional attributes to V. Therefore, we only need to show that the created in Step 3 auxiliary views make V self-maintainable.

First, consider the case when Step 4 from Algorithm 1 was not applied and let us use V^C to denote the MV with underlying query $Q_C(T_1,...,T_t)$. Then Theorem 1 implies that $V^{C\ new} = Q_C(V_1^{new},...,V_t^{new})$. The new value for V can be computed by applying the grouping and aggregation from Q to $Q_C(V_1^{new},...,V_t^{new})$ and therefore the selected set of auxiliary views makes V self-maintainable.

Next, consider the case when Step 4 from Algorithm 1 was applied. Then

$$V^{new} = V^{old} \oplus Q\ (\Delta T_1, V_2^{new},...,V_t^{new}),$$

where $\oplus$ is a new operation that calculates the correct value for the count, sum, and avg attributes. In particular, an addition/deletion of a tuple from $Q(\Delta T_1, V_2^{new},...,V_t^{new})$ causes the value of the count attribute in the matching tuple in V^{old} to be incremented/decremented by 1. Similarly, it causes the `sum` attribute in this tuple to be incremented/decremented by the value of the attribute on which the summation is performed in the tuple that is added/deleted from $Q\ (\Delta T_1, V_2^{new},...,V_t^{new})$. Note that tuples that have a 0 for the count attribute should be removed from the query result for V^{new}. Finally, the value of an `avg` attribute is calculated as the result of dividing the value of the `sum` attribute by the value of the count attribute.

Note that Algorithms 1 and 2 will have to be modified if updates are allowed. In particular, attributes can be classified as *protected* and *exposed* (see [QGMW96]). Protected attributes are projected in the underlying query of the MV, but no predicates are defined on them. Conversely, exposed attributes are the ones on which selection or join predicates are defined. Updating a protected attribute will not affect the two algorithms. However, in the presence of updates on exposed updates Step 4 of Algorithm 1 can not be applied. Similarly, Step 3 of Algorithm 1 cannot be applied to add predicates on exposed attributes. Finally, Steps 5 of Algorithm 1 cannot be applied if the path function *Pf* passes through tables that contain exposed attributes.

5. CONCLUSION

The paper presents novel algorithms for creating auxiliary views in the context of a data warehouse environment. The algorithm for MVs defined over queries without grouping and aggregation creates smaller auxiliary views than existing algorithms by exploring a richer set of integrity constraints. The algorithm for minimizing the size of auxiliary views for MVs defined over queries with aggregation solves a novel problem.

One topic for future research is focusing on the problem of completeness, that is, showing that the two algorithms produce a minimal set of auxiliary views relative to the explored types of integrity constraints.

Diagnosing the Context of Inter-Organizational Systems by Mapping Key-Players

Albert Boonstra, University of Groningen, Landleven 7, Groningen, The Netherlands, 9700 AV; E-mail: albert.boonstra@rug.nl

ABSTRACT

Inter-organizational systems (IOS) are generally used in a context of various interested parties. If these parties are not identified and if their power and interests related to the IOS are not explored and taken into consideration, implementation is likely to become a disappointing and troublesome affair. This paper presents a diagnostic method for the identification of stakeholders involved in IOS and the assessment of their power and interests with respect to these systems. The diagnostic approach is illustrated by means of an in-depth case study. The case study indicates that addressing power and interest relationships may help make the critical success factors in the implementation and improvement of inter-organizational systems more explicit. On the basis of the case study, conclusions are drawn regarding the application and usefulness of the diagnostic approach.

Keywords: inter-organizational system, stakeholder, interests, power, diagnosis

INTRODUCTION

Especially since the rise of the Internet, there has been a clear tendency toward the use of inter-organizational systems (IOS). Many organizations as well as industry boards and government departments are involved in the development and implementation of such systems. The possibilities of IOS are clear: closer links between value chains of organizations can lead to lower transaction costs and a quicker delivery of goods and services. Also intangible benefits of IOS are considered to be important, including an improvement in services and closer partnerships. Although the benefits seem to be attractive, many of the parties involved in the development and use of IOS have already experienced that the potential benefits are not always achieved easily. Although some systems have become success stories, others are not doing so well at all and can even be called failures. So, some IOS are taking off very quickly whereas others are only accepted hesitantly. Clearly, some systems have achieved high penetration among target users, whereas others appeal to a few intended users only. This illustrates that the implementation of IOS systems is a complicated endeavor, both from a technical point of view and from many other perspectives, including strategic, organizational, political, and cultural viewpoints. Moreover, a large number of stakeholders from different organizations are involved in developing and using IOS. For this reason, the question who participates in the analysis, development and implementation of IOS becomes even more difficult, since decisions are no longer only made internally (Pouloudi, 1997; Cavaye, 1995; Webster, 1995).

This paper therefore presents a diagnostic framework, which aims to assess the potential critical success factors from the power and interest perspectives of the various stakeholders. This framework can be used to predict the potential success and critical factors playing a role in the implementation and improvement of IOS. By applying the framework, IOS developers and implementers will be able to assess potential risks and identify barriers to the use of IOS. On the basis of that assessment, focused actions can be taken to alter power/interest positions in ways that stimulate a successful implementation.

THEORETICAL BACKGROUNDS

Perspectives on Stakeholders

It has been generally acknowledged in the literature that the development of information systems requires the participation of interested parties and that the willingness and the effectiveness of this participation influences whether the resulting system is successful. Normally these participants include developers, intended users and managers. However, in the case of an IOS this range of people and parties is much broader. It crosses organizational borders, which means that the stakeholders are more loosely coupled. Identifying these stakeholders and exploring their perspectives in terms of their interests in the system and their power to 'make or break' the system are essential steps in establishing a diagnostic framework aimed at assessing the critical factors of an IOS (Pan et al., 2003). As part of the diagnostic framework, a practical technique is required to identify these groups and individuals.

Stakeholders can be identified in many different ways (Mitchell et al., 1997). There are different kinds of stakeholders, such as persons as well as groups inside and outside an organization. In this research study we have adopted Freeman's classical definition of stakeholders to IOS: "A stakeholder is any group or individual who can affect or is affected by the IOS" (Freeman, 1984, adapted to IOS by the authors).

Relevant questions that help identify relevant groups and individuals in this context are for example (Pouloudi, 1997; Cavaye, 1995):

- Who are the sponsors and the initiators of the system?
- Who have to adopt the system and make it work?
- Who are the intended users?

Answers to these questions may reveal stakeholders not yet identified by the top-down approach or make it possible to refine certain categories of stakeholders into relevant subgroups.

Stakeholders' Interests

When the stakeholders are identified, their interests have to be connected with the IOS. This means that part of the analysis consists of the assessment of the stakeholders' perception of the IOS. How do they interpret the IOS (Walsham, 1993) and to what extent do they believe that the IOS will fit their values and help them attain their objectives? In other words: what are their perceived interests in the IOS?

The degree to which parties are interested in an IOS can vary from low to high (Coltman, 2001). In case of a low interest level, the stakeholder may be inclined to believe that the IOS will lead to increasing operational costs as well as a decrease in efficiency due to incompatible internal and external technologies, and that it will offer insufficient support in the control of the primary process. On the other hand, a high degree of interest relates to the perception that an IOS contributes to the overall goals of the company.

Within the context of this study, it is not relevant whether perceptions are realistic. The perceived (dis)interest normally includes several elements and it is often based on strategic, organizational, financial and behavioral aspects (Chen, 2003; Coltman et al., 2001; Parker et al., 1988; Porter, 2001). These aspects are not of

equal relevance to all stakeholders: intended users have other kinds of interests than business managers. This means that the dimensions and the diagnostic questions should be prioritized in relation to the stakeholder in question. Questions that may help identify the degree of interest of a stakeholder in an IOS are:

Strategic Interests of Stakeholders
- Does the IOS affect the power, autonomy and independence within the value chain?
- Does the IOS lead to competitive advantage?
- Is the IOS instrumental in reaching new customers or does it lead to losing customers?

Operational/Organizational Interests of Stakeholders
- Is it easy or difficult to implement the IOS?
- Is it easy or difficult to link the IOS with internal business systems?
- Are the operational risks of the IOS high or low?

Financial Interests of Stakeholders
- Are the initial investments in the IOS high or low?
- Are the operational costs of the IOS high or low?
- Are the financial risks of the IOS high or low?

Behavioral Interests of Stakeholders
- Is the IOS compatible with the current culture, values and working procedures?
- Is the IOS easy to learn and use?
- Is the IOS useful for the intended users?

Power

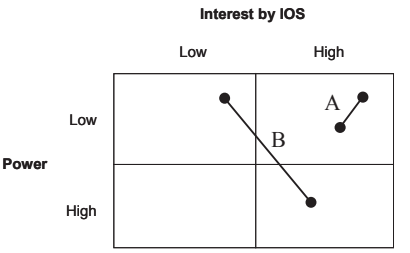
Another element of the framework is an analysis of the power relations among the parties involved. A powerful party with a clear interest in an IOS can apply its power to force less powerful parties to also start using the IOS, independent of their perceived interest in it (Standifera et al., 2003). At the same time, if certain parties only have little interest in an IOS it might be rather difficult for parties with a great deal of interest but a lack of power to implement an IOS successfully. In this paper, we will define power as the capacity to exert one's will over others in order to realize certain intended benefits. Since power is the capacity to exert one's will, it is possible to indicate the source of this capacity, or in the context of IOS: parties may possess different sources of power to urge others to use (or not to use) an IOS.

Processual
- Can the stakeholder force other stakeholders to comply with the implementation and use of the IOS?
- Can the stakeholder independently block the implementation and use of the IOS?
- Is the stakeholder (economically) dependent upon a party who can force another party to comply with or block the implementation and use of the IOS?

Institutional
- Does the stakeholder have the resources to develop and implement the IOS?
- Does the stakeholder have the size and/or resources to block the implementation or use of the IOS?
- Does the stakeholder has sufficient formal or legal authority to force others to use the IOS?

By linking the dimensions of power and interest, stakeholders involved in setting up and implementing an IOS can be categorized in a matrix. In this way, different IOS relationships can be distinguished. IOS relationship A for instance (figure 1), shows all characteristics of a balanced IOS. In this situation both parties believe that they can benefit from applying an IOS and they both possess an equal amount of power when it comes to its development and implementation. Relationship B on the other hand, can be categorized as an unbalanced IOS. In this case, one party benefits significantly more from the IOS than the other one does.

Figure 1. Example of a balanced and unbalanced IOS relationship



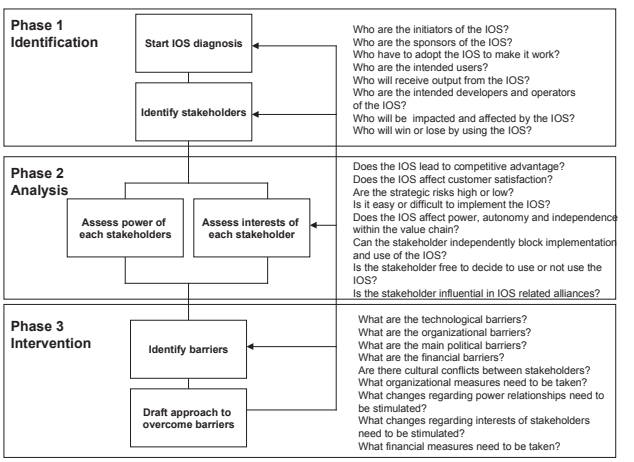
THE FRAMEWORK

The perspectives explained above can be combined in a diagnosing framework for the assessment of barriers to the development and implementation of an IOS. Figure 2 summarizes the main stages of diagnosis as well as the key issues to be addressed when applying the framework. The diagnosis starts with a formal agreement on the (proposed) IOS, its aim, the characteristics of the IOS and the planning of the development and implementation process. Then, the stakeholders involved are further identified (phase 1) in accordance with the guidelines as described above. In phase 2 the power and interests of each stakeholder are assessed by applying the dimensions and issues addressed in the previous section. Finally, the fourth phase concentrates on addressing the main barriers to the implementation of the IOS or, in case the IOS has already been developed, the operating-barriers. This phase obviously includes an action plan encompassing the issues of power relations as well as the interests in and alternatives to changing the IOS relationships.

RESEARCH METHODOLOGY

The empirical part of our study is founded on an in-depth study of an IOS project that took place during the period 1997-2004. The case study deals with the introduction as well as the operating phase of a dedicated and complex IOS in the retail sector. The initial research objective of the project was to study the potential benefits of and the barriers to the implementation of an IOS linking a cooperative wholesaler to its affiliate members. During the early stage of adoption however, it appeared that political processes played an important role and it was therefore generally expected that the success or failure of the IOS would be closely linked to the interests and power of the IOS parties involved in these processes. It was for this reason that the research objective of the project gradually shifted from a feasibility study to a monitoring study, aiming at exploring how power and interest relationships interact with each other and how the operation and modifications of the IOS are influenced by these two dimensions. However, this was clearly a 'how' question about a contemporary set of events over which the researcher has

Figure 2. Overview of the diagnosing framework



no control. It also had some open and explorative characteristics. Consequently, a case-study approach appeared to be the most appropriate choice (Yin, 1991) and we therefore conducted a longitudinal case study in order to compare the different strategies used by companies to implement and adopt an IOS.

WHOLESALER - MULTI-STORE CASE[1]

Episode 1: Backgrounds of the Project and Agenda Formation

At the end of the 1990s, after a long period of discussions and informal meetings, Wholesale Corp. decided to initiate a feasibility study on the design and implementation of an IOS. Wholesale Corp. is a purchasing organization representing independent retail formulas in the Netherlands. By means of joint purchasing, Wholesale Corp. is able to achieve substantial financial benefits for its members, e.g. supermarkets and retailers. Wholesale Corp. covers about 20% of the entire food market in the Netherlands and represents 23 affiliated members, including Multi-store Corp. Multi-store Corp. is a medium-sized chain of supermarkets consisting of three distribution centers and 26 stores. The company has a turnover of €200 million and employs about 2000 employees. Figure 3 summarizes the main good flows as well as the information flows among the stakeholders involved in the supply chain.

In 1999, Wholesale Corp. conducted a study on designing and implementing an IOS. Five driving forces triggered this study:

- the exchange of data between Wholesale Corp. and its affiliated members is characterized by high volumes;
- the food market is under high pressure to reduce costs;
- many supermarkets and retailers experience decreasing profit margins;
- supermarkets are confronted with a high competitive market forcing Wholesale Corp. to be more efficient;
- the aspect of 'time' is crucial in the ordering-process of food and retail products.

The feasibility study mainly focused on the technical aspects of the IOS and included issues, such as IOS-software, the protocols to be used, the necessary technological changes to be made and the costs associated with implementing an overall IOS standard to be applied by Wholesale Corp. and its members. Clearly, during the early stage of adopting the IOS many stakeholders were involved in the project. A project group of senior managers representing different business areas (sales, logistics, finance, IT) from Multi-store Corp., Wholesale Corp., and some other affiliated members worked closely together with external consultants. The group actively gathered information about the financial and technological benefits of the IOS and an assessment was made of the strategic risks to each of the stakeholders. With the aid of the diagnosing tool, also the issue of power was addressed by the group project. Especially representatives of Multi-store Corp. feared they would become dependent on Wholesaler Corp. So during several project meetings, this issue was explicitly addressed. Obviously, the discussions contained some political elements. The meetings, which were focused on the elements of power and dependence, were therefore chaired by an external consultant specialized in group processes. At the end of 1999, it was concluded that both Wholesaler Corp. and Multi-store Corp. would benefit from an IOS and an agreement was made upon the functionality requirements of the system. The project group also defined an action plan enabling the stakeholders to overcome potential barriers.

Episode 2: Development and implementation of the IOS

In 2001, Wholesale Corp. started with the development and implementation of an electronic procurement system that linked the ordering systems of the supermarkets and retailers to a central database. A substantial reduction in transaction costs, a further optimization of internal processes and increasing service delivery levels were expected to be the main benefits of the IOS. However, the implementation of the IOS within both Multi-store Corp. and Wholesale Corp. was confronted with numerous problems. Although some of these problems seemed to be of a technical nature, Wholesale Corp. also faced a number of organizational difficulties in its communication with Multi-store Corp. Project meetings were often canceled, information was not provided in time and pilot projects were often delayed severely. By the end of 2001, only a few functionalities of the IOS had been implemented, which were only partly used by Multi-store Corp. In 2002, both Multi-store Corp. and Wholesale Corp. concluded that the costs of implementing the IOS had largely outreached the benefits. It was therefore decided to reassess the functionalities of the IOS and to re-design the administrative procedures between Multi-store Corp. and Wholesale Corp. At the same time though, the implementation and usage of the IOS by Wholesale Corp. and some large supermarket chains appeared to be a great success. By means of a sophisticated IOS the leading three supermarkets were all successfully linked to Wholesale Corp.

Episode 3: Identifying Power and Interests

Starting from our model depicted in figure 1, the analysis showed that initially both parties possessed important sources of power. At the start of the project, the interdependence between Wholesale Corp. and Multi-store Corp. was strongly related to the company goals of Wholesale Corp. When buying products from suppliers, Wholesale Corp. was expected to represent the interests of its affiliated members, including those of Multi-store Corp. As a consequence, Wholesale Corp. strongly favored the development and implementation of an IOS, which was reinforced and stimulated by an informal strategic alliance between Wholesale Corp. and some large supermarket chains. The ability to develop and maintain a complex and sophisticated IOS as well as the control over an influential IOS alliance consisting of Wholesale Corp. and some large chains of supermarkets can be considered as the main sources of power of Wholesale Corp.

Regarding the (potential) interests in the IOS, at the start of the project both Wholesale Corp. and Multi-store Corp. were convinced of the benefits of implementing an IOS. It was expected that the IOS would be helpful in optimizing the internal processes of both companies and that it would significantly contribute to a reduction in the transaction costs. It was therefore concluded that the initial IOS situation for both parties could be categorized as one with high power and interest levels (see figure 4). In 2003, Multi-store Corp. was convinced that the benefits of the IOS did not outweigh the costs. Consequently, the IOS situation of Multi-store Corp. as it was initially assessed changed from a high power, high interest situation to a high power, low interest situation (see figure 4).

Figure 3. Overview of the relationships between the stakeholders involved in the supply chain

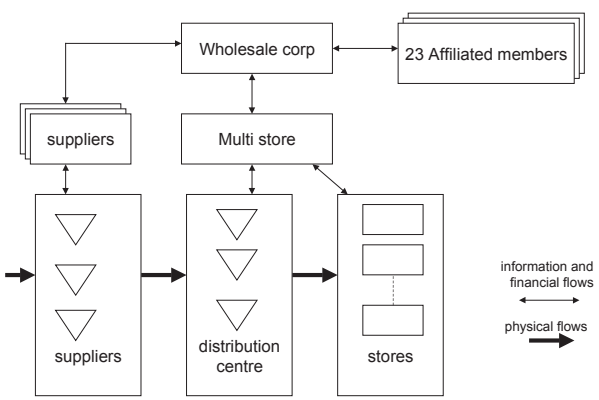


Figure 4. The dynamic character of the IOS-relationship

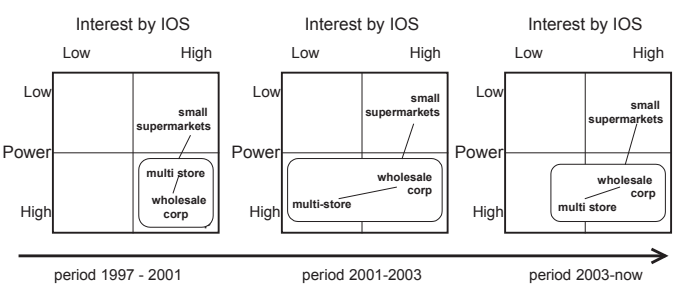

DISCUSSION

IOS are often presented as beneficial for all user organizations. The general assumption is that such systems may help to strengthen business relationships between participants. Stronger partnerships are normally associated with benefits such as clearer patterns of supply and demand, just-in-time, lower transaction costs, and closer vertical integration (Cavaye, 1995). However, closer partnerships can also have disadvantages. Partner organizations might feel overshadowed by powerful business partners and they may have to give up part of their independence. They may become dependent on their more powerful IOS partners, a dependency that may have existed before the IOS partnership, but that will become stronger and more explicit and tangible when the organization becomes electronically linked with the more powerful partner.

Stakeholders

The framework as presented in this article can be a helpful tool in identifying the most relevant stakeholders involved in an IOS proposal. The guiding questions as well as the other approaches mentioned in the backgrounds section are effective methods to identify this group. With respect to IOS projects, stakeholders can be divided in initiators, developers, implementers, and users and/or sponsors of the system. Identifying stakeholders is an important activity in relation to a broader goal, which is the management of stakeholders. Promoters of a certain IOS initiative have a clear interest in building an effective coalition of parties that may not have the same interests, but that may find each other through pursuing congruent goals that can be (partially) achieved by the successful implementation of an IOS.

Interests

The diagnostic framework acknowledges that IOS partners may have a variety of reasons to support or to resist an IOS initiative. These reasons can be divided in strategic, operational, financial, technological and behavioral motives. However, this categorization is only meant as a tool to identify all sorts of reasons that may influence the stakeholders' interpretations. These interpretations determine the attitude toward the IOS. In practice, the reasons are intertwined. In the case history, Wholesale faced numerous technological barriers when trying to introduce the IOS. However, these technological barriers appeared to be the result of miscommunication and the fact that parties were not prepared to exchange crucial information or change their organizational processes in favor of the IOS to be introduced. The technological problems were actually often used as an alibi and as a means to exert power and influence the other IOS party. It is the challenge of the analyst to talk to interest parties, to interpret their opinions and to gain insight into their real interests.

Dynamic Process

The presence of stakeholders as well as their interests and power are subject to change over time. This means that due to changing environments, the progressive nature of the system, and the shifting interpretations and perceptions of the parties involved, IOS development is not static but inherently dynamic. Sometimes these changes are the result of a well defined and explicit decision-making process. In the case history, Multi-store deliberately moved its position from a high interest, high power situation toward a low interest and high power situation. However, the dynamic character of IOS design and implementation is more often the result of implicit processes. Changing market circumstances, technological evolutions, or actions from other parties may influence the interpretations and actions of the different stakeholders.

CONCLUSIONS

In this paper we have offered a diagnostic method for identifying stakeholders and assessing their power and interests. The method's framework can be used before and during an IOS project, but also afterwards, to evaluate the project and to explain its degree of success as well as particular problems. This may improve an organization's learning capabilities during the process of starting new projects. Sufficient insight may also help executives of interested organizations to use their influence to move the project into the desired direction. McDonagh (2003) notes that IOS projects are frequently managed with a technical rather than an organizational focus, which reflects the relative isolation of the executive and user communities. "Executive communities view it as an economic imperative while IT specialists view it as a technical imperative. The coalescent nature of these two imperatives is such that human and organizational considerations are regularly marginalized and ignored". The framework as described in this paper may help business managers, executives and IT specialists become aware of the broad range of issues related to the development of inter organizational systems.

Teaching Java™: Managing Instructional Tactics to Optimize Student Learning

Henry H. Emurian, Information Systems Department, UMBC, 1000 Hilltop Circle, Baltimore, MD 21250, USA; E-mail: emurian@umbc.edu

INTRODUCTION

Direct mastery of the core knowledge in a discipline is increasingly recognized as a fundamental requirement to applying and extending that knowledge to solve novel problems. That recognition implies an instructional design to overcome the empirically verified shortcomings of teaching tactics that provide minimal guidance during a student's learning experiences (Kirschner, Sweller, & Clark, 2006). In that regard, our previous work consistently confirmed the value of programmed instruction in teaching introductory Information Systems students a Java applet as a first technical training exercise in preparation for advanced learning (Emurian, 2004, 2005, 2006a,b). Similar value of programmed instruction is evident in its applications within other disciplines, such as chemistry (Kurbanoglu, Taskesenligil & Sozbilir, 2006). The objectives of our work are to apply programmed instruction and to assess its effectiveness as a tactic to promote a common level of mastery by all students for a designated learning objective in Java programming. An optimal level of mastery is taken to reflect a *true gain* in learning (Anderson, Corbett, Koedinger, & Pelletier, 1995).

Among several recommendations for effective learning principles to promote retention and transfer of knowledge, however, are repeated practice with different instructional modalities (Halpern & Hakel, 2003) and socially supported interactions (Fox & Hackerman, 2003). The modalities that have been adopted in our classroom applications include (1) programmed instruction, (2) lectures with hands-on learning, and (3) collaborative peer tutoring. Although these tactics are demonstrably effective in promoting programming skill, software self-efficacy, and generalizable knowledge, our most recent assessment of learning effectiveness showed room for improvement in the goal of achieving maximal learning in all students on tests of far transfer following the collaborative peer tutoring (Emurian, 2006b). To potentiate the effectiveness of the collaborative peer tutoring, then, the present evaluation was undertaken with a modification to the instructions and materials that were presented to students to prepare for peer tutoring and to use during the collaboration session. The procedure also allowed the collaborating students to view and discuss together the questions that constituted the tests of far transfer. Finally, the Java program to be learned by students as the first technical exercise was updated to Java swing, and it contained more items to be mastered in comparison to the previous work in this area of classroom applications and research.

METHOD

Subjects

Subjects were 13 graduate students, four females and nine males, taking IS 613 (*GUI Systems Using Java*) during a four-week summer session (Summer 2006). The class met three times each week, and each class lasted three hours. The course was designed for Information Systems students, and the prerequisite was one prior programming course.

The background characteristics of the students were as follows: age (median = 28 years, range = 23 to 33), number of prior programming courses taken (median = 3, range = 1 to 15), rated prior Java experience (median = 2, range = 1 to 5 on a 10-point scale presented below), and rated prior programming experience (median = 5, range = 2 to 8 on a 10-point scale presented below).

The research protocol was exempt from informed consent by the Institutional Review Board, and the course syllabus clearly indicated that questions both embedded in the Java tutor and administered during several assessment occasions in class were eligible to appear on a quiz. The course description and syllabus provided information about the Java tutor and the collaborative peer tutoring, and they presented the rationale for the repetition of initial learning using the several different instructional modalities under consideration.

Material

Java Program

The instructional tactics in this study were based upon teaching students a JApplet program that would display a JLabel object within a browser window. The program was arbitrarily organized into 11 lines of code (*e.g.*, ***JLabel myLabel;***) and 37 separate items of code (*e.g.*, ***getContentPane()***). The 11 lines of code are as follows:

```
(1) import javax.swing.JApplet;
(2) import javax.swing.JLabel;
(3) import java.awt.Color;
(4) public class MyProgram extends JApplet {
(5) JLabel myLabel;
(6) public void init() {
(7) myLabel = new JLabel("This is my first program.");
(8) getContentPane().setBackground(Color.yellow);
(9) getContentPane().add(myLabel);
(10)}
(11)}
```

Access to the web-based Java tutor, as presented below, will also show the complete program as part of the tutor's instructions to the student.

Questionnaires[1]

Java software self-efficacy was assessed by requesting a rating of confidence, for each of the 23 unique items of code (*e.g.*, ***import***) in the program, in being able to use the Java code to write a program that displays a text string, as a JLabel object, in a browser window. The scale anchors were ***1 = No confidence.*** to ***10 = Total confidence.*** Twelve multiple-choice questions were administered that required applying a general concept of Java object-oriented programming to solve. These questions did not appear within the Java tutor, and they were intended to assess far transfer or meaningful learning (Mayer, 2002). Each question had five choices, and for each question, a rating of confidence was made that the selected choice was the correct choice. The scale anchors were ***1 = Not at all confident.*** to ***10 = Totally confident.*** Ratings of classification and functionality learning for eight Java identifiers were also obtained, but they are beyond the scope of this paper.

The pre-tutor questionnaire also solicited demographic information, to include age, sex, and college major. The total number of prior programming courses taken was also requested. Two programming experience rating scales were presented, one for general programming experience and one for Java programming experience. For both scales, the anchors were ***1 = No experience. I am a novice.*** to ***10 = Extensive experience. I am an expert.***

The post-tutor questionnaire omitted the demographic information, and it assessed evaluations of the tutor for (1) overall effectiveness, (2) effectiveness in learning Java, and (3) usability. The anchors were ***1 = Lowest value.*** to ***10 = Highest value***.

Procedure

Java Tutor

At the first class meeting, students completed the pre-tutor questionnaire. Students next completed the web-based Java tutor[2]. The tutor taught a JApplet that

displays a text string, as a JLabel object, in a browser window on the web. The Java code and a brief description of the eight stages of the tutor are presented as part of the open source material[3]. When a student finished the tutor, he or she next completed a post-tutor questionnaire, which duplicated the software self-efficacy ratings and multiple-choice rules questions and confidence ratings. The student next accessed a set of questions and guidelines, which were posted on Blackboard, that were to be used to structure the collaborative peer tutoring session during a subsequent class. This material also presented a link to access the textual explanations of the items and lines of code that were presented in the Java tutor. The instructions with this material indicated that the questions presented were eligible to appear on a quiz.

Lecture

At the second class meeting, the author gave a lecture on the program taught in the Java tutor. The students wrote the code in a Unix™ text editor during the lecture, which repeated the information presented in the tutor. The students were also taught the HTML file, used to access the Java bytecode file, as a URL on the web. Support was provided so that all students successfully ran the JApplet program at the conclusion of this lecture-based exercise.

This lecture required approximately one hour to complete, and the remaining class time was spent on the next unit of material, which related to the life cycle of an Applet. Students were encouraged to help each other during the subsequent classes in the semester, which combined lectures and hands-on demonstrations, with the understanding that files were not to be copied without prior permission of the instructor.

Interteaching

At the third class meeting, a collaborative peer tutoring session occurred based upon the dyadic "interteaching" model (Boyce & Hineline, 2002). Students formed six groups of two and one group of three students for the session, which lasted one hour. The assignment was for the students to discuss the set of questions and guidelines made available at the conclusion of the Java tutor work undertaken at the first class meeting. Also presented was the questionnaire, and students were encouraged to discuss the items together prior to answering individually. This was the major innovation in the study, providing the opportunity for students to discuss the rules questions together. The interteaching questionnaire instructions stated that the 12 rules questions were eligible to appear on a quiz, but the remaining items were there only to assess instructional effectiveness of the interteaching session. The interteaching questionnaire also requested ratings of the effectiveness of the session for (1) learning the material and (2) readiness to be tested on the material, where ***1 = Not effective*** to ***10 = Totally effective***.

During the interteaching session, students posted questions on a Blackboard discussion board, and the instructor provided feedback. For the 12 rules questions, the correct selection was never given. Instead, the instructor responded in a way that made certain that students understood the general principle underlying the correct choice, and this process was occasionally iterative.

On the same day as the interteaching session, the instructor posted an announcement on Blackboard giving a rules question that was answered incorrectly by two of the students. The announcement was as follows: "Some students answered 'c' below for this question [also presented in the announcement]. The 'c' choice is not correct because JScrollPane is a class, not an object. An object name begins with a lowercase letter. If you have a question about this, please send me email." All student inquiries were answered privately in a way to promote understanding of the principle involved. The correct answer was not given.

Graded Quiz

At the fourth class meeting, a quiz was administered that included questions embedded within the Java tutor and the 12 rules questions as indicated above. The graded quiz did not include any rating assessments.

RESULTS

Figure 1 presents boxplots of correct answers on the rules test over the five assessment occasions. For each of the 12 questions answered during the Pre-Tutor assessment, one student did not select any answer, but instead indicated being unprepared to answer. The figure shows graphically that the median total correct answers increased over the first four occasions and reached the ceiling of 12 on the Interteaching occasion. A Friedman test (Conover, 1971, p. 264) was significant (Chi-Square = 42.259, df = 4, p = 0.000). The figure also shows that the greatest change occurred between the Pre-Tutor and Post-Tutor occasions, and both medians were 12 for the Interteaching and Quiz occasions. A Welch robust test (Maxwell & Delaney, 2004, p. 134), based on the differences, Di, in correct answers between successive pairs of occasions over the five occasions, was significant (W = 10.889, p = 0.000). Planned pairwise comparisons were significant[4] for D1 compared to D2 (W=10.145, p = 0.005), not significant for D2 compared to D3 (W = 1.513, p = 0.231), and significant for D3 compared to D4 (W = 12.295, p = 0.003).

Figure 1. Correct answers on rules test

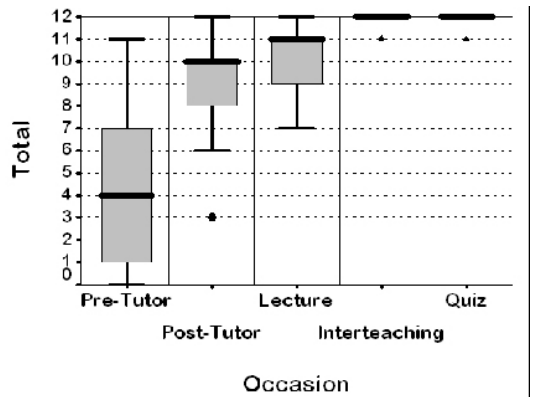

Figure 2 presents boxplots, over four successive occasions, of the ratings made by the students regarding confidence that the selected answer on the rules test was correct for answers that were Right and for answers that were Wrong. Ratings were not obtained during the graded quiz. The number below each boxplot reflects the number of students who answered Right and/or Wrong over the four assessment occasions, and that is the reason that the frequency for a boxplot is sometimes less than 13 (*e.g.*, number of students giving incorrect answers for the interteaching occasion). The Welch robust test, used because of unequal sample sizes, was significant for Right answers (W = 16.632, p = 0.000) and for Wrong answers (W = 40.864, p = 0.000). The latter test was based on the first three occasions because the variance for the Interteaching occasion was zero. For Right answers, planned pairwise comparisons were significant for Pre-Tutor and Post-Tutor (W = 27.398, p = 0.000), not significant for Post-Tutor and Lecture (W = 0.108, p = 0.745), and not significant for Lecture and Interteaching (W = 4.959, p = 0.044) occasions. For Wrong answers, planned pairwise comparisons were significant for Pre-Tutor and Post-Tutor (W = 55.646, p = 0.000) and not significant for Post-Tutor and Lecture (W = 1.220, p = 0.282) occasions. An overall comparison of confidence ratings between Right and Wrong answers was significant (W =

Figure 2. Confidence in accuracy of rules test answers

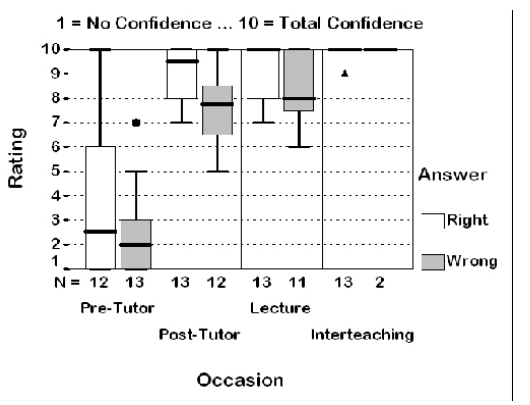

Figure 3. Interteaching evaluation

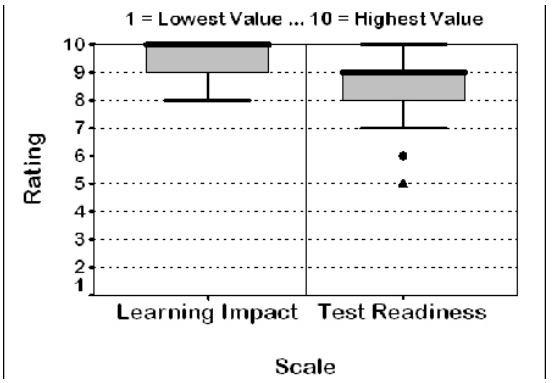

Figure 5. Evaluation of the tutor

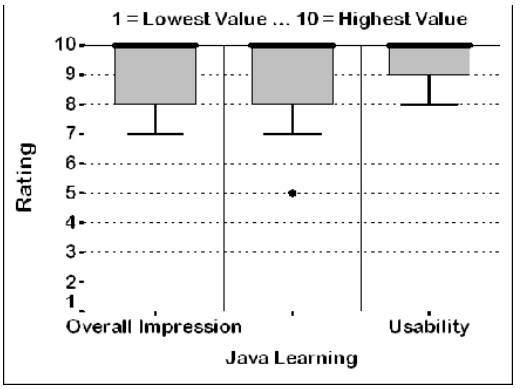


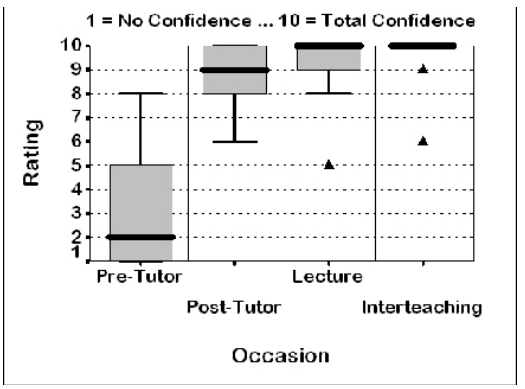
9.481, p = 0.003). Confidence generally increased over the assessment occasions, reaching the ceiling for correct answers after the lecture. However, confidence was seen to increase for both correct and incorrect answers, although an overall comparison favored the correct answer choices.

Figure 3 presents boxplots of ratings on the interteaching evaluation, which was administered at the conclusion of the interteaching session. The figure shows graphically the students' reported value in the interteaching session even when it occurred after using the Java tutor and after running the program on the web. The median rating of learning impact reached the scale's ceiling of ten, with eight being the lowest rating observed. The rating of test readiness was only slightly less, with a median of nine. A Friedman's test was significant (Chi-Square = 5.444, p = 0.020). Similar to our previous work, the ratings of test readiness were lower than corresponding ratings of learning impact. These show that the students reported value in the collaborative peer tutoring even when the session followed several other instructional experiences.

Figure 4 presents boxplots of software self-efficacy ratings across the first four assessment occasions. These ratings were not obtained during the graded quiz. Each boxplot is based upon the median rating over the 23 unique items of code in the program for the 13 students. Cronbach's alpha reliability of the ratings within each assessment exceeded 0.90, and all were significant ($p < .05$). A Friedman test was significant (Chi-Square = 32.614, df = 3, p = 000). A Welch test, based on the differences in correct answers between successive pairs of occasions, was significant (W = 30.222, p = 0.000). Planned pairwise comparisons of the differences, Di, were significant for D1 compared to D2 (W = 60.215, p = 0.000) and not significant for D2 compared to D3 (W = 1.330, p = 0.260). Software self-efficacy increased over the assessment occasions, and it reached the ceiling following the lecture.

Figure 5 presents boxplots of ratings of evaluation of the tutor taken during the Post-Tutor assessment. Medians for all three scales reached the scale ceiling of ten, with only a single outlier observed for Java Learning. These data show that students reported value in their use of the tutor.

Figure 4. Software self-efficacy



DISCUSSION

The results of this study show the value of applying several different instructional modalities in furtherance of having Information Systems students achieve a common level of skill and understanding in a simple Java applet, presented as a first technical exercise in a semester-long course. The data support the utility of this approach as reflected in students' rules test performance and software self-efficacy, which progressively improved over the successive assessment occasions. Rehearsal is an intuitively obvious and well-researched factor in knowledge and skill acquisition (*e.g.*, Salas & Cannon-Bowers, 2001), and the present study shows how structured rehearsal may be managed using the several modalities under consideration. Principles underlying such managed skill acquisition with different instructional modalities are presented elsewhere (Fox & Hackerman, 2003; Halpern & Hakel, 2003).

Having students discuss rules questions together enhanced understanding in the present context. Similar to our previous observations, however, students showed "overconfidence" in incorrect rules answers, and that issue requires exploration in the design of future work. Importantly, students reported value in the Java tutor and in the collaborative peer tutoring, and taken together with the lecture, these approaches to managing rehearsal in the classroom environment converge on what are increasingly recognized as vital ingredients to facilitate science education, in general (DeHaan, 2005).

This study constitutes a systematic replication (Sidman, 1960) of a set of teaching tactics that were revised with the expectation that student learning would be improved as a consequence. The methodology reflects design-based research, which is a type of formative evaluation (Collins, Joseph, & Bielaczyc, 2004) that is emerging as an alternative methodology in support of developing and assessing improvements in instructional design within the context of the classroom (Bell, Hoadley, & Linn, 2004; Design-Based Research Collective, 2003). In that regard, the order of presenting the several instructional tactics was determined by anecdotal observations of student performance over the several classroom evaluations that were previously undertaken in this stream of work. It was decided that a hands-on lecture would benefit from students' prior rehearsal with the Java code and that collaborative peer tutoring would benefit from the cumulative learning obtained from the programmed instruction and the lecture. Since the components in the current ordering are well received by students and since a desired learning outcome was achieved, we have the view that it is worthwhile now to direct our attention to developing advanced instructional material, rather than to "prove" the optimal ordering under conditions of a traditional "effect-size" experiment. Support for that view is implicit within designed-based research and has been discussed by educational scholars (*e.g.*, Mayer, 2004; Sackett & Mullen, 1993).

There are many approaches to teaching computer programming, ranging from an emphasis on mathematics and algorithms (Hu, 2006) to supportive programming environments such as BlueJ (Kolling, Quig, & Rosenberg, 2003), DrJava (Hsia, Simpson, Smith, & Cartwright, 2005), Problem-Based Learning (Tsang & Chan, 2004), PigWorld (Lister, 2004), and the Environment for Learning to Program

(Truong, Bancroft, & Roe, 2005).The instructional tactics adopted here in the classroom at the start of a semester's work are based initially upon *programmed instruction*, which is a form of structured and optionally automated instruction, as discussed by Emurian and Durham (2003) and Emurian, Wang, and Durham (2003) with respect to teaching computer programming. They also include *interteaching*, which is a form of collaborative peer tutoring (Boyce & Hineline, 2002). As implemented in the present context, these tactics originated from behavior analysis, and the Cambridge Center for Behavioral Studies[5] provides fundamental definitions and a wealth of information regarding the philosophical underpinnings and applications of this approach to science, in general, and to education, in particular. Finally, these tactics are to be understood as providing only an initial series of learning experiences to students in preparation for subsequent learning with other instructional and program development tools and techniques, to include the use of an integrated development environment (IDE) such as Eclipse.

Behavior analysis is one promising approach in identifying the ontogenetic instructional learn units (Greer & McDonough, 1999) whose mastery provides the textual tools essential for advanced understanding, thinking, and problem solving in the domain of computer programming and beyond (Skinner, 1957). Teachers facing the difficult challenge of providing effective instruction to the diversity of students who enroll in introductory computer programming courses need to be mindful of all approaches to helping their students succeed. The present study represents one set of instructional tactics that are demonstrably effective for Information Systems students.

Supporting Interorganizational Processes with Interaction Flows and Business Rules

Peter Rittgen, University College Borås, Allégatan 1, 501 90 Borås, Sweden; E-mail: peter.rittgen@hb.se

ABSTRACT

Framework contracts are the main instrument to regulate the cooperation of organizations but they are rarely sufficiently elaborated to actually support the daily routine of interaction. In order to provide this support we suggest the development of interaction flows, interorganizational workflows that describe routine behaviour on a detailed level (sunny-day scenario). They are complemented by business rules which cover exceptional behaviour.

1. INTRODUCTION

The principal mechanisms to coordinate economic activities are hierarchies (internal coordination) and markets (external coordination). Two major theories have been put forward to explain why a particular mechanism is preferred in a given situation: agency theory (Wilson, 1968) and transaction cost economics (Williamson, 1975). Based on these theories it is typically assumed that companies choose their organizational structure and network of trading partners in such a way that the sum of both costs is minimized. Regarding the impact information technology on governance structures, (Malone, Yates, & Benjamin, 1987) suggested that it will lower transaction costs and therefore, ceteris paribus, lead to an increase in market coordination. Empirical evidence (Holland & Lockett, 1997) shows that companies often operate in a "mixed mode" blending aspects from both markets and hierarchies.

In this situation organizations have to rely on contracts to regulate their cooperation. Such framework contracts should provide for sufficiently detailed rules to facilitate process design and IT support. But in reality we often find that the contract only covers few issues (prices, terms of delivery) and leaves it to the responsible managers on each side to work out the details between them. As a consequence the process organization is often ad-hoc and inefficient. Such a situation can be avoided if the framework contract also provided for a description of the necessary interorganizational workflows. The following chapters elaborate this idea.

We base our approach on Business Action Theory (Goldkuhl & Lind, 2004). It divides a process along two dimensions into phases and layers. The phases are: proposals, commitments, fulfilments and assessments, complemented by pre- and post-transactional activities. The layers are transaction group, business transaction, exchange, action pair and business act. We extend this classification scheme by a third dimension: regularity, which consists of regular and exceptional behaviour. This extension is driven by the need to balance complexity and level of detail in the process model. We therefore suggest to split it into regular and exceptional behaviour, where the former is covered by an interaction flow model and the latter by business rules. We show how we applied this approach to a case.

2. BUSINESS ACTION THEORY

Business Action Theory (BAT) is a framework for business interaction. Its origins are in Speech Act Theory (Searle, 1969) and the Theory of Communicative Action (Habermas, 1984) but considers also material (i.e. physical) aspects. According to BAT a business transaction is divided into four main phases: proposals, commitments, fulfilments and assessments. They are complemented by pre- and post-transactional activities. In addition to this BAT also defines layers of actions that represent levels of granularity (Lind & Goldkuhl, 2001). The layer dimension is orthogonal to that of the phases and on each layer a process is composed of elements of the next lower level.

The basic layer contains business acts which can be communicative and/or material. Communicative acts are speech acts in the sense of Speech Act Theory. They are performed in the social (or intersubjective) world. An example of a communicatice act is placing an order. Material acts are performed in the physical (or objective) world. An example of that is the delivery of a pallet. There is no strict demarcation between the two types of acts because business acts are often multi-functional. Delivery of a pallet constitutes, for example, both the material act of moving the physical object and the communicative act of fulfilling the commitment to deliver.

On the second layer business acts are arranged in pairs of action and reaction (or trigger and response). Some authors claim that only such combinations of speech acts should be considered as action pairs that lead to a deontic change, i.e. a commitment or accomplishment in the social world (Weigand & van den Heuvel, 1998; Weigand, van den Heuvel & Dignum, 1998; both papers use the term transaction instead of action pair). This claim is challenged by (Lind & Goldkuhl, 2001) who argue that there are relevant business action pairs that do not lead to deontic changes. When, for example, a customer places an order and the supplier refuses it, no commitment has been made nor has anything been accomplished. But this sequence still constitutes admissible and relevant business behaviour. The refusal might for example trigger the placement of a respective order with a different supplier.

On the third level one or more action pairs form an exchange. This is meant in the most general sense of something that is given in return for something else (e.g. a product in return for money). With respect to a particular exchange the things exchanged belong to the same category. The categories are: interests, proposals, commitments, values (products, services, money) and assessments. They are closely related to the phases so that a business transaction can also be defined as a sequence of exchanges (fourth level). The fifth layer, transaction group, groups consecutive transactions between the same partners.

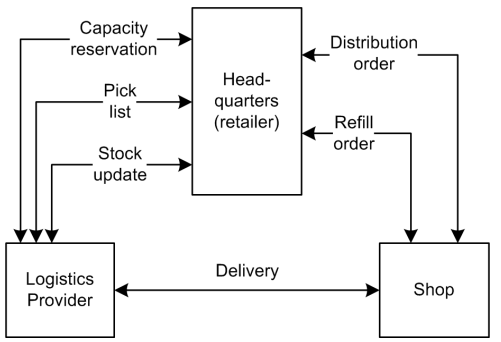
3. MODELING INTERACTIONS BETWEEN ORGANIZATIONS

Some business modeling methodologies provide their own modeling languages, e.g. Dynamic Essential Modeling of Organization (Dietz, 1999). In contrast to this BAT does not come with its own language. Instead its proponents suggest to use the language of SIMM (Situation adaptable work and Information systems Modelling Method) (Goldkuhl, 1996). The loose coupling between method and language might be seen as a disadvantage but (Lind & Goldkuhl, 1997) defend this approach. SIMM contains among other things a number of different diagram types for describing collaboration, interaction, process, action, problem, strength and goal. In our case the Interaction Diagram provided a suitable view. It describes interaction between actors within and between organizations. Its primary elements are actors (in roles) and actions. Actions can be initiated by some actor and directed towards another (single-headed arrows) or they can be mutual (double-headed arrows). Fig. 1 shows the interaction between the three organizations involved in our project.

The main actors are the Logistics Provider, the Headquarters of the retailer and the Shop. The figure shows the exchanges that are performed during order handling. It starts when Headquarters reserve capacity for handling a certain amount of ordered items in advance of the actual order. The Logisitics Provider (LogPro) allocates staff and space so that the reserved capacity can be provided at the time the respective order arrives. But the capacity required by the order might actually be higher or lower than the one that was reserved.

The product assortment of the retailer consists of basic-range products and seasonal products. The latter are distributed to the Shop according to turnover quota (distribution order). This is triggered by Headquarters. Orders for basic-range

Figure 1. The interaction diagram of the case (exchange level)



products are initiated by the Shop. This happens when the Shop is running low on certain products (refill order). Headquarters will forward both types of orders to LogPro in form of a pick list. The delivery to the Shop will then be performed by LogPro which includes picking items, packing them and handing them over to the carrier. The delivery consists of a material act (moving the goods to the Shop) complemented by a communicative act (confirmation of delivery). The material act also has a communicative function of its own: Through it LogPro states that they have performed the delivery and thereby fulfilled their obligation.

Periodically Headquarters will also ask for an update of the stock. This is necessary because they run their own warehouse management system which is not integrated with that of LogPro. The process described so far was part of the business analysis we performed in the project mentioned above. As a result we found out that the existing framework contract was vague which led to a series of problems including:

1. Broken patterns: One important characteristic of a business transaction is that each business act is related to another in a pattern of initiative and response. This means that the sequence of business acts needs to be followed in the sense that the pattern should not be broken. Going back to the empirical setting it can be identified that Headquarters supply estimates (as an initiative) without getting a response. There is thus a pattern of interaction when establishing the framework contract and another one when realizing the business transaction. The interaction pattern that glues framework contract and business process is thus broken. This has the effect that Headquarters cannot be sure of the capacity that will be available at the time of order and LogPro does not reserve the required capacity. The estimates made by Headquarters are therefore neither informative nor directive and hence do not imply mutual commitments. As a consequence, the contract should be specified in such a way that encourages the parties to keep the patterns intact.
2. Business rules: There are no rules that guide the interplay between the overall framework contract and the embedded business transactions. Such rules are necessary to regulate the details of interaction and to provide infrastructural support such as IT systems.
3. Indistinct communication structures: It is often unclear who communicates with whom regarding which issue.
4. Lack of trust: Different interpretations of the contract by the parties led to expectations that were not fulfilled. This led in turn to a lack of trust in succeeding transactions.
5. Excessive communication: A considerable amount of personal interorganizational communication was spent on handling everyday work. This was only necessary because of insufficient specification of routine procedures in the framework contract.
6. High transaction costs: Ad-hoc solutions to exceptional problems increased transaction costs.

In this situation it soon became clear that the solutions to these problems require a relatively detailed specification of the coordination process down to the level of business acts. Moreover, according to issues 1 and 2 this detailed process description has to be part of the framework contract itself to ensure that the internal workflows in each party to the contract are aligned with the overall interorganizational process. This poses a substantial problem because the resulting interaction model would be too large and complex to be included in a contract. As a consequence it would be difficult to achieve understanding on all sides of such a contract and the chances of reaching an agreement would be even smaller. The following section pursues a possible solution to this problem.

4. INTERACTION FLOW AND BUSINESS RULES

As mentioned in the previous section, an improved support for interorganizational processes requires the specification of the interaction on the level of business acts. Fig. 2 shows, as an example, the result of decomposing the pick list exchange of fig. 1 into its business acts assuming that the exchange requires only the minimum of two conversations (actagenic and factagenic) with one action pair each. These consecutive conversations aim at reaching an agreement about 1) the execution of an action, and 2) the result of that execution, respectively.

This scenario does not provide for exceptional behaviour. Headquarters send a pick list to LogPro which is confirmed. LogPro then picks the ordered items from the shelves and packs them onto pallets (which are subsequently picked up by a carrier). Thereafter the delivery is reported by LogPro and confirmed by Headquarters (after having received the corresponding confirmation from the Shop). If we make the same assumptions for the remaining exchanges of fig. 1 we arrive at the Interaction Diagram in fig. 3.

This diagram already exhibits a substantial complexity but it does still not cover cases where something goes wrong. We therefore decided to take a closer look at the process with respect to the frequency of each act. In the course of this analysis we discovered:

- Some business acts are rarely performed in reality. Putting them into the diagram would crowd it without improving understanding of the process. Such exceptional behaviour can better be treated separately in form of business rules. Business rules are listed in a table in the form of a textual description.

Figure 2. The interaction diagram of the pick list exchange (business-act level)

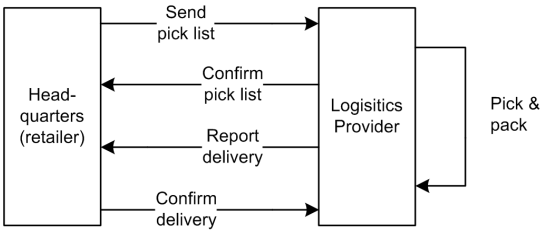


Figure 3. The interaction diagram of the case (business-act level): r = request, p = promise, s= state, a = accept, e = execute

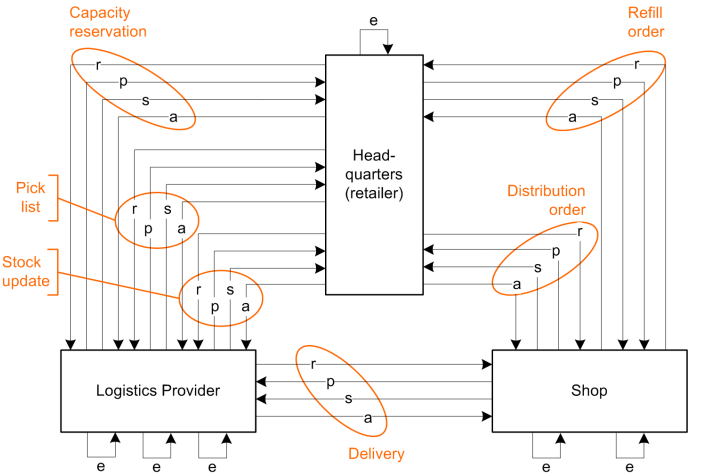


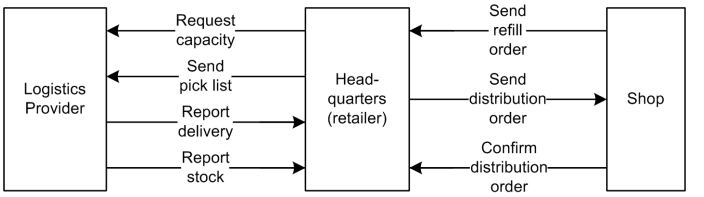
- Some business acts are often performed repeatedly with the same result or their result is usually not required. In such a situation it can be more appropriate to drop this act from the diagram (in the positive, regular case) and replace it with a business rule that covers the negative case instead (i.e. the exception). An example for this is the act "Confirm pick list". This confirmation is usually not needed because the act of sending the pick list is automated and hence quite reliable. So instead of having the confirmation act in the interaction diagram we will assume that the pick list was sent and specify a rule that provides for the case of a failure.

This means that we introduce a third dimension into Business Action Theory: regularity. It refers to the frequency with which a certain action is performed in relation to the overall business process. A regular action is one that is performed in (almost) every instance of the business process. An exceptional action is performed only in a fraction of the instances. Along this dimension the business action can be divided into a number of classes that depends on the application scenario. Each class is associated with a (possibly different) modeling language that fits this type of business action. In our case we found it useful to define two classes: regular and exceptional. The regular class is associated with the Interaction Diagram, the exceptional class with business rules. The borderline between the classes is usually not sharp and critical cases have to be assessed individually.

An Interaction Diagram on the business-act level that represents regular behaviour is called an Interaction Flow because its level of detail is such that it corresponds to a workflow of the interaction. Consequently it can be used not only for the framework contract but also as a basis for setting up the internal workflows in each participating organization. The latter could then be supported by workflow management systems.

Fig. 4 shows the Interaction Flow for our case. The flow starts when Headquarters send a request for capacity. Such a request is always granted provided that the limits specified in the framework contract are not exceeded. Hence no further interaction is triggered. At some later point in time Headquarters send a distribution order for seasonal products to the Shop. This distribution order has to be confirmed by the Shop because they often have to make corrections (i.e. this is a regular act). Independent of that the Shop can also send a refill order when the stock is running

Figure 4. The interaction flow of the case



low on certain products of the basic range. Such an order is, as a rule, not confirmed by Headquarters because a sufficient stock is assumed for these prodcuts. Only in the exceptional case of an out-of-stock situation they would send a respective notification. This is covered by a business rule (see table 1). Any kind of order is forwarded to LogPro in the form of a pick list. It contains detailed information on type and amount of products to be delivered to each Shop and it triggers a number of internal activities by LogPro such as picking the products from the shelves, packing them into boxes and stacking the boxes on pallets to be picked up by a carrier. Upon completion of this work LogPro will report the delivery. Again there is no confirmation and exceptions are handled by a business rule, such as complaints about missing items and returns of wrong items (see table 1). A daily stock report is sent automatically via file transfer without it being requested.

Regular and exceptional actions can be seen as complements of each other. A regular action is one that is performed in the majority of instances of a business process, i.e. it covers the "normal case" (so-called sunny-day scenario). The remaining instances represent "unusual cases" which are dealt with by a set of exceptional actions (rainy-day scenarios). Regular and exceptional actions together should cover all possible cases. It should be noted that there can be situations where all cases occur only occasionally and a regular case is hard to identify. In such a situation the decision regarding the regularity of the action should be guided by the suitability of the respective method (i.e. in our case Interaction Flow vs. business rule).

Table 1. The business rules of the case

Exchange	Business act	Performer	Adressee	Business Rule
Refill order	Accept order	Headquarters	Shop	A refill order is per default accepted and hence not confirmed. In case of out-of-stock a respective notification is sent.
	State/accept delivery	Covered by delivery		
Distribution order	State/accept delivery	Covered by delivery		
Delivery	Request/promise delivery	Covered by refill/distribution order		
	Accept delivery	Shop	LogPro	This is implied by the receipt of the delivery. If items are missing or wrong ones have been sent a respective complaint is sent to LogPro and wrong items are returned to LogPro.
Capacity reservation	Confirm reservation	LogPro	Head-quarters	A request for a capacity (forecast of required capacity) is always granted and hence not confirmed.
Pick list	Accept pick list	LogPro	Head-quarters	The pick list is accepted per default and no confirmation is sent. If the amount of items exceeds the limit specified in the general terms and conditions of the framework contract (in relation to the reserved capacity) a special arrangement is made (e.g. the warehouse staff is rescheduled, the unit price is raised).
	Confirm picking	Headquarters	LogPro	This is implied by the receipt of the delivery by the Shop and assumed by LogPro. The claims are handled directly between LogPro and Shop (return/resend).
Stock update	Request update	Headquarters	LogPro	Updating of the retailer's warehouse system is done via an automatic, daily file transmission containing a stock report. Request and promise are therefore obsolete.
	Promise update	LogPro	Head-quarters	
	Accept update	Headquarters	LogPro	The receipt of the stock report is assumed. If transmission fails, manual trouble-shooting is invoked.

5. RELATED AND FUTURE RESEARCH

The research we have performed so far shows the feasibility of the approach with respect to the case. An issue that we have barely touched is that of workflow management support. We already pointed out that Interaction Flows provide sufficient detail for the development of a workflow model. But conventional workflow technology is limited to deployment within an organization. A possible solution lies in the integration of decentralized workflow management systems. This is the object of current research (Jang, Choi, & Zhao, 2004; Shen & Liu, 2001).

The rigorous description of the interorganizational process could extended to the static part. e.g. the general terms and conditions. Simulation can facilitate both reengineering of the process itself and the derivation of static contract parameters from the simulation results (e.g. period of delivery based on the simulated time from order to delivery).

In the areas of electronic commerce and virtual organizations there is a growing interest in more formalized contracts (Artyshchev & Weigand, 2005; Milosevic, Linington, Gibson, Kulkarni, & Cole, 2004; Weigand & Xu, 2003). The existing approaches are often technology-driven and there is a need to complement them with rigorous approaches that have a strong business orientation. Our research takes a step in this direction. But formalized contracts (e.g. eContracts) are not only beneficial in electronic commerce or automated transactions. They can also make a substantial contribution towards the support of interorganizational business processes and workflows.

6. CONCLUSION

Business Action Theory offers a stable framework for the analysis of interorganizational processes and the SIMM language provides a suitable diagram, the Interaction Diagram, to model them from an interaction perspective. But this approach is fraught with a trade-off: In order to translate the contract into a workflow specification the Interaction Diagram has to be on a detailed, i.e. business-act level. But in order to reach an agreement on it all parties have to understand it. We balance these needs by splitting the interaction model into two parts, one for regular behavior and one for exceptions, thus introducing a third dimension into BAT. In our application the first part is modeled as an Interaction Flow, a special case of the Interaction Diagram, to facilitate the design of workflows. For the second part we have chosen business rules, an informal language that employs textual information in form of a table.

A case study involving a logistics provider and a retail chain was performed to prove the feasibility of the approach. To ensure the authenticity of the models we used seminar-based modeling sessions that involved participants from both organizations. A seminar leader elicited information from them to design a preliminary version of a model. This was then discussed and the feedback was used to adapt, extend or detail the model. This process was repeated until the required scope and level of detail were reached and no further improvements could be achieved.

Transforming Procurement in the UK Immigration Directorate

Elayne Coakes, University of Westminster, Westminster Business School, 35 Marlyebone Road, London, NW1 5LS, UK; E-mail: coakese@wmin.ac.uk
Nanette Young, Auld Scott & Company, Windmill Hill Business Park, Whitehall Way, Swindon, SN5 6QR, UK; E-mail: mail@auldscott.co.uk

ABSTRACT

This paper discusses the Procurement Transformation Project of the UK Government's Immigration and Nationality Directorate. The project was designed to change the current procurement processes and to enable the frontline business units to undertake these activities. Through the use of Sveiby's (2001a) Ten Knowledge Strategy Issues a knowledge management strategy was devised and knowledge of the business requirements for goods and services procurement was successfully developed within the stakeholder community. Tangible benefits such as salary savings and improved organisational design were realised. Additionally, intangible benefits of increased staff knowledge, process understanding, and knowledge sharing within the improved social network were also achieved. This paper demonstrates that a practical implementation of knowledge management activities in the supply chain, devolving decision-making to the front-line staff, can make significant procurement savings and improve relationships within the stakeholder community.

Keywords: Knowledge strategy; procurement; supply chain management; innovation; business process transformation.

1.0 INTRODUCTION

This paper describes how knowledge management was established as one of the key elements of success for the Procurement Transformation Project of the UK Government's Immigration and Nationality Directorate (IND).

The Procurement Transformation Project (PTP) was designed to support and empower frontline business units to undertake routine local transactional and operational procurement. The PTP focussed on increasing knowledge and value within the procurement community and its stakeholders, through using Sveiby's (2001) Ten Knowledge Strategy Issues to support the business requirements.

This paper discusses the link between knowledge, innovation and business processes. It looks at Sveiby's work related to Knowledge Strategy and the Knowledge Based approach to organisations; and considers the use of knowledge management in procurement and business processes in the Public Sector and Government, illustrating this with the case of the Procurement Transformation Project.

1.1 Research (and Methods)

This was not a research project per se and so no questions were formulated prior to undertaking the work.

This was commercial consultancy project whereby the academic was presented with archival data by the consultant for analysis. Informal conversations were also conducted to clarify issues, timelines, and understandings.

Whilst an element of grounded theory was utilised in that no preconceptions as to what the data might reveal were formulated and no propositions developed, a full grounded data analysis was not performed. Rather a top level content analysis was performed to in order to classify and theme the data. This permitted the academic to apply different theory to different parts of the data for academic understanding of the process and to ensure that the data was partitioned appropriately. This high level open coding produced some interesting outcomes whereby the consultant commented "I hadn't thought of the project being like that", and additionally permitted sufficient segmentation so that more than one interpretation of the data could be taken and thus written up as academic papers (see Coakes and Young, 2006; Coakes and Young, 2007 forthcoming).

2.0 KNOWLEDGE, INNOVATION AND BUSINESS PROCESSES

In the section below we consider the link between innovation in business processes and knowledge. Whilst the IND is a public sector body, its role is to provide a service to other UK Government departments and thus, we would argue can be considered in the light of the literature that relates to the service sector.

Prajogo's (2006) article considered the link between innovation and business performance and discussed the existing literature assumptions relating to innovation in service firms. The literature suggests that such innovation is largely technological (Gallouj, 2002). Service firms it is argued are less radical than manufacturing and their emphasis is on continuity rather than newness (Voss et al, 1992). Innovation in such firms is mostly adopted and thus is concentrated on process rather than product (Gallouj, 2002) where such innovations are rapidly implemented but easily copied (Voss et al, 1992) - process innovation is thus a prime area of concern.

2.1 Process Innovation

In the case study discussed below relating to the IND, the major innovation was indeed related to a change in processes - in which a technological innovation was utilised to facilitate a process innovation. According to Popadiuk and Choo (2006) technological innovation relates to the 'knowledge of components, linkages between components, methods, processes and techniques that go into a product or service…(whereas) process innovation is concerned with introducing new elements into an organisation's operations such as input materials, task specifications, work and information flow mechanisms and equipment used to produce a product or render a service' (p303) (see also Afuah, 1998).

Stamm (2003) compares the major differences between incremental and radical innovation through 9 foci. These foci - time frame; development trajectory; idea generation; process; business case; players; development structure; resource requirements; and unit involvement, indicate who should be involved and how the project should be undertaken. In the case described below, the project falls very much into the incremental innovation category as indicated by Table 1.

Incremental innovation is appropriate for business processes in terms of continuous (quality) improvement, where radical organisational change is not required but rather improved support and greater efficiency (within the supply chain).

In addition, there are a number of models of innovation in the literature (for example Abernathy and Clark, 1985; Henderson and Clark, 1990; Tushman et al, 1997; Chandy and Tellis, 1998) which consider both technology and market perspectives in describing the type of innovation and its level of radicalism for the organisation. Technology is considered to impact on the market whereby new technology may produce new markets or market knowledge, or enhance penetration to the existing market and develop existing knowledge. The market of course can also be considered as the client and, in today's environment we can also consider that the market can be the supply-side value-chain. Technical innovation, whether it is radical, incremental, or indeed generational (Tushman et al, 1997), represents a change from existing firm practices and activities and thus requires project management and knowledge management of what is required, when, and

by whom. Innovation it is also argued (Popadiuk and Choo, 2006) depends on knowledge creation and in their paper they juxtapose a number of ideas relating to innovation and the types of knowledge creation that can produce them. In particular, they infer that sharing mental, emotional, and active knowledge can generate ideas to produce value for the organisation, suppliers and customers; and that knowledge based on the value chain produces innovation for both component and architectural elements of the firm. In addition, they pair procedural knowledge with market orientation and change in technology; and whole company knowledge with localised and functional area innovation.

The formal management of organisational knowledge in an organisation requires the organisation to formulate a knowledge strategy and to allocate resources to this end. Localised and functional area innovation, such as process innovation, can be guided through its development phases by answering Sveiby's Ten Strategy questions as discussed below.

2.2 Sveiby and Knowledge Strategy

In 2001(a), Sveiby identified ten issues or questions that should be asked to guide (knowledge) strategy formulation in the firm. These are:

1. How can we improve the transfer of competence between people in our organisation?
2. How can we transfer some of our competence to customers, suppliers and other stakeholders?
3. How can our people learn more from customers, suppliers and other stakeholders?
4. How can we support our customers' conversations with their customers, or host communities?
5. How can we use competence from customers and suppliers to add value to our systems, processes? Services, practices and products?
6. How can our customers and suppliers learn by accessing our systems, processes, services, practices and products?
7. How do we integrate systems, tools, processes and practices effectively internally?
8. How can we convert individually held competence to systems, tools and templates?
9. How can we improve individual's competence by using systems, tools and templates?
10. Strategic Purpose: how can the value of creation capacity of the whole system be maximised?

Sveiby emphasises three major aspects of the firm - customer relationships, internal structure, and employee competence. These elements make up what *Sveiby* calls 'knowledge capital'. The purpose of Knowledge Management for Sveiby (2001b) concerns how the organization best can nurture, leverage and motivate people to improve and share their Capacity to Act. Indeed, Sveiby says you should regard the organisation as consisting of knowledge, people, and the relationships between people. He proposes a knowledge-based approach to the organisation which recognises the fact that performance excellence does not exclusively mean financial performance. Under a knowledge-based approach the primary objective of actions is to enhance the value of all assets of the organisation by enhancing knowledge flows, generating intangible revenues, reducing intangible costs, and enabling knowledge creating processes (Sveiby 2001c).

If we consider Sveiby's three major aspects of the firm in the light of business processes, and in particular, the supply chain, we can see that process innovation needs to improve employee competence and knowledge, and that an organisational structure that empowers employees is likely to achieve this. It is also evident in the supply chain process that stakeholder relationships (both internal customer and external supplier) are of great importance and must be managed effectively and with understanding of their environments to formulate requirements. Formulating a strategy that develops competences and increases understanding is thus important in any organisation whether Public Sector or not.

3.0 KNOWLEDGE MANAGEMENT IN PROCUREMENT AND BUSINESS PROCESSES FOR GOVERNMENT ORGANISATIONS

Innovation in the public sector has not often been considered as being either radical or frequent. Additionally, it is often thought that innovation comes from the top and is not initiated by the front-line staff (Borins, 2000). However Borins' study showed this was not the case and many innovators in the public sector had the same entrepreneurial characteristics as those in the private sector and were prepared to be creative, to take risks and break rules and (even) not to be bureaucratic.

In the public sector, Borins' (2000) study showed that the most frequent reason for innovation was internal problems such as procurement (as cited below for our case organisation), but additionally, political initiatives were also high on the reason list for change and innovation with ICT (Information Communication Technology) frequently provided these opportunities.

Procurement in Government organisations is traditionally an area that has been looked at many times for ways to cut costs and to streamline the business processes and workflow to increase efficiency (Hsieh et al, 2002). To support business requirements procurement there needs to be a time-scheduled sequence comprised of the materials and components (Bowersox et al, 2002). ICT has long been involved in ways of stream-lining and numerous systems have been designed to improve the workflow. However, as with so many ICT systems, there has been a steady failure rate. Hsieh et al (2002) attribute these failures to diverse internal cultures (within the business units involved in the process); technical issues relating to the technology and systems; and human-computer interface issues.

Procurement is an essential component of an organisation's supply chain. It connects internal business units with external suppliers and is typically complex with, according to Hsieh et al (ibid) upwards of 15 different processes involved. Associated with these processes are numerous documents and activities and a variety of decision points for action along the supply chain. Many ICT systems pass the procurement decisions to the suppliers and thus organisations are reliant on their suppliers' knowledge and understanding of the business situation rather than using an internal understanding of the situation. This has caused significant problems for some organisations when the suppliers make the wrong decisions (see Solectron Corp as discussed in Engardio, 2001).

Procurement is about connecting up the diverse elements of the supply chain across unit and organisational boundaries and cultures and human understandings of the situation. Thus utilising and sharing knowledge across the procurement process will assist in helping with issues such as determining the optimal mix of order size and suppliers; controlling the timing of ordering and order delivery; managing product quality; and improving the management of cash-flows.

Best practices in utilising knowledge management (to assist in procurement) have been put forward by the APQC[1] (as described in Wimmer, 2005). These include creating a team approach; focusing efforts on business objectives and measuring tangible outcomes; and using a blend of knowledge-sharing approaches that incorporates people, processes, organisation and technology - the classical socio-technical approach. Wimmer also points out that learning cultures are not prevalent in governmental organisations and knowledge management has to be introduced in such a way that it can be seen to provide an immediate benefit. Knowledge management that preserve the organisation's Intellectual Capital she says, will not only cover the initial investment but will also add additional future value. Indeed, knowledge management is so difficult to introduce into public sector organisations that Sinclair (2006) argues it needs to be done by stealth… Sinclair also argues that this could be a result of senior managers' attitudes towards organisational structure and control which emphasises centrality over knowledge flows.

The intention of including knowledge in a procurement supply chain must be to lift the chain management from the 'ad hoc' level (Lockamy & McCormack, 2004) through to a higher level such as (initially) 'linked' but essentially up to 'integrated' and finally 'extended'. An integrated chain is where vendors and suppliers cooperate in the process and collaborative forecasting is performed. The extended chain has supply chain competition, and collaboration is through multi-firm teams with common processes, goals and a broad authority.

Seeley (2002) argues that effective knowledge management comes from connecting knowledge activities to processes that create value. Merely capturing, stockpiling, and transferring knowledge does not automatically lead to organisational performance enhancement (Swan, 2003). Successful processes indeed are (frequently) knowledge enabled (Smith & McKeen, 2004); yet to date this is not well developed in organisations. Successful processes will also link informal tacit knowledge into these activities and will be built within an organisational context and culture that supports (Marchand et al, 2000). An understanding of the context may also improve the process outcomes and execution (El Sawy & Josefek, 2003) and may elucidate the issues surrounding problems and uncertainties in the process.

The case study we describe below shows how the building of knowledge in the Procurement Transformation Project attempted to answer Sveiby's ten questions and also set out to link in this tacit knowledge that was held in the Immigration Service so that it was built into the processes and thus answered Smith and McKeen's current criticisms.

4.0 THE PROCUREMENT TRANSFORMATION PROJECT

Background

This project was carried out between January 2005 and April 2006 for the UK Immigration and Nationality Directorate (IND) within the Home Office.

The Immigration and Nationality Directorate (IND) is part of the Home Office. (Home Office, 2006a). The Home Office is the government department responsible for ensuring that the citizens of the UK " live in a safe, just and tolerant society by putting public protection at the heart" (Home Office, 2006b) of all they do. They are responsible for the police in England and Wales, national security, the justice system and immigration. The strategic objectives of the IND are to:

- Strengthen borders, use tougher checks abroad so that only those with permission can travel to the UK, and ensure that they know who leaves so that they can take action against those who break the rules.
- Make fast track asylum decisions, remove those whose claims fail and integrate those who need protection.
- Ensure and enforce compliance with UK immigration laws, removing the most harmful people first and denying the privileges of Britain to those who arrive illegally.
- Boost Britain's economy by bringing the right skills from around the world, and ensuring that the UK is easy to visit legally. (IND, 2006a)

The IND's work is underpinned by Home Office Aim 6: to manage immigration in the interests of Britain's security, economic growth and social stability. This means that their work includes the following areas:

- Immigration
  Considering applications from people who want to come to the UK to work, do business, visit relatives, take a holiday, or settle permanently.
- Nationality
  Deciding applications from people who want to become British citizens.
- Asylum
  Responsibility for processing all claims for asylum and asylum support made in the United Kingdom
- Border control and entry clearance
  Last year, the UK Immigration Officers facilitated the arrival of more than 12 million passengers who were subject to immigration control. British Diplomatic overseas visas staff decide applications from people who need to get permission to enter the UK before they travel.
- Law enforcement
  Enforcing and framing the immigration laws. It is their job to deter illegal workers and illegal entrants - Immigration Officers have legal powers to detain and remove them from the country.
- Appeals
  They share targets with the Department for Constitutional Affairs, the department with responsibility for the Asylum and Immigration Tribunal (IND, 2006b).

4.1 The PTP

The primary objective of the Procurement Transformation Project was to empower and support the frontline business units to undertake routine local transactional and operational procurement. The core PTP objective emanated from IND strategic business drivers which were to deliver the recommendations of the Government White Papers by Gershon (2004) and Lyons (2004) which related to the utilisation of assets, through releasing resources for the frontline units within the Home Office, and lowering the cost of resources needed to provide public services.

In particular the project set out to:

- Assist the organizational objectives by designing effective corporate governance to enable local procurement;
- Develop suitably trained staff;
- Increase the capacity of the central procurement unit to undertake and sustain local and operational buying at the frontline and high value strategic procurement at the centre;
- Enhance IND commercial activity by creating a procurement community of practice through knowledge sharing, utilizing the Procurement User Group (PUG) meeting format, commercial development workshops and a web based portal.

The Approach

The project was undertaken in a controlled environment based on a formal project management methodology (Prince II™). A Project Board was appointed to review progress at critical stages and reference to peer sounding boards was used throughout the project as and when needed.

Commencing with formal approval, the project completed a critical analysis of procurement activity and existing procurement skills through a gap analysis of skills, competences, information and technology. A formal Benefit Management tracking process was prepared at the commencement of the project and updated throughout the project. The analysis stage informed the proposed future structure of procurement within the hubs and the potential benefits arising. A review at the conclusion of this stage was undertaken to ensure buy-in of relevant key stakeholders, to consider the benefits and to confirm the continuance of the project.

A knowledge management strategy was developed from the "10 Knowledge Strategy Issues" and the "Knowledge based theory of the Firm" created by Karl-Erik Sveiby (2001).

The KM strategy for the project focused on increasing the knowledge and value within the procurement community and relevant stakeholders, and subsequently the 10 Sveiby strategies were developed to support the business requirements to effectively and efficiently procure goods and services.

As a result of the project analysis, minimal procurement competences and knowledge were identified in "frontline" business units and was identified that a recently implemented ERP system was not delivering its planned efficiencies. The ERP system was a powerful tool but the users were not fully aware of how it could be used and were unaware of its role in the supply chain and the totality of the system. As a result the first phase of the KM implementation focused on 5 of the Sveiby strategies and "individual competence" by:

- Improving the transfer of competence between people in the organization;
- Transferring competences to customers, suppliers and other stakeholders;
- Learning more from customers, suppliers and other stakeholders;
- Converting individually held competence to systems, tools and templates; and
- Improving individual's competence by using systems, tools and templates.

The PTP realities were that, through the use of the Prince II™ formal project management method, Stamm's innovations were all achieved.

5.0 OUTCOME AND BENEFITS

The project delivered both tangible and intangible benefits as the business units were receptive and open towards learning and a consensual style of organisation - these benefits were:

Table 1. Incremental innovation categorisation (as per Stamm)

Focus	Stamm's description	The PTP realities
Time frame	Short-term - 6-24 months	√
Development trajectory	Step by step. High levels of certainty.	√
Idea generation	Incremental. Critical events anticipated.	√
Process	Formal, staged.	√
Business case	Business case produced initially	√
Players	Cross-functional team. Clear roles.	√
Development structure	Cross-functional team within existing business unit.	√
Resources	Provided within team, standard process.	√
Operating unit	Involved from beginning.	√

Tangible

- Management reports for cross business procurement activity were derived from the ERP system;
- Procurement awareness workshops and material were developed and implemented;
- Procurement organizational design was undertaken;
- Buyer job specifications were developed and implemented;
- Salary savings were made as a result of the role scope changes;
- £700,000 plus savings were made through local training which enabled a wider usage of the GPC (Government Procurement Card i.e. a type of internal credit card), and the local decision-making and buying competences developed;
- A benefit tracking document was developed.

Intangible

- Local staff understanding of relationship between system activity and procurement practice was developed;
- An improved relationship with suppliers developed;
- Greater leverage in procurement negotiations occurred;
- An enlarged social network developed for informal sharing of procurement practices;
- There was knowledge sharing for system improvement;
- Enhanced system training was undertaken;
- Supply chain awareness was developed.

6.0 CONCLUSIONS

As John Ruskin said[2]:

It is unwise to pay too much, but it is worse to pay too little. When you pay too much, you lose a little money. When you pay too little, you sometimes lose everything.

Procurement is about providing the end users of the item procured with what they need, when they need it, and at the best value to the organisation. Procurement is a very complex task that is achieved through matching the multiple supplier offerings, through competition, with the multiple requirements of the purchasing organisation. Procurement has legal, ethical, specification, and supplier appraisal aspects. In all of these there are business processes that need to be undertaken and matched and integrated with each other. In each business process there will be found *sticky* knowledge (Coakes et al, 2004) which is related to tacit knowledge that will need to be considered and transferred. As argued above this sticky knowledge is often not transferred within the supply chain and procurement processes. As can be seen from the description of the work of the IND, their functions and connections within the UK Home Office are multiple and diverse. These multiple functions and activities can only complicate the procurement process. There is a requirement for a varied knowledge base and in-depth knowledge in a variety of fields of expertise.

In this paper therefore, we demonstrate through a case study of a UK project how knowledge within business processes and the supply chain for procurement can be identified, explicated, and made valuable through devolving decisions to those at the frontline of the decision-making process. Through utilising local knowledge, and developing competences and learning, with a change in organisational structure and management style, significant savings in procurement can be made.

Multi-Grounded Development of Enterprise Modeling Methods: The Case of SIMM

Peter Rittgen, University College Borås, Allégatan 1, 501 90 Borås, Sweden; E-mail: peter.rittgen@hb.se

ABSTRACT

Multi-Grounded Theory (MGT) extends Grounded Theory by further grounding processes, most notably theoretical grounding. As an example for applying MGT we use the enterprise modeling method SIMM, which is empirically grounded, and show that this method can profit from grounding it also in an external theory. We outline a procedure called communicative and material functions analysis that can be used for this purpose and apply it to Business Action Theory. With the help of the extended method we analyze a business situation in order to follow up the commitments that are made in the course of a business process with the ultimate aim of detecting flaws in that process.

1. INTRODUCTION

Grounded Theory (GT; Glaser, Strauss 1967; Glaser 1992; Glaser 1998; Strauss, Corbin 1998) was introduced to provide a systematic procedure for deriving categories and theoretical constructs from empirical data. GT is, strictly speaking, not a theory but rather a method for theory development. Its characteristics are the relatively short iteration cycles and a process of continual improvement. Starting with a small set of empirical data we develop an initial understanding of the problem field, which then can be used to gather further empirical data in a more controlled fashion, leading to an improved understanding and so on until we reach theoretical saturation.

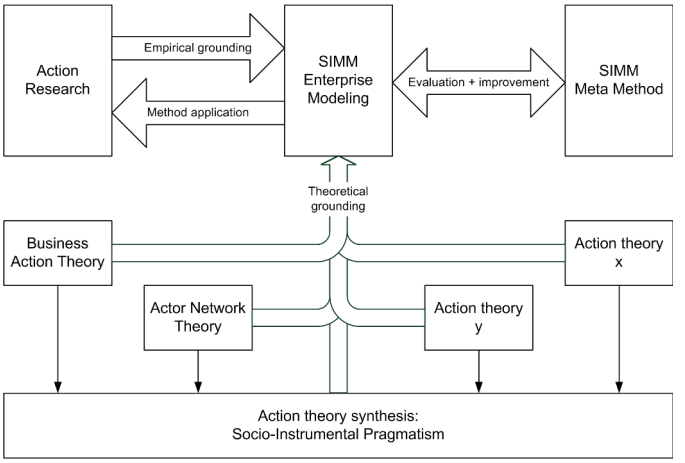
GT started out in sociology but has since been applied in a variety of fields including informatics. In the latter it has also been used to develop modeling methods, typically based on action research. An example of such a method is SIMM (Situation-adaptable work and Information systems Modeling Method; Goldkuhl 1996). SIMM has been empirically grounded in action research projects some of which are documented in (Lind, Goldkuhl 1997; Melin, Goldkuhl 1999; Axelsson et al. 2000; Goldkuhl, Melin 2001; Axelsson, Segerkvist 2001; Lind et al. 2003; Melin, Axelsson 2004; Johansson, Axelsson 2004; Johansson, Axelsson 2005; Haraldsson, Lind 2005). SIMM provides both a method for enterprise modeling and a meta-method for evaluating modeling methods.

Empirical grounding proceeds as follows: SIMM Enterprise Modeling is applied in an action research project. The experiences gained from the use of the method are evaluated with the SIMM Meta Method and corresponding changes to SIMM Enterprise Modeling are made. In a further round of action research these changes are consolidated and further improvements are made (see fig. 1).

GT has been criticized for being restricted to a purely inductive approach. It is argued that we cannot ignore the knowledge that established theories might contribute. Consequently, (Goldkuhl, Cronholm 2003) suggest that further grounding processes are required in addtion to the existing empirical grounding process, most of all a theoretical grounding process. They call this new approach Multi-Grounded Theory (MGT).

If we want to apply MGT in the context of enterprise modeling we must identify a suitable theory that can function as external theory for theoretical grounding. For the purpose of this paper we have chosen Business Action Theory (BAT; Goldkuhl 1996; Goldkuhl 1998; Goldkuhl, Lind 2004) because some preliminary work has already been done in that area. E.g. (Goldkuhl 1996) has extended SIMM to cover communicative actions, which are essential in BAT. Many other important concepts such as layers and phases have been disregarded, though. It is the purpose of this paper to complete the theoretical grounding of SIMM in BAT.

Figure 1. Multi-grounded development of an enterprise modeling method



This can be considered as a first step, as a grouding in other action theories might also be considered. But as the choice of external theory is contingent there are strong arguments to synthesize the relevant theories as Goldkuhl (2005) pointed out. The result, Socio-Instrumental Pragmatism (SIP; Goldkuhl 2002; Goldkuhl 2005), is a general ontology of social action. So far it is not sufficiently developed to provide a basis for theoretical grounding. We therefore restrict our approach to BAT for the purpose of this paper.

The remaining sections are structured as follows: We first introduce BAT and the generic layered patterns for business modeling. This framework is then refined by combining phases and layers. We proceed by applying communicative and material functions analysis to it, followed by a classification of the resulting functions, and finally leading to the extension of SIMM in terms of BAT concepts. We conclude by presenting an application of the extended method for the purpose of commitment analysis.

2. BUSINESS ACTION THEORY

The elementary unit of behavior in BAT is a business act. It comprises both a language act and a material act. A language act is an elementary communicative activity in spoken or written form directed from one actor to another with the aim of changing the mental state of the latter. A material act is an elementary physical activity directed from an actor to the material world with the aim of changing its state.

Strictly speaking, and as observed by Goldkuhl (1996), language and material acts are not so much distinct and separate acts but rather functions (or aspects) of one and the same business act. For example, the business act of delivering goods is, perhaps in the first place, a material act. i.e. transporting "stuff" from one place to another. But at the same time it has a communicative function, i.e. it implies the language act "We have fulfilled the commitment we entered by accepting the respective order."

This means that a deeper understanding of business action must be grounded in an analysis of these functions. We call this analysis 'communicative and material functions analysis' and use it as a basis for deriving concepts for modeling business actions. The objectives of such an analysis are

1. to find the communicative and material functions that are inherent in a generic or specific business act,
2. to classify the identified functions, and
3. to derive suitable concepts for business action modeling.

We apply the procedure to BAT itself to derive concepts for enterprise modeling that refine and extend an existing method: SIMM. A business process in BAT is divided into 6 phases:

1. Business prerequisites phase
2. Exposure and contact search phase
3. Contact establishment and proposal phase
4. Contractual or commitment phase
5. Fulfilment phase
6. Completion or assessment phase

BAT was introduced by Goldkuhl (1996) and was enhanced in (Goldkuhl 1998) and (Goldkuhl, Lind 2004). It is ontologically rooted in Socio-Instrumental Pragmatism (SIP; Goldkuhl 2002), which combines communicative (social) and material (instrumental) aspects of actions. The roots of BAT are Speech Act Theory (Austin 1962; Searle 1969) and the Theory of Communicative Action (Habermas 1984).

In BAT business interaction involves two principal players, supplier and customer (see fig. 2). The phases are constituted by generic business actions on each side of the transaction (see table 1).

The business actions follow a certain execution logic but the whole transaction is by no means linear. In the proposal phase, for example, the supplier can make any number of offers where each one will typically meet the customer's needs better than the preceding one. Likewise the customer can make a series of inquiries that usually become more and more "realistic". These loops terminate when offer and inquiry are sufficiently close to each other to reach an agreement whereupon we enter the contractual phase. In an ideal scenario this consists of the customer placing an order and the supplier confirming it. Both actions together constitute a contract the fulfilment of which is subject of the next phase. Here the supplier, again ideally, delivers the products/services and sends a corresponding invoice. The customer receives the delivery and makes the payment, which the supplier finally receives. In the completion phase each party decides whether they accept the delivery/money or make a claim, i.e. request the fulfilment of that part of the contract they consider unfulfilled.

Orthogonal to the phases (Lind, Goldkuhl 2001) introduced another dimension: layers. They extend and modify the layers originally suggested by Weigand and van den Heuvel (1998). Layers refer to the granularity of an action and they are, from fine grain to coarse grain: business act, action pair, exchange, business transaction and transaction group.

Figure 2. A business transaction in BAT (Lind, Goldkuhl 2005)

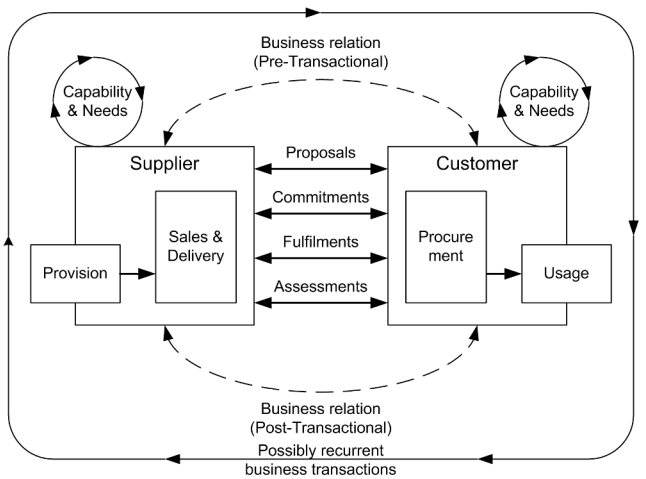


Table 1. Generic business actions

Phase	Supplier	Customer
Prerequisites phase	Product/offer development	Identification of problems/ needs
Exposure & contact search phase	Offer exposure	Contact search
Proposal phase	Offer	Inquiry
Commitment phase	Order confirmation	Order
Fulfilment phase	Delivery, Invoice, Receipt of payment	Receipt of delivery, Payment
Assessment phase	Acceptance, Claim	Acceptance, Claim

3. REFINING THE FRAMEWORK

A theoretical grounding in BAT has to take into account both dimensions, phases and layers. Strictly speaking, the phases are only a refinement of a particular layer, namely the transaction layer. To derive BAT concepts for SIMM we also need a refinement of the other layers. Such a refinement is suggested in figure 3.

On the fifth and final layer the same customer and supplier engage in a number of transactions over a longer period of time thus forming a stable business relation (Axelsson et al. 2000; Goldkuhl, Melin 2001). The transaction layer is divided into exchanges (they correspond to the phases). An exchange consists of two handover actions: One directed from supplier to customer and the other vice versa. These handovers usually happen one after the other where the second happens in return for the first but the order is not predefined, i.e. in some cases the supplier hands over first and in others the customer. An action pair is a pair of actions where the first one is a trigger (initiative) and the second a response. Actions can have a dual function so the response of one action pair can be the initiative of another. A business act is elementary and has a primary function which is always communicative but can also have a secondary function (communicative or material).

4. COMMUNICATIVE AND MATERIAL FUNCTIONS ANALYSIS

A business act consists of one or more functions. Goldkuhl (1996) gives the example of a (commercial) offer, which can be a single business act that has two communicative functions,

1. that of requesting the potential customer to buy (i.e. to place an order),
2. that of committing the potential supplier to sell (i.e. to deliver) under certain conditions.

Figure 3. Structure of the layers

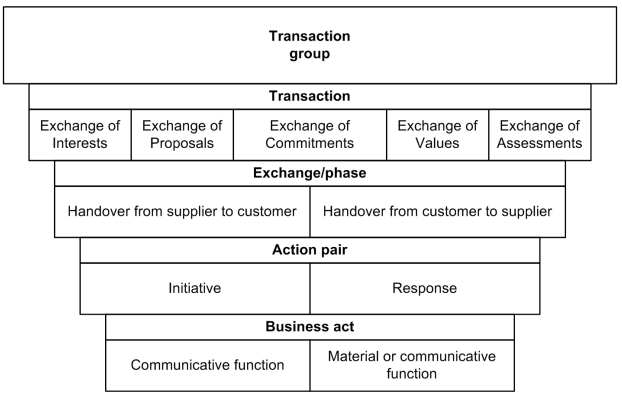

Table 2. Communicative & material functions of the generic business actions

Business Action	Communicative/material function	Business Action
Offer exposure	*State* general offer	Offer exposure
Contact search	*Express* interest	Contact search
Inquiry	*Request* commercial offer + *Express* interest	Inquiry
Commercial offer	*Offer* delivery + *Request* order	Commercial offer
Order	*Request* delivery + *Offer* payment	Order
Order confirmation	*Promise* delivery	Order confirmation
Delivery	*Transfer* merchandise/*Perform* service + *State* delivery	Delivery
Invoice	*Request* payment + *State* contract fulfilment [supplier]	Invoice
Receipt of delivery	*Accept* delivery + (*Accept* contract fulfilment [supplier])	Receipt of delivery
Payment	*Transfer* money + *State* contract fulfilment [customer]	Payment
Receipt of payment	*Accept* payment + (*Accept* contract fulfilment [customer])	Receipt of payment
Acceptance	*Accept* contract fulfilment [supplier or customer]	Acceptance
Claim	*Request* contract fulfilment [supplier or customer]	Claim

If we apply that kind of analysis, which we call communicative and material functions analysis, to the remaining generic business actions we get the results shown in table 2.

These results show that a business act typically has one or two functions. The communicative function is always present (even in the case of material acts) but there might be another function of either type. This is reflected in the model of figure 3.1. The generic business action "receipt of delivery or payment" can in some cases imply the acceptance of the contract fulfilment. In other cases the acceptance is stated explicitly (i.e. separately in the assessment phase) or a claim is made.

We are aware of the fact that such a list of generic actions and their functions can only serve as a recommendation that covers some typical or common situations. It is not meant to be a prescriptive template for all business interactions. Using that analysis in a different context might yield different actions and even different functions concerning the same actions. But the results can nevertheless be useful to find a set of recurring material and communicative functions that can be used as a pattern for a modeling language.

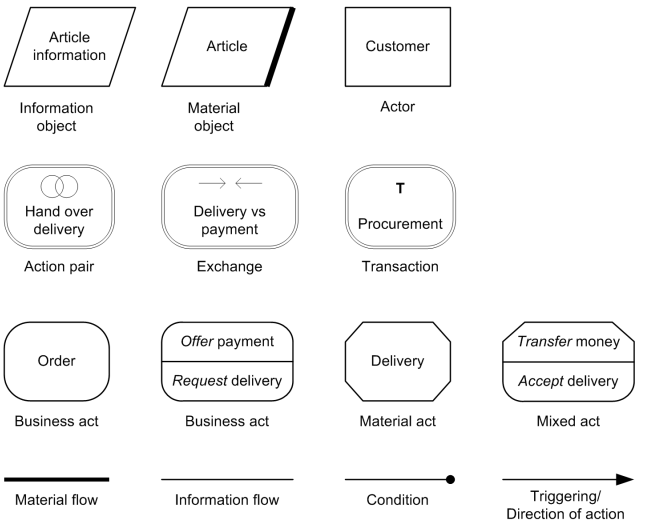
5. EXTENDING SIMM

The results from the communicative and material functions analysis are now used to enrich the SIMM method. This extension is part of theoretical grounding with the external theory being BAT. The techniques for such an extension are offered by (situational) method engineering (Ralyté et al. 2003). The idea behind method engineering is to design methods in such a way that they fit the specific modeling situation. This can be done in different ways. One way is to extend an existing method. Using this approach, we enrich and refine the language of SIMM with the concepts from the analysis.

SIMM provides three basic categories: actors, actions and (action) objects. The latter are divided in information and material objects. Examples of them are shown in fig. 6.1 but SIMM offers many additional types. For non-elementary actions the circumference is drawn as a double line and an inscribed symbol identifies the layer (see fig. 4). If a material function is involved we may use an octagon. The box is labelled with the business act or the respective function(s) where the function header is italicized.

Among the notational elements there are also four types of arcs. The condition arc allows us to show that one action is a condition for another action with the black dot being attached to the latter. The arrow serves two purposes. If it points from one action to another, the former triggers the latter. If it points from one actor to another, it represents an action that is directed from the first actor to the second. In this case the name of the action is written along the arrow. It can be accompanied by a symbol denoting the layer. For communicative or material functions we can also use a circle or a diamond, respectively. As an alternative to the arrow form of the action the boxed form of the action can be interlaced with the arrow.

Figure 4. Concepts for business action modeling and their notation



6. APPLYING THE EXTENDED METHOD: A CASE STUDY

Commitment analysis in terms of language action was introduced by Auramäki et al. (1988). We performed it in a project with two companies that have a very close business relationship. One of them is the headquarters of a retail chain, the other a third-party logistics provider (LogPro). Our goal was to detect and solve major problems in their relationship. For this we analyzed order processing and delivery. We intended to use SIMM Interaction Diagrams but required additional information on the type and level of an action so we enriched the diagram with the features introduced above. The result is shown in fig. 5.

The process starts when Headquarters send an estimate regarding the required capacity for future orders. There are three types of orders. A customer order is initiated by the Shop on behalf of a customer who wishes to buy an article that is not currently available. The refill order is triggered by Headquarters when the stock is running low. Both are on the action-pair level because they require confirmation from the partner. The third type is called distribution order. It is based on a negotiated budget and the Shop is obliged to accept it. This order is therefore only a single speech act with an informative character. The budget negotiation, however, is bilateral. It consists of an exchange of budget proposals initiated by Headquarters.

All orders are combined into one and forwarded to LogPro. LogPro will perform delivery to the Shop. Headquarters inform the Shop about an upcoming delivery and receive a confirmation when it arrives (delivery handshake). In regular intervals LogPro bill their services to Headquarters.

In the next step we developed detailed Interaction Diagrams. The one for LogPro and Headquarters is shown in fig. 6 on the business-act level. It shows that Headquarters send a capacity estimate first. On the day of delivery a pick file is

Figure 5. Enriched interaction diagram

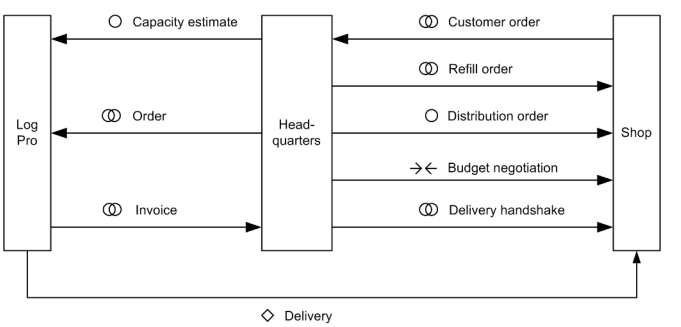


Figure 6. Detailed interaction diagram

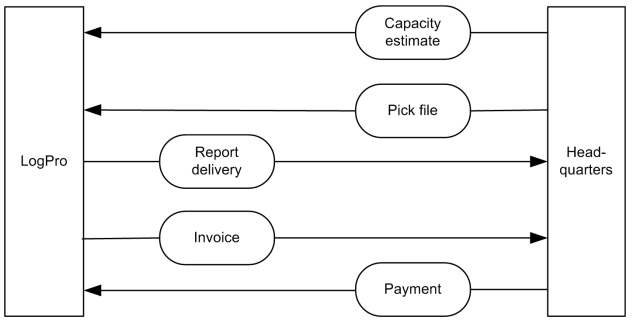


transferred to LogPro that contains the order data. This is used to pick the articles from the shelves and to pack them. As soon as they are on their way, LogPro reports delivery to Headquarters. At the next billing occasion LogPro send an invoice and Headquarters make the respective payment.

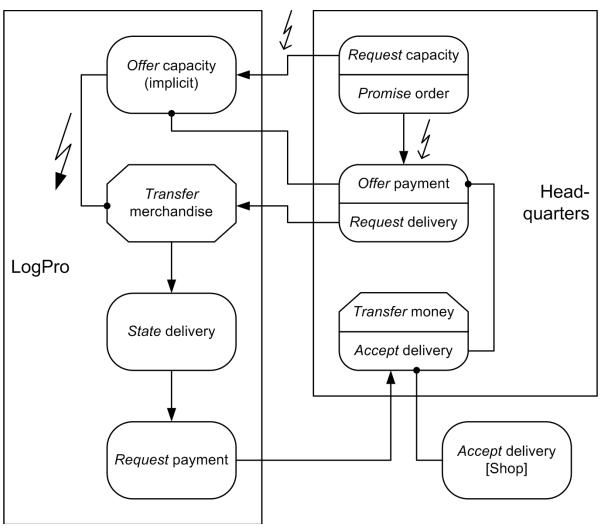
For commitment analysis we need more information about how actions are related to each other. This implies exhibiting their communicative and material functions that lead to the establishment or fulfilment of commitments and the conditional and causal relations between them. This helps us to uncover broken commitments. For this purpose we employ a Business Act Diagram (see fig. 7).

The capacity estimate implies a request to provide this capacity and a promise to place a respective order. LogPro offers to provide the capacity subject to the order and the implied offer of payment. The capacity offer is implicit (i.e. not communicated) because LogPro is required to provide it by virtue of the frame contract. The provision of capacity is a condition for performing the delivery that is triggered by the respective request from Headquarters (a function of the order). The other function, offer payment, is subject to an accepted delivery. The delivery triggers a respective report (state delivery) which in turn initiates the invoice (request payment). The latter triggers the payment (transfer money) but only if the Shop has confirmed the arrival of the delivery. Headquarters confirm acceptance of the delivery towards LogPro implicitly by paying the invoice. Therefore "Transfer money" and "Accept delivery" are functions of the same business act.

The Business Act Diagram has shown us that commitments are broken in three different places (see the flash symbols in fig. 7):

1. Headquarters promise that the order will require the requested capacity but in reality orders often deviate substantially from the estimates.
2. The request for capacity is not in a suitable format for LogPro so that capacity planning does not work but Headquarters rely on it.
3. Due to 1 and 2 the prerequisites for delivery are often not given leading to higher costs and occasional failures to meet delivery deadlines.

Figure 7. Business act diagram



We have used this approach for other parts of the business process where we also succeeded in identifying bad commitment management.

7. CONCLUSION

According to MGT a modeling method can be informed by grounding it in some theory or theories. We have chosen Business Action Theory to inform the existing enterprise modeling method of SIMM. Grounding is performed via a procedure called communicative and material functions analysis. The result is an extended method that reflects the properties of the theory. We have shown the usefulness of this approach in the context of a case study involving the analysis of commitments in an interorganizational business process. Future research might investigate the theoretical grounding of enterprise modeling in a more general theory or ontology.

Evaluating Complexities in Software Configuration Management

Frank Tsui, Southern Polytechnic State University, 1100 S. Marietta Parkway, Marietta, GA, 30060, USA; E-mail: ftsui@spsu.edu
Orlando Karam, Southern Polytechnic State University, 1100 S. Marietta Parkway, Marietta, GA, 30060, USA; E-mail: okaram@spsu.edu

INTRODUCTION

In software engineering, software configuration management tools such as Apache Ant, CVS or ClearCase [1, 3, 5, 9] are often included as an integral part of constructing large information systems or managing changes in information systems [7, 8, 11]. It is often assumed that the organizations involved in the development and support of information systems have naturally embraced the concept of software configuration management. While enterprises engaged in medium to large size information systems development and support do subscribe to the concept of configuration management, many smaller establishments only pay lip services to this important activity. In this paper we will explore the reasons behind this through analysis of levels of complexity in software configuration management (SCM). First SCM will be discussed, categorized and divided into four different dimensional areas. Then a set of volume metrics related to these dimensional areas will be defined. Levels of complexities of SCM, in terms of volume metrics, will be explored. We will utilize a real case of a software application development to demonstrate the utility of these metrics and how the levels of complexity of SCM may be used to help the decision process of incorporating SCM and SCM tools. Ultimately, our goal is to provide a clear measure of the degrees of SCM and an ordering scheme of implementing SCM.

SOFTWARE CONFIGURATION MANAGEMENT

Configuration management initially started with the management of pieces and parts. In software systems this often meant the management of files. As software systems became more complex and larger in size, the number of files and the structure that needed to be placed on top of the files had to be managed. Also, software systems became more expensive, and the life span of a software system extended into multiple years after its initial release. The large number of changes to the software system and the lengthy period of maintenance cycles of a software system needed some form of change management. This precipitated the inclusion of change control as an essential component of software engineering. SCM, as a discipline of managing parts and managing changes, started to grow in scope. It is an integral part of the software processes described by Software Engineering Institute [10]; however, it continues to be a domain of software engineering that is understood by a relatively small number of information and software engineering experts.

A software configuration management system provides a wide range of functionality. Dart [6] first classified this range of concepts into fifteen areas as follows:

- Repository
- Distributed component
- Context management
- Contract
- Change request
- Life-cycle model
- Change set
- System modeling
- Subsystem
- Object pool
- Attribution
- Consistency maintenance
- Workspace
- Transparent view
- Transaction

Not all of these functionalities are implemented by any single SCM tool. These functional areas are inter-related in serving four critical dimensions of software configuration management [4,11].

- a mechanism that describes the artifacts that will be managed
- a mechanism to capture, access, and control the artifacts
- a mechanism to construct a specific product out of the artifacts
- a mechanism that describes the relationship among the artifacts

Artifact Identification

In order to manage a large number of pieces of software artifacts, we must be able to identify and specify those artifacts that are produced through the development and support activities. The decision of which artifacts need to be managed is based on the project and the process. If the deployed process of the software project states that only executable source code is of importance and that is the only artifact type that needs to be managed, then we only need to label code pieces and manage the changes to the code. On the other hand, if other artifacts from the requirements, design, and test phases are considered important, then the mechanism must include all of them. The mechanism must be able to identify and specify the artifacts within each artifact type. In addition, a specific piece of artifact, regardless of type, may experience several iterations of changes. In order to control changes, each version of the changes may need to be kept. Thus, the artifact identification mechanism must be able to allow different level of sophistication, which is in turn dependent on the over all software process employed.

Let A be the set of artifacts that the software project process has determined to manage. Then for a specific artifact x in A, there needs to be at least three attributes: name, version and type. Thus for x, the three attribute components formulate a unique identifier as follows.

artifact identifier = name **.** version **.** type

Name may be a string of characters of some predetermined length. Version may be an integer of some predetermined number of positions. Type may be a two position code to identify artifact types such as requirement, design, logic code, screen code, data base table, help text, test case, etc. The symbol, ".", separates the three components of the identifier.

Artifacts Capture and Control

After each piece of software artifact can be uniquely identified, it still needs to be managed. There are two components to this dimension. First, all the artifacts must be captured. This is a fundamental activity of configuration management. If there is no one place where all the pieces and parts are kept, then assembling and building a system would be left to a high degree of chance of failure. Something inevitably is lost at the worst time such as the night before the software product release. The larger is the number of individual pieces of artifacts, the greater is the opportunity to lose something.

The second part is the access and control of the artifacts. There is rarely a situation where nothing is changed. Practically every type of artifact in software development and support experiences some degree of change. These changes must be conducted under a controlled process or the software system will quickly degenerate into a non-manageable system. The degree of control required depends on several parameters:

- number of artifacts under configuration management
- the anticipated amount of changes
- the number of people involved in the project
- the geographical and time distribution of work efforts related to the changes

Check-in and Check-out [1,3,5,9] are the two most often mentioned functions related to the access and control of artifacts. Check-out is the retrieval function. Except for security reasons, all artifacts may be retrieved. If an artifact is retrieved for the purpose of viewing, then another function, such as View, may be used. However, if an artifact is retrieved with the intent of performing a change to it, then it must be retrieved with the Check-out function. This is so that any conflict from multiple changes to the same artifact can be controlled. An artifact which is Checked-out is balanced with a Check-in of that artifact. An artifact that is currently Checked-out may not be Checked-out by another party until it is formally returned through Checked-in. Once a Checked-out artifact is updated through a Check-in, then essentially a new version of that artifact is formed. Thus the Check-out and Check-in pair of mechanism, along with version update, not only controls multiple changes but also keeps a history of the changes. Beyond this pair of basic control function, there are many other functions, such as compare or version incrementing, that exist to support the control mechanism. The amount of capture, access and control functionality needed, again, depends on the project.

Construct or Build

It would be somewhat pointless to have all the pieces identified, collected and put under control unless we are able to build a final software system that executes correctly. The construction activity is sometimes known as the Build. The simplest Build is the compile and link of a single module. Most of software systems are composed of a number of artifacts that require a much more complicated, multiple statements direction which includes the following information.

- the files which contain the different sources for compilation
- the target files for the results of compilation
- the different files required for the activity of linking
- the target files for the results of linking

More formally, the Build process may be described as two levels of relations, R1 and R2.

R1 is the relation that describes where the identified artifacts are stored and can be accessed.

R1 = A x F where, A is the set of identified artifacts and F is the set of folders or libraries where these artifacts are stored

R2 is the relation that maps R1 into steps of compile and link activities. The specific numerical order is important here. Thus it is defined as follows.

R2 = R1 x N where, R1 is defined as above and N is the natural numbers, which serve as an ordering mechanism

Thus the relation, R2, may be viewed as a sequence of steps in the build.

Software code Build is composed of and dependent on how well the two relations, R1 and R2, are constructed.

The time for a code Build cycle is directly related to R2, which is the sequence of steps to copy, compile, and link the code. Often times the Build cycle for a large, software system requires several mid-way interruptions and attempts to correct errors due to complexity of R1 or R2.

A comprehensive Build for a complete software product that includes the construction of executable code and of non-executables, such as User Guide or Read Me First notes, today requires multiple tools and different methodology. There does not exist one Build tool that can construct multiple artifact types. In order to perform such a complex Build, the SCM system must include the capability to handle, not just multiple versions of artifacts, but also relationships among multiple artifact types.

Artifact Relationships

With very small software projects, there may not be a complicated relationship among the artifacts. However, even with managing just one type of artifact, such as code, we need to account for the pieces of source code and the pieces of executable code. The source code is the artifact developed by the "coders". The executable, on the hand, is the post-compiled code. In order for the developed software to execute, often it requires the use of many other existing components. The obvious ones are the underlying operating system, the data base system, and the network system. In addition, there may be executable code from system and private libraries that must be included for the developed source code to compile and execute properly. Thus even within the code artifact type there may need to be a further differentiation of sub-types of code.

For very large projects where the process dictates that multiple types of artifacts are needed, two types of relationship within the project need to be considered.

- Intra-artifact relationship and
- Inter-artifact relationship

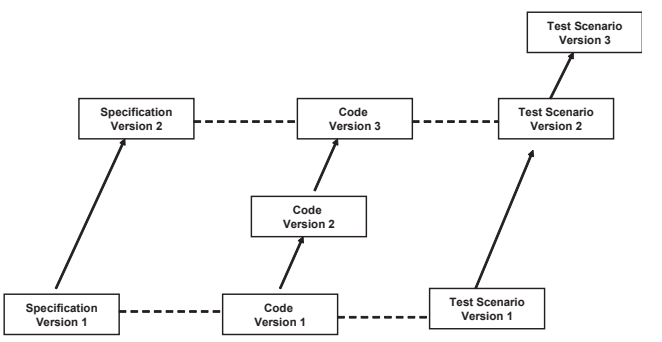
The intra-artifact relationship defines the relationship of the pieces within an artifact type. In the case of the executable software code artifact, the intra-relationship is stated in a set of statements related to the compilation and linking of the source code and reuse of other code in different libraries. This is a relatively simple software build process. If we require the use of other executable code such as a Tomcat [2] middleware or a specific database, then those executable code libraries must also be included in a larger build process where there is still a single artifact type but a large number of artifacts residing in different places.

The inter-artifact relationship defines the connections among different artifact types such as a requirement specification text, a source code which implemented that requirement, and a test scenario to test that implemented source code against the requirement specification. The relationship among these three types of artifacts may be further complicated when we introduce versions of the changes within each artifact type. See Figure 1.

Note that in Figure 1, the inter-artifact relationship among the specification, code, and test scenario artifacts are represented with dashed lines. The intra-artifact relationship is shown with solid arrows. There are two versions of specifications, three versions of code, and three versions of test scenarios. Associated with the first version of specification are version 1 and version 2 of code and version 1 of test scenario. The reason behind having two versions of code may be due to some error correction made to version 1 of code after conducting a test with version 1 of test scenario. Thus version 2 of code is the most updated version related to version 1 of specification and version 1 of test scenario. When the specification is updated to version 2, a code change is made and the related code is vesion3. The test scenario is updated to version 2 to reflect the corresponding changes made to version 1 test scenario. It is possible that the test scenario version 2 had an error and required a further update to create a version 3 test scenario. Thus specification version 2, code version 3 and test scenario version 3 form another inter-relationship among these three artifact types.

Keeping and maintaining a web of these relationships for a large software project can quickly turn into a nightmare. As the degree of complexity of inter and intra

Figure 1. Inter-relationship and intra-relationship



artifact relationships increases, an automated tool to help manage these relationships would definitely be a plus.

An ideal software product build would need to extend the current code Build. As such, the set of artifacts, A, in R1 would need to include all types of artifacts. R1 may be expanded to R1'. First define A_{tn} and $R1'_{tn}$.

A_{tn} = set of artifacts of type n

$R1'_{tn} = A_{tn} \times F$

Then, the extended R1, which includes more than one type of artifacts, is defined as:

$R1' = <R1'_{t1}, R1'_{t2}, - - -, R1'_{tn}>$

The activities of compile, link, merge, etc. depending on the artifact type, A_{tn}, for the second component of universal build would be defined as follows.

$$R2' = \{ R1'_{t1} \times N, \; R1'_{t2} \times N, \; \ldots \; R1'_{tn} \times N \}$$

Thus a general software product Build, which includes multiple artifact type relationships, is composed of R1' and R2'.

METRIC FOR SOFTWARE CONFIGURATION MANAGEMENT

In this section some basic metrics that applies to the four major dimensions of SCM will be introduced. The first metric gauges the volume of software artifacts that needs to be managed. Thus it impacts the dimensions of i) artifact identification and ii) artifact capture and control. SCM volume is an accumulation of all the uniquely identifiable artifacts. The SCM artifact volume, AV is defined in terms of the components of the artifact identifiers: name, version and type.

$$AV = \sum \text{unique artifact} = \sum \text{type} \sum \text{version} \sum \text{name}$$

Note that for each artifact name within an artifact type, there may be different number of versions. Pick the artifact name, across all the artifacts, which has the largest number of versions. Let that version number be version-max. Then the volume of the software product is bound by AVmax.

$$AV \leq AVmax = (\#\text{ of types}) * (\text{version-max}) * (\#\text{ of names})$$

The second metric is associated with SCM build. The normal code Build deals with just the single artifact type, code. Code build volume, CBV, may be measured in terms of R1 and R2. The ideal software product build may handle multiple artifact types. Thus SCM build volume for the ideal build, IBV, may be measured in terms of R1' and R2'.

First we define CBV as composed of two volumes, a) VR1, volume of R1 and b) VR2, volume of R2. Assume an element, a, to be an artifact of code type, and f to be an element of folders or libraries.

CBV = (VR1, VR2) where
VR1 = # of pairs in A x F $= \sum (a, f)$
VR2 = # of steps in the sequence {R1 x N}

Note that these two volumes, VR1 and VR2 can not just be arithmetically added together to give CBV a single number because they are two different units. VR1 is pairs in A x F, and VR2 is elements in a sequence. IBV is also defined in terms of its components, R1' and R2'.

IBV = (VR1', VR2') where
$VR1' = \sum R1'_{tn} = \sum (A_{tn} \times F) = \sum \text{type} \sum (a_{type}, f)$
$VR2' = \sum \text{type} \sum (R1'_{type} \times N)$

Thus IBV is a pair composed of a volume, VR1', and VR'2. VR1' is the sum of pairs of (artifact, folder) across all the artifact types that is to be built, and VR2' is composed of number of steps in a sequence of build activities for each artifact type summed across all artifact types included in the software product build. Thus both CBV for code and IBV for more general build may be used as metrics for the dimensionalities of iii) artifact build of SCN and iv) artifact relationships of SCM.

UTILITY OF SCM METRICS

In this section we will describe our experience with a small application software project and the utility of these metrics in the decision process of whether an SCM tool needs to be brought in.

The application software project was initiated in 2002 to automate the graduate admissions process for three graduate departments. There are three major functional areas in the application software. Initially, requirements were collected and documented. Several rounds of requirements modifications were incorporated and a final specification document was produced. The developers then took over and the product was constructed and tested. All the discovered defects were fixed and the product was released with a 2 weeks period of product support by the original developers. The project statistics are as follows.

- Duration: 4.5 months
- # of people: 14 (part-time)
- People effort: 1344 person hours
- Major Artifact Types: Requirements Specification, Code, Test Cases, Test Reports
- Build Artifacts: 20 Java code files, 27 JSP code files for screens, 19 relational tables
- System platform: Apache Tomcat, Microsoft Window, Access DB

The initial developers managed the requirement specification as one evolving artifact, using an excel spreadsheet to track the major functional requirements. The requirements were collected by multiple persons, but the actual authoring of the specification was performed by one person. The implementation team divided the work among 1) data base code, 2) screen code and logic code by functional areas and 3) a control logic flow code. Essentially, the design and coding efforts were carried out pretty much together by the implementers, and the unit tested versions of the code were all submitted to one person who replaced existing code with new submissions. Thus only one version of code was ever kept.

The Build activity included only one artifact type, code. Only one final version of the requirements was kept and that related to the entire set of code artifacts. Test cases were kept but not controlled. Thus, code version is 1, and there were a total of (20 + 27 + 19) or 66 unique code artifacts.

$$AV = \sum \text{type} \sum \text{version} \sum \text{names} = \sum \text{names} = 66$$

CBV = (VR1, VR2) = (18 , 44) where
VR1 = 18 pairs of (a, f)
VR2 = 44 steps in the sequence of instructions

The application software product was essentially composed of the requirement document and one final version of code artifacts. So there was no reason to consider artifact relationship. The software product build is the same as code build, and IBV = CBV. For this level of complexity, the SCM utilized was an accounting of a list of artifact names and a code build with Apache Ant tool [1].

The application software has gone through two more rounds of modifications. Although several code artifacts were modified, no new code artifact was added to

the software application system. Since the newest version just replaced the existing version, no change history was kept. After two years and two maintenance cycles, the SCM metrics remained the same, with AV = 66, and CBV = (18 , 44).

Now the software application is in its fourth year and there is a large set of new requirements. The new software project will involve more than just minor modifications. First the current running system must be kept running, and a duplicate but completely separate application system needs to be made. Thus there will be 2 versions of all the code artifacts. The new set of requirements will be associated with the second code version, and the old requirements of 4 years ago will be associated with the existing code version. The large set of new requirements is expected to add some new code artifacts and modify some old code artifacts. Thus the new AV is expected to be much larger than 66. The CBV for the new project may not increase much beyond the current CBV. However, because of the need to maintaining two versions, each associated with a different set of requirements document, we have to consider 2 IBVs. For IBV of the original application software system, the VR1' is the same as adding 1 requirements artifact in a separate library or one new pair (a, f) to the old VR1. Thus VR1' = 18 + 1 =19. Similarly, VR2' just include one more instruction step to build the requirements document. So VR2' = 44 +1 = 45. Since we do not expect too much change in the build instruction, the IBV for the second version may not differ much from the IBV of the first version. The big difference this time can be summarized as follows.

1. A large increase in AV is expected for the second version of application of software.
2. Since there will be two application versions, the original AV is still there.
3. There will be an association of requirements to code. Thus there will be two IBVs.

Even though the actual software project is still fairly small as the original version and no increase in development complexity is anticipated, we are now maintaining two versions of software products. This increased complexity of SCM is forcing us to consider the incorporation of additional SCM tools.

CONCLUDING REMARKS

We have introduced a set of volume metrics, AV, CBV, and IBV to gauge the SCM complexity. We have also found that when AV is small and only CBV is involved, the SCM complexity can be managed with minimal tool. But once we grow the AV and start to deal with multiple IBV metrics, it is an indication to start considering sophisticated SCM tools.

An area for future extension is to investigate the volume metric for managing the impact of changes and the impact of building non-code artifacts. This would take the IBV to another level of measurement.

ABSTRACT

Our final goal is to utilize a cognition viewpoint for engineering of better design of human communication tools. In this paper, we extend the concept of affordance to cover human-to-human communication and propose the novel concept of ''human affordance,'' which is afforded from humans, not artifacts. As one possible utilization of the concept, we introduce the example of affordance in evaluating the strength of agreement / disagreement phrases. In text-based communication, it is important for mutual understanding to effectively afford information about how a person feels about the text itself. This paper presents experimental results on understanding the strength of agreement/disagreement and presents one simple example to augment human affordance in text-based communication.

INTRODUCTION

Human-to-human communication often fails due to a lack of appropriately afforded information. For example, text-based communication such as text chat or instant messenger sessions suffers from many weaknesses compared to face-to-face communication; these include a lack of facial expressions, gestures, and intonation. These are important for conveying how a person feels or what he/she is thinking about. In text-based communication, it is important for mutual understanding to effectively afford information about how a person feels about the text itself.

The term of affordance comes from the perceptual psychologist Gibson, who provided an ecological alternative to cognitive approaches (Gibson, 1966; 1979). His theory is that *the affordances of the environment are what it offers the animal, what it provides or furnishes, either for good or ill*. Many studies in a psychology field focused on affordance in human communication (Acker & Valenti, 1989), however the concept of affordance is popular in the field of user interface design as it provides a means of enhancing usability (Norman, 1988).

In this paper, with regard to utilizing a cognition viewpoint for engineering, we extend the concept of affordance to cover human-to-human communication and propose the novel concept of ''human affordance,'' which is afforded from humans, not artifacts. A model of human affordance is defined as a set of perceptual information and human factors. One advantage of human affordance is the focus it places on human factors which yields user-centered designs.

Accordingly, we describe the significance of augmenting affordance in text-based human communication and illustrate the concept through examples although this work is explanatory in nature. We analyze the human affordance found in typical agreement/disagreement phrases in order to better augment human affordance in text-based communication. This paper presents the experimental results on evaluating the strength of agreement / disagreement and presents one simple example to augment human affordance in text-based communication by phrase replacement.

RELATED WORK

Text-based communication is getting popular as shown by examples such as text chat, instant messaging, and email. Several studies have examined text chat systems. Farnham et al. proposed a scripted chat system that uses Lead Line (Farnham et al., 2000) which allows users to add a layer of pre-authored structure to regular text chat. Vronay et al. identified the text chat problems related to the loss of timing-specific information (Vronay et al., 1999). Jozsef analyzed the impact of interactive graphics and text on social influence (Jozsef, 1994). DiMicco et al. introduced instant messaging with a skin conductivity channel (DiMicco et al., 2002).

Decision support is an important research field related to mutual understanding. Kenneth et al. reviewed group decision support for computer-supported cooperative work (Kenneth & John, 1988). Richard et al. explained the process of perspective taking and its roles in human communication, mutual trust, and organizational learning (Richard et al., 1992). John et al. described the significance of a common report space in addition to the messaging space (John et al., 1991). Mera et al. proposed a method to analyze users' affirmative/negative intentions from multiple utterances in spoken dialogs (Mera et al., 2001). Since these papers did not consider affordance in communication, they lack the ability to truly understand and thus support the user.

One example of research on affordance is the analysis of the concept of affordance to employ it for understanding human activity (Baerentsen & Trettvik, 2002). Most studies on affordance, however, lie in the field of engineering, particularly the design of user interfaces (Amant, 1999; Conn, 1995; Gaver, 1991; 92). Designing Computer-Mediated Communication (CMC) systems is also an important research field (Cassell et al., 2000; Bradner & Mark, 2001). (See the ''Human Affordance'' section describing ''awareness.'')

Authors have studied on typical responding phrases used in agreement/disagreement in communication (Ihara & Kobayashi, 2005). This paper discusses affordance for agreement / disagreement from the viewpoint of engineering in order to realize better system designs for text-based communication.

PROMOTING MUTUAL UNDERSTANDING IN TEXT-BASED COMMUNICATION

Table 1 shows the methods that can be used to promote mutual understanding in text-based communication. In this table, 1 and 2 enhance the presentation of the text. The remainder, 3, 4, and 5, alter the design of the statement (word) database.

Enhanced Presentation

In method 1, attributes are added to a text when it is presented to the partner such as a bigger font or red coloring. This method provides users with immediate understanding through visual comprehension. For example, Bodine et al. developed an instant messenger around kinetic Typography (Bodine & Pignol, 2003). Donath analyzed the effectiveness of graphics in online conversations (Donath, 2002). In method 2, a text is presented together with other media like voice. For example, synthesized speech with intonation may reinforce the expressive power of a text. Rothkrantz et al. added facial expressions to text balloons in cartoons (Rothkrantz & Wojdel, 2000). This is an example of combining text with graphics.

Statement Database Design

In method 3, a statement database is enlarged by addition of explicit statements. One of most typical examples is the ''smiley'' which presents an emotion by a sequence of a few letters like :-). Smileys are so symbolic and explicit that users can easily understand the partner's intention to express his/her emotion. On the other hand, method 4 restricts the statements available to prevent misunderstand-

Table 1. Methods to promote mutual understanding in text-based communication

	Method	Advantage	Examples	Approach
1	Add visual attributes to text	Immediate understanding through visual comprehension	Change size or color of fonts	Enhanced presentation
2	Use a text with other media	Reinforce text expressiveness	Play with synthesized speech	Enhanced presentation
3	Add explicit statements to database	Symbolic and explicit expressions	The ”smiley”	Statement database design
4	Restrict statements available in database	Simplified expressions	Textbook	Statement database design
5	Add attributes to statements in database	Familiar statements with higher expressiveness	Strength of agreement/disagreement	Statement database design

ing. A school textbook is an example of this approach in terms of using only easy words. Method 5 adds attributes to statements in a database. This method makes it possible to use familiar statements without adding or restricting the statements available. Our approach to setting the strength of agreement / disagreement of each statement is one example of this method.

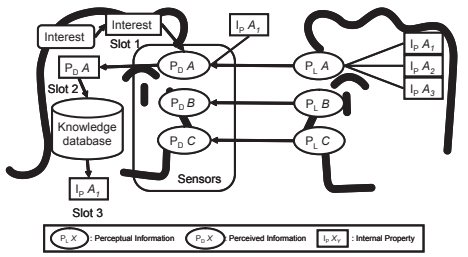
HUMAN AFFORDANCE

Definition

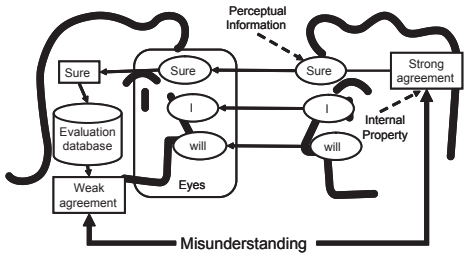
Affordance involves relationships or their properties. It is difficult to define affordance in precise analytical terms. One definition of general affordance is a set of perceptual information of an environment and an internal property of the environment such as a human's action capability. Similarly human affordance can be defined as a set of perceptual information of the human and the internal property of the human. For example, one internal property, the emotion of agreement, can be perceived from the facial expression of a smile as a piece of perceptual information. Note that human affordance focuses on an individual in human-to-human communication while social affordance (Acker & Valenti, 1989; Valenti & Good, 1991; Loveland, 1991; Kadar & Effken, 1994; Stoffregen, 2004), studied in a psychology field focuses on a relationship or interaction in a community.

Awareness has been discussed as one of the most important factors in a CMC system (Bradner, 2001; Dourish & Bly, 1992; Erickson et al., 1999). The term of awareness is related to existence or state. On the other hand, the focus of affordance is on a set of perceptual information and an internal property which is not necessarily limited to dynamic properties such as state, but includes static properties such as ability. For example, consider the user who knows important information but who hesitates to speak out. Awareness research does not discuss this kind of property.

Figure 1. Human affordance model



(a) A general human affordance model.



(b) A human affordance model of agreement.

Human Affordance Model

Figure 1-(a) shows the cognition model based on human affordance introduced in this paper. In this figure, (1) the giver offers three kinds of perceptual information, P_LA to P_LC, to the perceiver. Perceptual information P_LA is related to three internal properties, I_PA_1 to I_PA_3. The perceiver has sensors such as eyes or ears, which are used to gather the perceptual information from the giver. (2) Interest which exists in the perceiver's mind, establishes an entry in a sender slot in the perceiver; (3) the slot's content interacts with perceived information P_DA. (4) Based on the content of the sender slot, the corresponding perceived information P_DA is focused on which creates an entry in a receiver slot. (5) The receiver's knowledge (his/her database) which is referred to according to the content of the receiver slot makes an entry in a receiver's cognition slot. The perceiver's database has a lot of knowledge about the relationship between common perceptual information and internal properties. The result of this process is that the giver affords internal property I_PA_1 to the perceiver.

The above is a quite simple but highly applicable affordance model. This applicability is important to easily employ the model for engineering with a same metaphor. A set of perceptual information and internal property can be defined automatically or manually according to a situation or a person. In some cases user profiles or agent-based communication support techniques would be effective to identify the set of perceptual information and internal property.

Perceptual Information and Internal Properties

Perceptual information can be categorized into the kinds discerned by sensors; eyes, ears, nose and skin. A more detailed classification of perceptual information can be made based on components of the perceptual information and measurable parameters. For example, hairstyle is associated with ''look'' and utterance frequency in a chat is a measurable parameter. Moreover, changes in these parameters are also perceptual information. Internal properties can be divided into states and nature. A state is a dynamic factor as a facial expression or thought, which changes moment by moment. Nature covers static factors such as ability or priority.

Difficulties in Affordance Cognition

An everyday artifact does not have many affordances and its main affordance is clearly discernible. For example, most people understand that a mug is a tool for holding liquids to be drunk. A human, however, is capable of a wide variety of actions and has many internal properties. It is not easy to recognize human affordance due to this variety and the restriction that we are limited to perceptual information (appearance) in assessing an unknown person. This is true whether we are holding a face-to-face meeting or using a text chat system, although it is obvious that the problems are much stronger in the latter.

Human affordance cognition can fail in three ways:

1. No useful perceptual information is provided
2. Insufficient perceptual information is provided
3. Wrong perceptual information is provided.

In the first case, we say that the internal property is not expressed. For example, a participant knows something of value but makes no expression or utterance. In the second case, the perceptual information provided is insufficient. For example, the low image resolution provided by most videoconferencing systems hinders smooth interaction based on facial expressions. The most common solution is to improve transmission quality. In the third case, the perceptual information cannot be used to discern the internal property. An example is a participant who smiles while actually being unhappy about what is being discussed. In everyday life, we use a priori knowledge to prevent such misunderstandings. A lack of positive confirmation may be useful in understanding the participant's true feelings. In this case, the priori knowledge of ''he would say something if he were happy'' can be used to infer his true internal property. This paper discusses one example of the third case; wrong understanding of agreement/disagreement in text-based communication.

AFFORDANCE AUGMENTATION

The above problems in affordance cognition can be solved by an affordance augmentation system (AAS). Such a system can offset the lack of or incorrect perceptual information by creating the right affordance. It can also enhance affordance to make up for insufficient perceptual information.

People tend to believe that a quiet participant has no interesting or useful information. If the AAS could recognize the value of the participant, it could encourage him/her to speak forth. This means that the AAS would create the true and useful affordance. Consider a videoconference system that uses facial avatars based on computer graphics and can enhance the motion of facial parts such as the eyes. An emotion as an internal property may be conveyed by graphics enhancement instead of using a photorealistic video. In another case, one problem with text chat among people is cognition of the utterance requests by participants. The AAS can graphically enhance the utterance requests of key participants by actions such as framing their windows in red.

Affordance augmentation has two advantages. One is that it more fully utilizes computers for human communication. The other is to create a really effective communication style that is unavailable in the real world and differs from face-to-face communication in everyday life.

HUMAN AFFORDANCE IN AGREEMENT / DISAGREEMENT

People afford their agreement / disagreement to a partner in communication using several types of agreement / disagreement phrases. However, the strength of agreement / disagreement that a partner feels about each phrase is not necessarily same as that of agreement / disagreement that they put into their response. Some people overestimate and others underestimate. The overestimation type of user may misunderstand weak agreement as strong agreement. The underestimation type of user may not understand or accept the other's comment as praise. This failure of human affordance leads to inhibit mutual understanding.

Figure 1-(b) shows one example of human affordance model in the case of agreement. In this figure, a user responds to a partner by using a sentence of ''Sure, I will...'' This responding user employs ''Sure'' as a strong agreement word. In this case the implementation of human affordance model definition is that ''Sure'' as a visible letter sequence is perceptual information and that the user's evaluation of strong agreement is internal property. In this example, the partner understands ''Sure'' as a weak agreement, thus there is a misunderstanding between their evaluations for the agreement strength of the word ''Sure''.

To decrease such a misunderstanding, it is important to identify the human affordance in agreement / disagreement phrases and to design a better method for affordance augmentation which can be applied for engineering.

EXPERIMENTS

Experimental Design

We analyzed responding phrases of agreement / disagreement to identify the human affordance in agreement / disagreement phrases. We collected about 100 responding phrases and used questionnaires to rate the strength of agreement / disagreement. In these experiments, phrase type and user type were analyzed to explore better augmented human affordance in text-based communication.

Collecting Responding Phrases

We asked one hundred fluent English speaking subjects to list as many responding phrases that express agreement / disagreement as possible. The subjects were asked not to consider the situations in which the phrases could be used. The collected data included phrases used in both oral conversations and text-based conversations. We collected 67 phrases for agreement and 42 phrases for disagreement.

Rating the Collected Phrases

Questionnaires were used to rate the responses in terms of the strength of agreement / disagreement. The subjects were another one hundred fluent English speakers who were categorized into 10 groups by gender and age (teens to 50s). The strength of agreement / disagreement was assigned one of five levels from ''strong (5)'' to ''weak (1).'' In the questionnaires, radio buttons for each level were positioned at equal intervals on the screen.

RESULTS

It is important to identify phrase type in order to design better usage of agreement / disagreement. For mutual understanding, it is better that most users evaluate similarly the strength of agreement / disagreement. The success of the phrase usage depends on reliable metrics that can well represent the strength of agreement / disagreement.

Tables 2-(a) and 2-(b) list the top ten phrases of large and small standard deviation (shown as SD in the table) in rating by all subject groups in gender and age,

Table 2. A listing of the top ten phrases of large and small standard deviation in rating

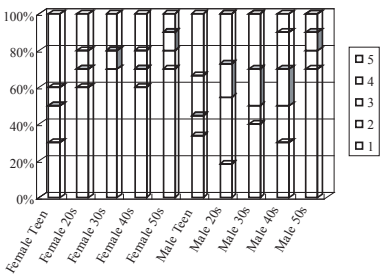
(a) Phrases: care needed.

Agreement (SD)	Disagreement (SD)
Whatever (1.55)	Whatever (1.49)
Yeah (1.53)	Nah (1.40)
Yea (1.47)	Well (1.35)
Yup (1.45)	Oppose (1.35)
Mm-hmm (1.44)	Uh uh (1.34)
I know (1.42)	Not (1.30)
Uh huh (1.38)	Nope (1.29)
Alright (1.37)	Not a chance (1.29)
Awesome (1.34)	I don't think so (1.28)
Totally (1.33)	No way (1.28)

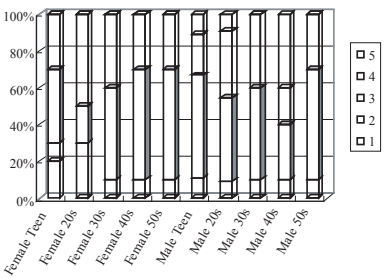
(b) Phrases: no care needed.

Agreement(SD)	Disagreement(SD)
That sounds good(0.83)	Of course not(0.94)
Absolutely (0.91)	No(1.03)
Excellent(0.93)	Can't(1.03)
That's right(0.93)	I don't know about that(1.03)
You're right(0.94)	Absolutely not(1.05)
Sounds good to me(0.96)	Stop(1.05)
That's true(0.97)	Not really (1.05)
I totally agree(0.98)	That's wrong(1.06)
Great(1.00)	Never(1.07)
Definitely (1.00)	Disagree(1.10)

Figure 2. Rating results for two types of phrase



(a) Rating results for "Whatever" (agreement).



(b) Rating results for "That sounds good".

respectively. The phrases shown in Table 2-(a) need to be handled with care while those in Table 2-(b) can be used relatively freely.

The most interesting phrase in Table 2-(a) is ''Whatever'' which ranked at the top of both agreement and disagreement columns. Figure 2-(a) is the rating result for ''Whatever'' in agreement. In this figure, the horizontal axis categories each subject group in gender and age and the vertical axis plots the ratio of each rated level in the evaluation. As shown in Figure 2-(a), subjects in each gender and age group assessed the expression ''Whatever'' quite differently. This is because ''Whatever'' can be used for either agreement or disagreement. A subject who rated ''Whatever'' as a 5 may have misunderstood weak agreement as strong agreement and someone who rated it 1 may not have understood other's praise.

On the other hand, as shown in Figure 2-(b), most subjects evaluated the expression ''That sounds good'' in the same way. ''That sounds good'' is a very safe phrase in terms of avoiding misunderstanding in communication.

DISCUSSIONS

One simple way of augmenting human affordance for an overestimating type of user is replacing the phrase that the partner used with another phrase of weaker agreement / disagreement. We compared two subjects in order to explore the potential of phrase replacement. The most overestimating user in our experiments overrated the strength of agreement phrases by 1.16 on average compared to the average user.

Figure 3 shows a comparison of the ratings produced by the normal user and the ''adjusted'' ratings by the overestimating user. In this figure, the vertical axis plots those ratings. The adjusted ratings were calculated by subtracting the factor of 1.16 from the original rating; subtraction was not performed on phrases that both users rated 5. As shown in Figure 3, this simple subtraction created 25 matched ratings by those two users (originally, there were 14 matches). Also, in Figure 3, a vertical line between o and x means a gap between the rating by the normal user and the adjusted rating by the overestimating user. As shown in the figure, the number of large gaps (more than 2) decreased from 14 to 7.

A lot of methods can be used for augmenting human affordance in agreement / disagreement. Here is one example for the overestimating user. Both phrases ''Excellent'' and ''Sounds good to me'' are phrases for which no care is needed in Table 2-(b). However, ''Excellent'' is a high rating phrase and may be overestimated by the overestimating user. Thus, using ''Sounds good to me'' instead of ''Excellent'' is better for the overestimating user. The fact is that the overestimating user rated ''Excellent'' as 5 but rated ''Sounds good to me'' as 3, while the normal user rated ''Excellent'' as 3.

CONCLUSION

In this paper, we proposed the novel concept of ''human affordance'' which is afforded from humans, not from artifacts and presented its definition and model with perceptual information and internal properties of humans. We also introduced experimental results on understanding the strength of agreement / disagreement in text-based communication. Analyses of those results in phrase type and user type provided findings towards better augmentation methods of human affordance in text-based communication.

This work envisions that the new paradigm of human affordance will be a key design foundation for human-to-human communication systems in terms of user-centered design. Future work includes developing and evaluating affordance augmentation methods as a user support technology.

ABSTRACT

This work presents a computational tool for remotely monitoring data servers (Kipo System). To achieve this, the system contains a society of agents, where each agent performs a specific role within the process. Among the existing agents, two should be remarked: the Solver Agent, and the Supervisor Agent. The first one employs a case-based reasoning approach to interpreting and defining an action to be taken, given the detected fault. The latter one has an important role, as it constantly verifies the activation states of each agent. Through the Kipo System, a decrease in attendance times for faults on data servers could be experienced. This has corroborated our initial expectations on the adequacy of such agent's technology for this type of domain.

1. INTRODUCTION

Several software systems were developed for monitoring network behavior, as well as the operational conditions of its hardware and software components. Among the desired issues to be checked, we may include the memory available to the users, the working conditions of specific applications (such as databases), and many others. In these cases, information regarding the system's operational state, errors, and other collected data can be obtained through the analysis of log files, for example.

Many large, and even medium and small corporations have Information Technology (IT) departments, where specialized professionals are responsible for the preventive and corrective maintenance of the existing computational resources, besides other functions. They have to control the actions that identify undesired situations before they occur, avoiding unnecessary maintenance calls.

This way, the presence of identifying mechanisms, which can detect errors and undesired situations in the equipment, storage media, and data is of great importance. If the information could be retrieved remotely, without human presence, this system would be of major interest. Thus, the development of an identifying architecture which can, almost instantly, detect failures, undesired situations or potentially warning situations, is a very important issue for these corporations. As a consequence, the corporations may experience a reduction of the corrective maintenance calls, a reduction in there operational costs with personnel, and an improvement of their QoS (Quality of Service), assuring data and systems more trustable, among other gains.

This paper presents a monitoring system named Kipo[1], which uses intelligent mechanisms, designed to aid the monitoring work of geographically dispersed computers. Section 2 reviews some related works. Section 3 presents the application domain, and the next section presents the system architecture and functioning. Finally, Section 5 presents some concluding remarks.

2. APPROACHES

Since the objective was to obtain an "intelligent autonomy" regarding to the detection and sending of error information, intelligent agents characteristics were incorporated, because this technology aims at achieving some degree of "intelligence" in computer based systems [Wooldridge 95]. Solutions involving agents have been researched and applied in application areas such as air traffic control, data mining, and information retrieval, among many others [Kristensen 98].

Another research area in Artificial Intelligence (AI) is the Case-Based Reasoning (CBR), an AI paradigm mainly based on the idea that knowledge of past experiences may guide the human behavior [Kolodner 93]. This way, CBR means to use previous experiences to understand and to solve new problems.

There are some possible integrations between CBR and other approaches, such as [Marling 05, Rezende 06, Julio 06] The proposed architecture combines agents and CBR characteristics to provide intelligence with some degree of autonomy, and use of past experiences to help in the remote monitoring context.

Differently from most existing case based systems, in the proposed one, the data input will be based on parameters sent by the agents, when they detect failures. Moreover, the process of knowledge acquisition used was based on the actions that would be performed by local operators when noticing a failure.

The establishment of similarity metrics in CBR systems is one of the most important issues to achieve efficiency in such systems [Freitas 96]. Determining the similarity degree is an important component to identify the usefulness of a case. Another point to be considered is that the usefulness of a case also depends on its purposes, and which of its aspects were relevant in the past [Goel 05]. The similarity degree aims at attributing a numeric value to the similarity between two cases. All the cases stored are evaluated comparatively to the input problem (case). Usually, a similarity degree in the interval [0,1] is associated among the attributes of certain dimensions [Kolodner 93]. In the context of the architectural view presented, we used the syntactic similarity as the similarity measure. In this case, the greatest the number of coincident words between the problem description and the description of each case, the greatest the similarity degree achieved.

3. APPLICATION DOMAIN

In order to represent the use of intelligent agents and CBR in the remote corporative applications monitoring problem, it was chosen to apply them to geographically distant data servers, interconnected through a corporative network. This kind of servers usually has data servers used by several applications, and these applications need to work 24 hours a day, 7 days a week. Moreover, in the studied cases, there was only one administrator, who was responsible to guarantee the servers' operational state, as well as data integrity. Theses professionals use queries, which compute information to be compared with previously established tolerance thresholds for each monitored situation.

In the other hand, there are several professionals accessing computational resources stored in the data servers. Independently of the security policy adopted, the administrator is responsible to assure the integrity of both the data and the data structure, even if users with access rights try to modify them.

This way, if someone tries to erase a table or to modify a table's structure, this action has to be notified, so that another corrective action can be performed. Obviously, it is difficult to imagine a single person controlling all aspects of a database, without the aid of an automated system that identifies these kinds of situations, and reports them in time to avoid or minimize damage. Figure 1 depicts a general domain view of the system Kipo, exemplifying the studied situation.

Figure 1. General view of the application domain

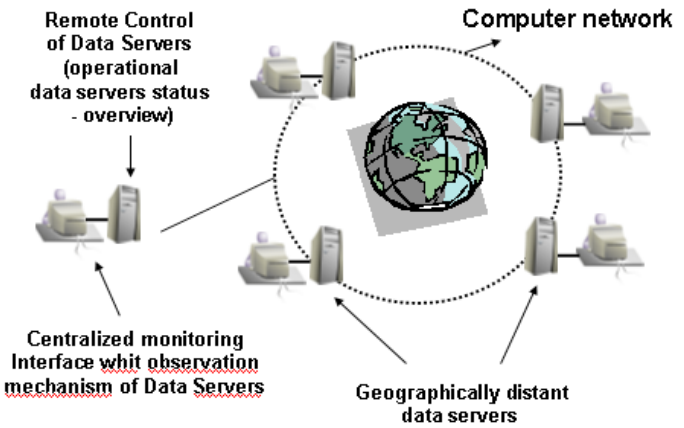

Figure 2. The main components of the Kipo architecture

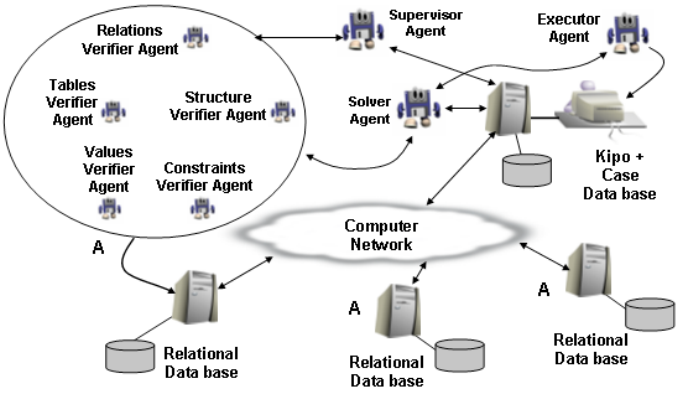

Based on AI artifacts characteristics presented before, the system Kipo uses agents installed in the monitored servers, which, with a CBR agent, automatically detect and solve or inform failures and undesirable situations. An example of a failure situation could be an inactive service, the bad functioning of a specific port, the undesired change of a data base table, or even a server turned off. As examples of undesired situations, we could include a query returning an unexpected result, out of a tolerance interval, for instance. The normality standards are defined through a separated interface.

4. SYSTEM ARCHITECTURE

The motivation for the development of the system architecture included the use of agents and case-based applications for failure detection in computer networks. There are several similar works, including: Project P712 [Corley 98], SPIN [Hakima 98], PathFinder [Hart 01], SNMP [Puliafito 99], MAG [Gavalas 99], MCE [White 98], and EPSRC [Cruickshank 01], among others.

Based on these systems' behavior, the proposed model gives a new solution for the proposed domain. This way, the use of agents in the system Kipo implements alarm mechanisms, e-mail communication, and error correction, which are immediately performed after the error recognition or after a predetermined time period. These alarms can be observed through a centralized monitoring interface. This interface enables a quick and useful observation mechanism to the professional, and may be used to identify and anticipate possibly critical situations.

The Kipo architecture is composed by several intelligent agents' categories present in the data servers, each one with a specific purpose. The agents behavior and the comparing parameters they use are configured by the monitoring professional. Besides periodically perform their monitoring tasks, the agents also communicate with a supervisor agent. The detected errors are reported to a solver agent, which evaluates the situation by using CBR mechanisms. After this, it forwards the problem and its solution to an executor agent. Figure 2 depicts the main components of the proposed architecture.

The following agents' definitions detail how the system works, giving a better understanding of the architecture:

Solver Agent. This agent is responsible for the interpretation and execution of problems reported by other agents. It receives standard error situations as input, informing the sending agent, the computer identification, and the problem identified. Then, the solver agent checks for the best solution to be performed in a database, and sends a command to an executor agent. The solver agent uses CBR, checking for similarities between the reported problem and previous problems, using syntactic similarity. Figure 3 shows the agent's behavior. The arrow 1 represents the query performed by the solver agent. The arrow 2 indicates it sending an action solicitation to the executor agent, after consulting the database. The arrows with number 3 represent the possible actions to be performed by the executor agent, such as an alarm, e-mail, or error correction.

Executor Agent. This kind of agent receives information from solver agents, and they are responsible for correcting errors, sending e-mails informing about errors or updates in the database, which are related to monitoring the operational situation, among others.

Structure Verifier Agent. This agent is responsible for verifying unauthorized modifications in existing table structures. Initially, it consults the list of tables to be checked, as well as their expected structure. Then, it compares with the existing tables in the local database. Eventual discrepancies are communicated to the solver agent. Figure 4 shows this kind of agent's behavior. The correct structure of the database has to be stored and read previously, which is indicated by arrow 1. Auxiliary tables are created and used for future comparations (arrow 2). Then, periodical consults are performed in the reference database (arrow 3), and compared to the monitored tables (arrow 4). If there is any error, it is sent to the solver agent (arrow 5). The solver agent will forward the problem to the executor agent (arrow 6), which will decide if it will just report the error via e-mail, or if it will put in the monitoring interface, or if it will solve the problem (arrows 7).

Relations Verifier Agent. This agent is responsible for verifying unauthorized modifications in the predefined relations among the tables. They consult the relations of the reference database, and then, they compare them with the existing relations in the local database. Eventual differences are reported to the solver agent.

Values Verifier Agent. This kind of agent is responsible for verifying if the values get by specific queries are between predefined limits. The queries are edited using an ANSI SQL syntax interface, and unexpected results to the queries are reported to the solver agent.

Figure 3. Solver agent's behavior

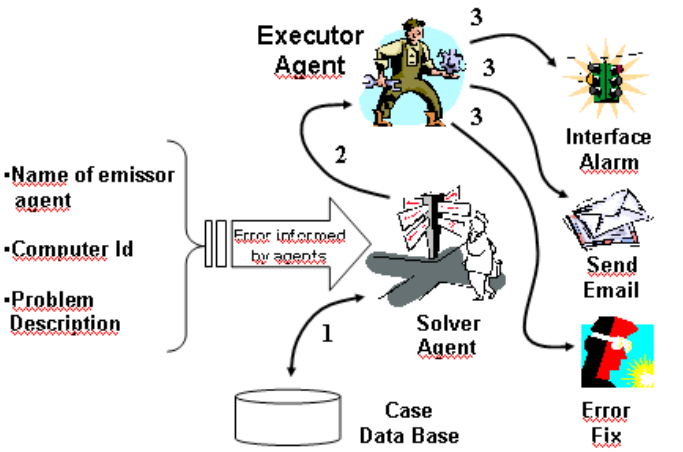

Figure 4. Structure verifier agent's standard behavior

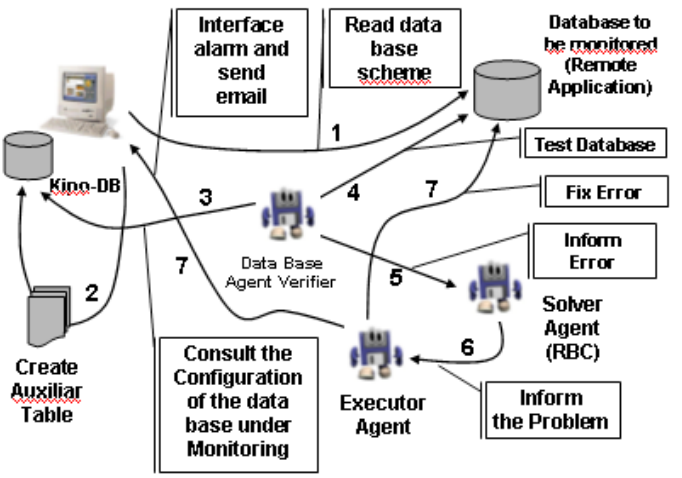

Constraints Verifier Agent. This agent is responsible for verifying if unauthorized modifications in the predefined table constraints are performed. To do this, it consults the constraints descriptions in the reference database, and compare them with the constraints in the local database. Eventual discrepancies are reported to the solver agent.

Results Analyzer Agent. This agent compares the results got with the thresholds stored in the remote monitoring system database. Eventual discrepancies are reported to the solver agent.

Tables Verifier Agent. This kind of agent verifies if there is any table lacking in the database being monitored. To do this, it consults the list of tables in the reference database. If any table was wrongly deleted, it informs the solver agent.

Supervisor Agent. The Kipo system aims at assuring to the remote supervisor of the system a safe and trustable panorama of its software and data. Thus, safe mechanisms to verify the agents are needed. The supervisor agent supervises other agents, verifying, for example, if a server was turned off, or if it has hardware problems. The behavior of such agents is quite simple: when a remote monitoring interface is activated, its related agent is automatically activated. A signal (input parameter) identifying the sending agent is then waited. All agents, regardless of function, localization or characteristics, send periodically this type of information to the supervisor agent, assuring that they are active. A list of all agents can be consulted in the monitoring system database. Thus, if a signal is not received within a maximum amount of time, the supervisor agent updates its operational state to "without communication".

The developed architecture can be installed in any computed connected to a corporate network with databases. It uses a monitoring interface, which is responsible for the configuration of the various existing components, such as databases, information used by the agents to supervise the databases, monitoring screens, etc. An example is the interface used to check the general monitored events panorama (Figure 5), and the configuration interface, responsible for configuring the agents' behavior (Figure 6).

Figure 5a illustrates a monitored objects general state. It is based on color conventions, where the green color represents objects with normal behavior, the yellow objects means any abnormality, and red objects represents problems. Through this interface, it is possible to verify the geographical localization of the object (city, neighborhood, etc.), the description of the objects in a particular location (name, IP address, etc.), and the monitored objects list. For each object, it is possible to retrieve information about its behavior, as well as about its current operational state. The configuration interface presented in Figure 5b is used to establish each agent's behavior, regarding to their class, the periodicity of their communication with the verifier agents, their execution periodicity, and information about their function.

The agents were implemented using Java. All the agents have to consult the reference database computer (the node where the remote monitoring system is installed) to behave as established by the monitoring interface. This way, the agents need to send queries, to retrieve their syntax in the reference database, and to execute them. If necessary, they compare the query result with the values stored in the reference database. Depending on the result, they decide if they send a message to the remote monitoring system.

5. CONCLUDING REMARKS

An important contribution of this work was to explore the use of agents and CBR in the remote monitoring of computer networks domain, more specifically detecting errors and abnormal situations in distributed databases within the network. Usually, this task is performed with a human supervisor. The Kipo system auto-

Figure 5a. Remote monitoring interface

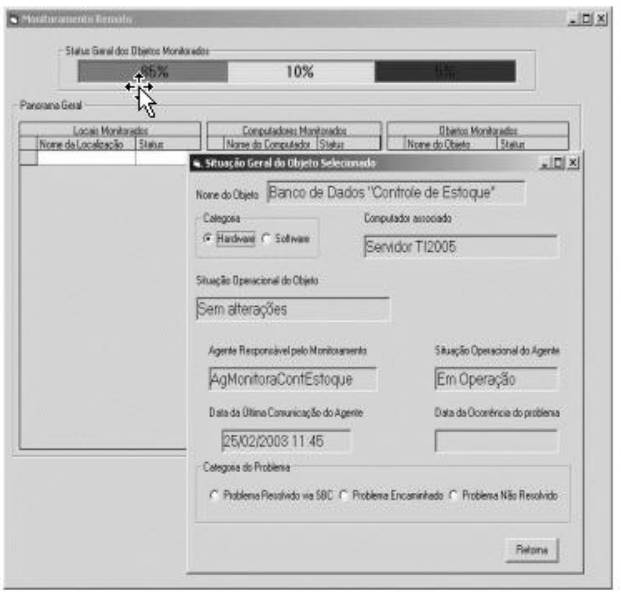

Figure 5b. Configuration interface

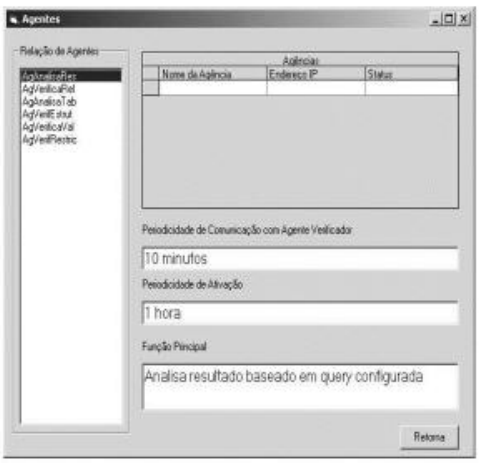

matically identifies and diagnoses failures, analyzes them through a case-based mechanism, signalizes the failure in an appropriate interface, automatically corrects the failure if this action is possible, and sends an e-mail describing the event occurred. Because the system tries to immediately identify failures and abnormal situations, it permits that these abnormalities to be rapidly resolved by the system agents or by another professional responsible by the monitoring system. In this context, the Kipo system is able to significantly aid to reduce the system maintenance time. Moreover, the rapid detection of failures and abnormal situations contributes to reduce the corrective system maintenance, which can be expensive to the corporations.

Currently, we are analyzing the system's first and promising results, and proposing new tests to obtain a wider set of comparative experiments. These results will be presented in a future paper.

The Effect of Hidden Units in Neural Networks on Identifying Data Duplication Records

Abdullah Al-Namlah, Ministry of Defense and Aviation, RSADF/Computer Directorate, P.O. Box 21386, Riyadh, 11475, Saudi Arabia; E-mail: alnamlah@hotmail.com

ABSTRACT

Learning algorithms have been widely used to solve different problems in the field of Artificial Intelligence. Presently there are many learning algorithms; each is used depending on specifics of the problem to be solved. Examples of learning algorithms can be found in the field of Artificial Neural Networks (Neural Nets) where these algorithms are used to train the neural nets (as an example, Backpropagation algorithm). Neural nets have been used in data quality problems where a complex database has a lot of duplicate data (dirty data). By using neural nets, it was demonstrated that they can be a very useful tool to identify duplicate and non-duplicate records in the database. In this paper, we show the impact of internal architecture of neural network (hidden units) on the accuracy of results.

INTRODUCTION

Neural Networks are one of the most popular advanced modeling techniques (Barth, 1997). A neural network is an information processing system that can be used to store and recall data or patterns and classify them. It has the capability to learn by examples. Neural networks have proven to be quite effective for a broad range of problems, and are especially useful for predicting events when there is a large pool of data during the learning process. Neural Networks are of interest to both academics and practitioners in many areas like signal processing, medicine, pattern recognition, speech recognition, and even in business (Harston, 1990). Chiang, Urban and Baldridge (1996) developed a neural network to forecast the net asset value of mutual funds, and found the model to perform well in forecasting processes. Another example of using neural nets in business was to predict daily stock prices for three German stocks (Schoneburg, 1990). In 1995, Jain and Nag applied a neural net to the problem of pricing initial public offerings (Jain and Nag, 1995).

Lately, neural networks have been used in the field of Computer Science to address data quality during the software maintenance process (Al-Namlah and Becker,2003). Neural nets also have been used in the data quality field where a complex database has a lot of duplicate data (dirty data), and showed that they can be a very useful tool to identify duplicate and non-duplicate records in a database (Al-Namlah, Becker and Koksal,2002) and (Al-Namlah,2003).

DATA DUPLICATION PROBLEM

Data duplication means the database has stored duplicate data about an object. Conversely, non-duplication is defined by English (1999), as "The degree to which there is a one-to-one correlation between records and the real-world object or events being represented" (English, 1999, p. 142).

There are many processes that lead to having duplicate data in a database. Common processes that lead to this situation (Milrud, 2001) are:

1. Merging two or more databases as in the case of creating a data warehouse.
2. Using the system to generate a unique number for each row and assign it as a primary key.

Data duplication adds costs in at least two ways: First, it leads the organization to have more data than it needs. Brauer (2001) reports that an acquiring company learned long after the deal was closed that their new consumer business only had 50% of the customers as they thought because of the large amount of duplicate data in their customer database (Brauer, 2001). Second, data duplication affects the correctness of all the processes that depend upon this data, such as business reports.

Sending duplicate mail to customers leads to additional costs that can be alleviated if the company cleans their customer database. Here are some of the costs involved in having duplicate data:

- The cost of duplicate faxes, mailing and other forms of communication
- The cost of printing and production of additional mail services
- The cost of inaccurate results from analysis of data and subsequent reports
- The cost of inaccurate forecasting due to the misleading number of records
- The negative impact presented to potential clients receiving duplicate mail
- Time consumed by salespeople to contact the same customer

To prevent these additional costs, business organizations should consider eliminating duplicate records before they start using their data warehouses.

DATA DUPLICATION METRICS

Before highlighting the past efforts and the results of our work, we introduce metrics that are used to evaluate the data duplication solution. Researchers in the area of solving data duplication problems have used the following metrics:

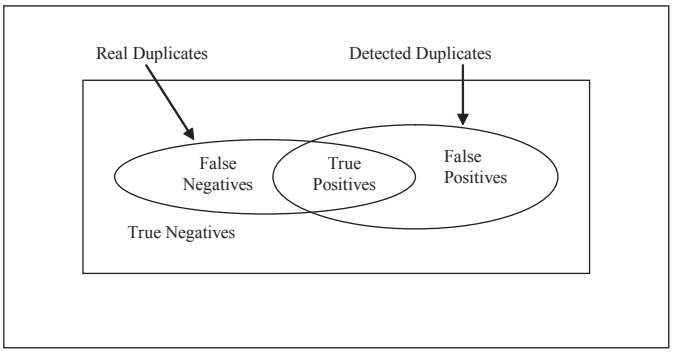
1. ***False negatives*** are also called *missed matches* (Winkler, 1995) and some researchers call them *misses*- which are those duplicate records where the approach fails to identify them as duplicates (see Figure 2).
2. ***False positives*** are also known as *false matches* (Winkler, 1995), which include those records that are not duplicates but the approach wrongly identifies them as duplicates (see Figure 2).
3. ***True positives*** *are* those records that are duplicates and the approach correctly identifies them as duplicates (see Figure 2).
4. ***True negatives*** are those records that are not duplicates and the approach correctly identifies them as not duplicates (see Figure 2).
5. ***Recall*** is also known as *percentage hits* (Lee et al., 2000), and is defined as the percentage of duplicate records being correctly identified. Higher recall is achieved by accepting records with low degrees of similarity as duplicates. Recall is computed as follows:

$$Recall = \frac{|True\ Positives|}{|Misses| + |True\ Positives|}$$

6. ***Precision*** is contrasted with recall; the percentage of correct predictions among all pairs of records that have been identified as duplicates (McCallum, Nigam and Ungar, 2000). Higher precision is achieved by accepting records with a higher degree of similarity as duplicates (Monge & Elkan, 1996; Lee et al., 2000; Do et al. 2002). Precision is computed as follows:

$$Precision = \frac{|True\ Positives|}{|True\ Positives| + |False Positives|}$$

Figure 1. Data duplication metrics (from Do et al. (2002), pg. 224)



PREVIOUS EFFORTS TO SOLVE DATA DUPLICATION PROBLEM

Record duplication is a complex problem that many researchers have tried to solve, using a variety of approaches. One of the most effective approaches is (Hernandez & Stolfo, 1995), and almost all subsequent researches have referenced this approach as a unique and effective way of solving the data duplication problem. Since the process of identifying data duplicates in databases involves matching the corresponding attributes in two different records, some efforts have focused on the field matching algorithms used to find the degree of similarity between two corresponding database fields. Monge and Elkan (1996) describe three record matching algorithms and evaluate their performance on real-world datasets. These are the basic field matching algorithm, recursive field matching algorithm and Smith-Waterman algorithm. Monge and Elkan (1996) found that recursive field matching and Smith-Waterman algorithms could achieve 100% recall while the basic algorithm could only achieve 90% recall. One fact to consider is that the Smith-Waterman algorithm has lower precision than the other two algorithms. A main contribution of the Monge and Elkan (1997) study is that it gives a relatively domain-independent algorithm to detect approximate duplicate records. It also shows how to compute transitive closure of the "is duplicate of" relationship by incrementally using a union-find data structure.

Lee et al. (2000) presents a knowledge-based framework for intelligent data cleaning. The framework consists of three stages: pre-processing, processing, and (validation and verification) stages. In the preprocessing stage, data records are first conditioned and scrubbed of any anomalies, and then data type and format are standardized. In the second stage, conditioned records are fed into an expert system engine together with a set of rules. The rules are fired in an opportunistic manner when conditioned records are fed into the expert system engine. These rules are responsible for identifying duplicate records, updating records that have missing data, and raising certain alert rules when some constraints are violated. The third and last stage is to generate a log report, which is used as an audit trail for all actions that have been done to the database records.

McCallum et al. (2000) used a technique for clustering, called canopies, to solve the problem of grouping large, high-dimensional data sets such as clustering textual bibliographic references. A canopy is a subset of the data elements to be clustered, and each data item that appears in a canopy is within some distance threshold from the center of the canopy (which is another data item).

Cohen and Richman (2002) have used the canopy approach, and presented an adaptive scheme for entity-name matching and clustering. What is meant by adaptive in this paper is that accuracy can be improved by training, like the nature of most learning methods. The entity-name matching means matching names for two different sources to identify those names that belong to the same object. The main use of the canopy approach in their scheme is to compute the set of candidate pairs to be compared in a subsequent stage. This way, the canopy approach restrains the number of items in each canopy and then another expensive edit distance is used to compare the items under each canopy. By doing this, overall time complexity is reduced since not all data items in the two resources are compared against each other using an expensive edit distance.

In (Al-Namlah, 2003) we showed that combining neural nets with other methods such as the one used by (Hernandez & Stolfo, 1995), was a powerful mechanism in uncovering data duplication. Our results showed that this approach reduced time complexity, uncovered duplicate records, and reduced the number of false positives and misses when uncovering duplicate records. However, there were some variables related to the neural net that were not studied in detail in this effort. One of them is the effect of the internal architecture (hidden layer) of the neural net on accuracy of the results. This paper details the effect of the number of hidden units in the hidden layer on overall results for resolving the data duplication problem.

NEURAL NETWORK ARCHITECTURE

Artificial neural nets are mathematical models that have been developed to imitate the biological neural net and they share common properties. The following assumptions are made to generalize artificial neural nets so that they are similar to human neural biology (Fausett, 1994):

- The information is processed in multiple central processing units called neurons (units).
- Neurons interchange signals through a highly connected net.
- Each connection between two neurons has an associated weight.
- Each neuron computes the output by summing all incoming signals (net input) and applies an activation function to the net input

The internal architecture of the neural net consists of nodes that are highly connected. Each connection has a weight, and as the neural network is trained, the weights are adjusted. When these weights no longer need to be adjusted during the training phase, the neural net has learned from provided examples. Then, it should be able to recognize (memorize) exact and (generalize) similar (generalize) patterns when it sees them in future applications (Fausett, 1994).

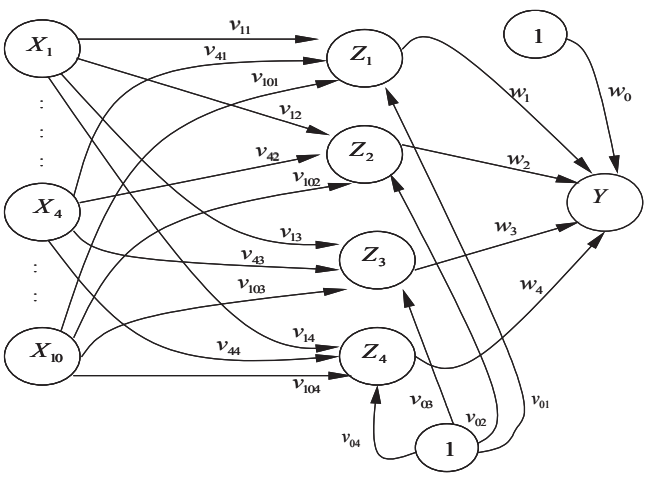
Neural nets are usually characterized by their internal architectures and methods that are used to train them. Training a neural net involves changing the weights to reflect current understanding to the behavior of the problem under investigation. In general, there are two methods of training: *supervised* and *unsupervised*. *Supervised training* is accomplished when the provided training examples (also can be referred to as training vectors or training patterns) consist of two parts: input example and output target.

In order to have a reasonable number of training pairs, we use the following formula (Baum and Haussler, 1989)

$$\frac{W}{P} = e$$

where W is the number of weights in the net, P is the number of training pairs, and e is the accuracy of classification expected. In our study, we start the algorithm

Figure 2. Neural net architecture



by assuming e=0.01 and the total weights W= 44, which suggests 4,400 training pairs. We train the net using a back propagation algorithm with Nguyen-Widrow (1990) initial weights. After the net is trained, we capture the final weights and use them in performing ten separate tests for different sets of data. The net has a ten-unit input layer (X_i), variable of units in the hidden layer (Z_i), and a single unit output layer (Y). As an example, Figure 2 shows the neural net architecture with four hidden units.

To test the effect of the hidden layer on accuracy of the end result of the net, number of the hidden units in the hidden layer will vary. Each time we change the number of hidden units, we train the net until it reaches the stability phase and then weights are captured to be used in the test phase. In this work we tested the results when the hidden layer had 2, 3, 4, 5, 6, 8, 10 and 12 units. Results of these tests are detailed in the Experimental Results Section of this paper.

EXPERIMENTAL RESULTS

The database used to test our proposed method was generated by the same database generator used by Hernandez (1996). This database generator allowed us to generate data with prior knowledge about duplicate data records. Furthermore, the database generator as described in (Hernandez, 1996) provided a large number of parameters that helped us perform controlled studies. These parameters include size of the database, percentage of duplicates in the database, and amount and type of error in any attribute to be introduced**.**

The layout of generated records consists of the following fields: social security number, first name, middle initial, last name, street number, street address, apartment #, city, state, and zip code. Some of these fields can contain null values as a simulation of errors that can happen in real life databases. The names were chosen randomly from a list of 63,000 real names. The cities, states and zip codes are all from the U.S.A.

In order to test effect of the hidden layer on accuracy of the neural net in identifying duplicate records, we built 8 neural nets with 10 input units, one hidden layer and one output unit. The difference between these neural nets is the number of units in the hidden layer. The 8 neural nets have 2, 3, 4, 5, 6, 8, 10 and 12 units respectively. After building each one of these neural nets we trained it using the 4,400 training examples. After the training we tested the neural net by feeding it with 501,360 records. Among these 501,360 there were 295,689 duplicate records, and 205,671 non-duplicate records. Table 1 shows the results of these tests.

Table 1 shows that when the neural net has only 2 units in the hidden layer, 294,842 out of 295,689 duplicate records were correctly identified by the neural net as duplicates (true positives), where 847 duplicate records were misses, i.e. the neural net failed to identify them as duplicates (false negatives). Furthermore, 205,639 out of 205,671 non- duplicate records were correctly identified by the neural net as non-duplicates (true negatives), where only 32 non-duplicate records were wrongly identified as duplicates (false positives). As a result of the above identification, recall was computed as follows:

$$Recall = \frac{|True\ Positives|}{|Misses| + |True\ Positives|} = \frac{294{,}842}{847 + 294{,}842} = 0.997$$

Table 1. The result of identifying duplicate records with different number of hidden units

Metric	Number of Hidden Units							
	2	3	4	5	6	8	10	12
True Positives	294,842	294,607	295,037	295,037	294,927	294,644	294,932	294,867
False Negatives	847	1082	652	652	762	1045	757	822
True Negatives	205,639	205,651	205,621	205,637	205,649	205,386	205,534	205,393
False Positives	32	20	50	34	22	285	137	278
Recall (%)	99.7	99.6	99.8	99.8	99.7	99.6	99.7	99.7
Precision (%)	100	100	100	100	100	99.9	99.9	99.9

and the precision was computed as follows:

$$Precision = \frac{|True\ Positives|}{|True\ Positives| + |False\ Positives|} = \frac{294{,}842}{294{,}842 + 3} \approx 1$$

We should take notice that the best overall results were obtained when the neural net had 3, 4 and 5 hidden units. The net with 3 hidden units was the best in identifying non-duplicate records, while the net with 4 and 5 hidden units was the best in identifying duplicate records. By reviewing the overall results, all 8 neural nets were excellent in their recall and precision. This is almost complies with (Rumelhart, McClelland, & PDP Research Group, 1986) that a set of N orthogonal input patterns can be mapped onto $\log_2 N$ hidden units to form a binary code with distinct patterns for each of the *N* input patterns.

It should be noticed that in our proposed solution we are always trying to obtain the maximum value of both precision and recall metrics together by doing a balance between them. It might be observed as an example, Monge and Elkan (1996) found that recursive field matching and Smith-Waterman algorithms could achieve 100% recall whereas our proposed method the best achieved 99.8%, however, we should consider the other metric (precision) in both solutions as well as other advantages such as the ability to improve the results through learning among others, that are not the subject of this paper. Detailed advantages of our solution can be found at Al-Namlah.(2003).

SUMMARY AND FUTURE WORK

In this study we found that internal architecture has an effect on the results of a neural net in identifying duplicate records. What we mean by internal architecture involves number of hidden units in the hidden layer. It was also observed that it is not necessarily the increase of hidden units that makes a neural net more capable of identifying duplicate records as noticed when the neural net had 8, 10, and 12 hidden units.

Theoretical results show that one hidden layer is sufficient for a backpropagation net to approximate any continuous mapping from the input patterns to the output patterns, to an arbitrary degree of accuracy (Fausett, 1994). Future work will include a practical study regarding the effect of number of hidden layers on the accuracy of a neural net in identifying duplicate records.

ABSTRACT

The objective of this research was to examine the outsourcing of IT functions in Malaysian organizations; in particular how variables like perceived service quality of outsourcer and relationship quality affect outsourcing success. The research adopted a cross-sectional approach and employed both self-administered and mailed survey procedure. The unit of analysis is organizational level. In order to achieve the research objective, data was analyzed using structural equation modeling. The measures seem to demonstrate internal consistency for Malaysian organizations. The study confirms that perceived service quality of outsourcer determines both relationship quality and IT outsourcing success. However, there was no link between relationship quality and IT outsourcing success for Malaysian organizations. Lastly, the finding indicates that the proposed research model is good fit to the observed data.

Keywords: Service quality, relationship quality, information technology outsourcing, structural equation modeling

1. INTRODUCTION

Information technology (IT) outsourcing is neither a new nor an emerging trend. In recent years, the growth of IT outsourcing has been phenomenal. In year 2001, the worldwide spending on IT outsourcing services already reached over USD60 billion and the figure was expected to grow by a 5 year compound average growth rate (CAGR) of 12 per cent[1].

In Malaysia, the International Data Corporation (IDC) expected the IT outsourcing market to grow at 34.2% over the next five years since year 2004. The nature of services being provided and the type of contracts that are being signed, according to IDC, would largely determine the IT outsourcing market size[2]. IDC also forecasted that the Malaysian IT outsourcing market would hit the US$164 million mark by 2005 (Manecksha, 2003).

The IT outsourcing market for the financial sector in Malaysia has been largely shaped by the Financial Master Plan of the Malaysian Central Bank revealed in year 2001. One notable key principle of the plan was the encouragement for banks to outsource non-core back office and IT processes towards enhancing internal efficiency and enabling focus on selling and marketing financial services products. Several blue chip Malaysian banking firms answered this call. Malaysia's anchor banks such as, Maybank and Bumiputra Commerce Berhad notably and recently announced the signing of major IT outsourcing agreements. In year 2003, Maybank signed an outsourcing agreement estimated at RM1.3 billion over a 10-year period with the CSC Group to outsource IT infrastructure services in Malaysia and Singapore[3]. The Bumiputra Commerce Berhad, signed a USD250 million outsourcing contract for a period of over 10 years with EDS Malaysia. Malaysia also sees the trend of outsourcing IT functions in government-linked companies[4]. In year 2003, Permodalan Nasional Berhad (PNB), Malaysia's leading fund manager signed a major IT outsourcing agreement for a period of three years with HeiTech Padu Berhad a local home-grown IT service provider[5]. In Malaysia, the outsourcing of IT functions does not limit itself within the financial industry. In the transportation industry, the Malaysian Airlines Systems in year 2003 awarded a US$116 million outsourcing contract to IBM Global Services[6].

While the IT outsourcing trend in Malaysia has been encouraging, empirical studies on the contributions of perceived service quality of outsourcer and relationship quality between client and outsourcer to IT outsourcing success seem to lack. Hence, this paper aims to determine whether perceived service quality of outsourcer and relationship quality between client and outsourcer predict IT outsourcing success in Malaysian organizations. In this research, the client evaluates the service quality of outsourcer and the quality of relationship between the client and outsourcer. In other words, the research assumes the perspective of client in an outsourcing arrangement.

This paper is organized into six sections. This section has introduced the research area. A review of literature is in section two. Section three depicts the hypotheses and research model. Section four presents the methodology. The findings and discussions are available in section five. The last section provides the conclusions of this study.

2. REVIEW OF LITERATURE

This section reviews the literature on IT outsourcing success, perceived service quality of outsourcer and relationship quality between client and outsourcer.

2.1 IT Outsourcing Success

In the past, researchers attempted to provide several definitions of IT outsourcing success. Grover *et a*l., (1996) defined outsourcing success as the benefits derived from the practice of turning over part or all of an organization's IT functions to be administered by one or several external service providers. The outcome of IT sourcing decisions meeting expectations was referred to as outsourcing success (Lacity and Willcocks, 2001). Lee and Kim (2003) defined outsourcing success as the level of fitness between service receiver requirements and outsourcing outcomes delivered by the service provider. More recently, IT outsourcing researchers seem to focus on client's experience of integrated outsourcing success (Grover *et al.,* 1996, Lee and Kim, 1999; Lee, 2001; Lee and Kim, 2003). Clients derive three main benefits of outsourcing success, namely:

- *strategic benefit*: the ability of a firm to focus on its core business by outsourcing routine IT activities' (Lacity and Willcocks, 1998; Williams, 1998)
- *economic benefit:* the ability of a firm to use expertise and economies of scale in human and technological resources of the service provider and to manage its cost structure through unambiguous contractual arrangement (Smith *et al.,* 1998; Klepper and Jones, 1998; Bryson and Ngwenyama, 2000).
- *technological benefit*: the ability of a firm to gain access to leading-edge IT and to avoid the risk of technological obsolescence that results from dynamic changes in IT' (Lacity and Willcocks, 1998, Aubert *et al*., 1999, Lee *et al*., 2000).

2.2 Perceived Service Quality of Outsourcer

The quality of service is thought to be the core criterion for overall customer service (Parasuraman *et al.,* 1991). Service quality is defined as the overall support delivered by the service provider, regardless whether such support is handled by the IT department, a new organizational unit or outsourced to an Internet service provider (DeLone and McLean, 2003). From the service receiver perspective, the service quality delivered by service provider may contribute to outsourcing success (Grover *et al*., 1996; Jiang *et al*., 2003).

IS researchers have been assessing service quality using the SERVQUAL instrument. Based on Parasuraman *et al.,* (1988), the service quality dimensions in the SERVQUAL instrument comprise the following elements namely:-

- *Tangibles:* appearance of outsourcer's physical facilities, equipment, personnel and communication materials;
- *Reliability:* outsourcer's ability to perform the promised service dependably and accurately;
- *Responsiveness:* outsourcer's willingness to help customers and provide prompt service;
- *Assurance:* knowledge and courtesy of outsourcer's employees and their ability to convey trust and confidence;
- *Empathy:* caring, individualized attention which the outsourcer provides to its customers.

Grover *et al.,* (1996) found that service quality had a direct effect on IT outsourcing success in 188 firms in the United States. They concluded that improved service quality and fostering relationship between outsourcer and client had a significant and positive impact on the success of application development and maintenance outsourcing functions. However, only reliability and tangibles constructs were considered in the assessment of service quality in their research. In an empirical research among 168 users and 168 IS professionals, Jiang *et al*,. (2002) concluded that the SERVQUAL was a valuable analytical tool for IT managers.

2.3 Relationship Quality

A working relationship, according to Henderson (1990), is reflected by a long-term commitment, a sense of mutual cooperation, shared risks and benefits, and other qualities consistent with concepts and theories of participatory decision making. In recent years, managing relationship has been regarded as an important role in the effective acquisition and management of emerging information technologies (Grover *et al.,* 1996, Koh *et al.,* 1999, Lee and Kim, 1999, Lee *et al.,* 2004). Consistent with these arguments, researchers suggested that IT outsourcing relationship quality encompasses:-

- *Benefit and risk sharing*: this refers to the degree of articulation and agreement on benefits and risks between partners (McFarlan and Nolan, 1995). Lee and Kim (1999) concluded that benefit and risk share had a positive effect on outsourcing success. Sun *et al*., (2002) found mutual benefit had the greatest impact on outsourcing success.
- *Trust*: the degree of confidence and willingness between IT outsourcing partners (Lee and Kim, 1999; Sabherwal, 1999; Mohr and Spekman, 1994). Sabherwal (1999) found that trust as a key factor in outsourcing of information system development projects. Lee and Kim (1999) found trust had a significant effect on outsourcing success. Wietz *et al.* (2004) found support for the relationship between trust and multiple service channel cooperation
- *Commitment:* cooperative behaviors that provide the context in which both partners could achieve joint goals without raising opportunistic behavior (Mohr and Spekman, 1994). Lee and Kim (1999) indicated that commitment was significantly associated with outsourcing success. Sun *et al.* (2002) found that there was a positive relationship between commitment and IT outsourcing satisfaction.
- *Knowledge sharing:* the extent to which critical or propriety information is communicated between partners (Lee and Kim, 2003). Lee (2001) found knowledge sharing was significantly associated with the degree of attainment of outsourcing benefits.
- *Business understanding:* the degree of understanding in behaviors, goals and policies between partners (Lee and Kim, 1999). Lee and Kim (1999) found business understanding had a significant effect on outsourcing success from both business and user perspectives. Rai *et al.,* (1996) identified congruity in relationship affected strategic alliances between organizations in IT industry.

Crosby *et al.,* (1990) suggested that service quality could influence relationship quality. On the contrary, Gwinner *et al.,* (1998), in a qualitative research, suggested that customers in service industries might remain in a relationship even if they perceived the core service attributes to be less than superior service quality provided that they received important relational benefits. Similarly, Zeithaml *et al.,* (1996) found that service quality directly influenced relational quality. In Australia, Wong and Sohal (2002) indicated that there was a positive and direct relationship between service quality and relationship quality for shoppers in a retail chain department store. More recently, Roberts *et al.,* (2003) research showed that managers needed to consider not only the quality of the service provided but also the quality of consumers' relationship with the organization. However, the context of the research was not in IT outsourcing but consumer purchases.

2.4 Gap in the Literature

To the best of the researchers' knowledge, empirical research on perceived service quality of outsourcer and relationship quality in the context of IT outsourcing continues to remain an under-investigated research area especially in developing nations like Malaysia.

3. RESEARCH HYPOTHESES & RESEARCH MODEL

The objective of this research was to examine the outsourcing of IT functions in Malaysian organizations; in particular how variables like perceived service quality and relationship quality affect outsourcing success. Based on the literature review, the hypotheses of this research are listed as follows:

H_1: *Perceived service quality of outsourcer is associated with IT outsourcing success in Malaysian organizations.*

H_2: *The relationship quality between outsourcer and client is associated with IT outsourcing success in Malaysian organizations.*

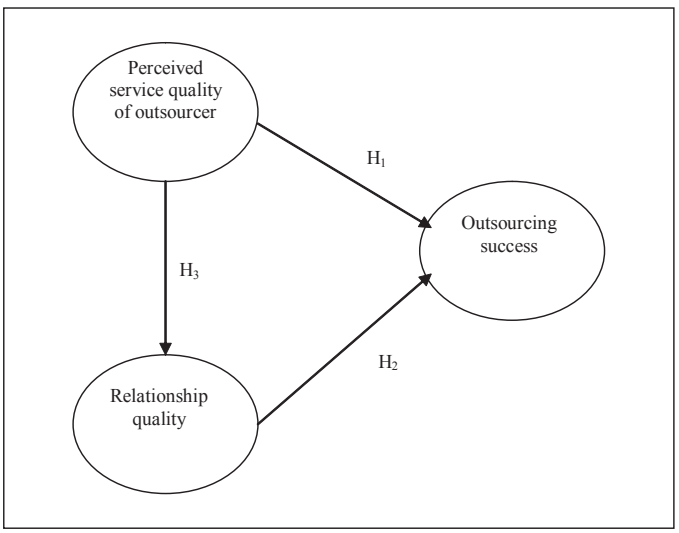
H_3: *Perceived service quality of outsourcer contributes to relationship quality between outsourcer and client in Malaysian organizations.*

Figure 1 shows the research model, depicting the various hypotheses.

4. METHODOLOGY

The research adopted a cross-sectional approach and employed both self-administered and mailed survey procedure. Measures of IT outsourcing benefits were adapted from Lee *et al*. (2004). Respondents were required to evaluate agreement to statements that used a seven-point Likert scale. A seven-point represents "strongly agree" while a one-point represents "strongly disagree". Measures of perceived service quality IT outsourcer were adapted from Jiang *et al*., (2002). Respondents were required to evaluate agreement to statements that used a seven-point Likert

Figure 1. Research model



scale. A seven-point represents "strongly agree" while a one-point represents "strongly disagree". Measures of relationship quality were adapted from Lee and Kim (1999). Respondents were required to evaluate agreement to statements that used a seven-point Likert scale. A seven-point represents "strongly agree" while a one-point represents "strongly disagree".

The unit of analysis in this research is organizational level. According to IT outsourcing literature, many empirical studies set out the measurement of organizational characteristics using the 'key informant' approach. IT managers or the equivalent level to such position holders were selected as key informant to provide information on an aggregated unit of analysis of their outsourced IT functions. Target responding organizations broadly consisted of government and private sectors situated in Putrajaya and the Klang Valley. A sampling frame was formulated based on listing in the Malaysian government official website, Federation of Malaysian Manufacturers (FMM), Small and Medium Industries Development Corporation (SMIDEC) and Bursa Malaysia (the Malaysian Stock Exchange). The estimated number of population was 2475.

We conducted a pre-test among academics as well as practitioners in government and private sectors. Consequently, we incorporated their feedback in ensuring the quality of the questionnaire. We then distributed 50 questionnaires to both government and private organizations in a pilot study. Out of 50, we only received 23 or a response rate of 46%. The questionnaire was revised based on suggestions made. Using stratified systematic sampling method, a total of 960 questionnaires were distributed and e-mail alerts were generated. Data were collected through paper-based questionnaire and web site from April 2005 until July 2005.

5. FINDINGS AND DISCUSSION

In total, we received 162 questionnaires (approximately 18% response rate). Only 143 were found usable for analysis. Unusable questionnaires included those that were returned completely unanswered, incomplete responses on key variables, and organizations that did not practice outsourcing. Data was cleaned and coded accordingly in SPSS Version 13.0. Data was then analyzed using both SPSS Version 13.0 and AMOS Version 5.0. An analysis on non-response bias was conducted by employing post hoc strategy. The early and late respondents were compared on key constructs. There was no significant difference on major variables.

Table 1. Profile of responding organizations

Characteristics	Frequency	Percent
By Industry		
Government	60	42.0
Other services	36	25.1
Manufacturing	22	15.4
Banking and finance	12	8.4
Education	7	4.9
Telecommunication	6	4.2
By total number of employees		
Less than or 50 *(small size organizations)*	13	9.1
51 – 149 *(medium sized organizations)*	18	12.6
Over 150 *(large organizations)*	112	78.3
By the availability of IT department		
Available	118	82.5
Unavailable	25	17.5
By degree of integration		
Minimal outsourcing (below 20% of IT budget)	47	32.9
Selective outsourcing (between 21%-80% of IT budget)	62	43.4
Comprehensive outsourcing (more than 80% of IT budget)	34	23.7
Types of IT functions outsourced		
Application development	112	78.3
Hardware maintenance	110	76.9
Telecommunication/network	91	63.6
Application maintenance	82	57.3
IT consulting	55	38.5
Data center	32	22.4
Help desk	26	18.2
End user support	27	18.9
Others	8	5.6

5.1 Profile of Responding Organizations

Table 1 shows the profile of responding organizations.

The majority of the responding organizations belonged to the government sector (42%). The remainder organizations were in the private sector. A *t*-test was performed to determine if there could be a significant difference. The finding shows that there was no significant difference. Hence, the sample consisting of 143 organizations was treated as one sample and subsequently used in further analysis.

The majority (82.5%) of the responding organizations indicated that they had IT departments. Only a small proportion (17.5%) did not have IT departments.

In terms of degree of integration for outsourcing, the majority of responding organizations indicated that they conducted selective outsourcing (43.4%). Only 23.7% conducted comprehensive outsourcing.

The majority of the organizations (78.3%) outsourced application development. This was followed closely by hardware maintenance (76.9%). Telecommunication/network was ranked third (63.6%). Slightly more than half (57.3%) of the sample indicated that application maintenance were outsourced. Over a third of the organizations (38.5%) outsourced IT consulting to third parties. Slightly over a fifth (22.4%) outsourced their data center. The remaining organizations outsourced help desk, end-user support and others.

5.2 Reliability and Internal Consistency Check

Table 2 shows the Cronbach's coefficient α that was used to assess the reliability of all multi-item scales.

All scales showed reasonable reliability ranging from .866 to .959. They were well above Norusis (2002) generally accepted alpha level .80, indicating good scales.

5.3 Evaluation of the Structural Model

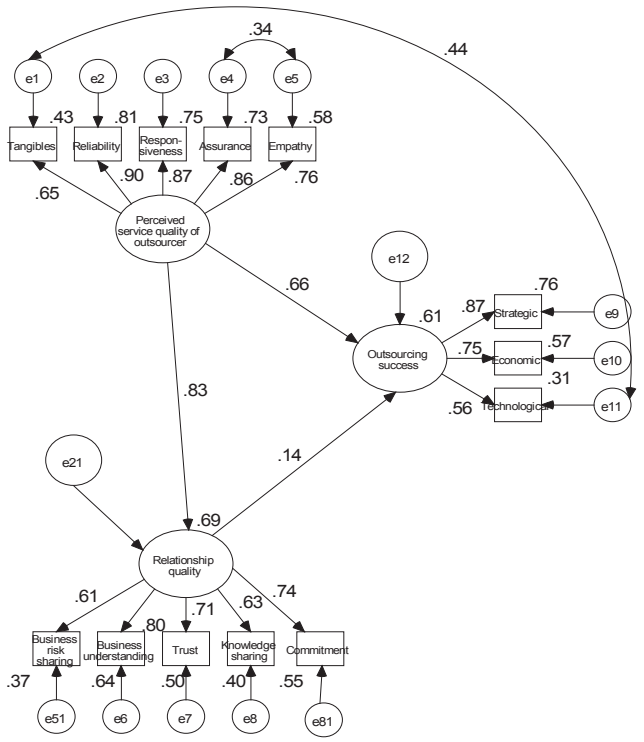
Multi-item constructs were measured using a summated scale derived as the average value of all items pertaining to the constructs. AMOS 5.0 was used to test the structural model. Figure 2 shows the standardized parameter estimates.

Perceived service quality of outsourcer predicted IT outsourcing success (β=.66, $p<.01$) and relationship quality (β=.83, $p<.01$). Higher levels of perceived service quality of outsourcer resulted in greater IT outsourcing success in Malaysian organizations while greater levels of perceived service quality of outsourcer resulted in clients' experiencing higher levels of relationship quality with outsourcer. The model explained substantial item variance: 61% of the variance in IT outsourcing success and 69% in relationship quality, suggesting that perceived service quality is important in explaining outsourcing success and relationship quality. This finding is consistent with Grover *et al.,* (1996) and Jiang *et al.* (2002). The finding that perceived service quality is linked to relationship quality in IT outsourcing success supports Crosby *et al.* (1990) and Roberts *et al*., (2003) work. Against expectation, the hypothesized significant relationship between relationship quality and IT outsourcing success in Malaysian organizations was not supported (β=.14, $p>.05$). This finding appears to be inconsistent with many previous studies (Mohr and Spekman, 1994; Sabherwal, 1999; Lee and Kim, 1999; 2002; Lee, 2001; Sun *et al*., 2002). One possible explanation for the nonsignificant relationship might be a mediating effect for the relationship between relationship quality and IT outsourcing success; culture could be a possible mediating variable. Beulen and Ribbers (2003) suggested cultural issues played an important role in managing IT outsourcing relationships in Asia. Besides, cultural similarity was considered important to create convergent values to help lead to outsourcing success (Henderson, 1990; Fitzgerald and Willcocks, 1994). This is left for investigation in future studies.

Table 2. Cronbach's coefficient for constructs

Factors	α
Outsourcing success (9 items)	.866
Perceived service quality of outsourcer (21 items)	.959
Relationship quality between client and outsourcer (17 items)	.923

Figure 2. Structural model



The confirmation of the overall proposed model was important in providing empirical evidence on predictors of IT outsourcing success (see Table 3).

The χ^2=97.405, df=60, p=.002. According to Raykov (2000), χ^2 and p-value are not the only indicators for model fit. The indicators GFI, NFI, IFI, TLI and CFI for the research model are greater than .90; which indicate good fit to data. The RMSEA=.06 which is approaching .05 indicates a reasonable fit to data (Diamantopoulos and Siguaw, 2000). Overall, the finding indicates that the fit for the structural model for IT outsourcing success was good. In conclusion, there is evidence to support the notion that the model explains a substantial percentage of the variance of the construct.

Table 3. Goodness of fit measures

Fit measure	Value for the research model
χ^2	97.405
Degrees of freedom	60
p-value	.002
GFI	.902
Adjusted GFI	.852
Normed fit index (NFI)	.917
Relative fit index (RFI)	.892
Incremental fit index (IFI)	.966
Tucker Lewis index (TLI)	.956
Comparative fit index (CFI)	.966
RMSEA	.06

6. CONCLUSIONS

The objective of the research was to determine whether perceived service quality of outsourcer and the relationship quality between client and outsourcer predict IT outsourcing success in Malaysian organizations. The research affirms that perceived service quality of outsourcer determines both relationship quality and IT outsourcing success. This phenomenon is consistent with findings of organizations in other countries. In contrast with previous studies, the research did not find a link between relationship quality and IT outsourcing success for Malaysian organizations. Culture might be a mediating variable between relationship quality and IT outsourcing success. Hence, the research enhances our understanding in the role of perceived service quality of outsourcer and relationship quality on IT outsourcing success especially in Malaysian organizations. Overall, the findings call for outsourcers in Malaysia to focus on and enhance the quality of IT services in sustaining relationship quality and attaining benefits from outsourcing.

Some limitations exist and should be acknowledged. Firstly, the research used cross-sectional approach and was static in nature. Therefore, the research did not directly examine the temporal aspects. Future research may consider longitudinal approach. Secondly, the research used single respondent. The perspective was IT managers. Future research may employ actual observations or interviews with different actors conducted at different managerial levels in selected organizations or industries to obtain the benefits of triangulation in understanding the outsourcing phenomenon. Third, this research examined the proposed research model only from the service receiver's perspective. Analysis of the relationship that includes service provider's perspective would be crucial in developing and sustaining high-quality relationship over time. Fourthly, future studies should investigate the mediating effect of culture on the relationship between relationship quality and IT outsourcing success. Finally, results of this research may not be completely generalized and may have to be carefully interpreted since the setting was restricted to Malaysia. The practice of outsourcing in Malaysia and its socioeconomic environment may have played a distinct role to the findings of this research.

Time for Reflection: Going Back to Autopoiesis to Understand Knowledge Management

Paul Parboteeah, Loughborough University, Epinal Way, Loughborough, Leicestershire, LE11 3TU, UK; E-mail: p.parboteeah@lboro.ac.uk

ABSTRACT

The field of Knowledge Management has lots of ideas and models, but the problem lies in that the discipline has no solid foundations on which to build new ideas and developments. A lot of the theory in knowledge management is scientifically unfounded and unproven, possibly a result of the difficulty in testing ideas resulting in numerous debates and leaving little time for new developments in the field. The paper introduces the concept of applying Autopoiesis to the Knowledge Management field in order to provide the discipline with a foundation from which to build.

1. KNOWLEDGE MANAGEMENT

1.1 What can we learn from revisiting the Building Blocks of Knowledge Management?

Knowledge management is a relatively young discipline, and is rapidly evolving with new ideas. Whilst knowledge management can be defined as using knowledge as the key asset to drive organisational survival and success (Jashapara, 2004), numerous methods and perspectives exist for implementing knowledge management systems.

There is general agreement among the academic community that definitions of knowledge have their foundations in the work carried out by Ryle and Polanyi (Ryle, 1949; Polanyi, 1967), providing a logical behaviourist perspective. Polanyi suggests that knowledge exists on a continuum between tacit knowledge and explicit knowledge. Tacit knowledge is explained by Ryle as 'knowing how' whilst explicit knowledge is described as 'knowing that'. Ryle provided the example of a person riding a bike. The person has tacit knowledge in that they know how to stay upright, but often they can not explain what keeps them upright. The main idea behind tacit and explicit knowledge appears to be that 'we can know more than we can tell' (Jashapara, 2004).

Davenport and Prusak (1998) extended the work of Ryle and Polanyi to create a continuum with experience (tacit knowledge) and information (explicit knowledge) at each end. 'Insight', 'values' and 'data' were also added as recognition that 'there is no knowledge which is totally tacit and none without at least some tacit aspect' (Eraut et al., 1998). This approach recognises that whilst a person may not have experience of something, they can still have an insight or information about an experience.

Nonaka (1994), whose work was based on that of Ryle and Polanyi, attempts to show that knowledge can be converted between tacit and explicit form, and vice versa, and be transferred between different people. Whilst recognising this takes place, Nonaka does not provide any framework as to how this might happen or what processes are involved. Nonaka's work is almost holistic in its approach.

Whilst most authors have different views on what knowledge is, an agreement that the ideas are based on the work of Ryle and Polanyi means that regardless of what the finer points of the definition are, there is a common understanding that knowledge can exist on a continuum between tacit and explicit knowledge. An understanding of what knowledge is, allows an analysis of what knowledge management is and how knowledge management has developed.

1.2 The History of Knowledge Management

Metaxiotis et al. (2005) split the history of knowledge management into three generations. The first generation was concerned with defining knowledge management, investigating possible systems and looking at the benefits of such systems. Advances in artificial intelligence also prompted study into how knowledge could be represented and stored. The second generation recognised the influence knowledge management could have in management information systems, for example creating frameworks and instigating organisational change.

The third, and current, generation is based on new insights and practices developed from the second generation. According to Wiig (2002), the third generation is more 'integrated with an enterprise's philosophy, strategy, goals, practices, systems and procedures'. This is in recognition that knowledge management has links wider than information management. The third generation reflects the work of Ryle and Polanyi by emphasising the link between knowing and action (Paraponaris, 2003).

The three generations of knowledge management have given rise to numerous definitions, although two authors have tried to create a definition that encompasses current views. Jashapara (2004) defines knowledge management as:

'the effective learning processes associated with exploration, exploitation and sharing of human knowledge (tacit and explicit) that use appropriate technology and cultural environments to enhance an organisation's intellectual capital and performance'

and Davenport and Prusak (1998) define knowledge management as:

'concerned with the exploitation and development of the knowledge assets of an organisation with a view to furthering the organisations objectives. The knowledge to be managed includes both explicit, documented knowledge, and tacit, subjective knowledge'

Both of these definitions consider exploiting knowledge, but then deviate to focus on separate things. Jashapara (2004) is more concerned with sharing knowledge and different methods for sharing, whilst Davenport and Prusak (1998) are more concerned with developing and managing knowledge. Whilst both definitions are different, they are complementary and necessary, since without the ability to develop and manage an organisation's knowledge, it is impossible to exploit and share it.

As this paper has shown, knowledge management theory has lots of ideas and different routes for research. However, the problem is that the research is very conceptual, with high level ideas, and needs to be grounded in science to become sufficient for new and necessary improvements in knowledge management.

1.3 People Focused KM

As knowledge management is concerned with people, substantial work was done to develop the idea of knowledge networks, as introduced by Seufert et al. (1999). Based on the idea of networks and social interactions, knowledge networks were defined as 'a number of people, resources and relationships among them, who are assembled in order to accumulate and use knowledge primarily by means of knowledge creation'. This definition implies that people are working together to share knowledge with the common aim of knowledge creation. Seufert et al. (1999) suggest a framework for knowledge networks, but they neglect to suggest a mode

of implementation. This is probably because 'an integrated approach is required which includes both tacit and explicit knowledge' (Seufert et al., 1999)

Schőnstrőm (2005) has since focused on creating knowledge networks because 'the intentional creation of knowledge networks has only, to a limited degree been treated by KM researchers' (Schőnstrőm, 2005). Seufert et al. (1999) identified two types of knowledge networks, intentional and emergent. The work by Schőnstrőm (2005) focuses on intentional networks, because emergent networks cannot be created. Schőnstrőm (2005) identifies three key learning points from the experiment. First, that knowledge activist must exist in the organisation and be willing to act as network coordinators. Second, that knowledge networks must form part of a company's strategy. Top management support is vital in the implementation of any new mode of operating. Third, that knowledge networks are not immune to organisation restructuring. This is simply because the very basis on which the networks are created can be removed or changed.

2. IS THERE A CONSENSUS TO THE FOUNDATIONS OF KM?

Metaxiotis et al. (2005) have reviewed all of the main agreements and disagreements in the field of knowledge management. The authors suggest that there are agreements with regards to the definition of knowledge management, the benefits of knowledge management, the factors influencing knowledge management and how learning is associated with knowledge management. However, the review so far has shown that there is general disagreement among academics about what constitutes a definition of knowledge management, but it could be that Metaxiotis et al. (2005) are commenting about the complexity and ambiguity surrounding the field.

Among disagreements, Metaxiotis et al. (2005) list frameworks for implementation, whether Information Technology (IT) is a central interest to knowledge management and if knowledge can actually be managed. These are important disagreements. For example, if no framework can be agreed upon, then no system can ever be developed and implemented. With regards to IT, whilst it may not be central to a knowledge management system, it should be essential to implementing a system, especially in firms of considerable size. It is generally accepted that IT will play some part in knowledge management because many authors (Holsapple, 2005; Junnarkar and Brown, 1997) have written about the application of software in knowledge management. The last disagreement Metaxiotis et al. (2005) mention is perhaps the most important; if knowledge can never be managed, then all that can be done is to create systems that can facilitate knowledge sharing among employees.

Despite knowledge management being a relatively young field, organisational learning is a more mature area which has been integrated into knowledge management (Jashapara, 2004). Organisational learning is defined by Senge (1990) as:

'Organizations where people continually expand their capacity to create the results they truly desire, where new and expansive patterns of thinking are nurtured, where collective aspiration is set free, and where people are continually learning to learn together'

The principle of this definition is that employees must be continually learning so that an organisation can learn. Whilst this is true, employee learning does not happen in isolation. This definition also recognises that there must be an interaction and sharing of knowledge between employees for learning to make a difference organisationally.

3. ORGANISATIONAL LEARNING

The learning organisation is a new concept. Yeo (2005) defines a learning organisation as an organisation that "embraces the importance of collective learning as it draws on a larger dimension of internal and external environments." The difference between organisational learning and a learning organisation is that organisational learning is a process an organisation goes through to learn, whereas a learning organisation is a type of organisation (Yeo, 2005). The implication is that whilst all organisations can learn, only learning organisations are continually learning and improving. There is an assumption that learning organisations will be better able to manage knowledge.

Organisational learning is categorised by three stages (Yeo, 2005). The first stage is concerned with individual learning, the second stage with people solving problems by using other team members. The third stage is concerned with the external environment, and how people try to solve problems with respect to external resources. The only criticism is that Yeo does not provide any detail on how the three stages occur or the processes in them.

One important concept in organisational learning is single and double loop learning, originally developed by Argyris and Schon (1978). Single loop learning occurs when an entity modifies their behaviour when there is a difference between expected and actual outcomes. In comparison, double loop learning, occurs when an entity revisits the assumptions and values that led to the behaviour in the first place (Smith, 2001). It is important to consider single and double loop learning because these theories provide the foundations which explain how people learn, and ultimately how organisations learn.

Kim (1993) created a model of organisational learning based on Argyris and Schon's (1978) theory of single and double loop learning. Kim's (1993) integrated model shows the link between individual and organisational learning and all the factors important in the transfer of knowledge.

4. BIOLOGICAL APPROACHES TO KNOWLEDGE MANAGEMENT

Maula (2000) and Hall (2005) have taken a biological approach to knowledge management and organisational learning. Maula (2000) suggests that since organisations are 'living systems that reproduce themselves' the theory of autopoiesis can be applied to them. Maula considers the organisation as a whole with a corporate memory and one boundary, and says that as organisations portray certain characteristics, they are autopoietic. However, Maula (2000) does not provide any detailed analysis to validate his work, or the claim that organisations are living systems.

Hall (2005) gives a more detailed application of autopoiesis to organisations, by explaining how organisations meet the six criteria necessary to be autopoietic, as identified by Varela et al. (1974). Although Hall (2005), like Maula (2000), still only considers the organisation as a whole, and does not consider processes within the organisation.

5. CURRENT KNOWLEDGE MANAGEMENT GAPS

Given the current literature there seems to be several gaps that have been identified and these are:

1. No accepted definition of knowledge or knowledge management
2. No explanation of whether knowledge can actually be managed
3. Disagreements on role and use of IT in knowledge management (Metaxiotis et al., 2005)
4. No commonly accepted framework/toolkit
5. The lack of actual implementations (Schőnstrőm, 2005)
6. Superficial biological approaches (Hall, 2005; Maula, 2000)

There may be numerous reasons why no or very little literature has been found on these topics. First, the lack of agreement on areas such as how knowledge is composed means no consensus can be gained to enable further research. Further research in other disciplines may be needed, for example human cognition. Human cognition is an important area because if it is possible to understand how people learn and generate knowledge, it will be easier to create a system based on that knowledge. There are also difficulties regarding the nature of organisations. Unless an organisation's exact structure can be recorded, it will be impossible to prescribe a knowledge management tool. A third problem occurs with autopoiesis itself. As autopoiesis is such a complex theory, many authors have either applied it to knowledge management at the conceptually very high level, or indicated that it is too complicated, and needs to be significantly simplified to be applied to organisations. However, this could be due to a lack of understanding about autopoiesis.

6. WHAT IS AUTOPOIESIS?

Autopoiesis is a theory which shows what it means to be living. Previously, living entities had been defined by listing their characteristics. However, the counter argument against this approach is that if a machine could mimic these characteristics then it should be considered living. This is evidently wrong, and autopoiesis provides the new approach needed. Instead of defining entities by

their characteristics, Maturana and Varela (1980) define entities by the relationship between the components in the entity. There is also an assumption that living systems are discrete, autonomous entities.

Combining these two ideas, Maturana and Varela (1980) propose that it is the relationship between the processes in living system that realises the entity's ability to be discrete, autonomous and self producing. Autopoiesis could then be defined as the maintenance of an entity's organisation, or relationships between its processes. Maturana and Varela (1980) go onto explain that the network of processes is self producing, in other words the network of processes realises its own existence.

In defining autopoiesis, Maturana and Varela are careful to distinguish between organisation and structure (Maturana and Varela, 1998). Organisation refers to the relationship between the processes that realise the entity, whereas structure refers to the actual components within the entity. For example, when considering living entities, they all have the same organisation, which is autopoietic, but they have different structures, enabling observers to see them as different animals/birds/insects.

When developing the theory of autopoiesis, it was also necessary to define how such entities would interact with each other, in relation to their organisation and structure. The theory of how autopoietic entities interact was developed in structural coupling. This states that any entity, autopoietic or not, can only trigger change in an autopoietic entity. In other words, the autopoietic entity can only change according to its structure.

7. CAN AUTOPOIESIS SOLVE THE PROBLEMS WITH KM?

Preliminary research by Parboteeah and Jackson (2006) shows how autopoiesis can be applied to knowledge management, namely models of organisational learning. The authors are instrumental in breaking down autopoiesis to be useful in knowledge management. After successfully creating a model of autopoietic organisational learning, they propose areas of research that could yield useful results. These areas include creating systems based on their proposed model and other areas of knowledge management to which autopoiesis can be applied.

Several other attempts have been made to apply autopoiesis to organisations (Hall, 2005; Limone and Bastias, 2006), but they have been superficial and avoided actual implementation issues.

In applying autopoiesis to knowledge management, it is hoped the phenomenology normally associated with living systems: self reproduction, the spontaneous creation/destruction of new entities and self specification, can be applied to knowledge management. The self reproduction aspects of living systems could give new insights into knowledge creation, and how a knowledge management system could aid this. Alternatively, this aspect could foster a knowledge management system that will aid or promote innovation and the appropriate culture.

There is also an aspect of autopoiesis that looks at the interactions between two or more entities, called structural coupling. Structural coupling could also be used to enhance a knowledge management systems ability to create knowledge. However, structural coupling could be more suited to applications looking at the issue of collaboration, and the sharing of knowledge among employees.

With an increasing number of organisations going global in their operations, a knowledge management system that can resolve cultural issues will be increasingly important. Culture, should not be an issue with an autopoietic knowledge management system because the system will be self-specifying, meaning that any knowledge stored will include any assumptions/cultural aspects.

Autopoiesis could also be used as a validation tool for knowledge management models. This could prove useful in determining if some models are better than others, if models can be improved after applying autopoiesis, or simply by reducing the number of potential models in circulation.

This research aims to further the work of Parboteeah and Jackson (2006) and will aim to determine the usefulness and practicality of applying autopoiesis to knowledge management. The research will be carried in five stages. The first stage will attempt to formally specify autopoiesis, and hence make it more accessible, and stage two will create tools to model organisations and knowledge management systems. Stage two sets the ground work for stage three which will look at creating an autopoietic knowledge management system at an organisation which already has a knowledge management system. Stage four will attempt to create a knowledge management for an organisation that has no formal knowledge management system. The final stage will aim to create a framework or toolkit to enable future organisations to create an autopoietic knowledge management system.

8. CONCLUSION

Following a review of current knowledge management literature, numerous problems were identified, which included a lack of reported implementations, a lack of a common framework and a lot of unfounded ideas. The field of knowledge management would benefit from unifying all of the current ideas into one model. This unifying model would help to create a foundation for knowledge management from which new ideas can be developed and so helping the field of knowledge management to move forward.

As has been identified by this paper, the current work on autopoiesis is too abstract and conceptual to be of substantial use in knowledge management. Formalising autopoiesis will help to make autopoiesis and its associated theories more accessible and more easily applied to other disciplines. It is hoped that using autopoiesis in knowledge management will help to create a deeper understanding of issues in knowledge management, such as what constitutes knowledge and how it can be mapped. These are all ideas which the authors hope will be addressed by the ongoing research that is taking place.

Knowledge Losses in the Capturing Process

Lena Aggestam, University of Skövde, Box 408, 541 28 Skövde, Sweden; E-mail: lena.aggestam@his.se

ABSTRACT

To be competitive organizations need to manage the knowledge resource. One aspect of doing this is to build IT-supported knowledge repositories. Successful knowledge repositories require that stored information is updated and relevant. The importance of the capturing process is obvious. To run the capturing process efficiently requires identifying "all" knowledge, evaluating it and sorting out knowledge which should not be stored, i.e. managing knowledge losses. Based on theoretical and empirical studies, this paper complements the capturing process in an existing framework with knowledge losses in order to take a first step to make the framework implementation-oriented. Furthermore, in order to show the potential usefulness of this approach, we present some initial guidelines for how to manage the identified knowledge losses.

Keywords: Knowledge repositories, the capturing process, knowledge losses, guidelines

1. INTRODUCTION

To be competitive organizations must reuse knowledge from earlier experiences and learn how to not do the same mistake over and over again. "*If failure is ignored, denied or repressed, the opportunity to learn from past mistakes is lost.*" (Chua and Lam, 2005, p. 7). One way to enhance knowledge reusing is to develop IT-supported knowledge repositories. A large number of Knowledge Management (KM) projects fail (e.g. Storey and Barnett, 2000; Senge, 1999), and the question is *how* organizations can implement and manage KM (e.g. Sena and Shani, 1999; Wong and Aspinwall, 2004). Aggestam (2006) proposes a framework for IT-supported KM (FIT-KM) from the perspective of knowledge repositories (Figure 1). FIT-KM shows *what* this is about, but lacks support for *how* to do it. This paper *aims* to take a first step to extend this framework to an implementation one.

One dimension of KM success is user satisfaction (Jennex and Olfman, 2006). This requires high quality in stored information, which in turn prerequisites capturing "all" knowledge, evaluating it and sorting out knowledge which not should be stored, i.e. reducing unwanted knowledge losses as well as increasing wanted ones. The *goal* for this paper is to complement *"Capture New Knowledge"* in FIT-KM with knowledge losses, and present some *initial* thoughts about how to manage them. These thoughts make no claims to be complete; but to show the potential usefulness of the approach. Little research exists that relates knowledge losses to knowledge processes, and to the best of our knowledge, this approach when developing a KM implementation support has not earlier been used. The *research method* is a qualitative analysis based on a literature study, and a case study performed through participation in a KM implementation project. One case study can be justified if it is purposeful and provides a large amount of information (Gummesson, 2001). While unwanted losses results from not running this process efficient, and wanted losses the opposite, we in both studies focused on success factors.

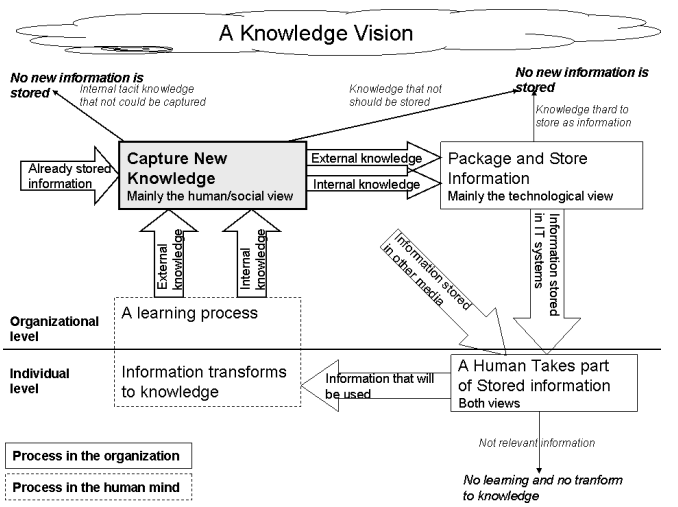
2. BACKGROUND

Focusing on the capturing process, 2.1 gives an introduction to FIT-KM, while 2.2 describes the case.

2.1 FIT-KM

FIT-KM, Figure 1, describes what IT-supported KM is from the perspective of knowledge repositories (Aggestam, 2006).

Figure 1. FIT-KM and the focus of this paper (from Aggestam, 2006)



The remainder of this chapter discusses the focused process, *Capture New Knowledge*.

Capture New Knowledge aims to capture already stored information, and different types of knowledge which has potential for being stored in the repository. Knowledge can not exist outside the human mind, thus the repository can only hold information that supports knowledge transformation. The capturing process includes an identification activity as well as a selection element. FIT-KM separates between internal and external knowledge. Internal knowledge is knowledge that people hold in their minds (Wiig, 1993), and knowledge that is held, e.g., in books and IT systems, is external knowledge, information (our remark). Information can be processed by IT, but knowledge requires humans (Swan et al, 1999). Another common distinction is between tacit and explicit knowledge (e.g. Gore and Gore, 1999). FIT-KM lacks this separation. Tacit knowledge is rooted in individual actions, experiences, ideals etc. (Gore and Gore, 1999; Nonaka and Takeuchi, 1995), and not easy to identify and express (e.g. Blodgood and Salisbury, 2001). Explicit knowledge is easier to express and can, in contrast to tacit knowledge, also easily be processed by a computer (Nonaka and Takeuchi, 1995). Table 1 summarizes this.

New in Capture New Knowledge refers to knowledge which supporting information not is stored in the repository, and/or not is conscious for employees. FIT-KM identifies here two potential losses, one wanted and one unwanted.

Table 1. Different types of knowledge

	Internal knowledge	External knowledge
Tacit knowledge	e.g. "know-how"	-
Explicit knowledge	e.g. Stockholm is the capital of Sweden	e.g. documented, "information"

2.2 Case Study

The project EKLär is in the area of health care, more precisely focusing on the treatment of leg ulcers. EKLär aims to develop an IT-supported knowledge repository for learning and sharing of best practices with respect to treatment and prevention methods for leg ulcers[1]. The approach used in EKLär, Enterprise Knowledge Patterns (EKP), combines Enterprise Modelling (EM) with organisational patterns (Stirna, Persson and Aggestam 2002). It is characterized by a strong emphasis on stakeholder participation and the use of Organizational Patterns in order to identify possible knowledge chunks and their content.

The project is carried out in three main phases: preparation, implementation, and evaluation, where the evaluation phase is in its initial stages. **The preparation phase** continued for approximately six months, and aimed to collect knowledge about the domain, and gain approval for the main purpose of the project. Data were collected during 19 interviews and 2 observations. **The implementation phase** continued for approximately fifteen months. It included daily works to develop the repository and hands-on-learning to teach the stakeholders how to manage knowledge. Data were mainly collected during project meetings. An average of one meeting a month lasted a half to a whole day. The meetings were documented through models and patterns developed, and also by detailed notes. The notes for each meeting were summarized and sent to the participants. Further collected data include relevant documents as well as similar projects from other hospitals. The aim of the initial meetings was to identify which knowledge area to focus on. The result was a compromise between the identified needs in the preparation phase and what the hospital staff regarded to be the most important knowledge to be taught. On this basis, the work proceeded to capture relevant knowledge, and package and store it. As work proceeded the nurses became increasingly autonomous and carried out more and more work between our meetings. One important issue was to decide which technical tool to use. The project decided to use an existing technical solution, which the hospital had already decided to invest in. A critical step is making the result survive after the project is finished. In EKLär this requires that the repository it is kept up-to-date. This work is still progressing, parallel with the evaluation phase. **The evaluation phase** has been going on for 4 months. So far, we have made 8 observations using "think aloud" protocols. The observations were taped and transcribed. In relation to the observation we asked questions based on Jennex and Olfman (2006) KM success model in order to identify the potential for the repository to being successful.

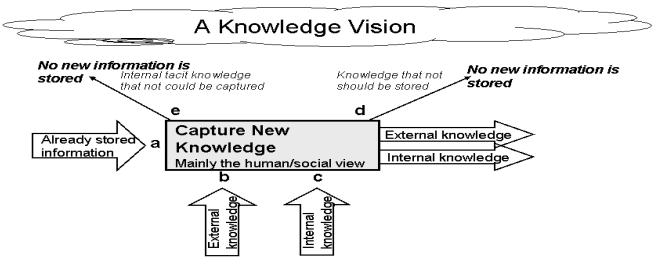
3. ANALYSIS

We have compared data with data, with existing theories, and previous results. This is a key to qualitative research analysis (Gummesson, 2005). In order to enable traceability we throughout the analysis kept empirical and theoretical data separated. We summarize what we have done, but not *how* our minds were thinking. Intuition is like a brother or sister to common sense (Gummesson, 2001), and not easy to describe. It is not possible to include all data that has been input to the analysis[2], but in order to clarify we give examples from both EKLär and literature.

1. *Analyzing data from the perspective of Capture New Knowledge.* This results in two lists of success factors; one list originates from theoretical data, and one from empirical. This step also shows factors, not specific for capturing, but important to manage from the beginning of the project, and throughout the whole. Some of these concern things that must be done *before* the project start. For example, the project must convince the users (e.g. Chua and Lam, 2005), and the needed participation from employees require teaching (e.g. Davenport and Prusak, 1998). With regard to the focus of this paper we decided to exclude these factors. Other general factors concern passing knowledge to "Package and Store Information". In EKLär we discussed who are responsible for this, and how would it be done. From a maintenance perspective this is crucial if the repository will be successful in the long run. These factors we placed in an own group called "Other factors". For clarity reasons, they are described in the next step.
2. *Grouping success factors in accordance with FIT-KM* (**a–e** in Figure 2)
   - ***a.*** *Already stored information:* We must separate between information already stored *in* the organization, and information stored *outside*. In the literature this is to our knowledge not explicitly mentioned, but in EKLär this was obvious. Examples of information stored outside are a Danish net based knowledge repository, and films distributed from the material suppliers. EKLär also high lightened legal aspects, what information are we allowed to reuse? This legal aspect impacts if knowledge could be stored or not, and we concern them to influence the already identified wanted loss in FIT-KM. Furthermore, in EKLär there was information as different types of programs and recommendations that no one in the beginning relates to EKLär. The used EKP approach enhances the work to identify this information. It is a good idea to start with a review of existing external knowledge (Gore and Gore, 1999), which lightens that there could be information no one knows about. To scan potentially relevant information is time-consuming. Asymmetry of knowledge is a problem (Davenport and Prusak, 1998), and managing knowledge only within silo-oriented communities represent great risks that business-critical knowledge is neglected (Chua and Lam, 2005).
   - ***b.*** *External knowledge:* There is external knowledge which the knowledge knower does not want to share with others. Political processes between different stakeholders, e.g. IT and media affairs, must be managed (Chua and Lam, 2005), and individuals must overcome imperatives as wanting to be where they are (e.g. Sun and Scott, 2005). There must be a knowledge sharing attitude (e.g. Busch and Richards, 2004). The quickest and easiest ways to affect the culture are changes in the reward and punishment system (Schein, 2004). The willingness to share knowledge was not a problem in EKLär, possible with regard to the fact that they are use to share knowledge. External knowledge is the same as information, and we argue that this process is included in the former one. Both are about willingness to contribute, and prerequisites that the information is known.
   - ***c.*** *Internal knowledge:* The analysis clears the need to differentiate between internal *tacit* and internal *explicit* knowledge. KM should include both because if it only concerns explicit then it could be difficult to distinguish it from *information* management (Loermans, 2002). Comparing to tacit knowledge, explicit knowledge is easy to capture *if* the knowledge owner wants to share it. Success factors for capturing explicit knowledge concern the same thing as discussed in the former groups. A key in KM is the degree to which tacit knowledge can be captured and transformed into explicit knowledge (Gore and Gore, 1999). Nonaka and Takeuchi (1995) identify four knowledge conversion modes. With regard to the strong emphasis on participatory design, to our experience the EKP approach enables these:
     - Socialization (from tacit to tacit): In accordance with EKP we have develop the repository together in the project group. In this group we have share experiences, mental models etc. which enhance socialization.
     - Externalization (from tacit to explicit): Using patterns we have in the project group had successive rounds of meaningful dialogue in order to reveal hidden tacit knowledge.
     - Combination (from explicit to explicit): In the project group concepts have been combined with existing data and knowledge, both in the hospital and outside, in order to create more shareable specifications.

     The EKP approach also assists internalization (from explicit to tacit). Internalization is about *using* knowledge and outside the scope of this paper. Visiting each others working places is another way mentioned in EKLär aiming to identify tacit knowledge.
   - ***d.*** *Knowledge that not should be stored:* This is a wanted loss already identified in FIT-KM. The analysis strengthens its importance, and clari-

Figure 2. Analyze step 2



fies the critical role the vision plays here (e.g. Blodgood and Salisbury, 2001; Wong and Aspinwall, 2004). The analysis reveals the importance to differ between the knowledge vision and knowledge goal. The vision is strategic, but in line with this, for each KM project, there must be a goal to evaluate against. The importance of both becomes more and more obvious in EKLär as it proceeds. Should further knowledge areas be incorporated or not? What knowledge vision does the top management has for the whole hospital? Top management has responsibility for the vision. (Gore and Gore, 1999; Davenport and Prusak, 1998), and senior management support is critical. (e.g. Chua and Lam, 2005; Davenport and Prusak, 1998). Factors here also include the importance of updating. It is not only a question about putting in new information, it is also necessary to take away information. This concerns mainly the next process, "Package and Store Information", but often brings to the fore in the capturing process.

e. *Reducing internal tacit knowledge loss:* The key here is to convert tacit knowledge to explicit knowledge, and the discussion in point c is applicable.

Other factors: KM has to be adapted to business and knowledge processes (Remus and Schub, 2003). A lack of effective mechanism to distil knowledge from debriefs and discussions results in valuable knowledge remained obscured (Chua and Lam, 2005). In EKLär this work is in its initial phase, but we plan a lot of effort to identify capturing points, i.e. to find the link between new generated knowledge and the capturing process. For this the content, its structure and relevance, is important (e.g. Chua and Lam, 2005; Davenport and Prusak, 1998), and the method used to develop it. We argue that the EKP approach enhances this work by its structure of knowledge chunks.

3. *Analyzing each group from the perspective of knowledge loss*

The analysis reveals four new losses and embeds knowledge for how to manage them.

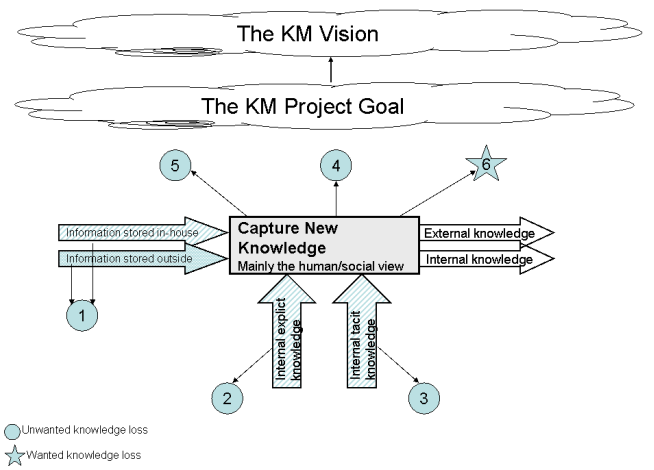
4. RESULTS

The analysis results in four unwanted knowledge losses and some further aspects to already identified losses in FIT-KM. It also reveals some lacks in FIT-KM as no

- separation between internal tacit and explicit knowledge
- knowledge goal
- separation between information stored in and outside the organization.

Furthermore, the input "External knowledge", is both wrong and overflow. It emerges from the individual level and concerns *internal* knowledge an individual has created when using information, and it is the same thing as information which is already covered in FIT-KM. Figure 3 shows the extended and updated version of Capture New Knowledge.

Figure 3. Knowledge losses in the capturing processes



Numbers 1-6 in Figure 3 refer to knowledge losses, where losses 1-4 result from the work presented in this paper. Number 1-5 concern unwanted losses, and number 6 a wanted one. Number 1-3 refer to losses meaning that knowledge does not even reach the capturing process, and the need of a structured approach to identify *when* new knowledge has been created is obvious. It is not enough that knowledge is known, and the knowledge owner is willing to share it, the KM process must also be integrated in organizational processes, and supported of the technical tool. With regard to the goal for this paper, the remainder of this section will elaborate the 6 losses.

1. There is information stored in other media as documents, books, protocols etc. This information can be found inside the organization, in the actual department or in another one, or outside. If no one knows about this information, or thinks about it from the perspective of the actual KM work, it will never reach the capturing process. Furthermore, there is also information which is known, but the knowledge knower does not want to disseminate it. This information is already stored somewhere else, but if it is not integrated and related with other organizational knowledge it will probably be hard to find and reuse.
2. This is about willingness. The knowledge knower is the knowledge owner. With regard to the fact that actual knowledge is explicit it must be known. However, one further problem can be that the knowledge owner does not think about it as relevant for the repository.
3. Like number 2 the knowledge knower is always the knowledge owner, but it varies if the knowledge owner is conscious about the knowledge or not. If the knowledge is known, reasons for losses are willingness or unconscious about the knowledge.
4. An important part is to pass captured relevant knowledge to the next process. If this not is integrated in daily processes, or supported by IT-tool, there is a great risk that the knowledge never is stored.

Table 2. Supporting knowledge losses

Initial Guidelines	**Knowledge loss**
G1. Use an approach, e.g. EKP, that forces employees studying information from other perspectives comparing to how it is stored and structured. This also enhances combination.	1
G2. Increase employee's reserved time for searching and evaluating information.	1
G3. Introduce reward system that encourage willingness to share knowledge	1,2
G4. Disseminate early successes as success stories (Chua and Lam, 2005).	1,2,3
G5. Stimulate networks, both formal and informal, to create relationships. Relationships increase the flow of information (Sun and Scott, 2005).	1,2,3
G6. Try to identify points in organizational processes which indicate that knowledge has been created.	1,2,3
G7. Visit each others working places and learn by sitting on in a class.	1,2,3
G8. Base discussions on a tool, e.g. EKP, to force thinking from another perspective in order to enhance externalization.	3,5
G9. Structure the content in such way that it enhances updating, e.g. knowledge chunks.	4
G10. Pay attention to the employees who should maintain the repository when choosing technical support.	4
G11. Store information about knowledge owners	5
G12. Describe the goal in adaptive ways so employees understand what it is about.	6
G13. Relate knowledge that is identified as relevant to the knowledge goal.	6
G14. Study captured relevant knowledge from the perspective of legal aspects.	6

5. There is internal tacit knowledge that not could be captured. Comparing to number 3, the knowledge owner is conscious about it and wants to share it, but there is a lack of methods, processes etc. to capture it. An alternative could be to store information about the owner.
6. There is knowledge that not should be stored. Reasons for this are for example that it does not contribute to the knowledge goal, or that it is illegal to store it.

The analysis embeds knowledge for how to attack these losses. In Table 2 we present some initial thoughts concerning this. The leftmost column presents the thoughts in form of guidelines, and the rightmost its corresponding knowledge loss/es.

Some unwanted losses depend primary on organizational culture, e.g. if a member in the organization wants to share knowledge or not, while some would get concrete benefit from tool support, e.g. to reveal already stored information in the organization. Work aiming to influence the culture is a long time work. However, even losses caused primarily of culture will get benefits from more directly activities as for examples reward systems (G3) and reserved time in regular tasks (G2). Even different types of tool and method support have the same effect, e.g. EKP (G1, G9) and how the repository is build and structured (G10, G11). If it is easy to share knowledge the willingness to do it will increase and this will have positive effects on the knowledge sharing culture.

5. CONCLUSION AND FUTURE WORK

In this paper we have complemented the process *"Capture New Knowledge"* in FIT-KM with four knowledge losses, and presented some initial thoughts for how to manage knowledge losses. Furthermore, the results show the potential usefulness of this approach when developing a KM support. This is in accordance with the goal for the paper, and a first step to extend FIT-KM to an implementation one has been taken.

Presented guidelines are initial thoughts which must be refined and complemented. This future work must pay attention to demands as

- if the capturing process is a start one in a new KM project or if it is a process in ongoing KM
- strategic and operative levels
- different roles in KM work

Systematic effort to track and measure success of KM projects is needed (Chua and Lam, 2005). From the perspective of the KM success model presented in Jennex and Olfman (2006) the capturing process mainly influences the Knowledge Quality dimension. We argue that this dimension is valuable when evaluating the further developed guidelines.

Towards Measuring the Complexity of Information Systems: A Language-Critique Approach

Christoph Rosenkranz, University of Frankfurt, Campus Bockenheim, Mertonstr. 17, 60325 Frankfurt, Germany; E-mail: rosenkranz@wiwi.uni-frankfurt.de
Roland Holten, University of Frankfurt, Campus Bockenheim, Mertonstr. 17, 60325 Frankfurt, Germany; E-mail: holten@wiwi.uni-frankfurt.de

ABSTRACT

Organizations increasingly depend on information technology for their operation. Consequently, complexity of information systems becomes an important issue for management. This paper shows how the combination of conceptual modeling with the concept of variety from cybernetics contributes to the measurement of complexity for the analysis and diagnosis of information systems. Building on language critique, we propose that conceptual models are marks of the shared understanding of a language community. Consequently, conceptual models are a means to make the variety of an information system visible. Within an information technology controlling setting, we apply our approach for the diagnosis of a controlling and reporting system used in the German subsidiary of a large European bank. We show how conceptual models can significantly contribute to organizational analysis if used in combination with an established cybernetic theory.

Keywords: Complexity, Variety, Language Critique, Conceptual Modeling.

1. INTRODUCTION

Organizations invest greatly in information technology (IT) and information systems (IS) in order to improve their operational and strategic position (Laudon & Laudon 2005, p. 7). But not all organizations are successful in this (Brynjolfsson 1993). The interaction between IT and organization is complex and influenced by many mediating factors, including the organization's structure, standard operating procedures, politics, culture, environment and management decisions (Laudon & Laudon 2005, p. 77). As a consequence, complexity of IS becomes a subject for IS research.

Complexity is a multi-facetted term which has many possible meanings (Flood & Carson 1993). Since complexity is something subjective (Ashby 1973, p. 1), perceived by an observer, the complexity of the system being observed can be described as a measure of the perceived effort that is required to understand and cope with the system (Backlund 2002, p. 31). This makes the analysis and design of complexity of IS more difficult. Since unnecessarily complex IS seem undesirable, we should find methods to reduce complexity. However, we cannot address this problem unless we have a shared meaning of what comprises the complexity of an IS. Furthermore, it would be desirable to compare several organizations or IS regarding their complexity (Backlund 2002, p. 40). Then, how can we measure the complexity of an IS? Can we categorize the factors for complexity in IS and organizations if complexity depends on the subjective understanding of an observer? Or are we able to deduct a general and intersubjective measurement for complexity?

In this paper, we propose to combine concepts from cybernetics with a language-based approach for conceptual modeling in order to measure the complexity of an IS. In the remainder of the paper we proceed as follows. First, we introduce variety as a measure for complexity. Then, we present our understanding of conceptual models based on language critique. Afterwards, we propose that conceptual models are a means to make variety visible. We apply and test our approach in an action case study.

2. VARIETY AS A MEASURE FOR COMPLEXITY

The cybernetic concept of variety is a measure for complexity, and defines the number of manifestations or patterns of behavior, the possible states of a system (Ashby 1964, p. 126). Variety, in relation to a set of distinguishable elements of a system, means either 1) the number of distinct elements, or 2) the logarithm to the base 2 of this number. Measured in logarithmic form, the unit of variety is the bit. If a situation has a variety of 32, or 5 bits, it will take five "yes/no" decisions to eliminate the uncertainty implicit in that variety – because $32 = 2^5$ (Beer 1981, p. 45). In theory, it is possible to count all possible states. If this is not directly possible, we can make comparisons ("something has more or less variety than another thing") or apply ordinal scaling ("This product has a rank of five"). Consequently, we are able to compare things that are different in nature.

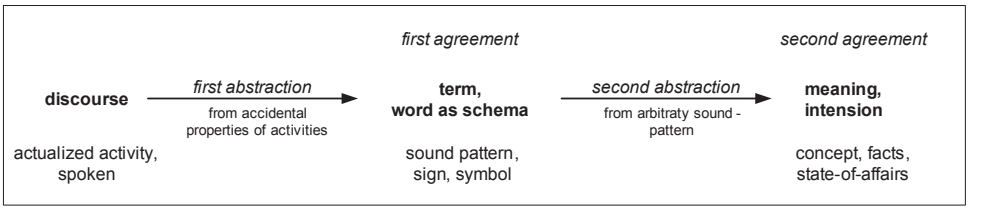
Ashby's *Law of Requisite Variety* is one important driver for the design of complexity reduction: "Only variety can destroy variety" (Ashby 1964, p. 207). This forms a problem because in order to make a system responsive to change, we need to possess as much variety as the system itself exhibits. With systems that exhibit massive variety, such as organizations and IS, only reducing the environmental variety or increasing the manager's own internal variety enables us to cope with this problem (Jackson 2000, p. 73).

In this paper, we follow Backlund's call to explore the usefulness of variety as a measure when applied to organizations and IS (Backlund 2002, p. 40). But several charges have been put forward against the use of variety (Jackson 2000, pp. 172-177, 207). Most severe seems to be Ulrich's attack (Ulrich 1981). Ulrich argues that variety operates only at the syntactic level, which is solely concerned with whether a message is well formed or not, in the sense of readability. Consequently, according to Ulrich, variety ignores the meaning and significance of messages for the receiver (semantics and pragmatics). This argument falls short considering our approach based on language critique.

Language critique, a branch of constructive philosophy known as the "Erlangen School" of Kamlah and Lorenzen (Kamlah & Lorenzen 1984, Lorenzen 1987), provides useful insights and backup for our understanding. By separating *language* (as a schema which one knows how to speak) and *discourse* (as linguistic action and activities), Kamlah and Lorenzen separate concepts from their linguistic usage (Kamlah & Lorenzen 1984, p. 41). Discourse means the repeatedly actualized usage of concepts in changing combination and variation. Thus, discourse is an actualized activity, whereas language comprises potential activities, or activity-schema (Kamlah & Lorenzen 1984, p. 45). The transition from an actualized activity to its activity-schema is called an *abstraction*. Terms are syntactical representations used in discourse with fixed conventions (*first abstraction*), whereas in order to get concepts, we abstract from the phonetic form of terms (*second abstraction*), see Figure 1 (Lorenzen 1987, pp. 115-118).

The question of how the conventions that align syntax, semantics and pragmatics of symbols are formed can be answered using the construct of a *language community*. Kamlah and Lorenzen argue that language as a system of signs promotes mutual understanding as "a 'know-how' held in common, the possession of a 'language community'." (Kamlah & Lorenzen 1984, p. 47). A new term is introduced by *explicit agreement* between language users with respect to its usage (*first agreement*) and meaning (*second agreement*) (Kamlah & Lorenzen 1984, p. 57). This agreement leads to a relation of concept and term, and is shared by a language

Figure 1. Agreements and abstractions in language critique (Holten 2003a, Holten et al. 2005)



community as the knowledge of using this term. Accordingly, if members of a group of people communicate, and each has an aligned semantic and pragmatic dimension of a symbol (or term) in mind, then this group of people forms a language community. The implications for our work are that the semantic and pragmatic dimensions of symbols need to be introduced together. If a language community has been created, based on a language (re)construction of a domain, the members of this language community share the pragmatic dimension of a symbol.

Usually, conceptual models are understood as part of a method, a planned and systematic approach (Braun et al. 2005). Conceptual modeling deals with the process of building or interpreting a conceptual model whereby the stakeholders reason and communicate about a domain in order to improve their common understanding of it (Gemino & Wand 2004, p. 80). According to our understanding, conceptual models play a significant role in making language communities explicit: conceptual models are designed through linguistic actions of a language community. Therefore, they are an expression of a shared language understanding, so-called *marks* (Kamlah & Lorenzen 1984, p. 46, Holten 2003a, pp. 33-91). Marks are written-down or printed writing-signs (Kamlah & Lorenzen 1984, p. 51). They are actualized as activities by the one who produces the marks in *writing* them, and again actualized by the one who *reads* them (Kamlah & Lorenzen 1984, p. 46). Models as marks create persistent things. Like road signs or written words, models are solidified activities which stay put and can be read.

Following this, conceptual models can be used as a formalized way of stating the intersubjective consensus of a language community. Then, truth or correctness of statements depends on the consensus of the group of people that constructed the conceptual models (Kamlah & Lorenzen 1984, pp. 101-111). For example, in IS development, mere understanding of the syntax or even the specific semantics of a specialized modeling language or grammar is not the most crucial factor. Of far greater significance are the pragmatics, the unstated assumptions that reflect the shared (common sense) knowledge of people familiar with the social, business and technical contexts within which the proposed system will operate (Ryan 1993, p. 240). Therefore, conceptual models are intensively used in requirements engineering to facilitate the process of creating a language community.

Although variety – like complexity – is an inherently subjective concept, it becomes intersubjective for the members of a language community as soon as the language community is created. A member of the language community is able to distinguish between data (syntax and semantics, term) and information (pragmatics, meaning) and to relate the two. Once a language community has been created, variety as a measure of complexity for the used terms considers pragmatics and semantics respectively. As a result, Ulrich's argument falls short considering language critique. Language restricts the possibilities to communicate the possible states of a system (Daft & Wiginton 1979). Variety is a measure of the number of possible states of a system. Based on the conceptual models as marks of the shared understanding of a language community, we are able to measure this variety. In the next section, we use an action case to show how the variety of an IS can be made visible by conceptual models.

3. VARIETY IN IT CONTROLLING: AN ACTION CASE

3.1 Research Methodology & Action Case Description

Every research approach is based on fundamental philosophical assumptions (Myers 1997, Lee 2004). We believe that a *constructive philosophy* (Lorenzen 1987) which integrates interpretive and positivist approaches is required. Consequently, we assume that an objective world exists (*ontological realism*), but that our cognition of this world is subjective or private (*epistemological subjectivism*) (Holten et al. 2005, p. 177). We argue that due to this subjectivity, cognition relies upon the (re)construction of reality through linguistic action. After having created a subjective understanding of everyday meanings within the observed organization, which provides the basis for the interpretive understanding, we create a positivist understanding in order to explain the empirical reality – the explanation being a scientific theory which can be tested against the subjective meaning as recorded in the interpretive understanding (Lee 1991, pp. 351-354). Following this, we apply our understanding of variety and conceptual models within an action case study (Hughes & Wood-Harper 1999).

The action case domain concerns IT controlling at FSB AG, a German subsidiary company of the FSB banking group[1]. The FSB Group is among the leading asset managers and financial service providers throughout Europe (as measured by managed capital). Within the FSB Group all operative tasks concerning IT are delegated to FSB IT, a wholly owned subsidiary of FSB Group. For example, this includes the development and maintenance of networks, mainframes, host systems, databases, servers and user support (e. g. helpdesk). FSB IT Development (FSB ITD) is a department of FSB AG that conducts development and controlling of IS for the German business units. FSB ITD develops and supports IS (*development functions*). Additionally, FSB ITD plans and controls both self-developed IS as well as IS developed by FSB IT in order to make the IT usage transparent for the German business units and divisional management (*controlling functions*). A management IS (based on a data warehouse solution using an Oracle database) is used for reporting and controlling in general. The management of FSB ITD approached our research group, voicing difficulties in their IT controlling processes. Especially the reporting was mentioned as an area of concern, creating frustration amongst the business units.

3.2 Data Collection & Interpretation

The action case study lasted from November 2004 to August 2005. We conducted a series of initial semi-structured interviews with different stakeholders. The interviews focused on the IT controlling process and on the roles within it. They were of variable length, ranging from 30 minutes to 90 minutes. The stakeholders selected for the interviews were head of IT controlling at FSB ITD, IT controlling staff, system developers, head of business unit and service staff (from business units). Additionally, we had full access to the MIS and to the created reports. The transcripts and notes from our interviews, administrative documents and printouts of the generated reports were collected in a project diary. The diary served as the main source of data for the following interpretation.

We used conceptual models for the interpretation of the reports, choosing MetaMIS as a modelling language. MetaMIS has been originally developed for the specification of management views on business processes (Holten 2003b, Holten et al. 2005). The approach has been previously applied in similar contexts (e. g. Holten et al. 2002, Holten & Laumann 2004).

Initially, we constructed conceptual models based on our understanding of the reports, which were refined by insights gained from the interviews and observation of controller activities. Afterwards, all project participants at FSB AG were made familiar with the MetaMIS approach, which resulted in a common language to discuss the conceptual models. Repeatedly, the models were refined together with all participants. This resulted in a common presentation of facts about the IT controlling and reporting system in such way that all participants could understand it and relate it to their objectives. Additionally, the conceptual models ensured that we as researchers understood what is really happening in IT controlling at FSB AG. Consequently, we engaged into a language (re)construction, using the

conceptual models as marks of the pragmatic dimension of the domain in focus in order to create a mutual understanding and a language community.

3.3 IT Controlling at FSB AG

FSB ITD in its controlling function creates detailed reports of IT usage. An in-depth analysis of the constructed models revealed that the reporting is purely cost-based. The costs for the IT supplied by FSB IT are based on internal transfer prices for IT items which usually are used for the chargeback of IT costs. These prices are negotiated between the divisional management of the German business units and FSB IT's management. The chargeback structure is initially applied for the resource bargaining during periodical budgeting negotiations between FSB IT and the business units. As a result, the charged items are extremely resource-oriented (e. g. measured as "costs per CPU second"). The created models are extremely large and intricate, mirroring this phenomenon (see Figure 2).

The models show that the variety of this item catalogue is very high: it lists over 550 single items, grouped according to 85 services. Each of these items is used in several IS, for which both price negotiation and controlling are undertaken. Usually, a management decision is the selection of one possible state from all the others. In our case, there are approximately 550 items in total – each with a price accuracy down to Euro and cent. The average IS includes about 150 items. FSB AG has approximately 150 IS in total for which IT chargeback and reporting are conducted. Additional complexity arises because even these items are not constant over time, but change between and during budget periods. In the example of a document management system, the models revealed that nearly two-thirds of the charged items for this system changed between two budgeting periods.

The *potential* variety of the IT controlling and reporting system, as revealed by the conceptual models, and reflected in the item catalogue, appears as approximately

$$V \approx \text{number of IS} \times \text{set of possible combinations using 150 items} = 150 \times 2^{150} \approx 157 \text{ bits}$$

Note that we did not consider the additional variety that results from the changing item structure. In order to identify a particular item – an item for an IS – we need to select one out of that total variety. Even with grouping, constraints and categorization of items, which leads to a reduction of numbers (and which is a rather fruitless task since the item structure is constantly changing), a decision for an IS is a matter of selecting "yes/no" answers for more than 150 items on an average. Consequently, the numbers involved in calculating variety for IT controlling are enormous.

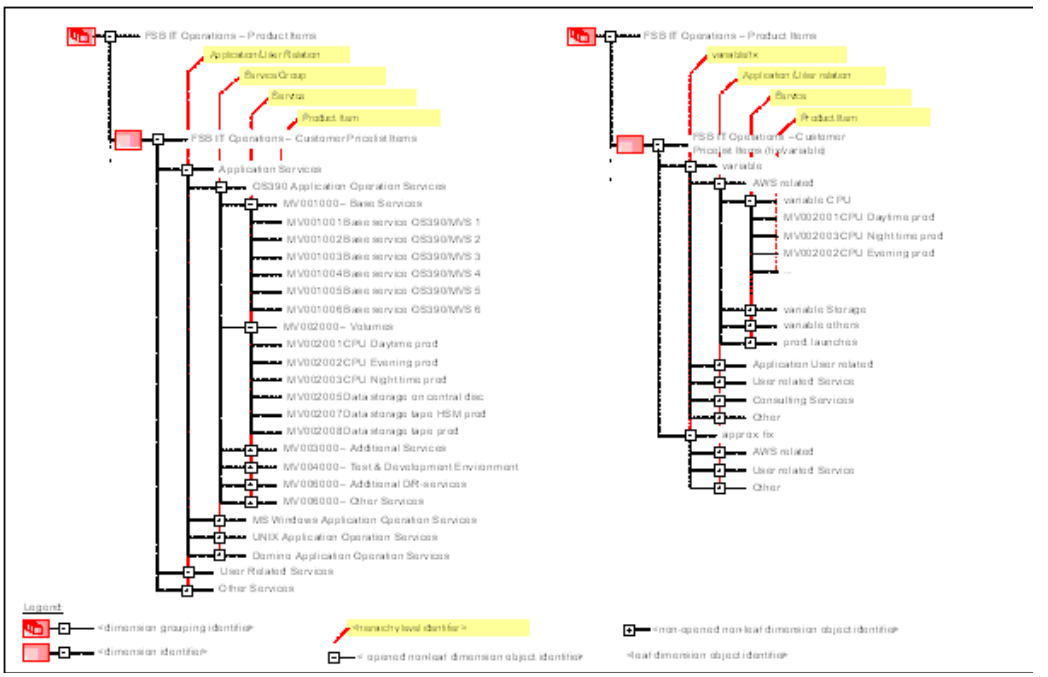
The models point to a high variety within the coordinatory function of FSB ITD: the item structure used for IT controlling 1) has many items, and 2) is changing often. The change of the item structure during and between budgeting periods even makes things more complex.

4.4 Matching with Theory: Hypothesizing on the Establishment of Requisite Variety

The IT controlling and reporting system exhibits a proliferating variety. We gained this insight by analyzing the conceptual models as marks of the language community in focus. The conceptual models enabled us to make that variety visible. According to Ashby's Law, varieties tend to equate naturally (only variety absorbs variety). Consequently, the proliferating variety will be compensated by other means. The *actual* variety must be less enormous than the potential variety. As a result, we hypothesized that in order to establish requisite variety, either 1) *attenuation* on the side of the business units reduces the external variety, or 2) *amplification* on the side of the business units increases the internal variety (Beer 1979, pp. 89-93). Both types of adjustment establish requisite variety and should be detectable accordingly. In order to corroborate or falsify this hypothesis about the establishment of requisite variety, we subsequently conducted a second set of unstructured interviews. The questions for these informal interviews were derived from our application of Ashby's Law. In addition, we used the conceptual models as a starting point for discussions.

Following our analysis, it is not surprising that our hypothesis about the establishment of requisite variety was corroborated. To summarize our results, people from FSB AG's business units have difficulties to understand the IT controlling reports. They are not "written in business language" and "not related to the daily affairs". In addition, the pure number of the provided information generates a feeling of information flooding. In order to cope with these problems, the business units have developed various strategies. For example, one business unit appointed two people with a background in IT that are responsible for the analysis of the IT reports and for the understanding of the item catalogue. Accordingly, this business

Figure 2. Excerpt of MetaMIS model (item catalogue)



unit establishes the missing internal variety by amplification. In addition, other amplifiers and attenuators have been identified, e. g. most prominent the complete disregard of the reports delivered by the IT controlling and reporting system.

4. DISCUSSION & CONCLUSION

According to our findings, the implemented IT controlling and reporting system at FSB AG is not designed with regard to requisite variety. It is quite clear by the different strategies employed by different business units that the existing IT controlling system fails to deliver meaningful information, i. e. information that makes the usage of IT transparent to the business units. For example, this leads to the need of people with expert knowledge in order to establish requisite variety for divisional management, and consequently to a misuse of resources (time, people and/or money). As a practical recommendation, the system should be redesigned in order to fulfill its cybernetic role as a regulator. We propose that this problem could be solved by a reduced item catalogue, made up of terms that are understandable by both business units and IT departments (Zarnekow & Brenner 2003, Nolan 1977).

In this paper, we showed how conceptual modeling and cybernetics can be combined in order to measure complexity. By using language critique as a means to understand conceptual models as marks of a language community, we were able to construct models in order to generate an interpretive understanding of the IS in focus, and to use variety as a measure for the complexity of this IS. Next, we confronted Ashby's Law as a theory with our interpreted observations. Based on Ashby's Law, we generated the hypothesis that due to the failed design of the IT controlling and reporting system, requisite variety asserts itself in other ways. Consequently, we generalized from the interpreted observations to a theory. Using the concept of variety and Ashby's Law as a theory in order to test our hypotheses, we make certain that our research approach is both rigorous and relevant. Our understanding based on language critique shows how conceptual modeling can be applied as a tool for diagnosis.

ABSTRACT
Conceptual modelling deals with the process of building or interpreting a conceptual model whereby the stakeholders reason and communicate about a domain in order to improve their common understanding of it. In this paper, we argue that the common engineering-driven view on conceptual models is only one possible perspective. Based on language critique, we show how conceptual models can be used as an important instrument for information systems research. We argue that researchers need to take on three roles in order to integrate interpretive and positivist approaches, and we combine our view with an existing framework for research based on (Lee 1991).

Keywords: Information Systems Research, Language Critique, Conceptual Modelling, Methodology.

1. INTRODUCTION

The traditional understanding of conceptual modelling focuses on what we call the *engineering-driven view of conceptual models*. From this perspective, conceptual models are part of a method, a planned and systematic (engineering) approach (Braun et al. 2005) which deals with the process of building or interpreting a conceptual model whereby the stakeholders reason and communicate about a domain in order to improve their common understanding of it (Gemino & Wand 2003, p. 80). The engineering-driven view has a long tradition in the information systems (IS) research community, especially regarding the construction and application of conceptual modelling languages and grammars for the specification of business requirements. Conceptual modelling and reference modelling are considered to be important instruments for analyzing and solving several technical and organizational design issues on an application level, enterprise level or industry level (Moody 2005, p. 244). Although conceptual modelling and the construction of modelling languages tailored to specific problem domains are well understood, open questions remain, e. g. regarding the construction of conceptual models (Wand & Weber 2002, Weber 2003), the evaluation of conceptual models (Shanks et al. 2003, Gemino & Wand 2004) or the quality of conceptual models (Moody 2005). From this perspective, conceptual modelling and conceptual models are *subjects* of research.

In contrast, we propose a *research-driven view of conceptual models*. As Silverman argues, IS researchers would do well to think a long time before rushing into yet another interview-based study (Silverman 1998, p. 19). Instead of focusing on how people 'see things', we have to focus on how people 'do things' (Silverman 1998, p. 3). In this regard, conceptual models are a means for forming an interpretive understanding. In practice, they are often used for several purposes, e. g. to support the development, acquisition, adoption, standardisation and integration of IS (Maier 1999). Every organization usually has a large collection of various conceptual models. For example, UML or ERM diagrams are used for software and architecture design, flow chart diagrams or event-driven process chains for ISO or Sarbanes-Oxley Act certification, and BPML/N for workflow specification. Incidentally, conceptual models are a means for the researcher to develop a common understanding of a problem domain with experts and practitioners (Ribbert et al. 2004). This results in a presentation of facts about the system in focus in such way that all stakeholders can understand it and relate it to their objectives.

Clearly, there is a need to address relevant problems for organizations. If a rigorous theory provides backup, why not leverage conceptual models as a useful source of knowledge? The issues that arrive from this understanding of conceptual models are fundamentally different in nature to the engineering-driven view. How can conceptual models contribute to the testing of theories? What are the consequences for research methodologies?

2. AN ARGUMENT: A LANGUAGE-BASED UNDERSTANDING OF CONCEPTUAL MODELS

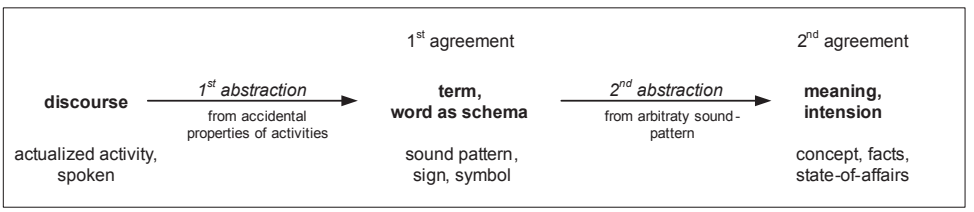
Several fields like linguistics, philosophy, psychology or neurology inquire about the nature of language. Following this, Lyytinen adequately demonstrated the importance of language for IS research (Lyytinen 1985). Nevertheless, there is no consensual answer to the question as to how meaning is given to language. Wittgenstein argued that every perception of the world is language-bound, so that language becomes the 'mediator' between reality and an individual (Wittgenstein 1922, 5.6). Nothing is an object "inherently"; it only becomes an object as we talk about it. For this reason we use language to represent some meaning that we conceive (Bühler 1934, p. 254).

In linguistics, de Saussure's seminal work conceptualized a linguistic sign as a union of a *concept* – the signified (signifié) – and a *sound image* – the signifier (significant) (de Saussure 1974, p. 66). According to de Saussure, the combination of concept and sound image is arbitrary. Therefore, a language consisting of linguistic signs is based on conventions (de Saussure 1974, p. 67). Following de Saussure, Morris proposed that a language consists of a set of interrelated signs, or *symbols* (Morris 1971, p. 24). Both de Saussure's and Morris' approaches are based on conventions as a precondition for meaningful language-based communication, and both separate a concept from its representation. By symbols, Morris addresses only what de Saussure termed the signifier. As the "lore of symbols", semiotics consists of three subordinate branches: syntactics, semantics, and pragmatics (Morris 1971, pp. 22-43). Syntactics (or syntax) deals with relations of symbols to one-another. People who want to communicate by language need syntactical conventions in order to create a common understanding of interrelated symbols. Semantics deals with the relation of symbols to concepts. These conventions are necessary for language-based communication in order to address one object with the same symbol. Pragmatics deals with the relation of symbols to their interpreters, and addresses the understanding of symbols to language users.

In accordance with Ågerfalk and Eriksson, we argue that traditional conceptual modelling research has focused too much on the syntactic and semantic aspects of language and too little on the pragmatics (Ågerfalk & Eriksson 2004). But where Ågerfalk and Eriksson use speech act theory as a theoretical foundation for conceptual modelling, we focus on language critique in order to explain the role of conceptual models for IS research.

Language critique, a branch of constructive philosophy known as the "Erlangen School" (Kamlah & Lorenzen 1984, Lorenzen 1987) provides useful insights and support for the research-driven view of conceptual modelling. By separating *language* (as a schema which one knows how to speak) and *discourse* (as linguistic action and activities), Kamlah and Lorenzen separate concepts from their linguistic usage (Kamlah & Lorenzen 1984, p. 41). Discourse means the repeatedly actualized usage of concepts in changing combination and variation.

Figure 1. Agreements and abstractions in language critique (Holten 2003, Holten et al. 2005)



Thus, discourse is an actualized activity, whereas language comprises potential activities (activity-schema) (Kamlah & Lorenzen 1984, p. 45). The transition from an actualized activity to its schema is called an *abstraction* (Figure 1). Terms are syntactical representations used in discourse with fixed conventions (1st abstraction), whereas in order to get concepts, we abstract from the phonetic form of terms (2nd abstraction) (Lorenzen 1987, pp. 115-118).

The question of how the conventions that align syntax, semantics, and pragmatics of symbols are formed can be answered using the construct of a *language community*. Kamlah and Lorenzen argue that language as a system of signs promotes mutual understanding as "a 'know-how' held in common, the possession of a 'language community'." (Kamlah & Lorenzen 1984, p. 47). A new term is introduced by *explicit agreement* between language users with respect to its usage (1st agreement) and meaning (2nd agreement) (Kamlah & Lorenzen 1984, p. 57). This agreement leads to a relation of concept and term, and is shared by a language community as the knowledge of using this term. Accordingly, if members of a group of people communicate, and each has an aligned semantic and pragmatic dimension of a symbol (or term) in mind, then this group of people forms a language community. The implications for our work are that the semantic and pragmatic dimensions of symbols need to be introduced together. If a language community has been created, based on a language (re)construction of a domain, the members of this language community share the pragmatic dimension of a symbol. All members have the same concept in mind if they are confronted with a symbol of the language and vice versa.

According to this understanding, conceptual models play a significant role in making language communities explicit: conceptual models are designed through linguistic actions of a language community, and therefore are an expression of a shared language understanding, so-called *marks* (Kamlah & Lorenzen 1984, p. 91, Holten 2003). Marks are written-down or printed writing-signs (Kamlah & Lorenzen 1984, p. 51). They are actualized as activities by the one who produces the marks in *writing* them, and again actualized by the one who *reads* them (Kamlah & Lorenzen 1984, p. 46, Gemino & Wand 2003). Models as marks create persistent things: solidified activities which stay put, are produced and can be read. By this means, conceptual models can be used as a formalized way of stating the intersubjective consensus of a language community (Ribbert et al. 2004). Conceptual models provide a starting point for communication as the written expression of the shared understanding of the language community that is part of every IS as a socio-technical system (e. g. business users, experts, managers, IT experts, programmers et cetera). New concepts and problems that every changing organization constantly encounters need to be introduced and explicitly agreed upon by this language community.

At the moment, it is of no interest for us how a consensus has been achieved, e. g. by enforcing a dominant power position, or by engaging into a reasonable discourse. All that matters is that a mutual understanding of concepts and terms has been created. Then, in accordance with (Ribbert et al. 2004), truth or correctness of statements depends on the consensus of the group of people that constructed the conceptual models (Kamlah & Lorenzen 1984, pp. 101-111).

3. THE IDEA: IMPLICATIONS FOR IS RESEARCH

Every research approach is based on fundamental philosophical assumptions (Myers 1997, Lee 2004). Based on these assumptions, IS researchers have debated competing philosophical paradigms for research, mostly represented by the two labels positivism (Jenkins 1985) and interpretivism (Walsham 1995a). Although the differences and boundaries between research positions have ever been a cause for discussion and argument among IS researchers, recent contributions argue for a conciliation and the acceptance of each others key assumptions and arguments as ontological and epistemological paradigms (Weber 2004).

Different positions not withstanding, given the richness and complexity of the real world, a research approach best suited to the problem under consideration, as well as the objectives of the researcher, should be chosen. The over-riding concern of our research approach is that the research we undertake should be both relevant to the research questions in focus and rigorous in its operationalization. Due to our understanding of language, we believe that a *constructive philosophy* (Lorenzen 1987) which integrates interpretive and positivist approaches is required for this purpose. Consequently, we assume that an objective world exists (ontological realism), but that our cognition of this world is subjective or private (epistemological subjectivism) (Holten et al. 2005, p. 177). We argue that due to this subjectivity, cognition relies upon the (re)construction of reality through (linguistic) action.

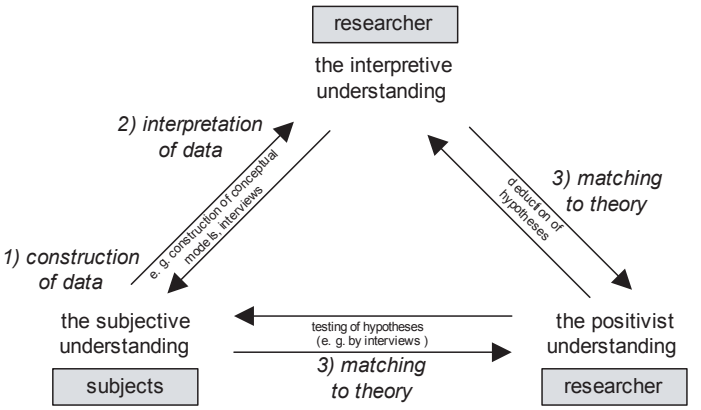
Following our language-based understanding of conceptual modelling and our philosophical assumptions, our research approach is characterized by three roles that the researcher adopts during her or his investigation. By anchoring our approach in language critique, we provide a new and alternative rationale from the philosophy of science. Our approach fits with a framework for the development of scientific theories as proposed by Lee (Lee 1991, Lee 2004). After having created a subjective understanding of everyday meanings and common sense within the observed organization, which provides the basis for the interpretive understanding, the researcher creates a positivist understanding in order to explain the empirical reality – the explanation being a scientific theory which can be tested against the subjective meaning as recorded in the interpretive understanding (Lee 1991, pp. 351-354). The result is an integrated framework for an interpretive and positivist understanding (see Figure 2). By taking up the three roles, the researcher acts in character with the processes described by Lee. Furthermore, she or he is conscious of the boundaries for research which are defined by these roles. The three roles can be applied and embodied during known research methods, e. g. action research (Baskerville & Wood-Harper 1996, Baskerville & Myers 2004), case study research (Yin 2003, Walsham 1995b, Barrett & Walsham 1999) or action case studies (Hughes & Wood-Harper 1999). We argue that engaging into the three roles allows the researcher to collect rich and meaningful data for answering his research questions.

1) Construction of Data

The first role refers to the *construction of data*, wherein the researcher acts as a participant and engages in practical work within an organization as a partner in active problem solving. We exist "all along" within a subjective understanding of the world which is linguistically articulated (Kamlah & Lorenzen 1984, p. 5). Participating in a language community thus becomes a prerequisite for any observation. In order to generate a mutual understanding, researchers and other participants actively create a language community, aligning their language constructs during projects. Thus, an inter-subjective understanding of the research domain is created. In doing so, the researcher gains access to observations in this research domain. Based on the observations, she or he is enabled to collect and construct data. This includes the collection of *existing* conceptual models.

Adopting a strategy akin to Langley, the researcher chooses to plunge deeply into the processes themselves, collecting fine grained qualitative data (Langley 1999, p. 691). This is a common characteristic of field studies which take place in the natural environment of the phenomenon, and where the researcher uses systematic techniques for the collection and recording of data (Cavaye 1996). Like an ethnographer, the researcher should begin by using and participating in

Figure 2. Framework for research (adapted from (Lee 1991))



everyday interactions and focus on "How do participants do things?" (Maynard 1989, p. 144).

2) Interpretation of Data

The second role concerns the *interpretation of data*. The extracted data and observations need to be analyzed and interpreted. The researcher makes statements about the research domain, which are based on common agreement and are understandable for the language community. This is in line with Lee's and Baskerville's generalizing from empirical statements to other empirical statements (Type EE generalizability) (Lee & Baskerville 2003). A researcher must thus repeatedly go from his own interpretive understanding to the subjective understanding and then back again to his own interpretive understanding (Klein & Myers 1999, p. 71).

Following our argument in section 2, the mutual construction of new conceptual models of the IS or organization under examination is a suitable tool for this interpretation. The conceptual models as marks ensure that the researchers actually understand what is happening in the research domain, if these descriptions are created and discussed by the language community consisting of all project participants. Conceptual models based on participatory action in operational processes are actualized activities of how people do things. The jointly discussion and refinement of these conceptual models serves to test the interpretive understanding recorded in the models against the subjective understanding.

3) Matching to Theory

In the third role, a *matching to theory* takes place. The researcher confronts a theory with her or his interpreted observations in order to deduct meaningful hypotheses. Generally, we understand theory as a means for describing, explaining and predicting as for design and action as well (Gregor 2006, pp. 626-630). Consequently, the researcher generalizes from the interpreted observations to a theory (Type ET generalizability) (Lee & Baskerville 2003). From this generalizability concept stems the idea that one case may yield as many information as many cases, since science operates with conjectures and jumps to conclusions, even after one single observation (Popper 1965). In IS research, this means the deduction of hypotheses about the organization and the IS in focus in order to match the findings with a theory.

It is an important accomplishment to construct correct conceptual models (correct in the sense of a correct interpretive understanding of a domain in focus, as in the engineering-driven view). But for science, the interpretation is but one link in the chain. Science interprets a domain, relates this interpretation to theories and subsequently tests these theories. As Lee shows, there is no discrepancy between interpretive and positivist positions. Therefore, we ask for an empirical checking of hypotheses. Consequently, we need to confront the interpretive understanding, and hence the conceptual models, with theories.

An example for an application of our research approach is a recent action case study carried out at a logistics service provider which was acquired by a bigger corporation (Laumann et al. 2007). The new management decided to analyse the reporting within the organization, since reporting consumed a lot of time. A conceptual modelling language was used to model the actual reporting, to get an overview of the company-wide reporting and to establish a fit between the information channels and the new functions after the integration into the corporation. Based on Ashby's Law of Requisite Variety (Ashby 1964) and the Viable System Model (Beer 1985) as underlying theories, hypotheses were proposed for the causes of the identified problems and were subsequently tested. To sum it up, the reporting was not any more appropriate for the new structure and strategy of the organization and had to be reorganized. The reporting information system was redesigned with respect to requisite variety.

4. CONCLUSION

By applying language critique in order to qualify conceptual models as marks, and hence as a formalized way to describe the consensus of a language community, we are able to leverage conceptual models as a source of knowledge and as an instrument for creating and testing an interpretive understanding for IS research.

Based on this, we described how conceptual models and the creation of a language community are important steps in participatory research in order to create an interpretive understanding of a subject matter. In this regard, both existing conceptual models and models mutually created by researchers and participants are useful – the first as collected data, the second as an instrument for interpretation.

As a next step, we plan to apply and refine this framework in different research domains, and to conduct a survey in order to qualify existing research as matching to our approach. Furthermore, other interesting questions for research arise from our approach, e. g. how consensus is actually achieved within a language community. We encourage other research to use this framework, and to criticize it for refinement.

ABSTRACT

Many organizations are interested in building their enterprise architectures using the Zachman framework. They hope to solve the problems of misalignment between business processes and information systems along with gaining a desired level of interoperability and flexibility in their IT environment. However, in most cases the Zachman framework remains as a conceptual framework more than a pragmatic one. This causes a serious doubt as to whether the enterprise could satisfy the motivations of employing the Zachman framework. Model driven architecture (MDA) is addressed in this paper as a framework, which is in a very high synch with the Zachman framework. MDA provides a means of flexible reusable model-driven development environment that is being applied in more and more situations everyday. It is also based on commonplace technologies, which makes it popular amongst software engineers and IT specialists. In this paper, we show that MDA could be the key that opens the world of reality to the Zachman framework. Not only does MDA have everything the Zachman framework needs to be practical, but it also follows the same logical structure and very similar metadata language as the Zachman framework.

Keywords: MDA, Zachman, Architecture, MOF, Conceptual Graphs.

1. INTRODUCTION

The Zachman framework (as firstly introduced Zachman (1987)) is considered as of the major origins of Enterprise Architecture (EA) (Wilton, 2001). According to Schekkerman (2005), 25% of current EA-related activities are being done using the Zachman framework, which is the highest rate amongst all the other frameworks.

The Zachman framework aims at reducing the problems of building information systems without strategic and/or business-related considerations. It categorizes different stakeholders' viewpoints into a fixed set of perspectives through which, everybody could find the exact information he/she is interested in. The framework also captures the knowledge of enterprise via abstracting it into a collection of integrated features.

A key factor of the Zachman framework is that it promises the alignment between business and technology because it provides all stakeholders with the same pattern of information. However, this promise could not be realized without having a mechanism to ensure that different viewpoints have correctly been transformed to each other.

Another important issue is the ability of the Zachman framework to capture the enterprise knowledge in an integrated scheme. In practice, it is very hard to track this ability because modelers use different sets of models with no common background. These problems alongside with other ones (Fatolahi & Shams, 2006) mandate the use of the Zachman framework as a conceptual tool. This means that enterprises could not benefit from all of the advantages of the Zachman framework in practice.

Model driven architecture (MDA) is the OMG's solution to increase model reusability and design-time interoperability. MDA deals with model as an asset rather than a cost. A very important feature of MDA is the facility to transform models among different areas. Not only is it easier to build automatic model mappings in the MDA context, but MDA could also be beneficiary when the model transformation is done manually. MDA provides a collection of popular standards beneath a common philosophy to facilitate the process of quality software design and implementation.

We believe that MDA can be used as a source to supply all the modeling needs of the Zachman framework. This is because MDA:

1. provides a strong approach for model transformation. This means that using MDA, it is possible to build models, which are true transformations of each other or at least very close mappings. This capability makes MDA a good choice to solve the challenge of perspective transforming and tracking within the Zachman framework.
2. provides a broad collection of flexible modeling standards based on a single simple basic notation. Therefore, one can apply MDA-based modeling notations all over the Zachman framework with a high chance to preserve the integrity of the enterprise's knowledge.
3. separates modeling concerns just as the Zachman framework does.
4. levels metamodeling in the same way the Zachman framework does.
5. uses a metamodeling language that could be easily translated to the one used by the Zachman framework.

In this paper we try to address some of the problems regarding the Zachman framework using MDA. Employing the two frameworks with each other, we hope for enterprise architectures that would be well defined and understood by all the stakeholders because of the Zachman framework; ones that would be easily developed and maintained because of the popularity of the MDA framework and its supporting tools.

The rest of this paper is organized as follows. In Sections 2, we introduce the Zachman framework and MDA. In Section 3, we mention related work and discuss the similarities and differences of the current research with the previous ones. Section 4 addresses the adaptability of MDA and the Zachman framework with an emphasis on metamodeling languages and levels. In Section 5, some issues regarding the current research are discussed. At last, we provide a summary along with a plan for future work in Section 6.

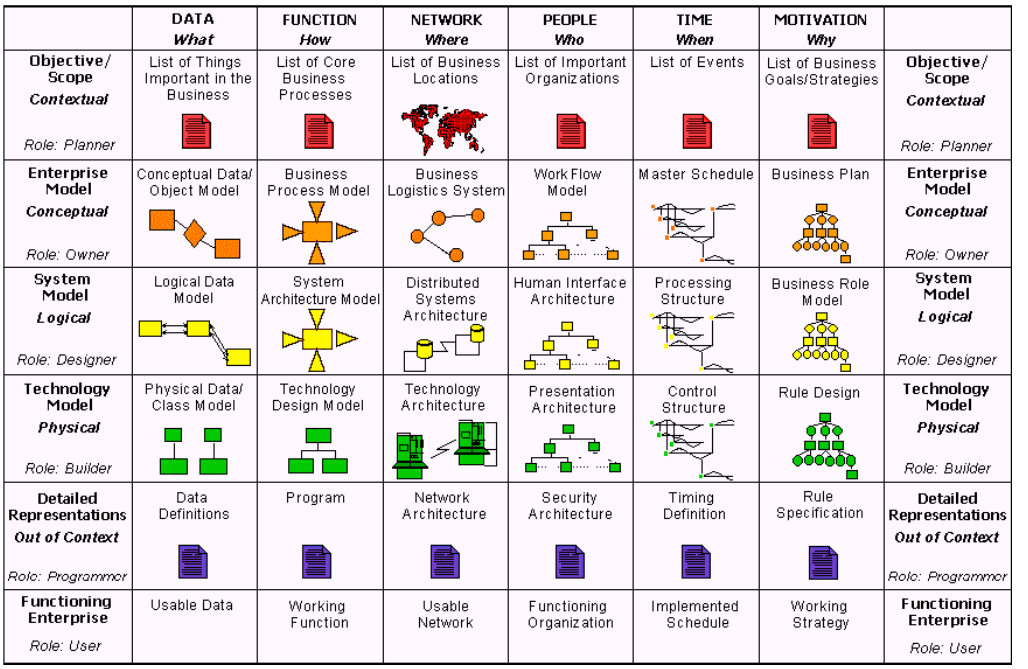
2. BACKGROUND

2.1. The Zachman Framework

Figure 1 is a depiction of the Zachman framework. The Zachman framework consists of six rows and six columns. Rows represent different stakeholders' perspective in building enterprise architecture. Columns are different ways in which, we describe the same product for different purposes. Crossing each row by each column, results in a cell, which contains a unique model.

As it can be seen in Figure 1, the first row is a definition of the context for the enterprise. In the second row, the enterprise is modeled using business modeling techniques. within the third row, the IT environment is conceptually modeled. These design models are mapped onto technology dependent design models in the fourth row. The fifth row contains implementation models. Since systems

Figure 1. The Zachman framework



development is often an outsourced task, which is not performed by the organization itself, this row is supposed to be out of context for the EA. The last row corresponds to the real working enterprise.

Columns of the framework facilitate abstraction of the enterprise's knowledge in a way that is suitable for modeling purposes. Each column is supposed to answer a single question regarding the enterprise. "What are important things for the enterprise?" is answered by the *Data* column. "How does it run?" is answered using the *Function* column. "Where is it located?" is answered in the *Network* column. "Who are acting within the enterprise?" is answered by the *People* column. "When does it perform its businesses?" is answered using the *Time* column and "Why the enterprise does the businesses?" is answered in the *Motivation* column.

2.2. Model Driven Architecture (www.omg.org/mda)

MDA proposes four different layers of modeling. The most top layer is the layer of *Computation-Independent Models* (CIM). CIM represents models, which are valid in spite of the computational options. Business models reside in this layer. Then we have the layer of *Platform-Independent Models* (PIM). PIM acts as a standpoint of systems/software design and architecture. However, it does not contain any information about specific platforms. The third layer, *Platform-Specific Models* (PSM) deals with the technological details of platforms. Here, logical design models are expressed in terms of certain platforms. At the lowest level, there are *Implementation-Specific Models* (ISM[1]). These are real-world objects and components, which act as a running version of the system.

The Meta-Object Facility (MOF) (www.omg.org/mda) is the heart of MDA. MOF provides a means of building new modeling languages and/or transforming different languages each to the other. The MOF is composed of very simple but strong enough elements to describe any other modeling language. Although MOF does not provide any specific notation, it is possible (and convenient) to use basic UML Class modeling notations (with few considerations) to depict MOF models.

MDA admits two levels of MOF-based languages. The first level addresses languages, which are rooted in the MOF itself. In fact, some of these languages such as CWM and UML are even older than MOF, but eventually OMG has refactored them to comply with the MOF. The second level deals with the UML profiles. This level involves different UML extensions. In order to facilitate model exchange amongst different tools and standards, XMI Metadata Interchange (XMI) is also a part of MDA.

3. RELATED WORK

The work closest to ours is reported by (Frankel, et al., 2003). This article shows how different perspectives of the Zachman framework maps to the MDA ones. This is shown in table 1. It also contains a valuable classification of MOF-based models, which can be used to fill in the different cells of the Zachman framework. For example, they propose CWM for the entire *Data* column or *UML Scheduling Profile* for a fraction of the *Time* column. Although we accept this approach, our paper extends the solution with bridging the metadata behind the two frameworks and mapping their hierarchy of metamodeling.

Another interesting work is provided by (B´ezivin & Gerb´, 2001), where the author discusses a precise definition for the MDA framework using CGs. It is worth-mentioning that the paper is published when MOF was not commonplace. The other work is published by (Fatolahi & Shams, 2006), which investigates the capability and popularity of UML models, when applying to the Zachman framework.

In summary, it can be concluded that the related-work has been generally focused on recognizing appropriate models for different parts of the Zachman framework and in the case of (Frankel, et al., 2003) a mapping between the perspectives of Zachman framework and the stages of MDA. Although the work of (B´ezivin & Gerb´, 2001) tries to define MDA using CGs, we do not see an explicit mapping between CGs and MOF in it. Our research is focused on mapping MOF and CGs alongside with discussing the similarity of the approach of the two frameworks towards metamodeling in practice.

Table 1. MDA layers vs. perspectives of the Zachman framework

Perspectives of the Zachman Framework	Layers of MDA
Planner	N/A
Owner	CIM
Designer	PIM
Builder	PSM
Sub-Contractor	ISM
User	N/A

4. ALIGNMENT

4.1. Separation of Concerns

Each row of the Zachman framework could be supplied with models from a certain MDA layer. Our discussion excludes the first row of the Zachman framework. This row represents the planners' viewpoint, which is supposed to be full of textual discriptions of different aspects of enterprise architecture planning, such as constraints, important features, limitations, geographical distribution, etc. We also do not mention the last row that is assigned to the real-working enterprise, which is not related to modeling.

The second row is the owners' perspective. This is the row, which describes different features of the business. This row is the area of different business modeling techniques. Since the models of this row are non-computational, we can use CIM to build the models of this row.

The third row represents the designers' viewpoint. Information systems are designed in this row. However, this design is a platform-independent modeling activity. Models to fill in this row come from PIM.

The standpoint of technology is indicated in the fourth row. In this row, design is simply transformed into technology-dependent modelings. For example, if we chose J2EE as the platform, design *Entities* would become *Entity Beans* here. This is why, we select MDA's PSM as our source for filling this row of the Zachman framework.

Programmers' role is compromised within the fifth row, where the building blocks of the architecture are made up. Because this row deals wholely with the implementation issues, we can feed it using ISM.

4.2. Model Assignment

Although there could be several valid approaches to assign a collection of models to each column of the Zachman framework, the important point is that both (Frankel, et al., 2003) and (Fatolahi & Shams, 2006) show that the family of MDA standards or some subsets of it could cover the Zachman framework. In fact, based on one of the rules of the Zachman framework (Sowa & Zachman, 1992) *there must be a simple, basic and unique model for each column*. Elements of such a model for different columns are provided in table 2. As long as a language can satisfy this rule it could be considered as a valid option. However, there is no guarantee that the chosen language reaches an acceptable level of popularity. Fortunately, this is the main advantage of the MDA, which deals with a family of popular languages.

4.3. MOF vs. CG

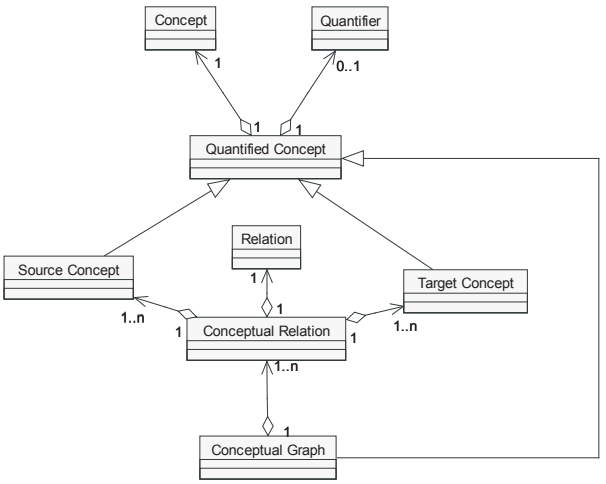
A very important factor to guarantee the quality of final enterprise architecture using the Zachman framework is its integrity. Integrity is gained through applying a set of rules. A question is to know if MDA could facilitate the usage of the Zachman framework. If MDA wanted to facilitate the usage of the Zachman framework, it should support the integrity mechanism of the Zachman framework, which is specified using the metadata language Conceptual Graph (CG) (Sowa, 2000). We address this challenge by providing metamodels showing that the language used to describe each framework could be formally defined using the language of the other framework.

The metadata language of the Zachman framework is CG (Sowa & Zachman, 1992). There is a simple and interesting relationship between CG and MOF. Figure 2 shows how MOF could describe CGs. A *conceptual graph* is composed of some *concept*s and *relation*s. For example, *a cat is on a mat*, is a CG of two concepts, *cat* and *mat*, and a relation, *on*. Usually a concept is being preceded by a quantifier, which is *a* (or more formally *exists*) in this case. Figure 3 is a representation of this CG. Quantifier *a* is not shown because it is the default quantifier. Figure 4 shows how this CG is synthesized using our metamodel. This is a very simple CG but our metamodel is also capable to describe more subtle CGs, including nested CGs. This is done through the generalization association between *Conceptual Graph* and *Quantified Concept* in Figure 2.

Table 2. Essential modeling elements for columns of the Zachman framework

What?	How?	Where?	Who?	When?	Why?
Entity	Function	Node	Agent	Time	Ends
Relation	Argument	Link	Work	Cycle	Means

Figure 2. MOF metamodel for conceptual graphs



We can see that each *Concept* plus an optional *Quantifier* results in a Quantified Concept like "a cat". This could be a target or a source concept. For example, as it can be seen in Figure 4, "a cat" is recognized as a *Source Concept* and "a mat" is realized as a *Target Concept*. A number of source and target concepts then aggregate to a *Conceptual Relation* through a *Relation*, which is "on" in the case of Figure 3 (and Figure 4). Finally, a *Conceptual Graph* is composed of some *Conceptual Relations*.

On the other hand, consider Figure 5 as an essential part of MOF imported from UML metamodel (OMG, 2005). Figure 6, presents a valid CG to express this metamodel. Symbol, *T*, is used as a means of repeating a concept. As it can be seen, multiplicity of MOF associations is shown using quantifier *{*}*, which means a set of concepts. In Figure 6, a "meta" relation represents the generalization from the general type toward the specific type. An "own" relation is used to show the aggregation association among two types.

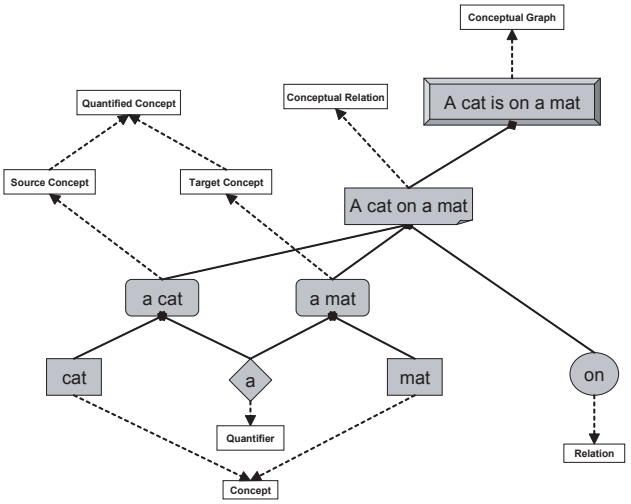

Figure 5. A part of a UML metamodel expressed using MOF

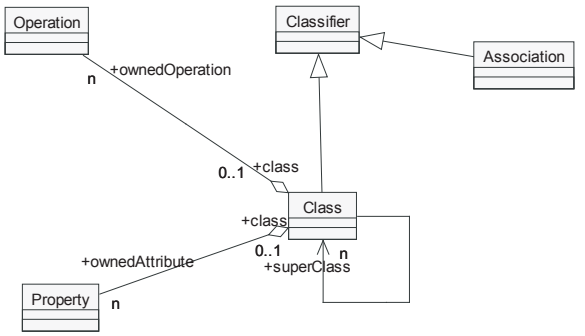

Figure 6. The conceptual graph describing the UML metamodel of Figure 5

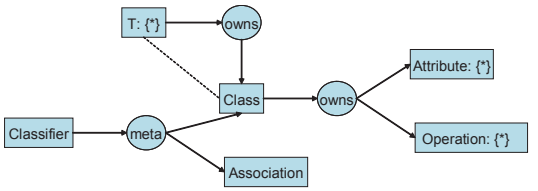

Figure 7. The stack of the Zachman framework

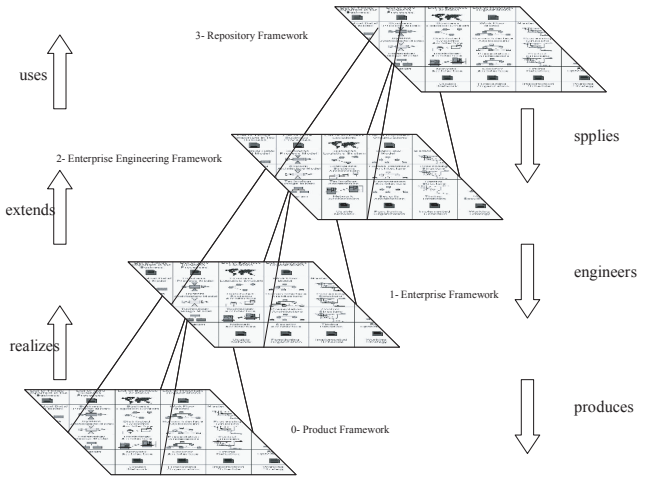

4.4. Metamodeling

An important question would be the ability of MDA to match with the hierarchical structure the Zachman framework provides to maintain reusable and scalable enterprise architectures. We provide general guidelines and ideas to apply MDA at different abstraction levels.

The Zachman framework is not just a pattern to build enterprise architectures; it also provides a mechanism for maintaining the enterprise knowledge. This mechanism guarantees the ability and scalability of the enterprise architecture. This means that the framework makes it possible to change the enterprise at any time using the stack of architectures Figure 7, shows the stack of the Zachman frameworks (Inmon, et al, 1997). MDA has the same mechanism to supply the framework with the models required for each level of this stack. This mechanism is defined within table 3.

According to Figure 7:

1. The framework at level 0 represents the architecture framework for the products of the enterprise. This product could be a software package or an airplane. A product is composed of real working objects, i.e. objects with certain serial numbers. This level could be equivalent to MDA's M0.
2. Architecture for the enterprise itself is modeled within the level 1. The enterprise architecture at level 1 defines the resources and methods through which, the enterprise generates its products. Thus, this level is a supplier for level 0. Since this is the specific enterprise that produces certain products of level 0, architects have to elaborate it using domain-specific models. Therefore, level 1 grabs its modeling essentials from MDA's M1.
3. Level 2 deals with planning, modeling, building and maintaining the enterprise. Enterprise engineers reside at this level. The enterprise engineering framework consists of tools and methods required to define different enterprises. Metamodels are critical for such an activity. Enterprise engineers need metamodels to extend them for the specific aspects of certain enterprises. Using MDA, they can select metamodels from M2. They may extend *UML Activity Model*s to describe the enterprise's workflow or create profiles of *CWM* to define the enterprise's warehousing mechanism (both will then appear at level 1).
4. Finally, there is the Repository Framework at level 3. This is the most abstract framework, which is used to manage enterprise engineering tasks. In fact, enterprise engineers refer to this framework as a general source for all the materials they need in order to develop or maintain an enterprise. Because metamodels are used as a means of enterprise engineering, the repository framework as the supplier of the enterprise engineering framework must also provide a mechanism of handling metamodels. This is why we assign MDA's M3 to this level. MOF is used as the metametamodeling language for all the languages and standards of level 2. It also assures the interoperability of the enterprise models, resulting in everything the Zachman framework promises for: interoperability, flexibility and maintainability.

Table 3. MDA metamodeling mechanism

M3 (MOF)	Metametamodeling layer, including the most abstract materials required to build new languages and interoperability standards.
M2 (UML, CWM, …)	Metamodeling layer, providing the notation and formalism that can be used to model specific domains and systems. This layer is fed by M3.
M1 (User Model)	Projections of M2 in terms of certain user requirements. This includes different extensions of M2 to model the specifications of a certain subject. Examples are UMP profiles.
M0 (Runtime Model)	Runtime objects. Running versions of M1.

Table 4. Mapping the metamodeling mechanism of the Zachman framework and MDA

MDA Metamodeling layer	The Zachman Framework
M3 (MOF)	Repository Framework
M2 (UML, CWM, …)	Enterprise Engineering Framework
M1 (User Model)	Enterprise Framework
M0 (Runtime Model)	Product Framework

Table 4 summarizes the mapping of metamodeling layers of both frameworks.

5. DISCUSSION

Despite of all the similarities, there are some differences between the Zachman framework and MDA. The concept of platform in MDA is different from the similar notion within the Zachman framework. From the viewpoint of the Zachman framework all technological platforms are considered the same and are addressed within the fourth row. For example, Oracle DBMS and .Net framework both belong to a unique category. The case is not the same with MDA, where the architect has to define his/her purpose of the platform explicitly. As a result, a platform-independent model is not necessarily a pure logical model. For example,

a PIM may be independent from .Net but not from the Oracle DBMS; that is the platform means just .Net.

The Zachman framework has a recursive nature. This means that each subset of the framework could be a new framework by itself. For example, as we discussed, the enterprise framework is a product of the Function column of the enterprise engineering framework. MDA does not support this recursiveness explicitly. The mapping of table 4 seems to resolve this problem, but yet the Zachman framework support of the recursive frameworks could be different than the structure of Figure 6.

A possible solution to this conflict is to consider different technologies and standards as members of different columns in the fourth row. For example, we have DB2 in the first column and DCOM in the second column. Since the logic of the Zachman framework is recursive, it is possible to think about each cell independently (Sowa & Zachman, 1992). We could isolate the cell at the fourth row and first column; then restrict the concept of platform to DB2, resulting in *DB2 Specific Model*. We iterate this process within other columns. (e.g. considering DCOM as the platform results in DCOM *Specific Model* for Function column)

6. CONCLUSION AND FUTURE WORK

So far, we have shown that MDA could fit with the Zachman framework very well. Since MDA supports a large collection of standard modeling languages, there is a good chance to assign a subset of MDA to each cell of the Zachman framework. Further, there are many tools and methodologies in use or under development in accordance with MDA.

One of the main benefits of MDA is that it facilitates the process of model transformation. On the other hand, model transformation is one of the major threats against the Zachman framework. MDA makes model transformation easier, more accurate and automated. Here, we find a big set of open problems, which are different MDA mapping functions and transformation paths throughout the Zachman framework.

This research is not just about a conceptual mapping between the Zachman framework and MDA. We believe that these two frameworks could collaborate with each other to build EAs in practice. The purpose of Sections 4.3 and 4.4 was to dismiss the gap between conceptual frameworks and practical applications. According to 4.3, MOF could be translated to CG; so, every model described with MDA is capable to fit within the Zachman framework. The discussion of the Section 4.4 promotes the ability of architects to support all levels of the Zachman framework using MDA.

As our future research, we will mainly focus on different MDA transformation functions to convert and/or track models through adjacent rows of the Zachman framework. Besides, we will be declaring the application of the notion of platform in MDA using the recursive logic of the Zachman framework. Clearly, we will need more and more tools and techniques to support our research. Therefore, this would be an indispensable track of our future research too.

ABSTRACT

In Australia, all recent higher education reforms have been driven by new legislation detailed in The Higher Education Support Act (HESA) 2003 that mandates and regulates the conditions under which tertiary institutions are able to be run and funded. In anticipation of the HESA enactment, Victoria University in Melbourne, Australia, conducted an institutional wide assessment of the University's position regarding HESA compliance and found that the University needed to rationalise course structures and progression rules, including standardization of subject sizes (Lister Review, 2003). This paper reports upon the adoption of a uniform system of subject size and associated credit points has necessitated a major course review of our Information Technology undergraduate program. This review, which posed a number of challenges at both School and inter-faculty levels, was informed by the needs of the stakeholders: the University, academics, the Australian Computer Society, industry and students. An insight into issues of importance on the IT curriculum is discussed before arrival at a HESA compliance program for our degree.

INTRODUCTION

In Australia, all recent higher education reforms have been driven by new legislation detailed in The Higher Education Support Act (HESA) 2003 that mandates and regulates the conditions under which tertiary institutions are able to be run and funded. In anticipation of the HESA enactment on 1 January 2005, Victoria University in Melbourne, Australia commissioned a taskforce to conduct an institutional wide assessment of the University's position regarding HESA compliance or otherwise. After an examination of all university course offerings, a major recommendation of the review obligated that *"the University rationalise course structures and progression rules, including the standardisation of subject sizes"* (Lister Review, 2003, Recommendation 17).

In 2004, an audit undertaken on the range of subject sizes and their credit point allocations in operation at the University highlighted disturbing anomalies. The investigation found a broad spectrum of unit sizes with differing credit point values ranging from 2 to 20 points and it exposed inequalities for different student majors in that the same unit of study could be awarded different credit point values dependent upon the program where the unit was undertaken. This audit underlined the need for the creation of a fair and equitable credit point system that would be accurate and consistent for all undergraduate and postgraduate courses. In addition, such a structure would ensure equitable course fee arrangements across the University's offerings and it would provide a transparency intelligible to students, staff and the community (Lister Taskforce, 2004a).

Through its Academic Board, the University instructed a working party to describe a uniform structure and a framework for a more suitable credit point system. The working party was also tasked with drafting a policy, entitled "The Credit Point System" for implementation by faculties. Subsequently, the Academic Board, at its June 2004 meeting, approved the introduction of the proposed new credit point system and the adoption policy that needed to be fully operational and HESA compliant by January 2006 (Lister Taskforce, 2004b).

Charged with implementing the new policy, individual faculties needed to align their existing courses with the new credit point arrangements. The Faculty of Health, Engineering and Science devolved the responsibility for the revision of the undergraduate Information Technology (IT) degree program to the School of Computer Science and Mathematics, where it underwent an extensive academic review. This paper describes the new credit point system and the impact of its implementation upon the IT degree program offering at Victoria University. By examining the needs and considerations of the respective stakeholders, the paper offers an insight into the process of arriving at a HESA compliant program which meets the statutory requirements and has academic and educational merits.

HISTORICAL BACKGROUND

Prior to 2006, the undergraduate Information Technology (IT) degree was a three year full time program, comprised of six study semesters. In the first year, students were introduced to core subjects in IT that laid a foundation of computing technology and these units included hardware, software, mathematics and statistics. The second and third year curriculum comprised both core and electives, which allowed student flexibility to pursue their particular strengths and interests. A

Table 1. IT program structure at Victoria University prior to HESA

Unit of study		Year	Semester	
Year 1				
SCM1311	Programming 1	1	1	15
SCM1312	Programming 2	1	2	15
SCM1114	Introduction to Computing & the Internet	1	1	15
SCM1115	Computer Systems and Architecture	1	2	15
SCM1613	Applied Statistics 1	1	1	15
ACE1141	English Language & Communication 1	1	1	7
ACE1142	English Language & Communication 2	1	2	8
OR SCM1614	(For those not doing ACE1141 and ACE1142): Applied Statistics 2	1	2	15

SCM3312	Intelligent Systems	3	2	12
SCM3313	Software Engineering 2	3	2	12
	One elective	3	2	12

significant part of the degree was an industry based project spanning two semesters in the final year of study; regarded as a 'dress rehearsal' for IT students about to graduate and face the needs of the commercial world. To develop the necessary advanced written and oral communication skills for successful completion of the Project, students must undertake two mandatory co-requisite units in English Language and Communication. A detailed pre-HESA compliant course structure is shown in Table 1.

A quick inspection of Table 1 illustrates that the pre-HESA IT degree program was comprised of units of varying credit points. However a less obvious anomaly is that dependent upon their English language proficiency, students needed to complete either 28 or 29 units of study for their degree program. Those lacking in English language skills were required to undertake two enabling English language subjects valued at 8 and 7 credit points each, whilst proficient language students were enrolled in a single 15 point elective instead. All first year students enrolled in the remaining core units, which carried 15 credit points each. In the second and third year of the program all units to be undertaken were valued at 12 credit points each. So a typical fulltime student carried 4 units of study per semester in the first year and 5 units in each subsequent semester, which summed to 360 credit points over their undergraduate degree.

THE NEW CREDIT POINT MODEL AND POLICY

To be HESA compliant, all University programs were expected to adopt a 48 credit points per semester model for fulltime study; typically comprised of 4 units of study, each assigned a 12 credit points (cp) value. This standard model is known as the 4 * 12 model. The model further stipulated that 1 cp represented an average student workload of approximately 1 hour per week over a standard 12 week semester. It was hoped that the adoption of a standard system of credit points throughout the University would remove the anomalies identified by the audit process and ensure equitable course fee arrangements across the University's offerings. In addition, the model allowed for a more systematic approach to course planning in relation to student workloads. It was deemed that a full-time student would accrue 96 credit points (2 * 4 * 12 cp) yearly over two semesters and that 96 cp equated to 1.0 equivalent fulltime student load for measurement of funding by the Australian government. As such, the model provided a transparency intelligible to the government and the University and at the same time, the model enabled students to make more realistic planning in their studies (Lister Taskforce, 2004a).

The policy document entitled "The Credit Point System" outlined the framework for converting all existing programs in the University to the 4 * 12 model in two sequenced steps. Step 1 required that each respective course of study be identified as one of three types of amendments and Step 2 involved carrying out the amendment by revision of the entire course structure under the new model.

For Step 1, all existing programs were classified as one of the following three types of amendment: Type 1- Arithmetic Amendment that related to courses of study which involved no structural change (a mere arithmetic change to the standard 12 cp for each unit of study); Type 2- Minimal Structural Amendment that related to courses of study which required a minimal structural amendment (no more than 20% change); Type 3- Major Structural Amendment that related to courses of study which required a major reconfiguration (more than 20% change). Following which, Step 2 involved the preparation and submission of the full course credit point conversion document to be subsequently approved by the Faculty Course Approvals Committee, Faculty Board of Studies and the University's Academic Board.

CONSIDERATIONS FOR IMPLEMENTATION

So how could the 'decree' of the new (4 * 12 cp) program model be implemented in the undergraduate IT degree by the School of Computer Science and Mathematics? Examination of the pre-HESA IT program described above, revealed inconsistencies in the number of units for different year levels within the degree. As well, there was no uniformity in the unit values within and across year levels. In fact, the total number of units for the awarding of the degree was dependent upon a student's language proficiency!

For the School of Computer Science and Mathematics, the imposition of HESA compliance dictated an interruption to the timing of regular four yearly course reviews. However, in line with the prescribed steps, several course review meetings were held during late 2004 to nominate the category of amendment for revision of the IT program. These meetings identified that a Type 2 amendment would be the most appropriate since a fulltime second and third year load comprised of 5 units of study per semester (5 * 12 cp), thereby simplifying the retrofitting of the existing degree structure to the new standard 4 * 12 model. Further the first year could, with some readjustment, be aligned with the model.

For the course review committee, this identification of amendment type was a relatively simple task. However, implementing the amendment for Step 2 was a lengthy and complicated process. Retrofitting the existing course structure to incorporate the new 4 * 12 model credit point system posed a number of challenges at both School and inter-faculty levels. Some issues considered in this conversion exercise included questions like:

- How would the proposed changes maintain or enhance the educational outcomes of the course?
- Would the modification impact on the taught load of another School or Faculty?
- What would be the validity and relevance of the new course mapping to the various stakeholders (the University, academics, professional bodies, industry and students)?
- And how could the needs of the key stakeholders in the process be taken into consideration?

STAKEHOLDERS' NEEDS

a) The University

HESA compliance meant that all higher education units of study in Australia are assigned a credit point value, being a measure of the proportion of the year's workload that the subject represents to a student. Additionally, within a university, a unit must carry the same credit point value irrespective of the program in which the unit is undertaken. An important aspect of the Act's implementation was the introduction of an electronic information and communication system, the Higher Education Information Management System (HEIMS), to inform the community at large. HEIMS has two portals: a public portal where potential students would be able to access information such as higher education courses, units of study, unit costs and admission requirements, and a private portal – a personal site for students to access their enrolment and other details (HEIMS, 2006). Thus, as a step toward compliance, Victoria University needed to supply information for the public through HEIMS.

One of the aims of the "The Credit Point System" policy was to achieve no nett loss of taught load, including service teaching across and between faculties. Another consideration in the implementation of Step 2 was the completion of a standard proforma for effecting program conversion. This was particularly pertinent to English language teaching staff from the School of Communication, Culture and Languages in another faculty who serviced the language and communication teaching of the pre-HESA IT program.

Independent of HESA, Victoria University's "Core Graduate Attributes (CGA) Policy" embodied the broad aim of preparing students for lifelong learning in the four scholarship categories of discovery, application, integration and learning. To this end, the policy was developed with the stated objective of improving employment outcomes for its graduates and the policy mandates that a necessary condition for fulfilment of all undergraduate programs is for students to complete an assessment that encapsulates the four scholarships (Miliszewska & Tan, 2004a). Thus, this capstone assessment must be embedded within a core unit of study at final year level of the IT degree.

b) Academics

Hurst et al. (2001) concur with us that the primary driving force for academics involved in the teaching of the IT degree program is the validity and value of curriculum for students, both current and prospective. Moving to 4 * 12 cp per semester, as it appeared on paper, would result in fewer units being taught and thus implied that the breadth and depth of syllabus might not be covered. To effect the review would require the re-identification of core content within the curriculum. So despite a reduction in the number of units, it would be important to ensure that there would be no overall loss of teaching content.

Guided by the requirements of the accreditation body, the Australian Computer Society (ACS), staff identified the core body of knowledge to include programming, software engineering, conceptual modelling, databases, data communications, security, computer organization & architecture, and mathematics. A fundamental

inclusion in the course was a capstone task to provide students with an opportunity to work on a real-life software development through two Project units where they synthesized and consolidated their knowledge (Miliszewska & Tan, 2004b). These units would be the final and all-encompassing subjects in the degree program. It would be expected that students would also acquire non-technical skills like project management and awareness of business practices (Fairchild & Taylor, 2000; Novitzki, 1998). These important units would be supported by the English language lecturers who, although not familiar with the computing side of the projects, could play a vital role in helping students realize the importance of good communication and presentation skills.

c) ACS & Industry

The ACS, as the accreditation body, is responsible for the standards of knowledge in IT degree programs throughout Australia. This organization examines the quality of a program through an assessment of the content and structure of syllabi against the Society's core body of knowledge. A set of ACS mandatory skills including project management, interpersonal communication, and professional practice must be incorporated within a program before it can be accredited.

A research on employer satisfaction with graduate skills found that Computer Science graduates lacked problem solving and communication skills (AC Nielsen Research Services, 2000). Relatively low ratings were given by employers assessing new graduates in their written and oral business communication skills, initiative, leadership qualities, personal presentation, and problem solving skills. Employers wanted graduates with all of those skills together with knowledge, intellect and a willingness to learn (Harvey et al., 1997).

d) Students

In Australia, political weight is attached to student evaluations, where they used as a performance indicator by the independent auditing body Australian Universities Quality Agency (AQUA) to assess the quality of a university. It would be a foolhardy department that chose to ignore their students' desires and interests since it is the second most important driver for curriculum change in Australian computing departments (Gruba et al., 2004).

In their research of what students want from their IT programs, Venables et al. (2006) found that students were very pragmatic. Student priorities included transparency of unit worth for planning, admission requirements and the value to employers of the degree program. Students expected that their program would be professionally accredited and incorporate cutting edge technologies.

THE RESPONSE

The Course Review Committee saw the extra ordinary revision imposed by HESA as an opportunity to restructure and enhance the educational outcomes of the course so that it better addressed the core body of knowledge in ICT programs as required by the ACS. However the implementation of the new 4 * 12 cp program necessitated a reordering of material to reduce the number of study units from 28/29 to 24. To consider the needs of all stakeholders and weigh possible alternatives became a very time consuming 3 months process, relying upon the collegial goodwill amongst the more than 30 staff representing programming, information systems, internet technologies and networking, security, mathematics and English streams.

To accommodate the new 3 year program, an increase was made in the number of face-to-face contact hours with students from 3 to 4 hours a week for all second and third year units and a minimal change was needed to revamp first year units. In deciding upon core components, the response was guided by both the ACS framework documents and the CGA policy of the University, the two final year Project and two English units were included as mandatory in the degree. However, due to the increase in face-to-face contact hours, the original 4 units were reorganized into 3 units. Note that no loss of taught load for the School of Communication, Culture and Languages staff occurred as some study material was incorporated into the second Project unit. In addition, the two semesters first year enabling English subjects were consolidated into a single subject resulting in an identical number of hours to be taught at the first and third year level. Also the restructure of the IT program allowed the introduction of new topics and subjects, for example, the shifting of a unit in Database Systems 1 from second year to first year had facilitated the introduction of an additional elective in the second year. To strengthen our program in the area of data structures and algorithms, a formal elective in Discrete Mathematics was introduced as a core unit in the first year instead. The resulting program HESA compliant structure is shown in Table 2 below.

Table 2. HESA compliant IT program structure at Victoria University

Unit of study		Year	Semester
Year 1			
RCM1311	Programming 1	1	1
RCM1115	Computer Systems & Architecture	1	1
RCM1711	Mathematical Foundations 1	1	1
RCM1613	Applied Statistics 1	1	1
RCM1312	Programming 2	1	2

RCM3312	Intelligent Systems	3	2
RCM3313	Software Engineering 2	3	2
	One elective	3	2

At the end of an exhausting review process, the Course Review Committee delivered what they believed to be an enhanced and academically sound IT degree program situated on top of a HESA compliant structure. Whilst being sensitive to the needs of all stakeholders, the new structure achieved no reduction in taught load of academics whilst improving the fit with the ACS mandatory body of knowledge for the discipline and complying with the University's CGA policy. Overall, the IT program has achieved a tighter structure with fewer electives spanning the core body of knowledge. With the addition of extra face to face contact time per elective, it is now possible to cover more advanced level topics which added extra breadth and depth in information technology that had not been previously possible.

CONCLUSIONS

Satisfying the needs and expectation for all stakeholders in a normal cycle of academic review for any program is challenging enough. It is particularly more difficult when the impetus for change is driven by an external force, such as national legislation. Typically, in these instances the timing can be problematic, especially where political machinations for funding can come into play; academics charged with the responsibility for implementation do not necessarily have the same goals in mind as their financial masters! Rather academics concern themselves more with the learning outcomes and the core body of knowledge within their discipline (Toleman et al., 2004).

For continuing students migrating to the new structure, the sudden artificial transition to the 4 * 12 model caused many problems. Dependent on which set of previously completed units a student possessed, the new structure progressed some students and retarded others within the same cohort. To nullify this erratic effect and ensure fairness to all members in the student body, a specific individual mapping was created for every single student in the program. This created an enormous administrative burden for the academic advisor. The first implementation of the new HESA compliant program took effect for the academic year commencing in

March 2006. With only one semester completion, at the time of writing, anecdotal evidence from students and staff has indicated that the new system does allow for more in-depth coverage of materials particularly with the additional face-to-face contact within specific courses. However, a more systematic analysis is planned for the future, along with consideration of the implications on existing study pathways for students articulating into the program through recognition of prior learning or credits transfer.

In this paper we offer an insight into the process of arriving at HESA compliancy; in this instance the local implementation involved taking a more lateral view of the degree versus the longitudinal view of the institution. The issues under consideration are not unique to this degree program or this University. In a 2003 survey of 19 different Australasian higher education institutions covering 75 different cases of curriculum change, Gruba et al. (2004) concluded that "there needs to be a balance between institutional objectives and that of academic staff." Overall the study found that most academics, like us, remained confident that their programs were academically sound despite being under considerable institutional pressures to implement changes for financial concerns. It does however raise the overriding and most important question of

Who SHOULD drive the changes in the IT curriculum – government, institution, professional bodies, industry, employers or students?

ABSTRACT

Encouraging Asian students, particularly those with poor English proficiency, to participate fully in university classes has long been recognized as a major challenge. This paper reports on a study into addressing this issue within the discipline Information Technology. The researchers interviewed 20 academics from a Faculty of Information Technology at an Australian University as well as conducting focus groups of 36 local and Asian students. A number of cultural and language factors were identified and several strategies for improving class participation by Asian students were suggested.

INTRODUCTION

Participation in class is a valuable teaching method to encourage a more active involvement in learning. However, our experience shows that class participation represents a major problem for many students, especially Asian students, undergraduates more so than postgraduates. Academics in our Faculty often complain about Asian student passivity but to date there has been little research into the promotion of Asian student class participation within the discipline of Information Technology (IT). IT has its own particular challenges:

- a different subject matter
- students who are more focused on technology rather than activities requiring oral or written expression
- larger classes than in the humanities (e.g., 30 in tutorials and labs at the authors' university, with lectures often in the hundreds)
- and high numbers of international students, especially Asian students.

This paper presents the initial findings of an investigation to determine strategies for improving Asian international students' class participation in face-to-face tutorials and small lectures within the IT Faculty at an Australian University. The research focuses on Asian students since they are usually the most under-represented group in class discussion and also because they comprise the majority of international students in the Faculty. The top five source countries for international students at our university are China, India, Indonesia, Vietnam and Thailand (F. Guo 2006, e-mail communication, 15 Sep.). Therefore the contribution of this paper will be useful in shaping our knowledge of why Asian students are under-represented in class participation, how Asian students view class participation, what barriers these students put forward for not participating and how we as instructors can overcome these barriers and ensure that participation is worthwhile to all concerned, particularly in cross-cultural settings.

The paper is organized in the following manner: the first sections provide an overview of the literature exploring cultural factors in class participation. Details of the research project and methodology are then stated. The preliminary results of the research are presented. Finally the key points are summarized and conclusions drawn.

BACKGROUND: EXPLORING CULTURAL FACTORS IN CLASS PARTICIPATION

Erickson (2004, pp 31-32) indicates that:

" ...everything in education relates to culture ... Culture shapes and is shaped by the learning and teaching that happen during practical conduct of daily life within all the educational settings we encounter as learning environments throughout the human life span – in families, in school classrooms, in community settings ..."

Culturally learned norms, rules and beliefs affect the way people communicate as well as predict the effect of their communication on others. Consequently, both students and instructors will bring their own culture and this will affect their expectation of instructor behaviour, their perception of what is proper classroom conduct, and what they view as appropriate learning methods and goals (Lee & Carrasquillo 2006; Winbush 1995; Kato 2001; and Chu & Kim 1999).

Tierney (1992) states that university reflects the culture of mainstream or dominant society. Accordingly, in Western universities it is believed that class participation is important since it will help to reinforce the curriculum, as well as improve presentation and social skills. These universities are full of their own social conventions, such as rules for class presentations, student attitudes to hierarchy and the subtleties of English usage, which may be unclear or unknown to overseas students (Dunphy 1998).

Asian Students

Sheehan and Pearson (quoted in Liu 2001) found that Asian students in Western classrooms expect instructors to tell them what to do and they believe that what the lecturer said is the truth. They are taught to follow it to the letter and memorise it, not to question, disagree or speak in the class. They believe that asking questions or speaking up in class is disrespectful. They often feel frustrated when they try to memorise the extensive readings given by the instructor and consequently are reluctant to participate in class.

Asian students prefer to rely on discussions in their own native language with their co-nationals in order to share their opinions or solve problems. They usually do the required pre-reading or activities before class and believe that any questions arising from pre-reading can be answered by a second reading or listening to the lectures attentively, not by asking questions. They experience language difficulties and are uncomfortable speaking up in class (Liu 2001).

When Asian students have questions, they prefer to ask their co-national or other classmates after class rather than asking their lecturer during class. If they have to ask the lecturer, they will try to do it after class (Liu 2001). This preference is affected by their previous experience in their home country. Most Asian countries have large class sizes: if the students ask questions in class, the lecture would not finish on time, and therefore the instructor prefers students to discuss any issues that they have after class.

Asian students also have a different concept of class participation than other students. They believe that class participation is responding to questions, as opposed to actively interacting with peers and asking their *own* questions. Furthermore, they are hesitant to comment on other students' presentations and prefer direct feedback from the instructor, compared to whole class critiques. Consequently, Asian students have become stereotyped as passive and unresponsive in class participation. (Chu & Kim 1999).

Sifianou (1997) states that there is a big difference in how silence is interpreted in Anglo and Asian cultures. Asian people consider that silence is the norm and talk is only desirable if there is something that needs to be conveyed, whereas English-speaking people deem that talk is desirable and is a way to show affection and social interaction.

A pilot survey on Asian students' participation in US universities by Liu (2001) revealed that the main barriers to class participation for Asian students are their belief that being quiet in the class shows respect for instructors. It is also connected to the Confucian concept of face saving by avoiding making mistakes in class and the need to preserve harmony. They believe that silence is an indication that the student is listening attentively and thinking actively. When they do not understand, they expect that other students will speak up and ask similar questions and consequently their issues will be addressed.

Further research by Liu (2001) in US universities found that, even if Asian students understand the importance of participation and want to participate, they often have to wait to get an opening to speak and then they are sometimes interrupted by their American classmates which subsequently silences them. Some American students speak up to fill in the silence because they misinterpret Asian students' silence as meaning they have nothing to say. Other American students interrupt because they want to help and inadvertently take over the conversation.

Asian students, regardless of whether they participate or not in class, agree that class participation is important to engage new ideas and gain knowledge (Liu 2001). However they believe that they can benefit from class participation without actively participating. They learn by listening attentively to other people's interactions. Preparation, knowledge and prior experience affect their participation mode.

These results support research by Tsui (1996) which identified five barriers to class participation:

1. Insufficient English proficiency
2. Fear of making mistakes and being ridiculed by classmates
3. Insufficient time to think (instructors' intolerance of silence)
4. Unequal opportunity to participate
5. Complex language usage by the instructor.

RESEARCH METHODOLOGY

To investigate strategies for improving class participation, particularly with Asian students, we explored:

- Student perceptions and expectations in relation to learning, in particular their attitudes to discussing, speaking and presenting in class;
- Cross-cultural issues and barriers with regard to participation; and
- Teacher experiences and strategies to foster effective participation.

The research followed a qualitative approach: focus groups and semi-structured interviews (McGovern 2003; Morse & Richards 2002).

Staff Interviews

Twenty academics from the Faculty were interviewed. Staff members were chosen partly on the basis of their availability and willingness to be interviewed, and partly in order to represent a broad cross-section of the various subject areas of IT. Interviewees were also selected to cover the full spectrum of academic levels from part-time tutor and associate lecturer to professor. The interviews were audio recorded and a partial transcription of each interview was undertaken. Interviews were semi-structured and based on a number of questions covering general class participation issues as well as cultural factors.

Student Focus Groups

Five focus groups were conducted, two for local undergraduates, two for Asian undergraduates, and 1 for postgraduates (combined local and Asian due to insufficient applicants), with a total of 36 participants. Students volunteered to participate by responding to advertisements on the intranet. In each focus group students were asked about their preferred learning style and about what factors affected their participation. Comments by students were organized and typed up during the focus groups.

RESULTS

Staff Interview

The Challenges of Asian Student Participation in the IT Classroom

On the challenge of trying to get all students to actively participate, there was general agreement that a very few people will do all the talking if allowed. With few exceptions, interviewees agreed that the biggest challenge was getting Asian students to participate because they are:

a lot quieter and not able to communicate as well – it could be because English isn't their first language; that's obviously going to inhibit them – but there is also the cultural part where they don't think it is appropriate to question the lecturer.

Several academics believed that Asian students have got an extra hurdle to overcome before they start participating because English is not their first language. The students also have problems understanding the lecturers, especially if the lecturer speaks too softly or uses colloquialisms. On the other hand, the lecturer might also have problems in understanding the Asian student. It has been suggested that one needed to speak slowly and clearly to accommodate Asian students.

Two interviewees believed that lack of English proficiency was not the only factor that hinders Asian students from participating since even using online discussion boards to help them overcome the language issue, as well as being given encouragement, still failed to make them participate.

Several interviewees described Asian students as "culturally shy", very reserved, not used to speaking up and afraid of losing face if they made a mistake. Asian students' upbringing taught them to respect their teacher: therefore, unless the teacher called their name and asked questions, they will not say anything. It is considered disrespectful to question the teacher. In this case, they are very different from Australians students who are much more interactive, dare to get involved and present their opinions.

Several interviewees said that Asian students have different expectations about teaching and learning methods based on their experience in their home countries. They were used to a "more didactic learning space" and unaware of educational practices in Australia. Some academics saw the Asian women students as the most timid about participating: in addition to the reasons already cited, the overwhelming predominance of men in IT classes was thought to be intimidating and create a very masculine atmosphere.

Strategies to Promote Class Participation by Asian Students

There was general agreement that it was "quite a challenge" finding ways of promoting class participation in multicultural classes with mixed race, gender, ethnicity and culture, especially with the increasing number of Asian students. However, there was no clear consensus about the best way of tackling this problem except that one needed to be very proactive. Various approaches were used by different staff members with more or less success. A couple of lecturers talked about the need to clearly convey one's expectations to the students at the beginning of semester so that they knew what was expected of them. For example, when awarding marks for class participation as a method of encouraging the students, they must be made aware of the difference between mere attendance and real participation.

Several staff members noted the importance of openly encouraging students to speak out, and also creating a comfortable atmosphere in the classroom. A number of academics regularly asked students to introduce themselves to the class or to the student sitting next to them as a way of creating activity and getting students over the first hurdle. Other academics recommended asking non-intrusive questions first, not asking them to express their opinions but more to say things that they know. These activities formed an icebreaker and also, because they talked about something they knew better than anyone else, it gave confidence to the Asian students and at the same time provided an insight to others.

Nominating the students by name was also one of the most popular strategies since a lot of Asian students would not participate unless they were directly called upon. Giving Asian students more time to discuss issues with their group first before they have to give their opinions was also mentioned. It gave more confidence and gave them time to formulate the answers in the English language.

Academics used a variety of participatory classroom activities but by far the greatest number recommended small-group discussions, with a representative of each group reporting back to the class afterwards:

First they have to be in small groups so that they know what they can tell and they can hide behind the group. Specially I think some cultures, they don't dare to express their opinion, but if they have to speak for a group they would do and indirectly give their own opinion.

Several interviewees mixed students from a variety of cultures through the groups and changed the groups as needed. This spread the good English speakers around, got people to be more aware of other people's cultures and activities as well as got them to learn from each other and made the Asian students feel welcome.

One interviewee suggested a group activity called "Interviewing an expert" in which the student has to be the expert from another country (the country which they originated from). At the end the students who have posed the questions have to present the expertise they have learned to the class.

It was also suggested that group presentations were better than individual presentations, because they provided a shorter amount of time for the audience if the presenter was an Asian student with poor English.

Another suggestion was formative assessment. Early in the semester (weeks 3-5), the lecturer should ask for some written feedback from everyone about how they are finding the class, their comfort level in asking and answering questions, asking for help, etc. This created an inclusive learning space for all students.

Student Focus Groups

Preferred Learning Style of Asian Students

There were several commonalities in preferred learning style. While most local students favoured interaction with their instructors and liked to talk and discuss issues, most Asian students said that they preferred Question and Answer at the end of the lecture, they liked to ask questions one on one with the instructor, mostly after class, and they were inclined to study or research individually.

As long as discussion was conducted in small groups, several Asian students liked subjects that required participation because it provided interactions, made the tutorial more lively, helped them to absorb the knowledge and gain other information, forced them to think more widely than the lecture or books, as well as provided opportunities to ask questions and clear any doubts. Getting the correct answer, if there was one, from the tutor after the discussion was seen as important. Some students also mentioned that it depended on the subject and also depended on the work given. One student said that he liked participation if he could ask for help in relation with the assignments, another if it provided workshop support and yet another student preferred practical work in the laboratory.

All Asian students and local students agreed class participation in tutorials was worthwhile. They also agreed that participation helped to clarify their understanding, gave opportunity to learn from each other and get better understanding. It helped to build public speaking skills, assisted in solving problems and answering questions, as well as making it more interesting and enjoyable. Asian students also put forward additional reasons such as: it gave them the opportunity to practice English and improved proficiency, helped them to learn how to interact with the instructor and the class, eliminated the fear of asking, improved the quality of participation skills and helped them to get to know more people. They also emphasized that the participation should be held in tutorials, not in lectures where it would become an interruption.

While they agreed that participation was worthwhile, only one Asian student said that participation was enjoyable. Several students forced themselves to participate because they realized that it was a good training and they will need it in the workplace. They also tried participating because they understood that they will learn more from discussion. Several students also said that they are a bit shy to participate.

Factors that Affect Participation of Asian Students

Both Asians and Locals said that fear of saying something stupid was one of the factors that prevented them from participating. It also depended on whether they had knowledge about the subject, whether they had prepared for the class, and their own individual mood and personality. If they participated and couldn't be understood, most Asian students said they would feel bad and may not participate again, compared to most Local students who would find other ways of getting their message across. Only three Asian students said that they would probably try other ways such as discussing the matter after class one on one with the teacher. One suggested using email or online discussion boards. Another would try to improve their English and IT knowledge. A third student would try to clarify what they meant, getting some help either from the tutor or other students, or would rephrase the sentences or give examples.

A big factor that Asian students commented on was that they liked to know ahead what information would be dealt with in class and therefore preferred to have the opportunity to prepare by reading. They had additional factors related to lack of proficiency in the English language, which led to lack of understanding, and inability to translate or clarify their answers. Another issue was the dominating player, where class participation was taken over by certain people, consequently providing no opportunity or time for Asian students to participate.

Tutor style, attitude and control of the class were essential as was the timing of the class and the class environment. Some students said that it depended on the quality of the questions, the level of the tutor's preparation and knowledge of the subject, and also whether the subject was interesting. Asian students believed that the instructor should ask questions equally to all students and give feedback and clarification of the material as well as give a summary to enhance student understanding. Asian students also hoped that the instructor would use simple vocabulary and give them more time to take notes. In addition, students wanted their effort in the tutorial to be recognized, for example by being a component of the subject's overall assessment.

CONCLUSION

This study of Asian students in the field of Information Technology confirms many of the findings that a number of researchers have found in other discipline areas (Lee & Carasquillo 2006, Chu & Kim 1999, Egan 1996). The major findings include that full participation of international students, particularly those from Asia, is hindered by a lack of English language proficiency as well as fear of making mistakes and losing face. Students voiced a strong preference for being given an opportunity to prepare properly for the class so that they could participate more.

An important finding was that all the Asian students involved in the study believed that class participation was worthwhile. This highlights the need for teachers to develop better strategies for including Asian students. The fact that only one of these students actually liked participation also points to the necessity for participatory activities to be enjoyable and less stressful. In addition, teachers should take into account Asian students' preferred methods of participation, for example, having a Question-and-Answer session at the end of class.

Moreover, the research provided a number of interesting strategies to improve class participation with Asian students. A key issue is to match the student and teacher expectations of learning in the class: teachers must clearly establish how the class will be organized and what sorts of activities students will engage in. An effective way to stimulate discussion is to divide the class into small groups: this is less intimidating for students whose English is poor. Spreading the good English speakers around the groups also helps. Some of the academics considered that the cultural backgrounds of the Asian students could be used to enhance the learning of the class rather than being viewed always as a deficit: for example, students can learn about other cultures.

The researchers acknowledge that the grouping together of all Asian students, regardless of their culture or English-language proficiency, tended to generalize the issues in this study and create a monolithic view. The researchers are also aware that there is a possibility that the really shy Asian students might not have volunteered to join the focus groups, thus affecting the results. Future research needs to be conducted to overcome these limitations. Focus groups will need to separate different nationalities and take account of different levels of English ability, for example Indian versus Chinese students.

Learning Objects and Semantic Web in Education: From Students' Analysis to New Perspectives for Their Use

Antonio Cartelli, University of Cassino, Via Zamosch, 43–03043 Cassino (Fr), Italy; E-mail: cartan@unicas.it

ABSTRACT

The work aims at giving a new perspective in ICT use in education by integrating web technologies in traditional teaching-learning processes. First it proposes the analysis of the difficulties students meet while attending both traditional and on line courses, then the factors influencing students' performances are discussed and alternative assessment instruments based on ICT use are reported. At last recent hypotheses on the introduction of learning objects and semantic Web in education are analyzed and e-learning strategies and instruments are compared with the results from traditional teaching contexts. As a consequence an adaptive e-learning strategy is suggested.

Keywords: Learning difficulties, Learning Object, Meaningful learning, Semantic Web, Teaching planning, Unit of Learning.

INTRODUCTION

Didactics and the disciplines interested in teaching planning and carrying out, always devoted their attention to three different elements in the teaching-learning process:

a) topics to be learned from students and their order and organization,
b) teaching process and its phases,
c) subjects (usually students) the teaching action was planned for.

During last decades (mostly in the second half of twentieth century) cognitive, sense-motor and affective taxonomies were developed (Bloom 1956, Mialaret 1999) to better define the strategies didactical process had to be based on (i.e., analysis of pre-requisites, planning and carrying out of teaching, evaluation, assessment and feedback). The process was in fact hypothesized to be cyclic, due to the feed back from students which could induce the planning of recovering actions when the expected results were not attained (Nicholls & Nicholls, 1983).

Recently different elements, including the introduction of ICT instruments and strategies, intervened to modify the well settled teaching-learning processes in education; two among them are analyzed in a greater detail in what follows:

a) students' learning features and assessment when e-learning environments are used,
b) the development of new instruments, like learning objects (LO) and semantic Web, to support continuous education and lifelong learning and to improve high and advanced education.

ICT AND STUDENTS' LEARNING

During last decades educational research evidenced the presence of many problems and difficulties in students' learning and especially:

1) preconceptions, misconceptions, and mental schemes, leading students to wrong interpretation of phenomena (for a survey of the work produced in this field the site of the Meaningful Learning Research Group http://www.mlrg.org/ can be seen),
2) the possible dependence of students' performances from their learning styles,
3) the importance of alternative instruments (i.e. portfolios) in students' assessment due to the value that people's performances and competences have in knowledge society.

The increase in the amount of the information to be managed, the frequent use of ICT in teaching and education and the need for the monitoring of the teaching process induced many scholars to experiment special information systems for facing the above problems (Cartelli, 2005).

Preconceptions, Misconceptions, Mental Schemes, and ICT

Literature shows that wrong ideas can be interpreted in at least two different ways (Driver & Erickson, 1983): a) mental schemes, if only the coherence of people's ideas in the analysis of phenomena is considered (with no reference to scientific paradigms); b) preconceptions or misconceptions, when people's ideas are compared and evaluated with respect to right scientific paradigms.

Many studies (Cartelli, 2002) carried out all over the world with differently aged people (from students to workers, from professionals to teachers etc.) show that:

- wrong ideas can be found in almost all scientific disciplinary fields;
- a lot of strategies and instruments have been proposed to overcome the problems people meet, based or not on IT and ICT strategies, and adopting or not constructivist strategies (supported or not by ICT). Nevertheless the good results of those experiences rarely were compared with traditional teaching and never were systematically used in education or adopted on a large scale (nationally or internationally wide spread);
- some experiments report that wrong ideas can persist in students (also if they attended the special courses described above) when they are forced to face special situations.

As an example the author's experience in basic computer science (CS) courses is reported here. First of all some wrong ideas were detected while analyzing students' learning on: computer input/output, human-computer interaction (when a GUI was used), data storing and retrieving, basic operations with a mouse etc.; it was then hypothesized that an e-learning platform based on traditional teaching elements and continuously monitoring the didactic process could help students in overcoming the difficulties reported above, while being a powerful instrument for the management of teaching. The information system the author planned and carried out (Cartelli, 2003), very similar to an e-learning platform, had CMS and CSCLS features. Notably:

- a well structured knowledge tree for the topics to be taught/learned was used for the course,
- special auto-evaluation surveys, integrated with the course's pages were available to students (i.e., many questions easily accessible for students were planned, on the basis of the wrong ideas formerly detected),
- various communication areas implementing virtual environments for teachers/professors, tutors, and students were used (to improve communication),
- a system for the management of students' evaluation and assessment tests was made available to teachers,
- two functions for the analysis of the students' access to course materials and the use they made of the communication services were continuously accessible.

The system was experimented with two different sets of students and had positive results as regards the number of students passing ending examinations; there was in fact only 20% student loss, while more than 65% of the students

had positive, if not excellent scores. At the end of the courses a deeper analysis of students' data showed unexpected results and some limits for the system: 1) many students still evidenced the presence of misconceptions (more than 43% of the universe); 2) the great amount of data generated by the second set of students (more than 300 subjects) made very difficult the continuous monitoring of the didactical process by means of the functions described above and could be analyzed only at the end of the course.

Meaningful Learning, Learning Styles, and ICT

It has to be noted that a unique definition of meaningful learning has not jet been found and at least two definitions are available. The former one, credited to Ausubel (1990), is based on the following statements: a) the logical meaningfulness of the topic to be learned; b) the presence in the topic to be studied of special knowledge elements making easier the insertion of new knowledge into previous knowledge; and c) motivation to learn. The latter definition credits Jonassen (1995) with the following statement: knowledge construction (internal and external negotiation), context (meaningful and authentic environment), and cooperation (among students and teachers) are the basic elements for the definition of an environment leading to meaningful learning (which is active, constructive, cooperative, intentional, conversational, and reflexive).

Also under the hypothesis of both the above definitions, little or no dependence has been shown between the students' meaningful learning of topics and their performances at ending examinations, neither in traditional contexts nor in virtual environments and online courses.

Recently some studies have been carried out on the possible dependence of students' success on their learning styles (in distance education and e-learning courses).

First Kovacic and Green (2004) report of significant differences in the performances they registered in different learners' types in a computer concepts class. The authors identified the students requiring additional learning support for passing examinations and used the Felder-Silverman model for the detection of their learning styles. After the evaluation and classification of the students' learning styles according to the model they found statistically significant differences in their performances – that is, students with reflective, sensing, verbal, and global learning preferences had the best performances both in in-course assessment and in final examination. The authors explained this result with the vantage the learners received from current teaching styles and from the learning environment (course material and online students' support).

Other scholars (Kumar, Kumar & Smart, 2004) used pre- and post-tests based on the Grasha-Riechman Student Learning Styles Scale (another model for the analysis of students' learning styles) on a sample of 65 students (both graduate and undergraduate). They compared the number and types of learning styles at the beginning and at the end of the course and found relevant changes in the their distribution. For the authors the observed changes were due to the instructional strategies and to the technologies they adopted in the class (i.e., the use of collaborative projects and course management software increased the number of collaborative, participant, and independent learning styles among students).

Students' Assessment and ICT

Knowledge society and lifelong learning require a more efficient evaluation of the knowledge and skill people develop both while attending courses and while integrating out-school experiences into formal education. The portfolio of competences, one of the instruments recently developed, has had a great success in certifying students' success in educational activities (i.e., people acquisition of good skills and competences). There has also been a significant increase in the number of online portfolios at different levels of education; they tend in fact to combine the benefits of traditional portfolio-based assessment with the paper-saving and other benefits of online environments.

Love and Cooper (2004), while investigating the key factors for the design of information systems for online portfolio-based assessment identified four weaknesses: 1) design mostly omit key educational and administrative issues while focusing on technical aspects; 2) "online portfolios" are often made only of a single essay, a project report or presented as a Web-based electronic facsimile of a conventional document; 3) many designs for online portfolio are based on an over-narrow view of value distribution and do not take all stakeholders into account; and 4) designing of online portfolio assessment systems are often not well integrated with overall course design processes.

As a conclusion online portfolio systems feel significantly short of their potential, and in many cases are inferior to conventional portfolio assessment and other more traditional assessment approaches.

TEACHING, LEARNING OBJECTS AND SEMANTIC WEB

Learning Objects (LOs) were firstly introduced for their adaptation and reuse features and are nowadays experimenting new interest for their possible insertion in traditional teaching; new didactical proposals introduce teaching strategies in LOs' structure (i.e., a learner centered teaching activity is hypothesized). In such a way LOs can be used in schools and university and not only in contexts of lifelong learning (Fini & Vanni, 2005).

The new hypotheses for LOs' structure and use neither cancel nor modify the problems until now evidenced for them: a) the lack of a clear and shared definition of LO and the different models and standards until now proposed for them, b) the doubts on the pedagogical neutrality of LOs and on their reusability (depending for some authors on the pedagogical aims of didactical actions and for others on the educational contexts they are referred to).

Furthermore Semantic Web is even more seen as a valid instrument supporting teachers' work and reducing everyday workload.

From LOs to UOLs

Some scholars recently hypothesized the application of learning theory ideas to the planning and using of LOs in constructivist and collaborative teaching-learning contexts; in other words the construction of learner-centered or community-centered environments strongly based on the use of LOs was hypothesized (Fini & Vanni, 2005).

The hitting of the above target was performed with the inclusion into the LO model of the planning strategies guiding its choice and use (Alvino & Sarti, 2004). As a consequence LO structure was extended to contain the tacit knowledge and the meta-cognition depending on the adopted materials and reusability laid no more on the adopted materials but on the ways they were used for (i.e., LO becomes very similar to a "best practice" rather than a "piece of content" to be recombined with other content elements).

The theoretical change emerging from the above hypotheses induced R. Koper (2001) to propose a new language, called EML (Educational Modeling Language) and very similar to UML and XML, for the definition and description of teaching/learning environments. The EML language doesn't manage LOs, its basic elements are called UOLs (Units of Learning), each UOL describing learning activities and all elements involved in the teaching/ learning process (i.e., the actors such as teachers, students, tutors etc. and materials, learning environments etc.).

Koper's work aimed at the construction of conceptual models for teaching/learning activities, letting people completely describe them in a formal way, adapt them to any pedagogical model, use them for supporting collaborative work and personalize them on the basis of students' prerequisites; the same conceptual models could also manage the collection of students' data and portfolios while respecting usual defined standards.

EML has been accepted from the Global Learning Consortium IMS and is know called IMS Learning Design (LD). It aims at the reusability of teaching/learning activities (i.e. templates to adapt to different situations or teaching experiences to re-produce).

Role and Function of the Semantic Web in Education

The basic idea of the semantic web, as stated from Tim Berners-Lee, is relatively straightforward: to create a layer on the existing web enabling advanced automatic processing of the web content, so that data can be shared and processed both by humans and software.

This declared result is obtained through the use of Resource Description Framework (RDF)-related technologies but there are also many other technologies for the creation of semantics. Some among them are reported below (Koper, 2004):

1. Unified Modeling Language (UML), providing a collection of models and graphs for the description of the structural and behavioral semantics of complex information systems,

2. XML and XML Schemas, to structure data and documents according to personal or community defined vocabularies (within which semantics can be implemented),
3. RDF and RDF-Schema, the metadata approach from the W3C, defining semantic meaning for data on the web (i.e., multiple semantic perspectives of the same data are possible),
4. Topic Maps, defining arbitrarily complex semantic knowledge structures and allowing the exchange of information for collaboratively building and maintaining of indexes of knowledge,
5. OWL – Ontology Web Language, implementing the semantic description of a domain by means of the specification of its concepts and relationships,
6. Latent Semantic Analysis, based on the use of programs for the understanding of natural language,
7. Software Agents, rather ill-defined, but commonly identified as pieces of software acting proactively (they are adaptive and (semi-) autonomous and can communicate with other agents and human creators).

An important question, strictly related to the educational semantic web, is concerned with the representation of a course in a formal, semantic way, so that it can be interpreted and manipulated by computers as well as humans. R. Koper (2001) refers to this process in terms of 'Educational Modeling'. He also states that Educational Modeling can be useful to solve (all or parts of) the following problems: development of flexible web-based courses (adaptable to learner features), preservation and sharing of knowledge on effective learning design, instantiation of e-learning courses in Learning Management Systems (LMSs), development of software agents supporting learners and staff in managing the workflow of activities, adaptation of didactical materials to individual learner's features (automatically driven by the descriptions of the conditions for adaptation), sharing and re-use of (all or parts of) e-learning courses, creation of more advanced and complex (but consistent) learning design and, at last, performing research into more effective and efficient learning design.

CONCLUSION AND FUTURE TRENDS

LOs and Semantic Web have had useful and interesting applications in continuous education, adult education and lifelong learning so that many authors suggested their application in traditional education, i.e. school and university.

The use of UOLs and EML by R. Koper can be seen as an example for the introduction of social-constructivist pedagogical approaches and different teaching models (active, learner-centered and community-centered) in educational practices supported by ICT.

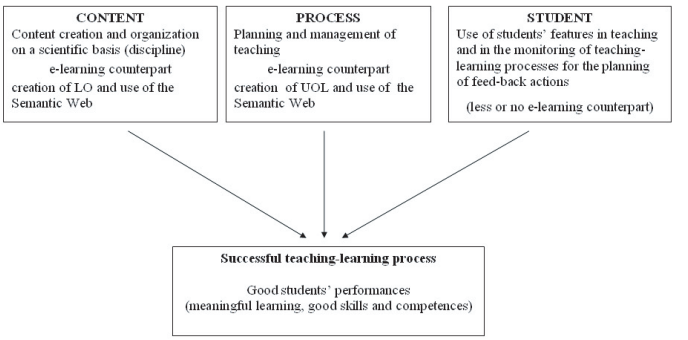
If everything seems to sound good there is, in the author opinion, an obstacle for the hitting of the target of a successful teaching by means of ICT in the above projects: it is the underlying presence of positivistic and deterministic ideas in all hypotheses formerly reported. In the projects involving ICT use in education the determinism is implicitly included in the optimistic idea that the right management of topics and discipline contents and the right control of teaching-learning processes can guarantee an efficient and meaningful learning in students. Otherwise stated the planning of special and well defined LOs, also made under the consideration of the right dependencies from other topics (which can be other LOs or more complex structures like the ones in the semantic Web) and when inserted in the processes of knowledge construction performed by one or more ULO (which can be individually or socially planned), do not guarantee, in the author's opinion, the students' acquisition of the right knowledge, skills and competences.

If e-learning aims at exiting from the important but limited field of lifelong learning and adult education, to become an essential element of school education (also in the limited hypothesis of integration of ICT into traditional educational processes), it cannot ignore the results of traditional teaching. Two key phenomena must be especially managed:

a) the introduction of feed-back and recovery actions in teaching processes governed by ICT,
b) the support to strategies helping students to overcome their difficulties and to acquire a meaningful learning.

A comparison between traditional teaching activities and their possible implementations by means of ICT can be useful to better understand the problems described above.

Figure 1. Elements affecting teaching-learning process and their e-learning counterparts



In figure 1 it is reported a comparison between traditional teaching and e-learning and in the last box it clearly appears the lack of adequate instruments and strategies in e-learning contexts.

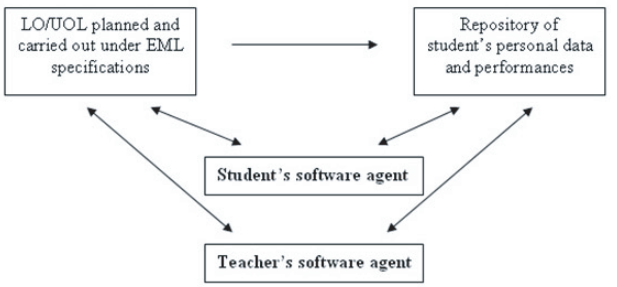
The lack of contact points between traditional teaching and e-learning in the last box is neither synonymous of the ICT exclusion from the corresponding processes, nor means that there is no experience or research involving its use. As reported in the first section of the paper there are many examples of studies collecting data on:

a) students' features and their modifications during the interaction with discipline topics in real and virtual environments;
b) students' messages, opinions and answers in forums, surveys and e-discussion instruments,
c) impact of e-learning strategies on students' learning and performances.

As a consequence it can be hypothesized the presence of the following scenarios for the integration of ICT in teaching:

- for the purists of learning objects theory and/or semantic Web there are at least two solutions (both depending or not on teachers' support to students' work and strongly based on a careful analysis of teaching-learning process): a) the need for special LOs and/or UOLs the student must interact with, when he/she does not succeed in hitting the target of a teaching action based on former different LOs/UOLs, b) a more complex structure for usual LOs and/or UOLs, which must have within them the functions for the analysis of students' learning styles (and other features), the functions to evaluate teaching action, the planning of recovering and support actions (when the right targets are not attained) and further learning materials and actions to be used for the recovering work,
- for artificial intelligent scientists the proposal of special systems, very similar for their structure to the well known ITS (Intelligent Tutoring Systems) or ICAIS (Intelligent Computer Assisted Instruction Systems), could better answer to the need of controlling the teaching-learning action and in helping students to improve their performances (main problem with this hypothesis is the presence of the same mechanistic hypotheses supporting the first solutions),
- at last an intermediate and adaptive solution can be proposed. It is based on the following three elements: LOs and/or UOLs and their semantic representations, repositories of students' data and software agents (respectively for students and teachers). It has the main advantage, in the author's opinion, that it doesn't lay on mechanistic ideas and gives new value and functions to teachers and educational research. Its main features are:
  - student's software agent collects student's data and stores them in a repository, furthermore, when the student interacts with the e-learning course, it transmit them to the LO/UOL,
  - the teacher's software agent proposes the student's case history to the teacher while suggesting possible didactical routes for the student; soon after teacher's choices are transmitted to the student's repository so that student's software can better guide him/her in the interaction with e-learning materials

Figure 2. Model of the adaptive teaching-learning process as hypothesized in third option



- data coming from student interaction with course materials and the results of evaluation and assessment are respectively transmitted to the teacher's and student's repository.

In the first case the teacher has good elements for planning possible recovering actions, in the second case the student's portfolio and the panorama of student's features can be completed. Figure 2 synthesizes the process described above.

Further elements making the third proposal useful for the integration of e-learning instruments in traditional teaching are:

a) notwithstanding the great deal of study and research carried out until now there is no definite and complete map for all factors influencing/conditioning students' learning,
b) it is not known if it will be ever possible to completely determine all factors influencing students' performances and learning, because of the dependence of these factors from the environment and the learning context (as an example it has to be remembered the case of computer science misconceptions: wrong ideas manifested from students have changed with the time, due to the introduction of GUIs).

A serious consideration of the above statements is fundamental for the individualization of students' learning and for the reduction of teaching automation in e-learning experiences.

ABSTRACT

Knowledge transfer has received increasing attention in recent years. This is evident from many knowledge transfer initiatives and projects reported in the literature. However, how to measure the success of knowledge transfer projects still remains as a challenge because knowledge transfer is a very complex process. This paper focuses on knowledge transfer facilitated by Information and Communication Technologies (ICT). It attempts to develop a conceptual model for identifying the causal factors affecting the success of ICT based knowledge transfer. Drawing from relevant literature it also proposes a set of associated measures for each dimension in the model. The success model of ICT-KT is based on a modification of a Delong & Mclean information system success model. Six dimensions in the model are developed, including Knowledge quality, System quality, Service quality (with sub-dimensions of E-service quality and Extension quality), Use, User satisfaction and Net benefits. Preliminary measures associated with each dimension are discussed and directions for future research identified.

Keywords: ICT based knowledge transfer (ICT-KT); success model; success measures

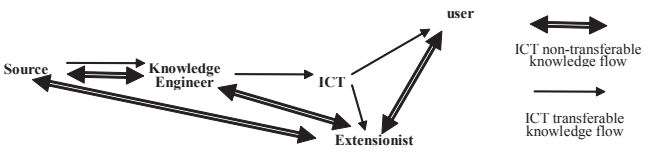
1. INTRODUCTION

In knowledge transfer, "human interaction and the resulting creation of objective knowledge is the key to progress" (Nonaka and Peltokorpi, 2006). In practice, knowledge is transferred not only in the form of one-to-one but also adopting one-to-many approaches. When developing countries need to cope with transferring knowledge to a large number of recipients scattered across remote rural regions, ICT based knowledge transfer (ICT-KT) is an effective solution. Transferring knowledge from a source to a knowledge disadvantaged recipient is defined by Lin et al. (2005) as a sender-advantage asymmetric structure.

Following a sender-advantage asymmetric structure, Feng et al. (2006) investigated a range of ICT-KT projects in China, which were launched for promoting the knowledge transfer from the national key universities to rural farmers. It was found that large amounts of ICT transferable knowledge were codified into expert systems available for non-expert users. As to the remaining ICT non-transferable knowledge a face-to-face approach was adopted. The knowledge extensionist, a role of a broker between expert, knowledge engineer and user, undertakes tasks of transferring ICT-non-transferable knowledge to bridge the communication gap and technical gap between the source and user and ensuring the success of knowledge transfer. The ICT-KT framework is shown in figure 1.

In practice, knowledge can be transformed in many ways to make it transferable. In the context of ICT-KT, face-to-face contact for the enhancement of effective non ICT transferable knowledge transfer has been noted by researchers. In a knowledge transfer process defined by Szulanski (2000) he argues the necessity of an external assistance to the knowledge user. Such close local support is important for a satisfactory level of user's absorption of new knowledge. Hainse and Goodhue (2003) describe a knowledge transfer triangle in transferring knowledge of ERP. The triangle consists of local implementer, ERP knowledge vendor, and the knowledge consultants, who "provide additional skills, knowledge, or simply manpower that is not available at the implementer or the vendor, or is too expensive if procured from the vendor".

Figure 1. The ICT-based knowledge transfer framework



The ICT-KT framework can be conceptually supported by knowledge repository theory (Argote and Ingram, 2000). The theory points out that knowledge transfer takes place in a network, which consists of three basic knowledge repositories (people, tools, and tasks). The ICT-KT framework is a typical knowledge transfer network consisting of the three knowledge repositories.

Regarding the role of an extension service in multi-path knowledge transfer process, Ray and Bhawuk (2002) demonstrate the importance of an extension service in transferring both conceptual and experimental knowledge from the source to recipients in their knowledge transfer scheme. The role of knowledge extensionist in ICT-KT is to enhance the completeness of knowledge transfer when the application of ICT-KT with vast field learners is expected to achieve a high standard of efficiency at the same time.

2. CONCEPTUAL BASIS OF ICT-KT SUCCESS MODEL

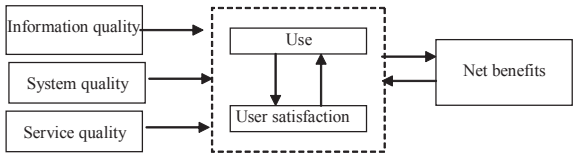
Cummings and Teng (2003) summarise four definitions of knowledge transfer success. The first looks at the engagement of knowledge transfers within a period of time. Based on communication theory, the second defines knowledge transfer as producing satisfactory results to recipients in time and on budget. Underpinned by technology transfer and innovation theory, the third is the re-creation of the source knowledge in the recipient side. The forth approach, drawing from institutional theory, regards knowledge transfer as a recipient acquiring "the ownership of, commitment to, and satisfaction with" the knowledge.

Ko et al. (2000) find that majority of knowledge transfer literature has adopted the source-recipient generic model. They define the knowledge transfer as "the communication of knowledge from a source so that it is learned and applied by a recipient". In management information systems study, communication theory is one of the most important grounds to support the conceptual development. In ICT-KT framework, ICT-transferable knowledge is transferred with its repository, an information system. To measure this part of ICT-KT success, the definition of knowledge transfer success based on communication theory is adopted.

2.1 D&M information Systems Success Model

DeLone and Mclean (1992, 2003) developed the D&M model to measure the success of information systems based on communication theory. Their original model in 1992 has been used by many researchers in the last decade. Communication theory was originally employed by Mason (1978) to measure the information system success. In Mason's study information is regarded as the product and the

Figure 2. The updated D&M model (DeLone and Mclean, 2003)



success of information system is divided into five levels to be measured: production, product, receipt, influence on recipient, and influence on system. Shown in figure 2, D&M further developed and updated this model towards a six dimensions of information system success: information quality, system quality, service quality, use, user satisfaction, net benefits.

2.2 Knowledge Transfer Process Model and the Quality Dimensions

Szulanski (2000) developed a process model to illustrate the process of knowledge transfer. The model consists of four stages of knowledge transfer: (1) initiation, work prior to the transfer; (2) implementation, between the decision to transfer and start of actual use of new knowledge; (3) ramp-up, actual use until satisfactory performance; and (4) integration, work after satisfactory performance being achieved. Four stages of the process model not only indicate a sequence of knowledge transfer process, but also a relationship of causality flows at the same time. This approach is also reflected in D&M model development (DeLone and Mclean, 2003). Underpinned by the same model development strategy, it is argued that a success model for ICT based knowledge transfer can be established based on D&M IS success model.

By combining Szulanski's process model with a causal relationship flow along the process, a holistic view of the knowledge transfer process and ICT-KT success can be drawn in figure 3. Following the process model, the causal relationship can be addressed in sequence of (1) Knowledge Quality and ICT System Quality; (2) Service Quality, with sub-dimensions of E-Service and Extension Service; (3) Use and User Satisfaction; and (4) Net Benefits.

2.3 SERVQUAL, E-S-QUAL and Service Quality

To measure the service quality, Parasuraman et al. (1985, 1988) developed SERVQUAL, which have five measuring dimensions. With the emergence of e-business, Pitt et al. (1995) argue that D&M model is designed to measure the effectiveness of IS system that focusing on products rather than service. With this view in mind they suggest that SERVQUAL is an appropriate instrument for measuring IS service quality. Therefore, Pitt et al. (1995) added SERVQUAL as an extra dimension in D&M model together with system quality and information quality.

The inclusion of SERVQUAL into D&M model provides a possibility to the further development of D&M model toward measuring the success of ICT-KT. With regard to its validity, we argue that the service quality Pitt et al. (1995) investigated is the e-service quality rather than the traditional people delivered service. Therefore, employing SERVQUAL to measuring the quality of information system service can be challenged (Kettinger and Lee, 2005). DeLone and Mclean (2003) realised the limitation of the original model and attempted to modify the model in 2003.

Also influenced by the emerging phenomena of e-business, SERVQUAL has been further adapted to E-S-QUAL, a multiple-item scale for measuring the web based service quality (Zeithaml et al. 2002; Parasuraman et al. 2005). E-service in E-S-QUAL is defined by Parasuraman et al. (2005) as the customer shopping online. Regarding the ICT based knowledge transfer, it is reasonable to adopt the E-S-QUAL to measure transfer service quality. For example, in e-learning system, many learning activities are supported by the ICT system and students pay for receiving education online. Another ICT KT project is online expert systems or web based knowledge repositories. In this case, knowledge recipient may have to pay for receiving knowledge/service from the system.

3. ICT-KT SUCCESS MODEL

The proposed ICT-KT success model is illustrated in figure 4. Based on the updated D&M model (DeLone and McLean, 2003), the model depicts the basic process and causal relationship of ICT based knowledge transfer. Service Quality and Information Quality have been modified to reflect the characteristics of knowledge transfer systems. The success of knowledge quality previously developed based on knowledge transfer process model by Szulanski (2000) is introduced into ICT-KT success model. Service Quality is subdivided into E-service Quality and Extension Quality. Information Quality is replaced by knowledge quality.

4. DISCUSSION ON ASSOCIATED MEASURES IN EACH DIMENSION

Having proposed the ICT KT success model, the following section attempts to discuss the possible measures which can be used in each dimension.

4.1 Knowledge Quality

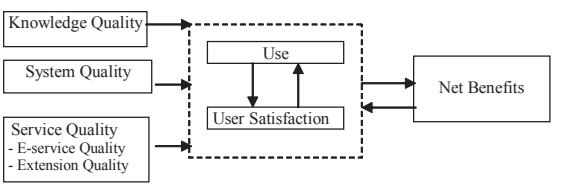
One of the most difficult dimensions to be measured could be the knowledge quality. Kane et al. (2005) empirically tested the influence of knowledge quality to the effectiveness of knowledge transfer. In their definition, knowledge quality is the gap between the knowledge of a source's and a recipient's. With empirical evidence they argue that superior knowledge will be more likely to be transferred from a source to a user than inferior knowledge. To measure the knowledge quality in general, potential items can be drawn from a number of influential empirical studies on knowledge transfer success. The first group of possible measures are as following.

- *Superior knowledge:* knowledge to be transferred is advantaged than the existing knowledge of recipient (Kane et al. 2005)
- *Tacitness:* implicit and noncodifiable accumulation of skills that results from learning by doing (Simonin, 1999)
- *Specificity*: transaction-specific skills and assets that are utilized in production processes and provision of services for particular customers (Simonin, 1999)
- *Complexity:* the number of interdependent technologies, routines, individuals, and resources linked to a particular knowledge or assets (Simonin, 1999);
- *Unproven Knowledge:* Degree of conjecture on the utility of the transferred knowledge (Szulanski, 2000)
- *Embeddedness:* A recognized characteristic of knowledge that can be transferred with people, tools or routines (Cummings and Teng, 2003)
- *Articulability:* the extent to which knowledge can be verbalized, written, drawn or otherwise articulated (Cummings and Teng, 2003)
- *Knowledge distance*: the degree to which the source and recipient possess similar knowledge foundations (Cummings and Teng, 2003)

Secondly, some other literature focuses on the ICT transferable knowledge, or information, in their research context. Holsapple and Lee-post-2006-used quantita-

Figure 3. An holistic view of the knowledge transfer process and ICT-KT success

Figure 4. Proposed ICT-KT success model



tive method to develop matrix measures for e-learning. They empirically verified the causal relationship between knowledge quality and use and user satisfaction in e-learning programmes. Therefore, a group of measures on information quality suggested by DeLone and McLean (1992) can be introduced as the preliminary measures of knowledge quality in general. These measures include: *Importance, Relevance, Usefulness, Informativeness, Usableness, Understandability, Reliability, Currency, Timeliness, Uniqueness, freedom from bias.*

Thirdly, a group of measures suggested by DeLone and McLean (1992) can be introduced as the potential quality measures of knowledge in the format of ICT transferable knowledge. They are *Readability, Clarity, Format, Appearance, Content, Accuracy, Precision, Conciseness, Sufficiency, Completeness, comparability, Quantitativenss.*

4.2 System Quality

In a broad sense knowledge transfer systems are information systems. The quality measures of information systems are still applicable to ICT-KT. Thus, the original measures in D&M model can be employed. The full set of system quality measures can be found in DeLone and McLean (1992).

4.3 Service Quality

Service quality is defined as the gap between expected service and perceived service (Parasuraman et al. 1985). This is true in ICT-KT context. Measures on service quality can be drawn from the general concepts in knowledge management literatures. As discussed in the introduction, ICT based knowledge transfer is normally supported by knowledge extentionist as a complimentary service to enhance the transfer effectiveness and success. Therefore, the service quality should include both E-service quality and extension quality. Further, researchers have noticed that the social-cultural factors play an important role in knowledge transfer (e.g. Alavi et al. 2006). Both e-service and extension service should not be an exemption of their influence.

In marketing theory, user's satisfaction is achieved from entire service they received from different means. Potential measures of general service quality can be:

- *Knowledge friendly:* positive orientation to knowledge exploration, creation and sharing (Davenport, 1998)
- *Clarity:* the project terminology is designed toward most effective communication (Davenport, 1998)
- *Multiple channels:* knowledge transferred through multiple channels that reinforce each other (Davenport, 1998)
- *Protectiveness*: specialised technological, personnel, and price in access to proprietary knowledge (Simonin,1999);
- *Cultural distance*: differentials of values, beliefs, language proficiency and alignment between individuals (Simonin1999; Cummings and Teng, 2003);
- *Organisational distance*: degree of dissimilarity in business practices, institutional heritage, and organisational culture between organisations or communities (Simonin,1999; Cummings and Teng, 2003)
- *Source not Perceived as Reliable:* Degree to which the donor of the best practice is perceived as reliable (Szulanski, 2000)
- *Source lacks Motivation*: Motivation of the source unit to support the transfer (Szulanski, 2000, Davenport, 1998)
- *Barren organizational Context:* Degree to which the organizational context supports the development of transfers (Szulanski, 2000, Davenport, 1998)
- *Project priority:* different degrees of attention and/or resources can be received in knowledge transfer activities (Cummings and Teng, 2003)
- *Transfer activities*: establishment and management of administrative structure based on assessment of knowledge, and the mechanism to facilitating knowledge transfer (Cummings and Teng, 2003)

4.3.1 E-Service Quality

E-Service is provided in accordance with e-commerce and e-business. E-S-QUAL is a set of measures for the E-Service quality. Suggested by Parasuraman et al. (2005), E-S-QUAL has two different measuring scales, the first is a 22-item scale of four dimensions: efficiency, fulfilment, system availability, and privacy; the second is a subscale with 11 items in three dimensions: responsiveness, compensation, and contact. The subscale is developed to measure the quality of service recovery. It is apparent that E-S-QUAL was developed in the context of e-business, not knowledge transfer services specifically. Modifications need to be made to apply their measures in ICT KT.

4.3.2 Extension Quality

Knowledge extension is a sort of service delivered by field extenionist, a face-to-face delivered service. Firstly, empirical measures suggested by KM literature can be adopted as described below:

- *Experience*: the capability in possessing the relevant tacit know-how to fill in the gaps left by codified descriptions(Simonin,1999);
- *Arduous Relationship:* Ease of communication and intimacy of the relationship (Szulanski, 2000)
- *Physical distance*: the difficulty, time requirement, and expense of communicating and getting together face-to-face (Cummings and Teng, 2003)
- *Organisational infrastructure:* establishment of the roles and organisational groups whose members have the skills to serve as the resources for individual projects (Davenport, 1998)

Secondly, SERVQUAL can be adopted as the initial constructs toward the final measures. Parasuraman et al. (1988) define the five dimensions of SERVQUAL are: tangibles, reliability, responsiveness, assurance, empathy. Within the five dimensions, the tangible is a dimension that is not particularly relevant to knowledge extension. A list of 18-item instrument developed for SERVQUAL shown in table 1 in appendix can be adopted as the second group of preliminary scales for further development of Extension Quality of ICT-KT.

4.4 Use and User Satisfaction

Darr and Kurtzberg (2000) argue that successful knowledge transfer occurs when source knowledge is not only shared with but also used by a recipient. Firstly, empirical measures in the KM literature on use and user satisfaction can be adopted.

Use

- *Recipient Motivation*: Motivation of the recipient unit to support the transfer (Szulanski, 2000; Davenport, 1998)
- *Learning cultural:* The need for a culture of learning in an organization or an individual to facilitate learning in general, and knowledge transfer specifically (Cummings and Teng, 2003)

User satisfaction

- *Recipient's Absorptive Capacity:* Ability of the recipient unit to identify, value and apply new knowledge (Szulanski, 2000, Tsai and Tsai, 2005)
- *Recipient's Retentive Capacity:* Ability of the recipient unit to support the routine use of new knowledge (Szulanski, 2000)

Secondly, two dimensions and related measures specified by DeLone and McLean (1992) can be employed as the potential items for measuring the use and user satisfaction of ICT-KT. However, *Information satisfaction* and *Difference between information needed and received* should replace by *knowledge.*

4.5 Net Benefit

DeLone and McLean (1992) proposed a set of measures on the organisational impact in their original model and net benefit in their revised model. Most of those measures on the organizational impact are rather product/service marketing oriented and lack a general scope. Within those measures, *Contribution to achieving goals* is viewed as an appropriate measure for net benefit. DeLone and McLean (2003) suggested five measures for net benefits in the revised model, including *Cost savings, Expanded markets, Incremental additional sales, Reduced search costs, Time savings.* Davenport (1998) points out that the link to economic performance or industry value is a key factor leading to knowledge project success. Following this argument, three potential measures, *Cost savings, Time savings, Improvement of economic performance or industry value* can be adopted firstly.

Secondly, as ICT-KT is, in nature, designed to transfer knowledge in the one-to-many form, measures on impact on individuals should be considered. Argote and Ingram (2000) note that knowledge transfer can take place at both individual level and group level. It is argued that organizational impact can only be realised with successful individual impact. It is inevitable that knowledge transfer at the

organisational level must involve the transfer at the individual level (Tsai and Tsai, 2005). More importantly, ICT-KT at the individual level is crucial in its success. O'Hagan and Green (2004) conclude that the knowledge transfer is dependent on the quality and quantity of social interaction between individuals. When the knowledge is transferred with some tacit components numerous individual exchanges are called for (Nonaka, 1994). DeLone and McLean (1992) suggest a set of decision effectiveness to measure the Individual Impact of IS success. This set of measures can be adapted as the second group of measures on net benefit. The modified two new sets of measures are *Personal valuation of ICT-KT and Willingness to Pay for Knowledge.*

5. FUTURE RESEARCH AND CONCLUSION

Future research will be carried out to test and validate the ICT-KT success model. Although the model is adapted from the D&M model, which has been empirically validated a number of modifications are made in terms of the dimensions and associated measures in the context of ICT-KT. The validation of the model can be achieved using empirical evidence to be collected with the current ICT based knowledge transfer projects in China, such as web based expert systems and web based training and education systems for rural extension in agriculture and aquaculture. Churchill (1979) suggests a procedure for developing multi-item measures for marketing research. The procedure is followed by Parasuraman and his colleagues in developing SEVQUAL and E-S-QUAL. The similar procedure can be employed for developing and refining the measures within each dimension using interview and questionnaire surveys.

This research has conceptually adapted the D&M model for ICT based knowledge transfer success but must be considered a preliminary study in nature. The model facilitates the mechanisms for measuring that ICT-KT actually takes place in both objective and subjective dimensions. However, this model is limited to applications in a sender-receiver asymmetry structure of knowledge transfer, within which the sender is in a knowledge advantaged position.

Multi-Layer Decision Support Model for Value and Cost Analysis of IT Solutions: Hierarchical Approach

Tadeusz Krupa, Warsaw University of Technology, Narbutta 85, 02-524 Warsaw, Poland; E-mail: tkrupa@op.pl
Teresa Ostrowska, Warsaw University of Technology, Narbutta 85, 02-524 Warsaw, Poland; E-mail: tmostrowska@op.pl

ABSTRACT

The article presents mechanisms of value and cost evaluation that accompany decision making processes in hierarchical systems, while performing complex IT projects. Every designing operation, performed in set deterministic or probabilistic conditions, is a decision making activity (selection activity) that initiates expected value and costs that occur with it. AIDA method has been selected as a starting point of the model's structure. The scope of applying of this method has been extended to modeling of decision making process in a hierarchically structured organization. Deliberations have been limited to the deterministic model with the assumption that selection of every decision, from the finite set of variants, is evaluated in two categories: V – expected benefits and C – incurred costs. Making a decision "agreed" in many layers is crucial for hierarchic structures. It is necessary to assure its global realization ability and maximize the expected value in relation with estimated costs. Deliberations are exemplified with a decision making process which accompanies launching a new IT project with cost-based limitations.

INTRODUCTION

The use of multilayer decision support model for value and cost analysis of major IT projects results from the analogy to the manner in which this kind of decisions are prepared and undertaken. The most common practice, present in many enterprises – especially financial institutions and insurance companies, considers two levels of decision making about IT project and their complex structure: strategic decisions level (s) and tactical decisions level (t).

Strategic decisions level considers the following aspects:

(0s) business strategy of the enterprise,
(1s) expected benefits,
(2s) incurred costs,
(3s) available technology,
(4s) reliable suppliers and contractors,
(5s) guaranteed safety.

Tactical decisions level includes the following aspects:

(0t) IT introduction strategy,
(1t) IT introduction program,
(2t) IT projects management,
(3t) scope and cost of IT audit,
(4t) scope and cost of outsourcing,
(5t) license purchase cost,
(6t) infrastructure purchase cost,
(7t) implementation cost.

Both presented decision levels permeate each other creating a network of cause-and-effect relationships. Their solution cannot be unambiguous due to indetermination or random character of macroeconomic (e.g. turbulent market) or technological (e.g. innovations in the areas of nano- and biotechnology) phenomena.

Routine decision making processes in hierarchical systems realization are accompanied by many phenomena which should be identified and managed. In case of unique ventures like IT projects to its managing, in general meaning, specific IT solutions are used. These solutions support: planning and organizing activities, budgeting, technical and logistic operations as well as controlling and corrective actions.

Project management occurs when the variant that has been chosen to realization is revealed from all of its more or less documented variants.

This article deals with the stage of creating and designing an IT project as well as estimating its economical effects for the organization that implements the project.

AIDA* method was selected as a starting point for the creation of the whole model. Its scope of use and implementation was expanded to decision making process modeling in a hierarchically structured organization.

According to the AIDA technique, decision making process is a process of preparing *alternative variants of decision* (AVD) and a process of selecting one of these variants for realization. Determining inwardly alternative *decision areas* (D_i) that consist of *elementary decisions* (d_{ji}) and indicating *mutually contradictory elementary decisions* that are included in different decision areas - is performed during this process.

In order to generate AVD, so called apexes of tree of results are formed. This process is accompanied by estimation of the V value growth and estimation of cost C connected with this project for the organization that implements the project (see Fig. 1).

Successive steps leading to a multilayer decision making model are presented in the following fragments of the article: *Decision making process – basic assumptions; AIDA method; AIDA method in solving a single-layer model; Estimating value and costs in single-layer model; Construction of a multilayer model; AIDA method in solving a multilayer model and Estimating value and costs in multilayer model.*

DECISION MAKING PROCESS: BASIC ASSUMPTIONS

Decision making process is a *alternative variants of decision* (AVD) preparation process as well as selection of one of the variants for further realization.

Preparing the AVD consists of determining relevant *decision areas* (D_i), for a set decision problem, which will provide partials of the *elementary decisions* (d_{ji}) that are not contradictory in constructed AVD model.

This part of the article deals with a single-layer decision-making process model in a strictly theoretical (general) manner.

In order to avoid terminological misapprehensions the meaning of keywords used in the article is presented below:

- *Decision Problem* (DP) – set of decision-making areas that specify particular areas of decision making process,
- *elementary decision* (d_{ji}) – making this decision implicates elaborating D_i and selecting one suitable d_{ji},
- *Variant of Decision* (VD) – sorted n elements indicated for realization, created from single elements (elementary decisions d_{ji}) that belong to sets of elements alternative to each other, namely decision areas (D_i),

- *Decision Preparation Process* (DPP) – process of elaborating D_i as well as AVD generation process connected with indicating *Variants of Decisions* (VDs) that are the most beneficial for further realization,
- *Decision Space* (DS) – collection of all non-contradictory AVDs,
- *Hierarchical system* – from the mathematical point of view it is a partly sorted structure that consist of: elementary decisions, decisions areas and variants of decisoins.

Example of a single-layer DP model in the form of graph is presented in Fig.1. D_1, D_2, D_3 symbols stand for decision making spaces; $d_{11,}$ $d_{21,...,}$ d_{33} symbols stand for elementary decisions.

Capital letters V, C mark the proportional share of a particular decision area in organizations value growth and IT project realization costs. Small letters v, c stand for proportional share of particular elementary decision in proportion to remaining elementary decisions from a considered decision area in organizations value growth and IT project realization costs.

Creation of DP graph model starts from eliminating these D_i, which collections include only one elementary decision and eliminating repetitive elementary decisions.

Apexes of the graph that correspond with elements of one decision making area are connected with lines (dotted line). Lines symbolize the fact that connected elements are alternative. Due to aprioristic collisions of some of the elements, that belong to different decision areas, suitable apexes of the marked with these elements are connected as well (continuous line).

AIDA METHOD

Designing decisions in single-layer model is performed by the activity of defining DP as a decisoin areas collection and defining relationships between elements present in these areas (see Fig. 1) without the necessity to undertake separate analysis of morphological relations between the elements of each collection.

AIDA method elaborated by J. Luckman distinguishes from other well-known methods of morphological analysis (morphological box, randomization with the use of sets, Moles methods) with high efficiency and relative simplicity.[1, 2]

Initial stage of performance of this technique is specifying decision areas recorded as, so called, *Formulating Sets* (FS). Every D_i has homological properties that is its elements in specific variants of the solution can be exchanged by others. Cartesian product of all decision areas determines the *Decision Space* (DS) of particular *Decision Problem* (DP).[3]

AIDA method can be used for two different goals:

- to generate admissible elements of the decision area,
- to generate discrete stages trajectory of solving DP in the DS.

First case presents decision areas decomposition process that leads to the form of AVDs, from which the final result is selected. In second case AIDA is used to generate "quick" variants of decision that are interpreted as discrete stages of *Decision Preperation Process* (DPP) in the DS.

Process of generating elements and trajectories of the DS should be evaluated both in quantitive and qualitative way. The most promising use of AIDA method is in case of major and complex decision areas - that is every time when the moment of making a decision should be preceded with the stage of generating all or almost all VDs.

In some of the practical uses it is necessary to take into consideration the limited available time to take particular decision and costs connected with elaborating DPP – in this aspect the AIDA method can be used to prepare a limited number of decision making variants which should include an optimal variant (it concerns especially the tasks of steering in conditions with system parameters of great dynamics or searching for results variants in conditions that include a considerable number of probabilistic limitations). Second collection of AIDA method uses can be related directly to realization of complex IT projects, which budgets usually account for millions of dollars and the benefits and costs of implementation occur simultaneously with the time of managing the project.

AIDA METHOD IN SOLVING A SINGLE-LAYER MODEL

Any decision area (represented by so called formulating set) will be marked as $\mathbf{D_i}$, and $\mathbf{d_{ji}}$ stands for a j-th elementary decision of this area.

Decision space (DS) of morphological analysis is signified as $\mathbf{D_1 \times D_2 \times ... \times D_m}$ or as a set of vectors $\{<d_{j1}, d_{j2}, ..., d_{jm}>\}$, with the assumption that $\mathbf{d_{ji} \in D_i}$ and that the power of any decision making area $|\mathbf{D_i}|$ is a limited value.

The solution of a decision problem (DP) is the defined set of decision areas $\mathbf{D_i}$ and generated and evaluated correct vectors $<\mathbf{d_{j1}, d_{j2}, ..., d_{jm}}>$ at a decision tree (see Fig. 2).

The essence of AIDA method is to perform the four following steps:

[a] determine inwardly alternative decision areas that describe the set problem,
[b] determine contradictory elementary decisions that are in different decision making areas,
[c] generating and eliminating these VDs of the decision areas which include contradictory pairs of elementary decisions,
[d] sorting and analyzing remaining VDs.

The procedure of generating VDs is based on the decomposition of the DP graph model. Decomposition is based on systematic separating inwardly stable variants of formulating set's. Inwardly stable set is the one which fulfills two conditions:

- It consists of as many decision making elements as there are decision areas,
- It does not include pairs of elementary decisions that eliminate each other.

For example in $\mathbf{D_1}$, $\mathbf{D_2}$, $\mathbf{D_3}$ decision areas (see Fig. 1) the following sets are inwardly stable: $\{\mathbf{d_{11}, d_{22}, d_{33}}\}$, $\{\mathbf{d_{11}, d_{12}, d_{13}}\}$, $\{\mathbf{d_{21}, d_{32}, d_{23}}\}$.

Generating VDs has the following agenda:

(a) the power (number of elements) of each formulating set is specified,

Figure 1. Example of a single-layer DP graph model

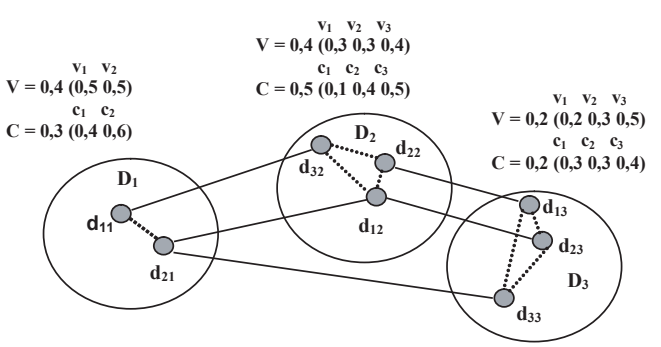

Figure 2. Example of tree of results for single-layer model

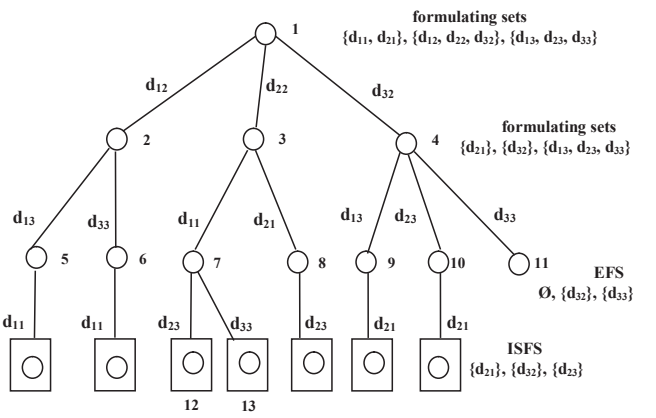


(b) formulating sets are sorted according to the decreasing value of their power,
(c) formulating sets of elementary decisions that are included in all decision areas are divided into as many groups of sets as the value of largest formulating set's power,
(d) apexes of the tree of results are formulated together with the lines growing out of them, which have specific groups of formulating sets attributed to them.

Realization of operations (a) to (d) is exemplified at the tree of results in Fig. 2.

It is necessary to take into consideration that while creating formulating sets for newly created apexes of lower levels of the tree, there cannot be any elementary decisions that are alternative to these elementary decisions towards which the formulating sets division takes place. If, due to the division, the power of one of the formulating set becomes equal to 0 (the set is empty) – it indicates that this particular group of formulating sets is eliminated from the process of division and marked as EFS (Eliminated Formulating Sets). If the power of all formulating sets in a particular group equals 1 – this group becomes the variant of inwardly stable set of decisions and is marked as ISFS (Inwardly Stable Formulating Set). Remaining formulating sets are sorted decreasingly due to the value of their power and the realization of (c) and (d) operations is triggered again.[4, 5]

The operations (a) - (d) are repeated until the groups of formulating sets will consist only of EFS and ISFS elements. Groups marked as ISFS are the collection of allowable results that is the set of all possible VDs, which do not include pairs of alternative elementary decisions.

In the tree of results (see Fig. 2), ISFS that reflect the lowest level of apexes are marked with a frame.

The gained ISFS results are:

$\{d_{11}, d_{22}, d_{33}\}$, $\{d_{11}, d_{12}, d_{13}\}$, $\{d_{21}, d_{32}, d_{23}\}$, $\{d_{11}, d_{12}, d_{33}\}$, $\{d_{11}, d_{22}, d_{23}\}$, $\{d_{21}, d_{22}, d_{23}\}$, $\{d_{21}, d_{32}, d_{13}\}$

ESTIMATING VALUE AND COST IN A SINGLE-LAYER MODEL

Process of generating formulating sets for every apex of tree of results (see Fig. 2) is accompanied by estimating of the value growth of the organization implementing the IT project together with estimation of the cost of project's realization (see Fig. 1).

In order for the estimation to be possible an assumption is necessary: every $\mathbf{D_i}$ percentage share, on the scale of **[0..1] x 100**, is set both in **V** value and costs **C** – with additional assumption that sum of each of these shares in all decision areas equals **100**.

For the example presented at Fig. 1 sums of all shares are as following:

$$V_{D1} + V_{D2} + V_{D3} = 100$$
$$C_{D1} + C_{D2} + C_{D3} = 100$$

V-C characteristics for particular $\mathbf{d_{ji}}$ in every $\mathbf{D_i}$ are determined similarly:

$$v_{d11} + v_{d21} = 100 \qquad c_{d11} + c_{d21} = 100$$
$$v_{d12} + v_{d22} + v_{d32} = 100 \qquad c_{d12} + c_{d22} + v_{d32} = 100$$
$$v_{d13} + v_{d23} + v_{d33} = 100 \qquad c_{d13} + c_{d23} + v_{d33} = 100$$

For each group of formulating sets connected with the developed tree apex with **x** index, **max** and **min** of expected percentage value (V_x^{max}, V_x^{min}) and expected percentage cost (C_x^{max}, C_x^{min}) are determined. Results of particular calculations for the presented example at Fig. 1 are collected in Tab. 1.

Analysis of the tree of results presented in Fig. 3 indicates that three of the best relations between cost of IT project realization and increase of organization's value can be achieved in a form of a result marked as No 5, No 6 and No 13.

Upper and lower **V–C** limitations can be used in automatic model revision in models with hundreds or thousands elements. In such case there are aprioric limitations for allowable scope of diversity separately for parameter **V** and **C**. V-trees and C-trees of results are constructed; the best **V/C** solutions are present in a mutual part of both trees.

Reached solution (apex) No 6 with **V/C = 1,68** is present in mutual part of both trees where $\mathbf{V \geq 42}$ and $\mathbf{C \leq 25}$.

CONSTRUCTION OF A MULTILAYER MODEL

In hierarchical systems the decisions are made on several layers according to the situation present in adjacent layers. Process of designing and taking the decision is dependent on the character of the organization – although decisions in higher layers are always based on the decisions in lower layers – and symmetrically: decisions in lower layers are based on decisions in higher layers. Therefore we can observe two interdependent streams of decision preparation.

Fig. 4 illustrates mutual placement of decision making problems at higher (strategic), intermediate (tactical) and operational layers. It is easy to observe that decision area (that includes elementary decisions) at a higher layer becomes a decision problem for the layer placed beneath it.

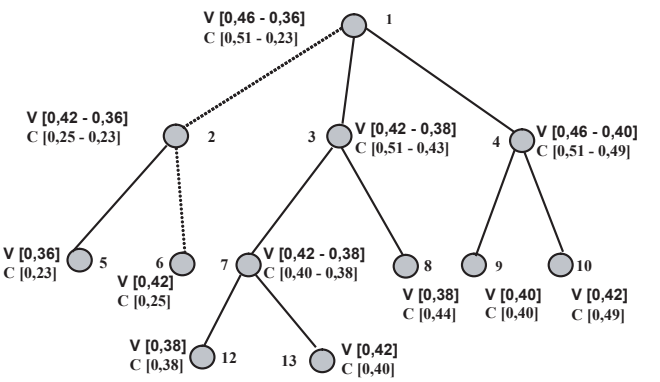
Structure of a multilayer DP graph model (see Fig. 4) is based on the following rules:

- each defined decision area placed at a certain DP layer or at a adjacent layer has all possible elementary decisions determined,
- for a collection of elementary decisions that belong to a decision area of higher layer a DP of lower layer has to be determined, its solutions in a form of alternative variants of decision (AVD) should unambiguously relate to particular elemetary decisions (see Fig. 4, elementary decisions No 5, No 6, No 13 and relevant AVDs as DP solutions in a tactical layer),

Table 1. Example of proportional value estimation for formulating sets

No	Group of formulating sets	next No	V^{max}	V^{min}	C^{max}	C^{min}
1	$\{d_{11}, d_{21}\}, \{d_{12}, d_{22}, d_{32}\}, \{d_{13}, d_{23}, d_{33}\}$	2,3,4	0,46	0,36	0,51	0,23
2	$\{d_{11}\}, \{d_{12}\}, \{d_{13}, d_{33}\}$	5,6	0,42	0,36	0,25	0,23
3	$\{d_{11}, d_{21}\}, \{d_{22}\}, \{d_{23}, d_{33}\}$	7,8	0,42	0,38	0,51	0,43
4	$\{d_{21}\}, \{d_{32}\}, \{d_{13}, d_{23}, d_{33}\}$	9,10,11	0,46	0,40	0,51	0,49
5	$\{d_{11}\}, \{d_{12}\}, \{d_{13}\}$	ISFS	0,36	0,36	0,23	0,23
6	$\{d_{11}\}, \{d_{12}\}, \{d_{33}\}$	ISFS	042	0,42	0,25	0,25
7	$\{d_{11}\}, \{d_{22}\}, \{d_{23}, d_{33}\}$	12,13	0,42	0,38	0,40	0,38
8	$\{d_{21}\}, \{d_{22}\}, \{d_{23}\}$	ISFS	0,38	0,38	0,44	0,44
9	$\{d_{21}\}, \{d_{32}\}, \{d_{13}\}$	ISFS	0,40	0,40	0,49	0,49
10	$\{d_{21}\}, \{d_{32}\}, \{d_{23}\}$	ISFS	0,42	0,42	0,49	0,49
11	$Ø, \{d_{32}\}, \{d_{33}\}$	EFS	-	-	-	-
12	$\{d_{11}\}, \{d_{22}\}, \{d_{23}\}$	ISFS	0,38	0,38	0,38	0,38
13	$\{d_{11}\}, \{d_{22}\}, \{d_{33}\}$	ISFS	0,42	0,42	0,40	0,40

Figure 3. Example of estimating solutions for a single-layer model



- partial overlapping of separate DPs in the form of mutual decision areas is possible (one ecision area belongs to one or more different decision problems),
- decision areas placed on operational layers should include only aprioric elementary decisions which cannot be the result of searching AVDs for even more detailed decision areas,
- number of elementary decisions in particular decision area should be limited to the smallest possible number of the most beneficial solutions according to **V/C** ratio – which means significant value growth in proportion with smallest cost growth,
- values of **V** and **C** in the aspect of cost for any decision area of particular higher layer should be the sum of $\mathbf{V}_s$ and $\mathbf{C}_s$ values for all $\mathbf{s} \in \mathbf{S}$, where $|\mathbf{S}|$ is a number of decision areas partials of a layer that is directly beneath,
- decision-making problems decomposition should be limited to the smallest possible number of layers.

Example

Global expected value of organizations value growth is equal to **V = 300 mln $**, project cost equals approximately **C = 80 mln $**. Decision area including elementary decisions No 5, No 6 and No 13 is placed in the strategic layer (see Fig. 4) and is responsible for **30%** of **V** growth (**90 mln $**) and **40%** of **C** cost (**32 mln $**). Decision areas $\mathbf{D}_1$, $\mathbf{D}_2$, $\mathbf{D}_3$ placed in the tactical layer are responsible for cost-based and percentage share according to values presented in Tab. 2.

Real cost of the IT project is dependent on elementary decisions undertaken on each decision making layers. Real evaluation of organizations value growth will be verified by the market.

ESTIMATING VALUE AND COST IN A MULTILAYER MODEL

Estimating the market value growth created due to engagement of an enterprise in implementation of a new IT project is an endeavor of high responsibility. Commonly encountered issue of significantly exceeding the budget and not being able to meet deadlines for projects of this type has been statistically proved.

Table 2. Example of V-C relation in decision-making layers

	D_1	D_2	D_3	Σ
V [%]	40	40	20	100
C [%]	30	50	20	100
V [mln $]	36,0	36,0	18,0	90,0
C [mln $]	9,6	16,0	6,4	32,0

Figure 4. Multilayer DP graph model (includes the Fig. 1 model with results No 5, No 6 i No 13 at a strategic layer)

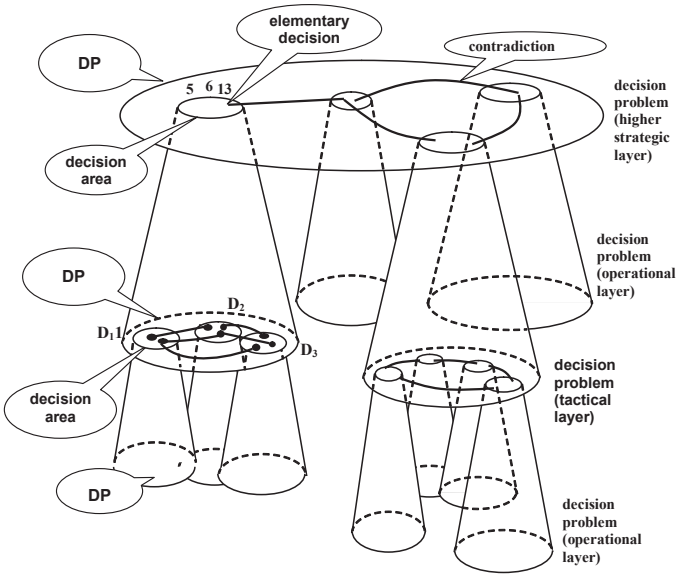


Table 3. Example of three decision variants in tactical layer

No	Groups of formulating sets	Share of AVD in D_1 [mln $]			ΣV / ΣC	V/C
		D_1	D_2	D_3		
5	$\{d_{11}\}, \{d_{12}\}, \{d_{13}\}$	18,00	10,80	3,60	32,40	4,54
		3,84	1,60	1,92	7,36	
6	$\{d_{11}\}, \{d_{12}\}, \{d_{33}\}$	18,00	10,80	9,00	37,80	4,73
		3,84	1,60	2,56	8,00	
13	$\{d_{11}\}, \{d_{22}\}, \{d_{33}\}$	18,00	10,80	9,00	37,80	2,95
		3,84	6,40	2,56	12,80	

On the basis of prior considerations the part of alternative variants of decision (AVD) with the No 5, No 6 and No 13 in particular decision areas has been converted as well as the value of **V/C** relation has been calculated.

The most profitable result has not been changed in proportion to the proportional share and, what is especially intriguing, it proved to be better than a simple reference of expected global organizations value growth (**V = 300 mln $**) to project cost (**C = 80 mln $**), which in this case equals **V/C = 3,75** (see Tab. 3). This result can indicate that decisions reached and estimated in parallel on two layers can be more precise than in a single-layer model.

Presented argumentation has some simplifications that were necessary to separate two layers (strategic and tactical) and prove that calculations elaborated in tactical layer are more precise than simple reference of global **V/C** values in strategic layer in case of the model presented in Fig. 4 .

SUMMARY

Presented approach towards hierarchic decision-making processes modeling in IT solutions has been corroborated with many test-runs performed on IT tools prototypes.[6, 7]

The article deals with an attempt to introduce weighted evaluations of economic type into a hierarchical model, which are assigned to decomposed decision making problems, layers of decisions and areas and particular elements of decisions. It is illustrated with computational examples – however, the Author is aware of the fact, that not all of the issues could be presented in a sufficient level of detail due to the complexity of this problems and editorial limitations.

Main limitation of the presented model is an assumption of model's static nature and lack of probabilistic characteristics – although the latter are being tried to change with the approximation of "percentage share/effect" of particular decision in the whole solution. Another inexactitude would be omitting the influence of synergetic relations at the value and costs. These kind of relations occur naturally due to the correlation between particular decision elements.

Author is aware of listed imperfections of the model and will be gradually eliminating them in further research on the essence and economical characteristics of highly structured decision making processes.

The Adoption and Implementation of Knowledge Management in Healthcare Operations

Nilmini Wickramasinghe, Center for the Management of Medical Technology (CMMT), Illinois Institute of Technology, 565 West Adam Street, Suite 406, Chicago, IL 60661, USA; E-mail: nilmini@stuart.iit.edu

ABSTRACT

The importance of knowledge management (KM) to organizations in today's competitive environment is being recognized as paramount and significant. This is particularly evident for health care in this country. The US healthcare system is facing numerous challenges in trying to deliver cost effective, high quality treatments and is turning to KM techniques and technologies for solutions in an attempt to achieve this goal. What is becoming of particular interest is the adoption and implementation of KM and associated KM technologies in the healthcare setting, an arena that has to date been notoriously slow to adopt technologies and new approaches for the practice management side. We examine this issue by studying the barriers encountered in the adoption and implementation of specific KM technologies in healthcare settings. With some empirical data we then develop a model that attempts to draw some conclusions and implications for orthopaedics.

Keywords: healthcare, knowledge management, adoption, implementation, orthopaedics

1.0 INTRODUCTION

The industrial economy has given way to the electronic economy creating an entirely new set of rules, opportunities, threats, and challenges (Accenture). The growth of electronic commerce (e-commerce) is vast, complex, and rapidly expanding. The evolution of the 'Information Age' in medicine is mirrored in the exponential growth of medical web pages, increasing number of online databases, and expanding services and publications available on the Internet. In order to make sense of the mass of data and information that is now being generated, organizations are turning to knowledge management techniques and technologies.

The healthcare sector is no exception to this. What we believe is not only interesting but also critical to understand is the adoption and implementation of knowledge management techniques and technologies in the healthcare sector–an industry that has to date been very slow to embrace new information technologies to benefit the administrative, as opposed to the clinical, aspect of medical practice (Battista and Hodge, 1999). To date, little has been written about knowledge management (KM) in health care, and even less on the phenomenon of the adoption and implementation of KM technologies and systems (Shakeshaft and Frankish, 2003).

In this paper we address the void in the literature by presenting some results from a study of KM adoption in a select healthcare setting. This is a case of KM in orthopedics practice in the United States. We analyze this case with a model that identifies the barriers to the process of adoption and implementation of KM in healthcare organizations. We believe that this type of research may lead to a better understanding of what it is about KM that is so crucial for health care today, and the better processes and mechanisms that would help in its implementation (Eger et al., 2003).

2.0 THE HEALTHCARE INDUSTRY

Health care is not only a growing industry but it is also the biggest service business on the globe. Between 1960-1997 the percentage of Gross Domestic Product (GDP) spent on health care by 29 members of the Organizations for Economic Cooperation and Development (OECD) nearly doubled from 3.9 to 7.6% with the US spending the most–13.6% in 1997 (OECD Health Data 98). Hence, healthcare expenditures are increasing exponentially and reducing them; i.e., offering effective and efficient quality healthcare treatment, is becoming a priority globally. Technology and automation have the potential to help reduce these costs (Institute of Medicine, 2001; Wickramasinghe, 2000).

In their continuing effort to increase the role of technology in their operations, healthcare providers are employing many opportunities to incorporate IT and telecommunications with e-commerce strategies to improve service and cost effectiveness to its key stakeholders. Many such e-initiatives, including the e-medical record, are currently being implemented in various countries; however, these alone have been found to be insufficient in achieving the desired performance and economic goals without also incorporating KM techniques and technologies into clinical and administrative practices (Wickramasinghe and Mills, 2001).

2.1 Key Factors Influencing the US Healthcare Sector

In the US, two key factors are leading the various stakeholders throughout the healthcare industry to adopt various new technologies and their aims are to enable these organizations to practice better management. These factors are: (i) managed care and (ii) the Health Insurance Portability and Accountability Act (HIPAA, Public Law 104-191).

Managed care was introduced over a decade ago as an attempt to stem the escalating costs of health care in the US. It is aimed at creating value through competition, with the intended result of providing adequate quality health care and yet to minimize, or at least to hold, the line on costs (Wickramasinghe & Silvers, 2003) The principal participants involved in any managed care arrangement include the following five categories of stakeholders: the Managed Care Organization (MCO), the purchaser, the member, the healthcare professional, and, if applicable, an administrative organization (Knight, 1998).

The Health Insurance Portability and Accountability Act was signed by President Clinton on 21 August 1996. This Act is definitely providing a strong impetus for the US healthcare sector to embrace various e-technologies because it aims to improve the productivity of the American healthcare system by encouraging the development of information systems based on the exchange of standard management and financial data and by using EDI (Electronic Data Interchange). In addition, the Act also requires organizations exchanging transactions for healthcare to follow national implementation guidelines for EDI established for this purpose. This poses many significant challenges to healthcare institutions. A key challenge is the need to make significant investments in technology to facilitate and enable these functions to take place and to also develop the appropriate standards and protocols required. In 2005-2006 the Bush Administration has also announced several initiatives to encourage the use of information technology in healthcare delivery.

2.2 The Future for Healthcare

Health care has been shaped by each nation's own set of cultures, traditions, payment mechanisms, and patient expectations. Given the common problem facing health care globally, i.e., exponentially increasing costs, no matter which particular health system one examines, the future of the healthcare industry will

be shaped by commonalities based on this key unifying problem and the common solution; namely, the embracing of new technologies to stem escalating costs and improve quality healthcare delivery.

Currently, the key future trends that will perhaps significantly impact health care include: (i) empowered consumers, (ii) e-health adaptability; and (iii) a shift to focus on healthcare prevention. Key implications of these future trends include (i) health insurance changes, (ii) workforce changes as well as changes in the roles of stakeholders within the health system, (iii) organizational changes and standardization, and (iv) the need for healthcare delivery organizations and administrators to make difficult choices regarding practice management (Wickramasinghe, 2000). In order to be well positioned to meet and manage these challenges within the US and elsewhere in the world, healthcare organizations are turning to KM techniques and technologies. Thus, as the role of KM in health care increases in importance, it becomes crucial to understand the process of adoption and implementation of KM systems.

3.0 THE NATURE OF KNOWLEDGE MANAGEMENT

Knowledge is a critical resource in any organization and is also crucial in the provision of health care. Access to the latest medical research knowledge is often the difference between life and death, between accurate or erroneous diagnosis, and between early intervention or a prolonged and costly hospital stay. Knowledge management deals with the process of creating value from an organization's intangible assets(Wickramasinghe and Mills, 2001; Edwards et al., 2005). It is an amalgamation of concepts borrowed from the artificial intelligence/knowledge based systems, software engineering, BPR (business process re-engineering), human resources management, and organizational behavior (Purvis et al. 2001). Knowledge management deals with conceptualization, review, consolidation, and action phases of creating, securing, storing, combing, coordinating, and retrieving knowledge. In essence, then, knowledge management is a process by which organizations collect, preserve, and utilize what their employees and members know about their jobs and about activities and procedures in their organization (Xu and Quaddus, 2005).

3.1 The Need for Knowledge Management

Sustainable competitive advantage is dependent on building and exploiting core competencies. In order to sustain competitive advantage, resources which are idiosyncratic (thus scarce) and difficult to transfer or replicate are required. A knowledge-based view of the firm identifies knowledge as the organizational asset that enables sustainable competitive advantage especially in hyper competitive environments or in environments experiencing radical discontinuous change.

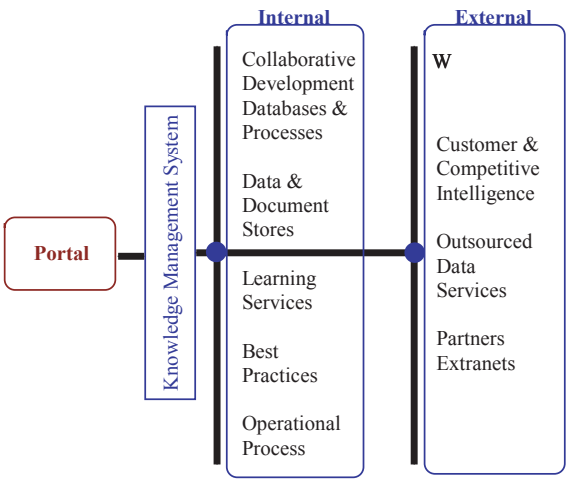
Thus, it makes sense that the organization that knows more about its customers, products, technologies, markets, and their linkages should perform better Gafni and Birch, 1993). Many organizations are drowning in information overload yet starving for knowledge. Knowledge management is believed to be the current savior of organizations, but its successful use entails much more than developing Lotus Notes' lessons learnt databases. Rather it involves the thoughtful design of various technologies to support the knowledge architecture of a specific organization (Wickramasinghe and Mills, 2001).

3.2 The Value of Knowledge Management To Healthcare Organizations

Knowledge management is a still relatively new phenomenon and a somewhat nebulous topic that needs to be explored. However, organizations in all industries, both large and small, are racing to integrate this new management tool into their infrastructure. Knowledge management caters to the critical issues of organizational adaptation, survival, and competence in the face of increasingly discontinuous environmental change (Rubenstein and Geisler 2003). Essentially, it embodies organizational processes that seek synergistic combination of data and information processing capacity of information technologies, and the creative and innovative capacity of human beings.

Knowledge management realizes the importance of safeguarding and using the collective knowledge and information of an organization. Through surveys, interviews, and analysis, knowledge management seeks to excavate, measure, assess, and evaluate the knowledge and information held within an organization with the intention of making the organization more efficient and profitable. Essentially, knowledge management sifts through the collective knowledge of an organization, codifies it into an information base, and then spreads it throughout the organization so it can be easily accessed (Wickramasinghe and Mills, 2001; Geisler, 2006).

Figure 1. Aspects of a generic knowledge management system and their importance in the organization



The knowledge management system is extremely helpful in internal and external sectors of an organization. Internally, knowledge management is designed to enhance the maintenance and organization of the data bases. Externally, it aims to make a better impact on the customer and external partners. Figure 1 depicts the importance of knowledge management in an organization.

3.3 The Role of Knowledge Management in Healthcare Organizations

The healthcare sector is characterized by its diversity and the distributiveness of its component organizations. There is a continuous process of generation of knowledge within each of these components (such as providers, patients, suppliers, payers, and regulators), as well as an immense volume of knowledge created at the interfaces among these organizations(Jadad et al., 2000; Pavia, 2001).

Healthcare provider organizations are special type of organizations in that they are for the most part motivated by topics such as quality and service, but without the profit drivers that animate private industry. At the same time they are highly professional institutions, populated by people with specialized knowledge that needs to be constantly updated, shared, and leveraged (van Beveren, 2003). This phenomenon creates even more pressure on healthcare providers and others in the sector to manage the knowledge that flows through the sector.

Although there has been little empirical investigation of how knowledge management benefits healthcare organizations, it is safe to assume that its contributions would be at least as positive as they are being shown in other sectors of the economy (Eid, 2005).

The role of knowledge management in healthcare organizations would be important in both clinical and administrative practices. Clinical care would be much more effective with increased sharing of medical knowledge and "evidence-based" experience within and among healthcare delivery organizations (Nykanen and Karimaa, 2006).

Administrative practices in healthcare organizations will benefit from the systemic interfaces of knowledge about technology, costs, "best-practices," efficiencies, and the value of cooperation. Such effects of knowledge creation and sharing would make it easier and more effective to manage the healthcare organization.

Finally, the role of knowledge management is especially crucial in the *interface* between the clinical and administrative functions. By and large these two categories of activities are separated by differentiations such as professional specializations, role in the organization, and goals and standards of practice. Hence, there is a tendency to avoid sharing knowledge and exchanging experience-based lessons so as not to upset the existing balance of power of the organization.

4.0 BARRIERS AND FACILITATORS TO THE ADOPTION AND IMPLEMENTATION OF KNOWLEDGE MANAGEMENT IN HEALTHCARE ORGANIZATIONS

There are four categories of barriers to the adoption and implementation of knowledge systems in healthcare organizations. The first is *technology* factors. These barriers are: (1) the attributes inherent in the technology, such as *compatibility* with other systems, *complexity*, and *trialability*; (2) *applicability* to the task for which the technology is being adopted; (3) *ease* of *maintenance*; (4) *quality* (in terms of errors, breakdowns, and non-responsiveness); and (5) ease of *updating* or *replacement*. Relative *ease of use* will impact the degree of implementation of the technology. Technologies that are very complex, not compatible with existing systems, or hard to maintain and to update or replace will be more difficult to adopt (Fichman and Kemerer, 1999; Kaplan, 1987).

The second category of barriers is the set of *organizational* barriers. These include the traditional barriers to technology adoption, such as political rivalries, lack of senior management support for such technology and innovation, and prior experience of the organization with similar types of technologies and their implementation. Unsuccessful past events tend to hinder any current attempts to adopt and implement technology.

In healthcare organizations there is also the added burden of the differences among organizational units in their assessment of needs for the technology and the hindering effects of the high specialization of clinical departments. The reality in such organizations is a considerable differentiation in how needs are assessed and what they mean to other units across the organization. Difficulties in establishing systemic value for a technology will hinder its adoption and implementation. Unless the technology under consideration has a wide appeal to a variety of clinical specialties (e.g., a diagnostic innovation), there will be resistance from other units and specialties to the adoption of a technology whose perceived value is restricted to a single clinical specialty (Scott et al., 2006).

A third category is *human factors*. These include cultural barriers, a complex learning curve needed to implement the technology, and unfavorable perception of the role of the technology, its value to the organization, and its chances of successfully contributing to tasks and goals of the organization Brender et al., 2006; Martens and Goodman, 2006).

In the healthcare environment there is also the impact of barriers inherent in the technological aptitudes of the clinical personnel, and their attitudes towards technological innovations in the practice of medicine (Laupacis, 1992). The usual formula for adoption of technologies by medical professionals is to follow other industries where such technologies have been implemented and successfully diffused. Only then would healthcare organizations assume the risk of adoption and their clinical personnel would be willing to adopt and implement.

The fourth and final set of barriers is the *economic factors* of the cost and cost-benefits of the technology. In the healthcare delivery environment capital expenditures for costly technological innovations are evaluated with extra care. An excellent case must be made for the value to be derived from the adoption of the technology before the purchase is authorized. It is less arduous for healthcare organizations to approve and adopt less costly technologies with widespread use in the organization.

4.1 Facilitators to Adoption and Implementation

The factors that seem to facilitate the adoption and implementation of healthcare technology are not necessarily the inverse or lack of barriers. They are affirmative factors that act to make the adoption and the implementation processes more feasible.

Two categories of these facilitating factors can be described. The first is the pressures that the external environment imposes on healthcare delivery organ izations(Wickramasinghe and Reddy, 2006). This includes such factors as the requirements imposed by payers and regulators for billing and reporting purposes. These requirements may be based on administrative and clinical procedures and methodologies that must be made possible with the adoption and implementation of innovative technologies. Thus, healthcare delivery organizations would feel compelled to act and to facilitate the adoption of these technologies.

The second category includes factors inherent in the processes of healthcare delivery and in the perceived need to make them more productive and more efficient. For example, medical errors are embedded in the processes of healthcare delivery. This problem may trigger and facilitate the adoption and implementation of technologies, whose purpose is to alleviate the problem (Institute of Medicine, 2001).

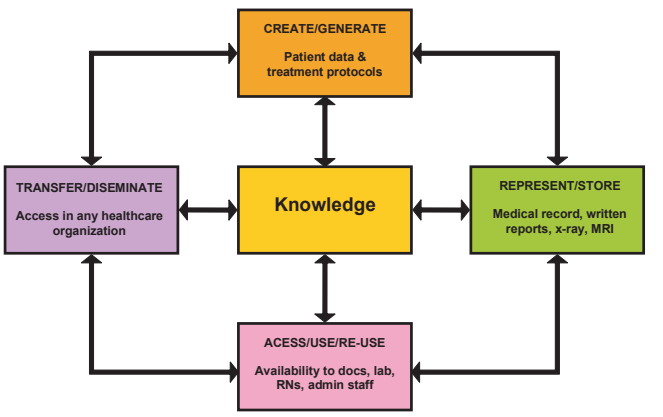
Another example includes the need to make procedures more efficient, due to such economic realities as "capitation," DRGs (Diagnosis Related Groups), and "managed care." When payors set limits to reimbursements for diagnoses and treatments, hospitals will explore ways to be more efficient and to reduce the cost of practice of medicine. Technology becomes one of the solutions, hence the impact of this situation as a facilitator of the adoption and implementation of healthcare technologies (Shakeshaft and Frankish, 2003; Nykanen and Karimaa, 2006; Kaplan, 1987).

5.0 CLINICAL EXAMPLE: OPERATING ROOM

The orthopaedic operating room represents an ideal environment for the application of a continuous improvement cycle that is dependant on the application of the tools and techniques of KM. For those patients with advanced degeneration of their hips and knees, arthroplasty of the knee and hip represent an opportunity to regain their function. Before the operation ever begins in the operating room, there are a large number of interdependent individual processes that must be completed. Each process requires data input and produces a data output such as patient history, diagnostic test and consultations. From the surgeon's and hospital's perspective, they are on a continuous cycle of addressing central issues regarding access, quality and value at the micro level, or individual patient level, as well as at the macro level, or monthly/yearly target level. The interaction between these data elements is not always maximized in terms of operating room scheduling and completion of the procedure. Moreover, as the population ages and patient's functional expectations continue to increase with their advanced knowledge of medical issues; reconstructive Orthopaedic surgeons are being presented with an increasing patient population requiring hip and knee arthroplasty. Simultaneously, the implants are becoming more sophisticated and thus more expensive. In turn, the surgeons are experiencing little change in system capacity, but are being told to improve efficiency and output, improve procedure time and eliminate redundancy. However, the system legacy is for insufficient room designs that have not been updated with the introduction of new equipment, poor integration of the equipment, inefficient scheduling and time consuming procedure preparation. Although there are many barriers to Re-Engineering the Operating Room such as the complex choreography of the perioperative processes, a dearth of data and the difficulty of aligning incentives, it is indeed possible to effect significant improvements through the application of the KM. Figure 2 outlines critical KM steps that become important in such a setting

The entire process of getting a patient to the operating room for a surgical procedure can be represented by three distinct phases: preoperative, intraopertive and postoperative. In turn, each of these phases can be further subdivided into the individual yet interdependent processes that represent each step on the surgical trajectory. As each of the individual processes are often dependant on a previous event, the capture of event and process data in a data warehouse is necessary. The diagnostic evaluation of this data, and the re-engineering of each of the deficient

Figure 2. The key steps of knowledge management



processes will then lead to increased efficiency. For example, many patients are allergic to the penicillin family of antibiotics that are often administered preoperative in order to minimize the risk of infection. For those patients who are allergic, a substitute drug requires a 45 minute monitored administration time as opposed to the much shorted administration time of the default agent. Since the antibiotic is only effective when administered prior to starting the procedure, this often means that a delay is experienced. When identified in the preoperative phase, these patients should be prepared earlier on the day of surgery and the medication administered in sufficient time such that the schedule is not delayed. This prescriptive reengineering has directly resulted from mining of the data in the information system in conjunction with an examination of the business processes and their flows. By scrutinizing the delivery of care and each individual process, increased efficiency and improved quality should be realized while maximizing value. For knee and hip arthroplasty, there are over 432 discrete processes that can be evaluated and reengineered as necessary through the application of a spectrum of KM tools and techniques (Wickramasinghe and Schaffer, 2006).

In terms of the four major categories of barriers and facilitators we identified earlier the case vignette of the operating orthopaedic OR exhibits instances of all of these. In each stage from pre-operative, intraopertive and finally postoperative various clinical and administrative technologies are necessary. By adopting the spectrum of KM tools and techniques what we find is that it becomes easier to monitor and evaluate these various technologies in action which in turn results in more effective use of the technology and efficient surgeries with heightened results. The continuous improvement also facilitates enhanced co-ordination between the various people, form surgeons, to nursing staff and even the patient, involved throughout the pre-operative, intraopertive and postoperative stages; once again with the result of superior operations and the achievement of the six quality aims outlined by the American Institute of Medicine(Institute of Medicine, 2001) and hence addresses many of the human and organizational barriers. Finally, in terms of economic factors, more efficient and effective performance as measured by faster throughput, higher quality and superior results together leads to a decrease in costs which are to a large extent due to the cumulative additive effect of various inefficiencies (Wickramasinghe and Scahffer, 2006).

6.0 DISCUSSION AND CONCLUSION

The preceding discussion has served to highlight the significance and key role for knowledge management in healthcare today. Specifically, this was done by discussing some of the major challenges facing healthcare today in terms of demographics, technology and finance and how KM tools and techniques might help to ameliorate this situation. In addition major barriers and facilitators were identified that must be considered when trying to implement an appropriate KM solution in helahtcare. Finally, an example of how beneficial the incorporation of such a perspective is in redesigning the current state of the orthopaedic OR to a future state of the OR was given. Taken together then, this paper serves to under score the importance of taking a holistic approach to addressing the challenges currently faced by healthcare. Furthermore, by focusing on diagnosing the current state and then finding appropriate solutions so it is possible to prescribe strategies to make the key inputs into the healthcare information system more effective and efficient it will then be possible to realize the value proposition for healthcare. While medical science has made revolutionary changes, healthcare in contrast has made incremental changes at best. The disparity between these two is one of the major reasons why today's healthcare industry is faced with its current challenges. We believe that by embracing the tools and techniques of KM it will be possible for healthcare to make evolutionary changes and thereby meet patients great expectations.

Aspects of Knowledge Transfer in eXtreme Programming

Jaana Nyfjord, Stockholm University/Royal Institute of Technology, Forum 100, SE-164 40 Kista, Sweden; E-mail: jaana@dsv.su.se

ABSTRACT

The reason why software projects remain vulnerable to failure is essentially based on a knowledge management (KM) problem. One observation, however, is that the research in this area assumes, or is restricted to, traditional software development approaches. By excluding newer ways of developing software, such as agile software development, important aspects of KM in software engineering have been omitted. In this paper, a theoretical analysis of extreme Programming (XP) from a KM perspective is presented. The aim is to gain understanding of how the two fields relate but also to investigate to what extent aspects of KM can be beneficial to XP. The result shows that XP is more aligned with KM than expected. More importantly, the result suggests that a creative approach to KM can generate improved efficiency, higher productivity and higher quality in multi-team XP projects. A framework that can be used to analyse how XP supports KM in multi-team settings is also proposed.

1. INTRODUCTION

The failure and cancellation rate of software projects around the globe is still alarming. A significant number of the classic problems of delayed projects, cost overruns and meeting objectives keep being reported in surveys by for example the Cutter Consortium [10] and the Standish Group [20]. The question is why these problems remain, despite well-established knowledge about them.

Backlund [2] explains that the reason to why software projects remain vulnerable to failure is essentially based on a knowledge management (KM) problem. Organisations fail to learn from their own experiences. This is also supported by for example Ye and Fay [21], who argue that many software projects fail particularly because of the lack of knowledge transfer between the members of software project teams.

According to Backlund [2], the solution to this problem is to encourage software developers to learn from their own and others' experiences and to use this knowledge to change their development practices. Iivari [13], Ye and Fay [21] and Wastell [22] go even further and suggest that the software development process should be viewed as an ongoing learning process engaging both domain specialists and software professionals. There is plenty of research arguing for the importance of KM in software development activities. Much of the work in software engineering carried out over the last twenty years should confirm this fact [3]. One observation, however, is that the research in this area assumes, or is restricted to, traditional software development approaches. By excluding newer ways of developing software, such as agile software development [1], important aspects of KM in software engineering have been omitted.

The suggestions made by for example Backlund [2] and Wastell [22] perfectly agree with the principles of the Agile Manifesto, which clearly states the value of individuals and interactions and constant customer collaboration for successful software development project outcomes [1]. The agile principles of daily collaboration between business people and developers, of face-to-face conversation for conveying information and knowledge, of building projects around motivated individuals and of continuous reflection to adjust behavior are only a few examples demonstrating what needs to be in place for a software project to succeed. This makes the agile family of methods a promising candidate to investigate from a KM perspective. Moreover, by elucidating some of the general benefits and challenges of KM and by making them explicit to the agile community may provide insights that could further enhance agile methods, such as eXtreme Programming (XP) [4] [5].

In this paper, the result of a theoretical analysis of aspects of knowledge transfer in XP is presented as a first attempt to clarify and elucidate the relationship between these two domains. The analysis is based on XP as a representative of the group of agile software development methods because XP is the agile method that is most widely used [9][1].

2. WHY KM AND XP?

In today's competitive economy where many organisations uncover the most opportunities from intellectual rather than physical capital [14], it is crucial that knowledge is managed. Knowledge management in software teams is no exception. The large amount of knowledge acquired during software development, e.g. knowledge associated with the development process, the business domain of the project and the developed software [2][13] must be managed for several reasons: (a) as a means to help software development teams to be able to leverage that knowledge and (b) which can prevent software projects from failing as discussed previously [2] [21] [22]. The fact that, organisations that make sure that knowledge transfer is taking place in a systematic and controlled manner have shown to demonstrate great cost savings [6] [12] [14] [16], should be enough as argument in this context. More importantly, the argument applies to XP teams as well. XP is a minimalist, highly disciplined software development method, which when used appropriately, has a proven capability to produce planned results in a timely manner. However, potential method improvements can and should always apply. To be even more efficient, effective, productive and successful, XP teams need to be equipped with appropriate support to further improve and facilitate the development of software. This could, in certain contexts, be achieved by introducing and by clarifying the value of KM to XP. For example, in terms of supporting scalability of XP which is an issue that has been heavily debated over the past years, e.g. by Boehm and Turner [6], Cao et al. [7], Crocker [8], Paulk [17] and Reifer et al. [18]. In small co-located XP teams, managing knowledge and knowledge transfer may not be an issue, but for larger or distributed XP teams, it is believed that KM may provide valuable support for scaling XP. Effective management of knowledge between projects is another issue that calls for further exploration. For example, finding patterns or techniques, e.g. on the basis of retrospectives [21], for fine-tuning behaviour also in inter-project situations could help in achieving gains in performance. Thus, it is argued that a structured analysis of XP from a KM perspective is needed. It is important to gain understanding of how the two fields relate as well as to investigate to what extent aspects of KM can be beneficial to XP. In the following, the results of the first step towards this goal will be discussed.

3. CHALLENGES OF KNOWLEDGE TRANSFER

Knowledge is transferred in organisations everyday, in a controlled or/or uncontrolled way. Ideas exchanged by people in the hallways, information forwarded in emails or posted on notice boards are only a few examples of everyday knowledge transfer. The question is how an organisation or a team can transfer knowledge effectively so that the whole organisation or team can truly benefit from it.

There are several theories about how to control knowledge transfer. For example, Dixon [12] presents a spiral model specifying eight steps that must be taken for creating and leveraging knowledge within an organisation. The model specifies three criteria that determine how a particular transfer method will work in a particular situation. The three criteria: who the intended receiver is, nature of task and type of knowledge to be transferred have an impact on the choice transfer

method and how knowledge can be translated into a usable form [12]. Davenport's and Prusak's [11] reasoning about successful knowledge transfer involves the same ideas. When knowledge is to be transferred, the transfer method must always suit the culture and this involves considering factors that have an impact on the transferring process, such as the kind of knowledge to be transferred and the culture of the team [11]. The latter have also identified a set of common cultural factors, "frictions", which challenge effective knowledge transfer. In Table 1, the frictions and possible solutions to prevent these frictions from occurring are summarised [11].

4. ANALYSIS OF XP FROM A KM PERSPECTIVE

KM is a large multi-disciplinary field. Therefore, it necessarily covers a larger domain than relevant for the analysis focused on in this paper. For example, it specifies a number of areas that primarily describe KM practices and activities from a business and managerial point of view, which are not always specific to software engineering or XP [11][12][14][16]. However, this research aims at clarifying and elucidating the relationship between KM and XP, starting with an investigation to determine whether, and to what extent, XP deals with some of the major challenges of effective knowledge transfer as presented in Table 1 [11]. Consequently, the analysis focuses on this topic.

XP is analysed as a whole method, including its values, principles and primary practices [5]. However, individual parts of XP are discussed when specifically addressing any of the cultural frictions. In Table 2, a summary of the results of the analysis is presented. In the second column, the XP values, principles and practices that are comparable to the solutions suggested by Davenport and Prusak [11] are indicated.

According to Davenport and Prusak [11], the values, norms and behaviours that make up a team's culture are the principal determinants of how successfully important knowledge is created and transferred. This analysis shows that all the XP values, principles and primary practices are in various degree counterparts to the solutions to effective knowledge transfer [11]. In the following subsections an accompanying motivation for the results in Table 2 is presented.

4.1 Values

All of the frictions that can inhibit effective knowledge transfer are accounted for in the values of XP. Lack of trust, lack of time and meeting points, having people from different cultures on the team, intolerance for mistakes and beliefs that knowledge is ascribed to certain individuals or groups [11] are covered by the values of communication, respect, feedback, courage and simplicity [4] [5].

Table 1. Cultural factors that inhibit knowledge transfer and possible solutions [11]

FRICTION	POSSIBLE SOLUTIONS
Lack of trust	Build relationships and trust through face-to-face meetings
Different cultures, frames of reference, vocabularies	Create common ground through education, discussion, teaming, publications, job rotation
Lack of time and meeting places	Establish times and places for knowledge transfers: talk rooms, fairs, conference reports
Status and rewards go to knowledge owners	Evaluate performance and provide incentives based on sharing
Lack of absorptive capacity in recipients	Educate employees for flexibility; provide time for learning; hire for openness to ideas
Belief that knowledge is prerogative of particular groups, "not invented here-syndrome"	Encourage non-hierarchical approach to knowledge; quality of ideas more important than status of source
Intolerance for mistakes or need for help	Accept and reward creative errors and collaboration; no loss of status from not knowing everything

Table 2. How XP deals with "frictions", i.e. with barriers to effective knowledge transfer

FRICTION	XP		
	Values	**Principles**	**Practices**
Lack of trust	Communication; Respect; Courage; Feed-back	Humanity; Mutual benefit; Accepted responsibility; Improvement; Reflection; Opportunity	Whole team; Sit together; Informative workspace; Pair programming; Slack
Different cultures, frames of reference, vocabularies	Communication; Respect; Courage; Feed-back; Simplicity	Humanity; Diversity; Mutual benefit; Improvement; Reflection; Opportunity	Whole team; Sit together; Informative workspace; Pair programming; Stories; Test-first programming
Lack of time and meeting places	Communication; Respect; Feed-back; Simplicity; Courage	Mutual benefit; Diversity; Improvement; Reflection; Opportunity	Whole team; Sit together; Informative workspace; Pair programming; Weekly/Quarterly cycles
Status and rewards go to knowledge owners	Respect; Feed-back; Communication; Courage	Humanity; Failure; Mutual benefit; Reflection; Opportunity	Whole team; Sit together; Informative workspace; Pair programming; Weekly/Quarterly cycles; Continuous integration
Lack of absorptive capacity in recipients	Communication; Respect; Feed-back; Courage; Simplicity	Humanity; Failure; Mutual benefit; Reflection; Opportunity	Whole team; Sit together; Informative workspace; Pair programming
Belief that knowledge is prerogative of particular groups, "not invented here-syndrome"	Respect; Communication; Feed-back; Courage; Simplicity	Humanity; Failure; Mutual benefit; Reflection; Opportunity; Improvement	Whole team; Sit together; Informative workspace; Pair programming
Intolerance for mistakes or need for help	Respect; Communication; Feed-back; Courage; Simplicity	Humanity; Failure; Mutual benefit; Reflection; Opportunity; Improvement	Whole team; Sit together; Informative workspace; Pair programming; Test-first programming

Communication in XP means building relations by conveying information to and within a development team through openness and steady face-to-face conversation, which prevents frictions such as lack of trust and lack of understanding from occurring.

Feedback is closely related to communication and addresses the value of keeping the project and the team on track. It is also emphasised that feedback is most useful if it is done rapidly. The time between an action and its feedback is critical to learning and the ability to making any changes or corrections needed [4]. In this respect, XP encourages effective knowledge transfer, knowledge creation and the establishment of learning environments. More importantly, the overall goal of communication and feedback is to achieve a shared understanding among team members to strengthen teambuilding and the feeling of shared project responsibility, which prevents status and rewards from going to knowledge owners but which also discourages a hierarchical approach to knowledge.

To accomplish good communication and feedback requires respect and tolerance among team members. Therefore, respect is one of the core values in XP. By respecting other peoples' backgrounds and frames of reference, common grounds for constructive collaboration, discussion and knowledge and information exchange can be built. In this context, respect also mitigates the risk for intolerance for mistakes. XP instead pushes for creativity and time for learning. Errors are regarded as a mechanism to learning rather than failure. To be creative and to learn new things also requires courage, which is emphasised through the value of courage in XP.

Related to all the previous values is simplicity, which facilitates communication, feedback as well as courage. For example, a simple design with very simple code or simple documentation can be easily understood by every person in the team, whether a customer or programmer, which also provides a foundation for effective knowledge transfer.

4.2 Principles

The XP principles can be regarded as counterparts to the solutions to overcome cultural frictions in knowledge transfer presented by Davenport and Prusak [11]. The XP principles of humanity, mutual benefit, diversity, failure, reflection, opportunity and improvement are particularly comparable to common ways of resolving cultural problems of knowledge transfer.

The principle of humanity signifies the need to meet basic human needs in projects, such as building relationships and connection, which is primarily accomplished by communication in XP. The most effective way to communicate is through face-to-face conversation because conversation allows dialogue, i.e. it allows explanation, clarification and direct feedback. In this respect, humanity facilitates building relationships which creates incentives to share ideas and knowledge and therefore amplifies knowledge transfer. Davenport and Prusak [11] state that conversation is fundamental to knowledge transfer because it provides a simple way to discover what people know and to share knowledge with colleagues, which results in new or improved knowledge for the whole organisation.

The principle of mutual benefit is probably the most important of all the XP principles. Basically, it means maintaining good working relationships in a project team. By making sure that everyone on a project team are benefited from any project activities, e.g. documentation, provides a starting place for good working environments and gives a concrete incentive for people to share and exchange ideas.

The principle of diversity suggests that effectiveness comes from teams where people come from different backgrounds, with different skills and perspectives. The key is, at any stage of the project, to make people with important or necessary skills available as a resource for a project to succeed. This principle therefore undoubtedly encourages knowledge transfer.

Failure is another principle that clearly encourages knowledge transfer. More specifically, this principle addresses the problem of intolerance for mistakes or need for help which can inhibit effective knowledge transfer. Because valuable knowledge can sometimes be difficult to obtain, one way is to try out different solutions where failure can provide an important learning mechanism [5].

Related to failure are the principles of opportunity, reflection and improvement. In XP, improvement is imperative. To reach quality and excellence, problems need to be seen as opportunities for change, for learning and for improvement. For this to take place, a team needs to reflect on their work, i.e. on how they work. This is realised through project retrospectives [19] or similar techniques, which include analysing factors of success and failure and to openly expose them and to learn from them.

4.3 Practices

The practices of XP can be viewed as "techniques for rapidly building and disseminating knowledge among members of a development team" [5], where the goal is to have all team members share the same view and expectations of the system and the project. As indicated in Table 2, this is primarily achieved by the XP practices of whole team, sitting together, informative workspace, stories, incremental design and pair programming. The first three practices are tightly interrelated. The basic idea of whole team in XP is that the team consists of people with the all skills and knowledge necessary for a project to succeed, which includes both customers and developers. The aim is also to build projects around motivated individuals who share the responsibility for supporting each other's work and the growth and learning of the whole team [5].

The practice of whole team is reinforced by the practice of sitting together. In XP, the whole team works co-located in an open space, which provides time for physical proximity and for meeting and discussing face-to-face. It is argued that the more time the team works physically co-located, the more humane and productive the project [5]. By working together and physically closer to each other improves communication, makes it easier to build relationships and naturally establishes time and places for knowledge transfers, which are keys to overcome many of the cultural barriers to effective knowledge transfer.

In addition, the practice of informative workspace, e.g. a big visible chart, does not only convey project related information to any interested stakeholder, it also serves as a natural meeting point at any time because this is where an XP team gathers for the daily stand-up meeting [4], for project planning or for any discussion for that matter. This prevents a situation where difficulties with finding meeting places would occur. Furthermore, the fact that informative workspaces are visible and open to everyone provides a mechanism for spreading information and knowledge itself, which is also reflected by the name of the practice. In this way, also the problem of beliefs that information or knowledge is sanctioned to particular people, i.e. the "not invented here-syndrome" [11], is solved.

Stories create common ground for discussion and exchanging ideas and knowledge about the system to be developed. Stories also help the team to find common vocabularies and to define a common frame of reference which facilitates knowledge transfer.

From a knowledge transfer perspective, the XP practices of incremental design, weekly and quarterly cycle allow a team to collect information, learn the system and the technology and understand customer needs in small, iterative steps. Such an approach provides time for feedback and for making timely changes and refinements rather than making early design decisions based on speculative guesses which can have a negative impact on the learning process as well as on the project results.

Pair programming involves many well-known knowledge transfer techniques, such as pair work, shadowing and mentoring [12]. More specifically, pair programming provides space for dialogue between two persons and aims to increase overall quality by offering team members the possibility to clarify ideas, exchange knowledge and help each other with the tasks at hand. This is regarded best practice for transferring or recreating tacit knowledge [14]. With shadowing for example, a less experienced developer observes more experienced developers in their activities to learn how their more experienced counterparts approach their work. By discussing his or her observations with the expert, tacit knowledge is made explicit and knowledge transfer is truly achieved [14]. In addition, as all pairs in an XP team rotate on a regular basis enables spreading knowledge about the project throughout the entire team which mitigates the risk of loosing critical knowledge if a person would leave the team.

5. CONCLUSIONS

To successfully transfer an individual's knowledge in practice, a team must actively work out ways to make personal knowledge available to others. This is a central activity in the knowledge creating company [16]. By providing guidance on how to build relationships, create incentives for sharing knowledge, build up acceptance for creative errors and for learning in software projects, this analysis shows that good support for knowledge creation and knowledge transfer can be identified in all the values, principles and practices of XP. More specifically,

based on this analysis, our conclusion is that within a single team XP practices are sufficient for KM and no separate KM is needed. Based on our experiences, the real KM challenge lies in how to share the knowledge created in XP teams with other parts of the organisation. By using the framework used in this analysis it would be possible to analyse how XP supports KM in multi-team settings. Our understanding is that XP does not support KM in these cases. More specifically, the result gives substantial support to an underlying hypothesis that KM can provide valuable support to large XP teams, thereby facilitating scalability - an issue that has been heavily debated over the past years. If the hypothesis were verified, the KM effects measured and empirically validated would provide a good foundation for designing recommendations for how to use KM when scaling up XP.

ABSTRACT

In this paper, we elaborate on how feature selection methods traditionally used in classification problems can be adapted for clustering problems, assuming that the number of clusters is not known a priori. Computational complexity of each described algorithm is provided. Empirical results in six bioinformatics datasets illustrate that the adaptation of four well-known supervised methods for feature selection (correlation-based, consistency-based, wrapper of k-NN classifier, and C4.5) can be useful for clustering tasks.

1. INTRODUCTION

Successful data mining applications depend on several factors. The availability of suitable feature selection methods is one of such factors. Feature selection involves choosing a subset of original variables (attributes) by eliminating the redundant, uninformative, and noisy ones. This issue has been broadly investigated in supervised learning tasks for which datasets with many features are available, like in text mining and gene expression data analysis. Under this perspective, there are many potential benefits of feature selection like, for instance [3]: facilitating data visualization and understanding, reducing the measurement and storage requirements, reducing training and utilization times, and defying the curse of dimensionality. Many of these benefits can also be achieved in unsupervised learning (clustering). However, most of the existing supervised methods for feature selection rely on assessing how well some features discriminate among a set of predefined classes. These classes are not available in clustering tasks, in which one seeks to identify a finite set of categories (clusters) to describe a given dataset. In this sense, it is difficult to assess the relevance of a subset of features for describing classes that are not known a priori. Since the optimal number of clusters and the optimal feature subset are inter-related, the feature selection task becomes even more challenging when the number of clusters is unknown [7], which is our assumption in this work.

Although many algorithms for clustering have been proposed in the literature, relatively little work has been done on feature selection for clustering [2][7]. Most clustering methods assume that all features are equally important [2]. However, some features may be more important than others for inducing clusters. In these cases, feature selection methods can be useful. Liu and Yu [9] provide a comprehensive survey of feature selection algorithms for classification and clustering. In brief, there are two fundamentally different approaches for feature selection [8]: wrapper and filter. The former evaluates the subset of selected features using criteria based on the results of clustering algorithms, i.e., the clustering method is wrapped into the feature selection procedure. The latter involves performing feature assessments based on intrinsic properties of the data. These properties are presumed to affect the performance of the clustering algorithm, but they are not a direct measure of its performance, i.e., the feature set is filtered without considering the clustering algorithm that will be ultimately used. In general, filters are less computationally expensive than wrappers, which may be superior in relation to the quality of the clusters found. It is also possible to combine filters and wrappers, obtaining hybrid approaches. Doing so, one can expect to have a reasonable tradeoff between efficiency (computational effort) and efficacy (partition quality). In this sense, we here elaborate on how feature selection methods traditionally used in classification problems can be adapted for clustering tasks.

2. CLUSTERING ALGORITHM

We assume that *clustering* involves the partitioning of a set $\mathbf{X}$ of instances into a collection of mutually disjoint subsets $\boldsymbol{C}_i$ of $\mathbf{X}$. Formally, let us consider a set of N instances $\mathbf{X}=\{\mathbf{x}_1,\mathbf{x}_2,...,\mathbf{x}_N\}$ to be clustered, where each $\mathbf{x}_i \in \Re^\rho$ is a vector consisting of ρ measurements. The instances must be clustered into non-overlapping groups $\mathbf{C}=\{\mathbf{C}_1,\mathbf{C}_2,...,\mathbf{C}_k\}$ where k is the number of clusters, such that:

$$\mathbf{C}_1 \cup \mathbf{C}_2 \cup ... \cup \mathbf{C}_k = \mathbf{X}\ ,\ \mathbf{C}_i \neq \varnothing, \text{ and } \mathbf{C}_i \cap \mathbf{C}_j = \varnothing \text{ for } i \neq j. \quad (1)$$

After partitioning the dataset, instances that belong to the same cluster should be more similar to each other than instances that belong to different clusters. Therefore, it is necessary to devise means of evaluating similarities between instances. This problem is often tackled indirectly, i.e. distance measures are used to quantify dissimilarities between instances. Several dissimilarity measures can be used for clustering tasks. We here use the Euclidean distance.

The simplified silhouette [5] is used for estimating the number of clusters. Before describing the *simplified silhouette*, let us introduce the silhouette proposed in [6]. Consider an instance i belonging to cluster $\mathbf{A}$. So, the average dissimilarity of i to all other instances of $\mathbf{A}$ is denoted by $a(i)$. Now let us take into account cluster $\mathbf{C}$. The average dissimilarity of i to all instances of $\mathbf{C}$ will be called $d(i,\mathbf{C})$. After computing $d(i,\mathbf{C})$ for all clusters $\mathbf{C} \neq \mathbf{A}$, the smallest one is selected, i.e. $b(i) = \min d(i,\mathbf{C})$, $\mathbf{C} \neq \mathbf{A}$. This value represents the dissimilarity of i to its neighbor cluster, and the silhouette $s(i)$ is:

$$s(i) = \frac{b(i) - a(i)}{max\{a(i)\ b(i)\}} \quad (2)$$

The higher $s(i)$ the better the assignment of instance i to a given cluster. In addition, if $s(i)$ is equal to zero, then it is not clear whether i should have been assigned to its current cluster or to a neighboring one. Finally, if cluster $\mathbf{A}$ is a singleton, then $s(i)$ is not defined and the most neutral choice is to set $s(i) = 0$ [6]. The average of $s(i)$ over $i = 1,2,...,N$ can be used as a criterion to assess the quality of a given partition. Doing so, the best data partition is achieved when the silhouette is maximized.

The original silhouette [6] depends on the computation of all distances between instances, leading to a computational cost of $O(N^2)$, which is often not sufficiently efficient for real-world applications. To circumvent this limitation, a *simplified silhouette* can be used. The simplified silhouette (SS) [5] is based on the computation of distances between instances and cluster centroids. More specifically, the term $a(i)$ of Eqn. (2) becomes the dissimilarity of instance i to its corresponding cluster ($\mathbf{A}$) centroid. Similarly, instead of computing $d(i,\mathbf{C})$ as the average dissimilarity of i to all instances of $\mathbf{C}$, $\mathbf{C}\neq\mathbf{A}$, distances between i and the centroid of $\mathbf{C}$ are computed. While these modifications reduce the computational cost from $O(N^2)$ to $O(N)$, empirical results [5] suggest that the partition quality may be not significantly affected.

The computation of the original silhouette [6], as well as of its *simplified* version [5], only depends on the partitions found. Therefore, such silhouettes can be applied

to assess partitions found by several clustering algorithms. We adopt the *k*-means algorithm to obtain partitions to be evaluated by the simplified silhouette (SS). Roughly speaking, *k*-means is designed to minimize the sum of distances between instances and nearest centroids. From the SS criterion viewpoint, good partitions are also obtained when this minimization is suitably performed, as well as when the clusters are well separated. Thus, although other clustering algorithms could be used, our approach favors a synergy between *k*-means and SS. In particular, we perform multiple runs of *k*-means (for different values of *k*) and then choose the best obtained partition according to the SS value. It is also known that *k*-means may get stuck at suboptimal solutions for a given *k*. To alleviate this limitation, one can perform multiple runs of *k*-means for a fixed *k*. Fig. 1 summarizes the sampling strategy here used to find data partitions. The *correct* number of clusters k^* is automatically estimated by means of the simplified silhouette.

Provided that the computational cost of *k*-means is $O(t \cdot k \cdot \rho \cdot N)$, where *t* is the number of iterations, the overall computational cost of the sampling strategy for *k*-means (Fig. 1) is estimated as $O((k_{max} - k_{min}+1) \cdot np \cdot (t \cdot k \cdot \rho \cdot N))$. In what concerns the minimum and maximum number of clusters (k_{min} and k_{max}, respectively) let us assume a scenario in which domain knowledge is not available. In such a scenario, searching for a solution in a suitable subset of the search space in terms of *k* is desirable. To that end, a rule of thumb [11] involves choosing values for *k* from the set $\{2,...,N^{1/2}\}$. Then, the resultant overall computational cost of the used sampling strategy for *k*-means is estimated as $O(\rho \cdot N^2)$ - assuming that the number of assessed partitions, *np*, and the number of *k*-means iterations, *t*, are significantly less than *N*. From this point of view, if domain knowledge regarding k^* (or a range for its probable values) is available and $k^* << N$, then the resultant overall computational cost of the used sampling strategy for *k*-means is estimated as $O(\rho \cdot N)$.

So far, we have described a procedure to find data partitions (the *correct* number of clusters k^* is estimated according to the SS criterion), assuming that a set of ρ features is provided. In the next section, we discuss how feature selection methods traditionally used in classification problems can be adapted for clustering problems.

3. METHODS FOR FEATURE SELECTION

Most of the commonly used supervised methods for feature selection rely on assessing how well some features discriminate among a set of predefined classes, which are not known in clustering problems. Therefore, supervised feature selection methods cannot be directly applied in these problems. However, the difficulty originated from the lack of information concerning the classes can be circumvented by assuming that a set of clusters can be modeled as being a set of different classes. Doing so, supervised methods can be adapted for selecting features in clustering tasks. In our work, we hypothesized that supervised methods can be used to determine the relevant features that model a set of clusters obtained by *k*-means. In this sense, a simple alternative involves running *k*-means for all available features and then select the relevant ones according to their importance to the found clusters. Although this approach is reasonable, the optimal number of clusters and the optimal feature subset are often inter-related [7]. Since we assume that the number of clusters is not known a priori, i.e., it is estimated by the silhouette-based clustering method (Fig. 1), we believe that an exploratory approach is better suited for our purposes.

An exhaustive search for all the possible feature subsets is often computationally intractable – the order of the search space is $O(2^p)$. Thus, sequential search algorithms (e.g. forward, backward, and bidirectional) are widely used. Forward methods tend to be particularly problematic when supervised methods are adapted for clustering problems, mainly because it is difficult for them to select feature subsets that are good *copredictors* of the clusters if none of these *copredictors* is a good *predictor* of the clusters by itself [1]. In these cases, backward selection can succeed because it works by eliminating features rather than successively adding them. However, backward methods are often less efficient than forward methods. Although the approach here used does not strictly conform to the commonly used categorization for sequential selection, it can be viewed as a backward method, because it removes features from an initially complete set, as presented in the algorithm illustrated in Fig. 2. This algorithm was designed for exploring the interactions between clustering results (i.e., number of clusters and corresponding partitions) and selected features. As discussed in Section 2, the computational complexity of step 2 is estimated as $O(\rho \cdot N^2)$ when $k_{min}=2$ and $k_{max}=N^{1/2}$ – assuming that domain knowledge is not available to set *k*. Let us call *I* the number of iterations of the algorithm depicted in Fig. 2. Thus, with a little notation abuse, the overall computational cost of this algorithm is $O(I \cdot [\rho \cdot N^2 + M])$, where *M* is the computational cost of each particular feature selection used in step 3. In the following, we briefly describe four well-known supervised feature selection methods that can be used in this step.

3.1 Correlation Feature Selection (CFS)

Correlation-based feature selection (CFS) [4] evaluates subsets of features by means of a heuristic that considers the usefulness of individual features for predicting the class (in our case cluster labels represent the classes) along with the level of inter-correlation among them. Let $\bar{r}_{cf}$ be the average feature-class correlation and $\bar{r}_{ff}$ be average feature-feature inter-correlation. The $Merit_s$ of a feature subset S containing ρ_s features is given by:

$$Merit_s = \frac{\rho_s \cdot \bar{r}_{cf}}{\sqrt{\rho_s + \rho_s \cdot (\rho_s - 1) \cdot \bar{r}_{ff}}} \quad (3)$$

The numerator estimates the prediction capability of the features in S in relation to the cluster, whereas the denominator indicates the redundancy level among them. The correlation between two discrete random variables (features) X and Y is computed according to the Symmetrical Uncertainty (SU):

$$SU = 2 \cdot \frac{H(Y) - H(Y|X)}{H(Y) + H(X)} \quad (4)$$

Figure 1. Sampling strategy for k-means

1. Choose k_{min}, k_{max}, and *np*.
2. SSV← -1; / SSV = Simplified Silhouette Value /
3. For each $k \in \{k_{min},...,k_{max}\}$ do:
   3.1 Generate *np* random initial partitions of instances into *k* nonempty clusters;
   3.2 Run *k*-means for each initial partition generated in step 3.1, and compute its corresponding simplified silhouette. Let the best obtained value be BOV;
   3.3 If (BOV>SSV) then {
   SSV←BOV;
   $k^* \leftarrow k$;
   Hold the corresponding partition for k^*.
   }
4. Return SSV and its corresponding data partition for k^*.

Figure 2. Adapting supervised feature selection for k-means

Let the complete feature set be *C,* and the feature subsets obtained in two consecutive iterations be *S'* and *S''*. The algorithm for feature selection can be summarized as:

1. *S'*← *C*; / initially all features are used to get partitions /
2. Run the adopted sampling strategy for *k*-means considering the feature subset *S'*;
3. *S''* ← {feature subset achieved from supervised selection, for which the clusters of the current partition are considered classes};
5. If (*S''*=*S'*) then:
   5.1 Hold the current partition and the respective feature subset;
   5.2 Stop.
   Else (S'← S'' & go to Step 2);

where *H(Y)* and *H(Y/X)* are given by equations (5) and (6) respectively:

$$H(Y) = -\sum_i p(y_i)\log_2 p(y_i) \quad (5)$$

$$H(Y|X) = -\sum_j p(x_j)\sum_i p(y_i|x_j)\cdot\log_2 p(y_i|x_j) \quad (6)$$

where $p(x_j)$ is the probability for values of *X*. Numeric features are discretized before computing correlations, and a forward selection technique is used to search for the feature subset. The complexity of CFS can be estimated as $M=O(\rho^2 \cdot N)$, then the total computational cost of the algorithm depicted in Fig. 2 is estimated as $O(I\cdot[\rho\cdot N^2+\rho^2\cdot N])$ when CFS is used in step 3.

3.2 Consistency-based Evaluation (CBE)

Liu and Setiono [10] propose that two instances are inconsistent if they match except for their class labels. Assuming that *NC* is the number of distinct combinations of feature values for a given subset of features *S*, the consistency of this subset can be measured by:

$$Consistency_S = 1 - \frac{\sum_{i=1}^{NC}(|D_i| - |M_i|)}{N} \quad (7)$$

where $|D_i|$ and $|M_i|$ are the number of occurrences of the *i*th feature value combination and the cardinality of the majority class, respectively. *N* is the number of dataset instances. Numeric features are discretized before computing the consistency of a given set of features *S*, and a forward selection technique is used to search for the subset of features. The overall computational cost of the algorithm depicted in Fig. 2 is estimated as $O(I\cdot[\rho\cdot N^2+\rho^2\cdot N])$ when CBE is used in step 3.

3.3 Wrapper of k-NN Classifier (W-KNN)

This method uses the *k*-Nearest Neighbor (*k*-NN) classifier [1] as the target learning algorithm to assess the quality of subsets of attributes by means of a forward selection based search. Each feature subset is evaluated according to the *k*-NN accuracy achieved in cross-validation procedure. The *k*-NN classifier was chosen because it is a distance-based method. Since the clustering method used in this work is also based on the computation of distances between instances, a synergy between feature selection and clustering can be favored. The incorporation of W-KNN in the algorithm summarized Fig. 2 leads to a computational cost estimated as $O(I\cdot\rho^3\cdot N^2)$.

3.4 C4.5 Decision Tree

The *C4.5* [12] classifier performs feature selection as part of a decision tree building process, in which a subset of features is selected according to an information gain criterion. We assume that the features selected by *C4.5* can also be interesting to model the clusters of a given partition. More precisely, features selected by *C4.5* will form *S´´* in step 3 of the algorithm in Fig. 2. The overall computational cost of the resultant algorithm is estimated as $O(I\cdot\rho\cdot N^2)$.

3.5 Computational Complexity Summary

It is expected that the number of iterations (*I*) of the algorithm depicted in Fig. 2 is significantly less than both ρ and *N*. Indeed, the experimental results to be reported in the next section somehow support this claim. Considering that this assumption is reasonable, Table 1 summarizes the overall computational costs of the feature selection methods here used (2nd column). In the last column we provide corresponding estimates for applications in which domain knowledge is available to set the number of clusters (see discussion in Section 2 for further details).

Table 1. Time complexity summary

Method	k_{min}=2 and $k_{max}=N^{1/2}$	Domain knowledge
CFS	$O(\rho\cdot N^2+\rho^2\cdot N)$	$O(\rho^2\cdot N)$
CBE	$O(\rho\cdot N^2+\rho^2\cdot N)$	$O(\rho^2\cdot N)$
W-KNN	$O(\rho^3\cdot N^2)$	$O(\rho^3\cdot N^2)$
C4.5	$O(\rho\cdot N^2)$	$O(\rho\cdot N\cdot log_2 N)$

4. EMPIRICAL EVALUATION

The assessment of clustering accuracy often requires datasets for which the clusters are a priori known. We have performed experiments in six bioinformatics datasets [13]. Five datasets, here called Bio1, Bio2, Bio3, Bio4, and Bio5, are composed of 400 genes (instances) described by 20 measurements (features). These are formed by synthetic data with error distributions derived from real-world data, and contain six approximately equal-sized clusters. In addition, we have used a real-world dataset (*yeast galactose*) that is composed of 20 measurements and 205 genes. In this dataset, the expression patterns reflect four functional categories (clusters). The datasets used in the experiments reported here take into account four repeated measurements. From now on, the correct clusters will be called classes, whereas the term cluster will refer to each group of similar instances found by a clustering algorithm. However, although the class corresponding to each gene is known a priori, this information was not used in the clustering process. Thus, the quality of the partitions obtained can be assessed by verifying the degree for which the obtained clusters match the classes. Since the assessed approaches have systematically found a number of clusters that is approximately equal to the correct ones, a simple and intuitive way of evaluating the accuracy of the obtained partitions involves applying some measure of classification quality like the class error (CE), which is the percentage of the instances misclassified in relation to the total number of instances.

In all experiments, we have set k_{min}=2, $k_{max}=N^{1/2}$, and *np*=20, following the elaboration described in Section 3. Tables 2-7 summarize the average results obtained in five runs of each method. In such tables, *I*, ρ*, *k**, *CE*, and *CT* stand for number of iterations, number of selected features, estimated number of clusters, class error and computing times (in a Pentium IV, 3 GHz CPU, 1 GB RAM), respectively. Small variances have been observed for all the assessed aspects. Accordingly, only subtle differences were observed in relation to the found partitions. Finally, the last line of each table refers to the results obtained from the sampling strategy for *k*-means without feature selection.

For most of the assessed methods, the subsets of selected features are significantly smaller than the complete feature sets. In brief, good data partitions were obtained in most of the performed experiments, suggesting that the assessed methods can be useful for clustering gene expression data. CFS presented considerably worse results in most of the performed experiments. CBE, W-KNN, and C4.5, by their turn, have presented similar results, though significantly different results have been obtained for particular datasets. For instance, C4.5 has shown a better performance than both CBE and W-KNN in terms of *CE* in Bio2, although selecting more features. On the other hand, both CBE and W-KNN have provided

Table 2. Dataset Bio1

Method	*I*	ρ*	*k**	CE (%)	CT(s)
CFS	1	17	6	0.00	3.5
CBE	1	2	6	0.50	2.7
W-KNN	1	2	6	0.00	27.7
C4.5	1	2	6	0.00	2.7
All features	-	20	6	0.00	2.0

Table 3. Dataset Bio2

Method	*I*	ρ*	*k**	CE(%)	CT(s)
CFS	1	19	5	16.75	3.1
CBE	1	2	4	33.75	2.1
W-KNN	1	2	4	33.25	25.0
C4.5	1	4	5	16.75	2.1
All features	-	20	5	16.75	1.4

Table 4. Dataset Bio3

Method	*I*	ρ*	*k**	CE(%)	CT(s)
CFS	1	18	6	0.00	2.8
CBE	1	2	6	0.25	2.0
W-KNN	1	2	6	0.00	28.8
C4.5	1	4	6	0.00	2.1
All features	-	20	6	0.00	1.4

Table 5. Dataset Bio4

Method	*I*	ρ*	*k**	CE(%)	CT(s)
CFS	1	11	4	33.50	2.6
CBE	1	2	4	33.50	2.1
W-KNN	1	2	4	33.50	25.6
C4.5	1	4	4	33.50	2.0
All features	-	20	4	33.50	1.5

Table 6. Dataset Bio5

Method	*I*	ρ*	*k**	CE(%)	CT(s)
CFS	1	1	6	0.25	1.8
CBE	1	1	6	0.25	1.9
W-KNN	1	2	6	0.00	39.1
C4.5	1	2	5	17.50	1.9
All features	-	20	4	33.50	1.4

Table 7. Dataset yeast

Method	*I*	ρ*	*k**	CE(%)	CT(s)
CFS	1	1	3	7.80	1.2
CBE	1	1	3	7.80	1.1
W-KNN	2	1	2	47.80	13.0
C4.5	1	2	3	7.32	1.2
All features	-	20	3	7.31	0.8

better partitions than C4.5 in Bio5. Finally, W-KNN has not performed well in *yeast*. In brief, CBE has shown a good tradeoff between clustering quality and computational effort required to achieve it.

To conclude, some results deserve further attention. The features selected in Bio5 allowed finding better partitions than those obtained by all features, illustrating how the removal of redundant and/or irrelevant features may even promote the improvement of the clustering process. Second, one or two features were enough to provide good partitions for *yeast*.

5. CONCLUSIONS

We have described how feature selection methods traditionally used in classification problems can be adapted for clustering problems. Analyses in terms of time complexity have been undertaken for all the studied methods. Also, empirical results in six bioinformatics datasets illustrated the performance of the assessed methods, which in general have provided good data partitions, while reducing the number of features. The results obtained by the consistency-based evaluation [10] suggest that it is promising for applications in which computational efficiency is a central issue.

An Integrative Framework for Achieving HIPAA-Compliance for Healthcare Information Systems

ABSTRACT

*Currently the Healthcare industry globally is contending with relentless pressures to lower costs while maintaining and increasing the quality of service. Robust Healthcare Information Systems (HCIS) become critical to enabling healthcare organizations address these challenges. In this paper, we propose an integrative framework for HIPAA compliant, I*IQ HCIS. We base this framework on an integration of the requirements for HIPAA compliance, the principles of Information Integrity (I*I), as well as the healthcare quality aims (Q) set forth by the Committee on the Quality of Healthcare in America (American Institute of Medicine, 2001). The power of this framework is that, while it has been developed taking into account critical issues pertaining to security in the US healthcare environment it is as relevant in any healthcare system. To illustrate its universality we discuss the appropriateness of this system in the UK NHS environment as well.*

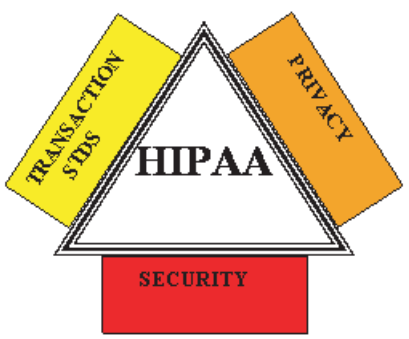
Keywords: HIPAA, Information Integrity, healthcare, healthcare information systems (HCIS), framework, privacy, security, standards, quality, NHS

1.0 THE HIPAA TRIANGLE

In the US, HIPAA (the Health Insurance, Portability and Accountability Act) focuses on three key elements; namely, security, privacy and standards for electronic submissions and exchange of healthcare information (American Institute of Medicine, 2001; HIPPA, 2001; Moore and Wesson, 2002). It is useful to conceptualize this as a triangle (figure 1) which highlights the fundamental elements of the HIPAA regulation; namely, security, transaction standards and privacy.

- **Security:** According to HIPAA, a number of security criteria must be met by all electronic healthcare transactions. Some of these criteria directly affect how healthcare systems can be accessed and interacted with by the users of healthcare information systems. Essentially, these security criteria fall into 3 main categories; namely administrative, physical and technical.

Figure 1. HIPAA triangle



- **Transaction Standards: The Standards for electronic health information transactions cover** certain electronic health transactions, including claims, enrollment, eligibility, payment, and co-ordination of benefits.
- **Privacy:** The final element of the HIPAA triangle deals with ensuring the **privacy of healthcare information.** Specifically, the Federal Register (Vol. 67, No. 157) details all the rules that must be adhered to with respect to privacy. The purpose of these rules is to maintain strong protections for the privacy of individually identifiable health information, addressing the unintended negative effects of the privacy requirements on healthcare quality or access to healthcare, and relieving unintended administrative burdens created by the privacy requirements. Thus, theses privacy requirements cover uses and disclosures of treatment and payment information and create national standards to protect individuals' medical records and other personal health information.

2.0 INFORMATION PRODUCERS, CONSUMERS AND INFORMATION FLOWS WITHIN THE HEALTHCARE SYSTEM

In order to fully capture the flows of information it is necessary to first identify the primary producers and consumers of data and information within the healthcare system. At the center of the information flows is the HCIS because not only does it connect the key players within the healthcare system in an efficient and effective manner but also it forms the central repository for key information such as patient medical records, billing, and treatment details. Hence, the HCIS provides the foundation for supporting the information flows and decision making throughout the healthcare system.

Healthcare procedures such as medical diagnostics, treatment decisions and consequent effecting of these decisions, prevention, communication and equipment usage can be thought of as iatric in nature (Perper, 1994). Integral to these iatric procedures is the generating and processing of information (Moore and Wesson, 2002). The patient naturally provides key information at the time of a clinical visit or other interaction with his/her provider. Such a visit also generates other information including insurance information, medical history, and treatment protocols (if applicable) which must satisfy regulatory requirements, payer directives and, obviously, the healthcare organization's informational needs. Thus, we see that from a single intervention many forms and types of information are captured, generated and then disseminated throughout the healthcare system. All this information and its flows must satisfy some common integrity characteristics such as accuracy, consistency, reliability, completeness, usefulness, usability and manipulability. Consequently, generating a level of trust and confidence in the information's content and processes. Since the information flows across various organizational boundaries, the challenge of ensuring information integrity is further compounded because any integrity problems will propagate with ripple effects following the same trajectory as the information itself. Given the high degree of inter-relatedness between the various players, the consequences of poor quality information (such as the cost of information integrity problems) are multiplied and far reaching. This highlights the need for robust, well designed and well managed HCIS (Applegate et al., 1986; Stegwee and Spil, 2001). Such a perspective

should not be limited to new systems, but rather, equally and perhaps of even more importance, should be applied to existing systems as well.

3.0 INFORMATION INTEGRITY AND QUALITY (I*IQ)

Given the critical role of information both within and between the information produces and consumers in healthcare (Chandra et al., 1995), it is imperative then that the information flowing both within the HCIS and between the key participants in the healthcare system must exhibit both the attributes and dimensions of the information integrity construct as well as satisfy the healthcare quality aims. Specifically, the information should display the attributes of accuracy, consistency, and reliability of content and processes as well as the dimensions of usefulness, completeness, manipulability and usability (Moore and Wesson, 2002; Chandra et al., 1995; Geisler et al., 2003).

3.1 Information Integrity

Information integrity is an emerging area that is 'not just about engineering the right properties of information but it also includes sensitivity to the context in which information is used and the purpose for its usage' (Geisler et al., 2003 p5; MAndke et al., 2003). More specifically it encompasses the accuracy, consistency, and reliability of the information content, process, and system. By focusing on the privacy, security and standards aspects of healthcare information, it would appear that HIPAA implicitly assumes certain characteristics of this information product such as its accuracy and reliability. However, in practice this may not always be the case, and from the perspective of the healthcare organization it is not sufficient to be HIPAA compliant, rather it must also ensure the information product satisfies the principles of Information Integrity (I*I) standards. Implicit in taking an Information Integrity perspective is the shift from viewing information as a byproduct to viewing it as an essential product (Huang et al., 1999). This requires following four key principles; namely that the information must 1) meet the consumers information needs 2) be the product of a well defined information production process 3) be managed by taking a life-cycle approach and 4) be managed and continually assessed vis-à-vis the integrity of the processes and the resultant information [ibid]. In order to actualize this I*I perspective, healthcare organizations then need to implement specific protocols.

3.2 Healthcare Quality Aims

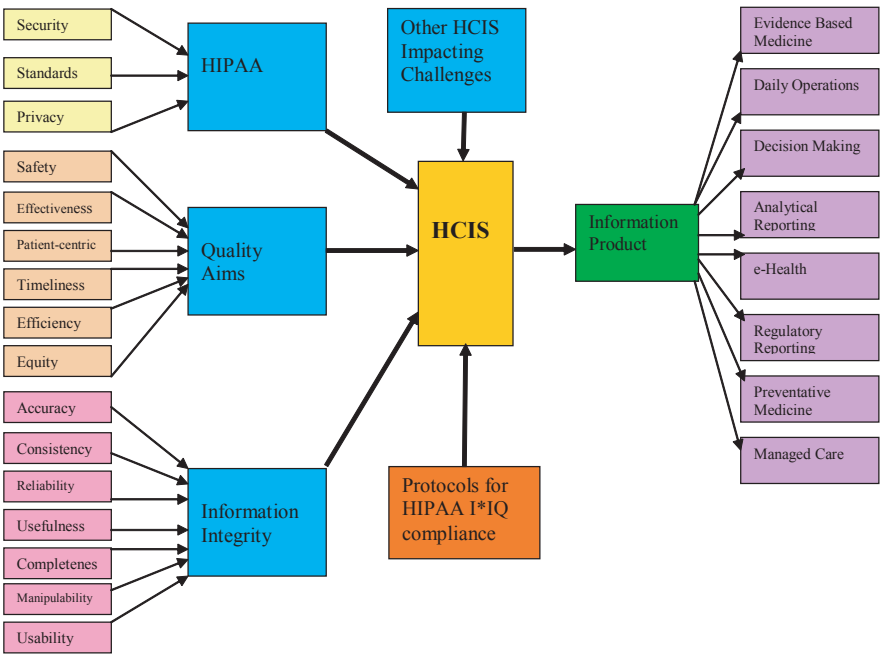
In the final report of the Committee on the Quality of Health Care in America (American Institute of Medicine, 2001), it was noted that improving patient care is integrally linked to providing high quality healthcare. Furthermore, in order to achieve a high quality of healthcare the committee identified six key quality aims; namely, 1) healthcare should be safe – avoiding injuries to patients from the care that is intended to help them, 2) effective - providing services based on scientific knowledge to all who could benefit and refraining from providing services to those who will not benefit (i.e. avoiding under use and overuse), 3) patient-centered – providing care that is respectful of and responsive to individual patient preferences, needs, and values and ensuring that patient values guide all clinical decisions, 4) timely – reducing waiting and sometimes harmful delays for both those receiving care and those who give care, 5) efficient - avoiding waste and 6) equitable – providing care that doesn't vary in quality based on personal characteristics. It is obvious that these quality aims can only be negatively impacted by poor information quality, flow and integrity. Conversely, a higher quality, flow and integrity of information will positively impact these quality aims by helping to reduce the large number of medical errors that currently permeate the healthcare system (Moore and Wesson, 2002; Chandra et al., 1995; Geisler et al., 2003). What becomes critical then is to incorporate these quality aims into the manufacturing of the information product so that the output is quality information. This requires the establishment of an information quality program which serves to: 1) articulate an information quality vision in healthcare business terms, 2) establish central responsibilities for information quality within the information product manufacturing processes, 3) educate the producers and consumers of information on information quality issues and 4) institutionalize and continuously evaluate and develop new information quality skills (Huang et al., 1999).

4.0 PROPOSED FRAMEWORK

Information systems/information technologies (IS/IT) are becoming key enablers and strategic necessities for organizations irrespective of their business sector (Haag et al. 2004; Scott Morton, 1991; Thorne and Smith, 2000). Hence, it should come as no surprise to expect HCIS to play a similar role for healthcare organizations; in particular, they should be viewed as key enablers for healthcare to meet the challenges with which healthcare is currently grappling. In order to systematically maximize and facilitate the full potential of HCIS to enable healthcare organizations cope with today's challenges, it is important to have a guiding to facilitate the design and management of robust HCIS. We propose the following integrative framework as a potential candidate.

The proposed framework integrates the key challenges of 1) the HIPAA triangle, 2) the six healthcare quality aims and 3) the core principles of information integrity currently facing all healthcare organizations in the US (Wickramasinghe

*Figure 2. An Integrative Framework for HIPAA I*IQ HCIS (adapted from Wickramaisnghe, 2006)*



and Sharma, 2005). Further, the framework (via the HCIS) also recognizes the multifaceted nature of the key participants within the healthcare system; in particular, the dynamics of their information requirements with respect to capturing, generating and disseminating of the necessary information. While our discussion focuses on the above three challenges impacting on the design and management of HCIS, the framework acknowledges the existence of other challenges. These challenges, though, are beyond the scope of this paper but are reflected in the framework for completeness. A key component of this framework is the protocols for ensuring HIPAA compliance, observing the principles of information integrity (I*I), and satisfying the healthcare quality aims (Q). Figure 2 depicts the proposed framework. Finally, the framework highlights the major deliverable from the HCIS; namely, the information product and its key applications to various healthcare practices and processes.

5.0 UK NHS ENVIRONMENT

In the UK, the National Health Service (NHS) is the "public face" of the publicly funded healthcare systems. The organisations provide the majority of healthcare in the UK (general practitioners, Accident and Emergency Departments, long-term healthcare and dentistry). Founded in 1948, they have become an integral part of British society, culture and everyday life. Private healthcare has continued in parallel to the NHS, largely paid for by private insurance, but still generally used by a small percentage of the population (and generally as a top-up to NHS services). NHS services are largely free at the point of delivery and are paid for by way of taxation. The NHS's budget for 2005-06 is over £80 billion and the Service employs over 1 million people and is ranked as one of the largest employers in the world. Healthcare in the UK has been the subject of global focus given the radical and far-reaching change programme currently taking place (NHS, 2006).

The lack of sufficient technological safeguards coupled with a lack of a comprehensive security vision and a policy statement on how to ensure healthcare information security are the major obstacles in way of the successful implementation and widespread uptake of the EPR concept. With the NHS, this viewpoint has been corroborated by the British Medical Association who have stated that currently "all the different parts of the NHS are not sufficiently encrypted and encoded up together" to ensure adequate information security to healthcare records (Crossley, 2002) . It is clear that there is existing technology that is in place and is sufficient to ensure that the EPR concept becomes a reality. However, the primary challenge continues to be the elusive hunt for a security mechanism that ensures the security of the information stored in EPR databases (Etheridge, 2001). The proposed integrative framework would be ideally suited to dealing with the new knowledge-based clinical era of the NHS.

6.0 CONCLUSION

In this maze of challenges currently facing healthcare, the need for well suited and high quality information that flows throughout the web of the healthcare system becomes paramount. HCIS can be used to most effectively and efficiently to facilitate the information flows and decision making throughout this healthcare system web. This should come as no surprise, given the general success of IS/IT in many business settings and the fact that healthcare is a data and information rich industry. However, what becomes a critical goal given the pivotal role for these HCIS then is to take a holistic and comprehensive approach to designing robust HCIS and subsequently effectively managing this asset. We have proposed an integrative framework as one approach to meeting this goal. Specifically, our framework considers the three key challenges of HIPAA compliance, the need for embracing the principles of I*I and the need to embrace the six healthcare quality aims. Moreover, the power of this framework lies in its universality since it is as suitable to the US healthcare environment which is essentially a private healthcare model as it is in the UK healthcare system which is dominated by a public model; namely the NHS.

Distribution-Collaboration Networks (DCN): An Organizational Transformation Perspective on the Development of E-Government Services

Konstadinos Kutsikos, University of the Aegean, Business School, 8 Michalon Street, Chios 82100, Greece; E-mail: kutsikos@aegean.gr
Dimitrios Makropoulos, London School of Economics and Political Science, Houghton Street, London WC2A 2AE, UK; E-mail: d.makropoulos@lse.ac.uk

ABSTRACT

The focus of this paper is to show that the development of e-government services needs to be fundamentally reconsidered if it is to achieve its raison d'être – the transformation of bureaucratic public sector agencies into a web of citizen-centric service providers. The status of current e-government initiatives is discussed and an emerging context for developing e-government services is presented: responsibility for public service provision may be distributed to multiple entities, and "public" value no longer needs to be provided by government alone. It can be provided through a system comprised of public agencies, the private sector, community groups, or citizens themselves, using communications networks as a mechanism for process management and conducting transactions. To investigate the intricacies of such a complex system, which we call a Distribution-Collaboration Network (DCN), we have developed a DCN Service Transformation Model. The main properties of this model are presented and its differentiating characteristics are analyzed, from an organizational transformation perspective. Based on that, we present certain guidelines for the development of e-government services along three dimensions: strategy, process engineering and technical infrastructure development.

1. INTRODUCTION

It is no secret that citizens across the globe are now asking for more efficient and effective public services that are citizen-centric - moving away from the bureaucratic status quo of the majority of organizations in the public sector.

Unfortunately, such a modernisation is not a straightforward task. Governments have been experimenting for a long period of time with a number of socio-political theories and models (Carnevale, 2002; Denhardt and Denhardt, 2002; Frederickson and Johnston, 1999; Kettl, 2002; Kettl, 2000). E-government has been more recently recognized by governments, researchers and practitioners alike as a source of potential solutions. This discipline investigates how information and communications technologies (such as wide area networks, the Internet, and mobile computing) can be used by public sector organizations to exchange information with and provide public services to citizens, businesses, and other arms of government.

Current research and practice in the realm of e-government is mostly technology-driven, focused on issues related to the transfer of existing processes and services to the digital world. This is, in turn, reflected on the most widely used e-government service development models.

Such a model is promoted by the European Union's Information Society Directorate General (Bradier, 2004) and is comprised of five different levels: a) *Publish*: services at this level act as passive information bulletin boards; b) *Interact*: citizens can search for and browse dynamic content on the web site of such an e-government service; c) *Transact*: this level corresponds to interactive systems and services, where citizens can exchange information with a government agency; d) *Integrate*: existing processes integrate with e-government activities for e-services belonging to this level; e) *Transform*: encapsulates radical implementations, often including significant process reengineering and new service development.

Cap Gemini, the international management consultancy, has introduced a similar model (Wauters and Van Durme, 2005) comprised of four development levels: *a) Information*: services at this level act as passive information bulletin boards; b) *One-way interaction*: simple interactive services, offering basic functionality, such as downloadable forms; c) *Two-way interaction*: this level corresponds to interactive systems and services, where citizens can exchange information with a government agency; d) *Transaction*: full electronic case handling for citizen requests.

We believe that most of such research efforts are missing the *organisational* and *transformative* aspects of e-government service development. Our baseline argument is that public services (online or otherwise) may be delivered by public sector entities in collaboration with third-party entities, such as the civil society, corporations, etc. The extent of service providers' distribution and the type of service providers' collaboration (organizational transformation issues) may have a severe effect on the development of an e-government service. In turn, this should eventually affect the adoption of the service by the public.

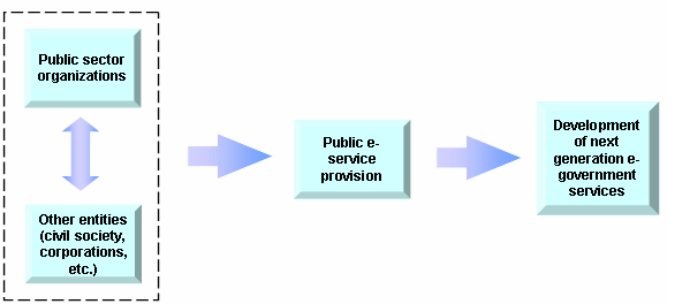
Interestingly, this twin concept of 'distribution – collaboration' is oftentimes not considered in the realm of e-government because:

- Provision of public services (online or otherwise) is considered to be an almost exclusive right of public sector agencies
- Adopting a collaborative model of distributed public service providers will necessitate organisational transformation - a traditionally difficult realm to incorporate in service development.

2. OBJECTIVES

This paper aims to bridge the above research gap by describing an exploration of: a) the organizational structure of systems arising from the creation of different links among entities involved in e-government service provision; b) the influence

Figure 1. Our research model



of this structure on the development (from design to implementation) of e-government services. Figure 1 depicts the broad research model.

Within this model the research question addressed was, "How complex are the organizational transformation issues for e-service provision when multiple and potentially conflicting stakeholders are involved, and how does this complexity map into the implementation of e-government systems?" Thus, the focus of our research is on the interconnection of organizational transformation principles and information systems thinking for developing a new generation of e-government services.

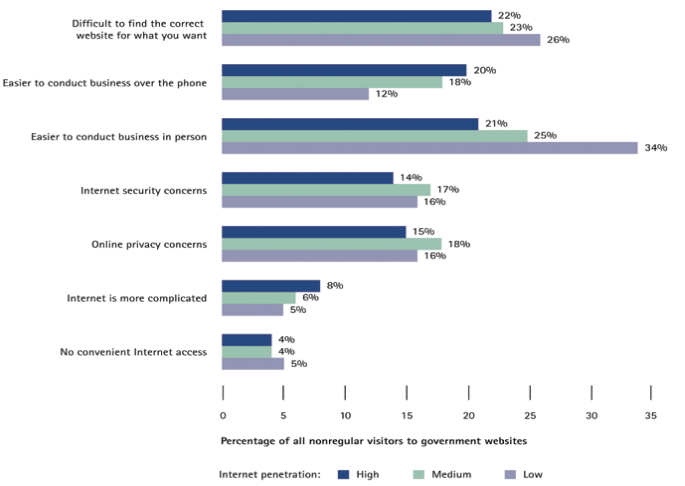
3. METHODOLOGY

Initially, we investigated a number of existing and planned e-government services, mostly developed in European Union countries. The focus was on defining comparison parameters and evaluation criteria, with emphasis on three key realms: strategy, process engineering, and technical infrastructure development.

We also analyzed a large amount of statistical and survey data, collected by government agencies and highly reputable corporations (mainly management consultancies). This analysis was complemented by a review of a number of academic efforts on e-government, systems analysis and design, and organizational transformation.

Finally, the authors' professional experience from their involvement in the development and implementation of e-government initiatives in the UK and Greece provided a set of insightful case studies that were incorporated in this research.

Figure 2. Barriers to More Frequent Use of E-government Services (Average Values from a Sample of 12 Countries – Spain, France, Italy, Singapore, Belgium, Germany, Australia, Canada, USA, Sweden, UK, Ireland – source: Rohleder and Jupp, 2005)



4. E-GOVERNMENT TODAY

The majority of current e-government efforts are focused less on the citizen and more on the public sector organizations' own perspective – the need to move existing processes and services to the digital world. In doing so, significant value can be realized. A recent report from the UK National Audit Office (Rohleder and Jupp, 2005) revealed that 20% of postal applications to the UK's Cattle Tracing System were inaccurate. The result has been that the UK Department for the Environment, Food and Rural Affairs has paid UK£9 million each year since year 2000 in extra staffing costs to rectify the errors. In contrast, the National Audit Office found that only 1% of electronic requests were inaccurate. As a result, the Department for the Environment, Food and Rural Affairs has called for more electronic applications to reduce mistakes, cut the number of extra staff required to correct errors and avoid potential fines from the European Union.

However, from a citizens' perspective, survey data from multiple sources increasingly point to a not-so-positive direction. They point to a citizens' perception that many e-government services have been implemented neither with them in mind nor for the benefit of the civil society but for the convenience and own bureaucratic goals of the government agencies themselves. Figure 2 in the following page shows that citizens across the globe are unsatisfied by the use of current e-government services to interact with public sector organizations (Rohleder and Jupp, 2005).

Indeed, the first three barriers to the use of e-government services (shown in figure 2) encapsulate this dissatisfaction. The cause for these established perceptions may range from citizen frustration when using such services, to lack of marketing e-government services to the citizens. The underlying message, however, is that citizens largely fail: a) to experience tangible benefits from current e-government services, and b) to differentiate them from their offline counterparts.

Finally, from a technology perspective, the current e-services' attempt to simply replicate/transfer internal systems and processes to the Web leaves largely unexploited a core technology for e-government, namely networking. Indeed, the main (and yet unrealized by e-government services) benefit of fully exploiting network technologies is the ability to create new forms of value by focusing on core organizational competencies and creating partnerships for non-core activities.

5. DISTRIBUTION-COLLABORATION NETWORKS (DCN)

The above lackluster results combined with socio-political developments of the recent years are creating new realities for public service provision and the related design of e-government services. These realities point to a new direction of how governments will need to operate from now on and turn the spotlight on the twin concept of 'distribution – collaboration':

- distribution of public service provision to multiple entities (which may not be public sector organizations), and
- collaboration of multiple organizations for delivering public services.

(Tapscott, 2004) describes a number of such recent socio-political realities. First of all, civil society and corporations are now more involved in governance. The private sector, from individual corporations to entire industries, is increasingly focused on competing in a global economy where borders and national laws are seen as irrelevant or hindrances. Civil society - the collection of associations, trade unions, religious and cultural institutions, advocacy groups and people as individuals - is using network-based technologies to communicate and collaborate in ways previously unimaginable. Together, these actors are redefining the nature of public services. For example, civil society organizations, such as the group that created the US environmental initiative Scorecard, are providing new information services that are superior to those currently offered by government.

In addition, citizens increasingly turn to non-governmental entities for receiving 'public value'. Many governments have given priority to their role as financial administrators, focusing on controlling expenditures, paying down debt and trimming entitlements. This is in almost complete contrast to previous generations when public service and the role of government were expanding. Thus, citizens are turning to other entities for services previously offered exclusively by government. For example, corporations now deliver public services ranging from parking tickets to education.

Furthermore, political power is shifting towards collaborative groups of organizations. Communications networks have made geography less relevant to the formation and mobilization of interests and organizations, such as advocacy groups, businesses, cultural associations and trade unions. The declining relevance of borders is a fundamental challenge to the centuries-old basis of national governments and international institutions, most of which are defined by geopolitical power rather than economics or communications. Power is shifting away from national governments towards collaborating supranational organizations, such as the European Union and the World Trade Organization, or local levels of government.

We note that the above realities exhibit a common pattern: responsibility for public service provision is distributed to multiple entities and "public" value no longer needs to be provided by government alone. It can be provided through a system comprised of various public agencies, the private sector, community groups, or citizens themselves, using communications networks as a mechanism for process management and conducting transactions.

We call such a system of distributed organizations that are collaborating for providing public services a Distribution-Collaboration Network (DCN). At an organizational level, it is comprised of interconnected public, private and/or civil society participants. At a technological level, it is supported by network-based technologies (such as the Internet, mobile computing, etc). The importance of DCNs stems from their structure which positions them to deliver a number of benefits over the established bureaucratic forms of government:

- leverage innovation, value and commitment from a broader group of participants
- deliver higher value to the public, including services previously not possible
- deliver services at a lower cost, because the use of network-based organizational and technical infrastructures can significantly lower the search, contracting, and collaboration costs
- in general, introduce new levels of agility, responsiveness and flexibility to the way governments are addressing public needs.

6. THE DCN SERVICE TRANSFORMATION MODEL

Adopting a DCN model of public service provision can have the benefits described above. However, such an adoption entails a new way of thinking from government officials and a challenging organizational transformation for the public sector – both rightfully considered as being difficult tasks to undertake.

Furthermore, such an organizational transformation will be very closely related to the development of a new generation of e-government services aligned with the DCN concept.

Hence, in order to understand the development needs of such services and their impact on the organizational transformation towards a DCN structure, we have investigated a number of existing and planned e-government services, mostly developed in European Union countries. By analyzing their key success factors and limitations, and combining them with lessons learnt from our own involvement in the development of e-government services in the UK and Greece, we developed our DCN Service Transformation Model (depicted in figure 3). In this model, e-government services differentiate along two dimensions, corresponding to the twin-concept underlying a DCN: Service Providers' Distribution, and Cross-Entity Collaboration.

In terms of Service Providers' Distribution, a Low value indicates that a small number (one or two) of statically contracted entities are involved in the development/provision of an e-government service. A High value indicates that responsibility for such service provision lies with a dynamically changing large group of organizations.

In terms of Cross-Entity Collaboration, a Low value indicates that collaboration among involved entities is limited to mostly communication tasks for developing the e-service. In contrast, a High value points to the direction of market-like interactions among service providers.

These two parameters combined define the fundamental characteristics of our model, and their corresponding impact on an organization's transformation towards a DCN structure. Mapping the impact onto guidelines for developing e-government services is achieved by describing it on the basis of certain system-defining parameters:

- *Strategy and Policies*: what are the goals and scope of e-government services to be developed?
- *Processes*: what are the basic processes needed for the execution of Strategy?
- *Technology*: what are the key elements of the technical infrastructure that will enable the successful implementation of Processes?

Based on the above, we can group e-government services that correspond to our model in three major levels: *E-enhanced* services, *Coordinated* services, and *Networked* services.

6.1 E-Enhanced Services

E-government services of this type are under the exclusive auspices of a public sector organization. Usually, a small number of technology firms are contracted for a support role and for infrastructure development. The main focus is on mapping existing processes and organizational structures on the digital realm. Most of the current generation e-government services are of this type.

In more detail, this level is characterized by Table 1.

6.2 Coordinated Services

For delivering Coordinated e-government services, a lead entity (most often but not necessarily from the public sector) coordinates a larger but controlled group

Figure 3. The DCN service transformation model

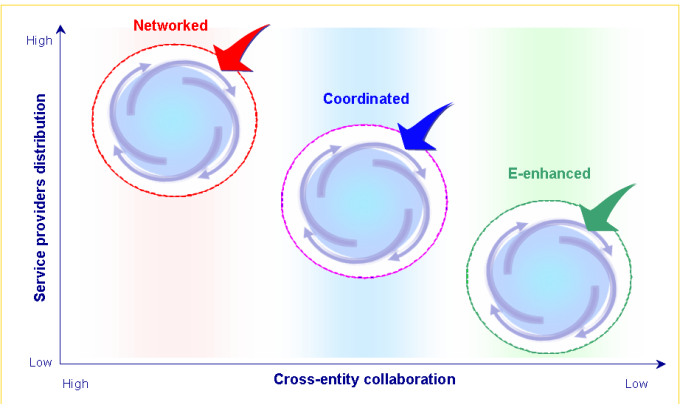


Table 1. E-enhanced services: Key determinant characteristics

Determinant	Characteristics
Strategy and Policies	• One entity for public service provision • "We can do it all ourselves better than others" • Minimal analysis of how well needs are being met • Quality controls are primarily financial • Limited trust of partners
Processes	• Map offline processes to digital realm • Functional silos abound with little formal cross-functional working • Global and local processes conflict or duplicate • Mainly paper-based processes • Front-end webization
Technology	• Little standardisation of data/information definitions between entities involved • Information sharing restricted to non-confidential items

Table 2. Coordinated services: Key determinant characteristics

Determinant	Characteristics
Strategy and Policies	• One leader for group of entities for public service provision • Some recognition of core competencies and the need to work more closely with other organisations • Some trust relationships in place but more individual-driven rather than organisation-driven
Processes	• Limited engineering of cross-entity processes • Processes mostly automated
Technology	• Basic use of collaboration solutions, e.g. web-based email & video/ computer conferencing • Adoption of some common data standards and taxonomies to ease the information flow, e.g. consistent definition of terms • Confidential information shared on an "as-needed" basis

Table 3. Networked services: Key determinant characteristics

Determinant	Characteristics
Strategy and Policies	• One network-based system for public service provision • All policies, functional objectives and procedures are fully aligned and visibly act in accordance with the shared partnership vision • Partners are regularly prioritised and de-prioritised based on their value add to the network • Flat, empowered organisational structure with decisions made at the lowest level possible • Pro-active knowledge sharing to continually deepen relationships
Processes	• Cross-entity processes as *the* modus operandi • Detailed process metrics allow for scenario-based planning and improvements involving all partners • End-to-end processes continually improved with partners
Technology	• Industry standards implemented as an integral part of collaboration platform (SOAP, WSDL, UDDI, WSFL) • Comprehensive use of multimedia to aid interactions • Ubiquitous application level integration with partners • Rich flow of communication upwards, downwards and sideways

of government agencies, businesses and/or civil society groups in order to offer a single point of service. Collaboration among the participating entities is guided and prescribed, and may involve limited cross-entity process reengineering.

In more detail, this level is characterized by Table 2.

6.3 Networked Services

E-government services at this level realize the full extent of Distribution-Collaboration Networks. A large group of organizations (of any type) is participating in the development of the service and such participation can be dynamic and market-like. Cross-entity collaborative processes are in place, data standards have been adopted and there is ubiquitous application-level integration among all involved entities. E-government services of this type are most effectively developed when there is a sense of community among the distributed service providers and a culture of knowledge sharing and consensus can be established.

In more detail, this level is characterized by Table 3.

7. FUTURE WORK

The above research findings are the results of the first phase of our ongoing research initiative on e-government transformation services. There is a number of directions we aim to follow in order to fully understand and develop the DCN system.

First of all, we are intensifying our cooperation with researchers in social sciences, in order to ensure that our work is not an isolated exercise in information systems development. For example, we need to better understand the (potentially conflicting) roles that public service organizations may undertake (supplier, regulator, policy-maker, purchaser, partner, etc.), thus clarifying the roles that they can assume in different DCNs.

In addition, we need to understand the full spectrum of intricacies of complex systems of the kind of a DCN. To that extent, one of the directions we are currently working on is the development of a maturity model, in order to assess an organization's readiness for participating in the development of DCN-type e-government services. A major issue in this effort will be the definition of the organizational and technological parameters (i.e. two of the key transformation drivers) that will be introduced in the maturity model.

Finally, in order to evaluate the practical implications of our propositions, we plan to initiate the development of a service implementation model. Its main goal will be the understanding of critical deployment issues of DCN-type e-government services, for each level of our DCN Service Transformation Model. The development and testing of the service implementation model will be benefited by a parallel project for the design of an e-government service dealing with the issuance of building permits in Greece (this is a Coordinated service, as per our model).

8. CONCLUSIONS

Many of the current e-government services or service development activities have hit a roadblock. Although the initial results were encouraging, survey data increasingly indicate that citizens consider many e-government services to have been implemented neither with them in mind nor for the benefit of the civil society but for the convenience and own bureaucratic goals of the government agencies themselves.

In other words, it seems that many such services were 'assimilated' by government bureaucracies, instead of targeting the original goal of transforming these bureaucracies into citizen-centric service providers.

These lackluster results along with socio-political developments of the recent years are creating new realities for public service provision and the related design of e-government services. These realities point to a new direction of how governments will need to operate from now on and turn the spotlight on our twin concept of 'distribution – collaboration': a) distribution of public service provision to multiple entities (which may not be public sector organizations), and b) collaboration of multiple organizations for delivering public services.

A DCN encapsulates this concept, from a systems point of view, and our DCN Transformation model aims to shed light on its complex structure. Our research findings point to certain basic guidelines for governments to create significant public value through a new generation of e-government services:

- **Determine the roles and/or competencies that public sector organizations must abandon, retain or attain in the digital era.** As part of a DCN, public sector agencies may be able to deliver value in new ways, or create new forms of value for citizens. This, in turn, may necessitate either a handover of their traditional roles (either partially or totally), or the undertaking of new responsibilities to satisfy new roles.
- **Embrace innovative citizen-centric concepts and gear towards their implementation.** DCNs are about sharing power, opening up the decision-making process, and collaborating for creating public value. The corresponding e-government services that can be developed may offer not just the opportunity to 'do the job better' but to re-engage the society in the process of governing.

Design of Reputation Systems in Online Auction Marketplaces: A Comparative Market Study

Kai Riemer, European Research Center for Information Systems (ERCIS), University of Münster, Leonardo-Campus 3, 48149 Münster, Germany; E-mail: kai.riemer@ercis.de

Dorothee Korn, European Research Center for Information Systems (ERCIS), University of Münster, Leonardo-Campus 3, 48149 Münster, Germany

ABSTRACT

Reputation systems aim at facilitating the emergence of trust between transaction partners in online auction marketplaces. In this paper the reputation systems of the six largest online auction marketplaces in the German market are evaluated. To this end, a catalogue of criteria regarding design options for reputation systems was developed. Since eBay is widely criticized for shortcomings of its reputation system, it was assumed that its five competitors have a vital interest in distinguishing themselves in this important aspect of auction platform design. The results of the empirical analysis however point to the contrary. Reputation systems largely show a dominant design with only marginal deviations in detail. The reasons for this, the actual differences between the reputation systems, as well as general limitations of reputation systems are discussed.

INTRODUCTION

Online auctions have developed into a successful and widely used trade channel among consumers and businesses. Online auction marketplaces (e.g. eBay) have several advantages for trading partners such as easy market access, fast transactions, or price transparency. However, these advantages come at the cost of several risks, especially from the perspective of the buyer. The buyer cannot see and evaluate the product and thus has to trust in the seller's honesty when determining a bidding strategy. Furthermore, the buyer has to pay the seller upfront and thus to take the risk of being defrauded by not being delivered with the described product.

The auction platform provider is only responsible for running the platform but not involved in the actual transactions. Any transaction risks are borne by the trading partners (Resnick *et al.*, 2000). In order for successful transactions to actually happen, some form of trust has to emerge between the trading partners. Auction platform providers have developed reputation systems in order to facilitate trust emergence and to provide incentives for trading partners to engage in positive trade behavior (Dellacoras, 2003).

The Role of Reputation Systems in Trust Formation

In traditional business relationships trust originates from recurring personal contacts. However, in online platforms anonymous buyers and sellers meet to engage in one off deals. Reputation systems function as mediators between buyers and sellers by allowing the necessary levels of immediate trust to emerge (Dellarocas, 2000; Resnick et al., 2000). Reputation systems collect, distribute, and aggregate feedback about the conduct of market participants (Resnick et al., 2000).

A reputation reflects the past behavior and serves as an indicator for the future behavior of a user ("shadow of the future") (Friedman and Resnick, 2001). A reputation originates from a collection of assessments of past transactions and manifests itself as a score and a list of comments which together are part of the so-called user profile. By doing so, past experiences are shared and made available for all users in the marketplace as a form of public good (Dellarocas, 2004). The reputation of a seller can be seen as a measure of his trustworthiness that holds a certain value (Melnik and Alm, 2002; Shmatikov and Talcott, 2005). This is reflected in the willingness of buyers to pay a higher price for the same item in cases where the seller shows a better reputation (Lucking-Reily *et al.*, 2000; Resnick *et al.*, 2002).

A well-working reputation system is not only important for the actual trading partners, but also for the auction provider whose aim it must be to achieve and maintain a critical mass of buyers and sellers on the platform. If sellers are motivated to behave cooperatively by the reputation system this has a spill-over effect on the reputation of the entire platform. Consequently, a reputation system is a vital component in attracting new users. For the trading partners, the reputation system reduces the uncertainty in transactions over distance; it provides mechanisms that negatively mark deceitful and positively acknowledge cooperative behavior. Moreover, existing user profiles resemble switching costs and increase customer retention. Hence, online auction providers should have a vital interest in the success of their reputation systems.

A Comparative Market Study

Existing reputation systems, especially the one of the market leader eBay, are criticized for a range of shortcomings. Firstly, it is comparatively easy for a seller with criminal energy to forge a reputation of positive feedback by setting up a large number of fake or very low priced transactions or by joining criminal circles of users who exchange positive feedbacks. Secondly, the eBay system allows the users to dish out so-called revenge assessments; it allows the seller to return to the buyer a negative rating out of spite even in cases where the buyer gave a legitimate negative feedback. This opens the door for putting pressure on the buyer. Finally, setting up fake accounts under a false identity is also a considerable problem. This might potentially damage the reliability of the whole reputation system. Given that the eBay reputation system is all but perfect the question arises how other providers go about the design of their reputation systems. How do they differentiate from the incumbent player and which conclusions can be drawn from this for the improvement of the eBay platform?

To pursue these questions, the paper reports on an expert evaluation of reputation systems in the German market for online auctions. Its main research question is: "How do competitors use their reputation systems to differentiate from the incumbent player eBay in order to attract users on the basis of a more advanced and secure reputation system?" This question is based on the assumption that competitors should have an interest to create a more trustworthy environment in order to win over change-willing users. To deal with this question, design aspects of reputation systems were identified based on a combination of literature analysis and empirical investigation. In the following paragraphs a brief overview of these requirements is provided before the evaluation is discussed.

DESIGN REQUIREMENTS OF REPUTATION SYSTEMS

Designing reputation systems is challenging: Buyers want reliable and rich information that supports the identification of trustworthy sellers (Resnick and Zeckhauser, 2001). Reputation systems should ensure fairness in the rating process and encourage the seller to comply with the descriptions of the auction offering and to engage in cooperative behavior (Dellarocas, 2000). Sellers on the other hand want the reputation system to distinguish between good and bad reputations in order to be rewarded for cooperative behaviour. Finally, auction providers want the reputation system to encourage trustworthy behaviour that leads to a cooperative code of conduct on the platform. According to Resnick et al. two phases can be distinguished in a reputation process: 1) In the feedback or rating process users

are assessed by other users and feedback is stored in a database. 2) In the decision process the condensed feedback of all transactions is presented as a seller's profile to support a buyer decision. The following design aspects form the criteria catalogue for the empirical evaluation of the six reputation systems.

Design of the Rating Process

At the end of an auction transaction users have to be motivated by the reputation system to rate their counterparts in a fair and honest manner. In designing the rating processes providers have to take into consideration the following aspects:

- Who is entitled to give feedback (Kollock, 1999)? In a bidirectional feedback process both parties are allowed to rate the quality of the transaction. However, such an approach is prone to the problem of revenge assessments.
- Does the platform provide incentives to give feedback (Resnick and Zeckhauser, 2001)? Here, it is a matter of avoiding the "free-riding" problem by which users benefit from positive ratings of other users but do not place assessments themselves.
- Is the rating mandatory, i.e. are there sanctions for users otherwise?
- How is the assessment structured (Kollock, 1999), i.e. in which way is the feedback extracted, by selecting a judgment from a drop-down list, by allocating point values, by text comments etc.?
- How is a single feedback incorporated in the user profile? Does the system provide a percentage value of positive ratings?
- Is it possible to make amendments to an existing feedback? In case of a conflict does the provider allow to delete a feedback?
- Is it possible to comment on a feedback? This can be helpful in documenting a dispute so that other users are able to judge for themselves.
- Does the system encourage honest ratings (Dellacoras, 2003; Resnick and Zeckhauser, 2001)? Which mechanisms are provided in this context?
- Can feedbacks be hidden? If so, users might be able to hide comments to guise a negative reputation.

Design of the Decision Process

The design of the decision process is crucial, because the usefulness of a reputation system is determined by how good a buyer is supported in accessing existing user profiles. The following aspects have to be dealt with:

- How are potential buyers informed about the feedback mechanism and its role in establishing trust?
- How are the feedback profile and the feedback score presented? Is the buyer able to immediately comprehend the reputation of the seller on the actual auction page?
- How can the buyer access additional information on the seller's reputation?
- How is the feedback history presented? An aggregate score (e.g. the difference of positive and negative ratings) does not reflect the particularities of the underlying auction transactions. Further information on the feedback history is necessary.
- Is there a filter with which the buyer can search in the detailed profile (history) of the seller, e.g. is it possible to filter for negative feedback?
- The profile might be accomplished with additional data on the seller, e.g. information on the registration date or whether the seller is active as a commercial trader or as a private person.
- In addition, the provider might allow users to undergo a specific registration process that incorporates an official identification to confirm the identity of the user and thus to enervate problems of anonymity.
- Is the reputation profile always displayed besides the user name, or only if the user is active as a seller (Resnick and Zeckhauser, 2001)?

RESULTS OF EMPIRICAL EVALUATION AND DISCUSSION

In order to investigate our research questions we evaluated the reputation systems of the six largest online auction providers in Germany. Since Germany is the second largest online auction market[1] our results should be typical of and thus transferable to other Western countries. Using the criteria presented above the following platforms were analyzed: eBay.de, Hood.de, Auxion.de, BesteAuktion.de, Ricardo.ch and Azubo.de[2]. All platforms were evaluated by two experts independently. The results were then discussed; in the few cases where results differed agreement was reached by further specifying the evaluation criteria. Detailed evaluations of the six providers can be found in the appendix; we focus our discussion on significant overlaps and differences.

Dominant Design of Reputation Systems across all Six Platforms

The initial assumption of this study was that competitors should have an interest in differentiating their reputation systems to avoid a range of problems well-known from eBay, and more importantly to gain a competitive advantage to attract new customers. However, this assumption cannot be confirmed based on our study. To the contrary, it turns out that the reputation systems show very strong similarities in nearly all design aspects. This holds true for both the rating process as well as the decision process:

- User assessments on five of the six platforms consist of a text comment plus a rating in the categories "positive" (+1), "neutral" (0) or "negative" (-1). Then an aggregate score is calculated, mostly by adding positive and subtracting negative ratings or by calculating a percentage. Only Azubo came up with a different way of extracting customer assessments (see later).
- All platforms follow the distinction in short user profiles available on the actual auction page and a detailed history accessible on one or more separate pages.
- On all platforms profiles are only shown on the actual auction page; it is not possible to use user reputations as a search or selection criterion in browsing for products.
- The representation of the short profiles generally follows the same patterns although numerical values and symbols vary slightly with most of the competitors showing even less information than eBay.
- On the history page all user comments and ratings are listed and most providers show a breakdown of all ratings as a matrix of the three categories (+ / o / -) and time periods.
- Most platforms provide a function for filtering the list of comments.

Overall, the deviations between the platforms are limited to details and mostly manifest in the fact that the five competitors lack behind eBay in terms of range of features as well as their presentation. Only few features indicate some form of independent development. By and large, we see a dominant design of reputation systems in the market for consumer-oriented online auctions.

A dominant design of a product or a service exists when it permeates a marketplace to the extent that it forces all actors in the market to standardize, e.g. to adhere to the dominant design (Abernathy, 1978). Players newly entering such a market feel immediately constrained in their design freedom while having to take over the established design features (Utterback, 1994). If a dominant design has emerged, design variations only take place within narrowly defined margins. Dominant designs often appear by way of imitation in cases where one dominant player controls the majority of the market (Voss, 2004). Clearly, this well-describes the market for online auction marketplaces in Germany. Moreover, with its transparency and openness the Internet lends itself to imitation processes making it easy for competitors to copy front-end features (e.g. reputation systems) since their design is well visible to the public.

Reasons for competitors imitating the eBay reputation system can lie in reducing the design uncertainty; the auction providers need not experimenting with mechanisms when the dominant player already demonstrates their successful functioning. On the other hand, it can be assumed that eBay's dominance exerts a conditioning effect on consumers. Many consumers have already learned and are accustomed to the interaction with the particular design eBay has chosen for its reputation system. If a competitor wants to deviate significantly from the dominant design, he risks not being able to connect with the established customs inherited by customers. He might thus lose the ability to attract customers who are willing to switch over from eBay. In line with this interpretation, the six reputation systems are found to follow design patterns dominated by eBay with rather marginal differences that lie within the borders of an otherwise uniformly interpreted reputation systems design.

Design Differences in Detail

Drawing from the differences presented in table 1 it can be argued that eBay is one step ahead of its competitors in some important aspects of reputation systems design. This can be seen as typical for a market leader. eBay provides the most comprehensive set of features for buyers to evaluate the past behavior and transaction history of a seller. Only a combination of various types of information about the seller and his activities puts the buyer in a position to comprehend the level of seller reputation, to make an informed decision, and hence to avoid unpleasant surprises. The short profile and rating score is only one source of information

Table 1. Areas in which eBay is ahead of most of the competitors

Design aspects	Explanation
Assessments are counted only from different users (only one per user)	This is an important precondition to prevent problems of friendly assessments with the intention to construct a positive reputation profile. Nevertheless, for smaller auction providers with only few active users in particular product groups of the platform the problem arises that profiles are built much more slowly. This may significantly delay the achievement of a critical mass of users.
Additional user information	eBay provides the most comprehensive list of additional information on the seller while two of the competitors do not even give information about the registration date of the user (is it a newly registered of long established user?).
Underlying auction can be accessed from the comments list in order to learn about the product and its value	The value and type of products sold by a seller in the past gives a good account of his activities: Were many cheap items purchased or sold to quickly build up a profile? Did the seller auctions a different type of product in the past and recently switched to another branch? This can be an indicator for an account that has been hijacked by someone else of for dishonest intentions of the seller (e.g. seller switching from baby clothes to high value tech items).
Profile of the assessing user is displayed in the list of ratings (on the history page)	By doing so, it becomes obvious if a seller receives a lot of assessments of newly registered user that were only set up to artificially improve the profile. Besides, the buyer can see in the profiles of other users if it is likely that the seller will engage in revenge assessments once a problem occurs and the buyer places a negative rating.
Number of withdrawn bids is displayed	How does the seller behave as a buyer? This additional context information can be a valuable jigsaw piece to judge the seller as a person.
Detailed rules of conduct and information on the assessment system available	Education of the users is an essential precondition to avoid cases of misconduct, deception, and fraud. Here, eBay as the market leader is at the center of user fraud and thus is confronted with the majority of security problems. Hence, eBay is very active in the communications department.

which has to be complemented with other information, e.g. on the type and value of products of the underlying auctions that the seller received positive feedback for and the reputation of the users who gave their feedback. Only then is the buyer able to detect cases in which users tried to artificially enhance their profiles. In regards to these features the five competitors all show significant room for improvement. This holds also true for the ways in which the reputation system and its features, the ways of using the system, and means of avoiding problems are communicated by the platform provider (for detailed results please refer to the appendix).

While the incumbent is clearly leading the way in most areas of reputation systems design, some of the differences between the platforms nevertheless reflect some independent development by the competitors. At the same time these differences mark areas in which eBay could further improve its reputation system (see table 2). In particular, the specific filtering options on the detailed history pages are to be mentioned here. These filters allow users to quickly gain an overview of negative assessments, a feature that further improves the buyer's situation in establishing a comprehensive picture of the seller's past behavior. Another feature that can reduce fraud on auction platforms is a mandatory user identification process by means of postal address (Ricardo.ch), telephone number (BesteAuktion), or passport photocopy (auxion.de); introducing such a feature would significantly increase the cost of setting up fake identities at eBay. Finally, Azubo's compulsory and sophisticated feedback mechanism might inspire eBay to move towards a more differentiated way of eliciting feedback in order to give the user a mechanism to utter dissatisfaction with particular seller actions without having to place an overall negative assessment. Without such a mechanism negative conduct might go uncovered since users might simply follow the path of least resistance and place a positive feedback. This might especially be the case when the buyer has to fear negative revenge assessments. However, no competitor had any mechanism in place to prevent such revenge assessments.

Table 2: Measures of competitors that go beyond the features of eBay

Design aspects	Explanation
Mandatory user identification by mail, phone or bank account	A secure identification of the users can help to prevent multiple identities and to expel dishonest users permanently from the platform. However, for a market leader like eBay this can lead to considerable expenses and in the short term might hamper platform growth.
Additional visualization of detailed profile	A bar chart visualization (like the one used by Azubo) can assist the user in quickly comprehending the development of a user's reputation over time.
Possibility to fast and easily filter for negative ratings	This is an important feature to get a comprehensive picture of the seller and his activities. In combination with an easy access to the profile of an assessing user this helps uncovering sellers who engage in revenge assessments.
Differentiation of the judgment in several dimensions (see Azubo.de)	A differentiation in behavior of the seller (communications and shipment) and the product quality allows a better evaluation of a seller. It also allows handing in critical judgments without having to place an entirely negative assessment, which most users want to avoid. Hence, this feature might lead to a more honest rating behavior and richer information.
Incentives to place assessments quickly	The more time elapses until users hand in their assessments the longer can seller misconduct go uncovered. Timely information is essential to limit fraud.
No time restrictions for handing in assessments	An artificial time restriction leads to unwanted tactics like users waiting up to the last second to place negative assessments in order to not having to fear a revenge assessment.

LIMITATIONS OF THE REPUTATION SYSTEMS

Besides the dominant design of their reputation systems the six platforms in our sample also share a set of important limitations, some of which were already mentioned at the beginning of the paper. A comprehensive list of all possible problems would go beyond the scope of this paper; some typical problems however became obvious during the course of our enquiry.

A typical problem mentioned in the literature is the artificial creation of positive profiles by means of so-called 'profile baking circles' in which users exchange positive assessments based on low-value transactions deliberately setup for this purpose (Bhattacharjee and Goel, 2005; Dellarocas, 2000). In order to raise the cost for this kind of tactics eBay decided to only count one assessment per user in calculating rating scores. The competitors however did not follow this measure so far; one reason might be that this would significantly limit the growth of feedback profiles, which is a problem for smaller platforms with only limited numbers of users.

Another problem is that the current profile might not truly reflect a seller's actual behavior at any given point in time, reason being that there is a time lag between the end of a transaction and the buyers handing in their assessments. In addition, the formal clarification process demanded by the providers in case of a dispute also delays the publication of negative assessments. One way to speed up the feedback process is to give incentives for timely assessments, e.g. in terms of an extra quarter point added to the score (see BesteAuktion) and by marking in the profile the existence of an ongoing dispute.

Another significant problem of the reputation systems lies in the possibility of unwarranted revenge assessment. While all providers permit commenting on a negative feedback using a short statement, a deletion of unwarranted assessments is tedious and only possible in special cases and with mutual consent of both parties. Such a process might even reward a seller for putting pressure on a buyer who placed a justified negative feedback. Hence, the risk remains that buyers are blackmailed or that sellers have their reputation damaged by competitors who bid on the seller's auction in order to deliberately harm their reputation (Dellarocas, 2000). Revenge assessments can be prevented by means of making the assessments available only when both parties have finished submitting their feedbacks. Of course, this has to be combined with making feedback mandatory and with speeding up the process. Otherwise users might be able to prevent the other party's feedback from being published by not submitting their own feedback, which would allow them to suppress negative feedback.

CONCLUSIONS

The contribution of this study is twofold. Firstly, a criteria catalogue for evaluating online auction reputation systems was compiled. Secondly, the empirical evaluation of the six largest auction platforms in Germany revealed a dominant design of reputation systems that is shaped and dictated by eBay as the incumbent player. Not only are the competitors not able to differentiate from eBay in this important area of platform design, they even lack behind in terms of range and quality of features. Consequently, eBay is not only able to demonstrate market leadership in economic terms, but also in the design of crucial aspects of the trading platform. It can be argued that, albeit the problems discussed above, eBay's reputation system is up to the task and fulfils customer needs to a satisfactory level as other studies have shown (Resnick and Zeckhauser, 2001; Resnick et al., 2000). However, online reputation systems still have certain limitations in simulating trust mechanisms well-known from traditional off-line markets (Bolton *et al.*, 2004). As we have argued above, there is still considerable room for improvement to tackle some of the most prevalent problems that allow or even abet online auction

fraud. This leaves room for further research on the design of reputation systems, especially since our study took an outside perspective using expert evaluation to rate the reputation systems. Further research should extent our work in two directions: Experimental studies should explore the perspective of average users while international comparative studies should aim at contrasting the situation in different national markets.

ENDNOTES

1 http://investor.ebay.com/downloads/12105_ebay_GS.pdf

2 Following recent statistics [May 2006] from www.auktionssuche.de these are the six largest consumer-oriented auction providers in Germany; eBay features 15,000,000 auctions while the runner-up Hood.de only accounts for 900,000 auctions.

APPENDIX

Table 3: Detailed evaluation results, part 1

		eBay.de	hood.de	auxion.de	BesteAuktion	ricardo.ch	azubo.de
Rating process (profile building)	Who is eligible to give feedback?	Buyer and seller	Buyer and seller	Buyer and seller	Buyer and seller	Buyer and seller	Buyer and seller
	Is there an incentive/ compensation for giving feedback?	no	no	no	yes, user gets a quarter scoring point	no	no
	Is giving feedback mandatory?	no	no	Yes. When buyer does not give feedback, the seller automatically receives a positive rating.	no	no	no
	Structure of the feedback?	Three categories (positive/neutral/negative) plus short comment.	Three categories (positive/neutral/negative) plus short comment.	Three categories (positive/neutral/negative) plus short comment.	Three categories (positive/neutral/negative) plus short comment.	Three categories (positive/neutral/negative) plus short comment.	Answering of three questions regarding seller user behavior (Answers good/med/poor)
	How is a rating incorporated in the profile?	A score is calculated by adding positive and subtracting negative ratings; only one rating per member is counted.	Like eBay, but all ratings are counted.	Number of positive, neutral and negative ratings are added up as scores; all ratings are counted.	Number of positive, neutral and negative ratings are added up as scores; all ratings are counted.	A percentage of positive ratings in relation to all ratings is cal+G15culated	Answers to the three questions are calculated into a score for the three categories pos/neutr/neg.
	Is it possible to modify or delete an existing feedback/rating?	no, deleting a comment is only possible in special cases and when both parties agree	no, deletion is only possible in special cases (offensive ratings, advertising)	no	no	no, deletion is only possible in special cases (offensive ratings, advertising)	no
	Comments on feedback possible?	yes	yes	yes	yes	yes	yes
	Feedback guidelines: how is fairness and honesty be encouraged?	Detailed guidelines and rules of conduct	Detailed guidelines and rules of conduct	Very limited / no information	Very limited / no information	Detailed guidelines and rules of conduct	Detailed guidelines and rules of conduct
	Is it possible to hide ratings or comments?	No, a user can only declare his profile private and hide ALL ratings.	no	no	no	no	no

Table 4: Detailed evaluation results, part 2

		eBay.de	hood.de	auxion.de	BesteAuktion	ricardo.ch	azubo.de
Decision process (feedback usage)	Where can information regarding the reputation system be found?	Following the link "help" and "ratings" detailed information can be found	Like eBay, but information is quite limited	Only limited information, hidden somewhere in the "help" pages.	Following the link "help & hints" and "other" information can be found (but very limited)	Following the link "help"; information is quite detailed	Following the link "help" - "extra" - "rating system"; information is very limited
	How is the rating score visualised?	Score value, plus coloured star symbol (starting with a score of 10). Powerseller symbol for high volume sellers.	Score value, plus up to 7 stars depending on number of positive ratings (starting with 5), plus percentage value.	Number of positive, neutral and negative ratings are displayed as scores.	Number of positive, neutral and negative ratings are displayed as scores, plus star and crown symbols in gold, silver, bronze depending on number of positive ratings	Percentage value plus a number of up to 4 stars, displayed in 5 different colours. Diamant symbol in addition, when score > 99%.	Score value plus up to 5 stars in 3 different sizes (starting with 5 positive ratings).
	How can further information be accessed?	By clicking on the score value or a dedicated link a page with a detailed profile can be accessed	By clicking on the score value or a dedicated link a page with a detailed profile can be accessed	By clicking on a dedicated link a page with a detailed profile can be accessed	By clicking on the user name a page with a detailed profile can be accessed	By clicking on the user name a page with a detailed profile can be accessed	By clicking on the user name a page with a detailed profile can be accessed
	How is the feedback history be presented?	Table with number of pos/neutr/neg ratings in different time periods / List of ratings, user comments with short profile of this user, date, and link to the resp auction, and whether user was buyer of seller	Table with number of pos/neutr/neg ratings in different time periods (plus visualization as bar chart)/ List of ratings, user comments with short profile of this user, date, and link to the resp auction, and whether user was buyer of seller	Number of pos/neutr/neg ratings / List of ratings, user comments, date, and link to the resp auction, and whether user was buyer of seller (profile of user cannot be accessed)	More or less a list of ratings with comments and short profile of this user (no link to auction or info whether user was seller or buyer)	Table with number of pos/neutr/neg ratings in different time periods / List of ratings, user comments with short profile of this user, date, and whether user was buyer of seller (no link to the auction)	Bar chart visualisation of pos/neutr/neg ratings and using the rating questions / List of ratings, user comments with short profile of this user, date, and whether user was buyer of seller (but no link to auction)
	Is there a filter to search for positive of negative feedback or to change the appearance of the profile?	Filtering for seller/buyer comments and for different time frames (filtering for negative ratings is only accessible when filtering for a time period)	no filter, only one listing	Filtering for pos/neutr/neg ratings and for received and given ratings	Filtering for pos/neutr/neg ratings.	Filtering for pos/neutr/neg ratings and listing of own ratings given by the user.	no filter, only one listing
	What additional user information is available?	"Registered since", "commercial/ private", "my page", plus icon for verified users.	"Registered since", "commercial/ private", "my page"	"Registered since", "my page", "ratings by this user", plus icon for verified users	None	"Registered since", but only accessible in detailed profile	"commercial/ private", "my page"
	Is there a user identity verification?	optional, using the PostIdent by Deutsche Post AG	no, only verification of email address	optional, using passport photocopy	mandatory, by receiving a PIN number over the phone	mandatory, activation code received by post	optional, using a money transfer of one cent to the users bank account
	Is the profile always presented or only for sellers?	always	always	Profile is only shown for sellers, and only in an auction.	always	always	always

On the Determinants of Enterprise Risk Management Implementation

Kurt Desender, Universitat Autonoma de Barcelona, Campus Bellaterra, 08193 Barcelona, Spain; E-mail: Kurt.Desender@uab.es

ABSTRACT

Corporate governance failures and new legislation and recommendations have emphasized the importance of control and risk management in reducing agency costs and preventing fraudulent reporting. The objective of this paper is to investigate how a company's board characteristics influence the decision to invest in enterprise risk management. This paper contributes mainly to field of corporate governance research by providing new evidence on the relationship between board characteristics and enterprise risk management. In addition we also suggest a measure to test the quality of enterprise risk management derived from the COSO theoretical paper on enterprise risk management. The main results of this research is that board independence alone does not induce higher enterprise risk management quality, while boards with a separation of CEO and chairman, boards with both an independent board and a separation of CEO and chairman are more likely to adopt ERM.

1. INTRODUCTION

The Enron failure, together with other high profile corporate collapses, has led to a debate concerning the efficiency and the role of corporate governance. These corporate governance failures culminated in the passage of the Sarbanes Oxley Act (SOX) on July 30, 2002, which have emphasized the importance of control and risk management in preventing fraudulent reporting. While strong theoretical arguments exist as to why a firm should employ enterprise risk management (hereafter referred to as ERM), the main drivers for the implementation have been new corporate governance codes.

The purpose of this paper is to investigate how a company's board characteristics influence the decision to invest in enterprise risk management. This paper contributes mainly to field of corporate governance research by first providing new evidence on the relationship between board characteristics and enterprise risk management. In addition we also suggest a measure to test the quality of enterprise risk management derived from the COSO theoretical paper on enterprise risk management.

The main results of this research is that board independence alone has no significant relationship with the enterprise risk management quality, while the separation of CEO and chairman, or the combination an independent board combined with a separation are more likely to adopt ERM. In what follows, we discuss the background and motivation. Then the focus is on the research method that will be used. Finally, we describe in more detail the results.

2. BACKGROUND AND MOTIVATION

Since the corporate scandals and the creation of new corporate governance codes, enterprise risk management has been considered as a valuable element of the corporate governance structure. Since there is a separation between ownership and control, and managers' objectives are not necessarily aligned with those of the organization, managers may have incentives to behave opportunistic (Jensen and Meckling 1976; Watts and Zimmerman 1983). Existing agency theory proposes a series of mechanisms that seek to reconcile the interests of shareholders and managers, including the utilization of internal control mechanisms such as monitoring by non-executive directors (Fama and Jensen, 1983), monitoring by large shareholders (Shleifer and Vishny, 1986), the incentive effects of executive share ownership (Jensen and Meckling, 1976) and the implementation of internal controls (Matsumura and Tucker, 1992). An additional instrument of shareholder monitoring is the statutory audit whereby independent auditors report annually to shareholders on the appropriateness of the financial statements prepared by management (Watts and Zimmerman, 1983). The clear implication for corporate governance from an agency theory perspective is that adequate monitoring or control mechanisms need to be established to protect shareholders from management's conflict of interest – the so-called agency costs of modern capitalism (Fama and Jensen, 1983).

COSO-ERM (2004) defines enterprise risk management as a process, effected by an entity's board of directors, management and other personnel, applied in strategy setting and across the enterprise, designed to identify potential events that may affect the entity, and manage risks to be within its risk appetite, to provide reasonable assurance regarding the achievement of entity objectives.

In the hypothetical Modigliani and Miller world of corporate finance, risk management does not add value. However, in the non-frictionless environment of the real world, risk management by the firm can create value in one or more of the following ways (Meulbroek, 2002). Risk management can create value: (1) in ways that investors cannot duplicate for themselves; (2) facilitate the risk management efforts of the firm's equity holders; (3) decrease financial distress costs; (4) lower the risk faced by important non-diversified investors (such as managers and employees); (5) reduce taxes; (6) reduce the firm's capital costs through better performance evaluation and reduced monitoring costs; and (7) provide internal funding for investment projects and facilitate capital planning.

While strong theoretical arguments exist as to why a firm should employ enterprise risk management, the main drivers for the implementation have been reports of best practice such as the Joint Australian/New Zealand Standard for Risk Management, Committee of Sponsoring Organizations of the Treadway Commission (COSO) in the U.S. (arising out of control breakdowns in the Savings and Loan industry), CoCo (the Criteria of Control model developed by the Canadian Institute of Chartered Accountants), the Toronto Stock Exchange Dey Report in Canada following major bankruptcies, and the Cadbury report in the United Kingdom.

The purpose of this paper is to investigate how a company's board characteristics influence the decision to invest in enterprise risk management. If enterprise risk management reduces agency costs and improves governance structure, board of directors should be pushing the implementation of enterprise risk management. Two characteristics of the board of directors stand out in the literature as being of the greatest interest for effective corporate governance: independence of the board members and the duality of CEO and Chairman (Willekens and Sercu, 2005).

3. HYPOTHESIS DEVELOPMENT

We consider the relationship between two board characteristics, independence and separation of CEO and chairman and the degree of implementation of enterprise risk management.

Board of Directors

Fama and Jensen (1983) theorize that the board of directors is the highest internal control mechanism responsible for monitoring the actions of top management. Furthermore, Kleffner et al. (2003) investigate the impact of corporate governance recommendations about risk management on the implementation of enterprise risk management amongst Canadian firms. They find that 31 percent of their sample had implemented enterprise risk management (ERM), while 29 percent where at the moment investigating it. The participating companies indicated as most important driving forces behind the implementation the encouragements from the board of directors and the concern for directors' and officers' liability. The study indicates the importance of the demand for effective control and risk

management practices.

Board Independence

In their respective reports on corporate governance, both Cadbury (1992) and Hampel (1998) emphasize the value of increased non-executive representation on boards' suggesting that non-executives are capable of bringing greater independence and impartiality to board decisions. Consistently, Beasley (1996) finds an inverse relation between the percentage of outside directors on the board and the incidence of fraudulent financial reporting. Similarly, Firms with a majority of inside directors are found to be more likely to engage earnings management compared to a control sample matched by industry and size (Peasnell, et al., 2000). Furthermore, non-executives are expected to favor more extensive risk management and (internal or external) auditing in order to complement their own monitoring responsibilities, since they have the objective of identifying and rectifying reporting errors deliberately or otherwise made by managers. In a similar context, O'Sullivan (1997) finds that companies with a higher proportion of non-executive directors are more likely to purchase the monitoring of directors' and officers' insurance compared to boards with a lower proportion of non-executives. This suggests that companies with greater non-executive representation may favor a more comprehensive control, risk management and (internal or external) audit. The incentive of outside directors to prevent and detect such opportunistic reporting behavior by management potentially is driven by three factors:

First, the directors may seek to protect their reputations as experts in monitoring because the market for directors punishes those associated with corporate disasters or poor performance (see Fama and Jensen 1983; Gilson 1989). Second, from a legal liability perspective, directors who fail to exercise reasonable care in discharging their monitoring responsibilities may be subject to severe sanctions (see Gilson 1989). Third, shareholders often suffer significant losses in the wake of financial reporting problems (Beasley et al. 1999), so directors seeking to protect shareholder wealth may seek higher quality controls, risk management and (internal or external) audit.

In order to reduce the likelihood of fraudulent reporting, and opportunistic behavior in general, board could demand investments in higher quality control and risk management practices and/or purchase of higher quality audit services. Numerous studies have reported a positive relationship between the independence of the board and the demand for external audit quality, as measured by the audit fees (O'Sullivan, 2000; Carcello et al., 2002; Hay and Knechel, 2004). Therefore, one may view outside directors as more concerned with the quality of the financial and non-financial reports than are management directors, who face greater conflicts of interest.

HYPOTHESIS 1: *There is a positive relation between the percentage of outside directors on the board and enterprise risk management.*

Separation of CEO and Chairman

The UK Code of Best Practice (Cadbury Committee, 1992) recommends that the positions of chair and CEO should be held by different individuals. In addition, Jensen (1993) points out that when the CEO also holds the position of the chairman of the board, internal control systems may fail, as the board cannot effectively perform its functions including those of evaluating and firing CEOs. Similarly, Fama and Jensen (1983) argue that concentration of decision management and decision control in one individual reduces a board's effectiveness in monitoring top management. There is some evidence in the literature that firms perform better when the CEO and chairman function are separated. Pi and Timme (1993), Baliga et al. (1996) find that firms combining the CEO-chairman titles perform worse than firms that do not combine them.

HYPOTHESIS 2: *There is a positive relation between the separation of CEO and chairman and enterprise risk management.*

HYPOTHESIS 3: *There is a joint positive relation between enterprise risk management on the one hand and board independence and the separation of CEO and chairman on the other hand.*

4. SAMPLE SELECTION

We focus our study on one particular industry to maximize statistical power and because different industries may have different framework and different needs. The sample is composed entirely of firms from SIC code 2834-Pharmaceutical preparations. This industry has been used in previous research (Vanstraelen et al., 2003; Robb et al., 2001). Firms in this particular industry are faced with a wide array of risks and appear to display a sufficient amount of variation in enterprise risk management practices. The pharmaceutical industry is a competitive industry with pressure to perform, generating incentives to cut corners if results are not satisfactory. In addition, the SEC enforcement list contains several pharmaceutical companies that manipulated numbers in response of bad results. Therefore, we believe that focusing on this sector will allow us to study the impact of board characteristics on enterprise risk management. We selected randomly 100 firms, however because of missing data we only retained 75 firms. The data we collect is related to the fiscal year 2003. To assess the quality of enterprise risk management, we use publicly available data, such as 10-K's, proxy statements related to fiscal year 2003 and the company website. All other data is electronically collected via Datastream.

5. RESEARCH METHOD AND DEFINITION OF VARIABLES

We propose an Ordinary Least Squares to test our hypotheses. We test the quality of the ERM against the board characteristics, board independence and separation of CEO and chairman position, firm size, free float, leverage, beta and the auditor.

$$ERM = f(BODI, SIZE, BETA, LEV, DT, EY, KPMG, PWC) \quad (1)$$

$$ERM = f(CEOC, SIZE, BETA, LEV, DT, EY, KPMG, PWC) \quad (2)$$

$$ERM = f(BODI, CEOC, BODICEOC, SIZE, BETA, LEV, DT, EY, KPMG, PWC) \quad (3)$$

Quality of Enterprise Risk Management

We use the COSO (1992, 2004) framework and prior work by Knechel (2002) to define relevant control and risk management procedures and derive an aggregate enterprise risk management measure. We use control and risk management measures which reflect the organization's own assessment of control and risk management efforts. For each company, the annual report was evaluated for information about specific types of controls and risk and related enterprise risk management practices. We consider 7 aspects of ERM, similar to COSO-ERM framework (2004). Similar to Knechel (2002), we expect that the disclosure of control and risk management practises indicates that the organization is very sensitive to the need to identify and manage those specific risks. The measure of enterprise risk management we use is composed out of 91 questions, scoring 1 or 0. The total average score is about 32%, which means that on average firms provide information on 32% of enterprise risk management issues included in our framework.

Independent Variables

A number of typical measures of the quality of the board were included in the model. Consistent with this previous research (e.g. Carcello *et al*., 2002), we examine the following measures of the quality of the board of directors.

- BODI: Percentage of the Board of Directors that are considered to be independent.
- CEOC: Dummy = 0 if the CEO is also the Chairperson of the Board of Directors, 1 otherwise. We attach a positive value to the separation of CEO and chairman.
- BODICEO: Dummy = 1 if both the board is independent and the CEO and Chairman different persons.

Control Variables

- ***Agency costs.*** Agency costs arise from both equity and debt financing. We include free float (FF) to control for agency costs of equity, and leverage (LEV), measured as long-term debt over total assets, as a proxy for the agency costs between a company and its outside debtholders (Watts and Zimmer-

man 1986). Milgrom and Roberts (1992) argue that larger shareholders are possibly more willing and able to play an active monitoring role. Therefore, the agency cost of equity will be higher for firms with high public ownership and hence more need for enterprise risk management.

- ***Size.*** We include firm size, measured by total assets. Company size is associated with both internal and external agency costs (Adbel-Khalik, 1993).
- ***Beta.*** We include a measure for the perceived amount of risk by investors. We hypothesise that firms with high beta risk are perceived to be more risky. This may be because a firm is operating in a more volatile environment.
- ***Audit Firm.*** We believe that audit firms may have an impact on the implementation of enterprise risk measurements. This variable can take 5 different values: Non-Big 4, KPMG, E&Y, D&L and PwC. We take as reference category the non-Big 4 auditors.

6. RESULTS

We first discuss the descriptive statistics. In figure 1, we present and interpret the most important descriptive information for the dependent variable. We observe that firms score well on objective setting and risk identification, while they score weakly on control activities score and monitoring. In addition, we see a large variation in the total enterprise risk management scores between the minimum total score of 2 and a maximum of 75, with 67% of the observations between 17 and 41.

Next, we present descriptive statistics for the test and control variables. On average the pharmaceutical firms have large boards (an average of 8 members). The average board independence is around 73% and in the majority of the cases the CEO occupies the seat of the chairman of the board (contrary to corporate governance recommendations).

The pharmaceutical firms are on average relatively large, with a mean of 6802 million dollars of assets. Furthermore, the average firm has more than 50% of its shares are publicly traded. The average market risk (beta) is 1,57 time higher compared to the overall stock exchange and on average 18% of the total assets consist of long term debt.

High correlation amongst independent variables could affect the significance level of the variables. We checked for multicollinearity and found no problem (value of VIF of 2,34). We first test the relationship between ERM implementation and board independence, subsequently the relationship between ERM and separation of CEO and chairman and finally the relationship between ERM the combination of independence with separation as test variable. We depict the results in figure 3.

We see that our proposed models are all significant and explain between 30% and 38% of the variance in the dependent variable. The first model, with board independence as test variable is strongly significant, but board independence does not help to explain the variance in the dependent variable significantly. Therefore we can not reject hypothesis 1. Besides, we conclude from the first model that all control variables show the expected sign, except the leverage. We expected a positive relationship rather than a negative. Leverage and the beta risk are weakly significant, while firm size and the KPMG auditor are highly significant. Free float, Deloitte, Ernst & Young and PwC show a non-significant relationship.

In the second model, we introduce the separation of CEO and chairman as test variable. We predicted a positive sign, given that it takes 0 if there is no separation and 1 if there is separation. The model now explains more of the variance in the dependent variable, with an adjusted R^2 of 28% and is highly significant ($p < 0,00$). The test variable is highly significant ($p < 0,00$) and positive, indicating a positive relationship between enterprise risk management practices and the separation of the CEO and chairman. In contrast to board independence, the separation of CEO and chairman has a positive influence on the adoption of ERM practices. It may be that the board independence shows no results because the board operates differently when the CEO is also the chairman. Jensen (1993) points out that when the CEO also holds the position of the chairman of the board, internal control systems fail, as the board cannot effectively perform its key functions including those of evaluating and firing CEOs. Similarly, Fama and Jensen (1983) argue that concentration of decision management and decision control in one individual reduces a board's effectiveness in monitoring top management.

Furthermore, we investigate the influence of an independent board with a separation of CEO and chairman on the adoption of internal control measures. We obtain a slightly improved model, compared to model 2. The test variable is highly significant. From the results above we conclude that the separation of CEO and Chairman plays an important role in the adoption of enterprise risk management. In addition, model 3 tests whether there is an interaction effect between the separation of the CEO and chairman and an independent board work even better.

Figure 1. Descriptive statistics of enterprise risk management scores

	average	max score	median	min	Max	st dev	average %
Internal environment	5,12	17,00	5,00	0,00	14,00	3,21	0,32

Figure 3. Regression results: ERM explained by board characteristics

		Model 1	Model 2	Model 3
C		-4,45 (-,442)	-14,693 (-1,54)	-9,563 (-1,43)
BOD-I	+	1,47 (,158)		-8,27 (-,950)
CHCHC	+		7,911*** (2,72)	-5,301 (0,22)
BOD-I CEOC	+			26,552*** (2,997)
FF	+	2,402 (,268)	6,246 (1,000)	6,146 (1,047)
LEV	+	-9,941* (-1,748)	-9,102* (-1,699)	-8,434 (-1,645)
SIZE	+	1,765*** (3,103)	2,278*** (4,118)	2,227*** (4,172)
BETA	+	1,500* (1,047)	1,366* (1,795)	1,393* (1,799)
D&T	?	3,804 (1,134)	2,230 (,788)	2,006 (,745)
E&Y	?	4,011 (1,505)	3,315 (1,127)	2,990 (1,034)
KPMG	?	11,641*** (2,876)	13,06*** (3,66)	14,29*** (3,889)
PwC	?	-1,472 (-,351)	-4,812 (-1,16)	-3,435 (-1,014)
R^2		,296	,360	,394
adj R^2		,198	,280	,293
Prob(F-stat)		,004	,000	,000

We observe that the board independence and separation of CEO and chairman become insignificant, while the interaction term is highly significant. It seems that it is important to combine a separation of CEO and chairman with an independent board to stimulate enterprise risk management adoption. Our results are in line with the results from Kleffner et al. (2003) which indicates the importance of the board in stimulating the adoption of control and risk management measures. We repeated the analysis using an equally weighted measure for enterprise risk management quality and obtain very similar results.

7. CONCLUSION

The paper analyses how board characteristics are related to the adoption of enterprise risk management. We found that board independence alone has no significant relationship with the ERM quality. The separation of the CEO and the chairman and the combination of an independent board with a separation of CEO and chairman, however are significantly related to the adoption of ERM. Firms with a separation of CEO and chairman, or firm with an independent board combined with a separation are more likely to adopt ERM. Given that board members have incentives to promote ERM in order to reduce own responsibility, our results indicate the importance of the separation of CEO and chairman in the adoption of enterprise risk management.

Incorporating Personal Information into RDF

Sabah S. Al-Fedaghi, Kuwait University, P.O. Box 5969, Safat 13050, Kuwait; E-mail: sabah@eng.kuniv.edu.kw

ABSTRACT

This paper introduces an RDF-based ontology to model personal information. The triples construct is applied to 'atomic' private statements. RDF is divided into two modes: personal information mode (PIRDF) and non-personal information mode. PIRDF is a restrictive version of RDF where its constructs follow the triple format such that the semantic subject of the atomic private statement coincides with the subject of the RDF triple. Also, related (compound) pieces of personal information are made in an RDF independent collection to preserve their relationship. Literals are not allowed to embed personal information. These restrictions do not introduce any change in the syntax of RDF. Privacy protection mechanisms can be constructed upon PIRDF.

INTRODUCTION

The Resource Description Framework, RDF, is a framework for describing and interchanging machine-understandable metadata. It facilitates knowledge sharing and exchange through automated processing of Web resources in such areas as content rating, intelligent agents, intellectual property, and privacy preferences and policies. According to the World Wide Web Consortium, "Using a metadata schema to describe the formal structure of privacy practice descriptions will permit privacy practice data to be used along with other metadata in a query during resource discovery, and will permit a generic software agent to act on privacy metadata using the same techniques as used for other descriptive metadata" (Kim et al. (2002). Of special importance in the context of Semantic Web is to automate interaction regarding personal information and autonomously decide what information to exchange. A fundamental abstraction in achieving this is identifying basic 'units' of personal information.

In this paper we discuss how to define and incorporate these 'units' of personal information into a Semantic Web service model. It also proposes to construct an ontological foundation for modeling identifiable-person type of resources separate from other types of entities. Accordingly, our RDF model consists of 'person-resources' represented as nodes that refer to identifiable persons and statements about these persons. One clear advantage of such a model is that there are well-defined nodes of distinct entities: identifiable persons. In general, resources are divided into resources that represent identifiable persons and resources that identify anything else. The basic characteristic of personal information is that it uniquely identifies a real person. This person is not an interpretation that depends on namespaces. He/she is a single person who has been or was documented to exist in this world and may have several identities and descriptions. Identifiable human beings are the only "resources" that have this ontological unique identification.

Section 2 discusses related works that deal with privacy in RDF. Its contention is that there is no current work on personal information ontology below the level of specification languages for privacy policies and a user's privacy preferences. The materials in section 3 are a review of the personal information definition and classification given in Al-Fedaghi (2005), where "atomic units" (RDF triple-like constructs) of personal information are introduced. Section 4 gives our main contribution: describing refined 'atomic personal information' (called self-statements) and mapping them to (private) triples. In this paper we assume familiarity with RDF.

PRIVACY AND RDF

Our work aims at developing a model - based on personal information ontology - for RDF that is used for the purpose of analyzing and classifying personal information. 'Personal information ontology' in this paper refers to the categories of personal information that exist in the privacy domain, thus, the ontology produces a catalog that details the types of pieces of information and their relationships that are relevant for privacy (Jacob, 2003). We deal with the following problems:

(a) How to define personal information, its types, its relationships, and its mappings to its proprietors? The answers to these questions are adopted from Al-Fedaghi (2005).
(b) How to represent personal information in the RDF model? The answer to this question is accomplished through mapping personal information statements to RDF triples and imposing some restrictions on these triples.

We concentrate on a version or mode of RDF that involves only personal information. For example, *John is 32 years old,* is atomic personal information because it embeds a single referent of type *person*. *This conference is in Canada* is non-personal information because it does not embed a referent of type person. *John likes Mary* is compound personal information because it embeds two referents of type person. The atomic personal information *John's car is White* embeds two assertions:

(1) The non-personal information *The car is White,* and
(2) What we call 'self-statement': *John has a car*. This self-statement forms our 'private RDf triple' with the person-resource: John.

Currently, in such formalisms as P3P (see Al-Fedaghi (2006)) and RDF there is no explicit distinction between personal information and "owned" information. The P3P works even if the data is not "private" in the sense that it refers to a *person*. In our ontology of personal information, the system would "recognize" personal information and would distinguish it from non-personal information. Agents will be able to recognize that the requested data is private data (of the agent's owner or otherwise) and responds accordingly. We propose to mold pieces of personal information in a restricted form of RDF.

There are several attempts to link personal information to RDF. RDF is proposed as a mechanism to create a "privacy ontology group with a charter" (Hogben, 2002). Kolari et al.(2005) propose to overcome the problem of restrictive expression capabilities of APPEL through "the use of privacy policies described in an RDF based policy language, Rei, which can make policy decisions over actions and associated restrictions modeled using a Web privacy ontology" (Kolari, 2005). We claim that our ontological treatment of personal information in the context of RDF is a useful contribution to building privacy into the Semantic Web. According to Kim et al. (2002), ontology for building privacy into the Semantic Web is needed now.

PERSONAL INFORMATION

We view 'personal information' as a symbolic form that 'informs' about a single human being. 'Information' here means the 'semantic content' of a linguistic statement or assertion. A personal information theory includes a universal set of personal information agents, $Z = V \cup N$, of two fundamental types of entities: *Individual* and *Nonindividual*. *Individual* represents the set of natural persons V and *Nonindividual* represents the set of non-persons N in Z.

Definition: Personal information is any linguistic expression that has referent(s) of type *Individual*. Assuming that p(X) is a sentence such that X is the set of its referents, there are two types of personal information:

(1) p(X) is atomic personal information iff X ∩ V = is the singleton set {x }.
I.e., atomic personal information is an expression that has a single human referent.
(2) p(X) is compound personal information iff | X ∩ V | > 1.
I.e., compound personal information is an expression that has more than one human referent.

In Al-Fedaghi (2005), the relationship between individuals and their own atomic personal information is called *proprietorship*. Proprietorship of personal information is different from the concepts of possession, ownership, and copyrighting. If p is a piece of atomic personal information of v ∈ V, then p is proprietary personal information of v and v is its *proprietor*. Proprietorship gives "permanent" rights to the proprietor of personal information.

One of the most important acts on personal information is the act of *possession*. A single piece of atomic personal information may have many possessors; where its proprietor may or may not be among them. A *possessor* refers to any agent in Z that knows, stores or owns the information. Human beings are conceptualized as personal information proprietors; however, they are not the sole sources of this information. For example, companies and government agencies in N can produce and possess (non-proprietary) personal information.

Any compound personal statement is privacy-reducible to a set of atomic personal statements (Al-Fedaghi, 2005). For example *John and Mary are in love* can be privacy-reducible to *John and someone are in love* and *Someone and Mary are in love*. Atomic personal information is said to be *self-statement* if its *subject* is its proprietor and 'only its proprietor'. A framework for the derivation of self-statements from atomic personal information is given in another paper. For example, *John's house is burning* is not self-statement because it expresses two pieces of information: (a) *John has a house* and (b) *The house is burning*. Statement (a) is self-statement because its 'subject' is its proprietor. The statement (b) is non-personal statement because its 'subject' is not a person but a house. The term 'subject' here means the entity about which the information is communicated. It is an important notion when it is tied with the notion of 'subject' in RDF triples. In many cases the 'semantic subject' means that the individual affects (agent) or is-affected-by (patient) something, as reflected by the verb of the sentence. For example, in *The company invited John to an interview*, it is not clear that John is the (semantic) subject. However, *John is invited to an interview by the company* shows that John is being subjected to an action. The principle that we will follow is: the proprietor of the atomic statement has priority in being a subject when there is another entity that has a claim to being a (semantic) subject of the verb. For example in *John trained the do*g and *The dog is trained by John,* the subject is John. In *John's house is burning,* John clearly has less claim for the verb of "burning', while in *John trained the do*g, John is the trainer and the dog is the trainee, hence both have equal claim to the verb.

A self-statement's structure is the typical (subject, predicate, object) form of assertions. The (semantic) 'object' here is either an 'attribute' of the subject (e.g., tall, brave, etc.) or a non-individual entity (e.g., as in *John trained a dog*, *John derives the car*, *John loves stakes*, etc.) Every atomic personal statement is reducible to a set of self-statements and non-personal statements. Here, because of space limitation we claim that this is intuitively reasonable. It reflects the common sense notion, that a statement is about entities in reality, which can be classified into different categories (ontological objects).

PERSONAL INFORMATION RDF

The basic RDF model contains statements as parts of descriptions of some resources. We propose two modes of the RDF model:

(1) Personal Information mode of RDF (PIRDF) that facilitates all dealings with personal information.
(2) Non-personal information mode of RDF, which is the ordinary mode of RDF.

Any information in the non-personal information mode of RDF is considered as non-privacy-related information, while information in PIRDF is handled as privacy-related information of some proprietor. PIRDF may include non-personal information, but this personal information is there because it 'complements' the semantics of some personal information. For example, in *John takes drug x23 which is used to treat cancer*, both the self-statement *John takes a drug* and the non-personal information *The drug is called x23 and used to treat cancer* are handled by PIRDF. These statements are treated as a collection of triples in order to facilitate reconstructing the semantics of the original statement, if such reconstruction is needed. Also, treating a set of statements as an RDF collection is the method used in PIRDF to represent compound personal information.

Personal information in PIRDF is treated in a special way to protect the privacy of proprietors. We will not deal with this side of PIRDF, and concentrate in this paper on the method of describing personal information in PIRDF. Our strategy is not to introduce any new feature to the standard RDF, rather we propose measures that restrict modeling triples in a way suitable for personal information. These restrictions are as follows:

(1) The subject of any RDF triple that represents self-statement is always a proprietor. It is also allowed to have the proprietor as the object in a reification statement with attribute: subject. The reason for making the proprietor as the subject of this type of triples is because it is the "semantic" subject of the corresponding self-statements. Thus, we merge the 'triple subject' with the semantic subject. This provides unique identification of personal information according to the content of the triple (subject + type: person), hence, it is not necessary to 'RDF-type' private statements. The resulting graph reflects the proprietor as the center of his/her personal information sphere as shown in figure 1.

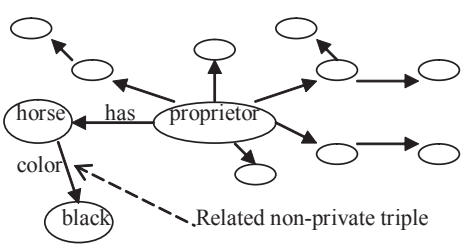
Compound personal information is represented as a set of triples of atomic personal information in an RDF collection. The reason for this is to allow the system to clearly identify the proprietor of any piece of personal information. Thus, the triple (John, threatens, Alice) is not allowed and replaced by (John, threatens, someone) and (Alice, being-threatened-by, someone). The method of representing these two triples without persons being allowed as objects is an open problem. Notice that the purpose in this type of modeling is to clearly distinguish John's personal information from Alice's personal information. It is possible that Alice is not permitted to know who threatens her (e.g., mental health confidentiality); however, she may have the right to know that she is the object of a threat.

A "resource" is defined in RDF as *anything that has identity*. In general, according to RFC 2396 (Berners-Lee et al., 1998) "A resource can be anything that has identity... Not all resources are network "retrievable"; e.g., human beings, corporations, and bound books in a library can also be considered resources." PIRDF describes a special type of resources: 'identified persons' class that is defined as the RDF schema vocabulary:

:Proprietors rdf:type rdfs:Class.

We denote this type of resource as 'person resource', for short, *pe*source. This pesource is an *information entity* that is realized through a set of atomic personal information. Every pesource is uniquely identified in the PIRDF. A person as an 'information entity' is a known ontological concept. According to Floridi (1998), all objects including human beings are 'information objects': "[A] person, a free and responsible agent, is after all a packet of information... We are our information... personal information is a constitutive part of a me-hood" (Stein et al., 2000). We observe that there is a difference between the conceptualization of a human being as an information entity and as a personal information entity. Thus, for us a pesource is an information entity formed from a set of pieces of atomic personal information.

Figure 1. The proprietor is always the (semantic and syntactical) subject of the private triples



PIRDF maintains the informational ontology of each proprietor through maintaining his/her personal information. It identifies pieces of personal information of each proprietor. These pieces of personal information are treated with special consideration in terms of: operations that include: disclosure, possession, consistency, sharing, etc. Non-personal information is treated in an ordinary way.

Using our terminology for personal statements, we can categorize triples that correspond to personal statements as follows:

(a) A non-private triple is a triple that does not contain any resource that denotes a person.
(b) A private triple is a triple that represents a self-statement.

In RDF, the subject is the node the statement is about. It is either an URI reference or a blank node. In PIRDF, the proprietor is always the subject of private triple. We assume that all personal information statements are in the form of self-statement. The subject of personal information triple refers to the subject of a self-statement.

Example: Suppose that we have the atomic information *Ernest Hemingway's FAREWELL TO ARMS is located at AF.123*. It embeds the two statements:

(a) Ernest Hemingway authored FAREWELL TO ARMS
(b) FAREWELL TO ARMS is located at AF.123

PIRDF gives special considerations to represent facts about persons, not about books, houses, etc. Assume that Ernest Hemingway is an entity of type person declared as proprietor in :Proprietors**.** Being a subject of triple (a) represents an implied type of the triple, thus we don't have to introduce the type 'private' to be associated with statement (a). A private triple is a triple where the subject is of type person. This is a very useful convention.

Alternatively, We could have considered both:

Ernest Hemingway authored FAREWELL TO ARMS,
FAREWELL TO ARMS is authored by Ernest Hemingway

as forms of personal information. However, in this case we have to distinguish between the "semantic subject" (what the statement is about) and the RDF subject. In *FAREWELL TO ARMS is authored by Ernest Hemingway,* the (privacy) "semantic object" is Ernest Hemingway while the RDF subject is (the book): FAREWELL TO ARMS.

In the original example, the other piece of information: *FAREWELL TO ARMS is located on AF.123* is non-personal information. Hence, it has no special consideration in PIRDF. It could be represented, if we like, as *AF.123 is the location of FAREWELL TO ARMS*.

In PIRDF world, the distinction between private and non-private triples is important. PIRDF is a partial, simplified conceptualization of the world created for the purpose of handling personal information and defined in a formal, machine-processable language.

In RDF, URIs identify network-accessible things, things that are not network-accessible, and abstract concepts. In PIRDF, identifiable network-accessible 'things' are of two kinds: privacy-based and non-private-based things. Without loss of generality, we assume privacy-based things are textual materials. Similarly, things that are not network-accessible are categorized into persons and non-persons.

In RDF, a URI is just a node that has a URI label on it, where the URI identifies the resource represented by the node. Since the URI directly identifies the resource represented by a node, RDF assumes that nodes with the same URI represent the same resource. A URI may be complemented with an optional fragment identifier, URIref. In PIRDF each proprietor is mapped uniquely to a single entry in the vocabulary pirdf:proprietor. This does not prevent from using different synonyms that are mapped to a single URIref in pirdf:proprietor. In principle, a proprietor may choose to have several "personal information personalities" through having more than one URIref in pirdf:proprietor. In this case he/she has two different "personal information spheres." This is an implementation issue similar to the problem of the uniqueness of RDF resources. However, the uniqueness of proprietors is easier to handle because of the already ultra-importance of identification of persons inside and outside the network. We will assume that each proprietor identifier represents a single person.

Example: Consider the following familiar compound personal information:

Ralph Swick says that Ora Lassila is the creator of the resource http://www.w3.org/Home/Lassila.

According to the W3C Recommendation (1999), figure 2 represents its graph form. We can criticize this graph representation on the ground that it does not correspond with the linguistic structure of the statement, which is in the triple form,

(*Ralph Swick says* (*Ora Lassila is the creator of the resource http://www.w3.org/Home/Lassila*)).

The main "subject" in the graph is the 'statement', while the original main subject *Ralph Swick* has become a value of an attribute to the statement. So, semantically, the whole graph is about 'the statement': about its subject, its object, its predicate, and its 'attributer'. This is not a suitable graph representation in PIRDF, because personal information is always about the proprietor: he/she is the subject.

Figure 3 shows the graph form of the given statement in PIRDF.

It has two atomic statements:

(1) *Ora Lassila is the creator of the resource http://www.w3.org/Home/Lassila.*
(2) Ralph Swick says statement (1)

This example illustrates another allowable position of the proprietor in PIRDF: as an object of the attribute: subject. Clearly, this case is syntactically discoverable.

The two atomic pieces of personal information (1) and (2) embed identities of proprietors. The personal information (1) is represented in the shown triples. Notice that PIRDF assumes that the only way to identify a proprietor is through his/her pirdf:proprietor identification.

Example: Suppose the we want to express the statement (Johannesen, 2004): *Tom borrowed a book from Mike*. In RDF, this can be expressed through a blank node that has connections to different properties as follows:

Figure 2. Reification in RDF

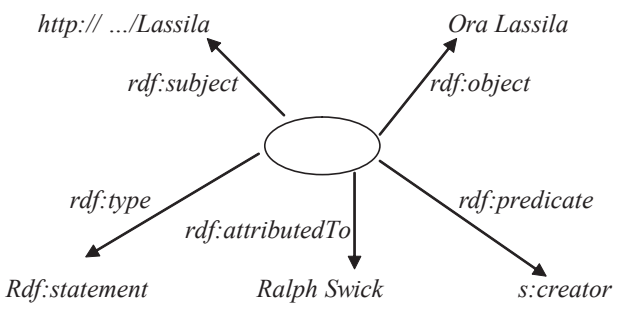


Figure 3. Reification in PIRDF

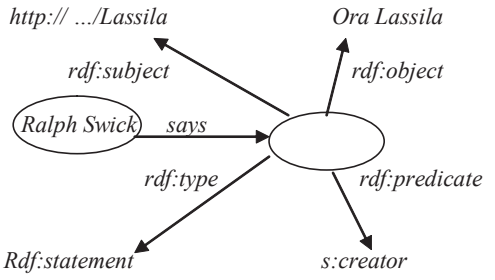

_:a rdf:type x:Borrowing
_:a x:who prs:Tom
_:a x:fromWhom prs:Mike
_:a x:what _:b
_:b rdf:type x:Book

This specification is described as "not the easy way to do the Semantic Web" (Johannesen, 2004). In PIRDF, the compound personal information *Tom borrowed a book from Mike* can be implemented as a collection of two triples: *Tom borrowed a book* and *Mike has a book* as shown in figure 4. Thus, the notion of compound personal information embeds the concept of a set.

Example: Consider the familiar RDF expression: (:Jane :daughterOf :John, : Jennifer). It can be represented in PIRDF as shown in figure 5.

Different personal assertions are distinguished as follows:

The personal information of Jane: *Jane is the daughter of some parents*
The personal information of John: *John is the father of someone*
The personal information of Jennifer: *Jennifer is the mother of someone*

It may sound somewhat odd to say that *Jane is the daughter of some parents*. However, imagine that the graph represents the database of an adopting agency. Then even Jane should not know her parents without permission.

The design of PIRDF requires several modifications with regard to literals. The general rule here is, it is not allowable to make literal personal information. Thus, *The newspaper headline is: John is a killer* may be described in RDF as the triple (<http://…newspaper> <http://…headline> "John is a killer"). However, in PIRDF, it is necessary to factor out personal information as shown in figure 6.

CONCLUSION

We have introduced elements of 'personal information modeling' in RDF. The proposed model is based on two foundations: defining personal information in terms of statements that refer to persons, and representing statements as RDF triples. The result is a preliminary RDF-based ontology of personal information. Space limitation does not allow more details to achieve further specification of such ontology. Our contribution is a first step towards focusing on the problem of personal information ontology below the level of modeling privacy preferences and policies.

Figure 4. Graph of Tom borrowed a book from Mike in PIRDF

Figure 5. Jane is the daughter of John and Jennifer in PIRDF

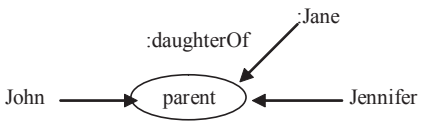

Figure 6. PIRDF allows the proprietor to be the object, if the attribute is 'subject'

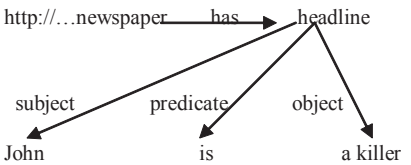

There are several extensions to the basic PIEDF model. For users, their triples include:

- Private triples and related non-private triples,
- Sets of triples that represent compound personal information,
- Triples that represent personal information in the possession of the user.

Thus, in building a rules system, each of these types of personal information is treated differently. Generally, how PIRDF influences the rule system and policy language needs to be investigated. Also, several constructs of PIRDF present interesting issues in the new formalisms such as OWL (see Al-Fedaghi (2006)).

What Practitioners Are Saying About the Unified Modeling Language

Brian Dobing, University of Lethbridge, 4401 University Drive W., Lethbridge, AB, T1K 3M4, Canada; E-mail: brian.dobing@uleth.ca
Jeffrey Parsons, Memorial University of Newfoundland, St. John's, NF, A1B 3X5, Canada; E-mail: jeffreyp@mun.ca

INTRODUCTION

The Unified Modeling Language (UML) was formally introduced in the late 1990s, with much of it based on earlier object-oriented systems analysis and design (OOAD) methods. The UML quickly became the language of choice for modeling object-oriented systems and there are now numerous books, many written by practitioners, which describe the UML and suggest approaches for using it. The UML has continued to evolve, notably with the release of UML 2.0, driven largely by a "best practices" approach. This paper offers qualitative evidence of the broad scope of practitioner views on the UML in the form of comments from by UML practitioners in response to a survey on UML usage patterns. The range of comments suggests some interesting directions for future research.

RESEARCH METHODOLOGY

A web survey containing 38 questions, many with multiple parts (e.g., a list of possible reasons for not using a particular UML diagram), was developed and posted on the web in March 2003. The Object Management Group (OMG) supported the project by sending an email to their members to inform them of the survey, and by posting a link on their main web page. The survey was "intended for current systems analysts/architects who have used or considered using the UML in systems development projects" and some initial items asked about that experience. A few respondents did not belong to our target population, but no reported comments or data come from them. There were no rewards offered for participating, except for a copy of the results, so there was no incentive for non-UML practitioners to complete the survey with fictitious responses.

Most of the questions used standard Likert scale items and check boxes. Some of this quantitative data was presented and analyzed in Dobing and Parsons (2006). Respondents were also given substantial opportunities to add comments and further explanations. This paper focuses on these written responses, selected from 52 surveys. While these comments may not always reflect the majority views of the UML practitioner community, they are useful in identifying issues and concerns among a group of people who are largely committed to the UML and to its continued improvement.

The quotes provided in this paper are generally as submitted with any minor modifications (generally to preserve grammatical correctness) inserted in square brackets. Typographical errors have been corrected without any indication. Any use of upper case for emphasis has been left as in the original.

RESULTS

This section addresses some important UML issues which received higher levels of written responses. As might be expected with a relatively new language, it is being used in quite different ways by different people. As one respondent put it:

Used, vs. used appropriately, is probably a telling difference. Many places are using the components but in a relatively brain-dead manner. I don't think this is a UML issue. It is a brain-dead issue.

Of course, one developer's "best practice" can be another's "brain-dead manner." Our goal is not to offer solutions but simply to identify some of the issues about which UML practitioners feel strongly and are trying to address. These, in turn, should be useful in guiding further research in this area.

Use Cases

The UML is a language and not a development methodology, but all the major books on the subject adopt the "Use Case-driven" approach espoused by Jacobson (1992). There are some critics (e.g., Anderson, 1999; Simons, 1999), but most warn about incorrect application (e.g., using too many, going into too much detail, etc.) and do not reject Use Cases completely. However, our survey found that only 63% of respondents employed Use Cases in at least one-third of their projects. One respondent was "curious [about our] bias … towards Use Case narratives" saying "This is not a mandatory way to elicit initial requirements." Others described Use Cases as "close to useless," "just unformatted text notes," and "too imprecise to invest much effort in." "The ambiguity of Use Cases in particular is problematic." Another argued for a more limited role, saying "They are critical in defining the boundary behavior of the system but only that." Thus, there is a sharp discrepancy between practice and conventional wisdom in the literature.

One respondent questioned whether the Use Case Narrative is a model, asking:

Use cases allow technologists to build something that resembles a business solution. They are useless in modeling the actual business processes. ... Yes, you can put some information into a narrative, but is that a model?

Perhaps the key underlying issue concerns the role of Use Cases in requirements gathering, which is their intended purpose, and in design where the other UML diagrams are more relevant. One respondent stated:

Use Cases MUST be combined with functional requirements and constraints. Use Cases only show the behavior of the system.

Behavior is, of course, exactly what a Use Case Narrative is designed to show, 'what' not 'how' (Jacobson et al., 1994, p. 146). Whether the 'how' includes the user interface remains a concern. Constantine and Lockwood (1999, p.102) argue in favor of 'essential' Use Cases, which exclude interface details, claiming that "conventional use cases typically contain too many built-in assumptions … about the form of the user interface." But respondents who commented on this issue generally took the opposite view. One stated that "end-users have difficulties [when] validating a Use Case Narrative without any draft of the UI." Another goes further, saying, "It is easier for clients to understand the functionality of software through user interface sketches." While it is important to "promote better Use Case writing styles," there was no consensus among our respondents on what the style should be.

Use Cases were acknowledged to be useful in "defining test cases" and "effort estimation." The associated Use Case Diagrams, which generally were viewed less favorably, provide an "overall view" and help with "scheduling [and] risk assessment." While consistent with the literature, these are not generally considered the key reasons justifying Use Case development.

Other respondents identified alternatives. One "eliminated Use Case Narratives in favor of Activity Diagrams" while another said that "a state model hierarchy is sufficient." 'State model hierarchy' is not a UML term, or even one commonly associated with system development, but is used in connection with knowledge bases for expert systems. Some indicated they use "text" instead but without specifying how their documentation differs from Use Cases.

Another issue with Use Cases is their organization and maintenance. This is particularly true for those who favor more of them with more detail. One respon-

dent who did not use them stated, "My guess is it would be too hard to store and recover the Use Case narratives to use them in later [maintenance]." Of the 39 respondents who reported the number of Use Cases on "typical" projects, the top 15 ranged from 100 to 800. We did not ask about average length. One proponent said, "our typical Use Cases consume one - two pages each." but an infrequent user said that "Use Cases tend to become remarkably complex and highly error prone - have seen Use Cases as large as 250 pages." One reason for this variation may be the lack of any official UML specification. The OMG (2005. p.574) simply states that "Use Cases are typically specified in various idiosyncratic formats such as natural language, tables, trees, etc." There are now several books devoted to Use Cases (Armour and Miller, 2001; Cockburn, 2001; Adolph and Bramble, 2003; Bittner and Spence, 2003; Denny, 2005; Övergaard and Palmkvist, 2005) along with a few web sites, notably Cockburn's (http://www.usecases.org). But that isn't sufficient for one respondent who argues, "too much written but still too little [clarity on] what goes where [and] tools - little benefit for the time and effort invested in Use Cases."

There is insufficient understanding of why so many practitioners are avoiding Use Cases and what they are using as alternatives. Also, if a project has no Use Cases it certainly isn't Use Case driven. What, if anything, is driving their projects?

Activity Diagrams

We would expect differences of opinions on all UML diagrams but, after Use Cases, they were expressed most sharply for the Activity Diagram. One proponent stated, "We are currently using Activity Diagrams for the detailed specification of all Use Cases" while another said they were "useful to understand business activities [and] useful to understand the flow of activities in a Use Case." Another called for client involvement, "These being the only container we have that can hold business process information, it is critical that business people are engaged as much as possible." Their role was explained more fully:

Activity diagrams are very important when the client begins to describe process-like behavior and logic. Good to help understand and convey a business process, or an underlying algorithm. In these cases, I think an Activity Diagram is essential – compared to pure text.

However, others took strongly critical positions. One simply said, "'Activity' actually - sorry – sucks." According to different respondents, "they are very time-consuming to produce," have "unclear semantics and an unclear connection to the rest of the UML Diagrams," do not represent "the concept of a 'business process,'" are redundant "if Use Cases are well written and well modeled," lack a "wealth of information" about them in the literature and have "very poor tool support and integration (via tools) with the rest of the notation." Some suggested modifying them, "[without] the Erikkson Penker extensions … UML Activity Diagrams would be pretty useless for business modeling" and "we used Activity Diagrams, but with our own semantics." Others said "they need to be more like DFDs if they're to be useful" and "neither the concept of a 'business process' is well represented, nor is the value of good old DFD diagrams available." The latter respondent also claimed to "have developed an interesting and useful notation for processes/tasks/workflow." Alternatively, perhaps they are not sufficiently connected to the Class Diagram:

UML does not handle business process modeling. Activity Diagrams are the nearest, but: (a) I want to show classes, not instances. (b) I want to show resources (as classes!) input and output…

Thus, practitioners seem to have very different expectations for how Activity Diagrams should be used, and thus on how they should be improved.

Project Communication

Communication within the project team has long been considered critical for successful outcomes. Questions on this topic generated a large number of responses. As noted earlier, the UML literature generally stresses the importance of Use Cases for client-analyst communication and the remaining diagrams for analyst-programmer communication. (However, it should be noted that not all projects have distinct clients, analysts and programmers.) In our survey, respondents reported that clients were more involved with the more technical UML diagrams than the literature would suggest (Dobing and Parsons 2006). However, this may reflect the types of clients involved in these projects. In some cases, the clients were likely engineers. And in any organization, when introducing new technology the initial clients are often chosen based on their enthusiasm for trying new approaches.

Some respondents supported the view in the UML literature. For example, one respondent said, "[The Class Diagram] is too far from the business customers and users to be effective [or] useful," while another described it as "the most important diagram for technical members." The separation of Use Cases and Class Diagrams was also mentioned:

Class diagrams are nearly all at a design level, so have little to do with requirements (except that they result from requirements).Class diagrams are essential to deriving/documenting a long-lived, robust, software architecture.

These problems may be exacerbated when analysts take the view of the respondent who said "the only benefit of Use Case diagrams is to please managers."

Simply put, "The only problem is communicating with people not familiar with the UML." But how should that familiarity be achieved? One view is that clients, in general, will not be interested in or able to understand the UML. Those holding this view argue that the UML is "too geeky and techie for non-technical people" and "[our clients] eyes glaze over when we try to present UML/UP artifacts." If analysts proceed anyway, "explaining the notation sometimes dominates the discussions." As a result, there is "little involvement of key business people." These respondents conclude: "give up on this goal" and "don't try – UML is technical, clients are not."

Others see training as the solution. They emphasized the "need to educate clients … in UML," and called for "more awareness programs conducted in the industry." "The most important one is to get the client understanding OO and UML formalism, once this is achieved, you're in heaven." In some earlier informal discussions with early adopters of the UML, we found that sending both developers and clients to joint training sessions was common. Perhaps more efforts of this type are needed. Another said, "Other parties usually don't speak UML. You guys should do something about it." It's not clear if this refers to the OMG or academics, but as members of the latter group we need to think about whether students outside Information Systems majors should be exposed to the UML.

The complexity of the UML is a concern when training anyone in its use, and particularly clients. Simplification is one suggestion:

I think the only way is to teach clients to understand UML diagrams at the necessary conceptual level. This can be achieved by publishing a set of simple articles that use the minimal UML notation and describe [to] customers how it should be read. ... Maybe there is a need to define [a] basic subset used for Analysis. Maybe there should be subspecs describing these basic aspects.

More specifically, "Stereotypes and fancy arrowheads on class and sequence diagrams are details that are lost on the client."

Training is also needed within the technical staff, along with changes in attitude. There were references to "overnight experts [who] refuse to listen to anyone who's done the work before," "people not being able to model … modeling is HARD" and "misunderstanding of the object oriented concept (for analyst and programmers)." There were concerns about both "Luddite programmers," who are presumably experienced but not in object-oriented methods or the UML in particular, and "new staff and novice software developers."

Some of the solutions suggested include consistent terminology across products ("Terminology is the key to success … Visio calls this that and IBM calls this that and J2EE calls this that …"),, "introduce a Use Case Flow Diagram" (to show possible flows), "low-fidelity pieces – sort of a 'UML for Dummies'," agile modeling (and some related practices), and executable UML (which received quite strong support).

As system projects, development teams, and the number of stakeholders affected become continually larger, communication becomes even more important. A common language, such as the UML, can be very helpful. However, the wide variation in how the UML is used, including how it is augmented and handled by different tools, limits that commonality.

Augmenting the UML with Additional Modeling Approaches

We asked respondents which other modeling constructs they have used to augment the UML. The suggestions were numerous and varied. Entity relationship diagrams were the most popular. One reason was that "data is persisted in an RDBMS," e.g., "an Oracle database." E-R Diagrams were not being used instead of the Class Diagram. Of the 17 respondents who reported using E-R Diagrams specifically or just data modeling in general, 15 said they used Class Diagrams on every project. Other older approaches used include Data Flow or Process Flow Diagrams and, more generally, Structured System Analysis and Design. Respondents did not address whether they were using older approaches to phase in conversion to UML or if they planned to retain them in the longer term, although one said that flowcharts were an "appeasement for crusty [business analysts]" and another noted that "[customers] have a tradition of descriptions in a certain format and are not used to a UML view of the system." Some respondents also mentioned using alternative object-oriented approaches, including OMT (Booch), Shlaer-Mellor, Class Responsibility Collaborator (CRC) cards, and Coad/Yourdon.

There were six respondents who used supplementary approaches for user interfaces. As one respondent noted, "UML does not really cover this as such." Respondents were later asked about possible difficulties that had occurred that "could be attributed to the UML." Of the five categories listed, user interface was checked most frequently (36%). Thus, this would appear to be area for further development within the UML. One respondent suggested a possible product:

Lucid [from elegance technologies (www.elegancetech.com)] is a framework for user interface development. It is used very frequently in my company because there are no tools in UML for user interface modeling.

There are other products in this domain, although none were recommended in this survey.

Respondents also used additional tools for enterprise architecture, including Popkin Software and ICONIX. Others did not specify the approach used, e.g., "P2P, 2-tier, n-tier, centralized and distributed architectures."

There is a long list of other products being used to augment the UML, including IDEF (Knowledge Based Systems), Business Process Modeling (OMG), TurboCase (Hatley-Pirbhai method real-time systems) code prototypes ("see it, believe it!") and "ad hoc bubble diagrams." Six respondents reported using their own approaches and another five used various extensions (e.g., "a proprietary spatio/temporal extension" and "extensions for web applications") to the UML.

In answering this question, a number of criticisms of the UML were also put forward. They said the UML is "just a language, so [it] is just adequate for 'drawing' thoughts" and "the UML just a notation." The latter is correct, but many of the alternatives suggested are essentially notations as well. Another said:

[UML] methods ... are too constraining for the average customer. They want to do UML but balk at all the discipline and structure that is required to make it work.

In summary, the UML is often being used with other approaches. Some pre-date the UML and are used for continuity; others supplement the UML to provide additional capabilities. The extent and variety of these practices is a challenge to the claim of a "Unified" language.

Tools

Considerable dissatisfaction was expressed with both the quality ("nobody really implements the standard") and cost of UML tools available at the time this survey was completed. Rational products were used most frequently, with TogetherSoft a distant second. There were over 40 products mentioned in total, but this includes Microsoft Office products (e.g., using Word for Use Cases) and other system development tools not specifically designed for the UML market. Visio came third, but again cannot be considered a full UML tool although it does support the notation. The highly fragmented nature of this market is clearly an issue in the development of good UML tools, and no doubt contributes to problems getting different tools to work together. One, perhaps too cynical, observation was that developers see providing greater interoperability as a competitive disadvantage:

this is not a priority for CASE tool developers as this would allow analysts to change the tools they use in a too easy way.

One lengthy response sums up the general feeling:

One point that might be of more use is asking why there are no (zero) tools that completely support the full UML spec? As well as why tools are of such minimal use on large projects. Who is directing these tool development projects? I guess they start with Use Case diagrams of the problem domain. That would contribute to the use - but I think the problem is elsewhere. You should find a small group of enterprise architects who have also developed large real-world projects and fund them to develop usable tools. The reason I participated in this survey is in the hope we might someday see a tool that provides 15% of what is needed.

Software development tools have generally not received much attention from academic researchers. However, they can have considerable influence over how their underlying methodology is used.

CONCLUSIONS

A survey of UML use revealed considerable differences in the level of use and perceived value of UML diagrams (Dobing and Parsons 2006). This paper provides clues about possible reasons for these differences and points to opportunities for further research.

One concern is that the informality and lack of standards for writing Use Case Narratives limit their usefulness, both for documenting business processes and for supporting the development of other UML artifacts, especially in view of the amount of effort needed to create them. Given that UML advocates often prescribe a "Use Case driven" approach, research is needed to better understand why practitioners disagree on the value of Use Cases, as well as to develop and evaluate potential guidelines for using them consistently and effectively.

A second issue arising from the comments is the lack of agreement on the role and value of Activity Diagrams for describing business processes, as well as their relationship to Use Case Narratives and other UML diagrams. Some respondents found them to be very useful, while others held the opposite view. This suggests the need for research to better understand the role Activity Diagrams should play in UML models.

Another concern raised in the comments from respondents is the (un)suitability of UML diagrams for communication with clients. Despite quantitative evidence that clients are more involved in the development, review, and approval of UML artifacts than the existing practitioner literature suggests (Dobing and Parsons 2006), comments suggest that these diagrams are too technical for clients to understand and use. Clearly, there is a need for research to examine the use and usefulness of UML diagrams in communicating with clients.

Finally, despite the scope and complexity of the UML, some organizations are augmenting it with other modeling approaches. Further research is needed to understand whether this is done to accommodate transitions from older methods to the UML, or because of perceived limitations of the UML.

In conclusion, despite the standardization UML has brought to object-oriented analysis and design, there is a wide range of opinions about how to use the language and how useful the various constituent diagrams are. This offers a significant opportunity for researchers to contribute to a better understanding of effective UML adoption.

1. INTRODUCTION

The popularity of the Internet makes it an attractive option for conducting surveys – it has even been predicted that online-questionnaires will replace traditional delivery methods [3]. Although online-questionnaires offer many [e.g., 7, 15, 24] advantages over traditional paper-based questionnaires, the nature of the electronic medium itself brings some unique challenges [e.g., 3, 6, 11, 15]. To support the creation of online-questionnaires that fully exploit the advantages whilst addressing the challenges, guidelines have been derived to support online-questionnaire design [22].

An environmental scan of existing online-questionnaire design tools found that little, if any, support is currently incorporated within tools to *guide* online-questionnaire design according to the essence of these guidelines [24]. A logical step towards better supporting online-questionnaire design is, therefore, to practically and effectively incorporate the online-questionnaire design guidelines into design tools. This paper reflects on the pros and cons of various candidate support mechanisms which we considered during the realization of this step. The discussion is, necessarily, biased towards our goal and constraints; it is not our intention to extrapolate generic implications from our reflections, but rather to discuss our systematic comparison process and resulting observations in the hope that both may be useful to researchers and developers faced with a similar challenge.

Section 2 provides some limited background information about online-questionnaires and the guidelines derived to support their design; readers are referred to [22-24] for more detail. Section 3 reflects on a comparison of candidate support mechanisms which we undertook to identify appropriate mechanisms for incorporating the guidelines into a commercially available online-questionnaire design tool. The paper concludes with an outline of our planned future work.

2. BACKGROUND

Generating a respondent-friendly questionnaire can pose many challengers for designers, especially inexperienced designers [23, 30]. Design is a complex activity, often involving too much information to feasibly consider without support [10]; *with* support, however, there is potential for designers to be more productive and to produce better quality artifacts [30]. One means by which to provide such support for online-questionnaire design is in the form of design guidelines.

Until recently, online-questionnaire design guidelines have, however, been somewhat scarce [6, 25, 34, 39]. In an attempt to overcome the lack of a practical reference guide, Lumsden [22] derived an extensive set of online-questionnaire design guidelines from principles in the relevant domains of website, paper-questionnaire, and online-questionnaire design. Informed by research on website design, the guidelines have a strong focus on accessibility and usability, such as issues concerning visually impaired users and the elderly [24].

Despite their relevance there are, however, several problems generally associated with the practical use of guidelines [16, 18, 26]: when manifested as a physical document, guidelines are often impractical and therefore ignored [16]; when they must be manually located from a central source they become de-contextualized, lessening their apparent applicability and/or reducing awareness of guideline violation [18]; designers may not know how to interpret and apply abstract guidelines correctly [16, 26]; and guidelines can conflict with one another – increasing the cognitive demands placed on designers [16, 26] – and some (e.g., those relating to design consistency) can be hard to manually enforce. Limiting the practical effectiveness of guidelines, these issues can be addressed by incorporating guidelines into design software and thereby making guidelines an integral and active part of the design process.

Rarely do available online-questionnaire design tools incorporate support for the essence of Lumsden's guidelines [24]. In the rare instances where guidelines are incorporated, they are typically conveyed via defaults and non-context sensitive help facilities. Where defaults are used, designers are not advised about the possible side effects of modifying the default choices. Non-context sensitive help facilities, such as documentation commonly found under a help menu, provide inadequate support because designers must discontinue their design activity and manually search for design guidance – the interruption, combined with inconvenience, making this an unlikely occurrence.

In a trial evaluation of Lumsden's guidelines, based on their current hardcopy manifestation, they were shown to add considerable value to the resulting design of an online-questionnaire [23]. For reasons already noted, it is unlikely that the guidelines will achieve widespread practical adoption and impact in their current paper form. Our aim is, therefore, to investigate how best to incorporate the guidelines within an online-questionnaire design tool such that they inform the design from a practical, active (as opposed to their current passive) perspective.

Online-questionnaire design tools are complex applications and, since current tools (as already mentioned) provide minimal active design *guidance*, we investigated other genres of software design tools in order to systematically review potential candidate support mechanisms for use within the context of online-questionnaire design tools. The remainder of this paper discusses the results of this evaluative process.

3. ASSESSING CANDIDATE SUPPORT MECHANISMS

We define a *support mechanism* to be a user interface element (or set of related elements) that assists a designer in creating better products and/or in solving problems.

To allow us to *systematically* assess existing support mechanisms relative to our problem domain, we had to first establish a set of criteria to guide our comparison. We based our set of criteria on the fact that design support within an online-questionnaire design tool should [24]:

- point out sub-optimal decisions;
- be context-linked to actions;
- set up best choices by default;
- educate a designer about guidelines; and
- automate certain tasks.

We added the criterion that the support mechanism within the tool should be able to provide suggestions to the designer, as well as a number of other criteria as

Table 1. A consequence table

	Primary Supports			
Criteria	critic	wizard	knowledge repository	automated design creator
Increases chances of creating respondent-friendly questionnaires	1st	2nd	4th	3rd
can point out sub-optimal decisions	Y			
can be context-linked to actions	Y	Y		
can set up best choices by default		Y		Y
can educate user about guidelines	Y		Y	
can automate tasks		Y		Y
can provide suggestions	Y			
Approach meets desirable implementation criteria	1st	3rd	4th	1st
been implemented in a web environment	Y	Y	Y	Y
could encode all guidelines (All, Most, Some, None)	Most	Some	None	Most
could be implemented within my time frame	Y	Y	Y	Y
Supported by others' research	1st	3rd	4th	2nd
positive author comments	1st	3rd	4th	2nd
negative author comments	1st	3rd	4th	1st
Overall:	1st	3rd	4th	2nd

shown in Table 1. We used *consequence tables* [17] (see Table 1) to support our goal-specific comparison process.

3.1 Support Mechanisms

Via a systematic literature review, we identified several potentially appropriate support mechanisms – originating in critiquing systems [31, 36, 38], learning systems [21, 29, 40], help systems [1, 2, 5], and automated systems [4, 20, 35] – and categorized the mechanisms as follows:

- Critics;
- Wizards;
- Knowledge Repositories;
- Automated Design Creators; and
- Scaffolds and Supplementary Supports.

Critics

A *critic* is an intelligent agent that provides assistance during the design process [31] by analyzing a designer's solution [36]. A critic can analyze a design according to various criteria, such as guideline adherence, completeness, design consistency, and alternative design choices [37]. Feedback from the analysis is then presented to the designer (often as a list of messages); once the feedback is considered, appropriate design modifications can be made. Critics are found in critiquing systems – these systems are responsible for generating and presenting critic feedback, activating and de-activating critics, and updating internal design representations.

Wizards

A *wizard* guides a user through a process on a step-by-step basis [1]. A user is typically presented with options for selecting/entering desired preferences and properties; the wizard then automatically performs corresponding tasks based on the user's specifications.

Knowledge Repositories

A *knowledge repository* stores and displays information that can assist a designer in making educated design decisions. Some systems have included design guidelines as hypertext references so that a designer is not required to laboriously reference a paper document [18, 19]. Others have included statistics about past design decisions [16] so that such knowledge can provide additional context.

Automated Design Creators

Some researchers are concentrating on *automated generation techniques*, such as methods found in the fields of expert systems [20, 35], generative programming [4, 33], and model-driven development [9, 14]. A common aim among these systems is to provide a designer with the ability to specify design requirements and/or objectives after which the system produces a corresponding design. Some systems allow a designer to manually modify the solution once generated [9].

Scaffolds and Supplementary Supports

Scaffolds are defined as "*software features that address the cognitive obstacles learners face so they can engage in the work in an educationally productive manner*" [29, p.81]. With the support of scaffolds, students are often able to successfully perform work which likely would not otherwise have been possible [29].

A natural bi-product of providing practical guidance to designers during the creation of an online-questionnaire – and an important anticipated outcome of exposure to appropriate support mechanisms during design activities – is furthering the learning of online-questionnaire designers. As such, although our educational objective is not as explicit as it is in e-Learning systems, we chose to include scaffolds in our evaluation because we believe scaffolds may be a useful approach for conveying the information contained in guidelines.

We classify a range of other mechanisms as *supplementary supports* – e.g., templates, hypertext, defaults, and examples – which can be used by any of the primary mechanisms previously described. For example, a wizard can use hypertext to link to other actions in an interface.

3.2 Candidate Comparison

We believe that the nature of scaffolds and supplementary mechanisms makes them better suited, and more powerful, as complementary supports in our context; for instance, a critic that alerts a designer to an ill-advised modification of a default property offers more support than a system that only includes defaults with no advising capabilities. With this in mind, we systematically compared the relative merits of the other mechanisms to act as a primary support. Table 1 shows our primary comparison criteria, divided into sub-criteria. The "positive/negative author comments" sub-criteria are further divided as shown in Table 2; we evaluated each on the three point scale shown. The following discussion is from the perspective of comparing a critiquing system to the remaining three candidates relative to our specific goal; this standpoint was adopted both for ease of discussion and because, upon initial review, the critiquing approach seemed potentially the most capable of meeting our specific needs. In essence, the discussion serves to confirm this observation.

3.2.1 Favorable Characteristics

Since many critiquing systems demonstrate the potential to include a large number of guidelines, it seems that a critic has the capability of supporting the majority of Lumsden's extensive guidelines. This is important because it maximizes the comprehensiveness of active support that can be offered to a designer. Consider this capability in comparison with the other noted mechanisms. Since a wizard is primarily suited towards procedural tasks, it is likely that a wizard could only provide active support for very specific guidelines – for instance, those guidelines

Table 2. Assessed positive and negative criteria – Yes = Y; Sometimes/Somewhat = S; No = N

		Primary Supports			
	Criteria	critic	wizard	knowledge repository	automated design creator
Positive	promote reflection on decisions	Y	N	N	S
	reduce design error costs	Y	Y	S	Y
	support during design context	Y	S	N	S
	novice considers expert issues	Y	N	S	N
	designed for real work environments	Y	Y	Y	S
	part of natural design process	Y	N	S	N
	ideal for structured tasks	S	Y	N	Y
	no need to search for guidance	Y	Y	N	Y
	can link to other UI services	Y	Y	Y	Y
	ideal for novice users	N	Y	S	S
	user acquires knowledge	Y	S	S	S
	guidance is searchable and/or explorable	S	N	Y	N
	good for consistency & low-level issues	Y	Y	N	Y
	decisions can be made for user	N	S	N	Y
	user can guide system to desired solution	N	N	N	S
	speed up development	S	S	S	S
	improve quality of work	S	S	S	S
Negative	potential for designer resistance/reluctance	N	S	Y	N
	feedback may not be viewed	S	Y	Y	Y
	designer may be left to perform many manual tasks	N	S	N	Y
	feedback may be irrelevant	S	Y	S	Y
	creativity may be stifled	S	S	Y	N
	concentration may be interrupted	S	Y	N	Y
	designer may not be encouraged to reflect on decisions	S	S	Y	N
	mechanism is often explicitly invoked	Y	N	N	S
	cannot run concurrently while designer modifies design	Y	N	Y	Y
	assistance opportunities typically designer responsibility	Y	N	N	Y
	mechanism not well integrated into design environment	Y	Y	N	Y
	feedback may be overwhelming	S	Y	N	Y
	designer may be forced to read documentation	S	Y	N	Y
	designer may lose feeling of being in control	Y	S	Y	S
	designer's knowledge may not contribute to design	Y	S	Y	S
	resulting interfaces tend to look similar to one another	Y	N	Y	N

that pertain to the suggested structure (i.e., page breakdown) of an online-questionnaire. A knowledge repository is a passive form of support that is likely to manifest as a de-contextualized hyperlinked manual of guidelines, which would have to be manually searched by the designer. Finally, although an automated design creator could also encode a large portion of the guidelines, Eisenstein and Puerta have argued that "*the only way to build a system that is usable in real-world design projects is to focus on those areas of design that are particularly amenable to automation and leave other areas of design in human hands*" [8, p.75]. On this basis, it is likely that automating all of Lumsden's guidelines is not appropriate, albeit a semi-automated approach might be suitable. This is, in fact, the approach of critiquing systems: they provide an automated analysis tool that focuses on tedious and low-level details (a task ideally suited to computers), while leaving the designer in charge of making final design decisions.

A second attractive feature of a critic is its ability to encourage a novice designer to think like an expert [30]; critics actively bring relevant issues and possible trade-offs to the designer's attention. In comparison, wizards seldom allow such opportunities to present themselves since they are automated tools that aim to *hide* details from a user. Despite the expert knowledge contained within a knowledge repository, the process of obtaining this information is far too passive and laborious to make it a viable means by which to encourage expert thinking. Although an automated design creator can also encourage expert thinking (e.g., [8, 28]), the process is not as explicit as in a critiquing system. Further criteria favoring a critic include its ability to explicitly educate a designer about guidelines, as well as actively pointing out sub-optimal design decisions and providing suggestions on possible fixes [37]. Using a wizard can lead to some transfer of knowledge, but not to the extent that comes from interacting with a critic, and very rarely are explicit educational opportunities provided in an automated design creator. A knowledge repository can promote learning, but in a reactive fashion. None of the other three approaches offer analysis and advice provision capabilities.

Finally, the concept of critiquing is a *natural* part of design [31]; to improve an artifact, a designer must determine whether aspects of the design need improving and if so, the means by which to make the corresponding improvements.

3.2.2 Unfavorable Characteristics

While there are many favorable characteristics to support the critic approach, we must equally consider the disadvantages or unfavorable characteristics of this approach. Principal amongst these is the potential for user reluctance; one study showed that critics were seen to challenge designers' authority and the critiquing was perceived as antagonistic [37]. The study viewed negatively the fact that designers anticipated the criticism and performed design actions in an effort to avoid the firing of feedback (although some might argue it to be a positive outcome). Whatever one's stance, a subsequent study [30] suggests that, unsurprisingly, it is the design of the critic feedback and corresponding interaction, as opposed to the critic metaphor itself, that determines designer response to the support mechanism.

While the possibility exists for a designer to resist a critic, the same risk is equally real for the other three support mechanisms. Novice users prefer lots of guidance and limited choices, while expert users tend to favor less guidance and the availability of many options [27]; as such, it is highly likely that a wizard could be viewed as restrictive by experienced designers. Users rarely consult passive documentation and online-help [2] and so although, being easily ignored, knowledge repositories are less likely to meet explicit resistance, as a solution in our context they are less likely than a critic to be effective *because* they can so easily be disregarded. Finally, automated design creators are often criticized on account of the limitations they place on the extent to which a designer can actively bring his/her knowledge to the design process [38] and users of expert systems typically resent being placed in a passive human-computer interaction role [35]. In contrast, researchers have argued in favor of critics because such mechanisms

encourage collaborative problem solving [12, 31, 35, 38]. Instead of a one-sided problem solving approach, both the designer's and system's knowledge play a key role in the design process [38].

Robbins [31] asserts that existing critiquing systems force the designer to engage in too many manual tasks, namely: modifying a design in response to critic feedback; enabling/disabling relevant/irrelevant critics; and instructing the system in how a critique was resolved. Although theses issues are important, they are essentially facets of the interaction design (and hence, usability) of a critic as opposed to concerns about its inherent ability as a concept to effectively support a designer. Furthermore, leaving the designer in control is a *strength* of critiquing systems; the ability to, for example, manually modify a design is a desirable characteristic in such software. A wizard can be used to start a design session from a default template, but complete construction of a questionnaire is unlikely to be possible without some manual designer intervention. Indeed, only certain aspects of questionnaire creation are amenable to automation and manual design decisions and modifications are unavoidable. Of all four mechanisms, knowledge repositories place the heaviest manual burden on the designer; guidelines must be manually searched, read, and interpreted. At the other end of the spectrum, as already mentioned, an automated design creator typically does not provide *enough* opportunities for manual intervention. Although some automated design creators (e.g., [33]) allow a designer to actively engage with the system and manually select components for the later automated generation phase, we believe that having to choose a multitude of low-level design components places no fewer demands on the designer than a critiquing system.

Finally, critiquing systems are sometimes criticized on account of the degree to which they can potentially interrupt a designer's task concentration [13]. While certainly a valid concern, interruption is not always a negative issue; a critic educates a designer by posing appropriate questions in real time and reflection is encouraged. Reflection is a part of the mental process during design and researchers [13, 32, 37] often cite psychological theories to support the use of the critic mechanism on these grounds.

4. SUMMARY AND FUTURE WORK

As the first step towards incorporating guideline support within an online-questionnaire design tool, we have conducted an environmental scan of appropriate design support mechanisms used in other genres of software design tools. We have concluded that the advantages of a critic outweigh its potential disadvantages within our specific context. We believe that this natural user interface metaphor, which encourages self-critiquing of a work-in-progress, is the most appropriate mechanism for supporting an online-questionnaire designer.

We observed that critiquing systems normally focus on visual feedback – typically relying on the presentation of textual messages to convey critiques. Alternative modalities (such as audio feedback) could prove to be beneficial in better supporting designer-critic dialogue; indeed, Ericsson suggests that "*better cues are needed*" to signal comments needing immediate attention [10]. We therefore propose to investigate alternative means of presenting critic feedback to a designer. Once we have completed our development phase, we intend to conduct extensive usability studies to determine the precise aspects of our design that do and do not work in the context of online-questionnaire design; on the basis of the findings of such studies, we hope to improve on our initial design and identify which components of support benefit from automation and which should be left in the control of the designer.

As noted in the introduction, we acknowledge that the discussion presented here is biased towards our goal and constraints. Although we have not, therefore, extrapolated generic implications from our reflections, we hope that this discussion concerning our comparative observations will prove useful to researchers and developers faced with a similar challenge. Furthermore, we hope our observations might also prove useful in terms of knowing what to look for when selecting a well-supported online-questionnaire design tool in the future!

ABSTRACT

Trust is often considered to be a primary factor in the implementation of a collaborative information sharing system. These systems have become more common in organizations since the increase in the need to be more efficient and effective. Trust, it is often said, must be present prior to the exchange of often sensitive information. Based upon the results of a mail-based survey, we did not recognize trust in an established information sharing system as a key success factor, since it is replaced by contractual agreements defining the limitations of the transferred information usage. The derivation of the theory and the supporting evidence relating to information sharing is presented.

1. INTRODUCTION

Trust is often stated in literature as being of critical importance in the creation and maintenance of an information sharing system. These systems are becoming quite common as the need for systems efficiency becomes not only important but necessary. The necessity for increased responsiveness has resulted in various types and levels of communication between elements in an organization's supply chain being established. Information sharing presents many distinct advantages to an organization but simultaneously opens the firm's critical and often sensitive information to the review of persons outside the firm. The structures that are needed to ensure a successful implementation are not identical though to those that ensure the successful maintenance of the same information sharing system. Trust, though critical in the implementation, is replaced by legal and contractual stipulations as the system ages.

The literature shows a multiple models of diverse elements in a complex series of theories that the respective authors say affect inter-organizational information sharing. These factors are predominantly influenced by individual behaviors, organizational behavior, inter-organizational relationships, and others that can be distributed into broad political and social contexts (Schermerhorn 1975). The importance of interorganizational information sharing is that it provides benefits to organizations including economies of scale, lower overhead and reduced risks (Alexander, 1995). The technology theory influencing information sharing is a vast and dynamic collection of database, communications, and network theories.

In this paper we deal with the role of trust within the information sharing systems. Based upon the results of a mail-based survey, we determined 10 key success factors for an established information sharing system. Trust, which did not occur as a factor among them, seems to be replaced by contractual agreements defining the limitations of the transferred information usage. Some our conclusions are based also on field studies of the FLUID-WIN and SEAMLESS projects (Delina 2007).

Empirical Research on Information Sharing

Theoretical studies, and simulations to justify such, abound while empirical pieces are primarily limited to a few case studies with quite few broad-based empirical studies existent. In the short amount of time that Information Sharing has been studied, the trends in the dissolution of vertical integration have strengthened and alliances within a supply chain have become more common. Organizations have changed in that they now need to gather materials or goods in a manner and at a speed that the demands of the customer are considered.

In the development stages of interorganizational information systems, the structures underlying the system implementation are dynamic and complex. Two or more organizations are involved and numerous technological and social considerations must be made. Compromise is often necessary to accomplish any goal and such is more often the rule than the exception. Under these circumstances, trust is necessary since adjustments to contractual stipulations would be a hindrance. Information sharing structures for post hoc implementations have been but minimally explored.

Often, information sharing occurs in an ad hoc fashion via methods that are devised anew with each interchange: that is, single-use, single-purpose mechanisms. Trusting that the organization, that the information is being given access to, is not entirely self-serving in that it serves the purpose of not requiring a revision of contractual agreement each time as an exclusion to that contract presents itself.

However, as the system of sharing becomes more mature and the volume and frequency of information sharing grows, a more permanent mechanism for defining the limitations of the information exchange and usage often becomes beneficial, one that can function repeatedly and serve a variety of purposes. Strategic information is of great interest in sharing and infrastructure-building, due to the high cost of its production, its potential for re-use, and its value in strategic decision making. An information-sharing infrastructure links organizations with common goals and tasks by means of defined standards, navigation and conversion tools, shared "framework" information, and institutional structures such as supply-chain relationships.

Inter-Organizational Information Sharing Literature Review

Inter-organizational information sharing is not a new concept but has been widely researched over the past thirty-five years since the empirical research of Schermerhorn (1977). These organizations work in a cooperative/competitive manner described by Lado et al. (1997). Aspects of trust in information exchange have been researched by Thompson (1991) and Thompson & Hastie (1990). Kemp & Smith (1994) found that the level of information shared correlated to the benefit derived for each participant. Though mature computer-based information sharing organizations and structures have not specifically been investigated, findings regarding more traditional means of information sharing have found that (1) shared information is based upon an initial expectation of trust (2) shared information results in faster mutual decisions (3) higher costs (4) decreased complexity (Butler 1999) (5) that shared information has strategic importance (6) correlated strategies (Doyle & Snyder, 1999) (7) a shared vision (8) mutual understanding and (9) routinization of synergistic interactions (Jassawalla & Sashittal, 2000).

The structure of the paper is to describe existing industry structures and benefits in section 2. Research objectives are described in section 3 with a comprehensive description of the methodology employed in section 4. The empirically derived model and descriptions of the factors is presented in section 5 followed by the conclusions in section 6.

2. INDUSTRY STANDARDS ON INFORMATION SHARING

Standards do not yet exist for database structures but information sharing between autonomous organizations is often desired or mandated. By autonomous firms using compatible data descriptions, data can be shared without translation or modification. Enterprise Resource Planning systems, with their limited array of translation

capabilities can communicate with a like system with little or no modification to either system. The effect is often described as "seamless" since the transaction of information sharing works in a like manner as a request or transmittal of data from an internal source (Palaniswamy, Frank, 2000). The evolution of business database systems towards "common" systems software definition is having the effect of achieving a minimum standard of compatibility that should eventually create a voluntary standard for data sharing.

Information sharing can reduce the cost of failure, operational costs and improve the scheduling and efficiency of current resources. It also provides intangible benefits such as improved quality with increased customer and shareholder satisfaction. To place confidence upon the achievement of these goals in something as intangible as trust is unlikely in an organization, that must report to its owners the detail of its actions. Such situations eventually result in written agreements that describe the actions and responsibilities of the organizations involved. These formal agreements are legally binding contracts and have legal remedies available with possible penalties for the firm violating the contract. Trust, being intangible does not always have legal remedies for its violation.

As organizations increasingly access the benefits offered by the inexpensive computer and communications technology, the problems and concerns that accompany the benefits become more apparent. The information that can be used to improve the actions of the supply chain and simultaneously reduce associated expenses is also often of a critical nature and need be protected from competitors and others.

Shared information can have a distinct influence on organizational cultures, strategies and behavior. Using shared information is often either a technological problem or an organizational one. It is difficult to fully anticipate how the information will be retrieved, combined, and employed. This tends in the implementation stage to disrupt most rigidly hierarchical organizational structures and influences the formation of more "organic" managerial structures. These organic structures then evolve, along with the information system, back to the more rigid, less organic structures involving contracts rather than trust to oversee the actions of the participants.

3. RESEARCH OBJECTIVES

This research examines the aspect of trust of information sharing and how relationships are mediated by that trust within an established information sharing. Trust aspects in information sharing are often considered to be crucial in previous studies of factors influencing the success of information systems. The research described here is that of already established. No study to date investigates what influence trust constitutes in an established information sharing system. Several studies have investigated the importance of trust in implementing an information sharing system but none to date have sought to explain "trust" as the system evolves. This study will seek to fill this void.

Trust is considered in this research as a feeling or belief that a partner organization will act in the best interests and without malice in actions that involve their partner. Providing strategic information without cost to supplier chain partners can strengthen the both organizations and provide a competitive advantage. Trust, it is said, is required in implementing a system of information sharing since strategic information could be used either constructively or destructively. But, as this research reveals, the need for trust is not constant and as the information sharing system ages and evolves, it diminishes in importance to the level of insignificance.

4. RESEARCH METHODOLOGY AND RESEARCH DESIGN

This study was of organizations that were determined a priori to have a need for sharing information. The keywords used in gathering the list of organizations were such that the organizations in the study were those that had suppliers and would place a greater level of demand on those suppliers than what would be considered normal. The organizations studied were chosen because of the production of products that had a great variety of demand and product parameters, those factors that had already been determined to affect supply chain performance and costs. Though previous empirical studies have found that trust exists in implementing an information sharing system, this study infers through its failure to discover a correlation that at some point following the implementation, the importance of trust diminishes. The firms involved in the study still benefited from sharing information but that they did not place any reliance on trust. The action of information sharing correlated to producing competitive rewards with few concerns of vulnerability as earlier studies had found.

The systems involved in this study, though physically more vulnerable because of increased levels of access, were typically not very complex though and thus correctable should any such problem occur. Organizations that share information with their supply chain partners have the ability to create highly efficient supply chains. This efficiency translates into increased customer satisfaction through improved quality and responsiveness, and increased revenue due to lowered costs. Sharing information with supply chain partners will initially need trust to counter the lack of an established system to manage the information transfer and usage but then evolve into contracts and formal agreements that regulate the application and ownership of the information.

A total of 680 questionnaires were directed to organizations drawn at random from a meta-search of organizations that met a predefined list of criteria. The questionnaire was composed of 121 questions all based on either yes/no answers or a Likert scale. In total, two questionnaires were mailed along with two follow-up requests to each firm selected for the survey. From the returned questionnaires, 110 were found to be usable, which represented a response rate of 16.1%. Surveys were returned from employees of organizations in various geographic locations and within various positions in their respective supply chains. The firms were both service and physical goods manufacturing firms of various sizes.

Multiple principal component based factor analyses with post hoc validation modeling were conducted to assess the validity of the survey measures and to determine the underlying factors and components influencing the success of an information sharing system; "success" being defined in this instance as a system that is used and provides some economic benefit. The factor analysis was applied to the survey responses and questions that had linear statistical similarities were clustered together. These clusters were clarified using Lisrel, a Structural Equation Modeling program, to strengthen the internal cohesiveness of the individual factors. The elements comprising the factors have individual internal correlations to the factors of at least 50 percent. These conglomerate factors were all statistically related to the factor defining success. The factors all have chi-square values exceeding 2.5. An ARTMAP neural network was used to correlate the factors to Successful Information Sharing, basing success on the financial viability of the firm and its respective industry, after sufficient time had passed to generate an effect. The ARTMAP correctly classified the firms, based upon these factors, 90 percent of the time. The scale for success was 6 categories ranging from high profitability in a growth industry to severe financial duress or bankruptcy.

5. RESULTS

The components – factors - identified by the factor analyses are: (1) Centralized Information Sharing Control, (2) Maintain and Update Information Sharing Rules, (3) Significant Exchange of Information, (4) Defined Use of Information, (5) Collaboration with Suppliers, (6) Cooperative Competition, (7) End-to-End Connectivity, (8) Formed Supply Alliances (9) Replace Traditional Communication with IT, and (10) Share Frequently with Suppliers. These are illustrated in Figure 1 and each of these components is discussed in the following.

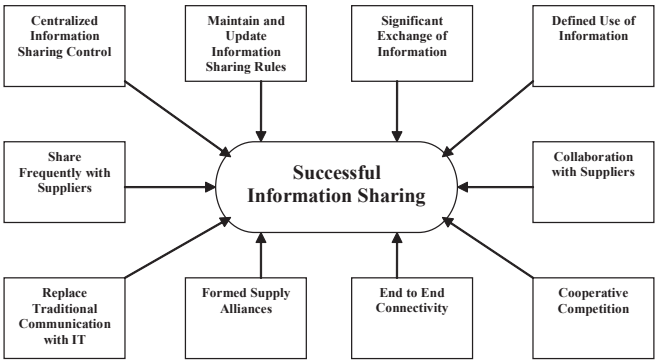
Centralized Information Sharing Control

Information is often critical and possibly of a sensitive nature to a firm. Not all information is shared and often decisions are necessary that limit or restrict the disclosure of information. These decisions, to both maintain accountability and consistency are best accomplished in a centralized "information clearing house". Though many studies have decreed that information is best used when disseminated throughout the organization, the control of such information is best suited to a centralized location.

Maintain and Update Information Sharing Rules

The sharing of information is not a fixed and static structure that needs no maintenance. As the type and level of information changes so must the rules regulating how, what, when, etc. must change to suit the conditions of information exchange. This provides the organizations within the system a level of security and confidence that the information that they provide and receive is within a set of defined uses while outside of their control. These rules also provide a basis for legal remedies should any organization with the chain act improperly with the information that the access or disseminate. It is interesting to note that "trust"

Figure 1.



is not existent within the model. Trust is an important aspect in developing a relationship for information sharing since the structures are either not or just minimally defined and abuses can occur. The more mature system uses rules and contracts to define contingencies.

Significant Exchange of Information

The cost to maintain information sharing systems must be offset by a benefit in excess of such cost in order to justify the continuation of the system. A high level and significant quantity of relevant shared information communications can represent both increased profitability and reduced costs to organizations. Organizations maintain an information-sharing environment with their supply chain partners to their mutual benefit. Information sharing is an economically viable alternative to forecasting and other estimates of an organizations supply chain partner's actions.

Defined Use of Information

Information within the organization receiving it must have a purpose and that purpose should be known to the organization that supplies the information. There are two primary reasons for this (1) the organization that provided the information will have a greater sense of security in knowing that the intent of requesting the information is for some purpose that is beneficial to the receiving organization. This will minimize the probability of misuse. (2) In understanding the potential use of the requested information the firm that provides the information may be able to improve on the type, level or transmittal of the requested information in such a way that improves the efficiency of the action. Organizations in a supply chain are concerned not only about the information gathered and/or mined by their supply chain partners but also as to the intent behind the use of the collected data (D'Amico, 2000).

Collaboration with Suppliers

An organization that works cooperatively with their suppliers can benefit in reduced inspection costs, increased responsiveness, product development input and improved profitability. Collaborating with ones suppliers would imply that information is being exchanged. The action creates the structures and system that provides the basis of information sharing. Collaboration, when the tenets of the action are mutually defined, can greatly benefit all the firms involved.

Cooperative Competition

Organizations have learned over the past years that to compete in a "cut throat" manner is often detrimental to each organization in the long run. The new levels of competition enabled by reduced trade barriers and increased levels of foreign competition have forced organizations to reevaluate their relationships with their competitors. Organizations now often act in such a way as to be competitive but to respect each other's markets and not to intrude. New markets or those not previously serviced by a direct competitor are open for exploitation but the traditional environs of a competitor are perceived as "off limits". There are numerous examples of two primary competitors in all out trade wars with the result of each losing a significant portion of their traditional markets to a third previously unconsidered competitor.

End-to-End Connectivity

End-to-End Connectivity is the establishment of communications resources to span the breadth of the supply and distribution channels. The information that is gathered form customers is thus available to suppliers thus reducing the whiplash effect that so often is disruptive to estimating trends in inventory levels. This component stresses the need for physical linkages from one end to the other of all the supply and distribution channels to gather and disseminate the maximum amount of information available and allow for its direction to the appropriate individual or organization. The information flow then assumes a matrix structure not unlike the early structure of the Internet since it is comprised of a simple series nodes and pathways through which information is channeled and reviewed.

Formed Supply Alliances

An established, lengthy, and cooperative relationship between a supplier and the supplied organization creates faith and defined cooperation between the elements of a supply chain. Trust is not significant here in that such is not legally defensible nor is it readily defined in what is permitted or restricted. An alliance that defines specifically each others actions and responsibilities creates the need and the basis for greater levels of information sharing. Supply chain alliances affect the costs, the responsiveness and the viability of the organizations involved.

Replace Traditional Communication with IT

The traditional means of communication in organizations, telephone, facsimile machine, mail all have difficulties in the transmission and distribution of information or data. Using the communications tools of EDI, the Internet, or more advanced Enterprise Systems, a firm can redistribute, store, sort and distribute to multiple sources the information or data that is gathered. The structure of the connections of these tools does not eliminate the more traditional means of communication but instead augments the tools to make the organization's information sharing more efficient and effective.

Share Frequently with Suppliers

When information is sporadically shared, the structures and efficiencies achieved languish and deteriorate. Information flow that is relatively constant allows an organization to have confidence in its value since it is validated by the information of a similar nature that follows. Frequency provides a usage and justification to the monetary outlays for the associated physical and organizational structures that are used to share information.

6. CONCLUSIONS

Integrating and sharing information in interorganizational settings involves a set of complex interactions. The organizations involved must establish and maintain collaborative relationships in which information and data of a sensitive and critical nature is transferred outside of the direct control of the organization. The sharing processes often involve significant organizational adaptation and maintenance. The purpose of this research is to develop a model of information sharing structures in these settings. Many organizations are looking for ways to optimize their supply chains as a means to create a competitive advantage. Consequently, these same organizations are modifying their business processes to accommodate the demands that sharing information places on an organization. To that end, this study addresses the issue of developing a comprehensive model regarding the supply chain system and the solutions needed to optimize it. The exploratory model does suggest that supply chain managers should consider the components of the model in order to achieve supply chain success. Though there were a great number of responses on the returned surveys that indicated that the respondent firms lacked "trust" in both their suppliers and customers, these same firms conducted business with these same firms and individuals with little to no intent of implementing any change. "Trust" is seemingly to abstract a factor to precisely define. Our contention is that "trust' does exist but is not specifically and uniquely defined. The actions of the firms would indicate that given a structure of defined uses and responsibilities of information that sufficient "trust", whether specifically defined as such, does exist.

ABSTRACT

This paper analyzes simulation as a knowledge base for decision support and its' usefulness in application on three cases: 1) post-decision analysis of the reengineering process, 2) warehouse optimization in an uncertain environment, and 3) decision-making process supported by simulation in a laboratory environment. The paper describes the methodological aspect of simulation as part of the anticipative system and the practical application of simulation and interaction between user, simulation model and scenario in the process of seeking for a solution to a managerial problem as decision support in a business system. Results of all three cases show the effectiveness of simulation in decision support and prove simulation to be a powerfull tool in organizational learning.

Keywords: simulation, learning, reengineering, information, warehouse optimization

1. INTRODUCTION

The role of simulation methodology in the decision assessment of complex systems is constantly increasing. Human knowledge, simulation model and decision methodology combined in an integral information system offers a new standard of quality in management problem solving. Simulation model is used as an explanatory tool for a better understanding of the decision process and/or for learning processes in enterprises and in schools. Many successful businesses intensively use simulation as a tool for operational and strategic planning and enterprise resource planning (Schniederjans and Kim, 2003; Muscatello et. al, 2003). Experiences described in literature, (Homer, 1996) emphasize that in a variety of industries actual problems can be solved with computer simulation for different purposes and conditions. At the same time, potential problems can be avoided and operative and strategic business plans could also be tested. Currently the most intensive research efforts are concentrated on a combination of simulation methods and expert systems (Dijk et. al, 1996; Coyle, 1996). Although there is a considerable amount of work devoted to simulation methodology, there is a lack of its application in practice especially in small- and mid-sized companies. The reason lies not in the methodology itself; the real reason is rather in the problems of methodology transfer to enterprises and the subjective nature of decision-making. However, there are several problems, objective and subjective, that are the reason why this well established methodology is not used more frequently.

One of the objective problems is model validation, which is very important for any model-based methodology. The validity of the model of a given problem is related to the soundness of the results and its transparency for users. According to Coyle (1996), a valid model means well suited to a purpose and soundly constructed. According to Forrester (1968), it is pointless to discuss validation without reference to a particular situation. There is no way to prove usefulness of the model of complex systems such as enterprises in advance (Forrester, 1994).

The second problem, the subjective one, is related to the transparency of the methodology and data presentation (Kahneman and Tversky, 1979), preferences of the decision-maker to use a certain decision style and poor communication between methodologist and user. The simulation methodology is a paradigm of problem solving where the personal experience of users as well as their organizational culture play an important role (e.g., in transition countries: market economy, ownership, etc.). This article describes tree different cases demonstrating the usefulness of simulation methods for decision assessments in enterprises.

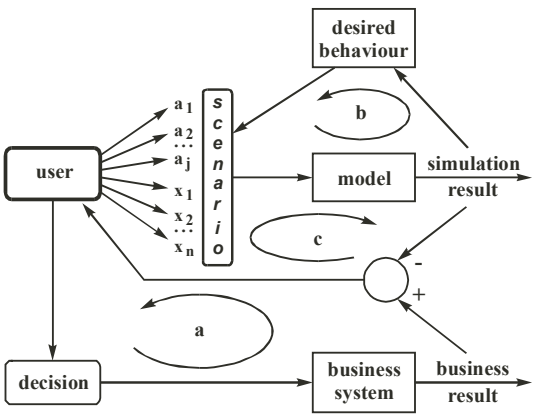
2. SIMULATION METHODOLOGY AS A BASE FOR DECISION SUPPORT

Many authors prefer the simulation method as a holistic approach for assessment of decision-making (Gopinath and Sawyer, 1999; Simon, 1997; Sterman, 2000) however; user confidence in it is of crucial importance (Chen and Liaw, 2001). The main problems of each managerial system are the comprehensiveness of information concerning the state and the environment within appropriate time. This means that a mathematical model of the process and a model of the environment are required. However, in enterprises processes due to the complex dynamics resulting from the stochastic interaction and delay it is hard task to get a confident model. Decision-makers though cover a broader perspective in problem-solving than could be obtained solely through simulation. Both simulation interacted with human experience create a new quality at the condition that users is convinced in the value of simulation methodology. The principal representation of the proposed approach is shown in Figure 1 where the principle of interaction between the user, simulation model and scenario interaction is exposed (Kljajić, 1994).

The following three basic loops are emphasized:

a) The causal or feed-back loop, representing the result as a consequence of former decision-making, and being a part of management experience and history of the system. From the learning aspect this loop could be named "learning by experience".
b) The anticipative or intellectual feedback loop, which provides the feed forward information relevant for decision making. This loop consists of the simulation model of the system, criteria function and scenarios. The simulation scenarios consist of two subsets: a subset of input that anticipates the state of nature

Figure 1. The principle diagram of the simulation methodology for decision support in enterprises



(exogenous scenarios) – and a subset of alternatives (endogenous scenarios). They give the answer to the basic question concerning the problem situation for which the answer is being sought. In literature it is known as the *what-if* analysis. The generation of scenarios of the simulation system that responds to the *what-if* is based on different scenarios anticipating future impacts of the environment on the system.

c) The *a posteriori* information loop represents the pragmatic validation of the model concerning model applicability and former decision-making. This loop represents the pragmatic validation of the model. A comparison of prior information concerning the simulated impact of the selected strategy on system behaviour with the actual results allows us to evaluate the value of the model and improve it. In this way learning is enabled on the basis of *a priori* assumptions on the model and not just on the basis of empirical experiences.

Loops a) and b) are the basic ones for learning and knowledge acquisition for improved decision-making. Loop c represents the pragmatic validation of the model which supports users' confidence in the simulation methodology.

3. POST-DECISION ANALYSIS OF PRODUCTION LINE SELECTION BY SIMULATION METHODS

Described methodology was applied in a medium-sized factory, a manufacturer of concrete goods, for the purpose of reengineering process assessment. Due to the increased demand for a specific article and better quality requirements of products, the firm's management considered investing in a new production line. The decision assessment has been organized at two hierarchical levels. The model at the top level is used for the assessment of the enterprise's strategy (continuous simulation). At the bottom level the model is used for discrete event simulation (DES), necessary for operation planning and testing production performance. The system structure of the simulation model consists of entities connected in a flow diagram in Figure 2. The diagram is sufficiently abstract to allow understanding of the problem and precise enough to provide valid experimentation on the model. As soon as one becomes satisfied with the "picture" of the process, he/she proceeds to the building of the simulation model. From the decision-making aspect the state equation of the simulated system is described by Equation (1):

$$y(k+1) = f(y(k)\ x(k)\ a)\ \ k = 0,1,2,..N \tag{1}$$

where $y \in Y$ represents the vector of state variables such as inventory, cash, income, liabilities, backlog, etc., $x_i \in X$ represents the system input: market demand, and $a_j \in A$ represents the control variables (alternatives). The decision strategy was defined as: choose the alternative a_j for the market demandy x_i and its probability $p_i \in P$, which satisfies the performance function reflected by the manager's preferences. Performance of alternatives $a_i \in A$ in Equation (1) was obtained through DES as shown in Figure 2. Two criteria were considered:

Maximal expected value (EV) (of profit) defined by Equation (2):

$$\max \boldsymbol{E}\ \ (a_j) = \sum_i C_{ij}\, p_i \tag{2}$$

where C_{ij} represents the values of the i-th input at j-th alternative, and linear weighted sum of multiple criteria defined by Equation (3):

$$\max J(a_j) = \sum_{r=1}^{m} w_r J_r(a_j) \tag{3}$$

where w_r represents the weight of the r-th objective, which reflects the decision-maker's business policy preference. The individual objective $J_r = q(y,x,a)$ in Equation (3) is a function of the state of the system, the state of the market and the chosen alternative in achieving the goal. The multiple criteria and its weighting for the evaluation of scenarios were defined by the decision group using the group support system. Saaty's AHP method (1990) was used to determine the relative importance of the objectives w_r and a pair-wise comparison of alternatives a_j for the r-th objective. The alternatives a_i in Equation (1) represents suppliers of the new production line, which were considered in the decision-making besides the existing technology. The suppliers denoted as alternatives: $a_i = a_1, a_2, a_3, a_4$ and their costs in monetary units as: c_i= 0, 371, 392, 532, respectively. Experts estimated the market demand X_i and its probability $p(X_i)$ for the next 5 years. For a detailed description of alternatives one should look at Kljajić et al. (2000). The financial aspect of reengineering was modelled as the continuous simulation model. The block diagram in Figure 2 shows the main material, financial and information flows of the manufacturing system. Net income is represented as an element dependent on different supplier options simulated on DES. This approach provides a unique framework for integrating the functional areas of management – marketing, production, accounting, research and development, and capital investment. An expert group determined Unit Sale Price and Market Demand Function necessary for different production scenarios. The scenarios are defined as a combination of: Unit Sale Price, Unit Production Costs, Market Demand and Other Operating Expenses. Market demand is defined on the basis of current orders and future estimation, which was determined by the company's expert group. The production plan forms the input for DES with the purpose of evaluating the utilization and capacity constraints of the considered alternative. The simulator of the business system allows us to make an analysis of the investment effects, depreciation plan, risk of drop in sales, delivery time and change in sale prices. The model is used for predicting financial and production system efficiency. Four scenarios representing the market demand were simulated for each alternative. The EV of the payoff for alternatives for the 8-year period were computed according to Equation (2).

Several other requirements for the new technology were additionally imposed: Quality of Products, Net Profit, Risk of Company Ruin, Market Demands and Flexibility of Technology. The decision group consisting of enterprise experts carefully determined the relation between the key criterions.

As a result of the decision-making and final judgment, alternative a_3 was chosen. It scored first rank, evaluated by the EV and multicriteria evaluation, considering the period of an 8-year horizon. The longer time period, however, proposed as the best solution alternative a_4, which had been seriously considered for the final judgment.

Data obtained from the production of concrete goods over the past four years, which is a reasonable period for post-decision analysis, were used for the model validation of the decision process. Validation was carried out by comparing the business outcomes with the anticipated responses of the business model according Figure 1. Figure 3 represents EV of Net Income of the selected alternative a_3 (Curve 1), the actual Net Income (Curve 2), and the estimated Net Income in case decision makers would have selected alternative a_4 (Curve 3) in time (from 0 to t_0 the first four years, and from t_0 to 96 months the future four years).

We see that the curves 1 and 2 correlate, both staying in the average region of positive performance of the analysed production process. The observed increase at the beginning in Curve 2 (actual Net Income) is due to one year loan moratorium. However the predicted value of Curve 2 (from t_0 on) is slightly below EV. These results can be explained by lower demand, which should reflect in lower Net Income. Curve 3 represents estimated Net Income in case decision makers would have selected a_4. It is characterized by a fully automated production pro-

Figure 2. Causal loop diagram of the simulation model for decision assessment

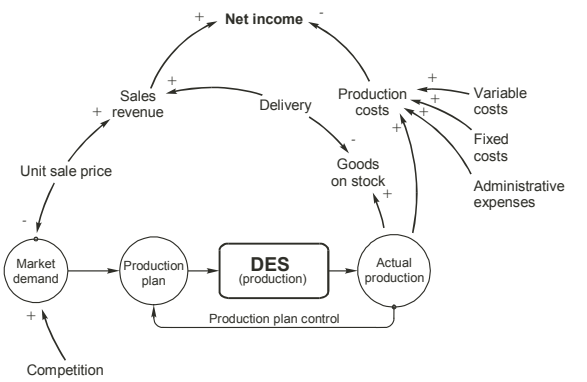


Figure 3. EV of Net Incom (Curve 1), realized Net Income (Curve 2) and predicted Net Income of the alternative a_4 (Curve 3)

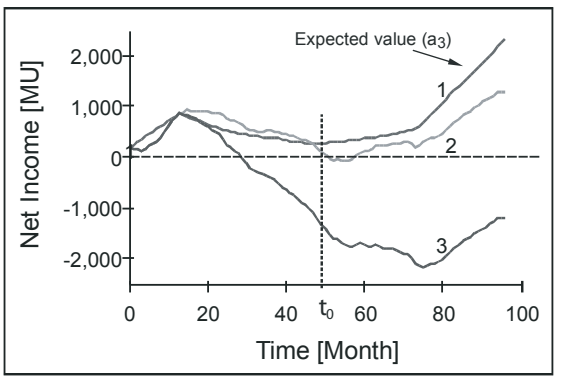


cess, which can ensure a high quality and quantity of products and was seriously considered for purchase.

One can learn from this lesson what would happen if we had chosen alternative a_4 instead of a_3. At the anticipated ratio of demand on the market sales it could not cover the financial burden of such volume. This means that the company would suffer a financial crisis shortly after the implementation of such technology.

4. WAREHOUSE OPTIMIZATION IN AN UNCERTAIN ENVIRONMENT

In this case, we were dealing with a typical warehouse for storing products for further build in. The consumption of products depends on a production plan, which can be predicted with a certainty for six weeks. Lead time, for every product, is not variable. The problem occurs at defining the ordering quantity, because we have to consider the past orders and the variable consumption of a specific product. Long lead times also represent a problem, because they are usually much longer than the time period in which the production plan can be predicted with a certainty. The main goal of optimization was to rationalize warehouse ordering process, this means determining the interval between orders and the quantity to be ordered, so that the warehouse will operate with minimal common costs.

From control point of view, our problem can be described with the difference equation:

$$x(k+1) = x(k) + d(k) - p(k)\,, k = 0,1,2..n \tag{4}$$

$$x(0) = x_0$$

where *x(k)*, represents stock variable, *d(k)* material delivery and *p(k)* production process. The delivery function *d(k)* is delayed for an average time of an order *o(k)*. Time delays are stochastic.

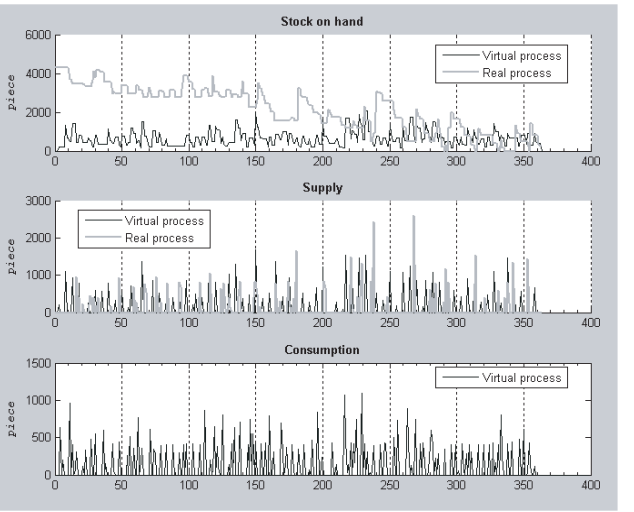
$$d(k) = o(k - \varphi(\tau_d)) \tag{5}$$

where $\varphi(\tau_d)$ represents discrete uniform probability density function *(pdf)*. In order to compensate the stochastic delivery delay, the order policy *o(k)* has to be defined as:

$$o(k) = f(x(k),\ d(k - \varphi(\tau_d)),\ p(k + \tau_p)) \tag{6}$$

where τ_d represents the time delay and τ_p the production plan. It is necessary to find such *o(k)* to minimize the following cost function:

Figure 4. Stock, supply and consumption dynamics for the observed case



$$J(o(k)) = \sum_{0}^{n} q(x(k),\ u(k),\ w(k)), k = 0,1,2,..n \tag{7}$$

for $x\min \le x \le x\max$. In equation (7) *c* and *h* represents the cost of units of material on stock and its transportation.

In order to improve the stock control problem, a simulation approach has been chosen where heuristics and fuzzy control algorithm were tested.

The experiment was performed with the actual historic data for seven years provided by the observed company. The results for one case (product) are presented. The company has confirmed the simulation inventory level dynamics based on the above-mentioned data. They have also confirmed the validity of the costs the simulation model has calculated. The model was changed in the "ordering" module to try out new ordering strategies. A Monte Carlo simulation was used for variation of consumption unreliability. Fifty simulation runs for every strategy on new simulation models were run, using only consumption data. On the basis of these simulation runs, average costs and average stock-outs were calculated. With several simulation runs and a calculation of average values, we have tried to minimize the influences of the random generator, which represents the stochastic environment.

Figure 4 presents results for the Real Process and Virtual Process. The Real Process is represented by the brighter line and the Virtual Process is represented with a darker line. The first graph presents stock level dynamics, the second delivery dynamics and the third the consumption dynamics throughout simulation time (time unit is weeks). The results shown in Figure 4 can be used to indicate similarities or differences between the two processes. The supply dynamics graph indicates some similarities in the ordering strategy – some peaks (representing order quantity) are very similar but with some time delay. However, the simulation results of ordering have produced much lower costs than the Real one for the 65%.

The simulator also allows us to compare two methodologies used in the ordering process: heuristics of the warehouse operator and algorithm based on simulation and fuzzy logic. From the Figure 4 one can observe, from the stock variable, the operators' "learning by experience". Namely, starting from high stock value, the operators' ordering strategy slowly improves over time approaching optimal strategy obtained by simulation. From the obtained results we can deduct about the usefulness of simulation method for the operator training for new ordering strategy.

5. DECISION-MAKING SUPPORTED BY SIMULATION MODEL AND GROUP FEEDBACK INFORMATION

The goal of the conducted experiment was to acquire knowledge of the group decision process supported by the system dynamics (SD) model and influence of feedback information. A model of the business system was applied at the experi-

ment with decision groups. The model consists of: production; workforce and marketing segments that are well known in literature (Hines, 1996; Sterman, 2000 and Škraba et. al, 2003). Model shows that Product Price (r_1) positively influences Income. However, as prices increase, Demand decreases below the level it would otherwise have been. Therefore the proper pricing that customers would accept can be determined. If Marketing Costs (r_3) increase, Demand increases above what it would have been as a result of marketing campaigns. The production system must provide the proper inventory level to cover the demand, which is achieved with the proper determination of the Desired Inventory value (r_4).

The experiment considered the task of strategy determination with an explicitly defined multicriteria function. The optimal criteria function value (CFV) was determined at $J = 1.5$.

Experiment was conducted under three experimental conditions: a_1) determination of business strategy without application of a formal model, a_2) determination of the strategy with application of a formal SD model and, a_3) determination of the strategy with application of a formal SD model with subjects interaction supported by the group feedback information. 147 senior university students participated in the experiment. We hypothesized that the model application and group feedback information positively influence the convergence of the decision process and contribute to higher criteria function values.

The results of the decision process conducted under experimental conditions: a_1) (N_1=52), a_2) (N_2=55), and a_3) (N_3=40) presented as deviation of CFV from the optimal CFV, are shown in Figure 5.

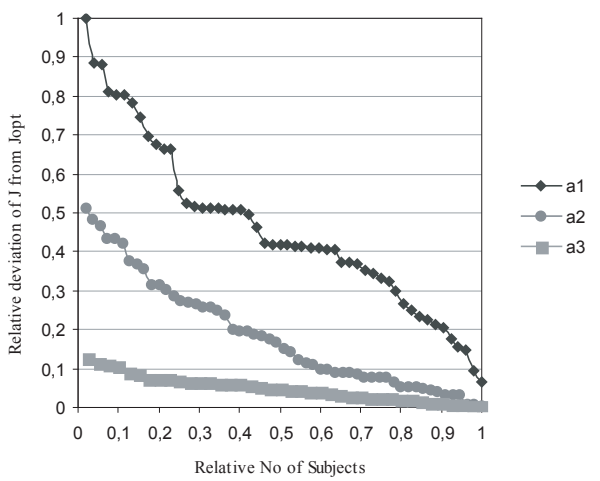
The lowest deviation values were obtained in experimental condition a_3) where group information feedback was applied. Results marked a_2) and a_3) were gathered with the aid of the SD model, and the results marked a_1) where assessment was done without a formal model, were gathered by writing them in a paper form. The single factor ANOVA showed that there are highly significant differences in CFV among groups on a $p = .000$ level of confidence. Therefore, the hypothesis that the model application and group feedback information positively influence the convergence of the decision process and contribute to higher CFV was confirmed.

The anticipative value of information using Shanon - Harkevič equation can be measured:

$$I(a_i) = k \log(p(a_i) / p_0) \qquad (8)$$

where p_0 and $p(a_i)$ represent the probability of achieving a goal without or with information, respectively, and a k constant. In practice, it is impossible to get a probable released goal in advance. This problem derives from the nature of the decision process. However, the simulation model of the process and anticipation of possible future impact from the environment can provide useful information to management. In our case, it is obvious and can be observed in Figure 5. Let us suppose that objective function equation can take each value from the unit square interval with equal probability if the experimental subject has no knowledge of the goal. The probability p_0 is then reciprocal to the unit square area of $P0 = 1$. In our case it means maximal entropy of the experiment. With experimental condition a_1), a_2) and a_3) we introduced information proportional to the area of reduction. By estimating the area $P1=1/2$, $P2=1/4$, and $P3= 1/16$ and taking its reciprocal value we obtained the probability of $p(a_i)$. Using equation (8) we can estimate the information content of the experimental condition. In the tested case, based on equation (8) where $k = 1$, the following is noted: $I(a_3) = 4$, $I(a_2) = 2$, $I(a_1) = 1$, and $I(a_0) = 0$ bit. (Note that due to the normalization of the area in Figure 5 and $P0=1$, reference is being made to the relative value of information obtained through experiments a_1, a_2 and a_3, where generality is not being affected).

Figure 5. Normalized deviations of CFV from the optimal CFV for experimental conditions a_1), a_2), and a_3)



6. CONCLUSIONS

This paper analyzes simulation as a knowledge base for decision support and its' usefullness in application.

Four years of experience in a concrete production company, where new production line was chosen by employing simulation methodology, was analyzed. The predictive validation of the simulation model as well as simulation methodology for decision assessment was done by comparing actual data with those predicted of the chosen alternative in four years period. A comparison showed that the gained predictions were a relevant estimation of future company development after the reengineering process was completed. More over, post decision analysis showed how good was the rational decision of alternative a_3, comparing to the competing alternative a_4.

Warehouse optimization in a production company by simulation methodology was studied. The simulation model was validated on a company's historic data. The results also show how the operators' ordering strategies improved in time as he/she learned from experience. The same experiences one could aquire by experimenting on a model in shorter time.

Influence of the SD model and group feedback information on a decision-making process was analyzed in a laboratory setting. Hypothesis that the model application and group feedback information positively influence the convergence of the decision process and contribute to higher CFV was confirmed.

The basic advantage of the described approach lies in the interactivity and transparency of the model representation. By experimenting on a simulation model, the user enhances knowledge about the studied process and improves judgment about alternatives. In this way the range of *bounded rationality* in decision-making could be enhanced.

Keeping High Quality in Higher Education with Less Funding: Possible?

Juha Kontio, Turku University of Applied Sciences, Joukahaisenkatu 3-5, 20520 Turku, Finland; E-mail: juha.kontio@turkuamk.fi

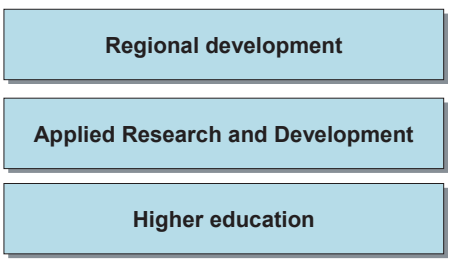
1. INTRODUCTION

The quality of the education is one of the key areas universities and universities of applied sciences should focus on (Ministry of Education Finland 2003). The focus of all development actions should clearly be on quality and impressiveness of operations as well as in strenghening internationalization (Opetusministeriö 2006). Quality of education is also emphasized in the development plan of the Regional Council of Southwest Finland (Varsinais-Suomen liitto 2005). While focusing on quality the institutes should take care of that also national and international compability remains and gets better (Ministry of Education Finland 2005). Globalization and competition have led to a situation where the trust into your own national higher education quality is not enough rather in every country the higher education should be understandable and trusted also internationally (The Finnish Higher Education Evaluation Councill 2005).

At the same time as quality is emphasized more duties are presented to Universities and Universities of Applied Sciences. In Finland, for example, in 2003 applied research and development was introduced as the third main duty in the new act of Universities of Applied Sciences (see Figure 1). The other two main duties are higher professional education and regional development. Despite these new duties the funding was not increased. In addition to new duties also requirements to provide even more high-cost hands-on-training and working life related education have increased. (Ministry of Education Finland 2005) This places Universities of Applied Sciences in a very challenging position; how to maintain quality and correspondence to working life in education?

Ministry of Education understands that unfortunatelly these cannot be provided at the moment due to tight costs and suggests that combining research- and development and services with education might be the solution and a source for additional funding (Ministry of Education Finland 2005). Using R&D to serve also education is a natural way to increase working life focused education. This focusing on working life requirements in education is constantly mentioned in different reports and publications. For example the president of European University Association writes that higher education institutes have to educate experts to working life requirements (Winckler 2006). Also many Finnish future evaluation reports define that it is essential that expert resources match with the working life positions (Ruokanen 2004; SITRA 2005; Wikström, Haikkola et al. 2005). Universities of Applied Sciences should focus on educating professional experts capable of really doing things. The aim of Universities of Applied Sciences should not be in producing new knowledge rather in using and applying it (Ruokanen 2004). In addition, Ministry of Education has stated that more and more quick changes in our environment and working life requires that interaction between education, research and working life should be further promoted (Ministry of Education Finland 2003). Will this be also the solution for the funding problem and the quality matter as well?

Figure 1. Main duties of Universities of Applied Sciences



This paper presents a case study. We present the actions and ideas that the faculty of Telecommunication and e-Business at Turku University of Applied Sciences has taken to survive with the funding. We start with the research methodology and describe our current environment we are operating in. In section 3 we introduce our solutions. In section 4 we talk about the challenges we still have to tackle. Finally, section 5 is for discussion.

2. RESEARCH METHODOLOGY

This paper uses qualitative approach and is a descriptive single case study. In general, a case study aims for in depth-understanding of the context of the phenomenon (Cavaye 1996). Furthermore, a descriptive case study presents a complete description of a phenomenon within its context (Yin 2002). A case study is well-suited to capturing the knowledge of practioners and to document the experiences of practice (Benbasat, Goldstein et al. 1987). This paper follows interpretitive tradition of the case research. It means that there is no objective reality, which can be discovered by researchers and replicated by others (Walsham 1993; Broadbent, Darke et al. 1998). During the period this paper is about (2004-2006) the researcher acted like action researcher (Walsham 1995) as he was a member of the case organization.

The unit of analysis in this research is the faculty of Telecommunication and e-Business at Turku University of Applied Sciences. Universities of Applied Sciences are normally regional higher education institutions providing higher professional education with close connection to working life. In Finland there are in parallel with Universities of Applied Sciences traditional Universities that focus more on scientific research and provide higher education in connection with it.

The faculty of Telecommunication and e-Business operates in two cities and has eight different degree programmes. Four of the programmes are arranged in Turku and rest four in Salo. We educate both bachelors of engineering and bachelors of business administration. Optimal study time for engineering students to study their 240 ECTS (see http://ec.europa.eu./education/programmes/socrates/ects/index_en.html) is four years whereas optimal study time for business administration students is three and half years as their degree program is 210 ECTS. The faculty has approximately 1500 students of which roughly 550 study in Salo campus and 950 in Turku campus. Our degree programmes are listed in the Table 1.

The main research question in this paper is: **How to keep up high quality in higher education with less funding**? The basic idea is to describe the actions and solutions we have introduced to solve the challenging funding situation.The first thing we must understand is the basic structure of the funding; how funding is defined; from where the funding is coming; why there are less funding available.

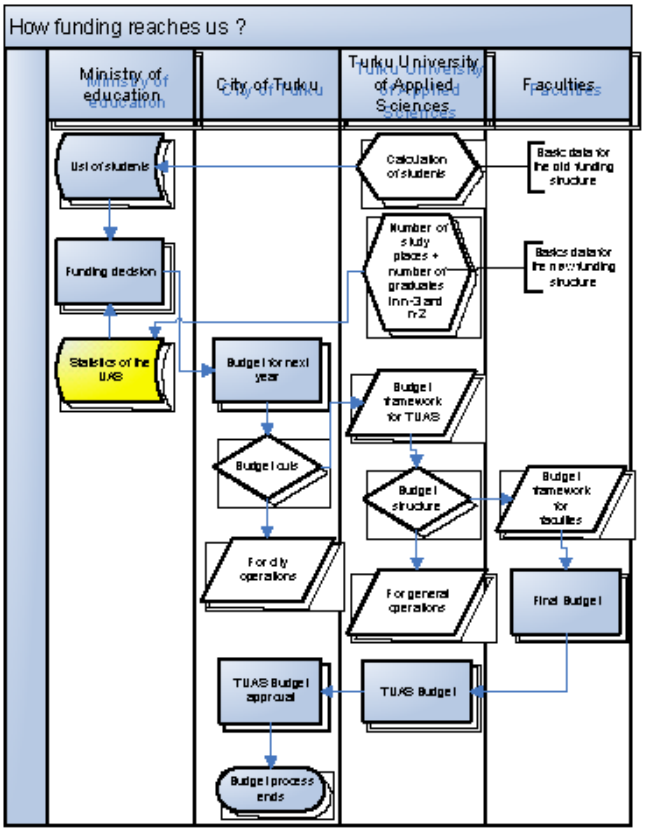
Figure 2 shows the overall structure of the funding. Ministry of Education gives the basic funding to the administrator of the University of Applied Sciences. In our case the ministry funding is paid to City of Turku. The city is expected to forward the same amount to the University of Applied Sciences. However, there aren't any regulations about what will happen if this is not happenning.

Earlier the funding based only on number of students present at certain moment. There were two so-called calculation days when the number of students was calculated. Only students studying within the normal study time were accepted. If someone has exceeded his normal study time he was not accepted to the count of the students. The new 2003 act changed the funding structure significantly. Now 70% of the funding is defined by the number of study places and 30 % is based on number of graduates within two previous years.

Table 1. Degree programmes in telecommunication and e-business

Degree Programme	Credits ECTS	Discipline	Students
Library and Information Services	210	Information Services	85
Business and Administration - English/German - Finnish	210	Business	176
Business Information Technology - English - Finnish	210	Information Systems	196
Information Technology - English - Finnish	240	Information Tech-nology	727
Electronics	240	Computer Engineer-ing	259

Figure 2. Funding process at Turku University of Applied Sciences



The basic funding that City of Turku receives for Turku University of Applied Sciences has steadily increased, but the problem is that they do not forward all of the funding to the university. For example in 2007 the sum that we receive is about 4.4 million Euros smaller than the original funding from the Ministry of Education. Another problem is that the budget framework has been almost the same for many years and not even index revisions have been done. However, at the same time salaries have raised 2 to 3 percentages per annum.

Data for this paper is collected through active observations, own experiences and active involvement in daily operations of the faculty during 2004-2006.

3. OUR SOLUTIONS

Basically there are two ways to survive when funding is decreasing. You have to cut your costs and you have to increase your income. Table 2 lists solutions that we have taken during recent years when our basic funding has not increased.

Most of our costs come from salaries and side costs. Teacher resources are expressed in working hours. The more resources we give for some task the more expensive it is. An obvious target for cost cutting was therefore number of contact hours that are the most typical item in teachers' yearly working hours. However, we wanted to do this cost cutting in a controlled way. Therefore we defined quite precise guidelines how to define resources for different tasks. We needed an exact guideline that defined for example what the basic resource is for a teacher per one credit in a course/project. This basic resource may then rise if certain circumstances are fulfilled, but it may also drop if other circumstances are fulfilled. The circumstances that raise the resource are for example

- first time implementation of a course
- foreign language
- new pedagogigal method will be introduced in the course.

The circumstances that lower the resource are for example

- pedagogigal methods used
- same course is delivered many times.

Altogether, the basic starting resource per one credit is now lower than it used to be.

At the same time students own responsibility was increased. This reducement did not lower the quality rather it helped us to improve the quality because we had to think more carefully how we implement our courses.

In practical level we have done many other reforms as well. We have used a lot of time redefining and improving our general processes and actual study process as well. We have increased co-operation between degree programmes and disciplines. Different degree programs have more common studies than earlier. At the same time we have introduced different pegagogigal methods to make studying more interesting. We have introduced for example problem based learning in topics like entrepreneurship and computer architectures. In addition we have more learning-

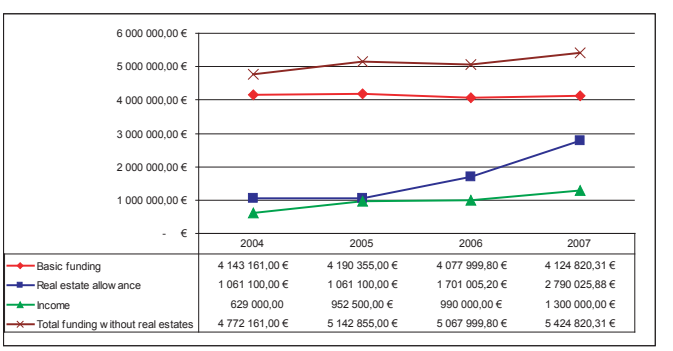
Teaching arrangements	X	

Figure 3. Funding during 2004-2007



by-doing projects with real-life assignments. Altogether we have enabled multi-disciplinary learning (Kontio 2006). The goal of these reforms was to provide necessary amount of high-quality courses with reasonable costs.

The most important solution to keep up the quality was the decision to determinedly increase our income. For this purpose a R&D-manager was hired and assistants to her. The R&D-manager is responsible to follow all kinds of funding sources and to help setting up project and funding applications to various financiers. The expertise for the project contents comes from our teachers, but the project management is helped by R&D-manager and/or the assistants. The teacher expertise is essential for our applied R&D-projects and therefore we have to make room for this work in teachers' yearly working hours.

Figure 3 shows that our efforts have been successful. Our income has risen since 2004 very rapidly and is now over two times more than in 2004. The main financers of our income are European Union, National funding agencies and companies participating in different projects. This income increase has provided us additional resources and a way to develop our operations.

An essential idea of our project proposals is that there is some connection to our higher education process. This means that students earn part of the needed credits in R&D-projects. Making this possible requires that the project proposals always have some connection to the curriculum. However, even more important is that the proposals have working life partners and other partners as well. The connection to curriculum is either made through a large R&D-module, a single course or thesis. The connection requires that the curriculum is flexible and these things can be done within the education.

Thesis is the most typical way how students earn credits in R&D-projects. Thesis topics are part of the projects and supervisor resources come from the the project funding not from the basic funding. Another typical way to connect R&D-projects and teaching is to provide our processes as pilot environments. This way teaching serves the R&D-project and pilots the developed results or provides a test bed for developing something new. Examples these kinds of projects are for example

- SEM-to-SME: The goal was to progress teaching of entrepreneurship in participating institutes by applying Student Entrepreneurship Model developed in Turku University of Applied Sciences.
- CIP Worklab: The goal was to study how working life expertise in library and information services could be collaborated with the higher education of the same field.
- Mobile TV: The goal was to study different technologies of digital video broadcasting according to the goals set by the collaborating companies.
- AMK-WLAN: The goal was to study wireless networks in Finnish Universities of Applied Sciences and to provide suggestions how to build a nation wide wireless network.

Another example of supporting income increase is creating connection with our international affairs and R&D. Traditionally our international affairs have concentrated on managing student and teacher exchange. We wanted to benefit from this existing partner network more and we created a network of R&D-peoples with our partner institutes. Now our R&D-coordinators can easily look for possible partners to different project proposals; they have the contacts and knowledge of the key interest areas in different institutes.

We have also done structural arrangements in our faculty to decrease costs and to improve quality. We close down two of our English degree programmes and join them to equivalent Finnish degree programmes. This way the basic student group size of a degree programme is getting bigger. We have also sharpened our degree programmes and defined clearer focus for each of them. We have for example reduced the number of specializations in each degree programme. We have also screened out overlapping programmes. For example we screened out our Finnish internet technology programme and concentrated this field in our English programme. Similarly we defined that IT programme in Salo campus focuses on software engineering instead of embedded systems that is one of the focus areas in Turku campus.

4. CHALLENGES

We have done quite a lot to survive with the budget where the basic funding has stabilized in a certain level. These introduced new methods and arrangements provide us the necessary growth and playground, but there are still challenges that we need to focus on.

A big challenge is to get more and more of our teachers involved with R&D-projects. At the moment there are only limited numbers of active teachers taking part in R&D. Usually these teachers are also the most wanted in teaching courses. The work load of some teachers is getting too heavy and we need to find additional personel in our R&D-projects. The problem is not that there is lack of R&D or project skills among the rest of the teachers rather quite many have come to our institute especially because they want to teach! Our idea of combining teaching with R&D-projects hopefully also eases this fundamental problem. Usually these projects also give additional resources to teacher compared to a normal resource defined in a normal course.

The previous figure (Figure 3) showed that our income has constantly rised. The second challenge is to keep the responsibility of making income relatively equal within our eight different degree programmes. However, we cannot spread the income goal just by dividing it into eight parts and defining it as the income goal for a degree programme. We must understand and know the differences of our degree programmes. In some degree programmes the R&D-readiness is higher than in others i.e. there is for example stronger working life knowledge and they might have more teachers with a post-graduate degree. Our solution to support this is that we have a R&D-team where every degree programme has own representatives. This team coordinates and plans our R&D-actions and therefore the role of the representatives is very important. A representative is like a messenger for the rest of the degree programme. As R&D-projects provide natural learning environments it is important that the messages from R&D-team are understood in the degree program.

Our third challenge is quite near to the second one. The challenge is that we have defined a goal for 2007 that in every degree programme there should be a large 2-3 years R&D-project worth at least 120000 euros per year. If we succeed in this challenge degree programs have additional resources through there projects and better opportunities to arrange the education. This challenge automaticly defines our fourth challenge i.e. we need people that are fluent in writing and generating good and realiable applications to the funding sources. At the same time we need people who know different funding possibilities and the content and focus areas of these funding programs. Our R&D-manager and her assistants have actually offered these services, but the more projects and applications there will be the less time they can offer for one application/proposal.

The fifth challenge we are facing is the fact that part of our basic funding bases on the number of graduates. Therefore it is essential that the number of drop-out students stays low and majority of the students graduate. Our challenge is to provide as interesting and versatile education that students stay with us. Introducing problem-based learning and learning-by-doing have both been answers to this way. However, we must constantly gather feedback and develop our study methods better. The majority of our basic funding is based on number of study places in our degree programmes and there we are facing a challenge that we cannot really interact any more. Statistics Finland has produced a statistics about young generations entering higher education between 2006 and 2025. The statistics show for example that in our region the number of young people is first rising but drops until the end of the period. This is just a fact that will influence higher education in Finland, but there is not much to do about it. A possible way to tackle this challenge is to concentrate even more on R&D. While less teachers are needed in actual teaching there are more teachers for projects.

Final challenge is the need for additional structural changes that are in connection with the statistics mentioned above: less young people need less study places. We need to alter our structures into more cost efficient direction and focus on providing high quality education in our special fields. An additional possibility is to collaborate with tradional universities and take advantage of the best practices in both systems.

5. DISCUSSION

The idea of this paper was to describe how to keep up high quality with less funding. Quality of education is very essential for every higher education institute. For us the quality issue has concreted because our basic funding has kind of stabilized into the level where it currently is. While the cost are all the time raising we needed to take actions to keep the educational level and to improve the quality of it. Of the two choice strategies for surviging with descreasing budgets we have built our solution more based on the increasing income. The increasing income does not alone solve our challenges with the quality of education but it gives us the opportunity to develop our operations and take advantage of the increased

funding. For example the new pegadogial methods (problem-based learning and learning-by-doing) are both direct answers to the quality issue. They are both also answers to the requirements that we should educate experts that are capable of really doing things.

The combination with R&D and education has proven to be a success story. However, we must emphasize that this has not meant that basic education is paid with R&D-funding. Our curricula have clear places for R&D-projects and our students work on these projects like normal developers and researchers. Students' work has thus very clear development or research targets. Now that some of the total credits are financed through R&D-projects we have actually more resources to arrange the rest of the courses and credits. We have turned the new additional duties into our victory. A good example is one of our small degree programmes Library and Information Services. Year 2006 was the first ever in the history of the degree programme when the budget is in balance. The reason is obvious; there are two quite large R&D-projects that cover part of the credit production.

R&D-projects provide us also a natural way to increase working life based education. R&D-projects themself provide us information what is happening in working life but they are also concrete examples of the working life for students. Students' commitment to real-life projects is also much better than in dummy projects. It is not only the students who gain from R&D-projects. These projects benefit our teachers as well. Being part of these projects a teacher gets up-to-date feeling and observations what are the challenges companies are working on at the moment. This information serves again education when the teacher is planning his/her teaching. Altogether we have ideas to further strengthen the relationship between education and working life. There is a worldwide innovative initiative that aims to bring engineering education and real-world demands on engineers closer to each other (CDIO 2006). Our aim is to start own development project based on the CDIO ideas in 2007.

In our case the individuals have been in a central role. We have very motivated and open-minded degree programme managers and a R&D-manager who share this common idea about creating relationships between teaching and R&D. Everyone has understood that R&D is giving us new opportunities; it is not cutting the teaching resources rather vice versa. The positive atmosphere feeds new R&D-initiatives among our teachers and is generating kind of avalanche among R&D. Increasing income leave more and more money for teaching. We have introduced versatile teaching methods that would have not been possible without additional funding.

Finally, our experiences are very encouraging and we see that there are ways to keep high quality even when the basic funding mechanism is not increasing. We also see that the solution is not to downsize operations rather look for new opportunities and new ways of doing things.

INTRODUCTION

A municipal wireless network (MWN) is a government-sponsored wireless metropolitan area network (MAN). The number of municipal wireless networks proposed and built in the U.S. has continued to grow over the last five years, with some analysts are forecasting an 8,400% increase in area covered by MWNs by 2010 in the U.S. (Information Week, 2006)

When a municipality (i.e., town, city, or county) decides that it needs an MWN, it typically partner with vendors who can supply the expertise to design, install, and operate the network, as well as the necessary equipment. To find such partners, they issue a Request for Proposals (RFP), a document which details the municipality's goals, its business model for funding the deployment and future maintenance of the network, and any relevant constraints and assets the city may have. Issuing a clear and effective RFP is crucial to the success of the ensuing project. Effective RFPs clearly articulate the city's goals along with a realistic business model so that vendors can respond with valid and diverse proposals (Richardson, 2005). Ineffective RFPs may fail to attract vendors, give rise to projects which may never be completed, or produce networks too expensive to maintain in the long run.

In this paper, we formalize an evaluation framework that can be used by decision makers and city planners to specify their RFPs for MWNs. In addition, the paper conducts a case study of three municipalities; it applies the developed framework to actual projects of three cities in order to assess the likelihood of the success of the ensuing projects. It is found that an effective MWN RFP forms the basis for planning a successful project. Such RFP includes clearly-defined goals and financial models, which should be clear as to avoid the need for later clarification. An effective RFP should result in a network built on schedule and on budget during deployment, as well as a network consuming predictable expenses to run. Finally, the RFP should communicate in detail the types of services the city expects from the network, so the vendor can work to deliver them and the city can avoid future issues of accountability.

MOTIVATIONS OF MWN DEPLOYMENTS

A *municipal wireless network* (MWN) is a wireless metropolitan area network that is sponsored, and possibly built and operated, by a municipal government (which may be a town, city or county). It is built to provide wireless MAN service to people, typically within the city limits of a municipality but sometimes exceeding them based on cooperative agreements (Cherry, 2006). The service may be offered at low or no cost. Municipalities deploy MWNs for four major reasons: to stimulate economic development, to provide a last-mile alternative, to address digital divide issues, and to enhance city services (Shamp, 2004).

In terms of *economic development*, a major hypothesis among municipal governments is that the municipal supply of broadband Internet service to its constituents will directly stimulate a city's economy, as well as induce people to both visit the city and possibly relocate to it (Ford, 2005; Ford and Koutsky, 2005). This goal may include promoting the city's reputation as a technologically advanced community, bringing in tourists and encouraging people to move to the city. Research has indicated that MWNs have a positive impact on business vitality in communities (Ford, 2005; Ford and Koutsky, 2005; Goth, 2005).

In terms of *last-mile access* issues, in some cases incumbent carriers may not be interested in deploying a broadband communication network to a city or to an area of a city due to a perceived low ROI. The low ROI may be due to the fact that broadband deployment is expensive and requires much capital invested upfront with uncertain demands and future revenues. In other cases, broadband services may be available only at a high cost from a monopoly carrier in the city. In all these cases, a city may decide it has an obligation to provide another last-mile alternative to its citizens.

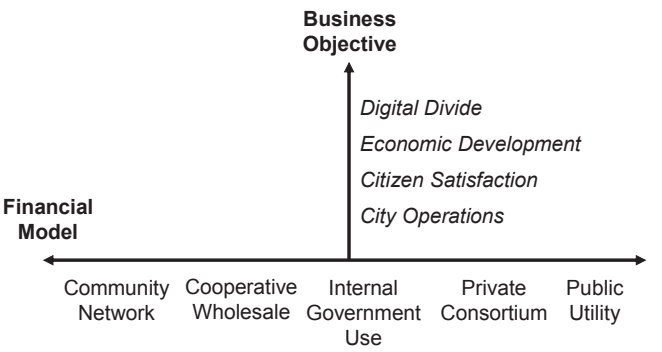
Digital divide may also be a reason behind an MWN deployment. Digital divide refers to the gap between those who have ready access to computers and the Internet and those who do not have access to those technological resources. The economically disadvantaged and those with low literacy skills (computer or otherwise) are more at risk of being on the disadvantaged side of the gap. As a result, they may be increasingly marginalized in a modern knowledge-based economy. Many cities see a great need to close this divide and treat MWNs (in combination with computer training and low cost computer programs) as a way to do so.

Lastly, many cities want to deploy MWNs in order to streamline and enhance *city services* and help their municipal workers to more effectively perform their jobs. The municipal employees include emergency responders such as police or firemen and other workers such as parking enforcers and building inspectors. In addition, cities also want to make it easier for its citizens to access city services by providing web portals to city departments, accessible via the MWN.

EVALUATION FRAMEWORK

A successful deployment of MWNs requires that there be a clear purpose for such a network and a set of identified benefits. It is necessary to balance competing or overlapping objectives and establish priorities so that outcomes are clear and can be measured. Municipalities should carefully evaluate community needs so that technological, financial and opportunity readiness can be realistically assessed. The Civitium report (Richardson, 2005) starts with the RFP Lifecycle process with business planning. Intel (Intel, 2005) puts business plan development very early in the process, placing it just after identifying a core action group and reaching out to technology providers. Five business models are currently used by communities to deploy wireless broadband and "choosing a business model that provides sufficient funding and allows the community to meet its project objectives is critical – and can be difficult." (Stone and Richardson, 2005, p. 10) Other models in the literature, such as strategic alliance and new operator (Chang, Yu, and Tsai, 2006),

Figure 1. An evaluation framework of MWN RFPs



are also included in the proposed set of five models. The five financial models are built from different mixes of public and private funding streams, acknowledged capital assets, and control opportunities:

- Community Network: This type of network is wholly funded by the government through grants, taxes or other revenue.
- Cooperative Wholesale: Government funds the deployment, serves the public needs and sells excess capacity to private providers.
- Internal Government Use: Public or grant monies fund the broadband deployment for government use only (e.g., police, fire, and utility).
- Private Consortium: Both community and subscribers pay for service though the community may also leverage city assets.
- Public Utility: This model is akin to that used for water and gas in which there is a separate enterprise that may show annual profits and losses.

The model fundamentally affects the city's priorities. If the city feels that its operational needs are already well met and that invigorating the business community is paramount, then clearly the model would not be one of focusing on city operational needs. If a controlling piece of legislation prohibits a network wholly funded by the municipality, then a community network model would not apply. Therefore, city stake-holders need to clarify and prioritize the near-term benefits they seek and assess how the MWN fits into the city's strategic objectives.

In addition, an effective RFP for a MWN should contain evidence of a community process in which one or more of the following business objectives can be identified and prioritized in the context of the municipality: (Intel, 2005, p. 6)

- City Operations: Increase efficiency through real-time, high-speed, remote access to databases related to government services (e.g., police and building inspection)
- Citizen Satisfaction: Improve access to services and enable a higher degree of interactivity with and responsiveness from those services.
- Economic Development: Enhance local commerce through improved business and community support.
- Digital Divide: Assure egalitarian access to the network through affordability and publicly accessible environments.

By combining the five financial models and four business objectives, this study proposes an evaluation framework shown in Figure 1. Through the RFP, the vendor should be given clear directions regarding the city's business intent so that the competing implementation factors of cost, speed, and quality of service can be optimally balanced for the local application. If an issued RFP does not communicate such intent, a vendor is then typically left to making best guesses (usually biased to lowest cost) and would not be able to deliver a clear and effective response. In this study, we analyze three cases of RFPs issued by municipalities around the U.S. and examine their business objective and financial model.

RESULTS

Houston, Texas

Houston covers an area of 639 sq. miles and has 2 million people. Within its city proper, it has 40 colleges, universities and institutes. The city released its RFP for a city-wide wireless network (Houston, 2006) on March 17, 2006.

Business Objective: Improve City Services

Throughout the RFP, though there are statements regarding the digital divide and reference to public safety, the document emphasizes city or public services as the business priority. Houston's objective is to expand the network's use beyond the intelligent parking meters to work-order management of field personnel and automation of traffic signaling with the ultimate goal of fundamentally reducing the city's communications expenses (Houston, 2006, p. 10). The goal of public access is primarily achieved through a financial model in which service providers offer affordable and reasonable rates to businesses and consumers.

Financial Model: Private Consortium

Houston adopts a view that the city sets policy and serves as a catalyst and service providers are the financiers and managers (Houston, 2006, p. 20). The clearest indication of Houston's expected financial model for the MWN is the statement on "Private Sector Cooperation – The City's role shall be that of a catalyst – to improve and enhance the market for broadband services in Houston. The City seeks to fulfill this role by collaborating with the private sector in a mutually-beneficial partnership." (Houston, 2006, p. 11) This is followed by Section 2.4 on "Use of City Assets" and the statement "The City intends to leverage its significant real estate holdings, as well as rights…" The same section gives more details on the number and placement of signal towers, traffic lights and other rights the city intends to contribute.

Nevertheless, buried in the business model statement the city claims all rights to the "Capture Portal in terms of both revenue related to commercial content and advertising on this page, as well as management of the pages' design, branding, layout, development and maintenance" (Houston, 2006, p. 21) which suggests that the MWN will be branded as the city's own. Thus one can surmise that the city's expectation is that the service provider's financial model will largely depend on its ability to sell network access to other service providers and retailers.

Conclusion

The Houston RFP provides a clear and workable perspective on the city's MWN. It is non-ambiguous on the city's intentions, which is improving its operations though "Value to the Community". In addition, this value is measured by the wholesale, discounted, and promotional rates offered to the population and is listed first in the evaluation criteria (Houston, 2006, p. 17). In this respect, "Value to the City" in terms of compensation and proposed rates will undoubtedly weigh heavily and be less negotiable in meeting expectations.

Fairfax, Virginia

The city of Fairfax, Virginia covers 6.3 sq. miles and has a population of 22,000. It published an RFP on March 16, 2006 for the installation of a Wi-Fi network that will encompass the city as well as some of the immediate surrounding areas. An analysis of the Fairfax RFP shows that the RFP is not clear on the scope of the network, how it is to be built, or who will pay for it. The RFP may need more clarification and detail as to the city's expectations.

Section 3 "Goals" of the RFP is where the RFP defines its goals for the network. The critical goals (Section 3.1) for this project are loosely defined. For example, Section 3.1.1 requires that the network encompass a "service area consisting generally of the City of Fairfax" (Fairfax, 2006, p. 4) but does not specify exactly where the coverage boundary should be.

The RFP may have intended to keep requirements at a high level based on the first paragraph of Section 12.0 "Definitions of Basic Requirements". Paragraph 12.1 states: "Throughout this RFP, the City has elected to define basic requirements for the network, while encouraging maximum flexibility and creativity by Offerors. The requirements below are defined on a summary level, and Offerors are encouraged to propose (and elaborate on) a solution that best meets the City's stated goals." (Fairfax, 2006, p. 11) However, when evaluated using the proposed framework, this open, summary approach does not clearly define the business objectives of the network, and the responding vendors may have to estimate more detailed objectives and devise solutions that may be suboptimal.

A later section, Section 14.0 "Business Model and Policy Questions", does not contain a more detailed description of the MWN's business model. The section contains a series of questions put forth to the vendor to clarify how its proposal will meet Fairfax's needs for a wireless network. As an example, Section 14.2 asks: "How does your proposed solution/approach specifically address the

City's stated goals and requirements?" (Fairfax, 2006, p. 13) According to the proposed framework, a better approach would be that the city first answers these questions by means of focus groups, town hall meetings, and/or surveys before issuing an RFP.

The Fairfax RFP does not specify much detail in terms of specific business objective and financial model. As a result, vendors may not be able to provide focused responses to the RFP. Based on the proposed framework, it is recommended that cities first identify the feasibility of the project and specifically discern how best to build the network.

South Sioux City, Nebraska

South Sioux City, Nebraska has an area of 30 sq. miles and a population of 12,000 people. In contrast with Houston and Fairfax, South Sioux City has a completed, deployed MWN. South Sioux City's MWN is entirely devoted to city services. It is noted that Nebraska is one of the 15 states with "anti-MWN" legislation, having passed State Bill LB-645 which categorically forbids municipalities from providing communications and information services of any kind to citizens (Freepress, 2006).

Business Objective: Improve City Services

South Sioux City had a legacy mobile wireless network used by 20 police and emergency vehicles. The legacy network was an 800MHz leased radio system used to connect to the city's own local-area network. The legacy technology had a limited bandwidth, and it severely limited the ability of public safety officers to transmit or receive video/photo data concerning suspects during investigations. In addition, the leased radio system had a yearly maintenance cost of $27,000 (South Sioux City, 2006). As a result, the city chose to roll out a new MWN using pre-certified WiMAX technology. The technology satisfies the requirements of mobile access (i.e., maintaining connection while clients are moving at vehicular speeds) and long range.

Financial Model: Internal Government Use

In addition to a well-scoped business objective, South Sioux City also has a clearly-defined financial model for its MWN. The initial capital investment for the MWN was funded by a Department of Homeland Security grant, and maintenance costs are covered by the retirement of the legacy radio system.

Conclusion

Due to a well defined scope of work and an established budget, South Sioux City was able to effectively increase the capacity of their wireless network from 9600 bps (using the legacy system) to 1.5 Mbps downstream and 512 Kbps upstream (using the pre-certified WiMAX technology). The MWN covers the entire target population, and the coverage even exceeds the original target in some areas. The success of South Sioux City's MWN has led to similar deployments of MWNs by several other municipalities in Iowa, Nebraska, and Minnesota adopting similar business objectives and financial models (South Sioux City, 2006).

DISCUSSIONS

In addition to the important criteria of business objective and well-defined financial model, there are other factors for municipalities to consider when deliberating an MWN deployment. These factors include municipal characteristics and legal issues.

Municipal Characteristics

Many different municipalities are considering MWN deployments, from 50-person townships, to rural counties covering hundreds of square miles, to major cities with millions of people. The particular characteristics on the city have a large effect on design, expectations, and costs. These characteristics include:

- City-specific requirements: What area of the city and what percentage of that area must be covered? What is the minimum desired service level (bandwidth)? How will the backhaul be handled?
- City assets: What assets does the city bring to the table? Many cities can offer utility or light poles, or rooftops of government buildings as places to site antennas. They may also have an existing fiber optic network which can be leveraged as backhaul connections.
- Maintenance operations: Once deployed, the MWN has to be maintained and operated. The responsibility of maintenance has to be clearly defined (e.g., maintained by city workers, vendors, or both).
- Evolution path: Due to rapidly evolving technologies, an MWN can be expected to become obsolete in three to five years, the timeframe of which generally follows typical IT upgrade cycles. The city needs to clearly specify what the expected life of the deployed MWN is and what process to take to initiate the upgrade cycle for the next MWN.

Legal Issues

There are two major legal considerations for municipalities considering the deployment of an MWN. The first is the primary hurdle: state and federal law. Currently, there are legislations pending at both the federal and state levels concerning the role of public entities in deploying telecommunications services which have traditionally been provided by the private sector. There are currently federal bills in committees in both the House and the Senate regarding MWNs. One is Senate Bill S.1294 (Community Broadband Act of 2005), which is an amendment to the Telecommunications Act of 1996 intended to preserve the right of localities to provide broadband services (S.1294, 2005). A competing House Bill, H.R. 2726 (Preserving Innovation in Telecom Act of 2005) actually prohibits municipalities from providing broadband or telecommunication services unless private enterprise has already failed to do so (H.R.2726, 2005). Since federal laws may supersede state laws, any municipality interested in deploying an MWN should maintain an active political presence and be cognizant of the legislative environment. However, given the popularity of MWNs (and subsequent legal challenges that will arise from cities fighting any federal law prohibiting MWNs), it seems unlikely that any congressional passage will have a major effect in the immediate future.

Regarding state legislation, there are two states—Iowa and Ohio—that have pending "anti-MWN" legislation, and 15 states that have already passed laws prohibiting or restricting MWN deployment. One such state, Pennsylvania, has a compromise law that allowed the Philadelphia MWN project to go forward, but prohibits other municipalities from deploying MWNs (Hamblen, 2005; Patton, 2006).

The second legal issue is obtaining licenses in the event an MWN deployment uses wireless technologies that operate in licensed spectrum (regulated by the Federal Communications Commission). Many wireless technologies use unlicensed bands, but the advantage of using licensed band is a lower interference generated by competing systems (of carriers or consumers). Municipalities wishing to deploy MWNs in licensed spectrums need to coordinate with the FCC

CONCLUSION

This paper discussed the motivations for MWN deployments and proposed an evaluation framework of RFPs issued by municipalities. The research considers three municipalities and applies the developed framework to their actual projects. It is found that an effective MWN RFP forms the basis for planning a successful project. Such RFP includes clearly-defined goals and financial models, which should be clear as to avoid the need for later clarification. From the cases studied, regardless of the size or scope of the RFPs, clear business objectives and focused financial models should increase the likelihood of useful vendor responses. In addition, vendor proposals can be fairly compared. In contrast, responses to an RFP that lacks a clear business plan and financial model may only be compared either quantitatively (by cost, for example) or qualitatively, and thus cannot be uniformly evaluated. Moreover, other factors such as city characteristics, costs, and legislative environment which influence the MWN design and analysis process are also discussed.

Improving Work Autonomy in Workflow Systems: A Configuration Choice

Irene Vanderfeesten, Technishe Universiteit Eindhoven, PO Box 513, 5600 MB Eindhoven, The Netherlands; E-mail: i.t.p.vanderfeesten@tm.tue.nl

INTRODUCTION

Some 40 years ago, software engineers had to take care of implementing each piece of the information system they were developing themselves, including the operating system, database routines, and user interface. Workflow systems (WfS's) have been positioned as the latest step in a trend where generic tasks are taken out of applications (Van der Aalst and Van Hee, 2002). Just like there are now off-the-shelf system solutions for data management, workflow takes care of coordinating the steps in a business process – freeing programmers from the need to hard-code this logic.

The principal advantage of employing a WfS is that it brings back the focus of IT support for business operations to the *entire* business process, instead of its elementary processing steps. This *process-orientation* or *process-awareness* in present WfS's is also pleaded by advocates of movements that emerged in parallel to workflow management, like Business Process Redesign (Davenport and Short, 1990) and Supply Chain Management (Christopher, 1992). Organizational advantages of process-orientation have clearly materialized in the form of improved business performance, reduced number of inter-functional conflicts and an improved "esprit de corps" (McCormack, 2001).

However, there are also indications that the use of a WfS may not be received with enthusiasm alone. Employees (the potential users) and work psychologists fear that WfS's might lead to a mechanical approach to office work, where man is seen as an exchangeable resource (like a machine) and not as a human being. In a study by Küng (Küng, 2000, p. 310), an interviewee at an organization described the effects of a WfS introduction like this: "Jobs became more monotonous. The system forces the employees to work strictly according to the process definition. Through the use of the workflow system, we now have some kind of 'chain production' in the office." Interestingly, the same empirical study has concluded that overall job satisfaction across the 5 various studied WfS implementations was influenced positively!

This is a paradoxical situation, which has not been dealt with satisfactorily so far. The main premise of this paper is that workflow systems are so inherently flexible, i.e. they can be configured in so many different ways, that the effects on job satisfaction may be highly dependent on the chosen configuration, e.g. compare (Poelmans, 2002). In earlier exploratory work (Vanderfeesten and Reijers, 2006), we identified a number of WfS "tuning" options that may influence the job satisfaction of employees positively (in particular their autonomy), while keeping the essence of the delivered support from a business perspective intact. The current paper builds on this work by proposing a fine-grained model of work distribution, which helps to understand how different configuration decisions may influence job satisfaction. Limited case studies within three organizations using this model indicate that in practice very restrictive configurations are in effect, which offer much room for improving the autonomy of employees using WfS's.

This paper is organized as follows. First we give more background for the two areas on which this research is built: workflow and job design. These two areas are linked by looking at the impact of workflow systems on task characteristics, mainly autonomy. Next, we focus on a very specific part of workflow systems: the distribution of work in a workflow system. We elaborate on the configuration options a workflow system has in this respect and on their impact on work autonomy. The paper ends with some concluding remarks and limitations of this approach.

WORKFLOW SYSTEMS AND WORK AUTONOMY

In this section we first clarify a number of important concepts in the area of workflow systems. Next, we elaborate on the area of job design and finally we summarize related work in the combination of these areas.

Workflow Systems

A workflow system is a software product that supports the specification, execution, and control of business processes (Ellis & Nutt, 1993; Georgakopoulos, Hornick & Sheth, 1995; Jablonski & Bussler, 1996). It is a proactive system that manages the flow of work and that defines, creates, and manages the execution of workflows through the use of software that is able to interpret the process definition, interact with workflow participants and where required, invoke the use of IT tools and applications (WfMC, 1999). Commercial WfS's have been around since the early nineties; while their conceptual predecessors can be traced back to the seventies (see e.g. Ellis, 1979). They have become "one of the most successful genres of systems supporting cooperative working" (Dourish, 2001, p.52).

To enable a workflow system, a process model has to be defined. Such a process model is a static representation of the steps (*activities*) in the process and the order in which they have to be executed. Moreover, the process definition also contains information about the people (*resources*) that are allowed to execute the steps (e.g. information on authorization, roles, knowledge, capabilities that are needed).

The process model describes in general the way how incoming *cases* are handled step-by-step. A certain case has specific characteristics that determine its right way through the process model. When an activity in the process model has to be executed for that case the workflow system checks which resources are allowed to execute the *activity instance* and it sends this piece of work to the individual or shared worklist of the authorized employees. The employee selects the piece of work, performs it and finishes it. Depending on the configuration of the workflow system the control of the execution process is entirely with the system or for large parts with the employee.

Job Design

From the area of job design a number of studies is available that deal with the impact of jobs having certain characteristics on the humans performing this job. By job design we mean the content of the job that an individual or group undertakes (for example the tasks and roles they fulfill) and the methods they use to undertake their work (Holman, Clegg & Waterson, 2002). The most dominant framework in the area of job design is developed in the 1970's by Hackman and Oldham (Hackman & Oldham, 1975, Hackman & Oldham, 1976). This model is used to define task characteristics and to understand their relationship to employee motivation, performance and satisfaction. According to this theory a job can be characterized in terms of five core job dimensions:

- **Skill variety** – the degree to which the job requires a variety of different activities so the worker can use a number of different skills and talent.
- **Task identity** – the degree to which the job requires completion of a whole and identifiable piece of work.
- **Task significance** – the degree to which the job has a substantial impact on the lives or work of other people.
- **Autonomy** – the degree to which the job provides substantial freedom, independence, and discretion to the individual in scheduling the work and in determining the procedures to be used in carrying it out.

- **Feedback** – the degree to which carrying out the work activities required by the job results in the individual obtaining direct and clear information about the effectiveness of his or her performance.

Workers who have jobs that score highly on these task characteristics are more motivated, more satisfied and work harder (Robbins, 2001). Thus, when a job scores high on these task characteristics this has a positive influence on, for instance, the productivity of the employee. Autonomy seems to be the most important task characteristic.

The Impact of Workflow Systems

Implementing a workflow system in an organization can have great effects on various parts of this organization. Remember for instance, the quote of the employee in the interview that stated that his work had changed to a more chain production like environment.

According to Sarmento this impact of the implementation of a workflow system can be observed in several domains (i.e. productivity, knowledge, collaboration, coordination, and communication), and at different levels of abstraction (the organizational level and the task level) (Sarmento, 2000a; Sarmento, 2000b). In this paper we particularly focus on the impact on users' productivity on the task level.

There is a large body of academic research that is focused on examining the determinants of computer technology acceptance, (e.g. Moore and Benbasat 1991, Taylor and Todd, 1995). Utilization studies are rare in the field of WfS's, although a seminal case study on the (lack of) acceptance of a WfS is reported by Bowers et al. (1995). User satisfaction with information systems, i.e. the extent to which users believe the information system available to them meets their information requirements, has also gained much research attention (e.g. Ives et al., 1983; Gelderman, 1998), but not in particular in relation to WfS's. A notable exception is the work by Poelmans (2002), which includes the tentative conclusion that not the selection of the right WfS, but the way it is configured and implemented is crucial in the success of a workflow implementation. Success is measured in terms of perceived usefulness, quality of information, and end-user satisfaction.

In our previous work we have generated a number of general tuning measures to reconfigure a workflow system according to the users' needs (Vanderfeesten & Reijers, 2005, Vanderfeesten & Reijers, 2006). These tuning measures mainly focus on improving the autonomy of the employee working with a workflow system, to overcome the problem of very rigid systems and boring, monotonous work. After the more general tuning measures, a detailed focus on the process of working with a workflow management system is taken in this paper. In the remainder of this paper we will specifically look at the work distribution in a workflow system and its effect on autonomy.

DISTRIBUTION OF WORK IN WORKFLOW SYSTEMS

A workflow system is driven by a static and abstract model of the business process that is supported by the system. As we have seen earlier such a process model consists of a number of activities and their respective ordering. When a new case (e.g. an insurance claim of a specific person for a specific accident) arrives at the process it will follow a route through this process model**.** All the abstract activities in the process model are instantiated for this specific case and for every activity a *'work item'* is created.

The course of instantiating and executing a work item is explained in Figure 1. When a case arrives at a certain step in the process model the right *'activity instance'* is generated. Next, the resources that are authorized to execute the activity instance are assigned, which makes it a *'work item'*. The work item then is distributed to the right resource(s) and, finally, is selected and executed by the right resource(s).

For this research we specifically focus on the distribution procedure of a work item, because we believe this part of the execution chain has the highest potential to improve work autonomy. Going into more detail for the distribution procedure, we identify three steps: notification, receipt, and scheduling. In the *notification* step the system notifies the authorized employee(s) that a certain work item is ready to be executed. In the *receipt* step the employee(s) receive(s) the work item on his/her worklist. Finally, the work items to be executed are *scheduled*, either by the system or by the employee, and the execution is started (see Figure 2).[1]

Figure 1. The relationship between cases, activities, and resources

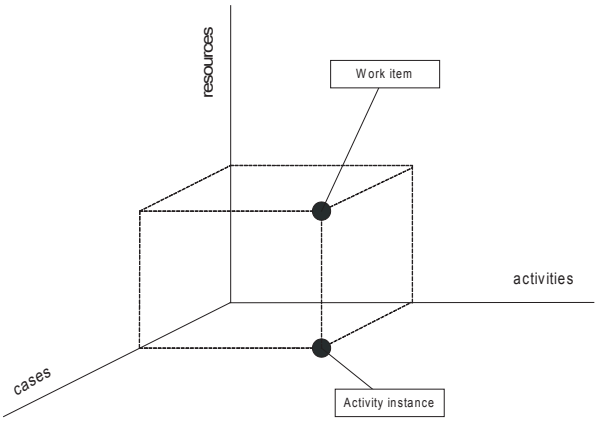

Figure 2. The steps of the execution chain, that are taken for the execution of an activity instance

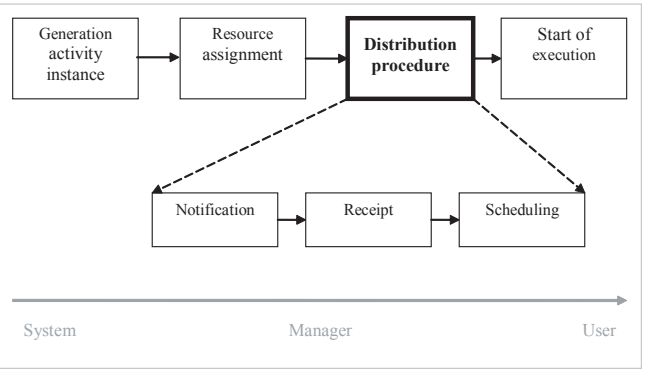

Note that the influence of the user changes in the chain of steps that is described in Figure 2: the generation of an activity instance and the resource assignment is completely done by the workflow system itself, while the receipt, scheduling and start of execution require an increasing involvement from the user.

For each of the steps in the distribution procedure several configuration options are available. These configuration options are identified by critically assessing several theoretical descriptions of workflow systems (zur Muehlen, 2004; Zeng & Zhao, 2005; Russell, ter Hofstede, Edmond & van der Aalst, 2004). Due to space limits we will not elaborate on all of them but we will give some examples to show their meaning.

In the notification step for instance the work items can be *allocated* or *offered*. In case of allocation, the workflow system puts the work item on the worklist of an employee, while in case of offering the work item is presented to the employee and the employee himself/herself decides whether it will be put on his/her worklist. It is clear that the latter case increases the autonomy of the user.

A second configuration option in the notification step is the notification to *one* or *more employees*. In case of more employees, the employees have the freedom to choose work items, which will increase their autonomy.

One of the configuration options in the receipt step is the *selection* or *acceptance* of a work item. When a work item is notified to the employee(s), the employee can select it from the list or accept it. By selecting, the employee makes a conscious decision, which also will improve the sense of autonomy.

Another option is the transportation to the individual worklist in the receipt step. This can be done directly to the *individual worklist* or through a *shared worklist* from which the employee can select one of the items. Through a shared worklist

the employee has an overview of all the work and the work that is performed by his/her colleagues, which will improve autonomy and task significance.

Finally, one of the options in the scheduling step is the *time of execution*. When execution has to be started immediately after notification and acceptance, the employees have less freedom than when they can determine themselves at which time they start execution of the work item.

Of course not every arbitrary combination of configuration options is possible; some choices exclude others. For example, when choosing a notification to one employee the transport to the individual worklist cannot go via a shared worklist. And in the case of individual worklists (without a shared worklist in between) in combination with the allocation of work items, the employee will only be able to select work items instead of accepting them.

The two most extreme distribution scenarios are:

(1) a work item is offered to more employees on a shared worklist, one of them selects the work item, puts it on his/her own worklist and starts the execution of the work item whenever he or she feels like doing it.
(2) A work item is allocated to only one specific employee. The employee has to accept it (rejection is not possible) and has to start working on it immediately.

From these two scenario's it is clear that the first one provides the most freedom and autonomy to the employee.

Case Studies

As a first step in our empirical investigations on the distribution of work in workflow systems, we have conducted six exploratory case studies. In these case studies three organizations were involved: a Dutch banking and insurance company, a Dutch bank and a Dutch municipality. For each organization two important processes have been studied on the distribution patterns that were used. The first company uses two different workflow systems: COSA and SAP. The other two companies use only one system for both processes: Staffware.

First, we examined whether the configuration options were really present in the systems. Next, we investigated the situation for the specific processes, by studying the process models, interviewing system developers and other stakeholders, and by checking documentation about the configuration options. Among the results of these case studies are two remarkable conclusions:

(1) In *all* cases, some kind of standard configuration of the workflow system was used, which provided little autonomy. This standard configuration consists of a shared worklist from which all authorized employees can select the work items they are going to perform. Indeed, the employee has some autonomy, but it could still be increased. For instance, in the Dutch banking and insurance company, the COSA system provides for a way to select work items an employee wants to work on from a shared worklist, transfer them to the employee's individual worklist and start execution of the work item whenever the employee prefers. However, this configuration was not used in our case study.
(2) The type of software program seems to be an important determinant for the available configuration options. In the cases of the Dutch bank and the Dutch municipality, the Staffware system was used. Staffware does not provide a facility to reject a work item or send a work item to another employee. Thus, all possible configurations with an offering pattern are not valid, which restricts the number of possibilities to increase autonomy.

CONCLUSION

In this paper we argued that the human side of IT is very important and that it does not need to be difficult to take people into consideration in the development of a workflow system. By only making small configuration changes in a workflow system, the system can be much more pleasant to work with. We believe that the degree of work autonomy is very important for employees, so that problems of chain production work in the office can be overcome (i.e. very mechanistic and boring work).

In earlier work we already identified some general 'tuning' measures to increase the autonomy of employees working with workflow systems. In this paper, we deepened the focus of these measures on a specific part of the workflow system: work distribution. We presented our hypotheses on several configuration options and we conducted six exploratory case studies to investigate the current situation of work distribution in organizations.

The most important limitation of this work is that we look at a small and very specific part of the workflow system. However, we feel this is the most important part of the system concerning people, since the work distribution is the step in the whole process where the work is actually offered to specific employees. Thus, this exactly is the part where autonomy is created for employees or where it is reduced.

Another limitation is that this is still a very theoretical approach, only supported by a small number of exploratory case studies. Therefore, it would be good to conduct a bigger field research, investigating the possibilities that current systems offer to adjust their configuration and the degree to which these possibilities are actually used in organizations to avoid monotonous and boring work.

ACKNOWLEDGMENT

This research is supported by the Technology Foundation STW, applied science division of NWO and the technology programme of the Dutch Ministry of Economic Affairs. We would like to thank Tjeerd de Koning for his creative ideas, input and support.

1. PROJECT PROBLEM

Approx. 2,000 students complete the 'Bachelor of Business Administration' or 'Bachelor of Business Economics' Programme in the Department of Economics and Business Administration at Justus-Liebig University Giessen. During the first four terms, all the students attend the same compulsory courses on the basics of economics and business adminstration. The following are some of the compulsory courses:

- Introduction to Business Administration
- Basic Costing
- Basic Finance
- Introduction to Economics
- Mathematics and Statistics
- Corporate Accounting (Bookkeeping and Financial Accounting)
- Business Planning and Organization
- Operations Research
- Basic Information Management

These compulsory courses each consist of a lecture (2 hours a week) and a complementary seminar (also 2 hours a week). The lectures are all held in a large lecture theatre to an audience of 400-700 students present. The accompanying seminars are a consolidation of the content of the lectures, using practical applications, examples and tasks. The content of the seminars mainly involves applying a calculation method to solve a business problem. In all the seminars the software product Microsoft Excel (spreadsheet) is used to practise the methods of calculation, as this is also the instrument that is most frequently implemented in business practice. At the end of term, the students are required to attend an examination for each compulsory course, which is based on the content of the lecture and its accompanying seminar.

The compulsory course 'Basic Information Management' provides an example of the problems typically arising from the accompanying seminar. Until winter term 2005/2006 these seminars were attended by groups of maximum 20 students in the department's PC pool (limited number of PC working places). In order to offer all students a place in a seminar we therefore had to carry out 22-24 seminars per term, for which we hired, instructed and paid 10-12 tutors. By winter term 2005/2006, the organisational workload and the financial expense of this had reached a scale that was no longer feasible for the department. An additional problem was that the students were attaining varying levels of knowledge by the end of term due to the sheer quantity of seminars and tutors. Ultimately, the course was characterized by all the well-known problems of large scale courses – problems with organisatisation, finance and quality. These problems exist in all the compulsory courses mentioned above to a similar extent and, as a result, the entire department and all its lecturers and students are affected.

2. PROJECT OBJECTIVE

In summer 2005, the Department of Economics and Business Adminstration launched a pilot project to solve this problem. In winter term 2005/2006 (October 2005 to February 2006) the accompanying seminars for the compulsory course 'Basic Information Management' were no longer carried out as a multitude of seminars with student presence, but were offered to approx. 500 student as web-based trainings (WBT) online for self-study. The SCORM-compatible WBT was available in the students` personalized website area at all times ('SPIC' – Students Personal Information Center; executed in the learning management platform 'WPS' – Schwickert 2004, WPS 2006). Each student can therefore see individually which WBT has been completed, when and how often it has been completed and the test results achieved.

The WBT was not intended as an introduction to the software products MS Excel and MS Access – we assumed that students already had a basic knowledge of the software. The WBT was primarily intended to teach students how the software products can be used to solve business problems.

The self-study per online WBT was accompanied by components requiring presence, so that the students were not left completely to their own resources. This included an introductory session at the beginning of term, a briefing session mid-term, an examination training session at the end of term (all in a big lecture theatre for all students) and an open weekly advisory service in the PC pool to deal with individual questions. This mix of e-components and presence components was intended to greatly simplify the organisation of courses, significantly reduce the funds required and standardize the knowledge transfer at the desired level for all students.

3. PROJECT IMPLEMENTATION

In June 2005, a project seminar was started at the Chair of Business Administration and Information Management. Project seminars are an integral part of the compulsory program for the depth subject Information Management in the Economics and Business Administration Course at Justus-Liebig University Giessen. A project seminar deals with a real IT problem. In a period of approx. 3-4 months a team of 3-4 students of the depth subject Information Management work practically towards finding a solution for the IT problem. This can, for example, be the planning and design of a software product, or it can also be a survey of a specific IT topic. In this case, the task of the team of 4 students was to create an integrated series of web-based trainings (WBT) for the seminar mentioned above.

In the period from June 2005 to the end of October 2005 the team created a total of 13 WBT using MS Excel and MS Access to solve business problems. During the 5-month project Prof. Schwickert and two of his research assistants were intensively involved, advising the team. First, a content concept for the entire WBT series was drawn up, based on the materials that had been tried and tested in the previous presence seminars. Then the materials were divided between the individual WBTs and structured into indvidual scripts for each WBT. From mid-August 2005, the individual WBTs were produced successively. The authoring tool EasyProf and the tools TurboDemo, Captivate and Photoshop were deployed.

Each WBT was initially produced as a protype and subsequently developed further in an evolutionary manner with 1-2 weekly reviews. The team was able to base the production of the WBTs on a methodic and didactic concept and a layout and design concept that had been developed in a research project at the Chair of Business Administration and Information Management from April to July 2006 (Schwickert et al. 2005).

In the first half of October 2005, all WBTs were subjected to final intensive quality control by three student test groups. In the last week of October 2005 all WBTs were made available to approx. 500 students online. The WBTs of this series can be used online at http://wi.uni-giessen.de/ gi/home/Schwickert/elearning/ online (WBT 2006).

4. RESULTS AND EXPERIENCES

The course was carried out as described in '2. Project Objective'. The frequent use of the WBT and very low use of the accompanying support – the online forum and the presence advisory service – were particularly striking. Also surprisingly, the examination results on the WBT contents were visibly better better than in the previous terms, during which the seminars had been held face-to-face in classrooms.

- E-Learning Component 1:
  The subject matter of the seminars accompanying the lectures was offered online to the students in a series of 13 consecutive WBTs (each with learning contents, practical exercises and tests) for self-study. From October 2005 to June 2006, we registered a total of approx. 16,700 WBTs completed by, suprisingly, approx. 800 different students.
- E-Learning Component 2:
  Throughout the lecture period, we offered a supervised online forum in which the students could discuss the seminar contents with eachother and the lecturer. This forum was only moderately used.
- Presence Component 1:
  At the beginning, during and towards the end of the lecture period we held three presence sessions ('briefings') in a lecture theatre, at which Prof. Schwickert was availabe to consolidate and explain certain contents. The initial session was attended by approx. 450 students, the middle session by 200 students, the final session by only approx. 100 students.
- Presence Component 2:
  Throughout the lecture period, we offered two 2-hour open advisory sessions per week in the PC pool. These advisory sessions were used by only approx. 20 students!
- Presence Component 3:
  The final examination which was based on the contents of the lectures and seminars was, as accustomed, a presence examination (half of the tasks on the lecture contents, half on the seminars) held at the end of the lecture period. The examination tasks on the contents covered by the WBT were more difficult than in previous terms, when the contents were taught face-to-face. Nevertheless the examination results on these contents were significantly improved.

From an organisational point of view, the entire course ran smoothly. While approx. 30-40 students (of approx. 500 participants) experienced some technical problems using the WBT online from their work stations at home during the first weeks of term, by mid-November 2005 we registered no more problems at all. The workload for supervising the online forum was marginal, the two 2-hour open advisory sessions in the PC pool could have been halved.

While it had cost approx. 9,000 euros per term in previous winter terms to employ tutors to carry out the presence seminars, the total direct costs in the 2005/2006 winter term amounted to 3,000 euros. This amount was necessary for the purchase of authoring tools and the employment of a student tutor to carry out the weekly presence advisory sessions.

Finally, the quality objectives were fulfilled. The significantly improved examination results with a higher requirement level speak for themselves. The widespread student acceptance for this type of teaching was reflected in the online evaluation of the course. In the approx. 200 completed questionnaires there was not one single negative evaluation of the seminar. Far from it – the quality and the 'learning aptitude' of the WBTs were consistently assessed very positively, as was the possibility to complete the WBTs where they wanted and when they wanted. Similarly, students appreciated the fact that the transfer of knowledge was not completely electronic, but accompanied by periodic briefings and an advisory service on site.

The quality of the teaching program is enhanced decisively by the blended learning concept, due to the fact that the course materials – their quantity, contents and external form – are presented to all the students uniformly. In conventional classroom seminars these characteristics depend heavily on the individual qualifications of the numerous tutors and the varying levels of previous knowledge of the seminar particpants. The project demonstrates that WBTs make it possible to boost the level of subject matter without making excessive demands on the students and guaranteeing individual supervision.

In the next two winter terms 2006/2007 and 2007/2008 the compulsory course 'Basic Information Management', which was tested in this pilot project, will continue to be offered in this same form with online WBTs. The costs for acquiring the authoring tools no longer apply, the WBTs can be used again without modifications, the presence advisory sessions will be halved. In the next winter terms the costs incurred for the seminar accompanying the compulsory course 'Basic Information Management' will amount to max. approx. 1,200 euros. In comparison to winter 2004/2005, when the exercises were last carried out as presence seminars, the costs will have been cut by approx. 85%.

5. ORGANISATIONAL FRAMEWORK AND PERSPECTIVE

A further result of the pilot project at the Chair for Business Adminsitration and Information Management was that a concept has been developed on the basis of which the other chairs in the department can integrate blending learning using the model described with WBTs. This includes an organisational process model, a didactic guideline on WBT authoring, ready-made WBT templates and suitable authoring tools.

Since May 2006, this concept has been applied to the compulsory course 'Introduction to Business Administration'. This course will be offered in winter term 06/07 (starting October 2006) for approx. 700 first year students. The lecture on 'Introduction to Business Adminstration' will be held as a presence course, as in the past. The subject matter covered in the complementary practical seminars will be offered in a series of successive WBTs online for self-study, supported by presence briefings, tutor advisory sessions and supervised online forums. In this case also, a team of students has worked under supervision on an integrated WBT series within the framework of an information management project seminar. The WBT series has been ready for use since September 2006.

In November 2006, a WBT project seminar, based on the concept from the pilot project, will be launched to support the large scale 'Costing' course. The same is scheduled for the basic education in mathematics and statistics, as well as for basic finance from January 2007.

Blended learning is therefore spreading rapidly and 'bottom up' within the department. The individual chairs in the department are ultimately convinced because the quality of studying and teaching in the Department of Economics and Business Administration benefit from the increase in student motivation to learn. Similarly, the quantitative benefit is driving the project forwards. Considerable financial economies, particulary as regards personnel costs, have been achieved. It's worth emphasising that no chairs have had to make specific investments for blending learning, other than the one-time purchase of authoring tools (approx. 1,000 euros) As demonstrated in the project, it can be achieved with the resources available: good students and good staff. A WBT series covering a complete seminar course can be developed and ready for operation without problem within 3-4 months.

By mid-2007 accompanying exercises will be offered for five of the nine compulsory courses mentioned in chapter one online per WBT, based on the concept resulting from the pilot project. In year 2007 alone, a reduction in costs of approx. 40,000 euros will be achieved and this, importantly, without reducing the quality of education.

The Consumer Ethics of the Virtual Environment: An Aetiology

Savvas Papagiannidis, Newcastle University, Armstrong Building, Newcastle upon Tyne, NE1 7RU, UK; E-mail: Savvas.Papagiannidis@ncl.ac.uk

INTRODUCTION

Free-form, massive multiplayer online games have resulted in the migration of many real world activities to virtual worlds and environments. These often exceed what is possible in the 'real' physical world, but in most cases are still just reflections of it. In this paper we will focus on the commercial applications that virtual worlds can host and more specifically on the potential ethical issues that arise when trading in virtual environments. We will present the case of *Second Life* and illustrate some of the key consumer-related ethical issues that arise from this virtual environment.

The next section examines important key attributes of the virtual environment of Second Life and illustrates its popularity and usage. This is followed by an analysis of consumer ethics within the game, whilst a separate section outlines a number of key recommendations. The last section concludes our analysis.

WHEN PLAYING IS LIVING

"Online games" mostly refer to games that are played over the Internet using PCs and game consoles. Such games are often based on existing stand-alone games that have been extended to support a small number of players or may even involve thousands of players simultaneously. Massively Multiplayer Online Role Playing Games (MMORPG) usually evolve around a theme that defines the goals of the game or encourage a free-form style of playing, leaving this up to the participants.

One of the most popular MMORPGs is Second Life, which according to its web site (www.secondlife.com) on the 1st of October 2006 had more than 800,000 users, 343,000 of whom had logged in the system within the previous 60 days, and had spent around $382,000 in the preceding 24 hours. The popularity of Second Life is not only due to the fact that participating is inexpensive, as creating a basic account is free (premium accounts cost around $72/year), but mainly due to the opportunity it provides the participants with to make anything they want out of the game. In Second Life users create the game, develop characters, objects and so on, and developers mainly manage the game and provide creative tools (Working Party on the Information Economy, 2005). To participate in Second Life a user needs only to download and install the required software. The user can then connect to the grid and customise the avatar, i.e. the virtual character that will be representing him or her in the virtual world, when exploring the grid, and interact with other users and the various in-world (i.e. within the virtual world) objects and buildings.

As the game has its own in-world currency that can be exchanged for real world currency, it is not surprising to find that many businesses in and out of Second Life have been established to cater for the in-world needs. Architects, fashion designers, automotive manufacturers, realtors and night club owners are a few among the growing number of entrepreneurs who provide their products and services in-world.

In a presentation in March 2006, Philip Rosedale and Cory Ondrejka (2006) of Linden Labs, the company developing and managing Second Life, provided an array of interesting statistics that illustrates the penetration and economic potential of the game:

- 25% of Second Life's users were from outside the USA, with the UK being the second-largest country of origin.
- The average age of users was 32, and the median age of users was 36.
- 43% of users were female, 50% were female 'by use'.
- There were $5 million USD in virtual transactions per month conducted between users.
- 180,000 distinct objects were sold in a 30-day period roughly spanning February, 2006.
- 75% of users were buyers, 25% were sellers. Among the sellers 'low hundreds' of them identified Second Life as their full-time job.

Perhaps more important than the above demographics about Second Life users is the reference of Ondrejka, the vice-president of product development at Linden Labs, to the '1% rule' (Arthur, 2006) that 60% of their users create their own content compared to less than 1% of readers of the online encyclopaedia, Wikipedia (Keegan, 2006). This suggests that more than half of the users can potentially assume a selling role in-world.

As no licence is required, establishing an in-world business is relatively straight forward. In fact, if the business does not require retail space (e.g. if one selects to become a bodyguard or dancer or a private detective) then one is already in business by simply connecting to the grid. On the other hand, if it does require space (e.g. if someone decides to become a casino operator or a vacation resort owner), one may need to first buy land in order to develop a property on it or alternatively rent space from someone else. Trading also takes place on the web and many in-world entrepreneurs and companies maintain web sites that promote and sell their products and services.

The next section will discuss the implications of in-world consumer behaviour focusing on the ethical-related issues arising, in other words focusing on the computer ethics emanating from the consumer presence in Second Life (for computer ethics see for example Spinello and Tavani, 2001).

CONSUMER BEHAVIOUR & ETHICS OF THE VIRTUAL ENVIRONMENT

Before addressing the consumer-related ethics within the virtual environment, it is appropriate to illustrate the key stages of the computer ethics revolution. In the 1940s and 1950s, the seminal work by Wiener (1950) provided the concrete foundations of computer ethics research and analysis, followed by further work in the 1960s and 1970s by Parker (1968) and by Weizenbaum (1976) and Maner (1980) respectively. The above researchers were pioneers in the evolving field and were located in the US. Nevertheless, by the 1990s, that field attracted large interest from other continents, especially from Europe. In terms of providing a definition of the computer ethics phenomenon, Bynum (2001, p.16) indicates its overarching and broad dimensions by noting that: "computer ethics identifies and analyses the impacts of information technology on social and human values like health, wealth, work, opportunity, freedom, democracy, knowledge, privacy, security, self-fulfilment, etc".

Moor (1985) also argued that the information technology (IT) revolution would be a two-stage process; the first one focusing on the technical development and use of IT whilst the second stage aiming to bring together the technical and social aspects by blending the IT systems and processes with the human and social interactions concerned. We could argue that Second Life is part of the second stage considering its strong human, social and consumer element, even though all these aspects are evolving at a very fast pace.

As far as the consumer element is concerned, which is the purpose of this section, the virtual environment that games like Second Life create and in particular the avatars, behind which one could hide, may change the perceptions and behaviour of consumers. For example, in real life one may not want to be seen in a specific setting (e.g. purchasing appealing lingerie at a retail store), but would not mind going to that retail store in the form of an avatar. Avatars may provide a stronger

sense of protection as they wrap a protective privacy layer around the real user. However, as the user is immersed in the game and spends more time developing a character and relationships and links with other ones, this may result in changes in the avatar's behaviour. One may not have to 'worry' about the implications of being seen by real people in an in-world shop, but this may also apply to an avatar seen in a retail store by other avatars. Hence, we are witnessing the emergence of two types of consumer behaviour (one real and one virtual) with distinctive ethical repercussions.

Similarly, Johnson (2001) notes the three key characteristics emanating from the Internet technology in relation to ethical concerns. The first one is scope, due to its global reach and interactive nature; secondly, the anonymity as was pointed out earlier and the reproducibility of information via that technology. Accordingly, in Second Life, one can earn money by undertaking various in-world activities. However the ability to exchange real money for in-world money suggests that those privileged in the real world can become privileged in the virtual world too. Supporting a virtual lifestyle could be equally as expensive as the real one. The user's spending power can determine to a great extent their decision making when it comes to spending. Still, as many real-world needs simply do not exist or at least could be 'avoided', users may decide to prioritise their needs based on different criteria (Foxall et al., 1998). These could be more influenced by the latest in-world trends, which may be completely different from the real-world ones. More interestingly, at the consumer level, there may exist two completely different sets of rules when it comes to spending decision-making, as a virtual character may represent a persona which is completely different from the real one.

In addition, in-world consumers are as open to manipulation as happens in the real world (see for example, Crisp, 1987), although one should emphasise two important points. The first is that although the social, educational and economic barriers to entering a virtual world are virtually non-existent, virtual worlds are often populated by well-defined types of users. What differentiates these users is not their real-world attributes and characteristics, but their in-world ones, which they can use to manipulate others. This is especially true in cases where more experienced users take advantage of 'newbies', i.e. inexperienced users. On the other hand, avatars are controlled at the end of the day by real people and how quickly experience is gained and how this is applied to protect oneself or manipulate someone else depends on the individual. Therefore, one could argue that avatars are equally prone to being manipulated.

It is worth mentioning that all users have to behave and act according to the defined sets of rules that owners and developers of the game, i.e. Linden Lab for Second Life in this case, have set. These are appropriate for the theme of each world and ensure not only that there is a framework within which avatars need to operate, but also that real world users are protected too. For example privacy and harassment issues are always taken very seriously. Enforcing these is a non-trivial task. In fact, in many cases it may not be possible actually to do so. Consequently great emphasis is put on peer monitoring, with users reporting behaviours that do not meet the set standards. The organisers are then called to investigate each case and decide whether there has been a violation and what action needs to be taken. In addition to the organiser's rules, other sets of rules adopted by the communities themselves may also apply. These could be simple etiquette rules or even terms and conditions which an avatar has to comply with, if access to a product or service or location is to be granted.

Another important issue when considering consumer ethics in a virtual world is to examine which code of 'ethics' actually applies. Is it the one that applies in the real world or is it a new code of ethics that arises from the very nature of the world in which the users operate? For example, the nature of the products and services traded can cause deviations from real-world ethical standards. The above raises the question whether any real life consumer segments are applicable in the virtual environment and whether some of those lose their importance. Are we dealing with a different set of consumer segments in the virtual world and overall, which are the key real-world attributes (lifestyle, age, gender, class, occupation, income, etc) that influence and contribute to the virtual world behaviour?

Finally, other themed MMORPGs may encourage 'unethical' behaviour according to real-world behaviour in order for the user to achieve the desired aim. Within some MMORPG worlds, killing or stealing may be actions that should be taken, as otherwise there will be little point in participating. An example with commercial focus would be that of the pyramid scheme in Eve Online, which allowed a user to net 700 billion ISK (game currency), which could be converted to more than $119,000 if sold on Ebay (Spamer, 2006). This example illustrates how manipulation is possible, even when it comes to well-known real-world exploitation schemes. Considered within the games boundaries one could argue that profiting from such a scheme would not have been unethical or illegal. On the other hand, the ability to convert in-world currency to real currency does raise questions about what indirect impacts on the real world such cases may have. Virtual worlds are not isolated artificial spaces anymore, but vibrant, highly-interactive and quickly evolving places that can reach the real world in numerous direct and indirect ways.

RECOMMENDATIONS

The previous section highlighted many ethical issues and raised a range of questions. There is an urgent need for the development of appropriate frameworks (although this in itself raises the issue of who decides what is 'appropriate' or not) that will guide the commercial development of MMORPGs and other interactive virtual environments, especially when in-world currencies could be converted to real world money. There are currently no specific policies or regulatory frameworks in relation to commercial activities in virtual environments, notwithstanding the fact that the virtual environment represents a very recent phenomenon.

Taking into account the global use of virtual environments, an important question is whether the introduction of a global advisory or event regulatory body could have a universal appeal and influence, or whether different countries, organisations or communities might introduce separate legislative codes. The former requires the development, introduction and conformance to the same set of standards of conduct and, at the same time, consideration of the country-specific similarities and differences such as consumers' income inequalities, the divide between information rich and information poor citizens and the existing country legislative procedures to name but a few. In light of this, Spinello (2000) considered some options for possible internet governance and provided three top-down models: first, direct government-state intervention, secondly, coordinated international intervention and thirdly, self-internet governance. Spinello (2000) illustrates the major costs and benefits of adopting each model. For example, the first model (direct government – state intervention) could be abused by consumers who look around for more relaxed country environments and, overall, it entails a strong enforcement difficulty. The second model (coordinated international intervention) could potentially address the shortcomings of the first model due to the global nature of virtual environments as it would be possible to transcend geographical boundaries, although at the same time, it could become cumbersome due to implementation and bureaucracy problems. The third model (self-internet governance) is the favourite choice for the US government, but nevertheless it has some key problems related to accountability and management of politics between the stakeholders involved.

Still, it could be the basis of the introduction of community advisory or regulatory bodies at a game-level, so that the unique attributes and characteristics of each game and community are taken into consideration. Their members could represent all major stakeholder groups and especially the gamers. Although initially this could be perceived by game developers as giving away significant control power it would help build trust and confidence in the game's platform, ensuring its longer term prosperity. Also, the opportunity for all stakeholders to take part in the decision making process would ensure that the development of the game is directly influenced by those that matter the most: i.e. the users. Allowing stakeholders to be actively involved could make them feel more valuable, which would further build the feeling of trust among the members of the community. For example, such bodies could act as a barrier for possible manipulation of consumers' privacy and guarantee the continuous protection of consumer interests, while for the firms involved an open democratic forum could help increase the credibility and legitimacy of trading. Such community bodies could then collectively interface with real-world bodies like consumer associations or policy makers.

Another issue to consider is whether all consumers / citizens were given the chance to participate in that environment and, therefore, try to maximise possible social inclusion. In light of this, we need to examine the financial implications and especially the cost of acquiring virtual objects and property and the resultant transactions between buyers and sellers. For example, who is going to monitor such transactions and who will authenticate and validate them? What about overcharging and possible avoidance of opportunistic behaviour, which is commonplace in the UK physical property market? Will any legal documents be issued, such as the virtual property equivalent of deeds? Questions such as these are often addressed by the terms and conditions of each game, which are drawn up by the

company developing the game. In many cases this could lead to controversy. For example in Second Life the terms and conditions state that Linden Lab has the absolute right to manage, regulate, control, modify and/or eliminate the in-world currency as it sees fit at its sole discretion, without any liability to the users. This highlights the implicit risks that a growing number of entrepreneurs take when trading in such emerging markets.

To address ethical consumer and business issues such as these we would suggest three overarching levels: firstly, the micro level, where we are encountering consumer-specific issues; secondly, the meso level, where we are encountering the firms and the resultant IT systems used; thirdly, the macro level, where we are dealing with governments, regulatory bodies and other stakeholders which will be responsible for setting the agenda for the ethical use of these systems by all participants involved. To maximise the effect of these upon issues of consumer ethics, ongoing discussion between participants of these three levels is needed. We suggest the immediate introduction of standards of conduct for both the users – consumers and firms involved. The participating firms will have to consider the corporate social responsibility dimensions and it is our suggestion that a corporate ethical responsibility matrix (and indices) could be further developed and refined based on an ongoing dialogue. In addition, a stakeholder analysis could also be co-employed, especially at the macro-level of the proposed framework, which could maximise an analysis of social responsibility matters by highlighting to firms their key ethical responsibilities. According to Spinello (2000), some of the key stakeholders to be included in that analysis are the individual users and households, consumer associations, firms, non-profit organisations, software and other IT vendors, internet service providers, regulatory agencies and organisations, interest groups, national and local governments and media.

This generates a number of interesting challenges for marketers who do not necessarily know to whom they are marketing and how the decision making process actually takes place. The key emerging question is who decides on what to spend when in a virtual world? Is it the avatar or the real user behind it and which one is mainly expressed? In Second Life, where there is no defined goal for the users to achieve, other than what they feel is of interest for them, the activities that take place are more often similar to the activities undertaken in real life. As a result, one would expect that the ethics sets would be comparable in most cases. This argument could be extended to consumer ethics as well, as most of the transactions undertaken are based on real transacting models and the in-world currency is linked to real world currency. Second Life itself has a defined set of Community Standards, but these are mostly behavioural guidelines rather than an attempt to provide a consumer or business behaviour framework.

In fact, it is questionable whether the developers of a world such as that of Second Life could and would actually try to enforce regulatory frameworks, as it was demonstrated in the CopyBot case. CopyBot started as an attempt to reverse engineer Second Life, but was then used to copy other users' content. This caused the community to protest against those using CopyBot and as a result Linden Labs had to proclaim the use of such software as a violation of their terms and conditions (Linden, 2006). Still, in the short term, without the tools to protect assets and monitor any copying they could only act on users' abuse reports. Not surprisingly this has serious implications for those in-world entrepreneurs that were trying to make a profit who felt threatened and many of them participated in an anti-CopyBot boycott (Neva, 2006). Many other users felt threatened too. As Wagner James Au (2006a) pointed out: "in a world where everyone by definition can, with a few clicks, become a content-creating entrepreneur, the debate has become egalitarian, pitting creator against creator, each with their own personal view of what constitutes theft and fair use, and the degree of faith they place in having their IP rights kept sacrosanct in Second Life". A few days later it seemed that the users' worst fears had not materialised (Au, 2006b), but nevertheless this example demonstrates the potential implications and challenges of adopting and enforcing regulatory frameworks.

The above indirectly challenges a fundamental aspect of MMORPGs, that of gaming. MMORPGs such as Second Life should not be seen just as games, but as highly complex communities. Only then does the real significance of the issues discussed above become clear and potential solutions could be sought. The degree of applicability of the recommendations made will depend on the nature of virtual worlds and more specifically on their various themes. The theme will probably dictate potential approaches to regulating the environment and equally importantly the degree of regulation that is needed.

CONCLUSIONS

During the past few years, we have witnessed the evolution and development of the phenomenon of massively multiplayer online role playing games and the vast majority of indications predict that its popularity will soar. The focus of this exploratory paper was on the consumer ethics that such environments may raise and their potential implications. We have also provided recommendations that can be taken up by policy makers, firms, consumer associations and other stakeholders.

We hope that the current paper has shed some light on the consumer-related ethical issues of virtual environments and other similar 'spaces' in general, in their present state, and highlighted their broad and overarching nature. Future research could consider an interdisciplinary research approach by bringing social scientists and natural scientists together, including consumer marketing researchers, psychologists, computer engineers and lawyers to name but a few. It could also consider both qualitative and quantitative approaches which could result in models to test the strength of relationships between the variables of interest.

Efficient P2P Knowledge Sharing: Performances and Incentives

Yung-Ming Li, Institute of Information Management, National Chiao-Tung University, Hsinchu, 300, Taiwan; E-mail: yml@mail.nctu.edu.tw

ABSTRACT

In this paper, we address the performance issue of Peer-to-Peer (P2P) knowledge sharing community based on two indices: the knowledge variety and the knowledge transfer. For each performance index, we examine Nash equilibrium and social equilibrium of knowledge contribution. While under-provision of knowledge contribution is a common phenomenon, the equilibrium results drawn from each criterion are significantly dissimilar. Results reveal the condition for the social optimality to sustain. Thus, in order to enhance the performance of knowledge sharing, incentive mechanisms are presented to realize an efficient knowledge sharing community.

Keywords: knowledge sharing, performance index, incentive mechanism, ash equilibrium, Social optimum.

1. INTRODUCTION

The concept of the knowledge sharing is becoming an emerging topic. Global operating firms especially capitalize this concept and take advantage of differences in labor costs, human capitals, and suitable production sites. For example, Toyota has opened up several subgroups of manufacturing sites in China and Southeast Asia to gain the labor advantage. Another example is that Microsoft has established numerous local headquarters in different countries to recruit the local human capitals and to convert their expertise into localized software product. Evidence has shown that organizations that are capable of transferring knowledge more effectively are more likely to sustain in the industry than those that have less capability of doing that (Argote, Beckman, and Epple, 1990).

Others view knowledge sharing or transfer should be incentive-aligned. Since the interest between the employees and employers does not always consistently work on the same direction, literatures has shown that incentive, the essence of motivation, plays a role in inducing employees to operate in the firm's interest. (Prendergast, 1999) The subtle question left to ponder will be how to carefully design a compensation contract, including options, discretionary bonuses, profit sharing, and efficient wages, and if the incentive needs to be immaterial only, material only, or rather a blended of both. (Semar, 2004) While material incentive are mostly in the form of direct monetary allowance, immaterial incentive is associated with working environment, contract extension, corporate resource assignment, etc.

Other than the incentive issue, knowledge sharing or knowledge transfer is the process, through which one group is affected by the experience of another (Argote, 1999). Intra-units are learning and benefiting from each other in order to speed up the production process or lower down the unnecessary labor costs. Transferring knowledge, whether at the individual, group, department, or division level is a usually laborious and time-consuming, and difficult task. Obviously, such transference needs a channel. Tsai (2001) claims the fact that prior to achieving access to a new knowledge, it needs to require a networking effect. With a great design of unit network, such channel will be a way to stimulate and support innovative activities. Moreover, in Swart and Kinni's work (2003), they suggest that for the success of the organization, knowledge be integrated between different units and be shared throughout. The rational is that the critical knowledge and skills may become localized within the project team as time passes (Wegner, 2000; Yanow, 1999).

The above studies have addressed the importance of knowledge sharing and incentive. Building the suitable environment and setting up the incentive will function to promote knowledge sharing or motivate staffs. In this paper, we focus on establishment of the knowledge sharing indices on a Peer-to-Peer (P2P) environment: knowledge variety and knowledge transfer. The proposed performance metrics are critically important and easily justified. Participants will benefit from the knowledge variety provided in the community. On the other hand, participants also benefit from more replicas of the same knowledge in a decentralized sharing environment because it is more likely a participant can get the knowledge from a closed participant. Consequently, the performance cost of knowledge can be improved. Through these indices, we may understand how parameters, two that will be proposed and each of which has its own appropriate quality, affect the sharing performance. We further introduce the concept of Nash equilibrium. Nash (1950) showed that in any finite game (i.e., a game in which the number of players n and the strategy sets $S_1, S_2, S_3, ..., S_n$ are all finite) there exists at least one Nash equilibrium. Note that Nash equilibrium is often generalized as a non-cooperative outcome. We make use of this concept, combine with another concept—the social optimum, generalized as a cooperative outcome, simply representing the summation of all individuals' payoffs, and incorporate the issue of incentive into the framework, which helps maintain the social optimum. Incentive, furthermore, can be analyzed in the context of public good provision. There are a few discussions regarding public goods, including Samuelson (1954), Olson (1965), Smith (1980), Cornes and Sandler (1984, 1985), and Andreoni (1985). Of these researchers, Samuelson and Olson are the classics references on the public good theory and the related topics in group size. Smith conducted his experiment to determine if the public good are subject to "free ride" in a voluntarily sharing environment. Cornes and Sandler, and Andreoni claimed that a consumer's utility depends not only on the aggregate amount of contribution, but also on his own contribution.

The idea that emerges in our study is the assignment of incentive. We attempt to establish the condition for the incentive that will mitigate "free ride" phenomenon and further make the social optimum sustainable. Our results show that knowledge contributions are quite different based on the knowledge variety and knowledge transfer performance criteria.

The remainder of this paper is organized as follows. In section 2, we discuss the knowledge indices. In section 3, we analyze the performance and incentive mechanism based on knowledge availability. In section 4, we re-examine the performance and incentive mechanism based on knowledge transfer. We provide a discussion in Section 4 and present the conclusion in Section 5.

2. PERFORMANCE INDEX OF KNOWLEDGE SHARING

When we evaluate a salesperson working performance, we often check on the number of orders he can get for the company. If the number of orders is massive, he may be evaluated as a great salesperson with an outstanding performance. Similarly, the knowledge sharing performance can be evaluated based on the knowledge varieties and the needed time for participants in the knowledge sharing community to retrieve certain knowledge. An efficient community may enlarge the knowledge pool and shorten the time for information retrieval. Suppose a knowledge worker has a need to retrieve a knowledge that is related to his work. If she acquires the relevant information in a short period of time and is satisfied with it, we say the knowledge sharing community has a distinguished performance in directing her to the correct knowledge. The knowledge sharing community has a bad performance, otherwise. Thus, we propose two simple but

important factors that will affect the efficiency of knowledge sharing. They are the knowledge availability and the knowledge transfer. One the one hand, knowledge availability index reflects the possibility degree an (ad-hoc) requested knowledge can be found through the community, alternatively, we can interpret the index as the maximum number of knowledge varieties participants can retrieve from the community. On the other hand, knowledge transfer index represents the expected effort (e.g. delay time) for completing a knowledge transfer of certain type of knowledge request. The transfer effort can be indirectly measured according to the expected replicas of a homogeneous knowledge provided in the community since the performance can be improved by selecting a better partner to conduct the knowledge transfer activity. We conduct the analysis under self-enforced and efficient knowledge sharing configurations according to these two performance considerations and suggest the incentive mechanisms for aligning the objective of individual participant and the organization.

3. KNOWLEDGE AVAILABILITY (VARIETY)

Before we make knowledge communicated in the community, it is important to understand that the formation of knowledge involves difficulties and the nature of knowledge is structural. There are various attempts to describe "knowledge" as the term "structure." Rauch-Hindin (1988) firstly noted the presence of structure in knowledge. Then Gaines, Rappaport, and Shaw (1992) further defined four types of knowledge structure: informal, structured, formal, and computational knowledge. When the information becomes knowledge and pooled into the community, we are concerned with the sharing performance. In this section, we propose that the knowledge variety is the factor that will affect the performance for knowledge sharing in the community. We will make the following assumptions. At first, we assume that the participant will receive the value of v_i from process of the successful sharing of certain knowledge. She will, of course, incur the cost of c_i if she shares certain knowledge. Secondly, more knowledge variety is better for the knowledge sharing environment. More varieties mean that the difficulty level for requesting a random type of knowledge will be reduced and it becomes easier for any participant to gain that random type of knowledge in the community. Then, let M_0 denote the number of elements in the knowledge domain and i be the participant who provides a random type of knowledge. If each knowledge variety has the same popularity, then we assume x_i is the probability that participant i shares an arbitrary file. We further assume $0 \le c_i / v_i \le 1$, which is the cos-benefit ratio of knowledge sharing. Since no one is willing to pay more than what she receives, thus, the ratio of c_i / v_i, which does not exceed one, makes intuitively sense. In the context of reliability, we denote $H = 1 - \prod_{i=1}^{n}(1 - x_i)$ as a probability that the knowledge sharing process is successful in the community. Multiplied by the maximum number of knowledge elements M_0, this gives the expected number of knowledge varieties, M, the following expression

$$M(x_1, x_2, \cdots, x_n) = HM_0 = \left(1 - \prod_{i=1}^{n}(1 - x_i)\right)M_0 .$$

Furthermore, the expected payoff to agent i is taken to be

$$U_i = v_i M - c_i x_i M_0 = v_i \left(1 - \prod_{i=1}^{n}(1 - x_i)\right)M_0 - c_i x_i M_0 \qquad (1)$$

3.1. Nash Equilibrium (Self-Enforced Community)

In this section, we examine the outcome where single participant chooses effort unilaterally.

Equation (1) can be rewritten as

$$U_i = v_i \left(1 - \prod_{i=1}^{n}(1 - x_i)\right)M_0 + \left(v_i \prod_{j \ne i}^{n}(1 - x_j^*) - c_i\right)x_i M_0 .$$

The above equation represents a non-cooperative utility function. The individual objective is to maximize this utility function subject to the following best response knowledge sharing function given to the participant i, which is

$$x_i^* \begin{cases} = 1 & if \ \prod_{j \ne i}^{n}(1 - x_j^*) > c_i / v_i \\ \in [0,1] & if \ \prod_{j \ne i}^{n}(1 - x_j^*) = c_i / v_i \\ = 0 & if \ \prod_{j \ne i}^{n}(1 - x_j^*) < c_i / v_i \end{cases}$$

See Fig 1 below for how participant i respond according to other participants' move.

Whether the participant i's best response is to share or not share depends solely on where $\prod_{j \ne i}^{n}(1 - x_j^*)$ lies. Given $\prod_{j \ne i}^{n}(1 - x_j^*)$ lies above $\frac{c_i}{v_i}$, the participant i must share in order to make the sharing community successful. In contrast, given $\prod_{j \ne i}^{n}(1 - x_j^*)$ lies below $\frac{c_i}{v_i}$, the participant i may choose not to share. The necessary condition for a knowledge sharing community to emerge is $0 < H < 1$. If the participant i contributes, we have $0 < x_i < 1$; that is, the equilibrium knowledge sharing level of each participant can be drawn by solving the following equations simultaneously.

$$\prod_{j \ne i}^{n}(1 - x_j) = c_i / v_i, \ \forall i \in \{1, \cdots, n\}$$

After some mathematic simplifications, we obtain the knowledge availability equilibrium

$$H^{N^*} = 1 - \left(\prod_{i=1}^{n} \frac{c_i}{v_i}\right)^{1/(n-1)} \qquad (2)$$

and the knowledge sharing level of participant is

$$x_i^{N^*} = 1 - \frac{v_i}{c_i}\left(\prod_{i=1}^{n} \frac{c_i}{v_i}\right)^{1/(n-1)} \qquad (3)$$

Under Nash equilibrium, Equation (2) is the optimum probability that the knowledge sharing community will work. In other words, it indicates the optimum probability that a participant gives a random type of knowledge, needed by the members in the knowledge sharing community. Equation (3) is the optimum probability that an arbitrary given file is shared by a participant. In practice, this probability needs to exhibit an upward trend as the number of participants who possess a random type of knowledge increases. The number of knowledge varieties in equilibrium is $M^{N^*} = \left(1 - \left(\prod_{i=1}^{n} \frac{c_i}{v_i}\right)^{1/(n-1)}\right)M_0$. We will compare this probability with the probability under the social optimum level.

3.2. Social Optimum (Efficient Community)

We perform similar calculations in this section so as to derive the socially optimal content availability H^{W^*} in the community and individual knowledge sharing level $x_i^{W^*}$. The difference between the social optimum and Nash equilibrium is that while Nash equilibrium focuses on the unilateral optimization, the social optimum dwells its focus on the coordinated effort. Precisely, Equation (1) needs to be adjusted so as to maximize social benefits subtracted by social costs.

$$U_w = \sum_{i=1}^{n} U_i = \Sigma_{i=1}^{n} v_i \left(1 - \Pi_{i=1}^{n}(1 - x_i)\right)M_0 - \Sigma_{i=1}^{n} c_i x_i M_0 \qquad (4)$$

Similarly, the socially optimal individual knowledge sharing level is given by solving the following equations simultaneously.

$$\Pi_{j \ne i}^{n}(1 - x_j^*) = \frac{c_i}{\Sigma_{i=1}^{n} v_i}, \ \forall i \in \{1, \cdots, n\} \qquad (5)$$

Finally, the optimality functions for both H^{W^*} and $x_i^{W^*}$ are as follows:

$$H^{W^*} = 1 - \left(\prod_{i=1}^{n} \frac{c_i}{\Sigma_{i=1}^{n} v_i} \right)^{1/(n-1)} \quad (6)$$

$$x_i^{W^*} = 1 - \frac{\Sigma_{i=1}^{n} v_i}{c_i} \left(\prod_{i=1}^{n} \frac{c_i}{\Sigma_{i=1}^{n} v_i} \right)^{1/(n-1)} \quad (7)$$

Socially optimal number of knowledge varieties is

$$M^{W^*} = \left(1 - \left(\prod_{i=1}^{n} \frac{c_i}{\Sigma_{i=1}^{n} v_i} \right)^{1/(n-1)} \right) M_0 .$$

Investigating these two functions, we realize that $x_i^{W^*} \geq x_i^{N^*}$ and $M^{W^*} \geq M^{N^*}$. We turn to the related interpretation of public good. In a centralized environment developed in our model, $x_i^{W^*} \geq x_i^{N^*}$ reflects the fact that pure public goods would be undersupplied by voluntary contributions and that there exists an incentive for a participant to free ride since no one can be excluded from the benefits of public good. By definition, free-ride means that contributing less than his marginal valuation to the cost of the public good.

In an extreme case, when $x_i^{N^*} \cong 0$, non-provision of public goods becomes a consequence of the strong free riders phenomena.(Brubaker, 1975) However, any level below $x_i^{N^*}$ suggests the sub-optimal quantities of public goods.

3.3. Socially Optimal Compensation

Inconsistent interest between personal level and social level contributes to the difference in effort level. Under Nash condition, the participant *i* cares about personal interest only and maximizes it, whereas in the social optimum situation, the sharing effort is underprovided. However, a proper amount of compensation makes the participant *i* not play Nash and still exert the sharing effort even in the social situation.

For simplicity, the sharing community is divided into two categories: one group consisting of only one participant, *i*, the other group consisting of all other participants. (e.g. $\sum_{j \neq i}^{n} paticiapnt\ j$) The proposed incentive framework is a treatment for the participant *i* only and does not have any power to predict the amount of incentive requested by any other participants in the other category. Two assumptions are subtle. At first, the incentive will make participant who receives it share. Secondly, it is a possibility that other participants who do not receive any compensation may free ride. The following is the proposed framework.

Proposition 1: *The social level of effort can be induced and be optimally sustainable when the incentive compensation, r_i, equals $\frac{c_i \Sigma_{j \neq i}^{n} v_j}{\Sigma_{j=1}^{n} v_j}$ for the participant i.*

Proof. At first, let U', denoted as the compensation function, entails an incentive term, $r_i x_i M_0$. This function and Equation (1) are very much the same with exception of $r_i x_i M_0$. Our objective is to derive the value of this incentive.

$$U' = v_i \cdot \left(1 - \prod_{i=1}^{n} (1 - x_i)\right) M_0 - c_i x_i M_0 + r_i x_i M_0 \quad (8)$$

The best response knowledge sharing function of participant *i* is given by the following expression:

$$\left(v_i \prod_{j \neq i}^{n} \left(1 - x_j^*\right) - c_i \right) + r_i = 0 \quad (9)$$

Equation (5) can be rewritten as

$$\left(v_i \prod_{j \neq i}^{n} \left(1 - x_j^*\right) - c_i \right) + \Sigma_{j \neq i}^{n} v_j \prod_{j \neq i}^{n} \left(1 - x_j^*\right) = 0 \quad (10)$$

Investigating Equation (9) and Equation (10), we understand that

$$r_i = \Sigma_{j \neq i}^{n} v_j \prod_{j \neq i}^{n} \left(1 - x_j^*\right).$$

Substituting $\prod_{j \neq i}^{n} \left(1 - x_j^*\right) = \frac{c_i}{\Sigma_{i=1}^{n} v_i}$ into r_i, r_i becomes the following expression:

$$r_i^{W^*} = \Sigma_{i=1}^{n} v_i \prod_{j \neq i}^{n} \left(1 - x_j^{W^*}\right) = \frac{c_i \Sigma_{j \neq i}^{n} v_j}{\Sigma_{i=1}^{n} v_i} \quad \square \quad (11)$$

Equation (11) indicates a unique value of the incentive, which is a minimally required compensation for the participant *i* in the knowledge sharing community. Moreover, Equation (11) suggests a redistribution of wealth. Varian (1986) studies this topic and stated that any change in the wealth distribution that increases the aggregate wealth of current contributors will necessarily increase the equilibrium supply of the public good. This viewpoint corresponds to our result. The amount of incentive implies an increase in supply of public good. If this amount of incentive is in its optimal condition, then it is immediate that the supply of public good is also in its optimality.

4. KNOWLEDGE TRANSFER (REPLICA)

In previous section, we have examined the knowledge sharing community configurations based on knowledge variety. We further introduce another performance index, the knowledge transfer. The performance of knowledge transfer is closely associated with the number of replicas of a given knowledge in the community. Different from the knowledge variety, the knowledge replica is defined as coexistence of homogeneous knowledge. In the knowledge sharing community, we need some identical knowledge to exist because this helps participants more easily gain certain type of knowledge from a "closer" community member. Since x_i is the probability that the participant *i* shares certain knowledge, we denote the expected number of replicas of a type of knowledge in the community as $R(x_1, x_2, \cdots, x_n) = \sum_{i=1}^{n} x_i$. We further assume that the transfer effort (e.g. delay) between any two participants is a random variable with value drawn from a transmission delay density function. Participants always retrieve knowledge from a community member with a minimum transfer effort. Denote the expected minimum transfer effort among *k* community members by $T(k)$. Using order statistics, we have:

$$T(k) = \int_0^{\infty} t \cdot k \cdot (1 - F(t))^{k-1} \cdot f(t) \cdot dt ,$$

where *f*(*t*) and *F*(*t*) are the PDF and CDF for the transfer effort. In this paper, we analyze the community configuration based on uniform distribution $U[0, T_0]$, where T_0 is the upper bound of transfer effort. Thus, given individual knowledge sharing level $(x_1, x_2, \cdots, x_n)$, the expected transfer effort is:

$T(R) = \left(\sum_{i=1}^{n} x_i + 1\right)^{-1} T_0$.

Lastly, we denote the value of a transfers knowledge as v_i , and assume the cost of transfer effort (e.g. delay cost) and sharing cost for a knowledge are β_i and c_i respectively. The utility function is defined as follows:

$$U_i = v_i - \beta_i T(R) - c_i x_i = v_i - \beta_i \left(\sum_{i=1}^{n} x_i + 1\right)^{-1} T_0 - c_i x_i \quad (12)$$

4.1. Nash Equilibrium (Self-Enforced Community)

Following similar approach, individual's self-selected knowledge sharing level can be obtained by solving the first-order conditions simultaneously:

$$\frac{\partial U_i}{\partial x_i} = \beta_i T_0 \left(x_i + \sum_{j \neq i}^{n} x_{j \neq i}^{\ *} + 1 \right)^{-2} - c_i \leq 0, \forall i$$

The best response knowledge sharing function for participant *i* is

$$x_i^{N^*} = \max \left\{ \sqrt{\frac{\beta_i T_0}{c_i}} - \left(\sum_{j \neq i}^{n} x_{j \neq i}^{\ *} + 1 \right), 0 \right\} \quad (13)$$

Thus, the expected number of knowledge replicas of a type of knowledge is

$$R^{N^*}(x_1, x_2, \cdots, x_n) = \sum_{i=1}^{n} x_i^{N^*} = \max_i \{\sqrt{\frac{\beta_i T_0}{c_i}} - 1\} \quad (14)$$

We can easily find that the self-selected knowledge sharing level is

$$x_i^{N^*} = \begin{cases} \sqrt{\frac{\beta_i T_0}{c_i}} - 1 & \text{if } i = \arg\max_j \{\beta_j / c_j\} \\ 0 & \text{otherwise} \end{cases}$$

For a self-formed knowledge sharing community, only the participant with the maximum ratio of transfer effort cost (e.g. time value) to sharing cost contributes knowledge.

4.2. Social Optimum (Efficient Community)

We are concerned with the social optimum so we sum up the utility from all participants and get the following expression:

$$W = \sum_{i=1}^{n} U_i = \sum_{i=1}^{n} \left(v_i - \beta_i \left(\sum_{i=1}^{n} x_i + 1 \right)^{-1} T_0 - c_i \cdot x_i \right) \quad (15)$$

With first-order condition:

$$\frac{\partial W}{\partial x_i} = \Sigma_{i=1}^{n} \beta_i T_0 \left(\sum_{i=1}^{n} x_i + 1 \right)^{-2} \le c_i, \forall i \quad (16)$$

Socially optimal expected number of replicas of a type of knowledge is:

$$R^{W^*}(x_1, x_2, \cdots, x_n) = \sum_{i=1}^{n} x_i^{W^*} = \max_i \{\sqrt{\frac{\Sigma_{i=1}^{n} \beta_i T_0}{c_i}} - 1\} \quad (17)$$

Finally, the socially optimal individual knowledge sharing level is derived:

$$x_i^{W^*} = \begin{cases} \sqrt{\frac{\Sigma_{i=1}^{n} \beta_i T_0}{c_i}} - 1 & \text{if } i = \arg\min_j \{c_j\} \\ 0 & \text{otherwise} \end{cases}$$

For an efficient knowledge sharing community, only the participant with the minimum sharing cost is required to contribute knowledge.

Investigating Equations (14) and (17), we realize that $R^{W^*} \ge R^{N^*}$. This finding suggests that more knowledge replicas increase the knowledge density in the sharing community and shorten the transferring distance among participants. For such shortened distance, the transfer of the knowledge may become easier.

4.3. Socially Optimal Compensation

In this section, we return to consider the optimal incentive to induce the sharing effort in social level for the participant *i*. See the following framework.

Proposition 2: *The social level of effort for the participant i who have the minimum sharing cost can be induced and be optimally sustainable when the incentive compensation,* r_i, *equals* $\Sigma_{j \ne i}^{n} \beta_j T_0 \left(\sqrt{\frac{\Sigma_{i=1}^{n} \beta_i T_0}{\min_i \{c_i\}}} \right)^{-2}$.

Proof. Similar to the proof in **Proposition 1**, we, at first, impose an incentive term r_i on Equation (12). Thus, it becomes

$$U_i' = v_i - \beta_i \left(\sum_{i=1}^{n} x_i + 1 \right)^{-1} T_0 - c_i x_i + r_i x_i \quad (18)$$

The first-order condition for Equation (18) is

$$\frac{\partial U_i'}{\partial x_i} = \beta_i T_0 \left(x_i + \sum_{j \ne i}^{n} x_j^* + 1 \right)^{-2} - c_i + r_i = 0 \quad (19)$$

Secondly, we rewrite Equation (16)

$$\left(\beta_i T_0 \left(\sum_{i=1}^{n} x_i^* + 1 \right)^{-2} - c_i \right) + \Sigma_{j \ne i}^{n} \beta_j T_0 \left(\sum_{i=1}^{n} x_i^* + 1 \right)^{-2} = 0 \quad (20)$$

Investigating Equation (19) and Equation (20), we understand that

$$r_i^{W^*} = \Sigma_{j \ne i}^{n} \beta_j T_0 \left(\sum_{i=1}^{n} x_i^* + 1 \right)^{-2} = \Sigma_{j \ne i}^{n} \beta_j T_0 \left(\sqrt{\frac{\Sigma_{i=1}^{n} \beta_i T_0}{\min_i \{c_i\}}} \right)^{-2} \quad \square,$$

which is exactly the incentive condition under which the participant *i* needs to be compensated to exert the social optimal level of effort. For our purposes, the incentive mechanisms in this section and in Section 3.3 affect the participant *i*only and do not apply to any other knowledge contributors. This mechanism also reveals a compensating relationship between the participant *i* and the operator in the sharing community. We see that the community in general could benefit by the participant *i*'s contribution. The participant *i* receives the compensation $r_i^{W^*}$ in exchange.

4. DISCUSSION

There is more to the issue of incentive than just the Nash and social optimum configurations. Consider the following prisoner's dilemma. In Prisoner's dilemma, each player has two strategies: confess (or fink) and not confess (or be mum). Playing Fink is the dominated strategy for both players, then (Fink, Fink) is the unique solution to this game, a so-called Nash equilibrium. Let's classify it as a non-cooperative outcome and compare it with another outcome (Mum, Mum), classified as a cooperative outcome. Even though the cooperative outcome allows both parties to gain the most benefits, it is relatively unstable because either player has an incentive to deviate against each other to gain the free charge. Thus, the non-cooperative outcome of (Fink, Fink) will be an equilibrium, at which no one has an incentive to deviate.

Our model is really an extension and application of the prisoner's dilemma. Owing to the insight derived from the prisoner's dilemma, there is no cooperation in its one-period design. Cooperation cannot be maintained in the one-period game because there are no future periods to impose punishment on the behavior which deviates from a cooperative solution. (Pecorino, 1999) Thus, to quantitatively determine the amount of incentive in our model is indeed an initiative. This amount of incentive will guarantee that for a particular participant in the knowledge sharing community, he will achieve the cooperative outcome and maintain the cooperation as equilibrium.

Nevertheless, our model is still a one-period game and cannot be generalized to predict the equilibrium in the context of infinitely repeated game. Other than the assignment of incentive, what conditions will make the game that is played infinite times sustainable? Or, stated differently, what conditions will affect participants' sharing decision? What is the setting of this super game? And, how will all other participants, not just a particular participant, be facilitated to achieve the cooperative outcome? Those questions remain the core focus in the next research stage and will help to devise a cooperative mechanism.

5. CONCLUSION

This paper allows us to draw the conclusion in two ways. At first, we obtained the relationship between the knowledge sharing performance and factors that might affect the performance. Interestingly, as the numbers of varieties and replicas go

upward, there is a positive effect in the knowledge sharing. Thus, in order for knowledge sharing to be successful, the amount of knowledge has to be both extensive and intensive. Secondly, we proved that a proper incentive assignment may enhance the knowledge sharing. This may be seen as a social optimum condition if it needs to be achieved.

We must emphasize that it remains possible, of course, that there are other undefined factors other than knowledge variety and knowledge replica that may affect the sharing behavior. Thus, the methodological design in this paper limits the interpretations. Future research is needed on the implications for knowledge sharing in organizations. For example, suppose new member who want to search for some specific knowledge, how may the searching time vary under variety-intensive condition? In addition, categorization of knowledge according to its properties may become another factor to affect the knowledge sharing performance. The rationale is that item that is always properly stored means that it will be found easily.

ABSTRACT

The objectives of the study are to identify relevant key intention determinants to Wikis use and to better understand the knowledge creation processes through an investigation of the individual planning and writing patterns. Surprisingly, perceived usefulness (technology utility) was found not significant to intention to use; while image became the strongest determinant to behavioral intention to use. Individual factors such as computer self-efficacy, personal innovativeness with technology were both significant determinants. Open-end survey items collected significant details from individual student journalists about their knowledge creation processes. Implications to Wikis implementation and limitations of the study are discussed.

1. INTRODUCTION

A Wiki is a website that can be edited by anyone. The very successful case Wikipedia, the free encyclopedia, has 13,000 active contributors, working on over 3,800,000 articles in more than 100 languages (Wikipedia, 2006). With the Wikis technology, companies push for corporate collaboration (e.g., Fontana, 2006) and enterprise operation (e.g., Gibbs 2006); while education institutions employ to enhance teaching and learning processes (e.g., Naish, 2006; Raman et al. 2005).

However, Wikis system will not work if no one uses it. This is especially true as Wikis typically is a collaborative tool that requires users to create and enrich the content. "Researching the background of Wikis use indicates that like all new ways to improve on existing services introducing Wikis requires a carefully managed rollout and some real effort," (Gibbs, 2006). It is therefore important to study the Wikis phenomenon to better understand the process in order to provide better guidance to implementation strategies.

Therefore, the objectives of the study are to: (1) to identify relevant key motivators to Wikis system use; and (2) to better understand the knowledge creation processes through posting using Wikis.

The paper is organized as follows. The next section matches motivational variables from prior literature and an analysis of the Wikis phenomenon. Hypotheses are developed to explain effects of the variables toward the intention to use of Wikis systems. Then, research methodology is explained with details in subjects, data collection and data analysis methods. Results of data analysis and model testing are reported. This is followed by a post hoc analysis of the process of use patterns. Implications, limitations and conclusions are discussed at the end.

2. LITERATURE REVIEW

Wiki is described as one of the most promising and rapidly emerging innovations in knowledge management (Gordon 2006). Basically, a Wikis "is a type of website that allows users to add, remove, or otherwise edit and change all content very quickly and easily, sometimes without the need for registration," (Wikipedia, 2006). Wikis is an information resource centralized online database nature and a powerful collaboration tool because of its open editing characteristics (Naish, 2006). While good e-learning is about informing, collaborating and meeting online, Wikis do all these things well (Naish, 2006).

User technology acceptance has been studied considerably in prior IS research (e.g., Legris, Ingham & Collerette 2003; Venkatesh, Morris, Davis & Davis 2003). A survey of prior studies identifies several perspectives on key intention determinants to technology acceptance, including technology utility perspective, social perspective and individual perspective.

Technology Utility Perspective: Perceived usefulness, which refers to the degree to which a person believes that using a particular system would enhance his or her job performance (Davis 1989, p.320), was found to be a key determinants to acceptance, across a variety of technologies, including standard office tools (e.g., Hu, Clark & Ma, 2003); email (e.g., Kettinger & Grover 1997); computer-based training system and rapid application development software (e.g., Bhattacherjee & Premkumar 2004), and mobile multimedia services (e.g., Pagani 2004).

Social Perspective: Wikis provide a transparent platform for users' interaction and information exchange that increase the socialization process, enabling collaboration to generate fast final output (Gordon 2006, ibid). Prior studies found that social determinants, including social influence, social presence and image, affected behavioral intention to technologies. Social influence, defined as the degree to which an individual perceives that important others believe he or she should use a system (Venkatesh et al. 2003, ibid), is a direct determinant of behavioral intention to technology (e.g., Venkatesh et al., ibid), however, it is also found that significant direct effect only appeared in mandatory organizational settings (e.g., Venkatesh & Davis, 2000). Social presence is the degree to which people establish warm and personal connections with each other in a communication setting (Short, William & Christis 1976). On the one hand, social presence / perceived information richness is based on a medium's ability to provide feedback, offer numerous cues, be personalized, and rapidly synthesize complex information (Daft & Lengel, 1986) and empirical studies found that higher perception of system's social presence and feedback results in greater use of the system (Kettinger & Grover, 1997, ibid). However, from the collaborative perspective, reduction in social presence cause users to be more ready to give up their positions in favor of the collective position in the communication setting, hence, cause users to be more uninhibited during discussion (Jessup, Connolly & Galegher, 1990) and cause users to generate more novel arguments and engage in more one-upmanship behavior (Sia, Tan & Wei, 2002). Image is defined as the degree to which use of a system is perceived to enhance one's image or status in one's social system (Moore & Benbasat, 1991) and this the perceived image / status enhancement variable is found to be a significant determinant to attitude towards a system (e.g., Karahanna, Straub & Chervany, 1999); and a significant determinant to perceived usefulness towards a system (e.g., Venkatesh & Davis, 2000, ibid). Identification refers to one's conception of self in terms of the defining features of a self-inclusive category (of the system, in particular, the Wikis online community) that renders the self stereotypically "interchangeable" with other group members, and stereotypically distinct from outsiders (Hogg, 1992). Identification resembles aspects of normative and informational influence (Deutsch & Gerard, 1955), as well as referent power (French & Raven, 1959), and is characterized by the community member's social identity. However, prior studies found that social identity has only indirect significant effect through desire towards intention (Dholakia 2004) but has no significant direct effect on behavioral intention to virtual communities (Bagozzi & Dholakia 2002).

Individual Perspective: Computer self-efficacy reflects an individual's beliefs about his or her capabilities to use computers (Compeau, Higgins & Huff, 1999, p.147) and was found to be a determinant to system acceptance (Compeau et al., 1999, ibid) and a significant anchor to perceived ease of use (Venkatesh 2000). Personal innovativeness with technology represents the degree to which an individual is willing to try out any new information technology (Agarwal & Prasad, 1998). Personal innovativeness with technology influences system usage via their effects on perceived usefulness and perceived ease of use beliefs (Lewis, Agawal & Sambamurthy, 2003) and had significant correlation with usage intention (Agarwal & Prasad, 1998, ibid).

Table 1. Summary of research variables and the corresponding hypotheses

Research Variables	Hypotheses	Source
Perceived Usefulness	H1*: Individual users' perception on the usefulness of Wikis would influence behavioral intention to the use of Wikis.*	Davis (1989)
Social Influence	H2*: Social influence is a direct determinant of behavioral intention to use Wikis.* H3*: Social influence has a positive direct effect on perceived usefulness of an individual user towards Wikis.*	Venkatesh & Davis (2000)
Social Presence	H4*: Social presence is a direct determinant of behavioral intention to use Wikis.* H5*: Social presence has a positive direct effect on perceived usefulness of an individual user towards Wikis.*	Kettinger & Grove (1997)
Image	H6*: Image is a direct determinant of behavioral intention to use Wikis.*	Karahanna et al. (1999); Moore & Benbasat (1991)
Social Identity	H7*: Social identity is a direct determinant of behavioral intention to use Wikis.*	Bagozzi & Dholakia (2002); Dholakia et al. (2004)
Personal Innovativeness with Technology	H8*: Personal innovativeness with technology is a direct determinant of behavioral intention to use Wikis.*	Lewis et al. (2003); Agarwal & Prasad (1997)
Computer Self-efficacy	H9*: Computer self-efficacy is a direct determinant of behavioral intention to use Wikis.*	Compeau et al. (1999)

3. MOTIVATION & HYPOTHESES DEVELOPMENT

This study aims at exploring the key intention determinants of collaborative writing platform Wikis in order to shed light on better strategies to the successful implementation of Wikis. Table 1 summarizes the constructs and the corresponding hypotheses.

4. METHODOLOGY

4.1. Background

Since February 2006, a Student-Written Wiki (named, HKNews) has been setup for the Department of Journalism & Communication at a private local university in Hong Kong. All the students in the department can access to HKNews and participate in the development of this online shared knowledge base by contributing original real everyday life news stories to HKNews. Students enroll in different news writing and editing courses under the undergraduate journalism program and contribute their writing assignments to the shared knowledge base. Finally, the HKNews becomes an updated shared web-based knowledge resource for both the undergraduate students and the general public.

4.2. Subjects

There are in total 526 undergraduate students in the Department of Journalism and Communication. At the end of the academic year 2005-2006, a survey instrument was distributed to all of them through individual course lecturers. 138 (26%)

Table 2. Background of respondents

Demographic Variable	Sample Composition
Gender	Male: 28(20.3) Female: 110 (79.7)
Age	Mean: 21.5
Year of Study	Yr 1: 15 (10.9%) Yr 2: 40 (29.0%) Yr 3: 66 (47.8%) Yr 4: 17 (12.3%)
Computer Experience	Very little: 15 (10.9%) Fair: 75 (54.3%) Good: 45 (32.6%) Expert: 3 (2.2%)
Wikis Experience	Not at all: 7 (5.1%) A little: 38 (27.5%) Fair: 51 (37.0%) Familiar: 41 (29.7%) Very familiar: 1 (0.7%)
General Computer Usage	Rarely: 5 (3.6%) Sometimes: 22 (15.9%) Frequently: 47 (34.1%) Always: 64 (46.4%)
General Internet Usage	Rarely: 5 (3.6%) Sometimes: 15 (10.9%) Frequently: 47 (34.1%) Always: 71 (51.5%)
Visit, read or post articles on HKNews Wikis site last month	Rarely: 57 (41.2%) Sometimes: 47 (34.1%) Frequently: 27 (19.6%) Always: 6 (4.3%) Missing data: 1

questionnaires were completed and returned. The low response rate was partly due to the high absent rate at the last class.

4.3. Methods

The survey instrument was divided into three parts. Part A collected demographic data and usage pattern of the respondents. Part B consisted of 28 statements asking their opinion toward HKNews Wikis system in a seven point Likert's scale where 1 represented strongly disagree and 7 represented strongly agree, except computer self-efficacy which was measured by a ten point scale ranging from not at all confident to totally confident. The 28 statements included eight constructs in total and the items were adopted from various prior studies (see Table 1). Part C consisted of 8 open end questions asking about the process of writing for HKNews. This serves as a post hoc analysis to provide explanation to the use pattern.

5. ANALYSIS AND RESULTS

5.1. Instrument Validity

Construct items have means ranging from 3.36 to 4.93 (standard deviation ranging from 0.89 to 1.38), except computer self-efficacy items ranging from 6.32 to 7.28 (standard deviation ranging from 1.69 to 1.85). Internal construct consistency was evidenced by Cronbach's alpha coefficients ranging from 0.77 to 0.96, where the literature suggests a threshold of 0.7 or above (Nunnally & Berstein, 1994).

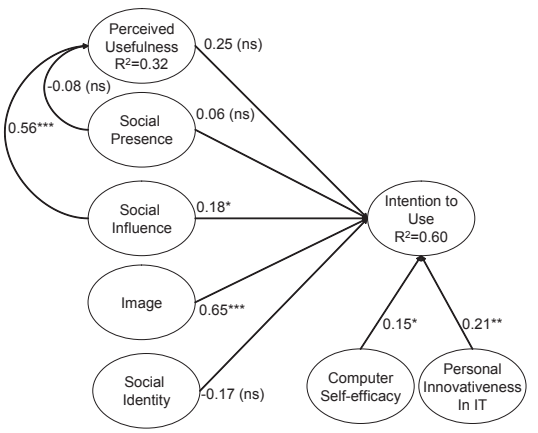
Construct validity of the measurement instrument via discriminant and convergent validity was analyzed. Exploratory factor analysis (using Principal Component extraction method, and Varimax with Kaiser normalization rotation method) found that construct items' factor loadings ranging from 0.69 to 0.91, well above the suggested 0.5 for significant loadings for corresponding component (Hair et al., 2006) while no significant cross-loadings between components were found.

5.2. Model Testing Results

We tested the model with structural equation modeling conducted by LISREL 8.71. The chi-square to degree of freedom ratio was 2.23, satisfied the requirement of being less than 3.0 (Hair et al., 2006). The goodness-of-fit indices, including NNFI, CFI, IFI were all 0.89, close to the suggested level of 0.9 (Hair et al., ibid, 2006). However, GFI has a lower value than suggested (0.71). The limitation of the interpretation of model testing results will be discussed further in later sections of this paper.

The path coefficients were listed in the model testing results diagram below (see Figure 1). Social presence and social influence combined together explaining 32% variance of perceived usefulness (R^2=0.32, for reduced form) while all constructs had a combined effect explaining 60% variance of intention to use (R^2=0.60, for reduced form).

Figure 1. Structural equation modeling testing results



**p<0.05; **p<0.01; ***p<0.001; ns: non-significant*

6. POST HOC ANALYSIS

Respondents were asked to freely express themselves about the use pattern of HKNews at Part C of the questionnaire. All the answer scripts were typed and coded for analysis.

Benefits from Using Wikis: Fewer than half of the respondents expressed a positive attitude from using the system, "lots of reference," "to increase knowledge," "can read others' articles easily," "search for topics or ideas to write." On learning, "convenient for me to find my work," "can check and review (my) own articles at anytime easily," On the system features, "convenient," "user-friendly," "easy to use," "highly access (accessible)," "beautiful layout." A way to publication seems important to the student journalists, "many people can read my writing," "have own record for the public to know." On the other hand, about one-fifth of the respondents, however, showed negative attitude in using the system, "it increases workload," "complicated and a waste of time," and having "poor group pressure (to do so);" and about the system, for example, "it is complex," "difficult to get start and use," "no instructions / instructions not clear enough," "not user friendly," "quite confusing," "speed is low," "not personalized / non-private," while "works are easily deleted by others."

Taking Reference: A significant majority did not read articles before writing their own, because of time constraints, "How come we have time!" "It would affect the planning of my writing," Even they read, they may read only the "topic" or "headline" "focus on the lead of article,"; "to avoid my content of my article (are) the same as the others." Taking references also has benefits "to learn more things about one event," "notice their view point in article and match with mine, so that I can have larger range of opinion,"

How to choose articles? Nearly half of the students do not plan their reading but choose articles at random. Nearly one quarter chooses someone they know; while another quarter chooses someone works better. The reasons for taking references at random because "there are too many articles," "there are so many people on HKNews that I don't know so I just read randomly with no special preference," "I don't know whose working is better than me / especially in different years," just "for interest," "just search the articles which the titles are attractive," "depends on the heading/titles," "I want to read different style of articles," "want to read different people especially from someone I don't know," "to get more detailed information and different angles," "to take a look of the work pattern or what would other choose to write,"

The reasons for them to choose someone they know, such as "I am not interested in reading articles of unknown people," and "I know him/her and realize his/her standard of writing skills."

7. DISCUSSION

Based on prior validated scales, this study examines key intentional determinants of student journalists acceptance to collaborating writing platform Wikis, in which Wikis are used to develop a shared online resources of a specific context. The scale validity is once again confirmed and the model fit is found acceptable. The strength of individual constructs is then measured by their path coefficients. Here follow the discussion of the analysis results.

Technology utility perspective: Surprisingly, perceived usefulness is found non-significant in the overall model, contradictory to most of the prior empirical work in technology acceptance (Legris et al., 2003). However, there may be plausible reasons for the results. In the past, students submit written news articles in hardcopies to instructors. Posting news articles onto Wikis takes students extra time and effort but do not help the writing process. At the beginning stage of the deployment of Wikis, shared resources are not rich enough to create value for students to help the different writing stages in planning, generating ideas, and taking references. While acknowledging the long term benefits in developing such an online shared resource, it is also a fact there is no immediate short term benefits to student journalist users because creating this shared resource changes the work pattern and needs extra time and effort.

Social perspective: student journalist users create a community while using Wikis. Everyone's work becomes transparent to all users. Users interact with each other through the listing of news headlines, news articles, and the profile of individual student journalist. However, this does not mean that all social factors significantly determine individual users' acceptance decision. The model testing finds that social presence and social identity are non-significant to intention to use. Social influence, on the other hand, has a direct significant but weak effect

on intention to use and has a very strong and significant effect on perceived usefulness. Moreover, image is the strongest social factor that significantly affects intention to use. As discussed above, users do not realize the short term value of Wikis at the time being. However, at the time users recognize the technology utility benefits of Wikis, social influence would become a strong and significant determinant which has both a direct and indirect effect on intention to use. Image, as a determinant to acceptance decision has empirical support from prior studies (e.g., Moore & Benbasat 1991). However, it has never become such a strong determinant against all other utility, social and individual factors. Student journalists have a very strong view on image and correlate it to their acceptance decisions. A review of the items used in measure this construct, it is all about how the individual user view their status, image, and prestige positions of using Wikis in the community. To benefit from this finding, management should try the utmost best to realize student journalists' needs for image concern within the community while using Wikis.

Individual perspective: Both computer self-efficacy and personal innovativeness with technology have direct significant effect on intention to use. This can be explained by the fact that Wikis are really new for most student journalists, actually, new to many organizations and individual users. Those early adopters of technology and those have higher confidence on technology use would most probably have a higher intention to use Wikis. A review of the background of student journalists find that more than 60 per cent of them have only fair or little experience to computers, which support the view that student journalists are more aware of the self-assessment of their own resources, computer skills and Wikis experience in acceptance decisions. Management in deployment of such a large scale of collaborative work should consider providing refresher training courses / workshops and easy to approach technical support, probably by volunteer, peer community users.

8. LIMITATIONS

There are several limitations in this study. The study confines to a specific context that journalism undergraduates using Wikis. Moreover, because of the low GFI value, the model testing results have potential limitations and require additional care in interpreting the results though the measurement instrument exhibits both reliability and validity in data analysis. On the other hand, this is the first year the Wiki system fully implemented while students have only limited usage of the system. This would affect how the students value the system. Lastly, future studies shall examine Wikis effect on quality of written work.

9. CONCLUSIONS

To fully utilize Wikis system, users must use it. Wikis depend on the contribution of participants to enrich the content. Probably it would be a vicarious circle that if users do not find rich content, they would not visit the system. There should be more research in the area in order to better understand the cognitive processes of the individual users, the social processes among the community, and the behavioral processes of how individual users use Wikis.

ABSTRACT

Enormous motivation is required from students just to cope with the material, let alone learn from Traditional IT courses. It was not surprising, therefore, to find in four classroom studies in UGRU that only 37% students want to learn IT using traditional methods. Understanding the situation, in spring 2005 UGRU introduced a new ICT program. Still it is not enough. Different students have different styles and strategies of learning. Recognising this fact, we strongly believe that simulations can be an effective counter to many of the aforementioned issues while also providing equal opportunities to men and women in higher education in the Arab World. Professor SMILE (SiMulated Integrated Learning Environment), an intelligent, critical and creative thinker, can help the future generation learn ICT effectively.

1. INTRODUCTION

Teaching and learning in Higher Education in the United Arab Emirates have recently undergone a major paradigmatic shift, from the traditional format to one in which students are actively engaged in their own learning process. This is true for IT as well as other subjects. While core values that are central to Islamic beliefs are retained, the methodology now focuses on teaching curriculums based on thinking, rather than rote memorization.

In spring 2005, the University General Requirements Unit (UGRU) of the United Arab Emirates University (UAEU), replaced the traditional Information Technology (IT) curriculum with a new Information and Communication Technology (ICT) curriculum. Evaluation of the new ICT curriculum, in terms of educational goals, content, teaching methods and assessment, revealed the following facts. The UGRU lecturers find the new ICT curriculum better than the traditional curriculum in all these areas. In particular, it integrates thinking skills into the technologically oriented curriculum. On the other hand, evaluation showed that there still remains much to be done to achieve objectives. There is a widening gap between present and future Information Technology (IT), taught in higher education, and the real use of IT. Educators are confused and students are bewildered by this. We strongly believe that simulations can be an effective way of narrowing this gap. This research paper will also focus on the usage of case-study based intelligent simulation technology in higher education. Particular emphasis would be given to its pioneering implementation within the UAE University's UGRU program.

Professor SMILE[1] is an innovative, intelligent, robust and ubiquitous computer system created to teach ICT to students in higher education. Its implementation is object oriented, and it incorporates a Discrete Event Simulation (DES) shell. Its design also makes it available on internet, mobile systems, and adaptable for the use of disabled persons. It can be used to teach Mathematics, English, Arabic, Science, Engineering and IT courses. It is a versatile system which can be upgraded to teach most of the things a human being can teach.

1.1 Prelude

First let us understand and analyze creativity, communication, collaboration, environment, and the human brain. Perhaps we should begin with a more basic question: what do we mean by creativity? The basis of creativity is achieving something that did not exist previously, breaking down established patterns, seeing things in a new way. But what drives people to think of something new? How does the creative process work? The creative process may manifest itself in different ways. "Chance favors the prepared mind," the famous scientist Louis Pasteur once said. Pathologist Peyton Rouse spoke likewise of "a prepared mind making its own chances." Are we going to prepare our students using new tools of information technology for future and using creative and critical thinking, value of good communication, and habits of collaboration or waiting for the chances[1]?

Several influences have converged to create a new emphasis on the teaching of a thinking skills based IT curriculum around the world. Prominent among these are workplace readiness and the constructivist movement[2]. Although education in the Arab nations was tied to religious fundamentalism during the 20th century and traditional teaching techniques relied primarily on rote learning within a lecturer-centered, religious-oriented context, teaching thinking in IT is not at all antithetical to the Holy Qu'ran. In fact, more than 640[2] verses in the Holy Qu'ran challenge believers to use their minds for critical thinking, problem-solving, creative thinking, and decision-making. In the 21st century, it is particularly important to cultivate these skills to enable our youth to function effectively in their own world as well as in the global community[3]. The new ICT curriculum focuses on critical and creative thinking. Perkins[5] notes six basic priorities for lecturers who actively teach for understanding rather than for memorization. Cognitive research and theory has changed the way many in the education system think about educational practice, including curriculum design, assessment, and learning environments. Greeno, Collins, and Resnick[6] emphasize that the design of learning environments can support cognitive or brain-based learning. Brooks and Brooks[4] describe several of these. For example, students need to be provided with curriculum holistically, emphasizing large concepts, rather than the fragments, or basic skills as building blocks that is typically the current approach[7]. These skills are used intelligently in the new ICT curriculum.

2. REASONS FOR BIRTH OF PROFESSOR SMILE

Some of the reasons for the birth of Professor SMILE are as follows: (i) There is a gap in present and future Information Technology (IT), taught in higher education, and real use of IT. (ii) Educators are confused and students are bewildered about IT programs in higher education. (iii) Traditional IT courses require enormous motivation to go through the material, let alone learn from it. (iv) Serious concerns can be raised regarding gaining relevant knowledge or developing required skills through traditional approach. (v) Different students have different styles and strategies of learning.

It was surprising to find in four classroom studies that not more than 37% students in UGRU want to learn IT using traditional methods. The rise of affordable computers and the internet have made IT learning ubiquitous. Yet much of what is offered under the guise of e-learning completely fails to make use of the essential features of either the computer or the Internet. More often than not the computer is used as little more than a television or a post box. Attempts to address

Table 1. IT students' likes, dislikes, and suggestions about classes, courses, and teachers

Likes/ Dislikes	Art		Business		Science		Total	
	Yes %	No %	Yes %	No %	Yes %	No %	Yes %	No %
I want to use internet instead of books from library for writing my research (papers/projects).	94.87	5.13	100.00	0	80.95	19.05	91.55	8.45
I want to use computer (blackboard programs, etc.) for learning in class not a teacher.	41.03	58.97	36.36	63.64	38.10	61.91	39.44	60.56
I want to take exams by using computer not on paper.	53.85	43.59	54.55	45.46	71.29	28.71	60.56	39.44
I want to study in a government university not in a private university.	69.23	30.77	90.91	9.09	90.48	9.52	78.87	21.13
I want to have higher education only for excellent students.	41.03	58.97	45.46	45.46	42.86	57.15	42.25	57.75
I want to have no exam, only project work, home work and quizzes to promote students to the next class.	61.54	38.46	54.55	45.46	52.38	47.62	57.75	42.25
I want to study to increase my knowledge other than for passing the Examination.	66.67	33.33	72.73	18.18	71.29	28.71	69.01	30.99
I do not like teachers who always ask me to come on time to the class	56.41	41.03	54.55	45.46	42.86	57.14	53.52	46.48
I do not like teachers who always keep me busy in studies whole period.	74.36	23.08	45.46	54.55	52.38	47.62	64.79	35.21
I want to eat and drink in the class while studying.	61.54	38.46	63.64	36.36	57.14	42.86	60.56	39.44
I do not want to come to class on Wednesday.	79.49	17.95	54.55	45.46	61.91	38.10	71.83	28.17
I want to talk with my friends in the class even when my teacher is teaching.	35.90	56.41	27.27	72.73	33.33	61.91	36.62	63.3
I do not like teachers who want me to do more study in class to get good marks but no rest.	43.59	53.85	63.64	36.36	42.86	57.15	47.89	52.11
I like that teacher who wants me to do very little study in class and gives more free time.	48.72	51.28	27.27	72.73	38.10	57.14	43.66	56.34
I feel angry with teachers who give me low marks even my work is poor.	56.41	41.03	63.64	36.36	38.10	57.14	53.52	46.48
I always want good marks in exam whether I study or not.	66.67	33.33	36.36	63.64	42.86	57.14	54.93	45.07
I like Arabic songs and Dances.	56.41	38.46	27.27	72.73	42.86	57.14	49.30	50.70
I want to sing in my free time.	51.28	43.59	54.55	45.46	57.14	42.86	54.93	45.07
I want to dance in my free time.	43.59	51.28	45.46	54.55	33.33	66.67	42.25	57.75
I like to play games (indoor/outdoor) more than studies.	53.85	46.15	36.36	63.64	57.14	42.86	52.11	47.89

this situation by making instruction interactive typically fall short, in part for the same reasons, but also because of a failure to understand what is essential about interactivity[8].

We strongly believe that simulations can be an effective counter to many of the aforementioned issues. In fall 2004, research was conducted by the authors of this paper in classrooms of UAE University to find IT students' likes, dislikes, and suggestions about classes, courses, and teachers. The results are summarized in Table 1.

According to Harvard professor Dr. Howard Gardner in his multiple intelligence theory, students generally exhibit strength and weaknesses across the following types of learning methods: (i) A linguistic learner (excels at words); (ii) A logical learner (excels at numbers); (iii) A spatial learner (excels at visualizing); (iv) A musical learner (excels at music); (v) A kinesthetic learner (excels at physical activity); (vi) An interpersonal learner (excels at relationships); (vii) An intrapersonal learner (excels at working alone); (viii) A naturalistic intelligence; or (ix) An intelligence existential[9]. Our research about learning styles and strategies about UAE University students revealed interesting outcomes. The results are summarized in Table 2. All the earlier reasons are instrumental in the birth of Professor SMILE, an intelligent system to teach ICT to students of higher education. The capabilities of Professor SMILE are enormous, which future generation of learners will appreciate.

3. ARRIVAL OF PROFESSOR SMILE: A NEW INTELLIGENT SYSTEM

The prototype of Professor SMILE was developed using state of the art techniques of software engineering. The system architecture is open and object oriented. It uses rule based (both forward and backward chaining) reasoning at present with a facility to attach neural computing based artificial intelligence and DES modules which have been tested separately.

3.1 Design, Development Stages and Software Engineering Life Cycle

For the development of any simulator there are six main stages. Figure 1 shows a high-level view of the activities required to produce a system in terms of the stages that a system goes through. The development of Professor SMILE has gone through the three stages and the fourth is continuing. We used the classic

Table 2. Learning styles and strategies of some ICT students

How do You want to learn ICT?	Number of Students	% of Students
By words (A linguistic learner)	3	2.57
By Pictures (A spatial learner)	21	17.95
By Doing Step by Step (A logical learner)	20	17.09
By Music (A musical learner)	7	5.98
By Moving or Dancing (A kinesthetic learner)	13	11.11
By working alone (An intrapersonal learner)	24	20.51
By working in a group (An interpersonal learner)	29	24.79
Total	117	100

Figure 1. Design and development stages used for Professor SMILE

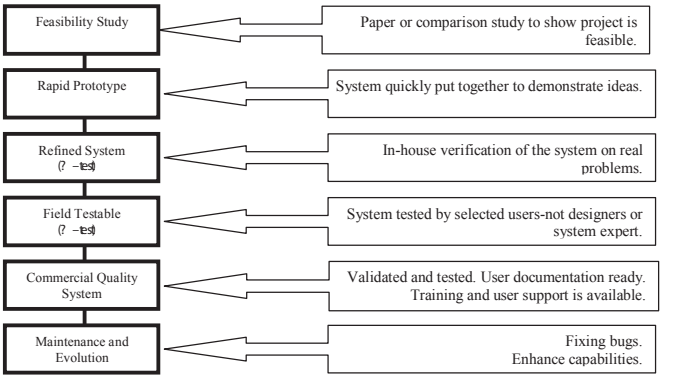

Figure 2. A rule-based expert system mechanism that has been used in design of Professor SMILE

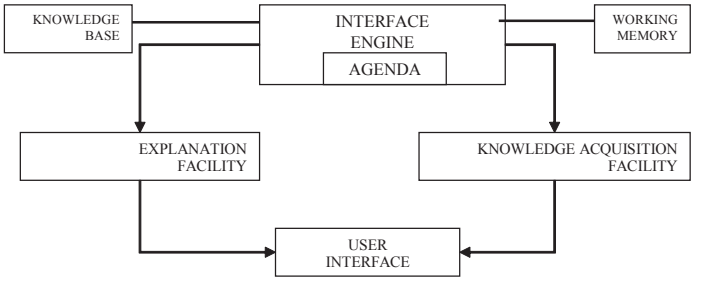

waterfall model for development of software modules to be incorporated with Professor SMILE. In the waterfall model each stage ends with a verification and validation (V & V) activity to minimize any problem in that stage. Also, notice that the iterations go back and forth only one stage at a time. This represents the iterative development between two adjacent stages in order to minimize the cost compared to the higher cost of iterating development over several stages. The main design is "Event Driven. The system is capable of generating "Brain Map" for the problems it encounters.

3.2 Technology

Some of the components are as follows: (i) Visual Basic Version 6.0; (ii) Speech to Text and Text to Speech conversion: SAPI 5.1 (Microsoft); (iii) Use of Agent: CSAgent (Microsoft); and (iv) Expert Systems, Neural Computing , and DES Model. (v) *Computer Systems:* Windows XP, Windows 2000, and Windows NT. (vi) *Portability:* Linux and UNIX after converting VB code to any other language.

3.2.1 Artificial Intelligence (AI) Module

The expert system module of Professor SMILE uses forward and backward chaining in its design. We have a future plan to incorporate neural computing and DES modules with expert system. Figure 2 shows a Rule-based Expert System mechanism. In a rule-based system, the inference engine determines which rule antecedents, if any, are satisfied by the facts. Two general methods of inferencing are commonly used as the problem-solving strategies of expert system: forward chaining and backward chaining[10].

3.3 Future Plan For Professor Smile

We will use Discrete Event Simulation (DES) Model in future. Any addition of a software module to Professor SMILE is very easy because its design philosophy is open software architecture. DES is where a "simulation model" of a system is created using the idea of: "Entity" flow. Some of the features of this model are as follows: (i) It can visualise the concepts/processes involved in designing and writing a program. (ii) It is object orientated visually. (iii) It has simple 2D animation to enhance visualisation of the processes. The area of DES application in academic education is new except for courses in simulation. Professor SMILE is first to use DES as a shell to help students visualize and animate the process flow of program development life cycle (PDLC), the main steps of a general algorithm and writing a program. It can be expanded to cover many other types of process we want to visualize in the academic world.

Another improvement will be application of Neural Networks with existing Rule Based Expert System. The designers of this project have a good expertise in prediction of learner outcome using neural networks. The connectionist approach [which applying neural networks] is based on the supervised or unsupervised learning paradigms [10]. But there are some situations, like in learning environment, where these paradigms cannot be used in isolation because scenario changes continuously. An artificial neural network functions by receiving a set of input facts, processing these facts, and then producing a set of values calculated from these facts[10]. The training of a network is important, which is the major distinction criterion for different neural networks. The neural networks used here are based on two different paradigms; supervised and unsupervised learning paradigms. In our case we are using back-propagation network. McCulloch-Pitts neurons are the basic units of neural networks, shown in Figure 3(a). The basic

Figure 3. (a) An artificial neuron, and (b) a back-propagation Net

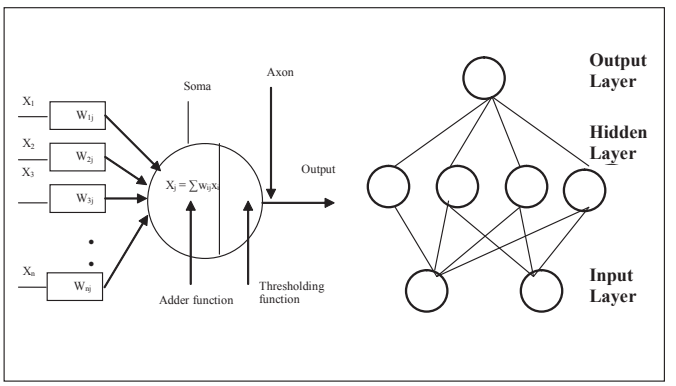

Figure 4. The first screen of Professor SMILE when it is loaded and running

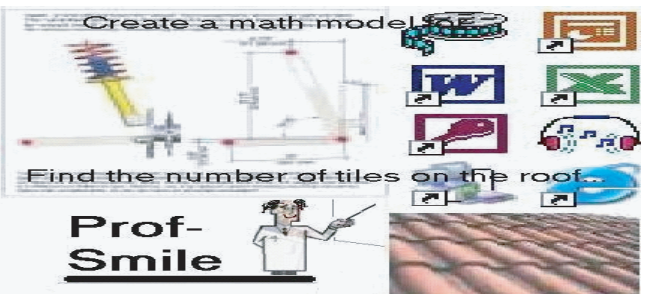

configuration of the neural networks based on the supervised learning paradigm is shown in Figure 3(b).

There are two distinct operations, which take place during the training phase; the first one is the feed forward computation and update of the weights based upon the error of the network's output. Typically each neuron in the network uses the same activation function and threshold value. First, the connection weights between the hidden and output layers are adjusted along with the activation thresholds in the output nodes. In the second state, the connection weights between the input and the hidden layers are adjusted along with the activation thresholds in the hidden layer to reduce error in the output. This error is defined as

$$E_p = 0.5*\sum(t_{pj} - o_{pj})^2 \quad (1)$$

Where E_p is a measure of error on input/output pattern p and $E = \sum E_p$ is the overall measure of error. Here t_{pj} is the value of target output, and o_{pj} is the output value of the network. With hidden units there is a possibility of getting stuck in local minima. The derivatives can be calculated by generalized δ rule. The generalized δ rule works for layered feed forward networks with any number of hidden layers between the input and output layers. The following equation is used in the learning algorithm to calculate the change in weight (ξ) whenever the node (neuron) is an output node. Here, w_{kj} are the weights between the layers.

$$\xi_{pj} = o_{pj}(1 - o_{pj})\Sigma k \xi_{pk} w_{kj} \quad (2)$$

The application of the generalized delta rule involves two phases. During the first phase, called the forward phase, the input is presented to and propagated forward through the network to compute the output value o_{pj} for each output unit. For each processing element, all current outputs are compared with the desired output, and the difference, or error, is computed. The second phase, called the backward phase, involves a backward pass through the network during which the error signal is passed to each unit in the network and the appropriate weight changes are made. Only when these two phases are completed, can the new inputs be presented. Neural networks based on both paradigms were simulated and evaluated for prediction and performance. Our research also concludes that neural networks based on the supervised learning paradigm require a lot of training time, are unstable, very sensitive to tuning parameters, and generally get stuck in local minimas. On the other hand the neural networks based on the unsupervised learning paradigm are significantly faster and are less sensitive to tuning param-

Table 3. Typical examples of the tasks provided by Professor SMILE

Example 1:
What is the number of rectangular roof tiles, to cover the roof area shown in the picture? Assume each rectangular tile is 30cm by 15cm
Case 1 assumes tiles just touch.
Case 2 assume tiles overlap 1cm all the way round its perimeter.
Example 2:
Create a simple math model of the car suspension for a simple two spring two mass damper system.
Example 3:
You work for a telephone company. Your boss has asked you to answer some questions about smart phones. He also wants some information on customers. Do the following Tasks.
a) Your company sells 6 different Smart-Phones. The sales for 2004 are in the Smart-Phones Sales 2004.doc file. Your company wants you to calculate the profit for each model.
a1. Choose the best software to use.
a2. Make sure the information about the Smart-Phones is clear and easy to read.
a3. Calculate the profit that each model is making.
Profit = (Price - Cost)*Number Sold
a4. Save your document as Smart????? Where ????? are the last 5 digits of your id number?
b) The company has decided to sell only 5 different Smart-Phones in the future. Which phone do you think they should STOP selling? Give your reasons.
Example 4:
You are the manager of a new perfume shop, which is about to open. Create a flyer for your shop and also make it into a web page.

Figure 5. (a) User is prompted for the choices of different varieties. (b) User can choose different learning modes. (c) User can become administrator or learn DBA activities. (d) User has a choice of different subjects to study. (e) The choice can be of different areas, learning and testing modes, etc. (f) The systems generated "Brain Map" for number of tiles on roof problem. (g) Professor SMILE provides a possible answer for roof tiles problem. (h) Computer generated "Brain Map" for Smart Phones Scenario

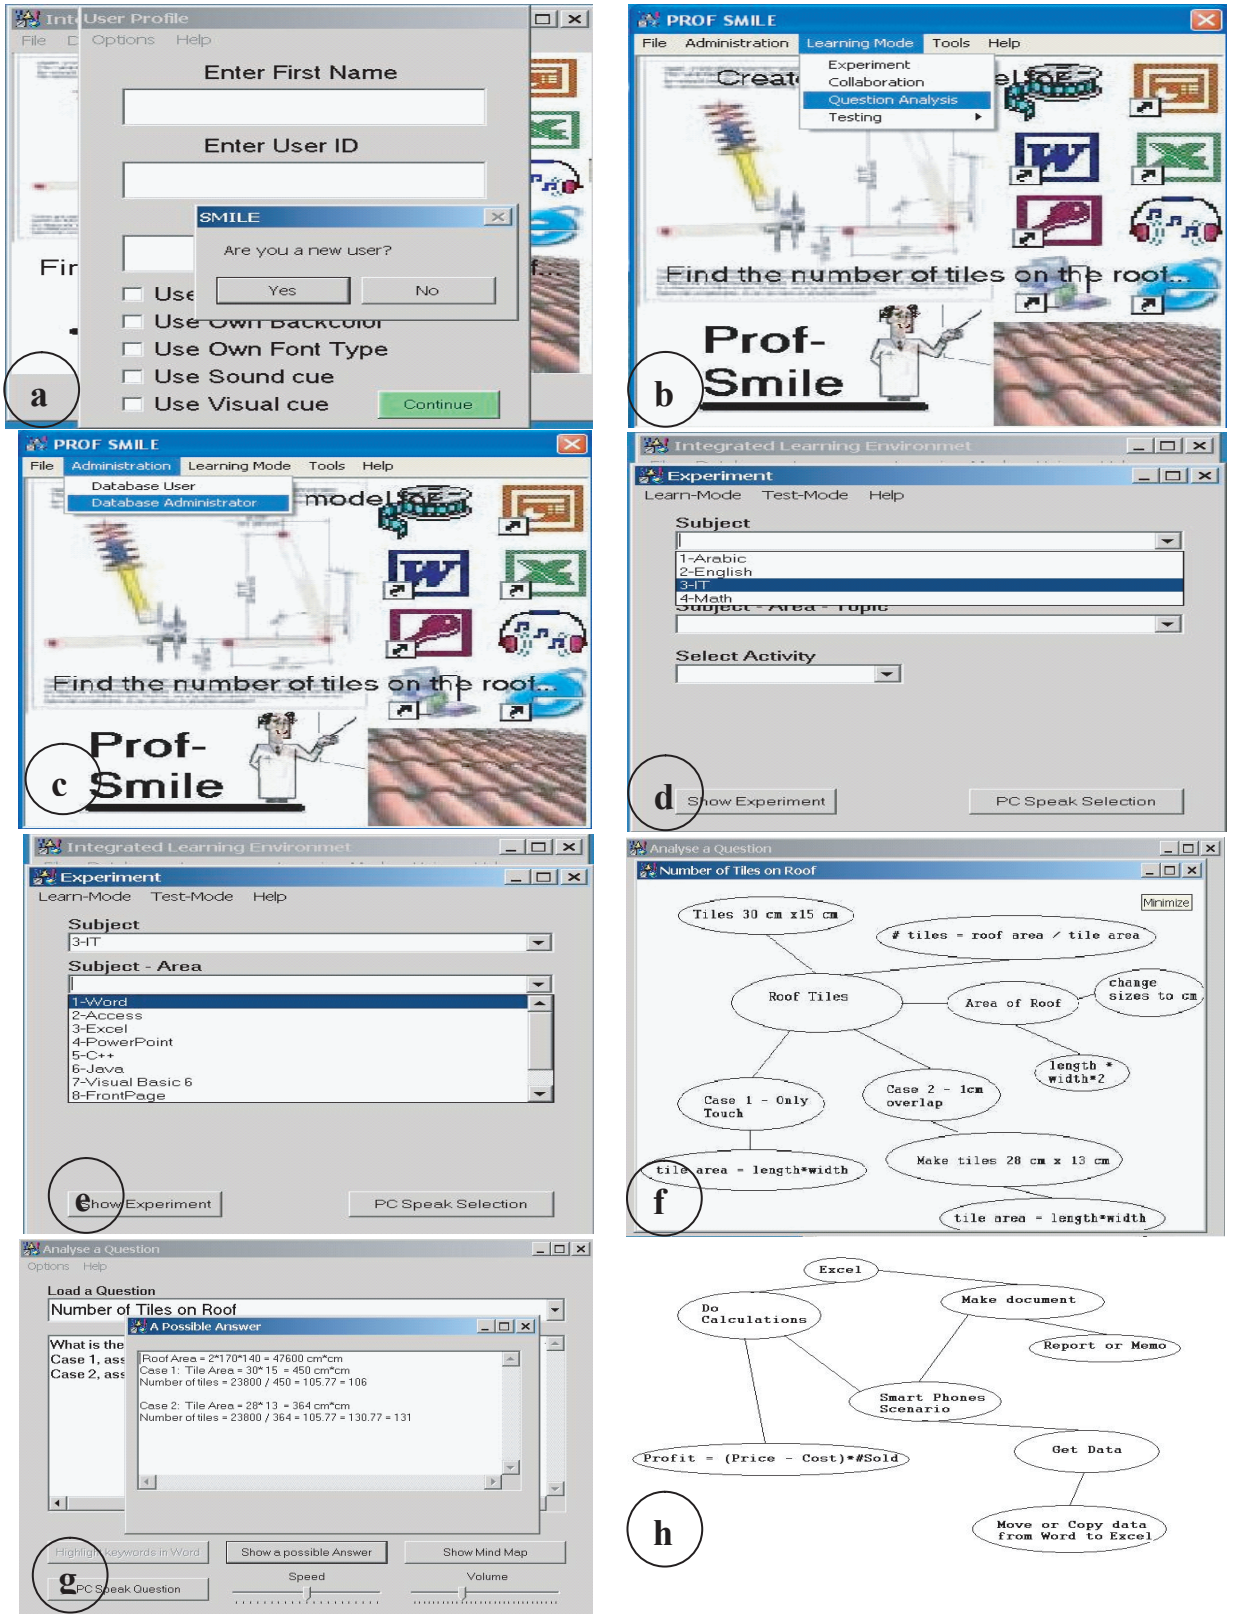

Figure 6. (a) Physically disabled person has a choice of different facilities and options. (b) Calculation of the tiles for a disabled person. (c) Let us analyze the roof tiles problem. (d) Solution of Car Suspension problem. (e) A better method of solving a problem for a disabled person

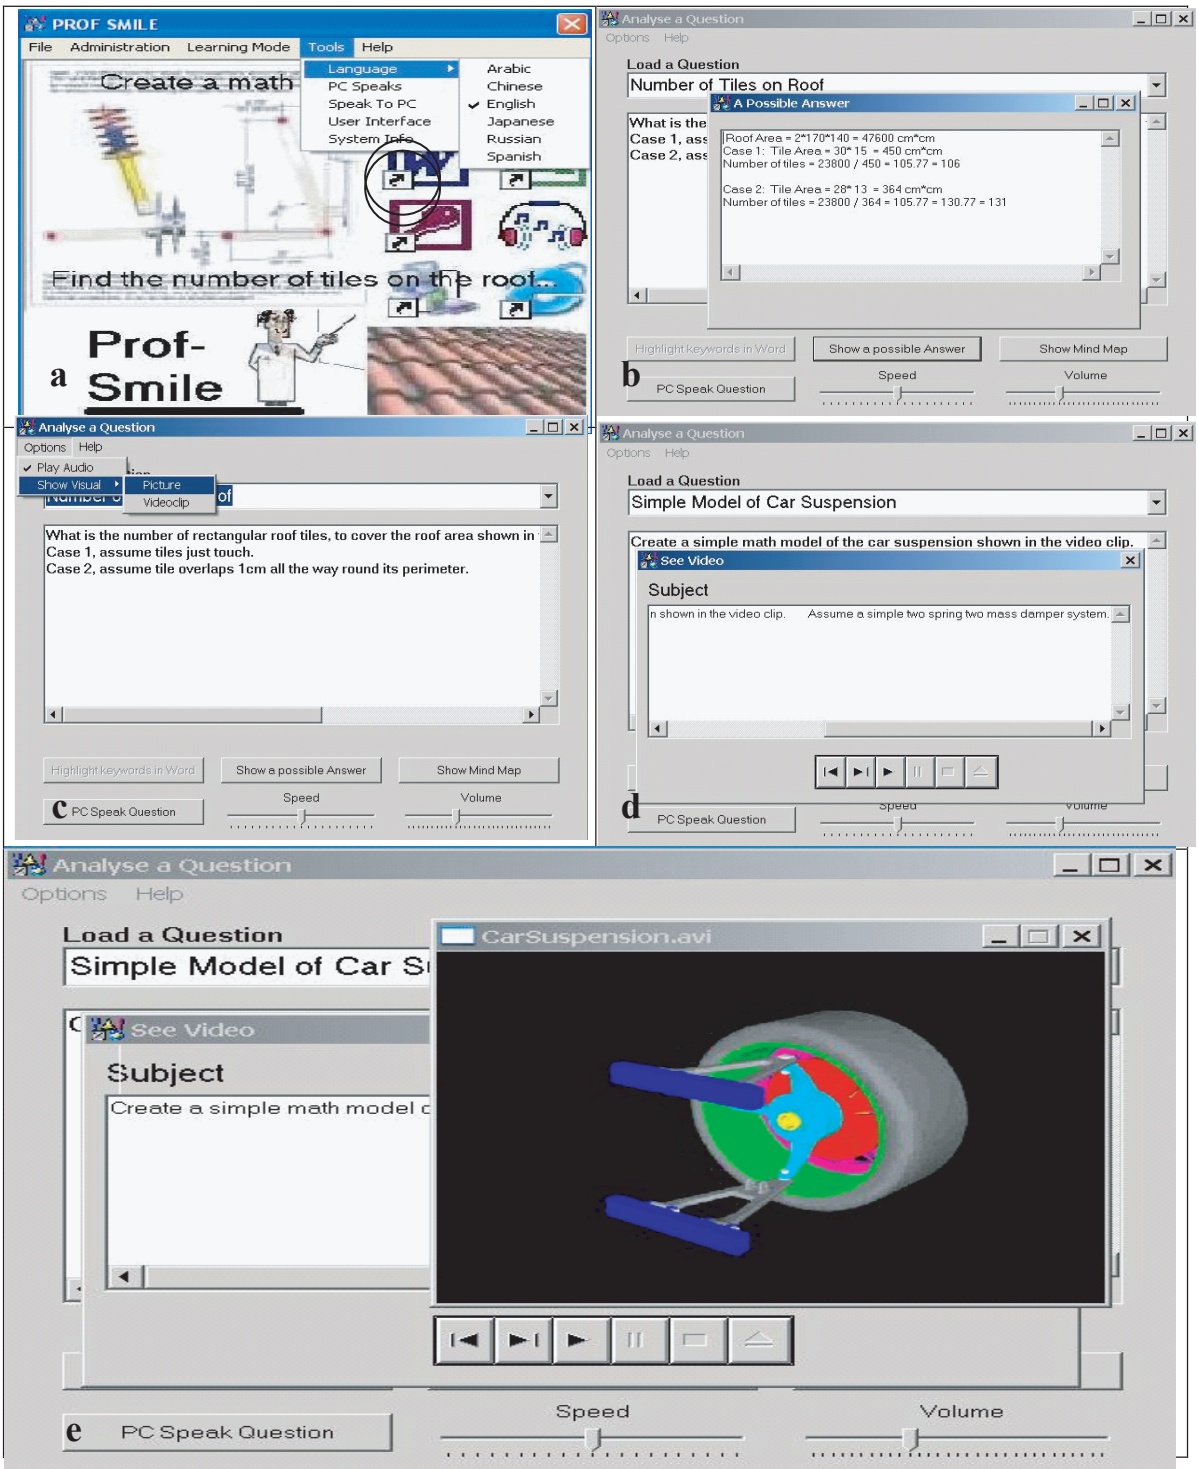

eters. The neural networks based on both paradigms simultaneously along with feature enhancement on every step provide a much faster, robust solution which is less sensitive to tuning parameters. Neural networks could be easily used for prediction of learning outcomes of any cluster of university students based upon their past performance. The developed and tested neural computing module will also be incorporated with Professor SMILE.

4. TEACHINGS OF PROFESSOR SMILE

4.1 Why Learn from Professor SMILE?

Some of the compelling reasons are as follows: (i) It understands the learning requirements of students. (ii) It is available all the time. (iii) It is intelligent. (iv) It does not show negative human emotions. (v) It does not follow any religion. (vi) Cheaper and less dangerous to simulate than build, buy or operate a real system. (vii) Its software tools provide a highly visual 2D or 3D animated model of your "system". (viii) It provides a tool to play very realistic "what-if" games. (ix) User can see animated flow of various data objects. (x) Various Model Parameters can be modified e.g.: Realistic processing time delays can be used in various objects.

4.2 Learn To Design and Solve Complex Problems with Professor SMILE

Professor SMILE finds it easy to teach the following difficult IT topics using a simple DES (Discrete Event Simulation) model and enhance students' visualization: (i) The Program Development Life Cycle (PDLC); and (ii) the Steps of the General Algorithm.

4.3 Learning Process For Normal Person

The normal person can start learning from Professor SMILE by keying the basic personal information which helps the system to build a user profile. The student profile is used by most of the system modules. Some of the Professor SMILE's interactive screens are shown in figures 4 -6. Some typical examples of the tasks provided by Professor SMILE are shown in Table 3.

4.3 Learning For Physically or Mentally Disabled Person

The system has also been designed keeping in mind the problems faced by physically or mentally disabled persons. They can choose to speak, listen or feel the system. If any touch-coded sign language is available, it can also be incorporated into the system. The physically challenged person has an obvious choice of speaking out his information through microphone. He/She can hear computer-generated output through a speaker or headphones.

CONCLUSION

Our research clearly shows that there is a wide gap between present and future Information Technology (IT), taught in higher education, and real use of IT. It also shows that different students have different styles and strategies for studying IT.

Certain changes were made in the IT curriculum with respect to educational goals, content, teaching methods, and methods of assessment. Regarding teaching methods, lecturers now share the class time with the students, thus engaging them in their learning experience. Generally speaking, the new curriculum has successfully changed from a textbook, lecturer-centered model to a learner-centered model, providing more active student participation in the educational process.

Still it is not enough. The gap has been narrowed but not closed. For example, course content in the new ICT curriculum does not contain all the information needed for students to learn a subject, thereby requiring the students to do their own research to complement the information in their texts. Some areas still need improvement, but the current trend is one that will be consistent with guiding our students to become critical and creative thinkers, able to search out, understand, analyze, and synthesize the information they will need to become world citizens and world leaders.

We strongly believe that simulations can be an effective counter to many of the aforementioned issues. Professor SMILE is an innovative, intelligent, robust and ubiquitous computer system to teach ICT to students in higher education. Its implementation is object oriented and it also incorporates a DES shell which no other working academia project uses at this time. Its design also makes it available on internet, mobile systems and it is ideal for use by disabled people. It can be used to teach Mathematics, English, Arabic, Science, Engineering and IT courses. It is a versatile system, which can be upgraded to teach most things a human being can teach. This model has already been tested with some students to obtain data on what students find difficult to conceptualise and understand in IT. The project is currently continuing. Piloting in other institutions may be a possibility in the future. We are available to help others start similar projects in academia and industry; however, the nature and terms of help would be different for industry and academia. The new ICT is a gift of the UAE University to a new Arab world along with an innovative, intelligent, critical and creative thinker, Professor SMILE, to teach the future generation.

ACKNOWLEDGEMENT

The authors are very grateful to the UGRU, UAE University authorities for their helpful cooperation during the period of study. The authors are very grateful to Dr. Anita Rosenfield, Yavapai College, Sedona, Arizona, Mr. Stephen Boylan, Mr. Hussain Ahmed, Mr. Tago Ranginya, Mr. Mused Al-Ward, Mr. Hussein Chehime, Mr. Paul McKenzie, Dr. Brian Bielenberg, and Dr. Mohamed Al Zarooni, Dean of UGRU, UAE University.

ABSTRACT

In recent years, knowledge management (KM) has received increasing attention from researchers and practitioners. In 2005, Peachey, et al. explored the KM literature that appeared in information systems (IS) journals. However, while many KM articles initially appeared in IS journals, KM-specific journals have begun to appear on the scene. This research reviews the literature published in KM-specific journals from 2000 to 2005. Using content analysis, this research explores the literature in KM-specific journals to determine the nature of the body of knowledge in KM. The results indicate that, although the coverage of KM topics within KM-specific journals is fairly evenly distributed, the KM topic of knowledge transfer has been receiving the greatest amount of attention by researchers and practitioners contributing to these journals. Additionally, the comparison of the two bodies of literature (KM and IS journals) shows that there are differences in the coverage of knowledge application.

1. INTRODUCTION

Knowledge management (KM) was first addressed as an identified concept in industries/ functions that were basically selling knowledge (e.g., professional services, pharmaceuticals, and research and development) [3]. Since then it has quickly moved into other industries and now is expected to be adopted in virtually every business unit and function (ibid). Peachey et al. [14] showed evidence of this rapid growth in their 2005 study of KM in the leading information systems (IS) journals. They found that over 2,000 articles were written on the subject from 2000-2004.

Peachey et al. [14] proposed that "understanding the future direction of research in KM requires that we first know what constructs in KM have received the most attention from researchers and where there currently are gaps in the published research." Thus, their study was designed to learn what types of KM articles had been published in the IS journals. To conduct the study, they developed a hybrid framework by combining the KM topics of *knowledge creation*, *storage/retrieval, transfer*, and *application* from Alavi and Leidner [1] with the KM topics of *knowledge generation*, *codification* and *coordination*, *transfer*, and *roles/skills* from Davenport and Prusak [4]. The study found all of the KM framework topics represented in the IS literature, with the KM topic of *knowledge transfer* being addressed more (approx. 42% of the time) than any of the other four KM topics. Peachey et al. [14] suggested that concentrating research on just one or two KM topics could cause an imbalance in KM research as a whole (ibid, p. 68). Given these findings, the purpose of the current study was to extend the research to focus on KM-specific journals.

2. EVOLUTION OF KM-SPECIFIC JOURNALS

With the work of Peachey, et al., we have an idea of the KM topics covered in IS journals. Similarly, Guo and Sheffield [6] identify IS journals as well as management science journals that publish a significant number of KM articles. Recently, KM-specific journals have begun to appear. Although no *official* "KM-specific journal" definition exists, one can be defined as a specialized publication dedicated to KM research and practice [9]. Furthermore, a KM-specific journal's main focus is to advance body of literature in KM by publishing articles only pertaining to KM that may not be published in IS or other discipline-focused journals.

Over the last five years, the number of KM-specific journals has begun to grow. For instance, Schwartz [16] identified a number of outlets "with major aspects of KM as a primary focus" [p. xxiv]. Jennex and Croasdell [9] also identified three journals that "surfaced to address KM research exclusively" [p. ii]: *Knowledge Management Review, The Journal of Knowledge Management, and Knowledge Management Research and Practice*. The evidence suggests the body of knowledge for KM is growing, and as Schwartz suggests "[there is a] compelling need to create a logical structure that maps out the field of knowledge management across its diverse disciplines' [16, p. xxv]."

With the findings of Peachey et al. concerning IS journals, the researchers felt a similar investigation of KM-specific journals would be informative as to the current state of and future development of the KM discipline.

3. RESEARCH QUESTIONS

Given the discussion above, the following research questions were proposed:

RQ1: *What are the dominant KM topics addressed in KM-specific journals?*

RQ2: *Is the KM literature in IS journals different than that being published in KM-specific journals?*

4. LITERATURE REVIEW

In attempting to define knowledge management, Alavi and Leidner reference Von Krogh's [17] definition of knowledge management: "Knowledge management refers to identifying and leveraging the collective knowledge in an organization to help the organization compete" [17, p. 113]. Alavi and Leidner further state that "knowledge management is largely regarded as a process involving various activities" [1, p. 114].

Two frameworks were selected to form a basis for the categorization of topics for this research. First, Alavi and Leider [1] was chosen based on the desire to compare the KM-specific journals with the results of the previous IS journal study [14]. Additionally, this framework is the fourth most often cited article in KM research [8].

Choosing the second framework was more challenging. Rubenstein-Montano et al. [15] examined 26 different knowledge management frameworks published in both academic and practitioner literature. In their review, they noted that "Holsapple and Joshi present the most comprehensive framework in the existing literature and are most closely aligned with the results of this study" [15, p. 10]. Given the strength of this recommendation and Holsapple and Joshi's extensive research in KM, we selected this framework for inclusion in this study.

Alavi and Leidner [1] created a KM framework with four KM categories, or focus topics:

1. knowledge creation
2. knowledge storage/retrieval
3. knowledge transfer
4. knowledge application.

Alavi and Leidner [1] provided extensive definitions of the KM topics. *Knowledge creation* was defined in a manner similar to Nonaka [12, 13] as the continual interplay between tacit and explicit knowledge.

Knowledge storage and retrieval are those activities that an organization engages in to capture and locate knowledge for future use. Additionally, as stated by Davenport and Prusak [4], codification activities that put knowledge in a form that is useable for others are part of storage and retrieval activities.

Knowledge transfer is the process where knowledge flows from one entity to another such as between individuals, groups, organizations, or any combination thereof.

Knowledge application is the focus on use of organizational knowledge for competitive advantage.

Holsapple and Joshi [7] created a framework which consisted of five KM focus topics:

1. Managerial influences
2. Resource influences
3. Environmental influences
4. Activities
5. Learning/projection as outcomes

Holsapple and Joshi's research to produce the framework involved over "31 recognized researchers and practitioners in the KM field" [7, p. 235]. They claim the results of the Delphi panel yielded "a relatively comprehensive framework on which KM research and practice can develop" [7, p. 255]. Bartczak [2] also found the framework to be robust when used as grounding theory for a case study investigation of six military organizations practicing KM.

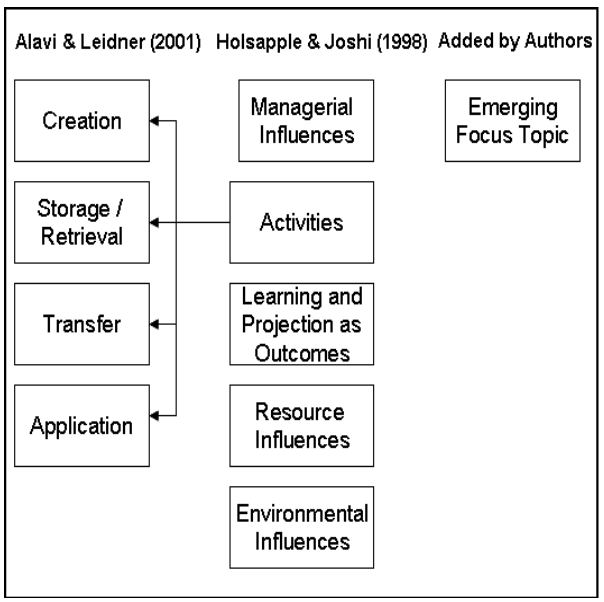
According to Holsapple and Joshi, *managerial influences* are influences that come from those employees within an organization who are in charge of KM functions [7].

Resource influences include the elements of knowledge resources, human resources, and material resources [7]. Each of these resources provides important capabilities for the conduct of KM.

Factors external to an organization that have a direct effect on how KM is conducted are *environmental influences* [7]. The six main factors that comprise *environmental influences* are: competition, fashion, markets, technology, time, and the GEPSE (governmental, economic, political, social, and educational) climate.

Activities are processes that people employ in the conduct of KM within an organization [7]. The four major activities which Holsapple and Joshi identify are acquiring, selecting, internalizing, and using knowledge.

Figure 1. KM topics framework



Learning occurs when an organization attempts to modify its human knowledge resources, and *Projection* is concerned with enhancing an organization's standing within its environment (e.g., its reputation/competencies in the market) [7].

Our challenge was to synthesize those KM topics into an overall framework. In an effort to capture possible *emerging topics* not addressed by the framework, we allowed a placeholder. The final framework is shown in Figure 1.

5. METHODOLOGY

This study used content analysis methodology based on Neuendorf's model [11]. Content analysis allows the researcher to utilize a step-by-step approach for assigning literature (in this case, KM) to a predetermined set of categories. The categories were provided by the model developed in the previous section.

A selection of articles from five KM-specific journals was examined for this study. Of the 469 articles included in these journals, 317 were deemed specifically relevant to this study. The methodology followed the steps highlighted below.

5.1. Theory and Rationale

This first step involved determining "what content will be examined and why." The literature review provided the information for the "what" and "why." The "what" in this review were the articles in the selected journals that reflect research in some aspect of KM. The "why" in this paper was a determination whether there exists a difference in the topic coverage in KM between the two sets of journals (leading IS journals and KM-specific journals).

5.2. Conceptualization

This step focuses on what variables are to be used in the study and their conceptual definitions. The conceptualizations were taken from the comparison work from Peachey et al. [14].

5.3. Operationalizations (Measures)

In order to answer the research question, this study first examined the articles in a manner similar to the study of the KM articles in the leading IS journals [14]. Each KM topic was considered to be an independent operational variable or measure. For an article to be coded in a specific category, specific research into the topic had to be present.

5.4. Coding Schemas

Human coders were used to conduct the research. A detailed code book and code form was created for use by the coders.

5.5. Sampling

The population of interest consisted of articles published in KM-specific journals. To determine what publications could be considered KM-specific journals and which of those journals should be used for the research, four distinct criteria were established. The first criterion was that the journal had to be currently in publication. This criterion did not preclude electronic journals as long as the respective websites were kept current. The second criterion was that KM-specific journals had to be peer-reviewed. The third criterion was that the journals had to specify KM as their primary focus area. The final criterion was that only journal articles published within the last five years, covering the period from January 1, 2000 to September 30, 2005, were coded.

Using these criteria, five KM-specific journals were identified: *Electronic Journal of Knowledge Management*, *Journal of Knowledge Management*, *Knowledge Management Research & Practice, Journal of Knowledge Management Practice* and *International Journal of Knowledge Management.* Due to the small number of journals, it was decided to use a census of the articles rather than sampling a subset.

5.6. Training the Coders

All coders had taken at least one graduate-level KM class and four were trained on coding in person. Each coder was given an eight page instruction sheet that provided detailed descriptions and specific examples of each topic. The fifth

coder was not trained in person but had participated in similar research and was aware of the definitions of the KM topics.

5.7. Coding

Each of the 317 articles was coded by the primary researcher and one of the other four coders, ensuring a minimum of two coders per article. Each coder, with the exception of the primary author, reviewed approximately 64 articles. The coders reviewed each article and scored it in a particular topic category.

5.8. Inter-Coder Reliability

Neuendorf recommends the use of raw percent agreement which she states is "the most popular coefficient in the business and the social and behavioral sciences" [11, p. 148]. However, we selected to employ a more rigorous measure, Krippendorff's alpha-reliability [10], in an effort to eliminate the effects of chance agreements between coders.

5.9. Tabulation and Reporting

For purposes of this research, simple descriptive frequency calculations were employed to answer the research questions.

6. ANALYSIS AND RESULTS

6.1. Reliability

Intercoder reliabilities were calculated for each measure on the criterion of *agreement*. Seven of the eight *percent agreement* (PA) scores across all coders were above .60, and varied from a low of .58 to a high of .77. In her discussion of acceptable levels of inter-coder reliabilities using the more liberal raw percent agreement index, Neuendorf states that coefficients of .90 or greater would be acceptable to all, .80 or greater would be accepted in most situations, while below that there is less agreement [11]. As our Krippendorff's alpha reliability index was more conservative in nature, we believe the reliabilities (.58 - .77) were acceptable for this study. Table 1 outlines these results.

6.2 Findings

The distribution of KM topics across the KM-specific journal articles is shown in Table 2. The body of literature does contain all of the KM topics identified in the KM topic framework developed for this study. Secondly, the body of literature for KM- specific journals reflects a wide dispersion of topics ranging from a low percentage of coverage for the *environmental influences* and *knowledge application* topics to a high percentage of coverage for the *knowledge transfer* topic. In addition, there was one new "emerging" topic discovered during analysis. The emerging topic of *knowledge mapping* was found to be discussed in six percent of the articles reviewed.

Table 1. Intercoder reliability

KM Topic	Overall
Creation	.67
Storage/ Retrieval	.68
Transfer	.58
Application	.73
Managerial Influences	.77
Learning/ Projection as Outcomes	.63
Environmental Influences	.74
Resource Influences	.65

Table 2. KM topic coverage in KM specific journals

Number of articles where topics were observed and the percent of the sample population		
KM Topic	**Num**	**%**
Creation	102	32
Storage and Retrieval	113	36
Transfer	217	68
Application	55	17
Managerial Influences	90	28
Learning/Projection as Outcomes	92	29
Environmental Influences	36	11
Resource Influences	151	48
Emerging KM Topic: Knowledge Mapping	20	6

RQ 1 was answered by tabulating the number of units (i.e., KM-specific journal articles)

that contained each variable (i.e., KM topic). These tabulated numbers were then divided by the total units included in the study. The resulting percentages showed the distribution of KM topics across the KM-specific journal articles.

RQ 2 was answered by comparing the distributions calculated for RQ 1 against the distributions identified by Peachey et al. 413] for the leading IS journals. Since this study included more KM topics than the Peachey study, only the similar categories (i.e., *knowledge creation*, *knowledge storage/retrieval*, *knowledge transfer*, and *knowledge application*) were compared. Additionally, since this research used a simple descriptive frequency calculation method vice the proportional calculation method used in the Peachey study, the data collected from RQ 1 was recalculated using the proportional calculation method to ensure proper comparison.

In this study, if the coder identified an article as addressing a topic, it was coded with a 1 so an article could have from 1 to n for a total score where n is the total number of KM topics addressed in the article. Peachey et al. [14] weighted the coding so that in an article that addressed one topic, the topic would receive a 1. If an article researched two topics, each topic would receive a .5, and so on. The difference between coding methods explains the difference between the percentages shown in Table 2 and those illustrated in Figure 2.

After performing the recalculations we compared the four KM topics side-by-side and determined whether the bodies of KM-specific journals' and the leading IS journals' literature are similar or dissimilar. Figure 2 shows a graphical representation of the results of the two studies.

The results from the comparison of the two distributions showed only small differences. To determine if the differences between groups were significant, we first used a Chi-square test to determine if the distributions as a whole were different. The result was a value of 7.53 with 3 degrees of freedom and was significant at $p=.056$. From this we can infer that there is a significant difference (at $p<.10$) between the populations.

Next we examined the topics between KM journals and IS journals. The proportions were tested for equality by testing if the null hypotheses that the proportion of topic (KM journals) = proportion of topic (IS journals). The topic application showed a significant difference. The topics of *creation, storage* and *retrieval* and *transfer* did not show significant differences. Table 3 shows these results.

Figure 2: Percent of topic areas appearing in KM and IS journals

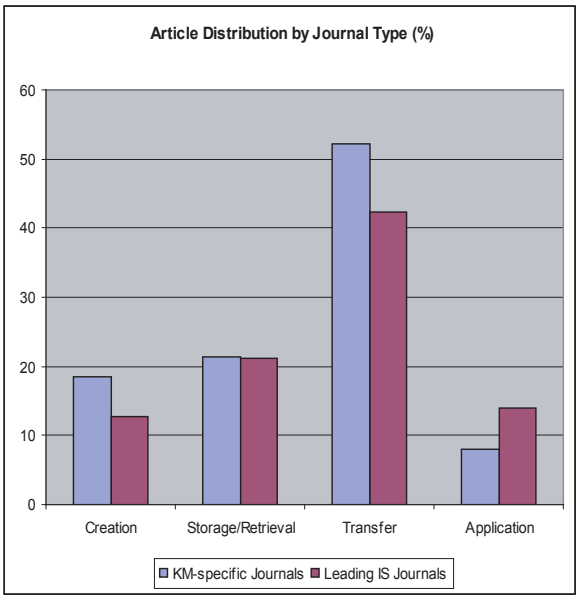


Table 3. Hypothesis tests of equality of topic coverage between KM and IS journals

KM Topic	P Value	Decision
Creation	.184	Do not reject
Storage and Retrieval	.642	Do not reject
Transfer	.316	Do not reject
Application	.04	Reject
Null Ho-Ha=0 and Alternative Ho-Ha≠0		

Table 4. Hypothesis tests of equality of topic coverage in KM Journals

	Storage and Retrieval	Transfer	Application
Creation	.744	**0.00**	**.03**
Storage and Retrieval	NA	**0.00**	**.013**
Transfer	**0.00**	NA	**0.00**
Application	**.013**	**0.00**	NA
Null Ho-Ha=0 and Alternative Ho-Ha≠0			

Lastly, we tested the proportions to determine if there were differences in the amount of coverage in KM journals between KM topics. Each set of proportions was tested to determine if they were the same, i.e. Ho=Ha. All the proportions were statistically different at $p<.05$ with the exception of the difference between the proportion of creation and the proportion storage and retrieval. Table 4 shows the P-values. Significant results are shown in bold.

6.3. Summary

An assessment of the coverage of KM topic areas in KM journals supported the finding that all pre-identified topic areas were covered in KM journals during the years 2000-2005. In addition, a new emerging topic area was identified*: knowledge mapping*. The highest percentage of coverage (68%) was for knowledge transfer, perhaps indicating the high interest in this topic by practitioners as well as researchers.

When the coverage of KM topic areas in KM journals was compared with the coverage in IS journals, a statistically significant difference was found in *application* (greater coverage in IS journals).

When comparing the topic areas from the Alavi and Leidner [1] framework in KM journals, there was a statistically significant difference between all combinations of topics with the exception of *creation* and *storage* and *retrieval*. *Transfer*, which received the most coverage, was followed by the pair of *creation* and *storage/retrieval*. *Application* received the least coverage in KM journals.

7. CONCLUSIONS AND RECOMMENDATIONS

The results from RQ 1 reveal that the body of KM literature in KM-specific journals reflects the KM topics in the KM framework. The fact that *knowledge transfer* was the most frequently identified topic area may well reflect the keen interest in knowledge transfer by many organizational practitioners of KM. However, as stated by Peachey et al., practitioners may find it hard to properly deploy effective KM systems if "the other [KM topics are not] more fully developed" [14]. Another possible explanation for the emphasis on transfer is that the topic may not yet be explored enough to locate other dimensions within the topic. Even though *knowledge transfer* did get significant coverage, discussion of the remaining KM topics was rather evenly distributed. A good example of this even distribution can be found in the KM topics of *knowledge creation (32%)*, *knowledge storage and retrieval (36%)*, *managerial influences (28%)*, *learning and projection as outcomes (29%)*, and *resource influences (48%)*. As for *environmental influences*, the low percentage of coverage (11%) may be indicative of the struggle to "identify and characterize them in a "comprehensive, unified, and organized way" [7, p. 242]. Another possible reason for the lack of coverage may be due to the internal focus many researchers and practitioners are applying to KM.

As for RQ 2, the comparison of KM coverage in KM and IS journals showed a difference in the proportion of articles that address *application* (greater in IS journals). This may be evidence that IS journals are more receptive to KM research that is "applied" with respect to how IS tools and/or theory is used in support of KM efforts.

It must also be noted that, during the process of this research, the KM topic of *knowledge mapping* was found to be discussed in six percent of the articles reviewed. Although other researchers have considered this activity as a subcomponent of broader activities such as knowledge storage [1] and knowledge codification [4], others are addressing it as a separate activity under the KM umbrella.

7.1. FUTURE RESEARCH

The field of KM is in its infancy, and is likely to reflect many changes over the coming years. New journals are coming on line, old ones are evolving their editorial interests, and new areas of investigation are likely to evolve as well. Our first recommendation for future research might involve a time series study that would capture these changes and help to elucidate the changing nature of the field. A second suggestion involves the large number of articles published that address issues in knowledge transfer. It is quite possible that examination of these articles may provide insight into further refinement of the topic.

On the Definition of Exception Handling Policies for Asynchronous Events in Workflow Processes

Belinda M. Carter, University of Queensland, Brisbane, Australia; E-mail: bcarter@itee.uq.edu.au
Maria E. Orlowska, University of Queensland, Brisbane, Australia; E-mail: maria@itee.uq.edu.au

ABSTRACT

Exception handling during the execution of workflow processes is a frequently addressed topic in the literature. One important class of exceptions is those that represent predictable deviations from the normal behavior of the process that can be anticipated at design time. Such 'expected' exceptions are often caused by the occurrence of external events that are asynchronous with respect to the process. The desired exception handling response to these events will often depend on the current state of process execution. One important aspect of this state is the relevant process instance's progress through the process model, which can be expressed in terms of the set of currently executing tasks. In this paper, we present a qualitative discussion on issues relevant to the definition of policies for handling asynchronous, expected exceptions. First, we highlight the requirement for workflow control data to be referenced in the policies if these exceptions are to be handled in a meaningful way. We then demonstrate that the definition of exception handling policies is not a trivial exercise in the context of complex processes, and discuss correctness criteria for these definitions. Finally, we outline a methodology for policy definition to ensure that the policy for each event is complete and consistent with respect to all possible states of process execution for the relevant process model.

INTRODUCTION

Workflow technology is ideal for supporting highly repetitive and predictable processes. However, many processes are faced with the need to deal with exceptional situations that may arise during their execution [4]. Workflows may be affected by different types of exceptions: *system* failures such as hardware and software crashes and *logical* failures or exceptions. Logical failures refer to application-specific exceptional events for which the control and data flow of a workflow is no longer adequate for the process instance [10]. Many logical failures may be *unexpected*, and these must be handled manually on an ad hoc basis by knowledge workers. However, many exceptions are *expected* – the inconsistencies between the business process in the real world and its corresponding workflow representation can be anticipated, even if they might not be frequent [6]. That is, workflows describe the 'normal behavior' of a process whereas expected exceptions model the 'occasional behavior'.

Expected exceptions can be *synchronous* with respect to the flow of work, but most often they are *asynchronous* – that is, they can be raised at an arbitrary stage of the process, potentially during a long-duration activity [6]. This asynchronicity makes it difficult to model exceptions with 'synchronous' constructs like tasks and flows, but since the exceptions are strongly associated with the application domain, they are part of the semantics of the process and so therefore should be incorporated within the process definition [4]. Cancellations of customer orders and car accidents during a rental process are examples of asynchronous events.

In some applications, there may be one standard desired response to the occurrence of such an exception event, regardless of the execution state of the relevant process instance. However, in most real world scenarios, reaction to the events will often depend on the state of the process instance in execution. While there are multiple aspects of the execution state of a process instance, we define 'state' as the 'stage of progression' of the process instance, as expressed through the set of currently executing tasks, for the purposes of this paper.

For example, consider a simple business process for processing customer orders consisting of sequential tasks *Receive Order*, *Approve*, *Pack*, *Dispatch*, and *Bill*. Suppose that the customer may cancel their order, provided that it is not ready for dispatch. Thus, the policy for this exception event consists of two rules: if the customer attempts to cancel the order after the pack activity is complete, the cancellation is to be rejected; and if the customer cancels their order before the pack activity is complete, compensation tasks are to be executed in order to perform a 'semantic undo' of the order.

The focus of this paper is on defining such policies for handling expected exceptions that are based on external events that occur asynchronously with respect to the process. Exceptional situations are usually very complicated [8] and we argue that it is easy to define policies that may produce unintended execution behavior. In the following sections, we present a brief introduction to the basic principles of workflow specification and execution, and then summarize the related work. We then describe the definition of exception handling policies, demonstrate the complexity in reasoning about policies defined over complex process models, and discuss relevant correctness issues. Finally, we outline a methodology for the definition of 'correct' policies with respect to all possible states of process execution. We conclude with an outlook for future research.

WORKFLOW SPECIFICATION AND EXECUTION

Before we can consider exception handling, let us first briefly summarize the basic principles of workflow specification and execution that are required for the subsequent discussion. Before a workflow process can be enacted, it must be specified. The process model describes the order of execution of tasks according to the business policies and resource/temporal constraints. Each task (or activity) is a logical unit of work within a process that may be either manual or automated but performed by a single workflow participant. In this paper, we will adopt graphical process modeling notation whereby rectangles represent forks and synchronizers (concurrent branching constructs) and ovals represent choices and merges (alternative branching constructs). A process *instance* is a particular occurrence of the process, for example, a particular order represents an instance of an order processing workflow.

A *workflow management system* (*WFMS*) is a system that completely defines, manages, and executes workflows. In this paper, we adopt the standard functionality for a WFMS, including states for activity execution, as presented in [14]. During process execution, the WFMS maintains internal *control data* that includes the internal state information associated with the various process and activity instances under execution. There are also two types of data that flows between activities. *Workflow application data* is manipulated directly by the invoked applications. *Workflow relevant data* (also known as '*case data*'), is the only type of application data accessible to the WFMS, and can be thought of as a set of global variables.

RELATED WORK

Exception handling is not a new concept, and has attracted considerable attention in the literature. Many approaches for flexible process enforcement have been proposed. The first approach is to encode the entire workflow process through a set of rules, thereby ensuring complete flexibility. For example [3] and [7] present approaches where the process is described through a set of *Event-Condition-Ac-*

tion (ECA) rules (c.f. [13]). However, while processes encoded through rules enable all predefined behavior to be enforced, it is well known that large sets of rules can interact in unknown ways (e.g. [13]). The importance of verification of the process model before deployment has been emphasized in [12]. Representing the entire process through sets of rules also makes it difficult to visualize the process, which is a drawback when it comes to validation and maintenance. Ultimately, since the process is validated and maintained by business domain experts, the process should be specified in an intuitive way. Therefore, as much of the process logic as possible should be represented in the graphical process model – that is, the entire core process, at a minimum, and ideally the exception handling functionality too.

As already noted, this paper primarily addresses the issue of policy definition for handling expected exceptions that are based on external events that occur asynchronously with respect to the process. (Readers are referred to [9] for a framework to support ad hoc interventions when dealing with unexpected exceptions.) Essentially, there are two approaches for incorporating exceptional cases into a process model – 'exception rules' and 'exception workflows' [11]. The first approach is to implement exceptions through an explicit exception rule base [11]. Each exception is modeled by an ECA rule, where the event describes the occurrence of a potentially exceptional situation, the condition verifies that the occurred event actually corresponds to an exception that must be managed, and the action reacts to the exception [4]. A different approach is presented in [10] where the core process is dynamically modified at run-time based on a set of rules – when exceptional events occur during process execution, the AgentWork system identifies the workflow instances to be adapted, determines the change operations to be applied, and automatically performs the change for those instances.

Alternatively, exceptions can be modeled as workflow processes themselves [11]. This approach is taken in [2], which introduces the notion of Worklets, which are 'an extensible repertoire of self-contained sub-processes and associated selection and exception handling rules'. Choosing the most applicable worklet to execute in response to a particular exception is achieved by evaluating conditions that are associated with each worklet. These conditions are defined using a combination of current data attribute values and the current state of each of the worklets that comprise the process instance. It is noted that the set of states for a worklet-enabled process may be deduced by mining the process log file (c.f. [1]) but that full exploration of the specification of such conditions is yet to be completed.

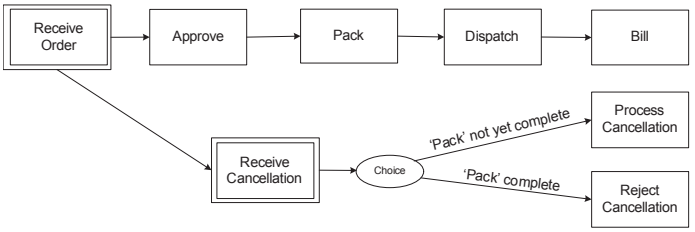
Another approach is to consider the exception handling processes as sub-processes within the core process. In the 'event node approach' discussed in [4], the workflow model includes a particular type of node, called an event node, which is able to observe asynchronous events and to activate its successor in the workflow graph when the event is detected. However, once again, it was noted that upon observation of an event, conditions 'can be used to select, among several exception management alternatives, the most adequate to deal with the current workflow state' [5], and to our knowledge, this issue has not yet been addressed in the literature. The definition of such conditions is the focus of this work.

EXCEPTION HANDLING POLICIES

An *Exception Handling Policy* ('*policy*') can be thought of as a set of ECA rules whereby for each such '*policy rule'* (*PR*), the *Action* is a sub-process ('exception handling fragment' in [6]) that is to be performed on observation of an *Event*, if the process execution state satisfies a particular *Condition*. The process execution state could involve many elements such as resource information and case data values, but for the purposes of this paper, we assume that the 'state' is described only through the set of currently executing tasks. The action may or may not involve terminating currently active tasks for that process instance, as dictated by the business requirements. The impact of the exception on the core process comprises the 'resolution' phase of the exception handling procedure, and while we acknowledge the importance of this phase, we focus our attention on the 'detection' and 'diagnosis' phases only in this paper (c.f. [11]).

While such policies could be defined and enforced through a set of rules, we emphasize that the underlying principles are the same if the exception handling is incorporated into the process model. We will adopt the event node approach for this discussion but it should be noted that these observations are generic and therefore applicable even if a worklet-style approach is adopted. For the sake of illustration, we distinguish a type of activity that assists with process coordination, called an *event listener*, which corresponds with the notion of an event node described in [4]. An event listener is an automated task that automatically completes on detection of a specific event. We emphasize the special role of these tasks in graphical process models by differentiating them with a two-line boundary. Event listeners allow the WFMS to observe relevant events asynchronously from the standard process in execution, enabling an immediate reaction to the event occurrence (following completion of the event listener task). This approach is also attractive because the exception handling functionality is incorporated into the process model but, due to the modular nature of the model, it is trivial to construct a view of the core process (or isolate a particular exception) for visualization purposes. It is also very extensible because the core process does not have to be modified. The example order process, incorporating the exception policy described earlier, is depicted in Figure 1. Observe the different process behavior on observation of the cancellation event according to the current state of the process instance.

Figure 1. Example scenario: Cancellation of customer order



Some of this exception handling process logic can be captured in the process model through the position of the event listeners – they can be placed at appropriate points such that if the event occurs before then, it is not observed by the process instance and therefore no action is taken. However, it will be usually be the case that a decision is (also) required to be made about how to handle the exception based on the workflow control data after it has occurred. To achieve this functionality (using standard modeling constructs, at least), a choice is required to be placed in the process model after the event listener activity to enforce the different PRs, where the choice conditions describe the status of the underlying process instance.

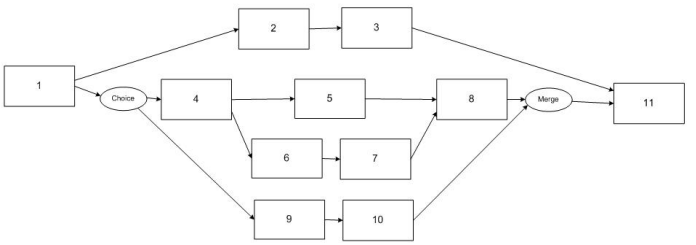
Generally, the conditions for choice constructs in a workflow process are based on case data that is generated during the activities that comprise the process (for example, an insurance application might undertake different treatment depending on whether it has been approved, with this decision being made during the execution of an activity). However, in order to enforce exception handling policies, workflow control data must also be referenced in the choice conditions. As already noted, this is a different type of data, maintained in the workflow log. From a specification point of view, there is no requirement that the choice conditions be defined on workflow relevant data only. We note that this reference to control data may impact on the underlying data model and system design, but we assume that such issues are resolved for the purposes of this paper.

CORRECTNESS ISSUES AND POLICY DEFINITION METHODOLOGY

We now consider the issue of correctness of exception handling policies. Note that we refer here to structural correctness rather than semantic correctness (that is, 'verification' rather than 'validation') since semantic validation depends on the particular application domain and so cannot be automated. We argue that there are two primary correctness criteria for exception handling policies – consistency and completeness. *Consistency* implies that no states have multiple actions defined for them, and *completeness* implies that there is an action defined for every possible execution state. If the exception handling behavior is incorporated into the process model then the choice conditions to be evaluated following the event listener must be mutually exclusive and collectively exhaustive, respectively, to satisfy these properties.

In graphical process models with no branches in the core process, each process instance is executing exactly one task at any point in time, and so these conditions are relatively simple to specify and verify. However, when concurrent branches are introduced into the process model, each process instance may be executing multiple activities at any point in time, and all combinations of these activities must be considered when defining policies. For example, for the process model

Figure 2. Example process model for discussion



depicted in Figure 2, the possible states are: *(1), (2, 4), (3, 4), (2, 5, 6), (2, 5, 7), (2, 8), (3, 5, 6), (3, 5, 7), (3, 8), (2, 9), (2, 10), (3, 9), (3, 10)* and *(11)*.

In general, it is difficult to reason about the correctness of policies when the process contains a large number of activities and choice/split structures. Since a thorough consideration of all possible states for a process instance is a complex task, it is therefore plausible and perhaps even likely that process designers may inadvertently omit one or more states when defining policies. For example, if one PR deals with the case where an event is observed 'before' reaching state *(3, 5, 6)* and another PR deals with the case where an event is observed 'during or after' reaching that state, the required behavior for the case where the instance state is *(2, 5, 6)* is not defined, and so the policy definition is not complete. Note that the intention during specification *may* be that no reaction is required in this case, but a case could be made for requiring the definition of a PR for all such states with a corresponding action of 'No Action', in order to make it explicit that all states were indeed considered during the definition of the policy but that exception handling behavior is not required in particular situations. This requirement for completeness would help to ensure that the exception handling policies are an accurate and complete source of 'process knowledge', making it easier to understand, verify and ultimately maintain the policies.

The consistency of the policy should also be checked to ensure that if an exception event is observed, there is only one possible way of handling the exception. As for completeness, this property is not trivial to check in policies defined on complex processes. For example, a policy that is defined such that an action is performed if an event is observed 'after' state *(2, 4)* and another is performed if an event is observed 'during or before' *(3, 5, 7)* is inconsistent because there is a conflict for state *(3, 5, 6)* – both policies apply in this case, which may or may not have been intended.

In addition to being *complete* and *consistent*, PRs should be defined only for *valid states* of the process instance, otherwise the policy will be unnecessarily complicated with 'noise'. This 'simplicity' can be considered a secondary correctness criterion for exception handling policies. For example, the specification of a PR for *(2, 4, 9)* is also erroneous since this combination of activities is not a valid state due to the choice construct in the process model.

We argue that tools should be provided to either prevent errors from being introduced in the first place or to detect errors in the model before deployment, just as for the specification of the core process model. In the remainder of this section, we briefly propose a systematic method for the specification of policies in line with the former approach.

First, all tasks are assigned unique identifiers, and all instance sub-graphs are generated (c.f. [12]). The set of all possible states is then generated for each instance type, and the union of the sets is the set of possible states for the process model. Clearly, the set of states could be large – the cardinality is dependent on the number of forks in the model, branches for each fork, and activities on each branch. However, all cases must be considered in order to prevent erroneous policies being defined. Also, since this set is a feature of the process model, it can be reused to define policies for an arbitrary number of events, once it has been generated.

The set of states is then partitioned for each policy, with one PR (and action) per partition. We call the set of states in each partition the *scope* of a PR – that is, the set of states of execution for which the action associated with the PR is relevant. Thus, each PR has an event to be observed, a scope, and an action to be performed if the execution state at the time of event occurrence is contained within the set of states comprising the scope.

Once the policies have been defined, the method for enforcing them clearly depends on the exception handling approach that is adopted. However, if only event listeners and other standard workflow modeling constructs are employed, the event listener is immediately followed by a choice construct in the process model, and the scope of the policy corresponds to the choice construct condition that must be satisfied for the relevant sub-process to be executed. That is, each state corresponds to a logical disjunct in the choice condition that must be satisfied for the action associated with the policy to be performed. Upon observation of the event (and completion of the event listener activity), the condition expressions are evaluated using the current control data for the instance. In order to ensure completeness and consistency of the policy definition, every state must be a disjunct of exactly one condition for each exception event. The condition on one of the alternative branches will always be satisfied and the action (sub-process) associated with the relevant policy is then performed.

CONCLUSIONS AND FUTURE WORK

Although workflow exceptions occur infrequently, their handling should be automated whenever possible. In this paper, we discuss the definition of policies to handle expected, asynchronous exception events. The desired reaction in response to these events will often depend on the current state of process execution, and we argue that the definition of exception handling policies for complex processes is a challenging exercise. We have introduced correctness criteria for such policies and outlined a methodology for policy definition to ensure that the policy for each exception event is correct with respect to all possible states of process execution.

In our future work, we will develop a methodology for the automated verification of exception handling policies for any arbitrarily complex workflow model. We will also relax the restriction that state is described only through process instance position (currently executing tasks) and consider case data and other types of workflow control data in policy definition and subsequent verification. Finally, we will consider the development of a software tool to assist with the specification and verification of exception handling policies.

ABSTRACT

Firms believe that new technologies can change the way we do business similar to the way the Internet has changed commerce. Today, an emerging technology so called RFID (Radio Frequency Identification) would change the way of current business processes between firms and suppliers and customers. This study focuses on contextual variables such as environmental, organizational, and technological dimensions as major determinants of RFID investment intention and moderator effect such as trust and power with partners in the context of supply-wide. Survey was resulted in 250 out of the 90 firms which RFID is already either implemented or is willing to adopt. Uncertainty, organizational size, top management support, IT infrastructure, and tag compatibility influence positively the likelihood of RFID project initiation. In turn, while trust of trading partners moderate between competitor's competition, top management support and the likelihood of RFID project initiation, whereas power of trading partners moderate the relationship between uncertainty, size, top management support and the likelihood of RFID project initiation.

Keywords: IT investment, IT infrastructure, Radio Frequency Identification Systems (RFID), Adoption.

1. INTRODUCTION

During the last decade, the large potential impact of the Internet in firms, especially, supply chain management, was timely important and indispensable in the digital economy (Swaminathan and Tayur, 2003). Collaboration by supply chain partners over Internet can potentially save $223 billion with the reduction in transaction, production, and inventory costs (Keenan and Ante, 2002). Even though many companies adopted the new supply chain systems, each functional department of those companies still requires manual works to initialize or finalize their processes, i.e., for example, manual data entry, manual scanning barcodes, unorganized information results. It implies that firms still require huge intervention of human labor forces to create valuable information; meanwhile, it happens possibly inaccurate data or information from the semi-automatic processes (Scharfeld, 2001).

To solve this problem, a new technology introduced in industries called Radio Frequency Identification (RFID) technology, which stands for a technology that involves tags that emit radio signals and devices called readers that pick up the signal (www.epcglobalinc.org) is going to be a $3 billion market within five years as this sophisticated tracking technology gradually begins replacing its cheaper but still less powerful than the bar code system (http://en.wikipedia.org/wiki/RFID). IDC reported that the investment of RFID has already carried $91.5 million until 2003 and expect the investment to increase $1.3 billion until 2008, and record the annual growth of 70%. Firms expect that the RFID systems will significantly accelerate supply chain productivity, performance and effectiveness throughout and across trading partners (Gramling et al. 2003). In order to start RFID project, firms have to perceive the internal facilitators or barriers as well as supplier relationship. As the previous collaborating systems (i.e., Electronic Data Interchange: EDI) reflected (Son et al., 2005), the role of trading partners' trust and power in collaborating systems make a different result.

Although IT adoption has been researched in various areas, it still remains to the most emerging technology such as RFID for business and supplier relations. With the emergence of RFID, many believed that firm would wary the effect of the significance. However, a few large firms are looking for a better solution for their organizational processes to exchange their information. Numerous studies via EDI, Internet, SCM, or interorganizational value-added network systems have found the effects of adoption and use, organizations are still willing to replace their existing systems with RFID systems for various reasons. Most importantly, RFID reduce considerably human intervention during the operational transactions.

The goal of this study therefore identifies the determinant for the RFID technology and system from a firm itself and shows particularly the trading partner's considerations. Surprisingly, empirical research on RFID adoption in organization has not found positive evidence insofar but also little known about the RFID adoption with partners. We address our research questions in our paper: What are the determinants of RFID project initiation on the firm level? How partners' trust and power moderates between the determinant and RFID project initiation? We explore the determinants and moderators of RFID, offer a conceptual model, and examine the relationship between identified factors and the likelihood of RFID project and trading partners' trust and power effect. We provide literature review in section 2, research model and hypotheses in section 3, research methodology, results, and discussion in section 4, conclusions, implications, and limitation in section 5.

2. LITERATURE REVIEW

2.1 RFID Technology/Systems

Like a bar code, a Radio Frequency tag is a data carrier. While a bar code carries data in a visible symbol and is read at optical or infrared wavelengths, and RFID device (or tag) carries data programmed into a chip and operates at radio frequencies, typically 125 KHz, 13.56 MHz, 2.45GHz and around 900MHz (AIM Inc WP-98/002R2). RFID systems have two different devices, which is actively transmitted called transponder; on the other hand, tags not actively transmit signals to a reader. Radio frequency in reader detects a tag at a remote distance without a necessity of any line, for example, a car that has an authorized tag can pass the entrance parking lot simply. RFID tags have specific data related to the identification of an object. Company will identify the tag attached on an object when a sale occurs, and then the tag will be deactivated after a consumer takes it out. RFID tags consist of a semiconductor chip with memory processing capability and a transmitter connected to an antenna. The tags have a different kind of memory type such as read only, write once, read repeatedly, or write and read together. Furthermore, recent tags have not a chip-called 'chipless tags' instead, these tags have a limitation of data storage, range and data transfer compared with chip-based tags. RFID tags can be divided into chip-based tags and chipless tags. RFID tags will be used mainly for payments, identification, information collecting or a

combination of the above (Intermec, 2003). The reader comprises an antenna and a controller. The controller codes, decodes, checks and stores the data, manages communications with the tags and communicates with the management system. Reader only reads data from the tags whereas an 'interrogator' reads data from the tags and writes data to them. The management system of RFID is the nerve centre for the application and forms part of the FRID user's information technology system. It is responsible for using the data received from and sent to the RFID tags for logistics and commercial management. Readers are also capable of reading all or only relevant parts of the data depending on how the system is programmed (AIM Inc, 2000).

2.2 Innovation and Adoption

Many innovation studies have researched in conceptual issue articles (Downs and Mohr, 1976; Ven de Ven, 1986) as well as empirical studies such as between innovation and performance (Damanpour and Evan, 1984), categorize types of innovations (Damanpour, 1987), and determinants and moderators of innovation (Damanpour, 1991). Damanpour (1991) explains the adoption of innovation that is the generation, development, and implementations of new ideas including a new product or service, a new production process technology, a new structure or administrative systems, a new plan & policy, program etc. Thong notes the Rogers(1983)'s definition of an innovation as "an idea, practice, or object that is perceived as new by an individual or other unit of adoption (p.190)'. Innovation occurs when a new idea is exercised and used across each employees or individuals (Damanpour, 1984), which is caused by not only firms' internal interest but also environmental factors (Damanpour and Evan, 1984), and which is the level of economic and social use of product and process consisting with needs and wants (Utterback, 1971). Innovation theory encompasses adoption, diffusion, and implementation of firms, which look for a better organizational efficiency and effectiveness (Damanpour, 1991). Innovation is a way of method to change organization, which is categorized as major three dimensions: administrative and technical, product and process, and radical and incremental (Damanpour, 1991). Administrative innovation refers to the wide range of changes in administrative core such as organizational structure, administrative processes, and management whereas technical innovation entails products, services, and production process technology that are primarily work activities in organization. Secondly, process innovation, which it improves production process through the new method, machines, or production systems. IS adoption may be included in this category, whereas, production innovation, which it introduces a new product, goods, or service to consumers. Finally, innovation can be realized radically (shock or big bang) or incrementally (gradually or phased approach). The adoption of IT is closely related to technical innovation and process innovation that can bring changes of organization processes or procedures.

Damanpour (1991) introduced 13 organizational determinants of innovation: specialization, functional differentiation, professionalism, formalization, centralization, managerial attitude toward change, managerial tenure, technical knowledge resources, administrative intensity, slack resources, external communication, internal communication, vertical differentiation. Premkumar et al (1994) reveal the most frequent cited factors of innovation such as compatibility, relative advantage, complexity, cost, communicability, divisibility, profitability, social approval, trialability, and observability. Ramamurthy and Premkumar (1995) categorize three dimensional determinant for IT diffusion: innovation factors (compatibility, complexity, cost-effectiveness, relative advantage), organizational factors (top management support, task scope, IS sophistication, championing), organizational learning (elapsed time after IS adoption). Tornatzky and Fleishcer (1990) have provided a considerable underlying dimension of determinant of innovation such as the context of environment, organization, and technology. Their theoretical framework provides a parsimonious view of determinant toward innovation; therefore, many IT researchers have applied their research framework into different type of applications in the various context (Chau and Tam, 1997; Chengalur-Smith and Duchessi, 1999; Chwelos et al., 2001; Forman, 2005; Grover and Goslar, 1993; Iacovou et al., 1995; Khoumbati et al., 2006; Premkumar, Ramamurthy, and Nilakanta, 1994; Rai et al., 1997; Thong, 1999; Zhu and Kreamer, 2005).

Environmental dimension: In early work of innovation, the environment conditions affect a firm to implement or adopt innovation (Mansfield et al. 1977; Utterback, 1971). Specifically, uncertainty in the competitive environment has received considerable attentions in the strategy literature. Milliken (1987) explains that the uncertainty is caused by the lack of information and the perceived inability toward prediction. Perceptions of environmental uncertainty occur when executives are unable to predict future changes in components of the environment or possess an incomplete understanding of the relationships among components of the environment. Much of the theoretical and empirical work on uncertainty has focused on perceptions of uncertainty in the firm's industrial environment (Tosi and Slocum, 1984). Environmental conditions in market are changing constantly through competition. Competitor is a major facilitator to enable a firm to think other strategic options (for example, IT investment) (Kim and Sanders, 2002). The competitor reactions or counter reactions on IT investments may affect the revenue or cost of a firm structure in a long-term base and can justify an IT investment decision making (Garud et al., 1998). In terms of bandwagon effect, bandwagons are not because of its innovation's benefit itself but because of pressure from other firms that have already adopted the innovation (Abrahamson and Rosenkorf, 1993). Abrahamson and Rosenkorf (1993) argued that technological, administrative, or strategic innovation would be adopted with bandwagon way if a firm feels losing competitiveness against competitors. Thus, competitors' pressures a firm to adopt an innovation as good as uncertainty in environmental conditions.

Organizational dimension: Ein-Dor and Segev (1982) introduced ten organizational context variables related to the success of MIS. These variables include organizational maturity, organizational size, organizational structure, organizational time frame, the organizational physiological climate toward MIS, the extra-organizational situation, organizational resources, rank and location of the responsible executive, and the steering committee. Among the ten organizational contexts, they stressed that size is recognized as an important determinant of organizational MIS structure both directly and indirectly. They measures organizational size as three measures: size relative to the relevant industry, number or employees, and total sales. Organizational size is traditionally the most critical factor to management literature (Dewar and Dutton, 1986; Moch and Morse, 1977). However, organizational size also has some controversial points that affect positively or negatively on innovation. Damanpour (1989; 1991) found that there is a positive relationship between organizational size and innovation, however, oppositely, large organization is usually more complex and slow, which make a firm to adapt to change hard and lead implementation slowly (Baker and Cullen, 1993). Many researchers have explained the reason of positive effect as following: economies of scale (Kimberly and Evanisko, 1981), slack resources (Eveland and Tornatzky, 1990), accessible outside resources (Attewell, 1992), and the dependable adoption risks (Hannan and McDowell, 1984), decision agility and prior technology experience (Zhu and Kreamer, 2005). In addition, management in organizational aspect is a critical factor as well. Empirical researches found that top management support has positively associated with IT implementation, success, effectiveness, and diffusion (Ramamurthy and Premkumar, 1995; Thong et al., 1996). Favorable attitude of top management toward innovation affect organizational climate and lead member's behavioral change, since top management has broad view of IT and responsibility of IT strategy, planning objectives, policies, and funding (Thong et al., 1996).

Technological dimension: Bharadwaj (2000) claims that the importance of IT capability of a firm and a firm's IT infrastructure that composes of computer and communication technologies and the shareable technical platforms and databases. In this age, as firms' IT infrastructure span not only entire organizations but also link key supplier and customers in helping its cross-functional processes and cross-selling opportunities. Developing a RFID system may require the current IT infrastructure including enterprise database, network, and operation system would combine seamlessly for the data flow from one application to another and from one part of an organization to another. Taniverdi (2005) asserts standardized IT infrastructure enable firms to span their business processes and provide information and knowledge exchange. Another important factor in technology dimension, current systems VS. New systems should be compatible. Compatibility is conceptualized as consistent existing practices, values, past experience or norms with a new adopting of innovation (Forman, 2005). IT comprises several aspects concerning the compatibility, which should fit with the legacy system, other organizational systems or new one such as hardware, software, and infrastructure, for example, integration of data from different database systems of other organizations, or between interorganizational systems (Ein-Dor and Segev, 1982). Researchers have claimed that those three dimensions (environment, organization, technology) have been consistently found to be important.

3. RESEARCH MODEL AND HYPOTHESES

Based on the literature, we suggest the likelihood RFID project initiation model shown in Figure 1. In this model, we conceptualized as consisting of environmental, organizational, and technological dimensions toward the initiation of RFID project directly and moderating effect of trust and power between firms and trading partners for the initiation of RFID project. Accordingly, we develop and test, firstly, determinants and dependents hypotheses representing: (H1, H2, H3) and, secondly, moderating effects on between the determinants and the likelihood of RFID project initiation representing: (H4, H5).

3.1 Environment

Environmental dimension are categorized as uncertainty and competitors (Miller and Droge, 1986). Uncertainty in this study is defined as the inability to predict product and service from changes in market. As the variety of products and services offer in market, firms are hard to predict market conditions. In addition, depending on the number of competitors and action of competitors, firms tend to pursue strategic options to cope with market conditions (Kim and Saunders, 2002). Concerning the environmental factors with IT&S innovative adoptions, there still be arguments on either a positive impact or not. Grover and Goslar (1993) found significant relationships between environmental uncertainty and the usage of these technologies, vice versa, others who applied the environmental factors in their open system adoption (Chau and Tam, 1997) and CASE tool adoption (Rai and Patnayakuni. 1996) did not find the significance or negative between the market uncertainty and adoption. The findings may be resulted in differently depending on the context, type of applications. The environmental issues including uncertainty and competitors are importantly related to RFID adoption whether firm are willing to invest to preempt the RFID future market such as Wal-Mart or slow because of environment uncertainty. Thus, we suggest the following hypotheses:

H1-1: The relationship between environment uncertainty and the likelihood of RFID project initiation has significantly associated.

H1-2: The relationship between competitor's action and the likelihood of RFID project initiation has significantly associated.

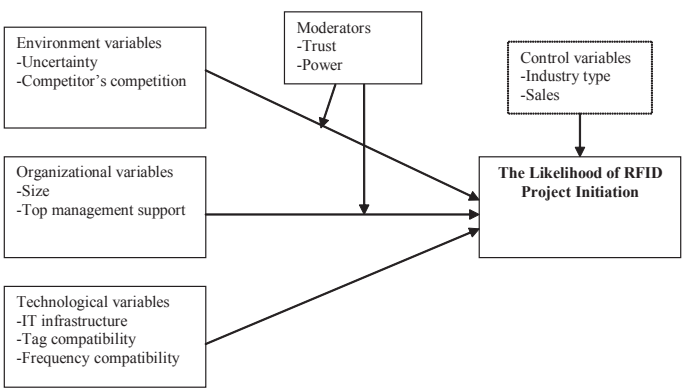
3.2 Organization

Ein-Dor and Segev (1982) posited that organization's size tend to affect organization context. They provide validity of measurement by the number of employees. Organizational size was found as strong determinant of innovation (Damanpour, 1989; 1991). Also, many empirical findings have shown the positive relationship with IT adoption ( ). In terms of RFID, many large firms such as Wal-Mart, Target, and DOD have interested in replacing Bar code systems as RFID as a strategic option. In addition, Damanpour (1991) posits that administrative intensity is one of critical determinant for innovation. Successful adoption of innovation always depends on largely on leadership, support, and coordination of manager. IT innovations always cope with risks of failure caused by the lack of financial support (Ramamurthy and Premkumar, 1995), therefore top management support is essential. In empirical research, top management support has positively associate with adoption, and diffusion (Ramamurthy and Premkumar, 1995, Thong et al., 1996; Wang et al., 2006). Given the potential of RFID to influence the firm's strategic interest and internal operational efficiency as well as its trading partner's relationships, top management will be strongly involvement necessary, need a strong support for initiating RFID project. Hence, we propose:

H2-1: The relationship between organizational size and the likelihood of RFID project initiation has significantly associated.

H2-2: The relationship between top management support and the likelihood of RFID project initiation has significantly associated.

Figure 1. The likelihood of RFID project initiation model



3.3 Technology

IS research has posited that IT infrastructure, IT maturity, and IS sophistication such as IT resource, skill, and expertise is positively associated with IT success, adoption, diffusion, and performance (Grover and Goslar, 1993; Ramamurthy and Premkumar, 1995, Tippins and Sohi, 2003; Taniverdi, 2005). Zhu and Kreamer (2005) show that EDI and Electronic Fund Transfer infrastructure make a firm easy to do Internet business. RFID is essentially necessary from the current IT infrastructure support so that data transactions can be seamlessly overall internal organization as well as external trading partners. In addition, IT compatibility refers to the degree of consistency with the existing legacy systems, procedures, and new systems (Forman, 2005). The more IT innovation compatibility exists, the more likely firms will adopt the new systems (Premkumar et al., 1994). Current state of RFID has lack of standards, which various applications and industries not only pursue different vendors' competing frequencies and protocol but also not even exist yet open systems (AIM inc, 2001). The key components of an RFID system are tag (Asif, 2005) and frequency (AIM Inc, 2001). Choice of tag and frequency wave is also primary importance in determining data transfer rates (AIM Inc, 2001). Thus, type of tag and frequency compatibility would be primary concerns for firms that are likely to adopt the RFID. Here, we propose the following hypotheses:

H3-1: The relationship between IT infrastructure and the likelihood of RFID project initiation has significantly associated.

H3-2: The relationship between types of RFID tag and the likelihood of RFID project initiation has significantly associated.

H3-3: The relationship between types of RFID frequency and the likelihood of RFID project initiation has significantly associated.

3.4 Moderator Effects

Some studies have shown evidence of a positive relationship between trust and power and EDI use and adoption (Hart and Saunders 1997;1998; Son et al., 2005). However, these findings have not discussed major determinants of innovation in theoretical basis that might affect innovation. We assume that the possibility of a moderating effect that affects the effectiveness of innovation adoption and use is consistent with traditional variables for the innovation theory. On the basis of Hart and Saunders (1997)'s study, we induce trust and power possible moderator effects of major innovation determinants on IT adoption. We will examine that trust and power could affect the relationship environmental and organizational dimensions and IT adoption. If these moderating effects exist, firms should focus on possible considerations for the adoption through adjusting the degree of trust and power with trading partners. For example, a new technology in the early stages of a market is influenced by uncertainty as well as by competitors' behavior. Also, it is important to remember that organizational factors are important element of innovation and thus both organizational size and its management support would be crucial to strengthen or weaken the relationship of determinant and IT adoption.

Trust: Hart and Saunders (1997) posit that trust is vital factor in interorganizational relationship. Its trustful relationship facilitate firms to invest their shareable resources rather that behave opportunistic action among other alternatives. Trust explained by Hart and Saunders (1997) is "the behavior of another will confirm to one's expectation and goodwill of another" (p.24) without exploring vulnerability. In terms of firm's trust, which one firms can make another firm perform better and would not make negative result for the firm (Son et al., 2005). Trust may not be build by artificial relation or just long-term trading but "fair dealing" between buyer and supplier in a reciprocal transaction (Hart and Saunders, 1997). In terms of IT systems, IT encourages firms to share information with their partners. Once firms and their partners make a co-investment on IT, its benefit arises from not just coordination but the reduction of uncertainty for the future. Son et al (2005) stress that reciprocal investment draws one party desires to stay relationship firmly into the future. To improve their collaboration through IT, firms first build trustful relationships with their partners. The collaboration based IT and trust enables the

firms to span their business processes and enrich their information sharing with partners. Thus, trust makes a strong relationship to bring co-IT investment and sharing assets and accomplish their strategic and operational outcomes through IT. RFID also needs to share information with between buyer and supplier more enhanced method, even individual customers. The main benefits of RFID exists transaction with suppliers and buyers having accurate information, visible stock data, physical inventory counts such as receiving, picking and shipping, and so on. To achieve this objective, firms need to build RFID into the entire supply chain of transaction and planning systems—of its own plans as well as those of its suppliers and customers. It is strongly necessary of firms to share RFID project plan based on partner's trust. Recently, Zhu et al (2006) study that a moderating variable affects between independent variables and dependent variable, which they incorporate a firm's prior experience of EDI the relationship between the adoption costs and the open-standard EDI adoption. They found that firms that have experienced EDI made a different response toward the Internet based Inter Organizational Systems (IOS). Based on the notion of moderating effect, we infer that the likelihood of RFID project initiation will be differently depending on trust. In this study, we assume that trust would moderate the relationship between environmental factors and organizational factor and RFID project initiation. Hence, we provide the following hypothesis:

H4-1: Trust with trading partners will moderate the relationship between environmental uncertainty and the likelihood of RFID project initiation.

H4-2: Trust with trading partners will moderate the relationship between competitors' competition and the likelihood of RFID project initiation.

H4-3: Trust with trading partners will moderate the relationship between organizational size and the likelihood of RFID project initiation.

H4-4: Trust with trading partners will moderate the relationship between top management support and the likelihood of RFID project initiation.

POWER: Hart and Saunders (1997) posit that power can affect change of a trading partner. A buyer-supplier relationship for adopting a new technology is resistant, hesitant, disobedient, or refuses from the trading partners. In those cases, firms that are more powerful use their power to less powerful partners to listen, and act for their proposal. Hart and Saunders (1997) define power as "the capability of a firm to exert influence on another firm to act in a prescribed manner" (p.24). Thus, using power for partners is a very useful method that adopts EDI (Chwelos et al., 2001). Generally, power depends on a firm's revenue, if a certain buyer generates a supplier's revenue with a large portion, the buyer can have power against the supplier under the condition of other alternatives to be options (Hart and Saunders, 1997). In case, the buyer pushes the supplier to accept its proposal. Vice versus, if the numbers of suppliers are small, unique (Williamson, 1985) or not any alternatives, then, buyers relatively more depend on suppliers, which oppositely decrease the control power for the supplier (Hart and Saunders, 1997). They explain potential power and exercised power, which potential power is a type of influence that is not yet exercised that most likely to influence in EDI adoption when a less powerful firm has already adopted EDI. On the other hand, exercised power is a type of influence in EDI adoption when a less powerful firm has not any EDI with any other trading partners (Hart and Saunders, 1997). Power can be exercised two ways: persuasive and coercive. Persuasive method is that firms that are more powerful give rewards or benefits to their partners in response to their request. Vice versus, coercive method is that firms that are more powerful threat verbally they would stop doing business or actual punishment to the firms that are less powerful unless they don't listen. Power allegedly frequently exercises in industries such as automobile, large retailers like Wal-Mart, Sears etc. (Hart and Saunders, 1997). However, there are not many researches on the moderating effect of power between determinants and dependent variables. Thus, we exploratory test that power will moderate the relationship between environmental factors and organizational factors and RFID project initiation. We suggest the following hypotheses:

H5-1: Power with trading partners will moderate the relationship between environmental uncertainty and the likelihood of RFID project initiation.

H5-2: Power with trading partners will moderate the relationship between competitors' competition and the likelihood of RFID project initiation.

H5-3: Power with trading partners will moderate the relationship between organizational size and the likelihood of RFID project initiation.

H5-4: Power with trading partners will moderate the relationship between top management support and the likelihood of RFID project initiation.

3.5 Control Variables

We consider two control variables to affect our results: Industry type and sales. First, industry type may significantly affect innovation adoption (Zhu et al., 2006), since industry-specific type may specially have interested in RFID adoption such as retailing and logistics, manufacturing, and IT&S software industries, which those industries would expect to achieve a major benefit from the automatic value chain activities. Second, firm size may significantly affect innovation adoption, because large firms may have more slack resource. Douma et al. (2006) assert that sales are a proxy for the size of a firm. Fiss (2006) used an alternative measure such as sales for firm size. Thus, our study set two control variables in our analysis, which variables are various industry type and broad range of sales, may affect our results.

4. RESEARCH METHODOLOGY

4.1 Data Collection

We collected data using survey questionnaire for a wide range of firms and industries from South Korea, in which RFID has either already implemented or being implemented or is plan to adopt RFID. The names and address of ninety firms that have interested in RFID is obtained from LGCNS Company, which is one of biggest IT service companies in South Korea. LGCNS provided the list of potential firms that are planning to adopt RFID for its potential RFID project. We made survey instruments based on IS literature and pretest them for 40 MBA students to ensure the validity of our data. Over two months from early October through late November of 2004, we conducted 250 survey by visit, mail, email, and fax for two or three people simultaneously at a same company (project manager, consulting partner, IS senior executives, task employee, middle managers), who are involved in RFID TFT(Task Force Team) out of 90 firms. They are all involved in RFID project. Before we contact each respondent, we call everyone and explain the purpose of this study, on the other hand, when we visit, we also explain to the respondents about the goal of this study. We collected totally 195 out of 250 surveys from the 90 companies. The response rate is 78%, unusable data is 24, then, 171 used for analysis (response rate: 68.4%). We collected data from various industries such but mainly retail & logistics (40.0%), manufacturer (26.7%) and sales range from over 50 million U.S dollar (15.5%), 1-5 million (30.0%), and 0.5-1 million (32.3%). The plan of RFID adoption will be within one year (42.1%), and 6 month (20.0%), being implemented (7.8%), and already implemented (8.9 %). See Table 1.

4.2 Data Analysis

Instrument Development: To develop the survey instrument, generally accepted instrument development guidelines were followed. Scale items are shown in

Table 1. Statistics of demographic

		Frequency	Percent
Industry	Manufacturing	24	26.7
	Plant & Constructing	7	7.8
	Retail & Logistics	36	40.0

Appendix A. Many items were derived from earlier work and adapted them to this study. However, scale items for tag and frequency compatibility were newly development. Although many scholars have developed compatibility, there is few for RFID tag and frequency. To measure used in this study is a 7 Likert scale (Strongly disagree =1 or Strongly agree =7) measure of detailed aspects of adoption determinants in IT&S implementation that researchers is likely to adopt. The development of the compatibility of tag and frequency was grounded in the work of ABI Research (2003).

Descriptive Statistics and Correlations: The Pearson Correlation Matrix for the likelihood of RFID initiation was analyzed. The correlation among the independent variables were conducted by the aggregated measure of each variables in Table 2.

Data Reliability and Validity: Table 3 shows the result of reliability test. The reliability analysis is conducted on the 24 items that measured the components for this study. Cronbach's alpha value is showed over 0.6, which the value is recommended as threshold for the exploratory research (Nonnally, 1978). All constructs had higher than 0.60 cutoff alpha values, ranging from 0.6213 to 0.8968.

For convergent validity, items having item-to-total correlation scores lower than 0.4 were dropped from further analysis in Table 4. Factor analysis is used to check discriminant validity. Because each variable was measured by multi-item constructs, factor analysis with Varimax method is conducted to check the unidimensionality among items. Items with factor loading values lower than 0.5 are deleted.

Table 3. Reliability

Variables	Items	Cronbach's Alpha
Environment Uncertainty	2	0.6328
Competitor's competition	3	0.6425
Organizational size		N/A
Top management support	3	0.8851
IT Infrastructure	5	0.8968
Tag compatibility	2	0.7555
Frequency compatibility	3	0.6213
Trust	3	0.8569
Power	3	0.8140

4.3 Regression Analysis

A hierarchical regression analysis tests our hypothesis. For each hypothesis, each dimension of independent variables is run for the dependent variable separately and control variables (industry type and sales) are included in each regression analysis as shown in Table 5. Our model is considered as an aggregated variable, and its correlation is computed. To meet the assumptions of regression analysis, we examined the linearity, constant variance, and normality (Hair et al., 1995). Our model includes industry type and sales as a control variable shown significant positive relationships between two control variables and the likelihood of RFID initiation. Table 5 presents the regression analysis results. In this study, we used a hierarchical regression analysis the following equation model.

Equation:

The Likelihood RFID Adoption =f(Independent variables, Control variables)

$Model1=\alpha_0+\beta_1 ENV\_U+\beta_2\ COPTR\_C+\beta_3 Industry+\beta_4 Sales+\varepsilon$

$Model2=\alpha_0+\beta_1 OS+\beta_2\ TMS+\beta_3 Industry+\beta_4 Sales+\varepsilon$

$Model3=\alpha_0+\beta_1 ITINFRA+\beta_2\ TG\_C+\beta_3 FRE\_C+\beta_4 Industry+\beta_5 Sales+\varepsilon$

The results supported hypotheses 1-1, 2-1, 2-2, 3-1, and 3-2. The likelihood of RFID project initiation is significantly associated with environmental characteristics (uncertainty), organizational characteristics (size, top management support), and technological characteristics (IT infrastructure, tag compatibility), and two control variables (industry type, sales) are also associated positively with the likelihood of RFID project initiation. One environmental characteristics (competitor's competition), and technological characteristics (frequency compatibility) are not significantly related to the likelihood of RFID initiation in Table 5.

Moderating effect is explained as the impact of a predictor variable that has on a criterion variable is rest on the level of a third variable called the moderator (Venkatraman, 1989). It will affect the direction of strength of relationship between independent variables and dependent variables.

Y = f(X, Z, X*Z), X, Z are independent variables, Y is dependent variable, and X*Z is represented as a joint effect. Moderating effect equation set into following way:

$Y=\alpha_0+\alpha_1 X+\alpha_2 Z+\varepsilon$

$Y=\alpha_0+\alpha_1 X+\alpha_2 Z+\alpha_3 X*Z+\varepsilon,$

4.4 Result and Discussion

We investigate two-dimensional sides for the likelihood of RFID project initiation. One hand is the determinant effects, on the other hand is the moderating effect on the relationship between determinants and the likelihood of RFID project initiation. The data analysis shows that environmental uncertainty has a major effect on the likelihood of RFID project initiation, whereas competitor's competition is not significantly related. Organizational size and top management support, both, are strongly effect on the likelihood of RFID project initiation, and IT infrastructure and tag compatibility influence positively the likelihood of RFID project initiation, except frequency compatibility is not related. As RFID technology emerges in market, many firms expect the benefits and predict their RFID potential impact on business, then, shows more positive attitude toward the RFID adoption under uncertainty. This result provides support for Grover and Goslar (1993)'s findings which uncertainty is positively related to telecommunication adoption. But, inconsistently, competitor's competition (competitive intensity) does not show a significant relation as good as Grover and Goslar (1993)'s. Organizational size and top management support are consistent with the IS literature. A firm that is a large size is likely to a chance to invest a new IT with enough slack resources (Forman, 2005, Teo et al. 2003; Zhu and Kreamer, 2005). Top management support is always critical factor for adoption innovation in a firm. If the innovation is viewed as a better solution for the firm than the existing system, it is paid attention by top management. Another major determinant affecting of the decision to adopt RFID is IT infrastructure, since the RFID technology should heavily depend on the existing systems. Compatibility of tag and frequency is a peculiar issue for RFID system that should carefully concern not likely other systems. RFID consists of the tag and frequency. Practically, the rate of data transfer is affected by the frequency of the carrier wave. The higher the frequency the higher the data transfer. Depends on the type of tags (passive or active tag), the passive tags are less expensive and unlimited operational lifetime but shorter read ranges, whereas the active tags is higher data transmissions rates, which has the ability to perform well in electromagnetically noisy environments (AIM Inc. White Paper, 2001). Depends on the type of tag and frequency, firms' RFID investment cost and overall organizational effectiveness would be different. RFID is a technological innovation that demands a large portion of IT budget of firms. Most of all, the tag and frequency will affect the future projects that would be extended based on the prior type of tag and frequency. In the context of RFID adoption by firms, the capacity of tag and frequency should be compatible with not only the current organizational process but also current using systems.

The moderating effects are also examined. When trust with trading partners is involved in the relationship between competitor's competition and the likelihood of RFID project initiation, the result changes statistically significance but negatively moderate on the relationship (β: -.509; $p<0.05$). Top management support also is negatively moderated by trading partner's trust (β: -2.256; $p<0.01$). In terms of the trading partner's power, the power moderates positively the relationship between environmental uncertainty and the likelihood of RFID project initiation (β: 1.233; $p<0.05$), whereas the power moderate negatively both relationship between organizational size and top management support (β: -2.960; $p<0.01$; β: -2.252; $p<0.01$). In addition, we show more specific further analysis about power, which a firm has higher power or lower power toward the trading partners. Figure 3 presents the moderating effects of power through graph. The high power group is relatively showing the higher moderating effect than the low power group does. In sum, uncertain business environment, organizational size, and top management support shows that there is moderating effect by firm's power. The moderating effect of trust is negatively engage in competitor's competition and top management support.

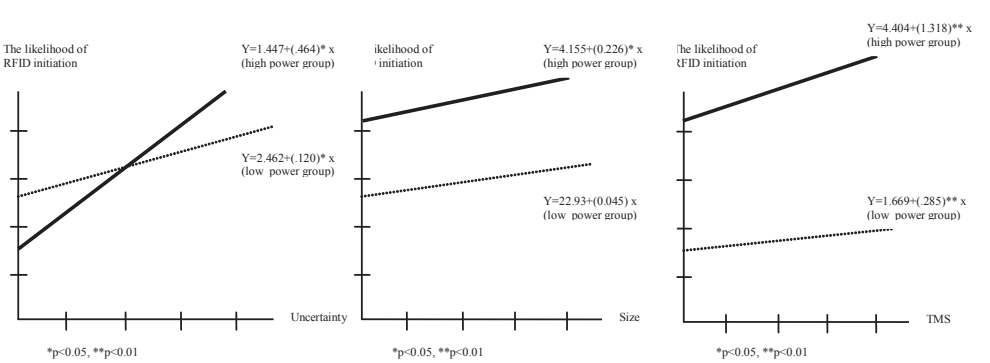
5. CONCLUSIONS

Technology adoption has widely been researching in IT&S areas with innovation theory. This study developed and tested an exploratory model of RFID adoption in early RFID stages. The results support the almost of all hypotheses that are suggested. Three deterministic variables and two moderating variables are important factors in explaining the consideration of RFID project initiation. Environmental uncertainty, organizational size, top management support, IT infrastructure, and tag compatibility have a direct impact on the likelihood of RFID project initiation, whereas the competitor's competition and frequency compatibility have no direct impact on the likelihood of RFID project initiation. In case of moderating effects, trust and power of trading partners show different results on the relationship between determinants and the likelihood of RFID project initiation. Trust moderates the competitor's competition and top management support on the likelihood of RFID project initiation, whereas power moderates the uncertainty, organizational size, and top management support on the likelihood of RFID project initiation. Therefore, the moderating effect supports partially our model.

There is a question why the degree of competition and top management support should be influenced by trust moderator. According to Premkumar and Ramamurthy (1994)'s findings, they found competitive pressure is related to reactive adoption of EDI, whereas top management support is related to proactive adoption of EDI. Those two factors are found evidence of a close relation with their trading partners (Hart and Saunders, 1998). Therefore, we assume trading partner' trust may strength or weaken the determinant and RFID adoption. Indeed, a substantially IT adoption should find more opportunities with trading partners than any other conditions. On the other hand, uncertainty, firm size, and top management support why should be influenced by power moderator. Power is the firm's ability to influence change in another firm that trade. We assume that large firm has more power to their partner than small firms do and top management support would be different depend on its partner's power under the uncertainty. For example, large firm can threaten to quit trading with partners unless the firm adopts RFID. This is why trust and power is as important and is supported as moderator. In sum, the trust and power play an important role for RFID adoption in interorganzaitonal IS system implementation.

The study provides some implications for both practitioners and researchers. In response to practical implications, the study explores the determinants and RFID adoption in early stage of RFID systems. Firms understand not only the benefits of RFID adoption but also the important factors that can facilitate to invest the RFID systems with trading partners. When RFID systems implement, trust and power of trading partners may influence. If the RFID system is not perceived as beneficial to the trading partners, there is no reason for partners to adopt it. The RFID must also be compatible with trading partners' benefits; otherwise, it would be conflict for both firms and trading partners to understand mutual interests. In terms of research implication, although this study is one of the empirical IT&S adoption researches, we explored RFID systems adoption in an early stage with a technological innovation theory.

Figure 3. Power effect between higher power group and lower power group



5. 1 Limitations and Future Research

This study has also some limitations that should be recognized. This study is the perception base of the employees who are involved in RFID task force team, so the results can be showed in a bias way from the side of a firm that has interest in RFID. Therefore, the results of this study should be carefully translated with caution. Second, there exists many other innovation characteristics to IT&S adoptions; we did not include the complete innovative variables that can affect the RFID adoption. Future research can examine other potential variables with other context.

APPENDIX A
Measurement Items

Constructs	Items	Scale
The likelihood of RFID initiation	Has your firm planned to adopt RFID technology in near future?	1= No plan 2= Within 3 years 3= Within 1 year 4= Within 6 months 5= Being implemented 6= Already implemented
Environmental Uncertainty	Prediction of product preferences change Prediction of the demand of product and service	Jaworski and Kohli (1993) Son et al. (2005) 7-Point Likert Scale
Competitor's Competition	The level of competition in our industry RFID that one competitor can initiate, others can follow readily One hears of a new rival develop/adopt the RFID systems	Adapted from Jaworski and Kohli (1993) Adapted from Reich and Benbasat (1990) 7-Point Likert Scale
Top management support	Top management supports for RFID project Top management willingness to take the (financial and organizational) risk involved in the adoption/development and implementation of RFID Top management's commitment to provide adequate financial and other resources for the development and operation RFID systems	Ramamurthy and Premkumar (1995),
Organizational size	The number of employees	Zhu et al. (2005)
IT infrastructure	IT expertise on RFID IT human professional resources Hardware resources Software resources Network resources	Adapted from Ramamurthy and Premkumar (1995),
Tag Compatibility	Compatibility with tag cost and total RFID systems' budget Compatibility with the existing IT infrastructure	Adapted from Ramamurthy and Premkumar (1995), ABI Research (2003)
Frequency Compatibility	Compatibility with industry characteristics Compatibility with the frequency's competitiveness Compatibility with the standardized frequency	
Trust	Trading partners and our company have a high level of mutual trust Trading partners and our company does fair trading Trading partners stands by its word	Son et al. (2005)
Power	Trading partner has influenced our decision to initiate RFID Trading partner, rather than our company, was the main force for RFID initiation Trading partner has used coercive techniques for initiating RFID project	Adapted from Son et al(2005) Adapted from Hart and Saunders (1997)
Sales	Less than $ 0.5 mill=1, $0.5-1 mill=2, $1-5 mill=3, $5-10 mill=4, $10-50 mill=5, Over $ 50 mill=6.	
Industry type	Manufacturing=1, Financing & Accounting=2, Plant & Constructing=3, Retail & Logistics=4, IT & IS Service=5, Non-profit Org=6.	

Innostructure: Managing Innovation as Business-Critical Infrastructure

Ron Fulbright, University of South Carolina Upstate, 800 University Way, Spartanburg, SC 29303; E-mail: rfulbright@uscupstate.edu

ABSTRACT

The last few years have seen increasing interest in organizational innovation—changing an organization to enhance its ability to sustain innovative thinking and problem solving. Most companies plan to increase spending on innovation this year continuing a five-year trend. However, executives report not being satisfied with the return on investment in innovation. We argue that the wrong metrics are being used because innovation is not being treated as a business-critical infrastructure. We propose a high-level architecture for an infrastructure supporting organizational innovation—the innostructure—and describe how performance of this infrastructure can be monitored and optimized.

INTRODUCTION

In 2004, the former Chairman of the Federal Reserve, Alan Greenspan, observed that the new paradigm of *globalization and innovation* represented a "one-time shift" in national and international economics (Greenspan, 2004). Globalization, the extension of the division of labor and specialization beyond national borders, is driving companies to be competitive in new ways. One response is the acceleration of the pace of innovation. Companies too slow to react to the changing marketplace are out-performed by more agile, sometimes foreign, companies. As a result, chief executives are spending on innovation and are trying to feel their way into an unknown future. According to the Boston Consulting Group (BCG), 74% of companies will increase spending on innovation in 2006, roughly the same as the 72% in 2005 and up from 64% in 2004 (Andrew, 2005), (Andrew, 2006).

However, the BCG studies also report that most executives are not satisfied with the return on investment in innovation spending. Reasons cited for this disappointment include:

1. difficulty in gauging costs and returns
2. development times that are too long
3. lack of coordination within the company
4. not enough insight into customers
5. risk-averse culture in the corporation.

We maintain the primary reason for the disappointment in gauging returns (#1) is that a direct measure of payoff from spending on innovation is not an appropriate assessment measure. We believe innovation should be woven into the fabric of the company itself as a business-critical infrastructure like information technology resources are today. No company today would be considered a serious company if it did not have telephones, fax machines, e-mail, computers, etc. The day is fast approaching when a company without an infrastructure supporting innovation, something we call the *innostructure*, will not be considered a serious company. Such an integration addresses the disappointment in coordination (#3).

History is replete with examples of corporate spending on fads and popular buzzwords enjoying popularity for a few years only to be lost in the rush to the future. We fear interest in innovation will wane accordingly due to the perceived lack of immediate results. This will not only be unfortunate, but a critical mismanagement of something we understand to be a critical business resource—innovation.

Our belief is that innovation is the emergent behavior of the complex adaptive system of humans, information, knowledge, wisdom, and market forces. We propose here the best way to architect the innostructure that supports this innovation is as a scale-free network of collaborators—something we call the *innovation metanetwork*. The metanetwork is an open collaborative system allowing customers and other outside parties to collaborate with company employees, addressing the disappointment in knowing customers (#4).

Constructing the innovation metanetwork as an emergent, scale-free network allows its performance to be monitored, measured, and controlled by objective metrics thereby replacing the troublesome metrics in #1.

WHY THE GLOOM?

The fact that most executives continue to increase spending on innovation while not being satisfied with the results is seemingly a paradox that begs for an explanation. Looking at the studies, we offer that the executives' expectations are misplaced. The executives appear to expect immediate and quantifiable impacts to the corporate bottom line (Andrew, 2006b). We maintain this is not the most effective way to measure corporate innovative effort.

As an illustration, consider what would happen if the CEO of the company wanted to know what the return on investment was in purchasing a new network router. Imagine if it were necessary to measure and report the increase in corporate sales attributable to the new router. It would be easy to show how effective bandwidth might increase and one could point to statistics showing reductions in network latency. Everyone would agree the new router was a good thing to have and no one would argue for its removal.

However, did the router increase corporate profit? The router, its installation, and the metric-gathering cost the company a non-zero amount of money. So to be profitable, does the router have to recoup its own cost in terms of increased sales? If so, how would you determine that an increase in sales would not have happened if the router had not been purchased?

The problem, of course, is there are many more things, other than the new router, that must happen for corporate sales to increase. True, increased network speed, because of the router, may allow a salesperson to respond to more customers and, therefore, close more sales. But because so much else goes into closing the sale, the contribution of the router is obscured.

We think a similar phenomenon is happening with those who are attempting to measure return on investments in innovation spending. The expectation seems to be that a tool will be purchased, someone will use it to produce the next great product, and the company will make a fortune all because it "invested" in the tool. This "eureka" scenario may very well happen, but more likely, and more realistic, is that use of the tool will incrementally improve something in the enterprise which will enable something else to happen, and so on, until ultimately, the effect snowballs to a threshold where a true bottom-line impacting event occurs.

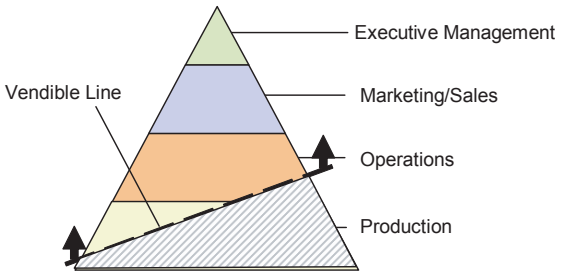
If this is true, the disappointed executives are looking at the wrong metrics. We believe innovation must be infused throughout the organization as a strategic infrastructure component. Therefore, the metrics one uses to measure success of that infrastructure should be oriented toward measuring the infrastructure itself rather than some ultimate application of the infrastructure.

WHY COMPANIES MUST INNOVATE

We begin by modeling an enterprise as a hierarchy shown in Figure 1. This is a visualization we have developed, called the Vendible Model, for in-class discussion of alternative sourcing (Fulbright, 2004)

Enterprises are modeled on the basis of the amount of resources produced internally versus the amount of resources purchased from external entities. The vendible line defines the boundary between internally sourced resources, the strategic regime, and externally sourced resources, the commodity regime.

Figure 1. The Vendible Model depicts the vendible line partitioning an enterprise into a part that cannot be outsourced, called the strategic regime (above the line), and a part that can be outsourced, called the commodity regime (below the line).



Resources of higher strategic value are depicted near the peak and the resources with lower strategic value are near the base. In general, the lower-valued resources get outsourced quicker than the higher-valued resources. This causes the vendible line to sweep upward as commoditization consumes more and more of the enterprise. However, the vendible line never reaches the top because if it did the enterprise would cease to exist. The entire enterprise would have been outsourced. On the other hand, the vendible line never reaches the bottom because no enterprise produces every resource that it needs. Even the smallest company buys something from a supplier be it paperclips, electricity, water, or any other commodity.

Vendible Model analysis shows us something important about enterprises: there is something in any enterprise that will never be outsourced. We call this core set of resources the *strategic kernel* and it represents the very essence of the enterprise itself.

What is contained in the strategic kernel? To answer that, we must first recall the definition of commodity as being a good or service that is traded primarily on the basis of price, and not on differences in quality or features. In other words, commodities are those things that are decidedly *not unique*. Since non-unique resources become commodities and fall below the vendible line, what remains in the enterprise are the resources that make the enterprise unique. The way an enterprise stays unique is to do something that no other enterprise is doing or can do. This is the very definition of *innovation*. The conclusion is not very surprising: companies must innovate to stay ahead of the competition. Leading companies in every industry already invest substantial amounts of resources in research and development departments. However, what is a new response to Greenspan's global economy is how companies will innovate in the future.

Globalization is leveling the playing field and allowing companies all over the world to compete in previously inaccessible markets. Companies are competing against a larger and more diverse group of competitors than ever before. However, something else is happening that is even more important. The time required for the concept-to-product cycle is getting shorter. A few decades ago, a company's new innovation could put it several years ahead of its competition. By the end of the millennium, this lead time had shortened to several months. Globalization, communication technology, information technology, culture, social, and political forces are pushing us into the knowledge age where innovative lead time will be measured in weeks. The large research and development department, that many companies have today, is not likely to respond fast enough for this future marketplace. Companies that do not become leaner, more agile, and continually adaptable will lose out to those companies that do. Being able to *continually* adapt will require companies to distribute its capacity for innovation throughout the company and create a corporate-wide culture of innovation.

To achieve this, a company's innovation quotient must be built into the fabric of the company itself, touching every job, every employee, every department, and every business practice. What we are describing here is the need for a new infrastructure for innovation. We call this the *innostructure*.

We in the industry have seen this kind of thing before. One time relegated to the data processing center, the infusion of IT infrastructure into companies has turned most employees into information workers, and has done so by distributed information resources throughout a company. We expect the same thing to happen to innovation. The infusion of innostructure will turn more and more employees into *innovation workers*.

In Business @ the Speed of Thought: Succeeding in the Digital Economy, Bill Gates makes a strong case for the increased need for IT-savvy thinking to permeate all aspects of business (Gates, 1999). He argues that without it, businesses will not remain competitive and not take advantage of the competitive levers provided by innovative state-of-the-art IT technology. Because we view information management's central role as turning information into knowledge, we see information resource management as the point of the spear leading the way to the innostructure.

THE INNOVATION METANETWORK

There are a number of innovation tools on the market and some companies are already employing these tools. The critical factor companies are lacking is the embedding of innovation tools into a sustaining infrastructure that promotes innovation as a way of doing everyday business. Our proposed innostructure is the *innovation metanetwork.*

We take "metanetwork" to mean a network that is superimposed on another network. Companies today have existing information technology infrastructures so any higher-level organization of resources using this infrastructure as a substrate is a metanetwork. The metanetwork supports innovation by facilitating sharing of knowledge and ideas among collaborators.

Visualizing the innostructure as a metanetwork is important because it leads to the identification of two important properties—a scale-free architecture and emergent behavior. These properties imply specific architectural features that can be constructed and measured empirically. This has the decided advantage of giving companies a metric that can be measured, tracked, and optimized—a control parameter.

At the most fundamental level, the metanetwork is a network of collaborators. Collaborators can communicate with each other about a piece of work, called an *opportunity*. An opportunity is a problem to be solved, an idea to be refined, or any other type of collaborative endeavor. Upon receiving an opportunity, a collaborator can either

- refer the opportunity to another collaborator thought to be able to contribute to the opportunity
- contribute to the opportunity
- respond to and refer the opportunity

How the contribution is made and how the piece of work is manipulated is not of concern here. Collaborators may or may not employ various tools in making a contribution. The key to innovation is the ability to explore alternative possibilities without distracting the work down fruitless paths. The way to achieve this is via an open forum promoting analysis, discussion, various viewpoints, and utilization of others' knowledge. This is the role of the innovation metanetwork.

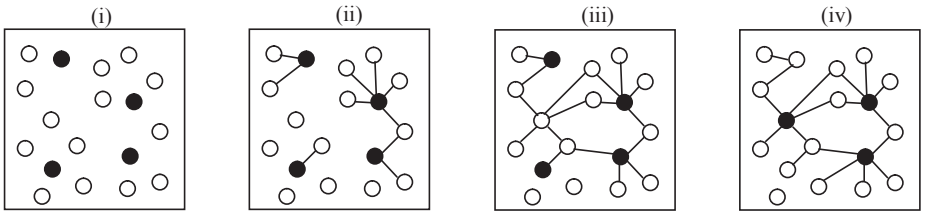
SCALE-FREE NETWORKS

Scale-free networks have proven to be most efficient in promoting information propagation (Barabasi, 2002). This is crucial to support the open and free exchange of ideas in the innovation metanetwork. Scale-free networks are characterized by the existence of a relatively small number of nodes connected to a relatively large number of other nodes. Such highly connected nodes are referred to as *hubs*. An important feature of a scale-free network is the "small-world phenomenon" in which any two nodes in the network are connected together by a small number of links, or "hops."

The airline system is an example of such a network. Cities like Atlanta, Charlotte, and New York are hubs for various airlines. A traveler can get from any departure city to any destination city by taking only one or two flights routed through at least one of the hubs. The Internet is another example of a scale-free network. Internet messages are routed through a relatively small number of switching points arranged in a hierarchy of highly connected hubs, called access points. Because of the small world phenomenon, information can propagate across a scale-free network efficiently.

Another important feature of a scale-free network is its ability to grow to any size without changing the basic architecture or suffering any degradation in information propagation efficiency. Ultimately, the goal of the innovation metanetwork is to develop a collaborative that is highly effective in routing opportunities to the collaborator that can best make a contribution. The hubs in this metanetwork

Figure 2. An efficient, small-world, scale-free collaborative network can be evolved. To seed the process, a set of referrers are initially appointed (i). As the performance of the group is monitored, some appointed referrers will prove to be efficient and others will not (ii). It is likely that individuals not originally appointed will step up and prove themselves to be efficient referrers (iii). Over time, a network of the most efficient referrers will evolve resulting in a maximally efficient, scale-free network (iv).



will be those who are very good at routing an opportunity to the appropriate collaborator. A mistake would be to try to identify these key individuals at the outset. Our proposal is to let the metanetwork self-organize. This can be achieved by appointing, at the outset, a number of referrers to act as the hubs and installing a feedback and monitoring mechanism. Initially, all opportunities will be forwarded to this group who will in turn, refer opportunities to others, and so on. The pattern of opportunity referral and the pattern of contributions across all collaborators will be monitored. A collaborator who refers opportunities resulting in contributions and to a wider range of others will be scored higher than one who never refers opportunities or whose referrals do not result in contributions. Collaborators with higher scores will tend to be sent opportunities first. Over time, the highly effective performers will rise and the under performers will be marginalized. As shown in Figure 2, this results in an optimal scale-free network.

EMERGENT BEHAVIOR

Even though the metanetwork will self-organize, it will be static once the prevailing pattern evolves. Researchers in nonlinear dynamical systems have shown that static systems do not achieve the highest degree of emergent behavior (Langton, 1986) Emergent behavior is the global behavior of a system arising from the complex interaction between the parts of the system and it has been shown that maximal emergent behavior occurs at an intermediate level of system complexity. If the dynamics of the system are tuned downed to a point where interactions are extremely ordered, very little emergent behavior is possible from the static system. Likewise, if the dynamics are tuned to the point of chaos, where interactions are totally random, little emergent behavior is possible. However, when system dynamics are tuned to an ideal intermediate level, between the ordered and chaotic regimes, emergent behavior arises from the system.

Emergent behavior often exceeds the abilities of the individual components and often exhibits qualities that can not be programmed or designed into the components. An emergent system is the classic example of the whole being greater than the some of the parts.

Recent work focuses on modeling human organizations as emergent systems. Following this line of research, we maintain that innovation is an emergent behavior of the complex adaptive system of humans, information, knowledge, and wisdom. Innovation is sometimes the result of individual effort, but more often, the result of collaborative effort and emerges from the contributions of several individuals. Therefore, the innovation metanetwork should promote the highest degree of emergence from the system of collaborators.

To do this, the pattern of referral and contribution that evolves naturally should be retained but not be allowed to remain static. Neither should it be totally randomized. Instead, the prevailing pattern should change slightly and incrementally over time, constantly exploring new routing possibilities. This can be achieved by occasionally routing an opportunity to a collaborator selected at random. This puts an element of chance and randomness into the system and the degree of randomness can be controlled by a single parameter.

What will be observed is that at low values of randomness, the global performance of the innovation metanetwork will be unchanged. As the amount of random routing is increased, emergent properties will be observed until a point where at some value of randomness, the emergent properties will begin to subside. At this point, the randomness will be such that it is beginning to interfere with the operation of the metanetwork. Tuning the randomness factor to values just below this point will keep the emergent behavior of the metanetwork at its maximum.

An emergent metanetwork will have two great benefits. First, the pattern of referrals and contributions will change and improve over time as the system explores and finds better routing solutions. Second, the amount of innovation arising from the collaborators will be higher than one would expect. This will be because instead of acting like a collection of individual innovators, the collective will be acting like a single super-organism achieving greater results than the individuals are capable of separately.

CONCLUSION

We have argued that increasing an organization's innovation quotient—the ability to sustain innovative thinking and problem solving—is a critical business concern and have offered a graphical visualization of one view of this argument, the Vendible Model. Increasing corporate spending patterns over the last several years bear witness to this observation. The troubling finding, however, is that corporate executives are discouraged by the return on investment in this spending. The explanation we offer is that innovation should be built into the fabric of the organization itself as a business infrastructure component. It is simply not possible to purchase a few innovation tools and expect the company's innovative output to measurably increase. Instead, steps must be taken to turn workers into *innovation workers* where innovation is something they do as a routine business practice. To make this vision a reality, we have argued that a communication and collaboration infrastructure be created, called the *innovation metanetwork*, providing the framework supporting innovative work processes. We feel the innovation metanetwork should be built with two critical features in mind: scale-free architecture and emergent behavior. The scale-free architecture will be evolved over time and insure the metanetwork can grow to any size while remaining maximally efficient. The emergent behavior feature will keep the metanetwork from stagnating and insure that it constantly improves itself over time. A fortunate result of this architecture is that it provides two measures for effectiveness that can be monitored and tracked.

Quality and Decision Variables: Impact-Focused Taxonomy

Zbigniew J. Gackowski, California State University Stanislaus, 801 W. Monte Vista Avenue, Turlock, CA 95382; E-mail: ZGackowski@csustan.edu

ABSTRACT

This paper presents an inquiry into the applicability of operation qualities identified for data and information to decision variables in general. It posits and demonstrates that they apply equally to data values, information values, elements of knowledge, physical factors in operations, and thus to decision variables used in decision-making to represent them. This approach leads to a universal hierarchical impact-focused taxonomy of decision variables of theoretical and practical importance in analyzing decision situations, their models, and in prioritizing research on decision situations.

Keywords: Quality, data, information, rules of reasoning and proceeding, operation factors, decision variables, universal taxonomy

INTRODUCTION

The theoretical and empirical research on data and information quality conducted for more than a decade and the operations-research approach to quality of factors in operations elucidate that the identified principles apply equally to decision variables in decision-making. On must, however, take a broader than the internal ontological view on quality. The teleological pragmatic viewpoint common in operations management, operations research, management sciences and decision sciences elucidates that the identified principles of operation quality apply to data values, information values, elements of knowledge (rules of reasoning and proceeding), physical factors in operations, and thus to the decision variables, which represent them all.

The presented approach is a purely theoretical one. Consequently, the presented taxonomy claims universal theoretical and rigorous practical validity. Survey-based empirical approaches such as TQM and TDQM are not considered here. They are of high practical value but alas of low scientific validity as they always are situation-specific only.

The main contribution of this paper is a universal hierarchical impact-focused taxonomy of decision variables. The main purpose of this paper is to present this concept for challenge and discussion. For focused reading, key terms in paragraphs are in **bold** font, emphasis in *italics,* highest emphasis underlined, and terms followed by a definition are in ***bold italics***.

A SHORT REVIEW OF LITERATURE

Based on **ontological foundations**, Wand and Wang (1996) proposed four data quality dimensions (complete, unambiguous, meaningful, and correct) that are intrinsic to system design and operations. However, they labeled them intrinsic to data. At the same time, Wang and Strong (1996) using empirical approach identified other about 179+ (later reduced to about 15-20) dimensions of quality mentioned in questionnaires by individuals representing data users or consumers.

Liu and Chi (2002) categorized different approaches to data quality as intuitive, empirical, and theoretical. They concluded, the "*Existing theoretical approaches are limited in their ability to derive a full-fledged measurement model*" and a "*generally accepted model has not yet appeared*" (p. 292). They developed a concept of **evolutional and theory-specific data/information quality** that evolves along the stages of data collection, organization, presentation, and application.

Oliviera, et al. (2005) claimed they presented *"***A formal definition of data quality problems**." The paper identifies and defines 30 specific possible distortions inflicted onto a set of entered data values assumed to be correct and updated. However, their formal definition is limited only to data in databases.

Anchoring the concept of data/information quality in operations research, management science, and decision science, Gackowski (2005) defined a theoretical teleological content-focused framework of ***operation quality requirements*** of data and information values viewed from the perspective of operations management. They pertain to data, information, elements of knowledge (rules of reasoning and proceeding), and any factor of substance.

QUALITY AND OPERATIONS

Point and Frame of Reference, Observer, Assumptions and Postulate

There are two fundamental keywords, '**quality**' and its adjective '**operation**' because it pertains to quality of factors in operations. A reliable theory must refer to a well-defined point of reference, observer, frame of reference, and a yardstick for measuring the results of operations:

Assumption 1a: The **main purpose** of operations is the main ***point of reference*** and it is measurable.

Assumption 1b: The ***observer*** is the decision-maker. Decision makers do not act in the actual reality – a **subject of science and technology**, but in their subjective reality, which is the **subject of phenomenology**. Usually, the two realities overlap only partially: (a) completely, only in structured decision situations, (b) not at all, in fully irrational decision making, and (c) partially, in semi structured decision situations, when part of the model is scientifically and technically sound, and the rest is subjective of unknown validity, hence of unpredictable outcome. Thus, decision situations are complex structures, which might be better handled by **complex analysis** (as defined in mathematics with complex variables, which are pairs of real and imaginary components) and become an extension of the theory of decision-making.

Assumption 1c: The ***frame of reference*** consists of:

- **sn –** a vector of all **states of nature** – independent environmental variables, which are beyond control of decision-makers and of significant materiality or impact on operations; they describe a part of the **circumstances** under which operations occur
- **V** – set of significant (by impact) dependant variables **v** under decision-makers' control,
- An adopted **criterion of effectiveness** of operations, and
- ***Assumption 2*:** Decision-makers employ only **rational** and **rule following** choices as defined by March (1994).

As long all of the above including the assumptions do not change, each variable:

- Is viewed and assessed the same way by rational decision-makers (observers),
- Is bound by the same logic, and
- All principles, to which qualities of operation factors are subject, remain unchanged.

Postulate** of **general relativity of variables: Rational observers view, perceive, and assess the same way all variables, as long the **purpose** and **frame of reference** remain unchanged. Nevertheless, when changes occur, it changes how even objectively identical operation factors and their qualities are seen, perceived, observed, and assessed by decision-makers. This is the **all-pervasive principle of relativity of all variables in informing and in all operations** in general. It employs the analogy of inertial frames in theoretical physics.

A unit of any adopted **measure of results** of operations $\mathbf{M_{RO}}$ may serve as a ***yardstick.*** This is under the assumption that $\mathbf{M_{RO}}$ is a function of the main purpose **P,** all states **s(v) є S(v)** of significant variables **v є V**, and of all significant states of nature denoted by vector **sn,** formally

$\mathbf{M_{RO} = M_{RO}[P, s(v), sn]}$ for all s(v)) є S(v) and v є V
(**Assumption 3**)

For instance in business, income after taxes, retained earnings, return on investment, return on equity, cost effectiveness, etc may measure the results. In public administration, measurable or only observable results can be derived from the entity's mission. In military operations, they may be described by the expected tactical or strategic objectives. For example, when cost effectiveness $\mathbf{C_E(O)}$ of operations **O** matters, then the percentage point of the ratio of the main purpose, **P** divided by the cost **C(O)** of operations **O** over time may serve as a unit of measure. Then formally: $\mathbf{M_{RO} = C_E(O) = 100*P/C(O)}$.

All of the above imply that a relatively complete qualitative cause/effect diagram of operations (known also as a fishbone diagram) is available or can be drawn. Such a diagram tries to identify all factors of significant materiality in the situation, the required actions to implement the decisions made, and/or the results.

Operation quality is defined here by distinct significant states of the factors' qualities (attributes, dimensions) that enable them to play a significant role in operations. If so, they all must be represented by corresponding variables in the decision situation matrix.

These factors can be **factors of substance** and **factors of symbolic nature**. ***Factors of substance*** may the four M's (material, method, machinery, manpower) and others including respective states of their significant qualities. In contrast to factors of substance, ***factors of symbolic nature*** may be data values, information values, and elements of knowledge meant as rules of reasoning and proceeding, again including respective states of their significant qualities. Operations factors may be:

- Already **available** such as any available substance, data, or elements of knowledge, and
- **Not yet available**, to be acquired or as yet even unknown to be recognized – such as any additional substance, information, or element of knowledge.

Operation variables acquire potential **materiality** from the purpose, circumstances and by the adopted criterion of effectiveness of operations. ***Materiality $M(v_x)$ of a specific variable v_x*** **is** defined as the difference in results of operations **RO** using $\mathbf{M_{RO}}$ as their measure when acting with all variables **V** and without the specific variable $\mathbf{v_x}$. Formally:

$M(v_x) = \mathbf{M_{RO}(V) - M_{RO}(V - v_x)}$

Significant materiality or impact on operations is defined by the condition $\mathbf{M(v_x) \geq Min\ (\Delta M_{RO})}$, where $\mathbf{Min\ (\Delta M_{RO})}$ is the threshold of significance expressed as a minimal increment $\mathbf{\Delta M_{RO}}$ **of** the measure of results $\mathbf{M_{RO}}$ the decision-makers care. Each decision variable **v** belonging to their set **V** must meet the following condition. Formally:

$\mathbf{V = E\ [M(v) \geq Min\ (\Delta M_{RO})]}$ for all v є V

After any new variable **ΔV** and its state **ΔS** has been recognized as significant, the previous set of significant variables $\mathbf{V_p}$ and their states $\mathbf{S_p}$ will be updated (augmented or reduced) to their respective current states $\mathbf{S_c}$ of variables $\mathbf{V_c}$. Formally:

$\mathbf{V_c = V_p + \Delta V}$ and $\mathbf{S_c = S_p + \Delta S}$

In general, ***quality requirements QR(v)*** for variables v є V can be represented as a vector of required states of their quality **rs(q(v)) є RS(q(v)),** and all of them can be represented by corresponding decision variables. Formally:

$QR(v) = [\mathbf{rs(q_1(v)), rs(q_2(v)), \ldots rs(q_n(v))}]$ for all q(v) є Q(V), v є V

Universal Taxonomy of Decision Variables

One of the first steps to knowledge is clear distinction of entities (objects, qualities, states, relationships, phenomena, etc) under investigation. One needs a rigorous taxonomy of qualities, their states, and the consequences of their changes. In science, the strongest taxonomy is the binary one. It is natural and logically perfect in accordance to the fundamental principles of thinking.

Most textbooks and empirical studies list under different names a plethora of qualities or dimensions of data/information quality for consideration as stated by Wang and Strong (1996). In operations, certainly one may identify easily hundreds or thousands more qualities. The major question is, however, how to examine those qualities in real life situations, how to focus the attention of the examiners, how to provide them with diagnostic guidelines? Which of them affect the situation results directly or indirectly, which are primary or secondary, necessary or optional, which are not fully attainable and therefore one must learn to act with only some acceptable level of quality. Because many are there, these qualities require a systematic uniform approach to research and their practical diagnostic examination.

In informing, these concerns lead to a universal taxonomy of all known and not-yet known data or information qualities and requirements related to them, which together with research in-progress on interdependencies among them (Gackowski, 2004 and 2006) provides many clues in this regard. The same applies to their taxonomies. Thus by the power of this abstraction one can move from the universal hierarchical impact-focused taxonomy of quality requirements for data and information values (Gackowski, 2005) to an equivalent taxonomy of decision variables in decision-making (see Table 1), which does not yet cover the distinction of their real and imaginary components.

Operation quality of data of information (Gackowski, 2005) identified only **five** direct universally necessary quality requirements, **four** direct secondary quality requirements, when economy of operations matters, and some situation-specific ones, which make them usable. Hence, a variable ***uv*** is usable, if:

uv **≡ (Interpretable** v **Recognizable) ^ Relevant ^ Significantly material ^ Operationally timely available ^ (Actionably credible** v **Actionably reliable) ^ meets all situation-specific necessary quality requirements.**

Similarly, an ***economically usable variable – euv*** must be first usable (**uv** – see above) and then meet the four direct secondary requirements, formally:

euv **≡ uv ^ economically [(interpretable** v **recognizable) ^ available ^ (credible** v **reliable)].**

To facilitate its comprehension it is necessary to reemphasize that in decision-making a variable (whether dependent or independent, deterministic or stochastic, discrete or continues) must represent all its significant states.

The ***universal hierarchical impact-focused taxonomy of sets of significant variables:***

Table 1. Schema of hierarchical impact-focused taxonomy of decision variables

Categories of Decision Variables			
Direct			Indirect
Primary		Secondary	
Universally Necessary	Situation-Specific	……. …….	……. ……. …….
…….	……..		

1. The taxonomy subdivides the universe of **variables V** into **direct** and **indirect** or subordinate variables.
   a. A change from the previous state $\mathbf{s_p}$ to the current state $\mathbf{s_c}$ of ***direct variables*** **s(dv),** where $\mathbf{dv \in DV \subset V}$ immediately affects the decision situation itself, and/or the actions to implement the decisions made, and/or the results of operations, which implies they change the value of the adopted measure of results of operations $\mathbf{\Delta M_{RO}}$, formally: $\mathbf{(s_p(dv) \neq s_c(dv)) \Rightarrow (\Delta M_{RO} \neq 0).}$ If any of the above listed requirements cannot be met, this implication remains valid.
   b. A similar change of states of ***indirect variables*** **s(iv)),** where $\mathbf{iv \in IV \subset V,}$ as the name suggests, only indirectly affects the situation, for it determines or contributes to states of other **indirect variables of a higher order** (closer to the direct ones and at the extreme to **direct variables**). When $\mathbf{s_p}$ and $\mathbf{s_c}$ respectively denote **previous** state **current** state of an indirect or direct variables, and $\mathbf{iv_n}$ and $\mathbf{iv_{n-1}}$ respectively denote **indirect variables** of n^{th} order and **indirect variables** of higher $(n-1)^{th}$ order, for n = 1 indirect variable of 0^{th} order is a direct variable $\mathbf{iv_0 = dv}$. It implies that changes of states of indirect variables of n^{th}-order causes a change of state of the related indirect variables of a higher order $\mathbf{iv_{n-1}}$ or at the extreme of direct variables. Formally: $\mathbf{(s_p(iv_n) \neq s_c(iv_n) \Rightarrow (s_p(iv_{n-1}) \neq s_c(iv_{n-1}))}$. Example: If any of the twenty indirect qualities identified by Gackowski (2006a) as contributing to "actionable credibility" among them definition, variability, bias correctness, precision, and currency cannot be met at least at an acceptable level the concerned variable must be dropped from the decision situation matrix and its definition at least partially redefined.
2. The **direct variables** are subdivided into **direct primary** and **direct secondary** variables. The primary ones are Boolean {true, false}, that is exists or not, a requirement is either met or not.
   a. Changes of states of the ***direct primary variables*** **s(dpv),** where $\mathbf{dpv \in DPV \subset V}$ result always in *qualitative* changes to the decision situations under consideration, which result in adding or eliminating a variable from consideration - labeled $\mathbf{\Delta V.}$ Such changes add or delete entire rows or columns from the matrix that represent the model of a decision situation. When the above requirements of usability cannot be met, again, it requires at least a partial redefinition of the decision situation, which leads to quantitative consequences, as well. Formally: $\mathbf{(s_p(dpv)) \neq s_c(dpv)) \Rightarrow [(V_p \neq V_c) \wedge (\Delta M_{RO} \neq 0)],}$ where $\mathbf{V_c = V_p + \Delta V.}$
   b. Changes to states of the ***direct secondary variables*** **s(dsv),** where $\mathbf{dsv \in DSV \subset V}$ mainly *quantitatively* change the results of operations; hence, they may not necessarily be of significance $\mathbf{(\Delta M_{RO} \geq Min\ (\Delta M_{RO}))}$. Nevertheless, if the subsequent quantitative changes reach a critical point that is, if the current state $\mathbf{s_c \in C(s(dsv))}$ belongs to the set of critical states **C**, they may trigger a qualitative change of situations. Then they become necessary, as well. The secondary variables are mostly of economic nature. If not only effectiveness, but also economy of results matters, the secondary variables also may become necessary, however not universally necessary. Formally: $\mathbf{(s_p(dsv) \neq s_c(dsv)) \Rightarrow [(\Delta M_{RO} \neq 0) \wedge If\ (s_c(dsv) \in C(s(dsv))}$ then also $\mathbf{(V_p \neq V_c)]}$. Example: Usually environmental requirements must be met within a certain prescribed range, of course at cost. However, when the upper lawfully acceptable level has been exceeded, heavy fines may be imposed and even the entire operation suspended.
3. The **direct primary variables** are divided into those of **universal necessity** versus those that are necessary in specific situations, **situation-specific necessary**. Changes to their states are Boolean {true, false} and always redefine the decision situation by adding or deleting entire rows or columns from the decision situation matrix.
   a. The ***direct universal primary variables*** are always necessary. Changes to their states **s(dupv),** where $\mathbf{dupv \in DUPV \subset V}$ add or eliminate them from consideration. Formally: $\mathbf{(s_p(dupv) \neq s_c(dupv)) \Rightarrow (V_p \neq V_c)}$ always redefines the decision situation.
b. The ***direct primary situation-specific variables*** are necessary also. Changes to their states **s(dpssv),** where $\mathbf{dpssv \in DPSSV \subset V}$ also add to or eliminate variables from considerations, however they are not universally necessary only under situation-specific conditions. Formally: **If situation requires** then $\mathbf{(s_p(dpssv) \neq s_c(dpssv)) \Rightarrow (V_p \neq V_c)}$. Example: Restricted availability of information in a competitive situation, otherwise, when available to all, it may lose its advantage, hence materiality).

Research Priorities

Once a universal hierarchical result-determined taxonomy of variables has been defined, it nearly automatically prioritizes the sequence of their diagnostic examination and any corresponding research. These priorities, again, do not yet cover the distinction of the real and imaginary components of variables.

1. ***First priority.*** The variables that represent the **direct universal primary requirements** should be the immediate subject to scrutiny. By the principle of usability (Gackowski, 2005), they must be **interpretable** or **recognizable**, **relevant**, of **significant materiality** of impact, operationally **timely available**, and **actionably credible** or **reliable**. If any of the five requirements is not met, the variable that represents the affected decision factor is out of commission. In addition, in operations, any factor must be **effectively complete** that is be usable together with other usable factors for a task to be accomplished, which gives us the sixth universally necessary requirement. All the above suffice for only effective operations, not necessarily economically effective. It pertains to all-out efforts such as special operations or terror acts, where economy is secondary. All the above requirements, if not met, call for a qualitative redefinition of decision situations. Materiality measures the importance of the variable.
2. ***Second priority***. When economy matters, which is an all-pervasive principle in business, not necessarily in administration or military operations, four additional **direct secondary requirements** play an important role. Then the affected factor (represented by a decision variable) must be **economically interpretable** or **recognizable**, **timely available**, **actionably credible** or **reliable**, and **economically effectively complete** together with its companion factors. Now, the direct secondary requirements are also necessary, however, not universally necessary. Any changes to them, usually cause quantitative changes only, as long, any of them does not reach a critical state (for example, cannot exceed the limits required by law). Then again, it will cause a redefinition of the decision situation.
3. ***Third priority.*** All the rest belongs to **indirect quality requirements**. Depending on the length of the chain of their interdependencies, there are indirect requirements of the first, second, and subsequent orders. This fact again, clearly prioritizes the diagnostic sequence of their examination and respectively any related research about these factors.

Components of the proposed framework and model for research are anchored in basic scientific principles. Hence, they do not require extensive empirical validation except fore coming up with examples to the contrary or other objections with regard to the logic of the model. Then the model may require a revision. The proposed model and framework needs, however, be discussed and challenged.

SUMMARY, CONCLUSIONS, AND LIMITATIONS

A formal definition of operation quality requirements of data and information, and any other factor in operations offers an insight that with no or only some terminological modifications it equally applies to factors of substance. In decision-making, all of them, if only significant, are decision variables. They all are decision variables subject to the same universal hierarchical impact-focused taxonomy. If this taxonomy remains substantially unchallenged, it qualifies as basic research in contrast to applied research of situation-specific limited validity.

Some principles of operation quality by which the quality requirements are governed, and pertain to decision variables may be summarized as follows:

1. **The principle of *relativity* of variables in decision-making.** Quality requirements are determined by the purpose **P** and circumstances of operations described by the vector **sn** of significant states of nature, the criterion of assessment of effectiveness of operations, and the assumption that decision-making is limited to rational and rule following choices (see the Postulate of Relativity).
2. **The principle of *pervasiveness* of materiality of factors.** A factor in operations confers its materiality upon all its qualities and its corresponding necessary task-specific usable companions represented by corresponding decision variables.
3. **The principle of *usability* of factors in operations** (when it meets all the **universally necessary** (**interpretable or recognizable**, of significant **materiality,** operationally timely **available**, and actionably **credible** or actionably **reliable**) and the other **situation-specific necessary quality requirements** that pertain to the corresponding decision variables.

4. **The principle of *degradation* of decision situations by declining usability of factors represented by variables**. If the usability of a factor:
   a. **Is certain**, the decision-maker deals with a **deterministic situation** at least in the area affected by the factor
   b. **Is only probable** (the most likely case), the decision-maker deals with a **stochastic situation** to the same extent as above
   c. **Is not attained,** for instance when not timely available or not actionable reliable/credible, the decision-maker **games** to the same extent. It may be the case even when operations are not triggered, for instance when a threat is ignored.

This first attempt assumes a single main purpose with no conflicting requirements and constraints imposed upon decision makers. The impact-focused taxonomy of decision variables opens the door for research by modeling and simulating decision situations, as systems of state transitions, where the results by whatever adopted measure are a function of states of decision variables. Simulations will facilitate the quest for more complex quantitative dependencies and likely the discovery of other yet unknown interdependencies. Based on a formal theoretical model, research results of simulations conducted under rigorously controlled conditions promise results of a lasting validity when compared with pure empirical studies conducted without such taxonomy. Hence, the presented taxonomy seems to be a theoretical progress and of practical value in analyzing decision situations, decision-making, and the related research.

Teaching Online Information Systems Courses with Virtual Machines

Li Chao, University of Houston-Victoria, 3007 N. Ben Wilson, Victoria, TX 77901; E-mail: chaol@uhv.edu

ABSTRACT

This paper considers the issues on setting up online computer labs for teaching the information systems courses that require intense hands-on practice. Due to limited technical support, budget, and space, it is always a challenge for a small university to implement online teaching for courses in the information systems curriculum. Often, faculty members in a small university need to be involved in the construction and management of online computer labs in addition to their normal teaching and research workload. The virtual machine technology can be used to ease some of the burdens of online computer lab construction and management.

1. INTRODUCTION

As the Internet technology advances, more and more courses are taught online now. Many academic fields have developed effective solutions for online teaching and learning. Generally, for courses with no lab activities, such as some of the courses in English, history, and education, the implementation of online courses are relatively easy. Many commercial learning management system (LMS) software packages such as WebCT are available to support this type of courses. Instructors post lecture notes, images, and assignments on a WebCT. Students read the online course content or download the files and read the materials off-line. LMS can also be used as knowledge management such as grading, hosting discussion groups, and presenting multimedia course content (Itmazi and Megías, 2005). For many information systems courses, this way of online teaching is not adequate because hands-on practice is a very important part of the curriculum.

Using the virtual machine technology can effectively overcome many difficulties for online hands-on practice. The Virtual machine technology can be used to create online computer labs that meet the requirements of teaching and hands-on practice. Two popular virtual machine software packages are VMware and Microsoft Virtual Server. The virtual machine technology has been used in computer technology certification training (Lammle & Tedder, 2003). When purchasing training materials, virtual machines are provided to simulate underlying IT products for learners to perform hands-on practice off-line. For the off-line use of the virtual machine technology to teach technology-based courses, the author can only find one report by Correia and Watson (2006) who used the software VMware to create 60 virtual computers for teaching computer network courses. The use of the virtual machine technology in constructing online computer labs is still in its early stage. There are few publications available.

This paper will first discuss the difficulties for teaching information systems courses online. Then, it will describe the virtual machine technology and how it can be used to support the teaching and hands-on practice for some information systems courses. This paper will provide some information about the advantages of using the virtual machine technology and possible hands-on activities that can be accomplished by using the virtual machine technology. It will also discuss some design and management issues. The last topic to be covered in this paper is about students' responses to the online information systems courses.

2. DIFFICULTIES IN PERFORMING HANDS-ON PRACTICE ONLINE

Unlike students in other fields, our information systems students have to play the roles of system administrators, network managers, and database administrators. It is inevitable that they will learn through mistakes made in operating systems, networks, and database management systems. An online information systems course needs an online computer teaching lab to support these hands-on activities. Some difficulties encountered in developing this kind of online computer lab are:

- Setting up fully functioning online computer labs requires sophisticated skills and experience in developing remote access services, enforcing security measures, and creating a highly interactive Web site. Often, the labs are built on the client-server architecture with a highly secured remote access mechanism. To better support the needs of students and faculty members, lab technicians should also be knowledgeable about the course content and should be able to update the online computer labs according to the current IT trend. Faculty members also need to fully understand the technologies used in the online lab.
- It is expensive to create and manage online computer labs. In our information systems curriculum, many of the courses require some lab activities on IT products. The requirements for hardware and software are different for different courses. It is difficult for small universities to cover every course with different technology requirements. The labor cost is also a great concern. Many small universities do not have the budget to support an experienced technical support team or hire consulting companies for constructing and managing the labs.
- It requires great effort to manage online computer teaching labs. The course content in the information systems curriculum is changing rapidly. The course content is often updated every semester. It takes a group of technicians to frequently redesign and update the online computer labs. Many small universities may not have dedicated computer service staff for daily maintenance of these computer labs. It is a nightmare for a small computer service department to handle so many different technologies and to update these technologies so frequently.
- Technical support is another difficult area. Many of our students are new to the lab facilities. They have little experience on using the hardware and software in the lab. Even worse, students in some information systems courses such as network management and database administration have to be given the system administrator' privilege in order to perform server-side operations. From time to time, students crash the operating systems, networks, or databases because of wrong configurations or other mistakes. When technical problems occur, it is difficult to get technical support due to lack of detailed information about students' projects and the shortage of technicians on campus.

Because of these difficulties, many hands-on based information systems courses are not fully online. Some of the online information systems courses require students to purchase the necessary technologies for hands-on practice. Many of our students cannot afford to purchase all the required hardware and software. Even if some students are able to purchase all the hardware and software for their classes, they may configure them differently; which may cause problems that prevent them from conducting some of the hands-on activities.

3. SOLUTION

As described above, many small universities have limited budget, limited technical support, and high demand for lab resources. Among the possible solutions for dealing with the challenge, the virtual machine technology provides a low cost, secure, and manageable solution. Virtual machines use software to accomplish the functionalities of hardware devices. On a physical computer, multiple virtual machines can be created and each can be installed with a different operating system and application software. These virtual machines can run concurrently

(Nathaniel Martinez, 2004). Originally, virtual machines are used to construct a testing environment for software and hardware consolidation. The technology reduces security risks and enables developers to quickly reconfigure computer systems for different testing tasks without the fear of destabilizing the systems for other users. For us, such a technology can be used to overcome the difficulties in developing an online computer teaching lab. The following are some of the advantages of the virtual machine technology when used for teaching online information systems courses.

- Affordability: Since multiple virtual computers can run concurrently on a single physical computer, it significantly reduces the cost and lab space. Even a small university can afford virtual machines.
- Flexibility: These virtual computers can communicate with each other through a virtual network created on the same physical computer. More importantly, virtual computers can be accessed through the Internet so that students can remotely access the online computer lab from anywhere and at any time. A virtual computer allows the lab developer to experiment with various lab configurations for different information systems courses in a fast and easy way. It is a great platform for the frequently updated computer labs.
- Manageability: The maintenance of virtual computers is relatively easy. You do not need to maintain network cables, power cords, and many other hardware devices. If a virtual computer crashes, you do not need to reinstall all the software. Instead, you can create a new virtual computer in a few minutes and link the newly created virtual computer to an existing backup of the virtual hard drive.
- Security: The virtual machine technology provides a much securer solution for teaching online courses. Students do not need to have the administrator's privilege for the physical computers. All they need is the administrator's privilege for the virtual computers. In such a way, students can only experiment with their own virtual network system and they have less chance to damage the university's network.

With the advantages mentioned above, the virtual machine technology is promising for teaching information systems courses.

For online use of the virtual machine technology, you may need another virtual technology, Virtual Private Network (VPN). Instead of using a physical network such as leased phone lines from a telephone company, VPN uses virtual connections to communicate with remote computers through the Internet. More information about VPN can be found in the book by Snader (2005). The following are some advantages of VPN.

- VPN allows students to log on to the online computer lab from anywhere and at any time through the Internet.
- VPN can be configured to allow students to log on to the online computer lab without directly working on the university's internal network. This greatly reduces the network's security risks.
- VPN provides the broadband Internet compatibility which is essential for GUI based hands-on practice.
- The cost of the VPN software is minimal. Operating systems such as Windows Server 2003 includes the VPN utility.

On the other hand, the virtual machine technology is not perfect for everything; the following are the restrictions that we may encounter when developing this kind of online computer lab.

- Due to the fact that multiple virtual computers are sharing the same physical computer, the performance of virtual computers in general is slower than that of a physical computer itself. This is not a serous problem for our lab activities since most of the lab projects are small projects when compared with the real enterprise level projects.
- Usually, for GUI based hands-on practice, we need a broadband Internet connection. Fortunately, most of our students have a broadband connection at home. For those who do not have broadband connections, they can go to a public library, or local community college campus to access the Internet.

In the next section, I will briefly describe how the virtual machine technology is used to support teaching and hands-on practice for various courses in the information systems curriculum on our campuses.

4. DESIGN OF COMPUTER LAB FOR ONLINE TEACHING

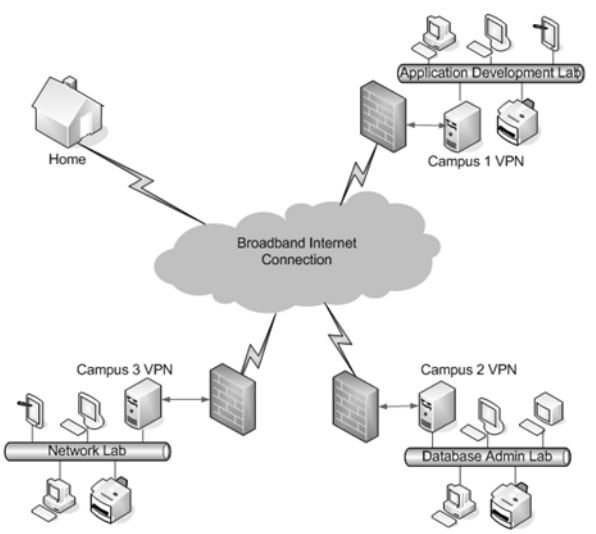
With the virtual machine technology, we are ready to develop an online computer lab for teaching various information systems courses that require intense hands-on practice. In this section, we will investigate how the virtual machines are used for supporting multiple information systems courses concurrently.

The first task is to investigate the requirements by the information systems courses. The courses that require hands-on practice can be classified into the following categories.

- The courses such as networking and system administration must allow students to have an administrator's privilege. Students will need to install and configure a network or operating system as part of their hands-on practice. No other courses should share the same computers with these courses since after reconfiguration, students of other courses may lose all their work or even are unable to log on to the computer system. The virtual machine technology is the best solution for this type of course.
- Students in the courses such as database administration or other application administration related courses must have the administrator's privilege for database servers and application servers so that they can perform the server-side administration tasks. The courses using various servers may share the same physical computer since the reconfiguration of one server normally has minimal impact on the other servers.
- In an information systems curriculum, courses related to application development and programming languages normally require a secure and stable physical computer as the server. The application development courses such as Database Application Development should not share the same server that also supports the Database Administration course since the reconfiguration of the database server can wipe out the database content created by the students in the application development course or prevent the students from other courses to log on to the database server. The virtual machine technology is a good platform for hosting the servers for application development courses on different virtual computers.

As mentioned earlier, the performance of virtual computers is a major concern. Due to limited budget, purchasing more powerful computers is often not an option for many small universities. One of the possible design options is to distribute the computing tasks to multiple less powerful computers. We can do that at different levels. First, let each physical PC host three or four virtual computers. In such a way, twenty PCs can host sixty to eighty virtual computers. Each virtual computer can handle a specific task. Next, to reduce network bottlenecks, we can distribute the VPN servers to multiple locations. As an example, consider our university which has three small campuses and each of them has the limited computer resources. To meet the needs of teaching and hands-on practice, a distributed computer lab can be constructed with three small labs, one on each campus. In such a case, we

Figure 1. Distributed online computer lab



can set up one VPN server for each campus. Each campus will host a computer lab that can support a certain type of courses. For example, the first lab can be used to support the network administration related courses, the second one can be used to support the database administration related courses, and the third one can be used to support the application development courses. The following figure demonstrates the design of the distributed online computer lab.

In Figure 1, the client computers such as students' home computers or notebook computers need to be configured so that they are able to remotely access the VPN servers. Based on the class enrollment, each VPN server has the local accounts for these students so that they can log on to the VPN server. Through the VPN server, the students can access each individual physical computer in the lab for hands-on practice. Each individual physical computer does not have to be an up-to-date powerful PC; a low-end Pentium IV PC has enough power to handle the hands-on practice for the information systems courses. Even the older Pentium III computers can get the job done if they are equipped with adequate memory for running the virtual computers.

5. EVALUATION OF ONLINE COMPUTER LAB

Our online computer lab has been used for two semesters. Is it a satisfactory solution in supporting online hands-on practice for information systems courses? We are also interested in what makes students take the online courses supported by the virtual technology and their reaction to this type of online courses. The response from students can be used as a guideline for further improvement.

At first, we were not sure whether it is doable to teach courses that require intense hands-on practice online, especially, to teach the information systems courses that require operations on the server side. To be on the safe side, we offered two sessions for each course, one session was a traditional face-to-face class, and the other one was a complete online class. The same instructor taught both sessions and the same teaching materials were used for both sessions. To give the students in the face-to-face class a chance to experience the online computer lab, we also permit them to use the online computer lab for their hands-on practice. Similarly, the students in the online session can participate in the face-to-face class and use the computer lab on campus. Initially, 42% of the students chose the face-to-face session and 58% of them chose the online session. At beginning of the semester, a survey was conducted to collect information about the students' background on taking online courses and the reasons that made them choose the online session over the face-to-face session, and vice versa. For the online session, the responses to some of the survey questions are listed in Table 1.

According to the survey results, the reasons for students to choose an online session are mainly due to the considerations of their job schedules, family activities, and class schedules. The students can take advantage of an online course to resolve the time conflicts. As indicated by the survey, 95% of the students have some knowledge or familiar with the course content and therefore they have confidence that they can handle the course work on their own. Other significant findings are: 100% of the students can access the Internet through their home computers and 95% of them have broadband Internet connections; 94% of the students use Windows XP Professional to access remote servers and 100% of the students can use their computers for online chatting and connecting to the VPN servers. A majority of these students are part time students. Only a small percentage of the students do not have the broadband Internet connection which is necessary for performing the hands-on practice using an online computer lab. For these students, we have arranged them to go to the nearest college campus to access the online computer lab. On the other hand, we are also interested in why some students chose the face-to-face session over the online session. The survey results for the face-to-face session are listed in Table 2.

The survey results indicate that the main reasons for a student to choose face-to-face are that they like to interact with instructors and classmates and they like to work in the campus computer labs which have better technical support and performance. Among these students, only about half of them have some previous knowledge about the course content, significantly less than those of the online session. A significant finding is that 83% percent of the students have taken other online courses. They come back to take the face-to-face class; this indicates that they are not satisfied with those online courses.

We have followed the same group of students for both sessions for two semesters. The average grades including exam and assignment scores for both sessions have no significant difference by the t-test with the significant level 0.05. About 5.8% of the students in the online session withdrew from the online class while no one withdrew from the face-to-face class. There is a significant change in the enrollment. Initially, 58% of the students enrolled in the online session and 42% of the students enrolled in the face-to-face session. At beginning, some of the students in the online session showed up in the face-to-face session whenever they could attend. On the other hand, some of the students in the face-to-face session used the online computer labs to complete their assignments at home. Now, for the coming semester in Fall 2006, only 16% of the students enrolled in the face-to-face session and 84% of the students registered for the online session. These are the same group students. What has caused such a dramatic change? One thing has to do with the students' confidence towards the online courses supported by the online computer labs. In order to find out how these students' learning

Table 1. Online session survey results

Question	Answer	Percentage
What are your reasons for enrolling in an online class? (Check all that apply.)	Want to have an experience about online classes.	5%
	Online classes do not conflict with my job schedule.	82%
	Online classes allow me to take care of my family.	57%
	The class I preferred was cancelled.	0%
	My preferred class is offered at an inconvenient time.	18%
	Online classes require less study time.	0%
Have you taken an online class before?	No, it is the first time for me.	35%
	Yes, I have taken an online class before.	65%
What is your enrollment status?	Full-time (12 or more credit hours).	18%
	Part-time (less than 12 credit hours)	82%
From where do you log on to the course Web page? (Check all that apply.)	Home computer	100%
	Work computer	53%
	Campus computer	18%
	Public library	0%
What types of Internet connections do you use to access the online course materials? (Check all that apply.)	DSL	29%
	Cable	53%

	Part-time (less than 12 credit hours)	66%

behavior changes with time, we need to collect more data from the same group of students over time for longitudinal analysis which will provide us with more convincing conclusions.

6. CONCLUSION

This paper has discussed the issues related to the application of the virtual machine technology in developing online computer labs for hands-on practice. The virtual machine technology can be used to overcome many difficulties in performing hands-on practice online. Virtual machines provide an efficient solution to constructing an online computer lab so that the technology-based courses requiring hands-on practice can be completely taught online. The results of the analysis indicate that the students have gained confidence towards the online lab-based courses, and more and more students on our campuses are in favor of the online courses.

Reinventing Gantt's Chart

Daniel Brandon, Christian Brothers University, 650 East Parkway South, Memphis, TN 38104; E-mail: dbrandon@cbu.edu

INTRODUCTION

The "Gantt Chart" has been a key tool in project management and industrial engineering since the early twentieth century. Even today the Gantt chart along with the relatively modern "spreadsheet" are still the most commonly used and well understood tools for analyzing and presenting project schedules and progress thereon. However today's Gantt, while similar in basic concept to the original Gantt chart, has evolved considerably in terms of appearance and functionality.

This article researches the Gantt chart both looking back and forward. It is appropriate to present this research at this time on the one hundredth anniversary of the original Gantt chart. The article follows the Gantt chart's evolution, and then looks forward to hyperlinked web based "earned value enabled" Gantt charts emerging in the twenty first century.

THE ORIGINAL GANTT CHART

Henry Laurence Gantt (1861-1919) was a mechanical engineer and management consultant. He formulated his Gantt charts early in 20th century, about 100 years ago. The charts were used as a visual tool to show scheduled and actual progress of tasks, types of work, and individuals. Now a commonplace project management tool, it was an innovation of great importance then. Gantt studied in great detail the order and types of tasks in industrial work, and his studies initially focused on Navy ship construction during WWI. He formulated "The Task Idea", and a couple years later presented it in Chapter VII of his book (Gantt, 1910). His "task" had a well defined procedure for carrying out the steps thereof, metrics to ensure proper completion of the task, metrics for approximate resources used to perform that type of task, and bonuses or some other type of motivation for a worker to complete the task in a timely and quality manner. Even today some of these components of tasks are not quantified in our construction of schedules. His definition of a schedule was a series of ordered tasks charted on a calendar.

Gantt charts had visual task bars and they outlined the sequence and duration of project tasks. His original charts were organized by person, and also showed work type ("piece" or "day" work), absence, termination, promotion, and bonus situations. One of Gantt's main areas of study was worker motivation, hence the inclusion of that additional type of information on his charts. An original chart from his book (Gantt, 1910 and 1919) is shown in Figure 1, which compares the same time period in 1909 and 1910. Gantt charts were later used on large U.S. domestic construction projects like the Hoover Dam started in 1931.

With the advent of WWII, the growing complexities of projects and a shrinking war-time labor supply demanded new organizational structures. Complex network diagrams called PERT charts and the critical path method were introduced and combined with Gantt charts, giving managers greater control over very large and extremely complex projects (such as military weapon systems) where tasks were highly interdependent. Later his charts were used on large peace time projects such as the U.S. interstate highway system started in 1956.

A typical Gantt chart of this era is shown in Figure 2. Here each task is represented as a horizontal bar and is a time-line view of the tasks. Now each task may have one or more resources assigned thereto. This chart is a bar graph where the length of each bar designates the start and finish dates for each task. Each task is typically labeled with its ID (or WBS code) and description.

In the early 1990s link lines (as shown in Figure 2) were added to these task bars depicting dependencies between tasks. Today there are many variations of the basic Gantt chart where more information is added in task ID area or in the graphic area with the bars. In the graphic area there may be: use of color, precedence

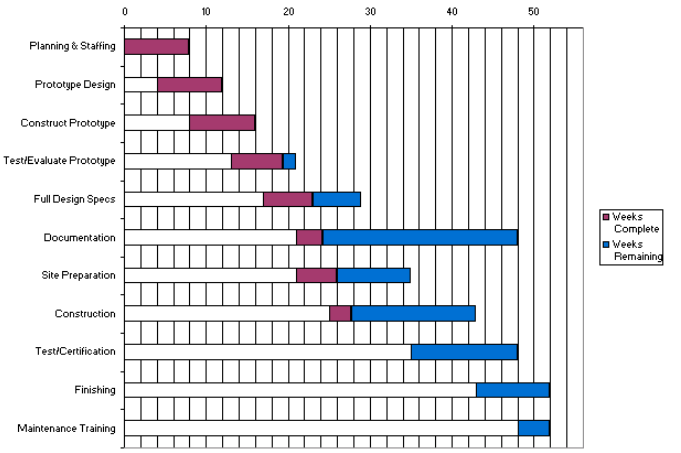
Figure 5. Gantt chart from spreadsheet



relations, shading in the bars to show percent completions of the tasks; coloring or other notation of the bars to show tasks on the critical path, and milestones (zero length event markers). In the task ID area there may be a WBS hierarchy, phasing, envelopes, or other information about the tasks in additional columns. Figure 3 is an example of a Gantt chart with other such information.

However even the modern Gantt chart is not without some problems in regard to the representation of a project schedule and the progress thereon:

- It portrays an even distribution of both planned and actual effort from the start of a task to the end of that task (particularly when per-cent complete shading of the bars is used).
- It is not generally interactive, and does not respond to user actions (i.e. mouse clicks) to change the content, level of detail, or perspective of the information displayed
- It is not immediately apparent what tasks may be in trouble in regard to schedule or cost parameters
- It does not show true schedule variances (i.e. EVA schedule metrics)
- It does not show cost information (planned, actual, and EVA variances)

MANAGEMENT AND TECHNOLOGY ADVANCES

In the last twenty years or so a number of management and technology advances have occurred many of which have been applied to the basic Gantt chart. These advances remove some of the problems previously itemized and also provide other utility. Such management and technology advances include electronic spreadsheets, relational database management systems (RDBMS), earned value analysis (EVA), management by exception, management "dashboards", client/server computing, hypertext, and the Internet/WWW.

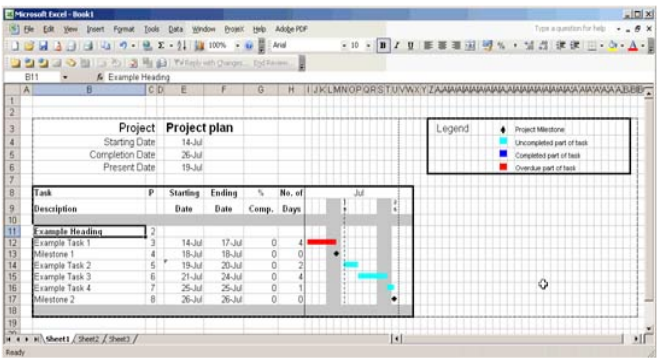
The most commonly used computer software for project management (and business in general) is the spreadsheet program. Spreadsheets are easy to learn, easy to use, inexpensive, generally available, and adaptable to most project management tasks. Consider the project planning and progress information shown in the spreadsheet of Figure 4; the last two columns are calculated columns. A graphical representation in the form of a classical Gantt Chart can also be created from the spreadsheet data in the first three columns using the "charting" capability in most modern spreadsheet programs (such as Microsoft Excel). In addition one can also use the columns for "weeks completed" and "weeks remaining" to draw a Gantt Chart showing progress as illustrated in Figure 5.

The Excel chart wizard was used to create Figure 5 with the columns for "task", "start week", "weeks complete", and "weeks remaining"; the first part of each bar was made the same color as the chart background (the chart may be shown in black and white here, but the "completed' and "remaining" parts of each bar are a different color).

There are also spreadsheet "add-ons" available from a number of vendors to facilitate Gantt chart creation; one such add on is illustrated in Figure 6.

Today internet based Gantt charts are starting to be used. These are typically created using hypertext markup language (HTML) tables and cascading style sheets (CSS) as is the example in Figure 7 from the FiveAndDime system. This variation of the basic Gantt chart is a "Cost Based Gantt Chart" where "bars" are

Figure 6. Gantt chart using an Excel add-on



represented as a series of cost numbers for each time period of each task. This provides for a non-linear distribution of cost (and resources) across the time span for the task and allows one to quickly see at a glance both the time for a task and the cost distribution (cash flow).

EARNED VALUE ANALYSIS

"Earned Value" (EV) is a value (usually expressed in currency) of the work accomplished up to a point in time based upon the planned (or budgeted) value for that work. The original U.S. government's term for earned value is "Budgeted Cost of Work Performed" (BCWP). Earned value terminology was originally

Figure 7. Cost-based Gantt chart as Web table (www.fiveanddime.biz)

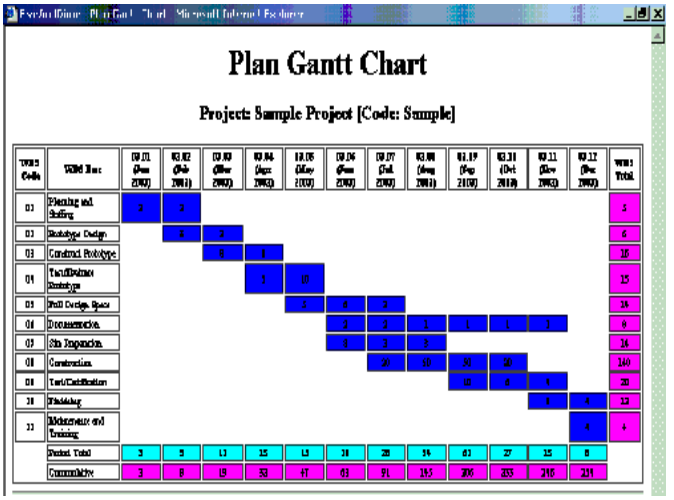


Figure 8. Graphical EV analysis

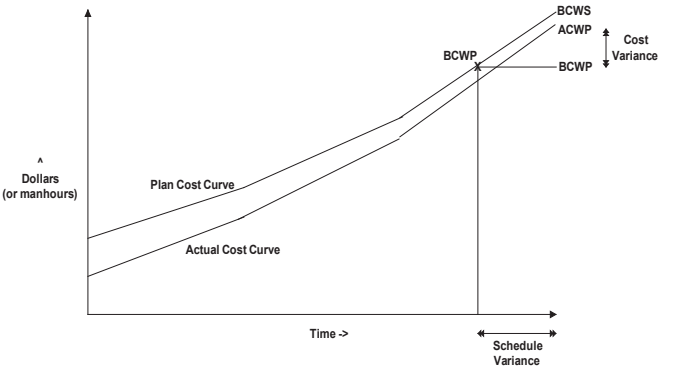

formalized in US DoD (Department of Defense) standard 7000.2. The ANSI standard (ANSI/EIA-748-1998) on Earned Value Management Systems (EVMS) was approved in May of 1998 and later adopted by the DoD. Other governments and organizations have adopted similar standards for earned value such as the Canadian General Standards Board (CGSB 187.1-93 November1993).

EVA (or EVM – Earned Value Management) is a "progress versus plan" based metric to evaluate the true performance of a project in terms of both cost deviation and schedule deviation. It also provides a quantitative basis for estimating actual completion time and actual cost at completion; EVA can provide an early warning of project time and/or cost problems as early as 15 percent into the project (Fleming, 1998).

In EVA the three key terms and definitions are:

BCWS – budgeted cost of work scheduled (the cumulative planned cost) as of a certain point in time
ACWP – the cumulative actual cost of work done as of a certain point in time
BCWP – this is the "earned value" and is determined from the product of the budgeted cost of each work packet times the percent complete of each work packet as of a certain point in time

Variances between the three values BCWS (planned cost), BCWP (earned value), and actual cost (ACWP) yield the earned value metrics. There are earned value metrics available for both cost and schedule variances. The basic cost metrics are:

Cost Variance (Dollars) = BCWP - ACWP
Cost Variance (%) = (BCWP - ACWP) * 100/BCWP
Cost Performance Index (CPI) = BCWP/ACWP
Estimated Cost at Completion (EAC) = ACWP + (BAC - BCWP)/CPI
Or in its simpler form EAC = BAC/CPI

Where BAC is the budget at completion, ACWP is a "sunk cost", and (BAC - BCWP) is the estimated remaining work. The CPI is also called the "cost efficiency factor"; and values less than one indicate that the project is costing more than planned, or that one is getting CPI of a dollar for each one dollar spent. This is good prediction formula if one expects that future performance will be similar to past performance. There are several other (EAC) formulas, and the most appropriate depends upon project type, whether past performance is a good indicator of future performance, and when in the project the EAC is calculated (Christensen, 1995). For a complete discussion of EVA cost formulas and methods is referred to the following references: Brandon, 2006; Webb, 2003.

The basic schedule metrics are:

Schedule Variance (Dollars) = BCWP - BCWS
Schedule Variance (Months) = (BCWP - BCWS)/(Planned Cost for Month)
Schedule Variance (%) = (BCWP – BCWS) * 100/BCWS
Schedule Performance Index (SPI) = BCWP/BCWS
Estimated Time to Complete (ETTC) = ATE + ((OD – (ATE * SPI))/SPI
Or in a simpler form ETTC = OD/SPI

Where ATE is the actual calendar time already expended and OD is the original duration. The SPI is also called the "schedule efficiency factor"; and values less than one indicate that the project is taking more time than planned.

The EV can be projected onto the planned cost (BCWS) curve to graphically show deviations. This is illustrated in Figure 8 (Brandon, 2006), which shows the planned cost and actual cost curves for a project analysis for the example here through July. The schedule variance in time is also shown in that figure along the time axis.

There are also other formulas which can be used for ETTC, and some may be better as a project draws closer to completion. In addition there are EAC formulas that use both the CPI and SPI; for a complete discussion of EVA schedule formulas and methods is referred to the following references: Brandon, 2006; Webb, 2003.

EVA uses a percent complete for each work packet to calculate an earned value for each packet. This value requires knowledge of the planned cost and the percent complete; it does not require knowledge of the actual cost. Thus EVA schedule variances can be calculated without any knowledge of actual costs. For some projects or some organizations, the determination of actual costs may not be practical in an accurate and/or timely manner. However, EVA can still be performed partially without any actual cost data including the SPI and estimated time to complete.

For many projects most of the cost is labor, and that being the case there are several ways that one can expedite the gathering of actual cost information or approximating cost information. One effective EVA method is to represent cost in terms of person-hours instead of currency (Brandon, 1998). All of the EVA formulas still apply there is just a change to the dimension. This often provides sufficient accuracy for project control purposes, even where there is considerable variation between pay rates on the project team. Even non-labor costs can be converted back into equivalent person-hours using a standard average overall labor rate. This has another advantage for the project manager, since it focuses his attention on the matters that he can control (Brandon, 2006).

EVA AND GANTT CHARTS

Traditional project progress reporting of schedule progress (as represented in classical Gantt charts) cost is neither as accurate or as effective in the early identification of problems, nor in projecting time to complete as is EVA. However EVA can be integrated into modern Gantt charts to overcome these shortfalls. Some modern software programs are capable of such a combination to present a more complete picture of project performance; an example of such a presentation is shown in Figure 9.

Figure 9. EVA on Gantt (Kidasa Software, www.kidasa.com)

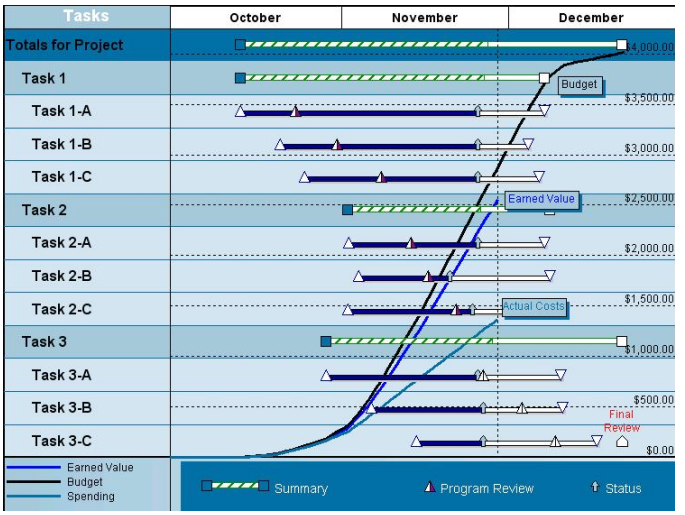

Figure 12. Project cost plan graph

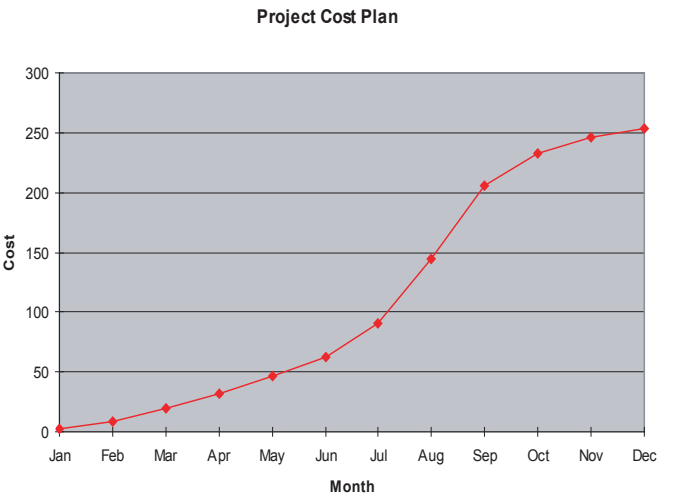

To illustrate how effective a combination of EVA and Gantt analysis can be, we will revisit a brief case study from an earlier publication (Brandon 1998, 1999).

For this example, the WBS consists of two levels, zero and one; and this is shown graphically in Figure 10 for level zero. Each level zero WBS item is further broken down into sub tasks at level 1; for example the breakdown of the "Test Prototype" task is shown in Figure 13.

The "cost plan" is shown in Figure 11 as a spreadsheet rolled up to the top level (level 0) of the WBS; this is also illustrated graphically in Figure 12.

A "bottom-up" estimation method is used to develop the cost plan, where there is another spreadsheet which shows the estimated cost and schedule for associated the level one work packets as shown in Figure 13 (for one of the level zero items – Test/Evaluate Protoype).

As the project progresses, actual costs are incurred by the effort expended in each work packet. These costs along with the percent complete of each work packet are collected each week work for this case study. This information is typically shown superimposed on the Gantt chart as percent complete numbers inside of the bars or shading a portion of each bar in an amount proportionate to the percent complete value. An example of this Gantt chart is shown in Figure 14. Figure 15 is an example of the planned and actual cost in currency (dollars) thru July for this case study. For most organizations these two types of displays are presented to management to report project performance as of a point in time. In that figure the planned cost curve is marked using the diamond symbols, and the actual cost curve is shown with the triangle symbols.

Figure 14. Case study Gantt chart

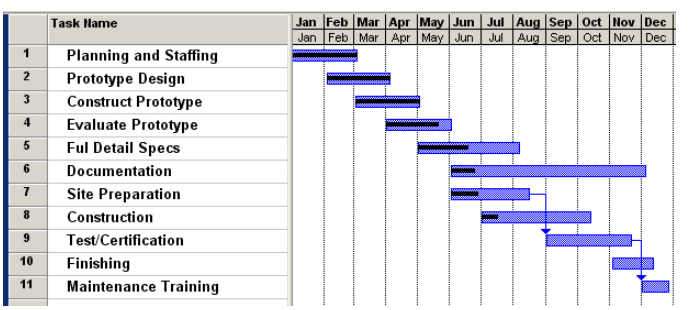

Figure 15. Planned and actual cost plan graph

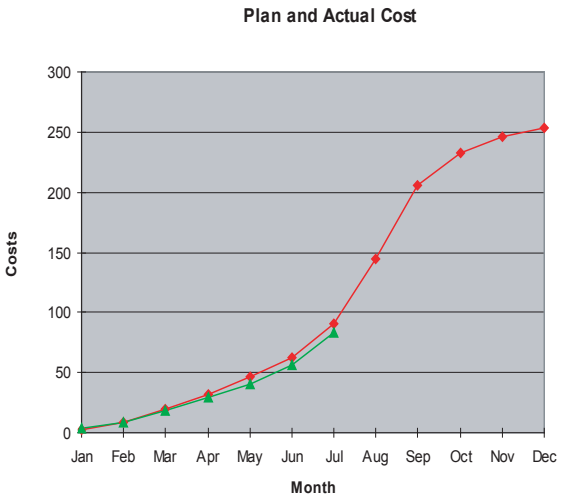

The problem with these usual methods is that they do not provide a clear quantitative picture of the true project status, nor do they provide a quantitative means for extrapolating project cost to complete or completion date. For the example project here, consider the Gantt chart above (which also shows the task percent complete as dark bars stripes inside the bars) and the actual cost versus budget graph. The project is not over budget (actual cost of $83,000 versus planned cost of $91,000), however it is hard to determine if it is on schedule or not. Actually this project is well behind schedule and is over-spent as the forthcoming earned value analysis will show.

For this case study, Figure 16 shows the EVA calculation through July. Note that the calculation of EV does not involve actual costs, but is simply the product of the percent complete and the planned cost.

Percent complete is determined for each work packet and then EV is calculated for each packet. The total project earned value at a point in time is determined by a WBS rollup of the EV values. A WBS rollup example is shown in Figure 17, for the level one tasks corresponding to the level zero item of "test/evaluate prototype".

In the example project herein, the schedule variance is -0.67 months (behind schedule) and the cost variance is -10,000 dollars (over spent). The estimated time to complete is 15 months instead of the 12 months planned, and the estimated cost to complete is 289,000 instead of 254,000. The calculation of these numbers for our example using the previous formulas is implemented in the spreadsheet of Figure 18.

Estimated Cost at Completion	**289**

INTERACTIVE WEB GANTT IMPLEMENTATION

Modern project management methods and modern information technology are now being integrated to produce "super-charged" Gantt charts. Figure 19 shows a display from the web based FiveAndDime system for this case study showing EVA calculations (as well as percent complete and cost data) with a familiar spreadsheet

Figure 19. EVA display in Gantt table (www.fiveanddime.biz)

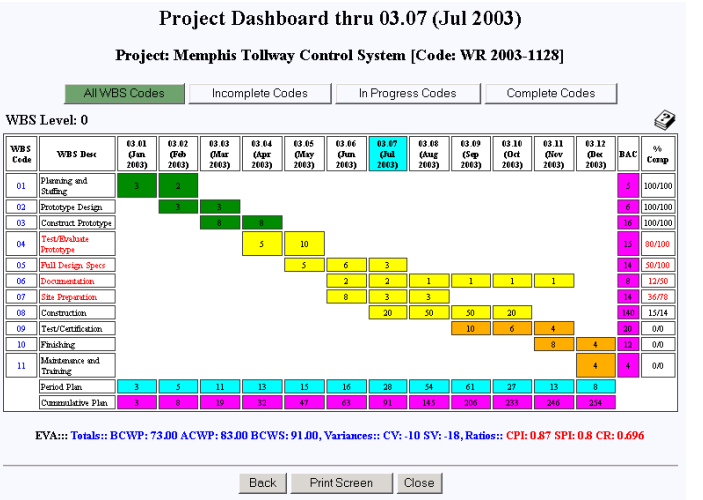

Figure 20. EVA drill down (www.fiveanddime.biz)

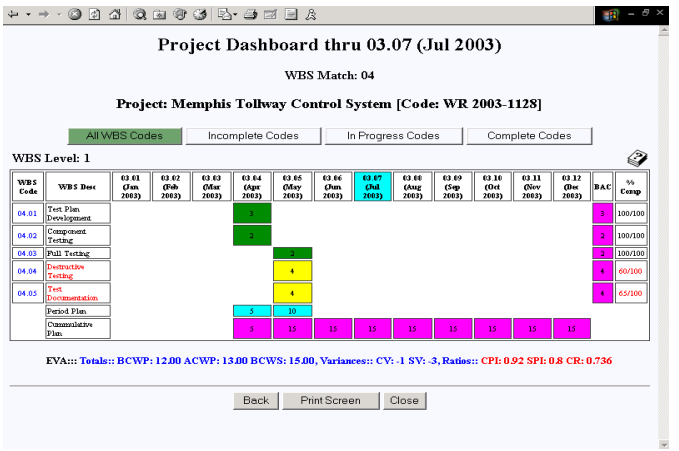

type Gantt chart format. Such web based systems make project information available anywhere in the world on any device that supports a standard web browser (without any custom client configuration necessity whatsoever) - even on modern PDA's and cell phones. Some emerging 21st century software is also now based on "open source software" to drastically reduce the cost involved with software licenses. For example, FiveAndDime is based on the open source "LAMP" stack (Linux, Apache, MySQL, and PHP).

In figure 19, the color in the Gantt chart bars is green for completed tasks, yellow for tasks in progress, and orange for tasks not yet started. The last column for percent complete shows a ratio where the numerator is the rolled up percent complete and the denominator is the percent complete that should have been obtained as of the reporting date; the value of that ratio is actually the EVA SPI for that task. WBS codes that have either the CPI or SPI below unity are displayed in red.

EVA greatly facilitates "management by exception". When there is a problem with a project as indicated by CPI and/or SPI less than unity, one can "drill down" in the earned value analysis to lower levels of the WBS. For example if the overall project index(s) is below unity, then one can select the level zero WBS codes that have their index(s) below unity; and then so on to the next level (level one for the case study herein).

Modern Gantt charts can also support this drill down capability and some software systems allow a PM to drill down interactively. Figure 20 is a screen shot from FiveAndDime showing a drill down from level zero to level one. This was accomplished by clicking on a particular WBS code (Evaluate Prototype) on the level zero display (Figure 19, where WBS codes with a CPI or SPI below unity are shown in red).

CONCLUSION

The Gantt chart has undergone many and significant changes since its introduction a century ago. Today's Gantt charts include earned value analysis so that effective performance management can be accomplished. Which of the new presentation formats available may be a matter of personal preference, however the interactive web based products have numerous clear advantages such as "drill down" capability. Even though Henry Gantt may not initially recognize the 21st century web enabled Gantt chart, the basic concepts and visualization he introduced have still been preserved.

ABSTRACT

This paper sets out to investigate military physicians' perceptions and usage regarding a mobile medical information system during their military service in the Finnish Defence Forces. Longitudinal data were gathered in September and December of 2005, and April 2006 by three semi-structured surveys. The military physicians (n=31) had positive perceptions of the mobile medical system, and had used it in their daily military training. But the perceived usefulness, in the terms of effectiveness and usefulness of the system, had declined significantly in April 2006. The same trend has also been found in their perception of ease of use, in the aspect of "easy doing what I want to do". The changes of the physicians' assessments and beliefs toward the system are explained. Insights of the findings and implications for system improvement are discussed.

Keywords: mobile medical information system, usefulness, ease of use, military physicians, longitudinal study

1. INTRODUCTION

Health information technology has been adopted by military medicine in different environments and for different purposes[1]. One early adopter is the U.S. Military that is, thanks to its large resources, in the forefront of development. For example, the U.S. army medical staff has been equipped with a point-of-care handheld assistant BMIS-T (implemented on Hewlett-Packard iPAQ Pocket PCs) based on Microsoft Windows Mobile software[2]. This mobile system can help the military medics in a critical part of their job—tracking medical information on the troops under their care. The system also helps medics to make quicker and more accurate diagnoses and treatment decisions, as well as helps them to reduce the paperwork when treated personnel are moved to e.g., military hospitals. Another new electronic system, a logistic tracking system by Intermec mobile computing, lowered U.S. military drug costs by $389 million in year 2004[3]. Very recently, 3M has developed and installed an RFID-based system[4] to the U.S. Army to track medical records at the US facility in Ford Hood, Texas. These examples have shown that mobile technology is playing an increasingly important role in supporting military medicine.

However, these systems are in use in a very large organisation with massive resources. Smaller national defence forces (e.g. Finland) have generally allocated fewer resources to implement health information technologies. There are systems developed originally for civilian purposes, which could improve the efficiency of military medicine without the development cost of a tailored system. In this paper we present some insights that we have obtained from a longitudinal study by investigating the adoption and usage of a mobile medical information system among thirty one physicians during their military service in the Finnish Defence Forces from September 2005 to April 2006.The research was designed to detect the changes of the physicians' perceptions of the system, i.e. usefulness and ease of use over the time. The structure of the paper is arranged as follows: In the next section, we briefly review the relevant literature. The research method is discussed in Section 3. Results are reported in Section 4, followed by discussion and conclusion at the end of the paper.

2. LITERATURE

2.1 Theoretical Background

Users' perceptions of and intentions to adopt an information system (IS) and the rate of diffusion and penetration of technology within and across organizations are two important foci of IS research (e.g. Straub et al., 1995). Well-accepted theories, for examples, the Technology Acceptance Model (Davis et al., 1989), the UTAUT (Unified Theory of Acceptance and Use of Technology) (Venkatesh et al., 2003) have provided good explanations of the adoption and usage of technology in different socio-technical contexts. The conclusions of many studies based on these theoretical approaches have indicated that perceived usefulness and perceived ease of use are two fundamental factors determining a user's acceptance of technology. These theories have recently been applied to explain user adoption of mobile technology (e.g. Pedersen and Nysveen, 2003; Han 2005). Perceived usefulness and ease of use of a specific mobile system are also found to be important determinants of technology adoption behaviour.

There are two temporal dimensions of adoption behaviour. One is pre-adoption or initial adoption behaviour (initial adoption, first-time usage and possible rejection at the pre-implementation stage). The other is post-adoption or post-implementation behaviour, (sustained continuous usage, and discontinued usage). In the two dimensions, users usually have different beliefs regarding the technology (Karahanna et al., 1999). As users gain more experience of a system, their beliefs and attitude towards the system might change. Such changes have major impacts on human behaviour regarding continuous system usage (Bhattacherjee and Premkumar, 2004).

2.2 A Mobile Medical Information System

The mobile medical information system, investigated in this research is a set of medical information and knowledge databases. It contains doctors' handbook, the EBMG (available in both, English and Finnish) with Cochrane abstracts, pharmacology database Pharmaca Fennica with a wireless update service for a complete medicine price list, the international diagnosis code guide (ICD-10) in Finnish, a laboratory guide by the Helsinki University Hospital, an emergency care guide issued by the Meilahti Hospital, a medical dictionary of over 57,000 terms, and a comprehensive database over health-care related addresses and contact information (pharmacies, hospitals, health centres). The content of the system is generated by an XML (eXtensible Mark-up Language) database. The system functions in most mobile devices operated by different systems, e.g., Symbian, Palm OS, and Windows CE. The device most commonly used as a platform in Finland is the Nokia Communicator (9210, 9300, and 9500). The mobile medical system is delivered on a 256 MB memory card, and is self-installing, containing the search engine, user interface programs, and core databases. Currently, an update of the system is available and is delivered on memory cards. In the near future,

the system will be able to update itself partly or completely through the wireless networks. The price list, part of the Pharmaca Fennica (the pharmacopoeia) is already able to update itself through the wireless data link provided by the mobile device. The databases have been updated to include a drug interaction database originally developed by the Karolinska Institute, Sweden.

3. RESEARCH METHOD

Theories of user technology acceptance can contribute greatly to understanding user behaviour regarding technology. These theories have served as the theoretical background and generated some important concepts that we have focused on in this study. A "practice-driven" approach has been adopted to design our research due to the fact that in the early stages of studies, of an exploratory nature (like our study), it is better to conduct studies in a natural setting, rather than from a pre-established theoretical perspective (Sharker et al., 2003, Zmud, 1998).

A longitudinal study was carried out from the autumn 2005 to the spring 2006. On September 6, 2005, with support from Pfizer Finland Ltd. and Duodecim Publishing Ltd, thirty one physicians, later in this paper called military physicians, (including some medical students) undergoing their military service in the Finnish Defence Forces, were given a Nokia Communicator 9210 equipped with a mobile medical information system. After the first user training session of the system[5] (on the same day they got the system), we distributed our first, semi-structured, questionnaire to collect their demographic information and to investigate their initial perceptions of perceived usefulness and ease of use of the system. The structured measurements were borrowed from previous established research with changes in wording to make them appropriate for the mobile medical information system and the military medicine context. In December 2005, after the military physicians had used the mobile medical system for a time of approximately three months, we conducted the second survey, to study the use of the system and the opinions regarding the system being used for military purposes in the field conditions. Nineteen valuable answers were returned. In the spring 2006, these physicians were relocated to different garrisons to continue their military service. In April 2006, the third survey that had a similar structure and questions with the previous surveys was distributed. Twenty-one physicians responded the survey.

The data analysis was primarily descriptive in nature. Frequencies and some central tendencies were calculated to illustrate physicians in the military service, their usage, and assessments towards the mobile medical information system. Potential differences in their behaviour over the three points in time were tested by ANOVA (Sig. < 0.05). The Scheffé test was used for *post hoc* tests.

4. RESULTS

4.1 Demographic Information of the Study Group

Of the thirty one participants, twenty-three have graduated and have become qualified physicians, eight are still medical students. Among the 31 participants, one has earned a doctoral degree in medicine, and two have, or will, become qualified pharmacists. The gender distribution was 30 male and one female. The mean age of the group was 25.19 years, the youngest being 20 and the oldest 28. Among the participants, twenty-two have never used a Nokia Communicator (any models) prior to the first survey, eight indicated prior usage. Seven have used the mobile medical information system before; among them, two have used it for 1 year (one of the two was the female physician in the group), two have used it for some months, and 3 have tried for a few hours.

In order to know whether the participants were familiar with the contents of the databases in the mobile medical information system, we also collected information regarding the usage of Terveysportti[6], the Finnish health care portal in the Internet in the first survey. Excluding 6 missing answers, all have used it ranging from 7 months to 5 years. They have used it for education/learning purpose (n=30), for patient consultation (n=21), and for completing their specialisation knowledge (n=8).

In general, this group was young, male–dominated, and familiar with the contents of the mobile medical system.

Table 1. Usefulness of the mobile medical information system

Perceived Usefulness	Mean			F	Sig. (p<0.05)
	Sep./05 (n=31)	Dec./06 (n=19)	Apr./06 (n=21)		
Improve medical knowledge	3.97	3.68	3.62	1.18	0.313
Enhance effectiveness in the field conditions	4.34	3.94 (n=18)	3.38	7.29	0.001
Improve my ability to make good decisions	3.83	3.74	3.33	2.25	0.114
Useful	4.58	4.32	3.38	14.25	0.000

4.2 Perceived Usefulness of the Mobile Medical Information System

The military physicians' perceived usefulness of the system was studied from four aspects: (i) using the system improves my medical knowledge; (ii) using the system enhances my effectiveness to do clinical work in the field conditions; (iii) using the system improves my ability to make good decisions; and (iv) I find the system useful for me. The military physicians' evaluation was measured using a five point scale, ranging from (1) strongly disagree to (5) strongly agree.

The perceived usefulness of the system, after a period of actual usage, was still positive in general (mean value > 3), but with a clearly declining trend (Table 1) across the study period. The *F*-ratios for the analysis of variance on the aspects of effectiveness and usefulness were significant at the 5% level ($F_{effectiveness} = 7.29$, df =2, 65, $p<0.05$; $F_{useful} = 14.25$, df=2, 68, $p<0.05$). Consequently, the Scheffé Test was used to compare pairs of the means in order to assess where the differences lie. It was found that at the 5% level of significance, the assessment of effectiveness of the system in April 2006 (M=3.38) was significantly lower than those in September 2005 (M=4.34), but the means of that in September and in December 2005 did not differ from each other. The evaluation of the usefulness of the system in April 2006 (M=3.38) was also significantly lower than those in September (M= 4.58) and in December (M= 4.32), but that the means of those of the two times in 2005 did not differ from each other. A very important insight we obtain from the results is that military physicians have gradually found that the system is not very useful in their military training. As they have obtained more experience from their actual usage in the different working environments, they have evaluated the usefulness of the system quite differently from their initial hype of the system. There are several reasons. Firstly, it might be due to the differences between the civilian and military medicine. The mobile medical system is designed for civilian physicians (see Han 2005, Harkke, 2006), the contents of the system lacks of a focus on military medicine. The longer time they worked in the field conditions, the higher demand for the contents specifically suited for military medicine would be raised, and the more limitations of the current contents would be shown. The second reason may due to the fact that military physicians used the system in the tough field conditions. The weather was cold and humid during the study period. Therefore, the natural environment gave rise to the high requirements on the physical robustness of the mobile device. The Nokia communicator is not very suitable to be used in such conditions (Han et al., 2006; Tétard et al., 2006). The drawbacks of the physical device may shed a shadow on the usefulness of the system. The third reason goes to the limitation of the mobile medical system itself. As a standalone system, it contains only the medical knowledge and information, but lacks of integration with other important systems which contain some crucial information, e.g. soldiers' health records. The last reason may be the possible effect of the changing working environment from the field conditions to the garrisons after December 2005. In the different garrisons these physicians can't access to the Internet, but they have other traditional databases which are accessible, i.e. books, CDs. The possible increasing usage of the traditional databases may also lead to less use of the mobile medical system in their daily work, thus, decreased positive perceptions of it in terms of effectiveness and usefulness.

4.3 Perceived Ease of Use of the Mobile Medical Information System

The military physicians were asked to indicate their perceived ease of use of the system. Questions about four aspects were asked: (1) learning to operate the system is easy for me; (2) I find it easy to get the mobile medical system to do what I need to do; (3) It is easy for me to become skilful in using the system; and (iv) I find the system easy to use. The evaluation was measured using a five point scale, ranging from (1) strongly disagree to (5) strongly agree.

The military physicians' perceived ease of use of the mobile medical system was positive in general with most of the mean value> 4 at the three points of time (Table 2). It is interesting to notice that the evaluation has displayed an increased trend from September to December 2005, but declined afterwards, especially the aspect of "easy doing what I need to do". The *F*-ratio for the analysis of vari-

Table 2 Ease of use of the mobile medical information system

Perceived Ease of Use	Mean			F	Sig. (p<0.05)
	Sep./05 (n=31)	Dec./06 (n=19)	Apr./06 (n=21)		
Easy learning to use	4.65	4.84	4.52	1.85	0.165
Easy doing what I need to do	4.19	4.47	3.57	5.45	0.006
Easy to become skilful	4.42	4.53	4.19	1.16	0.320
Easy to use	4.32	4.42	4.05	1.38	0.258

ance was significant at the 5% level ($F = 5.45$, df = 2, 68, $p < 0.05$). The post hoc Scheffé test showed that the difference lied between the evaluations of December 2005 with that of April 2006. The changing working environment may be one of the reasons to explain the differences. In a comparison with the accessibility of the traditional databases (books, CDs), it might be not easy enough to use the mobile medical system.

4.4 Usage Behaviour

4.4.1 Usage Intention

In the first survey in September 2005, the military physicians' behavioural intention towards the system was also measured by asking, if they think they will use it in the future. There was one negative answer that indicated that the person would not use the system, several neutral responses (n=7) that indicated insecurity about the future use. Twenty-three (74.2%, n=31) military physicians expressed clear interest in using the system in the future.

4.4.2 Self-Reported Actual Usage

In the second and third survey we carried out in December 2005 and April 2006, we investigated the real usage of the mobile medical information system, in terms of usage frequency (Table 3), and volume of use during a period of one week (Table 4). The possible differences of the usage frequency and volume over the study period were performed by paired T-tests; neither of the results was statistically significant. Table 3 has shown that majority of the group have used the system on weekly basis. Two physicians have reported that they did not use it at all from the dataset in April 2006. A declined trend of usage volume was also found. As showed in Table 4, 14 physicians in April 2006, compared to 10 in December 2005 have used it less than half an hour per week. A possible explanation may go to the fact that as their hand-on experience of using the system grew, their speed to find information increased, thus, they spent less time on using it. Another explanation is the possible negative effect from their declining perceptions of usefulness of the system. Physicians do not use a system if it is not useful for their work (Jayasuriya, 1998). The third explanation may also go to the changing working environment across the study period. The increasing use of other databases would decrease the usage of the mobile medical system in terms of usage frequency and usage volume.

Table 3. Usage frequency

	Usage Frequency	
	Dec. 2005 (n=19)	Apr. 2006 (n=20)
I don't use it at all	0	2
About once a month	4	3
About once a week	4	4
Several times a week	7	8
About once a day	3	2
Several times a day	1	1

Table 4. Usage volume

	Usage Volume	
	Dec.2005 (n=19)	Apri.2006 (n=20)
< 0.5 hours	10	14
0.5-0.9 hours	6	5
1.0-1.9 hours	2	1
2.0-2.9 hours	1	0
3.0 or more hours	0	0

5. DISCUSSION

This paper investigates military physicians' perceptions on and usage of a mobile medical information system in the Finnish Defence Forces. The findings from the longitudinal study have provided us with important insights and implications.

The Military physicians have positive perceptions of the usefulness and ease use of the system, but with a declining degree, in some aspects significantly. They have used the system on a weekly basis and spent mostly less than a half an hour using it. The reasons for usage patterns presented above may give some implications for system improvement: (i) more contents of military medicine should be included into the system, such as major trauma handling, pain relief, detoxication and cleansing of chemical/radiation injury in a combat situation; hygiene, epidemiology, prevention of infectious disease outbreaks while soldiers are living under rough conditions (in field and out of casern); and some peculiarities of "military health"-mass vaccinations, epidemiology, skin disease, and occupation safety/risk issues specific for military in casern/barracks; (ii) more attention has to be paid to the mobile device which is adopted to implement the system. Measurements to increase its physical robustness in the field are required; (iii) possible integration of the system with other crucial health databases will enhance its effectiveness and usefulness for military physicians working in the field; (iv) it seems that military physicians perceptions and usage behaviour towards the system could be significantly influenced by the changing working environment. When they were not in the field they could use other information resources. The mobile system is seen primarily as a supplement to, rather than a substitute for, traditional medical databases which are delivered from wired internet, PC-based tools or in printed books.

The results from the longitudinal study and the three datasets have convinced us that such a mobile medical system is needed by military physicians, especially in the beginning of the study as well as in field conditions. However, the result from the last dataset has shown some significantly different evaluations. This may imply that in order to encourage the usage of the mobile medical system, we have to be sensitive to the physicians' working environment. In other words, the organization should strategically implement the system to the "mobile" military physicians, not to those who are stable at different garrisons.

6. CONCLUSION

This study has helped us understand how military physicians adopted a mobile medical information system during their military service, while also providing some indications of the actual usage patterns and some belief and behavioural differences across time. There seems to be a need for the kind of mobile medical system for military purposes, but some significant improvements have to be made to the civilian systems to make them fit the needs of military training and in order to increase the usage in the future.

A longitudinal study has given us the opportunity to detect more insights of the research phenomenon and also helped to reveal more important effects, such as changed working environments and temporal effects on human technology adoption behaviors.

The research reported here could be seen as a study reflecting the military physicians' reactions to mobile technology in general and the mobile medical information system in particular. Since the military physicians have used the system in their work practice, both in the field and in the garrisons, their appreciation of the system may be considered as a solid basis for future system development.

XML in a Data Warehouse Design: Performance Evaluation Utilizing Geological Data

Behrooz Seyed-Abbassi, University of North Florida, 4567 St. Johns Bluff Road S, Jacksonville, FL 32224; E-mail: abbassi@unf.edu
Lori Stowers Pusey, University of North Florida, 4567 St. Johns Bluff Road S, Jacksonville, FL 32224; E-mail: puseyl@aetna.com

ABSTRACT

The structure of XML data presents challenges when determining efficient ways to map it to a relational data warehouse. One of these challenges is the presence of multi-valued child elements. Translating multi-valued XML elements to a relational data warehouse may require the consideration of non-traditional approaches to the design of the data warehouse. Traditionally, the star schema has been the design of choice for data warehouses. However, the semi-structured nature of XML data may make the use of alternatives, such as the snowflake schema, more efficient. This paper presents the implementation details of methods for preserving XML data in a relational data warehouse that are based on the star and snowflake design schemas and compares the methods quantitatively and qualitatively for geological data sets.

Keywords: XML, data warehouse, star schema, snowflake schema, relational database, geological data

1. INTRODUCTION

Extensible Markup Language (XML) has become the accepted standard for exchanging data over the Internet [1]. As more organizations choose to collaborate and share information on the Web, the demand to access and mine XML data is dramatically increasing which in turn is resulting in the need to utilize design methodologies for effective storage and retrieval or warehousing of the XML information.

Many research projects, as well as software corporations (such as, Oracle [2], Microsoft [3], and IBM [4]), have initiated techniques and various methods for creating, storing, and retrieving XML information [5][6], including a variety of proposed methodologies for translating XML data to a relational environment [7]. Several published works cite the need to store XML data in a file system or a relational database environment, as well as address some of the difficulties that arise from the differences between the structure and semantics of XML data and that of relational data [8][9].

As noted by Shanmugasundaram, native XML databases do not have the "sophisticated storage and query capability already provided by existing relational database systems" and "do not allow users to query seamlessly across XML documents and other data stored in relational database systems" [10]. Two complications presented by XML data have been identified as recursion and multi-valued (or set-valued) elements [11].

In a relational data warehouse, the main issue in storing XML data is the potential inability to extract all the information necessary from the XML document and definition to develop a data warehouse design that accurately represents the XML data [12]. Another problem is the differences in "expressive power" of the relationships presented in an XML document's definition [13]. The source of these issues is the semi-structured nature of XML.

The presented research work addresses design issues of storing multi-valued XML data with many-to-many relationships, which results in multiple associations within a relational data warehouse. Two alternative methodologies for preserving this type of XML data are evaluated. Both methods involve decomposing the XML elements and storing their values in a relational table within the data warehouse. The first proposed alternative makes use of the snowflake schema in the design of the data warehouse tables, while the second alternative utilizes the traditional star schema. The details of the implementation of these alternative methods, along with quantitative and qualitative comparisons of the methods are described.

The paper is divided into the following descriptive sections. Background information on XML and the relational paradigm are given in sections 2 and 3 respectively, with XML storage and mapping in a relational environment considered in section 4. The alternative methodologies and the comparative study are described in section 5, followed by more specific information about the implementation processes in section 6. The testing results from running SQL queries against each method's data tables are given in section 7, with section 8 providing the conclusions of the research.

2. XML CHARACTERISTICS

XML is a text-based language with user-defined tags that preserve the semantics and relative context of information. The tags add flexibility to XML documents and semantic representation. XML has become the preferred language for exchanging data over the Web for two reasons. It is based on a standard and, therefore, vendor-neutral, and since it is text-based, XML can be viewed within any text editor [1]. In order to allow the consumer of an XML document to verify its validity, a document type can be used in conjunction with the document to define the allowable structures.

The three basic methods for storing XML documents are as a flat file, XML database, and relational database [14]. The flat file approach allows for the access of a specific XML document through the traditional file system hierarchy. The XML database approach involves the "direct access to XML documents and fragments of documents, and the ability to query across those documents and fragments" [14]. The relational database approach is more complex and involves decomposing (shredding) the XML document and storing element values in table fields. Of the three approaches for storing and accessing XML data, only the relational database allows for the creation of complex queries, can be integrated with other relational data, and provides mechanisms for transaction management and recovery [14].

3. RELATIONAL PARADIGM

Relational database, introduced by E. F. Codd in 1970 [15], is presented by collections of tables (or relations) that contain data items with similar properties (or attributes). In a table, each column corresponds to one of the attributes, and each row (or tuple) represents a piece of data (or record) containing those attributes. Data warehouses, which typically contain historical data or facts and are structured specifically for querying and reporting, can take advantage of the structure of relational database for design and implementation. However, because the data is historical or factual and unlikely to change, data warehouses tend to be denormalized and the data treated as read-only [15].

Two common schemas used for a data warehouse are the star and snowflake [16]. The star schema contains a single fact table that holds factual data (typically transactions) surrounded by multiple dimension tables that contain reference data (i.e., components that comprise each fact or transaction) [15]. The fact table consists

of a unique primary key for each fact, a foreign key reference to the primary key from each of the dimension tables, and optional measure data (such as quantity). The star schema models a many-to-one relationship between the fact table and each of the dimension tables.

The snowflake schema allows dimension tables from a star schema to be "organized into a hierarchy by normalizing them" [16]. This schema, therefore, allows for multi-valued attributes associated with a dimension table to be modeled using additional, hierarchical tables. However, because a data warehouse can contain an enormous number of records, performing joins between numerous tables can be costly in terms of query response time.

Typically, the star schema is used to represent the multi-dimensional data warehouse model and is better suited for querying, over the snowflake schema, because the data is denormalized [17]. The more normalized snowflake schema, while providing advantages when maintaining the data [17], requires additional table joins for queries that access the normalized data and can, therefore, increase the query response time [18].

4. STORING XML DATA IN RELATIONAL TABLES

There are three basic techniques to decompose (or shred) XML data for storage in relational tables: no decomposition, partial decomposition, and total decomposition [19][20]. They are differentiated by the extent to which the XML data is decomposed and by the way that XML is stored in relational tables. The decompositions into relational tables generally fall into two categories: those that start with an XML document and those that do not. Each approach varies in the number of relational tables that are created and in the structural information and element values that are captured.

The no decomposition approach (document-centric) involves storing the entire XML document as text in a flat file or relational table's field (e.g., as a character large object-CLOB) [20]. In partial decomposition, XML data is selected, decomposed, and stored in tables to allow quick access to specific data through SQL queries [19]. Total decomposition (data-centric) involves decomposing the entire XML document and storing its elements' and attributes' values in table fields. The third approach fully exploits the query power of relational databases, but is a complex implementation due to the differences in structure between XML documents and relational tables, and cardinality uncertainties inherent in XML schemas.

A schema-based approach for storing XML data in a relational data warehouse proposed by Golfarelli starts by translating an XML document into a graph and an algorithm applied to the graph to create an attribute tree from which a data warehouse conceptual design is developed. Golfarelli's method, unlike other methods, emphasizes the determination and evaluation of relationship cardinalities within the graph. These cardinalities show a to-one or to-many relationship between elements and their child elements (or sub-elements) [13].

Because of their structure, XML documents benefit from either the partial or total decomposition for storing XML information in a relational data warehouse. Both methods can handle multi-valued sub-elements in XML format using Golfarelli's methodology for to-one and to-many associations.

5. DATA WAREHOUSE DESIGN METHODOLOGIES

The focus of the proposed methodologies is on the problem of how to best capture multi-valued XML data within the confines of a relational data warehouse. Because of the inherent structure of a data warehouse, the fact table often contains a very large number of records, which means that performing table joins between the fact and dimension tables can be costly in terms of query response times. This is one reason why the denormalized star schema is generally the preferred design for a data warehouse.

The first methodology decomposes non-multi-valued elements and stores their values in data warehouse dimension table fields similar to Golfarelli's approach. However, instead of dropping multi-valued child or sub-elements altogether, the method is modified in order to capture the multi-valued sub-element data by storing the data in XML format within a field. Because the multi-valued elements are not decomposed, no table hierarchies are created and the star schema is maintained.

The second proposed alternative uses a variation of the star schema that includes additional hierarchical tables, thus creating a snowflake schema. This method, like the star schema, fully decomposes the XML data and captures its element values in the data warehouse tables and makes use of an additional table to hold the decomposed multi-valued element data. The additional table is then linked via a foreign-key field to the dimension table that holds the parent element data; thus creating a one-to-many relationship between the dimension table and the added table creating a normalized snowflake.

6. IMPLEMENTATION PROCESS

The following subsections summarize the implementation process for the two proposed design methods, including the XML data chosen for translation and storage, the design of the data warehouses, and the queries applied to the data tables.

6.1 Geological XML Data

To evaluate the performance of XML in the design of a data warehouse, the initial testing has been completed with text-based geological XML data to provide the foundation for future expansion to support more complex semi-structured data. The implementation process utilized the U.S. Geological Survey's (USGS) website [21] for historical XML data available in their earthquake advisories. The historical earthquake data consists of the date and time or origin, geographic coordinates (latitude and longitude), depth, magnitude, station used for the magnitude measurement, region, and additional magnitudes. A sample data format for an earthquake is presented below with the field names and data examples separated by :=.

Date:= 1/1/2004
Origin Time (UTC) (HH:MM:SS):=20:59:31.9
Latitude:= 8.310 S
Longitude:= 115.788 E
Depth:= 45
Magnitude:= 5.8
Station No. Used:= 119
Region:= Bali, Indonesia
Additional Magnitudes (Formula/Value/Station):= Mw/5.8/GS, Mw/5.8/HRV, mb/5.5/GS, Ms/5.4/GS

The earthquake data from 2000-2005 were converted to a modified XML earthquake advisory format and grouped by month resulting in 72 XML documents. To populate the data warehouses with a sufficient amount of data to show query access time differences between the methodologies, the data within the 72 documents (i.e., 6 years worth of data) was quadrupled to create over 100 years of data.

6.2 Implementation of the Data Warehouse Design

A fact table within the data warehouse consists of all of the data associated with an earthquake advisory, including the data for the advisory in which the event is reported as well as the event data. The following data items provided a complete earthquake advisory record or fact:

- Advisory title
- Advisory publish date
- Event date
- Event latitude, longitude, and depth
- Event region
- Event magnitudes (one or more)
- Magnitude source
- Magnitude formula
- Magnitude value

The design for each data warehouse as shown in Figures 1 and 2 includes a single fact table and dimension tables to hold the event advisory data. Time data is represented in a separate dimension table. The fact table contains foreign keys for the publish date and event date that refer to the time dimension table's primary key.

A separate dimension table is used to hold the publisher name. Using a separate dimension table avoids unnecessary duplication and leaves room to include advisories published by other organizations in the future. A separate dimension table is also used to hold the advisory title and link for the same reasons. The fact table contains foreign keys that link it to the publisher and advisory dimension tables.

Figure 1. Star schema data warehouse logical schema

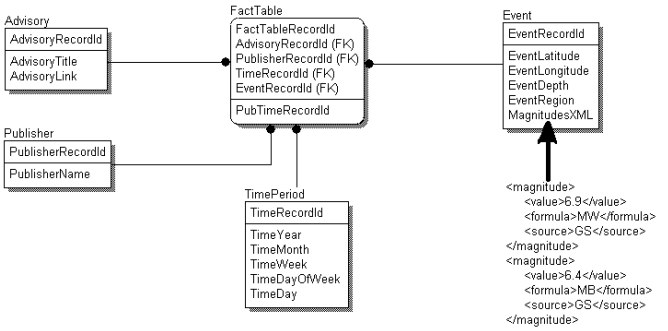

Figure 2. Snowflake schema data warehouse logical schema

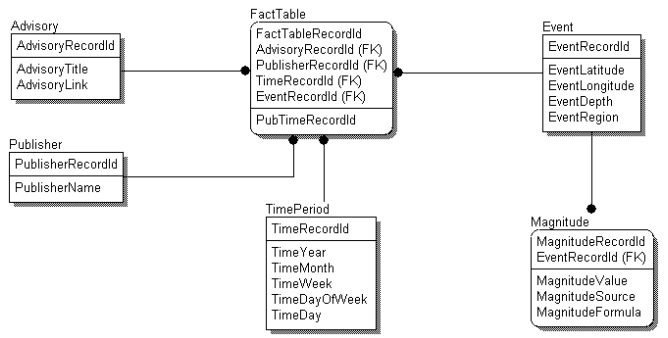

The event region, latitude, longitude, and depth are represented in their own dimension table and the unique identifier included as a foreign key in the fact table. Magnitude data is stored differently for the two methods. The star schema method stores magnitude data in XML format for each event as presented in Figure 1. This means that the magnitude data is maintained in the original XML document format and stored as text within a table field called the Event table.

The snowflake schema method uses a separate, hierarchical table to store the multi-valued magnitude data. This means that each magnitude is maintained in a separate row with the source, formula, and value each contained within a column. In addition to the general structure of the snowflake schema's fact and dimension tables, Figure 2 shows the multi-valued XML data broken down into individual fields and records, and stored in a separate table. The table contains a foreign key reference to the primary key of the dimension table, which holds the parent element data.

6.3 Queries

Queries used to compare response times between the two methods are representative of the types of queries that might actually be applied to the earthquake advisory data in the real world. The queries are also designed to test the technique each method uses to store the multi-valued magnitude data. These queries, in a business language format, are:

1. Retrieve all earthquake event records
2. Retrieve a single earthquake event record for a given date and region
3. Retrieve all earthquake event records that had a magnitude >= 7
4. Retrieve earthquake event records that had a magnitude equal to the maximum magnitude across all records
5. Retrieve the average magnitude over all earthquake event records

The goal when translating these queries to SQL is to extract the information with a single query to the data warehouse, when possible. Multiple queries, however, are necessary in some cases. The SQL queries for the star schema method, where magnitude data is stored as XML for each event, involved using an extraction function applied to the XML text in order to retrieve each individual element's data value. Because there may be multiple magnitude source, magnitude formula, and magnitude value nodes for each event, these nodes must be accessed via a subscript. In addition, because the number of subscripts necessary to access the source, magnitude, and value nodes for each record varies, queries use the maximum number of subscripts and require additional processing to filter any null values returned. The SQL queries for the snowflake schema require an additional join of the Magnitude table.

7. RESULTS

The data tables for the two data warehouses were created using Oracle 10g [2] server with a dual Xeon processor. All queries were executed five times and the average of the five runs taken as the representative response time for that query.

In addition, indices were created in an attempt to maximize query response times. An index was created for each table's primary key and functional indexes were created for magnitude values within each data warehouse. The response times for Queries 1, 2, and 3 for the Star Schema and Snowflake Schema methods show less than an order of magnitude difference, while the Query 4 and 5 response times for the two methods show several orders of magnitude difference. The variations between the two sets of queries are a result of the differing query complexities caused by the manner in which the multi-valued XML data is stored and, therefore, must be accessed in the two methods. Queries 1, 2, and 3 involve either no or

Figure 3. Response times (milliseconds) for queries without calculations or aggregations

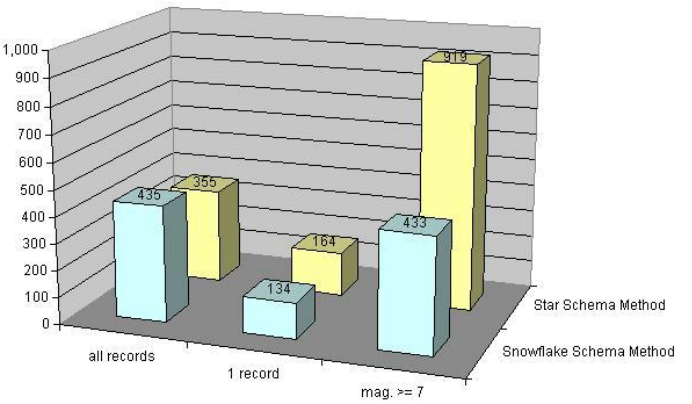

Figure 4. Response times (milliseconds) for queries with calculations or aggregations

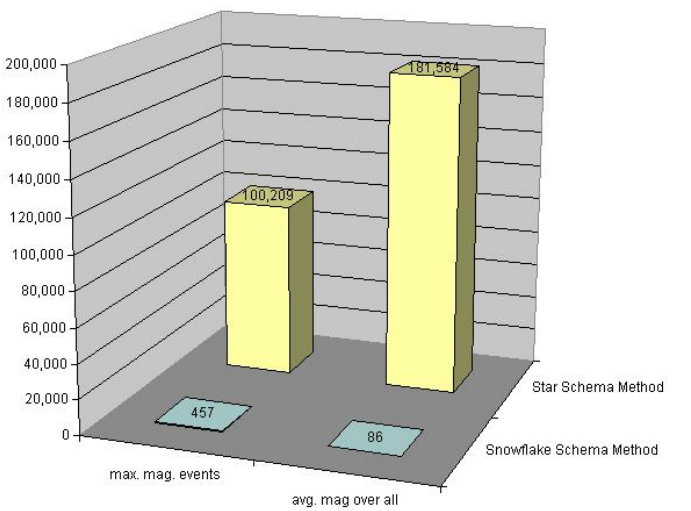

Figure 5. Response time average over all queries (milliseconds)

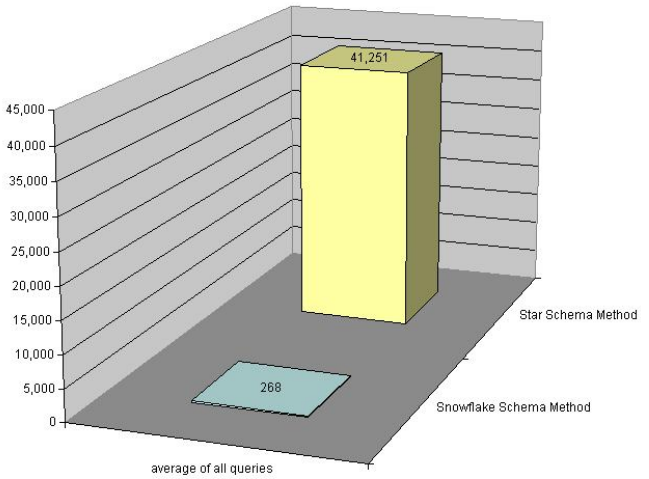

simple filtering, while Queries 4 and 5 involve calculations or aggregations of the multi-valued magnitude data, which is stored differently in the Star Schema and Snowflake Schema methods.

The response times (Figure 3) for Query 1 (retrieve all records) show that the Snowflake Schema is slightly slower than the Star Schema. Although the query for the Star Schema makes use of an XML extraction function, which is built into Oracle, to extract the magnitude data, the Snowflake Schema method actually takes slightly longer (435 vs. 355 ms for the Star Schema method). This is most likely due to the increased time it takes to join records, which is greater for the Snowflake Schema method because it has an extra table.

The response times for Query 2 (retrieve a single specific record) show that both the Star Schema and Snowflake Schema methods are comparably efficient at retrieving a single record (164 ms for the Star Schema method vs. 134 ms for the Snowflake Schema method). Even though the Snowflake Schema method requires the extra join for Query 2, the criteria for retrieving the single record translates into a much faster execution plan that filters for the search criteria before scans on the hierarchical table are performed.

The response times for Query 3 (retrieve all records that have a magnitude >= 7) show the Snowflake Schema method to be almost twice as fast as the Star Schema method (433 vs. 919 ms for the Star Schema method). The query for the Star Schema requires a comparison for each of the multi-valued XML elements, which adds extra filter criteria. The Snowflake Schema method, however, can take advantage of the relational database's built-in ability to join and filter.

Queries 4 and 5 (Figure 4), which involve aggregations of the multi-valued magnitude data, have response times that show differences between the Star Schema and Snowflake Schema methods that are several orders of magnitude in size.

The response times for Query 4 (retrieve all records with the maximum magnitude) show that the Snowflake Schema method is much faster than the Star Schema (457 vs. 100,209 ms for the Star Schema method). Response times for Query 5 (retrieve the average magnitude of all records) also show the Snowflake Schema method to be faster (86 vs. 181,584 ms for the Star Schema method).

Like Query 3, Queries 4 and 5 require access to and extraction of the multi-valued magnitude data. With the Star Schema method, Queries 4 and 5 must access the XML elements twice, once to perform a calculation or summation and a second time to perform an aggregation. Because of the need to extract the XML text elements in the Star Schema method, Queries 4 and 5 become cumbersome, while the Snowflake Schema method, again, takes advantage of the relational database's built-in ability to join and filter.

The response time averages for all 5 queries (Figure 5) show that the snowflake schema method demonstrates a response time average that is 153 times faster than that of the star schema method. These results demonstrate that in this case, where the XML documents contain multi-valued magnitude data, the decomposition of the magnitude data into a snowflake schema is advantageous over attempting to maintain the traditional star schema.

8. CONCLUSIONS

A comparison of the methods from a quantitative standpoint, based on the query response times, shows that the snowflake schema method is consistently faster, and markedly faster in most cases, than the star schema. The star schema method has some response times that are comparable to the snowflake schema method. However, queries that require calculations (e.g., sum) or aggregations (e.g., average) of data values stored as XML demonstrated much slower response times with the star schema.

A comparison of the two methods from a qualitative standpoint, based on the experiences gained from implementing the methods, also shows that the snowflake schema method is preferable over the star schema. The star schema method required the use of a subscript when accessing multi-valued elements within the XML data. In addition, the star schema method required additional filtering when accessing a variable number of multi-valued elements and post-query processing when performing aggregates. The snowflake schema method required only one query and did not require filtering or post-query processing.

The implementation in this research has demonstrated that when storing multi-valued XML data, the snowflake schema demonstrates faster query response times than the star schema and may, therefore, be preferred over the star schema in cases involving the storage of semi-structured XML data. Finally, the type of data and the access methods necessary to retrieve the data should be an important consideration when making decisions regarding the design of a data warehouse.

ABSTRACT

This study examines the adoption factors for deployment of customer relationship management (CRM) in higher education institutions. While CRM is widespread in the corporate sector, its usage has been limited in higher education. With the rising service expectations, universities have to realign their strategies to serve students across their entire student life cycle. We used the case study approach to examine factors critical to CRM adoption in the higher education sector. The study is exploratory in nature, representing one of the first efforts to study CRM adoption in universities and colleges. Our findings suggest that groups with a clear understanding of student life cycle will be more likely to adopt CRM. We propose that a fit between the choice of CRM goal - strategic versus transactional CRM - and organizational factors will help determine the continuous adoption of CRM by higher education users.

INTRODUCTION

Customer relationship management (CRM) involves the deployment of strategies, processes, and technologies to strengthen a firm's relationships with customers throughout their life cycle – from marketing and sales, to post-sale service (Winer, 2001). While CRM is a widespread concept in the corporate world, it is a relatively new phenomenon in the higher education sector (Grant and Anderson, 2002).

In this paper, we examine the factors affecting the adoption of CRM technology in the higher education sector. Through a case study of a Midwest university, we intend to address three research questions: (1) What characteristics of an institution contribute to the adoption of CRM technology? (2) What factors influence adoption decisions? (3) What strategies can be applied to increase the success of CRM adoption in higher education institutions?

We use the innovation diffusion theory (IDT) (Rogers, 1995) and the unified theory of acceptance and use of technology (UTAUT) (Venkatesh et al., 2003) to guide data collection and analysis for this case study. This paper starts with a review of CRM research, its implications for colleges and universities, and research on IDT and UTAUT. It then presents the research methodology and data collection procedures. The paper concludes with a discussion of contribution of this research. Findings from this study will help us gain a better understanding of the specific needs of the higher education sector for CRM deployment.

LITERATURE REVIEW

Customer Relationship Management

CRM is an enterprise-wide initiative which focuses on developing and leveraging an in-depth view of customers across enterprise applications and business units. It promises to provide seamless integration of multiple business areas that touch the customer – marketing, sales, customer service and field support - through integration of people, process and technology (Satish et al., 2002). It is a combination of business processes and technology that seeks to understand a company's customers from the perspective of who they are, what they do, and what they like (Ryals and Knox, 2001). Along with other enterprise systems, such as enterprise resource planning (ERP) systems, companies are adopting CRM technologies to strengthen customer interactions and shifting their focus from business efficiency to business effectiveness (Sheng, 2002).

CRM in Higher Education

Higher education institutions are "student centric" organizations that encompass a wide range of student outreach and counseling activities such as admissions, academic advising, job placement and more.

While CRM usage is widespread in the corporate sector, higher education is far behind with CRM implementation (Grant and Anderson, 2002). Universities and colleges may benefit from CRM by improving student-facing processes (Chen and Ching, 2005), personalizing communications with students (Karimi et al., 2001), sharing information among departments (Chen and Ching, 2005), and increasing student retention and satisfaction (Bradshaw and Brash, 2001).

Student Life Cycle

Significant changes in the expectation of students, contribute to the relevance of relationship management strategy (Conant, 2002). While it might seem counter-intuitive to view students as customers, changes in the higher education sector necessitate this shift in thinking. Viewed from the CRM lens, the concept of customer life cycle can be mapped to the stages that a student progresses through when considering and using the services of a learning institution to form the student life cycle. Within a student life cycle, a student progresses though the following stages:

Suspect→ Prospect→ Applicant→ Admitted → Enrollee→Alumni

- Suspect: A suspect is any student who might be a potential candidate for the school.
- Prospect: A prospective student is at the information gathering and opinion forming stage.
- Applicant: A student is an applicant when he/she makes the decision to join the institution.
- Admitted: A student is admitted when the college makes a decision to accept the student.
- Enrollee: This is the stage where students become a part of the institution.
- Alumni: At this stage, students who are satisfied with their academic experience will develop long-term loyalty to their alma mater.

In view of corporate CRM activities, college student enrollment management activities of converting suspects to the admitted represent the marketing components of CRM; the conversion of admitted students to enrollees represent the component of sales; and the continuous enrollment and participation as alumni represent the retention and support components. However, student life cycle involves more complex interactions especially during the retention phase as academic programs, advising, and student life play critical role in student retention (Tinto, 2005).

Innovation Diffusion Theory (IDT)

IDT by Rogers (1995) emphasizes diffusion life cycle and addresses the differences in the pre- and post-adoption attitudes and beliefs. The innovation decision process leading to institutionalization of usage (Karahanna et al., 1999) may be conceptualized as a sequence of steps through which an individual passes from initial knowledge of an innovation (information), to forming a favorable or unfavorable attitude towards it (persuasion), to a decision to adopt or reject it (decision), to put the innovation to use (implementation), and to finally seeking reinforcement of the adoption decision made (confirmation) (Rogers, 1995). The IDT framework as highlighted below could enable us to examine CRM adoption through different stages of innovation life cycle.

Information→ Persuasion→Decision→Implementation→ Confirmation

Unified Theory of Use and Acceptance of Technology (UTUAT)
In addition to IDT, we used UTUAT framework which takes a more comprehensive view of technology adoption in an organization. The decision by a company to deploy a CRM system is in essence a technology adoption issue. Venkatesh et al (2005) present the unified theory of use and acceptance of technology (UTUAT) by integrating eight prominent but fragmented research models concerning user acceptance and usage of new technology. Unified theory identifies four determinants of user acceptance and usage behavior: (1) performance expectancy, (2) effort expectancy, (3) social influence, and (4) facilitating conditions. We used UTUAT to help us structure our research constructs and facilitate data collection.

RESEARCH METHODOLOGY

Because of the exploratory nature of this research, we used the case study method to examine CRM adoption in a single organization, a Midwest university. According to Lee (1989), case study method is well suited for exploratory studies where the sample sizes are relatively small. The case study method is particularly appropriate when the research and theory are at their early formative stage (Benbasat et al., 1987). According to Yin (1984), a single-case study approach is most useful when the phenomenon of interest, in this instance, user adoption factors and usage patterns, can not be clearly separated from the social, technological and organizational context in which they appear.

The case study strategy consists of defining the study focus, construction of framework to guide data collections, interviews, data collection and case analysis (Pick and Roberts, 2004). In our study, the unit of analysis is a department within a single institution. We included 37 members in nine departments/colleges. These groups provide a range of CRM adoption scenarios across different stages of student life cycle.

Data Collection Procedure
We used multiple sources of evidence to support the construct validity, including: structured email questionnaire, statement of business cases and other documents as appropriate. Internal validity has been ensured by constructing a detailed research framework with detailed steps. Reliability was addressed by adopting detailed case study protocol that documents the scheduling, interview procedures, recording, and follow-up questionnaire. The procedures for data collection involve the following steps:

Table 1. Participating departments

Department/ College	Number of Users	Adoption life cycle stage	Pre/post Adoption	Stage in student life cycle
Enrollment Management	6	Confirmation	Post-Adoption	Suspect, Prospect & Applicant
College A Admissions	5	Decision	Post-Adoption	Prospect
College E	6	Confirmation	Post-Adoption	Prospect & Applicant
College B	5	Decision	Pre-Adoption	Prospect, Applicant, Enrollee & Alumni
College D	3	Implementation	Post-Adoption	Prospect, Applicant, Enrollee & Alumni
College C	4	Implementation	Post-Adoption	Applicant & Enrollee
Student Affairs	3	Confirmation	Post-Adoption	Applicant & Enrollee
Financial Aid	2	Decision	Pre-Adoption	Applicant & Enrollee
College A Advising	3	Persuasion	Pre-Adoption	Enrollee

For each department, the research team conducted semi-structured interviews with the key decision maker and one or more users. Two parallel sets of interview questions were used for departments in the pre- or post-adoption stage, respectively. Based on IT diffusion adoption life cycle (Rogers, 1995), departments at a persuasion or decision phases were categorized as pre-adoption and those identified in the decision, confirmation and implementation phases were categorized as post adoption (Rogers, 1995).

An email survey questionnaire was sent to the interviewees, approximately two days after the interview. The questionnaire items were adapted from the UTUAT study (Venkatesh et al., 2003). Due to the small sample size, we only used the survey results to supplement interviews.

Participating Units
Users in nine departments participated in this study. Table 1 presents the diverse range of scenarios of CRM adoption at this institution. Each group of users is categorized based on the stage in adoption life cycle, pre- or post-adoption, and targeting students in terms of student life cycle.

FINDINGS

Research Case: Profile of the Target Institution
Our case study focuses on a Midwestern university which has metropolitan and suburban campuses. The university now supports well over 23,000 students and over 3000 faculty and staff. At the time of the study, the university had installed an enterprise CRM system (Enterprise CRM) as a part of enterprise resource planning (ERP) package, an Enrollment Management CRM (EM CRM), and two standalone CRM applications for two different colleges (College CRM). Therefore, the findings discussed below represent a diverse set of choices for CRM technology.

At the enterprise level, the IT department has deployed one-to-one communication module of the enterprise CRM package. For example, offices of student affairs utilize online marketing tools of the Enterprise CRM package to maintain an active relationship with enrolled students, particularly students at risk. The enrollment management division has recently adopted an EM CRM, niche software designed

GOAL	ORGANIZATION: Centralized	ORGANIZATION: Decentralized
Strategic CRM	Process Characteristics: Redefine existing processes and emphasize long-term relationship building with students Impact on student life cycle: Services students across the entire or significant portion of student life cycle Organizational Dependency: Service provider to other organizational units Role: CRM users and champion(s) Example: Enrollment Management	Process Characteristics: Redefine existing processes and emphasize long-term relationship building with students Impact on student life cycle: Services several stages of the student life cycle Organizational Dependency: Standalone organizational unit Role: CRM users Example: College E, College D
Transactional CRM	Process Characteristics: Automation of existing processes. Short-term and tactical in nature Impact on student life cycle: Services limited activities or a single stage of the student life cycle Organizational Dependency: Service provider to other organizational units Role: CRM users and champion(s) Example: Student Affairs, Financial Aid	Process Characteristics: Automation of existing processes. Short term and tactical in nature Impact on student life cycle :Services limited activities or a single stage of the student life cycle Organizational Dependency: Standalone organizational unit Role: CRM users Example: College C, College A Advising,

specifically for the higher education sector, to manage student recruitment funnel (from suspect to admitted stages of the student life cycle). The College CRM tools are either in-house applications or standalone systems designed to support admissions process, which are either used alone or in conjunction with Enterprise CRM. For example, College A's admissions office used enterprise CRM and its own email application to target prospects for open house and other recruiting events.

Group Segmentation: A CRM Grid

Based on our initial assessment of the user departments and groups, we conceptualized a framework to synthesize and segment the participating groups. As shown in Table 2, this CRM Grid segments the participating units according to the nature of their organizational responsibility and structure (centralized versus decentralized) and the goal of CRM adoption (strategic or transactional).

Organization

Organization defines the structure of the division/college/department in this university. An organization can be either centralized or decentralized in terms of its ownership of CRM process. Centralized units are service providers to other departments or colleges. They support and collaborate with other colleges on core business processes like recruitment, student affairs, and alumni relations. In most cases, they were the owners of enterprise-wide CRM process and technology solutions. Their role was not only as users of the system but as champions as well. Decentralized units are colleges and schools that are autonomous administrative units. These colleges have their own departments to take care of recruiting, admissions, and student and alumni relations. Since this university did not mandate the usage of an Enterprise or EM CRM application, CRM adoption is voluntary and based on needs. Decentralized units have resources to build or buy their own CRM systems. They were mainly CRM users who would rely on vendors or centralized departments to support the backend operations and data integration.

Goal

Goal defines the purpose for using CRM application in this university. Strategic CRM is long-term in nature and requires user departments to redefine their existing process. The CRM scope is broadly defined and users who viewed CRM as a strategic tool catered to all or most part of the student life cycle. CRM was seen as an important competitive advantage and was used to strengthen relationship with students. Transactional CRM is short-term and tactical in nature. It supports automation of existing process and requires little or no process changes. The main aim of using CRM for transactional purpose was cost reduction and improvement of efficiency. CRM did not redefine their current operations and was used to support only narrowly defined activities involved in one particular stage of student life cycle.

Examples

Using the CRM grid, we identified four groups of CRM users. An example for each group is provided below.

- Strategic-Centralized: Enrollment Management is a centralized division that handles the recruiting and admissions operations for the university. At the time of our study, the group had just implemented a new EM CRM suite to centralize interaction points with prospective students from suspects to the admitted. The new system helped them create communication plan around the early stages of student life cycle and enabled recruiters to customize their recruiting strategies based on segmentation.
- Strategic-Decentralized: College E is a well-established college which manages most of its own operations like recruitment, admissions and student retention. The college decided to invest in its own CRM suite because it had some unique steps in recruitment process and the college staff felt that the current IS support did not meet their needs. The usage of the new CRM suite helped them streamline their student-related processes and freed up the staff's time to focus on face-to-face interactions with students.
- Transactional-Centralized: Student Affairs manages all activities pertaining to student retention such as housing. They work with other colleges to streamline their student retention activities. At the time of the study, the group was collaborating with Information Services department to champion the usage of Enterprise CRM in other colleges. Within its own departments, they used it to streamline their existing communication operations, including online newsletter and event planning.
- Transactional-Decentralized: Admissions office in College A is responsible for graduate student recruitment. This college used the Enterprise CRM system to streamline its existing operations around event planning. Prior to using the Enterprise CRM systems, the college's admissions office communicated with students via postal letters, radio ads, and web banners. College A decided to use CRM to reduce costs and to personalize communications with prospective students.

OBSERVATIONS

Our study yielded a set of key criteria for adoptions of CRM technology as expectation (UTUAT, 2003).

Benefit Expectation

While CRM as a terminology was new to some user groups, most of them were using the technology in one way or another. One common factor that we found in all users, irrespective of their stage in the adoption life cycle, was the perceived or actual benefit of using CRM. An individual's perception of benefits attained through CRM influenced the group's decision to use it. For some of the users, the benefit was CRM's ability to have more personalized communication with the students, for others, cost saving was an important benefit.

Effort Expectancy

Effort expectancy is defined as the degree of use associated with the use of the system (Venkatesh et al., 2003) We found this to be a factor in many groups who decided against using Enterprise CRM, despite the fact that Enterprise CRM was available at no cost. Users expressed strong reactions to the effort required them to build new business processes into their existing operation. It was a decisive factor in two groups who decided to purchase their own CRM applications. Both groups perceived the existing Enterprise CRM system to be inadequate for strategic CRM and felt that it made their job more difficult.

Training Expectation

Training was seen as an important adoption factor among all users. Even users who were comfortable with technology expressed their desire to get trained prior to using the existing Enterprise CRM system. We found that training helped individuals who were initially intimidated by the system.

Collaboration and Support Expectation

Level of available support, especially from the university's IS staff, was seen as another important factor. We found that there was no social pressure to use the system, but all users wanted to be able to call for help when needed. Though the university had independent departments or units, they had to rely on IS staff for data integration, expert advise and hardware support. Most users felt that establishing a good relationship with the support groups helped them use CRM more effectively.

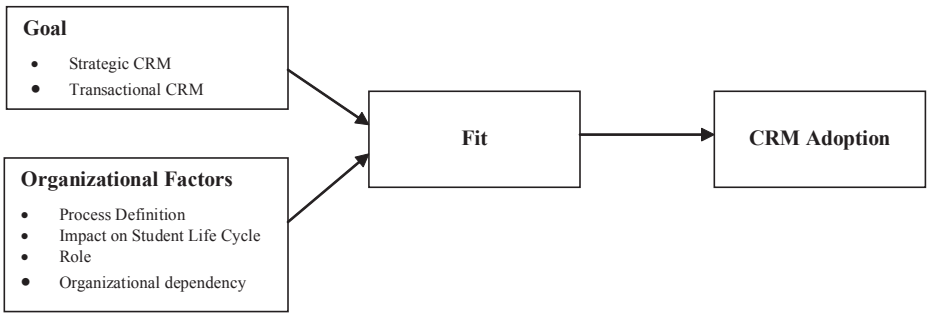
PROPOSITION

Based on our exploratory case study, we have postulated a CRM adoption model for the higher education sector (Figure 1). While there are many user acceptance models available, we believe that these models provide an overall perspective of user adoption which is not suitable to address the divergent needs and complex nature of the higher education sector. As we discussed earlier, departments within higher education have varied needs based on their goals and organizational factors. An appropriate fit between these two factors facilitates CRM adoption

This study uses the perspective that fit is a theoretically defined match between two related variables (Venkataraman, 1989) namely goal and organizational factors. Alexander and Randolf (1985) emphasize that fit, within a technology system context, exists when the organizational structure matches the required technology system. They have used this fit model as a predictor of performance.

Viewed from that perspective, our model proposes that the fit will be determined by the right combination of CRM goal (strategic or transactional) and organiza-

Figure 1. CRM fit model



tional factors (process definition, organizational role and dependency). A match between these two variables will enhance fit thereby facilitating successful adoption. More specifically,

- An organizational unit with a clear concept of student life cycle is more likely to achieve long-term benefits from a CRM initiative. An organization with a tactical view about CRM can also benefit by focusing on automating specific activities or a single stage of student life cycle.
- Organizations with centralized responsibilities play a champion role in promoting CRM usage. An appropriate fit of these factors will help determine successful adoption. However, misfit occurs when the CRM concept and technology is promoted for process redesign while the organization aims only for transactional CRM, or when a transactional CRM is promoted to an organization focusing on broadly defined interaction process. Such gaps will result in rejection or early termination of CRM technology. While long-term adoption is preferred, short-term adoption can also contribute to strengthening an institution's interactions with students.

IMPLICATIONS AND NEXT STEPS

This case study has identified approaches to the adoption of CRM in the higher education sector. The conceptual model contributes to a better understanding of determining a CRM fit based on organizational factors and CRM goal. As more universities adopt CRM, determining an appropriate fit can facilitate successful deployment of CRM. This research will help to expand the understanding on adoption factors in this sector. Despite the comprehensiveness of the proposed research model, we acknowledge some limitations which call for additional research. This project is a single case study and while it was well triangulated, future studies should expand the scope to include multiple cases and an empirical test of the proposed conceptual model through a survey study.

The Open Catalogue of Manuscripts in the Malatestiana Library: Balance and Perspectives

A. Cartelli, University of Cassino, Via Zamosch, 43, 03043 Cassino (FR), Italy; E-mail: cartan@unicas.it
M. Palma, University of Cassino, Via Zamosch, 43, 03043 Cassino (FR), Italy; E-mail: mpalma@unicas.it

ABSTRACT
The reasons for the project of a special information system for manuscripts' cataloguing and publication is first explained. The features of the Open Catalogue of manuscripts in the Malatestiana Library, which is the first example of implementation for that information system, are soon after described. The evolution of the system during last years and a balance of the activities involving students, researchers and general users are then reported. At last the developments and future applications for the open catalogue are drafted.

Keywords: manuscript, paleography, catalogue, Web, database, information system.

INTRODUCTION
Many experiences laying on the Internet have been carried out in Paleography during last years and many changes were introduced in the discipline's methods. Furthermore, especially planned information systems have been more and more used and everyday work and study processes of the discipline were consequently influenced.

The proposal of the Open Catalogue of manuscripts takes its place among the studies introducing innovation in Paleography research and study with the ICT and aims at the creation of connections with information sciences (i.e., IS, IT and ICT disciplines).

What Is Changed In Paleography Research Methods And Instruments?
ICT radically changed the approach scholars had with manuscripts for at least two reasons:

a) the way manuscripts were analyzed,
b) the medium scientist could adopt to share the results of their work,

in the first case it has to be noted that before the Internet researchers had to personally study manuscripts in archives or libraries; secondly they published the results of their research only by means of printed catalogues (before the use of web sites).

During last years the spreading of networking communication techniques produced relevant effects on the sharing of knowledge and information within the community of paleographers. First of all the Web was used to publish the images reproducing manuscripts pages, but it increased also the number of on line historical magazines, the collections of bibliographies, the use of on line databases etc. (Cartelli and others, 2001).

The above considerations and the proposals coming from newly defined disciplines like informing science (Cohen, 1999), led the authors to the definition of a special information system called "Open Catalogue". This system, which is described in the following section, has been adopted and carried out from the staff of the Malatestiana Library, an ancient Italian library hosting a consistent number of manuscripts.

CATALOGUES OF MANUSCRIPTS AND THE OPEN CATALOGUE
The history of manuscript cataloguing began between 17th and 18th century and notwithstanding the great work made by paleographers in these centuries an enormous amount of manuscripts still remains uncatalogued, if not unknown.

The main trouble with the study of old, handwritten books can be summarized as follows:

a) people simply don't know of manuscripts' existence (with respect to texts, where bibliographies and Internet resources make relatively easy to find a printed book, the same doesn't happen for manuscripts),
b) every manuscript is a unique book (i.e., there are no duplicates for it). Even if the text in two manuscripts is the same, as in the case of a model and its copy, they are never equal; two books can in fact be different for scripting style, physical appearance and even text, because a handwritten copy always contains some changes with respect to its source.

As a consequence the creation of a catalogue of manuscripts is a really difficult task, it requires a deep competence in a lot of fields, from philology to history, from history of art to paleography, from literature to library science.

In the authors' opinion time has come for a radical change in catalogue publishing. First of all the Internet can make available great part of the manuscript heritage all over the world (i.e., a good example for the new way of catalogues' publishing can be found in the choice of CDF in Germany, reported from Overgaauw, 2001); furthermore it is possible to give scholars new and more powerful tools to improve their work and let them create *Open Catalogues* (i.e., catalogues in progress, constantly changing with the continuous contribution of new information).

The Open Catalogue of Manuscripts
When the structure of the Open Catalogue was hypothesized two separated environments were planned (Cartelli & Palma, 2002): a former one where researchers and scholars had the scientific liability of the materials to be published and a latter one where people could occasionally or systematically obtain information (i.e., it couldn't be used to produce new data).

The above separation affected the way users could access the system and led to three different and separated access levels:

a. system and scientific administrator level; one or more persons with the scientific responsibility of the catalogue, who can enable researchers and scholars to access and manage the materials to be published (they can also manage the data produced by everyone),
b. scholars and researchers level; allowed people who can insert, modify, delete and display the materials to be published (manuscripts' descriptions, notes, images etc.),
c. general users level, where only the answers to specific queries can be obtained (i.e., the descriptions and images of manuscripts, bibliographies, notes etc.).

As regards the structure of the Open Catalogue it was based on five sections, to be intended in a flexible manner (i.e., the presence of each section depends on

the resources the library will have at its disposal and on the different solutions it will adopt for them) (Cartelli & Palma, 2003):

a) the first section is devoted to documents explaining the history of the library and its manuscripts;
b) the bibliography ordered by shelfmark and, eventually, alphabetically and chronologically, is housed in the second section;
c) in the third section the descriptions of the manuscripts, i.e. previous printed catalogues or ancient handwritten catalogues (suitably digitized) and new descriptions (according to nationally/internatio-nally defined standards) are stored;
d) the fourth section contains the images of the highest number of manuscripts in the library (possibly all);
e) the fifth and last section is made of a communication subsystem including electronic blackboards, chats, forums and special Web solutions granting the easier acquisition, writing and editing of texts among the members of a selected community of scholars interested in the materials in the library.

MALATESTIANA LIBRARY AND THE OPEN CATALOGUE OF MANUSCRIPTS

In the *Malatestiana libraria*, designed and built in the mid-15th century by Malatesta Novello, Lord of Cesena, 343 manuscripts, which give witness to his tastes and cultural inclinations, are housed. Malatesta Novello enriched the ancient volumes (about fifty) of the Franciscan convent with an invaluable collection of manuscripts which were especially copied and illuminated, and with codices which were purchased, received in donation, dedicated, or already part of his family's patrimony.

Further manuscripts come from the collection of Giovanni di Marco, the physician of Malatesta Novello (53 codices), from the choral books of the Cathedral (7 books), from the books of the Franciscan convent (8 books), from the Piana Library (59 manuscripts, which were the private library of Pope Pius VII), from the town library (12 manuscripts collected from dissolved religious houses in 19th century).

The staff of Malatestiana Library decided to adopt the idea of the open Catalogue and decided to find the resources for building it, mostly because it looked interesting and useful to have a *catalogue in progress*. The advantages of this choice were both immediate and evident:

- the possibility of proceeding in a programmed and gradual manner;
- the ability to retrieve all the information already acquired even in a partial and non-final form;
- the opportunity to extend the research to ancient sources that were difficult to access;
- the increase in the interactive updating of the information available by qualified specialists and scholars.

The web site for the Open Catalogue of manuscripts in the Malatestiana Library can be accessed from the portal of the Forlì-Cesena county (http://www.malatestiana.it/manoscritti/). The database accompanying the site was autonomously constructed with a personalized wwwisis 5.0 application.

The catalogue is made of four parts:

- the first part credits people working to the project and its carrying out,
- the second section contains general texts on the Library and the manuscript collections (i.e., the history of the library, Cesena humanistic culture, the scriptorium, the illumination, the collections etc.). First of all classical texts suitably digitized have been put on line, now special works and degree theses are adding to the former ones together with descriptions of the Library coming from foreign visitors,
- the third part lets users access manuscripts according to shelfmark, author and title. For each codex the description and the bibliography are reported. A program for a regular updating and retrieval of recent and previous bibliography, according to the resources of the Malatestiana Library and its goals has been planned. At the end of October 2006 every user will find the reproductions of 42 codices, although the Library staff plans to offer a complete reproduction of all the manuscripts;
- the fourth section plays a fundamental role in this project hosting users' requests, opinions and articles. Here, scholars or persons interested in the Library's manuscript collection can contribute with their observations, as well as publish their contributions online. Recently this section was enriched with two special functionalities: a) collaborative bibliography, by which everyone entrusted with the access to the section can insert his/her personal bibliographical records in the page, b) works in progress on two manuscripts, by which a community of study and research is granted the permission of accessing all the texts in the area.

The open catalogue neither excludes nor acts as a supplement to printed work, which is always possible and even desirable, because this has a particular type of diffusion and is permanent by nature. Instead, the open catalogue is updated constantly by the Library staff, particularly by those who are involved in manuscript preservation. It is their duty to actively administrate the site and to promote research even encouraging interested specialists to provide critical contributions.

CONCLUSION AND FUTURE TRENDS

Main remarks on the work carried out from Malatestiana staff during last three years is reported below:

- institutional librarians coordinated the work in the library and in the site and produced descriptions and bibliographies for the manuscripts,
- continuous contacts were kept with public and private institutions and with scholars interested in the study of manuscripts in the Malatestiana library,
- young and highly qualified people (i.e., people coming from special humanistic studies) was involved in the production of manuscripts' descriptions and other texts.

Furthermore, the use of web technologies contributed in changing the way of studying and working in paleography by introducing social-constructivist elements in everyday activities. Examples of communities of learning and of communities of practices based on ICT use were in fact detected.

At last it has to be noted the presence of factors influencing knowledge construction and development both on individual and social bases.

Towards Early Consideration of Non-Functional Requirements at the Business Process Level

Sebastian Adam, Fraunhofer IESE, Fraunhofer Platz 1, 67663 Kaiserslautern, Germany; E-mail: sebastian.adam@iese.fraunhofer.de
Joerg Doerr, Fraunhofer IESE, Fraunhofer Platz 1, 67663 Kaiserslautern, Germany; E-mail: joerg.doerr@iese.fraunhofer.de

ABSTRACT

Non-functional (or quality) requirements are one of the key issues that need to be addressed during the development of any software system. Experience has shown that as the alignment of business processes and the supporting information systems become increasingly close and robust, early consideration of non-functional aspects is needed to considerably reduce subsequent rework. In this paper, we present a method based on quality models and related checklists for integrated treatment of non-functional requirements in a measurable and testable way at the business process level. The benefit of such an early quality consideration consists of closer and more robust alignment between business processes and supporting information systems by providing early conflict solution, easier design derivation, and continuous traceability up to the strategic goals. This will lead to less rework effort during development or maintenance and thus to more flexible business support.

1. INTRODUCTION

In today's enterprises, business strategy, business processes, and business information systems are closely intertwined and are typically not considered separately any more [Allw05] (see also Figure 1). While business processes support the achievement of the underlying strategy, information systems support or even enable successful implementation of these processes. The mapping between business processes and information systems supporting these processes should thus be as close as possible [EmMa95] and as robust as possible [SmFi03] to allow rapid adaptation to any change, especially to organizational changes. Therefore, business processes have become an important source for requirements in information systems (here we use "information systems" in a very broad sense, ranging from one-function services to complex workflow implementations), independently of how the information system is implemented.

Nevertheless, present approaches used in industry typically address only the alignment of business processes and functional (system) requirements, while often neglecting non-functional aspects. Only few companies such as, e.g., [YYOI05] are going to annotate business processes with quality requirements.

In the majority of cases, however, even if non-functional (or quality) requirements (called NFRs) were identified as crucial with regard to the success of a product or project [CNYM99] [DKK+05], they are considered for the first time when the development of the supporting information systems starts – if at all. The Fraunhofer IESE NFR approach [KDP+05] is an example of such a system-targeted NFR elicitation method (see Figure 1).

However, especially for modern implementation strategies, the earliest possible consideration of non-functional requirements is needed to support some important decisions. In the Model Driven Architecture [OMG06], for instance, business processes are considered as parts of the computer independent models (which describe in an abstract manner *what* the system should support) and are used to derive platform (in)dependent models that describe *how* to build the system in a technology (in)dependent manner. Neglecting efficiency requirements in these models, for instance, may cause costly rework because these requirements typically have a great influence on the system architecture.

By contrast, the vision of Business Process Management Systems aims at executing business process descriptions without any additional development effort [SmFi03]. Instead of developing software to support the processes from scratch, an execution engine should be able to perform the processes (as workflows), integrating existing functionality based on service-oriented platforms. In this sophisticated vision, which – of course – still requires that many challenges are solved, business processes will be the only specification a system has to fulfill. This makes an upfront handling of NFRs during process modeling in a measurable and testable manner indispensable. Otherwise, services could only be selected based on their functionality, which might not be sufficient for achieving the intended business process support.

With our currently still evolving method presented in this paper, we thus intend to specify NFRs in a measurable form already at the business process level. We consider NFRs at this level as any required quality of the elements involved in a process needed to assure the process goals achievement. In this context, the often mentioned measurability is crucial, as NFRs such as "The function should be efficient" leave the developers to image what "efficient" might be. This, in turn bears the risk of failing the business goals, even if "efficiency" is explicitly considered as an important requirement.

While the motivation above has shown that NFRs are also needed on the level of business processes, the question of which quality aspects are important at this level and how they influence each other remains. Furthermore, the assurance of their measurability is also an open issue. The key concepts of our method presented in this paper therefore primarily focus on these questions.

As benefits of our approach, we expect from the business point of view:

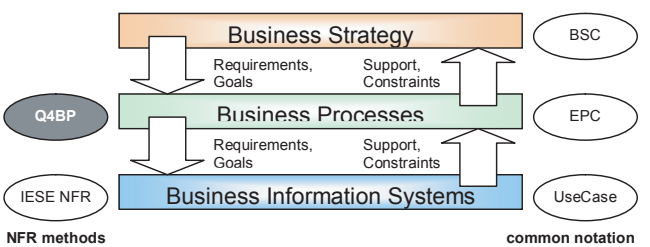
- being able to check whether the strategic goals can be successfully operationalized with the available resources
- less costly rework due to early requirements conflict resolution
- business processes that also fit best to quality needs.

From the IT perspective, we furthermore expect:

- closer alignment due to clearer dependencies on system requirements
- better traceability up to the strategic goals by bridging the gap between these goals and system qualities using NFRs on the business process level.

The remainder of this paper is structured as follows. In section 2 we present some related work. Section 3 briefly explains the basic concepts of our method, while

Figure 1. Requirements on different business levels



its application process is described in section 4. The paper closes with a summary and outlook in section 5.

2. RELATED WORK

Figure 1 depicts, according to [Oest95], how the three business levels (strategy, processes, and information systems) influence each other. Furthermore, common methods and notations are shown (to the left and to the right). Based on the business strategy goals that can be exemplarily specified using the Balanced Scorecard (BSC) [KaNo92], appropriate business processes, which could be specified with Event Driven Process Chains (EPC) [KeNS92], for instance, are derived. These processes are then used themselves to derive requirements for the supporting information systems, e.g., in terms of UseCases.

Publications such as [SmFi03] have identified this alignment of business processes and information systems as a key research aspect, referring to the vision statement that "business processes should be directly and immediately executable – no software development is needed". This emphasizes and underpins the notion of integrating additional requirements, especially quality issues.

Regarding the close and robust alignment of business processes and information systems, key research has already been done [RoSE04] [EtRo05]. All these publications however, solely address and cover the functional aspects, or cover the non-functional aspects in a very generic and not measurable manner [SoWa05], denoting them as soft-goals or organizational goals. Approaches for goal modeling (see [Lams04]) are important to support the expression of quality goals on the strategy level. These quality goals can then serve as a basis or rationale for expressing NFRs on the business process level and, finally, on the information system level. Therefore, the systematic derivation and analysis of NFRs on the business process level with regard to the strategic goals will be important work to be done. However, this is beyond the scope of this paper.

Methodologies addressing system NFRs and change guidance are available [ChNY96], [DKK+05], but do not specifically address the business process level and thus lack the potential support.

A consideration of business process qualities is part of process performance management [WWDV06] [BuGe04]. Performance management defines business relevant indicators, checks if the performed processes really fulfill them, and helps to identify room for improvement. While these indicators are requirements for the processes derived from the strategy (e.g., time and costs), requirements for the resources that are involved in the process execution (e.g., security or capacity constraints for systems, data or employees) are still missing. However, the resources need such requirements in order to be able to provide the required quality.

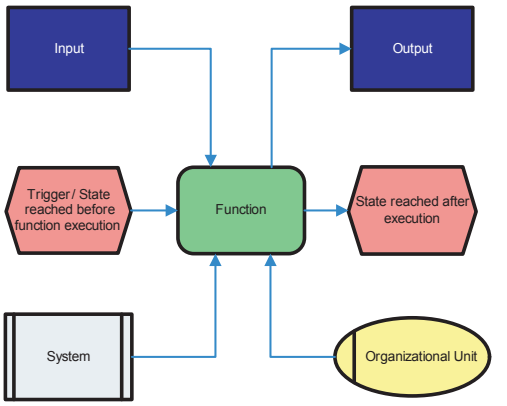
One of the key related research approaches regarding systematic NFR elicitation (the Fraunhofer IESE NFR Method) has been described in numerous publications, as for instance [DKK+05] [KDP+05] [DKKP03] [KeKD03]. By default, this work addresses only NFRs on the system level and is thus not directly applicable to the business process level, where other qualities might be important. Even if some qualities are overlapping on both levels, they are not identical or may even be completely inadequate (e.g., maintainability). However, parts of this work, such as the usage of quality models, checklist-based elicitation, and striving for measurable requirements, are the key fundament on which we have developed our methodology.

3. CONCEPTS OF NON-FUNCTIONAL REQUIREMENTS AT THE BUSINESS PROCESS LEVEL

In this chapter, we present a methodology called Quality Requirements for Business Processes "Q4BP" to address NFRs in a measurable and integrated manner already at the business process level. The goal from the IT perspective is to facilitate easier derivation of information systems from business process models. The goal from the business perspective is to build processes that address the strategic goals in a more suitable manner.

In order to keep our explanations simple, we here focus on enhancements of the notation of EPC. The reasons are that EPCs are widely used in industry and are easy to understand both for IT experts and for business experts. Furthermore, EPCs include all relevant concepts for business process modeling [Allw05] and are thus an appropriate notation for showing the possibilities of our approach. As our approach is intended to work with every business process notation, our future work will address other notations, especially those that are directly executable.

Figure 2. Main elements of EPC



An (extended) EPC typically depicts (see Figure 2) in which order business functions are performed, which states exist before and after each function execution, which organizational units are responsible for a function execution, which information system is used, and which inputs and outputs (in terms of material or data) are handled. EPCs allow specifying business processes on different levels of abstraction and systematically refining them. Furthermore, business rules can be attached. However, this does not refer to NFRs, as business rules are a kind of functional requirement in terms such as "If invoice amount is greater than 1000 $, allow a discount of 10%".

However, in the same manner, our method recommends enriching the process model elements with suitable NFRs derived from an overall quality model for business processes (which is still evolving). This quality model consists of many quality attributes concerning process elements (function, system, data, organization, etc.) that are hierarchically organized. On the top level, the most important attributes are efficiency, reliability, security, usability, and manageability (a subset from ISO 9126 [ISO03] that is modified according to its suitability to business processes). When assigning a value to a quality attribute associated metric, it becomes an NFR. In Figure 3, an excerpt from the quality model (on the left hand side) and an exemplary assignment to a business process element (on the right hand side) are shown.

In order to address the goal of eliciting measurable and testable NFRs, we refined the quality attributes (according to GQM [BaCR94]) in the same manner as the Fraunhofer IESE NFR Method, until a measurable level was reached.

Besides the hierarchical organization, the quality attributes within the model are classified according to the business process elements where attaching them makes sense (see table in Figure 3). Here, "Process time" is considered as a relevant attribute for "Process" and "Function", but not for other process elements. In

Figure 3. Excerpt from the quality model and exemplary usage

	Process	Function	System	Organization	Data or Material
Process time	X	X			
Response time			X		

contrast, "Response time" is only of interest for the "System" that supports the function. Of course, there exist dependencies between quality attributes on the business process level and on the information system level. These dependencies are also handled in our approach (see section 4). Nevertheless, the major part of the requirements for the information system level should not be attached to business processes at this stage but later when development starts. The reason is that we do not want to harm the business orientation by adding too much implementation relevant information. In general, only qualities regarding the process execution and the involved resources are of interest, while internal system qualities such as maintainability are neglected.

The identification of all important quality attributes for business processes is still a part of our current research. Until then, the relevant issues for a specific project have to be gathered using the method described in section 4.

4. APPLYING THE Q4BP METHOD

The procedure for applying our method is a specialization of the Fraunhofer IESE NFR method mentioned in the related work section. It is based on a set of experience-based artifacts, which are tailored to project-specific ones. Figure 4 depicts the main steps and artifacts when applying the method.

In a first step, for each business process modeling project, our reference quality model, which is a structured set of all possible quality attributes for business processes is taken and tailored (including extensions) to the specific needs of the project. This tailoring includes a discussion about the quality attributes that are relevant for the business processes and how these attributes are hierarchically organized or dependent. The tailoring stops when a metric for each attribute can be defined (e.g., minutes for "Process Time"). If quality attributes were found during the tailoring that do not exist in the current experience-based reference quality model, they are added after the tailoring to the experience-based model, too.

The quality model developed is then used to derive checklists that guide the systematic elicitation and specification of measurable NFRs for the business processes. For each high-level quality attribute, all related measurable attributes from a lower level are listed and mapped to the process elements they should be attached to. A section within the checklist might then be, for instance, "Efficiency of functions: Define for each function how long it should take (process time)."

Elicitation and specification require the business process models and enrich them with all non-functional aspects needed to achieve the intended business goals. So far, this procedure is quite similar to the proven Fraunhofer IESE NFR Method.

However, we strive for an easier-to-use method that does not need to be tailored every time it is applied. We assume that the tailoring and the improvement cycle are only needed as long as our reference quality model does not contain all relevant quality attributes concerning business processes. Because of the limited space available to issues described in a business process model, we expect our model to be almost complete one day, so that no individual tailoring will be necessary any more. Then, the reference checklists can be used directly to elicit the NFRs for business processes. Until then, we consider this methodology as a research support to finding all relevant attributes and their dependencies.

One important issue when eliciting requirements is the early detection and resolution of conflicts. As requirements conflicts often lead to change rework during system development, it makes sense to handle them during an earlier phase, in particular on the business process level. Problems can thus be solved business-like and not with regard to technical decisions.

Avoiding conflicts requires the consideration of each possible requirement dependency. Besides trivial dependencies between efficiency requirements, which are already handled in some current performance management approaches [BuGe04], other quality attributes may also affect each other. The reference checklists that contain clues about such dependencies and their underlying quality models are thus a helpful tool to avoid specifying processes that will not work as intended.

In this paper, we distinguish two types of conflicts: conflicts due to vertical and conflicts due to horizontal dependencies. The first type of conflict might occur when (sub-)processes are further refined and an NFR of the upper element conflicts with (the sum of) the lower ones. An example from the "efficiency" area is when the sub-functions including waiting time take more time than the upper process is allowed to take. In this case, either the process has to be performed in another way, reorganizing the sub-functions, or the requirements for the upper process have to be specified less restrictively. At this point, it becomes obvious that non-functional and functional requirements (also in business processes) influence each other. That is why our approach aims at the integrated handling of NFRs within business processes.

The second type of conflict arises from the relationships between different requirements, e.g., between efficiency and security issues: Encryption typically affects the response time of a system, whereas authentification affects the time needed to perform a function that is limited to authorized access. Considering this at the business process level might, for instance, lead to a process where authentification is realized once at its beginning using the system support of single-sign-on.

Besides the dependencies between different kinds of quality attributes attached to one process (element), there might also be relationships between requirements attached to different elements. Figure 5 shows, for instance, that requirements concerning data privacy may influence access control for functions, or the personality traits of the assigned employees. In the other direction, constraints regarding personnel or technical capacities might also influence functions and processes, e.g., inexperienced personnel might have higher requirements regarding the time needed to perform a function.

When business processes are enriched with conflictless NFRs, a helpful starting point for system development is given. The NFRs related to "System" elements are precise enough to adopt them directly during system development. As "Organizational units", "Functions", and "Data/Material" elements also influence the "System", the requirements attached to them also have to be considered for the information system to be developed. Here, we will establish in future work clear dependencies that allow translating them into requirements of the information system level. For instance, the privacy requirement from Figure 5 could lead to a system level requirement describing where the employee data have to be stored and how they should be encrypted.

The method presented in this paper was applied in a large information system company that uses business processes as a substantial element for their requirements specifications. First, we tailored models for efficiency and reliability by brainstorming which related attributes are important in business environments and how they could be measured. We found out that some attributes were very technical and thus appropriate for the information system, while others concerned the underlying processes.

Based on the developed models, we derived checklists by defining elicitation instructions that clearly depicted to which process element an NFR should be attached, how it should be measured, and which conflicts have to be checked and

Figure 4. Applying the Q4BP method

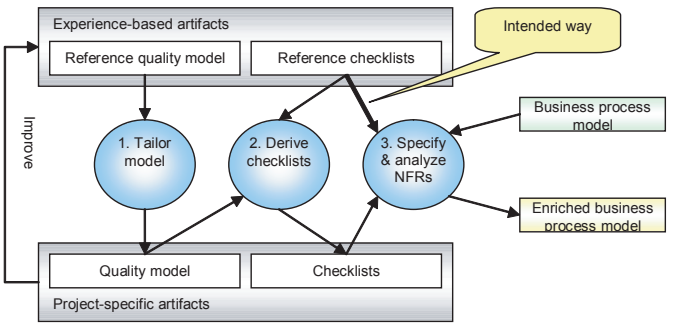


Figure 5. Dependencies between requirements attached to process elements

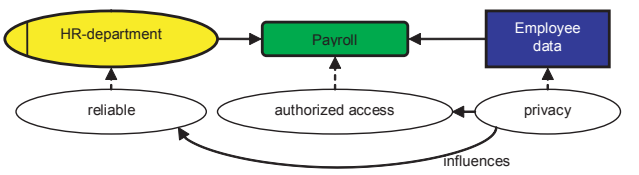

resolved if necessary. This checklist was then finally used to elicit concrete NFRs for an exemplary business process description. As the elicitation itself required little effort, we expect our method to be a suitable instrument for assuring the required process quality right from the beginning of any information system project.

5. SUMMARY AND OUTLOOK

In summary, our method explicitly addresses the problems of neglecting NFRs in business process and information system alignment as well as those of eliciting imprecise NFRs (e.g., "The process should be efficient"). Furthermore, conflicts between requirements that might lead to unintended process results can be identified and solved early in a business-like and not in a system-oriented manner.

From a business point of view, we see further benefits in being able to check whether or not the strategic goals will be successfully operationalized with the available resources. From an IT perspective, requirements or even design decisions for the system to be built can be derived more easily. The quality requirements defined on the business process level also allow selecting suitable software solutions by better comparing competitors (or their services). Finally, the hierarchical refinement of business processes and the attached NFRs facilitate the assurance that the overall process requirements are guaranteed even if each function is implemented by another system.

As one of our first future work projects, we will extend our method to other business process notations, especially to those that are executable. In this context we strive to build a business process meta model enriched with the relevant quality attributes.

Another important research topic is the identification of dependencies up to strategy goals and down to real information system requirements in order to provide continuous traceability and effective conflict resolution.

In parallel, our general method, the underlying quality model, and the related checklists have to be continuously evaluated and improved. Therefore, we will use our method in industry projects and academic case studies.

With regard to the vision of executable business processes in which "no software development is needed" [SmFi03], NFRs should be paid special attention. To support this vision, we strive to analyze how the identified business process quality requirements can be integrated, automatically assured, and evaluated in a formal and readable notation (such as BPEL [Juri04]).

ABSTRACT

Due to the spread of mobile handheld devices, new application fields like technical maintenance and mechanical inspections open up to their use. Yet, to fully benefit from their modern technical capabilities, standard interaction techniques need to be revised and new ways of accessing the abundance of technical documentation on the handheld need to be conceived. However, the display of technical illustrations on its tiny screen is still a difficult task. In this paper, we discuss an approach specifically conceived for technical drawings that aims at overcoming this difficulty. To underline its practicability, we also present our software prototype that incorporates this approach by utilizing the technical potentials of the standardized vector graphics format SVG.

INTRODUCTION

A meaningful and comprehensive technical documentation is essential for error-free, smooth operations in many industrial applications. It contains all relevant technical information on a product and is the basis for communication between different branches like design, production, assembly and maintenance, for example during the process of building complex machinery. Aside from part lists, procedures and manuals, the major part of technical documentations comprises drawings and schematics.

Technical drawings fall into one of several categories depending on their intended usage. The main distinction is between production drawings and assembly drawings. The former is used during design and production, whereas the latter is used in assembling and maintenance work. Therefore, production drawings generally focus on single component details like dimensions and surface finish, while assembly drawings depict dependencies between parts and subassemblies like relative position and attachment points. Unlike artist conceptions, technical drawings are subject to defined rules and norms regarding e.g. symbols, perspective, and line styles [ISO02].

Today, paper drawings have become all but extinct. Widespread use of Computer Aided Design (CAD) and Computer Aided Manufacturing (CAM) methods mean more and more drawings are available and are used throughout all stages of the production process in electronic form. This has the added benefit that illustrations for specific purposes can be derived from a single parent drawing. In this paper, we specifically focus on illustrations required for maintenance work. Servicing machinery in fixed installations, e.g. in power plants, is necessarily performed on-site, thus the service technician needs to bring the required documentation with him. Consequently, the bulk and weight of (potentially multi-part) printed manuals is rather undesirable.

Because of this, combined with the fact that mobile devices like PDA handhelds are becoming more and more common, there exist several projects that seek to utilize these devices as portable "e-handbooks" or even augmented reality (AR) applications, both for assembly [ART06] and maintenance [NPF+04, FR+06] tasks. One assumption for this paper, however, is the use of commonplace mobile devices instead of special viewing hardware or smart environments required for AR approaches. In practice, this constraint might often be based on availability and cost considerations. This inevitably leads to all the problems and technical limitations that such devices struggle with. We found that most comparable approaches concentrate on a single specific aspect, like pipe flow visualization [NPF+04], rather than addressing these in principle.

Therefore in the next section, these principal challenges of are briefly rehashed. In the two sections following thereafter, we present basic concepts that can be used to present technical drawings efficiently on small devices. These sections discuss concepts and techniques for presenting assembly drawings and circuit schematics, respectively, as typically used during maintenance tasks. In the last section we give some concluding remarks.

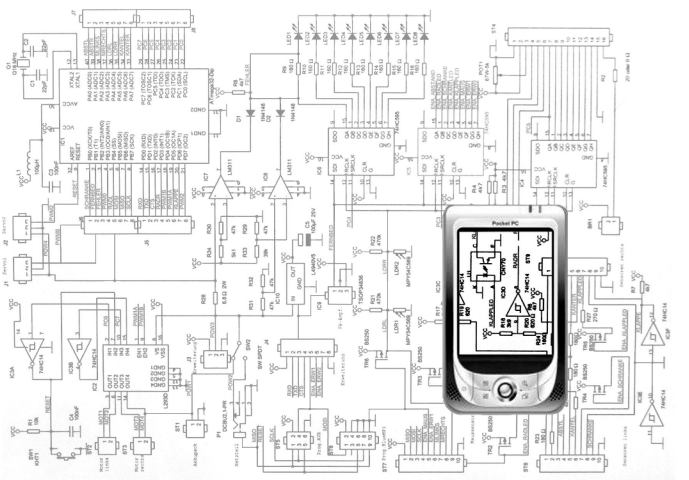
PROBLEM ANALYSIS

The constriction on run-of-the-mill mobile devices like PDA has some important ramifications. Aside from data security issues, limitations in storage and processing capability mean it is generally not feasible to employ a CAD-Viewer on the device, i.e. use CAD data directly. Therefore, some set of views suitable for a given task at hand must be pre-selected and converted into static illustrations. Even more importantly, due to the small size of typical handhelds, the available screen space is also very limited. The challenge in integrating even static technical illustrations in such an environment becomes apparent when the resolution of a typical PDA is contrasted to the resolution of a medium-sized circuit schematic:

The straightforward solution to the above challenge, scaling the illustration down to the size of the PDA screen, leads to unacceptable results. There would be indiscernible tiny or cluttered details, possibly further distorted by scaling artefacts. Therefore, the adaptation must consider the semantics of the technical drawing in order to select a subset of information to be displayed. This provided, there are basically two ways to solve the screen space problem:

- The display can be limited to show only a certain part of the entire technical drawing that fits the PDA screen, thus sacrificing the completeness of

Figure 1. Comparison of the screen resolution of a typical PDA (320x240 pixels) to the resolution of a medium-sized circuit schematic (1742x1275 pixels)



the representation but preserving its detailed depiction. The degree of this limitation can easily be chosen from several levels of segmentation that are appropriate for technical drawings -- like "Complete", "Functional Modules", "Sub-Modules" and "Individual Parts".
- A number of individual objects can be merged into new "compound objects" that take up less screen space, thus sacrificing the in-depth-depiction of all objects but preserving the completeness of the overall structure. This approach can also easily be graded into several levels of detail.

In combination, it is possible to gain results that are optimized with respect to both, completeness and depth, according to the demands of the task at hand that the user needs to carry out upon the drawing.

There are two principal choices for the graphics format used in these approaches: raster images (bitmaps), or vector graphics. The advantage in using bitmaps is that there are numerous established formats and out-of-the-box viewing software available. However, bitmaps have no notion whatsoever about the structure of the depicted content if they are not annotated with external metadata [FR+06]. They also suffer heavily from scaling artifacts, e.g. when originally thin lines are scaled down to sub-pixel width and are thus vanishing.

Vector graphics like the predominant SVG[1] standard, on the other hand, build on graphical primitives like rectangles and circles, and group these to form more complex shapes. Therefore vector formats do exhibit some inherent notion of structure that can be utilized in different levels of segmentation. Moreover, vector graphics are defined by means of geometric coordinates independent of pixel sizes and thus can be arbitrarily scaled without loss of quality. These advantages make vector graphics a much better choice as the basis for technical illustrations. As a matter of fact, many CAD packages provide an option to export selected views as SVG files.

In the following two sections we will discuss ways to use both approaches outlined above efficiently and using SVG drawings, for two typical use cases.

CONCEPTS FOR PRESENTING ASSEMBLY DRAWINGS

A maintenance technician typically needs assembly drawings at the work site to determine the best sequence of dismantling machinery in question, to locate parts that must accessed or attachment bolts of those to be removed, and detail information on components disassembled for repair. Finally, the technician needs to discern the correct alignment of components upon reassembly. Therefore, the visual representations by a mobile "e-manual" need to address all these different aspects.

Technical drawings for a given unit comprise a hierarchy of single component drawings, subassembly drawings and the general drawing. These drawing types already implement three levels of segmentation as postulated in the previous section. The general drawing will depict a complete overview of the entire machinery (likely with some simplifications), whereas subassembly and component drawings will sacrifice the completeness for subsequently more details locally.

However, these drawings may still require adaptation to fit small PDA screens, and to communicate certain aspects of the task at hand more efficiently. The visibility and perceptibility of relevant objects is essential for intent-based visualizations [SF91]. This is especially an issue when typical step-by-step, automatically generated assembly instructions [AP+03, HP+04] are created from a single (or few) available input images. It must therefore be possible to modify an existing base illustration to:

- Accentuate important parts/components in the illustration, or in reverse, subduing the component's context.
- Hide from the drawing parts irrelevant in the current context, or that occlude relevant geometry. This is especially important since the viewpoint cannot be changed in 2D graphics to resolve occlusions.
- Show details within their context. Very small parts like fastening screws are only drawn in conjunction with larger components, but may become indiscernible small if drawn to scale, especially when considering typical PDA screen diagonals. These parts should be displayed in an enlarged detail view.
- Explode the view to show the relative position and alignment of several parts with respect to each other. Explosion views are also used to show the direction in which parts must be pulled off/put back during assembly [AP+03]. This may require the addition of subsidiary lines for clarity.
- Label the illustration, e.g. for cross-referencing the illustration with additional information, e.g. part lists, or to link labeled view elements with additional audio outputs [FR+06].

In the following paragraphs, concepts to realize the above bullets using SVG are discussed. These concepts have been implemented in a software prototype deployable on Windows Mobile-based PDA.

The SVG format allows to hierarchically group vector primitives with the <g>…</g> tag, to assign a group common display attributes (color, line width etc.), and to assign a reference id to enable reuse of the defined geometry [Jac03]. It also allows embedding content from other SVG files into a composed drawing. Usually, grouping occurs according to graphical criteria, e.g. all background gradients or all lines with the same style. However, this ordering is not mandatory.

Instead, we propose a new concept where the groups are defined according to semantic criteria. First, all vector primitives constituting specific components are grouped together. Since groups can contain subgroups, the logical structure of machinery (single parts grouped into subassemblies grouped into main assemblies) can be reflected in the structure of the SVG file. It is also possible to define several graphical levels of detail for individual components in the same way. Any SVG file, e.g. from a CAD export, can be re-sorted using authoring tool developed for this purpose (Figure 2 (a)). Using these prepared SVG files as input to the "e-manual" application on a PDA, the above features can be supported efficiently.

Accentuation of single components is done by modifying their rendering attributes, e.g. through fill color, line thickness, or explicitly drawing the (usually invisible) bounding box in case of small objects (Figure 2 (b)). Technically, the SVG vector primitives associated with the component group have their corresponding attributes modified before they are passed on to the render engine. Thus, our concept keeps rendering of the content independent of the semantics required to identify the accentuated elements. Our software uses a task model to define the necessary semantics and to control the parameterization of the renderer [FR+06].

Information hiding can be achieved in a variety of ways. If a component should be removed from the illustration in its entirety, its associated geometry simply is not passed to the renderer at all (Figure 2 (b)). Another approach is to render the component geometry first, before all other components. Since SVG renderer by definition overwrite already drawn elements with later ones, this results the hidden component being pushed into the background. Like accentuation, the required semantics for both approaches are defined in the task model.

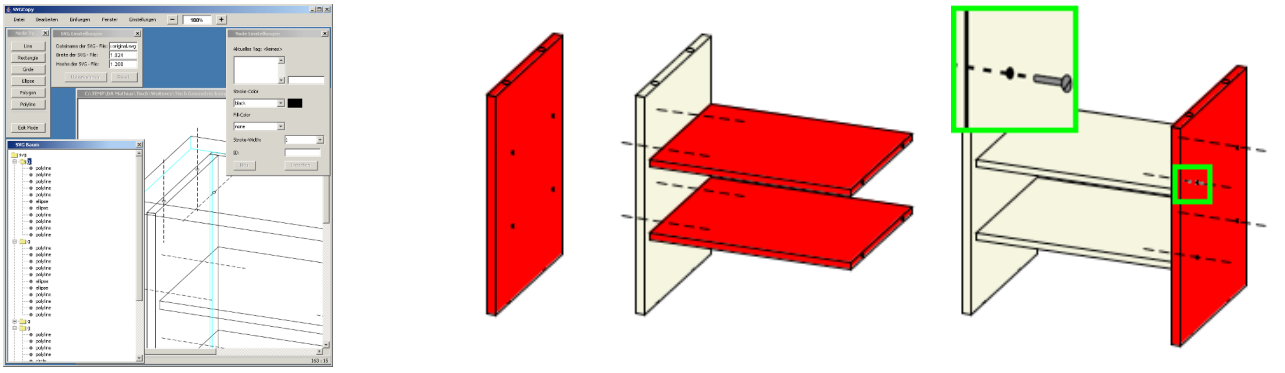
Information hiding can also be used as interactive tool [BS+94]. We implemented an "X-Ray lens" that modifies the representation to a wire-frame rendition within the lens area. It is a powerful new concept that allows a user to interactively examine regions of an illustration, revealing geometry otherwise hidden in the default view (Figure 3(a)). It is also usable on any SVG file even if no semantics from a task model are available. Technically, a temporal copy of all primitives within the lens area is created with the fill color attribute removed from the render attribute list. Note that if a primitive is only partially covered by the lens, it is split into two or more temporal primitives as needed to confine the modification to the lens area. The modified primitives are then substituted for the original ones when passed to the renderer.

Detail-in-overview displays can be implemented using SVG's viewport mechanism [Jac03]. For this, a rectangular region is defined around the part of interest. A viewport with appropriate scaling is defined and positioned on the display area. Then, all geometry within the defined region of interest is rendered into the viewport. The necessary scaling and clipping is done automatically by the SVG renderer (Figure 2 (b), right).

Explosion views can be created by displacing adjacent components so that these do no longer overlap. An automatic approach proposed in [AP+03] determines the displacement direction that affords the least distance by evaluating the bounding boxes of all affected components. However, to allow more complex displacements, in our prototype displacement vectors and subsidiary lines are defined explicitly. This information is stored to the SVG file using the XML namespace mechanism, enabling standard SVG agents to ignore it and still display the unexploded view correctly. Our prototype, on the other hand, uses an extension-aware SVG agent that decodes this information. Figure 3 (b) shows an example of an assembly instruction encoded as a single explosion view.

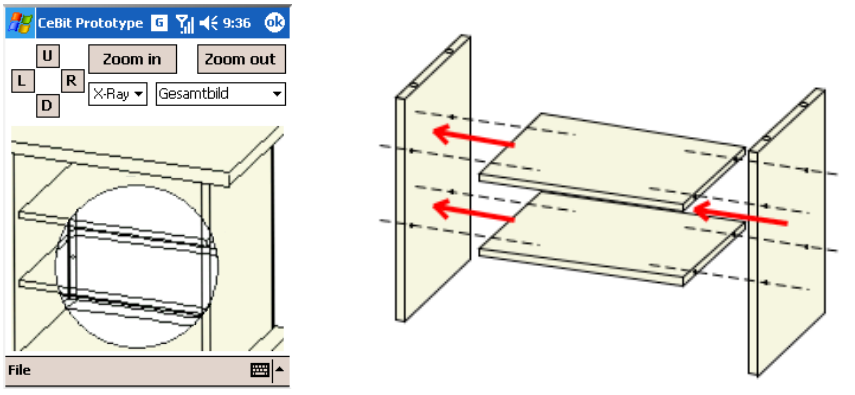
Labeling is an important aspect of technical illustrations [Tuf97], although the labeling problem has proven to be NP-complete [MS97]. Labeling in our pro-

Figure 2. Authoring tool for editing SVG group/symbol tag structures of input files (a), example for a step-by-step assembly instruction generated from a single input image using accentuation, information hiding, and detail-in-overview (b).



a *b*

Figure 3. Screenshot of the "X-Ray lens" used to reveal hidden geometry (a), generated explosion view with additional geometry (subsidiary lines) shown (b).



a *b*

totype is therefore either static, i.e. done by the content author or, if a WLAN connection is available, using a labeling service as described in [FL+06]. In both cases, textual labels are directly supported by SVG, so no extension of the renderer is needed.

CONCEPTS FOR PRESENTING STRUCTURES

In contrast to assembly drawings, structure representations like piping diagrams or technical process flows usually focus upon displaying the functional dependencies between different parts or modules. While the individual parts themselves can be represented by one of the techniques described in the above section, the depiction of their relationship to one another adds to the difficulty of bringing such structure representations to the limited screen of a handheld device. Approaches to overcome (or at least lessen) this problem, can again be derived from the two principal strategies –segmenting the structure or decreasing their depth. This section discusses these approaches specifically for circuit schematics in the context of electrical engineering, but the underlying principles can easily be adapted for structures from other technical fields as well.

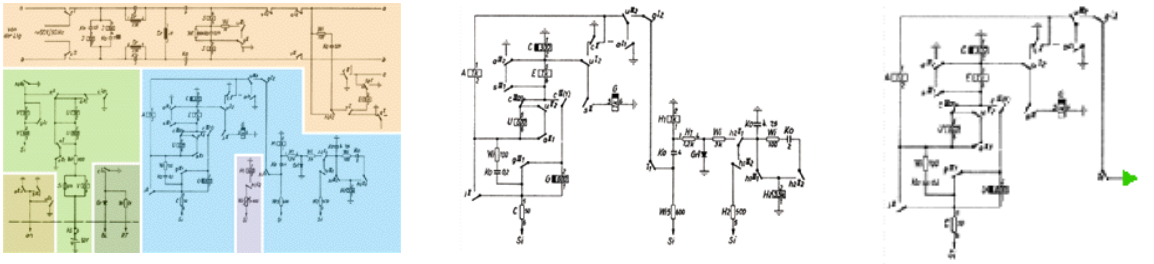
Segmentation can at first be used to partition the circuit schematic into its disjoint parts. These can be extracted and then displayed independently (see Figure 4 (a) and (b)) or combined into a new schematic as needed. This allows to reduce the content of the illustration to only those segments that are ultimately required for the task at hand. When there are no disjoint parts or further simplification of an extracted segment is needed, a folding method can be employed that hides additional subsections of the circuit drawing (exemplified in Figure 4 (b) and (c)).

Depth reduction uses on the other hand means of abstracting certain parts of a complex schematic. This is usually done by repeatedly combining several low-level parts into one high-level "compound part" that represents the merged elements as a functional block. This is common practice in electrical engineering where functional groups of parts are integrated into a single IC or circuit board to ease its repair and its interchangeability with updated, newer hardware.

Both of the presented methods suit the typical tasks that an electrical engineer needs to carry out upon a schematic very well. Thus, the aggregation of "low-level" components to reduce the depth of the schematic serves well in an overview that shows the main structure of the entire circuit. And segmentation and folding of the circuit are good ways to focus upon a certain section of the schematic. This is very helpful when measuring sections need to be identified or functional modules and individual parts must be located.

While the above ideas for reducing the visual complexity of circuit diagrams seem quite elementary and uncomplicated at first, their technical implementation is not. Especially the automated segmentation and abstraction of a schematic representation pose algorithmically complex tasks. Their realization is based upon a semantic annotation of the SVG geometry that basically models the topology of the described circuit. Unfortunately, our graphics format of choice – SVG – is only of limited use for their implementation. Since a standard SVG-file [Jac03] does not hold any information about the topology of the structure it contains, e.g. which geometric primitives are connected with each other by which (poly-)lines, an automatic processing of the above methods would be impossible. Yet, there have been first attempts to provide SVG with additional topological features that allow to exactly grasp the notion of geometric structures that are connected to one

Figure 4. A circuit schematic that is segmented into its disjoint sections (a), an already larger view of the light blue section only (b) and the even larger depiction of the same light blue section with one hidden part at the green arrow head (c).



a *b* *c*

another [TMM00, KMS04]. While these non-standard extensions will be simply ignored by a standard SVG-viewer, a customized SVG-viewer can take advantage of the additional topology information in the SVG-files and use it for the automatic deduction of possible folding points or unconnected circuits. Furthermore, the topology information also permits to run a final compaction step, for example to further compress the image or to adjust the image to a certain aspect ratio of the screen. Since the compaction of a given two-dimensional layout is NP-complete [SP82], heuristics or approximation algorithms may need to be employed to run the compaction in acceptable time [SL89, Wol84].

If, for certain reasons, one must not extend the SVG standard, an authoring tool can be used to manually annotate the schematic in SVG format with the needed information. Both, the segmentation into its connected parts or the selection of meaningful folding points, can be modeled directly in SVG via the <g>…</g> tag described in the previous section. Since the other parts of the proposed electronic handbook besides the circuit schematics need to be authored too (written text, photographs, video-tutorials, etc.), such an authoring tool for annotating circuit schematics can easily be plugged into the existing workflow and its toolset. While this requires an additional amount of effort on the side of the content provider, it guarantees the compatibility to all standard SVG-viewers. An example for both, our authoring tool and our client software using a standard SVG-viewing component can be seen in Figure 5.

Independently of the way in which such a screen-optimized circuit schematic is generated (manually with an authoring tool or automatically from a topology description), the above presented methods usually behave quite well for ordinary schematics. Yet, one has to bear in mind that if one tries to handle extremely large and highly connected circuit diagrams, a suitable reduction of its visual complexity might be hard or even impossible to obtain. Fortunately, since most of the complex functional blocks of a circuit are already integrated into higher-level parts like ICs or circuit boards, our experiences show that overly complex schematics occur only rarely in real world maintenance applications.

SUMMARY

As one can easily see from the above sections, providing CAD-derived illustrations for mobile handheld devices is an ambitious goal that gets increasingly difficult with the amount of automation involved. Especially the reduction of complex drawings to fit the small screen space of today's mobile devices poses a challenging problem. Yet, it is encouraging to see that already the basic techniques presented in this paper combined with the technical possibilities of a state-of-the-art vector graphics format like SVG show promising results. Also, the possibility to shift complexity issues and issues of standard conformity between the authoring process and the interactive mobile client allows the adaptation to a wide range of technical architectures and content creation workflows. In this paper, we have shown both – powerful authoring tools and prototypes of smart mobile clients that utilize their respective strategies to circumvent technical incompatibilities as well as runtime and screen bottlenecks.

Our ideas to further this study focus on additional automation possibilities using topologically annotated illustrations. Because describing the topology using a graph structure seems to lead towards unexpected benefits like the possibility to use a simple breadth-first-search to easily determine connected components or graph drawing algorithms for further optimization of the layout. Additionally,

a *b*

an evaluation of the proposed techniques and their acceptance by maintenance workers in different scenarios needs to be realized.

An Evolutionary Framework for Strategies of Spatial Technologies: Case Study Analysis

James B. Pick, University of Redlands, Redlands, CA 92373; E-mail: james_pick@redlands.edu

ABSTRACT

An evolutionary framework is presented for spatial information technologies in business. The framework has the three dimensions of extent spatial applications are customer-facing, the extent geography influences the business, and the extent of presence of spatially-enabled web integration platform versus traditional spatial platform. The evolution of the framework over time is towards more customer-facing, greater extent of geography in the business, and greater extent of spatially-enabled web integration platforms. The framework is tested by interviews of eighteen case study companies that vary in size and industry. Case study methodology is utilized. The research question asks whether strategic spatial focus is related to one or more of the framework dimensions. Results indicate that greater strategic focus of a company is associated with increases of spatially-enabled web integration platforms, but not with extent of geography in the business or with the extent spatial applications are customer-facing. The findings are compared to literature on frameworks of classifying spatially-enabled firms.

Keywords: Spatial technologies, strategic, framework, case study.

1. INTRODUCTION

Spatial technologies and geographic information systems (GIS) grew up in government (Longley et al., 2005), but have moved rapidly in recent years into the business sector (Francica, 2005). A few studies focusing on business spatial uses have emphasized the strategic aspects. The framework of Ghosal (1987) has been useful to understand IT strategy, and was extended to GIS in business (Murphy 1996). Ghosal pointed to three areas of strategic goals: efficiency in current operations, managing risks, and learning, innovating, and adapting. All the areas carry over to GIS strategies (Murphy 1996). Likewise, Ghosal's three areas of IT strategic tools (economies of scale, economies of scope, and exploiting factor differences) can apply also as GIS strategic tools (Murphy 1996.) A contributor to the goal of learning, innovating, and adapting is "organizational memory and learning" (Ghosal 1995). For spatial applications, GIS mapping and analysis can consolidate memory visually, reduce the complexity, and make learning easier. GIS can help an organization achieve its vision and strategic goals (Tomlinson 2003).

Use of these technologies is growing rapidly, including in the business sector. Daratech estimates that the market of core software and services for GIS was $1.7 billion in 2003 (Daratech 2004), while Longley et al. (2005) estimate the total worldwide expenditure on GIS and related activities is $15-20 billion.

The trend for spatial technologies in business has been to extend them from traditional GIS systems to enterprise-wide systems that run on web-based architectures (Sonnen and Morris 2005; Guerrero, 2005). A traditional GIS system refers to powerful desktops or client-servers running GIS commercial software. It has powerful functionality and requires geographic and GIS expertise to develop. The enterprise-wide systems tend to run under spatial web services architecture, which consists of servers connected to the web that provide spatial applications to web-connected clients. Also, enterprise servers such as those from ERP, CRM, and Business Intelligence can be connected to this web architecture. For instance SAS, a leading business intelligence vendor, has achieved tight integration of its server-based software to the server versions of ESRI's GIS software (Barnes 2005).

The objectives of this research are the following: (1) develop a conceptual framework of the evolution of spatial technologies in business, that takes into account how customer-facing the application is, how geographical the industry or firm is, and the extent the industry or firm uses a spatially-enabled, enterprise-wide integration platform, (2) analyze eighteen case studies of businesses and classify the cases in the framework, (3) analyze how strategic are the spatial applications for the case companies, and (4) answer the research question of whether the level of spatial strategy of firms is associated with dimensions of the framework.

The paper's *Research Question* is as follows: Is the extent that a company is strategic in its spatial technologies in year 2005 associated with one or more of the three dimensions in the evolutionary framework: the extent applications are customer-facing, extent the firm is geographic in its business, and/or extent the firm uses a spatially-enabled, enterprise-wide web integration platform.

The study is exploratory and utilizes qualitative, case-study methodology. Its goal is to raise issues of emerging spatial technologies for business and to gain understanding through exploratory analysis of case studies. The study is not intended to be statistically significant or to confirm research questions based on a large sample.

2. METHODOLOGY

The methodology for this research is case study (Yin 1993, Yin 1994). The case study strategy consists of definition of the study focus, framework construction, interviews, data collection, and case analysis. Case studies are often used to deepen insight into enterprises and their decision-making processes, sometimes more so than can be done with large sample surveys (Yin 1994). Case study investigation often has small sample sizes (Yin 1994). The present case study sample was determined by selecting eighteen firms, each in a different industry that is known to utilize GIS (see Table 1**).** The sample of firms is not randomly chosen, but is a convenience sample**.** Five of the industries were ones with high spatial technology use (oil and gas, utilities, retail, environmental services, and transportation) and seven were ones with moderate spatial technology use (banking, health care, marketing/advertising, newspapers, publishing, consulting, and consumer services). The firms were selected to have different size categories (6 large, 3 medium, 2 small), ownership structures (3 are private, 8 public), and corporate structures. The range of firms is broad in order to encompass a variety of spatial and strategic factors and to demonstrate a range of firms for the evolutionary framework. For each firm, the protocol is to interview the manager or executive responsible for spatial technologies. For one firm, that responsibility was split evenly between GIS technology and GIS marketing so both managers were included in the interview. The interviews utilized a standard interview protocol and set of general questions. They were transcribed in writing and tape recorded if permission was granted. The interview transcripts were sent to the interviewees for factual corrections. Secondary materials on spatial technologies in the firms were requested, and provided by most firms. They consisted of company reports, postings, and writeups. In addition, secondary business materials were obtained from company websites and standard business information services (Dun and Bradstreet 2005; Hoover's, 2005; Standard and Poors, 2005).

Responses to specific items on the interview protocol were used to position the company in the framework, in particular extent spatial is customer-facing; extent spatially-enabled, enterprise-wide web integration platform; and extent of geog-

raphy in the business. The latter refers to how important geographically-based products and services are in the firm.

3. EVOLUTIONARY FRAMEWORK OF SPATIAL TECHNOLOGIES

This section proposes an evolutionary framework that takes into account three key dimensions. Since GIS and spatial technologies are new to the business research few frameworks or theories have been proposed to account for their evolution and growth (Hackbarth and Mennecke 2005; Jarupathirun and Zahedi 2005).

A prior "geo-business application model" (Hackbarth and Mennecke, 2005) categorized geo-business applications by three dimensions: (1) type of agents (virtual, digital, physical), (2) type of products (virtual, digital, physical), and (3) type of processes (virtual, digital, physical). This model focuses on these virtual typologies, but does not take any account of the organization. The unit of analysis is the application. Another study considered a model of web-based spatial decision making where a variety of expectations led to perceived goal commitment and perceived task-technology fit, leading in turn to performance measures of spatial decision support systems (Jarupathirun and Zahedi 2005). The present paper's framework recognizes the whole industry or firm as the unit of analysis. No prior firm-level or industry-level conceptual models have appeared in the research literature for spatial technologies.

The present evolutionary model was developed by consultation with industry experts and by scrutiny of industry literature (Tomlinson 2003, Barnes 2005, Guerrero 2005, Maguire 2005, Reed 2005, Sonnen and Morris 2005) and several academic sources (Francica 2005, Lopez 2005). The model is a theoretical one that is based on three model dimensions that were repeatedly emphasized by the experts and the literature. The dimensions are: (1) extent that spatial applications are customer-facing, (2) extent that geography is part of the industry or business, and (3) extent that the industry or business utilizes a spatially-enabled enterprise-wide integration platform. The configuration of them into a three-dimensional space for categorization was the original work of the author, but was suggested by a three-dimensional categorization model for location-based-systems (Hackbarth and Mennecke 2005). There are numerous 2-D and 3-D categorization models in the IT field. The first dimension consists of the extent that spatial applications in the industry or company are directed towards a user base that is predominantly customers (i.e. customer-facing) versus spatial applications that are directed towards internal users. Internal users include executives, managers, marketing specialists, middle-level analysts, operations personnel, sales force, and field workers. Spatial applications at outsourcing providers that are closely associated with a firm are considered "internal," rather than customer-facing.

The extent of geography as part of the business refers to whether the major business products and processes relate closely to geography. An example of an industry closely linked to geography is transportation, for which the key processes of moving goods and services are inherently tied to geography; another example is the utility industry, for which the products of energy, purified water, and essential materials are provided through geographical network routing of transmission lines, pipelines, and specialized transport vehicles. Real estate is another obvious example, with land as its central element. On the other hand, the legal services industry has slight linkage with geography for its essential products and processes. Another less geographically-tied industry is financial services, since its vital products and services are not usually strongly linked to geography. In between in spatial intensity are industries such as health care, banking, metals manufacturing, and pharmaceuticals.

The extent that an industry or business utilizes a spatially-enabled web integration platform refers to whether it is based on "traditional" desktop or client-server spatial applications or is mostly based on the web-based and location-based enterprise architecture that consists of web servers, content servers, the web, thin and thick clients (Barnes 2005, Guerrero 2005, Lopez 2005, Maguire 2005, Sonnen and Morris 2005). Sometimes spatially-enabled portable mobile devices are included in this architecture by GPS and/or wireless links. In between are mixed architectures, in which industries for companies depend substantially on a mixture of the traditional technical GIS platform and the emerging web- and location-based integration platform.

The changes in the evolutionary framework over time are shown circa 1995 in Figure 1, and in 2005 in Figure 2. Figure 1 only shows two dimensions, since the spatially-enabled web integration platform was not present, but only the traditional desktop or client-server. Geography-tied industries such as transportation and utilities are shown with higher values on the x axis while ones with much less spatial linkage such as steel and private hospitals have low values. On the y axis, industries that are not customer-facing in spatial technologies include pest management and oil and gas, while industries such as real estate are moderately customer-facing, but no industries in the mid 90s are highly spatially customer-facing. The deficit of high customer-facing is because map delivery was still cumbersome, bandwidths were not high enough for effective interactive mapping, and businesses mostly had not yet recognized the benefits of providing maps and spatial analysis to customers.

In 2005, the complexion of industry distributions changed, and the web integration platform appeared, so it is added to the framework as the z dimension. Compared to 1995, there are only moderate changes in some industries with respect to ex-

Figure 1. Evolutionary framework of industry categories by two spatial dimensions, 1995

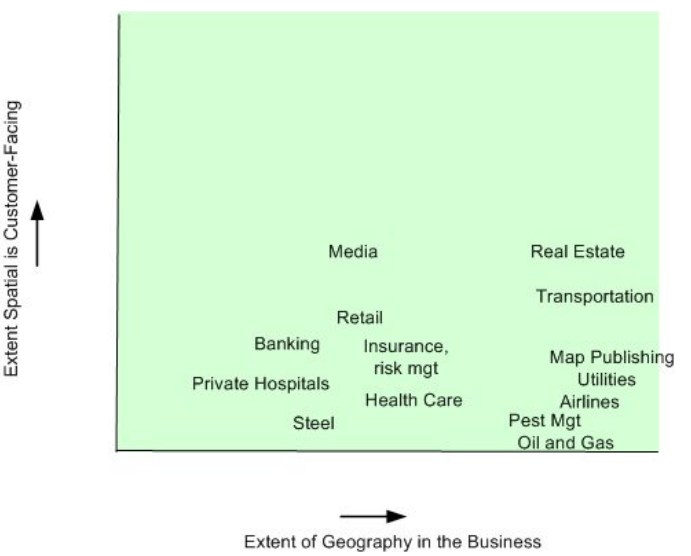

Figure 2. Evolutionary framework of industry categories by three spatial dimensions, 2005

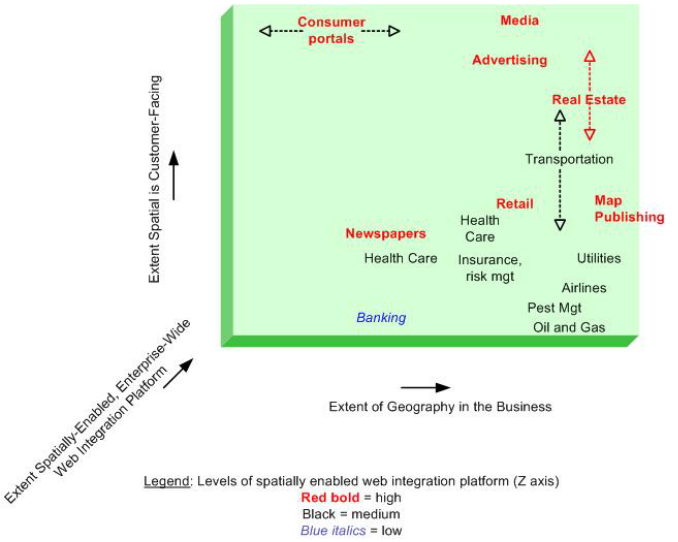

Figure 3. Evolutionary framework of industry categories by industry cases, 2005

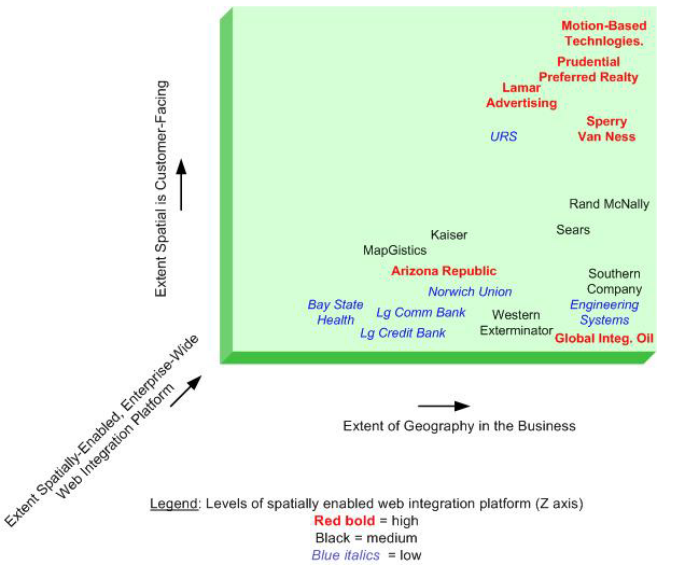

tent of geography in the business. These changes arose because some industries became more geographical. For instance, as banks consolidated and covered larger territories, some of their geographical-based functions, such as real estate and marketing, gained in importance. Likewise for private healthcare, the larger chains created through mergers and acquisitions resulted in more prominence for geography, such as in national marketing planning and competitive siting of hospitals and clinics. On the y-axis of extent customer-facing, there were substantial changes in some industries due to fast, web-based delivery of enhanced map products in real-time. An example is real estate, where increasingly multimedia and map enhancements occurred. This is typified by a product such as Realtor.Com, which is very customer-facing with real-time nationwide maps and multimedia. An industry not present in 1995 but strong today is consumer portals with products such as Google Map and Earth, Microsoft MSN, Yahoo Maps, and Amazon A9, that deliver detailed maps on a worldwide basis. At the low end of customer-facing, some industries remain from 1995 such as metals manufacturing and pest management, for which consumers are not demanding interactive spatial interfaces and the firms are not providing them. Some industries such as transportation have become more customer-facing in certain functions such as automated vehicle navigation (AVN) and marketing, but remain internally focused in design, manufacturing, and other areas.

In the z-axis dimension of extent spatially-enabled web integration platform, industries such as consumer portals, media, and real estate lead the way, with continual, powerful, and appealing delivery of maps and spatial analysis to customers. Industries that have mostly not adopted the web- based platforms include banks, steel, and pest management. These industries have not seen sufficient benefits in spatial applications to justify the high costs of upgrading from desktop/client-server to web-based enterprise platforms.

This evolutionary framework can be expected to change further, since spatial technologies are currently in a phase of rapid advancement in business, due to reduced costs and more realization of the competitive importance of the benefits (Sonnen and Morris 2005, Francica 2005). The framework can be useful to managers who conduct mid- to long-range planning of their spatial architecture and applications. This paper now turns to eighteen case studies of businesses that use spatial technologies. Based on case analysis, each firm will be placed on the 2005 evolutionary framework, and the extent each business has identified spatial applications as strategic will be compared to the three factors of the framework.

3.1 Summary of Findings

The detailed findings for each case study firm cannot be included in this paper, due to space limitations. The summaries of the individual cases are available by request from the author. This findings section contains a summary to the results as they pertain to the research question. The case study firms vary on the three dimensions of the evolutionary framework, as shown in Figure 3. Size of firm has no consistent association with position in the framework, which implies that barriers to entry are low for spatial technologies in business. The extent applications are customer-facing relates to type of industry. Consumer services, billboard advertising, newspapers, and retail are industries that serve large numbers of customers. By contrast, the oil and utilities industries are more proprietary about retaining geographic information. Furthermore, post 9-11, those industries have been restricted by government policy from making publicly available certain types of spatial information, such as detailed maps of their network configurations and loads. The giant Credit Bank is in the early process of shifting from centralized service of customers with credit needs that are not spatially-based to serving emerging retail customers who often need spatial displays, but the bank's traditional habits are not spatially-oriented. The pest industry has not yet offered spatial displays to its customers, who don't seem ready to use it.

Regarding the extent of geography in businesses, it is keyed closely to industry characteristics. Those with the largest geographical component come from oil and gas, utilities, GIS consulting, and consumer services, while geography is less important for banking and newspapers.

3.2 The Research Question

The research question can be answered based on the case study results, which are summarized in Table 2. Detailed description of each case appears in Pick (2006). It is evident that strategic level is not related to extent of customer facing. In comparing the extent the eighteen firms are spatially strategic to the adoption of spatially-enabled enterprise-wide web integration platforms, they are highly associated for this sample. Five of the six firms that adopted web-based, enterprise-wide platforms have high to very high strategic levels for spatial technologies, whereas six firms in the traditional client-server mode have predominantly low (five out of six) strategic levels for their spatial technologies. The six firms in the middle level of spatially-enabled enterprise-wide web integration platform have medium to high strategic levels (4 medium, 2 high) for spatial. The Research Question is supported for the positive association of strategic level and spatially-enabled, enterprise-wide web integration platform.

4. DISCUSSION AND CONCLUSION

Spatial technologies have expanded rapidly in the business world. Uses are evolving, supported by spatially-enabled, enterprise-wide web integration platform. Sometimes location-based-service capabilities are added. As costs lowered, more

Table 2. Case study sample – Company Name/Description, Industry, and Size (strategic level refers to strategic level of spatial technology in the business. Note: the colors in the last two columns refer to spatial strategic level, blue=high or very high,, white=medium, and yellow=low)*

MapGistics	small	low	Intermediate. Is partly web-based enterprise-wide	high

profitable uses were discovered. The present research proposes an evolutionary 3-dimensional framework for industry and firm applications of spatial technologies having three dimensions. The extent of customer-facing spatial applications has steadily expanded over time towards greater customer-facing. This is due both to the convenience and user-friendliness of the new technologies as well as to broader user bases. The extent geography is associated with the business has grown slowly, as the structure of industries altered or new industries emerged. An example is the web-portal industry sector, which emerged in the last eight to ten years and in 2005 took a giant step towards the general-public consumer with such offerings as Google Earth and Microsoft Virtual Earth. For established industries such as banking, the trend towards mergers and acquisitions can broaden the geography of the firm and make spatial applications more important.

Eighteen case studies were conducted of firms from different industries and size categories. Applications of spatial technologies are varied, but have advanced for all the firms as cost reductions and newer software and systems have made the technologies more beneficial and profitable.

The research question is supported by the positive association in 2005 of firm's spatial strategic level with spatially-enabled, enterprise-wide web integration platform. No association was evident between strategic level and customer-facing spatial application, nor between strategic level and extent of geography in the business.

The implications of the research are that a firm should evaluate its industry and determine how suitable it is to spatial technologies, as well as how much competitive advantage the technologies offer. Firms should consider deploying spatial applications on platforms that are web-enabled, as long as it can rationalize the investment from a cost-benefit standpoint. It should plan in the long term to evolve the applications to enterprise-wide. Some firms such as Motion-Based in this study have been able to leap-frog directly to full web-based enterprise spatial platforms and take the lead in market niches. Of course that increases risk and requires understanding of customer markets.

The research is exploratory. Future research can test the framework and the research question with a large sample survey that would statistically evaluate the preliminary findings reported here. This would lead to a more robust organizing framework. The research might be further strengthened by interviewing or surveying varied levels of employees in each firm, to assess each firm's responses from a variety of organizational perspectives.

Managers in businesses should consider what opportunities are present to improve productivity, lower costs, and strengthen strategic positioning through spatial technologies and GIS.

An Integrated Sugarcane Phenology and an Optimization Approach to Set Plant and Harvest Schedules Within a Mill Region

Kullapapruk Piewthongngam, Khon Kaen University, Khon Kaen 40002, Thailand; E-mail: pkullop@kku.ac.th
Kanchana Setthanan, Khon Kaen University, Khon Kaen 40002, Thailand
Jakrapun Suksawat, Khon Kaen University, Khon Kaen 40002, Thailand

ABSTRACT

As a result of separated planning between rain-fed sugarcane growers and sugar mills in Northeastern Thailand, the supply of sugarcane to the mills were fluctuated. This situation led both sugarcane farmers and sugar plants to produce below their profit maximization level. During the harvest season, the quantity of sugarcane harvested did not match the capacity level of the mills. Hence, the supply of sugarcane was under capacity in the early and late harvest season, but it was over capacity in the middle of the season. This problem portrayed the loss of the mills to operate under capacity and the loss of farmers when the cut-to-crush time exceeded 15 hours as a result of the over supply of the sugarcane on that particular day. This problem, however, could be solved through the supply chain management using the database management, sugarcane phenology modeling such as the DSSAT-CANEGRO and a heuristic method. The database was used to record land information, climate zones, soil structures, land sizes, and farm management. The information, then, was fed into the CANEGRO, which combined weather data, genetic characters, management strategies, and soil data in order to simulate expected outputs. The results of these simulations were used in heuristic programming to identify varieties, plant and harvest date for a particular sugarcane plot so that the capacity of a sugar processing plant was optimized as well as the farmer's revenue. The simulated maximum quantity of sugar that could be produced was 810 million kilograms; it was obtained from the start of the harvest season on January 6 until the end of November 9. The simulated result using the purposive algorithm was greater than the average of simulated randomly grown sugarcane by 243 million kilograms. Moreover, the results of the simulated randomly grown sugarcane depicted that the supply of sugar exceeded the capacity by 4 times and under it by 20 times on the average.

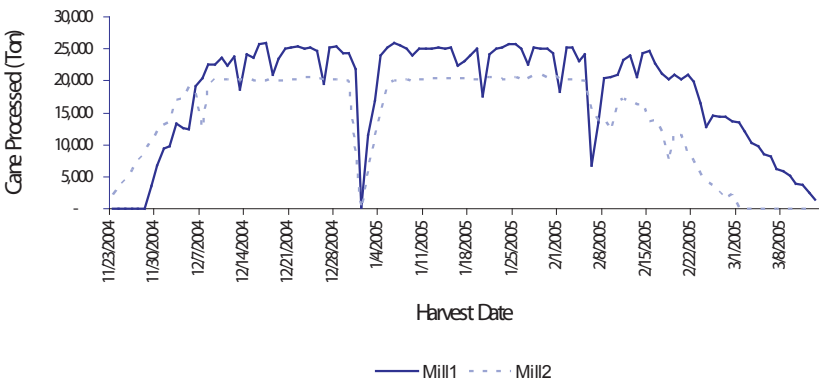
Keywords: Supply Chain Management, Heuristic, Sugar Industry, Quantitative Analysis, CANEGRO

INTRODUCTION

In recent years, sugar exporters have been competing fiercely in driving down their cost or pushing up their productivity. Severals engage in quest for better management. Hence, researchers have been conducting research for clearer vision on this matter. Most of them have concluded that collaboration between cane growers and sugar mills would pave the way to their ultimate goals. This collaboration plan is known as supply chain management. The collaboration will enable planners to set harvesting dates which will give optimum benefits to the sugar industry as a whole. Moreover, it possesses promising future application in marketing, transportation and warehouse management, etc. However, the road to this promising future has not been neatly paved.

In the Thai sugar industry, the unpaved road is traditionally adopted. Most of the Thai cane is rainfed, and the plant date is naturally fixed by the mother of nature. Also, growers' copycat habit leads them to grow the same variety of cane. Combining the two events, the sugarcane inevitably ripens at the same period. This incident triggers a big road block as shown in Fig. 1. The amounts of cane supplied to mills are under crushing capacity at the beginning and at the end of the harvest season while they are over capacity in the middle of the season. The under capacity operation causes high per unit fixed cost for mills while the over capacity one prolongs cut-to-crush delay which leads to lower recoverable sugar yield. From an interview with growers, the cut-to-crush delay sometimes lasts four days, and that portrays an unnecessary loss of 60 kg. per ton.

Figure 1. Tons of sugar produced daily in the 2004/2005 harvest season



Solutions for this phenomenon are as follows: First, exploiting genotypes of cane varieties is needed. Varieties of cane may differ in their mature characteristics or ripening time. As suggested by Gilbert et al.(2004), some varieties are early season mature; some are mid, and some are late season mature. Hence, a certain combination of varieties will enable capacity and yield optimization. Second, enhancing the ability to predict sugar yield is to be conducted. This element is a consequence of the first one. If a variety selection is a preferred method to solve this problem, an accurate yield forecast is needed so that decision makers can decide harvest schedules accordingly. Third, a mathematical tool to lay out estimated yield into a collaboration plan is to be applied. Because the plan involves numbers of participatory growers, together with daily yield prediction, the problem can be unimaginary large. Therefore, decision makers need a mathematical tool to sort it out.

LITERATURE REVIEW

Engineering/management researchers have been trying to combine yield estimation and mathematical programming to smooth out this problem for years. Their mathematical concepts are rather more advanced while they are still struggling with yield prediction. Whan, Scott and Jefferson (1978) were among very first researchers who dealt with the application of cane yield prediction. Their predicted methodology was a quadratic equation which was a function of cane age, years of crop cycles and cross products between cane age and years of crop cycles. Although they attempted to imitate a pattern of real cane yield over time, their method did not cover crucial factors such as weather distribution. Years later, Hahn and Ribeiro (1999) suggested a daily planning of the transportation of sugar cane to mills which minimized cost and waiting time. Although it was a big leap forward for the cane industry, they assumed the amount of ripening cane was known and given. Cane growers were free to make decisions regarding pant dates, varieties, and the amount of land to grow. Therefore, the situation ended up as the Thai case. Their solution seemed to fix the waiting time, but the growers were not able to harvest at their possible optimal level.

Another study by Higgins et al. (1998) portrays a close concept to this study. They obtained a monthly average yield from historical data of each region to set up a harvest schedule. Although they demonstrated an elegant framework, using monthly average data implicitly assumed the same weather distribution across the year. Recently Jiao, Higgins and Prestwidge(2005) have proposed a combination of statistical and optimization approaches to resolve harvest schedule problems. They divided cane varieties into groups of early, middle and late mature varieties. Then, they estimated the sugar content of cane(CCS) as a polynomial function of number of weeks after the harvest season started. Finally, they applied a linear programming to optimize the predicted CCS under respective constraints. Similar to Higgins et al., Jiao, Higgins and Prestwidge assumed the same weather pattern across the year.

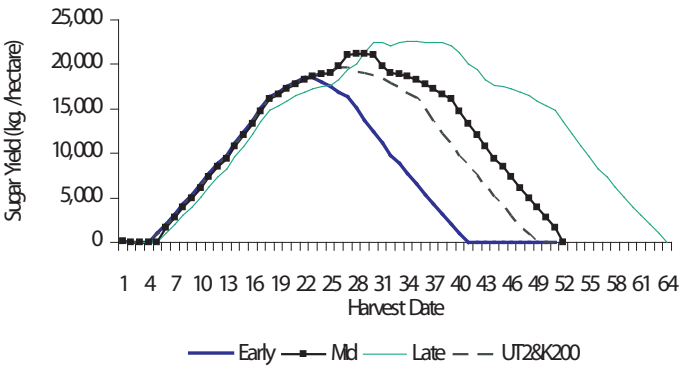
Plant phenologists have long been working on sugar yield estimation paralleled to the groups stated earlier. They successfully develop the state of art software programs for yield prediction. Two programs that have been widely used in cane industries are APSIM and DSSAT-CANEGRO. The two take similar approaches in dividing cane development into certain stages. Each stage differs in requirements of crucial factors such as solar radiation, water, temperature, nutrients, etc. A simulating process is created to imitate the development of plant growth in each stage. Hence, the program considers each important factor and each land plot separately and carefully. Although the simulated result possesses a promising future, it has not been applied for a group management. Rather, a single farm management is more commonly exploited.

To solve the problem of uneven cane supply and sugar mills' crushing capacity, we propose an integration of plant phenology programming and a heuristic approach. The details of this integration will be stated in the next section.

PLANT PHENOLOGY

Firstly, cane yield is simulated by the use of the DSSAT-CANEGRO. Due to the unavailable genetics coefficient for Thai cane except for UT2&K200, genetics of three varieties bundled with the DSSAT package, N14, NCo376, and GEOFF'S FAV were used. The coefficients were modified so that they could represent early, mid, and late season maturity. Degree-days(degree of highest temperature accumulated) from emergence to the harvest maturity of NCo376, N14, and GEOFF'S FAV were changed to 8.5, 7.0 and 6.5 thousand °C which represented late, mid and early season maturity consecutively. And the coefficient of UT2&K200 were obtained from Jintrawet et al.(1997).

Figure 2. Simulated results of 4 varieties on Chaiyaphum loamy sand planted in March



In this study, the management was assumed to be the same across the board and was constructed according to normal practice for Thai cane. The studied sugar mill is a mill located in Khon Kaen province. Growers who supplied cane to this mill, are in the provinces of Khon Kaen, Chaiyaphum and Loei. Therefore, weather distributions were separately created from the distribution of these provinces. There are two types of typical soil structures in these provinces, loamy sand and sandy clay. Combining the three weather stations together with the two types of soil, the studied areas were, then, classified into six different regions. As for planting periods, normal planting periods were around February, March and October. In summary, the simulated case was classified into 4 varieties, 6 regions, and 3 planting date. Therefore, it summed up to 72 different cases.

The examples of simulated yields were shown in Fig. 2. These yields were created from 4 varieties, planted in March on Chaiyaphum loamy sand. As indicated in Fig. 2, graphs of cane yield were crisscrossing. One interpretation is that each variety is to be harvested at a different date. If the harvest before period of 23 is needed, the early season mature variety should be chosen. Whilst, the period of 25, the UT&K200 will give more yields, and for the mid season mature variety, it is suitable for harvesting at the period of 27. Additionally, the harvesting beyond the period of 27, the late season mature should be selected.

INTEGRATION INTO A MATHEMATICAL PROGRAMMING MODEL FOR OPTIMIZATION

After predicted yields were obtained, we applied heuristic Algorithm to set plant and harvest dates which would give the highest amount of total sugar. The objective function of maximizing group outputs takes the following form:

$$\text{Max } Z = \sum_{s=1}^{n}\sum_{t=1}^{n}\sum_{k=1}^{4}\sum_{j=1}^{6}\sum_{i=1}^{3} Q_{ijkt} A_{ijkt} B_s$$

where Z is total sugar produced, Q_{ijkt} is the sugar yield from cane planted at period i in region j with variety k and harvested during period t, A_{ijkt} is the amount of land where cane was planted at period i in region j with variety k and harvested during period t, and B_s is the binary number which equals to 1 when it is harvested in the season and 0 otherwise

I	set of planting dates and $i \in I$, i equals to 1 to 3
J	set of regions and $j \in J$, j equals 1 to 6
K	set of varieties and $k \in K$, k equals 1 to 4
T	set of harvest dates and $t \in T$
S	set of harvest seasons and $s \in S$

Constraints

1. $\sum_{t=1}^{n}\sum_{k=1}^{4}\sum_{j=1}^{6}\sum_{i=1}^{3} A_{ijkt} \le L_j, \forall\, i \in I, \forall\, j \in J, \forall\, k \in K, \forall\, t \in T, s \in S$

   The first constraint ensured that sum of Area j which planted Variety k at Time i would not exceeds its maximum level. The total land available for the studied mill is 48 thousand hectares. Due to limitation of the detailed data, we assumed each region has equal amount of land, L_j equals to 8 thousand hectares.

2. $\sum_{k=1}^{4}\sum_{j=1}^{6}\sum_{i=1}^{3} Q_{ijkt} A_{ijkt} \le CAP_t, \quad \forall\, i \in I, \forall\, j \in J, \forall\, k \in K, t \in T, s \in S$

   This constraint is to say that the total amount of cane being harvested did not exceed crushing capacity, CAP_t.

3. The amount of land used were positive numbers.
   $A_{ijkt} \ge 0, \quad i \in I,\ j \in J,\ k \in K,\ t \in T,\ s \in S$

4. Only one harvest season was selected for a particular year. The interpretation is that the harvest season was to be continuous. Hence, the process would go on until the running out of land.

   $\sum_{s=1}^{n} B_s = 1, \forall\, s \in S$

SIMULATION MODEL

We constructed a heuristic algorithm to optimize the objective function. The detailed logic of the algorithm is described as follow:

1. Given 72 different cases simulated yield from the DSSAT-CANEGRO, the optimization model would start its first scenario, s = 1, by beginning the harvest season on t = 1.
2. First, it would search for the best sugar yield per hectare during that period, and fill up capacity with the best yield up to the amount of land available. Nonetheless, if after the harvesting best yield, the supply of cane was still insufficient to fill up the mill's capacity, the algorithm would search for the next best. The process would go on until the capacity was sufficiently filled. Then, the program would move on to the next harvest date and so on.
3. The filling up process went on until the amount of land subsided to zero. Then, the iteration process would start the next scenario s = 2 meaning the harvest season had begun on t = 2 and Step 2 was repeated. The process went on until $s = n$.

The optimization process is described by using the following pseudo codes.

Algorithm

```
SET each land = Maximum of land
SET capacity for each period equals to its maximum capacity
FOR each starting the harvesting season date
  FOR each harvesting time
    DO
      FOR each region
        FOR each variety
          FOR each planting period
            Obtain 'Current_Solution' from the result of DSSAT
            IF Current_Solution is an improvement over Best_Solution check
                if the solution is feasible (there is some land available for
                growing sugarcane and there is some capacity left to be filled
                up) THEN Best_Solution = Current_Solution
            ENDIF
          REPEAT
        REPEAT
      REPEAT
        Calculate sugar_produced which will be produced by land available
        IF sugar_produced is less than capacity THEN
        UPDATE capacity needed to be filled
        SET land available to grow next t equal to 0
        ELSEIF sugar_produced is greater than capacity THEN
        calculate land available for the next t and set capacity needed to be
            filled equal to 0
    UNTIL land_available = 0 or capacity_be_filled = 0
    RESET capacity and capacity_be_filled to initial value
    UPDATE total_sugar_accumulated
  REPEAT
  RESET total_sugar_accumulated = 0 and land_available to its maximum
      initial value
REPEAT
```

At the end of each scenario, the total amount of sugar is calculated. Then, these summation sugar yields were compared in order to retrieve an optimum solution from these calculated yields.

SIMULATING RESULTS

The result of comparison total simulated yields as shown in Fig. 3 suggested that the harvest season should start on January 6 and end on November 19 with an optimum sugar yield of 813 million kg.

Also, the proposed algorithm recommended a harvest schedule. The example of the schedule is shown in Table 1. It shows that, from January 6 until March 2,

Figure 3. Total simulated yields for each harvest season

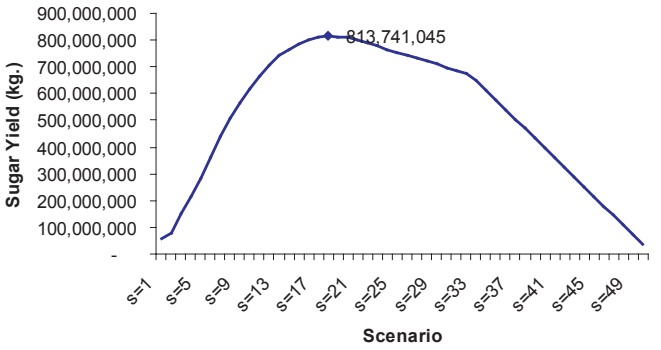


Table 1. Recommended harvest schedule

Harvest Date	Harvest Area (Hectare)	Variety	Plant Date	Region
Jan 6	1,582.0	UT2&K200	February	Chaiyaphum Loamy Clay
Jan 20	1,510.0	UT2&K200	February	Chaiyaphum Loamy Clay
Feb 3	1,458.0	UT2&K200	February	Chaiyaphum Loamy Clay
Feb 17	1,416.0	UT2&K200	February	Chaiyaphum Loamy Clay
Mar 2	1,416.0	UT2&K200	February	Chaiyaphum Loamy Clay
Mar 16	618.0	Mid Season	February	Chaiyaphum Loamy Clay
	810.0	Mid Season	February	Chaiyahum Sandy Loam
Mar 30	1,443.0	Mid Season	February	Chaiyahum Sandy Loam
Apr 13	1,443.0	Mid Season	February	Chaiyahum Sandy Loam
Apr 27	1,417.0	Late Season	February	Chaiyahum Sandy Loam
May 11	1,381.0	Late Season	February	Chaiyahum Sandy Loam
May 25	1,338.0	Late Season	February	Chaiyahum Sandy Loam
Jun 8	168.0	Late Season	February	Chaiyahum Sandy Loam
	2,178.0	Late Season	February	Chaiyahum Sandy Loam
Jun 22	2,476.0	Late Season	February	Chaiyahum Sandy Loam

Table 2. Recommended plant dates, areas, and varieties for each region

Region	Variety	Area (Hectares)	Planting Date
Chaiyaphum Sandy Loam	Mid season	3,696.0	February
	Late season	4,304.0	February
Total		8,000.0	
Loei Sandy Loam	Late season	7,226.0	February
	Late season	774.0	March
Total		8,000.0	
Khon Kaen Sandy Loam	Late season	8,000.0	February
Chaiyaphum Loamy Clay	UT2&K200	7,382.0	February
	Mid season	618.0	February
Total		8,000.0	
Loei Loamy Clay	Late season	8,000.0	February
Khon Kaen Loamy Clay	Late season	8,000.0	February

UT2&K200 planted on Chaiyaphum loamy clay in February should have been harvested with the amount of land indicated in the table. Whilst, from March 16 to April 13, the mid season variety grown on Chaiyaphum loamy clay and sandy loam should have been harvested. Next, the late season on Chaiyaphum sandy loam should have been harvested from April 12 to June 22.

According to the recommended planting schedule, the late season variety planted in February was recommended to grow on Chaiyaphum sandy loam, Loei sandy loam, Khon Kaen sandy loam, Loei loamy clay and Khon Kaen loamy clay for amount of land stated in Table 2. The mid season variety planted in February was recommended to grow on Chaiyaphum sandy loam and loamy clay. Finally, UT2&K200 planted in February was recommended to grow on Chaiyaphum loamy clay.

Because the result from optimization is a simulated one, its benefits are not known unless the model is supplied with the real world data. To show a potential benefit of this framework, we created 25 randomly grown scenarios. For each scenario, cane growers were to select a variety, the plant date and the amount of land on their own wishes and to harvest their canes when it was ripe. All 25 random scenarios showed lower total sugar yields, with an average of 570 million kg. The average randomly grown was 243 million kg. less than the former. Moreover, the result of these random scenarios showed uneven supply of cane which exceeded the sugar mill's capacity by an average of 4 times and was lower than the capacity by an average of 20 times.

CONCLUSIONS

The contribution of this research is to combine plant phenology with an optimization technique in solving supply chain management problems. Although the Thai cane industry will not be able to adopt this framework at this moment, we intend to illustrate a promising future application of the two fascinating tools which will lead to enhancing productivity of the industry as a whole. To get on track of this paved road, farmers' database is essential to the task. The mill needs to know the location, the amount of land, soil structures and the farm management style of each individual farmer. This information, then, will be fed to the optimization program to retrieve recommendations of plant dates, varieties and harvest dates.

ABSTRACT

In the past, much effort of healthcare decision support systems were focused on the data acquisition and storage, in order to allow the use of this data at some later point in time. Medical data was used in static manner, for analytical purposes, in order to verify the undertaken decisions. Due to the massive economical impact of today's health system, great changes in medical treatments are notable. Apart of the humanitarian and healing nature of medicine, this industry is becoming more and more business like. The exploitation of evidence-based guidelines becomes a priority concern, as the awareness of the importance of knowledge management rises.

Consequently, interoperability between medical information systems is becoming a necessity in modern health care. Under strong security measures, health care organisations are striking to unite and share their (partly very high sensitive) data assets in order to achieve a wider knowledge base and to provide a matured decision support service for the decision makers. Ontological integration of the very complex and heterogeneous medical data structures is a challenging task. Our objective is to point out the advantages of the deployment of a federated data warehouse approach for the integration of the wide range of different medical data sources and for distribution of evidence-based clinical knowledge, to support clinical decision makers, primarily clinicians at the point of care.

Keywords: data warehouse, clinical decision support systems, evidence-based medicine, knowledge management, wrapper, mediator, ontological integration

1. INTRODUCTION

Despite the scientific and technological development progress over the recent years in the healthcare delivery, a significant portion of the decision-making information on the treatment of a patient's illness is still based on unstructured information or even hand-written notation. Furthermore, patient records are distributed over many different locations, instead of being available when required at the point of care.

We propose a data warehouse (DWH) based approach, in order to enhance the process of clinical knowledge management, which is a prerequisite for a successful clinical decision support. The benefits of such a solution are:

- The most recent medical knowledge can be provided, in order to take treatment decisions, i.e. enabling the practice of evidence-based medicine. Due to the huge data volumes, a DWH approach is required for the production of evidence-based knowledge.
- Clinical business management can perform the desired knowledge-oriented strategic decision making, planning and management of the healthcare enterprise. The financial resources can be used more efficiently through the implementation of DWH-based clinical pathways. Henceforth, clinical business management is then enabled to negotiate appropriate care contracts based on accurate knowledge on resource utilization.
- Clinical DWH, which gathers all available data related to the patients, treatments and drugs they received, will represent an ideal knowledge base for research purposes.

The addressed issues are very demanding and comprehensive. In this paper we confine ourselves to handle one aspect – the goal of our paper is to point out the advantages of the deployment of DWH for integration of wide range of different data sources and for distribution of evidence-based clinical knowledge to support clinical decision makers.

The contribution of our work is to propose a DWH based, ontologically focused integration model for integration of heterogeneous health care data sources, which could even include external data suppliers or some third-party stakeholders' web services.

The remainder of the paper is organized as follows: in section 2, we present a short introduction into the concepts of DWH facilitating evidence-based medicine. An integrated health care information system, built upon a federated DWH is described in details in section 3. Section 4 outlines the advantages of the application of DWH technology for the support of care givers at the point of care via a case study. Section 5 deals with related work and finally, we conclude the paper in section 6.

2. DATA WAREHOUSE FACILITATING EVIDENCE-BASED MEDICINE

As discussed in related work [5], the business success of an organisation is highly dependable on the proactive use of information which is stored in its operational systems. A DWH integrates the relevant information, originating from the diverse internal and external data sources. Data in a DWH is prepared for users with different analytical and software skills, and consequently, having different types of requirements. A DWH should not only respond to pure reporting and data analysis requests but also support high-level users to track business trends, improve strategic decisions and enhance forecasting.

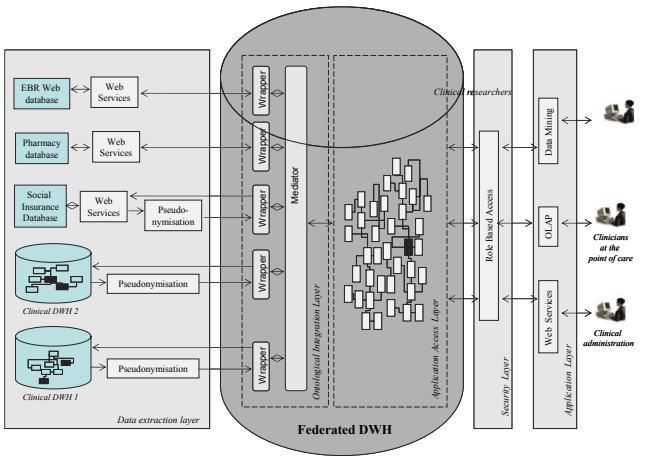
David Sackett [11] defines evidence-based medicine (EBM) as the conscientious, explicit, and judicious use of current best evidence in making decisions about the care of individual patients. Published clinical evidence is not necessarily sufficient for providing integrated support to care givers. EBM complements existing clinical decision making process with the most accurate and most efficient research evidence. Application of EBM concepts speeds up the transfer of clinical research findings into practice, leading to cost reduction and to the improvement of the healthcare process as the whole.

Both medical institutions and health insurance companies are primarily interested in increasing the patient healing rate and in reducing treatment costs. The right use of data warehousing in the area of EBM could prove as economically highly advantageous (in the long term) by the avoidance of duplications of examinations, by the automation of routine tasks and by the simplification of accounting and administrative procedures.

3. FEDERATED DWH MODEL FOR INTEGRATION OF MEDICAL INFORMATION SYSTEMS

During the last few years, healthcare organizations are confronted with massive knowledge processing challenges primarily caused by the increasing amount and

Figure 1. Medical federated DWH integration workflow



complexity of medical data. DWH offer a comprehensive support for gathering, analyzing and presenting medical data.

The system complexity, the heterogeneity of health care data sources, massive volumes of medical data and high number of concurrent users are the main reasons for the use of federated DWH integration model. As shown in Figure 1, the central point of such an integrated system is a federated DWH where all participants have access to and where the user's conceptual view is preserved.

In related work [10], we discussed the advantages of the federated approach against the centralized approach, in the aspects of cost-effectiveness, security and usability. A federated approach [1], [3] is required, when several independent organisations share their data for mutual purposes, but do not allow any physical copy of their data to be created in any external system. Most often, they demand to maintain full control of the access to their data. Highly confidential healthcare records are a typical example of such data. In case of interoperability in the health care domain, a federated DWH is therefore always a preferred solution.

3.1. Participators of DWH Federation

In our DWH model, the different medical treatment domains, i.e. the social insurance domain, the pharmaceutical domain and the evidence-based guidelines repository are participating in one federation. The existence of the federation is invisible to the users of the source systems.

The clinical DWH contains data which originates from a wide variety of data sources, such as:

- clinical data (patient, pharmaceutical, medical treatment, length of stay),
- administrative data (staff skills, overtime, nursing care hours),
- financial data (i.e. treatment costs, staff salaries, accounting)
- organizational data (facilities, equipment, room occupation)

The health insurance company stores information about patient encounters, treatments, therapies and drug prescriptions it supports. It communicates with the federation via web services.

Both clinical DWHs and the health insurance transfer their sensitive data to the federation, in case of a federated query. We assume that depersonalisation and pseudonymisation techniques are used to protect the confidentiality of patient data, as described in related work [2],[4],[10],[15],[16].

The pharmaceutical sector provides the federation with drug information such as medication description, packaging size, pharma-id number, indication group, pharmaceutical form (pills, juice etc.), and medication fee. In an analogous way to the insurance company, it uses web services to provide the federation with the necessary data.

The evidence-based rules repository is a collection of most accurate and most efficient research evidence. Through the web services, it provides the federation "on demand" with the best fitting guidelines for a given patient and given disease.

Since only a "single version of evidence" and a unique interpretation of the joined data should exist, it is necessary to have a unique singular common federated schema. For building the conceptual model of the federated DWH, just data relevant for further analyses and reporting are considered. In this phase, business users (from the domain of clinical/social insurance management) have to specify the respective sensitivity levels of data. The data modeller incorporates the specified privacy restrictions into the resulting logical data model.

3.2. Ontological Integration

The essential part of the integration of logical schemas of the underlying DWHs as well as of the data structures originating on the diverse participating legacy systems (such as relational or XML databases), is the ontological integration layer, as shown in the model depicted in Figure 1. Our model includes wrappers and mediator, which are two main architectural components of a mediated query system.

Wrappers encapsulate local data sources and export their functionalities and the metadata stored therein. They accept queries in a certain language and return metadata in a united form [12],[13]. The wrapper keeps locally the data schema for the specific data source it deals with. By integrating wrappers, we can cope with technical heterogeneities among local systems, without having to modify them.

The mediator [12], [13] handles the global queries from the application layer, unfold them into sub-queries and disperse these sub-queries to the relevant local data sources via their wrappers. The local results will be returned from wrappers; the mediator finally combines and presents the result to the client. Hence, the mediator will keep the global data schema and the mapping between global and local schemas. To maintain the dynamic mapping between local and global schemas, an ontological-based mediator/wrapper is one of the interesting problem solving approaches [13].

Figure 2 shows an example of how a user's query is handled by the wrappers and the mediator, from the query submission to the presentation of the result. On receiving the SQL query, the system performs the following:

1. DWH-Application invokes the mediator.

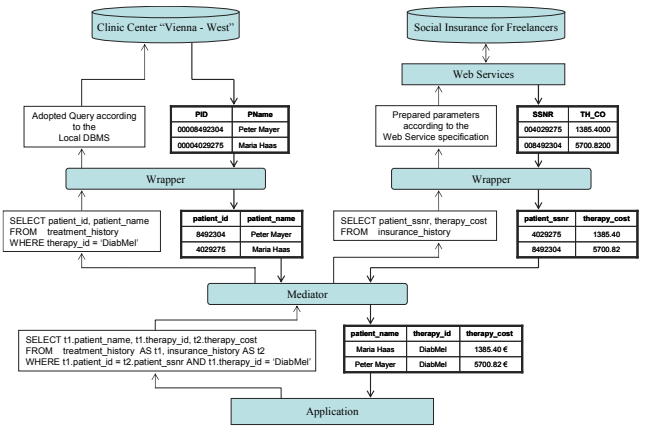
Query unfolding:

2. The mediator resolves the submitted query into partial queries, according to the exported schemas previously exposed by the wrappers. It determines which wrappers are relevant to the correspondent sub-queries.
3. The mediator passes the sub-queries to the affected wrappers.
4. A wrapper receives its sub-query and translates it into the format so that it can be understood by the underlying data source (database, web service etc.).
5. The wrapper forwards the adapted sub-query to the local DBMS or to the responsible Web Service for execution.

Query answering:

6. A wrapper retrieves answer data set, translates it into its exported schema.
7. The wrapper passes its answer data set to the mediator.

Figure 2. Mediated query system in health care environment



8. The mediator integrates partial query results into one answer set, transforms and formats it, so that it can be processed by the application.
9. The mediator passes the answer set to the application, so that it can be presented to the user.

The users of a federated DWH are not aware of the fact, that the data they are querying may be distributed across the network. Through data mining tools, web services, ad-hoc queries and predefined reports (OLAP tools), users are able to analyse data, as if they were physically stored in a centralised DWH. A role-based access model [14] guaranties that each user get access only to those data, which are necessary for the performing of his (her) tasks.

4. CASE STUDY: DWH SUPPORTING CLINICIAN AT THE POINT OF CARE

To illustrate the described DWH-based approach we present a case study, in which we suppose that the emergency room clinician is querying the federated DWH (as described in chapter 3) while examining the patient. The following scenario, which has not yet been implemented, builds the starting point of our case study: The diabetes patient, suffering from a progressive liver disease is complaining about itchy rash on her hands. Since the attending physician is not familiar with the patient's medical history and needs to handle quickly, he(she) is using federated DWH facilitating EBM, to find the most efficient therapy, which does not conflict with the patient's ongoing diabetes and liver disease treatment.

The clinician is using an OLAP tool, which is set up on the federation logical data model (LDM). One small but representative part of this model is shown in Figure 3. (In this paper, we are not handling data mining or web services based data retrieval. This is a part of an ongoing project and will be published in our future work.) Dashed arrows show the data flow between underlying data sources and resulting tables. Since the federation exists only on a virtual level, data are physically stored in their originating sources but queried and presented through the federation model.

The clinician is querying the patient's healthcare record, containing all the existing anamnesis/diagnostic data and all the patient's treatments in the past. Further, he(she) is interested in the patient's overall health condition (allergies and medication incompatibilities) as well as the personal data (age, weight, family predisposition to some diseases etc.). In addition, the clinician has to find out what kind of therapies will be covered by the patient's social insurance. Finally, he(she) is aiming at finding the treatment which proved to be the most effective under the given conditions.

The answering procedure takes place in two phases:

1. The user (the clinician) is querying the federated DWH by providing only the patient's name and the corresponding social insurance number. In the first step, the mediator sends queries containing these two parameters to all relevant participating sources (in this case study, these are: clinical DWHs, pharmacy and social insurance company). The aim of this step is to retrieve all patient data, which might be interesting as input for the second step, namely querying EBG database.
   Responsible wrappers return the corresponding data to the mediator, which in sequel joins them and produces a result data set.
2. In the second step, the resulting data set (containing patient's age, blood pressure, blood type, diseases history, list of received treatments and medications, social insurance categorisation etc.) is used as input parameter for the querying of the evidence-based guidelines database. The mediator forwards a new query to the EBG- database wrapper and retrieves the final data set.

Figure 3. Extract from federated DWH LDM with belonging data sources

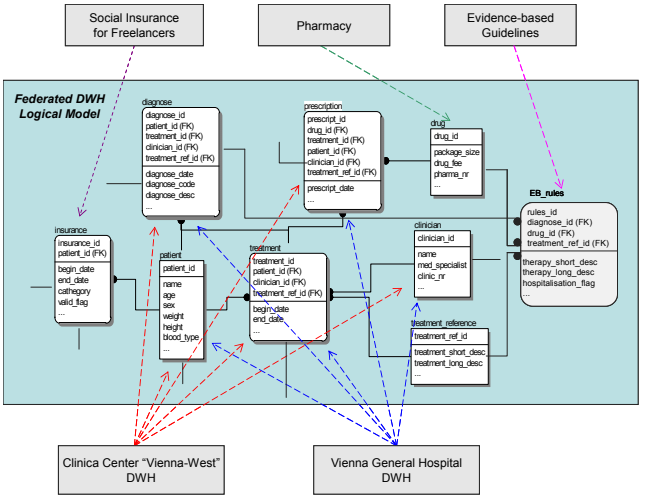


Figure 4. A part of tables involved into finding of the best fitting evidence-based rule for a given patient and given diseases

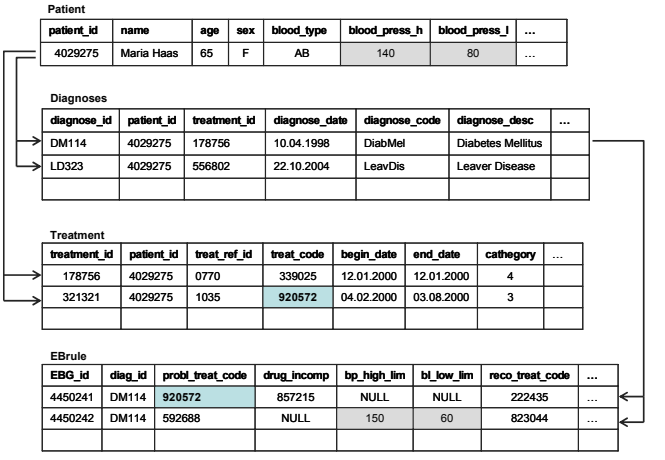

Patient

patient_id	name	age	sex	blood_type	blood_press_h	blood_press_l	...
4029275	Maria Haas	65	F	AB	140	80	...

Diagnoses

diagnose_id	patient_id	treatment_id	diagnose_date	diagnose_code	diagnose_desc	...
DM114	4029275	178756	10.04.1998	DiabMel	Diabetes Mellitus	
LD323	4029275	556802	22.10.2004	LeavDis	Leaver Disease	

Treatment

treatment_id	patient_id	treat_ref_id	treat_code	begin_date	end_date	cathegory	...
178756	4029275	0770	339025	12.01.2000	12.01.2000	4	
321321	4029275	1035	920572	04.02.2000	03.08.2000	3	

EBrule

EBG_id	diag_id	probl_treat_code	drug_incomp	bp_high_lim	bl_low_lim	reco_treat_code	...
4450241	DM114	920572	857215	NULL	NULL	222435	...
4450242	DM114	592688	NULL	150	60	823044	...

As shown in Figure 4, some of the existing treatment rules are disqualified due to medication or treatment incompatibilities. Since the proposed treatments must be adjusted to the patient's health risks, parameters like blood pressure may play the determining role in the treatment verification process. Nevertheless, the scope of a patient's social insurance contract (refers to treatment categorization) is significant for the determination of applicable treatment.

In our example, the evidence-based guideline with identification: EBG_id = '4450241' is not applicable, for the reasons of treatment incompatibility. Namely, in the past, Mrs. Haas has received a treatment with treatment_code = '920572', which is listed as problem treatment for this guideline.

The evidence-based guideline with identification: EBG_id = '4450242' is the best fitting guideline for Mrs. Haas's medical condition, so it is forwarded to the federated DWH.

In the last step, an OLAP tool presents the result to the clinician in an understandable and illustrative way.

5. RELATED WORK

Abidi et al. describe in [6] an Integrated Clinical Evidence System designed to augment the typical literature–based clinical evidence with additional technology-mediated clinical evidence. They propose a technology-enriched strategy to exploit advance computer technologies – knowledge management, data mining, case-based reasoning strategies and internet technology – within traditional evidence based medicine systems to derive all-encompassing clinical evidence derived from heterogeneous clinical evidence modalities.

The four steps in incorporating the best available research evidence in decision making is the subject of the research project in [9]. The authors formulate the following steps: asking answerable questions; accessing the best information; appraising the information for validity and relevance; and applying the information to patient care. Further, they state that applying evidence-based medicine to individual patients requires drawing up a balance sheet of benefits and harms based on research and

individual patient data. Wu et al. state in [8] that growing evidence indicates that the integration of clinical decision support into the computer-based patient record can decrease medical errors, enhance patient safety, decrease unwanted practice variation and improve patient outcomes. Clinical Pathways are the subject of research of Roeder et al., at the DRG Research Group at the Universitätsklinikum Münster [7]. They investigated 8 different international DRG-systems on the basis of data from cardiac surgery and concluded that the Australian AR-DRG-system excellently matches levels of complexity. Thus it provides a good basis for the German R-DRG-system, which will serve for the reimbursement of all in-patient cases, according to the German Ministry of Health.

A self-medication information system, which proposes to patients information and services on mild clinical signs and associated treatments, is illustrated in [17]. Given the simplified patient's electronic health record as input, an ontology is used to infer the right treatment proposal out of the self-medication knowledge base.

Integrating the Healthcare Enterprise (IHE) [18] is an initiative designed to stimulate the integration of the information systems that support modern healthcare institutions. It defines a technical framework for the implementation of established messaging standards to achieve specific clinical goals. The Cross-Enterprise Document Sharing (XDS) provides a general mechanism for sharing of documents between different healthcare enterprises. The main difference between IHE and our approach is that it does not facilitate statistical and in-depth analysis of clinical data, nor it offers pattern recognition capabilities.

6. CONCLUSION

The collaboration project for evidence-based medicine described in this paper merges data originating in a pharmacy database, a social insurance company database and diverse clinical DWHs. Our universal, simple and flexible common conceptual model enables potential future integrations of other health care organisations to be done seamlessly and with a minimum effort.

In this paper we showed, that a federated clinical DWH that facilitates evidence-based medicine is a reliable and powerful platform for production and dissemination of clinical knowledge. Knowledge originating from evidence-based medicine represents a valuable resource for healthcare policy makers. Integration of knowledge management into clinical decision support system enables strategic decision making for both clinical business management and for the caregivers at the point of care, which results in a better service for the patient, the medical personal and administrative staff.

ACKNOWLEDGEMENT

End User Computing and End User Development: Exploring Definitions for the 21st Century

Sandra Barker, University of South Australia, Australia; E-mail: sandra.barker@unisa.edu.au

ABSTRACT

As end user computing continues to impact on businesses around the world, students in the fields of business and management need to be aware of how EUC and EUD impact on their future careers. This paper examines the plethora of definitions from the last 25 years of literature from a student and academic perspective and looks at how students have made attempts towards the development of clearer definitions for the future.

INTRODUCTION

End user computing (EUC) is a theoretical issue which came to prominence in the early 1980s with the introduction of personal computers (PCs) and has now become prolific throughout business due to the decreased cost of the available PCs and the introduction of "easy-to-use" software application generators such as the Microsoft ® Office Suite and the more freely available Open Source software. End user computing has been defined in many ways however the most often used definition is one which incorporates the facts that end user computing involves the interaction of managers, professionals and operational level users with application software within their own working departments (Torkzadeh & Doll, 1993).

A review of the literature has identified that much research over the past 25 years has been particularly in the areas of end-user satisfaction with information systems (not necessarily end-user developed), end-user computing in terms of the general use of computers, the development of spreadsheet applications by end-users, and the identification of who end-users are and the organisational areas which are affected by end-users (Rockart & Flannery, 1983; Brancheau & Brown, 1993; Powell & Moore, 2002). There has also been significant research published on the issues that impact on end-user development but little regarding how this can be addressed in the current technological environment.

Over this 25 year period there has been a significant change in the available technology (hardware and software), the introduction of technology into education increasing the computer literacy of the users and a change in the information technology culture within organisations (Rockart & Flannery, 1983; Brancheau & Brown, 1993; McBride & Wood-Harper, 2002). However, the changes in technology and use of technology do not appear to have been reflected in the ways that end user computing and end user development are defined. This paper explores the definitions developed in the past literature and works towards the development of a more concise and relevant definition for the future which reflects these changes.

BACKGROUND

The first papers relating to End-user Computing (EUC) were published in the late 1970s (McLean, 1979 and Codasyl report, 1979, as cited in Cotterman & Kumar, 1989). In the 1970s computing was identified with mainframe computers and end-user computing appeared to relate to one of three types of computer use: indirect use (where computing tasks were undertaken for the requester), intermediate use (where instructions were given by the person requesting the information as to the format the information would take) and direct use (where information was retrieved by the user using a terminal).

The introduction of PCs in the early 1980s lead to EUC being reported as '…a rapidly growing and irreversible phenomenon' (Alavi & Weiss, 1985, p6). The research into EUC has lead to a number of differing definitions being developed dependent upon the researcher's experience and how they classified end-users.

DEFINING END USERS

Rockart and Flannery (1983) identified that in order to understand EUC it is necessary to know who the users are, where they work and what they do. As part of this they developed six classifications of end-users dependent upon their function within the organisation. These classifications were:

- Non-programming end-user: have access to computerised data through simple menus or structured instructions
- Command level end-user: access data on their own terms. They are classified as being willing to learn just enough about the software to obtain the data required
- End-user programmers: develop applications for use by themselves and others in their department. They are able to undertake some programming using command and procedural languages.
- Functional support personnel: actively support end-users from within their own department. These persons have a sophisticated understanding of the software being used in the organisation.
- End-user computing support personnel: most commonly a formal support centre who have good general knowledge of most programming techniques.
- Data processing programmers: uses who are the most knowledgeable within an organisation of the end-user programming tools being utilised. (Rockart & Flannery, 1983)

The first three of these classifications relate primarily to non-information systems specialists who either: (1) use computers in their daily business to obtain information; (2) can use more complicated commands to filter information to obtain relevant and complex results and (3) use computer language (coding) to develop software applications for their own use (or for the use of others in their department). The remaining classifications relate to the classification of support personnel who are available to develop applications for users or to assist the users in their development and/or use of software applications. These classifications expanded upon those defined by the Codasyl report (1979, as cited in Cotterman & Kumar, 1979) by being more prescriptive with their definition of how the end-users interacted with the technology. Early researchers (eg Rockart & Flannery, 1983) reported on a producer/consumer dichotomy when it came to describing end-users whilst other researchers (Leithseier & Wetherbe, 1985 as cited in Cotterman & Kumar, 1989) reported on the comparison between the end-user operator and the end-user developer.

Leithseier and Wetherbe (1986) amended their research to include a third component, that of the amount of control that the manager or user has over the computer resources. According to Amoroso (1988) end users are defined as those that develop applications according to their needs in an environment where they have access to personal computers, data and support resources. This definition did not take into account the research of Leithseier and Wetherbe (1985, 1986) or Rockart and Flannery (1983) which outlined specific categories of end users and the tasks that they performed.

Cotterman and Kumar (1989) developed a taxonomy of end-users based upon this research. It was already apparent at this early stage in the research into end-user

computing that some end-users (ie non-Information Systems trained users) were undertaking some application development. It was identified in their paper that it is imperative to understand who the users are to ensure that each class of user is treated appropriately and that the relevant training, education and management approaches are used to assist them in their daily tasks. The development of the user cube taxonomy was undertaken using a morphological analysis technique, identifying known variables and parameters from current literature, developing an orthogonal structure and then testing the taxonomy by using the previous classifications of end users to see if they fit in the new structure (Cotterman & Kumar, 1989).

The User Cube has been recently reviewed in an attempt to operationalise the taxonomy and assist in the classification of todays, more knowledgeable, end users (Govindarajulu, 2003). This review determined that the User Cube was an excellent starting point for the classification of users by using the dimensions of operator, developer and controller. It also highlighted that the users did not necessarily fall neatly into one of the three dimensions but that there could be much overlap between the dimensions leading to the inevitable 'power user' who is conversant in all of the dimensions.

DEFINING END USER COMPUTING

Davis and Olson (1985, cited in Amoroso, 1988, p50) defined EUC 'as the capability of users to directly control their own applications and computing needs.' Amoroso (1988, p50) identified that 'end-user computing has further been described as an alternative development approach in which the user can avoid the traditional development complexities, time delays, and communication problems'.

In the early 1990s, Brancheau and Brown (1993, p439) reviewed the previous 10 years of research into end-user computing. They commenced their paper by defining end-user computing as the 'adoption and use of information technology by personnel outside the information systems department to develop software applications in support of organisational tasks'. This paper concentrated on the research into the management issues related to end-user computing and used the Rockart and Flannery (1983) classification of users as a basis for the research. Brancheau and Brown (1993, p 477) concluded that 'failure to build on prior EUC research and failure to rely on theoretical knowledge accumulated in key reference disciplines have been major obstacles to furthering our understanding of EUC management'.

At the same time as Brancheau and Brown were espousing their thoughts a broader definition of EUC was introduced. Rainer and Harrison (1993, cited in Downey & Bartczak, 2005, p3) defined EUC 'as the direct, individual use of computers encompassing all the computer-related activities required or necessary to accomplish one's job'.

According to Garavan and McCracken (1993) EUC is defined as the managerial and professional use of computer power as compared with clerical tasks which use the same computer hardware.

A more refined and succinct definition of end-user computing was then proposed by Chan and Storey (1996, p119) where they stated that 'end-user computing was the autonomous use of information technology by knowledge workers outside the IS department' and that EUC is an 'important part of organizational computing today'.

Powell and Moore (2002) picked up where Brancheau and Brown left off using similar research criteria. Since their study followed the same parameters it seems logical that they used the same definition of EUC as Brancheau and Brown however this definition is solely targeted at the "development of applications" and does not look at the use of applications developed for end users. This makes the focus of the research limited to management issues related to end user application development rather than an overall view of the organizational issues being experienced due to the general usage of computers in business.

Martin, Brown, DeHayes, Hoffer and Perkins (2005) define end user computing as an activity which involves implementing all the applications for different levels, such as supportive applications, personal applications and organizational systems. Downey and Bartczak (2005, p4) researched previous definitions and concluded that the most appropriate definition, for their study, was to define EUC as 'the use and/or development of computing technology and software applications by end users to solve organizational problems and assist in decision making'.

From an academic standpoint, the term end-user computing has traditionally been used to refer to the study of the management issues involved with providing services for non-specialist users of information systems. That is essentially anyone who is not an IT specialist who may be involved in developing or supporting systems (Chaffey & Wood 2005, p.558).

As can be seen the definitions of the past have been specifically designed to match the research being undertaken. It is the belief of the author that this is leading to serious confusion not only within the academic community but also with practitioners and managers as to what actually constitutes end user computing and consequently what actually needs to be managed.

DEFINING END USER DEVELOPMENT

Harrison stated that 'EUD is an activity that has been around almost as long as computers' (cited in Pickard 2005, p. 1). Many of the definitions of end user computing within the literature refer to development as part of the definition (Brancheau & Brown, 1993; Downey & Bartczak, 2005; Shah & Lawrence, 1996; Shayo, Guthrie & Igbaria, 1999). However, 'the actual term of end user development would refer however to a non-IT specialist creating their own applications to support their work' (Chaffey & Wood 2005, p.559). McGill (2005) takes the definition a little further by identifying that the development could not only support the end-user developer's work but also the work of other end users in the department or organisation.

From a software engineering perspective, EUD is said to mean, in general, the 'active participation of end users in the software development process' (Costabile et al 2005, p.1). End-user development activities are said to vary from "customization to component configuration" as well as programming, with Office software providing customization facilities and Web scripting said to provide interactivity tools for end-users of Web sites (Fischer et al, 2004)

Jawahar and Elango (cited in McGill 2005, p. 21-22) explicate that EUD of applications form a significant part of organisational systems development 'with the ability to develop small applications forming part of the job requirements for many positions.'

Sutcliffe and Mehandjiev (2004) state that EUD is about taking control, not only of personalizing computer applications (EUC) and writing programs, but of designing new computer-based application without ever seeing the underlying program code.

What can be gleaned from these literature definitions is that end user development is an important part of end user computing and that it can support not only the end user developer in their daily duties but also the duties of other end users in the department.

STUDENT PERCEPTIONS AND DEFINITIONS

Students undertaking a Master of Business (Administrative Management) degree program are required to study a course in Data Management which concentrates on the role of the end user (particularly at an administrative or middle management level) in the data and information management within the organisation. As part of the course the twenty two students were required to research the past definition of end user computing and end user development and then, using the research, propose a new set of definitions which brought the area of research into the 21st century.

To provide a definition of EUC requires an understanding of who the end-users of today are and how they interact with technology. The only difference between the eighties and now is that end user computing is no longer a unique concept confined to the office or a narrow field of study, but has reached the point where practically every task performed in the business environment has a connection to an information system and can therefore be potentially be classified as EUC. As long as technology is used in the workplace and people are expected to use information systems or technology to perform their job, then the final definition in this paper is the most contemporary and applicable. An attempt to narrow the definition denies the fact that technology has become so integrated in both the personal and professional lives of people in developed countries that we are practically all engaged in end user computing on some level. (Student C)

Other	47 (from 37 different sources)	14 (from 11 different sources)

Students investigated a plethora of literature to inform their understanding of past definitions of the terms being investigated. Overall fifty eight resources (journal articles, textbooks and internet articles) were used in the development of this understanding. The most common sources are listed in Table 1.

Although the students predominantly cited definitions from literature that had already been sourced for them (either their textbook or required readings), many students were able to locate many other sources of literature which contained definitions of the terms under investigation.

Student B reflected the thoughts of the many of the students by commentingd that 'in the 21st century, EUC should consider as a group or an individual non-technical EU adopting any kind of information technology applications, including information generation and processing, web applications and multimedia approaches under a secure computing environment' While a few of the students were broader in their comments. These comments are best summed up by student C who stated that 'EUC in the twenty first century includes, everyone who uses information systems to deliver a service or develop solutions that provide an information output within an organisation.' Many of the students did not directly develop new definitions but chose to make comment on the definition that they believe best fit the requirements of the assignment. These students chose to reflect on the definitions from Chaffey and Wood (2005), Suttcliffe and Mehandjiev (2004) and Powell and Moore (2002).

Student D made some interesting observations by identifying that 'end user computing and development was now in the hands of the end users themselves, which arose from many reasons including wider use of cheaper and more powerful computers and more user friendly applications for example. Now end users have developed the skills to benefit from information technology much more than they had previously been exposed to during the early years.'

End-user computing and development is a widespread phenomenon; many organisations, despite their size and activity integrate it in their information strategy. The terminology has been subject to fundamental change resulted from technology advancements, change, organisational structures and the way we look at information and knowledge. The technology-based view has replaced by the humanised knowledge management focus. It has moved from being a tactical issue to be a major ingredient in organisation's information strategy. End-users now can respond quicker and more effective to problems due to the given control and responsibility. This can place the organisation on a leading edge, however, lack of training in the strategy and consequently poor development of applications can leave the organisation on a bleeding edge. (Student J)

Student G defined EUC in the 21st century as 'the resultant processing of data obtained and recorded by end users in conjunction with company objectives and overseen with company control.' This definition is quite interesting as it includes the end user as a primary part of the process rather than an outcome as found in the predominate literature of the past. However, in the opinion of the author, the most interesting definition of EUC offered by the students for the 21st century stated that 'end user computing is defined as the management of information technology systems and development, incorporating different levels of personnel to best pursue strategic objectives by facilitating organizational functional requirements' (Student V).

Very few of the students were able to determine a new definition for EUD which reflected the changes in technology and user expertise that have occurred over the past 25 years. Student B determined that '...a modified definition of the term EUD in the 21st century could define as a non-technical EU modified, generated or created customised application using existing IS and advancing technology, providing solutions to personal needs and demands'. On the other hand Student G postulated that 'EUD in the 21st century: the development of complex, server-based processing applications structured in conjunction with company objectives and designed for ease of use for the end users.' This is an interesting definition as it considers end user development as the development of applications for end users, not necessarily by end users. It is this definition that reflects the confusion being purported in previous literature and shows the need for a more definite, clear focus on the definitions of EUC and EUD.

Reflecting on the students' thoughts and attempts at defining the terms the author has developed new definitions for each of the terms. End User Computing (EUC) can now be defined as the use of computing technology and/or software applications, together with the enhancement and/or development of information systems by end users. On the other hand end user development (EUD) is, more specifically, the development, modification and/or enhancement of information systems applications by end users for individual, departmental or organisational use.

FUTURE RESEARCH

The literature of the past 25 years has given us plenty of definitions of end user computing and, to a lesser extent, end user development. The problem with this plethora of definitions is the confusion that can be caused when researching the topic. Researchers need to be aware of the exact context of each of the definitions and then attempt to relate the definition chosen to the context of their new research. Making an incorrect choice of definition could be disastrous as it could completely change the focus of the research being undertaken.

Students trying to understand the concepts of end user computing and end user development are also confused by the mass of slightly different definitions as can be seen in their attempts to redefine the terms given all of the background research.

Thus it is time for a more meaningful and direct definition of each term which will take us through the 21st century and all the possible changes in technology, user ability and technology use. The definitions proposed by the students are a good starting point however the time is now ripe for more in-depth studies of the perceptions and understandings of EUC and EUD in the practical arena with the opportunity to use these studies to finally propose serious 21st century definitions.

This research into the definitions of EUC and EUD forms the starting point for a more in depth look at end user computing and end user development in today's business environment being undertaken by the author. The key foci of this major project are the impacts of EUC and EUD on the business (from many perspectives) and the how management handles the plethora of end user applications being developed. By clearly defining the terms for the 21st century, the author believes that this future research will be easier to describe the terms to the participants which, in turn, will allow the results of the research project to be translatable into today's business environment.

PRACTICAL IMPLICATIONS

For the definitions to be of any practical use they must not only assist the academics in the contextualisation of their research but also allow end users and

managers alike to understand the concepts of EUC and EUD as they apply to their particular context. It will also give management the chance to develop policies and procedures in order to efficiently and effectively manage their personal who undertake end user development within their work environment.

CONCLUSION

This paper has shown that the plethora of definitions of EUC and EUD in the literature of the past has given rise to some serious confusing and misunderstanding by students and academics alike. In an attempt to dispel this confusion, students undertaking a Master of Business degree put forward their ideas and suggestions as to how these definitions could be better explained for the 21st century.

Although no one individual student was able to propose a new, more decisive description of these terms, the author has been able to use a combination of the literature with the student ideas to propose two new definitions which will be used to further the author's research in this field.

Although the author believes that these new definitions will hold in current and future business contexts the thoughts of Student V are pertinent and provide some indication of areas that need consideration when researching this area in the future.

Perhaps it is time to stop looking at the benefits of one group winning over the other and start looking more often at the benefits of both groups working collaboratively. In the end, in a society where development is most often driven by money, history tells us that the most cost effective option will probably endure. To this end the cost versus risk debate will go on until the risks on one end and the costs on the other are minimized. Once this point is reached the definition of end user computing may well look different again. (Student V)

Peter Green, The University of Queensland, QLD Australia 4072; E-mail: p.green@business.uq.edu.au

ABSTRACT

The lack of a holistic methodology for Business Process Management has resulted in much confusion for organizations wishing to deploy Business Process Improvement projects. We argue that in order to provide some guidance for process improvement projects in particular, we can turn to existing organizational theories. Accordingly, we propose the use of organizational theories as an aid to identify critical elements in Business Process Improvement (BPI). Agency, resource-based view of the firm theory, and stakeholder theories are used for this purpose. An a-priori model is presented and shows top management involvement, process managers, staff and technical BPI capabilities, and alignment of key stakeholders' requirements as factors affecting achieved levels of BPI.

INTRODUCTION

When organizations embark on Business Process Improvement (BPI) projects, unnecessary non-value adding activities are eliminated, and core activities are improved in order to achieve higher levels of process efficiency and effectiveness. This outcome is achieved by optimizing a number of factors, such as decreasing time and/or cost of processes, increasing quality of processes or improving allocation of resources, while being attentive to the expectations of external stakeholders (Bhatt, 2000; Valiris & Glykas, 2004).

The market forecast for organizations continuing to invest in BPI projects is more bullish than anytime before (Gartner, 2006). Indeed, a recent survey by Wolf and Harmon (2006) found that 58% of the 348 completed surveys were from organizations that spent up to US$500,000 in 2005. Between 25-40% of these projects were focused on process redesign, with 53% of surveyed organizations indicating that their process management efforts, and associated funding, would be stepped up in 2006. However, anecdotal evidence also suggests that organizations are having much difficulty in identifying their processes, let alone being innovative enough to optimize them. Partly to blame for the difficulties faced by organizations is the lack of holistic and versatile methodologies for Business Process Improvement in academic literature as well as the lack of common consensus on what exactly BPM and BPI are and what they involve. In the first steps to developing a theory-backed set of guidelines to enhance the success for Business Process Improvement initiatives, we turn to existing organizational theories in order to investigate whether these can suggest what an organization must consider in order to increase the chances of their BPI initiative being a successful one.

Accordingly, this paper provides an expose of organizational theories that can be applied to the field of BPI in order increase levels of BPI success. We identify three theories in particular, *viz.* Agency Theory, Resource-based View (RBV) of the firm Theory, and Stakeholder Theory, and reason their applicability to this domain. The presented work forms a basis for an *a-priori* model for improving the process of BPI.

The paper is structured as follows. The next section aims to set the context of this work by defining two central terms, *viz.* business process and Business Process Improvement, and providing a brief overview. The following sections introduce and reason the three chosen theories. The paper then introduces a suggested model for improving BPI impacts and concludes with a discussion of limitations and future work.

BACKGROUND

The constantly changing hyper-competitive markets demand higher levels of organizational flexibility and performance (cost, time, and quality). In response to this need, the 1990s witnessed a breakthrough in organizational re-structuring. Organizations were shifted from their traditional function-based operations to new process- and cross-functional based operations (Giaglis, 1999).

Despite the relatively long period of time that BPI has been utilized, the term still has a wide range of definitions and interpretations (Valiris & Glykas, 1999). Larsen *et al.* (1997) and Jones (1994) state that the problem of having a wide range of synonym constructs of BPI also extends to having various definitions of the same construct. Until a common understanding of the terminology is achieved, improvement of processes will be hampered. Therefore, it is important to start by specifying some common definitions in this area.

Business Process

For the purpose of this paper a 'Business Process' is a logical entity made up of a set of ordered activities that may cross functional boundaries such as the procurement process. This logical entity requires input, adds value to this input, and produces an output to achieve a specific goal in the organization (Bal, 1998; Davenport, 1993; Harrington, 1995; Paul, 1987).

Business Process Improvement

In a relatively short period of time, studies have developed numerous explanations and identified steps on how to achieve BPI. The efforts however were not coordinated, and a large range of isolated understandings of BPI now exist. Contributions to the field of BPI, by academics and practitioners alike, can generally be categorized according to two broad dimensions, *viz.*, breadth and depth. The breadth dimension (scope) forms the foci of BPI, such as technical issues, functions, processes, organizational structure, and change management. Whereas the depth dimension focuses on the degree of change expected from BPI, ranging from simple incremental improvements to the more radical re-engineered change. Archer and Bowker (1995) named these variations in terminologies "aliases". Examples of the aliases of Business Process Improvement include "business process innovation" (Davenport, 1993), "core process redesign" (Hagel, 1993; Heygate, 1993), "business restructuring" (Talwar, 1993), "business transformation" (Buckler, 1998), and "process re-engineering" (Hammer & Champy, 1993). These alternative terminologies refer in one way or another to Business Process Improvement.

For the purposes of this paper, 'BPI' represents any of these aliases, and any other variation[1] that refers to the concept of processes and improvement of their performance and design. Furthermore, we accept that the degree of positive change resulting from a BPI initiative refers to any type of process-based improvement whether it is the result of a continuous incremental improvement or a more radical improvement such as business process re-engineering (BPR). Hence, we define BPI as the activity of reducing work processes to their essential elements, by selecting, analyzing, and improving business processes to achieve significant improvements in performance, i.e. cutting costs, increasing revenues, saving time, improving quality, etc.

ORGANISATIONAL THEORIES

The methodology used in this research aims at utilizing the capability of the theories to provide a holistic view of Business Process Improvement requirements. Deriving factors from previously established and proven theories provides a well grounded and comprehensive understanding of the factors and a set of already established measures. These measures in turn can be used to assess the effect of the identified factors that influence BPI levels. Valiris *et al.* (1999, p.73) highlight the effect that organizational theories can have on BPI by stating that "organizational theory methodologies add more elements to [BPI] by addressing the need to focus on… people (agents), their accountabilities, their roles, their interactions, their activities, and their use of available resources". In agreement with Valiris *et al.* (1999), we discuss, in the context of BPI, three organizational theories and how these theories may impact BPI outcomes. Agency theory (AT), resource based-view of the firm theory (RBV), and stakeholder theory (ST) are selected as relevant theories because they offer different organizational focus and understanding. Other theories might also be applicable in this domain, however we argue that the three selected theories have a significant potential impact on the level of achieved BPI outcomes.

Agency Theory

Sometimes called *the principal-agent problem*, agency theory is based on a fundamental premise that owners (principals) establish a relationship with managers (agents) and delegate work to them (Alchian & Demsetz, 1972). Principals and agents have different self-interests (Jensen & Meckling, 1976), which creates an agency problem and requires mechanisms to minimize the problem in each instance.

Eisenhardt (1989) differentiates between two different uses of agency theory – the positivist and the general approach. The positivist approach focuses mainly on the "principal-agent relationship between owners and managers of large, public corporations" (Berle, 1932). The more general approach, followed in this paper, is the 'Principal-Agent' relationship that introduces Agency Theory as the "theory that can be applied to employer-employee, lawyer-client, buyer-supplier, and other agency relationships" (Harris & Raviv, 1979). The general Principal-Agent relationship can be applied to all levels in the organization, thus, providing this study a wider and more relevant coverage

Eisenhardt's (1989) view of agency theory has several implications for BPI. First, agency theory assumes that the basis of the organization is 'efficiency' (Eisenhardt, 1988, 1989), which is one of the fundamental drivers of BPI. It is in the interest of managers to make sure performance within their organization is efficient. Second, cross-departmental changes, such as those resulting from BPI, can have both positive and negative impacts on organizational structures and performances and can be faced with strong opposition. It is therefore suggested that providing strong management involvement for newly introduced changes delivers a sense of obligation and provides incentives for subordinates to accept newly introduced changes. Therefore, we argue that:

H1: *Top management involvement in BPI projects achieves higher levels of BPI.*

Moreover, Yu and Mylopoulos (1994) identify three different types of agency dependency in BPI within the organization, namely: goal, task, and resource. In addition, they provide three different levels of agency relationship: general, committed, and critical, which depend on the degree to which the agent will be affected if the job fails. This general understanding of agency theory is also applicable in process-based organizations and translates into different levels of commitment and into chains of hierarchical responsibilities that establish accountability and control and thus assist in minimizing the agency problems associated with BPI change. Therefore, agency theory, through its understanding of the different interests of staff in the organization, is capable of explaining the rationale in assigning agents (process owners) to different processes as well as explaining the effects of their involvement in BPI projects. It is also argued that business process ownership provides both commitment and a wealth of knowledge to BPI projects.

H2: *A higher level of authority represented in a "process manager" (agent) over the whole process positively influences the level of improvement of the business process.*

Resource-Based View of the Firm Theory

RBV focuses on the internal characteristics and performance of the organization (Porter, 1991). The theory suggests that organizations have different types of resources that fall under two categories: (a) cooperative and strategic, and (b) competitive and financial. The theory is based on the assumption that firms have idiosyncratic, not identical strategic resources. Resources are not perfectly mobile and therefore heterogeneous (Conner, 1991; Wernerfelt, 1984). Thus, organizations are collections of resources, and the scarcer the organizational collection of resources the less the competitive advantage they actually hold.

Moreover, aside from resources, RBV theory also focuses on capabilities. Capabilities are accumulated knowledge in organizations resulting from using its existing resources in an efficient and effective way to achieve its final goals (Idris, Abdullah, Idris, & Hussain, 2003). Capabilities are divided into four main categories: functional differential, positional differential, cultural differential, and regulatory differential (Coyne, 1986). These capabilities develop from existing skills and experience (functional), as preferences of previous actions (positional), as a result of the perceptions of the individual of the organizational stakeholders (cultural), or from organizational policies and regulations (regulatory) (Hall, 1991). Therefore, in the context of BPI, the theory implies that an organization with a culture supportive of BPI, with existing process-based change regulations, and with previous experience in conducting BPI projects, will attain higher levels of BPI capabilities.

BPI shares common standpoints with RBV theory. The commonality is embedded in the belief that resources and capabilities of the organization are limited, thus, surviving organizations tend to use their resources in a cost-effective way. Functioning at optimum levels can lead organizations to create competitive advantage. Sustaining competitive advantage, however, may require continual improvements to differentiate themselves from competitors (Attaran & Attaran, 2004). Sustained competitive advantage is achieved when capabilities are able to produce value, are rare, are imperfectly imitable, and are exploited by the organization (Barney, 1991). Similarly, BPI's fundamental philosophy focuses on improving existing operations within organizations allowing them to use resources more efficiently and effectively (i.e. produce value), and provides tailored solutions to solve specific organizational problems (i.e. unique and imperfectly imitable) (Valiris et al., 2004). Sustaining competitive advantage is specifically related to the human and technical capabilities. Organizational capability in terms of staff with existing BPI-related experience and the ownership and exposure to a variety of technical BPI tools have a major impact on the final results of the BPI project. This accumulated experience has value, is hard to imitate, transfer or substitute and can be exploitable by the organization and thus creates 'sustainable competitive advantage' in accordance with RBV theory. Therefore, RBV theory and its competitive advantage sustainability are tightly related to BPI. Hence:

H3: *A higher level of existing BPI staff capability accumulated through previous experience with BPI has a significant and positive impact on achieving a higher level of BPI; and*

H4: *A higher level of existing BPI related technical capability in an organization has a direct positive impact on achieving a higher level of BPI.*

Stakeholder Theory

A stakeholder in general as defined by Freeman (1984, p.41) is "any group or individual who can affect or is affected by the achievement of the organization's objectives". Freeman (1984) traces the term 'stakeholders' back to the Stanford Research Institute in 1963 defining the term as "those groups without whose support the organization would cease to exist" (Donaldson & Preston, 1995, p.31). Stakeholder theory helps to improve the value of the outcomes of the stakeholder decisions by identifying the interests of various stakeholder groups and prohibiting them from being disadvantaged (Andriof, Waddock, Husted, & Rahman, 2002), ultimately resulting in greater returns to shareholders.

Modern businesses have become more transparent and accountable in order to meet their new, interactive and responsive relationships with stakeholders. Stakeholders should be defined through their legitimate interests in the organization rather than the organization's interest in them (Donaldson *et al*., 1995). Therefore, recognizing obligations to stakeholders helps organizations to become successful (Andriof et al., 2002). This idea is also heavily supported by the agency theory. *Stakeholder focus* is the effort expended by the organization intending to satisfy the majority of the key stakeholders (Idris *et al*., 2003). Key stakeholders in BPI are identified

in terms of the degree of reliance and interaction with the process to be improved. Thus, the larger the process the higher the number of key stakeholders involved. Clarkson (1995) affirms that persistence in dissatisfying principal stakeholders may cause the organization to fail. However, building a trust relationship can significantly lower costs, and therefore impact their performance (Barney & Hansen, 1994; Hill, 1995). The impact of key stakeholders is asserted in a variety of fields such as firms performance (Berman, Wicks, Kotha, & Jones, 1999), decision-making (Wood, 1991), and corporate social performance (Anderson, 1989).

Furthermore, this argument does not deal with the moral foundation of the stakeholder theory and the principle of fairness. The theory does not imply either that all stakeholders should be equally involved in processes (Donaldson *et al.*, 1995). The focus of this research is on the capability of the theory to accomplish multiple purposes although these purposes are not necessarily entirely congruent. Thus, the theory assists in identifying a mechanism to recognize cross points among the different requirements of key stakeholders in a BPI project.

While BPR literature recommends that executives and key staff members to be involved in BPI (Motwani, Kumar, Jiang, & Youssef, 1998), Davenport *et al.* (2004) discovered that less than 30 percent of organizations have achieved even limited information exchange with their suppliers and customers (who are also part of the key stakeholder vision). From the stakeholder theory perspective, BPI personnel should consult with affected key people throughout the different phases of the project (i.e. analysis, design, and implementation) and identify middle ground solutions.

In summary, stakeholder theory, in the context of BPI, suggests that recognizing and aligning key stakeholders' concerns can have a positive impact on the results of the project in particular and the organizational performance in general. This area is largely neglected in the field of BPI. Accordingly, we argue that identifying and aligning with the interests of various key functional based personnel, as well as other external key stakeholder groups, during a business process improvement project has a significant and positive impact on BPI projects' final results.

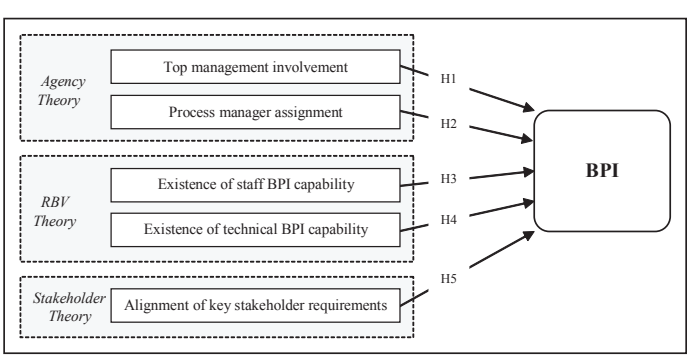
H5: *A higher level of alignment[2] of key stakeholder requirements throughout a BPI project positively enhances the final results of BPI.*

Increasing BPI Success Levels: A Theory-Based Model

Based on the hypotheses derived in the previous section, we derive a model that explains the factors that have a significant impact on the levels of achieved Business Process Improvement in organizations (see Figure 1). The model consists of five independent variables, *viz.* top management involvement, process manager assignment, existence of staff BPI capability, existence of technical BPI capability, and alignment of key stakeholder requirements, contributing to the achievement of higher levels of BPI results.

The empirical results from testing the model using both quantitative and qualitative methodologies will shed more light on a number of vital aspects in this field. First, the results will establish the potential capabilities of organizational theories in analyzing and solving BPI-based problems. Second, the results will show whether the theories are able, as we would expect, to forecast critical elements that can significantly advance the levels of BPI success. Finally, the approach will reemphasize the need maintain a well-built link at all times between theory and practice in any future BPI development.

Figure 1. A-priori research model



CONCLUSION

This paper provided a brief expose of the capability of organizational theories to identify and clearly explain a number of elements that are critical to ensuring better business process improvement. It is expected that deeper analysis of each of the theories will provide comprehensive insights and guidance to BPI. Therefore, we argue that creating a solid theoretical base for BPI will help identify more robust solutions and create strategic guidance to the professional development of Business Process Improvement, ultimately achieving better project outcomes.

The limitations of this work stem from the limited selection of theories chosen at this stage to explain factors that may affect BPI outcomes. Our future work in this area involves (1) identifying other potentially critical factors from the appropriate organizational theories through qualitative research theories such as semi-structured interviews with BPI experts, (2) empirically testing the *a priori* model and identifying any differences through an industry-based survey, and (3) identifying differences in the effect of the factors on various organizational contexts (e.g. industry, sector, size, culture, etc.).

The multi-method study will have an impact on theory and practice. First, it will add to the existing body of knowledge on organizational theory and its links to business process management in general. Second, the validated outcomes of the study are expected to be of significant interest to industry due to the current lack of guidance in Business Process Improvement, and Business Process Management in general (Indulska, Chong, Bandara, Sadiq, & Rosemann, 2006)

A Purposeful Framework for IS

Gaye Lewis, University of South Australia, Australia; E-mail: gaye.lewis@unisa.edu.au

ABSTRACT

This paper highlights the need for theories in IS that assign a key role to the influences of human intentionality. Ulrich's (1983) critical systems heuristics and activity theory both satisfy this requirement. A model based on the combination of these two theories is developed and explored in some detail. The background and description of Ulrich's (1983) critical systems heuristics is presented first and then the integration of activity theory with Ulrich's (1983) approach is examined within the context of IS. It is argued here that the combination of these two theories provides a powerful conceptual tool with practical applicability in the range of areas covered by the domain of IS.

1. INTRODUCTION

Gregor (2006) advocates an increased focus on theory development in IS and promotes the idea of integrating different theory types in order to strengthen the theoretical base within the discipline. Ghoshal (2005) contends that the current base of "bad" management theories is having a profound negative influence on management practices and describes how the underlying assumptions of causal determinism and deductive reasoning have permeated theories developed in and applied to the various management related fields. According to Ghoshal (2005), theories based on scientific models that do not include any role for human intentionality lead to a lack of morality and ethics which can, at least partially, explain some of the recent corporate collapses in the United States. Similarly, Gregor (2006) calls for theories that address the omission of causal reasoning commonly found in theories associated with logical positivism. Von Hayek (1989), Ulrich (1983) and Churchman (1979) also point out the potential dangers of using scientific models to analyze social phenomena.

This paper presents a theoretical framework based on the integration of activity theory and Ulrich's (1983) critical systems heuristics. The core strength of the framework arises from the significant role it attributes to human intentionality. Ulrich's (1983) framework would be classified in Gregor's (2006) taxonomy of theory types as a Type V theory which can be used for design and action. Activity theory qualifies as a Type II theory based on its explanatory power. It is argued here that the combination of the two theories results in a powerful conceptual tool for the design and evaluation of information systems in their organizational settings. The critical systems heuristics framework (Ulrich, 1983) encourages system designs that focus on the contribution of the people involved in and affected by the system. Activity theory highlights the role of tools (such as information and technology) and community in the information systems context and provides a more detailed framework for characterizing an organization's activities and the relationship between IS and business activities. In terms of contribution to a general conceptual framework for IS, the model presented here provides practical guidelines for IS research and practice based on theories that give prominence to the key role of human intentionality.

The basic premise of the purposeful systems approach (Ulrich, 1983) is that human activity systems should be seen as social systems, in contrast to theories that take a mechanistic or organic view. Ulrich (1983, p.334) defines a purposeful system as follows:

*"S [is] a purposeful system if S is **self-reflective** with respect to its own normative implications, seen from the point of view not only of the involved, but also of the affected, and if S has at least partial **autonomy** in determining its client, its purposes, etc."*

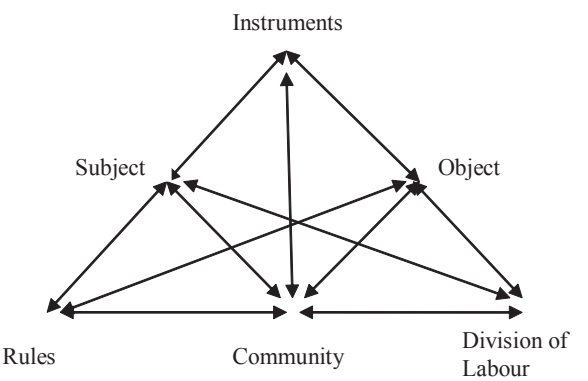
So, if an organization is viewed as a purposeful system, there will be some opportunity for all participants to reflect on the organization's purpose and to choose actions in relation to that purpose. This view of an organization can be contrasted with a mechanistic view where the role of participants is to perform specified duties in support of a well defined purpose. No opportunity is afforded to participants to question or contribute to the definition of goals. Employees mechanically perform specific roles. An organic view of an organization can be distinguished from a mechanistic conception in that employees have some control over how they perform their roles and achieve specified goals. However, no involvement in the definition of goals is supported. Employees decide **how** they will go about their jobs, but have no influence in relation to **what** they are expected to achieve or **why** it is important.

In terms of IS, both organizations and information systems can be seen as purposeful systems and Lewis (2002) highlights some of the potential benefits of applying Ulrich's (1983) framework in this context. Ulrich (1983) argues that the task of the social system designer is to facilitate critical reflection and motivation of those involved in the system, whereas the task of the designer of a mechanistic system is to define, codify and control the optimum configuration of the system. Dietz (2003, p.205) criticizes mechanistic approaches that don't *"do justice to the social character of human beings"*. Ghoshal and Bartlett (1995) point out that the underlying problem with traditional management approaches is in their objective *"to create a management system that minimize(s) the idiosyncrasies of human behavior"*. Ulrich's (1983) purposeful systems approach addresses these criticisms by providing a set of guidelines that encourages the contribution of all stakeholders potentially involved in and/or affected by a system.

Hasan (2002, p.30) proposes that activity theory is a good candidate *to "span and integrate the breadth of the field of IS providing it with unity and identity"*. Consistent with Ulrich's (1983) framework, activity theory also assigns a key role to the influence of human intentionality. As shown in Figure 1, activities are carried out by subjects in order to produce an object and/or outcome using instruments, according to rules and with a division of labor as defined by the associated community. In addition to the key role of human intentionality, activity theory also provides a framework for considering the use of tools and the influence of community which play an important role in any information system. Activity theory suggests that activities can be improved by exploring 'contradictions' within the activity. Incorporating this suggestion with Ulrich's (1983) guidelines for purposeful systems design enables the practical application of the theoretical framework in a range of areas covered by the domain of IS.

The next section will cover the purposeful systems approach in some detail, including its philosophical basis, an outline of how a purposeful system can be seen as a set of problem-solving processes and finally, a set of categories that can

Figure 1. Activity theory framework – adapted from Hasan (2002)



be used to define the various interests of stakeholders either involved in and/or affected by the system. The following section will highlight how activity theory constructs can be used to augment and extend the approach for the IS context. The proposed model uses activity theory to represent the set of problem-solving processes associated with purposeful systems in more detail and to define the link between information systems, their design and their use in a business context. The final section will begin to explore potential areas of application in IS and will also look at possible areas for further research.

2. THE PURPOSEFUL SYSTEMS APPROACH

2.1 Philosophical Basis

Ulrich (1983) developed the purposeful systems approach in order to provide a conceptual framework for critical social inquiry and design. The intent of the approach is to provide a set of guidelines for rational social planning that will help planners to avoid the drawbacks of contemporary, scientific systems approaches. Ulrich (1983) argues that contemporary approaches to planning suffer shortcomings because of their underlying scientific, reductionist assumptions. In the domain of social reality, these assumptions can mask the inherent human interests that are served by the system. In order to overcome these shortcomings, Ulrich (1983) maintains that a rational approach to social planning should expose the underlying assumptions that affect the design and operation of the social system being planned for. The purposeful systems approach addresses this by combining Kantian a priori science with a reinterpretation of the systems approach and applying the combination to the domain of social reality. The critical intent of Kant's philosophy and the practical heuristics provided by systems theory combine to form a powerful tool for assisting with rational social planning.

Social planning, which involves the activities of social inquiry and design, is basically about making choices that improve a particular social system. In the domain of IS, both the organization and the information systems that support the organization's activities can be seen as social systems. Ulrich's (1983) framework is meant to assist with planning activities and to make clear whose interests are being served by the improvements made to the system. Ulrich (1983) endeavors to translate Kant's a priori science from the domain of physical reality to the domain of social reality in order to develop a conceptual tool for thinking about social systems. Combined with this, the systems idea is used to identify components of the system that cannot be completely specified or controlled i.e. to clarify the boundaries of the system. This improves understanding of the whole system leading to opportunities for enhanced designs.

In Kant's development of a priori science, the domain of interest is physical reality. For social planning, the domain of interest is social reality. Within the domain of physical reality, the constructs of space and time are critical for thinking about the domain. For social reality, Ulrich (1983) proposes that the parallel concept for thinking is human intentionality, including self-consciousness, self-reflection and self-determination. Nothing can be understood within the domain of social reality without reference to human intentionality. In Ulrich's (1983) purposeful systems approach the construct of human intentionality is pervasive and is referred to as a "mapping dimension" used to define our conception of the social reality in question.

According to Ulrich (1983), Kant characterizes human thinking as having two fundamental components – reason and understanding. The principle of reason is used to reflect on understanding and can be used to reflect on and expose the underlying assumptions in any social system design. Reason itself has two components – theoretical reason that helps to understand "what is" and practical reason that questions "what ought to be" and incorporates the manifestation of free will. Ghoshal (2005, p.81) also identifies these aspects of thinking as important and points out that if we were to give up our reliance on scientific theories *"Business could not be treated as a science, and we would have to fall back on the wisdom of common sense that combines information on "what is" with the imagination of "what ought to be" to develop both a practical understanding of and some pragmatic prescription for "phenomena of organized complexity"".* Reason can be used to resolve conflicts that might otherwise be decided based on the prevailing distribution of power. Using the principle of reason to reflect on understanding is a difficult task and the guidelines provided by Ulrich (1983) are designed to assist with this task. The guidelines are also meant to ensure that the interests of all relevant parties are represented in the process. Without a set of guidelines to ensure rational planning, there is a risk that the objectives served by the system will not be representative of all those involved in and/or affected by the system.

2.2 Purposeful Systems & Problem-Solving Processes

According to Ulrich's (1983) definition as given in Section 1, the two significant aspects that characterize a purposeful system are the capabilities of self-reflection and partial autonomy. Dewey's (1997, p.6) definition of reflective thought is: *"Active, persistent and careful consideration of any belief or supposed form of knowledge in the light of the grounds that support it, and the further conclusions to which it tends."* Therefore, in a purposeful organization employees and broader members of society affected by the operation of the organization will continuously question the organization's vision, the underlying assumptions that support its validity and the implications of pursuing the vision. The mandate for partial autonomy of the system implies that the design of a purposeful organization will support and encourage participants to reflect and pursue actions based on this reflection.

Ulrich (1983) claims that every purposeful system must perform three types of problem-solving processes: inquiry, action and valuation processes. In terms of an organization as a purposeful system, inquiry processes are those that produce knowledge about the purpose (vision/mission) of the organization. Action processes define how the knowledge is put to use and valuation processes are those that facilitate reflection on how the production and use of knowledge affects all those who work and live with the system. These three problem-solving dimensions can be used to assess the purposefulness of an existing system, or to design a purposeful system. A purposeful system implements inquiry, action and valuation processes that encourage reflection and contribution by all those involved in and/or affected by the system.

2.3 System Boundaries

The final aspect of Ulrich's (1983) framework which is of interest here is a set of critically-heuristic categories of pragmatic mapping. These categories help to operationalize the definition of a purposeful system. For example, they help to identify who represents "the involved" vs. "the affected" and they assist in evaluating the capabilities of self-reflection and autonomy inherent in the system. The categories arise out of the systems conception of social reality – specifically by exploring the boundaries of the system in relation to those involved in the system and those affected by it. Ulrich (1983) developed the formulation of categories by asking questions about who might be involved or affected by the system, what their concerns might be and what implications each group and their concerns might have for the planner. The categories provide the planner with a framework for developing criteria to evaluate his/her conception of and design for a social system.

The boundaries of a social system can be explored by investigating four different groups of stakeholders. These include those who provide sources of motivation for the system, those who represent sources of control, those who act as sources of expertise, and those who represent sources of legitimation. An investigation of the roles and concerns of these four groups will help to surface, or make explicit, any underlying assumptions associated with a system's design. The investigation should use reason to reflect on understanding of the system by asking questions about 'what is' and 'what ought to be' in relation to each group.

So, for instance, in relation to the first group – sources of motivation – questions to be asked would include who the client is, what the purpose of the system is and how the success of the system can be measured. For the second group – sources of control – the questions would explore who the decision makers are, what they are able to control and what falls outside their domain of control. The third category – sources of expertise – would involve questions about who the designer is, what type of expertise is required and how the design can be evaluated. The final group to be considered – sources of legitimation - is meant to represent those affected by the system who do not contribute to its design or operation. Since this is such a potentially large and diverse group, a representative category of witness takes on the role of legitimizing the system. This category is concerned with emancipation of the affected. These categories should be kept in mind when 'designing' an organization and planning and developing information systems. The planner's task is to reflect on these categories in order to critically develop a comprehensive system design. Using reason to reflect on these categories of understanding suggests asking questions about "what is" and "what ought to be".

So, for example, questions should be asked about who actually plays the roles in each category as opposed to who should ideally be playing the roles.

It should also be mentioned that Ulrich (1983) envisions a process of discourse that would ensure reason is used to resolve conflicts and that the views of the affected are adequately represented. The philosophical basis for the practical discourse is derived from Kant's a priori science combined with Habermas' communication model. The discursive process would use the four categories above as a guideline for deciding whose views need to be represented in the discourse and would be designed to expose underlying assumptions in a system's design. Underlying assumptions are reflected in implicit boundary definitions which can be made explicit in a discourse following the guidelines outlined above. It is important to note that the goal of the dialogue would be to increase awareness of a design's implications and not to reach a consensual agreement between all of the groups. The discursive process will not be explored further in this paper. For the moment, it will be assumed that the onus is on the planner / system designer to consider the implications of his design for all of those involved and/or affected. The conditions required to ensure that the discourse occurs in an open environment with the appropriate participants would be an interesting avenue for future research.

3. INTEGRATING ACTIVITY THEORY FOR THE IS CONTEXT

The previous section detailed Ulrich's (1983) purposeful systems approach and highlighted how an organization can be viewed as a purposeful system with associated inquiry, action and valuation problem-solving processes. This section will incorporate activity theory constructs into the approach in order to provide a more detailed conception of an organization's processes / activities and to characterize the link between these activities and the information systems that support them. The basic components of activity theory are shown in Figure 1 and have been highlighted in an earlier section.

Each of the problem-solving processes described previously (inquiry, action and valuation) can be viewed as an activity and characterized by the components of activity theory as diagrammed in Figure 1. So, for example, an organization that manufactured shoes would have inquiry processes to determine how to manufacture better shoes, action processes to put this knowledge to use in the manufacturing process and valuation processes to reflect on the implications of the manufacturing process for all those involved in and affected by the process. Using activity theory to model these processes ensures consideration of the instruments used in the process, the community involved in the process and the rules that govern the process.

Information systems can be seen as activities in their own right. The object of an information system is to provide information which can be used to support business activities. Referring to Figure 1, if an information system is modeled using activity theory, the object on the right side in the middle of the triangle would be the information which then flows into the apex of the business activity triangle where it is used as an instrument to support that activity. Using activity theory to model business processes and their supporting information systems provides a method of characterizing the link between the two. When information systems are modeled as a separate activity, recognition is also given to the fact that the rules and community for the information system activity are not the same as the rules and community of the associated business activity. Taking this conceptualization one step further, information system design can be seen as an activity which produces an information system which is then used as an instrument in the ongoing activity of the information system.

In terms of Ulrich's (1983) purposeful systems approach, if an organization is viewed as a purposeful system, then the ongoing activities of an organization are its problem-solving processes which can be classified as inquiry, action and valuation processes. Activity theory can be used to model each of these processes and to define the link between these business processes and their associated information systems. Note that although the supporting information systems would then be viewed as separate triangles for each type of business process, they would not necessarily be distinct information systems in practice. The final step in applying the model within the IS context requires information systems professionals and business professionals to consider the concerns of the various groups of stakeholders when designing, enacting or evaluating information system activities (including information system design) and business activities or processes. This would require the categories described in Section 2.2 with associated interests to be considered in the context of the various business activities and their associated information systems.

4. POTENTIAL APPLICATIONS AND FUTURE RESEARCH

This paper has so far argued that a purposeful systems approach based on the combination of Ulrich's (1983) taxonomy of purposeful systems and activity theory would be a useful contribution towards a general conceptual framework for the IS discipline. The question as to how this approach can be specifically applied to the various areas of IS still remains. The framework would seem to fit naturally with research in the area of knowledge management given the classification of processes into inquiry, action and valuation processes that produce knowledge, use knowledge and reflect on the use of knowledge in support of organisational objectives. Lewis (2002) discusses the application of Ulrich's purposeful systems framework to Alavi's (2000) classification of knowledge management systems and concludes that the guidelines presented in the framework could be used to help with the design and development of knowledge management systems based on Alavi's (2000) network model.

Lewis (2004) also highlights the potential benefits of using the combined model, as presented here, to address issues related to strategic alignment. The ability to explicitly characterise the link between IS and business activities while modelling information systems activities and their environmental influences independently from the associated business activities offers opportunities for improved understanding of strategic alignment. The framework would also seem to have a natural fit with the area of business process management. Characterizing business processes as inquiry, action and valuation processes in support of an organization's purpose provides a conceptual link between **what** a business does (the processes or activities) and **why** (the purpose / vision or mission of the organization).

This paper has presented a theoretical framework with support for the particular orientation of the framework and some indication of its applicability in different areas of IS research and practice. Potential applicability in three areas was highlighted - knowledge management, strategic alignment and business process management. The diversity in these three areas helps to justify the suitability of the framework as a general conceptual tool for the discipline. This paper represents preliminary work which will form the basis for a larger research project in which empirical validation of the appropriateness and usefulness of the approach will be the next step. The main focus here has been to provide a detailed description of the framework and to highlight why it should be considered as a contribution towards a general conceptual framework for IS. The main strengths of the framework arise from its underlying philosophical focus on human intentionality combined with the practical nature of the guidelines it offers for the design and evaluation of human activity systems including organizations and information systems.

ABSTRACT

The past few years have seen a rapid development and momentous growth in mobile technologies and their diffusion into societies worldwide. The concept of Mobile Customer Relationship Management (mCRM) has emerged, as a one-to-one marketing strategy focused on services built for individual customers in an increasingly mobile world. However, the experience of many organizations, which deployed a Customer Relationship Management (CRM) strategy in the late 1980s and early 1990s, has left them sceptical. To address this, we propose that a Critical Success Factor (CSF) study of mCRM is both relevant and timely. In this paper, we establish the need for such a study and present a research framework.

INTRODUCTION

Globalisation of markets and the emergence of electronic business channels, enabled by the Internet, have resulted in a marketplace driven by consumers. During the late 1980s and early 1990s, to improve customer lifetime value (Reichheld 1995) and build market share in the consumer driven marketplace, many organizations invested in Customer Relationship Management (CRM) - a business strategy enabled by information technology (Peelan 2005). Following the dot.com bust and economic downturn, however, organizations confronted with the rationalisation of investment in electronic channels began questioning CRM initiatives. In the face of such scepticism and to provide guidelines for future deployment, studies on critical success factors or CSFs for CRM emerged (Williams and Ramaprasad 1996; Gordon 2002; Croteau and Li 2003). These studies proved crucial for organizations, which were confronted with investment optimisation to achieve long-term success.

While organizations are still coming to terms with the investments in CRM, in the past few years the marketplace has been subject to a radical paradigm shift. Consumers are becoming increasingly mobile, and therefore they have come to demand personalised services, anytime, anywhere (Nelson et al. 2003). This shift has been a consequence of the rapid diffusion and acceptance of mobile technologies and services in the world markets. For example, mobile subscriptions rose from 739 million at the end of the year 2000 to 2,168 billion at the end of the year 2005 (World Telecom Indicators 2006). The latest IDC reports reveal that the shipment of mobile devices in the second quarter of 2006 alone touched 20 million units (IDC 2006).

In order to meet the needs of the consumer market, the concept of mobile CRM (mCRM) has emerged as a one-to-one marketing strategy that focuses on services built for individual customers in a mobile world (Nelson et al. 2003). However, other than industry based success stories (Picarille 2004; Compton 2004; PA Consulting Group 2001), which are arguably vendor biased and the optimism of some commentators (Omatseye 2001; Pastore 2001), there are no rigorous critical success factor studies of mCRM to help organizations rationalise what will be yet another investment. In addition, the rapid evolution of mobile technologies and uncertainties regarding 3G-network diffusion, together with recent legal disputes surrounding patents (e.g. BlackBerry), understandably renders some organizations reluctant to deploy mCRM. Nevertheless, a metamorphosis from CRM to mCRM may well already be apparent (Nelson et al. 2003) because mCRM has the potential to become the future of CRM. Encouraged by the efficacy of CSF studies in CRM, we argue that the time is now appropriate for a CSF study of mCRM. This paper presents a research framework for a study of Critical Success Factors (CSFs) for Mobile Customer Relationship Management (mCRM) building on constructs identified in earlier CSF studies of CRM.

LITERATURE REVIEW

A review of related domains and the proposed CSF method is required as a precursor to the design of a research framework appropriate to the proposed study. In this section, we present an evolutionary review of developments from CRM to mCRM, highlighting links and differences. We also present some highlights from the existing CSF studies that have been influential in CRM deployments. Following this, we present a brief review of the method outlined by Rockart (1979) for undertaking critical success factor studies, to illustrate its application in the context of our proposed study.

Customer Relationship Management

Customer relationship management emerged in the late 1980s (Chen and Popovich 2003), as a business strategy, which enables organizations to realise the value of customer retention and to develop in a consumer driven global marketplace. It is a cross-functional, customer driven, technology integrated business process management strategy that maximises relationships, spanning an entire business. Underpinning this strategy is the concept of relationship marketing (Sheth and Pavatiyar 1995) and customer lifetime value, leading to return on investment. For example, studies by Reichheld (1995) demonstrate that even 5 percent increases in retention can deliver impacts as high as 95 percent on the net present value of customers.

CRM systems link front and back office functions via technology applications, with a business customer's touch points including Internet, email, sales, direct mail, telemarketing, call centres, advertising, pagers, stores, kiosks etc (Chen and Popovich 2003). During the second half of the 1990s, the deployment of CRM as part of an integrated eBusiness push was seen as a potential source of operational cost savings. For example, a call centre was able to service clients when there is non-availability of sales staff after hours, at significantly lower costs. Post the dot.com bust, however, businesses began to realise that automating processes, in particular by facilitating business-to-client (B2C) communication, is not sufficient to retain existing or to attract new customers. Some existing CRM implementations were observed to fail to yield expected benefits (Kotorov 2003). The fear of losing long term sustained market share to competition was compounded with a need for economic rationalisation of technology related investments, including CRM.

In the CRM context, critical success factors (CSFs) are those key factors that must be achieved for the success of CRM (Williams and Ramaprasad 1996). CSF studies have been used as a method to help organizations realise the full potential of CRM deployments in the boom period and to rationalise investments in the post dot.com bust period.

Amongst the major CSF studies of CRM reported in the literature are those of Williams and Ramaprasad (1996) conducted prior to the economic downturn and Gordon (2002) and Croteau and Li (2003), post the dot.com bust. These researchers have applied the concept of critical success factors, as described by Rockart (1979), to conceptualise, classify or categorise CSFs for CRM. They have, however, used various methods to elicit the CSFs, including combinations of literature/industry reviews, surveys, statistical analysis and extending technology adoption frameworks. In summary, the CSFs highlighted in the above studies are as presented in Table 1, in descending order of significance.

During the boom period, Williams and Ramaprasad (1996) identified that management commitment is crucial to CRM success, as it reduces resistance to the change that was required when CRM was implemented. Post the dot.com

CSF5	Organisational Readiness
CSF 6	Technical Awareness

downturn, Gordon (2002) elicited four CRM CSFs, based on an examination of best practices in 35 US and Canadian corporations. These four CSFs focussed on technology, people, processes and knowledge/ insights. While Gordon (2002) did not specify any particular order of significance, *management commitment and knowledge/insights* were highlighted as major CSFs.

Croteau and Li (2003) is arguably the recent work in the elicitation of CSFs for CRM. In a comprehensive literature review, and extending the work of Iacovou et al. (1995) on the technology based framework, they categorised five CSFs: CRM impact; perceived operational and strategic benefits; top management support; organisational readiness; and knowledge management capabilities. *CRM impact* refers to the actual ROI from CRM investments, rather than perceived benefits. While *management support* remained a crucial CSF, the *knowledge management capabilities* of the organization emerged as a significant CSF (Croteau and Li 2003:18).

CRM to mCRM

As pointed out in the introduction, we are now at a point in time when customers are demanding personalised services, when and where they need them (Nelson et al. 2003). The diffusion of mobile technologies into everyday life has been the major facilitator of this apparent shift -- which has the potential to change perspectives in relationship marketing (Sheth and Pavatiyar 1995). In the meantime, organizations which are apparently becoming cautious of technology related investments (Bull 2003) are searching for new ways of optimising their resources and have realised that deploying mCRM within their organizations might enable sales and service personnel to become more efficient:

"Mobile CRM has emerged as one of the more critical factors for success in today's competitive environment. In fact, the use of mobility, whether for the enterprise's field force or for servicing customers, will change the traditional approach of engaging customer relationship." (Tong 2004)

Peppers and Rogers (1999) view CRM as a one-to-one marketing process, which emerged from the deployment of sales force automation tools, augmented by advances in enterprise software technologies. Christopher et al. (1991) note that CRM has its roots in relationship marketing, with its emphasis on winning new customers, via the management of cost effective relationships, fostered by field personnel, namely the sales/service force. Conversely, the focus of mCRM is on field force personnel.

PeopleSoft (2002), which presented a comprehensive business case for mobile CRM, highlights the role of the sales force. They are of the opinion that an information gap exists in the traditional CRM life cycle. While sales people manage their notes, information, task lists etc in an organiser, mobile phone or handheld device, field technicians develop their own systems for managing schedules, for taking notes or tracking inventory. The result is that valuable information remains in an ad-hoc form, of which only part gets entered into enterprise-wide CRM systems at the end of the day or week. This information gap then translates into an inability of sales/service staff to address queries quickly. In the event of an employee leaving or being off-shored on a contract, the gap widens. Mobile CRM can address this gap by linking employees instantly into the enterprise-wide framework. Information is instantly transferred from field personnel's devices on to the organization's database.

PA consulting group (2001) has had concurrent deployments of CRM and mCRM and have already achieved success in enabling online access to customer information via the handheld mobile devices of their field personnel. Cingular Wireless in the US improved its interaction with its growing field sales force after successful deployment of mobile CRM in 2004 (Compton, 2004). MCRM helped Smith and Nephew, a provider of medical devices and surgical implants to orthopaedic surgeons at nearly 10,000 US hospitals to give hands-on service (Picarille 2004). Pitney Bowes Inc recently invested USD 20 million in mCRM (Solheim 2005) which has proven to be a cost efficient way of managing 1800 service personnel in real time.

The key to mCRM applications lies in connecting employees and their employers, in particular in developing and enhancing business-to-employee (B2E) sales applications, which was set to grow from USD 70 million in 2000 to USD 1.3 billion in 2005. While both CRM and mCRM are customer relationship focussed strategies, mCRM is apparently more useful in connecting front line personnel to the organization.

The pervasiveness of mobile devices such as phones and PDAs, and the increasing bandwidth available to these devices, via third generation mobile phone networks might also be critical to the success of mCRM. This may, however, be offset by apprehensions regarding 3G network diffusion and the legal patent disputes that the BlackBerry maker faced in 2005, in addition to media speculations and the volatility of the environment, rendering organizations sceptical about mCRM. As Beal (2005) pointed out, for years commentators predicted mCRM was ready to take off, only to be disappointed. To address this scepticism, and encouraged by the usefulness of CSF studies in CRM, we propose a comprehensive and structured study for eliciting CSFs for mCRM.

Toward CSFs for mCRM: A Proposed Study Using Rockart's Approach

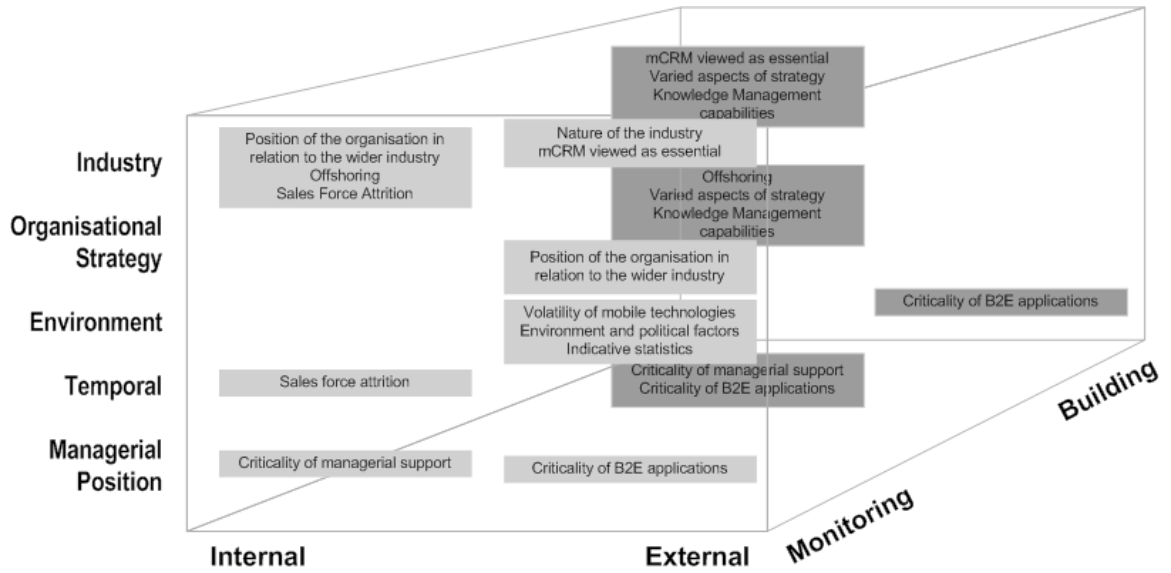
We acknowledge that the CSFs for CRM that were derived from previous studies (see Table 1) may be relevant to mCRM, in particular given their common roots in relationship marketing. However, given its apparent focus on the sales force and its dependence on *technologies* and *the environment*, we anticipated that additional CSFs may emerge for mCRM. Conversely, the CSF studies for CRM seem to have followed varied methods that may not be appropriate to establishing CSFs for mCRM. For example, none of the previous studies of CRM specifically take into account the need to investigate the *environment, political and economic sources* that may well be crucial to understanding the mCRM context. To study mCRM, therefore, we propose to revisit the three-step method, as prescribed by Rockart (1979), which explicitly takes all these influences into consideration.

Rockart (1979) offered a method to provide information to top management, based on Critical Success Factors (CSFs) or the 'few key areas where things must go right'. Specifically, CSFs were the limited number of areas in which satisfactory results will ensure successful competitive performance for the individual, department or organization. The basis of this method was a study conducted for eliciting the information needs of managers in three supermarkets situated in different geographical locations. The study revealed that depending on the manager's situation, organizational or industry context, the CSFs could differ.

The approach is particularly relevant to mCRM, as it provides guidance to managers in understanding where to focus their attention and assists in prioritizing investment decisions. Bullen and Rockart (1981) suggested there are five sources for an organization to consider when identifying CSFs: *the industry, the organization's strategy and industry position, the environment, temporal factors and the managerial position.*

The *industry* related sources are probed to identify a set of CSFs that are determined by the characteristics of the industry itself. For example, Rockart's initial study on the supermarket industry found that managers in each supermarket should be concerned about product mix, inventory, sales promotion and price. Conversely, each *organization* within any industry has its own unique characteristics, determined by its own history and current competitive strategy. *Environmental* factors are those that an organization has limited control over, including national politics, fluctuations in the economy, population trends and regulatory trends, which can contribute to CSFs. *Temporal* factors are those areas of activity within an organization that are critical for a short period of time. A crisis that results from the loss of a large number of executives in an air crash is perhaps a good example.

Figure 1. Potential mCRM CSFs in the Rockart model



Managerial position refers to those generic CSFs associated with the functions of management.

Bullen and Rockart (1981) then presented a useful classification of CSFs according to three dimensions: (a) the above five sources; (b) internal vs external; and (c) monitoring vs building. These are shown in a model adapted to present our conceptual framework (Figure 1). The *internal vs external* dimension refers to the fact that every manager will have internal and external factors that affect their team. Internal factors may relate to matters within managerial control while external factors may pertain to situations such as the availability of raw material that affects production, which falls outside managerial control. The *monitoring* dimension refers to CSFs that involve continued scrutiny of existing situations. Often these relate to actual performance versus budget, personnel turnover rates, or current status of product costs. The *building* dimension refers to those CSFs that involve the role of managers who spend time involved in change management or the implementation of new programs.

Thus, Rockart's model for conceptualising the CSFs takes into account various sources, augmented by multidimensional perspectives for CSF classification. Given the characteristics of mCRM discussed earlier, we argue that Rockart's framework may well prove appropriate to conceptualising and classifying possible CSFs for mCRM.

The three-step method as outlined by Rockart consists of an introductory workshop, interviews within the organization/s and a focus workshop. This paper is restricted to the presentation of the conceptual framework, which will be a preliminary step prior to the implementation of this method.

THE RESEARCH FRAMEWORK

In the proposed investigation of CSFs for mCRM, we revisit Bullen and Rockart's (1981) classification of CSFs according to three dimensions: (a) the five sources (industry, organisational strategy, environment, temporal, and managerial position) (b) internal vs external; and (c) monitoring vs building (see Figure 1). As such there are 20 cells in this classification scheme (5 by 2 by 2).

As a starting point, the six CSFs extracted from the appraisal of the extant literature on CSFs for CRM (see Table 1) were placed into the classification scheme. These were arguably limited to *organisational strategy* and *management support* sources and could be classified as *internal*, embracing both *monitoring and building*. However, we argue that for eliciting CSFs for mCRM, the perspective of the *nature of the industry, its relative position, environment related factors and temporal factors* are necessary. Subsequently, in Figure 1, we provide additional CSFs identified from the discussion of mCRM that can be used to seed a study that extends previous studies of CRM to the world of mCRM.

Specifically, the figure presents the three-dimensional view based on Rockart's classification model. Each of the cells relates to potential CSFs as could be extrapolated from existing CRM related CSFs as well as from the literature. Visibly, there are some overlapping dimensions. For example, mCRM may be viewed as essential to the *organisation* and thus become a CSF. However, the source of this CSF could be *industry* or the *organisation*. Specifically, if the *industry* at large regards mCRM is becoming essential to the organization, it becomes an *externally* motivated CSF, which needs to be *monitored*. Conversely if the organisation also feels that mCRM is essential for the success of the organization, it becomes a CSF that is *internally* motivated and that which an organization will *build* on. Offshoring is a CSF, which seems to have the potential to encompass all the dimensions. Managerial support is of *internal* orientation, but can be of *monitoring /building* dimension.

While Figure 1 is representative of these overlaps as well as 12 of the identified mCRM related CSFs. Table 2 supports the figure, mapping the sources against identified CSFs and their dimensions making it clearer that the sources can be varied for each CSF. At this time, we have only highlighted some of the potential CSFs identified to show the existing gaps that could not be addressed via CRM CSFs. For example, it is clear that all CRM CSFs were internally oriented, while there are a number of potential *external oriented* CSFs for mCRM identified. As the study progresses, more CSFs may emerge and some of the potential ones may merge together to form one CSF. The model as such with its 20 cells may or may not be completely filled with the mCRM CSFs.

Nevertheless, the usefulness of the Rockart model is evident due to its wider coverage of sources and dimensions that could well be relevant to mCRM, given its dependence on the environment, industry and technological factors. Thus, we establish that the model provides a complete structural framework for the proposed study.

CONCLUSIONS AND OUTLOOK

In this paper we have argued that with the development and diffusion of mobile technologies, customers are demanding personalised services when and where they need it. To address this, mCRM has emerged as a one-to-one marketing strategy and is often considered as an extension of CRM. However, organisations are reluctant to deploy a new strategy, given that CRM is yet to realise its complete value.

Table 2. Sources Vs identified CSFs/dimensions

Sources	Identified Potential CSFS and Dimensions
Industry	• Nature of the industry (External/Monitoring) • mCRM viewed as essential to the organization (External/monitoring) • Position of the organization in relation to the wider industry (Internal/Monitoring or External/Monitoring) • Offshoring (External/Monitoring)
Organization Competitive Strategy and Industry Position	• Varied aspects of organisational strategy (Internal/Monitoring and building) • Position of the organization in relation to the wider industry (Internal/Monitoring or External/Monitoring) • mCRM viewed as essential to the organization (Internal/building) • Organisational readiness and awareness of new technologies (Internal/Monitoring or Building) • Knowledge management capabilities (Internal/Monitoring and Building) • Influence of mergers/partnerships (External/Building) • Perceived and actual ROI (Internal/Monitoring and building) • Sales force attrition (Internal/monitoring or building) • Offshoring (Internal or External/Monitoring and building)
Environment	• Volatility of the mobile technologies (External/monitoring) • Changing consumer behaviour (External/monitoring) • Regulatory decisions within the telecom and mobile environments (External/Monitoring) • Economic/Political factors (External/monitoring) • Apprehensions surrounding mobile networks (External/monitoring) • Legal disputes in mobile environment (External/monitoring) • Indicative statistics (External/monitoring)
Temporal	• Sales force attrition (Internal/monitoring) • Offshoring (Internal/External and Monitoring/building)
Managerial Position	• Criticality of managerial support (Internal/Building or Monitoring) • Managerial support directed or participative with sales force (Internal/Building) • Criticality of B2E applications (External monitoring/building or Internal building) • Criticality of change in perspective to promote participation (External monitoring/building or Internal Building)

To address the scepticism of organisations and encouraged by the usefulness of CSF studies for CRM, we proposed a CSF study for eliciting potential mCRM CSFs, using the Rockart (1979) three-step process, adapting his conceptual model for the proposed research framework. We revisited Bullen and Rockart's (1981) classification of CSFs, presented as a model, classified according to three dimensions: (a) the five sources (industry, organisational strategy, environment, temporal, and managerial position) (b) internal vs external; and (c) monitoring vs building, for building a conceptual research framework as a percusor to this study, which is presented in the paper.

As a starting point, the six CSFs extracted from an appraisal of the extant literature on CSFs for CRM, were situated in the classification scheme, to make the gaps apparent. Further the potential CSFs identified from a comprehensive literature review were placed into the framework – emphasising the need to validate mCRM related CSFs. Based on this conceptual framework, we propose to undertake a study for eliciting mCRM CSFs initially in the healthcare sector.

Agile Approaches to Software Maintenance: An Exploratory Study of Practitioner Views

ABSTRACT

Whilst there has been some research into the application of agile approaches to the world of software maintenance, in this paper it is argued that there has not been a coherent investigation that focuses on the collection and analysis of the views and perceptions of agile software maintenance approaches held by experienced software maintenance professionals. In this paper, we report such an exploratory investigation, which has seeded the development of a simple framework for classifying collected views and perceptions. Specifically, a matrix framework has been introduced, to facilitate comparison of the levels of understanding of the issues affecting an agile adoption decision, and the extent to which an agile approach has been implemented. Examples of organizations operating in all four cells of this matrix have been presented.

Keywords: Software Maintenance, Agile Methods, Software Development

INTRODUCTION

Software maintenance has been long-recognized as placing before IT management a critical challenge (Martin & McClure, 1983). Indeed, it can be argued that maintenance decisions can be more critical to system users than decisions taken during software development. Further, with the ever-increasing rate of software development the burden of maintenance increases. Previously developed systems must be maintained to ensure their value and sustainability within an organization. Martin & McClure (1983, p.3) defines software maintenance as "an activity which imposes changes to a software system after its release to the user or customer" and provides varied rationale including: correction of errors, improving the overall design, interfacing a program to other programs and making necessary enhancements.

Many potential solutions or "silver bullets" have been proposed over the years to ease the burden of software maintenance, some boldly proclaiming a dramatic reduction of the burden. While the adoption of some of the "silver bullets" has addressed aspects of maintenance efforts, the burden of maintenance still remains (Bennett, 2000; April et al., 2005). April et al. (2005) even argues that the maintenance burden has been compounded by some of the proposed solutions.

Agile approaches have emerged as a challenge to the status quo as they propose a substantially different, radical philosophy and process for developing software. They are a collection of methodologies, processes and tools for the creative process, that anticipate the need for flexibility and apply a level of pragmatism to the delivery of a finished software product. They seek to deal with the limitations of traditional development approaches, especially the inability to cope with an unstable and rapidly changing requirements environment.

Whilst there has been some research into the application of such agile approaches to software maintenance, we argue that there has not been a coherent investigation that focuses on the collection and analysis of the views/perceptions of agile software maintenance approaches held by experienced software maintenance professionals. In this paper we report such an exploratory investigation, which has seeded the development of a simple framework for classifying aspects of the collected views and perceptions - a framework that may well underpin future studies.

BACKGROUND

In order to situate the present research it is necessary to explore the definitions of both maintenance and agile approaches.

The term "maintenance" has been used since the early 1960s to describe the delivered modification of software on an implemented system. Terms such as "change" or "modification" commonly described activities carried out by personnel participating in the original development, while maintenance usually implies the involvement of personnel who were not party to the original development (Chapin et al., 2001). As maintenance becomes increasingly complex, (including modifications and announcements, adaptive modifications, changes reflecting shifts in processing and environments), a more sophisticated definition of software maintenance is required. Sousa and Moreira (1998, p. 265) in part address this when stating that software maintenance can be viewed as "the modification of the software product after its delivery to the customer, to correct errors, to improve its performance or other attributes, or to adapt the product to a modified environment". For our purposes this is a suitably broad definition.

It is interesting to note that compared to the software development process, research into the maintenance of software is comparatively sparse (April et al., 2005). This may well be a consequence of the so-called software cost "iceberg" (Chapin et al., 2001). Costs and issues associated with software development are explicit and visible. Software maintenance costs surface gradually, later in the system lifecycle, and as such are less visible to management. This has been long argued. Swanson (1976) for example suggests that the metaphorical "iceberg" infers that "much goes on here that does not currently meet the eye, and further that our ignorance in this regard is, in a sense dangerous". Software maintenance is performed in response to software failures, environmental changes and in response to change requests made by users. These activities can be classified as Corrective Maintenance, Adaptive Maintenance and Perfective Maintenance. Yip (1995) suggests that the maintenance component could be as high as 70-75 percent of the overall life cycle cost. In the light of these figures it is perhaps surprising that software maintenance is often overlooked and that it has not been subject to the same intensive research as the software development process.

Of the research reported, a driving focus has been the role of maintenance as a means of resolving software failure (Dekleva, 1992). In addressing this, however, there have been many foci of research interest, including: the quality of the software and its documentation (Lientz & Swanson, 1981; Dekleva, 1992; Yip, 1995; Sousa & Moreira, 1998); coordination and management (Lientz, 1983; Yip, 1995, Sousa & Moreira, 1998); testing of software modifications (Dekleva, 1992; Martin & McClure, 1983); and the domain-specific nature of software (Sousa & Moreira, 1998). To address some of these problems a number of approaches have been proposed, including the adoption of technologies such as relational databases, fourth generation programming languages, object-oriented programming techniques, structured programming techniques, reuse of modules, metrics and computer-aided software engineering environments. All of these technologies, activities and processes have the capacity to reduce, in part at least, the burden of software maintenance.

It is important, however to recognize that the above address only a subset of identified maintenance problems. In order to facilitate a holistic approach to

software maintenance some researchers (e.g. Svenssen & Höst, 2005; Poole & Huisman, 2001; Schuh, 2001) have suggested that agile approaches may have something to offer.

"Agile" or "light weight" software development approaches have emerged over recent years. Proponents suggest that these approaches are revolutionary, and as such have stimulated passionate debate within the industry. The core characteristics and benefits of agile approaches are their emphasis on highly engaged and frequent communication between project participants and clients. This facilitates frequent and intuitive releases of products, which can be evaluated immediately. A further characteristic is the claimed reduction in price to produce quality products in a short period of time, without having to resort to short cuts (Avison & Fitzgerald, 2003). Examples of agile software development approaches include: eXtreme Programming (XP); Scrum; Feature Driven Development (FDD); and Crystal (Beck, 1999; Cockburn, 2002).

As a means of characterizing such approaches, the Agile Alliance (2006) has enunciated the core values underpinning agile approaches, as:

- A means of uncovering better ways of developing software by doing it and assisting others to do it;
- Valuing individuals, interactions, working software, customer collaboration and responding to change as items of most value to practitioners or teams who apply an agile approach; and
- Such considerations are valued over other considerations such as processes, tools, comprehensive documentation, contract negotiation, and the strict adherence to a plan.

Agile approaches have also been characterized in terms of the techniques/methods that typically feature, including: *Incremental Development*; *Time Boxing; MoSCoW Rules; JAD workshops; Prototyping; the roles of Sponsor & Champion; and the adoption of supporting Toolsets* (Avison & Fitzgerald, 2003).

AGILE APPROACHES AND SOFTWARE MAINTENANCE

Lientz (1983) identifies the user-oriented nature of software maintenance as one of the most critical challenges facing IT management. The advocacy of constant and timely communication, coupled with ready feedback and iterative releases, by proponents of agile approaches may, as such, be advantageous to software maintainers. Maintainers can seek to address problems through collaboration and communication with users, thus reducing the potential to introduce further problems (Cockburn, 2002).

Agile approaches as an alternative to the traditional waterfall approach in maintenance have been studied by several researchers. E.g. Poole and Huisman (2001) demonstrate that an agile approach, XP, might be introduced into an organization as a maintenance tool. However they have identified a strong correlation between effectiveness and customer commitment to communicate with the maintenance team. Schuh (2001) suggests, however, that agile approaches might not be a blanket solution to problems faced by the development and maintenance functions. Svenssen and Höst (2005) reinforce this view in their empirical study, suggesting that agile approaches need to be adjusted or adapted to suit an organization's circumstances and situation, and that following each of the processes suggested verbatim can be a recipe for disaster.

Studies conducted thus far have, in a sense, focused upon technical and procedural activities and benefits, as opposed to building a realistic understanding of how the broader philosophy of agile approaches might assist software maintainers and users. We argue that there is a gap in substantial research, capturing the views and perceptions of front line maintenance staff as to the potential capacity of agile approaches to assist them in the performance of their day-to-day software maintenance activities. The present study describes an exploratory study that lays the groundwork for addressing this gap.

RESEARCH APPROACH

To identify practitioners' views and perceptions of the applicability of agile approaches to maintenance, and to understand the factors that influence those views and perceptions, we chose an exploratory, qualitative research approach, administered through face-to-face semi-structured interviews. Eight participants were chosen from a pool of maintenance practitioners, working in some seven different organizations. All practitioners were working as maintenance officers and had at least two years experience – some substantially more. Due care was taken to ensure a range of different systems were represented, thus avoiding domain or software-specific selection. Participants came from organizations of various sizes and types, ranging from small businesses, maintaining web-based applications, to large organizations operating sizable ERP systems and software. Table 1 presents a summary of the participant profiles.

Table 1. Summary of participant profiles

Participant Code	Organization Type	System Maintained
P1	Large banking institution.	Customer information system
P2	Medium-to-large commercial software company.	Large, commercial ERP software system.
P3	Large banking institution.	Distributed Lotus Domino applications.
P4	Small contractor.	Miscellaneous software systems (research to marketing systems).
P5 & P6	Small to Medium Enterprise (SME).	Web-based, Microsoft.NET application.
P7	Small contractor.	Websites and web-based applications
P8	Medium to large international commercial software vendor.	Large, commercial ERP software system.

We acknowledge that the number of participants have limited the validity of findings. However, being a preliminary exploratory study, the scope of this research was set to finding some indicatory insights from practitioners, so as to provide a platform for launching into further research investigations. Therefore, this small sample was rendered sufficient.

INDUSTRY STUDY

To set the scene, the following statement from participant P2 characterizes the view held by all concerning the challenge of software maintenance, as they live it, day to day:

"... We have to deal with history and archaeology. And we recognize it, but time, resources, and money constraints don't allow you to re-architect the entire portfolio in one hit. So you're constantly battling the weight of the old product with all of the measures of some of the newer modules. And that's a tug of war that our sort of business has to wrestle with."

This characterization captures the essence of software maintenance, as a struggle between legacy systems and the unrelenting need and demand for change and progress. Further, an understanding of a system's past is essential, to assist in determining the future viability and applicability of a software system.

In characterizing the views/perceptions of the software maintainers we initially report 4 primary findings. Subsequently (next section), we present a simple framework which has been helpful in practically classifying the situations thus observed in the participant organizations. Theoretically, these classifications may be used for similar studies and could also be modified in accordance with the further situational findings.

Finding 1: Software Modifications and Enhancements vs. Software Corrections and Adaptations

Consistent with the extant literature, the participants confirmed that software enhancements or modifications to an implemented software system are the most significant maintenance activity they face (Lientz, 1983; Yip, 1995). For example, P3 indicated that a high volume of requests is for the provision of upgrades and new functionalities. This was corroborated by P5, P6&P7. It is noteworthy, however, that Sousa and Moreira (1998) identify adaptive maintenance activities as the most costly software maintenance activity, at odds with the present findings.

Finding 2: User/System Knowledge and Knowledge Management are Crucial

Lientz and Swanson (1983) identify knowledge, programmer effectiveness, product quality, time availability, machine requirements and system reliability to be the factors of most pressing concern to maintainers. Consistent with the primacy of knowledge in this list, participants in the present study emphasized the need for user knowledge and system knowledge, and that the lack of documentation and/or the ability to transfer knowledge, were key issues. This problem is further compounded by a user's/customer's lack of understanding of the difficulties and the issues surrounding the performance of software maintenance. P4 provided insight by suggesting that:

"...from a customer viewpoint, they often say there's a problem in the software, it doesn't do what I want it to do… (and) they would probably classify them as software defects, but of course, if the functionality wasn't in the original requirements specification; it's not a defect, it's a modification."

To address this problem, and to introduce some form of knowledge management to maintenance activities, P1, P3, P5&P6 proposed the standardization of practices, and P4 suggested managing customer expectations by involving customers in both the development and maintenance processes.

Finding 3: Prominence of Agile (or at least Flexible) Approaches in Present Software Maintenance

Software maintenance, unlike software development is not requirements driven but is rather event driven, triggered by unscheduled or random external events (Kitchenham et al., 1999). Software organizations do not have defined processes for the conduct of their software maintenance activities, or at best software maintenance is depicted crudely as the final activity in their software development process (April et al., 2005). This view might suggest that software maintenance follows an ad hoc process in many organizations, reflecting at best some coarse steps similar to those depicted within the traditional "waterfall" model of software development. In the present study, this view was supported by P4.

In contrast, many of the participants in the present study indicated that they are using some form of agile or at least flexible process. P1, P5&P6 reported that the use of iterative and incremental development approaches is a means of delivering readily assessable and tangible maintenance benefits to users, coupled with a means of prioritizing requests to deliver the optimum benefits. P1, P3, P5, P6&P8 also emphasized extensive customer participation and frequent feedback in the processes they employed.

It should be noted, however, that the use of such methods, incorporating features commonly associated with agile approaches, was not common to all participants. Indeed P2 and P7 reported adherence to a more traditional "waterfall" based approach of eliciting maintenance requirements from users and executing change requests.

Interestingly, while the approaches above have proven to be relatively successful, the participants did not formally recognize these as involving the use of "agile methodologies". Indeed, as P4 suggested:

"Agile methodologies, in a software maintenance environment, don't translate. Not unless it's a major, like 30 percent of the software is being changed then ok, but if it's a minor software defect change… if it's changes to features… there are stages to be done, waterfall stages. Define, design, code, test, implement."

This view is supported by the studies of Svenssen and Höst (2005) who suggested that a relative degree of adaptation and selection is required in order to successfully apply agile approaches to a software maintenance environment. Cockburn (2002) and Beck (2005) have also suggested that organizations or practitioners, interested in pursuing an agile approach, should select processes or methods which they can successfully apply within their particular domain and undertake a process of assessment and refinement, introducing new methods and refining existing methods in order to elicit the most value and benefit from agile approaches given their implementation context. Based on the responses collected from the participants in this study, the impression is that the participants are either unaware of the principles that drive agile approaches or that they are ignorant to such drivers and principles. With responses such as "a bit more rigor in following the process" (P5&P6) and "jumping into the code and fixing it (without appropriate documentation or knowledge of the software system)" (P3), it is appropriate that there is a degree of skepticism as to the notion of adapting an "agile methodology" as a basis for maintenance. This was expressed most clearly by P4:

"The word agile methodology is thrown around very much in the press. Agile was a buzzword 15 years ago and every time I read a magazine from the IEEE about every 3rd one had agile on the front cover. Each time you look at it, it means something different."

Finding 4: Superficial Understanding of Agile Approaches to Software Maintenance

One of the most interesting findings in the present research, in particular given the above observation of widespread use of methods/techniques that are commonly associated with agile methods, is that most participants, when probed, actually had, at best, superficial formal understanding of agile methodologies. Some participants who claimed an awareness of such approaches, when probed demonstrated substantial misunderstandings of some of the basic tenets of agile development. Boehm (2002) has previously observed this, expressing a view that agile approaches appear less disciplined than they really are, with people almost equating them to undisciplined hacking. Consistent with this, P3 stated:

"… how do we get good design in an agile approach? Because an agile approach, certainly in our case, tends to be jumping in and writing the code."

As an example of such misunderstandings, P5&P6, and to a limited extent P7, stated that they attempt to be flexible in the performance of their maintenance activities but in exercising this flexibility, they employ little adherence to set practices or standards. In summary, they view agile approaches as less disciplined than they really are, equating them, in a sense, to undisciplined hacking.

TAKING THE DECISION TO ADOPT AN AGILE APPROACH TO SOFTWARE MAINTENANCE

Reflecting upon the findings above, it is curious that whilst the maintainers studied saw their focus, somewhat conventionally, to be upon software enhancement and modification of implemented software systems (Finding 1) and argued that such tasks must be supported by substantial extant documentation and associated knowledge transfer mechanisms (Finding 2), they seemed to employ flexible approaches commonly associated with agile approaches which many saw as not supporting system documentation (Finding 3). Further, in many cases they displayed at best limited understanding of some of the basic tenets of agile methodologies (Finding 4).

This raises an interesting issue. To exercise an informed decision to adopt an agile approach in an organisational maintenance situation, it is reasonable to expect that the maintainer should understand agile approaches and the associated issues surrounding the operation of organisational maintenance processes. In the study however, this prerequisite knowledge does not seem to have uniformly been in place.

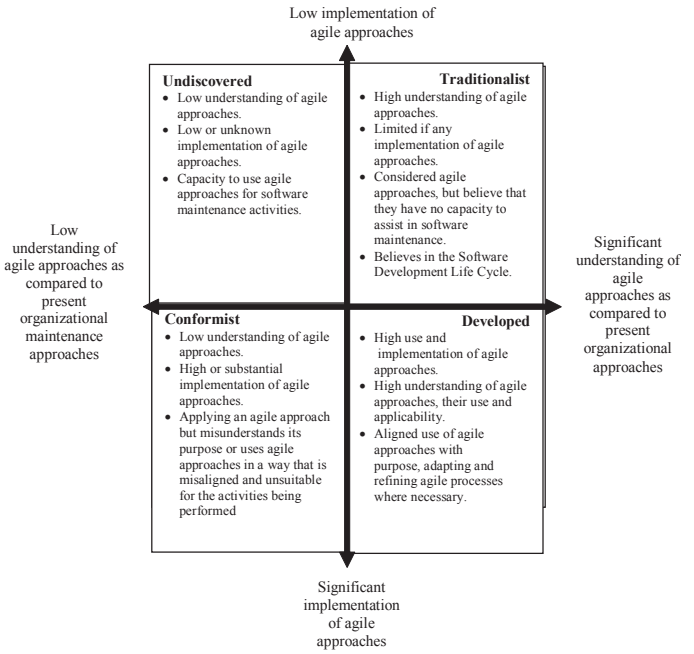
As a means of characterising the situations of the participants in the study, we introduce a matrix framework (Figure 1), to facilitate a comparison of the levels of understanding of the issues affecting an agile adoption decision and the extent to which an agile approach has been implemented.

The matrix involves two axes. The first reflects an organization's knowledge of agile approaches. An organization can possess varying degrees of knowledge of agile approaches, ranging from unaware or having a low understanding of agile approaches, to possessing substantial understanding and knowledge.

This axis also takes into consideration an organization's understanding of its present software maintenance processes, in particular how their present processes compare with agile processes.

The second axis records the level of implementation of an agile approach within the organization's software maintenance context, with organizations applying

Figure 1. The "Agile Understanding Matrix"



agile approaches or methods in varying degrees ranging from no (or low) implementation of agile approaches, to a situation where they apply a substantial implementation of agile approaches in support of performing their software maintenance activities.

As such, organizations can fall within four distinct quadrants characterised by different levels of understanding and different levels of implementation. These quadrants have been termed: undiscovered; traditionalist; conformist; and developed, for the purpose of this study, as shown in Figure 1.

Figure 2 provides a visual representation of the quadrants in which all 8 study participants fit, based on an analysis of the information collected. To illustrate the assessments made, one example for each quadrant is briefly presented.

CONCLUSION AND FUTURE RESEARCH

This research paper reports from an exploratory study that investigated whether agile approaches might have the capacity to assist software maintenance practitioners.

It was observed that the maintainers, somewhat conventionally, felt that their focus should be on software enhancement and modification of implemented software systems, which involves tasks supported by substantial extant documentation. Conversely, they seem to employ flexible agile approaches, which have been characterised as not supportive of such system documentation, with limited understanding of the basic tenets of agile methodologies.

We argue that to exercise an informed decision to adopt an agile approach in an organisational maintenance situation, the maintainer should understand the basic tenets and associated operational issues. Based on the participant situations in the study reported in the paper, a matrix framework has been introduced, to facilitate a comparison of the levels of understanding of the issues affecting an agile adoption decision and the extent to which an agile approach has been implemented.

The characterisation of organisations taking decisions concerning the adoption (or non-adoption) of agile software maintenance approaches, as developed in this paper, may well provide a framework for on-going study of software maintenance practitioner views. Further, based on the indicatory results of this study, which is limited by the number of participants, structured empirical studies could be initiated calling for participation from specific industry sectors and organisations classified by size. As we have pointed out earlier, there is a gap in substantial research, capturing the views and perceptions of front line maintenance staff as to the potential capacity of agile approaches to assist them in the performance of their day-to-day software maintenance activities. The results of empirical studies seeded from this preliminary study could be of valuable contribution to the body of knowledge in this area, benefiting both academia and practice.

An Exploratory Investigation of Instructors Acceptance of E-Learning

Hassan M. Selim, United Arab Emirates University, Al Ain P.O. Box 17555, United Arab Emirates; E-mail: hassan.selim@uaeu.ac.ae

ABSTRACT

The use of e-learning and information technologies in teaching have changed the instruction approaches. There are several factors that need to be considered while developing or implementing E-learning environment. This paper is intended to identify and measure e-learning critical factors as perceived by instructors. In line with the literature, five factors were identified and measured, namely instructor self efficacy, student perceived benefits, instructor attitude towards information technologies used in e-e-learning, instructor attitude towards the technical support of e-learning tools, and e-learning acceptance and usage by instructors. A sample of 606 instructors was used to validate the proposed e-learning factors. The results revealed that 40% of the instructors perceived technical support as the most critical factor in e-learning success. The instructor self efficacy was viewed as the most critical factor by 30% of the participants, while 31% viewed it as the third most critical factor. The items used in measuring each factor were validated and showed acceptable reliability and discriminant measures.

Keywords: Improving classroom teaching; e-learning; Evaluating CAL systems; Teaching/learning strategies.

INTRODUCTION

The use of E-learning and information technologies as teaching tools have expanded and changed the instruction approaches (Alavi, 1994; Selim, 2003, 2004, 2006). E-learning concept has been around for decades and is one of the most significant developments in the information systems industry (Wang, 2003). E-learning is the delivery of course content via electronic media, such as Internet, Intranets, Extranets, satellite broadcast, audio/video tape, interactive TV, and CD-ROM (Urdan & Weggen, 2000). Fostering e-learning acceptance among individual instructors remains a critical challenge for universities and e-learning service providers. E-learning acceptance by instructors is needed to develop an environment with minimum resistance.

Instructor attitudes towards e-learning are vital factors of developing efficient and effective e-learning environments for teaching. There are very few articles in the literature that address the acceptance of e-learning from the instructor's perception (Hu, Clark, & Ma, 2003; Kollias, Mamalougos, Vamvakoussi, Lakkala, & Vosniadou, 2005; Liaw, Huang, & Chen, 2006). This paper reports on an exploratory study aims to identify and measure the critical factors affecting e-learning acceptance by instructors. The exploratory study will lead to the development of an instructor e-learning acceptance model.

METHOD

Participants

An online survey was available on the World Wide Web and advertised to universities in the United Arab Emirates (Dubai, Abu Dhabi, and Sharja). Respondents for this study consisted of 606 instructors. Table 1 summarizes the demographic profile and descriptive statistics of the respondents. Instructor ages ranged from 22 to 61 years, with a mean age of 42.3 years (S.D. =8.3). Male respondents represented 81%. Instructors came from 31 different countries (see Table 2). Participants represented 11 colleges namely, business, engineering, medicine, law, science, humanities & social, education, food & agriculture, libraries, information technology, and general requirements. The majority of the participating instructors had 5 years or more experience with personal computers (89.1%).

Table 1. Demographic profile and descriptive statistics of surveyed instructors

Item		Frequency	Percentage

Instrument

This study proposed four factors that could lead to the acceptance of teaching using e-learning tools by instructors. The four factors are: (1) instructor self efficacy - ISE, (2) student benefits as perceived by instructors - SPB, (3) instructor attitude towards Information technology as an enabler of e-learning - IAIT, and (4) instructor attitude towards technical support provided by e-learning providers - IATS. A fifth factor was used to represent the e-learning usage - ELU. Each factor was represented by a latent construct that was observed via a number of indicators. Several survey instruments have been developed to measure e-learning satisfaction and acceptance (Angeli, 2005; Hu et al., 2003; Lee, Cheung, & Chen, 2005; Liaw et al., 2006; Selim, 2003, 2004, 2005, 2006; Shih et al., 2003). Therefore, various potential indicators exist to measure each factor. A survey instrument was developed that consisted of 6 sections, one for each one of the five factors in addition to a demographic characteristics section.

The instructor self efficacy (ISE) construct section included 6 items (ISE1-ISE6). The ISE factor was operationalized and validated by previous research (see Appendix for the item details). items ISE1 to ISE6 were adopted from (Compeau & Higgins, 1995; Hu et al., 2003) to capture instructor's self efficacy. The items were reworded to fit the e-learning context.

Six items were used in assessing the perceived students' benefits construct (PSB1-PSB6). The 6 items measured how the instructor perceives students' benefits of attending e-learning enabled classes. The items are listed in the appendix. Seven items were developed to measure the instructor's attitude towards information technology (IAIT) tools such as Internet, personal computers, course management systems, and student information system. The instructor's attitude towards technical support section consisted of 5 items (IATS1-IATS5) and all of them were developed to capture the effectiveness and efficiency of the provider's technical support. The last section was dedicated to capturing the perceived acceptance and usage of e-learning by instructors via 6 items (ELU1-ELU6), see the appendix.

The items were randomly arranged and some of them were negatively worded. All items used a five-point Likert-type scale of potential responses: strongly agree, agree, neutral, disagree, and strongly disagree. The instrument was pre-tested by a random sample of 100 instructors. Minor changes to the order and wording of the items resulted from the pre-testers opinions. A website was developed to publish the instrument. Emails were sent to instructors and faculty members of 4 major universities in the United Arab Emirates (Dubai, Abu Dhabi, and Sharja). The participants were informed that all data were anonymous and were to be used in assessing the acceptance and usage of e-learning technology. Table 3 shows the mean and variance of each item in the e-learning assessment instrument.

Instructors were asked to rank the four factors (ISE, PSB, IAIT, and IATS) based on their level of importance and criticality to the success of e-learning.

Table 3. Descriptive statistics of e-learning assessment indicators

Item	*Mean*	*S.D.*
ISE1	3.98	0.958
ISE2	3.81	0.986
ISE3	3.58	1.039
ISE4	3.44	1.075
ISE5	4.20	0.937
ISE6	3.34	0.989
PSB 1	3.53	0.972
PSB 2	3.46	0.940
PSB 3	3.96	0.910
PSB 4	3.50	0.946
PSB 5	4.03	0.905
PSB 6	3.50	0.907
IAIT 1	3.88	1.093
IAIT 2	3.55	1.043
IAIT 3	3.54	1.001
IAIT 4	3.37	0.963
IAIT 5	3.68	1.013
IAIT 6	3.52	0.926
IAIT 7	3.70	0.944

Item	*Mean*	*S.D.*
IATS1	3.38	1.050
IATS2	3.10	0.929
IATS3	3.32	0.910
IATS4	3.26	0.942
IATS5	3.07	1.026
ELU1	4.07	0.879
ELU2	4.09	0.804
ELU3	4.06	0.929
ELU4	4.23	0.865
ELU5	3.95	0.938
ELU6	4.03	0.890

The rating for each factor was placed between 1 and 4. Table 4 shows the rank of the four e-learning factors as perceived by instructors. The instructor attitude towards the technical support factor was given the most critical rank by 40% of the surveyed instructors. Perceived student benefits (PSB) and Instructor attitude towards information technology were perceived to be the least critical to the success of e-learning in teaching as perceived by 34% and 35% of the surveyed instructors, respectively. Instructor self efficacy was viewed as the most critical and important factor by 30% of the participants while 31% viewed it as the third important factor.

Table 4. E-leaning critical factors ranking

	1	2	3	4	Average
ISE	30% (184)	23% (140)	31% (186)	16% (96)	2.33
PSB	18% (108)	28% (168)	20% (124)	34% (206)	2.70
IAIT	20% (122)	23% (142)	21% (130)	35% (212)	2.69
IATS	40% (244)	29% (176)	22% (132)	9% (54)	2.00

Exploratory Factor Analysis

Exploratory factor analysis was conducted to identify the underlying critical items in each of the e-learning critical factors (ISE, PSB, IAIT, IATS, and ELU). The same factor analysis was used to validate the e-learning critical factors. LISREL version 8.54 was used to develop the polychoric correlation and asymptotic covariance matrices used in generating the factor loadings because all the items were represented by ordinal variables. Table 5 shows the output results for the Promax-rotated factor loadings. Items intended to measure the same e-learning factor must demonstrate a factor loading of >0.50.

The 6 items (ISE1-ISE6) proposed to measure the instructor self efficacy factor as a critical factor of e-learning success were highly correlated with it, as indicated by the factor loading values of >0.65 in Table 5. This testifies to the validity of the indicators used to capture the instructor self efficacy. The items comprised in this factor were related to the instructor's capabilities of implementing and using e-learning methods such as Internet, PCs, and LCD projectors. This factor was ranked as the most critical factor by 30% of the participants and third most critical factor by 31% of the participants (see Table 4).

The exploratory factor analysis applied to the 6 indicators used in measuring the perceived student benefits by using e-learning yielded good results. All items correlation values (loadings) with the identified factor (PSB) were >0.60. This factor captured instructor's perception about the effect of e-learning on student interactivity, quality of coursework activities, usefulness, and readiness.

The instructor's attitude towards the information technologies (IAIT) used in e-learning was measured by 7 indicators, all of them loaded with correlations of values >0.50. The indicators used in this factor were related to the ease of Internet access and navigation, web-based course management system, computer networks, student information system, and the information technology infrastructure reliability and effectiveness. Most of the instructor responses to the 7 items were positive. The instructors were mostly satisfied with the on-campus Internet access, and course websites available via the course management system used.

The instructor attitude towards the technical support (IATS) was measured using 5 indicators; all of them had factor loadings of > 0.60. All the items were related to the helpdesk and e-learning training. The last factor was related to the instructor perceived usage of e-learning in teaching as an indicator of their acceptance of this technology. The e-learning usage (ELU) factor was measured by 6 indicators; all of them had high factor loading values of > 0.65. The ELU factor included the intention of teaching e-learning based courses in the future, how e-learning fits into the instructor's teaching style, and the instructors' perception about e-learning in general. Instructors indicated positively that they will teach e-learning based courses in the future which indicated a positive attitude toward accepting the e-learning technology. Finally, it can be concluded that the indicators used in e-learning critical factors assessment instrument truly represented the concepts of interest.

E-learning assessment instrument's reliability was measured using Cronbach alpha. Table 6 shows Cronbach alpha values for the 5 e-learning assessment factors emerged from the factor analysis given in Table 5. The suggested accepted value of Cronbach alpha is ≥ 0.70 (Hair, Anderson, Tatham, & Black, 1998). All factors exhibited a high degree of internal consistency as the alpha values were ≥ 0.847. It was concluded that the indicators could be used to measure the factors with acceptable reliability. The average variance extracted, which reflects the overall amount of variance in the items accounted for by the factor. The average variance extracted is more conservative than Cronbach alpha as a composite reliability measure and its accepted value is 0.5 or above (Fornell & Larcker, 1981). As shown in Table 6, all the average extracted variance values are ≥ 0.69. Average extracted variance can be used to evaluate the discriminant validity. The square root of the average extracted variance for each factor should be greater than the correlations between that factor and all the other factors (Fornell & Larcker, 1981). Table 7 shows the correlation matrix of the e-learning assessment factors and the square root of the average extracted variance. The discriminant validity does not reveal any problems.

CONCLUSIONS AND FUTURE WORK

Information technology and intense competition are reshaping higher education institutions worldwide. E-learning has been integrated in several higher education institutions. Consequently, several adoption-related factors must be carefully

Table 6. E-learning survey instrument reliability

Factor	Cronbach Alpha	Variance Extracted
ISE	0.893	0.771
PSB	0.901	0.691
IAIT	0.888	0.730
IATS	0.847	0.795
ELU	0.909	0.777

evaluated before any adoption attempt is made by universities and instructors. The adoption of e-learning technology is a complex process of establishing and developing an integrated information technology system. This study, in line with the literature, identified and measured four critical factors that assist universities and instructors to adopt e-learning technologies. Critical factors which were identified and measured from instructor perceptions, included: instructor self efficacy, student perceived benefits, instructor attitude towards information technology, and instructor attitude towards technical support. The four factors impact the decision to adopt e-learning technology in higher education institutions.

A sample of 606 instructors was used to identify and measure the proposed e-learning factors. The instructors perceived the four factors as critical success factors in e-learning. The surveyed instructors indicated that technical support to e-learning tools and technologies is the most critical factor. Surprisingly 35% and 34% of the participants viewed instructor attitude towards information technology and perceived student benefits as the least important factors of successful e-learning. The instructors indicated that when a higher education institution attempts to adopt e-learning based courses the following factors should be critically considered:

- Instructors should have sufficient computing skills and enthusiasm.
- Construction of an effective information technology infrastructure in order to facilitate fast Web access, email, course management system, and other e-learning services.
- Establishment of reliable and responsive e-learning support services.
- Development of orientation programs to both students and instructors.
- Easy and fast Internet access

All indicators of the instructor self efficacy factor were important and significant measures. Generally, instructors felt comfortable using e-learning in teaching if they get sufficient training. Some instructors found it easy to get e-learning tools do what they wanted to do. Instructors perceived valuable student benefits such as better quality of coursework activities and better in-class interactivity.

The instructor attitude towards the information technologies used in e-learning was an important factor of e-learning success. Important items used in measuring this factor included reliability of the information technology infrastructure, Internet access and speed, course management system, and student information system. The instructor attitude towards the technical support of e-learning tool was viewed as critical success factor. Technical support factor was measured by how the helpdesk is responsive and effective. Instructors indicated that they would teach e-learning based courses in future assuring their positive attitude and support to e-learning technology and tools.

This study explored the instructors' perceptions in identifying and measuring e-learning critical factors within higher education schools. Further study can expand on this research to develop a causal research model that includes all the 5 constructs (ISE, PSB, IAIT, IATS, and ELU). The objective of the causal research model would be to study the effects of the first 4 factors on e-learning acceptance as indicated by ELU. The proposed research model can generate causal relationships among the 5 factors.

APPENDIX

E-learning Acceptance Instrument

Instructor Self Efficacy (ISE)

ISE1	I would feel comfortable using e-learning in teaching if I get training support from the university.
ISE2	I can learn how to implement e-learning in my teaching by myself.
ISE3	I find it easy to get e-learning methods to do what I want to do.
ISE4	I have become dependent on e-learning methods in both teaching and learning.
ISE5	I can handle technologies such as, course websites, PCs, and computer projectors effectively.
ISE6	I am getting the training I need to be able to use e-learning in my teaching from the university.

Perceived Student Benefits (PSB)

PSB 1	Utilization of e-learning has enabled students to submit better quality coursework activities
PSB 2	Students have come to rely on e-learning in performing their coursework
PSB 3	All in all I think that e-learning is extremely useful to the students
PSB 4	E-learning has improved student interactivity in class
PSB 5	Students need more orientation in order to utilize e-learning affectively.
PSB 6	Students are prepared to handle e-learning activities in the class

Instructor Attitude towards IT (IAIT)

IAIT 1	Easy on-campus Internet access
IAIT 2	Internet browsing speed is satisfactory
IAIT 3	I can count on the computer network to be “up” and running
IAIT 4	I can get student information from the student information system easily
IAIT 5	I can use any on campus PC using the same authentication
IAIT 6	Overall, the university information technology infrastructure is efficient
IAIT 7	It is easy to learn how to use the computer systems I need

Instructor Attitude towards Technical Support (IATS)

IATS1	I can get technical support from technicians easily
IATS2	The information technology people I deal with understand the day-to-day objectives of my teaching and learning needs
IATS3	The IT support teams takes real interest in helping me solve my teaching and learning problems
IATS4	When I make a request for service or assistance, support team normally responds to my request in timely manner
IATS5	I am satisfied with the level of e-learning technical support planning at my university

E-learning Usage/Acceptance (ELU)

ELU1	I intend to teach courses that use e-learning methods.
ELU2	E-learning is an effective method of teaching and learning.
ELU3	Using e-learning methods fir well into the way I teach.
ELU4	All in all I think that e-learning is an important tool for my university.
ELU5	I personally benefited from the existence of e-learning activities and tools in my university.
ELU6	Using e-learning methods would make my teaching more efficient and effective.

Exploring Change and Knowledge Management in Developing Countries: The Case of Iranian SMEs

Mostafa Jafari, Iran University of Science and Technology, Narmak, Tehran, Iran; E-mail: mos@iust.ac.ir
Peyman Akhavan, Maleke-Ashtar University of Technology, Iran; E-mail: akhavan@iust.ac.ir
Mohammad Fathian, Iran University of Technology, Narmak, Tehran, Iran; E-mail: fathian@iust.ac.ir

ABSTRACT

The main target of this research is to discuss two important strategic management disciplines in some Iranian SMEs. Change management and knowledge management will be discussed simultaneously for taking insight into the topic. Based on review of recent literature, this paper has identified major factors of both knowledge and change management disciplines in the field. For the research methodology, a structured survey has been implemented by the authors. The outcome of the research can be implemented as a guideline for change management during KM programs. This study provides an integrated perspective of critical issues for both knowledge and change disciplines in the organizations especially in SMEs of developing countries. It gives invaluable information and guidelines which hopefully will help the leaders to mange essential changes for accomplishing knowledge management through their organizations.

Keywords: Knowledge management, Change management, SME, Iran.

INTRODUCTION

If there is an even more ubiquitous topic writing about change, whether it is books, practitioner or academic journals, the topic of change is sure to be one of the most researched and well-published subjects (Washington and Hacker, 2005).

Attempts to impose order on what Weick and Quinn (1999) call "the sheer sprawl of the change management literature" have led to attempts at classification of change as either "discontinuous and episodic" or "continuous and emergent" (Treleaven and Sykes, 2005).

If there is one constant in the real business world, it is surely the change. Some researchers such as Attaran (2000) have declared that nearly 75 percent of all American corporations have gone through some type of systemic change program.

The concept of societal transformation today has also come to be associated primarily with the changes underway in former socialist countries. The process has been described in many different ways, such as "deep metamorphosis", "paradigm crisis," "crisis of working society," and "crisis of organized modernity" (Thurow, 1999).

In such a landscape, it is not surprising that knowledge and information management has emerged as one of the most popular strategic change management approaches in the dawn of the 21st century (Davenport and Prusak, 1998). Its supporters argue that organizations may achieve significant competitive advantages by analyzing the data and information that often remain unexploited in organizational systems and by transforming them into useful and actionable knowledge (Giaglis, 2002).

Adoption of knowledge management system in the organization may face with some challenges which is usually understood. This subject requires a specific change management program to lead knowledge management efforts in the organization.

It is necessary to say that we are now changing gradually from an information age to a knowledge age, where knowledge has been recognized as the most important aspect in human life. Individuals and organizations are starting to understand and appreciate knowledge as the most valuable asset in the emerging competitive environment. Knowledge is a powerful tool that can make changes to the world. It is now considered as the main intangible ingredient in the melting pot that makes innovation possible (Syed-Ikhsan and Rowland, 2004).

Bergeron (2003) defines knowledge management in this way:" Knowledge management is a deliberate, systematic business optimization strategy that selects, distills stores, organizes, packages, and communicates information essentials to the business of a company in a manner that improves employee's performance and corporate competitiveness".

Knowledge management is the process of managing knowledge and expertise in the organization in a way that facilitates identification, capture, codification, storage and sharing the knowledge which accelerates knowledge creation towards the strategies of the organization.

Change and knowledge retention affect a firm's knowledge production. Tradeoffs in the amount of resources dedicate to these activities influences the development and distribution of knowledge within firms across time (March, 1991). For instance, a firm that preserves the past via retention may dedicate fewer resources to creating knowledge through variation activity and to acquiring tacit knowledge and skills, or human capital. On the other hand, a firm may import more knowledge via inflows of human capital when it trades off exploiting the past for increasing knowledge creation or variation (change) activity. As a consequence, a general concern of studies examining learning and adaptation is the balance between a firm's variation and retention activities (Madsen and McKelvey, 1996).

Knowledge-based approach is a useful framework which is needed to give the depth to the study of discursive change processes. This framework focuses on both the emergent nature of change itself and on the reforms and recreations of knowledge produced in terms of organizational knowledge. It also offers an understanding towards change processes and covers the tensions generated during the process. Such re-conceptualizing of organizational change to address multi-vocality opens up new ways of researching which shows how organizing and re-organizing processes in organizations produce intended and unintended effects.

In this paper, we are supposed to discuss change management during knowledge management establishing program in some Iranian small and medium size enterprises (SME). This study will explore change efforts and KM programs simultaneously. It is important to say that knowledge management adoption in an organization requires some changes. The succession of KM program is dependent on the way changes are managed. If the changes are not implemented in a suitable way, the knowledge management program will face the failure. In this way, knowledge management programs have a close relationship with the related changes. That's why the authors are to discuss knowledge management and change management simultaneously in this research.

WHAT ARE SMES IN THE REAL WORLD?

The result of the knowledge revolution is represented by the new economy or the knowledge-based economy, which is radically different from the previous economy types known by mankind. Essentially, the knowledge-based economy is characterized by the conversion of knowledge into essential raw material, capital, products, production factors of the economy and through economic processes within which such activities as generating, selling, buying, learning, storing, developing, sharing and protecting the knowledge become a predominant and decisive condition

for profit generation and the long-term durability for the organizations including SMEs at micro level and economy at the macro level.

Until the middle seventies, SMEs had a minor role in the debate about economic development due to the dominance of the mass production paradigm in industry. After this period, this paradigm was increasingly challenged, leading to large firms' fragmentation, unemployment growth and creation of new SMEs (ACS, 1992).

There are a number of definitions of what constitutes a small to medium enterprise (SME). Some of these definitions are based on quantitative measures such as staffing levels, turnover or assets, while others employ a qualitative approach (MacGregor and Vrazalic, 2004). Meredith (1994) suggests that any description or definition must include a quantitative component that takes into account staff levels, turnover, assets together with financial and non-financial measurements, but the description must also include a qualitative component that reflects how the business is organized and how it operates (MacGregor and Vrazalic, 2004).

There are two main findings in the literature that have implications for economic policy concerning SMEs. The first is that the nature of innovation adoption differs according to the size of the firm. The second is that clusters of small firms or industrial districts can be important for regional development (Lebre, 1998).

As Rothwell and Dodgson (1993) warn, both SMEs and large firms have advantages in innovation adoption, but these advantages differ. While large firms have material advantages, due to their greater capability to support R&D, SMEs have behavioral advantages that stem from their greater flexibility and ability to adapt to changes in the market.

A combined study of Danish, Irish and Greek SMEs carried out in the early 1990's by Neergaard (1992) concluded that there were four main reasons for the acquisition of IT by SMEs. These were increased productivity, streamlining work procedures, better client service and better record keeping (Neergaard, 1992). Fink and Tjarka (1994) described their three reasons for IT acquisition as 'doing the right thing', 'doing things right' and 'improving the bottom line' in a study of Australian executives.

The differences between SMEs and their larger counterparts are highlighted even more when their approaches to IT are considered. Khan and Khan (1992) suggest that most SMEs avoid sophisticated software and applications. This view is supported by studies carried out by Chen (1993), Cragg and King (1993), Holzinger and Hotch (1993) and DelVecchio (1994). In addition, the locations of the SMEs are also important. Gillespie et al. (1995) note that the use of IT applications can vary in different regions of a country.

Considering the rapid changes in the competitive era, the SMEs should adapt themselves with the harmony of change, and while the knowledge is assumed as the main resource of organizations especially for innovations, knowledge management is so important for SMEs to lead their efforts towards competitiveness and innovation.

SMES IN IRAN

As above discussed, until the middle seventies, SMEs had a minor role in the debate about economic development due to the dominance of the mass production paradigm in industry. After this period, this paradigm was increasingly challenged, leading to large firms' fragmentation, unemployment growth and creation of new SMEs (ACS, 1992).

Nevertheless, the most SMEs in Iran are still traditional and their school of thought is belonged to last few decades. The today's dance of changes is dictating a new model thinking as a basic requirement. The SMEs in Iran have to restructure their way of thinking which has a deeply roots in their culture. The difference between culture in east and west is under the influence of school of thought they have been growing up under. In this way, to bring a change in SMEs, firstly should be started by changing the culture and beliefs towards the changes whether is possible or not. Then, the reengineering of the processes, approaches, techniques, methodologies, etc. should be started on the base of change management program. The way the SMEs in west are behaving in the case of change, is under the influence of the techniques and thoughts commonly used in that environment. The preliminary instruments used in daily activities in SMEs in west, is a big project in the SMEs in east. For example, the topic of knowledge management commonly used in SMEs in the west as a daily routine process, if is traced in eastern SMEs, no trace or little trace can be monitored. In Iran, hardly you may find the small scale industries with the knowledge management systems. The value of any organization in today's market is based on the brain ware and intellectual capital. So, the main and important factor in bringing changes in an organization is the ability and the power of knowledge. In this way, the relationship between change paradigm and knowledge management in Iranian SMEs can be clearly discussed. That is the main concept which has been recently understood by some technologic and knowledge based SME leaders in Iran little by little. The Iranian SMEs are almost weak in knowledge management, and it necessary to be discussed in micro and macro levels to bring and ease of related change in Iranian SMEs.

KNOWLEDGE MANAGEMENT IN SMES

According to the knowledge-based view of the firm (Grant, 1996; Spender, 1996), knowledge is regarded as the most important source of competitive advantage. We are living in a knowledge society that yields high returns on knowledge resources (Drucker, 1999). In the last 10 years the number of articles on knowledge management and intellectual capital has been increasing at an average annual rate of 50 percent (Renzl et. al, 2006).

Furthermore, the importance of knowledge management is clear to many organizations and the leaders search for the main reasons and factors for being successful in knowledge management system design and implementation through their organizations (Akhavan et al, 2006).

Nowadays mature governments have also understood the importance of knowledge and management of it, so the related activities are led by top levels and ranks in those countries especially in advanced and developed countries (Akhavan and Jafari, 2006).

Furthermore, it is important to say that the main component of the knowledge-based economy is the knowledge-based organization, which presents some characteristics which clearly differentiate it from the traditional industrial company, currently prevailing at international level. The knowledge based economy becomes the crucial component (engine) of the national and international economy. The transition to the knowledge-based economy is an inevitable, extremely complex and difficult process, which generates many opportunities and threats for SMEs. These opportunities are based on some factors such as the creation and commercialization of the new products, services and technologies; the amplification and diversification of demands on local, regional, national and international markets; the externalization of an important part of the activities for the big companies, state and public institutions; the extension of home work and tele-work for the companies; the development of the organizational and technical networking structured on branches and/or territorially and so on.

Niosi and Rivard (1990) reported that 'SMEs, as niche producers with a smaller range of technologies to offer, may provide easier learning opportunities to industrial firms in developing countries'. In addition, Gomes-Casseres and Kohn (1997) concluded that the competitive advantages of smaller US firms, which derived mostly from their technological leadership, allowed them to adapt and evolve with changes in the international economy, particularly in the industrializing parts of the world.

A SME offers two advantages in initiating research on knowledge management. As Davidson and Griffin (2003) comment, small businesses have contributed many innovative ideas and technological breakthroughs to our society. Further, decisions in a SME are often enacted within a shorter time frame than in larger organizations.

As Delahaye (2005) points out, it was once held that the two most basic resources available to an organisation were money and time and that one could be exchanged for the other. Unfortunately, though, there is no simple exchange equation between money and time, on the one hand, and knowledge on the other, as knowledge has to be created, learned and maintained not simply purchased and maintained (Delahaye, 2005). Further, knowledge is the primary resource for individuals, organisations and the economy (Drucker, 1995).

RESEARCH METHODOLOGY AND DATA COLLECTION

For the research methodology, the authors implemented a structured survey. At first, the main areas of the research domain were questioned from some experts that had sophistications in SME topic and also had some academic research in related domains. After that, a questionnaire was designed based on the feedbacks taken from the experts. The content of the questions has been summarized for better readability

Table 1. The 20 questions on KM and CM

No.	Criteria
Q1	Knowledge management is positively related with organizational size
Q2	Knowledge management is positively related with organizational mission
Q3	Knowledge is tacit rather than explicit in SMEs
Q4	Knowledge sharing is done face to face rather than IT deployment in SMEs
Q5	Learning is done experimental rather than applying the documents
Q6	CEO support and commitment is positively related with KM adoption in SMEs
Q7	Learning is positively related with training in SMEs
Q8	Learning is positively related with interactive participation of employees in SMEs
Q9	Learning is positively related with CEO support and commitment in SMEs
Q10	Learning is positively related with flat structures in SMEs
Q11	The changes are necessary for KM adoption in the organization
Q12	The process are appropriate for knowledge management
Q13	There is a translucent atmosphere in the organization
Q14	Confidence about job security
Q15	Confidence about salaries and rewards
Q16	Confidence about organizational job position
Q17	The hold sessions were effective for change programs
Q18	Motivation systems are very important for change and KM adoption
Q19	The employees accompany with changes
Q20	Reach to knowledge objectives in KM area after the changes

as listed in table 1. The selected response can be strongly disagree, disagree, no opinion, agree, or strongly agree that is evaluated by a Likert Scale.

The main sampling targets were senior managers and department managers who were involved in change and knowledge efforts in the organization.

The research targets were members of 31 SMEs in Iran, specializing and working in IT, communication and electronic domain including hardware and software, electronic and communication circuit design and implementation, ICT consulting and ICT services.

The questionnaire consists of two main parts; the first part was the questions related to knowledge management analysis in organization, and the other part was due to the change factors. The questions were asked in a unit questionnaire. The KM part had asked about knowledge, learning, and their relations with some important organizational features such as organizational size, organizational mission, organizational structures, CEO support and commitment. It also asked about some crucial factors for KM adoption such as training and IT deployment in the organization.

The "change" part of questionnaire asked about change factors from different perspectives. Some questions analyzed the "resistance against the change" factor with some questions about job security, salaries and rewards, and organizational position. If the agree rate of answers in these questions are high, it shows that the change program has not been successful and in this way, we should expect vulnerability in our KM programs. The other section of questionnaire change part analyses the necessity about the changes for KM adoption in the organization. The respondents are questioned about the fitness of available processes, structures, and totally, the current situation of the organization and the necessity of the changes.

Finally, the degree of reaching to knowledge objectives has been asked from the employees in order to understand the rate of success in our programs. Table 1 summarizes the content of the 20 questions.

DISCUSSION

After the reliability test, the questionnaires were analyzed by some statistical methods as follows. With reliability analysis, you can get an overall index of the repeatability or internal consistency of the measurement scale as a whole, and you can identify problem items that should be excluded from the scale. The Cronbach's alpha is a model of internal consistency, based on the average inter-item correlation. The Cronbach's alpha (Likert & Rensis, 1974) calculated from the variables of this research was 0.928, which showed high reliability for designed measurement scale. The selected response can be strongly disagree, disagree, no opinion, agree, or strongly agree that is evaluated by a Likert Scale as discussed.

CEO support and commitment is the important and common factor of every system that should be implemented or established in the organization (Akhavan et al, 2006). The analysis also showed that this factor is so important in the selected SMEs for KM adoption. This factor is also positively related with learning in the organization, which has been confirmed by questionnaire analysis through selected SMEs. It is because we can trace a consensus as much as 89 percent on the positive rate of respondents to the related question (number 9) showing the positive relation between CEO support and learning.

It is important to say that learning itself is the main element of a learning organization, and for moving towards learning organization, the requirements should be considered. CEO support can act as an enabler for the necessities of the learning process for moving towards learning organization.

On the other hand, the analysis showed that knowledge management is positively related to organizational mission. It means that the organizations with knowledge based missions need knowledge management more. As a matter of fact, we have a lot of SMEs in Iran which are playing important roles in Iranian industries and Iranian economics as a sensitive node in Iranian industrial network. Therefore, their missions are more important and sensitive because of the role they are playing in succeeding the Iranian industrial and economical missions. For example, those who are working in information technology, ICT, electronic, computer (hardware and software), and etc. are playing more important role in development and knwledge era. Therefore, we can say that they are the SMEs with the main frame of knowledge and modern technology.

The technologic/ high-tech organizations are highly dependent to their intellectual capital rather than physical assets. As most of the SMEs in this research have been selected from technologic ones including IT firms, and communication and electronic industries, they highly agree that the more advanced and strategic mission for the organization require strong necessity for knowledge management adoption in the organization.

The statistical analysis results showed that there is no relationship between knowledge management and the size of the organization. This may be resulted because of the nature of knowledge and the necessity of its management, free from the usual organizational features. Knowledge management can be established and implemented in every part of the organization including all departments and sub departments; and even it can be considered and generalized from micro level in the organization to a macro level in a country, that can facilitates knowledge based development (Akhavan et al., 2006).

It is important to say that the nature of SMEs supports tacit knowledge rather than explicit knowledge. The analysis also showed that the selected Iranian SMEs matter to tacit knowledge rather than explicit and believe that knowledge is tacit rather than explicit in the SMEs.

Meanwhile, the selected SMEs were limited from the geographical point of view, and because of their size, the skills and experiences of employees play an important role in the organizations. Also, as the work places are near to each other, the employees prefer to share their knowledge face to face rather than applying information technology. The analysis also confirms this opinion and the respondents in the selected SMEs prefer not to use IT for knowledge sharing. The respondents also believe that learning is also done through experience sharing between the employees and not through the documents. This may be because of the lack of an integrated documentation system or because of the previous explanations about fact to face knowledge sharing.

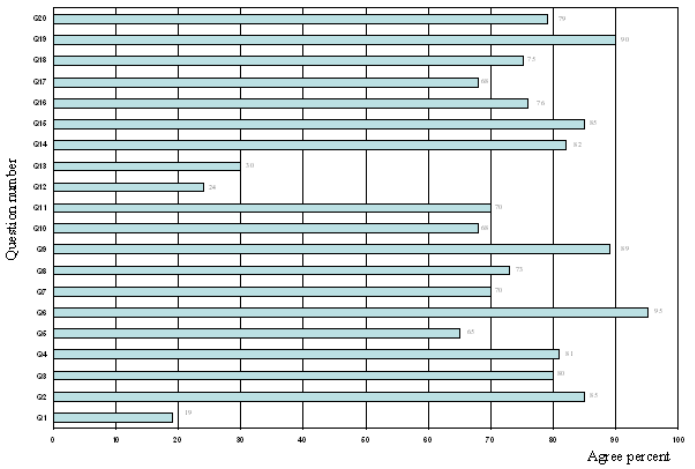
The questionnaire analysis also showed that learning is positively related with interactive participation of employees and flat structures in the SMEs. It is important to say that participation of employees in decision making process is dependent to flatness of the organization. Flat structures encourage employees to take part in decision making and management process by removing middle management layers.

The results also showed that learning is positively related with training. Training process can facilitate knowledge efforts and learning, because there are some skills that may be transferred by educations and training.

On the other hand, the results showed that the employees believe the nature of change and agree and accompany with it. It is also clear from the answers that the respondents believe that the current processes and structures of the organization are inappropriate and should be changed.

The analysis showed that motivation systems play an important role in change programs for KM adoption. The answers also showed that the change program has been successful in conquering against the important factor of "resistance against the change" because the employees were confident about relevant factors such as their job security, their salaries and rewards, and their organizational job

Figure 1. Agree percent of the questions



position. It may be because of the sessions and trainings hold for employees to get familiar with KM foundations and its benefits which helped the acceptance of change programs so much and it is also clear from the answers.

Finally the analysis showed that we have reached many of our knowledge objectives through the change program while most of the respondents were agree with it. Figure 1 shows the agree percent of answers for each question.

CONCLUSION

Nowadays, knowledge is known as a vital and the most important property of the organizations and knowledge management is playing undeniable role in existence of an organization. It gives the ability and power of competitiveness to the organizations. The most valuable thing in today's market is also knowledge and the most valuable organizations are those who can manage their valuable asset called knowledge. Having a successful knowledge management in an organization, is the result of different changes in the firm which should be managed completely.

This article enlightened the relationships between the changes which are necessary for KM adoption in the organizations and knowledge management itself in order to have a successful knowledge management in some Iranian SMEs. Furthermore, this research was designed in order to analyze change management during knowledge management adoption in those Iranian SMEs as the SMEs play an important role in the economies. We are experiencing a new kind of economy in the recent era that is known as knowledge economy which considers the knowledge as the main resource of the organization for innovation and competitiveness. Considering the SMEs as the micro element of the society and a part of macro economy, knowledge management is crucial for driving them towards sustainable competitiveness.

In this paper we explored knowledge management in some Iranian SMEs through a change program. A structured survey was designed and implemented. The findings showed that although the research was implemented in some SMEs, but the results showed that there is no relationship between organizational size and the need for knowledge management. Knowledge management can be considered as the need and requirement of an organization at any size. The results also showed that CEO support and commitment plays a vital role in knowledge management adoption and learning process. Learning itself was confirmed to be positively associated with some factors such as training, employee's participation, and flat structures.

Findings also showed that IT doesn't have an important role in knowledge management in selected Iranian SMEs. It may be resulted because of the level of IT deployment in Iran as a developing country. Although IT is being expanded widely in Iran, but it seems that the Iranian SMEs look at it as a tool for facilitating some of their works and processes and not as a strong tool and important enabler for knowledge management.

The analysis also showed that the change program has conquered against the "resistance against the change" factor and it has been successful in reaching the knowledge objectives as the respondents reached to consensus to the related questions. The answers showed that some related factors such as confidence about job security, confidence about salaries and rewards, and confidence about organizational job position reached consensus. These factors are directly showing the resistance against the change and the analysis showed that the employees are confident about them (job security, salaries and rewards, job position) which may be the result of different sessions and trainings and the motivation systems in the organization.

Healthcare Information Assurance: Identification Issues

Ludwig Slusky, California State University, Los Angeles, CA 90032; E-mail: lslusly@calstatela.edu

ABSTRACT

The paper summarizes identification issues pertaining to healthcare information assurance, including National Provider Identifier, identification in HIPAA, Electronic Medical Records, Electronic Data Interchange, and Disease Management. In conclusion, it discusses the need for further research of interlinks and dependencies among various identifiers of healthcare information to support confidentiality, integrity, and availability of a trustworthy national healthcare information system.

1. INTRODUCTION

Healthcare is a trillion-dollar industry in the United States, accounting for 14 percent of the nation's gross domestic product, with about 10 million employees sharing approximately 400 job titles. While the industry grows, it is also undergoing rapid transformation in the area of Web-based activities and increased security needs.

Healthcare providers and insurance companies amplified their Internet presence with Web-based applications such as online doctor-patient interactions, appointment scheduling, patient records administration, electronic claims, and online referral to specialists, computerized physician order-entry, dissemination of healthcare information over wireless networks to laptop computers and other devices, and many other forms of information delivery.

This paper reviews some issues of identification, de-identification, authentication, privacy and security for Healthcare Information Assurance and their application to a trustworthy national healthcare information system.

2. HIPAA

The Health Insurance Portability and Accountability Act (HIPAA), passed by Congress in 1996, recognizing the need for privacy and security protection of healthcare information, set national standards for identifiable Protected Health Information (**PHI).** It requires all health plans, healthcare clearinghouses, and healthcare providers that operate with PHI to comply with HIPAA's Privacy Rule and Security Rule.

2.1 HIPAA Components and Regulations

PHI is characterized as the following:

- It describes past, present, or future physical or mental health, or condition of an individual; or
- It describes a provision of health care to an individual; or
- It describes a payment for the provision of health care to an individual; or
- It identifies or provides a reasonable basis to believe it can be used to identify an individual.

Three main components of HIPAA are:

- Privacy of patients' PHI with national standards (The Privacy Rule),
- Security of electronic transactions with patients' PHI (The Security Rule), and
- Transactions and code set standards (for claims, enrollment, eligibility, payment, coordination of benefits, etc)

The Privacy Rule implemented on April 14, 2003 has privacy provisions applicable "to health information created or maintained by health care providers who engage in certain electronic transactions, health plans, and health care clearinghouses." [HSS 2006] It protects confidentiality of the individual's PHI when this PHI is used or disclosed in any form—paper, oral, electronic. HIPAA privacy and security regulations enforce accountability and apply to healthcare providers and to anyone who provides financial, legal, business, or administrative support to health care providers or health plans.

HIPAA privacy and security regulations enforce accountability and apply to healthcare providers and to anyone who provides financial, legal, business, or administrative support to health care providers or health plans.

HIPAA Transaction and Codes Sets regulations require that transmission of all healthcare data electronically be based on standard transactions, code sets, and identifiers. Thus, for Electronic Data Interchange (EDI), HIPAA has identified ten standard transactions (e.g., claims and encounter information, payment and remittance advice, and claims status and inquiry) and the code sets to be used in those transactions.

The four categories of code sets for claims are: pharmacy code set (from National Council for Prescription Drug Programs) and dental, professional, and healthcare institutional code sets (all three from Washington Publishing Company)

HIPAA regulations are based on the following Key Concepts:

- *Principle-based*. Complying with a series of security best practices and principles.
- *Reasonableness*. Mitigating all reasonably-anticipated risks by balancing resources and business requirements against the risks.
- *Full compliance.* Having workforce members of the covered entity in compliance with the regulations.
- *Documentation*. Having security processes, policies, and procedures approved and documented.
- *Ongoing compliance.* Revising security policies and procedures as needed, providing regular security training, and building awareness of the workforce.

2.2 HIPAA Security Rule

The HIPAA Security Rule established "national standards for the security of electronic health care information… This final rule specifies a series of administrative, technical, and physical security procedures for covered entities to use to assure the confidentiality of electronic protected health information." [Security 2003]

It specifies administrative, technical, and physical security procedures for covered entities to assure the confidentiality of "all electronic protected health information the covered entity creates, receives, maintains, or transmits." [Security 2003] It requires that each covered entity engaged in the electronic maintenance or transmission of identifiable health information pertaining to individuals assesses potential risks and vulnerabilities to electronically maintained or transmitted healthcare information and develop, implement, and maintain appropriate security measures to protect that information. [HSS 2006]

While HIPAA Privacy Rule applies to all PHI, the HIPAA Security Rule applies only to the **electronically maintained** or **transmitted** subset of PHI (ePHI).

Three basic categories of security mechanisms are: administrative procedures, physical safeguards, and technical security mechanisms. In addition, the security solutions must provide protection against the following:

- any reasonably anticipated threats or hazards to the security or integrity of such information;
- any reasonably anticipated uses or disclosures of such information that are not permitted or required by the Privacy Rule

Other important components of Healthcare information Systems that need protection are Electronic Medical Records EMR (also called electronic Health Records) and National Provider Identifiers (NPI).

Identification, de-identification, and authentication are common security concerns for various healthcare applications. They are addressed within the scope of the HIPAA Security Rule.

2.3 Implementation of HIPAA Privacy and Security Rules

A Privacy and Security Office in charge of consistent HIPAA compliance is responsible for Risk Analysis and Evaluation, as well as reporting of suspected security incidents and incident handling, including documentation, determination of notification requirements, remediation, and reporting to management. Overall, the HIPAA security standard requires comprehensiveness in terms of all aspects of security; scalability; and technological neutrality. Therefore, HIPAA Security Rule implementation must follow the guiding principles listed below:

- *Scalability.* All sizes of covered entities must comply with the rule, from the one-person doctor office to the insurance company with thousands of employees.
- *Comprehensiveness.* Principle of "defense in depth" as a unified security approach
- *Technology neutral.* No requirement for specific security technology (firewall or IDS) making selection a provider's choice.
- *Internal and external security threats* protection. Must protect ePHI against both internal and external threats.
- *Risk analysis*. Must regularly conduct thorough and accurate risk analysis.

Security Rule protecting identifiable PHI makes distinction between ''required'' and ''addressable'' specifications. Required implementation specifications are mandatory and must be met. Addressable specifications, depending on the specifics of the covered entity environment (size, capability, risk), are implemented as follows: if the covered entity determines that a given addressable specification is a reasonable and appropriate safeguard in its environment, it must implement the specification; otherwise, the covered entity may implement another equivalent measure or choose to not implement or substitute it at all if the standard can be met in some other way but to the same end result. [Security 2003]

Required implementation specifications are listed in Table 1.

Examples of addressable implementation specifications include Workforce Security with Clearance Procedure; Facility Access Control with Access Control and Validation Procedures; Access Control with Encryption and Decryption.

Table 1. HIPAA security rule "required" specifications

Standards	***Implementation of Required Specifications***
Administrative Safeguards	
Security Management Process	Risk Analysis
	Risk Management
	Sanction Policy
	Information System Activity Review
Information Access Management	Isolating Health Care Clearinghouse Functions
Security Incident Procedures	Response and Reporting
Contingency Plan	Data Backup Plan
	Disaster Recovery Plan
	Emergency Mode Operation Plan
Business Associate Contracts and Other Arrangements	Written Contract or Other Arrangement
Physical Safeguards	
Device and Media Controls	Disposal
	Media Re-use
Technical Safeguards	
Access Control	Unique User Identification
	Emergency Access Procedure

3. ELECTRONIC MEDICAL RECORDS (EMR)

"The EMR is the core component around which the totality of clinical care IT progress will necessarily revolve." [Hagland 2006]

Identification and authentication of Medical Records Information, i.e., assuring a reliable match of EMRs with patients, involves complex technical and social issues for potentially over 300 million EMRs accessible through a national health information network. It should be based on a technology-assisted authentication of the patient and an EMR compiled from multiple sources (and locations). However, such technological solution is likely to lead to a number of false-positive record authentications for a particular patient and, consequently, may result in significant health harm. Another problematic situation is authentication under accident or severe disability constraints: the patient may be unconscious or unable to communicate. Whatever the solution is it must strengthen portable EMRs and measures of their safety.

3.1 Identification of EMR

EMR Identity Management with the network-wide patient identifier helps to alleviate these problems and to integrate and exchange the patient's clinical and administrative information dynamically within a Healthcare Information Network (HIN), which may include hospitals, primary care physician, specialists, ambulatory care centers, etc.

The scope of the EMR is characterized by vastly different dimensions, such as the following:

- Continuum of care such as preventive, acute, post-acute, sub-acute chronic, long-term care, community and home care.
- Local needs and practice patterns that vary significantly in the information and functionality across the entire country.
- Clinical specialties such as emergency care, laboratory, radiology, pharmacy, intensive care, medical and surgical services, etc.
- Industry sectors such as hospitals, physicians and other clinicians, payers, community and social service organizations, government/public health, and even life science companies.

This inconsistency in data categories is further complicated by a patient's history, which may span many **legacy identifiers**. Thus, information can be sourced from multiple databases that were established over a long period of time. It may also include SSN, driver's license, individual hospital account and medical record numbers, lab system identifiers, pharmacy system identifiers, that had been changed or not valid any longer.

The solution to such disparity of identifying data is a cross-reference repository of identifiers across all systems, such as EMPI - Enterprise Master Person Index, which evolved from the previous hospital master patient index.

An Enterprise Master Patient Index (EMPI) can be described as a database that contains a unique identifier for every patient in the enterprise (including medical centers, clinics, practice offices, etc.) and provides a cross-reference for all systems, data records and applications throughout the healthcare information network. All registration systems would look to the EMPI to obtain patient information based upon several defined identifiers.

An EMPI will have either the deterministic indexing where one can search based on an exact match of the identifying aggregate data (e.g., combination of name, SSN, date of birth, sex) or the probabilistic searching mechanism based on truncated search data (e.g., truncated last name). A widely known example of it is a search using Soundex formula, which indexes names by their sound when pronounced in English so that matching can occur despite minor differences in spelling. Algorithm for Soundex formula are implemented in various computer languages, including Visual Basic. [Gillham 2001]

Implementation of an EMPI depends on the system architecture and may require conversion of the IT systems or a merge of the medical records. There are two types of patient/record identification: passive identification based on the existing patient's ID document (one factor identification and authentication) and active identification using the EMPI data and algorithms.

Development of EMR is progressing in the USA and in other countries. In the USA, there are plans to develop portable EMRs for every individual. However, a maze of EMR ownership and frequent incompatibility of technical, procedural and clinical requirements are hindering integration of EMRs. Thus, EMR systems are often lacking interoperability, offered on a variety of hardware and software platforms. Their approach and design are not consistent and they have no uniformity in interfaces, vocabularies, coding systems.

The key integration issues of EMRs lay in three areas: identification, authentication, and access control within the entire healthcare delivery chain; network security; and stakeholder commitment.

3.2 De-identification of EMR

One important approach for sharing patient publicly while protecting its privacy is de-identifying healthcare records. De-identified healthcare information (e.g., aggregate statistical data or data stripped of individual identifiers) requires no individual privacy protections and is not covered by the Privacy Rule.

New approaches for data de-identification have emerged to improve quality of research while protecting privacy. Among them, the following two methods of de-identification of PHI are most common:

- Statistical de-identification is performed by a qualified statistician who using accepted analytic techniques concludes that the risk of identification is substantially limited, i.e. that the information used alone or in combination with other reasonably available information is unlikely to identify the subject of the information.
- "Safe-harbor" de-identification method allows a covered entity or its business associate to de-identify information by removing specific PHI identifiers.

Researchers indicate that only 30-60% of all personally-identifying information can be found using the straightforward approach of global searching by the patient's name and replacing all occurrences with a pseudo name. Identifying information is often hidden in other correlated data and in the written free-form notes and letters exchanged among doctors. Other techniques yield to much better results to minimize risk to patient confidentiality. [Sweeney 1996]

For example, Scrub system uses multiple detection algorithms executed in parallel to label contiguous characters of text. Each detection algorithm is designed to recognize only one specific entity (e.g., name or address or date, etc.)

These detection algorithms are employed in a way similar to speech recognition: they use local knowledge sources (e.g., area codes, first names, medical terms) to determine whether searched words "sound" like identifiers (e.g.., medical terms, names). Then, the algorithm with the highest precedence and the greatest certainty above a minimal threshold prevails and its results may be made available for future use. [Sweeney 1996]

The accuracy of this technique is relatively high:

- 100% for well-defined references in the upper-lower case counterparts or numerical codes (such as names, addresses, organizations, cities, states, zip codes and phone numbers); however, this accuracy drops down to 94% when such reference is presented in all upper case letter configuration.
- 99% for more obscure references (such as nick names, abbreviations, ID numbers)
- 95% for references not distinguished by upper-lower case (95%)

HIPAA "Safe Harbor" de-identification of EMR requires that each of the 18 identifiers of the individual or relatives, employers, or household members of the individual must be removed from medical record information in order for the records to be considered de-identified. Examples of such identifiers include names, address, all elements of dates (except year), phone, email, Account numbers, biometric identifiers, and others.

"Safe harbor" de-identification may include the assignment of re-identification codes to the de-identified healthcare record information. These re-identification codes must be securely managed to prevent unauthorized access to information linking these codes with corresponding PHI.

4. NATIONAL PROVIDER IDENTIFIER (NPI)

In addition to the EMR identification, HIPAA requires standard unique identifiers for health care providers, as well as for health plans. National Provider Identifier (NPI), due for compliance by May 23, 2007 for large health plans and a year later for small plans, is the standard unique health identifier assigned to health care providers and an important component of Healthcare Information Assurance. NPI's 10-position number has a 9-position unique identifier plus one position for the check-digit data validation. It is intelligence-free, i.e., does not itself convey information about the provider, and it is compatible with health insurance card issuer standard.

All health care providers are eligible to receive an NPI, but only entities covered by HIPAA are required to use the NPI when submitting and processing electronic transactions. (For example, x-ray technicians and dental hygienists may apply for an NPI but are not required to have an NPI.)

Provider types affected by NPI requirements are legal entities characterized as entity type 1 or entity type 2:

- entity type 1 - individuals (e.g., physicians, dentists, nurses, pharmacists, and physical therapists),
- entity type 2 - organization health care providers and suppliers (e.g., hospitals, ambulatory care facilities, laboratories, HMOs, group practices, suppliers of durable medical equipment, pharmacies, etc.

Additionally, an organization may designate subparts of a covered organization healthcare (like departments, divisions), which are not legal entities themselves but need to be uniquely identified in standard transactions with their own NPIs (that does not apply to individuals). [NPI 2006]

The NPI is to replace all "legacy" identifiers that are currently used, such as Provider Identification Numbers (PINs), National Supplier Clearinghouse (NSC) numbers, Unique Physician Identification Numbers (UPINs), etc. It is also permitted to be used for other lawful non-HIPAA transactions and identification.

The Centers for Medicare & Medicaid Services (CMS) developed the National Plan and Provider Enumeration System (NPPES) to assign NPIs. The NPPES is designed to accept health care provider data (including those who do not participate in Medicare) for unique identification and assigning an NPI. The NPPES performs three required functions: (a) assign a single, unique NPI to health care provider; (b) collect/maintain information about health care providers; and (c) reactivate or deactivate NPIs. It also disseminates NPPES information. [NPPES 2006]

5. ELECTRONIC DATA INTERCHANGE (EDI) AND X12 STANDARD

Electronic Data Interchange (EDI), a fundamental component of the healthcare information network, is the computer-to-computer exchange of business data in standard formats (for example, Purchase Orders, Invoices, Shipment Notices, Health Care Claims). The data is structured by patient's identifier, transaction type, and code sets.

The X12 standard commonly used in healthcare networks defines data structure for electronically exchanged documents using 315 or more EDI transaction sets. The documents are organized as data separated by "delimiter" characters (not as fixed length fields) and include: Transaction Sets consisting of delimited data; Functional Groups consisting of related Transaction Sets; and Interchange wrapping Functional Groups. X12 standard does not define a transmission type.

A new Context Inspired Component Architecture (CICA) standard - the XML equivalent of the current X12 standard - enables XML-built business documents in a cross industry setting. The large-scale structure of this architecture has seven discrete levels of granularity - each level builds on the levels below it: from DOCUMENT level to PRIMITIVE level. CICA helps to facilitate a common reusable vocabulary across multiple industries and creates an environment for convergence with other standards of organizations, industry associations or data content committees. [CICA 2002]

6. IDENTIFICATION IN DISEASE MANAGEMENT (DM)

Disease Management (DM) is another area of healthcare information where patient identification is required.

DM has its own specificity in implementation of three tenets of information security: confidentiality, integrity, and availability. The major application processes of DM systems that require security protection are analytic systems, predictive modeling, stratification algorithms. They are at the core of DM and require full confidentiality, integrity, and availability protection. *Analytic systems* integrate data from several sources and provide early identification of members needing services. *Predictive modeling* of medical and pharmacy data (with automated health risk assessment tools and electronic clinical laboratory results) helps to identify high risk members. *Stratification algorithms* are designed to provide informational guidance to a nurse about health status and an acuity level of a patient. [Johnson 2004]

Three components of technological platform for healthcare systems deserve special attention: Web-based applications and data banks, email, and online biometric devices. Web-based healthcare information systems with online data banks for diagnostics, care progress tracking tools, and health care alerts delivered to a portable device are utilized by clinical practitioners more than ever. This information is often integrated into email or other communication systems that need to be protected. It should be noted that biometric devices coupled with communication mechanisms, which provide consistent collection of clinical information, automated transmission of results, and tracking of findings, have inherent information security vulnerabilities. [Johnson 2004]

7. TRUSTWORTHY HEALTHCARE INFORMATION SYSTEM (THIN)

The ultimate goal of IT development at healthcare organizations is building a trustworthy nationwide healthcare information system. The identifiers used for identification, de-identification, and authentication need to be interlinked to support Access Control with confidentiality, integrity, and availability of healthcare information.

The ultimate goal of IT development at healthcare organizations is building trustworthy healthcare information systems to meet the requirements of confidentiality, integrity, and availability specific to healthcare industry.

The information and processes to be protected are diverse in context, workforce preparedness, applications, geography, and technological platforms. Identification, de-identification, and authentication of protected patient information (PHI), medical records (EMR), and providers (NPI) in all kinds of healthcare systems are important for assuring *confidentiality* of information and are addressed in HIPAA's Privacy and Security Rules.

Integrity, i.e. protection from intentional or accidental unauthorized changes, and *availability* are obviously vital requirements for healthcare information and processes. Among two threats to availability of the healthcare information and processes – (a) human actions or natural disasters and (b) network intrusions like denial-of-service – the first threat is more likely to occur than the second one. All three types of control mechanisms – administrative (e.g., access control policies, operating procedures, contingency planning), physical (e.g., off-site backup storage), and technical (e.g., fault-tolerance mechanisms) – play important roles in assuring availability.

The priorities for implementation of confidentiality, integrity and availability (and, consequently, the use of identifiers) may differ from one application to another. For example, in EMR systems confidentiality is clearly a priority, while in DM systems integrity and availability could be of the same or higher concern as confidentiality.

Identification plays a particularly important role in DM applications where risks are characterized by higher single loss expectancy and interlinks to affected members of population are vital (particularly where mass health disaster may occur).

Database vulnerabilities and threats can sufficiently be enforced with common DBMS controls. Although discretionary access controls are prevalent in current healthcare systems, for large systems the preference should be given to the mandatory (policy based) or role-based access controls (with established sensitivity of data and appropriate protection mechanisms).

Use of portable devices, removable media, and email is a common practice in healthcare networks and as such may also have many vulnerabilities. Identification of these devices may also be required to support a high level confidentiality.

EDI exchanging information among various entities is a centerpiece of many healthcare systems. The standard transactions for healthcare systems include identifiers and are covered by HIPAA Transaction and Codes Sets regulations.

8. FUTURE WORK

Integration of various healthcare systems will further complicate issues of identification, de-identification and authentication. Future research will address interlinks and dependencies among various identifiers of healthcare information for modeling a trustworthy nationwide healthcare information system.

9. CONCLUSION

Identification and de-identification play an important role in authentication and security of healthcare information. Recently enacted regulations, while satisfying the needs of relevant systems, do not go far enough in viewing and defining various types of healthcare identifiers in an integrated manner. Model for trustworthy nationwide integrated healthcare systems will have to incorporate critical identifiers and the relationships among them to satisfy requirements of integrated healthcare information assurance.

Is Optional Web-Based Seminar an Effective Way of Learning as a Part of Information Management and Information Systems Development Course?

Pekka Makkonen, University of Jyväskylä, Finland; E-mail: pmakkone@jyu.fi

ABSTRACT

This paper describes the use of the web as a complementary addition to conventional lectures in the learning of the basic concepts of information management and information systems development. We utilize conventional lecture material, search engines on the web, and the Optima learning environment. The solution enables a web-based seminar supporting learning in various ways. First, in our approach the students compose a coursework report focusing on the main concepts of the subject area. This occurs by using lecture handouts and search engines on the web. Second, in the web-based seminar students can familiarize themselves with the coursework reports of other students. We claim that in this way learning can be promoted in the spirit of both cognitive and social constructivism. During the coursework and while in the seminar the students worked in small groups of two to four students or they completed the coursework as an individual task. In the web-based seminar the students had a workspace in the Optima environment for publishing their coursework presentations. At the final phase of the course the students were expected to familiarize themselves with the presentations of other groups. In this paper we analyze the benefit of our WWW-based seminar based on the goals of the course. At the beginning and end of the course the students were expected to analyze their own knowledge of the themes of our course. These themes were: (1) administrative view to information resources management, (2) technological view to information resources management, (3) building information systems, and (4) organizational applications. In addition, the students were expected to analyze how they experienced the coursework. The study found out that the WWW-supported coursework and seminar have a neutral effect on learning different themes of the course in most cases. However, the students of IT faculty benefited more from the web-based coursework in the learning of topics 1 and 3. We also found that the Optima-based coursework suits a little bit better for younger students, males and the students of information technology and it may be more effective as an individual task.

Keywords: Learning of information systems, web-based learning environment, constructivist learning.

INTRODUCTION

In a traditional classroom, learning occurs in the behaviorist manner (behaviorism). The traditional classroom puts a learner in the position of an object of assessment: an instructor initiates, a learner responds, and the instructor then closes the sequence by either accepting or rejecting the learners' turn (Sinclair & Coulthard, 1975). The constructivist learning approach (constructivism) contrasts to the behaviorist approach. From the perspective of these learning approaches, the last decade has been the time of constructivism even at the university level.

Traditional lecture-based teaching is problematic in many ways (Isaacs, 1994 & Rosenthal, 1995). Problems associated with this type of teaching include ineffectiveness, passiveness, and alienation of students. In the context of technology and related sciences, some revisions have been suggested to improve lecturing as a teaching method by activating students using, for example, co-operative learning in small groups and essay-writing assignments about technical topics (Isaacs, 1994). From this perspective lecturing is not without potential if the previously mentioned problems can be corrected, but other learning methods must also be considered.

In the constructivist approach learning is comprehended as the development of mental models. Brandt (1997) emphasizes that constructivism is an essential basis when applying the WWW for teaching and learning. It provides the teacher with a structure for teaching. By focusing on concepts and connecting them to mental models, teachers can gain both confidence and control over the amount of material they cover in the small blocks of time usually allotted to teaching and training. Integrated with experiences that learners use to alter and strengthen mental models, the constructivist approach to teaching information retrieval also gives users the structure needed to get the most out of the Internet.

Based on the aforementioned we suggest a coursework focusing on the main concepts of the learning area. First in this coursework, students need to report what they learned from a lecture handout and give some examples of learning. Second, the students need to search area-related information on the web and give some examples of learning. In this way the students can focus on the main concepts and enrich their learning in a constructivist way.

In the spirit of the social constructivist learning theory for improving the benefits of our web-supported coursework we suggest the use of a virtual learning environment (Optima) and its shared workspace feature. This occurs by publishing and presenting seminar work; by commenting on seminar works created by other students (or groups) and by reading comments expressed by other students.

This paper introduces our approach to carry out a web-supported coursework and seminar. Additionally, it provides the analysis of it focusing on the success of our coursework and seminar from the perspective of the goals of the course. This occurs by comparing the ratings of the students who completed the web-supported coursework to the ratings of the students who did not participate in this coursework.

Our analysis has many goals. We want to know

- how the students' knowledge of different themes was improved,
- how the students experienced the coursework methods, and
- whether age, group size, a gender and a faculty affected the effectiveness of the learning of different themes.

Before discussing the study itself, we first provide an overview of constructivism and the WWW in learning from the perspective of our study.

CONSTRUCTIVISM

Widely known and discussed views associated with (computer-supported) learning include behaviorism and its opposite, constructivism. Behaviorism is interested in a student's behavior (reactions) in relation to teaching (stimulus) while constructivism is interested in the mental processes which affect the behavior of a student (Risku, 1996). A traditional lecture is mainly based on the behaviorist approach while coursework and projects are typical constructivist learning. Most web-based instruction today is based on behaviorism (Morphew, 2002).

Jonassen (1994) summarizes what he refers to as "the implications of constructivism for instructional design". The following principles illustrate how knowledge construction can be facilitated by:

- providing multiple representations of reality,
- representing the natural complexity of the real world,
- focusing on knowledge construction, not reproduction,
- presenting authentic tasks (contextualizing rather than abstracting instruction),
- providing real-world, case-based learning environments, rather than predetermined instructional sequences,
- fostering reflective practice,
- enabling context-and content dependent knowledge construction, and
- supporting collaborative construction of knowledge through social negotiation.

According to Brandt (1997), constructivism asserts that learners construct knowledge by making sense of experiences in terms of what is already known. In constructivist learning the concept of a mental model is essential. Learning is comprehended as the development of a learner's mental models (or a student's knowledge structures). Brandt (1997) emphasizes that constructivism is an essential basis when applying the WWW for teaching and learning. While the goal of constructivism is to recognize and help to facilitate a learner's ability to construct knowledge when applied to teaching information retrieval on the Internet, it also provides the teacher with a structure for teaching. By focusing on concepts and connecting them to mental models, instructors and teachers can gain both confidence and control over the amount of material they cover in the small blocks of time usually allotted to teaching and training. Integrated with experiences that learners use to alter and strengthen mental models, the constructivist approach to teaching information retrieval also gives users the structure needed to get the most out of the Internet.

Despite the promise of constructivism several researchers emphasize the importance of guidance. For example, Silverman (1995) points out that by providing the right amount of traditional instruction, students seem to favor constructivist environments. Additionally, he suggests different tools (e.g. a multimedia authoring environment, better communication media, and easily integrated microworld simulators) to support lessons based on the constructivist approach.

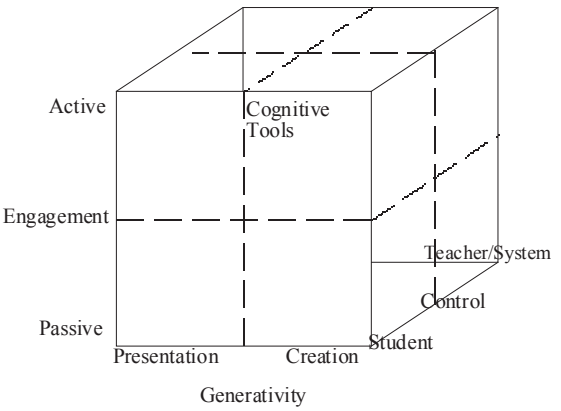
THE WWW IN LEARNING IN OUR CONTEXT

Vast information resources are available to teachers and students via the WWW. However, the problems inherent in any information system such as disorientation, navigation inefficiency and cognitive overload are multiplied on the Internet (Brandt, 1997). On the other hand, these problems can be overcome using a suitable pedagogical approach and/or appropriate tools.

In the case of coursework one approach may be by seeing Internet tools as cognitive tools, in other words, tools for knowledge construction. A cognitive tool is a term introduced by Jonassen in his discussion of hypermedia tools (Jonassen, 1992). He claims that cognitive tools actively engage learners in the creation of knowledge that reflects their comprehension and conception of the information rather than focusing on the presentation of objective knowledge. These tools are learner controlled, not teacher or technology driven. The use of a cognitive tool changes the role of the student into that of an active learner. Figure 1 shows cognitive tools in the general three-dimensional framework for computer-based learning. (Jonassen, 1992). These dimensions are generativity, control, and engagement.

In the same way, web-based tools, like Optima, can be seen in an active context. The students can use Optima and its presentation feature for introducing their ideas, receiving feedback, and managing coursework. This leads to learning by constructing knowledge based on both a student's own ideas and other students' ideas.

Figure 1. Cognitive tools in the general framework of computer-based learning



In the case of a web-based seminar it is useful to discuss the use of the WWW from the perspective of media research. Haythornthwaite (2001) stresses the interpersonal ties that affect the character of web-based communication. According to her, strong ties between students improve web-based communication: based on this we claim that traditional teaching and learning are needed as a part of a course. The traditional parts of a course develop these ties in the way that is not possible in a totally virtual training setting. In this way we can create contexts in which effective WWW-based learning is possible.

Based on the above, it is important to appreciate these views of learning while outlining courses and to understand the use of the WWW in learning. We stress the following three issues. First, we must discuss what the right amount of traditional (behaviorist) teaching should be. Second, we must analyze what is the right way to use the WWW. Active learning must be promoted and situations conducive for successful web-based learning must be created. Third, scaffolding support is needed to support constructivist learning based on the WWW. We claim that after the introductory course level many courses of information systems science can be built on the constructivist approach of learning. This occurs based on coursework that works as the core of the course.

METHODS

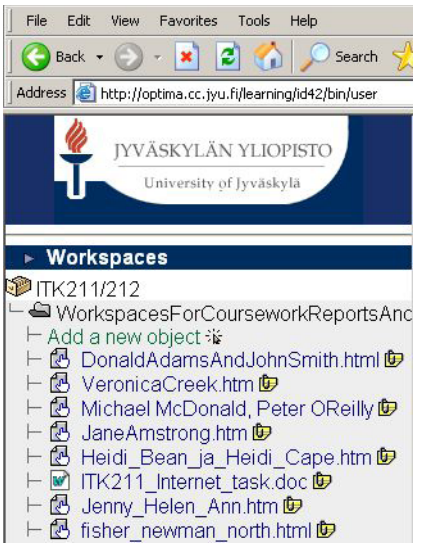
We pursued the study, including a WWW-supported coursework, using the Optima environment. In this section we describe our experiment, sample, and results.

Experiment

At the University of Jyväskylä, the themes of the course Information management and information systems development are (1) administrative view to information resources management, (2) technological view to information resources management, (3) building information systems, and (4) organizational applications. The course was inspired by a textbook, Information Technology for Management: Transforming Business in the Digital Economy (Turban et al., 2002). The course usually lasts for seven weeks including lectures (36 hours), coursework (feasibility study) as well as the final exam. The course given in fall 2004 also lasted for this length of time and included the above-mentioned activities and in addition material and activities on the WWW to support the lectures in the constructivist fashion.

To realize the benefit of the lecture notes we organized a coursework in which students were expected to enter their findings in their diaries. Before this the students were expected to familiarize themselves with the lecture handout of the course (128 pages) and try to find more information from the web to understand the possible difficult matters in our material. The students needed to report what (a) they learned based on the lecture handout, and (b) what useful links they found by using search engines and directories. Additionally, the students were expected to give various examples (for example www links) of what they had learned during the coursework. To promote the students' participation in the optional coursework, the students got credits by completing the coursework for the final examination. Although the coursework is a constructivist part of the course, the

Figure 2. Screenshot from students' workspace of web-supported coursework



teacher's office hours were available as an additional resource to promote their work. The students had six and a half weeks for the coursework before the final examination. The work was expected to be conducted as an individual task or in groups of two or three students.

The groups placed the presentations in the web-based workspace on the Optima web-based learning environment. Other groups were expected to familiarize themselves with these presentations. All the groups had permission to upload files to this workspace. Additionally, it was possible to attach comments regarding any work of other groups on this workspace. For authoring the coursework, the groups had six weeks. After these six weeks the groups were expected to comment on at three other coursework presentations. These comments were placed in the Optima workspace. The students had one week for this. In the comments the students were expected to clarify what they learned by reading a coursework report given by others.

Figure 2 shows the first view of students' workspace on Optima. With the help of this outlook the students had a possibility to upload and see files, and comment on the presentations created by other groups. By clicking a yellow button after the filename of a presentation the students were able to comment on the reports by other groups.

Sample

Forty-five students, 14 females and 31 males, whose mean age was 24 years (range 18-39 years), participated in the experimental group including the web-based seminar. 6 students studied informatics as a minor and 39 students as a major. 40% of them completed the coursework individually, 11.1% in groups of two students, 40% in groups of three students, and 8.9% in groups of four students. We call this group the WWW group in this paper.

Forty-six additional students, 10 females and 36 males, whose mean age was 23 years (range 17-46 years), were involved in the control group. 13 students studied informatics as a minor and 33 students as a major. We call this group the non-WWW group in this paper.

All the students had been initiated into the use of a PC and a WWW browser, and all of them were familiar with university lecturing. The pre-questionnaire conducted at the beginning of the course showed that the students both in the experimental group and the control group were at the same level concerning the main topics of the course: (1) administrative view to information resources management, (2) technological view to information resources management, (3) building information systems, and (4) organizational applications.

Collecting Data

The data for this study was collected by administering a questionnaire both at the beginning and the end of the course. The respondents rated the personal competence level of four main topics with regard to how excellent they considered the knowledge of each topic (where 1=very poor and 5=very good). Additionally, the respondents rated how beneficial they considered the coursework of the course (where 1=very useless and 5=very useful).

Results

How students' knowledge was improved

Since the data based on the responses of the students concerning the goals of the course agreed with the normal distribution, the one-way ANOVA test was appropriate for the analysis of the data. Concerning knowledge to learn different themes, and according to the one-way ANOVA test, the study found that the WWW-based coursework was equally useful in the learning in most cases. The statistical analysis did not show any difference between the groups except for the learning of building information systems. The details of the analysis concerning skills are shown in table 1. For this analysis the students were expected to analyze their skills based on a 5-point Likert scale in the questionnaires.

How students experienced coursework in general

Table 2 shows the students of the WWW-group ratings on the coursework and seminar in general. The students were expected to rate how they experienced the coursework generally. The result shows that their attitude is mainly positive in both groups concerning the coursework generally.

Evaluating the effect of age, group size, gender and faculty

In order to clarify whether age affects the learning of different themes, the Pearson correlation coefficients were calculated. Based on the correlations younger students appear to benefit from the web-supported coursework and the use of the Optima tool. Table 3 shows the details of our analysis in the non-WWW group and table 4 (see next page) in the WWW group.

Table 1. Analyzing the students' knowledge of different themes

	Mean at the beginning of the course			Mean at the end of the course		
	Non-WWW group	WWW group	P	Non-WWW group	WWW group	p
Administrative view to information resources management	2.46	2.53	.141	3.23	3.48	.070
Technological view to information resources management	2.39	2.47	.117	3.26	3.40	.435
Building information systems	2.44	2.33	.294	3.30	3.73	.004
Organizational applications	2.31	2.23	.156	2.83	3.00	.309

Table 2. Students' attitude concerning coursework generally

n	44
Mean	4.02
Very insignificant	0
Insignificant	2
Moderately significant	2
Significant	33
Very significant	7

Table 3. Analyzing ratings based on age in non-WWW group

At the beginning of the course	Administrative view to information resources management	Technological view to information resources management	Building information systems	Organizational applications
Correlation Coefficient	.188	.355	.379	.191
p	.210	.016	.010	.210
At the end of the course				
Correlation Coefficient	.280	.097	.224	.112
p	.059	.521	.134	.457

Table 4. Analyzing ratings based on age in WWW group

At the beginning of the course	Administrative view to information resources management	Technological view to information resources management	Building information systems	Organizational applications
Correlation Coefficient	.396	.412	.297	.438
p	.007	.005	.048	.003
At the end of the course				
Correlation Coefficient	.382	.285	.011	.315
p	.010	.058	.944	.035

By analyzing ratings based on group size we found that group size does not affect the learning of most themes. The one-way ANOVA test did not show significant differences in the ratings between the students who completed the individual course work (n=18) and the students who did the coursework in the groups (n= 24) at beginning of the course (p varying from .121 to .147). On the other hand, at the end of course we found the significant difference (p=.045) between the WWW-group and the non-WWW group concerning the learning of the building information systems theme. The learning of this theme worked better as an individual task.

The analysis of ratings based on gender shows that the gender affects the perceived benefit of any topic to learn ((1) administrative view to information resources management, (2) technological view to information resources management, (3) building information systems, and (4) organizational applications). By analyzing the ratings of females we found that the web-supported coursework does not affect the learning of most themes. The one-way ANOVA test did not show significant differences in the ratings between the female students both at the beginning and end of the course (p varying from .165 to .695). On the other hand, we found by comparing the ratings of males that web-supported coursework is beneficial for them. The one-way ANOVA showed no significant difference concerning ratings between the male students of the WWW-group and the male students of the Non-WWW-group (p varying from .145 to .907) at the beginning of the course. At the end of the course there was a significant difference between the groups concerning topic 1 (p=.022) and topic 3 (p=.009). These themes were better learned in the WWW-group.

Finally, we compared the ratings of the students of the faculty of information technology to the ratings of the students of other faculties (including open university, economics, humanities, and natural sciences). The analysis of ratings by using the one-way ANOVA test shows that the faculty usually affects equally the perceived benefit of the studied features ((1) administrative view to information resources management, (2) technological view to information resources management, (3) building information systems, and (4) organizational applications) in the coursework. At the beginning of the course the statistical analysis did not show the difference between the groups in any faculty. However, the analysis shows that the students of IT benefit more from the web-based arrangements in the learning of administrative view to information resources management (mean of the WWW group of IT faculty students is 3.40 and p=.029, mean of the non-IT faculty students is 3.21 and p=.255) and building information systems (mean of the WWW group of IT faculty students is 3.61 and p=.003, mean of the non-IT faculty students is 3.15 and p=.976).

DISCUSSION

In this paper we analyzed a web-supported coursework focusing on the effect on the topics to learn. The results show that a web-based coursework including a seminar is a potential way to organize a coursework if we have a crowded course. The results are promising because most teachers appreciate the cost-effectiveness of web-based education (Morphew, 2002). Our comparison shows that the Optima-based coursework suits a little bit better for younger students, males and the students of information technology, and it may be more effective as an individual task. The Optima-based coursework suits better for the students of the IT faculty in the learning of administrative view to information resources management and building information systems.

Our results show that the students´ attitude concerning web-supported coursework was positive. This could be the basis for the next step of our research. As mentioned the constructivist approach of learning is divided into two schools. In our approach the first phase, creating a coursework report, represents the cognitive constructivist approach of learning. In this phase the main focus of learning is concepts. In contrast to this, the second phase, participating in a web-based seminar, represents the social constructivist approach of learning. The key point here is interaction and brainstorming through the web in this phase. Based on this it is fruitful to compare the attitudes of the students concerning the first and second phase of the web-supported coursework. The phases present different sides of constructivism.

Nevertheless, this paper demonstrates that a successful seminar for a crowded course is possible using the Optima environment. Without the Optima or other related tools it may not be always possible. In this way the WWW brings new possibilities for education.

Mining Multiple Markets' Exchange Rate: An Artificial Intelligence Tools Survey

Chiu-Che Tseng, Texas A&M University–Commerce, P.O. Box 3011, Commerce, TX 75429, USA; E-mail: Chiu-Che_Tseng@tamu-commerce.edu

ABSTRACT

Foreign exchange rate prediction is an expanding industry with various commercial services throughout the world, employed various techniques providing foreign exchange rate predictions. This paper examined the daily exchange rate data from six different countries and used that data to discover the correlation relationship among them. In this study, we used five of the exchange markets' daily data to predict the sixth market's exchange rate of the next day. We used four different artificial intelligence algorithms as our tools and our experiments yield quite interesting results.

Keywords: Exchange rate, Prediction, Artificial Intelligence.

1. INTRODUCTION

It is often argued that it is futile to attempt to predict foreign exchange rates because the foreign exchange market is an efficient market. The market is efficient in that the major participants are believed to have access to all the current information that may impact on price or at the assumption that the historic exchange rate information contains no useful information that can be used to predict the future exchange rates.

Many empirical studies of the exchange rate market have used statistical analysis or more sophistic models such as artificial intelligence algorithms in an effort to uncover significant pattern in the historical exchange rate data. These studies have found that the exchange rate data appear to have no significant pattern.

A couple of studies have found evidence through their research marginally profitable in the foreign exchange market. Our study, in using five foreign exchange rate markets and predicting the future exchange rate of sixth market produced quite accurate results. We compared the performance of four different artificial intelligence algorithms through our data set and found that all have very high predictive accuracy.

2. RELATED WORKS

Based on the concept of speculative runs Alexander [6] shown that a currency that has risen significantly is likely to continue its upward trend and a currency that has fallen significantly will continue to follow its downward trend. Bleaney [5] examined the claim that error-correction models of exchange rates can perform well in out-of-sample forecasting tests at long horizons. Rose and Selody [1] performed a test on daily data on five mature exchange rate markets shown that the data reject the joint hypothesis of exchange rate market informational efficiency and no risk premium. Logue and Sweeney [3] in their study of the Franc/Dollar spot rate found that while the data seemed to be white noise using spectoral analysis, there were a number of simple trading rules which yielded at least marginal profits. The k percent rules are used which buy a currency after it has risen k percent from its previous low and see it after it has fallen k percent from previous high. Logue, Sweeney and Willet [4] later came to a different conclusion that the foreign exchange markets are at least weakly efficient. From their results shown that k percent rules yielding substantial profits as compared with a buy and hold strategy. In a recent study by Chen, Kuo and Hoi [7] found contradicting evidence that the hypothesis that GP can generate profitable trading strategies in the foreign exchange markets does not win strong support.

In this paper we evaluated the predictive accuracy of foreign exchange rate markets using a variety of artificial intelligence algorithms providing a good test of market efficiency and correlativity in the foreign exchange markets.

3. EXCHANGE MARKETS

The foreign exchange market exists whenever one currency is trade for another. Capital wise it is by far the largest trading market in the world. The parties involve are banks, corporations, governments, traders, etc. The foreign exchange market is unique because of its several characteristics:

- Large trading volume
- Liquidity of the market
- Large participants in the market
- Geographical diverse
- Long trading hours due to the different time zone
- Variety factors that affect exchange rates

There is no single unified foreign exchange market due to its over the counter nature of the currency trading, different currency instruments are traded on a number of interconnected markets. The main trading centers are in London, New York and Tokyo, but banks throughout the world participate. As the Asian trading hours end, the European hours begin, then the US and back to Asia. It is a non stop trading throughout the world. Traders can react to the news as it become available, rather than wait and response during the market hours.

There is little or no inside information in the foreign exchange markets as the rates are fluctuate due to various factors such as GDP growth, inflation, interest rates, deficits or surplus and other macroeconomic conditions.

Controversy about currency speculators and their effect on currency devaluations and national economics recurs regularly. Many economists argue that speculators perform the important function of providing a market for hedgers and transferring risk from the one to another. Others consider this argument to be based more on politics and free market philosophy than on economics. Currency speculation is considered a highly suspect activity in many countries. While investing in traditional financial instruments like bonds or stocks often is considered to contribute positively to economic growth by providing capital, currency speculation does not.

4. ARTIFICIAL INTELLIGENCE ALGORITHMS

Artificial intelligence algorithms have been widely utilized for computational intelligence in the field of finance and economic. In this study, we applied four different artificial intelligence algorithms: multi-layer perceptron, radial basis functions, support vector regression model and regression by discretization model. Here is a brief description of each:

Multi-layer perceptron - This neural network uses backpropagation to train. A neural network is a powerful data modeling tool that is able to capture and represent complex input/output relationships. The motivation for the development of neural network technology stemmed from the desire to develop an artificial system that could perform "intelligent" tasks similar to those performed by the human brain. Neural networks resemble the human brain in the following two ways:

1. A neural network acquires knowledge through learning.
2. A neural network's knowledge is stored within inter-neuron connection strengths known as synaptic weights.

The true power and advantage of neural networks lies in their ability to represent both linear and non-linear relationships and in their ability to learn these relationships directly from the data being modeled.

The most common neural network model is the multilayer perceptron (MLP). This type of neural network is known as a supervised network because it requires

a desired output in order to learn. The goal of this type of network is to create a model that correctly maps the input to the output using historical data so that the model can then be used to produce the output when the desired output is unknown. A graphical representation of an MLP is shown below in Figure 1.

In neural networks, an activation function is the function that describes the output behaviour of a neuron. The most common activation functions are sigmoid and Gaussian functions.

- Sigmoid function $f(\mu_i) = \frac{1}{1+e^{-\mu_i/\sigma}}$
- Gaussian function $f(\mu_i) = e^{-\mu_i^2/\sigma^2}$

Radial basis functions - a normalized Gaussian radial basis functions network. It uses the k-means clustering algorithm to provide the basis functions and learns either a logistic regression (discrete class problems) or linear regression (numeric class problems) on top of that. Symmetric multivariate Gaussians are fit to the data from each cluster. If the class is nominal it uses the given number of clusters per class. It standardizes all numeric attributes to zero mean and unit variance. Radial basis functions (RBFs) are the natural generalization of coarse coding to continuous-valued features. Rather than each feature being either 0 or 1, it can be anything in the interval , reflecting various degrees to which the feature is present. A typical RBF feature, i, has a gaussian (bell-shaped)response, $\phi_s(i)$,dependent only on the distance between the state, s, and the feature's prototypical or center state, ci , and relative to the feature's width, $\phi_s(i)$:

$$\phi_s(i) = \exp\left(-\frac{||s-c_i||^2}{2\sigma_i^2}\right).$$

The norm or distance metric of course can be chosen in whatever way seems most appropriate to the states and task at hand. Figure 2 shows a 1-dimensional example with a euclidean distance metric.

An RBF network is simply a linear function approximator using RBFs for its features. The primary advantage of RBFs over binary features is that they produce approximate functions that vary smoothly and are differentiable. In addition, some learning methods for RBF networks change the centers and widths of the features as well. Such nonlinear methods may be able to fit the target function much more precisely. The downside to RBF networks, and to nonlinear RBF networks especially, is greater computational complexity and, often, more manual tuning before learning is robust and efficient.

Figure 1. A MLP neural network model

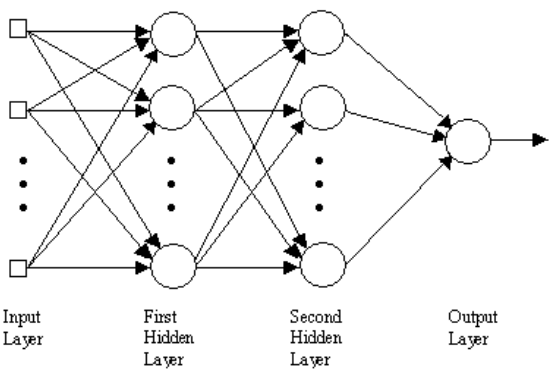

Figure 2. One-dimensional radial basis functions

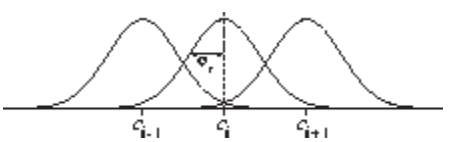

Support vector regression model - Implements Alex Smola and Bernhard Scholkopf's [2] sequential minimal optimization algorithm for training a support vector regression model. This implementation globally replaces all missing values and transforms nominal attributes into binary ones. It also normalizes all attributes by default. (Note that the coefficients in the output are based on the normalized/standardized data, not the original data.)

SMO was proposed [9] that puts chunking to the extreme by iteratively selecting subsets only of size and optimizing the target function with respect to them. It has been reported to have good convergence properties and it is easily implemented. The key point is that for a working set of 2 the optimization subproblem can be solved analytically without explicitly invoking a quadratic optimizer. While readily derived for pattern recognition by Platt

[1999], one simply has to mimic the original reasoning to obtain an extension to Regression Estimation. The modifications consist of a pattern dependent regularization, convergence control via the number of significant figures, and a modified system of equations to solve the optimization problem in two variables for regression analytically.

Note that the reasoning only applies to SV regression with the insensitive loss function - for most other convex cost functions an explicit solution of the restricted quadratic programming problem is impossible. Yet, one could derive an analogous non-quadratic convex optimization problem for general cost functions but at the expense of having to solve it numerically. The exposition proceeds as follows: first one has to derive the (modified) boundary conditions for the constrained 2 indices (i, j) subproblem in regression, next one can proceed to solve the optimization problem analytically, and finally one has to check, which part of the selection rules have to be modified to make the approach work for regression.

Regression by discretization- A regression scheme that employs any classifier on a copy of the data that has the class attribute (equal-width) discretized. The predicted value is the expected value of the mean class value for each discretized interval (based on the predicted probabilities for each interval).

5. EXPERIMENTS AND RESULTS

We used the exchange rate date of US/UK, US/Italy, US/Canada, Us/Japan, US/Singapore and US/Taiwan markets from 1990 to 2004. We selected the date from 1990 to 2003 as our training/validating data and 2004 as our testing data. We selected the daily data of US/UK, US/Italy, US/Canada, Us/Japan, US/Singapore as our input and the next day's US/Taiwan data as our predicted target.

We used an artificial intelligence software package called WEKA from University of Waikato. It is a data mining environment that provides various artificial intelligence and statistical algorithms and a unify format for input and output data.

We used ten folds cross validation on our training data and here are the training results.

In our training data, we can see that the regression by discretization (decision tree) algorithm is the most accurate.

We then applied the 2004 test data to the trained models. Here are the results.

Table 1. Training result from 10-fold cross validation

Algorithms	Correlation coefficient	Mean absolute error	Root mean square error
Multilayer perceptron	0.9803	0.0006	0.0008
Radial Basis Networks	0.993	0.0003	0.0005
Support Vector by Regression	0.9405	0.001	0.0013
Regression by discretization (decision tree)	0.9944	0.0003	0.0004

Table 2. Testing results (next day's predictive accuracy) from the 2004 data.

Algorithms	Mean absolute error	Root mean square error
Multilayer perceptron	0.0007	0.001
Radial Basis Networks	0.0044	0.0058
Support Vector by Regression	0.0029	0.0031
Regression by discretization (decision tree)	0.0053	0.0065

Figure 3. Multi-layer perceptron

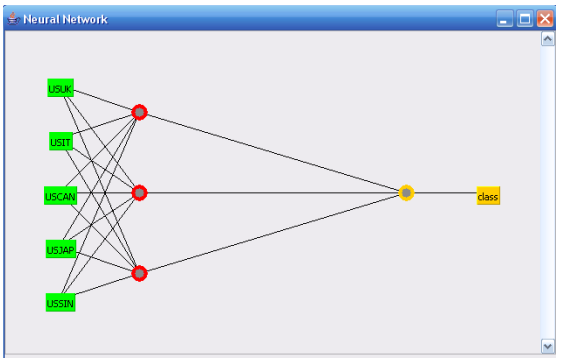

Figure 4. Actual and predicted output from 2004 testing data

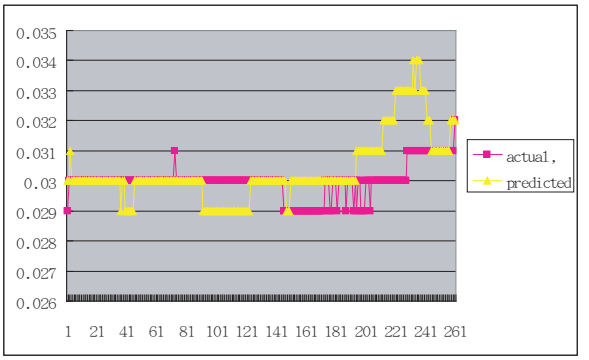

From the above experiments we conducted, we found that for out of sample testing (year 2004) the multi-layer perceptron (neural network) (see Fig. 3) had the lowest mean square error and root mean square error. Here are the actual and predicted output data from multi-layer perceptron using the 2004 testing data. (Fig. 4)

6. CONCLUSIONS AND FUTURE WORKS

Our finding in this study is quite interesting that it contradict the hypothesis that the foreign exchange rate market is efficient. In this study, we can get very accurate prediction using the data from other related markets. For the future work, we would like to expand the system to provide investor an exchange rate trading strategy based on the predicted output. And we would like to also expand the algorithms used in the study to include other major artificial intelligence algorithms used by other researcher in this area.

ABSTRACT

The U.S. Navy continues to be a major developer and procurer of information systems (IS), yet very limited research has been done to determine the factors that influence technology acceptance by naval personnel. Literature suggests that efforts to embrace information technology in improving decision-making and reducing workload heavily depend on the use of such systems. Moreover, previous research has shown the validity of the technology acceptance model (TAM) and computer self-efficacy (CSE) to model technology acceptance in numerous environments. However, very little research was done specifically addressing such technology acceptance with military combat IS. Thus, this study examines the applicability of the extended TAM with a CSE construct model to the U.S. Navy's combat IS. A survey sample of 237 sailors from five (5) different U.S. Navy aircraft carriers was used to assess such extended model on a U.S. Navy's combat IS. Results indicate that perceived ease-of-use, perceived usefulness, and CSE were valid antecedents of technology acceptance (as indicated by intention to use). Moreover, high Cronbach's Alpha was observed on all measures indicating additional reliability of the measures also in the context of military organizations.

Keywords: Technology acceptance model, computer self efficacy, IS in military/U.S. Navy, combat information systems, perceived usefulness of military IS, perceived ease of use of military IS, attitude toward military IS, intention to use IS in military.

INTRODUCTION

There is a large body of research regarding technology acceptance of information systems (Davis, 1989; Chau, 1996; Chau & Hu, 2001; Hu, Chau, Sheng, & Tam, 1999; Legris, Ingham, & Collerette, 2003; Venkatesh, Morris, Davis, & Davis, 2003; Ma & Liu, 2004), but a scarce number of studies regarding technology acceptance by members of the U.S. Navy. A common misconception of the military is that it is wholly structured. In reality, aboard a naval ship there are sometimes overlapping applications that a sailor can choose to use or ignore. Especially of interest is the usage or lack thereof of Decision Support Systems – that by their nature are designed to improve the quality of choices made by fleet personnel. There is anecdotal evidence that systems that provide situation awareness and decision support are not fully utilized by the intended audience.

Between 2001 and 2005, the U.S. Navy had an annual budget of about $120B (Globalsecurity.org, 2005). The exact amount that the Navy spends on information technology is hard to quantify, but a line item review of the budget indicates that the amount spent on information technology is measured in the billions of dollars (Globalsecurity.org, 2005). A focus of information technology development is to reduce shipboard manning. Achievement of this goal will require the development and integration of improved information systems (Bisantz, Rothe, Brickman, et al., 2003). It can be asserted that considering the funds being applied to information technology, a model for technology acceptance and the factors that influence information system usage should be determined (Davis, 1989; Chau, 2001).

Researchers have recommended replication of instruments and revalidation of models for unique environments (Amoako-Gyampah & Salam, 2004). Many technology acceptance studies have taken place in academic settings (Davis, 1989; Taylor & Todd, 1995; McFarland & Hamilton, 2006), but the military environment is different. Technology acceptance studies have been successfully replicated in many environments, but with varying factor loading between constructs (Legris, et. al., 2003). Examples of different environments where technology acceptance has been studied include a public hospital system (Chau & Hu, 2001), a construction-engineering environment (Lowry, 2002), Decision Support Systems in use in Egypt (Elbeltagi, McBride, & Hardaker, 2005) and a large corporation undergoing ERP implementation (Amoako-Gyampah & Salam, 2004).

Development of a technology acceptance model for the U.S. Navy will result in a validated instrument for assessing the acceptance and expected usage of an information system. A validated model also can be used as a tool to identify weaknesses in a technology implementation and adjust the approach. This information is valuable to a Program Manager who must make decisions on how to invest in system improvements.

THEORETICAL BACKGROUND

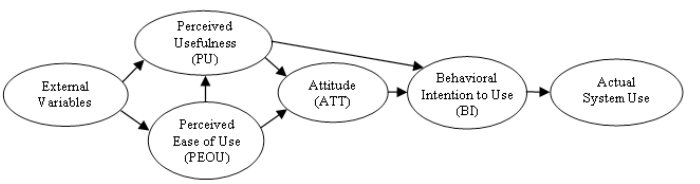
Technology Acceptance Model (TAM)

The Technology Acceptance Model (TAM) has been studied extensively with many of variations and in many different environments (Chau, 1996; Hu et al., 1999; Legris et al., 2003; Venkatesh et al., 2003). The TAM model is grounded in Theory of Reasoned Action (TRA) proposed and validated by Ajzen and Fishbein (1975). The essence of the model is in using users' perceptions about usefulness, ease of use, and attitude toward technology in order to predict users' intention to use as well as actual usage of a technology. The overall approach of TAM is predictive in nature, attempting to uncover the constructs that impacts users' intensions to use technology. Figure 1 provides an overview of the conceptual map proposed by Davis, Bagozzi, and Warshaw (1989).

Numerously various studies have validated the TAM model in different contexts (Venkatesh et al., 2003). However, no prior work was done on validating the TAM model in military context, in particular not on combat information systems. As such, this study is unique in its attempt to validate an extended TAM model in the context of antecedent construct that impact soldiers' intension to use combat information systems.

The factors in TAM that predict usage are perceived usefulness, perceived ease of use, and attitude. Perceived Usefulness is defined as "the degree to which a person

Figure 1. Davis, Bagozzi, and Warshaw (1989)'s conceptual map of the TAM model



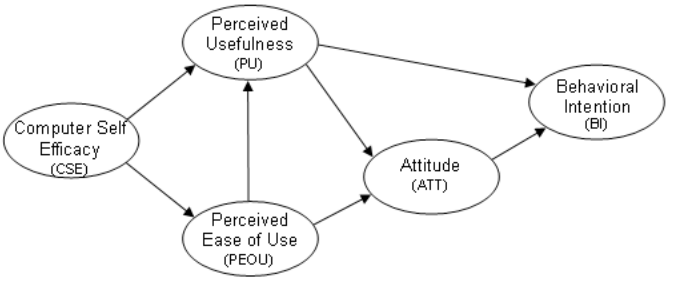
believes that using a particular system would enhance his or her job performance" (Davis, 1989, p. 320). Perceived Ease-of-use is defined as "the degree to which a person believes that using a particular system would be free of effort" (Davis, 1989, p. 320). Attitude has been defined by Yang and Yoo (2004) as a combination of "how much the person likes the object of thought" and "specific beliefs related to the object" (p. 20).

Hu et al. (1999) studied how well the TAM modeled physician's intention to use telemedicine. The study, with 408 participants, examined perceived usefulness, perceived ease-of-use, attitude, and intention to use. Hu et al. (1999) found that TAM was applicable to the professional environment of a hospital. The attitude construct was found to significantly influence intention to use. In contrast, perceived ease of use did not have a significant effect on perceived usefulness and attitude. Hu et al. (1999) concluded "the explanatory power of TAM, particularly the perceived ease of use factor, may weaken as the competency of the users increases" (p. 106). This finding suggests that "competency" is an external variable to the TAM. Thus, this study adds a measure of perceived computer competency, computer self-efficacy, as an external variable to the TAM.

Computer Self-Efficacy

Computer Self-Efficacy (CSE) construct immerged from the general concept of self efficacy by Compeau and Higgins' (1995) and is founded on the social cognitive theory (Bandura, 1977; 1982; 1984). CSE is defined as "an individual's perception of his or her ability to use a computer in the accomplishment of a job task" (Compeau & Higgins, 1995, p. 193). Numerous studies in literature suggest that CSE has a very high reliability and strong validity across different contexts (Agarwal, Sambamurthy, & Stair, 2000; Chung, Schwager; & Turner, 2002; Durndell & Haag, 2002; Hasan, 2006; Potosky, 2002; Sheng, Pearson, & Crosby, 2003; Stone, Arunachalam, & Chandler, 1996; Stone & Henry, 2003; Thatcher & Perrewe, 2002; Torkzadeh, Chang, & Demirhan, 2006; Yi & Im, 2004). Moreover, CSE has been validated in numerous studies with its relationship as an extension of the TAM model (McFarland & Hamilton, 2006; Venkatesh & Davis, 1996).

Figure 2. Conceptual map of the research model



Chau (2001) conducted a study of extending the TAM model with CSE on 360 business students. Although providing validation for the TAM model, his study suggests that CSE as well as computer attitude should impact perceived ease of use and perceived usefulness. There is evidence from literature to support the belief that CSE may serve as a predictor of PEOU and PU, there is little support in literature for using attitude as a predictor of the two constructs, indicating somewhat a deviation from the original TAM model. Thus, this proposed study attempted to validate the use of CSE as an external variable that impacts the key TAM constructs following the traditional TAM where attitude is between PEOU, PU and BI. Figure 2 provides a conceptual map of the proposed research model. The proposed modified model is based on the relationships proposed in the extension of the TAM model noted by scholars (McFarland & Hamilton, 2006; Venkatesh & Davis, 1996).

METHODOLOGY

A survey instrument was adapted from Chau and Hu (2001) which provides validated measures for the constructs relevant to perceived usefulness, perceived

Table 1. Descriptive statistics and Cronbach's Alpha

Summary of Measurement Scales: (n=206)				
Construct	**Measure**	**Mean**	**SD**	**Cronbach Alpha**
Computer Self Efficacy (CSE)				
CSE1	I am comfortable working with computers	1.85	1.28	
CSE2	If I am given some training, I can learn to use most computer programs	1.77	1.10	*0.77*
CSE3	I can learn to use most computer programs just by reading the manuals and help	2.86	1.67	
Perceived Usefulness (PU)				
PU1	Using [*] will improve my support of casualty control, situational awareness and logistical references	2.54	1.53	
PU2	Using [*] will enhance my effectiveness in supporting combat operations	2.27	1.27	*0.83*
PU3	I find [*] useful for my work on the ship	2.54	1.29	
Perceived Ease of Use (PEOU)				
PEOU1	It was easy for me to learn to use [*]	2.59	1.29	
PEOU2	It is easy for me to become skillful in [*]	2.67	1.27	*0.91*
PEOU3	I find [*] easy to use	2.72	1.36	
Attitude (ATT)				
ATT1	Using [*] is a good idea	2.25	1.28	
ATT2	Using [*] is pleasant	2.81	1.39	*0.65*
ATT3	Using [*] is beneficial to my ship	2.20	1.27	
Behavioral Intention (BI)				
BI1	I intend to use [*] for casualty control, situational awareness and logistical references as often as needed	2.54	1.36	*0.89*
BI2	To the extent possible, I will use [*] in my work	2.53	1.26	

* - *The name of the system was concealed for obvious reasons.*

ease-of-use, attitude, and behavioral intention to IS use. The measures used by Chau and Hu were adapted from measures validated by Taylor and Todd (1995) as well as Davis (1989). Computer self efficacy measures were adapted from Compeau and Higgins (1995). All measures for constructs (i.e. CSE, PU, PEOU, BI, and ATT) were adapted from their original sources noted above and slightly modified to fit within the survey format and better relate to the environment under study (i.e. a U.S. Navy's combat IS). This adaptation was accomplished by reviewing the survey instrument with subject matter experts experienced with the U.S. Navy's combat IS implementations on five U.S. Navy ships. The results of the subject matter expert reviews were minor wording changes to clarify the intent of the questions for the U.S. Navy sailors. The minor modifications included the notation to the system's name instead of generic notation of IS, particularly in the measures of the original TAM construct (i.e. PU, PEOU, ATT, and BI). The subject matter experts indicated that including the system's name may help reduce threats to internal validity (see questions text in Table 1).

An information system used by the combat systems department onboard U.S. Navy aircraft carriers was chosen as the target system for model testing. This IS is used by combat systems watch officers for situational awareness, casualty control, and maintenance management (Green, 2003). The system was selected for this study because its use is not mandatory, rather it is available to use at the discretion of the combat systems watch officer. The survey instrument was distributed onboard the five separate ships over a six-month period. The survey instrument was distributed on paper and was anonymously completed. Responses were collated and entered into two separate spreadsheets by two separate people. The separate spreadsheets were then compared to assure that no data entry errors were made. Any difference in data was traced back to the original survey questionnaire and the correct score was entered.

A total of five U.S. Navy aircraft carriers were represented in the sample. A total of 326 surveys were issued and 237 completed surveys were returned, for a response rate of 73%. The survey response rate was high because the sample population was a captive audience. Each of the 237 returned surveys were checked for completeness and analyzed to determine if the participant marked the same score for all items suggesting a response set. Kerlinger and Kee (2000) noted that "response-set can be considered a mild threat to validity measures" (p. 713). They noted that scanning the data for response-set and removing those from final analysis help with the overall validity of the results. Thus, the data were observed for response-sets indicating 31 cases of sailors who just marked the whole survey on the same score. Such response-sets were eliminated providing a total of 206 usable records for further analyses.

DATA ANALYSIS AND RESULTS

Analysis of Measurement Validity

Table 1 provides the results of the analysis of measurement validity. Results indicating that most measures produce a very high reliability of 0.91, 0.89, 0.83, 0.77, and 0.65 Cronbach's Alpha for PEOU, BI, PU, CSE, and ATT respectfully. These results provide an indication that the survey instrument is reliable in its measurements and consistent with results found in prior literature.

Model Testing Results

AMOS 6.0 was used to perform the path analysis model fit. Literature suggest seven common measures of model-fit analysis including chi-square/degrees-of-freedom (Chi-square/df), goodness-of-fit index (GFI), adjusted goodness-of-fit index (AGFI), normed fit index (NFI), non-normed fit index (NNFI), comparative fit index (CFI), and standardized root mean square residual (SRMSR) (Chau & Hu, 2001; Chau, 2001; Somers, Nelson, & Karimi, 2003). Within these seven model-fit measures, literature provides specific guidelines to the recommended values in order to indicate the performance of the model. Carmines and McIver (1981) recommended that a value of Chi-square/df less than three indicates good fit. Additionally, Somers et al. (2003) noted that Chi-square/df less than two indicates even "more restrictive [fit]" (p. 610) or a higher quality of model fit. Table 2 provides both the recommended values and the results of this study. Chi-square/df was found to be 1.6, which much lower than both the regular recommended value (<3.00) and the restrictive fit (<2.00) indicating a good support for the model-data fit. Two other common measures of model-fit analysis are GFI and AGFI. GFI measure is based on the amount of variance and covariance difference, while AGFI is similar to GFI but adjusted to the degrees of freedom relative to the number of variables in the model (Shumacker & Lomax, 2004). On both GFI and AGFI zero (0) indicates no fit and one (1) indicate perfect fit. Researchers suggested that values for GFI and AGFI above .80 and .90, respectively, indicate a good fit (Chau, 2001; Chau & Hu, 2001; Somers et al., 2003). Results of this study's model indicate support for the model fit with GFI of .93 and AGFI of .895. Additionally, three more common measures of model-fit analysis are NFI, NNFI, and CFI. For these three measures researchers suggested that values for grater than .90 indicates support for the model fit (Chau, 2001; Chau & Hu, 2001; Somers et al., 2003). Based on these model fit measures, results of this study's model indicate a near perfect model fit with NFI of .940, NNFI of .969, and CFI of .976 providing additional support for a good model-date fit. Mayers, Gamst, and Guarino (2006) suggested that SRMSR below .08 indicates good fit, between .08 and .10 indicates moderate fit and above .10 indicates poor fit. Shumacker and Lomax (2004) also concurs such model fit values. Results of this study's model indicate SRMSR of .054, which additionally supports the fitness of the model.

Table 2. Goodness-of-fit measures of the research model

Goodness-of-fit Measure (n=206)	Recommended Value*	Research Model	Chau (2001)
Chi-square (χ^2)		112.2	NR
Degrees of freedom (df)		70	NR
Chi-square/df	<3.00	1.602	2.09
Goodness-of-Fit Index (GFI)	>0.90	0.930	0.90
Adjusted Goodness-of-Fit Index (AGFI)	>0.80	0.895	0.88
Normed Fit Index (NFI)	>0.90	0.940	0.94
Non-Normed Fit Index (NNFI)	>0.90	0.969	0.91
Comparative Fit Index (CFI)	>0.90	0.976	0.94
Standardized Root Mean Square Residual (SRMSR)	<0.10	0.054	0.05

* - Per Chau (2001)
NR – Not Reported

Figure 3. Extended TAM and CSE model testing results

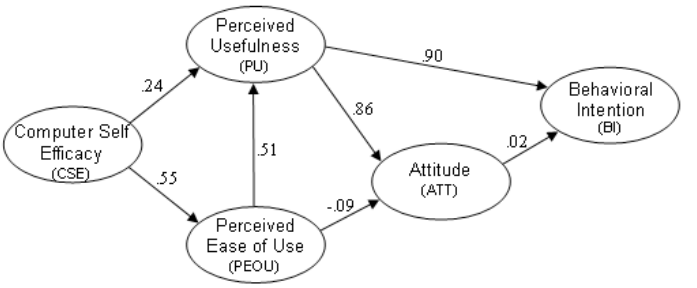


Figure 3 indicates the results of the model path. As noted the direct effect between CSE and PEOU appears to be stronger (.55) than the direct effect between CSE and PU (.24). The effect of PEOU on attitude and the effect of attitude on BI appear to be narrow. Additionally, a strong effect was found between PU and attitude (.86), while the strongest effect found was between PU and BI (.90). This finding suggests that one unit increase in sailor's perceived usefulness results in a .86 unit increase in their attitude towards the system and a .90 unit increase in their intention to use it. These results are consistent with the Hu et al. (1999) study.

DISCUSSION

The TAM model has long been a central model in IS research with numerous studies validating it in various contexts. However, very little work was done in the context of military information systems, in particular assessing IS that provide combat support. This study is very unique as it provides additional empirical evidence by validating the extended TAM model in the context of a U.S. Navy combat IS.

Results of the model show very strong validation with high degree of model fit and with better results of what published previously in non-military context. Moreover, analysis of measures validity indicates high Cronbach's Alpha for four of the instrument constructs calculated at over 0.75, while the remaining construct (attitude) provided an acceptable reliability measure of 0.65. These reliability results further validate the survey instrument proposed in literature.

Several limitations and opportunities for future research can be observed for this study. First, examination of any military information systems is an unexplored phenomenon. Although results of this study are valid as indicated by the analyses, additional measures should be explored in the context of military information systems. An observed limitation of this study deals with the high amount of response-set. Although this study was able to collect relatively high response rate (~73%) from the U.S. Navy sailors, there was a large amount (~10%) of respondents who simply marked the survey the same score on all measures in order to obey the request of their military superiors to participate in the study. Thus by providing response-set, these sailors prevented assessment of their true perceptions and feelings about this U.S. Navy combat IS. This resulted in the need to eliminate these response sets from the data prior to any analysis and a final response rate of 63%.

ACKNOWLEDGMENTS

The authors would like to thank William "Doug" Faulkner for invaluable help administering the survey for this study, the sailors aboard the five U.S. Navy aircraft carriers for participating in this study, and the anonymous referees for their careful review and valuable suggestions.

ABSTRACT

In this paper, we study the performance benefits of cell search algorithm. The purpose of the cell search algorithm in UMTS is to estimate the spreading code of the serving base-station and its corresponding timing offset. The search procedure consists of 3 sequential and distinct stages: (1) slot-boundary synchronization, (2) frame-boundary synchronization with code-group identification, and (3) scrambling code identification. Also, we study the performance benefits of estimating multiple "code-time" hypotheses in each stage of the cell-search process. In addition, we also study the effect of oversampling and non-ideal sampling. Our results indicate that, in the presence of non-ideal sampling, performance improves significantly if the received signal is oversampled by a factor of 4 or more. We also show that an estimating 4 "codetime" hypothesis instead of 1 in the cell-search stages reduces the search-time (i.e. the code-acquisition time) considerably, in particular at low SNR.

Keywords: WCDMA, UMT, SSC, PSC, FHT, CSD,P_{FA}, V_{TH}

1. INTRODUCTION

WCDMA is a wideband Direct Sequence Code Division Multiple Access (DS-CDMA) system, which means that the user information bits (symbols) are spread over a wide frequency bandwidth by multiplying the user data bits with a spreading code sequence of "chips" [1], [2]. In the asynchronous W-CDMA system each base station is identified by a unique scrambling code. The mobile station has to synchronize to the scrambling code of the serving base station in order to descramble the downlink traffic channels [3],[4]. The synchronization process is commonly referred to as the cell search procedure, i.e. cell search is the process of synchronization between the mobile and the base station. The purpose of the cell search algorithm in UMTS is to estimate the spreading code of the serving base-station and its corresponding timing offset. A three-step hierarchical cell search process has been introduced in the UMTS standard that is supported by several auxiliary synchronization channels [5]. These include the Primary Synchronization Channel (P-SCH), the Secondary Synchronization Channel (S-SCH), and the Common Pilot Channel (CPICH) [9].The cell search procedure is split into three stages, stage 1 performs slot synchronization, stage 2 performs frame synchronization and scrambling code group identification, and stage 3 acquires the cell-specific scrambling code.

2. CELL SEARCH ALGORITHM

We use the algorithms for code acquisition presented in [4],[5],[6] as baseline for benchmarking our enhanced algorithms. Since the frequency acquisition stage presented in [6] can be used without modification after stage 3, in our study, we assume an oversampled received signal at the mobile. However, as was mentioned above, after slot synchronization in stage 1, the signal is down-sampled to chip-rate for further processing.

The cell search algorithm is divided into the following stages:

(1) Slot boundary synchronization,
(2) Frame synchronization and code group identification,
(3) Scrambling code identification,
(4) Frequency acquisition, and,
(5) Cell identification.

The last two stages need to be performed only during initial cell search [10].

Stage 1: Slot Boundary Synchronization

During stage 1 of the cell search algorithm the mobile station uses the Primary Synchronization Code (PSC) to acquire slot synchronization to a cell. This is typically done with a single matched filter matched to the PSC which is common to all cells. The slot timing of the cell can be obtained by detecting peak values in the matched filter output. However, decisions based on observations over a single slot may be unreliable, when the signal-to-noise ratio (SNR) is low or if fading is severe. Reliable slot synchronization is required to minimize cell search time. In order to increase reliability, observations are made over multiple slots and the results are then combined. This ensures that the correct slot boundary is identified.

Stage 2: Frame Synchronization and Code Group Identification

During stage 2 of the cell search algorithm, the mobile station uses the Secondary Synchronization Code (SSC) to achieve frame synchronization and identify the code group of the cell found in stage 1. This is done by correlating the received signal with all possible SSC sequences and identifying the maximum correlation value. Since the cyclic shifts of the sequences are unique, the code group as well as the frame synchronization is determined in this stage.

Stage 3: Scrambling Code Identification

During stage 3 of the cell search algorithm, the mobile station determines the exact primary scrambling code used by the cell. The primary scrambling code is typically identified through symbol-by-symbol correlation over the CPICH with all codes within the code group identified in stage 2. In this stage, a threshold value is used to decide whether the code has been identified. The threshold value can be predetermined using a parameter called probability of false alarm rate.

2.1 Slot Synchronization

Conventional detection of the slot boundary entails:

(a) correlating the received data over 256 chips with the PSC,
(b) then performing this correlation over Nt slots, which is set to 15 slots (= 1 frame) in all our simulations ,
(c) then accumulating all the Nt correlation values, and
(d) finally selecting the hypothesis that corresponds to the maximum correlation value.

Matching Filter

A basic problem that often arises in study of communication systems is that of detecting a pulse transmitted over a channel that is corrupted by additive noise at the front of the receiver. The filter input X(t) consists of a pulse signal g(t) corrupted by additive noise w(t), as shown

$$X(t) = g(t) + w(t) \qquad 0 \le t \boxtimes T$$

Where T is an arbitrary observation interval. The pulse signal g(t) may represent a binary symbol 1 or 0 in a digital communication system . With the received signal X(t) used as filter input , the resulting filter output , y(t) is defined by the convolution integral :

$$(t) = \int_{-\infty}^{\infty} x(\tau)\, h_j(t-\tau)\, d\tau$$

Slot Matching Filter
The MS first needs to acquire the PSC which is common to all the BSs. These codes are of length 256 chips. The matched filter output is given by,

$$Y = \sum_{J=0}^{255} R_j \cdot C_{pj}$$

Where *Rj* is the jth sample of the received complex signal, and *Cpj* is the jth bit of the PSC.

PSC Sequence
The hierarchical sequences used for generating the PSC are constructed from two constituent sequences X1 and X2 of length n1 and n2, respectively, using the following equation [12]:

Cp (n) =X1(n mod n2) +X2(n div n1) modulo 2, n=0, 1,.., (n1*n2)-1

Where n1=n2=16. The constituent sequences X1 and X2 are both defined as:

X1=X2= (1, 1,-1,-1,-1,-1, 1,-1, 1, 1,-1, 1, 1, 1,-1, 1).

Slot Boundary Detection
A traditional matched filter implementation would require 256 taps and a large adder circuit. This would increase the delay as well as power consumption at the receiver which is not desirable. Thus, a hierarchical structure is used for performing the matched filter operations which will need lesser number of taps, reduced circuitry and lower power consumption. The hierarchical matched filter consists of two concatenated matched filter blocks. The first matched filter receives the input signals serially from the base station. After 16 clock cycles when the shift register 1 is filled, the data stored in the shift register 1 is matched in parallel with the code applied to the taps of the matched filter (tap coefficients). The tap coefficients are the PSC sequences which are the same for all the base stations [11],[12].Hence, the same matched filter structure can be used for all the base stations.

2.2 Frame Synchronization and Code Group Identification
During stage 2 of the cell search procedure, the MS uses the SCHs Secondary Synchronization Code (SSC) to achieve frame synchronization and identify the code group of the cell found in stage 1. This is done by correlating the received signal with all possible SSC sequences and identifying the maximum correlation value. Since the cyclic shifts of the sequences are unique, the code group as well as the frame synchronization is determined. The Secondary SCH consists of 15 sequences belonging to a family of cyclic codes (SSCs), each of length 256 chips. These SSCs are transmitted repeatedly in parallel with the Primary SCH. The procedure for constructing the cyclic codes is similar to that of the hierarchical sequence for the Primary SCH except that it uses specific sequences of length 16 from Table1 for each code group. The procedure for constructing the cyclic hierarchical sequence Csi,1 for slot 1 is exactly the same as constructing the hierarchical sequence Cp for the Primary SCH. The sequence Csi,1 for slot 1 will be referred to as the zero cyclic shift sequence as no shift is applied to the constituent sequence X1i. For slots 2 to 15, the cyclic codes are constructed from the two constituent sequences X1i,k-1 and X2i,k-1 of length n1 and n2 respectively using the following formula[12]

Csi,k(n)=X2i,k-1 (n mod n2)+X1i,k-1 (n div n1) modulo 2, n=0,1,..,(n1*n2)-1

Table 1. Sequences X1i and X2i for Code Groups 1 to 32

Code Group		Code Group	
1	1 1 1-1-1-1 1-1-1 1 1-1 1-1 1 1	17	1-1 1 1-1 1-1 1 1 1-1 1 1 1-1 1

13	1-1-1-1 1-1-1 1-1-1-1 1 1 1 1-1	29	-1 1-1-1 1 1 1 1 1-1 1 1 1 1-1 1
14	1 1-1 1 1 1-1-1-1 1-1-1 1-1 1 1	30	-1-1-1 1 1-1 1-1 1 1 1-1 1-1-1-1
15	1-1-1-1-1 1 1-1 1 1 1-1 1 1 1-1	31	-1 1 1 1-1-1 1 1-1 1 1 1 1 1 1-1
16	1 1-1 1-1-1 1 1 1-1 1 1 1-1 1 1	32	-1-1 1-1-1 1 1-1-1-1 1-1 1-1 1 1

where i is code group number, k=2,3,..,15 is slot number, n is chip number in slot, n1=n2=16, and the constituent sequences X1i,k-1 and X2i,k-1 in each code group i are chosen to be the following sequences from Table 1.The constituent sequence X2i,k-1 (inner sequence) is exactly equal to the base sequence X2i in every slot, i.e. X2i,k-1=X2i at all k.

The constituent sequence X1i,k-1 (outer sequence) are formed from the base sequence X1i by cyclic right shifts of X1i on k-1 positions (from 0 to 15) clockwise for each slot number k, from 1 to 15 . The generation of the cyclic codes can be understood clearly by considering the following example.

For the first code group the sequence is given by

X11,0=(1,1,1,-1,-1,-1,1,-1,-1,1,1,-1,1,-1,1,1), k=1 for slot 1, No cyclic shift

X11,1=(1,1,1,1,-1,-1,-1,1,-1,-1,1,1,-1,1,-1,-1), k=2 for slot 2, cyclic right shift by 1 position

X11,14=(1,-1,-1,-1,1,-1,-1,1,1,-1,1,-1,1,1,1,1), k=15 for slot 15, cyclic right shift by 14 positions.

The same procedure for forming the cyclic codes will be used for other code groups. Thus, for the 32 codes groups and 15 slots (in one frame), 512 different cyclic codes with a length of 256 chips each are constructed. These 512 cyclic codes are unique for each code group/slot locations pair. Thus, it is possible to

uniquely determine both the scrambling code group and the frame timing in the second stage of the initial cell search.

2.3 Scrambling Code Identification

After achieving code group and frame synchronization, the scrambling code is identified by correlating the symbols in the CPICH with all possible scrambling codes in the code group. The codes are generated using a scrambling code generator and the descrambling operation is carried out using a descrambler.

Scrambling Code Generator

Each cell is allocated one and only one primary scrambling code. The scrambling code sequences are constructed by combining two real sequences into a complex sequence. Each of the two real sequences are constructed as the position wise modulo 2 sum of38,400 chip segments of two binary sequences generated by means of two generator polynomials of degree 18 [14]. Let x and y be the two sequences respectively. The resulting sequences constitute segments of a set of Gold sequences. The x sequence is constructed using the primitive polynomial $1+X^7+X^{18}$. The y sequence is constructed using the polynomial $1+X^5+X^7+X^{10}+X^{18}$. The sequence depending on the chosen scrambling code number n is denoted as zn. Furthermore, let x(i), y(i) and zn(i) denote the ith symbol of the sequence x, y, and zn, respectively.

The sequences x and y are constructed as:

x(i+18)=x(i+7)+x(i) modulo 2, for i=0,1,..,218 - 20

y(i+18)=y(i+10)+y(i+7)+y(i+5)+y(i) modulo 2, for i=0,1,..,218 - 20

The nth Gold code sequence zn, n=0,1,..,218 - 2, is then defined as [11],[12]:

zn(i)=x((i+n) modulo (218 -1))+y(i) modulo 2, i=0,1,..,218- 2

Finally, the nth complex scrambling code sequence sn is defined as:

sn(i)=zn(i)+jzn((i+131,072) modulo (218-1)), i=0,1,..,38,399

Table 2. Masking functions used in Stage 3: Scrambling code generator

	Masking Function For I Channel Code In LFSR 1	Masking Function For Q Channel Code In LFSR 1
Code1	000000000000000001	001000000001010000
Code2	000000000000000010	010000000010100000
Code3	000000000000000100	100000000101000000
Code4	000000000000001000	000000001000000001
Code5	000000000000010000	000000010000000010
Code6	000000000000100000	000000100000000100
Code7	000000000001000000	000001000000001000
Code8	000000000010000000	000010000000010000
Code9	000000000100000000	000100000000100000
Code10	000000001000000000	001000000001000000
Code11	000000010000000000	010000000010000000
Code12	000000100000000000	100000000100000000
Code13	000001000000000000	000000001010000001
Code14	000010000000000000	000000010100000010
Code15	000100000000000000	000000101000000100
Code16	001000000000000000	000001010000001000

The pattern from phase 0 up to the phase of 38,399 is repeated for every radio frame.

The scrambling codes are divided into 512 sets each of a primary scrambling code and 15 secondary scrambling codes. The primary scrambling codes consist of scrambling codes n=16*i where i=0,1,..,511. The ith set of secondary scrambling codes consists of scrambling codes 16*i+k, where k=1,2,..,15. There is a one-to-one mapping between each primary scrambling code and 15 secondary scrambling codes in a set such that ith primary scrambling code corresponds to ith set of secondary scrambling codes [17]. The set of primary scrambling codes is further divided into 32 scrambling code groups, each consisting of 16 primary scrambling codes. The jth scrambling code group consists of primary scrambling codes 16*16*j+16*k, where j=0,1,..,31 and k=0,1,..,14. In this stage, 16 scrambling codes need to be generated in parallel.

In order to reduce the hardware utilization, in stage 3 of both the designs only one scrambling code generator is used to generate 16 codes in parallel when 32 code groups are used as shown in above figure. Sixteen masking functions are used to generate the codes in parallel. Masking functions can generate codes which have minimum overlap and reduce the hardware circuitry to a single scrambling code generator at the expense of a few logic gates.

Masking function for I and Q Channel Code in linear feedback shift register (LFSR) 2 were kept fixed as 000000000000000001 and 001111111101100000. Besides reducing the hardware from 16 code generators to one code generator, the design also reduces the ROM size to 32X18 from the size 512X18 if 16 code generators were used.

3. SIMULATION AND MODELING

3.1 Slot Synchronization

Figure 1, shows sample transmitter model, fig. 2, shows slot detector model

Figure 1. Transmitter model

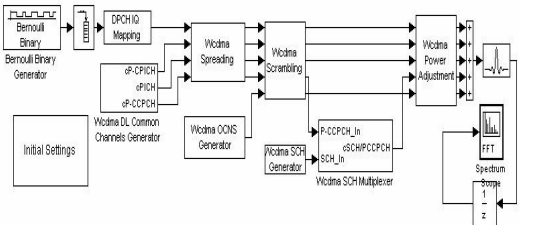

Figure 2. Slot detector model

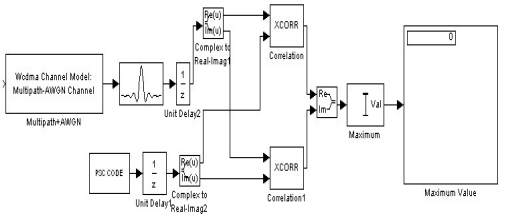

Figure 3. Individual stage of FHT

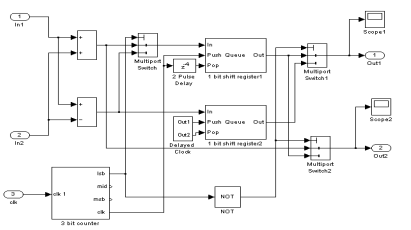

3.2 Frame Synchronization

Figure 3, shows an individual stage of the FHT. Each stage has an upper and a lower input terminal. The upper input terminal is configured to receive multiple input signals which are either Walsh chips (if the stage is the first stage of the FHT) or intermediate correlation coefficients (if the stage is not the first stage of the FHT)[15]. If an input of N-Walsh chips is to be processed then the upper input terminal receives N/2 input signal bits and the lower input terminal receives the other N/2 input bits.

Figure 4, shows the design for a FHT structure which is used for decoding a 16 chip sequence. The design proposed is a very compact and efficient implementation is used for decoding a 16 chip sequence. The design proposed is a very compact and efficient implementation as compared to previous designs

4. SIMULATION RESULTS

In the simulation results, when the received signal was correlated with the PSC sequences generated at the MS, some peak values were obtained and the maximum of those peak values was displayed as the slot value for that particular frame. In frame synchronization process, a FHT was used to match arbitrary SSC sequence with the frames and 16 values were obtained. In code synchronization process, the 16 values obtained are match with the values generated at the MS and the max of those values will be taken. The results satisfy most of the requirements of the parameters mentioned in the 3GPP specifications.

Figure 4. Design for a 16 chip FHT

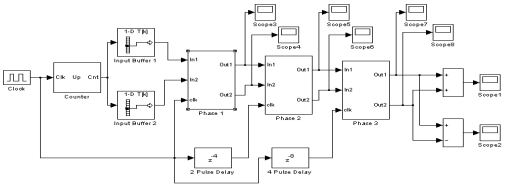

Figure 5. Code group detector model

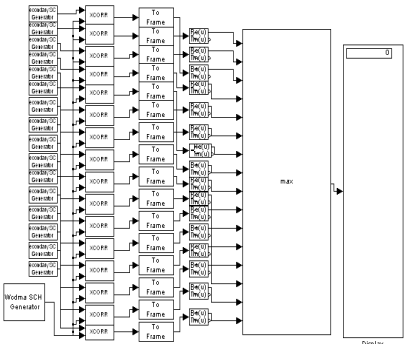

Figure 6. Scrambling code identifier model

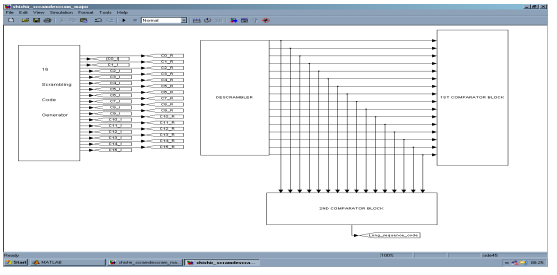

Figure 7. Spectrum for transmitted signal

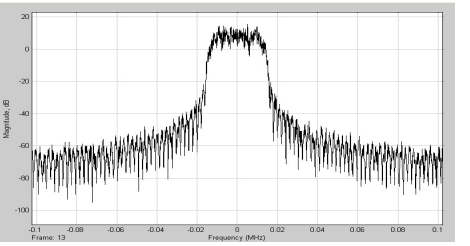

Figure 8. Maximum value in a frame

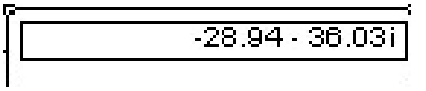

Figure 7, shows the spectrum for transmitted signal. The incoming signal is passed through a real-imaginary block to break signal into real and imaginary components. Similarly, PSC code signal is also broken into real and imaginary components. Those real parts are correlated together and the imaginary parts are correlated together. The final outcome of both the correlations is combined to form a complex value. Figure 8, shows the peak value obtained after correlating input signal with the codes generated by the PSC code generator is -28.94-36.03i. Figure 9,10,11,12 shows the first, second, third and final FHT scope. Figure 13, shows the Code Group values for real part of signal.

Frame Synchronization

In frame synchronization process, a FHT was used to match arbitrary SSC sequence with the frames and 16 values were obtained. Figure 5&6 shows stages

Figure 9. First FHT scope

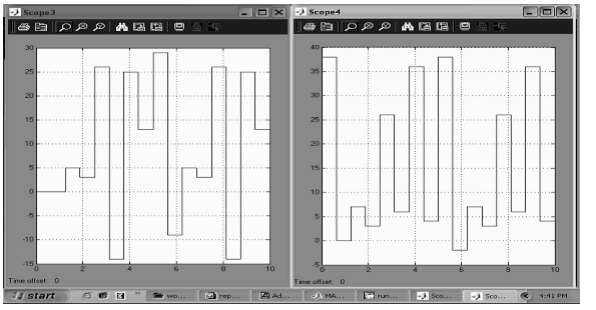

Figure 10. Second FHT scope

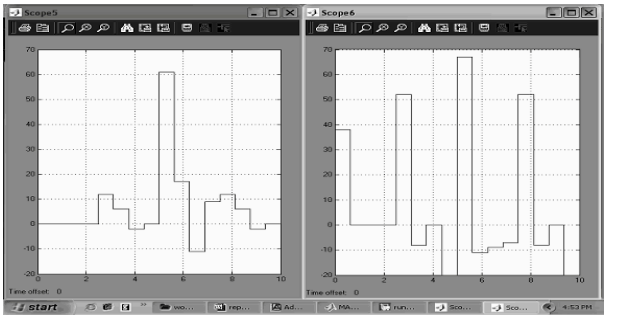

Figure 11. Third FHT scope

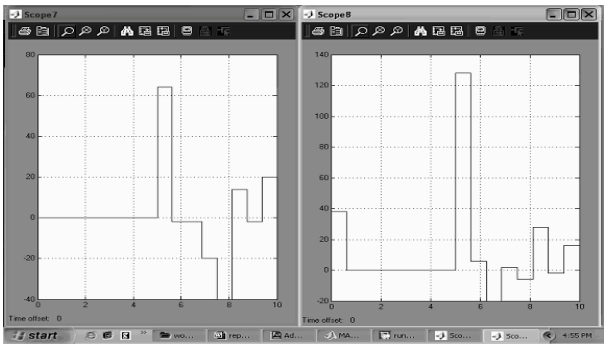

Figure 12. Final FHT scope

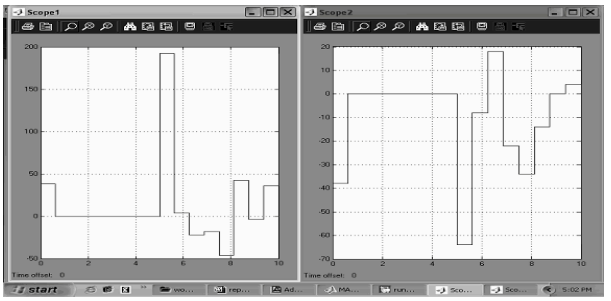

Figure 13. Code group values for real part of signal

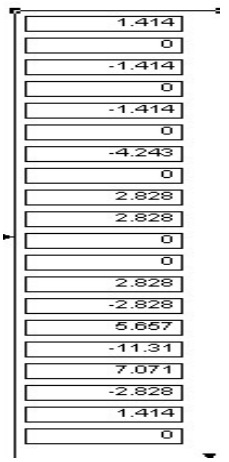

of the FHT. Each stage has an upper and a lower input terminal. The upper input terminal is configured to receive multiple input signals which are either Walsh chips (if the stage is the first stage of the FHT) or intermediate correlation coefficients (if the stage is not the first stage of the FHT). If an input of N-Walsh chips is to be processed then the upper input terminal receives N/2 input signal bits and the lower input terminal receives the other N/2 input bits. Figure 4 shows the design for a FHT structure which is used for decoding a 16 chip sequence.

Also, we study the system performance in terms of overall acquisition time Ta. The stage duration is held constant at N_I=15 (= 1 frame). The target false alarm probability is chosen to be $P_{FA}=10^{-4}$ for all simulations. We assume a frequency

Figure 14. Effect of oversampling (Nt=15, case I, non-ideal sampling, $P_{FA}=10^{-4}$)

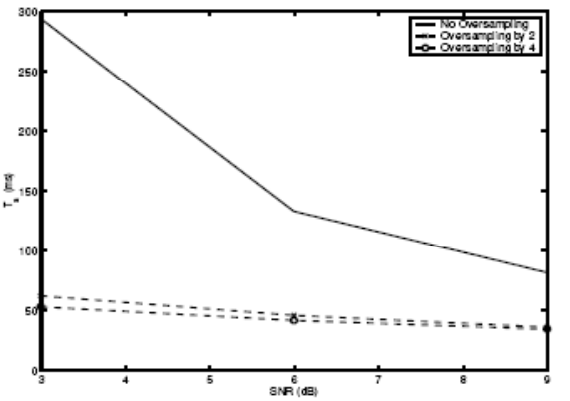

Figure 15. Influence of the number of candidates (Os=4, Nt=15, case II, ideal sampling, $P_{FA}=10^{-4}$)

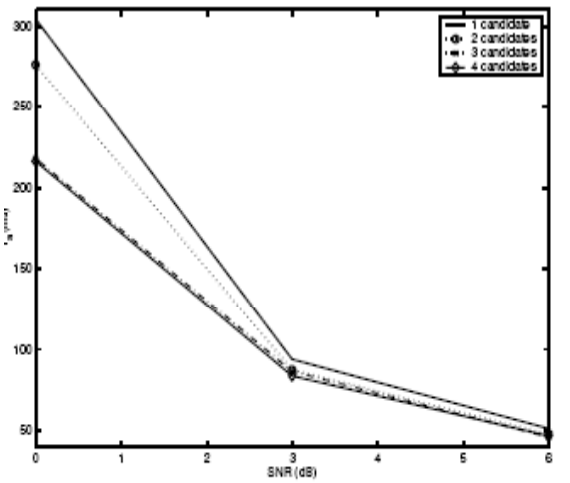

offset due to receiver oscillator inaccuracies of 20 kHz. Non-ideal sampling is introduced by means of a fractional delay filter that introduces a delay of half a sampling period (worst case). The advantage of oversampling becomes evident in Fig. 14. Chip rate sampling leads to unacceptable performance at lower SNR. Clearly, oversampling in the presence of non-ideal sampling reduces Ta dramatically. Furthermore, simulation results show a saturation of performance with increasing oversampling factors. Therefore, we assume an oversampling factor of Os=4 .

The dependence of the acquisition time Ta on the number of slot boundary candidates passed between stage 1 and stage 2 is illustrated in Fig. 15.

Clearly, the performance gain obtained by passing several candidates between stages increases at lower SNR, and it reaches 30% at 0dB compared to the case with a single time-code candidate. Furthermore, no noticeable performance improvements are observed beyond 3 time-code candidates.

CONCLUSIONS AND FUTURE WORK

This paper was able to study the various steps involved in the Cell Search process and an attempt was made to simulate them. Also we investigate the code and time synchronization of the cell search algorithm. In addition to code and time

synchronization, frequency synchronization between the MS and the BS needs to be achieved. When the received signal was correlated with the PSC sequences generated at the MS, some peak values were obtained and the maximum of those peak values was displayed as the slot value for that particular frame. In frame synchronization process, a FHT was used to match arbitrary SSC sequence with the frames and 16 values were obtained.In code synchronization process, the 16 values obtained are match with the values generated at the MS and the max of those values will be taken. Our study has shown that oversampling of the received signal can have a significant impact on the cell search performance in the presence of non-ideal sampling. We found that an oversampling factor of 4 was sufficient to mitigate the detrimental effects of non-ideal sampling, whereas chip-rate sampling leads to unacceptable performance. Furthermore, it was shown that the performance of the cell search algorithm in 3GPP UMTS can be improved significantly by passing several "code-time" candidates between the three stages of the hierarchical procedure. Our results show that with 4 candidates, saturation-performance is achieved for the propagation scenarios defined by the standard. Depending on the scenario, acquisition time can be reduced by up to 50% at low SNR values compared to the single candidate case. There is another cell search called target cell search, which needs to be performed during a call, and when a MS is in motion and moves from one cell to another. VLSI implementations to perform target cell search efficiently need to be investigated.

Business-to-Business Transaction Diffusion: X12 Standards

Moses Niwe, Stockholm University and Kungliga Tekniska Högskolan, Forum 100, SE-164 Kista, Stockholm, Sweden; E-mail: niwe@dsv.su.se

ABSTRACT

Accredited Standards Committee (ASC) and Data Interchange Standards Association (DISA) as the administrative arm is the United States business to business (B2B) transaction standard developing organization (SDO). This paper focuses on ASC's challenges in the standardization diffusion process of the X12 standard. Specific questions include what industry of X12 membership is most actively involved and what is the most active role played by the different organizations involved in the X12 B2B exchange? The progression of X12 membership is examined over the years, and strategies to improve this. The findings reveal that the most active sector is the computer and consulting industry followed closely by the healthcare which is driven by the Health Insurance Portability and Accountability (HIPPA) legislation. The Finance, and Insurance, show reluctance in joining the wagon probably because they formed there own alliances within the industry. Furthermore, the early adopters, the automotive sector, no longer participate in the X12 standard, because they have established their own B2B data platforms that support their business requirements.

Keywords: X12 standards, diffusion, and business to business e-commerce

1. INTRODUCTION

Business to business (B2B) e-commerce is a successful technological innovation involving sending and receiving information using computer technology which has been used for decades. The first electronic data exchange formats came with industrial suppliers to the United States (U.S.) government in the 1950s. As more players from different industries got involved, over the years the U.S. realized a need to develop common Electronic Data Interchange (EDI) formats and build cross industry standards to increase efficiency. In 1979 American National Standards Institute (ANSI) as the U.S. standardization member body of International Organization for Standardization (ISO) chartered Accredited Standards Committee (ASC) X12 to develop and maintain the cross-industry B2B U.S. standard. Today X12 is being modified to support EXtensible Markup Language (XML) as the newer syntax rising out of needs for organizations to reinvent their business processes and information technological infrastructures. The U.S. is still the region in the world responsible for the highest volumes of B2B revenues. United States based B2B e-commerce transactions continue to drive the global adoption rate (McGann, et al 2005).

The objectives of this paper are (1) to review the status of B2B e-commerce diffusion by X12 standards in the U.S. Specifically we assess X12 diffusion by industry sectors, (2) to identify the characteristics of main adopters in terms of roles played in the B2B supply chain, (3) to capture the strategies of increasing diffusion of X12 standards. These would be beneficial to other industrialized nations that are aiming to replicate the adoption pattern of the U.S.

The paper is organized as follows. Chapter 2 gives a brief background about B2B standards focusing on the X12 standard, followed by the methodology used in addressing the goals. Chapter 3 presents the research approach used for this study. Chapter 4 presents our empirical findings gathered at DISA and analysis of the findings. Chapter 5 presents our concluding remarks and issues for future work.

2. B2B STANDARDS

A standard as a key strategic element for successful e-commerce transactions among different trading partners is paramount (Reimers, 2001). Standards contribute to improving business processes, reducing purchase and inventory costs, increasing productivity and market efficiency, and taking advantage of new business opportunities with market intelligence techniques (Choudhury, 1997, Nelson and Shaw 2005, Medjahed et al, 2004).

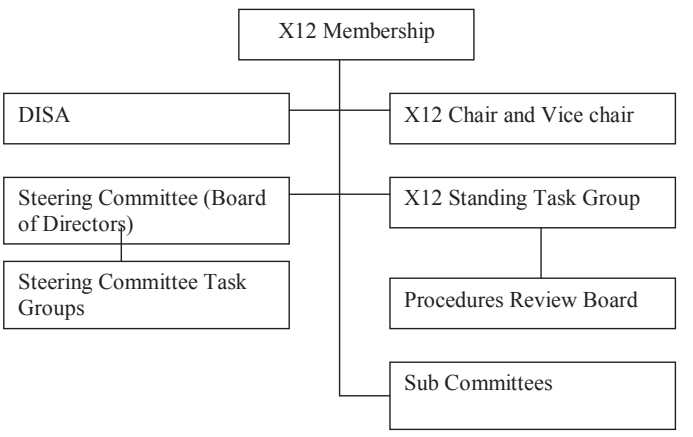
2.1 X12 Standards

Among many other standards, X12 was the first and still is the predominant cross-industry B2B electronic transactions standard in the U. S. (Cline, and Piazza, 1992). Since 1979, X12 has the mandate of developing the B2B transaction standards. In 1987, X12 created Data Interchange Standards Association (DISA) as a non profit to serve as its secretariat. Representatives from the various industries as employees of member companies, meet face to face three times a year, and vote on agreed upon standards that are published by ANSI ASC. Development of the standard is done in between the meetings as an ongoing process. The member company representatives continue to discuss through e-mail, or teleconference until a standard is approved for publication. Membership is open to all interested organizations. The ASC X12 standards and transaction sets are available at a fee from DISA. The general membership is responsible for electing a chair and vice chair every two years that makes up the management committee supported by a steering committee that includes the immediate past chair, vice-chair and elected members of the various subcommittees.

The technical and business processes knowledge is acquired from the members as they know best what kind of standards they need. There are Industry sub-committees, namely government, finance, transportation, and healthcare to address the specific needs of the industry. Figure 1 below shows the organizational structure of X12.

The (ASC) X12 published its first version in 1983, since then it publishes versions annually and releases transaction sets after the trimester meeting. The latest version is 5, release 3 (5030). The transaction sets which are an equivalent of smart documents in EDI, enable data to be exchanged between agreed upon business partners in various industries. ASC X12 facilitates electronic commerce with more than 315 transaction sets across government, education, finance, supply-chain, legal, transportation, healthcare and insurance industries. Since 1997 X12 has

Figure 1. X12 organizational structure



been cooperating closely with the United Nations, Electronic Data Interchange For Administration Commerce and Transport (UN/EDIFACT), the global standard in EDI transactions.

Adoption of X12 is predominant in the very large companies. Smaller and medium-sized companies (SMEs) do not have the infrastructure to tag documents using X12 and hence they do not want to spend the money on it because it is too expensive, difficult, and complex (Subramaniam, and Shaw 2002). Small companies want other ways to work around the costly issues but still get the benefits of doing B2B e-commerce (Amoroso, and Sutton, 2002). However it is still believed that the general adoption of B2B is heavily influenced by SMEs. The efficiencies and benefits are still in involving the SMEs because everybody gains that way (Wagner, 2003).

3. METHODOLOGY

In the first phase of data collection to gain an understanding of B2B e-commerce adoption across industry sectors, documentation sources of DISA were reviewed. In tables 1 and 2 we present relevant inferences showing the membership as a representation by sector, and role area. The sample size was 250 who comprise X12 membership at the time of data collection. The President of DISA, Mr Jerry Connors and current (ASC) X12 Chair, Dan Kazzaz were also interviewed. Before visiting the interviewees they were contacted, with a brief introduction to the purpose of the study. Each interview was approximately forty five minutes. First they were asked about scope and e-commerce applications that they have implemented in their respective roles and future plans. Secondly we asked them to recall general problems that they encountered from the diffusion process, and then we specifically discussed the strategic issues. The interviews were organised in a pattern as to look out for similar categories for the analysis stage.

Table 1. List of companies by industry (N=250)

User-Provider	10
Vendor- Provider	12
Not Identified,	27

4. ANALYSIS

The Analysis chapter presents the findings and interpretation of the results. The highest representative sector percentage is the computer and consulting industries at 34 percent. The computer and software industry have been at the lead of using advanced EDI to streamline processes. Combining XML techniques with the company's system configuration into a supply chain management is on the top of the agenda of most of the industry. The X12 efficiencies have attracted both the big and small businesses, software developers like Ahmer Taylor, I.M. to computer consultants like EDI Source Inc and IBM Corporation. Companies are actively involved in open channels in different forms of applications with their business customers. The other representative analogy of companies and firms under this sector representing the biggest percentage is the vastness of the industry, from general computer companies, consulting, and software companies to standards developers.

The Health sector follows at 32 percent using X12 adoption under the Health Insurance Portability and Accountability (HIPPA) act. This is probably one of the few sectors that have attracted government participation more than any other. This could be based on the reasoning that the other sectors are more driven by the private rather than the public systems.

The financial, and insurance is at 15 percent. This can be explained by the ease of developing XML standards with groups such as Interactive Financial Exchange (IFX) an open standard financial data protocol. Other competitors include Open Financial Exchange (OFX), dealing with small transactions and Automated Teller Machines (ATM) standards. In the industry there is no unified standard, but efforts are underway to have all these standards working compatibly. Interactive Financial Exchange has been struggling financially to keep going so they have not been able to get as many members to come to the table and work with them and pay dues to the organization. Problems come from most companies wanting to use the standards but not ready to be involved in the startup operations of setting up the framework. In the age of internationalization of products and services through the Internet, coupled with stiff competition, banks, insurance companies and other financial institutions need to strategically rethink the fundamental ways they provide financial services. A revolution is going on and for the financial institutions not using the right strategies. The member organisations in this category are banks, banking financial and banking government.

Transportation sector is at 7 percent. The high need of connecting business partners and their goods and services, internationally is hopefully going to bring more participation from the transportation sector. This is all geared at making trade in the industry faster and cost effective. The companies include general transportation, transportation-motor, transportation-rail, and transportation-ocean.

The combined sector at 12 percent includes all the other sectors that are not generally classified above; examples include manufacturing, apparel, and chemical for example DuPont Company. The industries like automotive that were expected to continue being major players are not well represented and Jerry Connors, DISA President has an explanation for that. "These were among the founding member companies in the 70s but as they implemented they found no need to develop new transactions and, hence they pulled out". Dan Kazzaz, the ASC X12, current chair concurs with this notion "it is hard to get big companies to continue working after they completed developing their core message."

As shown in table 2, generally as far role playing (in the B2B transaction) is concerned the majority are the users at 25 percent; we have some few user-providers at 10 percent and vendor-providers at 12 percent. The User refers to the companies and organisations in the supply chain that generally receive, standardized documents using B2B e-commerce. The General Interest Companies are the firms that have shown some level of adoption. These are actors with a two way relationship, in form of Users. In addition they send all their transactions over the EDI platform. They have possibility scenarios of many to one. Vendor-Provider these are more than users themselves in sending and receiving but they also provide the technical platform for the supply chain management, in the transaction process. Through secure and authenticated connections the vendor-providers authorize their respective end users for the B2B connections.

4.1 X12 Performances

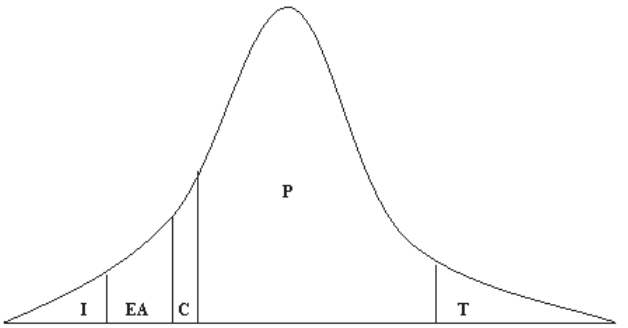
The use of X12 has been steadily growing from the mid 80's (see table 3) when the concept became popular for cutting costs and reducing processing time. However the late 90's and early 2000, plagued by the dotcom era problems, experienced a slight decline. This however is picking up as new models reveal how B2B e-commerce can reduce transaction costs such as time and effort in finding products, services solutions, potential buyers and suppliers. The highest percentage is from 2003 to 2006, (33 percent) which could be explained by regained confidence after the dotcom era. This also confirms (Bonaccorsi, and Rossi, 2002) reference made to the higher the number of adopters the higher the probability for others with the intent to adopt to join the band wagon effect.

Other issues include the telecommunication infrastructure, the greater numbers in the firms using the technology the greater the investment in the infrastructure which in turn brings in more adopters. In deciding to adopt there was reference of how many other adopters are in the sector and how many other intend to adopt. Other firms wait for early adopters to see their performance and decide whether

Table 3. Progression of EDI X12 membership in the last 2 decades

Period	%
1985-90	17
1991-96	27
1997-02	21
2003-06	33

Figure 2. From Moore (1991) showing adoption process



they will join or not. Critical mass of early adopters brings forth the industry pressure needed to bring in the majority and late adopters. Then the decrease as most firms adopt. These patterns with the sigmoid path as seen in figure 2 below. Starting with a few companies adopting the e-commerce technology and adoption increasing as other firms learned about the new technology. Other inferences include variables such as the size of the organization; value of the technology has little to do with the technology adoption. Technology adoption process has variances between the technology expectations and the technology value. This conforms to Moore's technology adoption life cycle (Moore, 1991) with the main categories of adopters as innovators (I), early adopters (EA), pragmatists (P), and the traditionalists (T). Chasm (C) is the time lag between the early adopters (EA), pragmatists (P).

4.2 Performance by Industry Sector

The healthcare industry in spite of being a late starter shows tremendous growth (as shown in table 1). Jerry Connors says "healthcare industry is the most active industry today." He adds that this is partly because the federal government of the U.S. mandated that all medical practices use the HIPPA law. And HIPPA requires requires that all medical practices and all healthcare insurance companies use X12 for claims and other administrative transactions. So, it is a constantly emerging situation that will be going on for a long time. Currently in the healthcare sector, there are many other different standards; X12 mostly works with administration and billing not clinical. There is a need to harmonize these standards so that they can be more interoperable.

In the 80s subsequent to the recession in the 70s, the automotive industry needed to change how it did business. In order to have just-in-time inventory you have to have messages from the manufacturer all the way through the supply chain coming in very quickily. The automotive sector had not been doing Just in Time (JIT) inventory replinshement, so they were either buying too much that created storage problems or too little and hence runing out of stock while they made their cars. As a result they knew that they needed to switch to JIT. This drove X12 adoption and they basically pumped the resources into X12 to make it happen for all their suppliers. For its sucess, software vendors, and standard organisations were needed for the suppliers to communicate. So, the automotive industry made it happen in their value chain. Similarly, the apparel industry pushed on the retail industry to try and save themselves and the apparel industry did not succed so well in saving themselves because they ended up sending all their manufacturing overseas. But they basically were trying to do JIT inventory for themselves. They picked up the same idea as they moved it to retail. The whole supply chain activities that happen inside the retail environment happen using the X12 standards.

Through the progression of years the big companies like General Motors concluded that they have got what they needed, so membership dropped to about half. Jerry Connors says "for a long time in the late 80s and 90s we had huge participation with a membership of up to 700 to 800 from all industries across the country, and thousands at the meetings." Mr. Connors adds that in the last few years some of the big companies have got what they needed; "they have B2B data platforms that meet their needs, so, they don't feel the need to participate as actively as they did before." With big companies it is very hard to get them to agree, some especially in the automotive industry felt the need to go international, which also affected X12 membership (see table 3). Today the automotive industry does not participate in X12 and has minimal representation with United Nations Centre for Trade facilitation and Electronic Business, (UN/CEFACT). As stated above they are not building new messages. Their participation is missed and there are efforts to bring the two organizations together to see this reversed. They have a wealth of experience and financial clout, which would greatly enhance the ASC X 12 performances. This would help X12 in general build better standards.

ASC X12, strategies of increasing diffusion of X12 include using the emerging language XML, with the highly acclaimed syntax neutral architecture called Context Inspired Component Architecture (CICA), which is more flexible and human readable than EDI. Jerry Connors, says" what we are tying to do with this architecture is to set ourselves for the long term future so that whatever comes along in XML we will be ready for it." With this approach ASC X12 with its experience and technical expertise, as the U.S. B2B primary standards body is leading the way to convergence of EDI and XML Standards to handle the business processes within an Internet based e-commerce environment. Challenges with the CICA architecture are that it is complicated. It is hard to get a wide group of people to understand that they can model their business and build messages simultaneously. Dan Kazzaz says, "What we are trying to do is to encourage the software community to develop tools, so that the data involved in a particular business message can be entered into the tool and the tool will help them model their message, the model can then automatically populate the X12 CICA." "This is a very high priority for us right now. The people at the end in the sub-committees vary in technical expertise; we want to create a platform that will allow as many as possible to build CICA complaint messages without having to understand all the new nuances of the architecture. If they enter the data it will come out the back end the way they want it and have strong, reusable component."

5. CONCLUDING REMARKS

All indicators show a continued interest in B2B e-commerce in the U.S. The obvious advantages that B2B e-commerce brings with it such as efficiency makes B2B e-commerce a perquisite across all industries in the transportation, government, real estate, healthcare, education, retail, grocery, warehousing, and financial services. However, there are considerable gaps and mysteries in the different sectors to the new adoption insights. The business relationships between many companies have been unique to their business processes, hence their concerns over the new ideologies that the ASC X12-XML would address all the bottlenecks in electronic business. In addition concerns with data security and the reliability of the standard still arise.

Our findings show that much of the healthcare sector has woken up to the potential of B2B e-commerce, as confirmed in the interview with the X12 Chair. From the interviews, among the challenges to adoption significant issues identified include; barriers to prioritization by top management, implementation obstacles such as integration with internal application systems and existing business methods, and, for banks, consideration of B2B e-commerce technologies as a close relation to corporate banking.

EDI platforms built by the Fortune 500 companies to exchange electronic messages were very expensive; hence they are not keen on the change because of the high investments in terms of time, money and human resources made earlier on. Besides, many of them believe they are doing fine with their EDI platforms and are not interested in investing more money in making vast changes, though some are willing to make small incremental changes as they watch closely the return of investment. Main questions still remain what is the move to XML going to get me? Hence the challenge for X12 remains to determine and teach its member-

ship and potential members the value proposition of using syntax neutral model (CICA) to create new messages. They intend to address this through a strategy of proposing new bodies of work and working to ensure that application software vendors support these new messages. Moving from EDI to XML by small increment changes, with compatible content, rather than big moves as the value of moving over is appreciated. E-commerce activity is geared towards empowering SMEs to participate. This is expected to bring back the software vendors to build relationships, hence increasing the diffusion rate. However, before all this happens, harmonization is needed for the different standards within X12 and the newer XML to be more interoperable. Efforts to address this are there but still in their early stages. Mr. Kazzaz, adds, "my vision includes seeing the American standard being synonymous with the international standards. Harmonizing the standards will create more efficiency." With this said challenges remain for ASC X12 like to get the competing standards groups to stop and evaluate the benefit that would come from harmonization.

6. FUTURE WORK

To further the research of B2B e-commerce adoption beyond the U.S., we propose to look at a comparative study of government case studies of U.S., versus European Union and its member states. Eliminating paper based business transactions with its expenses has been the main motivation behind business to business (B2B) adoption. As we have seen the more able larger organizations have seen tremendous growth in doing their business-to-business electronic transactions over the widely accepted standards of the US (ANSI X12) for the U.S. organizations. For European Union, a case study of Sweden and, UN EDIFACT, could be examined to compare the different firms, and present a synopsis of the adoption for the two predominant standards.

Peak Oil to Peak People: Education – A Resource in the Knowledge Society

Lalita Rajasingham, Victoria University of Wellington, New Zealand; E-mail: lalita.rajasingham@vuw.ac.nz

INTRODUCTION

This paper suggests that as oil supplies run out and prices rise in the knowledge economy, an education system is needed that is based on information technology rather than on transport and building technologies to provide an alternate resource for sustained economic growth. The world is at a tipping point where it is running out of oil, but not people. It is argued that the knowledge society will be based on the infinite resources of the world-its people. We need to tap and develop this resource through education and training and so move from peak oil to the production of peak people. The key driver of change is going to be innovative rethinking on how people are educated for an unpredictable, information technology-based future. The current debate under the rubric of globalisation is on peak oil, and a clear contradiction between peak oil theory, the continual increase in oil reserves and production, and the rising cost. Peter Huber and Mark Mills (2005) argue that the price of oil remains high because the cost of oil remains so low. We are not dependent on the Middle East for oil because the world's supplies are diminishing, but because it is more profitable to tap Middle East supplies. New sources are not being explored and new refineries not being built (Huber and Mills, 2005). Since the industrial revolution, world economies have run on oil. Societies have been through 'peaks' in critical resources throughout history, only to be saved by some human ingenuity and discovery of a new and 'inexhaustible' resource. It was oil that 'rescued' civilisation to deal with sustainable economic growth. Can highly educated peak people do the same? As the price of oil worldwide continues to soar, societies globally struggle to find alternative fuels that range from coal, solar, wind farms and nuclear energy to drive their economies. But these are still expensive, and the means to exploit alternative energy using technology remain oil fed. That oil will run out is certain; only the timing is not. However, when oil does run out or becomes unaffordable particularly for the developing nations and their growing populations, its decline will change the world in radical and unpredictable ways. Perhaps even more concerning is that because oil is a strategic resource, as supplies become scarce, societies are witnessing increasing geopolitical and global conflicts, environmental deterioration, pandemics and ideological and cultural clashes. Oil created the industrial society as we know it, but at the dawn of the knowledge society, it is a finite resource. Around the world, societies now believe that their future advancement can no longer only depend on their land, climate and extractive fuels, but rather upon the peak capability of their people. Therefore, with knowledge as competitive advantage, education for human resources development will be the engine that drives the global economy.

DUAL CRISES AND THE NEED FOR A NEW PARADIGM

Philip Coombs's 1968 classic *The World Crisis in Education* reflected a universal concern that educational systems were becoming dinosaurs out of synch with societies' needs. He revisited the issue in 1985 and found that in fact the crisis had deepened (Coombs, 1985).

Today we face two crises, peak oil and the crisis in education where current education systems seem unable to provide the dimensions and skills needed for problem solving in an unpredictable and fast-moving future.

The modern university as we know it is designed to operate according to the prevailing paradigm and infrastructures in the society in which it is located. It is based on building and transport technologies that bring together teachers, learners, knowledge and problems by providing communication networks to effect education. However, building and transport technologies based on depleting oil supplies are becoming more costly. At the same time, rapid advances in communication and information technologies especially the internet offer alternative and complementary learning spaces to respond to the increasing demand for tertiary education worldwide to up skill employees for the emerging, competitive, global knowledge economy.

FROM PLACE-BASED TO SPACE-BASED LEARNING

In his speech on July 26 2006 to the OAS, Nicholas Negroponte suggested that no matter which global problem we address, the solution always includes education. He argues that it is through using IT both as a tool of learning and as a window on the world that people will learn most.

Some of the main challenges facing universities today include the need to break away from the limitations of time and space the conventional classroom imposes; and to consider the impact of the internet as education becomes global competitive and commercial.

THE UNIVERSALS OF UNIVERSITIES: TEACHING/LEARNING/KNOWLEDGE

Some critical factors that constitute higher education, the universals of a university-the creation processing and application of knowledge to real-life problems in culturally appropriate ways-will not change whatever the episteme, the place, the language, the culture or the medium used. The main difference that distinguishes e-learning from on-campus learning is that instead of bringing students and teachers together physically by means of local transport systems and buildings for face-to-face interaction, e-learning uses computers and telecommunications to bring them together as telepresences on the global internet (Tiffin and Rajasingham, 2003).

The internet is still evolving and will continue to do so as computers become more powerful and wearable, and bandwidth increases. Today computers are an essential tool for communication as interactive multimedia on the internet allows the global networking of human intelligence in unprecedented and revolutionary ways.

Curricula designed for use in a particular institution within a particular nation and context and posted on the Internet are now open to scrutiny from a global perspective as the professional application of knowledge increasingly takes place in a global as well as in local contexts. The conventional university system is designed and localised for the nation in which it operates according to the rules, regulations, taxation, laws and language of that country.

Universities are associated with knowledge, which by singularly adding value is the engine that drives economic growth. But knowledge is an elusive and abstract concept that defies definition. Knowledge exists in explicit as well as implicit modalities. Not only is knowledge being deconstructed into a multiplicity of subjects, but is seen differently from university to university, country to country and language to language. The growing fragmentation of knowledge and lack of consensus as to what constitutes knowledge creates a context for discordant value and quality judgement. From a postmodern perspective, we see multiple 'knowledges' on the same theme (Lyotard, 1984) and all seek legitimisation for problem solving in their own cultural settings. As the university changes with a new episteme, so too must the knowledge it teaches and researches.

Today, professionals need to know about international practice as it operates in the global economy. Pandemics such as AIDS, SARS and Avian Flu, terrorism and

environmental issues know no frontiers, and people everywhere need to be able to collaborate internationally to deal with these global issues. The trickle down of knowledge over time is suddenly bypassed and so is the intermediary position of the teacher as education becomes learner-centred, non-linear, and self-directed, thus shifting paradigms.

Furthermore, universities face competition and commercialisation as students as fee-paying customers now compare and evaluate what is taught in other countries by using the World Wide Web and linking in chat rooms with students from around the world. Universities need to attract students, remove the regulatory and administrative barriers to developing innovative research and quality curricula. Let the customer decide what they want, and provide it. Good teachers and good researchers should be well remunerated and supported. The ineffective ones should go.

As education becomes big business, universities are challenged to resolve the dichotomy between business ideals and pedagogical imperatives that embody the universals of a university, and help improve the quality of **what** and **how** we teach with integrity and maintain their *raison d'etre*- the creation, processing, dissemination and application of knowledge. As universities face increasing fiscal constraints resulting from reduced government subsidies, they seek to become businesses for profit. With reduced staffing, increasing on-seat student numbers and cutting staff and student support systems, staff/student ratios rise. Inevitably, standards fall (Rajasingham, 2006).

THE NEED

What is needed is effective, cost-efficient, culturally appropriate instruction that can match the needs for global skills related to rapid technological change, delivered interactively at the convenience of the learner. The learner, no matter where their physical location will be able to interact with the teacher, content and one another in synchronous and/or asynchronous mode using text, words and still and moving images, and in future smell, taste and touch. A global virtual university on the internet could meet this need. It will be global, competitive, commercial, and will be on broadband using virtual reality (VR) HyperReality (HR) and artificial intelligence (AI) providing learning through our five senses.

Curricula design for the global market is needed to allow societies to act global, and then localise in consonance with local thinking and upgrade the relevance of what is taught. With instructional design principles for internet based learning, basic courses that are the currency of higher education whatever the country can be re-addressed from the multiple perspectives of different countries, cultures and languages to develop new curricula to match global concerns (Tiffin and Rajasingham, 2003).

FORWARD MARCH

Education is communications. Both are information intensive, technology-based and culturally contextualised activities. The 1900s saw the use of correspondence based on postal services and radio in education. The 1960s, saw educational television and the 1980s, the advent of the personal computer in education. The 1990s saw the use of narrowband internet and virtual reality in education. In this decade of the new millennium we see the rapid advances in computer power that bring new sophisticated clusters of technology such as nanotechnology, AI and HyperReality on broadband internet changing the way we bank, shop, play and learn.

Virtual universities today proliferate on the internet with variable success and shelf-lives. Globalisation and the rapid advances in the internet will introduce new ways of learning and teaching and challenge the traditional classroom, not replace it but to provide alternative and complementary communications environments that will extend educational opportunities for more people than is possible with conventional classrooms. This is the virtual class based on distributed virtual realities on the internet where teachers and learners and curricula interact in telepresence and make globalisation of education a reality for anyone, anywhere.

THE FUTURE UNIVERSITY: GLOBAL, MULTICULTURAL, MULTILINGUAL AND BIG BUSINESS

In his foreword to the text *The Virtual Class: Education in an Information Society* (1995) Reidar Roll, the Secretary General of the International Council for Distance Education made an important distinction between quality in what we now call e-learning, and quality in conventional education and argued that we are not only talking about better educated citizens but differently educated citizens. He called for a balance between the need for global skills and knowledge and the need to respect and preserve cultural identity. This is a yin and yang relationship between global and national education.

In ensuring quality education and the universals in curricula, it is argued that if knowledge varies according to a country or a culture, then global issues can only be addressed from the perspective of that country and culture. As universities offer their courses online and become competitive, the question as to who determines quality which is a complex and nebulous subjective concept becomes an issue that education must urgently address. When the quality of education is only measured and promoted by national standards we have a recipe for the kind of clash in cultures that we have today where one nation's freedom fighter is another nation's terrorist. No country is an island unto itself as all societies are inextricably interconnected through the internet. So what kind of university will be needed in the knowledge society?

Lev Vygotsky (1978) suggested that education at its simplest is the coming together for interaction between teacher, learner and problem. As there is a close relationship between universities, knowledge and civilisation, it is argued that teachers help learners to apply knowledge to problems. Vygotsky, however did not envisage that the teacher need not be human.

To respond to multiperspectives in a globalised world, the virtual university on the internet will need to be global, commercial, multilingual and multicultural, where students are equipped with global skills to solve global problems, and at the same time act local in consonance with their own cultures and social networks. The HyperClass is a step towards this.

THE HYPERCLASS IN THE VIRTUAL UNIVERSITY

The HyperClass is based on HyperReality, a technological platform conceptualised by Nobiyoshi Terashima. It allows the intermeshing of virtual reality (VR) physical reality (PR) and artificial intelligence (AI) in a way that is seamless and allows interaction in fully immersive environments. A HyperClass is the interactive conjunction of a real class made of atoms with a virtual class made of bits of information. It makes possible a future where the people and the objects around you may be real or may be virtual and may have human intelligence or artificial intelligence, providing multimediated, immersive simulated learning environments. Because HyperClasses in universities can exist in real and virtual dimensions at the same time, they will provide an intersection between the local and global dimensions in education.

A student could go to a conventional class in a conventional university or stay at home and use a PC and the internet to link to a virtual class in a virtual university. A HyperClass allows a student to do both. A HyperClass exists where the virtual and real dimensions intersect. This is a coaction field where students and teachers in a conventional classroom can synchronously interact with students and teachers in other universities that may be in other countries.

A coaction field conceptualised by Terashima (2001:9-12) is where students and teachers in a conventional classroom can synchronously interact for the purpose of learning with students and teachers in other universities, possibly in other countries. The HyperClass is where real and virtual dimensions of students and teachers intersect providing a common field to reconcile the learning that is local with learning that is global in order to understand the subject from multiple perspectives of other cultures than one's own (Tiffin and Rajasingham, 2001; 2003).

Participants in a HyperClass come together because of their interests in a specific subject on a shared domain of knowledge. In the HyperClass, the relationship between knowledge and problem domains suggests another important contrast to conventional classroom processes. In a conventional classroom the application of knowledge to problems is expressed symbolically, through alphanumeric notation and two-dimensional still pictures displayed on a display unit such as a whiteboard.

However, it is suggested that when problems have a real life referent in the participants' social reality, then classrooms with whiteboards may not be the best place for learning and proves the inadequacy of alphanumeric and diagrammatic instruction alone. The challenge is to transfer learning from the classrooms to real life situations and testing the application of knowledge to real life situations in whatever form they take in multimediated simulated environments. The

HyperClass introduces a new dimension in education with the juxtaposition of knowledge with problems that have a referent in physical reality (Tiffin and Rajasingham, 2001).

With HyperReality technology, objects are created in 3-D using an array of videocameras, creating a database/library of problem case studies that could include dangerous conditions. Learners could for example, be faced with a vast array of different situations and could seek solutions to their problems with the help of their teachers and peers from diverse cultural perspectives where each participant or group can manipulate the 3-D modelled learning objects (Terashima, 2001). A significant strength of HyperReality as contrasted with virtual reality today is that while the communication process in a virtual class is prescribed using the shapes and designs that have already been created as computer generated virtual reality by computer graphic designers, HyperReality on the other hand allows a syncretion of cultures, where the quality of the content being studied can be designed, altered, and objects modelled by the participants themselves to catalyse collaborative learning from multicultural perspectives, and this capability that is contextualised is critical for improving the quality of the knowledge content being studied. Problems can be real. But knowledge is always abstract (Rajasingham 2006).

LEARNING, TEACHING AND JITAITS

Perhaps the most profound aspect of the teacher/learner axis in a HyperClass is that the avatars of teachers and students may not necessarily represent human intelligence. Today we are familiar with the little cartoon character, a wizard looking like a paper clip that keeps popping up on the computer screen offering to help where someone has tried to programme a just-in-time (JITAIT) artificially intelligent teacher. In a HyperClass a teacher and a learner can be virtual or real. A virtual teacher can have human intelligence (HI) or artificial intelligence (AI). Teachers and learners can communicate synchronously, using speaking avatars, or asynchronously, using written words or visuals. Knowledge and problems can be embodied in the teacher and the learner or they can be represented alphanumerically, or in simulacra.

Today human teachers can only respond immediately to a learner in working hours and if there is only one student seeking help. In large classes student questions have to wait until a teacher is available. In higher education much learning is done asynchronously and students get feedback on an assignment a week or more after doing it and most students have forgotten the things they found difficult. It is time for the just in time artificially intelligent teacher (JITAIT). As the name implies, this is an AI teacher that can be available whenever and wherever a student needs help (Tiffin and Rajasingham, 2003).

JITAITs are expert systems, effective where the domain of knowledge they address is restricted, paradigmatic and orientated toward problem solving. A JITAIT can therefore be an expert teacher on a subject that formed the domain knowledge of a coaction field in HyperReality. JITAITs would always be ready to help any learner in the coaction field and would improve from each encounter with a learner provided it received feedback from a human teacher, and could act as personal teachers to individual students. JITAITs could have avatar form and a personality and act as a guide and mentor in the manner of the servant-tutor pedagogues of ancient Greece. As each intake of students asks the same questions and has the same problems, JITAITs can be used and at this level could be shared between human and AI tutors. As time went by and JITAITs handled more and more FAQ's, their role would increase and the student teacher ratio could be progressively increased without lowering quality.

The upper level is that of the subject specialist, the professors and professionals who have achieved academic stature through research, publications and experience and can arbitrate on content. Their primary purpose is to communicate a synthesis of the subject matter in a way that brings it up to date, places it in context and encourages students to question. They do this by lecturing, and are supported by a team of teaching assistants who do the tutoring at the local level, leaving the professor to lecture to very large classes. With e-learning they could stream their lectures to the whole world, and there need be no limits to the numbers who could attend. Instead of being salaried employees, professors who could attract such numbers would be valuable property and they could relate to their universities in the way authors relate to their publishers (Kats, 1999: 48) receiving royalties for each student taking their programme.

THE GLOBAL VIRTUAL UNIVERSITY

The infrastructure of the virtual university which is on the internet is the technology that makes possible telelearning, telebanking, teleworking, teleshoping and telemedicine without leaving one's home. Distance from any place need no longer be a limiting factor. It does not matter where the university is physically located and learners in any country can as easily access courses from the global virtual university as they can from their neighbourhood university. In fact as internet access increases for people who are housebound, in hospitals, at work or travelling, or for convenience, it offers an invaluable alternative access to educational opportunities.

In the case of modern universities, accreditation of a degree programme, who can teach and how is legally defined by the government that supports the university through taxation. Curricula were set in concrete and it took years to bring in changes. Inevitably, national universities as virtual universities promulgate the national culture. This was acceptable and successful in the industrial age. But in the knowledge society, it creates problems for global education that not only caters for the English speaking world, but also for multilingual and multicultural environments.

The internet is a strangely dynamic environment that changes the nature of access to knowledge and hence the very nature of higher education. Knowledge is no longer based on the scientific paradigm, fixed and an end in itself. Virtual universities on the Internet opens up choice in content as well as learning styles, and provided there is access to the internet, equity of opportunity becomes an achievable ideal.

However, it must be noted that the issue of accreditation of a global virtual university is critical. If learners can choose from a smorgasbord of subjects offered by different universities in the education marketspace for credit towards their degree, who will validate the degree and give appropriate credit value?

Perhaps there could be a board of eminent international scholars and professors in the manner of a top journal's editorial board to scrutinise quality and provide the accreditation. Further discussion on this important topic is beyond the scope of this paper.

IN CONCLUDING…

Seymour Papert said: "Errors benefit us because they lead us to study what happened, to understand what went wrong, and through understanding, to fix it" (Brand, 1988: 127).

Whereas conventional universities are geared to the study of what is known and what is knowable, virtual universities address the unknowable in order to prepare people who can shape the future.

A global virtual university will by definition be open to competition and commercialism. What happens to education as a public good when it is open to market forces? However, we have to find a balance between the old and the new; and between the virtual and the real. It is therefore critical to research on how the world's untapped resource, its people can be educated for an unpredictable, rapidly changing future.

This paper suggests that if globalisation is to mean anything other than continued exploitation and increasing differentials of wealth and poverty then the development of global virtual universities will be one way to meet the social and economic needs of the world in the 21st century.

From Specification to Implementation: A Method for Designing Multi-Agent Systems in a Transformational Style

Hong Lin, University of Houston-Downtown, 1 Main Street, Houston, TX 77002, USA; E-mail: linh@uhd.edu

ABSTRACT

The suitability of using the Chemical Reaction Metaphor (CRM) to model multi-agent systems (MASs) is justified by CRM's capacity in specifying dynamic features of multi-agent systems. This paper presents a module language that facilitates a transformational method for implementing the specified multi-agent systems. A computation model with a tree-structured architecture is proposed to support the module language. The computational model is a straightforward abstraction of networked computing sources with minimum assumptions. In this model, the multicast network functionality pragmatizes the implementation of communications and synchronization among distributed agents. The transformational method is a rewriting process that translates the CRM specification into a program in the module language.

Keywords: Multi-agent systems, the chemical reaction models, program specification, very high-level languages, distributed systems, software architecture

INTRODUCTION

Agent-oriented design has become one of the most active areas in the field of software engineering. The agent concept provides a focal point for accountability and responsibility for coping with the complexity of software systems both during design and execution (Yu, 2001). In this approach, a distributed system can be modeled as a set of autonomous, cooperating agents that communicate intelligently with one another, automate or semi-automate functional operations, and interact with human users at the right time with the right information. Such a model should be general enough to address common architectural issues and not be specific to design issues of a particular system.

The modeling issue in the abstract computing machine level has been studied in (Banâtre, Fradet, & Radenac, 2004), where the chemical reaction model (Banatre & Le Metayer, 1990 & 1993, Banatre, Fradet, & Radenac 2005a, Le Metayer, 1994) is used to model an autonomic system. Given the dynamic and concurrent nature of multi-agent systems, we find that the chemical reaction metaphor provides a mechanism for describing the overall architecture of the distributed multi-agent systems precisely and concisely, while giving the design of the real system a solid starting point and allowing step-by-step refinement of the system using transformational methods (Lin, 2004; Lin & Yang, 2006).

As pointed out in (Banâtre, Fradet, & Radenac, 2005b), however, a direct implementation of a CRM specification is unlikely to be efficient and the authors also pointed out that this is another exciting research direction. The difficulty in reaching an efficient implementation of CRM specifications is caused by the use of multisets as the basic data structures and that a direct implementation of the selection operations in the reaction rules requires a brute force testing of the data. We observe that implementation of CRM specifications in the system architecture level, e.g., the architectural specification of an MAS, and that in the programming level can be handled in different ways. By using network communication functions to facilitate reaction testing, we can implement the specifications without brute force testing. This implementation allows further refinement of node-specific programs using proprietary techniques.

The presentation of our method will be in the following organization: In the second Section, we present a brief description of the Chemical Reaction Metaphor; In the third Section, we describe the proposed method for implementing CRM specifications of MASs. Discussions and Conclusions are drawn in the last section.

THE CHEMICAL REACTION MODEL

Based on the computation model of CRM, The Gamma language (Banatre & Le Metayer, 1990 & 1993) was introduced to program the computation. In the Gamma language, parallelism is left implicit and therefore a Gamma program is a true natural parallel program. The Gamma language was found suitable for describing a distributed and/or evolving system consisting distributed entities that execute and interact with one another asynchronously and that are added into the system or deleted from the system dynamically. Follow-up researches revealed that the Gamma language can successfully address the architectural design issues since its computation model captures the dynamic characteristics of a distributed system (Inverardi & Wolf, 1995; Banatre & Le Metayer, 1996; Le Metayer, 1998). For instance, it is a distinguished language for the architectural design in coordination programming (Holzbacher, 1996), configuration programming (Kramer, 1990), and software architecture (Allen & Garlan, 1994; Garlan & Perry, 1995).

The basic term of a Gamma program is molecules (or γ-expressions), which can be simple data or programs (γ-abstractions). The execution of the Gamma program can be seen as the evolution of a solution of molecules, which react until the solution becomes inert. Molecules are recursively defined as constants, γ-abstractions, multisets or solution of molecules. The following is their syntax:

$M ::=$	$0 \mid 1 \mid \ldots \mid$ 'a' $\mid$ 'b' $\mid \ldots$	; *constants*
$\mid$	$\gamma P[C].M$	; *γ-abstraction*
$\mid$	M_1, M_2	; *multiset*
$\mid$	$\langle M \rangle$	; *solution*

The multiset constructor "," is associative and commutative (AC rule). Solutions encapsulate molecules. Molecules can move within solutions but not across solutions. γ-abstractions are elements of multisets, just like other elements. They can be applied to other elements of the same solution if a match to pattern P is found and condition C evaluates to true and therefore facilitate the chemical reaction. The pattern has the following syntax:

$$P ::= x \mid P, P \mid \langle P \rangle$$

where x is a variable. In addition, we allow for the use of tuples (written $x_1 : \ldots : x_n$) and names of types. For example, γ-abstraction

$$\gamma(x: \textbf{Int}, y: \textbf{Int})[x \geq y].x$$

can be interpreted as: replace x, y by x if $x \geq y$, which is equivalent to finding the maximum of two integers.

The semantics of γ-Calculus is defined as the following:

$(\gamma p[c].m_1), m_2$;*γ-conversion*	$= \phi m_1$	if match$(p / m_2) = \phi$ **and** ϕc
m_1, m_2 ;*commutativity*	$= m_2, m_1$	

$m_1, (m_2, m_3) = (m_1, m_2), m_3$
; *associativity*
$E_1 = E_2 \Rightarrow E[E_1] = E[E_2]$
; *chemical law*

The γ-conversion describes the reaction mechanism. When the pattern p matches m_2, a substitution ϕ is yielded. If the condition ϕc holds, the reactive molecules $\gamma p[c].m_1$ and m_2 are consumed and a new molecule ϕm_1 is produced. $match(p/m)$ returns the substitution corresponding to the unification of variables if the matching succeeds, otherwise it returns **fail**.

Chemical law formalizes the locality of reactions. $E[E_1]$ denotes the molecule obtained by replacing holes in the context $E[\ ]$ (denoted by $[\ ]$) by the molecule E_1. A molecule is said to be *inert* if no reaction can be made within:

$$Inert(m) \Leftrightarrow (m \equiv m'[(\gamma p[c].m_1), m_2] \Rightarrow match(p/m_2) = \textbf{fail})$$

A solution is inert if all molecules within are inert and *normal forms* of chemical reactions are inert γ-expression. Elements inside a solution can be matched only if the solution is inert. Therefore, a pattern cannot match an active solution. This ensures that solutions cannot be decomposed before they reach their normal form and therefore permits the sequentialization of reactions. The following inference rule governs the evolution of γ-expressions:

$$\frac{E_1 \rightarrow E_2 \quad E \equiv C[E_1] \quad E' \equiv C[E_2]}{E \rightarrow E'}$$

For example, assume M, N, and R are names of three types, and f and g are two molecules that transform an element of M into an element of N, and from N into R, respectively, a producer can be defined as the following γ-abstraction:

$$prod = \gamma(x: M)[\textbf{true}].\ \langle f, x\rangle: N, prod$$

and a consumer can be defined as:

$$cons = \gamma(x: N)[\textbf{true}].\ \langle g, x\rangle: R, cons$$

A producer-consumer program that allows stream processing in which the producer and the consumer work concurrently can be written:

$$PC\ M_0 = \langle M_0, prod, cons\rangle$$

where M_0 is the initial set of values of M type.

IMPLEMENTING ARCHITECTURE SPECIFICATIONS

Although there were discussions about implementing the Gamma language on parallel computers (Creveuil, 1991; Gladitz & Kuchen, 1996; Lin, Chen, & Wang, 1997), it is commonly accepted that there is no straight implementation of the Gamma language that is efficient. After all, the Gamma language was designed as a very high level language for program specifications and is, therefore, used to specify the architectures of the coordinating systems. In a sequel, node-specific software design in a distributed system still relies on conventional software engineering methods. In a distributed multi-agent system, the separation of architectural design and the design on proprietary platforms is deemed even more necessary for dealing with the complexity of the system (Lin, Lin, & Holt, 2003). Therefore, we will restrict the following discussion to implementing the Gamma specification of the multi-agent systems in the architectural level with a minimum assumption about the computation model supported by the underlying system.

Computation Model

The computation model on which we discuss the implementation of a Gamma specification is a multi-process system, with processes dynamically created and deleted and interacting with one another. No assumption is made about the allocation of the processes on distributed nodes of the underlying computing network. That is to say that multiple processes can run on a single node or on distributed nodes. The hierarchy of the multi-processes is a tree structure, in which processes have full control over the creation/deletion of their descendent processes in the lower level, but not vice versa. A process can "lock/unlock" its activities. Locking means the freeze of all local computations and unlocking is the reverse operation. However, locking/unlocking does not apply to communications between the manipulated processes and other nodes. Communications among nodes are performed through communication channels which support unicast and multicast communications. However, these communication functions are process based instead of IP address based. That is to say, for example, multicast involves a set of processes instead of a set of nodes with distinct IP addresses.

Module Specification

We propose a language for specifying processes that run on an execution environment that supports the above computation model. Processes are specified by *modules* in the module language. A module is composed of a name, a parameter list used to take initial data when the process starts running, and a body block consisting of sequentially executed statements.

```
module name(parameter-list)
begin
        statement-sequence
end
```

First-class values are stored in a data pool named pool(*mid*), where mid is the name of the module. We leave the data structures of the data pool unspecified to maintain high-level abstraction. Their implementation is left to the stage of coding in a concrete programming language, which is subject to proprietary platform technologies. We do assume, however, that data items are addressed in the data pool so that we can locate particular data items and delete them.

Each module is associated with two multicast groups: sync(*mid*) and dist(*mid*). sync(*mid*) is the multicast group used to implement atomic captures of molecules. It involves synchronization using *syn* and *ack* messages, as described above. dist(*mid*) is the multicast group for distributing produced molecules. We use *mid* as an argument to identify the multicast group to which *mid* belongs, such as sync(*mid*) and dist(*mid*). We may use sync or dist along if there is no ambiguity. Note that both sync and dist can be either syntactically (statically) or semantically (dynamically) checked. The syntactic check is used in this paper. We will show how to do the syntactic check in Section 3.4.

Operations performed by a process include local operations, communications, and process control operations. There are four local operations that can be performed by a process:

- Add(data): add data into the pool
- Delete(data): delete data from pool
- Select(): select a set of element in pool that may match the pattern. The set of selected elements is returned by the function if the selection is successful, or **fail** otherwise.
- Release(): release the selected elements and return them to pool.

two communication operations:

- Send(type, sid, data): send a message. type can be syn, desyn, ack, or dis. Semantics of Send operation differs with different types. A syn/desyn message is sent to all processes in multicast group sync, while an ack message is unicast to the sender of the syn message identified by sid. In addition, data field of the ack message is empty. A dis message is sent to all processes in multicast group dist and sid is insignificant.
- Recv(type, sids, data): Probe the message queue, return the first message (through parameters type, sids, and data), or **fail** (through function return

value) otherwise. Recv() function can return data sent by multiple senders identified by ids, e.g., Recv(ack, sync,) checks whether the syn message has been acknowledged by all processes in sync.

and five process control operations:

- Create(id, arg1, arg2, …, argn): create a module with the given name and argument list. The argument list is used to pass initial data set to the created module.
- Delete(id): delete the module whose id is specified in the parameter and collect the resulting multiset in pool of module id and join it with the local pool. Also, add id into the local pool. If module id is not inert, Delete(id) does not have effect and return immediately.
- Inert(): This is an overloaded operation. The default version (no argument) freezes local activities in the local module if no more actions can occur, and return **true**, or **false** otherwise; while the version with a module id (Inert(id)) tests whether module id is inert. Inert() function does not affect communications between the module and other modules. In addition, once a module is inert, a message is sent automatically to the solution module in the immediate upper level. If Inert() is called by a solution module, it automatically checks whether there are still active modules in the lower level by checking the received messages. A solution module will not become inert until all lower level modules are inert.
- React(): resume local activities in the local module. Also, once a module is re-activated, a message is sent automatically to the solution module in the immediate upper level.
- Thread(abs, arg1, arg2, …, argn) : create a thread, which runs the program represented by the abs parameter. This feature is used to support mobile agents, codes sent by other modules and run on the environment of the module that receives it. The mobile agent is run as a thread so that it shares the data in the execution environment of the receiving module. The result of the thread, if any, can be retrieved by <abs>.

The body block of a module consists of a sequence of statements separated by ";". A statement is either a call to the one of above operations, a conditional statement, or a looping statement. The following is the BNF definition:

block ::= begin *statement-sequence* end

statement-sequence ::= *statement* ; *statement-sequence* | empty

statement ::= *operations* | *conditional* | *looping*

conditional ::= if *reactions* fi

reactions ::= *reaction* ; *reactions* | empty

reaction ::= *cond* -> *actions*

cond ::= *actions*, *bool-expression*

actions ::= *action* , *actions* | empty

action ::= *statement*

looping ::= do *reactions* od

bool-expression ::= … ; an expression returning either **true** or **false**

operations ::= … ; the operations described above

The conditional statement has the following semantics: conditions are tested and one of the statements whose corresponding conditions test to **true** is executed. If none of the conditions tests to **true**, the control falls through the if statement and continues to execute the statement that follows it. Its semantics of the looping statement is: in each iteration, conditions are tested and one of the statements whose corresponding conditions test to **true** is executed. This process is repeated until none of the conditions evaluates to **true**. This semantics of the conditional and looping statements is non-deterministic since no rule is set to govern how to select the statement to execute when multiple conditions are evaluated to **true**.

Note that even the module language is still a high level specification language, e.g., it leaves data structures and underlying communication mechanisms unspecified and has nondeterministic control structures, it is a language based on the realistic computation model. No higher-order operations exist in a program in the module language.

For example, the three modules designed for the producer-consumer problem are in the following. PC is the solution module, which creates the producer module (prod) and consumer module (cons). In this particular program, sync is empty because the patterns of prod and cons do not intersect. Dist(prod) = {cons} and Dist(cons) = Φ, which means that the produced molecules are sent from prod to cons but not vice versa.

```
module PC(M0)
begin
   Create(prod, M0); Create(cons);
   do
      !Inert() ->                    ; polling the status of both prod and cons
   od
   Delete(prod); Delete(cons)
end

module prod(N)
begin
   do
      x: M = Select() -> Thread(f, x), Delete(x), Send(dist, cons, <f>);
   od
end

module cons()
begin
   do
      x: N = Select() -> Thread(g, x), Delete(x);
   od
end
```

The modules designed for the nth element program follow.

```
module nth(M0 n)
begin
    Create(sigma, M0);
    do
       Inert(sigma) -> Delete(sigma), Create(extr, pool, n);
    od
    Delete(extr);
end

module sigma(M)
begin
    do
       {(a, i): M, (b, j): M} = Select() and i < j and a > b
-> Delete((a, i): M, (b, j): M)), Add((b, i): M, (a, j): M);
    od
end

module extr(M, n)
begin
    do
       {(a, i): M, n: Int} = Select() and i = n -> Delete((a, i): M, n: Int),
    Add(a);
    od
end
```

The above module specifications have artificial simplifications that make them different from the module specifications obtained in an automatic transformation (depicted in Section 3.4). For example, in a reaction, there should be a test whether the sync group is empty before replacing elements. If the sync group is not empty, a syn message must be sent and acknowledged before performing the replacement. Similarly, after the reaction, there should be a test to the dist group.

By removing higher-order operations in the module level, we make the specification of the system closer to actual program. Implementation of the program in the module language can be carried out fairly directly on a system that supports the computation model of the module language. Note that the implementation of

local computations is out of the scope of this paper. It is left to the phase when the use of concrete language and platform are determined. We will rely on software engineering technologies for finding an efficient implementation of local computations. For example, further refinement of the specification should include the use of data structures to organize the data sets and implement the Select operation by an algorithm designed in accordance with the data structure.

We refer the readers to (Lin, 2006) for case studies of the proposed method. (Lin, 2006) uses a higher-order Gamma formalism proposed by Le Metayer (1994). More current studies including case studies and applications in Gamma Calculus is being prepared for publication in the near future.

DISCUSSIONS AND CONCLUDING REMARKS

The chemical reaction models were proposed years ago to address high-level design issues of large distributed systems. Our work shows that it can be used to design multi-agent systems in a top-down fashion and benefits the design methodology with the reasoning capability of a formal system. While have shown that implementing such a system is feasible on a network computing environment, we would like to point out that our method can only be exerted to the module level, i.e., we can only derive the system to the specifications of module interfaces and operations. The implementation of individual modules will rely on conventional software engineering technologies. Further studies are needed to address the issues concerning module implementation and, perhaps, module abstraction, if we are to follow a "bottom-up" approach to design the multi-agent system, i.e., build the system on top of a set of existing functional units that coordinate over networks.

We present a method for implementing multi-agent system specifications in Gamma Calculus using a transformational style. Our existing work has demonstrated that Gamma Calculus, the newest formalism of the chemical reaction models, is suitable to describe high-level architectural properties of multi-agent systems and allows for systematic derivation and implementation of the systems. In this paper, we present a set of rules that can be used to derive the specified system into a module language, which is an intermediate language that do not include any higher-order operations as those in Gamma Calculus and is supported by most common networking execution environment. This study paves the way for implementing the specified system by using a sequence of program transformation and offers a new method for multi-agent system design.

Implementing Process Improvement in Nine Software Organizations: A Case Study

Marcelo Jenkins, University of Costa Rica, San Jose, Costa Rica 2060; E-mail: mjenkins@ecci.ucr.ac.cr

ABSTRACT

This paper describes the experience of implementing a CMMI-based software process improvement (SPI) project in a group of nine software organizations. We explain the approach we followed to design and implement the project, enumerate the main problems we encountered during its implementation, and mention the principal lessons learned and the critical success factors we think should be considered for this type of projects. Finally, the project's results are summarized and future work is outlined. The issues discussed in this paper may interest software organizations, company consortiums, governments, and international financial institutions interested in conducting SPI projects involving software organizations.

Keywords: software process improvement, process maturity assessment, CMMI.

1. INTRODUCCTION

Quality is one of the most important competitive factors of a global industry such as software development. To demonstrate quality software organizations must assess their processes using international standards or models, such as the Software Engineering Institute's Capability Maturity Model Integration (CMMI) (Chrissis M.B. et al., 2004).

In July 2005, we initiated a software process improvement (SPI) project in 9 small and medium size software companies with the objective of improving their competitiveness. We used the CMMI as our quality model and initially focused on the 7 process areas at maturity level 2 in the first 9-month phase of the project.

In general small software organizations the necessary knowledge, expertise, and resources required to implement software quality programs by themselves. Their cash flow and available human resources do not allow them to make the necessary investments in training, consulting services, and human resources needed to implement a long-term software quality improvement program good enough to achieve CMMI maturity level 3 or above (Paulk M., 1999, Jenkins M., 2004a, Jenkins M., 2004b). In our case, a collaborative project with shared costs among the 9 participating companies was the only viable mechanism to implement the project.

Eight of the nine participating companies in our project are small (less than 60 employees), with an average size of 40 employees. The ninth company is a medium size organization of 220 employees. All of them develop management information systems (mainly ERP´s) of different kind, costume-made web systems, and banking systems. Three of the nine organizations had an ISO 9000:2000 quality certification before starting this project (ISO, 2000), which gave them a leg up, and only three them currently export software to other countries.

2. BACKGROUND

2.1 The CMMI

The Capability Maturity Model Integration (CMMI) (Chrissis M.B. et al., 2004) is a software quality management model proposed by the Software Engineering Institute (SEI) as a guideline for software process improvement and capability determination. The CMMI is the result of merging 3 previous models: the software CMM, the System Engineering Capability Model (SECM), and the Integrated Product Development Capability Maturity Model (IPD-CMM).
