## METHODS OF <br> MULTIVARIATE ANALYSIS

## WILEY SERIES IN PROBABILITY AND STATISTICS

## Established by WALTER A. SHEWHART and SAMUEL S. WILKS

Editors: David J. Balding, Noel A. C. Cressie, Garrett M. Fitzmaurice,
Harvey Goldstein, Iain M. Johnstone, Geert Molenberghs, David W. Scott, Adrian F. M. Smith, Ruey S. Tsay, Sanford Weisberg
Editors Emeriti: Vic Barnett, J. Stuart Hunter, Joseph B. Kadane, Jozef L. Teugels
A complete list of the titles in this series appears at the end of this volume.

# METHODS OF MULTIVARIATE ANALYSIS 

 Third EditionAlvin C. Rencher<br>William F. Christensen

\section*{CONTENTS}
Preface ..... xvii
Acknowledgments ..... xxi
1 Introduction ..... 1
1.1 WHY MULTIVARIATE ANALYSIS? ..... 1
1.2 PREREQUISITES ..... 3
1.3 OBJECTIVES ..... 3
1.4 BASIC TYPES OF DATA AND ANALYSIS ..... 4
2 Matrix Algebra ..... 7
2.1 INTRODUCTION ..... 7
2.2 NOTATION AND BASIC DEFINITIONS ..... 8
2.2.1 Matrices, Vectors, and Scalars ..... 8
2.2.2 Equality of Vectors and Matrices ..... 9
2.2.3 Transpose and Symmetric Matrices ..... 9
2.2.4 Special Matrices ..... 10
2.3 OPERATIONS ..... 11
2.3.1 Summation and Product Notation ..... 11
2.3.2 Addition of Matrices and Vectors ..... 12
2.3.3 Multiplication of Matrices and Vectors ..... 13
2.4 PARTITIONED MATRICES ..... 22
2.5 RANK ..... 23
2.6 INVERSE ..... 25
2.7 POSITIVE DEFINITE MATRICES ..... 26
2.8 DETERMINANTS ..... 28
2.9 TRACE ..... 31
2.10 ORTHOGONAL VECTORS AND MATRICES ..... 31
2.11 EIGENVALUES AND EIGENVECTORS ..... 32
2.11.1 Definition ..... 32
2.11.2 \(\mathbf{I}+\mathbf{A}\) and \(\mathbf{I}-\mathbf{A}\) ..... 34
2.11.3 \(\operatorname{tr}(\mathbf{A})\) and \(|\mathbf{A}|\) ..... 34
2.11.4 Positive Definite and Semidefinite Matrices ..... 35
2.11.5 The Product AB ..... 35
2.11.6 Symmetric Matrix ..... 35
2.11.7 Spectral Decomposition ..... 35
2.11.8 Square Root Matrix ..... 36
2.11.9 Square and Inverse Matrices ..... 36
2.11.10 Singular Value Decomposition ..... 37
2.12 KRONECKER AND VEC NOTATION ..... 37
Problems ..... 39
3 Characterizing and Displaying Multivariate Data ..... 47
3.1 MEAN AND VARIANCE OF A UNIVARIATE RANDOM VARIABLE ..... 47
3.2 COVARIANCE AND CORRELATION OF BIVARIATE RANDOM VARIABLES ..... 49
3.2.1 Covariance ..... 49
3.2.2 Correlation ..... 53
3.3 SCATTERPLOTS OF BIVARIATE SAMPLES ..... 55
3.4 GRAPHICAL DISPLAYS FOR MULTIVARIATE SAMPLES ..... 56
3.5 DYNAMIC GRAPHICS ..... 58
3.6 MEAN VECTORS ..... 63
3.7 COVARIANCE MATRICES ..... 66
3.8 CORRELATION MATRICES ..... 69
3.9 MEAN VECTORS AND COVARIANCE MATRICES FOR SUBSETS OF VARIABLES ..... 71
3.9.1 Two Subsets ..... 71
3.9.2 Three or More Subsets ..... 73
3.10 LINEAR COMBINATIONS OF VARIABLES ..... 75
3.10.1 Sample Properties ..... 75
3.10.2 Population Properties ..... 81
3.11 MEASURES OF OVERALL VARIABILITY ..... 81
3.12 ESTIMATION OF MISSING VALUES ..... 82
3.13 DISTANCE BETWEEN VECTORS ..... 84
Problems ..... 85
4 The Multivariate Normal Distribution ..... 91
4.1 MULTIVARIATE NORMAL DENSITY FUNCTION ..... 91
4.1.1 Univariate Normal Density ..... 92
4.1.2 Multivariate Normal Density ..... 92
4.1.3 Generalized Population Variance ..... 93
4.1.4 Diversity of Applications of the Multivariate Normal ..... 93
4.2 PROPERTIES OF MULTIVARIATE NORMAL RANDOM VARIABLES ..... 94
4.3 ESTIMATION IN THE MULTIVARIATE NORMAL ..... 99
4.3.1 Maximum Likelihood Estimation ..... 99
4.3.2 Distribution of \(\overline{\mathbf{y}}\) and \(\mathbf{S}\) ..... 100
4.4 ASSESSING MULTIVARIATE NORMALITY ..... 101
4.4.1 Investigating Univariate Normality ..... 101
4.4.2 Investigating Multivariate Normality ..... 106
4.5 TRANSFORMATIONS TO NORMALITY ..... 108
4.5.1 Univariate Transformations to Normality ..... 109
4.5.2 Multivariate Transformations to Normality ..... 110
4.6 OUTLIERS ..... 111
4.6.1 Outliers in Univariate Samples ..... 112
4.6.2 Outliers in Multivariate Samples ..... 113
Problems ..... 117
5 Tests on One or Two Mean Vectors ..... 125
5.1 MULTIVARIATE VERSUS UNIVARIATE TESTS ..... 125
5.2 TESTS ON \(\boldsymbol{\mu}\) WITH \(\boldsymbol{\Sigma}\) KNOWN ..... 126
5.2.1 Review of Univariate Test for \(H_{0}: \mu=\mu_{0}\) with \(\sigma\) Known ..... 126
5.2.2 Multivariate Test for \(H_{0}: \boldsymbol{\mu}=\mu_{0}\) with \(\boldsymbol{\Sigma}\) Known ..... 127
5.3 TESTS ON \(\boldsymbol{\mu}\) WHEN \(\boldsymbol{\Sigma}\) IS UNKNOWN ..... 130
5.3.1 Review of Univariate \(t\)-Test for \(H_{0}: \mu=\mu_{0}\) with \(\sigma\) Unknown ..... 130
5.3.2 Hotelling's \(T^{2}\)-Test for \(H_{0}: \boldsymbol{\mu}=\boldsymbol{\mu}_{0}\) with \(\boldsymbol{\Sigma}\) Unknown ..... 131
5.4 COMPARING TWO MEAN VECTORS ..... 134
5.4.1 Review of Univariate Two-Sample \(t\)-Test ..... 134
5.4.2 Multivariate Two-Sample \(T^{2}\)-Test ..... 135
5.4.3 Likelihood Ratio Tests ..... 139
5.5 TESTS ON INDIVIDUAL VARIABLES CONDITIONAL ON REJECTION OF \(H_{0}\) BY THE \(T^{2}\)-TEST ..... 139
5.6 COMPUTATION OF \(T^{2}\) ..... 143
5.6.1 Obtaining \(T^{2}\) from a MANOVA Program ..... 143
5.6.2 Obtaining \(T^{2}\) from Multiple Regression ..... 144
5.7 PAIRED OBSERVATIONS TEST ..... 145
5.7.1 Univariate Case ..... 145
5.7.2 Multivariate Case ..... 147
5.8 TEST FOR ADDITIONAL INFORMATION ..... 149
5.9 PROFILE ANALYSIS ..... 152
5.9.1 One-Sample Profile Analysis ..... 152
5.9.2 Two-Sample Profile Analysis ..... 154
Problems ..... 161
6 Multivariate Analysis of Variance ..... 169
6.1 ONE-WAY MODELS ..... 169
6.1.1 Univariate One-Way Analysis of Variance (ANOVA) ..... 169
6.1.2 Multivariate One-Way Analysis of Variance Model (MANOVA) ..... 171
6.1.3 Wilks' Test Statistic ..... 174
6.1.4 Roy's Test ..... 178
6.1.5 Pillai and Lawley-Hotelling Tests ..... 179
6.1.6 Unbalanced One-Way MANOVA ..... 181
6.1.7 Summary of the Four Tests and Relationship to \(T^{2}\) ..... 182
6.1.8 Measures of Multivariate Association ..... 186
6.2 COMPARISON OF THE FOUR MANOVA TEST STATISTICS ..... 189
6.3 CONTRASTS ..... 191
6.3.1 Univariate Contrasts ..... 191
6.3.2 Multivariate Contrasts ..... 192
6.4 TESTS ON INDIVIDUAL VARIABLES FOLLOWING REJECTION OF \(H_{0}\) BY THE OVERALL MANOVA TEST ..... 195
6.5 TWO-WAY CLASSIFICATION ..... 198
6.5.1 Review of Univariate Two-Way ANOVA ..... 198
6.5.2 Multivariate Two-Way MANOVA ..... 201
6.6 OTHER MODELS ..... 207
6.6.1 Higher-Order Fixed Effects ..... 207
6.6.2 Mixed Models ..... 208
6.7 CHECKING ON THE ASSUMPTIONS ..... 210
6.8 PROFILE ANALYSIS ..... 211
6.9 REPEATED MEASURES DESIGNS ..... 215
6.9.1 Multivariate Versus Univariate Approach ..... 215
6.9.2 One-Sample Repeated Measures Model ..... 219
6.9.3 \(k\)-Sample Repeated Measures Model ..... 222
6.9.4 Computation of Repeated Measures Tests ..... 224
6.9.5 Repeated Measures with Two Within-Subjects Factors and One Between-Subjects Factor ..... 224
6.9.6 Repeated Measures with Two Within-Subjects Factors and Two Between-Subjects Factors ..... 230
6.9.7 Additional Topics ..... 232
6.10 GROWTH CURVES ..... 232
6.10.1 Growth Curve for One Sample ..... 232
6.10.2 Growth Curves for Several Samples ..... 239
6.10.3 Additional Topics ..... 241
6.11 TESTS ON A SUBVECTOR ..... 241
6.11.1 Test for Additional Information ..... 241
6.11.2 Stepwise Selection of Variables ..... 243
Problems ..... 244
7 Tests on Covariance Matrices ..... 259
7.1 INTRODUCTION ..... 259
7.2 TESTING A SPECIFIED PATTERN FOR \(\boldsymbol{\Sigma}\) ..... 259
7.2.1 Testing \(H_{0}: \mathbf{\Sigma}=\boldsymbol{\Sigma}_{0}\) ..... 260
7.2.2 Testing Sphericity ..... 261
7.2.3 Testing \(\boldsymbol{H}_{\mathbf{0}}: \boldsymbol{\Sigma}=\sigma^{2}[(1-\rho) \mathbf{I}+\rho \mathbf{J}]\) ..... 263
7.3 TESTS COMPARING COVARIANCE MATRICES ..... 265
7.3.1 Univariate Tests of Equality of Variances ..... 265
7.3.2 Multivariate Tests of Equality of Covariance Matrices ..... 266
7.4 TESTS OF INDEPENDENCE ..... 269
7.4.1 Independence of Two Subvectors ..... 269
7.4.2 Independence of Several Subvectors ..... 271
7.4.3 Test for Independence of All Variables ..... 275
Problems ..... 276
8 Discriminant Analysis: Description of Group Separation ..... 281
8.1 INTRODUCTION ..... 281
8.2 THE DISCRIMINANT FUNCTION FOR TWO GROUPS ..... 282
8.3 RELATIONSHIP BETWEEN TWO-GROUP DISCRIMINANT ANALYSIS AND MULTIPLE REGRESSION ..... 286
8.4 DISCRIMINANT ANALYSIS FOR SEVERAL GROUPS ..... 288
8.4.1 Discriminant Functions ..... 288
8.4.2 A Measure of Association for Discriminant Functions ..... 292
8.5 STANDARDIZED DISCRIMINANT FUNCTIONS ..... 292
8.6 TESTS OF SIGNIFICANCE ..... 294
8.6.1 Tests for the Two-Group Case ..... 294
8.6.2 Tests for the Several-Group Case ..... 295
8.7 INTERPRETATION OF DISCRIMINANT FUNCTIONS ..... 298
8.7.1 Standardized Coefficients ..... 298
8.7.2 Partial \(F\)-Values ..... 299
8.7.3 Correlations Between Variables and Discriminant Functions ..... 300
8.7.4 Rotation ..... 301
8.8 SCATTERPLOTS ..... 301
8.9 STEPWISE SELECTION OF VARIABLES ..... 303
Problems ..... 306
9 Classification Analysis: Allocation of Observations to Groups;309
9.1 INTRODUCTION ..... 309
9.2 CLASSIFICATION INTO TWO GROUPS ..... 310
9.3 CLASSIFICATION INTO SEVERAL GROUPS ..... 314
9.3.1 Equal Population Covariance Matrices: Linear Classification Functions ..... 315
9.3.2 Unequal Population Covariance Matrices: Quadratic Classification Functions ..... 317
9.4 ESTIMATING MISCLASSIFICATION RATES ..... 318
9.5 IMPROVED ESTIMATES OF ERROR RATES ..... 320
9.5.1 Partitioning the Sample ..... 321
9.5.2 Holdout Method ..... 322
9.6 SUBSET SELECTION ..... 322
9.7 NONPARAMETRIC PROCEDURES ..... 326
9.7.1 Multinomial Data ..... 326
9.7.2 Classification Based on Density Estimators ..... 327
9.7.3 Nearest Neighbor Classification Rule ..... 330
9.7.4 Classification Trees ..... 331
Problems ..... 336
10 Multivariate Regression ..... 339
10.1 INTRODUCTION ..... 339
10.2 MULTIPLE REGRESSION: FIXED \(x\) 's ..... 340
10.2.1 Model for Fixed \(x\) 's ..... 340
10.2.2 Least Squares Estimation in the Fixed- \(x\) Model ..... 342
10.2.3 An Estimator for \(\sigma^{2}\) ..... 343
10.2.4 The Model Corrected for Means ..... 344
10.2.5 Hypothesis Tests ..... 346
10.2.6 \(\quad R^{2}\) in Fixed-x Regression ..... 349
10.2.7 Subset Selection ..... 350
10.3 MULTIPLE REGRESSION: RANDOM \(x\) 's ..... 354
10.4 MULTIVARIATE MULTIPLE REGRESSION: ESTIMATION ..... 354
10.4.1 The Multivariate Linear Model ..... 354
10.4.2 Least Squares Estimation in the Multivariate Model ..... 356
10.4.3 Properties of Least Squares Estimator \(\hat{\mathbf{B}}\) ..... 358
10.4.4 An Estimator for \(\boldsymbol{\Sigma}\) ..... 360
10.4.5 Model Corrected for Means ..... 361
10.4.6 Estimation in the Seemingly Unrelated Regressions (SUR) Model ..... 362
10.5 MULTIVARIATE MULTIPLE REGRESSION: HYPOTHESIS TESTS ..... 364
10.5.1 Test of Overall Regression ..... 364
10.5.2 Test on a Subset of the \(x\) 's ..... 367
10.6 MULTIVARIATE MULTIPLE REGRESSION: PREDICTION ..... 370
10.6.1 Confidence Interval for \(E\left(\mathbf{y}_{0}\right)\) ..... 370
10.6.2 Prediction Interval for a Future Observation \(y_{0}\) ..... 371
10.7 MEASURES OF ASSOCIATION BETWEEN THE \(y\) 's AND THE \(x\) 's ..... 372
10.8 SUBSET SELECTION ..... 374
10.8.1 Stepwise Procedures ..... 374
10.8.2 All Possible Subsets ..... 377
10.9 MULTIVARIATE REGRESSION: RANDOM \(x\) 's ..... 380
Problems ..... 381
11 Canonical Correlation ..... 385
11.1 INTRODUCTION ..... 385
11.2 CANONICAL CORRELATIONS AND CANONICAL VARIATES ..... 385
11.3 PROPERTIES OF CANONICAL CORRELATIONS ..... 390
11.4 TESTS OF SIGNIFICANCE ..... 391
11.4.1 Tests of No Relationship Between the \(y\) 's and the \(x\) 's ..... 391
11.4.2 Test of Significance of Succeeding Canonical Correlations After the First ..... 393
11.5 INTERPRETATION ..... 395
11.5.1 Standardized Coefficients ..... 396
11.5.2 Correlations between Variables and Canonical Variates ..... 397
11.5.3 Rotation ..... 397
11.5.4 Redundancy Analysis ..... 398
11.6 RELATIONSHIPS OF CANONICAL CORRELATION ANALYSIS TO OTHER MULTIVARIATE TECHNIQUES ..... 398
11.6.1 Regression ..... 398
11.6.2 MANOVA and Discriminant Analysis ..... 400
Problems ..... 402
12 Principal Component Analysis ..... 405
12.1 INTRODUCTION ..... 405
12.2 GEOMETRIC AND ALGEBRAIC BASES OF PRINCIPAL COMPONENTS ..... 406
12.2.1 Geometric Approach ..... 406
12.2.2 Algebraic Approach ..... 410
12.3 PRINCIPAL COMPONENTS AND PERPENDICULAR REGRESSION ..... 412
12.4 PLOTTING OF PRINCIPAL COMPONENTS ..... 414
12.5 PRINCIPAL COMPONENTS FROM THE CORRELATION MATRIX ..... 419
12.6 DECIDING HOW MANY COMPONENTS TO RETAIN ..... 423

\section*{Preface}

We have long been fascinated by the interplay of variables in multivariate data and by the challenge of unraveling the effect of each variable. Our continuing objective in the third edition has been to present the power and utility of multivariate analysis in a highly readable format.

Practitioners and researchers in all applied disciplines often measure several variables on each subject or experimental unit. In some cases, it may be productive to isolate each variable in a system and study it separately. Typically, however, the variables are not only correlated with each other, but each variable is influenced by the other variables as it affects a test statistic or descriptive statistics. Thus, in many instances, the variables are intertwined in such a way that when analyzed individually they yield little information about the system. Using multivariate analysis, the variables can be examined simultaneously in order to access the key features of the process that produced them. The multivariate approach enables us to (1) explore the joint performance of the variables and (2) determine the effect of each variable in the presence of the others.

Multivariate analysis provides both descriptive and inferential procedures-we can search for patterns in the data or test hypotheses about patterns of a priori interest. With multivariate descriptive techniques, we can peer beneath the tangled web of variables on the surface and extract the essence of the system. Multivariate inferential procedures include hypothesis tests that (1) process any number of variables
without inflating the Type I error rate and (2) allow for whatever intercorrelations the variables possess. A wide variety of multivariate descriptive and inferential procedures is readily accessible in statistical software packages.

Our selection of topics for this volume reflects years of consulting with researchers in many fields of inquiry. A brief overview of multivariate analysis is given in Chapter 1. Chapter 2 reviews the fundamentals of matrix algebra. Chapters 3 and 4 give an introduction to sampling from multivariate populations. Chapters 5, 6, 7, 10, and 11 extend univariate procedures with one dependent variable (including \(t\)-tests, analysis of variance, tests on variances, multiple regression, and multiple correlation) to analogous multivariate techniques involving several dependent variables. A review of each univariate procedure is presented before covering the multivariate counterpart. These reviews may provide key insights that the student has missed in previous courses.

Chapters \(8,9,12,13,14,15\), and 16 describe multivariate techniques that are not extensions of univariate procedures. In Chapters 8 and 9 , we find functions of the variables that discriminate among groups in the data. In Chapters 12, 13, and 14 (new in the third edition), we find functions of the variables that reveal the basic dimensionality and characteristic patterns of the data, and we discuss procedures for finding the underlying latent variables of a system. In Chapters 15 and 16, we give methods for searching for groups in the data, and we provide plotting techniques that show relationships in a reduced dimensionality for various kinds of data.

In Appendix A, tables are provided for many multivariate distributions and tests. These enable the reader to conduct an exact test in many cases for which software packages provide only approximate tests. Appendix B gives answers and hints for most of the problems in the book.

Appendix C describes an ftp site that contains (1) all data sets and (2) SAS command files for all examples in the text. These command files can be adapted for use in working problems or in analyzing data sets encountered in applications.

To illustrate multivariate applications, we have provided many examples and exercises based on 60 real data sets from a wide variety of disciplines. A practitioner or consultant in multivariate analysis gains insights and acumen from long experience in working with data. It is not expected that a student can achieve this kind of seasoning in a one-semester class. However, the examples provide a good start, and further development is gained by working problems with the data sets. For example, in Chapters 12-14, the exercises cover several typical patterns in the covariance or correlation matrix. The student's intuition is expanded by associating these covariance patterns with the resulting configuration of the principal components or factors.

Although this is a methods book, we have included a few derivations. For some readers, an occasional proof provides insights obtainable in no other way. We hope that instructors who do not wish to use proofs will not be deterred by their presence. The proofs can easily be disregarded when reading the book.

Our objective has been to make the book accessible to readers who have taken as few as two statistical methods courses. The students in our classes in multivariate analysis include majors in statistics and majors from other departments. With the applied researcher in mind, we have provided careful intuitive explanations of the
concepts and have included many insights typically available only in journal articles or in the minds of practitioners.

Our overriding goal in preparation of this book has been clarity of exposition. We hope that students and instructors alike will find this multivariate text more comfortable than most. In the final stages of development of each edition, we asked our students for written reports on their initial reaction as they read each day's assignment. They made many comments that led to improvements in the manuscript. We will be very grateful if readers will take the time to notify us of errors or of other suggestions they might have for improvements.

We have tried to use standard mathematical and statistical notation as far as possible and to maintain consistency of notation throughout the book. We have refrained from the use of abbreviations and mnemonic devices. These save space when one is reading a book page by page, but they are annoying to those using a book as a reference.

Equations are numbered sequentially throughout a chapter; for example, (3.75) indicates the 75 th numbered equation in Chapter 3. Tables and figures are also numbered sequentially throughout a chapter in the form "Table 3.9" or "Figure 3.1." Examples are not numbered sequentially; each example is identified by the same number as the section in which it appears and is placed at the end of the section.

When citing references in the text, we have used the standard format involving the year of publication. For a journal article, the year alone suffices, for example, Fisher (1936). But for books, we have included a page number, as in Seber (1984, p. 216).

This is the first volume of a two-volume set on multivariate analysis. The second volume is entitled Multivariate Statistical Inference and Applications by Alvin Rencher (Wiley, 1998). The two volumes are not necessarily sequential; they can be read independently. Al adopted the two-volume format in order to (1) provide broader coverage than would be possible in a single volume and (2) offer the reader a choice of approach.

The second volume includes proofs of many techniques covered in the first 13 chapters of the present volume and also introduces additional topics. The present volume includes many examples and problems using actual data sets, and there are fewer algebraic problems. The second volume emphasizes derivations of the results and contains fewer examples and problems with real data. The present volume has fewer references to the literature than the other volume, which includes a careful review of the latest developments and a more comprehensive bibliography. In this third edition, we have occasionally referred the reader to "Rencher (1998)" to note that added coverage of a certain subject is available in the second volume.

We are indebted to many individuals in the preparation of the first two editions of this book. Al's initial exposure to multivariate analysis came in courses taught by Rolf Bargmann at the University of Georgia and D.R. Jensen at Virginia Tech. Additional impetus to probe the subtleties of this field came from research conducted with Bruce Brown at BYU. William's interest and training in multivariate statistics were primarily influenced by Alvin Rencher and Yasuo Amemiya. We thank these mentors and colleagues and also thank Bruce Brown, Deane Branstetter, Del Scott,

Robert Smidt, and Ingram Olkin for reading various versions of the manuscript and making valuable suggestions.

We are grateful to the following colleagues and students at BYU who helped with computations and typing: Mitchell Tolland, Tawnia Newton, Marianne Matis Mohr, Gregg Littlefield, Suzanne Kimball, Wendy Nielsen, Tiffany Nordgren, David Whiting, Karla Wasden, Rachel Jones, Lonette Stoddard, Candace B. McNaughton, J. D. Williams, and Jonathan Christensen. We are grateful to the many readers who have pointed out errors or made suggestions for improvements. The book is better for their caring and their efforts.

\section*{THIRD EDITION}

For the third edition, we have added a new chapter covering confirmatory factor analysis (Chapter 14). We have added new sections discussing Kronecker products and vec notation (Section 2.12), dynamic graphics (Section 3.5), transformations to normality (Section 4.5), classification trees (Section 9.7.4), seemingly unrelated regressions (Section 10.4.6), and prediction for multivariate multiple regression (Section 10.6). Additionally, we have updated and revised the graphics throughout the book and have substantially expanded the section discussing estimation for multivariate multiple regression (Section 10.4).

Many other additions and changes have been made in an effort to broaden the book's scope and improve its exposition. Additional problems have been added to accompany the new material. The new ftp site for the third edition can be found at: \(\mathrm{ftp}: / / \mathrm{ftp}\). wiley.com/public/sci_tech_med/multivariate_analysis_3e.

We thank Jonathan Christensen for the countless ways he contributed to the revision, from updated graphics to technical and formatting assistance. We are grateful to Byron Gajewski, Scott Grimshaw, and Jeremy Yorgason, who have provided useful feedback on sections of the book that are new to this edition. We are also grateful to Scott Simpson and Storm Atwood for invaluable editing assistance and to the students of William's multivariate statistics course at Brigham Young University for pointing out errors and making suggestions for improvements in this edition. We are deeply appreciative of the support provided by the BYU Department of Statistics for the writing of the book.

Al dedicates this volume to his wife, LaRue, who has supplied much needed support and encouragement. William dedicates this volume to his wife Mary Elizabeth, who has provided both encouragement and careful feedback throughout the writing process.

\section*{CHAPTER 1}

\section*{INTRODUCTION}

\subsection*{1.1 WHY MULTIVARIATE ANALYSIS?}

Multivariate analysis consists of a collection of methods that can be used when several measurements are made on each individual or object in one or more samples. We will refer to the measurements as variables and to the individuals or objects as units (research units, sampling units, or experimental units) or observations. In practice, multivariate data sets are common, although they are not always analyzed as such. But the exclusive use of univariate procedures with such data is no longer excusable, given the availability of multivariate techniques and inexpensive computing power to carry them out.

Historically, the bulk of applications of multivariate techniques have been in the behavioral and biological sciences. However, interest in multivariate methods has now spread to numerous other fields of investigation. For example, we have collaborated on multivariate problems with researchers in education, chemistry, environmental science, physics, geology, medicine, engineering, law, business, literature, religion, public broadcasting, nursing, mining, linguistics, biology, psychology, and many other fields. Table 1.1 shows some examples of multivariate observations.

Table 1.1 Examples of Multivariate Data
\begin{tabular}{ll}
\hline Units & Variables \\
\hline 1. Students & \begin{tabular}{l} 
Several exam scores in a single course \\
Grades in mathematics, history, music, art, \\
2. Students \\
physics
\end{tabular} \\
3. People & \begin{tabular}{l} 
Height, weight, percentage of body fat, resting \\
heart rate
\end{tabular} \\
4. Skulls & Length, width, cranial capacity \\
5. Companies & \begin{tabular}{l} 
Expenditures for advertising, labor, raw materials \\
Various measurements to check on compliance \\
with specifications
\end{tabular} \\
7. Manufactured items & \begin{tabular}{l} 
Income, education level, length of residence, sav- \\
ings account, current debt load
\end{tabular} \\
8. Segments of literature & \begin{tabular}{l} 
Sentence length, frequency of usage of certain \\
words and style characteristics \\
Composition of various elements
\end{tabular} \\
9. Human hairs & \begin{tabular}{l} 
Lengths of various bones
\end{tabular} \\
10. Birds &
\end{tabular}

The reader will notice that in some cases all the variables are measured in the same scale (see 1 and 2 in Table 1.1). In other cases, measurements are in different scales (see 3 in Table 1.1). In a few techniques such as profile analysis (Sections 5.9 and 6.8 ), the variables must be commensurate, that is, similar in scale of measurement; however, most multivariate methods do not require this.

Ordinarily the variables are measured simultaneously on each sampling unit. Typically, these variables are correlated. If this were not so, there would be little use for many of the techniques of multivariate analysis. We need to untangle the overlapping information provided by correlated variables and peer beneath the surface to see the underlying structure. Thus the goal of many multivariate approaches is simplification. We seek to express "what is going on" in terms of a reduced set of dimensions. Such multivariate techniques are exploratory; they essentially generate hypotheses rather than test them.

On the other hand, if our goal is a formal hypothesis test, we need a technique that will (1) allow several variables to be tested and still preserve the significance level and (2) do this for any intercorrelation structure of the variables. Many such tests are available.

As the two preceding paragraphs imply, multivariate analysis is concerned generally with two areas, descriptive and inferential statistics. In the descriptive realm, we often obtain optimal linear combinations of variables. The optimality criterion varies from one technique to another, depending on the goal in each case. Although linear combinations may seem too simple to reveal the underlying structure, we use them for two obvious reasons: (1) mathematical tractability (linear approximations are used throughout all science for the same reason) and (2) they often perform well in practice. These linear functions may also be useful as a follow-up to inferential procedures. When we have a statistically significant test result that compares sev-
eral groups, for example, we can find the linear combination (or combinations) of variables that led to rejection. Then the contribution of each variable to these linear combinations is of interest.

In the inferential area, many multivariate techniques are extensions of univariate procedures. In such cases we review the univariate procedure before presenting the analogous multivariate approach.

Multivariate inference is especially useful in curbing the researcher's natural tendency to read too much into the data. Total control is provided for experimentwise error rate; that is, no matter how many variables are tested simultaneously, the value of \(\alpha\) (the significance level) remains at the level set by the researcher.

Some authors warn against applying the common multivariate techniques to data for which the measurement scale is not interval or ratio. It has been found, however, that many multivariate techniques give reliable results when applied to ordinal data.

For many years the applications lagged behind the theory because the computations were beyond the power of the available desk-top calculators. However, with modern computers, virtually any analysis one desires, no matter how many variables or observations are involved, can be quickly and easily carried out. Perhaps it is not premature to say that multivariate analysis has come of age.

\subsection*{1.2 PREREQUISITES}

The mathematical prerequisite for reading this book is matrix algebra. Calculus is not used [with a brief exception in equation (4.29)]. But the basic tools of matrix algebra are essential, and the presentation in Chapter 2 is intended to be sufficiently complete so that the reader with no previous experience can master matrix manipulation up to the level required in this book.

The statistical prerequisites are basic familiarity with the normal distribution, \(t\) tests, confidence intervals, multiple regression, and analysis of variance. These techniques are reviewed as each is extended to the analogous multivariate procedure.

This is a multivariate methods text. Most of the results are given without proof. In a few cases proofs are provided, but the major emphasis is on heuristic explanations. Our goal is an intuitive grasp of multivariate analysis, in the same mode as other statistical methods courses. Some problems are algebraic in nature, but the majority involve data sets to be analyzed.

\subsection*{1.3 OBJECTIVES}

We have formulated three objectives that we hope this book will achieve for the reader. These objectives are based on long experience teaching a course in multivariate methods, consulting on multivariate problems with researchers in many fields, and guiding statistics graduate students as they consulted with similar clients.

The first objective is to gain a thorough understanding of the details of various multivariate techniques, their purposes, their assumptions, their limitations, and so
on. Many of these techniques are related, yet they differ in some essential ways. These similarities and differences are emphasized.

The second objective is to be able to select one or more appropriate techniques for a given multivariate data set. Recognizing the essential nature of a multivariate data set is the first step in a meaningful analysis. Basic types of multivariate data are introduced in Section 1.4.

The third objective is to be able to interpret the results of a computer analysis of a multivariate data set. Reading the manual for a particular program package is not enough to make an intelligent appraisal of the output. Achievement of the first objective and practice on data sets in the text should help achieve the third objective.

\subsection*{1.4 BASIC TYPES OF DATA AND ANALYSIS}

We will list four basic types of (continuous) multivariate data and then briefly describe some possible analyses. Some writers would consider this an oversimplification and might prefer elaborate tree diagrams of data structure. However, many data sets can fit into one of these categories, and the simplicity of this structure makes it easier to remember. The four basic data types are as follows:
1. A single sample with several variables measured on each sampling unit (subject or object).
2. A single sample with two sets of variables measured on each unit.
3. Two samples with several variables measured on each unit.
4. Three or more samples with several variables measured on each unit.

Each data type has extensions, and various combinations of the four are possible. A few examples of analyses for each case will now be given:
1. A single sample with several variables measured on each sampling unit:
a. Test the hypothesis that the means of the variables have specified values.
b. Test the hypothesis that the variables are uncorrelated and have a common variance.
c. Find a small set of linear combinations of the original variables that summarizes most of the variation in the data (principal components).
d. Express the original variables as linear functions of a smaller set of underlying variables that account for the original variables and their intercorrelations (factor analysis).
2. A single sample with two sets of variables measured on each unit:
a. Determine the number, the size, and the nature of relationships between the two sets of variables (canonical correlation). For example, we may
wish to relate a set of interest variables to a set of achievement variables. How much overall correlation is there between these two sets?
b. Find a model to predict one set of variables from the other set (multivariate multiple regression).
3. Two samples with several variables measured on each unit:
a. Compare the means of the variables across the two samples (Hotelling's \(T^{2}\)-test).
b. Find a linear combination of the variables that best separates the two samples (discriminant analysis).
c. Find a function of the variables that will accurately allocate the units into the two groups (classification analysis).
4. Three or more samples with several variables measured on each unit:
a. Compare the means of the variables across the groups (multivariate analysis of variance).
b. Extension of \(3 b\) to more than two groups.
c. Extension of 3 c to more than two groups.

\section*{CHAPTER 2}

\section*{MATRIX ALGEBRA}

\subsection*{2.1 INTRODUCTION}

This chapter introduces the basic elements of matrix algebra used in the remainder of this book. It is essentially a review of the requisite matrix tools and is not intended to be a complete development. However, it is sufficiently self-contained so that those with no previous exposure to the subject should need no other reference. Anyone unfamiliar with matrix algebra should plan to work most of the problems entailing numerical illustrations. It would also be helpful to explore some of the problems involving general matrix manipulation.

With the exception of a few derivations that seemed instructive, most of the results are given without proof. Some additional proofs are requested in the problems. For the remaining proofs, see any general text on matrix theory or one of the specialized matrix texts oriented to statistics, such as Graybill (1969), Searle (1982), or Harville (1997).

\subsection*{2.2 NOTATION AND BASIC DEFINITIONS}

\subsection*{2.2.1 Matrices, Vectors, and Scalars}

A matrix is a rectangular or square array of numbers or variables arranged in rows and columns. We use uppercase boldface letters to represent matrices. All entries in matrices will be real numbers or variables representing real numbers. The elements of a matrix are displayed in brackets. For example, the ACT score and GPA for three students can be conveniently listed in the following matrix:
\[
\mathbf{A}=\left(\begin{array}{ll}
23 & 3.54  \tag{2.1}\\
29 & 3.81 \\
18 & 2.75
\end{array}\right)
\]

The elements of A can also be variables, representing possible values of ACT and GPA for three students:
\[
\mathbf{A}=\left(\begin{array}{ll}
a_{11} & a_{12}  \tag{2.2}\\
a_{21} & a_{22} \\
a_{31} & a_{32}
\end{array}\right)
\]

In this double-subscript notation for the elements of a matrix, the first subscript indicates the row; the second identifies the column. The matrix \(\mathbf{A}\) in (2.2) could also be expressed as
\[
\begin{equation*}
\mathbf{A}=\left(a_{i j}\right), \tag{2.3}
\end{equation*}
\]
where \(a_{i j}\) is a general element.
With three rows and two columns, the matrix \(\mathbf{A}\) in (2.1) or (2.2) is said to be \(3 \times 2\). In general, if a matrix \(\mathbf{A}\) has \(n\) rows and \(p\) columns, it is said to be \(n \times p\). Alternatively, we say the size of \(\mathbf{A}\) is \(n \times p\).

A vector is a matrix with a single column or row. The following could be the test scores of a student in a course in multivariate analysis:
\[
\mathbf{x}=\left(\begin{array}{l}
98  \tag{2.4}\\
86 \\
93 \\
97
\end{array}\right)
\]

Variable elements in a vector can be identified by a single subscript:
\[
\mathbf{x}=\left(\begin{array}{l}
x_{1}  \tag{2.5}\\
x_{2} \\
x_{3} \\
x_{4}
\end{array}\right)
\]

We use lowercase boldface letters for column vectors. Row vectors are expressed as
\[
\mathbf{x}^{\prime}=\left(x_{1}, x_{2}, x_{3}, x_{4}\right) \text { or as } \mathbf{x}^{\prime}=\left(\begin{array}{llll}
x_{1} & x_{2} & x_{3} & x_{4}
\end{array}\right),
\]
where \(\mathbf{x}^{\prime}\) indicates the transpose of \(\mathbf{x}\). The transpose operation is defined in Section 2.2.3.

Geometrically, a vector with \(p\) elements identifies a point in a \(p\)-dimensional space. The elements in the vector are the coordinates of the point. In (2.35) in Section 2.3.3, we define the distance from the origin to the point. In Section 3.13, we define the distance between two vectors. In some cases, we will be interested in a directed line segment or arrow from the origin to the point.

A single real number is called a scalar, to distinguish it from a vector or matrix. Thus \(2,-4\), and 125 are scalars. A variable representing a scalar will usually be denoted by a lowercase nonbolded letter, such as \(a=5\). A product involving vectors and matrices may reduce to a matrix of size \(1 \times 1\), which then becomes a scalar.

\subsection*{2.2.2 Equality of Vectors and Matrices}

Two matrices are equal if they are the same size and the elements in corresponding positions are equal. Thus if \(\mathbf{A}=\left(a_{i j}\right)\) and \(\mathbf{B}=\left(b_{i j}\right)\), then \(\mathbf{A}=\mathbf{B}\) if \(a_{i j}=b_{i j}\) for all \(i\) and \(j\). For example, let
\[
\begin{array}{ll}
\mathbf{A}=\left(\begin{array}{rrr}
3 & -2 & 4 \\
1 & 3 & 7
\end{array}\right), & \mathbf{B}=\left(\begin{array}{rr}
3 & 1 \\
-2 & 3 \\
4 & 7
\end{array}\right), \\
\mathbf{C}=\left(\begin{array}{rrr}
3 & -2 & 4 \\
1 & 3 & 7
\end{array}\right), & \mathbf{D}=\left(\begin{array}{rrr}
3 & -2 & 4 \\
1 & 3 & 6
\end{array}\right) .
\end{array}
\]

Then \(\mathbf{A}=\mathbf{C}\). But even though \(\mathbf{A}\) and \(\mathbf{B}\) have the same elements, \(\mathbf{A} \neq \mathbf{B}\) because the two matrices are not the same size. Likewise, \(\mathbf{A} \neq \mathbf{D}\) because \(a_{23} \neq d_{23}\). Thus two matrices of the same size are unequal if they differ in a single position.

\subsection*{2.2.3 Transpose and Symmetric Matrices}

The transpose of a matrix \(\mathbf{A}\), denoted by \(\mathbf{A}^{\prime}\), is obtained from \(\mathbf{A}\) by interchanging rows and columns. Thus the columns of \(\mathbf{A}^{\prime}\) are the rows of \(\mathbf{A}\), and the rows of \(\mathbf{A}^{\prime}\) are the columns of \(\mathbf{A}\). The following examples illustrate the transpose of a matrix or vector:
\[
\begin{array}{ll}
\mathbf{A}=\left(\begin{array}{rrr}
-5 & 2 & 4 \\
3 & 6 & -2
\end{array}\right), & \mathbf{A}^{\prime}=\left(\begin{array}{rr}
-5 & 3 \\
2 & 6 \\
4 & -2
\end{array}\right), \\
\mathbf{B}=\left(\begin{array}{rr}
2 & -3 \\
4 & 1
\end{array}\right), & \mathbf{B}^{\prime}=\left(\begin{array}{rr}
2 & 4 \\
-3 & 1
\end{array}\right), \\
\mathbf{a}=\left(\begin{array}{r}
2 \\
-3 \\
1
\end{array}\right), & \mathbf{a}^{\prime}=\left(\begin{array}{lll}
2, & -3, & 1
\end{array}\right) .
\end{array}
\]

The transpose operation does not change a scalar, since it has only one row and one column.

If the transpose operator is applied twice to any matrix, the result is the original matrix:
\[
\begin{equation*}
\left(\mathbf{A}^{\prime}\right)^{\prime}=\mathbf{A} \tag{2.6}
\end{equation*}
\]

If the transpose of a matrix is the same as the original matrix, the matrix is said to be symmetric; that is, \(\mathbf{A}\) is symmetric if \(\mathbf{A}=\mathbf{A}^{\prime}\). For example,
\[
\mathbf{A}=\left(\begin{array}{rrr}
3 & -2 & 4 \\
-2 & 10 & -7 \\
4 & -7 & 9
\end{array}\right), \quad \mathbf{A}^{\prime}=\left(\begin{array}{rrr}
3 & -2 & 4 \\
-2 & 10 & -7 \\
4 & -7 & 9
\end{array}\right)
\]

Clearly, all symmetric matrices are square.

\subsection*{2.2.4 Special Matrices}

The diagonal of a \(p \times p\) square matrix \(\mathbf{A}\) consists of the elements \(a_{11}, a_{22}, \ldots, a_{p p}\). For example, in the matrix
\[
\mathbf{A}=\left(\begin{array}{rrr}
5 & -2 & 4 \\
7 & 9 & 3 \\
-6 & 8 & 1
\end{array}\right)
\]
the elements 5,9 , and 1 lie on the diagonal. If a matrix contains zeros in all offdiagonal positions, it is said to be a diagonal matrix. An example of a diagonal matrix is
\[
\mathbf{D}=\left(\begin{array}{rrrr}
10 & 0 & 0 & 0 \\
0 & -3 & 0 & 0 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 7
\end{array}\right)
\]

This matrix could also be denoted as
\[
\begin{equation*}
\mathbf{D}=\operatorname{diag}(10,-3,0,7) \tag{2.7}
\end{equation*}
\]

A diagonal matrix can be formed from any square matrix by replacing off-diagonal elements by 0 's. This is denoted by \(\operatorname{diag}(\mathbf{A})\). Thus for the above matrix \(\mathbf{A}\), we have
\[
\operatorname{diag}(\mathbf{A})=\operatorname{diag}\left(\begin{array}{rrr}
5 & -2 & 4  \tag{2.8}\\
7 & 9 & 3 \\
-6 & 8 & 1
\end{array}\right)=\left(\begin{array}{lll}
5 & 0 & 0 \\
0 & 9 & 0 \\
0 & 0 & 1
\end{array}\right)
\]

A diagonal matrix with a 1 in each diagonal position is called an identity matrix and is denoted by \(I\). For example, a \(3 \times 3\) identity matrix is given by
\[
\mathbf{I}=\left(\begin{array}{lll}
1 & 0 & 0  \tag{2.9}\\
0 & 1 & 0 \\
0 & 0 & 1
\end{array}\right)
\]

An upper triangular matrix is a square matrix with zeros below the diagonal, for example,
\[
\mathbf{T}=\left(\begin{array}{rrrr}
8 & 3 & 4 & 7  \tag{2.10}\\
0 & 0 & -2 & 3 \\
0 & 0 & 5 & 1 \\
0 & 0 & 0 & 6
\end{array}\right)
\]

A lower triangular matrix is defined similarly.
A vector of 1 's will be denoted by \(\mathbf{j}\) :
\[
\mathbf{j}=\left(\begin{array}{c}
1  \tag{2.11}\\
1 \\
\vdots \\
1
\end{array}\right)
\]

A square matrix of 1 's is denoted by \(\mathbf{J}\). For example, a \(3 \times 3\) matrix \(\mathbf{J}\) is given by
\[
\mathbf{J}=\left(\begin{array}{lll}
1 & 1 & 1  \tag{2.12}\\
1 & 1 & 1 \\
1 & 1 & 1
\end{array}\right)
\]

Finally, we denote a vector of zeros by \(\mathbf{0}\) and a matrix of zeros by \(\mathbf{O}\). For example,
\[
\mathbf{0}=\left(\begin{array}{l}
0  \tag{2.13}\\
0 \\
0
\end{array}\right), \quad \mathbf{O}=\left(\begin{array}{cccc}
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0
\end{array}\right)
\]

\subsection*{2.3 OPERATIONS}

\subsection*{2.3.1 Summation and Product Notation}

For completeness, we review the standard mathematical notation for sums and products. The sum of a sequence of numbers \(a_{1}, a_{2}, \ldots, a_{n}\) is indicated by
\[
\sum_{i=1}^{n} a_{i}=a_{1}+a_{2}+\cdots+a_{n}
\]

If the \(n\) numbers are all the same, then \(\sum_{i=1}^{n} a=a+a+\cdots+a=n a\). The sum of all the numbers in an array with double subscripts, such as
\[
\begin{array}{lll}
a_{11} & a_{12} & a_{13} \\
a_{21} & a_{22} & a_{23},
\end{array}
\]
is indicated by
\[
\sum_{i=1}^{2} \sum_{j=1}^{3} a_{i j}=a_{11}+a_{12}+a_{13}+a_{21}+a_{22}+a_{23}
\]

This is sometimes abbreviated to
\[
\sum_{i=1}^{2} \sum_{j=1}^{3} a_{i j}=\sum_{i j} a_{i j}
\]

The product of a sequence of numbers \(a_{1}, a_{2}, \ldots, a_{n}\) is indicated by
\[
\prod_{i=1}^{n} a_{i}=\left(a_{1}\right)\left(a_{2}\right) \cdots\left(a_{n}\right)
\]

If the \(n\) numbers are all equal, the product becomes \(\prod_{i=1}^{n} a=(a)(a) \cdots(a)=a^{n}\).

\subsection*{2.3.2 Addition of Matrices and Vectors}

If two matrices (or two vectors) are the same size, their sum is found by adding corresponding elements, that is, if \(\mathbf{A}\) is \(n \times p\) and \(\mathbf{B}\) is \(n \times p\), then \(\mathbf{C}=\mathbf{A}+\mathbf{B}\) is also \(n \times p\) and is found as \(\left(c_{i j}\right)=\left(a_{i j}+b_{i j}\right)\). For example,
\[
\begin{aligned}
\left(\begin{array}{rr}
-2 & 5 \\
3 & 1 \\
7 & -6
\end{array}\right)+\left(\begin{array}{rr}
3 & -2 \\
4 & 5 \\
10 & -3
\end{array}\right) & =\left(\begin{array}{rr}
1 & 3 \\
7 & 6 \\
17 & -9
\end{array}\right) \\
\left(\begin{array}{l}
1 \\
3 \\
7
\end{array}\right)+\left(\begin{array}{r}
5 \\
-1 \\
3
\end{array}\right) & =\left(\begin{array}{r}
6 \\
2 \\
10
\end{array}\right)
\end{aligned}
\]

Similarly, the difference between two matrices or two vectors of the same size is found by subtracting corresponding elements. Thus \(\mathbf{C}=\mathbf{A}-\mathbf{B}\) is found as \(\left(c_{i j}\right)=\) \(\left(a_{i j}-b_{i j}\right)\). For example,
\[
\left(\begin{array}{lll}
3 & 9 & -4
\end{array}\right)-\left(\begin{array}{lll}
5 & -4 & 2
\end{array}\right)=\left(\begin{array}{lll}
-2 & 13 & -6
\end{array}\right)
\]

If two matrices are identical, their difference is a zero matrix; that is, \(\mathbf{A}=\mathbf{B}\) implies \(\mathbf{A}-\mathbf{B}=\mathbf{O}\). For example,
\[
\left(\begin{array}{rrr}
3 & -2 & 4 \\
6 & 7 & 5
\end{array}\right)-\left(\begin{array}{rrr}
3 & -2 & 4 \\
6 & 7 & 5
\end{array}\right)=\left(\begin{array}{lll}
0 & 0 & 0 \\
0 & 0 & 0
\end{array}\right) .
\]

Matrix addition is commutative:
\[
\begin{equation*}
\mathbf{A}+\mathbf{B}=\mathbf{B}+\mathbf{A} . \tag{2.14}
\end{equation*}
\]

The transpose of the sum (difference) of two matrices is the sum (difference) of the transposes:
\[
\begin{align*}
(\mathbf{A}+\mathbf{B})^{\prime} & =\mathbf{A}^{\prime}+\mathbf{B}^{\prime}  \tag{2.15}\\
(\mathbf{A}-\mathbf{B})^{\prime} & =\mathbf{A}^{\prime}-\mathbf{B}^{\prime}  \tag{2.16}\\
(\mathbf{x}+\mathbf{y})^{\prime} & =\mathbf{x}^{\prime}+\mathbf{y}^{\prime}  \tag{2.17}\\
(\mathbf{x}-\mathbf{y})^{\prime} & =\mathbf{x}^{\prime}-\mathbf{y}^{\prime} \tag{2.18}
\end{align*}
\]

\subsection*{2.3.3 Multiplication of Matrices and Vectors}

In order for the product \(\mathbf{A B}\) to be defined, the number of columns in \(\mathbf{A}\) must be the same as the number of rows in \(\mathbf{B}\), in which case \(\mathbf{A}\) and \(\mathbf{B}\) are said to be conformable. Then the ( \(i j\) )th element of \(\mathbf{C}=\mathbf{A B}\) is
\[
\begin{equation*}
c_{i j}=\sum_{k} a_{i k} b_{k j} . \tag{2.19}
\end{equation*}
\]

Thus \(c_{i j}\) is the sum of products of the \(i\) th row of \(\mathbf{A}\) and the \(j\) th column of \(\mathbf{B}\). We therefore multiply each row of \(\mathbf{A}\) by each column of \(\mathbf{B}\), and the size of \(\mathbf{A B}\) consists of the number of rows of \(\mathbf{A}\) and the number of columns of \(\mathbf{B}\). Thus, if \(\mathbf{A}\) is \(n \times m\) and \(\mathbf{B}\) is \(m \times p\), then \(\mathbf{C}=\mathbf{A B}\) is \(n \times p\). For example, if
\[
\mathbf{A}=\left(\begin{array}{lll}
2 & 1 & 3 \\
4 & 6 & 5 \\
7 & 2 & 3 \\
1 & 3 & 2
\end{array}\right) \quad \text { and } \quad \mathbf{B}=\left(\begin{array}{cc}
1 & 4 \\
2 & 6 \\
3 & 8
\end{array}\right)
\]
then
\[
\begin{aligned}
\mathbf{C}=\mathbf{A B} & =\left(\begin{array}{cc}
2 \cdot 1+1 \cdot 2+3 \cdot 3 & 2 \cdot 4+1 \cdot 6+3 \cdot 8 \\
4 \cdot 1+6 \cdot 2+5 \cdot 3 & 4 \cdot 4+6 \cdot 6+5 \cdot 8 \\
7 \cdot 1+2 \cdot 2+3 \cdot 3 & 7 \cdot 4+2 \cdot 6+3 \cdot 8 \\
1 \cdot 1+3 \cdot 2+2 \cdot 3 & 1 \cdot 4+3 \cdot 6+2 \cdot 8
\end{array}\right) \\
& =\left(\begin{array}{ll}
13 & 38 \\
31 & 92 \\
20 & 64 \\
13 & 38
\end{array}\right) .
\end{aligned}
\]

Note that \(\mathbf{A}\) is \(4 \times 3, \mathbf{B}\) is \(3 \times 2\), and \(\mathbf{A B}\) is \(4 \times 2\). In this case, \(\mathbf{A B}\) is of a different size than either \(\mathbf{A}\) or \(\mathbf{B}\).

If \(\mathbf{A}\) and \(\mathbf{B}\) are both \(n \times n\), then \(\mathbf{A B}\) is also \(n \times n\). Clearly, \(\mathbf{A}^{2}\) is defined only if \(\mathbf{A}\) is square.

In some cases \(\mathbf{A B}\) is defined, but \(\mathbf{B A}\) is not defined. In the above example, \(\mathbf{B A}\) cannot be found because \(\mathbf{B}\) is \(3 \times 2\) and \(\mathbf{A}\) is \(4 \times 3\) and a row of \(\mathbf{B}\) cannot be multiplied by a column of \(\mathbf{A}\). Sometimes \(\mathbf{A B}\) and \(\mathbf{B A}\) are both defined but are different in size. For example, if \(\mathbf{A}\) is \(2 \times 4\) and \(\mathbf{B}\) is \(4 \times 2\), then \(\mathbf{A B}\) is \(2 \times 2\) and \(\mathbf{B} \mathbf{A}\) is \(4 \times 4\). If \(\mathbf{A}\) and \(\mathbf{B}\) are square and the same size, then \(\mathbf{A B}\) and \(\mathbf{B A}\) are both defined. However,
\[
\begin{equation*}
\mathbf{A B} \neq \mathbf{B A} \tag{2.20}
\end{equation*}
\]
except for a few special cases. For example, let
\[
\mathbf{A}=\left(\begin{array}{ll}
1 & 3 \\
2 & 4
\end{array}\right), \quad \mathbf{B}=\left(\begin{array}{rr}
1 & -2 \\
3 & 5
\end{array}\right) .
\]

Then
\[
\mathbf{A B}=\left(\begin{array}{ll}
10 & 13 \\
14 & 16
\end{array}\right), \quad \mathbf{B} \mathbf{A}=\left(\begin{array}{rr}
-3 & -5 \\
13 & 29
\end{array}\right)
\]

Thus we must be careful to specify the order of multiplication. If we wish to multiply both sides of a matrix equation by a matrix, we must multiply "on the left" or "on the right" and be consistent on both sides of the equation.

Multiplication is distributive over addition or subtraction:
\[
\begin{align*}
& \mathbf{A}(\mathbf{B}+\mathbf{C})=\mathbf{A B}+\mathbf{A C},  \tag{2.21}\\
& \mathbf{A}(\mathbf{B}-\mathbf{C})=\mathbf{A B}-\mathbf{A C},  \tag{2.22}\\
& (\mathbf{A}+\mathbf{B}) \mathbf{C}=\mathbf{A C}+\mathbf{B C},  \tag{2.23}\\
& (\mathbf{A}-\mathbf{B}) \mathbf{C}=\mathbf{A C}-\mathbf{B C} . \tag{2.24}
\end{align*}
\]

Note that, in general, because of (2.20),
\[
\begin{equation*}
\mathbf{A}(\mathbf{B}+\mathbf{C}) \neq \mathbf{B A}+\mathbf{C A} \tag{2.25}
\end{equation*}
\]

Using the distributive law, we can expand products such as \((\mathbf{A}-\mathbf{B})(\mathbf{C}-\mathbf{D})\) to obtain
\[
\begin{array}{rlr}
(\mathbf{A}-\mathbf{B})(\mathbf{C}-\mathbf{D}) & =(\mathbf{A}-\mathbf{B}) \mathbf{C}-(\mathbf{A}-\mathbf{B}) \mathbf{D} & {[\text { by }(2.22)]} \\
& =\mathbf{A} \mathbf{C}-\mathbf{B C}-\mathbf{A D}+\mathbf{B D} \quad[\text { by }(2.24)] \tag{2.26}
\end{array}
\]

The transpose of a product is the product of the transposes in reverse order:
\[
\begin{equation*}
(\mathbf{A B})^{\prime}=\mathbf{B}^{\prime} \mathbf{A}^{\prime} \tag{2.27}
\end{equation*}
\]

Note that (2.27) holds as long as \(\mathbf{A}\) and \(\mathbf{B}\) are conformable. They need not be square.
Multiplication involving vectors follows the same rules as for matrices. Suppose \(\mathbf{A}\) is \(n \times p\), \(\mathbf{a}\) is \(p \times 1, \mathbf{b}\) is \(p \times 1\), and \(\mathbf{c}\) is \(n \times 1\). Then some possible products are \(\mathbf{A b}, \mathbf{c}^{\prime} \mathbf{A}, \mathbf{a}^{\prime} \mathbf{b}, \mathbf{b}^{\prime} \mathbf{a}\), and \(\mathbf{a b} \mathbf{b}^{\prime}\). For example, let
\[
\mathbf{A}=\left(\begin{array}{rrr}
3 & -2 & 4 \\
1 & 3 & 5
\end{array}\right), \quad \mathbf{a}=\left(\begin{array}{r}
1 \\
-2 \\
3
\end{array}\right), \quad \mathbf{b}=\left(\begin{array}{l}
2 \\
3 \\
4
\end{array}\right), \quad \mathbf{c}=\binom{2}{-5}
\]

Then
\[
\begin{aligned}
\mathbf{A} \mathbf{b} & =\left(\begin{array}{rrr}
3 & -2 & 4 \\
1 & 3 & 5
\end{array}\right)\left(\begin{array}{l}
2 \\
3 \\
4
\end{array}\right)=\binom{16}{31} \\
\mathbf{c}^{\prime} \mathbf{A} & =\left(\begin{array}{ll}
2 & -5
\end{array}\right)\left(\begin{array}{rrr}
3 & -2 & 4 \\
1 & 3 & 5
\end{array}\right)=\left(\begin{array}{lll}
1 & -19 & -17
\end{array}\right) \\
\mathbf{c}^{\prime} \mathbf{A} \mathbf{b} & =\left(\begin{array}{ll}
2 & -5
\end{array}\right)\left(\begin{array}{rrr}
3 & -2 & 4 \\
1 & 3 & 5
\end{array}\right)\left(\begin{array}{l}
2 \\
3 \\
4
\end{array}\right) \\
& =\left(\begin{array}{ll}
2 & -5
\end{array}\right)\binom{16}{31}=-123 \\
\mathbf{a}^{\prime} \mathbf{b} & =\left(\begin{array}{lll}
1 & -2 & 3
\end{array}\right)\left(\begin{array}{l}
2 \\
3 \\
4
\end{array}\right)=8 \\
\mathbf{b}^{\prime} \mathbf{a} & =\left(\begin{array}{rrr}
2 & 3 & 4
\end{array}\right)\left(\begin{array}{r}
1 \\
-2 \\
3
\end{array}\right)=8 \\
\mathbf{a b}^{\prime} & =\left(\begin{array}{r}
1 \\
-2 \\
3
\end{array}\right)\left(\begin{array}{ll}
2 & 3
\end{array}\right)=\left(\begin{array}{rrr}
2 & 3 & 4 \\
-4 & -6 & -8 \\
6 & 9 & 12
\end{array}\right) \\
\mathbf{a c}^{\prime} & =\left(\begin{array}{r}
1 \\
-2 \\
3
\end{array}\right)\left(\begin{array}{ll}
2 & -5
\end{array}\right)=\left(\begin{array}{rr}
2 & -5 \\
-4 & 10 \\
6 & -15
\end{array}\right)
\end{aligned}
\]

Note that \(\mathbf{A b}\) is a column vector, \(\mathbf{c}^{\prime} \mathbf{A}\) is a row vector, \(\mathbf{c}^{\prime} \mathbf{A} \mathbf{b}\) is a scalar, and \(\mathbf{a}^{\prime} \mathbf{b}=\) \(\mathbf{b}^{\prime} \mathbf{a}\). The triple product \(\mathbf{c}^{\prime} \mathbf{A b}\) was obtained as \(\mathbf{c}^{\prime}(\mathbf{A b})\). The same result would be obtained if we multiplied in the order \(\left(\mathbf{c}^{\prime} \mathbf{A}\right) \mathbf{b}\) :
\[
\left(\mathbf{c}^{\prime} \mathbf{A}\right) \mathbf{b}=\left(\begin{array}{lll}
1 & -19 & -17
\end{array}\right)\left(\begin{array}{l}
2 \\
3 \\
4
\end{array}\right)=-123
\]

This is true in general for a triple product:
\[
\begin{equation*}
\mathbf{A B C}=\mathbf{A}(\mathbf{B C})=(\mathbf{A B}) \mathbf{C} . \tag{2.28}
\end{equation*}
\]

Thus multiplication of three matrices can be defined in terms of the product of two matrices, since (fortunately) it does not matter which two are multiplied first. Note that \(\mathbf{A}\) and \(\mathbf{B}\) must be conformable for multiplication, and \(\mathbf{B}\) and \(\mathbf{C}\) must be conformable. For example, if \(\mathbf{A}\) is \(n \times p, \mathbf{B}\) is \(p \times q\), and \(\mathbf{C}\) is \(q \times m\), then both multiplications are possible and the product \(\mathbf{A B C}\) is \(n \times m\).

We can sometimes factor a sum of triple products on both the right and left sides. For example,
\[
\begin{equation*}
\mathbf{A B C}+\mathbf{A D C}=\mathbf{A}(\mathbf{B}+\mathbf{D}) \mathbf{C} \tag{2.29}
\end{equation*}
\]

As another illustration, let \(\mathbf{X}\) be \(n \times p\) and \(\mathbf{A}\) be \(n \times n\). Then
\[
\begin{equation*}
\mathbf{X}^{\prime} \mathbf{X}-\mathbf{X}^{\prime} \mathbf{A} \mathbf{X}=\mathbf{X}^{\prime}(\mathbf{X}-\mathbf{A} \mathbf{X})=\mathbf{X}^{\prime}(\mathbf{I}-\mathbf{A}) \mathbf{X} \tag{2.30}
\end{equation*}
\]

If \(\mathbf{a}\) and \(\mathbf{b}\) are both \(n \times 1\), then
\[
\begin{equation*}
\mathbf{a}^{\prime} \mathbf{b}=a_{1} b_{1}+a_{2} b_{2}+\cdots+a_{n} b_{n} \tag{2.31}
\end{equation*}
\]
is a sum of products and is a scalar. On the other hand, \(\mathbf{a b}^{\prime}\) is defined for any size a and \(\mathbf{b}\) and is a matrix, either rectangular or square:
\[
\begin{align*}
\mathbf{a b}^{\prime} & =\left(\begin{array}{c}
a_{1} \\
a_{2} \\
\vdots \\
a_{n}
\end{array}\right)\left(\begin{array}{llll}
b_{1} & b_{2} & \cdots & b_{p}
\end{array}\right) \\
& =\left(\begin{array}{cccc}
a_{1} b_{1} & a_{1} b_{2} & \cdots & a_{1} b_{p} \\
a_{2} b_{1} & a_{2} b_{2} & \cdots & a_{2} b_{p} \\
\vdots & \vdots & & \vdots \\
a_{n} b_{1} & a_{n} b_{2} & \cdots & a_{n} b_{p}
\end{array}\right) . \tag{2.32}
\end{align*}
\]

Similarly,
\[
\begin{align*}
\mathbf{a}^{\prime} \mathbf{a} & =a_{1}^{2}+a_{2}^{2}+\cdots+a_{n}^{2},  \tag{2.33}\\
\mathbf{a a}^{\prime} & =\left(\begin{array}{cccc}
a_{1}^{2} & a_{1} a_{2} & \cdots & a_{1} a_{n} \\
a_{2} a_{1} & a_{2}^{2} & \cdots & a_{2} a_{n} \\
\vdots & \vdots & & \vdots \\
a_{n} a_{1} & a_{n} a_{2} & \cdots & a_{n}^{2}
\end{array}\right) . \tag{2.34}
\end{align*}
\]

Thus \(\mathbf{a}^{\prime} \mathbf{a}\) is a sum of squares and \(\mathbf{a a}^{\prime}\) is a square (symmetric) matrix. The products \(\mathbf{a}^{\prime} \mathbf{a}\) and \(\mathbf{a a}^{\prime}\) are sometimes referred to as the dot product and matrix product, respectively. The square root of the sum of squares of the elements of \(\mathbf{a}\) is the distance from the origin to the point \(\mathbf{a}\) and is also referred to as the length of a:
\[
\begin{equation*}
\text { Length of } \mathbf{a}=\sqrt{\mathbf{a}^{\prime} \mathbf{a}}=\sqrt{\sum_{i=1}^{n} a_{i}^{2}} \tag{2.35}
\end{equation*}
\]

As special cases of (2.33) and (2.34), note that if \(\mathbf{j}\) is \(n \times 1\), then
\[
\mathbf{j}^{\prime} \mathbf{j}=n, \quad \mathbf{j}^{\prime}=\left(\begin{array}{cccc}
1 & 1 & \cdots & 1  \tag{2.36}\\
1 & 1 & \cdots & 1 \\
\vdots & \vdots & & \vdots \\
1 & 1 & \cdots & 1
\end{array}\right)=\mathbf{J}
\]
where \(\mathbf{j}\) and \(\mathbf{J}\) were defined in (2.11) and (2.12). If \(\mathbf{a}\) is \(n \times 1\) and \(\mathbf{A}\) is \(n \times p\), then
\[
\begin{align*}
& \mathbf{a}^{\prime} \mathbf{j}=\mathbf{j}^{\prime} \mathbf{a}=\sum_{i=1}^{n} a_{i},  \tag{2.37}\\
& \mathbf{j}^{\prime} \mathbf{A}=\left(\sum_{i} a_{i 1}, \sum_{i} a_{i 2}, \ldots, \sum_{i} a_{i p}\right), \quad \mathbf{A} \mathbf{j}=\left(\begin{array}{c}
\sum_{j} a_{1 j} \\
\sum_{j} a_{2 j} \\
\vdots \\
\sum_{j} a_{n j}
\end{array}\right) . \tag{2.38}
\end{align*}
\]

Thus \(\mathbf{a}^{\prime} \mathbf{j}\) is the sum of the elements in \(\mathbf{a}, \mathbf{j}^{\prime} \mathbf{A}\) contains the column sums of \(\mathbf{A}\), and \(\mathbf{A} \mathbf{j}\) contains the row sums of \(\mathbf{A}\). In \(\mathbf{a}^{\prime} \mathbf{j}\), the vector \(\mathbf{j}\) is \(n \times 1\); in \(\mathbf{j}^{\prime} \mathbf{A}\), the vector \(\mathbf{j}\) is \(n \times 1\); and in \(\mathbf{A} \mathbf{j}\), the vector \(\mathbf{j}\) is \(p \times 1\).

Since \(\mathbf{a}^{\prime} \mathbf{b}\) is a scalar, it is equal to its transpose:
\[
\begin{equation*}
\mathbf{a}^{\prime} \mathbf{b}=\left(\mathbf{a}^{\prime} \mathbf{b}\right)^{\prime}=\mathbf{b}^{\prime}\left(\mathbf{a}^{\prime}\right)^{\prime}=\mathbf{b}^{\prime} \mathbf{a} \tag{2.39}
\end{equation*}
\]

This allows us to write \(\left(\mathbf{a}^{\prime} \mathbf{b}\right)^{2}\) in the form
\[
\begin{equation*}
\left(\mathbf{a}^{\prime} \mathbf{b}\right)^{2}=\left(\mathbf{a}^{\prime} \mathbf{b}\right)\left(\mathbf{a}^{\prime} \mathbf{b}\right)=\left(\mathbf{a}^{\prime} \mathbf{b}\right)\left(\mathbf{b}^{\prime} \mathbf{a}\right)=\mathbf{a}^{\prime}\left(\mathbf{b} \mathbf{b}^{\prime}\right) \mathbf{a} \tag{2.40}
\end{equation*}
\]

From (2.18), (2.26), and (2.39) we obtain
\[
\begin{equation*}
(\mathbf{x}-\mathbf{y})^{\prime}(\mathbf{x}-\mathbf{y})=\mathbf{x}^{\prime} \mathbf{x}-2 \mathbf{x}^{\prime} \mathbf{y}+\mathbf{y}^{\prime} \mathbf{y} \tag{2.41}
\end{equation*}
\]

Note that in analogous expressions with matrices, however, the two middle terms cannot be combined:
\[
\begin{aligned}
(\mathbf{A}-\mathbf{B})^{\prime}(\mathbf{A}-\mathbf{B}) & =\mathbf{A}^{\prime} \mathbf{A}-\mathbf{A}^{\prime} \mathbf{B}-\mathbf{B}^{\prime} \mathbf{A}+\mathbf{B}^{\prime} \mathbf{B}, \\
(\mathbf{A}-\mathbf{B})^{2} & =(\mathbf{A}-\mathbf{B})(\mathbf{A}-\mathbf{B})=\mathbf{A}^{2}-\mathbf{A} \mathbf{B}-\mathbf{B} \mathbf{A}+\mathbf{B}^{2} .
\end{aligned}
\]

If \(\mathbf{a}\) and \(\mathbf{x}_{1}, \mathbf{x}_{2}, \ldots, \mathbf{x}_{n}\) are all \(p \times 1\) and \(\mathbf{A}\) is \(p \times p\), we obtain the following factoring results as extensions of (2.21) and (2.29):
\[
\begin{align*}
\sum_{i=1}^{n} \mathbf{a}^{\prime} \mathbf{x}_{i} & =\mathbf{a}^{\prime} \sum_{i=1}^{n} \mathbf{x}_{i}  \tag{2.42}\\
\sum_{i=1}^{n} \mathbf{A} \mathbf{x}_{i} & =\mathbf{A} \sum_{i=1}^{n} \mathbf{x}_{i}  \tag{2.43}\\
\sum_{i=1}^{n}\left(\mathbf{a}^{\prime} \mathbf{x}_{i}\right)^{2} & =\mathbf{a}^{\prime}\left(\sum_{i=1}^{n} \mathbf{x}_{i} \mathbf{x}_{i}^{\prime}\right) \mathbf{a} \quad[\mathbf{b y}(2.40)]  \tag{2.44}\\
\sum_{i=1}^{n} \mathbf{A} \mathbf{x}_{i}\left(\mathbf{A} \mathbf{x}_{i}\right)^{\prime} & =\mathbf{A}\left(\sum_{i=1}^{n} \mathbf{x}_{i} \mathbf{x}_{i}^{\prime}\right) \mathbf{A}^{\prime} \tag{2.45}
\end{align*}
\]

We can express matrix multiplication in terms of row vectors and column vectors. If \(\mathbf{a}_{i}^{\prime}\) is the \(i\) th row of \(\mathbf{A}\) and \(\mathbf{b}_{j}\) is the \(j\) th column of \(\mathbf{B}\), then the \((i j)\) th element of
\(\mathbf{A B}\) is \(\mathbf{a}_{i}^{\prime} \mathbf{b}_{j}\). For example, if \(\mathbf{A}\) has three rows and \(\mathbf{B}\) has two columns,
\[
\mathbf{A}=\left(\begin{array}{l}
\mathbf{a}_{1}^{\prime} \\
\mathbf{a}_{2}^{\prime} \\
\mathbf{a}_{3}^{\prime}
\end{array}\right), \quad \mathbf{B}=\left(\mathbf{b}_{1}, \mathbf{b}_{2}\right)
\]
then the product \(\mathbf{A B}\) can be written as
\[
\mathbf{A B}=\left(\begin{array}{cc}
\mathbf{a}_{1}^{\prime} \mathbf{b}_{1} & \mathbf{a}_{1}^{\prime} \mathbf{b}_{2}  \tag{2.46}\\
\mathbf{a}_{2}^{\prime} \mathbf{b}_{1} & \mathbf{a}_{2}^{\prime} \mathbf{b}_{2} \\
\mathbf{a}_{3}^{\prime} \mathbf{b}_{1} & \mathbf{a}_{3}^{\prime} \mathbf{b}_{2}
\end{array}\right)
\]

This can be expressed in terms of the rows of \(\mathbf{A}\) :
\[
\mathbf{A B}=\left(\begin{array}{c}
\mathbf{a}_{1}^{\prime}\left(\mathbf{b}_{1}, \mathbf{b}_{2}\right)  \tag{2.47}\\
\mathbf{a}_{2}^{\prime}\left(\mathbf{b}_{1}, \mathbf{b}_{2}\right) \\
\mathbf{a}_{3}^{\prime}\left(\mathbf{b}_{1}, \mathbf{b}_{2}\right)
\end{array}\right)=\left(\begin{array}{c}
\mathbf{a}_{1}^{\prime} \mathbf{B} \\
\mathbf{a}_{2}^{\prime} \mathbf{B} \\
\mathbf{a}_{3}^{\prime} \mathbf{B}
\end{array}\right)=\left(\begin{array}{c}
\mathbf{a}_{1}^{\prime} \\
\mathbf{a}_{2}^{\prime} \\
\mathbf{a}_{3}^{\prime}
\end{array}\right) \mathbf{B} .
\]

Note that the first column of AB in (2.46) is
\[
\left(\begin{array}{c}
\mathbf{a}_{1}^{\prime} \mathbf{b}_{1} \\
\mathbf{a}_{2}^{\prime} \mathbf{b}_{1} \\
\mathbf{a}_{3}^{\prime} \mathbf{b}_{1}
\end{array}\right)=\left(\begin{array}{c}
\mathbf{a}_{1}^{\prime} \\
\mathbf{a}_{2}^{\prime} \\
\mathbf{a}_{3}^{\prime}
\end{array}\right) \mathbf{b}_{1}=\mathbf{A} \mathbf{b}_{1}
\]
and likewise the second column is \(\mathbf{A} \mathbf{b}_{2}\). Thus \(\mathbf{A B}\) can be written in the form
\[
\mathbf{A B}=\mathbf{A}\left(\mathbf{b}_{1}, \mathbf{b}_{2}\right)=\left(\mathbf{A} \mathbf{b}_{1}, \mathbf{A} \mathbf{b}_{2}\right) .
\]

This result holds in general:
\[
\begin{equation*}
\mathbf{A B}=\mathbf{A}\left(\mathbf{b}_{1}, \mathbf{b}_{2}, \ldots, \mathbf{b}_{p}\right)=\left(\mathbf{A} \mathbf{b}_{1}, \mathbf{A} \mathbf{b}_{2}, \ldots, \mathbf{A} \mathbf{b}_{p}\right) \tag{2.48}
\end{equation*}
\]

To further illustrate matrix multiplication in terms of rows and columns, let \(\mathbf{A}=\) \(\binom{\mathbf{a}_{1}^{\prime}}{\mathbf{a}_{2}^{\prime}}\) be a \(2 \times p\) matrix, \(\mathbf{x}\) be a \(p \times 1\) vector, and \(\mathbf{S}\) be a \(p \times p\) matrix. Then
\[
\begin{gather*}
\mathbf{A x}=\binom{\mathbf{a}_{1}^{\prime}}{\mathbf{a}_{2}^{\prime}} \mathbf{x}=\binom{\mathbf{a}_{1}^{\prime} \mathbf{x}}{\mathbf{a}_{2}^{\prime} \mathbf{x}},  \tag{2.49}\\
\mathbf{A S A}^{\prime}=\left(\begin{array}{ll}
\mathbf{a}_{1}^{\prime} \mathbf{S} \mathbf{S a}_{1} & \mathbf{a}_{1}^{\prime} \mathbf{S} \mathbf{S a}_{2} \\
\mathbf{a}_{2}^{\prime} \mathbf{S \mathbf { a } _ { 1 }} & \mathbf{a}_{2}^{\prime} \mathbf{S} \mathbf{a}_{2}
\end{array}\right) . \tag{2.50}
\end{gather*}
\]

Any matrix can be multiplied by its transpose. If \(\mathbf{A}\) is \(n \times p\), then
\(\mathbf{A} \mathbf{A}^{\prime}\) is \(n \times n\) and is obtained as products of rows of \(\mathbf{A}\) [see (2.52)].
Similarly,
\(\mathbf{A}^{\prime} \mathbf{A}\) is \(p \times p\) and is obtained as products of columns of \(\mathbf{A}\) [see (2.54)].

From (2.6) and (2.27), it is clear that both \(\mathbf{A A}^{\prime}\) and \(\mathbf{A}^{\prime} \mathbf{A}\) are symmetric.
In the above illustration for \(\mathbf{A B}\) in terms of row and column vectors, the rows of \(\mathbf{A}\) were denoted by \(\mathbf{a}_{i}^{\prime}\) and the columns of \(\mathbf{B}\) by \(\mathbf{b}_{j}\). If both rows and columns of a matrix \(\mathbf{A}\) are under discussion, as in \(\mathbf{A A}^{\prime}\) and \(\mathbf{A}^{\prime} \mathbf{A}\), we will use the notation \(\mathbf{a}_{i}^{\prime}\) for rows and \(\mathbf{a}_{(j)}\) for columns. To illustrate, if \(\mathbf{A}\) is \(3 \times 4\), we have
\[
\begin{aligned}
\mathbf{A} & =\left(\begin{array}{llll}
a_{11} & a_{12} & a_{13} & a_{14} \\
a_{21} & a_{22} & a_{23} & a_{24} \\
a_{31} & a_{32} & a_{33} & a_{34}
\end{array}\right) \\
& =\left(\begin{array}{l}
\mathbf{a}_{1}^{\prime} \\
\mathbf{a}_{2}^{\prime} \\
\mathbf{a}_{3}^{\prime}
\end{array}\right)=\left(\mathbf{a}_{(1)}, \mathbf{a}_{(2)}, \mathbf{a}_{(3)}, \mathbf{a}_{(4)}\right)
\end{aligned}
\]
where, for example,
\[
\begin{gathered}
\mathbf{a}_{2}^{\prime}=\left(\begin{array}{lll}
a_{21} & a_{22} & a_{23} \\
a_{24}
\end{array}\right), \\
\mathbf{a}_{(3)}=\left(\begin{array}{l}
a_{13} \\
a_{23} \\
a_{33}
\end{array}\right)
\end{gathered}
\]

With this notation for rows and columns of \(\mathbf{A}\), we can express the elements of \(\mathbf{A}^{\prime} \mathbf{A}\) or of \(\mathbf{A} \mathbf{A}^{\prime}\) as products of the rows of \(\mathbf{A}\) or of the columns of \(\mathbf{A}\). Thus if we write \(\mathbf{A}\) in terms of its rows as
\[
\mathbf{A}=\left(\begin{array}{c}
\mathbf{a}_{1}^{\prime} \\
\mathbf{a}_{2}^{\prime} \\
\vdots \\
\mathbf{a}_{n}^{\prime}
\end{array}\right)
\]
then we have
\[
\mathbf{A}^{\prime} \mathbf{A}=\left(\mathbf{a}_{1}, \mathbf{a}_{2}, \ldots, \mathbf{a}_{n}\right)\left(\begin{array}{c}
\mathbf{a}_{1}^{\prime}  \tag{2.51}\\
\mathbf{a}_{2}^{\prime} \\
\vdots \\
\mathbf{a}_{n}^{\prime}
\end{array}\right)=\sum_{i=1}^{n} \mathbf{a}_{i} \mathbf{a}_{i}^{\prime}
\]
\[
\begin{align*}
\mathbf{A A}^{\prime} & =\left(\begin{array}{c}
\mathbf{a}_{1}^{\prime} \\
\mathbf{a}_{2}^{\prime} \\
\vdots \\
\mathbf{a}_{n}^{\prime}
\end{array}\right)\left(\mathbf{a}_{1}, \mathbf{a}_{2}, \ldots, \mathbf{a}_{n}\right) \\
& =\left(\begin{array}{cccc}
\mathbf{a}_{1}^{\prime} \mathbf{a}_{1} & \mathbf{a}_{1}^{\prime} \mathbf{a}_{2} & \cdots & \mathbf{a}_{1}^{\prime} \mathbf{a}_{n} \\
\mathbf{a}_{2}^{\prime} \mathbf{a}_{1} & \mathbf{a}_{2}^{\prime} \mathbf{a}_{2} & \cdots & \mathbf{a}_{2}^{\prime} \mathbf{a}_{n} \\
\vdots & \vdots & & \vdots \\
\mathbf{a}_{n}^{\prime} \mathbf{a}_{1} & \mathbf{a}_{n}^{\prime} \mathbf{a}_{2} & \cdots & \mathbf{a}_{n}^{\prime} \mathbf{a}_{n}
\end{array}\right) . \tag{2.52}
\end{align*}
\]

Similarly, if we express \(\mathbf{A}\) in terms of columns as
\[
\mathbf{A}=\left(\mathbf{a}_{(1)}, \mathbf{a}_{(2)}, \ldots, \mathbf{a}_{(p)}\right)
\]
then
\[
\begin{align*}
\mathbf{A} \mathbf{A}^{\prime}= & \left(\mathbf{a}_{(1)}, \mathbf{a}_{(2)}, \ldots, \mathbf{a}_{(p)}\right)\left(\begin{array}{c}
\mathbf{a}_{(1)}^{\prime} \\
\mathbf{a}_{(2)}^{\prime} \\
\vdots \\
\mathbf{a}_{(p)}^{\prime}
\end{array}\right)=\sum_{j=1}^{p} \mathbf{a}_{(j)} \mathbf{a}_{(j)}^{\prime},  \tag{2.53}\\
\mathbf{A}^{\prime} \mathbf{A} & =\left(\begin{array}{c}
\mathbf{a}_{(1)}^{\prime} \\
\mathbf{a}_{(2)}^{\prime} \\
\vdots \\
\mathbf{a}_{(p)}^{\prime}
\end{array}\right)\left(\mathbf{a}_{(1)}, \mathbf{a}_{(2)}, \ldots, \mathbf{a}_{(p)}\right) \\
& =\left(\begin{array}{cccc}
\mathbf{a}_{(1)}^{\prime} \mathbf{a}_{(1)} & \mathbf{a}_{(1)}^{\prime} \mathbf{a}_{(2)} & \cdots & \mathbf{a}_{(1)}^{\prime} \mathbf{a}_{(p)} \\
\mathbf{a}_{(2)}^{\prime} \mathbf{a}_{(1)} & \mathbf{a}_{(2)}^{\prime} \mathbf{a}_{(2)} & \cdots & \mathbf{a}_{(2)}^{\prime} \mathbf{a}_{(p)} \\
\vdots & \vdots & & \vdots \\
\mathbf{a}_{(p)}^{\prime} \mathbf{a}_{(1)} & \mathbf{a}_{(p)}^{\prime} \mathbf{a}_{(2)} & \cdots & \mathbf{a}_{(p)}^{\prime} \mathbf{a}_{(p)}
\end{array}\right) \tag{2.54}
\end{align*}
\]

Let \(\mathbf{A}=\left(a_{i j}\right)\) be an \(n \times n\) matrix and \(\mathbf{D}\) be a diagonal matrix, \(\mathbf{D}=\operatorname{diag}\left(d_{1}, d_{2}, \ldots\right.\), \(\left.d_{n}\right)\). Then, in the product DA, the \(i\) th row of \(\mathbf{A}\) is multiplied by \(d_{i}\), and in AD, the \(j\) th column of \(\mathbf{A}\) is multiplied by \(d_{j}\). For example, if \(n=3\), we have
\[
\begin{align*}
\mathbf{D A} & =\left(\begin{array}{ccc}
d_{1} & 0 & 0 \\
0 & d_{2} & 0 \\
0 & 0 & d_{3}
\end{array}\right)\left(\begin{array}{lll}
a_{11} & a_{12} & a_{13} \\
a_{21} & a_{22} & a_{23} \\
a_{31} & a_{32} & a_{33}
\end{array}\right) \\
& =\left(\begin{array}{lll}
d_{1} a_{11} & d_{1} a_{12} & d_{1} a_{13} \\
d_{2} a_{21} & d_{2} a_{22} & d_{2} a_{23} \\
d_{3} a_{31} & d_{3} a_{32} & d_{3} a_{33}
\end{array}\right)  \tag{2.55}\\
\mathbf{A D} & =\left(\begin{array}{lll}
a_{11} & a_{12} & a_{13} \\
a_{21} & a_{22} & a_{23} \\
a_{31} & a_{32} & a_{33}
\end{array}\right)\left(\begin{array}{ccc}
d_{1} & 0 & 0 \\
0 & d_{2} & 0 \\
0 & 0 & d_{3}
\end{array}\right) \\
& =\left(\begin{array}{ccc}
d_{1} a_{11} & d_{2} a_{12} & d_{3} a_{13} \\
d_{1} a_{21} & d_{2} a_{22} & d_{3} a_{23} \\
d_{1} a_{31} & d_{2} a_{32} & d_{3} a_{33}
\end{array}\right)  \tag{2.56}\\
\mathbf{D A D} & =\left(\begin{array}{ccc}
d_{1}^{2} a_{11} & d_{1} d_{2} a_{12} & d_{1} d_{3} a_{13} \\
d_{2} d_{1} a_{21} & d_{2}^{2} a_{22} & d_{2} d_{3} a_{23} \\
d_{3} d_{1} a_{31} & d_{3} d_{2} a_{32} & d_{3}^{2} a_{33}
\end{array}\right) \tag{2.57}
\end{align*}
\]

In the special case where the diagonal matrix is the identity, we have
\[
\begin{equation*}
\mathbf{I} \mathbf{A}=\mathbf{A} \mathbf{I}=\mathbf{A} \tag{2.58}
\end{equation*}
\]

If \(\mathbf{A}\) is rectangular, (2.58) still holds, but the two identities are of different sizes.
The product of a scalar and a matrix is obtained by multiplying each element of the matrix by the scalar:
\[
c \mathbf{A}=\left(c a_{i j}\right)=\left(\begin{array}{cccc}
c a_{11} & c a_{12} & \cdots & c a_{1 m}  \tag{2.59}\\
c a_{21} & c a_{22} & \cdots & c a_{2 m} \\
\vdots & \vdots & & \vdots \\
c a_{n 1} & c a_{n 2} & \cdots & c a_{n m}
\end{array}\right)
\]

For example,
\[
\begin{align*}
c \mathbf{I} & =\left(\begin{array}{cccc}
c & 0 & \cdots & 0 \\
0 & c & \cdots & 0 \\
\vdots & \vdots & & \vdots \\
0 & 0 & \cdots & c
\end{array}\right)  \tag{2.60}\\
c \mathbf{x} & =\left(\begin{array}{c}
c x_{1} \\
c x_{2} \\
\vdots \\
c x_{n}
\end{array}\right) \tag{2.61}
\end{align*}
\]

Since \(c a_{i j}=a_{i j} c\), the product of a scalar and a matrix is commutative:
\[
\begin{equation*}
c \mathbf{A}=\mathbf{A} c . \tag{2.62}
\end{equation*}
\]

Multiplication of vectors or matrices by scalars permits the use of linear combinations, such as
\[
\begin{aligned}
& \sum_{i=1}^{k} a_{i} \mathbf{x}_{i}=a_{1} \mathbf{x}_{1}+a_{2} \mathbf{x}_{2}+\cdots+a_{k} \mathbf{x}_{k} \\
& \sum_{i=1}^{k} a_{i} \mathbf{B}_{i}=a_{1} \mathbf{B}_{1}+a_{2} \mathbf{B}_{2}+\cdots+a_{k} \mathbf{B}_{k}
\end{aligned}
\]

If \(\mathbf{A}\) is a symmetric matrix and \(\mathbf{x}\) and \(\mathbf{y}\) are vectors, the product
\[
\begin{equation*}
\mathbf{y}^{\prime} \mathbf{A} \mathbf{y}=\sum_{i} a_{i i} y_{i}^{2}+\sum_{i \neq j} a_{i j} y_{i} y_{j} \tag{2.63}
\end{equation*}
\]
is called a quadratic form, while
\[
\begin{equation*}
\mathbf{x}^{\prime} \mathbf{A} \mathbf{y}=\sum_{i j} a_{i j} x_{i} y_{j} \tag{2.64}
\end{equation*}
\]
is called a bilinear form. Either of these is, of course, a scalar and can be treated as such. Expressions such as \(\mathbf{x}^{\prime} \mathbf{A y} / \sqrt{\mathbf{x}^{\prime} \mathbf{A x}}\) are permissible (assuming \(\mathbf{A}\) is positive definite; see Section 2.7).

\subsection*{2.4 PARTITIONED MATRICES}

It is sometimes convenient to partition a matrix into submatrices. For example, a partitioning of a matrix \(\mathbf{A}\) into four submatrices could be indicated symbolically as follows:
\[
\mathbf{A}=\left(\begin{array}{ll}
\mathbf{A}_{11} & \mathbf{A}_{12} \\
\mathbf{A}_{21} & \mathbf{A}_{22}
\end{array}\right)
\]

For example, a \(4 \times 5\) matrix \(A\) could be partitioned as
\[
\mathbf{A}=\left(\begin{array}{rrr|rr}
2 & 1 & 3 & 8 & 4 \\
-3 & 4 & 0 & 2 & 7 \\
9 & 3 & 6 & 5 & -2 \\
\hline 4 & 8 & 3 & 1 & 6
\end{array}\right)=\left(\begin{array}{ll}
\mathbf{A}_{11} & \mathbf{A}_{12} \\
\mathbf{A}_{21} & \mathbf{A}_{22}
\end{array}\right)
\]
where
\[
\begin{array}{ll}
\mathbf{A}_{11}=\left(\begin{array}{rrr}
2 & 1 & 3 \\
-3 & 4 & 0 \\
9 & 3 & 6
\end{array}\right), & \mathbf{A}_{12}=\left(\begin{array}{rr}
8 & 4 \\
2 & 7 \\
5 & -2
\end{array}\right), \\
\mathbf{A}_{21}=\left(\begin{array}{lll}
4 & 8 & 3
\end{array}\right), & \mathbf{A}_{22}=\left(\begin{array}{ll}
1 & 6
\end{array}\right) .
\end{array}
\]

If two matrices \(\mathbf{A}\) and \(\mathbf{B}\) are conformable and \(\mathbf{A}\) and \(\mathbf{B}\) are partitioned so that the submatrices are appropriately conformable, then the product \(\mathbf{A B}\) can be found by following the usual row-by-column pattern of multiplication on the submatrices as if they were single elements; for example,
\[
\begin{align*}
\mathbf{A B} & =\left(\begin{array}{ll}
\mathbf{A}_{11} & \mathbf{A}_{12} \\
\mathbf{A}_{21} & \mathbf{A}_{22}
\end{array}\right)\left(\begin{array}{ll}
\mathbf{B}_{11} & \mathbf{B}_{12} \\
\mathbf{B}_{21} & \mathbf{B}_{22}
\end{array}\right) \\
& =\left(\begin{array}{ll}
\mathbf{A}_{11} \mathbf{B}_{11}+\mathbf{A}_{12} \mathbf{B}_{21} & \mathbf{A}_{11} \mathbf{B}_{12}+\mathbf{A}_{12} \mathbf{B}_{22} \\
\mathbf{A}_{21} \mathbf{B}_{11}+\mathbf{A}_{22} \mathbf{B}_{21} & \mathbf{A}_{21} \mathbf{B}_{12}+\mathbf{A}_{22} \mathbf{B}_{22}
\end{array}\right) . \tag{2.65}
\end{align*}
\]

It can be seen that this formulation is equivalent to the usual row-by-column definition of matrix multiplication. For example, the (1,1) element of \(\mathbf{A B}\) is the product of the first row of \(\mathbf{A}\) and the first column of \(\mathbf{B}\). In the (1,1) element of \(\mathbf{A}_{11} \mathbf{B}_{11}\) we have the sum of products of part of the first row of \(\mathbf{A}\) and part of the first column of \(\mathbf{B}\). In the (1, 1) element of \(\mathbf{A}_{12} \mathbf{B}_{21}\) we have the sum of products of the rest of the first row of \(\mathbf{A}\) and the remainder of the first column of \(\mathbf{B}\).

Multiplication of a matrix and a vector can also be carried out in partitioned form. For example,
\[
\begin{equation*}
\mathbf{A b}=\left(\mathbf{A}_{1}, \mathbf{A}_{2}\right)\binom{\mathbf{b}_{1}}{\mathbf{b}_{2}}=\mathbf{A}_{1} \mathbf{b}_{1}+\mathbf{A}_{2} \mathbf{b}_{2} \tag{2.66}
\end{equation*}
\]
where the partitioning of the columns of \(\mathbf{A}\) corresponds to the partitioning of the elements of \(\mathbf{b}\). Note that the partitioning of \(\mathbf{A}\) into two sets of columns is indicated by a comma, \(\mathbf{A}=\left(\mathbf{A}_{1}, \mathbf{A}_{2}\right)\).

The partitioned multiplication in (2.66) can be extended to individual columns of \(\mathbf{A}\) and individual elements of \(\mathbf{b}\) :
\[
\begin{align*}
\mathbf{A} \mathbf{b} & =\left(\mathbf{a}_{1}, \mathbf{a}_{2}, \ldots, \mathbf{a}_{p}\right)\left(\begin{array}{c}
b_{1} \\
b_{2} \\
\vdots \\
b_{p}
\end{array}\right) \\
& =b_{1} \mathbf{a}_{1}+b_{2} \mathbf{a}_{2}+\cdots+b_{p} \mathbf{a}_{p} . \tag{2.67}
\end{align*}
\]

Thus \(\mathbf{A b}\) is expressible as a linear combination of the columns of \(\mathbf{A}\), the coefficients being elements of \(\mathbf{b}\). For example, let
\[
\mathbf{A}=\left(\begin{array}{rrr}
3 & -2 & 1 \\
2 & 1 & 0 \\
4 & 3 & 2
\end{array}\right) \quad \text { and } \quad \mathbf{b}=\left(\begin{array}{c}
4 \\
2 \\
3
\end{array}\right)
\]

Then
\[
\mathbf{A b}=\left(\begin{array}{l}
\mathbf{1 1} \\
10 \\
28
\end{array}\right)
\]

Using a linear combination of columns of \(\mathbf{A}\) as in (2.67), we obtain
\[
\begin{aligned}
\mathbf{A} \mathbf{b} & =b_{1} \mathbf{a}_{1}+b_{2} \mathbf{a}_{2}+b_{3} \mathbf{a}_{3} \\
& =4\left(\begin{array}{r}
3 \\
2 \\
4
\end{array}\right)+2\left(\begin{array}{r}
-2 \\
1 \\
3
\end{array}\right)+3\left(\begin{array}{l}
1 \\
0 \\
2
\end{array}\right) \\
& =\left(\begin{array}{r}
12 \\
8 \\
16
\end{array}\right)+\left(\begin{array}{r}
-4 \\
2 \\
6
\end{array}\right)+\left(\begin{array}{l}
3 \\
0 \\
6
\end{array}\right)=\left(\begin{array}{l}
11 \\
10 \\
28
\end{array}\right) .
\end{aligned}
\]

We note that if \(\mathbf{A}\) is partitioned as in (2.66), \(\mathbf{A}=\left(\mathbf{A}_{2}, \mathbf{A}_{2}\right)\), the transpose is not equal to ( \(\mathbf{A}_{1}^{\prime}, \mathbf{A}_{2}^{\prime}\) ), but rather
\[
\begin{equation*}
\mathbf{A}^{\prime}=\left(\mathbf{A}_{1}, \mathbf{A}_{2}\right)^{\prime}=\binom{\mathbf{A}_{1}^{\prime}}{\mathbf{A}_{2}^{\prime}} . \tag{2.68}
\end{equation*}
\]

\subsection*{2.5 RANK}

Before defining the rank of a matrix, we first introduce the notion of linear independence and dependence. A set of vectors \(\mathbf{a}_{1}, \mathbf{a}_{2}, \ldots, \mathbf{a}_{n}\) is said to be linearly dependent if constants \(c_{1}, c_{2}, \ldots, c_{n}\) (not all zero) can be found such that
\[
\begin{equation*}
c_{1} \mathbf{a}_{1}+c_{2} \mathbf{a}_{2}+\cdots+c_{n} \mathbf{a}_{n}=\mathbf{0} . \tag{2.69}
\end{equation*}
\]

If no constants \(c_{1}, c_{2}, \ldots, c_{n}\) can be found satisfying (2.69), the set of vectors is said to be linearly independent.

If (2.69) holds, then at least one of the vectors \(\mathbf{a}_{i}\) can be expressed as a linear combination of the other vectors in the set. Thus linear dependence of a set of vectors implies redundancy in the set. Among linearly independent vectors there is no redundancy of this type.

The rank of any square or rectangular matrix \(\mathbf{A}\) is defined as
\[
\begin{aligned}
\operatorname{rank}(\mathbf{A}) & =\text { number of linearly independent rows of } \mathbf{A} \\
& =\text { number of linearly independent columns of } \mathbf{A} .
\end{aligned}
\]

It can be shown that the number of linearly independent rows of a matrix is always equal to the number of linearly independent columns.

If \(\mathbf{A}\) is \(n \times p\), the maximum possible rank of \(\mathbf{A}\) is the smaller of \(n\) and \(p\), in which case \(\mathbf{A}\) is said to be of full rank (sometimes said full row rank or full column rank). For example,
\[
\mathbf{A}=\left(\begin{array}{rrr}
1 & -2 & 3 \\
5 & 2 & 4
\end{array}\right)
\]
has rank 2 because the two rows are linearly independent (neither row is a multiple of the other). However, even though \(\mathbf{A}\) is full rank, the columns are linearly dependent because rank 2 implies there are only two linearly independent columns. Thus, by (2.69), there exist constants \(c_{1}, c_{2}\), and \(c_{3}\) such that
\[
\begin{equation*}
c_{1}\binom{1}{5}+c_{2}\binom{-2}{2}+c_{3}\binom{3}{4}=\binom{0}{0} . \tag{2.70}
\end{equation*}
\]

By (2.67), we can write (2.70) in the form
\[
\left(\begin{array}{rrr}
1 & -2 & 3 \\
5 & 2 & 4
\end{array}\right)\left(\begin{array}{l}
c_{1} \\
c_{2} \\
c_{3}
\end{array}\right)=\binom{0}{0}
\]
or
\[
\begin{equation*}
\mathbf{A c}=\mathbf{0} \tag{2.71}
\end{equation*}
\]

A solution vector to (2.70) or (2.71) is given by any multiple of \(\mathbf{c}=(14,-11,-12)^{\prime}\). Hence we have the interesting result that a product of a matrix \(\mathbf{A}\) and a vector \(\mathbf{c}\) is equal to \(\mathbf{0}\), even though \(\mathbf{A} \neq \mathbf{O}\) and \(\mathbf{c} \neq \mathbf{0}\). This is a direct consequence of the linear dependence of the column vectors of \(\mathbf{A}\).

Another consequence of the linear dependence of rows or columns of a matrix is the possibility of expressions such as \(\mathbf{A B}=\mathbf{C B}\), where \(\mathbf{A} \neq \mathbf{C}\). For example, let
\[
\mathbf{A}=\left(\begin{array}{rrr}
1 & 3 & 2 \\
2 & 0 & -1
\end{array}\right), \quad \mathbf{B}=\left(\begin{array}{rr}
1 & 2 \\
0 & 1 \\
1 & 0
\end{array}\right), \quad \mathbf{C}=\left(\begin{array}{rrr}
2 & 1 & 1 \\
5 & -6 & -4
\end{array}\right)
\]

Then
\[
\mathbf{A B}=\mathbf{C B}=\left(\begin{array}{ll}
3 & 5 \\
1 & 4
\end{array}\right)
\]

All three of the matrices \(\mathbf{A}, \mathbf{B}\), and \(\mathbf{C}\) are full rank; but being rectangular, they have a rank deficiency in either rows or columns, which permits us to construct \(\mathbf{A B}=\mathbf{C B}\) with \(\mathbf{A} \neq \mathbf{C}\). Thus in a matrix equation, we cannot, in general, cancel matrices from both sides of the equation.

There are two exceptions to this rule. One involves a nonsingular matrix to be defined in Section 2.6. The other special case occurs when the expression holds for all possible values of the matrix common to both sides of the equation. For example,
\[
\begin{equation*}
\text { If } \mathbf{A x}=\mathbf{B x} \text { for all possible values of } \mathbf{x}, \text { then } \mathbf{A}=\mathbf{B} \tag{2.72}
\end{equation*}
\]

To see this, let \(\mathbf{x}=(1,0, \ldots, 0)^{\prime}\). Then the first column of \(\mathbf{A}\) equals the first column of \(\mathbf{B}\). Now let \(\mathbf{x}=(0,1,0, \ldots, 0)^{\prime}\), and the second column of \(\mathbf{A}\) equals the second column of \(\mathbf{B}\). Continuing in this fashion, we obtain \(\mathbf{A}=\mathbf{B}\).

Suppose a rectangular matrix \(\mathbf{A}\) is \(n \times p\) of rank \(p\), where \(p<n\). We typically shorten this statement to " \(\mathbf{A}\) is \(n \times p\) of \(\operatorname{rank} p<n\)."

\subsection*{2.6 INVERSE}

If a matrix \(\mathbf{A}\) is square and of full rank, then \(\mathbf{A}\) is said to be nonsingular, and \(\mathbf{A}\) has a unique inverse, denoted by \(\mathbf{A}^{-1}\), with the property that
\[
\begin{equation*}
\mathbf{A} \mathbf{A}^{-1}=\mathbf{A}^{-1} \mathbf{A}=\mathbf{I} \tag{2.73}
\end{equation*}
\]

For example, let
\[
\mathbf{A}=\left(\begin{array}{ll}
3 & 4 \\
2 & 6
\end{array}\right)
\]

Then
\[
\begin{gathered}
\mathbf{A}^{-1}=\left(\begin{array}{rr}
.6 & -.4 \\
-.2 & .3
\end{array}\right) \\
\mathbf{A A}^{-1}=\left(\begin{array}{ll}
3 & 4 \\
2 & 6
\end{array}\right)\left(\begin{array}{rr}
.6 & -.4 \\
-.2 & .3
\end{array}\right)=\left(\begin{array}{ll}
1 & 0 \\
0 & 1
\end{array}\right)
\end{gathered}
\]

If \(\mathbf{A}\) is square and of less than full rank, then an inverse does not exist, and \(\mathbf{A}\) is said to be singular. Note that rectangular matrices do not have inverses as in (2.73), even if they are full rank.

If \(\mathbf{A}\) and \(\mathbf{B}\) are the same size and nonsingular, then the inverse of their product is the product of their inverses in reverse order,
\[
\begin{equation*}
(\mathbf{A B})^{-1}=\mathbf{B}^{-1} \mathbf{A}^{-1} \tag{2.74}
\end{equation*}
\]

Note that (2.74) holds only for nonsingular matrices. Thus, for example, if \(\mathbf{A}\) is \(n \times p\) of rank \(p<n\), then \(\mathbf{A}^{\prime} \mathbf{A}\) has an inverse, but \(\left(\mathbf{A}^{\prime} \mathbf{A}\right)^{-1}\) is not equal to \(\mathbf{A}^{-1}\left(\mathbf{A}^{\prime}\right)^{-1}\) because \(\mathbf{A}\) is rectangular and does not have an inverse.

If a matrix is nonsingular, it can be canceled from both sides of an equation, provided it appears on the left (right) on both sides. For example, if \(\mathbf{B}\) is nonsingular, then
\[
\mathbf{A B}=\mathbf{C B} \quad \text { implies } \quad \mathbf{A}=\mathbf{C}
\]
since we can multiply on the right by \(\mathbf{B}^{-1}\) to obtain
\[
\begin{aligned}
\mathbf{A B B}^{-1} & =\mathbf{C B B}^{-1} \\
\mathbf{A I} & =\mathbf{C I} \\
\mathbf{A} & =\mathbf{C}
\end{aligned}
\]

Otherwise, if \(\mathbf{A}, \mathbf{B}\), and \(\mathbf{C}\) are rectangular or square and singular, it is easy to construct \(\mathbf{A B}=\mathbf{C B}\), with \(\mathbf{A} \neq \mathbf{C}\), as illustrated near the end of Section 2.5.

The inverse of the transpose of a nonsingular matrix is given by the transpose of the inverse:
\[
\begin{equation*}
\left(\mathbf{A}^{\prime}\right)^{-1}=\left(\mathbf{A}^{-1}\right)^{\prime} \tag{2.75}
\end{equation*}
\]

If the symmetric nonsingular matrix \(\mathbf{A}\) is partitioned in the form
\[
\mathbf{A}=\left(\begin{array}{ll}
\mathbf{A}_{11} & \mathbf{a}_{12} \\
\mathbf{a}_{12}^{\prime} & a_{22}
\end{array}\right)
\]
then the inverse is given by
\[
\mathbf{A}^{-1}=\frac{1}{b}\left(\begin{array}{cc}
b \mathbf{A}_{11}^{-1}+\mathbf{A}_{11}^{-1} \mathbf{a}_{12} \mathbf{a}_{12}^{\prime} \mathbf{A}_{11}^{-1} & -\mathbf{A}_{11}^{-1} \mathbf{a}_{12}  \tag{2.76}\\
-\mathbf{a}_{12}^{\prime} \mathbf{A}_{11}^{-1} & 1
\end{array}\right)
\]
where \(b=a_{22}-\mathbf{a}_{12}^{\prime} \mathbf{A}_{11}^{-1} \mathbf{a}_{12}\). A nonsingular matrix of the form \(\mathbf{B}+\mathbf{c c}^{\prime}\), where \(\mathbf{B}\) is nonsingular, has as its inverse
\[
\begin{equation*}
\left(\mathbf{B}+\mathbf{c c}^{\prime}\right)^{-1}=\mathbf{B}^{-1}-\frac{\mathbf{B}^{-\mathbf{1}} \mathbf{c c}^{\prime} \mathbf{B}^{-1}}{\mathbf{1}+\mathbf{c}^{\prime} \mathbf{B}^{-1} \mathbf{c}} \tag{2.77}
\end{equation*}
\]

\subsection*{2.7 POSITIVE DEFINITE MATRICES}

The symmetric matrix \(\mathbf{A}\) is said to be positive definite if \(\mathbf{x}^{\prime} \mathbf{A x}>0\) for all possible vectors \(\mathbf{x}\) (except \(\mathbf{x}=0\) ). Similarly, \(\mathbf{A}\) is positive semidefinite if \(\mathbf{x}^{\prime} \mathbf{A x} \geq 0\) for all \(\mathbf{x} \neq \mathbf{0}\). [A quadratic form \(\mathbf{x}^{\prime} \mathbf{A} \mathbf{x}\) was defined in (2.63).]

The diagonal elements \(a_{i i}\) of a positive definite matrix are positive. To see this, let \(\mathbf{x}^{\prime}=(0, \ldots, 0,1,0, \ldots, 0)\) with a 1 in the \(i\) th position. Then \(\mathbf{x}^{\prime} \mathbf{A x}=a_{i i}>0\). Similarly, for a positive semidefinite matrix \(\mathbf{A}, a_{i i} \geq 0\) for all \(i\).

One way to obtain a positive definite matrix is as follows:
If \(\mathbf{A}=\mathbf{B}^{\prime} \mathbf{B}\), where \(\mathbf{B}\) is \(n \times p\) of \(\operatorname{rank} p<n\), then \(\mathbf{B}^{\prime} \mathbf{B}\) is positive definite.
This is easily shown:
\[
\mathbf{x}^{\prime} \mathbf{A} \mathbf{x}=\mathbf{x}^{\prime} \mathbf{B}^{\prime} \mathbf{B} \mathbf{x}=(\mathbf{B} \mathbf{x})^{\prime}(\mathbf{B} \mathbf{x})=\mathbf{z}^{\prime} \mathbf{z}
\]
where \(\mathbf{z}=\mathbf{B x}\). Thus, \(\mathbf{x}^{\prime} \mathbf{A x}=\sum_{i=1}^{n} z_{i}^{2}\), which is positive ( \(\mathbf{B x}\) cannot be \(\mathbf{0}\) unless \(\mathbf{x}=\mathbf{0}\), because \(\mathbf{B}\) is full rank). If \(\mathbf{B}\) is less than full rank, then by a similar argument, \(\mathbf{B}^{\prime} \mathbf{B}\) is positive semidefinite.

Note that \(\mathbf{A}=\mathbf{B}^{\prime} \mathbf{B}\) is analogous to \(a=b^{2}\) in real numbers, where the square of any number (including negative numbers) is positive.

In another analogy to positive real numbers, a positive definite matrix can be factored into a "square root" in two ways. We give one method below in (2.79) and the other in Section 2.11.8.

A positive definite matrix \(\mathbf{A}\) can be factored into
\[
\begin{equation*}
\mathbf{A}=\mathbf{T}^{\prime} \mathbf{T} \tag{2.79}
\end{equation*}
\]
where \(\mathbf{T}\) is a nonsingular upper triangular matrix. One way to obtain \(\mathbf{T}\) is the Cholesky decomposition, which can be carried out in the following steps.

Let \(\mathbf{A}=\left(a_{i j}\right)\) and \(\mathbf{T}=\left(t_{i j}\right)\) be \(n \times n\). Then the elements of \(\mathbf{T}\) are found as follows:
\[
\begin{aligned}
t_{11} & =\sqrt{a_{11}}, t_{1 j}=\frac{a_{1 j}}{t_{11}} & & 2 \leq j \leq n \\
t_{i i} & =\sqrt{a_{i i}-\sum_{k=1}^{i-1} t_{k i}^{2}} & & 2 \leq i \leq n \\
t_{i j} & =\frac{a_{i j}-\sum_{k=1}^{i-1} t_{k i} t_{k j}}{t_{i i}} & & 2 \leq i<j \leq n \\
t_{i j} & =0 & & 1 \leq j<i \leq n
\end{aligned}
\]

For example, let
\[
\mathbf{A}=\left(\begin{array}{rrr}
3 & 0 & -3 \\
0 & 6 & 3 \\
-3 & 3 & 6
\end{array}\right)
\]

Then by the Cholesky method, we obtain
\[
\begin{aligned}
& \mathbf{T}=\left(\begin{array}{ccc}
\sqrt{3} & 0 & -\sqrt{3} \\
0 & \sqrt{6} & \sqrt{1.5} \\
0 & 0 & \sqrt{1.5}
\end{array}\right) \\
& \mathbf{T}^{\prime} \mathbf{T}=\left(\begin{array}{ccc}
\sqrt{3} & 0 & 0 \\
0 & \sqrt{6} & 0 \\
-\sqrt{3} & \sqrt{1.5} & \sqrt{1.5}
\end{array}\right)\left(\begin{array}{ccc}
\sqrt{3} & 0 & -\sqrt{3} \\
0 & \sqrt{6} & \sqrt{1.5} \\
0 & 0 & \sqrt{1.5}
\end{array}\right) \\
&=\left(\begin{array}{ccc}
3 & 0 & -3 \\
0 & 6 & 3 \\
-3 & 3 & 6
\end{array}\right)=\mathbf{A} .
\end{aligned}
\]

\subsection*{2.8 DETERMINANTS}

The determinant of an \(n \times n\) matrix \(\mathbf{A}\) is defined as the sum of all \(n\) ! possible products of \(n\) elements such that
1. Each product contains one element from every row and every column, and
2. The factors in each product are written so that the column subscripts appear in order of magnitude and each product is then preceded by a plus or minus sign according to whether the number of inversions in the row subscripts is even or odd.

An inversion occurs whenever a larger number precedes a smaller one. The symbol \(n!\) is defined as
\[
\begin{equation*}
n!=n(n-1)(n-2) \cdots 2 \cdot 1 \tag{2.80}
\end{equation*}
\]

The determinant of \(\mathbf{A}\) is a scalar denoted by \(|\mathbf{A}|\) or by \(\operatorname{det}(\mathbf{A})\). The preceding definition is not useful in evaluating determinants, except in the case of \(2 \times 2\) or \(3 \times 3\) matrices. For larger matrices, other methods are available for manual computation, but determinants are typically evaluated by computer. For a \(2 \times 2\) matrix, the determinant is found by
\[
|\mathbf{A}|=\left|\begin{array}{ll}
a_{11} & a_{12}  \tag{2.81}\\
a_{21} & a_{22}
\end{array}\right|=a_{11} a_{22}-a_{21} a_{12}
\]

For a \(3 \times 3\) matrix, the determinant is given by
\[
\begin{align*}
|\mathbf{A}|= & a_{11} a_{22} a_{33}+a_{12} a_{23} a_{31}+a_{13} a_{32} a_{21} \\
& -a_{31} a_{22} a_{13}-a_{32} a_{23} a_{11}-a_{33} a_{12} a_{21} \tag{2.82}
\end{align*}
\]

This can be found by the following scheme. The three positive terms are obtained by
\[
\left.\left(\begin{array}{c:c}
a_{11} & a_{12} \\
a_{21} & a_{13} \\
a_{31} & a_{23} \\
a_{32} & a_{33}
\end{array}\right)\right)
\]
and the three negative terms by
\[
\left(\begin{array}{c}
a_{11}, a_{12} \rightarrow \\
a_{21} \\
a_{31}, \\
a_{22}
\end{array}\right)
\]

The determinant of a diagonal matrix is the product of the diagonal elements; that is, if \(\mathbf{D}=\operatorname{diag}\left(d_{1}, d_{2}, \ldots, d_{n}\right)\), then
\[
\begin{equation*}
|\mathbf{D}|=\prod_{i=1}^{n} d_{i} \tag{2.83}
\end{equation*}
\]

As a special case of (2.83), suppose all diagonal elements are equal, say,
\[
\mathbf{D}=\operatorname{diag}(c, c, \ldots, c)=c \mathbf{I}
\]

Then
\[
\begin{equation*}
|\mathbf{D}|=|c \mathbf{I}|=\prod_{i=1}^{n} c=c^{n} \tag{2.84}
\end{equation*}
\]

The extension of (2.84) to any square matrix \(\mathbf{A}\) is
\[
\begin{equation*}
|c \mathbf{A}|=c^{n}|\mathbf{A}| \tag{2.85}
\end{equation*}
\]

Because the determinant is a scalar, we can carry out operations such as
\[
|\mathbf{A}|^{2}, \quad|\mathbf{A}|^{1 / 2}, \quad \frac{1}{|\mathbf{A}|},
\]
provided that \(|\mathbf{A}|>0\) for \(|\mathbf{A}|^{1 / 2}\) and that \(|\mathbf{A}| \neq 0\) for \(1 /|\mathbf{A}|\).
If the square matrix \(\mathbf{A}\) is singular, its determinant is 0 :
\[
\begin{equation*}
|\mathbf{A}|=0 \text { if } \mathbf{A} \text { is singular. } \tag{2.86}
\end{equation*}
\]

If \(\mathbf{A}\) is near singular, then there exists a linear combination of the columns that is close to \(\mathbf{0}\), and \(|\mathbf{A}|\) is also close to 0 . If \(\mathbf{A}\) is nonsingular, its determinant is nonzero:
\[
\begin{equation*}
|\mathbf{A}| \neq 0 \text { if } \mathbf{A} \text { is nonsingular. } \tag{2.87}
\end{equation*}
\]

If \(\mathbf{A}\) is positive definite, its determinant is positive:
\[
\begin{equation*}
|\mathbf{A}|>0 \text { if } \mathbf{A} \text { is positive definite. } \tag{2.88}
\end{equation*}
\]

If \(\mathbf{A}\) and \(\mathbf{B}\) are square and the same size, the determinant of the product is the product of the determinants:
\[
\begin{equation*}
|\mathbf{A B}|=|\mathbf{A}||\mathbf{B}| . \tag{2.89}
\end{equation*}
\]

For example, let
\[
\mathbf{A}=\left(\begin{array}{rr}
1 & 2 \\
-3 & 5
\end{array}\right) \quad \text { and } \quad \mathbf{B}=\left(\begin{array}{cc}
4 & 2 \\
1 & 3
\end{array}\right)
\]

Then
\[
\begin{aligned}
& \mathbf{A B}=\left(\begin{array}{rr}
6 & 8 \\
-7 & 9
\end{array}\right), \quad|\mathbf{A B}|=110 \\
& |\mathbf{A}|=11, \quad|\mathbf{B}|=10, \quad|\mathbf{A}||\mathbf{B}|=110
\end{aligned}
\]

The determinant of the transpose of a matrix is the same as the determinant of the matrix, and the determinant of the the inverse of a matrix is the reciprocal of the determinant:
\[
\begin{gather*}
\left|\mathbf{A}^{\prime}\right|=|\mathbf{A}|  \tag{2.90}\\
\left|\mathbf{A}^{-1}\right|=\frac{1}{|\mathbf{A}|}=|\mathbf{A}|^{-1} \tag{2.91}
\end{gather*}
\]

If a partitioned matrix has the form
\[
\mathbf{A}=\left(\begin{array}{cc}
\mathbf{A}_{11} & \mathbf{O} \\
\mathbf{O} & \mathbf{A}_{22}
\end{array}\right)
\]
where \(\mathbf{A}_{11}\) and \(\mathbf{A}_{22}\) are square, but not necessarily the same size, then
\[
|\mathbf{A}|=\left|\begin{array}{cc}
\mathbf{A}_{11} & \mathbf{O}  \tag{2.92}\\
\mathbf{O} & \mathbf{A}_{22}
\end{array}\right|=\left|\mathbf{A}_{11}\right|\left|\mathbf{A}_{22}\right| .
\]

For a general partitioned matrix,
\[
\mathbf{A}=\left(\begin{array}{ll}
\mathbf{A}_{11} & \mathbf{A}_{12} \\
\mathbf{A}_{21} & \mathbf{A}_{22}
\end{array}\right)
\]
where \(\mathbf{A}_{11}\) and \(\mathbf{A}_{22}\) are square and nonsingular (not necessarily the same size), the determinant is given by either of the following two expressions:
\[
\begin{align*}
\left|\begin{array}{ll}
\mathbf{A}_{11} & \mathbf{A}_{12} \\
\mathbf{A}_{21} & \mathbf{A}_{22}
\end{array}\right| & =\left|\mathbf{A}_{11}\right|\left|\mathbf{A}_{22}-\mathbf{A}_{21} \mathbf{A}_{11}^{-1} \mathbf{A}_{12}\right|  \tag{2.93}\\
& =\left|\mathbf{A}_{22}\right|\left|\mathbf{A}_{11}-\mathbf{A}_{12} \mathbf{A}_{22}^{-1} \mathbf{A}_{21}\right| \tag{2.94}
\end{align*}
\]

Note the analogy of (2.93) and (2.94) to the case of the determinant of a \(2 \times 2\) matrix as given by (2.81):
\[
\begin{aligned}
\left|\begin{array}{ll}
a_{11} & a_{12} \\
a_{21} & a_{22}
\end{array}\right| & =a_{11} a_{22}-a_{21} a_{12} \\
& =a_{11}\left(a_{22}-\frac{a_{21} a_{12}}{a_{11}}\right) \\
& =a_{22}\left(a_{11}-\frac{a_{12} a_{21}}{a_{22}}\right) .
\end{aligned}
\]

If \(\mathbf{B}\) is nonsingular and \(\mathbf{c}\) is a vector, then
\[
\begin{equation*}
\left|\mathbf{B}+\mathbf{c c}^{\prime}\right|=|\mathbf{B}|\left(1+\mathbf{c}^{\prime} \mathbf{B}^{-1} \mathbf{c}\right) . \tag{2.95}
\end{equation*}
\]

\subsection*{2.9 TRACE}

A simple function of an \(n \times n\) matrix \(\mathbf{A}\) is the trace, denoted by \(\operatorname{tr}(\mathbf{A})\) and defined as the sum of the diagonal elements of \(\mathbf{A}\); that is, \(\operatorname{tr}(\mathbf{A})=\sum_{i=1}^{n} a_{i i}\). The trace is, of course, a scalar. For example, suppose
\[
\mathbf{A}=\left(\begin{array}{rrr}
5 & 4 & 4 \\
2 & -3 & 1 \\
3 & 7 & 9
\end{array}\right) .
\]

Then
\[
\operatorname{tr}(\mathbf{A})=5+(-3)+9=11
\]

The trace of the sum of two square matrices is the sum of the traces of the two matrices:
\[
\begin{equation*}
\operatorname{tr}(\mathbf{A}+\mathbf{B})=\operatorname{tr}(\mathbf{A})+\operatorname{tr}(\mathbf{B}) . \tag{2.96}
\end{equation*}
\]

An important result for the product of two matrices is
\[
\begin{equation*}
\operatorname{tr}(\mathbf{A B})=\operatorname{tr}(\mathbf{B A}) \tag{2.97}
\end{equation*}
\]

This result holds for any matrices \(\mathbf{A}\) and \(\mathbf{B}\) where \(\mathbf{A B}\) and \(\mathbf{B A}\) are both defined. It is not necessary that \(\mathbf{A}\) and \(\mathbf{B}\) be square or that \(\mathbf{A B}\) equal \(\mathbf{B A}\). For example, let
\[
\mathbf{A}=\left(\begin{array}{rr}
1 & 3 \\
2 & -1 \\
4 & 6
\end{array}\right), \quad \mathbf{B}=\left(\begin{array}{rrr}
3 & -2 & 1 \\
2 & 4 & 5
\end{array}\right)
\]

Then
\[
\begin{array}{rlrl}
\mathbf{A B} & =\left(\begin{array}{rrr}
9 & 10 & 16 \\
4 & -8 & -3 \\
24 & 16 & 34
\end{array}\right), & \mathbf{B A} & =\left(\begin{array}{rr}
3 & 17 \\
30 & 32
\end{array}\right), \\
\operatorname{tr}(\mathbf{A B}) & =9-8+34=35, & \operatorname{tr}(\mathbf{B A})=3+32=35 .
\end{array}
\]

From (2.52) and (2.54), we obtain
\[
\begin{equation*}
\operatorname{tr}\left(\mathbf{A}^{\prime} \mathbf{A}\right)=\operatorname{tr}\left(\mathbf{A} \mathbf{A}^{\prime}\right)=\sum_{i=1}^{n} \sum_{j=1}^{p} a_{i j}^{2}, \tag{2.98}
\end{equation*}
\]
where the \(a_{i j}\) 's are elements of the \(n \times p\) matrix \(\mathbf{A}\).

\subsection*{2.10 ORTHOGONAL VECTORS AND MATRICES}

Two vectors \(a\) and \(b\) of the same size are said to be orthogonal if
\[
\begin{equation*}
\mathbf{a}^{\prime} \mathbf{b}=a_{1} b_{1}+a_{2} b_{2}+\cdots+a_{n} b_{n}=0 \tag{2.99}
\end{equation*}
\]

Geometrically, orthogonal vectors are perpendicular [see (3.14) and the comments following (3.14)]. If \(\mathbf{a}^{\prime} \mathbf{a}=1\), the vector \(\mathbf{a}\) is said to be normalized. The vector a can always be normalized by dividing by its length, \(\sqrt{\mathbf{a}^{\prime} \mathbf{a}}\). Thus
\[
\begin{equation*}
\mathbf{c}=\frac{\mathbf{a}}{\sqrt{\mathbf{a}^{\prime} \mathbf{a}}} \tag{2.100}
\end{equation*}
\]
is normalized so that \(\mathbf{c}^{\prime} \mathbf{c}=1\).
A matrix \(\mathbf{C}=\left(\mathbf{c}_{1}, \mathbf{c}_{2}, \ldots, \mathbf{c}_{p}\right)\) whose columns are normalized and mutually orthogonal is called an orthogonal matrix. Since the elements of \(\mathbf{C}^{\prime} \mathbf{C}\) are products of columns of \(\mathbf{C}\left[\right.\) see (2.54)], which have the properties \(\mathbf{c}_{i}^{\prime} \mathbf{c}_{i}=1\) for all \(i\) and \(\mathbf{c}_{i}^{\prime} \mathbf{c}_{j}=0\) for all \(i \neq j\), we have
\[
\begin{equation*}
\mathbf{C}^{\prime} \mathbf{C}=\mathbf{I} \tag{2.101}
\end{equation*}
\]

If \(\mathbf{C}\) satisfies (2.101), it necessarily follows that
\[
\begin{equation*}
\mathbf{C C}^{\prime}=\mathbf{I} \tag{2.102}
\end{equation*}
\]
from which we see that the rows of \(\mathbf{C}\) are also normalized and mutually orthogonal. It is clear from (2.101) and (2.102) that \(\mathbf{C}^{-1}=\mathbf{C}^{\prime}\) for an orthogonal matrix \(\mathbf{C}\).

We illustrate the creation of an orthogonal matrix by starting with
\[
\mathbf{A}=\left(\begin{array}{rrr}
1 & 1 & 1 \\
1 & 1 & -1 \\
1 & -2 & 0
\end{array}\right)
\]
whose columns are mutually orthogonal. To normalize the three columns, we divide by the respective lengths, \(\sqrt{3}, \sqrt{6}\), and \(\sqrt{2}\), to obtain
\[
\mathbf{C}=\left(\begin{array}{rrc}
1 / \sqrt{3} & 1 / \sqrt{6} & 1 / \sqrt{2} \\
1 / \sqrt{3} & 1 / \sqrt{6} & -1 / \sqrt{2} \\
1 / \sqrt{3} & -2 / \sqrt{6} & 0
\end{array}\right)
\]

Note that the rows also became normalized and mutually orthogonal so that \(\mathbf{C}\) satisfies both (2.101) and (2.102).

Multiplication by an orthogonal matrix has the effect of rotating axes; that is, if a point \(x\) is transformed to \(z=\mathbf{C x}\), where \(\mathbf{C}\) is orthogonal, then
\[
\begin{equation*}
\mathbf{z}^{\prime} \mathbf{z}=(\mathbf{C x})^{\prime}(\mathbf{C} \mathbf{x})=\mathbf{x}^{\prime} \mathbf{C}^{\prime} \mathbf{C} \mathbf{x}=\mathbf{x}^{\prime} \mathbf{I} \mathbf{x}=\mathbf{x}^{\prime} \mathbf{x} \tag{2.103}
\end{equation*}
\]
and the distance from the origin to z is the same as the distance to \(\mathbf{x}\).

\subsection*{2.11 EIGENVALUES AND EIGENVECTORS}

\subsection*{2.11.1 Definition}

For every square matrix \(\mathbf{A}\), a scalar \(\lambda\) and a nonzero vector \(\mathbf{x}\) can be found such that
\[
\begin{equation*}
\mathbf{A} \mathbf{x}=\lambda \mathbf{x} \tag{2.104}
\end{equation*}
\]

In (2.104), \(\lambda\) is called an eigenvalue of \(\mathbf{A}\) and \(\mathbf{x}\) is an eigenvector. To find \(\lambda\) and \(\mathbf{x}\), we write (2.104) as
\[
\begin{equation*}
(\mathbf{A}-\lambda \mathbf{I}) \mathbf{x}=\mathbf{0} \tag{2.105}
\end{equation*}
\]

If \(|\mathbf{A}-\lambda \mathbf{I}| \neq 0\), then \((\mathbf{A}-\lambda \mathbf{I})\) has an inverse and \(\mathbf{x}=\mathbf{0}\) is the only solution. Hence, in order to obtain nontrivial solutions, we set \(|\mathbf{A}-\lambda \mathbf{I}|=0\) to find values of \(\lambda\) that can be substituted into (2.105) to find corresponding values of \(\mathbf{x}\). Alternatively, (2.69) and (2.71) require that the columns of \(\mathbf{A}-\lambda \mathbf{I}\) be linearly dependent. Thus in \((\mathbf{A}-\lambda \mathbf{I}) \mathbf{x}=\mathbf{0}\), the matrix \(\mathbf{A}-\lambda \mathbf{I}\) must be singular in order to find a solution vector \(x\) that is not 0 .

The equation \(|\mathbf{A}-\lambda \mathbf{I}|=0\) is called the characteristic equation. If \(\mathbf{A}\) is \(n \times\) \(n\), the characteristic equation will have \(n\) roots; that is, \(\mathbf{A}\) will have \(n\) eigenvalues \(\lambda_{1}, \lambda_{2}, \ldots, \lambda_{n}\). The \(\lambda\) 's will not necessarily all be distinct or all nonzero. However, if A arises from computations on real (continuous) data and is nonsingular, the \(\lambda\) 's will all be distinct (with probability 1 ). After finding \(\lambda_{1}, \lambda_{2}, \ldots, \lambda_{n}\), the accompanying eigenvectors \(\mathrm{x}_{1}, \mathrm{x}_{2}, \ldots, \mathrm{x}_{n}\) can be found using (2.105).

If we multiply both sides of (2.105) by a scalar \(k\) and note by (2.62) that \(k\) and A - \(\lambda \mathbf{I}\) commute, we obtain
\[
\begin{equation*}
(\mathbf{A}-\lambda \mathbf{I}) k \mathbf{x}=k \mathbf{0}=\mathbf{0} \tag{2.106}
\end{equation*}
\]

Thus if \(\mathbf{x}\) is an eigenvector of \(\mathbf{A}, k \mathbf{x}\) is also an eigenvector, and eigenvectors are unique only up to multiplication by a scalar. Hence we can adjust the length of \(\mathbf{x}\), but the direction from the origin is unique; that is, the relative values of (ratios of) the components of \(\mathbf{x}=\left(x_{1}, x_{2}, \ldots, x_{n}\right)^{\prime}\) are unique. Typically, the eigenvector \(\mathbf{x}\) is scaled so that \(\mathbf{x}^{\prime} \mathbf{x}=1\).

To illustrate, we will find the eigenvalues and eigenvectors for the matrix
\[
\mathbf{A}=\left(\begin{array}{rr}
1 & 2 \\
-1 & 4
\end{array}\right)
\]

The characteristic equation is
\[
\begin{gathered}
|\mathbf{A}-\lambda \mathbf{I}|=\left|\begin{array}{cc}
1-\lambda & 2 \\
-1 & 4-\lambda
\end{array}\right|=(1-\lambda)(4-\lambda)+2=0 \\
\lambda^{2}-5 \lambda+6=(\lambda-3)(\lambda-2)=0
\end{gathered}
\]
from which \(\lambda_{1}=3\) and \(\lambda_{2}=2\). To find the eigenvector corresponding to \(\lambda_{1}=3\), we use (2.105),
\[
\begin{aligned}
(\mathbf{A}-\lambda \mathbf{I}) \mathbf{x} & =\mathbf{0} \\
\left(\begin{array}{cc}
1-3 & 2 \\
-1 & 4-3
\end{array}\right)\binom{x_{1}}{x_{2}} & =\binom{0}{0}, \\
-2 x_{1}+2 x_{2} & =0 \\
-x_{1}+x_{2} & =0
\end{aligned}
\]

As expected, either equation is redundant in the presence of the other, and there remains a single equation with two unknowns, \(x_{1}=x_{2}\). The solution vector can be written with an arbitrary constant,
\[
\binom{x_{1}}{x_{2}}=x_{1}\binom{1}{1}=c\binom{1}{1} .
\]

If \(c\) is set equal to \(1 / \sqrt{2}\) to normalize the eigenvector, we obtain
\[
\mathbf{x}_{1}=\binom{1 / \sqrt{2}}{1 / \sqrt{2}}
\]

Similarly, corresponding to \(\lambda_{2}=2\), we have
\[
\mathbf{x}_{2}=\binom{2 / \sqrt{5}}{1 / \sqrt{5}} .
\]

\subsection*{2.11.2 \(I+A\) and \(I-A\)}

If \(\lambda\) is an eigenvalue of \(\mathbf{A}\) and \(\mathbf{x}\) is the corresponding eigenvector, then \(1+\lambda\) is an eigenvalue of \(\mathbf{I}+\mathbf{A}\) and \(1-\lambda\) is an eigenvalue of \(\mathbf{I}-\mathbf{A}\). In either case, \(\mathbf{x}\) is the corresponding eigenvector.

We demonstrate this for \(\mathbf{I}+\mathbf{A}\) :
\[
\begin{aligned}
\mathbf{A} \mathbf{x} & =\lambda \mathbf{x} \\
\mathbf{x}+\mathbf{A} \mathbf{x} & =\mathbf{x}+\lambda \mathbf{x} \\
(\mathbf{I}+\mathbf{A}) \mathbf{x} & =(\mathbf{1}+\lambda) \mathbf{x} .
\end{aligned}
\]

\subsection*{2.11.3 \(\operatorname{tr}(A)\) and \(|A|\)}

For any square matrix \(\mathbf{A}\) with eigenvalues \(\lambda_{1}, \lambda_{2}, \ldots, \lambda_{n}\), we have
\[
\begin{align*}
\operatorname{tr}(\mathbf{A}) & =\sum_{i=1}^{n} \lambda_{i},  \tag{2.107}\\
|\mathbf{A}| & =\prod_{i=1}^{n} \lambda_{i} . \tag{2.108}
\end{align*}
\]

Note that by the definition in Section 2.9, \(\operatorname{tr}(\mathbf{A})\) is also equal to \(\sum_{i=1}^{n} a_{i i}\), but \(a_{i i} \neq\) \(\lambda_{i}\).

We illustrate (2.107) and (2.108) using the matrix
\[
\mathbf{A}=\left(\begin{array}{rr}
1 & 2 \\
-1 & 4
\end{array}\right)
\]
from the illustration in Section 2.11.1, for which \(\lambda_{1}=3\) and \(\lambda_{2}=2\). Using (2.107), we obtain
\[
\operatorname{tr}(\mathbf{A})=\lambda_{1}+\lambda_{2}=3+2=5
\]
and from (2.108), we have
\[
|\mathbf{A}|=\lambda_{1} \lambda_{2}=3(2)=6
\]

By definition, we obtain
\[
\operatorname{tr}(\mathbf{A})=1+4=5 \quad \text { and } \quad|\mathbf{A}|=(1)(4)-(-1)(2)=6
\]

\subsection*{2.11.4 Positive Definite and Semidefinite Matrices}

The eigenvalues and eigenvectors of positive definite and positive semidefinite matrices have the following properties:
1. The eigenvalues of a positive definite matrix are all positive.
2. The eigenvalues of a positive semidefinite matrix are positive or zero, with the number of positive eigenvalues equal to the rank of the matrix.

It is customary to list the eigenvalues of a positive definite matrix in descending order: \(\lambda_{1}>\lambda_{2}>\cdots>\lambda_{p}\). The eigenvectors \(\mathbf{x}_{1}, \mathbf{x}_{2}, \ldots, \mathbf{x}_{n}\) are listed in the same order; \(\mathbf{x}_{1}\) corresponds to \(\lambda_{1}, \mathbf{x}_{2}\) corresponds to \(\lambda_{2}\), and so on.

The following result, known as the Perron-Frobenius theorem, is of interest in Chapter 12: If all elements of the positive definite matrix A are positive, then all elements of the first eigenvector are positive. (The first eigenvector is the one associated with the first eigenvalue, \(\lambda_{1}\).)

\subsection*{2.11.5 The Product AB}

If \(\mathbf{A}\) and \(\mathbf{B}\) are square and the same size, the eigenvalues of \(\mathbf{A B}\) are the same as those of \(\mathbf{B A}\), although the eigenvectors are usually different. This result also holds if \(\mathbf{A B}\) and \(\mathbf{B A}\) are both square but of different sizes, as when \(\mathbf{A}\) is \(n \times p\) and \(\mathbf{B}\) is \(p \times n\). (In this case, the nonzero eigenvalues of \(\mathbf{A B}\) and \(\mathbf{B A}\) will be the same.)

\subsection*{2.11.6 Symmetric Matrix}

The eigenvectors of an \(n \times n\) symmetric matrix \(\mathbf{A}\) are mutually orthogonal. It follows that if the \(n\) eigenvectors of \(\mathbf{A}\) are normalized and inserted as columns of a matrix \(\mathbf{C}=\left(\mathbf{x}_{1}, \mathbf{x}_{2}, \ldots, \mathbf{x}_{n}\right)\), then \(\mathbf{C}\) is orthogonal.

\subsection*{2.11.7 Spectral Decomposition}

It was noted in Section 2.11 .6 that if the matrix \(\mathbf{C}=\left(\mathbf{x}_{1}, \mathbf{x}_{2}, \ldots, \mathbf{x}_{n}\right)\) contains the normalized eigenvectors of an \(n \times n\) symmetric matrix \(\mathbf{A}\), then \(\mathbf{C}\) is orthogonal. Therefore, by (2.102), \(\mathbf{I}=\mathbf{C} \mathbf{C}^{\prime}\), which we can multiply by \(\mathbf{A}\) to obtain
\[
\mathbf{A}=\mathbf{A C C} \mathbf{C}^{\prime}
\]

We now substitute \(\mathbf{C}=\left(\mathbf{x}_{1}, \mathbf{x}_{2}, \ldots, \mathbf{x}_{n}\right)\) :
\[
\begin{align*}
\mathbf{A} & =\mathbf{A}\left(\mathbf{x}_{1}, \mathbf{x}_{2}, \ldots, \mathbf{x}_{n}\right) \mathbf{C}^{\prime} & & \\
& =\left(\mathbf{A} \mathbf{x}_{1}, \mathbf{A} \mathbf{x}_{2}, \ldots, \mathbf{A} \mathbf{x}_{n}\right) \mathbf{C}^{\prime} & & {[b y(2.48)] } \\
& =\left(\lambda_{1} \mathbf{x}_{1}, \lambda_{2} \mathbf{x}_{2}, \ldots, \lambda_{n} \mathbf{x}_{n}\right) \mathbf{C}^{\prime} & & {[b y(2.104)] } \\
& =\mathbf{C D C}^{\prime} & & {[b y(2.56)] } \tag{2.109}
\end{align*}
\]
where
\[
\mathbf{D}=\left(\begin{array}{cccc}
\lambda_{1} & 0 & \cdots & 0  \tag{2.110}\\
0 & \lambda_{2} & \cdots & 0 \\
\vdots & \vdots & & \vdots \\
0 & 0 & \cdots & \lambda_{n}
\end{array}\right)
\]

The expression \(\mathbf{A}=\mathbf{C D C}^{\prime}\) in (2.109) for a symmetric matrix \(\mathbf{A}\) in terms of its eigenvalues and eigenvectors is known as the spectral decomposition of \(\mathbf{A}\).

Since \(\mathbf{C}\) is orthogonal and \(\mathbf{C}^{\prime} \mathbf{C}=\mathbf{C} \mathbf{C}^{\prime}=\mathbf{I}\), we can multiply (2.109) on the left by \(\mathbf{C}^{\prime}\) and on the right by \(\mathbf{C}\) to obtain
\[
\begin{equation*}
\mathbf{C}^{\prime} \mathbf{A C}=\mathbf{D} \tag{2.111}
\end{equation*}
\]

Thus a symmetric matrix A can be diagonalized by an orthogonal matrix containing normalized eigenvectors of \(\mathbf{A}\), and by (2.110) the resulting diagonal matrix contains eigenvalues of \(\mathbf{A}\).

\subsection*{2.11.8 Square Root Matrix}

If \(\mathbf{A}\) is positive definite, the spectral decomposition of \(\mathbf{A}\) in (2.109) can be modified by taking the square roots of the eigenvalues to produce a square root matrix,
\[
\begin{equation*}
\mathbf{A}^{1 / 2}=\mathbf{C D}^{1 / 2} \mathbf{C}^{\prime} \tag{2.112}
\end{equation*}
\]
where
\[
\mathbf{D}^{1 / 2}=\left(\begin{array}{cccc}
\sqrt{\lambda_{1}} & 0 & \cdots & 0  \tag{2.113}\\
0 & \sqrt{\lambda_{2}} & \cdots & 0 \\
\vdots & \vdots & & \vdots \\
0 & 0 & \cdots & \sqrt{\lambda_{n}}
\end{array}\right)
\]

The square root matrix \(\mathbf{A}^{1 / 2}\) is symmetric and serves as the square root of \(\mathbf{A}\) :
\[
\begin{equation*}
\mathbf{A}^{1 / 2} \mathbf{A}^{1 / 2}=\left(\mathbf{A}^{1 / 2}\right)^{2}=\mathbf{A} \tag{2.114}
\end{equation*}
\]

\subsection*{2.11.9 Square and Inverse Matrices}

Other functions of \(\mathbf{A}\) have spectral decompositions analogous to (2.112). Two of these are the square and inverse of \(\mathbf{A}\). If the square matrix \(\mathbf{A}\) has eigenvalues
\(\lambda_{1}, \lambda_{2}, \ldots, \lambda_{n}\) and accompanying eigenvectors \(\mathbf{x}_{1}, \mathbf{x}_{2}, \ldots, \mathbf{x}_{n}\), then \(\mathbf{A}^{2}\) has eigenvalues \(\lambda_{1}^{2}, \lambda_{2}^{2}, \ldots, \lambda_{n}^{2}\) and eigenvectors \(\mathbf{x}_{1}, \mathbf{x}_{2}, \ldots, \mathbf{x}_{n}\). If \(\mathbf{A}\) is nonsingular, then \(\mathbf{A}^{-1}\) has eigenvalues \(1 / \lambda_{1}, 1 / \lambda_{2}, \ldots, 1 / \lambda_{n}\) and eigenvectors \(\mathbf{x}_{1}, \mathbf{x}_{2}, \ldots, \mathbf{x}_{n}\). If \(\mathbf{A}\) is also symmetric, then
\[
\begin{align*}
\mathbf{A}^{2} & =\mathbf{C D}^{2} \mathbf{C}^{\prime}  \tag{2.115}\\
\mathbf{A}^{-1} & =\mathbf{C D}^{-1} \mathbf{C}^{\prime} \tag{2.116}
\end{align*}
\]
where \(\mathbf{C}=\left(\mathbf{x}_{1}, \mathbf{x}_{2}, \ldots, \mathbf{x}_{n}\right)\) has as columns the normalized eigenvectors of \(\mathbf{A}\) (and of \(\mathbf{A}^{2}\) and \(\left.\mathbf{A}^{-1}\right), \mathbf{D}^{2}=\operatorname{diag}\left(\lambda_{1}^{2}, \lambda_{2}^{2}, \ldots, \lambda_{n}^{2}\right)\), and \(\mathbf{D}^{-1}=\operatorname{diag}\left(1 / \lambda_{1}, 1 / \lambda_{2}, \ldots\right.\), \(1 / \lambda_{n}\) ).

\subsection*{2.11.10 Singular Value Decomposition}

In Section 2.11 .7 we expressed a symmetric matrix in terms of its eigenvalues and eigenvectors in the spectral decomposition. In a similar manner, we can express any (real) matrix \(\mathbf{A}\) in terms of eigenvalues and eigenvectors of \(\mathbf{A}^{\prime} \mathbf{A}\) and \(\mathbf{A A}^{\prime}\). Let \(\mathbf{A}\) be an \(n \times p\) matrix of rank \(k\). Then the singular value decomposition of \(\mathbf{A}\) can be expressed as
\[
\begin{equation*}
\mathbf{A}=\mathbf{U D V} \mathbf{V}^{\prime} \tag{2.117}
\end{equation*}
\]
where \(\mathbf{U}\) is \(n \times k, \mathbf{D}\) is \(k \times k\), and \(\mathbf{V}\) is \(p \times k\). The diagonal elements of the nonsingular diagonal matrix \(\mathbf{D}=\operatorname{diag}\left(\lambda_{1}, \lambda_{2}, \ldots, \lambda_{k}\right)\) are the positive square roots of \(\lambda_{1}^{2}, \lambda_{2}^{2}, \ldots, \lambda_{k}^{2}\), which are the nonzero eigenvalues of \(\mathbf{A}^{\prime} \mathbf{A}\) or of \(\mathbf{A} \mathbf{A}^{\prime}\). The values \(\lambda_{1}, \lambda_{2}, \ldots, \lambda_{k}\) are called the singular values of \(\mathbf{A}\). The \(k\) columns of \(\mathbf{U}\) are the normalized eigenvectors of \(\mathbf{A} \mathbf{A}^{\prime}\) corresponding to the eigenvalues \(\lambda_{1}^{2}, \lambda_{2}^{2}, \ldots, \lambda_{k}^{2}\). The \(k\) columns of \(\mathbf{V}\) are the normalized eigenvectors of \(\mathbf{A}^{\prime} \mathbf{A}\) corresponding to the eigenvalues \(\lambda_{1}^{2}, \lambda_{2}^{2}, \ldots, \lambda_{k}^{2}\). Since the columns of \(\mathbf{U}\) and \(\mathbf{V}\) are (normalized) eigenvectors of symmetric matrices, they are mutually orthogonal (see Section 2.11.6), and we have \(\mathbf{U}^{\prime} \mathbf{U}=\mathbf{V}^{\prime} \mathbf{V}=\mathbf{I}\).

\subsection*{2.12 KRONECKER AND VEC NOTATION}

When manipulating matrices with block structure, it is often convenient to use Kronecker and vec notation. The Kronecker product of an \(m \times n\) matrix A with a \(p \times q\) matrix \(\mathbf{B}\) is an \(m p \times n q\) matrix that is denoted \(\mathbf{A} \otimes \mathbf{B}\) and is defined as
\[
\mathbf{A} \otimes \mathbf{B}=\left(\begin{array}{cccc}
a_{11} \mathbf{B} & a_{12} \mathbf{B} & \cdots & a_{1 n} \mathbf{B}  \tag{2.118}\\
a_{21} \mathbf{B} & a_{22} \mathbf{B} & \cdots & a_{2 n} \mathbf{B} \\
\vdots & \vdots & \ddots & \vdots \\
a_{m 1} \mathbf{B} & a_{m 2} \mathbf{B} & \cdots & a_{m n} \mathbf{B}
\end{array}\right)
\]

For example, because of the block structure in the matrix
\[
\mathbf{C}=\left(\begin{array}{cccccc}
1 & 2 & 3 & 0 & 0 & 0 \\
4 & 5 & 6 & 0 & 0 & 0 \\
2 & 4 & 6 & 10 & 20 & 30 \\
8 & 10 & 12 & 40 & 50 & 60
\end{array}\right)
\]
we can write
\[
\mathbf{C}=\left(\begin{array}{cc}
1 \cdot \mathbf{B} & 0 \cdot \mathbf{B} \\
2 \cdot \mathbf{B} & 10 \cdot \mathbf{B}
\end{array}\right)=\mathbf{A} \otimes \mathbf{B}
\]
where
\[
\mathbf{A}=\left(\begin{array}{cc}
1 & 0 \\
2 & 10
\end{array}\right), \quad \mathbf{B}=\left(\begin{array}{ccc}
1 & 2 & 3 \\
4 & 5 & 6
\end{array}\right) .
\]

If \(\mathbf{A}\) is an \(m \times n\) matrix with columns \(\mathbf{a}_{1}, \ldots, \mathbf{a}_{n}\), then we can refer to the elements of \(\mathbf{A}\) in vector (or "vec") form using
\[
\begin{align*}
\operatorname{vec} \mathbf{A} & =\left(\begin{array}{c}
\mathbf{a}_{1} \\
\mathbf{a}_{2} \\
\vdots \\
\mathbf{a}_{n}
\end{array}\right)  \tag{2.119}\\
& =\left(a_{11}, a_{21}, \ldots, a_{m 1}, a_{12}, a_{22}, \ldots, a_{m 2}, \ldots, a_{1 n}, a_{2 n}, \ldots, a_{m n}\right)^{\prime}
\end{align*}
\]
so that vec \(\mathbf{A}\) is an \(m n \times 1\) vector.
If \(\mathbf{A}\) is an \(m \times m\) symmetric matrix, then the \(m^{2}\) elements in vec \(\mathbf{A}\) will include \(m(m-1) / 2\) pairs of identical elements (since \(a_{i j}=a_{j i}\) ). In such settings it is often useful to denote the vector half (or "vech") of a symmetric matrix in order to include only the unique elements of the matrix. If we separate elements from different columns using semicolons, we can define the "vech" operator with
\[
\begin{equation*}
\text { vech } \mathbf{A}=\left(a_{11}, a_{21}, \ldots, a_{m 1} ; a_{22}, a_{32}, \ldots, a_{m 2} ; \ldots ; a_{m m}\right)^{\prime} \tag{2.120}
\end{equation*}
\]
so that vech \(\mathbf{A}\) is an \(m(m+1) / 2 \times 1\) vector. Note that vech \(\mathbf{A}\) can be obtained by finding vec \(\mathbf{A}\) and then eliminating the \(m(m-1) / 2\) elements above the diagonal of A.

Assuming that all matrix dimensions for matrices \(\mathbf{A}, \mathbf{B}, \mathbf{C}\), and D are appropriate for matrix multiplication, the following important properties related to Kronecker products will hold true:
\[
\begin{equation*}
(\mathbf{A} \otimes \mathbf{B})(\mathbf{C} \otimes \mathbf{D})=(\mathbf{A C}) \otimes(\mathbf{B D}) \tag{i}
\end{equation*}
\]
\(\operatorname{vec} \mathbf{A B C}=\left(\mathbf{C}^{\prime} \otimes \mathbf{A}\right)\) vec \(\mathbf{B}\)
\((\mathbf{A} \otimes \mathbf{B})^{\prime}=\mathbf{A}^{\prime} \otimes \mathbf{B}^{\prime}\)
(iv)
\[
\begin{equation*}
(\mathbf{A} \otimes \mathbf{B})^{-1}=\mathbf{A}^{-1} \otimes \mathbf{B}^{-1} \tag{iii}
\end{equation*}
\]

Finally, following the discussion in Fuller (1987, Section 4.3), we can also define an \(m^{2} \times m(m+1) / 2\) matrix \(\mathbf{H}_{m}\) such that
\[
\begin{equation*}
\mathbf{H}_{m} \text { vech } \mathbf{A}=\operatorname{vec} \mathbf{A} . \tag{2.125}
\end{equation*}
\]

Further, we can define a generalized inverse \(\mathbf{H}_{m}^{+}=\left(\mathbf{H}_{m}^{\prime} \mathbf{H}_{m}\right)^{-1} \mathbf{H}_{m}^{\prime}\) so that
\[
\begin{align*}
\mathbf{H}_{m}^{+} \text {vec } \mathbf{A} & =\mathbf{H}_{m}^{+} \mathbf{H}_{m} \text { vech } \mathbf{A} \\
& =\text { vech } \mathbf{A} . \tag{2.126}
\end{align*}
\]

Consider, for example, the \(2 \times 2\) symmetric matrix
\[
\mathbf{A}=\left(\begin{array}{ll}
a_{11} & a_{12} \\
a_{21} & a_{22}
\end{array}\right) .
\]

Then
\[
\underbrace{\left(\begin{array}{l}
a_{11} \\
a_{21} \\
a_{12} \\
a_{22}
\end{array}\right)}_{\text {vec } \mathbf{A}}=\underbrace{\left(\begin{array}{ccc}
1 & 0 & 0 \\
0 & 1 & 0 \\
0 & 1 & 0 \\
0 & 0 & 1
\end{array}\right)}_{\mathbf{H}_{2}} \underbrace{\left(\begin{array}{l}
a_{11} \\
a_{21} \\
a_{22}
\end{array}\right)}_{\text {vech } \mathbf{A}}
\]
and
\[
\underbrace{\left(\begin{array}{l}
a_{11} \\
a_{21} \\
a_{22}
\end{array}\right)}_{\text {vech } \mathbf{A}}=\underbrace{\left(\begin{array}{cccc}
1 & 0 & 0 & 0 \\
0 & 1 / 2 & 1 / 2 & 0 \\
0 & 0 & 0 & 1
\end{array}\right)}_{\mathbf{H}_{2}^{+}} \underbrace{\left(\begin{array}{l}
a_{11} \\
a_{21} \\
a_{12} \\
a_{22}
\end{array}\right)}_{\operatorname{vec} \mathbf{A}} .
\]

\section*{PROBLEMS}
2.1 Let
\[
\mathbf{A}=\left(\begin{array}{lll}
4 & 2 & 3 \\
7 & 5 & 8
\end{array}\right) \quad \text { and } \quad \mathbf{B}=\left(\begin{array}{rrr}
3 & -2 & 4 \\
6 & 9 & -5
\end{array}\right)
\]
(a) Find \(\mathbf{A}+\mathbf{B}\) and \(\mathbf{A}-\mathbf{B}\).
(b) Find \(\mathbf{A}^{\prime} \mathbf{A}\) and \(\mathbf{A A}^{\prime}\).
2.2 Use the matrices \(\mathbf{A}\) and \(\mathbf{B}\) in Problem 2.1:
(a) Find \((\mathbf{A}+\mathbf{B})^{\prime}\) and \(\mathbf{A}^{\prime}+\mathbf{B}^{\prime}\) and compare them, thus illustrating (2.15).
(b) Show that \(\left(\mathbf{A}^{\prime}\right)^{\prime}=\mathbf{A}\), thus illustrating (2.6).
2.3 Let
\[
\mathbf{A}=\left(\begin{array}{rr}
1 & 3 \\
2 & -1
\end{array}\right), \quad \mathbf{B}=\left(\begin{array}{ll}
2 & 0 \\
1 & 5
\end{array}\right) .
\]
(a) Find \(\mathbf{A B}\) and \(\mathbf{B A}\).
(b) Find \(|\mathbf{A B}|,|\mathbf{A}|\), and \(|\mathbf{B}|\) and verify that (2.89) holds in this case.
2.4 Use the matrices \(\mathbf{A}\) and \(\mathbf{B}\) in Problem 2.3:
(a) Find \(\mathbf{A}+\mathbf{B}\) and \(\operatorname{tr}(\mathbf{A}+\mathbf{B})\).
(b) Find \(\operatorname{tr}(\mathbf{A})\) and \(\operatorname{tr}(\mathbf{B})\) and show that (2.96) holds for these matrices.
2.5 Let
\[
\mathbf{A}=\left(\begin{array}{rrr}
1 & 2 & 3 \\
2 & -1 & 1
\end{array}\right), \quad \mathbf{B}=\left(\begin{array}{rr}
3 & -2 \\
2 & 0 \\
-1 & 1
\end{array}\right)
\]
(a) Find \(\mathbf{A B}\) and \(\mathbf{B A}\).
(b) Compare \(\operatorname{tr}(\mathbf{A B})\) and \(\operatorname{tr}(\mathbf{B A})\) and confirm that (2.97) holds here.

\subsection*{2.6 Let}
\[
\mathbf{A}=\left(\begin{array}{rrr}
1 & 2 & 3 \\
2 & 4 & 6 \\
5 & 10 & 15
\end{array}\right), \quad \mathbf{B}=\left(\begin{array}{rrr}
-1 & 1 & -2 \\
-1 & 1 & -2 \\
1 & -1 & 2
\end{array}\right)
\]
(a) Show that \(\mathbf{A B}=\mathbf{O}\).
(b) Find a vector \(\mathbf{x}\) such that \(\mathbf{A x}=\mathbf{0}\).
(c) Show that \(|\mathbf{A}|=0\).
2.7 Let
\[
\begin{aligned}
& \mathbf{A}=\left(\begin{array}{rrr}
1 & -1 & 4 \\
-1 & 1 & 3 \\
4 & 3 & 2
\end{array}\right), \quad \mathbf{B}=\left(\begin{array}{rrr}
3 & -2 & 4 \\
7 & 1 & 0 \\
2 & 3 & 5
\end{array}\right), \\
& \mathbf{x}=\left(\begin{array}{r}
1 \\
-1 \\
2
\end{array}\right), \quad \mathbf{y}=\left(\begin{array}{l}
3 \\
2 \\
1
\end{array}\right) .
\end{aligned}
\]

Find the following:
(a) \(B x\)
(d) \(x^{\prime} \mathbf{A y}\)
(g) \(\mathrm{xx}^{\prime}\)
(b) \(\mathbf{y}^{\prime} \mathbf{B}\)
(e) \(x^{\prime} x\)
(h) \(\mathrm{xy}^{\prime}\)
(c) \(\mathbf{x}^{\prime} \mathbf{A x}\)
(f) \(x^{\prime} \mathbf{y}\)
(i) \(\mathbf{B}^{\prime} \mathbf{B}\)
2.8 Use \(\mathbf{x}, \mathbf{y}\), and \(\mathbf{A}\) as defined in Problem 2.7:
(a) Find \(x+y\) and \(x-y\).
(b) Find \((x-y)^{\prime} \mathbf{A}(x-y)\).
2.9 Using \(B\) and \(x\) in Problem 2.7, find \(B x\) as a linear combination of columns of \(\mathbf{B}\) as in (2.67) and compare with \(\mathbf{B x}\) found in Problem 2.7(a).
2.10 Let
\[
\mathbf{A}=\left(\begin{array}{ll}
2 & 1 \\
1 & 3
\end{array}\right), \quad \mathbf{B}=\left(\begin{array}{lll}
1 & 4 & 2 \\
5 & 0 & 3
\end{array}\right), \quad \mathbf{I}=\left(\begin{array}{ll}
1 & 0 \\
0 & 1
\end{array}\right) .
\]
(a) Show that \((\mathbf{A B})^{\prime}=\mathbf{B}^{\prime} \mathbf{A}^{\prime}\) as in (2.27).
(b) Show that \(\mathbf{A I}=\mathbf{A}\) and that \(\mathbf{I B}=\mathbf{B}\).
(c) Find \(|\mathbf{A}|\).
2.11 Let
\[
\mathbf{a}=\left(\begin{array}{r}
1 \\
-3 \\
2
\end{array}\right) \quad \text { and } \quad \mathbf{b}=\left(\begin{array}{c}
2 \\
1 \\
3
\end{array}\right)
\]
(a) Find \(\mathbf{a}^{\prime} \mathbf{b}\) and \(\left(\mathbf{a}^{\prime} \mathbf{b}\right)^{2}\).
(b) Find \(\mathbf{b} \mathbf{b}^{\prime}\) and \(\mathbf{a}^{\prime}\left(\mathbf{b} \mathbf{b}^{\prime}\right) \mathbf{a}\).
(c) Compare \(\left(\mathbf{a}^{\prime} \mathbf{b}\right)^{2}\) with \(\mathbf{a}^{\prime}\left(\mathbf{b} \mathbf{b}^{\prime}\right) \mathbf{a}\) and thus illustrate (2.40).
2.12 Let
\[
\mathbf{A}=\left(\begin{array}{lll}
1 & 2 & 3 \\
4 & 5 & 6 \\
7 & 8 & 9
\end{array}\right), \quad \mathbf{D}=\left(\begin{array}{ccc}
a & 0 & 0 \\
0 & b & 0 \\
0 & 0 & c
\end{array}\right)
\]

Find DA, AD, and DAD.
2.13 Let the matrices A and Be partitioned as follows:
\[
\mathbf{A}=\left(\begin{array}{ll|l}
2 & 1 & 2 \\
3 & 2 & 0 \\
\hline 1 & 0 & 1
\end{array}\right), \quad \mathbf{B}=\left(\begin{array}{lll|l}
1 & 1 & 1 & 0 \\
2 & 1 & 1 & 2 \\
\hline 2 & 3 & 1 & 2
\end{array}\right)
\]
(a) Find AB as in (2.65) using the indicated partitioning.
(b) Check by finding \(A B\) in the usual way, ignoring the partitioning.

\subsection*{2.14 Let}
\[
\mathbf{A}=\left(\begin{array}{rrr}
1 & 3 & 2 \\
2 & 0 & -1
\end{array}\right), \quad \mathbf{B}=\left(\begin{array}{ll}
1 & 2 \\
0 & 1 \\
1 & 0
\end{array}\right), \quad \mathbf{C}=\left(\begin{array}{rrr}
2 & 1 & 1 \\
5 & -6 & -4
\end{array}\right)
\]

Find \(\mathbf{A B}\) and \(\mathbf{C B}\). Are they equal? What is the rank of \(\mathbf{A}, \mathbf{B}\), and \(\mathbf{C}\) ?
2.15 Let
\[
\mathbf{A}=\left(\begin{array}{rrr}
5 & 4 & 4 \\
2 & -3 & 1 \\
3 & 7 & 2
\end{array}\right), \quad \mathbf{B}=\left(\begin{array}{lll}
1 & 0 & 1 \\
0 & 1 & 0 \\
1 & 2 & 3
\end{array}\right)
\]
(a) Find \(\operatorname{tr}(\mathbf{A})\) and \(\operatorname{tr}(\mathbf{B})\).
(b) Find \(\mathbf{A}+\mathbf{B}\) and \(\operatorname{tr}(\mathbf{A}+\mathbf{B})\). Is \(\operatorname{tr}(\mathbf{A}+\mathbf{B})=\operatorname{tr}(\mathbf{A})+\operatorname{tr}(\mathbf{B})\) ?
(c) Find \(|\mathbf{A}|\) and \(|\mathbf{B}|\).
(d) Find \(\mathbf{A B}\) and \(|\mathbf{A B}|\). Is \(|\mathbf{A B}|=|\mathbf{A}||\mathbf{B}|\) ?
2.16 Let
\[
\mathbf{A}=\left(\begin{array}{lll}
3 & 4 & 3 \\
4 & 8 & 6 \\
3 & 6 & 9
\end{array}\right)
\]
(a) Show that \(|\mathbf{A}|>0\).
(b) Using the Cholesky decomposition in Section 2.7, find an upper triangular matrix \(\mathbf{T}\) such that \(\mathbf{A}=\mathbf{T}^{\prime} \mathbf{T}\).
2.17 Let
\[
\mathbf{A}=\left(\begin{array}{rrr}
3 & -5 & -1 \\
-5 & 13 & 0 \\
-1 & 0 & 1
\end{array}\right)
\]
(a) Show that \(|\mathbf{A}|>0\).
(b) Using the Cholesky decomposition in Section 2.7, find an upper triangular matrix \(\mathbf{T}\) such that \(\mathbf{A}=\mathbf{T}^{\prime} \mathbf{T}\).
2.18 The columns of the following matrix are mutually orthogonal:
\[
\mathbf{A}=\left(\begin{array}{rrr}
1 & -1 & 1 \\
2 & 1 & 0 \\
1 & -1 & -1
\end{array}\right)
\]
(a) Normalize the columns of \(\mathbf{A}\) by dividing each column by its length; denote the resulting matrix by \(\mathbf{C}\).
(b) Show that \(\mathbf{C}\) is an orthogonal matrix, that is, \(\mathbf{C}^{\prime} \mathbf{C}=\mathbf{C C}^{\prime}=\mathbf{I}\).
2.19 Let
\[
\mathbf{A}=\left(\begin{array}{rrr}
1 & 1 & -2 \\
-1 & 2 & 1 \\
0 & 1 & -1
\end{array}\right)
\]
(a) Find the eigenvalues and associated normalized eigenvectors.
(b) Find \(\operatorname{tr}(\mathbf{A})\) and \(|\mathbf{A}|\) and show that \(\operatorname{tr}(\mathbf{A})=\sum_{i=1}^{3} \lambda_{i}\) and \(|\mathbf{A}|=\prod_{i=1}^{3} \lambda_{i}\).
2.20 Let
\[
\mathbf{A}=\left(\begin{array}{lll}
3 & 1 & 1 \\
1 & 0 & 2 \\
1 & 2 & 0
\end{array}\right)
\]
(a) The eigenvalues of \(\mathbf{A}\) are 1,4,-2. Find the normalized eigenvectors and use them as columns in an orthogonal matrix \(\mathbf{C}\).
(b) Show that \(\mathbf{C}^{\prime} \mathbf{A C}=\mathbf{D}\) as in (2.111), where \(\mathbf{D}\) is diagonal with the eigenvalues of A on the diagonal.
(c) Show that \(\mathbf{A}=\mathbf{C D C}^{\prime}\) as in (2.109).
2.21 For the positive definite matrix
\[
\mathbf{A}=\left(\begin{array}{rr}
2 & -1 \\
-1 & 2
\end{array}\right)
\]
calculate the eigenvalues and eigenvectors and find the square root matrix \(\mathbf{A}^{1 / 2}\) as in (2.112). Check by showing that \(\left(\mathbf{A}^{1 / 2}\right)^{2}=\mathbf{A}\).
2.22 Let
\[
\mathbf{A}=\left(\begin{array}{rrr}
3 & 6 & -1 \\
6 & 9 & 4 \\
-1 & 4 & 3
\end{array}\right)
\]
(a) Find the spectral decomposition of \(\mathbf{A}\) as in (2.109).
(b) Find the spectral decomposition of \(\mathbf{A}^{2}\) and show that the diagonal matrix of eigenvalues is equal to the square of the matrix \(\mathbf{D}\) found in part (a), thus illustrating (2.115).
(c) Find the spectral decomposition of \(\mathbf{A}^{-1}\) and show that the diagonal matrix of eigenvalues is equal to the inverse of the matrix \(\mathbf{D}\) found in part (a), thus illustrating (2.116).
2.23 Find the singular value decomposition of \(\mathbf{A}\) as in (2.117), where
\[
\mathbf{A}=\left(\begin{array}{rrr}
4 & -5 & -1 \\
7 & -2 & 3 \\
-1 & 4 & -3 \\
8 & 2 & 6
\end{array}\right)
\]
2.24 If \(\mathbf{j}\) is a vector of 1 's, as defined in (2.11), show that the following hold:
(a) \(\mathbf{j}^{\prime} \mathbf{a}=\mathbf{a}^{\prime} \mathbf{j}=\sum_{i} a_{i}\) as in (2.37)
(b) \(\mathbf{j}^{\prime} \mathbf{A}\) is a row vector whose elements are the column sums of \(\mathbf{A}\) as in (2.38)
(c) \(\mathbf{A j}\) is a column vector whose elements are the row sums of \(\mathbf{A}\) as in (2.38)
2.25 Verify (2.41); that is, show that \((\mathbf{x}-\mathbf{y})^{\prime}(\mathbf{x}-\mathbf{y})=\mathbf{x}^{\prime} \mathbf{x}-2 \mathbf{x}^{\prime} \mathbf{y}+\mathbf{y}^{\prime} \mathbf{y}\).
2.26 Show that \(\mathbf{A}^{\prime} \mathbf{A}\) is symmetric, where \(\mathbf{A}\) is \(n \times p\).
2.27 If \(\mathbf{a}\) and \(\mathbf{x}_{1}, \mathbf{x}_{2}, \ldots, \mathbf{x}_{n}\) are all \(p \times 1\) and \(\mathbf{A}\) is \(p \times p\), show that (2.42)-(2.45) hold:
(a) \(\sum_{i=1}^{n} \mathbf{a}^{\prime} \mathbf{x}_{i}=\mathbf{a}^{\prime} \sum_{i=1}^{n} \mathbf{x}_{i}\)
(b) \(\sum_{i=1}^{n} \mathbf{A} \mathbf{x}_{i}=\mathbf{A} \sum_{i=1}^{n} \mathbf{x}_{i}\)
(c) \(\sum_{i=1}^{n}\left(\mathbf{a}^{\prime} \mathbf{x}_{i}\right)^{2}=\mathbf{a}^{\prime}\left(\sum_{i=1}^{n} \mathbf{x}_{i} \mathbf{x}_{i}^{\prime}\right) \mathbf{a}\)
(d) \(\sum_{i=1}^{n} \mathbf{A} \mathbf{x}_{i}\left(\mathbf{A} \mathbf{x}_{i}\right)^{\prime}=\mathbf{A}\left(\sum_{i=1}^{n} \mathbf{x}_{i} \mathbf{x}_{i}^{\prime}\right) \mathbf{A}^{\prime}\)
2.28 Assume that \(\mathbf{A}=\binom{\mathbf{a}_{1}^{\prime}}{\mathbf{a}_{2}^{\prime}}\) is \(2 \times p, \mathbf{x}\) is \(p \times 1\), and \(\mathbf{S}\) is \(p \times p\).
(a) Show that
\[
\mathbf{A} \mathbf{x}=\binom{\mathbf{a}_{1}^{\prime} \mathbf{x}}{\mathbf{a}_{2}^{\prime} \mathbf{x}}
\]
as in (2.49).
(b) Show that
\[
\mathbf{A S A} \mathbf{A}^{\prime}=\left(\begin{array}{cc}
\mathbf{a}_{1}^{\prime} \mathbf{S} \mathbf{a}_{1} & \mathbf{a}_{1}^{\prime} \mathbf{S} \mathbf{a}_{2} \\
\mathbf{a}_{2}^{\prime} \mathbf{S} \mathbf{a}_{1} & \mathbf{a}_{2}^{\prime} \mathbf{S} \mathbf{a}_{2}
\end{array}\right)
\]
as in (2.50).
2.29 (a) If the rows of \(\mathbf{A}\) are denoted by \(\mathbf{a}_{i}^{\prime}\), show that \(\mathbf{A}^{\prime} \mathbf{A}=\sum_{i=1}^{n} \mathbf{a}_{i} \mathbf{a}_{i}^{\prime}\) as in (2.51).
(b) If the columns of \(\mathbf{A}\) are denoted by \(\mathbf{a}_{(j)}\), show that \(\mathbf{A} \mathbf{A}^{\prime}=\sum_{j=1}^{p} \mathbf{a}_{(j)} \mathbf{a}_{(j)}^{\prime}\) as in (2.53).
2.30 Show that \(\left(\mathbf{A}^{\prime}\right)^{-1}=\left(\mathbf{A}^{-1}\right)^{\prime}\) as in (2.75).
2.31 Show that the inverse of the partitioned matrix given in (2.76) is correct by multiplying by
\[
\left(\begin{array}{cc}
\mathbf{A}_{11} & \mathbf{a}_{12} \\
\mathbf{a}_{12}^{\prime} & a_{22}
\end{array}\right)
\]
to obtain an identity.
2.32 Show that the inverse of \(\mathbf{B}+\mathbf{c c}^{\prime}\) given in (2.77) is correct by multiplying by \(\mathbf{B}+\mathbf{c c}^{\prime}\) to obtain an identity.
2.33 Show that \(|c \mathbf{A}|=c^{n}|\mathbf{A}|\) as in (2.85).
2.34 Show that \(\left|\mathbf{A}^{-1}\right|=1 /|\mathbf{A}|\) as in (2.91).
2.35 If \(\mathbf{B}\) is nonsingular and \(\mathbf{c}\) is a vector, show that \(\left|\mathbf{B}+\mathbf{c c}^{\prime}\right|=|\mathbf{B}|\left(1+\mathbf{c}^{\prime} \mathbf{B}^{-1} \mathbf{c}\right)\) as in (2.95).
2.36 Show that \(\operatorname{tr}\left(\mathbf{A}^{\prime} \mathbf{A}\right)=\operatorname{tr}\left(\mathbf{A} \mathbf{A}^{\prime}\right)=\sum_{i j} a_{i j}^{2}\) as in (2.98).
2.37 Show that \(\mathbf{C} \mathbf{C}^{\prime}=\mathbf{I}\) in (2.102) follows from \(\mathbf{C}^{\prime} \mathbf{C}=\mathbf{I}\) in (2.101).
2.38 Show that the eigenvalues of \(\mathbf{A B}\) are the same as those of \(\mathbf{B A}\), as noted in Section 2.11.5.
2.39 If \(\mathbf{A}^{1 / 2}\) is the square root matrix defined in (2.112), show that
(a) \(\left(\mathbf{A}^{1 / 2}\right)^{2}=\mathbf{A}\) as in (2.114),
(b) \(\left|\mathbf{A}^{1 / 2}\right|^{2}=|\mathbf{A}|\),
(c) \(\left|\mathbf{A}^{1 / 2}\right|=|\mathbf{A}|^{1 / 2}\).
2.40 Let A and B be \(n \times k\) and \(p \times p\) matrices, respectively. Use the properties of Kronecker products in Section 2.12 to show that
\[
\left[\left(\mathbf{I}_{p} \otimes \mathbf{A}\right)^{\prime}\left(\mathbf{B} \otimes \mathbf{I}_{n}\right)^{-1}\left(\mathbf{I}_{p} \otimes \mathbf{A}\right)\right]^{-1}=\mathbf{B} \otimes\left(\mathbf{A}^{\prime} \mathbf{A}\right)^{-1} .
\]

\section*{CHAPTER 3}

\section*{CHARACTERIZING AND DISPLAYING MULTIVARIATE DATA}

We review some univariate and bivariate procedures in Sections 3.1, 3.2, and 3.3 and then extend them to vectors of higher dimension in the remainder of the chapter.

\subsection*{3.1 MEAN AND VARIANCE OF A UNIVARIATE RANDOM VARIABLE}

Informally, a random variable may be defined as a variable whose value depends on the outcome of a chance experiment. Generally, we will consider only continuous random variables. Some types of multivariate data are only approximations to this ideal, such as test scores or a seven-point semantic differential (Likert) scale consisting of ordered responses ranging from "strongly disagree" to "strongly agree." Special techniques have been developed for such data, but in many cases, the usual methods designed for continuous data work almost as well.

The density function \(f(y)\) indicates the relative frequency of occurrence of the random variable \(y\). (We do not use \(Y\) to denote the random variable for reasons given at the beginning of Section 3.6.) Thus if \(f\left(y_{1}\right)>f\left(y_{2}\right)\), then points in the neighborhood of \(y_{1}\) are more likely to occur than points in the neighborhood of \(y_{2}\).

The population mean of a random variable \(y\) is defined (informally) as the mean of all possible values of \(y\) and is denoted by \(\mu\). The mean is also referred to as the expected value of \(y\) or \(E(y)\). If the density \(f(y)\) is known, the mean can sometimes be found using methods of calculus, but we will not use these techniques in this text.

If \(f(y)\) is unknown, the population mean \(\mu\) will ordinarily remain unknown unless it has been established from extensive past experience with a stable population. If a large random sample from the population represented by \(f(y)\) is available, it is highly probable that the mean of the sample is close to \(\mu\).

The sample mean of a random sample of \(n\) observations \(y_{1}, y_{2}, \ldots, y_{n}\) is given by the ordinary arithmetic average
\[
\begin{equation*}
\bar{y}=\frac{1}{n} \sum_{i=1}^{n} y_{i} \tag{3.1}
\end{equation*}
\]

Generally, \(\bar{y}\) will never be equal to \(\mu\); by this we mean that the probability is zero that a sample will ever arise in which \(\bar{y}\) is exactly equal to \(\mu\). However, \(\bar{y}\) is considered a good estimator for \(\mu\) because \(E(\bar{y})=\mu\) and \(\operatorname{var}(\bar{y})=\sigma^{2} / n\), where \(\sigma^{2}\) is the variance of \(y\). In other words, \(\bar{y}\) is an unbiased estimator of \(\mu\) and has a smaller variance than a single observation \(y\). The variance \(\sigma^{2}\) is defined below. The notation \(E(\bar{y})\) indicates the mean of all possible values of \(\bar{y}\); that is, conceptually, every possible sample is obtained from the population, the mean of each is found, and the average of all these sample means is calculated.

If every \(y\) in the population is multiplied by a constant \(a\), the expected value is also multiplied by \(a\) :
\[
\begin{equation*}
E(a y)=a E(y)=a \mu \tag{3.2}
\end{equation*}
\]

The sample mean has a similar property. If \(z_{i}=a y_{i}\) for \(i=1,2, \ldots, n\), then
\[
\begin{equation*}
\bar{z}=a \bar{y} \tag{3.3}
\end{equation*}
\]

The variance of the population is defined as \(\operatorname{var}(y)=\sigma^{2}=E(y-\mu)^{2}\). This is the average squared deviation from the mean and is thus an indication of the extent to which the values of \(y\) are spread or scattered. It can be shown that \(\sigma^{2}=E\left(y^{2}\right)-\mu^{2}\).

The sample variance is defined as
\[
\begin{equation*}
s^{2}=\frac{\sum_{i=1}^{n}\left(y_{i}-\bar{y}\right)^{2}}{n-1} \tag{3.4}
\end{equation*}
\]
which can be shown to be equal to
\[
\begin{equation*}
s^{2}=\frac{\sum_{i=1}^{n} y_{i}^{2}-n \bar{y}^{2}}{n-1} \tag{3.5}
\end{equation*}
\]

The sample variance \(s^{2}\) is generally never equal to the population variance \(\sigma^{2}\) (the probability of such an occurrence is zero), but it is an unbiased estimator for \(\sigma^{2}\); that is, \(E\left(s^{2}\right)=\sigma^{2}\). Again the notation \(E\left(s^{2}\right)\) indicates the mean of all possible sample variances. The square root of either the population variance or the sample variance is called the standard deviation.

Table 3.1 Height and Weight for a Sample of 20 College-Age Males
\begin{tabular}{cccccc}
\hline Person & \begin{tabular}{c} 
Height, \\
\(x\)
\end{tabular} & \begin{tabular}{c} 
Weight, \\
\(y\)
\end{tabular} & Person & \begin{tabular}{c} 
Height, \\
\(x\)
\end{tabular} & \begin{tabular}{c} 
Weight, \\
\(y\)
\end{tabular} \\
\hline 1 & 69 & 153 & 11 & 72 & 140 \\
2 & 74 & 175 & 12 & 79 & 265 \\
3 & 68 & 155 & 13 & 74 & 185 \\
4 & 70 & 135 & 14 & 67 & 112 \\
5 & 72 & 172 & 15 & 66 & 140 \\
6 & 67 & 150 & 16 & 71 & 150 \\
7 & 66 & 115 & 17 & 74 & 165 \\
8 & 70 & 137 & 18 & 75 & 185 \\
9 & 76 & 200 & 19 & 75 & 210 \\
10 & 68 & 130 & 20 & 76 & 220 \\
\hline
\end{tabular}

If each \(y\) is multiplied by a constant \(a\), the population variance is multiplied by \(a^{2}\), or \(\operatorname{var}(a y)=a^{2} \sigma^{2}\). Similarly, if \(z_{i}=a y_{i}, i=1,2, \ldots, n\), then the sample variance of \(z\) is given by
\[
\begin{equation*}
s_{z}^{2}=a^{2} s^{2} \tag{3.6}
\end{equation*}
\]

\subsection*{3.2 COVARIANCE AND CORRELATION OF BIVARIATE RANDOM VARIABLES}

\subsection*{3.2.1 Covariance}

If two variables \(x\) and \(y\) are measured on each research unit (object or subject), we have a bivariate random variable \((x, y)\). Often \(x\) and \(y\) will tend to covary; if one is above its mean, the other is more likely to be above its mean, and vice versa. For example, height and weight were observed for a sample of 20 college-age males. The data are given in Table 3.1.

The values of height \(x\) and weight \(y\) from Table 3.1 are both plotted in the vertical direction in Figure 3.1. The tendency for \(x\) and \(y\) to stay on the same side of the mean is clear in Figure 3.1. This illustrates positive covariance. With negative covariance the points would tend to deviate simultaneously to opposite sides of the mean.

The population covariance is defined as \(\operatorname{cov}(x, y)=\sigma_{x y}=E\left[\left(x-\mu_{x}\right)(y-\right.\) \(\left.\mu_{y}\right)\) ], where \(\mu_{x}\) and \(\mu_{y}\) are the means of \(x\) and \(y\), respectively. Thus if \(x\) and \(y\) are usually both above their means or both below their means, the product \(\left(x-\mu_{x}\right)(y-\) \(\mu_{y}\) ) will typically be positive and the average value of the product will be positive. Conversely, if \(x\) and \(y\) tend to fall on opposite sides of their respective means, the product will usually be negative and the average product will be negative. It can be shown that \(\sigma_{x y}=E(x y)-\mu_{x} \mu_{y}\).

Figure 3.1 Two variables with a tendency to covary.

If the two random variables \(x\) and \(y\) in a bivariate random variable are added or multiplied, a new random variable is obtained. The mean of \(x+y\) or \(x y\) is as follows:
\[
\begin{align*}
E(x+y) & =E(x)+E(y)  \tag{3.7}\\
E(x y) & =E(x) E(y) \quad \text { if } x, y \text { independent. } \tag{3.8}
\end{align*}
\]

Formally, \(x\) and \(y\) are independent if their joint density factors into the product of their individual densities: \(f(x, y)=g(x) h(y)\). Informally, \(x\) and \(y\) are independent if the random behavior of either of the variables is not affected by the behavior of the other. Note that (3.7) is true whether or not \(x\) and \(y\) are independent, but (3.8) holds only for \(x\) and \(y\) independently distributed.

The notion of independence of \(x\) and \(y\) is more general than that of zero covariance. The covariance \(\sigma_{x y}\) measures linear relationship only, whereas if two random variables are independent, they are not related either linearly or nonlinearly. Independence implies \(\sigma_{x y}=0\), but \(\sigma_{x y}=0\) does not imply independence. It is easy to show that if \(x\) and \(y\) are independent, then \(\sigma_{x y}=0\) :
\[
\begin{aligned}
\sigma_{x y} & =E(x y)-\mu_{x} \mu_{y} \\
& =E(x) E(y)-\mu_{x} \mu_{y} \quad[\mathbf{b y}(3.8)] \\
& =\mu_{x} \mu_{y}-\mu_{x} \mu_{y}=0 .
\end{aligned}
\]

One way to demonstrate that the converse is not true is to construct examples of bivariate \(x\) and \(y\) that have zero covariance and yet are related in a nonlinear way (the relationship will have zero slope). This is illustrated in Figure 3.2.

Figure 3.2 A sample from a population where \(x\) and \(y\) have zero covariance and yet are dependent.

If \(x\) and \(y\) have a bivariate normal distribution (see Chapter 4), then zero covariance implies independence. This is because (1) the covariance measures only linear relationships and (2) in the bivariate normal case, the mean of \(y\) given \(x\) (or \(x\) given \(y)\) is a straight line.

The sample covariance is defined as
\[
\begin{equation*}
s_{x y}=\frac{\sum_{i=1}^{n}\left(x_{i}-\bar{x}\right)\left(y_{i}-\bar{y}\right)}{n-1} . \tag{3.9}
\end{equation*}
\]

It can be shown that
\[
\begin{equation*}
s_{x y}=\frac{\sum_{i=1}^{n} x_{i} y_{i}-n \bar{x} \bar{y}}{n-1} \tag{3.10}
\end{equation*}
\]

Note that \(s_{x y}\) is essentially never equal to \(\sigma_{x y}\) (for continuous data), that is, the probability is zero that \(s_{x y}\) will equal \(\sigma_{x y}\). It is true, however, that \(s_{x y}\) is an unbiased estimator for \(\sigma_{x y}\), that is, \(E\left(s_{x y}\right)=\sigma_{x y}\).

Since \(s_{x y} \neq \sigma_{x y}\) in any given sample, this is also true when \(\sigma_{x y}=0\). Thus when the population covariance is zero, no random sample from the population will have zero covariance. The only way a sample from a continuous bivariate distribution will have zero covariance is for the experimenter to choose the values of \(x\) and \(y\) so that \(s_{x y}=0\). (Such a sample would not be a random sample.) One way to achieve this is to place the values in the form of a grid. This is illustrated in Figure 3.3.

The sample covariance measures only linear relationships. If the points in a bivariate sample follow a curved trend, as, for example, in Figure 3.2, the sample

Figure 3.3 A sample of \((x, y)\) values with zero covariance.
covariance will not measure the strength of the relationship. To see that \(s_{x y}\) measures only linear relationships, note that the slope of a simple linear regression line is
\[
\begin{equation*}
\hat{\beta}_{1}=\frac{\sum_{i=1}^{n}\left(x_{i}-\bar{x}\right)\left(y_{i}-\bar{y}\right)}{\sum_{i=1}^{n}\left(x_{i}-\bar{x}\right)^{2}}=\frac{s_{x y}}{s_{x}^{2}} . \tag{3.11}
\end{equation*}
\]

Thus \(s_{x y}\) is proportional to the slope, which shows only the linear relationship between \(y\) and \(x\).

Variables with zero sample covariance can be said to be orthogonal. By (2.99), two sets of numbers \(a_{1}, a_{2}, \ldots, a_{n}\) and \(b_{1}, b_{2}, \ldots, b_{n}\) are orthogonal if \(\sum_{i=1}^{n} a_{i} b_{i}=\) 0 . This is true for the centered variables \(x_{i}-\bar{x}\) and \(y_{i}-\bar{y}\) when the sample covariance is zero, that is, \(\sum_{i=1}^{n}\left(x_{i}-\bar{x}\right)\left(y_{i}-\bar{y}\right)=0\).

\section*{- EXAMPLE 3.2.1}

To obtain the sample covariance for the height and weight data in Table 3.1, we first calculate \(\bar{x}, \bar{y}\), and \(\sum_{i} x_{i} y_{i}\), where \(x\) is height and \(y\) is weight:
\[
\begin{aligned}
\bar{x} & =\frac{69+74+\cdots+76}{20}=71.45 \\
\bar{y} & =\frac{153+175+\cdots+220}{20}=164.7 \\
\sum_{i=1}^{20} x_{i} y_{i} & =(69)(153)+(74)(175)+\cdots+(76)(220)=237,805
\end{aligned}
\]

Now, by (3.10), we have
\[
\begin{aligned}
s_{x y} & =\frac{\sum_{i=1}^{n} x_{i} y_{i}-n \bar{x} \bar{y}}{n-1} \\
& =\frac{237,805-(20)(71.45)(164.7)}{19}=128.88
\end{aligned}
\]

By itself, the sample covariance 128.88 is not very meaningful. We are not sure if this represents a small, moderate, or large amount of relationship between \(y\) and \(x\). A method of standardizing the covariance is given in the next section.

\subsection*{3.2.2 Correlation}

Since the covariance depends on the scale of measurement of \(x\) and \(y\), it is difficult to compare covariances between different pairs of variables. For example, if we change a measurement from inches to centimeters, the covariance will change. To find a measure of linear relationship that is invariant to changes of scale, we can standardize the covariance by dividing by the standard deviations of the two variables. This standardized covariance is called a correlation. The population correlation of two random variables \(x\) and \(y\) is
\[
\begin{equation*}
\rho_{x y}=\operatorname{corr}(x, y)=\frac{\sigma_{x y}}{\sigma_{x} \sigma_{y}}=\frac{E\left[\left(x-\mu_{x}\right)\left(y-\mu_{y}\right)\right]}{\sqrt{E\left(x-\mu_{x}\right)^{2}} \sqrt{E\left(y-\mu_{y}\right)^{2}}}, \tag{3.12}
\end{equation*}
\]
and the sample correlation is
\[
\begin{equation*}
r_{x y}=\frac{s_{x y}}{s_{x} s_{y}}=\frac{\sum_{i=1}^{n}\left(x_{i}-\bar{x}\right)\left(y_{i}-\bar{y}\right)}{\sqrt{\sum_{i=1}^{n}\left(x_{i}-\bar{x}\right)^{2} \sum_{i=1}^{n}\left(y_{i}-\bar{y}\right)^{2}}} . \tag{3.13}
\end{equation*}
\]

Either of these correlations will range between -1 and 1 .
The sample correlation \(r_{x y}\) is related to the cosine of the angle between two vectors. Let \(\theta\) be the angle between vectors \(\mathbf{a}\) and \(\mathbf{b}\) in Figure 3.4. The vector from the terminal point of a to the terminal point of \(\mathbf{b}\) can be represented as \(\mathbf{c}=\mathbf{b}-\mathbf{a}\). Then the law of cosines can be stated in vector form as
\[
\begin{align*}
\cos \theta & =\frac{\mathbf{a}^{\prime} \mathbf{a}+\mathbf{b}^{\prime} \mathbf{b}-(\mathbf{b}-\mathbf{a})^{\prime}(\mathbf{b}-\mathbf{a})}{2 \sqrt{\left(\mathbf{a}^{\prime} \mathbf{a}\right)\left(\mathbf{b}^{\prime} \mathbf{b}\right)}} \\
& =\frac{\mathbf{a}^{\prime} \mathbf{a}+\mathbf{b}^{\prime} \mathbf{b}-\left(\mathbf{b}^{\prime} \mathbf{b}+\mathbf{a}^{\prime} \mathbf{a}-2 \mathbf{a}^{\prime} \mathbf{b}\right)}{2 \sqrt{\left(\mathbf{a}^{\prime} \mathbf{a}\right)\left(\mathbf{b}^{\prime} \mathbf{b}\right)}} \\
& =\frac{\mathbf{a}^{\prime} \mathbf{b}}{\sqrt{\left(\mathbf{a}^{\prime} \mathbf{a}\right)\left(\mathbf{b}^{\prime} \mathbf{b}\right)}} . \tag{3.14}
\end{align*}
\]

Since \(\cos \left(90^{\circ}\right)=0\), we see from (3.14) that \(\mathbf{a}^{\prime} \mathbf{b}=0\) when \(\theta=90^{\circ}\). Thus a and \(\mathbf{b}\) are perpendicular when \(\mathbf{a}^{\prime} \mathbf{b}=0\). By (2.99), two vectors \(\mathbf{a}\) and \(\mathbf{b}\), such that

Figure 3.4 Vectors \(\mathbf{a}\) and \(\mathbf{b}\) in 3-space.
\(\mathbf{a}^{\prime} \mathbf{b}=0\), are also said to be orthogonal. Hence orthogonal vectors are perpendicular in a geometric sense.

To express the correlation in the form given in (3.14), let the \(n\) observation vectors \(\left(x_{1}, y_{1}\right),\left(x_{2}, y_{2}\right), \ldots,\left(x_{n}, y_{n}\right)\) in two dimensions be represented as two vectors \(\mathbf{x}^{\prime}=\left(x_{1}, x_{2}, \ldots, x_{n}\right)\) and \(\mathbf{y}^{\prime}=\left(y_{1}, y_{2}, \ldots, y_{n}\right)\) in \(n\) dimensions, and let \(\mathbf{x}\) and \(\mathbf{y}\) be centered as \(\mathbf{x}-\bar{x} \mathbf{j}\) and \(\mathbf{y}-\bar{y} \mathbf{j}\). Then the cosine of the angle \(\theta\) between them [see (3.14)] is equal to the sample correlation between \(x\) and \(y\) :
\[
\begin{align*}
\cos \theta & =\frac{(\mathbf{x}-\bar{x} \mathbf{j})^{\prime}(\mathbf{y}-\bar{y} \mathbf{j})}{\sqrt{\left[(\mathbf{x}-\bar{x} \mathbf{j})^{\prime}(\mathbf{x}-\bar{x} \mathbf{j})\right]\left[(\mathbf{y}-\bar{y} \mathbf{j})^{\prime}(\mathbf{y}-\bar{y} \mathbf{j})\right]}} \\
& =\frac{\sum_{i=1}^{n}\left(x_{i}-\bar{x}\right)\left(y_{i}-\bar{y}\right)}{\sqrt{\sum_{i=1}^{n}\left(x_{i}-\bar{x}\right)^{2} \sum_{i=1}^{n}\left(y_{i}-\bar{y}\right)^{2}}}  \tag{3.15}\\
& =r_{x y} .
\end{align*}
\]

Thus if the angle \(\theta\) between the two centered vectors \(\mathbf{x}-\bar{x} \mathbf{j}\) and \(\mathbf{y}-\bar{y} \mathbf{j}\) is small so that \(\cos \theta\) is near \(1, r_{x y}\) will be close to 1 . If the two vectors are perpendicular, \(\cos \theta\) and \(r_{x y}\) will be zero. If the two vectors have nearly opposite directions, \(r_{x y}\) will be close to -1 .

\section*{- EXAMPLE 3.2.2}

To obtain the correlation for the height and weight data of Table 3.1, we first calculate the sample variance of \(x\) :

Figure 3.5 Bivariate scatterplot of the data in Figure 3.1.
\[
\begin{aligned}
s_{x}^{2} & =\frac{\sum_{i=1}^{n} x_{i}^{2}-n \bar{x}^{2}}{n-1} \\
& =\frac{102,379-(20)(71.45)^{2}}{19}=14.576 .
\end{aligned}
\]

Then \(s_{x}=\sqrt{14.576}=3.8179\) and, similarly, \(s_{y}=37.964\). By (3.13), we have
\[
r_{x y}=\frac{s_{x y}}{s_{x} s_{y}}=\frac{128.88}{(3.8179)(37.964)}=.889 .
\]

\subsection*{3.3 SCATTERPLOTS OF BIVARIATE SAMPLES}

Figures 3.2 and 3.3 are examples of scatterplots of bivariate samples. In Figure 3.1, the two variables \(x\) and \(y\) were plotted separately for the data in Table 3.1. Figure 3.5 shows a bivariate scatterplot of the same data.

If the origin is shifted to \((\bar{x}, \bar{y})\), as indicated by the dashed lines, then the first and third quadrants contain most of the points. Scatterplots for correlated data typically show a substantial positive or negative slope.

A hypothetical sample of the uncorrelated variables height and IQ is shown in Figure 3.6. We could change the shape of the swarm of points by altering the scale on either axis. But because of the independence assumed for these variables, each

Figure 3.6 A sample of data from a population where \(x\) and \(y\) are uncorrelated.
quadrant is likely to have as many points as any other quadrant. A tall person is as likely to have a high IQ as a low IQ. A person of low IQ is as likely to be short as to be tall.

\subsection*{3.4 GRAPHICAL DISPLAYS FOR MULTIVARIATE SAMPLES}

It is a relatively simple procedure to plot bivariate samples as in Section 3.3. The position of a point shows at once the value of both variables. However, for three or more variables it is a challenge to show graphically the values of all the variables in an observation vector \(y\). On a two-dimensional plot, the value of a third variable could be indicated by color or intensity or size of the plotted point. Four dimensions might be represented by starting with a two-dimensional scatterplot and adding two additional dimensions as line segments at right angles, as in Figure 3.7. The "corner point" represents \(y_{1}\) and \(y_{2}\), whereas \(y_{3}\) and \(y_{4}\) are given by the lengths of the two line segments.

We will now describe various methods proposed for representing \(p\) dimensions in a plot of an observation vector, where \(p>2\).

Profiles represent each point by \(p\) vertical bars, with the heights of the bars depicting the values of the variables. Sometimes the profile is outlined by a polygonal line rather than bars.

Figure 3.7 Four-dimensional plot.

Stars portray the value of each (normalized) variable as a point along a ray from the center to the outside of a circle. The points on the rays are usually joined to form a polygon.

Glyphs (Anderson 1960) are circles of fixed size with rays whose lengths represent the values of the variables. Anderson suggested using only three lengths of rays, thus rounding the variable values to three levels.

Faces (Chernoff 1973) depict each variable as a feature on a face, such as length of nose, size of eyes, shape of eyes, and so on. Flury and Riedwyl (1981) suggested using asymmetric faces, thus increasing the number of representable variables.

Boxes (Hartigan 1975b) show each variable as the length of a dimension of a box. For more than three variables, the dimensions are partitioned into segments.

Among these five methods, Chambers and Kleiner (1982) prefer the star plots because they "combine a reasonably distinctive appearance with computational simplicity and ease of interpretation." Commenting on the other methods, they state, "Profiles are not so easy to compare as a general shape. Faces are memorable but they are more complex to draw and one must be careful in assigning variables to parameters and in choosing parameter ranges. Faces to some extent disguise the data in the sense that individual data values may not be directly comparable from the plot."

Table 3.2 Percentage of Republican Votes in Presidential Elections in Six Southern States for Selected Years
\begin{tabular}{lrrrccc}
\hline State & 1932 & 1936 & 1940 & 1960 & 1964 & 1968 \\
\hline Missouri & 35 & 38 & 48 & 50 & 36 & 45 \\
Maryland & 36 & 37 & 41 & 46 & 35 & 42 \\
Kentucky & 40 & 40 & 42 & 54 & 36 & 44 \\
Louisiana & 7 & 11 & 14 & 29 & 57 & 23 \\
Mississippi & 4 & 3 & 4 & 25 & 87 & 14 \\
South Carolina & 2 & 1 & 4 & 49 & 59 & 39 \\
\hline
\end{tabular}

\section*{E EXAMPLE 3.4}

The data in Table 3.2 are from Kleiner and Hartigan (1981). For these data, the preceding five graphical devices are illustrated in Figure 3.8. The relative magnitudes of the variables can be compared more readily using stars or profiles than faces.

\subsection*{3.5 DYNAMIC GRAPHICS}

In the previous section, we discussed several methods for static graphical displays. Over the past 25 years, there have been several new methods for visualization of multivariate data that employ computer animation and/or interactive approaches. Because these approaches have profoundly affected the world of statistical graphics, we discuss some dynamic graphics tools here.

For bivariate data, visualization of a data set is fairly straightforward with the standard scatterplot that shows the location of each observation in a two-dimensional space. For \(p\)-dimensional data, the problem is much more challenging because there is no simple way to show the locations of objects (observation vectors) in an arbitrarily large \(p\)-dimensional space. Finding ways to easily digest the "shape" of a high-dimensional data set is one of the primary goals of dynamic graphical methods. Of great importance is the use of low-dimensional projections of high-dimensional data. For example, we can create a two-dimensional projection (or "shadow") of an \(n \times p\) data matrix \(\mathbf{X}\) by post-multiplying it by a \(p \times 2\) projection matrix \(\mathbf{A}\).

The grand tour of a data set is a set of random projections of the data with a smooth interpolation between projections via intermediate projection matrices (Cook and Swayne, 2007; Asimov, 1985; Buja, Cook, Asimov, and Hurley, 2005). Most commonly, the data set is projected onto a two-dimensional space. When the projections are viewed in sequence as a movie, we see the data points so that the series of projections resembles a swarm of insects. The nature of the movements of the data swarm can provide profound insights about the essential dimensionality of the data as well as the existence of outliers or clusters of observations. Algorithms for the grand tour have been implemented in software packages such as ggobi (Swayne,
PROFILES 50 MASYLAND

Figure 3.8 Profiles, stars, glyphs, faces, and boxes of percentage of Republican votes in six presidential elections in six southern states. The radius of the circles in the stars is \(50 \%\). Assignments of variables to facial features are 1932, shape of face; 1936, length of nose; 1940, curvature of mouth; 1960, width of mouth; 1964, slant of eyes; and 1968, length of eyebrows. (From the Journal of the American Statistical Association, 1981, p. 262.)

Temple Lang, Buja, and Cook, 2003; Cook and Swayne, 2007) and R (Wickham, Cook, Hofmann, and Buja, 2011; R Development Core Team, 2010).

Interactive methods such as linked brushing of scatterplots and/or parallel coordinates plots have also proven to yield unique insights about the nature of a data set. For each of the \(n\) observations in the data set, the parallel coordinates plot (Inselberg, 1985; Wegman, 1990) places the \(p\) variables at equal intervals along one axis and on the other axis plots the scaled value of each variable as a dot. The \(p\) dots for a given observation are then connected to form a multi-segment line. If the variables are time points, this plot is identical to the profile plots used in Section 6.8. (For example, see Figure 6.3.) These plots are useful in illustrating the general correlation structure and highlighting those outliers that do not conform to the typical structure.

In linked brushing, multiple plots of a data set are connected (e.g., two scatterplots are linked together or a scatterplot is linked to a parallel coordinates plot). Observations of interest in one plot are manually "brushed" to change the observations' appearance. In a scatterplot, the brush will change the points' color or glyph (symbol). In a parallel coordinates plot, the brush will change the lines' color or line type. The power of linked brushing is that the same observations in the linked plots will be
appropriately altered, allowing the user to thoroughly explore the nature of outliers and the multidimensional dependencies among variables in the data set. While the static graphical methods discussed in Section 3.4 can illuminate many of the fundamental properties of a data set, dynamic graphics and linked brushing often provide additional insights about complex and often nonlinear relationships among variables.

\section*{- EXAMPLE 3.5}

The data set in Table 3.3 contains yield and soil quality measurements at each of 215 locations in a 16-hectare field. The Baker field (Colvin et al., 1997) consists of 8 transects ( \(y\) ) with 28 locations ( \(x\) ) on each transect. The first transect ( \(y=1\) ) lies along the southern boundary of the field, and the last transect ( \(y=8\) ) lies along the northern boundary, with rows roughly 48 meters apart. The locations within a transect run from west \((x=1)\) to east \((x=28)\) and are approximately 12.2 meters apart. Data at nine of the locations in the 8 by 28 layout are missing. At each location, the data set consists of corn yield in bushels per acre for 1997 (Corn97BU) and richness of 10 soil nutrients in parts per million ( \(\mathrm{B}, \mathrm{Ca}, \mathrm{Cu}, \mathrm{Fe}, \mathrm{K}, \mathrm{Mg}, \mathrm{Mn}, \mathrm{Na}, \mathrm{P}\), and Zn ).

We begin by considering a grand tour of the 10 soil richness variables. In the tour, we observe that many (but not all) of the projections indicate collinearity in the data [compare panels (a) and (b) of Figure 3.9 with panel (c) of the same figure]. Also apparent in a large of number of the projections observed during the grand tour is the presence of several outliers. By brushing the five outliers, we change the points from dots to X's. Linking the grand tour to a scatterplot of \(x\) (location within transect) versus \(y\) (transect) in Figure 3.9(d), we note that the 5 outliers are clustered near the western end of the fourth and fifth transect, which corresponds to a low elevation point in the field (Colvin et al., 1997). Linking these locations to a parallel coordinates plot of the soil richness measures (Figure 3.10), we note the ways in which the profiles for the five outliers deviate from the typical profile. Specifically, the outliers are characterized by unusually high amounts of \(\mathrm{Ca}, \mathrm{Mg}\), and Na coupled with comparatively low amounts of Fe .

To further illustrate the complicated dependence structures that can be decoded using linked brushing, consider the linked plots in Figure 3.11. Panel (a) of this figure gives a dotplot of Ca with random jitter added in the horizontal direction for ease of visualization. Panel (b) plots \(\log (\mathrm{Fe})\) against \(\log\) (yield) (i.e., \(\log\) of Corn97BU) and indicates a pronounced nonlinear relationship between these variables. By brushing the highest values of Ca , we uncover a complicated dependency between Fe and yield. When Ca is high, the linear relationship between \(\log (\mathrm{Fe})\) and \(\log\) (yield) is very weak. However, among low-Ca measurements, the linear relationship between \(\log (\mathrm{Fe})\) and \(\log\) (yield) is a relatively strong positive one.

Table 3.3 Baker Corn Field Measurements of Yield and Soil Richness
\begin{tabular}{|c|c|c|c|c|c|c|c|c|c|c|c|c|}

\hline
\end{tabular}

Figure 3.9 Grand tour of the soil richness measurements in Table 3.3. Panels (a), (b), and (c) show three different projections observed during the grand tour, and panel (d) indicates the geographic locations of the five outliers discovered by the grand tour and brushed to become \(X\) 's instead of dots.

Figure 3.10 Parallel coordinates plot of the soil richness measurements in Table 3.3. Highlighted lines are linked to the points denoted as outliers in Figure 3.9.

Figure 3.11 Linked and brushed plots of the Baker field data in Table 3.3. The dotplot of Ca in panel (a) is linked to the scatterplot of \(\log (\mathrm{Fe})\) versus \(\log (\mathrm{yield})\) in panel (b), with the points associated with high Ca brushed to appear as X's.

\subsection*{3.6 MEAN VECTORS}

It is a common practice in many texts to use an uppercase letter for a variable name and the corresponding lowercase letter for a particular value or observed value of the random variable, for example, \(P(Y>y)\). This notation is convenient in some univariate contexts, but it is often confusing in multivariate analysis, where we use uppercase letters for matrices. In the belief that it is easier to distinguish between a
random vector and an observed value than between a vector and a matrix, throughout this text we follow the notation established in Chapter 2. Uppercase boldface letters are used for matrices of random variables or constants, lowercase boldface letters represent vectors of random variables or constants, and univariate random variables or constants are usually represented by lowercase nonbolded letters.

Let \(\mathbf{y}\) represent a random vector of \(p\) variables measured on a sampling unit (subject or object). If there are \(n\) individuals in the sample, the \(n\) observation vectors are denoted by \(\mathbf{y}_{1}, \mathbf{y}_{2}, \ldots, \mathbf{y}_{n}\), where
\[
\mathbf{y}_{i}=\left(\begin{array}{c}
y_{i 1} \\
y_{i 2} \\
\vdots \\
y_{i p}
\end{array}\right) .
\]

The sample mean vector \(\overline{\mathbf{y}}\) can be found either as the average of the \(n\) observation vectors or by calculating the average of each of the \(p\) variables separately:
\[
\overline{\mathbf{y}}=\frac{1}{n} \sum_{i=1}^{n} \mathbf{y}_{i}=\left(\begin{array}{c}
\bar{y}_{1}  \tag{3.16}\\
\bar{y}_{2} \\
\vdots \\
\bar{y}_{p}
\end{array}\right)
\]
where, for example, \(\bar{y}_{2}=\sum_{i=1}^{n} y_{i 2} / n\). Thus \(\bar{y}_{1}\) is the mean of the \(n\) observations on the first variable, \(\bar{y}_{2}\) is the mean of the second variable, and so on.

All \(n\) observation vectors \(\mathbf{y}_{1}, \mathbf{y}_{2}, \ldots, \mathbf{y}_{n}\) can be transposed to row vectors and listed in the data matrix \(\mathbf{Y}\) as follows:
\[
\begin{align*}
& \text { (variables) } \\
& \begin{array}{llll}
1 & 2 & j & p
\end{array} \\
& \mathbf{Y}=\left(\begin{array}{c}
\mathbf{y}_{1}^{\prime} \\
\mathbf{y}_{2}^{\prime} \\
\vdots \\
\mathbf{y}_{i}^{\prime} \\
\vdots \\
\mathbf{y}_{n}^{\prime}
\end{array}\right)=\text { (units) } \begin{array}{l}
1 \\
i
\end{array}\left(\begin{array}{cccccc}
y_{11} & y_{12} & \cdots & y_{1 j} & \cdots & y_{1 p} \\
y_{21} & y_{22} & \cdots & y_{2 j} & \cdots & y_{2 p} \\
\vdots & \vdots & & \vdots & & \vdots \\
y_{i 1} & y_{i 2} & \cdots & y_{i j} & \cdots & y_{i p} \\
\vdots & \vdots & & \vdots & & \vdots \\
y_{n 1} & y_{n 2} & \cdots & y_{n j} & \cdots & y_{n p}
\end{array}\right) . \tag{3.17}
\end{align*}
\]

Since \(n\) is usually greater than \(p\), the data can be more conveniently tabulated by entering the observation vectors as rows rather than columns. Note that the first subscript \(i\) corresponds to units (subjects or objects) and the second subscript \(j\) refers to variables. This convention will be followed whenever possible.

In addition to the two ways of calculating \(\overline{\mathbf{y}}\) given in (3.16), we can obtain \(\overline{\mathbf{y}}\) from \(\mathbf{Y}\). We sum the \(n\) entries in each column of \(\mathbf{Y}\) and divide by \(n\), which gives \(\overline{\mathbf{y}}^{\prime}\). This
can be indicated in matrix notation using (2.38),
\[
\begin{equation*}
\overline{\mathbf{y}}^{\prime}=\frac{1}{n} \mathbf{j}^{\prime} \mathbf{Y} \tag{3.18}
\end{equation*}
\]
where \(\mathbf{j}^{\prime}\) is a vector of l's, as defined in (2.11). For example, the second element of \(\mathbf{j}^{\prime} \mathbf{Y}\) is
\[
(1,1, \ldots, 1)\left(\begin{array}{c}
y_{12} \\
y_{22} \\
\vdots \\
y_{n 2}
\end{array}\right)=\sum_{i=1}^{n} y_{i 2}
\]

We can transpose (3.18) to obtain
\[
\begin{equation*}
\overline{\mathbf{y}}=\frac{1}{n} \mathbf{Y}^{\prime} \mathbf{j} . \tag{3.19}
\end{equation*}
\]

We now turn to populations. The mean of \(y\) over all possible values in the population is called the population mean vector or expected value of \(\mathbf{y}\). It is defined as a vector of expected values of each variable,
\[
E(\mathbf{y})=E\left(\begin{array}{c}
y_{1}  \tag{3.20}\\
y_{2} \\
\vdots \\
y_{p}
\end{array}\right)=\left(\begin{array}{c}
E\left(y_{1}\right) \\
E\left(y_{2}\right) \\
\vdots \\
E\left(y_{p}\right)
\end{array}\right)=\left(\begin{array}{c}
\mu_{1} \\
\mu_{2} \\
\vdots \\
\mu_{p}
\end{array}\right)=\boldsymbol{\mu}
\]
where \(\mu_{j}\) is the population mean of the \(j\) th variable.
It can be shown that the expected value of each \(\bar{y}_{j}\) in \(\overline{\mathbf{y}}\) is \(\mu_{j}\), that is, \(E\left(\bar{y}_{j}\right)=\mu_{j}\). Thus the expected value of \(\overline{\mathbf{y}}\) (over all possible samples) is
\[
E(\overline{\mathbf{y}})=E\left(\begin{array}{c}
\bar{y}_{1}  \tag{3.21}\\
\bar{y}_{2} \\
\vdots \\
\bar{y}_{p}
\end{array}\right)=\left(\begin{array}{c}
E\left(\bar{y}_{1}\right) \\
E\left(\bar{y}_{2}\right) \\
\vdots \\
E\left(\bar{y}_{p}\right)
\end{array}\right)=\left(\begin{array}{c}
\mu_{1} \\
\mu_{2} \\
\vdots \\
\mu_{p}
\end{array}\right)=\boldsymbol{\mu} .
\]

Therefore, \(\overline{\mathbf{y}}\) is an unbiased estimator of \(\boldsymbol{\mu}\). We emphasize again that \(\overline{\mathbf{y}}\) is never equal to \(\mu\).

\section*{- EXAMPLE 3.6}

Table 3.4 gives partial data from Kramer and Jensen (1969a). Three variables were measured (in milliequivalents per 100 g ) at 10 different locations in the South. The variables are
\[
\begin{aligned}
& y_{1}=\text { available soil calcium } \\
& y_{2}=\text { exchangeable soil calcium } \\
& y_{3}=\text { turnip green calcium }
\end{aligned}
\]

Table 3.4 Calcium in Soil and Turnip Greens
\begin{tabular}{crrc}
\hline \begin{tabular}{c} 
Location \\
Number
\end{tabular} & \(y_{1}\) & \multicolumn{1}{c}{\(y_{2}\)} & \(y_{3}\) \\
\hline 1 & 35 & 3.5 & 2.80 \\
2 & 35 & 4.9 & 2.70 \\
3 & 40 & 30.0 & 4.38 \\
4 & 10 & 2.8 & 3.21 \\
5 & 6 & 2.7 & 2.73 \\
6 & 20 & 2.8 & 2.81 \\
7 & 35 & 4.6 & 2.88 \\
8 & 35 & 10.9 & 2.90 \\
9 & 35 & 8.0 & 3.28 \\
10 & 30 & 1.6 & 3.20 \\
\hline
\end{tabular}

To find the mean vector \(\bar{y}\), we simply calculate the average of each column and obtain
\[
\overline{\mathbf{y}}^{\prime}=(28.1,7.18,3.089) .
\]

\subsection*{3.7 COVARIANCE MATRICES}

The sample covariance matrix \(\mathbf{S}=\left(s_{j k}\right)\) is the matrix of sample variances and covariances of the \(p\) variables:
\[
\mathbf{S}=\left(s_{j k}\right)=\left(\begin{array}{cccc}
s_{11} & s_{12} & \ldots & s_{1 p}  \tag{3.22}\\
s_{21} & s_{22} & \ldots & s_{2 p} \\
\vdots & \vdots & & \vdots \\
s_{p 1} & s_{p 2} & \ldots & s_{p p}
\end{array}\right) .
\]

In \(\mathbf{S}\) the sample variances of the \(p\) variables are on the diagonal, and all possible pairwise sample covariances appear off the diagonal. The \(j\) th row (column) contains the covariances of \(y_{j}\) with the other \(p-1\) variables.

We give three approaches to obtaining \(\mathbf{S}\). The first of these is to simply calculate the individual elements \(s_{j k}\). The sample variance of the \(j\) th variable, \(s_{j j}=s_{j}^{2}\), is calculated as in (3.4) and (3.5), using the \(j\) th column of \(\mathbf{Y}\) :
\[
\begin{align*}
s_{j j}=s_{j}^{2} & =\frac{1}{n-1} \sum_{i=1}^{n}\left(y_{i j}-\bar{y}_{j}\right)^{2}  \tag{3.23}\\
& =\frac{1}{n-1}\left(\sum_{i} y_{i j}^{2}-n \bar{y}_{j}^{2}\right), \tag{3.24}
\end{align*}
\]
where \(\bar{y}_{j}\) is the mean of the \(j\) th variable, as in (3.16). The sample covariance of the \(j\) th and \(k\) th variables, \(s_{j k}\), is calculated as in (3.9) or (3.10), using the \(j\) th and \(k\) th columns of \(\mathbf{Y}\) :
\[
\begin{align*}
s_{j k} & =\frac{1}{n-1} \sum_{i=1}^{n}\left(y_{i j}-\bar{y}_{j}\right)\left(y_{i k}-\bar{y}_{k}\right)  \tag{3.25}\\
& =\frac{1}{n-1}\left(\sum_{i} y_{i j} y_{i k}-n \bar{y}_{j} \bar{y}_{k}\right) . \tag{3.26}
\end{align*}
\]

Note that in (3.23) the variance \(s_{j j}\) is expressed as \(s_{j}^{2}\), the square of the standard deviation \(s_{j}\), and that \(\mathbf{S}\) is symmetric because \(s_{j k}=s_{k j}\) in (3.25). Other names used for the covariance matrix are variance matrix, variance-covariance matrix, and dispersion matrix.

By way of notational clarification, we note that in the univariate case, the sample variance is denoted by \(s^{2}\). But in the multivariate case, we denote the sample covariance matrix as \(\mathbf{S}\), not as \(\mathbf{S}^{2}\).

The sample covariance matrix \(\mathbf{S}\) can also be expressed in terms of the observation vectors:
\[
\begin{align*}
\mathbf{S} & =\frac{1}{n-1} \sum_{i=1}^{n}\left(\mathbf{y}_{i}-\overline{\mathbf{y}}\right)\left(\mathbf{y}_{i}-\overline{\mathbf{y}}\right)^{\prime}  \tag{3.27}\\
& =\frac{1}{n-1}\left(\sum_{i=1}^{n} \mathbf{y}_{i} \mathbf{y}_{i}^{\prime}-n \overline{\mathbf{y}} \overline{\mathbf{y}}^{\prime}\right) . \tag{3.28}
\end{align*}
\]

Since \(\left(\mathbf{y}_{i}-\overline{\mathbf{y}}\right)^{\prime}=\left(y_{i 1}-\bar{y}_{1}, y_{i 2}-\bar{y}_{2}, \ldots, y_{i p}-\bar{y}_{p}\right)\), the element in the ( 1,1 ) position of \(\left(\mathbf{y}_{i}-\overline{\mathbf{y}}\right)\left(\mathbf{y}_{i}-\overline{\mathbf{y}}\right)^{\prime}\) is \(\left(y_{i 1}-\bar{y}_{1}\right)^{2}\), and when this is summed over \(i\) as in (3.27), the result is the numerator of \(s_{11}\) in (3.23). Similarly, the (1,2) element of \(\left(\mathbf{y}_{i}-\overline{\mathbf{y}}\right)\left(\mathbf{y}_{i}-\overline{\mathbf{y}}\right)^{\prime}\) is \(\left(y_{i 1}-\bar{y}_{1}\right)\left(y_{i 2}-\bar{y}_{2}\right)\), which sums to the numerator of \(s_{12}\) in (3.25). Thus (3.27) is equivalent to (3.23) and (3.25), and likewise (3.28) produces (3.24) and (3.26).

We can also obtain \(\mathbf{S}\) directly from the data matrix \(\mathbf{Y}\) in (3.17), which provides a third approach. The first term in the right side of (3.26), \(\sum_{i} y_{i j} y_{i k}\), is the product of the \(j\) th and \(k\) th columns of \(\mathbf{Y}\), whereas the second term, \(n \bar{y}_{j} \bar{y}_{k}\), is the \((j k)\) th element of \(n \overline{\mathbf{y}} \overline{\mathbf{y}}^{\prime}\). It was noted in (2.54) that \(\mathbf{Y}^{\prime} \mathbf{Y}\) is obtained as products of columns of \(\mathbf{Y}\). By (3.18) and (3.19), \(\overline{\mathbf{y}}=\mathbf{Y}^{\prime} \mathbf{j} / n\) and \(\overline{\mathbf{y}}^{\prime}=\mathbf{j}^{\prime} \mathbf{Y} / n\); and using (2.36), we have \(n \overline{\mathbf{y}} \overline{\mathbf{y}}^{\prime}=\mathbf{Y}^{\prime}(\mathbf{J} / n) \mathbf{Y}\). Thus \(\mathbf{S}\) can be written as
\[
\begin{align*}
\mathbf{S} & =\frac{1}{n-1}\left[\mathbf{Y}^{\prime} \mathbf{Y}-\mathbf{Y}^{\prime}\left(\frac{1}{n} \mathbf{J}\right) \mathbf{Y}\right] \\
& =\frac{1}{n-1} \mathbf{Y}^{\prime}\left(\mathbf{I}-\frac{1}{n} \mathbf{J}\right) \mathbf{Y} \quad[\text { by }(2.30)] . \tag{3.29}
\end{align*}
\]

Expression (3.29) is a convenient representation of \(\mathbf{S}\), since it makes direct use of the data matrix \(\mathbf{Y}\). However, the matrix \(\mathbf{I}-\mathbf{J} / n\) is \(n \times n\) and may be unwieldy in computation if \(n\) is large.

If \(\mathbf{y}\) is a random vector taking on any possible value in a multivariate population, the population covariance matrix is defined as
\[
\boldsymbol{\Sigma}=\operatorname{cov}(\mathbf{y})=\left(\begin{array}{cccc}
\sigma_{11} & \sigma_{12} & \cdots & \sigma_{1 p}  \tag{3.30}\\
\sigma_{21} & \sigma_{22} & \cdots & \sigma_{2 p} \\
\vdots & \vdots & & \vdots \\
\sigma_{p 1} & \sigma_{p 2} & \cdots & \sigma_{p p}
\end{array}\right)
\]

The diagonal elements \(\sigma_{j j}=\sigma_{j}^{2}\) are the population variances of the \(y\) 's, and the off-diagonal elements \(\sigma_{j k}\) are the population covariances of all possible pairs of \(y\) 's.

The notation \(\boldsymbol{\Sigma}\) for the covariance matrix is widely used and seems natural because \(\boldsymbol{\Sigma}\) is the uppercase version of \(\sigma\). It should not be confused with the same symbol used for summation of a series. The difference should always be apparent from the context. To help further distinguish the two uses, the covariance matrix \(\boldsymbol{\Sigma}\) will differ in typeface and in size from the summation symbol \(\sum\). Also, whenever they appear together, the summation symbol will have an index of summation, such as \(\sum_{i=1}^{n}\).

The population covariance matrix in (3.30) can also be found as
\[
\begin{equation*}
\mathbf{\Sigma}=E\left[(\mathbf{y}-\boldsymbol{\mu})(\mathbf{y}-\boldsymbol{\mu})^{\prime}\right], \tag{3.31}
\end{equation*}
\]
which is analogous to (3.27) for the sample covariance matrix. The \(p \times p\) matrix \((\mathbf{y}-\boldsymbol{\mu})(\mathbf{y}-\boldsymbol{\mu})^{\prime}\) is a random matrix. The expected value of a random matrix is defined as the matrix of expected values of the corresponding elements. To see that (3.31) produces population variances and covariances of the \(p\) variables as in (3.30), note that
\[
\begin{aligned}
\boldsymbol{\Sigma} & =E\left[(\mathbf{y}-\boldsymbol{\mu})(\mathbf{y}-\boldsymbol{\mu})^{\prime}\right]=E\left(\begin{array}{c}
y_{1}-\mu_{1} \\
y_{2}-\mu_{2} \\
\vdots \\
y_{p}-\mu_{p}
\end{array}\right)\left(y_{1}-\mu_{1}, y_{2}-\mu_{2}, \ldots, y_{p}-\mu_{p}\right) \\
& =E\left(\begin{array}{cccc}
\left(y_{1}-\mu_{1}\right)^{2} & \left(y_{1}-\mu_{1}\right)\left(y_{2}-\mu_{2}\right) & \cdots & \left(y_{1}-\mu_{1}\right)\left(y_{p}-\mu_{p}\right) \\
\left(y_{2}-\mu_{2}\right)\left(y_{1}-\mu_{1}\right) & \left(y_{2}-\mu_{2}\right)^{2} & \cdots & \left(y_{2}-\mu_{2}\right)\left(y_{p}-\mu_{p}\right) \\
\vdots & \vdots & & \vdots \\
\left(y_{p}-\mu_{p}\right)\left(y_{1}-\mu_{1}\right) & \left(y_{p}-\mu_{p}\right)\left(y_{2}-\mu_{2}\right) & \cdots & \left(y_{p}-\mu_{p}\right)^{2}
\end{array}\right) \\
& =\left(\begin{array}{cccc}
E\left(y_{1}-\mu_{1}\right)^{2} & E\left(y_{1}-\mu_{1}\right)\left(y_{2}-\mu_{2}\right) & \cdots & E\left(y_{1}-\mu_{1}\right)\left(y_{p}-\mu_{p}\right) \\
E\left(y_{2}-\mu_{2}\right)\left(y_{1}-\mu_{1}\right) & E\left(y_{2}-\mu_{2}\right)^{2} & \cdots & E\left(y_{2}-\mu_{2}\right)\left(y_{p}-\mu_{p}\right) \\
\vdots & \vdots & & \vdots \\
E\left(y_{p}-\mu_{p}\right)\left(y_{1}-\mu_{1}\right) & E\left(y_{p}-\mu_{p}\right)\left(y_{2}-\mu_{2}\right) & \cdots & E\left(y_{p}-\mu_{p}\right)^{2}
\end{array}\right) \\
& =\left(\begin{array}{ccc}
\begin{array}{c}
\sigma_{11} \\
\sigma_{12} \\
\sigma_{21} \\
\sigma_{22}
\end{array} \cdots & \sigma_{1 p} \\
\vdots & \vdots & \\
\sigma_{2 p} \\
\sigma_{p 1} & \sigma_{p 2} & \cdots \\
\sigma_{p p}
\end{array}\right) .
\end{aligned}
\]

It can be easily shown that \(\Sigma\) can be expressed in a form analogous to (3.28):
\[
\begin{equation*}
\boldsymbol{\Sigma}=E\left(\mathbf{y} \mathbf{y}^{\prime}\right)-\boldsymbol{\mu} \boldsymbol{\mu}^{\prime} . \tag{3.32}
\end{equation*}
\]

Since \(E\left(s_{j k}\right)=\sigma_{j k}\) for all \(j, k\), the sample covariance matrix \(\mathbf{S}\) is an unbiased estimator for \(\boldsymbol{\Sigma}\) :
\[
\begin{equation*}
E(\mathbf{S})=\mathbf{\Sigma} . \tag{3.33}
\end{equation*}
\]

As in the univariate case, we note that it is the average of all possible values of \(S\) that is equal to \(\boldsymbol{\Sigma}\). Generally, \(S\) will never be equal to \(\boldsymbol{\Sigma}\).

\section*{EXAMPLE 3.7}

To calculate the sample covariance matrix for the calcium data of Table 3.4 using the computational forms (3.24) and (3.26), we need the sum of squares of each column and the sum of products of each pair of columns. We illustrate the computation of \(s_{13}\).
\[
\sum_{i=1}^{10} y_{i 1} y_{i 3}=(35)(2.80)+(35)(2.70)+\cdots+(30)(3.20)=885.48
\]

From Example 3.6 we have \(\bar{y}_{1}=28.1\) and \(\bar{y}_{3}=3.089\). By (3.26), we obtain
\[
s_{13}=\frac{1}{10-1}[885.48-10(28.1)(3.089)]=\frac{17.471}{9}=1.9412 .
\]

Continuing in this fashion, we obtain
\[
\mathbf{S}=\left(\begin{array}{rrr}
140.54 & 49.68 & 1.94 \\
49.68 & 72.25 & 3.68 \\
1.94 & 3.68 & .25
\end{array}\right)
\]

\subsection*{3.8 CORRELATION MATRICES}

The sample correlation between the \(j\) th and \(k\) th variables is defined in (3.13) as
\[
\begin{equation*}
r_{j k}=\frac{s_{j k}}{\sqrt{s_{j j} s_{k k}}}=\frac{s_{j k}}{s_{j} s_{k}} . \tag{3.34}
\end{equation*}
\]

The sample correlation matrix is analogous to the covariance matrix with correlations in place of covariances:
\[
\mathbf{R}=\left(r_{j k}\right)=\left(\begin{array}{cccc}
1 & r_{12} & \cdots & r_{1 p}  \tag{3.35}\\
r_{21} & 1 & \cdots & r_{2 p} \\
\vdots & \vdots & & \vdots \\
r_{p 1} & r_{p 2} & \cdots & \mathbf{1}
\end{array}\right) .
\]

The second row, for example, contains the correlation of \(y_{2}\) with each of the \(y\) 's (including the correlation of \(y_{2}\) with itself, which is 1 ). Of course, the matrix \(\mathbf{R}\) is symmetric, since \(r_{j k}=r_{k j}\).

The correlation matrix can be obtained from the covariance matrix and vice versa. Define
\[
\begin{align*}
\mathbf{D}_{s} & =\operatorname{diag}\left(\sqrt{s_{11}}, \sqrt{s_{22}}, \ldots, \sqrt{s_{p p}}\right) \\
& =\operatorname{diag}\left(s_{1}, s_{2}, \ldots, s_{p}\right) \\
& =\left(\begin{array}{cccc}
s_{1} & 0 & \cdots & 0 \\
0 & s_{2} & \cdots & 0 \\
\vdots & \vdots & & \vdots \\
0 & 0 & \cdots & s_{p}
\end{array}\right) . \tag{3.36}
\end{align*}
\]

Then by (2.57)
\[
\begin{align*}
\mathbf{R} & =\mathbf{D}_{s}^{-1} \mathbf{S D}_{s}^{-1}  \tag{3.37}\\
\mathbf{S} & =\mathbf{D}_{s} \mathbf{R} \mathbf{D}_{s} \tag{3.38}
\end{align*}
\]

The population correlation matrix analogous to (3.35) is defined as
\[
\mathbf{P}_{\rho}=\left(\rho_{j k}\right)=\left(\begin{array}{cccc}
1 & \rho_{12} & \cdots & \rho_{1 p}  \tag{3.39}\\
\rho_{21} & 1 & \cdots & \rho_{2 p} \\
\vdots & \vdots & & \vdots \\
\rho_{p 1} & \rho_{p 2} & \cdots & 1
\end{array}\right)
\]
where
\[
\rho_{j k}=\frac{\sigma_{j k}}{\sigma_{j} \sigma_{k}}
\]
as in (3.12).

\section*{- EXAMPLE 3.8}

In Example 3.7, we obtained the sample covariance matrix \(\mathbf{S}\) for the calcium data in Table 3.4. To obtain the sample correlation matrix for the same data, we can calculate the individual elements using (3.34) or use the direct matrix operation in (3.37). The diagonal matrix \(\mathbf{D}_{s}\) can be found by taking the square roots of the diagonal elements of \(S\),
\[
\mathbf{D}_{s}=\left(\begin{array}{ccc}
11.8551 & 0 & 0 \\
0 & 8.4999 & 0 \\
0 & 0 & .5001
\end{array}\right)
\]
(note that we have used the unrounded version of \(S\) for computation). Then by (3.37),
\[
\mathbf{R}=\mathbf{D}_{s}^{-1} \mathbf{S D}_{s}^{-1}=\left(\begin{array}{rrr}
1.000 & .493 & .327 \\
.493 & 1.000 & .865 \\
.327 & .865 & 1.000
\end{array}\right)
\]

Note that \(.865>.493>.327\), which is a different order than that of the covariances in \(\mathbf{S}\) in Example 3.7. Thus we cannot compare covariances, even within the same matrix \(\mathbf{S}\).

\subsection*{3.9 MEAN VECTORS AND COVARIANCE MATRICES FOR SUBSETS OF VARIABLES}

\subsection*{3.9.1 Two Subsets}

Sometimes a researcher is interested in two different kinds of variables, both measured on the same sampling unit. This corresponds to type 2 data in Section 1.4. For example, several classroom behaviors are observed for students, and during the same time period (the basic experimental unit) several teacher behaviors are also observed. The researcher wishes to study the relationships between the pupil variables and the teacher variables.

We will denote the two subvectors by \(\mathbf{y}\) and \(\mathbf{x}\), with \(p\) variables in \(\mathbf{y}\) and \(q\) variables in \(\mathbf{x}\). Thus each observation vector in a sample is partitioned as
\[
\binom{\mathbf{y}_{i}}{\mathbf{x}_{i}}=\left(\begin{array}{c}
y_{i 1}  \tag{3.40}\\
\vdots \\
y_{i p} \\
x_{i 1} \\
\vdots \\
x_{i q}
\end{array}\right), \quad i=1,2, \ldots, n
\]

Hence there are \(p+q\) variables in each of \(n\) observation vectors. In Chapter 10 we will discuss regression of the \(y\) 's on the \(x\) 's, and in Chapter 11 we will define a measure of correlation between the \(y\) 's and the \(x\) 's.

For the sample of \(n\) observation vectors, the mean vector and covariance matrix have the form
\[
\begin{align*}
\binom{\overline{\mathbf{y}}}{\overline{\mathbf{x}}} & =\left(\begin{array}{c}
\bar{y}_{1} \\
\vdots \\
\bar{y}_{p} \\
\bar{x}_{1} \\
\vdots \\
\bar{x}_{q}
\end{array}\right)  \tag{3.41}\\
\mathbf{S} & =\left(\begin{array}{cc}
\mathbf{S}_{y y} & \mathbf{S}_{y x} \\
\mathbf{S}_{x y} & \mathbf{S}_{x x}
\end{array}\right) \tag{3.42}
\end{align*}
\]
where \(\mathbf{S}_{y y}\) is \(p \times p, \mathbf{S}_{y x}\) is \(p \times q, \mathbf{S}_{x y}\) is \(q \times p\), and \(\mathbf{S}_{x x}\) is \(q \times q\). Note that because of the symmetry of \(S\),
\[
\begin{equation*}
\mathbf{S}_{x y}=\mathbf{S}_{y x}^{\prime} \tag{3.43}
\end{equation*}
\]

Thus (3.42) could be written
\[
\mathbf{S}=\left(\begin{array}{ll}
\mathbf{S}_{y y} & \mathbf{S}_{y x}  \tag{3.44}\\
\mathbf{S}_{y x}^{\prime} & \mathbf{S}_{x x}
\end{array}\right)
\]

To illustrate (3.41) and (3.42), let \(p=2\) and \(q=3\). Then
\[
\begin{gathered}
\binom{\overline{\mathbf{y}}}{\overline{\mathbf{x}}}=\left(\begin{array}{l}
\bar{y}_{1} \\
\bar{y}_{2} \\
\hline \bar{x}_{1} \\
\bar{x}_{2} \\
\bar{x}_{3}
\end{array}\right), \\
\mathbf{S}=\left(\begin{array}{ll}
\mathbf{S}_{y y} & \mathbf{S}_{y x} \\
\mathbf{S}_{x y} & \mathbf{S}_{x x}
\end{array}\right)=\left(\begin{array}{ll|lll}
s_{y_{1}}^{2} & s_{y_{1} y_{2}} & s_{y_{1} x_{1}} & s_{y_{1} x_{2}} & s_{y_{1} x_{3}} \\
s_{y_{2} y_{1}} & s_{y_{2}}^{2} & s_{y_{2} x_{1}} & s_{y_{2} x_{2}} & s_{y_{2} x_{3}} \\
\hline s_{x_{1} y_{1}} & s_{x_{1} y_{2}} & s_{x_{1}}^{2} & s_{x_{1} x_{2}} & s_{x_{1} x_{3}} \\
s_{x_{2} y_{1}} & s_{x_{2} y_{2}} & s_{x_{2} x_{1}} & s_{x_{2}}^{2} & s_{x_{2} x_{3}} \\
s_{x_{3} y_{1}} & s_{x_{3} y_{2}} & s_{x_{3} x_{1}} & s_{x_{3} x_{2}} & s_{x_{3}}^{2}
\end{array}\right) .
\end{gathered}
\]

The pattern in each of \(\mathbf{S}_{y y}, \mathbf{S}_{y x}, \mathbf{S}_{x y}\), and \(\mathbf{S}_{x x}\) is clearly seen in this illustration. For example, the first row of \(\mathbf{S}_{y x}\) has the covariance of \(y_{1}\) with each of \(x_{1}, x_{2}, x_{3}\); the second row exhibits covariances of \(y_{2}\) with the three \(x\) 's. On the other hand, \(\mathbf{S}_{x y}\) has as its first row the covariances of \(x_{1}\) with \(y_{1}\) and \(y_{2}\), and so on. Thus \(\mathbf{S}_{x y}=\mathbf{S}_{y x}^{\prime}\) as noted in (3.43).

The analogous population results for a partitioned random vector are
\[
\begin{align*}
& E\binom{\mathbf{y}}{\mathbf{x}}=\binom{E(\mathbf{y})}{E(\mathbf{x})}=\binom{\boldsymbol{\mu}_{y}}{\boldsymbol{\mu}_{x}},  \tag{3.45}\\
& \operatorname{cov}\binom{\mathbf{y}}{\mathbf{x}}=\mathbf{\Sigma}=\left(\begin{array}{ll}
\boldsymbol{\Sigma}_{y y} & \boldsymbol{\Sigma}_{y x} \\
\boldsymbol{\Sigma}_{x y} & \boldsymbol{\Sigma}_{x x}
\end{array}\right) \tag{3.46}
\end{align*}
\]
where \(\boldsymbol{\Sigma}_{x y}=\boldsymbol{\Sigma}_{y x}^{\prime}\). The submatrix \(\boldsymbol{\Sigma}_{y y}\) is a \(p \times p\) covariance matrix containing the variances of \(y_{1}, y_{2}, \ldots, y_{p}\) on the diagonal and the covariance of each \(y_{j}\) with each \(y_{k}\) off the diagonal. Similarly, \(\boldsymbol{\Sigma}_{x x}\) is the \(q \times q\) covariance matrix of \(x_{1}, x_{2}, \ldots, x_{q}\). The matrix \(\boldsymbol{\Sigma}_{y x}\) is \(p \times q\) and contains the covariance of each \(y_{j}\) with each \(x_{k}\). The covariance matrix \(\boldsymbol{\Sigma}_{y x}\) is also denoted by \(\operatorname{cov}(\mathbf{y}, \mathbf{x})\), that is,
\[
\begin{equation*}
\operatorname{cov}(\mathbf{y}, \mathbf{x})=\boldsymbol{\Sigma}_{y x} \tag{3.47}
\end{equation*}
\]

Note the difference in meaning between \(\operatorname{cov}\binom{\mathbf{y}}{\mathbf{x}}=\boldsymbol{\Sigma}\) in (3.46) and \(\operatorname{cov}(\mathbf{y}, \mathbf{x})=\boldsymbol{\Sigma}_{y x}\) in (3.47); \(\operatorname{cov}\binom{\mathbf{y}}{\mathbf{x}}\) involves a single vector containing \(p+q\) variables, and \(\operatorname{cov}(\mathbf{y}, \mathbf{x})\) involves two vectors.

If \(\mathbf{x}\) and \(\mathbf{y}\) are independent, then \(\boldsymbol{\Sigma}_{y x}=\mathbf{O}\). This means that each \(y_{j}\) is uncorrelated with each \(x_{k}\) so that \(\sigma_{y_{j} x_{k}}=0\) for \(j=1,2, \ldots, p ; k=1,2, \ldots, q\).

\section*{■ EXAMPLE 3.9.1}

Reaven and Miller (1979; see also Andrews and Herzberg 1985, pp. 215-219) measured five variables in a comparison of normal patients and diabetics. In Table 3.5 we give partial data for normal patients only. The three variables of major interest were
\[
\begin{aligned}
& x_{1}=\text { glucose intolerance } \\
& x_{2}=\text { insulin response to oral glucose } \\
& x_{3}=\text { insulin resistance }
\end{aligned}
\]

The two additional variables of minor interest were
\[
\begin{aligned}
& y_{1}=\text { relative weight } \\
& y_{2}=\text { fasting plasma glucose }
\end{aligned}
\]

The mean vector, partitioned as in (3.41), is
\[
\binom{\overline{\mathbf{y}}}{\overline{\mathbf{x}}}=\left(\begin{array}{l}
\bar{y}_{1} \\
\bar{y}_{2} \\
\hline \bar{x}_{1} \\
\bar{x}_{2} \\
\bar{x}_{3}
\end{array}\right)=\left(\begin{array}{r}
.918 \\
90.41 \\
\hline 340.83 \\
171.37 \\
97.78
\end{array}\right) .
\]

The covariance matrix, partitioned as in the illustration following (3.44), is
\[
\begin{aligned}
\mathbf{S} & =\left(\begin{array}{ll}
\mathbf{S}_{y y} & \mathbf{S}_{y x} \\
\mathbf{S}_{x y} & \mathbf{S}_{x x}
\end{array}\right) \\
& =\left(\begin{array}{rr|rrr}
.0162 & .2160 & .7872 & -.2138 & 2.189 \\
.2160 & 70.56 & 26.23 & -23.96 & -20.84 \\
\hline .7872 & 26.23 & 1106 & 396.7 & 108.4 \\
-.2138 & -23.96 & 396.7 & 2382 & 1143 \\
2.189 & -20.84 & 108.4 & 1143 & 2136
\end{array}\right) .
\end{aligned}
\]

Note that \(\mathbf{S}_{y y}\) and \(\mathbf{S}_{x x}\) are symmetric and that \(\mathbf{S}_{x y}\) is the transpose of \(\mathbf{S}_{y x}\).

\subsection*{3.9.2 Three or More Subsets}

In some cases, three or more subsets of variables are of interest. If the observation vector \(\mathbf{y}\) is partitioned as
\[
\mathbf{y}=\left(\begin{array}{c}
\mathbf{y}_{1} \\
\mathbf{y}_{2} \\
\vdots \\
\mathbf{y}_{k}
\end{array}\right)
\]

Table 3.5 Relative Weight, Blood Glucose, and Insulin Levels
\begin{tabular}{crrrrr}
\hline \begin{tabular}{c} 
Patient \\
Number
\end{tabular} & \multicolumn{1}{c}{\(y_{1}\)} & \(y_{2}\) & \(x_{1}\) & \(x_{2}\) & \(x_{3}\) \\
\hline 1 & .81 & 80 & 356 & 124 & 55 \\
2 & .95 & 97 & 289 & 117 & 76 \\
3 & .94 & 105 & 319 & 143 & 105 \\
4 & 1.04 & 90 & 356 & 199 & 108 \\
5 & 1.00 & 90 & 323 & 240 & 143 \\
6 & .76 & 86 & 381 & 157 & 165 \\
7 & .91 & 100 & 350 & 221 & 119 \\
8 & 1.10 & 85 & 301 & 186 & 105 \\
9 & .99 & 97 & 379 & 142 & 98 \\
10 & .78 & 97 & 296 & 131 & 94 \\
11 & .90 & 91 & 353 & 221 & 53 \\
12 & .73 & 87 & 306 & 178 & 66 \\
13 & .96 & 78 & 290 & 136 & 142 \\
14 & .84 & 90 & 371 & 200 & 93 \\
15 & .74 & 86 & 312 & 208 & 68 \\
16 & .98 & 80 & 393 & 202 & 102 \\

19 & .83 & 85 & 296 & 116 & 60 \\
20 & .93 & 90 & 345 & 123 & 50 \\
21 & .95 & 90 & 378 & 136 & 47 \\
22 & .74 & 88 & 304 & 134 & 50 \\
23 & .95 & 95 & 347 & 184 & 91 \\
24 & .97 & 90 & 327 & 192 & 124 \\
25 & .72 & 92 & 386 & 279 & 74 \\
26 & 1.11 & 74 & 365 & 228 & 235 \\
27 & 1.20 & 98 & 365 & 145 & 158 \\
28 & 1.13 & 100 & 352 & 172 & 140 \\
29 & 1.00 & 86 & 325 & 179 & 145 \\
30 & .78 & 98 & 321 & 222 & 99 \\
31 & 1.00 & 70 & 360 & 134 & 90 \\
32 & 1.00 & 99 & 336 & 143 & 105 \\
33 & .71 & 75 & 352 & 169 & 32 \\
34 & .76 & 90 & 353 & 263 & 165 \\
35 & .89 & 85 & 373 & 174 & 78 \\
36 & .88 & 99 & 376 & 134 & 80 \\
37 & 1.17 & 100 & 367 & 182 & 54 \\
38 & .85 & 78 & 335 & 241 & 175 \\
39 & .97 & 106 & 396 & 128 & 80 \\
\(\vdots\) & \(\vdots\) & \(\vdots\) & \(\vdots\) & \(\vdots\) & \(\vdots\) \\
46 & .91 & 86 & 328 & 106 & 56 \\
\hline & & & & & \\
\hline & & & \\
\hline
\end{tabular}
where \(\mathbf{y}_{1}\) has \(p_{1}\) variables, \(\mathbf{y}_{2}\) has \(p_{2}, \ldots, \mathbf{y}_{k}\) has \(p_{k}\), with \(p=p_{1}+p_{2}+\cdots+p_{k}\), then the sample mean vector and covariance matrix are given by
\[
\begin{gather*}
\overline{\mathbf{y}}=\left(\begin{array}{c}
\overline{\mathbf{y}}_{1} \\
\overline{\mathbf{y}}_{2} \\
\vdots \\
\overline{\mathbf{y}}_{k}
\end{array}\right)  \tag{3.48}\\
\mathbf{S}=\left(\begin{array}{cccc}
\mathbf{S}_{11} & \mathbf{S}_{12} & \cdots & \mathbf{S}_{1 k} \\
\mathbf{S}_{21} & \mathbf{S}_{22} & \cdots & \mathbf{S}_{2 k} \\
\vdots & \vdots & & \vdots \\
\mathbf{S}_{k 1} & \mathbf{S}_{k 2} & \cdots & \mathbf{S}_{k k}
\end{array}\right) \tag{3.49}
\end{gather*}
\]

The \(p_{2} \times p_{k}\) submatrix \(\mathbf{S}_{2 k}\), for example, contains the covariances of the variables in \(\mathbf{y}_{2}\) with the variables in \(\mathbf{y}_{k}\).

The corresponding population results are
\[
\begin{gather*}
\boldsymbol{\mu}=\left(\begin{array}{c}
\boldsymbol{\mu}_{1} \\
\boldsymbol{\mu}_{2} \\
\vdots \\
\boldsymbol{\mu}_{k}
\end{array}\right)  \tag{3.50}\\
\boldsymbol{\Sigma}=\left(\begin{array}{cccc}
\boldsymbol{\Sigma}_{11} & \boldsymbol{\Sigma}_{12} & \cdots & \boldsymbol{\Sigma}_{1 k} \\
\boldsymbol{\Sigma}_{21} & \boldsymbol{\Sigma}_{22} & \cdots & \boldsymbol{\Sigma}_{2 k} \\
\vdots & \vdots & & \vdots \\
\boldsymbol{\Sigma}_{k 1} & \boldsymbol{\Sigma}_{k 2} & \cdots & \boldsymbol{\Sigma}_{k k}
\end{array}\right) . \tag{3.51}
\end{gather*}
\]

\subsection*{3.10 LINEAR COMBINATIONS OF VARIABLES}

\subsection*{3.10.1 Sample Properties}

We are frequently interested in linear combinations of the variables \(y_{1}, y_{2}, \ldots, y_{p}\). For example, two of the types of linear functions we use in later chapters are (1) linear combinations that maximize some function and (2) linear combinations that compare variables, for example, \(y_{1}-y_{3}\). In this section, we investigate the means, variances, and covariances of linear combinations.

Let \(a_{1}, a_{2}, \ldots, a_{p}\) be constants and consider the linear combination of the elements of the vector \(y\),
\[
\begin{equation*}
z=a_{1} y_{1}+a_{2} y_{2}+\cdots+a_{p} y_{p}=\mathbf{a}^{\prime} \mathbf{y} \tag{3.52}
\end{equation*}
\]
where \(\mathbf{a}^{\prime}=\left(a_{1}, a_{2}, \ldots, a_{p}\right)\). If the same coefficient vector \(\mathbf{a}\) is applied to each \(\mathbf{y}_{i}\) in a sample, we have
\[
\begin{align*}
z_{i} & =a_{1} y_{i 1}+a_{2} y_{i 2}+\cdots+a_{p} y_{i p} \\
& =\mathbf{a}^{\prime} \mathbf{y}_{i}, \quad i=1,2, \ldots, n \tag{3.53}
\end{align*}
\]

The sample mean of \(z\) can be found either by averaging the \(n\) values \(z_{1}=\mathbf{a}^{\prime} \mathbf{y}_{1}, z_{2}=\) \(\mathbf{a}^{\prime} \mathbf{y}_{2}, \ldots, z_{n}=\mathbf{a}^{\prime} \mathbf{y}_{n}\) or as a linear combination of \(\overline{\mathbf{y}}\), the sample mean vector of \(\mathbf{y}_{1}, \mathbf{y}_{2}, \ldots, \mathbf{y}_{n}\) :
\[
\begin{equation*}
\bar{z}=\frac{1}{n} \sum_{i=1}^{n} z_{i}=\mathbf{a}^{\prime} \overline{\mathbf{y}} . \tag{3.54}
\end{equation*}
\]

The result in (3.54) is analogous to the univariate result (3.3), \(\bar{z}=a \bar{y}\), where \(z_{i}=\) \(a y_{i}, i=1,2, \ldots, n\).

Similarly, the sample variance of \(z_{i}=\mathbf{a}^{\prime} \mathbf{y}_{i}, i=1,2, \ldots, n\), can be found as the sample variance of \(z_{1}, z_{2}, \ldots, z_{n}\) or directly from \(\mathbf{a}\) and \(\mathbf{S}\), where \(\mathbf{S}\) is the sample covariance matrix of \(\mathbf{y}_{1}, \mathbf{y}_{2}, \ldots, \mathbf{y}_{n}\) :
\[
\begin{equation*}
s_{z}^{2}=\frac{\sum_{i=1}^{n}\left(z_{i}-\bar{z}\right)^{2}}{n-1}=\mathbf{a}^{\prime} \mathbf{S} \mathbf{a} . \tag{3.55}
\end{equation*}
\]

Note that \(s_{z}^{2}=\mathbf{a}^{\prime} \mathbf{S a}\) is the multivariate analogue of the univariate result in (3.6), \(s_{z}^{2}=a^{2} s^{2}\), where \(z_{i}=a y_{i}, i=1,2, \ldots, n\), and \(s^{2}\) is the variance of \(y_{1}, y_{2}, \ldots, y_{n}\).

Since a variance is always nonnegative, we have \(s_{z}^{2} \geq 0\), and therefore \(\mathbf{a}^{\prime} \mathbf{S a} \geq 0\), for every \(\mathbf{a}\). Hence \(\mathbf{S}\) is at least positive semidefinite (see Section 2.7). If the variables are continuous and are not linearly related, and if \(n-1>p\) (so that \(\mathbf{S}\) is full rank), then \(S\) is positive definite (with probability 1 ).

If we define another linear combination \(w=\mathbf{b}^{\prime} \mathbf{y}=b_{1} y_{1}+b_{2} y_{2}+\cdots+b_{p} y_{p}\), where \(\mathbf{b}^{\prime}=\left(b_{1}, b_{2}, \ldots, b_{p}\right)\) is a vector of constants different from \(\mathbf{a}^{\prime}\), then the sample covariance of \(z\) and \(w\) is given by
\[
\begin{equation*}
s_{z w}=\frac{\sum_{i=1}^{n}\left(z_{i}-\bar{z}\right)\left(w_{i}-\bar{w}\right)}{n-1}=\mathbf{a}^{\prime} \mathbf{S} \mathbf{b} \tag{3.56}
\end{equation*}
\]

The sample correlation between \(z\) and \(w\) is readily obtained as
\[
\begin{equation*}
r_{z w}=\frac{s_{z w}}{\sqrt{s_{z}^{2} s_{w}^{2}}}=\frac{\mathbf{a}^{\prime} \mathbf{S b}}{\sqrt{\left(\mathbf{a}^{\prime} \mathbf{S a}\right)\left(\mathbf{b}^{\prime} \mathbf{S b}\right)}} \tag{3.57}
\end{equation*}
\]

We now denote the two constant vectors \(\mathbf{a}\) and \(\mathbf{b}\) as \(\mathbf{a}_{1}\) and \(\mathbf{a}_{2}\) to facilitate later expansion to more than two such vectors. Let
\[
\mathbf{A}=\binom{\mathbf{a}_{1}^{\prime}}{\mathbf{a}_{2}^{\prime}}
\]
and define
\[
\mathbf{z}=\binom{\mathbf{a}_{1}^{\prime} \mathbf{y}}{\mathbf{a}_{2}^{\prime} \mathbf{y}}=\binom{z_{1}}{z_{2}}
\]

Then we can factor \(y\) from this expression by (2.49):
\[
\mathbf{z}=\binom{\mathbf{a}_{1}^{\prime}}{\mathbf{a}_{2}^{\prime}} \mathbf{y}=\mathbf{A} \mathbf{y}
\]

If we evaluate the bivariate \(\mathbf{z}_{i}\) for each \(p\)-variate \(\mathbf{y}_{i}\) in the sample, we obtain \(\mathbf{z}_{i}=\mathbf{A} \mathbf{y}_{i}, i=1,2, \ldots, n\), and the average of \(\mathbf{z}\) over the sample can be found from \(\overline{\mathrm{y}}\) :
\[
\begin{align*}
\overline{\mathbf{z}} & =\binom{\bar{z}_{1}}{\bar{z}_{2}}=\binom{\mathbf{a}_{1}^{\prime} \overline{\mathbf{y}}}{\mathbf{a}_{2}^{\prime} \overline{\mathbf{y}}} \quad[\mathbf{b y}(3.54)]  \tag{3.58}\\
& =\binom{\mathbf{a}_{1}^{\prime}}{\mathbf{a}_{2}^{\prime}} \overline{\mathbf{y}}=\mathbf{A} \overline{\mathbf{y}} \quad[\text { by }(2.49)] \tag{3.59}
\end{align*}
\]

We can use (3.55) and (3.56) to construct the sample covariance matrix for \(\mathbf{z}\) :
\[
\begin{align*}
\mathbf{S}_{z} & =\left(\begin{array}{cc}
s_{z_{1}}^{2} & s_{z_{1} z_{2}} \\
s_{z_{2} z_{1}} & s_{z_{2}}^{2}
\end{array}\right) \\
& =\left(\begin{array}{cc}
\mathbf{a}_{1}^{\prime} \mathbf{S a} & \mathbf{a}_{1}^{\prime} \mathbf{S a} \\
\mathbf{a}_{2}^{\prime} \mathbf{S} \mathbf{a}_{1} & \mathbf{a}_{\mathbf{2}}^{\prime} \mathbf{S} \mathbf{a}_{2}
\end{array}\right) . \tag{3.60}
\end{align*}
\]

By (2.50), this factors into
\[
\begin{equation*}
\mathbf{S}_{z}=\binom{\mathbf{a}_{1}^{\prime}}{\mathbf{a}_{2}^{\prime}} \mathbf{S}\left(\mathbf{a}_{1}, \mathbf{a}_{2}\right)=\mathbf{A S A}^{\prime} \tag{3.61}
\end{equation*}
\]

The bivariate results in (3.59) and (3.61) can be readily extended to more than two linear combinations. (See principal components in Chapter 12, for instance, where we attempt to transform the \(y\) 's to a few dimensions that capture most of the information in the \(y\) 's.) If we have \(k\) linear transformations, they can be expressed as
\[
\begin{aligned}
z_{1} & =a_{11} y_{1}+a_{12} y_{2}+\cdots+a_{1 p} y_{p}=\mathbf{a}_{1}^{\prime} \mathbf{y} \\
z_{2} & =a_{21} y_{1}+a_{22} y_{2}+\cdots+a_{2 p} y_{p}=\mathbf{a}_{2}^{\prime} \mathbf{y} \\
& \vdots \\
z_{k} & =a_{k 1} y_{1}+a_{k 2} y_{2}+\cdots+a_{k p} y_{p}=\mathbf{a}_{k}^{\prime} \mathbf{y}
\end{aligned}
\]
or in matrix notation
\[
\mathbf{z}=\left(\begin{array}{c}
z_{1} \\
z_{2} \\
\vdots \\
z_{k}
\end{array}\right)=\left(\begin{array}{c}
\mathbf{a}_{1}^{\prime} \mathbf{y} \\
\mathbf{a}_{2}^{\prime} \mathbf{y} \\
\vdots \\
\mathbf{a}_{k}^{\prime} \mathbf{y}
\end{array}\right)=\left(\begin{array}{c}
\mathbf{a}_{1}^{\prime} \\
\mathbf{a}_{2}^{\prime} \\
\vdots \\
\mathbf{a}_{k}^{\prime}
\end{array}\right) \mathbf{y}=\mathbf{A y} \quad[\mathbf{b y}(2.47)]
\]
where \(\mathbf{z}\) is \(k \times 1, \mathbf{A}\) is \(k \times p\), and \(\mathbf{y}\) is \(p \times 1\) (we typically have \(k \leq p\) ). If \(\mathbf{z}_{i}=\mathbf{A} \mathbf{y}_{i}\) is evaluated for all \(\mathbf{y}_{i}, i=1,2, \ldots, n\), then by (3.54) and (2.49), the sample mean vector of the \(z\) 's is
\[
\overline{\mathbf{z}}=\left(\begin{array}{c}
\mathbf{a}_{1}^{\prime} \overline{\mathbf{y}}  \tag{3.62}\\
\mathbf{a}_{2}^{\prime} \overline{\mathbf{y}} \\
\vdots \\
\mathbf{a}_{k}^{\prime} \overline{\mathbf{y}}
\end{array}\right)=\left(\begin{array}{c}
\mathbf{a}_{1}^{\prime} \\
\mathbf{a}_{2}^{\prime} \\
\vdots \\
\mathbf{a}_{k}^{\prime}
\end{array}\right) \overline{\mathbf{y}}=\mathbf{A} \overline{\mathbf{y}}
\]

By an extension of (3.60), the sample covariance matrix of the \(z\) 's becomes
\[
\begin{align*}
& \mathbf{S}_{z}=\left(\begin{array}{cccc}
\mathbf{a}_{1}^{\prime} \mathbf{S} \mathbf{a}_{1} & \mathbf{a}_{1}^{\prime} \mathbf{S} \mathbf{a}_{2} & \cdots & \mathbf{a}_{1}^{\prime} \mathbf{S} \mathbf{a}_{k} \\
\mathbf{a}_{2}^{\prime} \mathbf{S} \mathbf{a}_{1} & \mathbf{a}_{2}^{\prime} \mathbf{S} \mathbf{a}_{2} & \cdots & \mathbf{a}_{2}^{\prime} \mathbf{S} \mathbf{a}_{k} \\
\vdots & \vdots & & \vdots \\
\mathbf{a}_{k}^{\prime} \mathbf{S} \mathbf{a}_{1} & \mathbf{a}_{k}^{\prime} \mathbf{S} \mathbf{a}_{2} & \cdots & \mathbf{a}_{k}^{\prime} \mathbf{S} \mathbf{a}_{k}
\end{array}\right)  \tag{3.63}\\
& =\left(\begin{array}{cccc}
\mathbf{a}_{1}^{\prime}\left(\mathbf{S} \mathbf{a}_{1},\right. & \mathbf{S} \mathbf{a}_{2}, & \cdots, & \left.\mathbf{S} \mathbf{a}_{k}\right) \\
\mathbf{a}_{2}^{\prime}\left(\mathbf{S a _ { 1 }},\right. & \mathbf{S a _ { 2 }}, & \cdots, & \left.\mathbf{S a _ { k }}\right) \\
\vdots & \vdots & & \vdots \\
\mathbf{a}_{k}^{\prime}\left(\mathbf{S} \mathbf{a}_{1},\right. & \mathbf{S a} \\
2
\end{array}\right) \\
& =\left(\begin{array}{c}
\mathbf{a}_{1}^{\prime} \\
\mathbf{a}_{2}^{\prime} \\
\vdots \\
\mathbf{a}_{k}^{\prime}
\end{array}\right)\left(\mathbf{S a}, \mathbf{a}_{1}, \mathbf{S a}_{2}, \ldots, \mathbf{S a}_{k}\right) \quad[\mathbf{b y}(2.47)] \\
& =\left(\begin{array}{c}
\mathbf{a}_{1}^{\prime} \\
\mathbf{a}_{2}^{\prime} \\
\vdots \\
\mathbf{a}_{k}^{\prime}
\end{array}\right) \mathbf{S}\left(\mathbf{a}_{1}, \mathbf{a}_{2}, \ldots, \mathbf{a}_{k}\right) \quad[\mathbf{b y}(2.48)] \\
& =\mathbf{A S A}^{\prime} \text {. } \tag{3.64}
\end{align*}
\]

Note that by (3.63) and (3.64), we have
\[
\begin{equation*}
\operatorname{tr}\left(\mathbf{A S} \mathbf{A}^{\prime}\right)=\sum_{i=1}^{k} \mathbf{a}_{i}^{\prime} \mathbf{S} \mathbf{a}_{i} \tag{3.65}
\end{equation*}
\]

A slightly more general linear transformation is
\[
\begin{equation*}
\mathbf{z}_{i}=\mathbf{A} \mathbf{y}_{i}+\mathbf{b}, \quad i=1,2, \ldots, n \tag{3.66}
\end{equation*}
\]

The sample mean vector and covariance matrix of z are given by
\[
\begin{align*}
\overline{\mathbf{z}} & =\mathbf{A} \overline{\mathbf{y}}+\mathbf{b}  \tag{3.67}\\
\mathbf{S}_{z} & =\mathbf{A S A}^{\prime} \tag{3.68}
\end{align*}
\]

\section*{■ EXAMPLE 3.10.1}

Timm (1975, p. 233; 1980, p. 47) reported the results of an experiment in which subjects responded to "probe words" at five positions in a sentence. The variables are response times for the \(j\) th probe word, \(y_{j}, j=1,2, \ldots, 5\). The data are given in Table 3.6.

These variables are commensurate (same measurement units and similar means and variances), and the researcher may wish to examine some simple

Table 3.6 Response Times for Five Probe Word Positions
\begin{tabular}{cccccc}
\hline \begin{tabular}{c} 
Subject \\
Number
\end{tabular} & \(y_{1}\) & \(y_{2}\) & \(y_{3}\) & \(y_{4}\) & \(y_{5}\) \\
\hline 1 & 51 & 36 & 50 & 35 & 42 \\
2 & 27 & 20 & 26 & 17 & 27 \\
3 & 37 & 22 & 41 & 37 & 30 \\
4 & 42 & 36 & 32 & 34 & 27 \\
5 & 27 & 18 & 33 & 14 & 29 \\
6 & 43 & 32 & 43 & 35 & 40 \\
7 & 41 & 22 & 36 & 25 & 38 \\
8 & 38 & 21 & 31 & 20 & 16 \\
9 & 36 & 23 & 27 & 25 & 28 \\
10 & 26 & 31 & 31 & 32 & 36 \\
11 & 29 & 20 & 25 & 26 & 25 \\
\hline
\end{tabular}
linear combinations. Consider the following linear combination for illustrative purposes:
\[
\begin{aligned}
z & =3 y_{1}-2 y_{2}+4 y_{3}-y_{4}+y_{5} \\
& =(3,-2,4,-1,1) \mathbf{y}=\mathbf{a}^{\prime} \mathbf{y} .
\end{aligned}
\]

If \(z\) is calculated for each of the 11 observations, we obtain \(z_{1}=288, z_{2}=\) \(155, \cdots, z_{11}=146\) with mean \(\bar{z}=197.0\) and variance \(s_{z}^{2}=2084.0\). These same results can be obtained using (3.54) and (3.55). The sample mean vector and covariance matrix for the data are
\[
\overline{\mathbf{y}}=\left(\begin{array}{c}
36.09 \\
25.55 \\
34.09 \\
27.27 \\
30.73
\end{array}\right), \quad \mathbf{S}=\left(\begin{array}{ccccc}
65.09 & 33.65 & 47.59 & 36.77 & 25.43 \\
33.65 & 46.07 & 28.95 & 40.34 & 28.36 \\
47.59 & 28.95 & 60.69 & 37.37 & 41.13 \\
36.77 & 40.34 & 37.37 & 62.82 & 31.68 \\
25.43 & 28.36 & 41.13 & 31.68 & 58.22
\end{array}\right)
\]

Then, by (3.54),
\[
\bar{z}=\mathbf{a}^{\prime} \overline{\mathbf{y}}=(3,-2,4,-1,1)\left(\begin{array}{c}
36.09 \\
25.55 \\
34.09 \\
27.27 \\
30.73
\end{array}\right)=197.0
\]
and by (3.55), \(s_{z}^{2}=\mathbf{a}^{\prime} \mathbf{S a}=2084.0\).
We now define a second linear combination:
\[
\begin{aligned}
w & =y_{1}+3 y_{2}-y_{3}+y_{4}-2 y_{5} \\
& =(1,3,-1,1,-2) \mathbf{y}=\mathbf{b}^{\prime} \mathbf{y} .
\end{aligned}
\]

The sample mean and variance of \(w\) are \(\bar{w}=\mathbf{b}^{\prime} \overline{\mathbf{y}}=44.45\) and \(s_{w}^{2}=\mathbf{b}^{\prime} \mathbf{S b}=\) 605.67. The sample covariance of \(z\) and \(w\) is, by (3.56), \(s_{z w}=\mathbf{a}^{\prime} \mathbf{S b}=40.2\).

Using (3.57), we find the sample correlation between \(z\) and \(w\) to be
\[
r_{z w}=\frac{s_{z w}}{\sqrt{s_{z}^{2} s_{w}^{2}}}=\frac{40.2}{\sqrt{(2084)(605.67)}}=.0358
\]

We now define the three linear functions
\[
\begin{aligned}
& z_{1}=y_{1}+y_{2}+y_{3}+y_{4}+y_{5} \\
& z_{2}=2 y_{1}-3 y_{2}+y_{3}-2 y_{4}-y_{5} \\
& z_{3}=-y_{1}-2 y_{2}+y_{3}-2 y_{4}+3 y_{5}
\end{aligned}
\]
which can be written in matrix form as
\[
\left(\begin{array}{l}
z_{1} \\
z_{2} \\
z_{3}
\end{array}\right)=\left(\begin{array}{rrrrr}
1 & 1 & 1 & 1 & 1 \\
2 & -3 & 1 & -2 & -1 \\
-1 & -2 & 1 & -2 & 3
\end{array}\right)\left(\begin{array}{l}
y_{1} \\
y_{2} \\
y_{3} \\
y_{4} \\
y_{5}
\end{array}\right)
\]
or
\[
\mathbf{z}=\mathbf{A y} .
\]

The sample mean vector for \(\mathbf{z}\) is given by (3.62) as
\[
\overline{\mathbf{z}}=\mathbf{A} \overline{\mathbf{y}}=\left(\begin{array}{r}
153.73 \\
-55.64 \\
-15.45
\end{array}\right)
\]
and the sample covariance matrix of \(\mathbf{z}\) is given by (3.64) as
\[
\mathbf{S}_{z}=\mathbf{A S A} \mathbf{A}^{\prime}=\left(\begin{array}{rrr}
995.42 & -502.09 & -211.04 \\
-502.09 & 811.45 & 268.08 \\
-211.04 & 268.08 & 702.87
\end{array}\right)
\]

The covariance matrix \(\mathbf{S}_{z}\) can be converted to a correlation matrix by use of (3.37):
\[
\mathbf{R}_{z}=\mathbf{D}_{z}^{-1} \mathbf{S}_{z} \mathbf{D}_{z}^{-1}=\left(\begin{array}{rrr}
1.00 & -.56 & -.25 \\
-.56 & 1.00 & .35 \\
-.25 & .35 & 1.00
\end{array}\right)
\]
where
\[
\mathbf{D}_{z}=\left(\begin{array}{ccc}
31.55 & 0 & 0 \\
0 & 28.49 & 0 \\
0 & 0 & 26.51
\end{array}\right)
\]
is obtained from the square roots of the diagonal elements of \(\mathbf{S}_{z}\).

\subsection*{3.10.2 Population Properties}

The sample results in Section 3.10.1 for linear combinations have population counterparts. Let \(z=\mathbf{a}^{\prime} \mathbf{y}\), where \(\mathbf{a}\) is a vector of constants. Then the population mean of \(z\) is
\[
\begin{equation*}
E(z)=E\left(\mathbf{a}^{\prime} \mathbf{y}\right)=\mathbf{a}^{\prime} E(\mathbf{y})=\mathbf{a}^{\prime} \boldsymbol{\mu} \tag{3.69}
\end{equation*}
\]
and the population variance is
\[
\begin{equation*}
\sigma_{z}^{2}=\operatorname{var}\left(\mathbf{a}^{\prime} \mathbf{y}\right)=\mathbf{a}^{\prime} \boldsymbol{\Sigma} \mathbf{a} . \tag{3.70}
\end{equation*}
\]

Let \(w=\mathbf{b}^{\prime} \mathbf{y}\), where \(\mathbf{b}\) is a vector of constants different from \(\mathbf{a}\). The population covariance of \(z=\mathbf{a}^{\prime} \mathbf{y}\) and \(w=\mathbf{b}^{\prime} \mathbf{y}\) is
\[
\begin{equation*}
\operatorname{cov}(z, w)=\sigma_{z w}=\mathbf{a}^{\prime} \boldsymbol{\Sigma} \mathbf{b} \tag{3.71}
\end{equation*}
\]

By (3.12) the population correlation of \(z\) and \(w\) is
\[
\begin{align*}
\rho_{z w}=\operatorname{corr}\left(\mathbf{a}^{\prime} \mathbf{y}, \mathbf{b}^{\prime} \mathbf{y}\right) & =\frac{\sigma_{z w}}{\sigma_{z} \sigma_{w}} \\
& =\frac{\mathbf{a}^{\prime} \mathbf{\Sigma} \mathbf{b}}{\sqrt{\left(\mathbf{a}^{\prime} \mathbf{\Sigma} \mathbf{a}\right)\left(\mathbf{b}^{\prime} \mathbf{\Sigma} \mathbf{b}\right)}} \tag{3.72}
\end{align*}
\]

If Ay represents several linear combinations, the population mean vector and covariance matrix are given by
\[
\begin{align*}
E(\mathbf{A} \mathbf{y}) & =\mathbf{A} E(\mathbf{y})=\mathbf{A} \boldsymbol{\mu}  \tag{3.73}\\
\operatorname{cov}(\mathbf{A y}) & =\mathbf{A} \mathbf{\Sigma} \mathbf{A}^{\prime} . \tag{3.74}
\end{align*}
\]

The more general linear transformation \(\mathbf{z}=\mathbf{A y}+\mathbf{b}\) has population mean vector and covariance matrix
\[
\begin{align*}
E(\mathbf{A} \mathbf{y}+\mathbf{b}) & =\mathbf{A} E(\mathbf{y})+\mathbf{b}=\mathbf{A} \boldsymbol{\mu}+\mathbf{b}  \tag{3.75}\\
\operatorname{cov}(\mathbf{A} \mathbf{y}+\mathbf{b}) & =\mathbf{A} \boldsymbol{\Sigma} \mathbf{A}^{\prime} \tag{3.76}
\end{align*}
\]

\subsection*{3.11 MEASURES OF OVERALL VARIABILITY}

The covariance matrix contains the variances of the \(p\) variables and the covariances between all pairs of variables and is thus a multifaceted picture of the overall variation in the data. Sometimes it is desirable to have a single numerical value for the overall multivariate scatter. One such measure is the generalized sample variance, defined as the determinant of the covariance matrix:
\[
\begin{equation*}
\text { Generalized sample variance }=|\mathbf{S}| . \tag{3.77}
\end{equation*}
\]

The generalized sample variance has a geometric interpretation. The extension of an ellipse to more than two dimensions is called a hyperellipsoid. A \(p\)-dimensional hyperellipsoid \((\mathbf{y}-\overline{\mathbf{y}})^{\prime} \mathbf{S}^{-1}(\mathbf{y}-\overline{\mathbf{y}})=a^{2}\), centered at \(\overline{\mathbf{y}}\) and based on \(\mathbf{S}^{-1}\) to standardize the distance to the center, contains a proportion of the observations \(\mathbf{y}_{1}, \mathbf{y}_{2}, \ldots, \mathbf{y}_{n}\) in the sample (if \(\mathbf{S}\) were replaced by \(\boldsymbol{\Sigma}\), the value of \(a^{2}\) could be determined by tables of the chi-square distribution; see property 3 in Section 4.2). The ellipsoid \((\mathbf{y}-\overline{\mathbf{y}})^{\prime} \mathbf{S}^{-1}(\mathbf{y}-\overline{\mathbf{y}})\) has axes proportional to the square roots of the eigenvalues of \(\mathbf{S}\). It can be shown that the volume of the ellipsoid is proportional to \(|\mathbf{S}|^{1 / 2}\). If the smallest eigenvalue \(\lambda_{p}\) is zero, there is no axis in that direction, and the ellipsoid lies wholly in a \((p-1)\)-dimensional subspace of \(p\)-space. Consequently, the volume in \(p\)-space is zero. This can also be seen by (2.108), \(|\mathbf{S}|=\lambda_{1} \lambda_{2} \cdots \lambda_{p}\). Hence, if \(\lambda_{p}=0,|\mathbf{S}|=0\). A zero eigenvalue indicates a redundancy in the form of a linear relationship among the variables. (As will be seen in Section 12.7, the eigenvector corresponding to the zero eigenvalue reveals the form of the linear dependency.) One solution to the dilemma when \(\lambda_{p}=0\) is to remove one or more variables.

Another measure of overall variability, the total sample variance, is simply the trace of \(S\) :
\[
\begin{equation*}
\text { Total sample variance }=s_{11}+s_{22}+\cdots+s_{p p}=\operatorname{tr}(\mathbf{S}) \tag{3.78}
\end{equation*}
\]

This measure of overall variation ignores covariance structure altogether but is found useful for comparison purposes in techniques such as principal components (Chapter 12).

In general, for both \(|\mathbf{S}|\) and \(\operatorname{tr}(\mathbf{S})\), relatively large values reflect a broad scatter of \(\mathbf{y}_{1}, \mathbf{y}_{2}, \ldots, \mathbf{y}_{p}\) about \(\overline{\mathbf{y}}\), whereas lower values indicate closer concentration about \(\overline{\mathbf{y}}\). In the case of \(|\mathbf{S}|\), however, as noted above, an extremely small value of \(|\mathbf{S}|\) or \(|\mathbf{R}|\) may indicate either small scatter or multicollinearity, a term indicating near-linear relationships in a set of variables. Multicollinearity may be due to high pairwise correlations or to a high multiple correlation between one variable and several of the other variables. For other measures of intercorrelation, see Rencher (1998, Section 1.7).

\subsection*{3.12 ESTIMATION OF MISSING VALUES}

It is not uncommon to find missing measurements in an observation vector, that is, missing values for one or more variables. A small number of rows with missing entries in the data matrix \(\mathbf{Y}\) [see (3.17)] does not constitute a serious problem; we can simply discard each row that has a missing value. However, with this procedure, a small portion of missing data, if widely distributed, would lead to a substantial loss of data. For example, in a large data set with \(n=550\) and \(p=85\), only about \(1.5 \%\) of the \(550 \times 85=46,750\) measurements were missing. However, nearly half of the observation vectors (rows of \(\mathbf{Y}\) ) turned out to be incomplete.

The distribution of missing values in a data set is an important consideration. Randomly missing variable values scattered throughout a data matrix are less serious
than a pattern of missing values that depends to some extent on the values of the missing variables.

We discuss two methods of estimating the missing values or "filling the holes" in the data matrix, also called imputation. Both of the procedures presume that the missing values occur at random. If the occurrence or non-occurrence of missing values is related to the values of some of the variables, then the techniques may not estimate the missing responses very well.

The first method is very simple: Substitute a mean for each missing value, specifically the average of the available data in the column of the data matrix in which the unknown value lies. Replacing an observation by its mean reduces the variance and the absolute value of the covariance. Therefore, the sample covariance matrix \(\mathbf{S}\) computed from the data matrix \(\mathbf{Y}\) in (3.17) with means imputed for missing values is biased. However, it is positive definite.

The second technique is a regression approach. The data matrix \(\mathbf{Y}\) is partitioned into two parts, one containing all rows with missing entries and the other comprising all the complete rows. Suppose \(y_{i j}\) is the only missing entry in the \(i\) th row of \(\mathbf{Y}\). Then using the data in the submatrix with complete rows, \(y_{j}\) is regressed on the other variables to obtain a prediction equation \(\hat{y}_{j}=b_{0}+b_{1} y_{1}+\cdots+b_{j-1} y_{j-1}+\) \(b_{j+1} y_{j+1}+\cdots+b_{y} y_{p}\). Then the nonmissing entries in the \(i\) th row are entered as independent variables in the regression equation to obtain the predicted value, \(\hat{y}_{i j}\). The regression method was first proposed by Buck (1960) and is a special case of the EM algorithm (Dempster, Laird, and Rubin 1977).

The regression method can be improved by iteration, carried out, for example, in the following way. Estimate all missing entries in the data matrix using regression. After filling in the missing entries, use the full data matrix to obtain new prediction equations. Use these prediction equations to calculate new predicted values \(\hat{y}_{i j}\) for missing entries. Use the new data matrix to obtain revised prediction equations and new predicted values \(\hat{y}_{i j}\). Continue this process until the predicted values stabilize.

A modification may be needed if the missing entries are so pervasive that it is difficult to find data to estimate the initial regression equations. In this case, the process could be started by using means as in the first method and then beginning the iteration.

The regression approach will ordinarily yield better results than the method of inserting means. However, if the other variables are not very highly correlated with the one to be predicted, the regression technique is essentially equivalent to imputing means. The regression method underestimates the variances and covariances, though to a lesser extent than the method based on means.

\section*{EXAMPLE 3.12}

We illustrate the iterated regression method of estimating missing values. Consider the calcium data of Table 3.4 as reproduced here and suppose the entries in parentheses are missing:
\begin{tabular}{crrr}
\begin{tabular}{c} 
Location \\
Number
\end{tabular} & \(y_{1}\) & \multicolumn{1}{c}{\(y_{2}\)} & \multicolumn{1}{c}{\(y_{3}\)} \\
\hline 1 & 35 & \((3.5)\) & 2.80 \\
2 & 35 & 4.9 & \((2.70)\) \\
3 & 40 & 30.0 & 4.38 \\
4 & 10 & 2.8 & 3.21 \\
5 & 6 & 2.7 & 2.73 \\
6 & 20 & 2.8 & 2.81 \\
7 & 35 & 4.6 & 2.88 \\
8 & 35 & 10.9 & 2.90 \\
9 & 35 & 8.0 & 3.28 \\
10 & 30 & 1.6 & 3.20
\end{tabular}

We first regress \(y_{2}\) on \(y_{1}\) and \(y_{3}\) for observations 3-10 and obtain \(\hat{y}_{2}=b_{0}+\) \(b_{1} y_{1}+b_{3} y_{3}\). When this is evaluated for the two nonmissing entries in the first row ( \(y_{1}=35\) and \(y_{3}=2.80\) ), we obtain \(\hat{y}_{2}=4.097\). Similarly, we regress \(y_{3}\) on \(y_{1}\) and \(y_{2}\) for observations 3-10 to obtain \(\hat{y}_{3}=c_{0}+c_{1} y_{1}+c_{2} y_{2}\). Evaluating this for the two nonmissing entries in the second row yields \(\hat{y}_{3}=\) 3.011. We now insert these estimates for the missing values and calculate the regression equations based on all 10 observations. Using the revised equation \(\hat{y}_{2}=b_{0}+b_{1} y_{1}+b_{3} y_{3}\), we obtain a new predicted value, \(\hat{y}_{2}=3.698\). Similarly, we obtain a revised regression equation for \(y_{3}\) that gives a new predicted value, \(\hat{y}_{3}=2.981\). With these values inserted, we calculate new equations and obtain new predicted values, \(\hat{y}_{2}=3.672\) and \(\hat{y}_{3}=2.976\). At the third iteration we obtain \(\hat{y}_{2}=3.679\) and \(\hat{y}_{3}=2.975\). There is very little change in subsequent iterations. These values are closer to the actual values, \(y_{2}=3.5\) and \(y_{3}=2.70\), than the initial regression estimates, \(\hat{y}_{2}=4.097\) and \(\hat{y}_{3}=3.011\). They are also much better estimates than the means of the second and third columns, \(\bar{y}_{2}=7.589\) and \(\bar{y}_{3}=3.132\).

\subsection*{3.13 DISTANCE BETWEEN VECTORS}

In a univariate setting, the distance between two points is simply the difference (or absolute difference) between their values. For statistical purposes, this difference may not be very informative. For example, we do not want to know how many centimeters apart two means are, but rather how many standard deviations apart they are. Thus we examine the standardized or statistical distances, such as
\[
\frac{\left|\mu_{1}-\mu_{2}\right|}{\sigma} \text { or } \frac{|\bar{y}-\mu|}{\sigma_{\bar{y}}} .
\]

To obtain a useful distance measure in a multivariate setting, we must consider not only the variances of the variables but also their covariances or correlations. The simple (squared) Euclidean distance between two vectors, \(\left(\mathbf{y}_{1}-\mathbf{y}_{2}\right)^{\prime}\left(\mathbf{y}_{1}-\mathbf{y}_{2}\right)\), is not useful in some situations because there is no adjustment for the variances or the
covariances. For a statistical distance, we standardize by inserting the inverse of the covariance matrix:
\[
\begin{equation*}
d^{2}=\left(\mathbf{y}_{1}-\mathbf{y}_{2}\right)^{\prime} \mathbf{S}^{-1}\left(\mathbf{y}_{1}-\mathbf{y}_{2}\right) . \tag{3.79}
\end{equation*}
\]

Other examples are
\[
\begin{align*}
& D^{2}=(\overline{\mathbf{y}}-\boldsymbol{\mu})^{\prime} \mathbf{S}^{-1}(\overline{\mathbf{y}}-\boldsymbol{\mu})  \tag{3.80}\\
& \Delta^{2}=(\overline{\mathbf{y}}-\boldsymbol{\mu})^{\prime} \boldsymbol{\Sigma}^{-1}(\overline{\mathbf{y}}-\boldsymbol{\mu})  \tag{3.81}\\
& \Delta^{2}=\left(\boldsymbol{\mu}_{1}-\boldsymbol{\mu}_{2}\right)^{\prime} \boldsymbol{\Sigma}^{-1}\left(\boldsymbol{\mu}_{1}-\boldsymbol{\mu}_{2}\right) . \tag{3.82}
\end{align*}
\]

These (squared) distances between two vectors were first proposed by Mahalanobis (1936) and are often referred to as Mahalanobis distances. If a random variable has a larger variance than another, it receives relatively less weight in a Mahalanobis distance. Similarly, two highly correlated variables do not contribute as much as two variables that are less correlated. In essence, then, the use of the inverse of the covariance matrix in a Mahalanobis distance has the effect of (1) standardizing all variables to the same variance and (2) eliminating correlations. To illustrate this, we use the square root matrix defined in (2.112) to rewrite (3.81) as
\[
\begin{aligned}
\Delta^{2} & =(\overline{\mathbf{y}}-\boldsymbol{\mu})^{\prime} \boldsymbol{\Sigma}^{-1}(\overline{\mathbf{y}}-\boldsymbol{\mu})=(\overline{\mathbf{y}}-\boldsymbol{\mu})^{\prime}\left(\boldsymbol{\Sigma}^{1 / 2} \boldsymbol{\Sigma}^{1 / 2}\right)^{-1}(\overline{\mathbf{y}}-\boldsymbol{\mu}) \\
& =\left[\left(\boldsymbol{\Sigma}^{1 / 2}\right)^{-1}(\overline{\mathbf{y}}-\boldsymbol{\mu})\right]^{\prime}\left[\left(\boldsymbol{\Sigma}^{1 / 2}\right)^{-1}(\overline{\mathbf{y}}-\boldsymbol{\mu})\right]=\mathbf{z}^{\prime} \mathbf{z},
\end{aligned}
\]
where \(\mathbf{z}=\left(\boldsymbol{\Sigma}^{1 / 2}\right)^{-1}(\overline{\mathbf{y}}-\boldsymbol{\mu})=\left(\boldsymbol{\Sigma}^{1 / 2}\right)^{-1} \overline{\mathbf{y}}-\left(\boldsymbol{\Sigma}^{1 / 2}\right)^{-1} \boldsymbol{\mu}\). Now, by (3.76) it can be shown that
\[
\begin{equation*}
\operatorname{cov}(\mathbf{z})=\frac{1}{n} \mathbf{I} . \tag{3.83}
\end{equation*}
\]

Hence the transformed variables \(z_{1}, z_{2}, \ldots, z_{p}\) are uncorrelated, and each has variance equal to \(1 / n\). If the appropriate covariance matrix for the random vector were used in a Mahalanobis distance, the variances would reduce to 1 . For example, if \(\operatorname{cov}(\overline{\mathbf{y}})=\boldsymbol{\Sigma} / n\) were used above in place of \(\boldsymbol{\Sigma}\), we would obtain \(\operatorname{cov}(\mathbf{z})=\mathbf{I}\).

\section*{PROBLEMS}
3.1 If \(z_{i}=a y_{i}\) for \(i=1,2, \ldots, n\), show that \(\bar{z}=a \bar{y}\) as in (3.3).
3.2 If \(z_{i}=a y_{i}\) for \(i=1,2, \ldots, n\), show that \(s_{z}^{2}=a^{2} s^{2}\) as in (3.6).
3.3 For the data in Figure 3.3, show that \(\sum_{i}\left(x_{i}-\bar{x}\right)\left(y_{i}-\bar{y}\right)=0\).
3.4 Show that \((\mathbf{x}-\bar{x} \mathbf{j})^{\prime}(\mathbf{y}-\bar{y} \mathbf{j})=\sum_{i}\left(x_{i}-\bar{x}\right)\left(y_{i}-\bar{y}\right)\), thus verifying (3.15).
3.5 For \(p=3\) show that
\[
\frac{1}{n-1} \sum_{i=1}^{n}\left(\mathbf{y}_{i}-\overline{\mathbf{y}}\right)\left(\mathbf{y}_{i}-\overline{\mathbf{y}}\right)^{\prime}=\left(\begin{array}{ccc}
s_{11} & s_{12} & s_{13} \\
s_{21} & s_{22} & s_{23} \\
s_{31} & s_{32} & s_{33}
\end{array}\right)
\]
which illustrates (3.27).
3.6 Show that \(\bar{z}=\mathbf{a}^{\prime} \overline{\mathbf{y}}\) as in (3.54), where \(z_{i}=\mathbf{a}^{\prime} \mathbf{y}_{i}, i=1,2, \ldots, n\).
3.7 Show that \(s_{z}^{2}=\mathbf{a}^{\prime} \mathbf{S a}\) as in (3.55), where \(z_{i}=\mathbf{a}^{\prime} \mathbf{y}_{i}, i=1,2, \ldots, n\).
3.8 Show that \(\operatorname{tr}\left(\mathbf{A S A}^{\prime}\right)=\sum_{i=1}^{k} \mathbf{a}_{i}^{\prime} \mathbf{S a}_{i}\) as in (3.65).
3.9 Use (3.76) to verify (3.83), \(\operatorname{cov}(\mathbf{z})=\mathbf{I} / n\), where \(\mathbf{z}=\left(\boldsymbol{\Sigma}^{1 / 2}\right)^{-1}(\overline{\mathbf{y}}-\boldsymbol{\mu})\).
3.10 Use the calcium data in Table 3.4:
(a) Calculate \(\mathbf{S}\) using the data matrix \(\mathbf{Y}\) as in (3.29).
(b) Obtain \(\mathbf{R}\) by calculating \(r_{12}, r_{13}\), and \(r_{23}\), as in (3.34) and (3.35).
(c) Find \(\mathbf{R}\) using (3.37).
3.11 Use the calcium data in Table 3.4:
(a) Find the generalized sample variance \(|\mathbf{S}|\) as in (3.77).
(b) Find the total sample variance \(\operatorname{tr}(\mathbf{S})\) as in (3.78).
3.12 Use the probe word data of Table 3.6:
(a) Find the generalized sample variance \(|\mathbf{S}|\) as in (3.77).
(b) Find the total sample variance \(\operatorname{tr}(\mathbf{S})\) as in (3.78).
3.13 For the probe word data in Table 3.6, find \(\mathbf{R}\) using (3.37).
3.14 For the variables in Table 3.4, define \(z=3 y_{1}-y_{2}+2 y_{3}=(3,-1,2) \mathbf{y}\). Find \(\bar{z}\) and \(s_{z}^{2}\) in two ways:
(a) Evaluate \(z\) for each row of Table 3.4 and find \(\bar{z}\) and \(s_{z}^{2}\) directly from \(z_{1}, z_{2}, \ldots, z_{10}\) using (3.1) and (3.5).
(b) Use \(\bar{z}=\mathbf{a}^{\prime} \overline{\mathbf{y}}\) and \(s_{z}^{2}=\mathbf{a}^{\prime} \mathbf{S a}\), as in (3.54) and (3.55).
3.15 For the variables in Table 3.4, define \(w=-2 y_{1}+3 y_{2}+y_{3}\) and define \(z\) as in Problem 3.14. Find \(r_{z w}\) in two ways:
(a) Evaluate \(z\) and \(w\) for each row of Table 3.4 and find \(r_{z w}\) from the 10 pairs \(\left(z_{i}, w_{i}\right), i=1,2, \ldots, 10\), using (3.10) and (3.13).
(b) Find \(r_{z w}\) using (3.57).
3.16 For the variables in Table 3.4, find the correlation between \(y_{1}\) and \(\frac{1}{2}\left(y_{2}+y_{3}\right)\) using (3.57).

\end{tabular}
(b) Find \(s_{z w}\) and \(r_{z w}\) using (3.56) and (3.57).
3.20 For the data in Table 3.7 define
\[
\begin{aligned}
& z_{1}=2 y_{1}+3 y_{2}-y_{3}+4 y_{4} \\
& z_{2}=-2 y_{1}-y_{2}+4 y_{3}-2 y_{4} \\
& z_{3}=3 y_{1}-2 y_{2}-y_{3}+3 y_{4}
\end{aligned}
\]

Find \(\overline{\mathbf{z}}, \mathbf{S}_{z}\), and \(\mathrm{R}_{z}\), using (3.62), (3.64), and (3.37), respectively.
3.21 The data in Table 3.8 consist of head measurements on first and second sons (Frets 1921). Define \(y_{1}\) and \(y_{2}\) as the measurements on the first son and \(x_{1}\) and \(x_{2}\) for the second son.
(a) Find the mean vector for all four variables and partition it into \(\left(\frac{\bar{y}}{\mathbf{x}}\right)\) as in (3.41).
(b) Find the covariance matrix for all four variables and partition it into
\[
\mathbf{S}=\left(\begin{array}{ll}
\mathbf{S}_{y y} & \mathbf{S}_{y x} \\
\mathbf{S}_{x y} & \mathbf{S}_{x x}
\end{array}\right)
\]
as in (3.42).
3.22 Table 3.9 contains data from O'Sullivan and Mahan (1966; see also Andrews and Herzberg 1985, p. 214) with measurements of blood glucose levels on three occasions for 50 women. The \(y\) 's represent fasting glucose measurements on the three occasions; the \(x\) 's are glucose measurements 1 hour after sugar intake. Find the mean vector and covariance matrix for all six variables and partition them into \(\binom{\overline{\mathbf{y}}}{\overline{\mathbf{x}}}\), as in (3.41), and
\[
\mathbf{S}=\left(\begin{array}{ll}
\mathbf{S}_{y y} & \mathbf{S}_{y x} \\
\mathbf{S}_{x y} & \mathbf{S}_{x x}
\end{array}\right)
\]
as in (3.42).

\section*{CHAPTER 4}

\section*{THE MULTIVARIATE NORMAL DISTRIBUTION}

\subsection*{4.1 MULTIVARIATE NORMAL DENSITY FUNCTION}

Many univariate tests and confidence intervals are based on the univariate normal distribution. Similarly, the majority of multivariate procedures have the multivariate normal distribution as their underpinning.

The following are some of the useful features of the multivariate normal distribution (see Section 4.2): (1) the distribution can be completely described using only means, variances, and covariances; (2) bivariate plots of multivariate data show linear trends; (3) if the variables are uncorrelated, they are independent; (4) linear functions of multivariate normal variables are also normal; (5) as in the univariate case, the convenient form of the density function lends itself to derivation of many properties and test statistics; and (6) even when the data are not multivariate normal, the multivariate normal may serve as a useful approximation, especially in inferences involving sample mean vectors, which are approximately multivariate normal by the central limit theorem (see Section 4.3.2).

Since the multivariate normal density is an extension of the univariate normal density and shares many of its features, we review the univariate normal density function

Figure 4.1 The normal density curve.
in Section 4.1.1. We then describe the multivariate normal density in Sections 4.1.24.1.4.

\subsection*{4.1.1 Univariate Normal Density}

If a random variable \(y\), with mean \(\mu\) and variance \(\sigma^{2}\), is normally distributed, its density is given by
\[
\begin{equation*}
f(y)=\frac{1}{\sqrt{2 \pi} \sqrt{\sigma^{2}}} e^{-(y-\mu)^{2} / 2 \sigma^{2}}, \quad-\infty<y<\infty \tag{4.1}
\end{equation*}
\]

When \(y\) has the density (4.1), we say that \(y\) is distributed as \(N\left(\mu, \sigma^{2}\right)\), or simply \(y\) is \(N\left(\mu, \sigma^{2}\right)\). This function is represented by the familiar bell-shaped curve illustrated in Figure 4.1 for \(\mu=10\) and \(\sigma=2.5\).

\subsection*{4.1.2 Multivariate Normal Density}

If \(y\) has a multivariate normal distribution with mean vector \(\mu\) and covariance matrix \(\boldsymbol{\Sigma}\), the density is given by
\[
\begin{equation*}
g(y)=\frac{1}{(\sqrt{2 \pi})^{p}|\boldsymbol{\Sigma}|^{1 / 2}} e^{-(\mathbf{y}-\mu)^{\prime} \boldsymbol{\Sigma}^{-1}(\mathbf{y}-\mu) / 2} \tag{4.2}
\end{equation*}
\]
where \(p\) is the number of variables. When \(\mathbf{y}\) has the density (4.2), we say that \(\mathbf{y}\) is distributed as \(N_{p}(\boldsymbol{\mu}, \boldsymbol{\Sigma})\), or simply \(\mathbf{y}\) is \(N_{p}(\boldsymbol{\mu}, \boldsymbol{\Sigma})\).

The term \((y-\mu)^{2} / \sigma^{2}=(y-\mu)\left(\sigma^{2}\right)^{-1}(y-\mu)\) in the exponent of the univariate normal density (4.1) measures the squared distance from \(y\) to \(\mu\) in standard deviation units. Similarly, the term \((\mathbf{y}-\boldsymbol{\mu})^{\prime} \boldsymbol{\Sigma}^{-1}(\mathbf{y}-\boldsymbol{\mu})\) in the exponent of the multivariate normal density (4.2) is the squared generalized distance from \(y\) to \(\mu\), or the Mahalanobis distance,
\[
\begin{equation*}
\Delta^{2}=(\mathbf{y}-\boldsymbol{\mu})^{\prime} \boldsymbol{\Sigma}^{-1}(\mathbf{y}-\boldsymbol{\mu}) . \tag{4.3}
\end{equation*}
\]

The characteristics of this distance between \(\mathbf{y}\) and \(\boldsymbol{\mu}\) were discussed in Section 3.13. Note that \(\Delta\), the square root of (4.3), is not in standard deviation units as is \((y-\mu) / \sigma\). The distance \(\Delta\) increases with \(p\), the number of variables (see Problem 4.4).

In the coefficient of the exponential function in (4.2), \(|\boldsymbol{\Sigma}|^{1 / 2}\) appears as the analogue of \(\sqrt{\sigma^{2}}\) in (4.1). In the next section, we discuss the effect of \(|\boldsymbol{\Sigma}|\) on the density.

\subsection*{4.1.3 Generalized Population Variance}

In Section 3.11, we referred to \(|\mathbf{S}|\) as a generalized sample variance. Analogously, \(|\boldsymbol{\Sigma}|\) is a generalized population variance. If \(\sigma^{2}\) is small in the univariate normal, the \(y\) values are concentrated near the mean. Similarly, a small value of \(|\Sigma|\) in the multivariate case indicates that the y's are concentrated close to \(\boldsymbol{\mu}\) in \(p\)-space or that there is multicollinearity among the variables. The term multicollinearity indicates that the variables are highly intercorrelated, in which case the effective dimensionality is less than \(p\). (See Chapter 12 for a method of finding a reduced number of new dimensions that represent the data.) In the presence of multicollinearity, one or more eigenvalues of \(\boldsymbol{\Sigma}\) will be near zero and \(|\boldsymbol{\Sigma}|\) will be small, since \(|\boldsymbol{\Sigma}|\) is the product of the eigenvalues [see (2.108)].

Figure 4.2 shows, for the bivariate case, a comparison of a distribution with small \(|\boldsymbol{\Sigma}|\) and a distribution with larger \(|\boldsymbol{\Sigma}|\). An alternative way to portray the concentration of points in the bivariate normal distribution is with contour plots. Figure 4.3 shows contour plots for the two distributions in Figure 4.2. Each ellipse contains a different proportion of observation vectors \(\mathbf{y}\). The contours in Figure 4.3 can be found by setting the density function equal to a constant and solving for \(\mathbf{y}\), as illustrated in Figure 4.4. The bivariate normal density surface sliced at a constant height traces an ellipse, which contains a given proportion of the observations [see Rencher (1998, Section 2.1.3)].

In both Figures 4.2 and 4.3 , small \(|\Sigma|\) appears on the left and large \(|\Sigma|\) appears on the right. In Figure 4.3(a), there is a larger correlation between \(y_{1}\) and \(y_{2}\). In Figure 4.3(b), the variances are larger (in the natural directions). In general, for any number of variables \(p\), a decrease in intercorrelations among the variables or an increase in the variances will lead to a larger \(|\boldsymbol{\Sigma}|\).

\subsection*{4.1.4 Diversity of Applications of the Multivariate Normal}

Nearly all the inferential procedures we discuss in this book are based on the multivariate normal distribution. We acknowledge that a major motivation for the widespread use of the multivariate normal is its mathematical tractability. From the mul-

Figure 4.2 Bivariate normal densities.

Figure 4.3 Contour plots for the distributions in Figure 4.2.
tivariate normal assumption, a host of useful procedures can be derived, and many of these are available in software packages. Practical alternatives to the multivariate normal are fewer than in the univariate case. Because it is not as simple to order (or rank) multivariate observation vectors as it is univariate observations, there are not as many nonparametric procedures available for multivariate data.

Although real data may not often be exactly multivariate normal, the multivariate normal will frequently serve as a useful approximation to the true distribution. Tests and graphical procedures are available for assessing normality (see Sections 4.4 and 4.6). Fortunately, many of the procedures based on multivariate normality are robust to departures from normality.

\subsection*{4.2 PROPERTIES OF MULTIVARIATE NORMAL RANDOM VARIABLES}

We list some of the properties of a random \(p \times 1\) vector \(y\) from a multivariate normal distribution \(N_{p}(\boldsymbol{\mu}, \boldsymbol{\Sigma})\) :
1. Normality of linear combinations of the variables in \(y\)

Figure 4.4 Constant density contour for bivariate normal.
a. If \(\mathbf{a}\) is a vector of constants, the linear function \(\mathbf{a}^{\prime} \mathbf{y}=a_{1} y_{1}+a_{2} y_{2}+\) \(\cdots+a_{p} y_{p}\) is univariate normal:
\[
\text { If } \mathbf{y} \text { is } N_{p}(\boldsymbol{\mu}, \boldsymbol{\Sigma}), \text { then } \mathbf{a}^{\prime} \mathbf{y} \text { is } N\left(\mathbf{a}^{\prime} \boldsymbol{\mu}, \mathbf{a}^{\prime} \boldsymbol{\Sigma} \mathbf{a}\right)
\]

The mean and variance of \(\mathbf{a}^{\prime} \mathbf{y}\) were given previously in (3.69) and (3.70) as \(E\left(\mathbf{a}^{\prime} \mathbf{y}\right)=\mathbf{a}^{\prime} \boldsymbol{\mu}\) and \(\operatorname{var}\left(\mathbf{a}^{\prime} \mathbf{y}\right)=\mathbf{a}^{\prime} \boldsymbol{\Sigma} \mathbf{a}\) for any random vector \(\mathbf{y}\). We now have the additional attribute that \(\mathbf{a}^{\prime} \mathbf{y}\) has a (univariate) normal distribution if \(\mathbf{y}\) is \(N_{p}(\boldsymbol{\mu}, \boldsymbol{\Sigma})\).
b. If \(\mathbf{A}\) is a constant \(q \times p\) matrix of rank \(q\), where \(q \leq p\), the \(q\) linear combinations in Ay have a multivariate normal distribution:
\[
\text { If } \mathbf{y} \text { is } N_{p}(\boldsymbol{\mu}, \boldsymbol{\Sigma}), \text { then } \mathbf{A} \mathbf{y} \text { is } N_{q}\left(\mathbf{A} \boldsymbol{\mu}, \mathbf{A} \boldsymbol{\Sigma} \mathbf{A}^{\prime}\right)
\]

Here, again, \(E(\mathbf{A y})=\mathbf{A} \boldsymbol{\mu}\) and \(\operatorname{cov}(\mathbf{A y})=\mathbf{A} \mathbf{\Sigma} \mathbf{A}^{\prime}\), in general, as given in (3.73) and (3.74). But we now have the additional feature that the \(q\) variables in Ay have a multivariate normal distribution.
2. Standardized variables

A standardized vector \(\mathbf{z}\) can be obtained in two ways:
\[
\begin{equation*}
\mathbf{z}=\left(\mathbf{T}^{\prime}\right)^{-1}(\mathbf{y}-\boldsymbol{\mu}) \tag{4.4}
\end{equation*}
\]
where \(\boldsymbol{\Sigma}=\mathbf{T}^{\prime} \mathbf{T}\) is factored using the Cholesky procedure in Section 2.7, or
\[
\begin{equation*}
\mathbf{z}=\left(\boldsymbol{\Sigma}^{1 / 2}\right)^{-1}(\mathbf{y}-\boldsymbol{\mu}) \tag{4.5}
\end{equation*}
\]
where \(\boldsymbol{\Sigma}^{1 / 2}\) is the symmetric square root matrix of \(\boldsymbol{\Sigma}\) defined in (2.112) such that \(\boldsymbol{\Sigma}=\boldsymbol{\Sigma}^{1 / 2} \boldsymbol{\Sigma}^{1 / 2}\). In either (4.4) or (4.5), the standardized vector of random variables has all means equal to 0 , all variances equal to 1 , and all correlations equal to 0 . In either case, it follows from property 1 b that z is multivariate normal:
\[
\text { If } \mathbf{y} \text { is } N_{p}(\boldsymbol{\mu}, \boldsymbol{\Sigma}) \text {, then } \mathbf{z} \text { is } N_{p}(\mathbf{0}, \mathbf{I})
\]
3. Chi-square distribution

A chi-square random variable with \(p\) degrees of freedom is defined as the sum of squares of \(p\) independent standard normal random variables. Thus if \(\mathbf{z}\) is the standardized vector defined in (4.4) or (4.5), then \(\sum_{j=1}^{p} z_{j}^{2}=\mathbf{z}^{\prime} \mathbf{z}\) has the \(\chi^{2}\) distribution with \(p\) degrees of freedom, denoted as \(\chi_{p}^{2}\) or \(\chi^{2}(p)\). From either (4.4) or (4.5) we obtain \(\mathbf{z}^{\prime} \mathbf{z}=(\mathbf{y}-\boldsymbol{\mu})^{\prime} \boldsymbol{\Sigma}^{-1}(\mathbf{y}-\boldsymbol{\mu})\). Hence,
\[
\begin{equation*}
\text { If } \mathbf{y} \text { is } N_{p}(\boldsymbol{\mu}, \boldsymbol{\Sigma}) \text {, then }(\mathbf{y}-\boldsymbol{\mu})^{\prime} \boldsymbol{\Sigma}^{-1}(\mathbf{y}-\boldsymbol{\mu}) \text { is } \chi_{p}^{2} \tag{4.6}
\end{equation*}
\]
4. Normality of marginal distributions
a. Any subset of the \(y\) 's in \(y\) has a multivariate normal distribution, with mean vector consisting of the corresponding subvector of \(\mu\) and covariance matrix composed of the corresponding submatrix of \(\boldsymbol{\Sigma}\). To illustrate, let \(\mathbf{y}_{1}=\left(y_{1}, y_{2}, \ldots, y_{r}\right)^{\prime}\) denote the subvector containing the first \(r\) elements of \(\mathbf{y}\) and \(\mathbf{y}_{2}=\left(y_{r+1}, \ldots, y_{p}\right)^{\prime}\) consist of the remaining \(p-r\) elements. Thus \(\mathbf{y}, \boldsymbol{\mu}\), and \(\boldsymbol{\Sigma}\) are partitioned as
\[
\mathbf{y}=\binom{\mathbf{y}_{1}}{\mathbf{y}_{2}}, \quad \boldsymbol{\mu}=\binom{\boldsymbol{\mu}_{1}}{\boldsymbol{\mu}_{2}}, \quad \boldsymbol{\Sigma}=\left(\begin{array}{ll}
\boldsymbol{\Sigma}_{11} & \boldsymbol{\Sigma}_{12} \\
\boldsymbol{\Sigma}_{21} & \boldsymbol{\Sigma}_{22}
\end{array}\right)
\]
where \(\mathbf{y}_{1}\) and \(\boldsymbol{\mu}_{1}\) are \(r \times 1\) and \(\boldsymbol{\Sigma}_{11}\) is \(r \times r\). Then \(\mathbf{y}_{1}\) is multivariate normal:
\[
\text { If } \mathbf{y} \text { is } N_{p}(\boldsymbol{\mu}, \boldsymbol{\Sigma}) \text {, then } \mathbf{y}_{1} \text { is } N_{r}\left(\boldsymbol{\mu}_{1}, \boldsymbol{\Sigma}_{11}\right)
\]

Here, again, \(E\left(\mathbf{y}_{1}\right)=\boldsymbol{\mu}_{1}\) and \(\operatorname{cov}\left(\mathbf{y}_{1}\right)=\boldsymbol{\Sigma}_{11}\) hold for any random vector partitioned in this way. But if \(\mathbf{y}\) is \(p\)-variate normal, then \(\mathbf{y}_{1}\) is \(r\)-variate normal.
b. As a special case of the preceding result, each \(y_{j}\) in \(\mathbf{y}\) has the univariate normal distribution:
\[
\text { If } \mathbf{y} \text { is } N_{p}(\boldsymbol{\mu}, \boldsymbol{\Sigma}) \text {, then } y_{j} \text { is } N\left(\mu_{j}, \sigma_{j j}\right), j=1,2, \ldots, p
\]

The converse of this is not true. If the density of each \(y_{j}\) in \(\mathbf{y}\) is normal, it does not necessarily follow that \(\mathbf{y}\) is multivariate normal.

In the next three properties, let the observation vector be partitioned into two subvectors denoted by \(\mathbf{y}\) and \(\mathbf{x}\), where \(\mathbf{y}\) is \(p \times 1\) and \(\mathbf{x}\) is \(q \times 1\). Or, alternatively, let \(\mathbf{x}\) represent some additional variables to be considered along with those in \(\mathbf{y}\). Then, as in (3.45) and (3.46),
\[
E\binom{\mathbf{y}}{\mathbf{x}}=\binom{\boldsymbol{\mu}_{y}}{\boldsymbol{\mu}_{x}}, \quad \operatorname{cov}\binom{\mathbf{y}}{\mathbf{x}}=\left(\begin{array}{cc}
\boldsymbol{\Sigma}_{y y} & \boldsymbol{\Sigma}_{y x} \\
\boldsymbol{\Sigma}_{x y} & \boldsymbol{\Sigma}_{x x}
\end{array}\right) .
\]

In properties 5, 6, and 7, we assume that
\[
\binom{\mathbf{y}}{\mathbf{x}} \text { is } N_{p+q}\left[\binom{\boldsymbol{\mu}_{x}}{\boldsymbol{\mu}_{y}},\left(\begin{array}{ll}
\boldsymbol{\Sigma}_{y y} & \boldsymbol{\Sigma}_{y x} \\
\boldsymbol{\Sigma}_{x y} & \boldsymbol{\Sigma}_{x x}
\end{array}\right)\right] .
\]
5. Independence
a. The subvectors \(\mathbf{y}\) and \(\mathbf{x}\) are independent if \(\boldsymbol{\Sigma}_{y x}=\mathbf{O}\).
b. Two individual variables \(y_{j}\) and \(y_{k}\) are independent if \(\sigma_{j k}=0\). Note that this is not true for many nonnormal random variables, as illustrated in Section 3.2.1.
6. Conditional distribution

If \(\mathbf{y}\) and x are not independent, then \(\boldsymbol{\Sigma}_{y x} \neq \mathbf{O}\), and the conditional distribution of \(\mathbf{y}\) given \(\mathbf{x}, f(\mathbf{y} \mid \mathbf{x})\), is multivariate normal with
\[
\begin{align*}
& E(\mathbf{y} \mid \mathbf{x})=\boldsymbol{\mu}_{y}+\boldsymbol{\Sigma}_{y x} \boldsymbol{\Sigma}_{x x}^{-1}\left(\mathbf{x}-\boldsymbol{\mu}_{x}\right)  \tag{4.7}\\
& \operatorname{cov}(\mathbf{y} \mid \mathbf{x})=\boldsymbol{\Sigma}_{y y}-\boldsymbol{\Sigma}_{y x} \boldsymbol{\Sigma}_{x x}^{-1} \boldsymbol{\Sigma}_{x y} \tag{4.8}
\end{align*}
\]

Note that \(E(\mathbf{y} \mid \mathbf{x})\) is a vector of linear functions of \(\mathbf{x}\), while \(\operatorname{cov}(\mathbf{y} \mid \mathbf{x})\) does not depend on \(x\). The linear trend in (4.7) holds for any pair of variables. Thus to use (4.7) as a check on normality, one can examine bivariate scatterplots of all pairs of variables and look for any nonlinear trends. In (4.7), we have the justification for using the covariance or correlation to measure the relationship between two bivariate normal random variables. As noted in Section 3.2.1, the covariance and correlation are good measures of relationship only for variables with linear trends and are generally unsuitable for nonnormal random variables with a curvilinear relationship. The matrix \(\Sigma_{y x} \boldsymbol{\Sigma}_{x x}^{-1}\) in (4.7) is called the matrix of regression coefficients because it relates \(E(\mathbf{y} \mid \mathbf{x})\) to x . The sample counterpart of this matrix appears in (10.57).
7. Distribution of the sum of two subvectors

If \(\mathbf{y}\) and \(\mathbf{x}\) are the same size (both \(p \times 1\) ) and independent, then
\[
\begin{align*}
\mathbf{y}+\mathbf{x} & \text { is } \quad N_{p}\left(\boldsymbol{\mu}_{y}+\boldsymbol{\mu}_{x}, \boldsymbol{\Sigma}_{y y}+\boldsymbol{\Sigma}_{x x}\right)  \tag{4.9}\\
\mathbf{y}-\mathbf{x} & \text { is } \quad N_{p}\left(\boldsymbol{\mu}_{y}-\boldsymbol{\mu}_{x}, \boldsymbol{\Sigma}_{y y}+\boldsymbol{\Sigma}_{x x}\right) \tag{4.10}
\end{align*}
\]

In the remainder of this section, we illustrate property 6 for the special case of the bivariate normal. Let
\[
\mathbf{u}=\binom{y}{x}
\]
have a bivariate normal distribution with
\[
E(\mathbf{u})=\binom{\mu_{y}}{\mu_{x}}, \quad \operatorname{cov}(\mathbf{u})=\boldsymbol{\Sigma}=\left(\begin{array}{ll}
\sigma_{y}^{2} & \sigma_{y x} \\
\sigma_{y x} & \sigma_{x}^{2}
\end{array}\right) .
\]

By definition \(f(y \mid x)=g(y, x) / h(x)\), where \(g(y, x)\) is the joint density of \(y\) and \(x\) and \(h(x)\) is the density of \(x\). Hence
\[
g(y, x)=f(y \mid x) h(x)
\]
and because the right side is a product, we seek a function of \(y\) and \(x\) that is independent of \(x\) and whose density can serve as \(f(y \mid x)\). Since linear functions of \(y\) and \(x\) are normal by property 1 a , we consider \(y-\beta x\) and seek the value of \(\beta\) so that \(y-\beta x\) and \(x\) are independent.

Since \(z=y-\beta x\) and \(x\) are normal and independent, \(\operatorname{cov}(x, z)=0\). To find \(\operatorname{cov}(x, z)\), we express \(x\) and \(z\) as functions of \(\mathbf{u}\),
\[
\begin{aligned}
& x=(0,1)\binom{y}{x}=(0,1) \mathbf{u}=\mathbf{a}^{\prime} \mathbf{u} \\
& z=y-\beta x=(1,-\beta) \mathbf{u}=\mathbf{b}^{\prime} \mathbf{u}
\end{aligned}
\]

Now
\[
\begin{aligned}
\operatorname{cov}(x, z) & =\operatorname{cov}\left(\mathbf{a}^{\prime} \mathbf{u}, \mathbf{b}^{\prime} \mathbf{u}\right) \\
& =\mathbf{a}^{\prime} \boldsymbol{\Sigma} \mathbf{b} \quad[\mathbf{b y}(3.71)] \\
& =(0,1)\left(\begin{array}{ll}
\sigma_{y}^{2} & \sigma_{y x} \\
\sigma_{y x} & \sigma_{x}^{2}
\end{array}\right)\binom{1}{-\beta}=\left(\sigma_{y x}, \sigma_{x}^{2}\right)\binom{1}{-\beta} \\
& =\sigma_{y x}-\beta \sigma_{x}^{2} .
\end{aligned}
\]

Since \(\operatorname{cov}(x, z)=0\), we obtain \(\beta=\sigma_{y x} / \sigma_{x}^{2}\) and \(z=y-\beta x\) becomes
\[
z=y-\frac{\sigma_{y x}}{\sigma_{x}^{2}} x
\]

By property 1 a above, the density of \(y-\left(\sigma_{y x} / \sigma_{x}^{2}\right) x\) is normal with
\[
\begin{aligned}
& E\left(y-\frac{\sigma_{y x}}{\sigma_{x}^{2}} x\right)=\mu_{y}-\frac{\sigma_{y x}}{\sigma_{x}^{2}} \mu_{x}, \\
& \begin{aligned}
\operatorname{var}\left(y-\frac{\sigma_{y x}}{\sigma_{x}^{2}} x\right) & =\operatorname{var}\left(\mathbf{b}^{\prime} \mathbf{u}\right)=\mathbf{b}^{\prime} \mathbf{\Sigma} \mathbf{b} \\
& =\left(1,-\frac{\sigma_{y x}}{\sigma_{x}^{2}}\right)\left(\begin{array}{ll}
\sigma_{y}^{2} & \sigma_{y x} \\
\sigma_{y x} & \sigma_{x}^{2}
\end{array}\right)\binom{1}{-\frac{\sigma_{y x}}{\sigma_{x}^{2}}} \\
& =\sigma_{y}^{2}-\frac{\sigma_{y x}}{\sigma_{x}^{2}} .
\end{aligned}
\end{aligned}
\]

For a given value of \(x\), we can express \(y\) as \(y=\beta x+(y-\beta x)\), where \(\beta x\) is a fixed quantity corresponding to the given value of \(x\) and \(y-\beta x\) is a random deviation. Then \(f(y \mid x)\) is normal, with
\[
\begin{aligned}
E(y \mid x) & =\beta x+E(y-\beta x)=\beta x+\mu_{y}-\beta \mu_{x} \\
& =\mu_{y}+\beta\left(x-\mu_{x}\right)=\mu_{y}+\frac{\sigma_{y x}}{\sigma_{x}^{2}}\left(x-\mu_{x}\right), \\
\operatorname{var}(y \mid x) & =\sigma_{y}^{2}-\frac{\sigma_{y x}^{2}}{\sigma_{x}^{2}} .
\end{aligned}
\]

\subsection*{4.3 ESTIMATION IN THE MULTIVARIATE NORMAL}

\subsection*{4.3.1 Maximum Likelihood Estimation}

When a distribution such as the multivariate normal is assumed to hold for a population, estimates of the parameters are often found by the method of maximum likelihood. This technique is conceptually simple: The observation vectors \(\mathbf{y}_{1}, \mathbf{y}_{2}, \ldots, \mathbf{y}_{n}\) are considered to be known, and values of \(\boldsymbol{\mu}\) and \(\boldsymbol{\Sigma}\) are sought that maximize the joint density of the \(y\) 's, called the likelihood function. For the multivariate normal, the maximum likelihood estimates of \(\boldsymbol{\mu}\) and \(\boldsymbol{\Sigma}\) are
\[
\begin{align*}
& \hat{\boldsymbol{\mu}}=\overline{\mathbf{y}}  \tag{4.11}\\
& \hat{\boldsymbol{\Sigma}}=\frac{1}{n} \sum_{i=1}^{n}\left(\mathbf{y}_{i}-\overline{\mathbf{y}}\right)\left(\mathbf{y}_{i}-\overline{\mathbf{y}}\right)^{\prime} \\
&= \frac{1}{n} \mathbf{W} \\
&= \frac{n-1}{n} \mathbf{S} \tag{4.12}
\end{align*}
\]
where \(\mathbf{W}=\sum_{i=1}^{n}\left(\mathbf{y}_{i}-\overline{\mathbf{y}}\right)\left(\mathbf{y}_{i}-\overline{\mathbf{y}}\right)^{\prime}\) and \(\mathbf{S}\) is the sample covariance matrix defined in (3.22) and (3.27). Since \(\hat{\boldsymbol{\Sigma}}\) has divisor \(n\) instead of \(n-1\), it is biased [see (3.33)], and we usually use \(S\) in place of \(\hat{\boldsymbol{\Sigma}}\).

We now give a justification of \(\bar{y}\) as the maximum likelihood estimator of \(\boldsymbol{\mu}\). Because the \(y_{i}\) 's constitute a random sample, they are independent, and the joint density is the product of the densities of the \(y\) 's. The likelihood function is, therefore,
\[
\begin{align*}
L\left(\boldsymbol{\mu}, \boldsymbol{\Sigma} ; \mathbf{y}_{1}, \mathbf{y}_{2}, \ldots, \mathbf{y}_{n}\right) & =\prod_{i=1}^{n} f\left(\mathbf{y}_{i}, \boldsymbol{\mu}, \boldsymbol{\Sigma}\right) \\
& =\prod_{i=1}^{n} \frac{1}{(\sqrt{2 \pi})^{p}|\boldsymbol{\Sigma}|^{1 / 2}} e^{-\left(\mathbf{y}_{i}-\boldsymbol{\mu}\right)^{\prime} \boldsymbol{\Sigma}^{-1}\left(\mathbf{y}_{i}-\boldsymbol{\mu}\right) / 2} \\
& =\frac{1}{(\sqrt{2 \pi})^{n p}|\boldsymbol{\Sigma}|^{n / 2}} e^{-\sum_{i=1}^{n}\left(\mathbf{y}_{i}-\boldsymbol{\mu}\right)^{\prime} \boldsymbol{\Sigma}^{-1}\left(\mathbf{y}_{i}-\boldsymbol{\mu}\right) / 2} \tag{4.13}
\end{align*}
\]

To see that \(\hat{\mu}=\overline{\mathbf{y}}\) maximizes the likelihood function, we write the exponent of (4.13) in terms of \(\overline{\mathbf{y}}\). By adding and subtracting \(\overline{\mathbf{y}}\), the exponent in (4.13) becomes
\[
-\frac{1}{2} \sum_{i=1}^{n}\left(\mathbf{y}_{i}-\overline{\mathbf{y}}+\overline{\mathbf{y}}-\boldsymbol{\mu}\right)^{\prime} \boldsymbol{\Sigma}^{-1}\left(\mathbf{y}_{i}-\overline{\mathbf{y}}+\overline{\mathbf{y}}-\boldsymbol{\mu}\right)
\]

When this is expanded in terms of \(\mathbf{y}_{i}-\overline{\mathbf{y}}\) and \(\overline{\mathbf{y}}-\mu\), two of the four resulting terms vanish because \(\sum_{i}\left(\mathbf{y}_{i}-\overline{\mathbf{y}}\right)=\mathbf{0}\), and (4.13) becomes
\[
\begin{equation*}
L=\frac{1}{(\sqrt{2 \pi})^{n p}|\boldsymbol{\Sigma}|^{n / 2}} e^{-\sum_{i=1}^{n}\left(\mathbf{y}_{i}-\overline{\mathbf{y}}\right)^{\prime} \boldsymbol{\Sigma}^{-1}\left(\mathbf{y}_{i}-\overline{\mathbf{y}}\right) / 2-n(\overline{\mathbf{y}}-\boldsymbol{\mu})^{\prime} \boldsymbol{\Sigma}^{-1}(\overline{\mathbf{y}}-\boldsymbol{\mu}) / 2} \tag{4.14}
\end{equation*}
\]

Since \(\boldsymbol{\Sigma}^{-1}\) is positive definite, we have \(-n(\overline{\mathbf{y}}-\boldsymbol{\mu})^{\prime} \boldsymbol{\Sigma}^{-1}(\overline{\mathbf{y}}-\boldsymbol{\mu}) / 2 \leq 0\) and \(0<\) \(e^{-n(\overline{\mathbf{y}}-\mu)^{\prime} \boldsymbol{\Sigma}^{-1}(\overline{\mathbf{y}}-\mu) / 2} \leq 1\), with the maximum occurring when the exponent is 0 . Therefore, \(L\) is maximized when \(\hat{\boldsymbol{\mu}}=\overline{\mathbf{y}}\).

The maximum likelihood estimator of the population correlation matrix \(\mathbf{P}_{p}\) [see (3.39)] is the sample correlation matrix, that is,
\[
\hat{\mathbf{P}}_{\rho}=\mathbf{R} .
\]

Relationships among multinormal variables are linear, as can be seen in (4.7). Thus the estimators \(\mathbf{S}\) and \(\mathbf{R}\) serve well for the multivariate normal because they measure only linear relationships (see Sections 3.2.1 and 4.2). These estimators are not as useful for some nonnormal distributions.

\subsection*{4.3.2 Distribution of \(\overline{\mathbf{y}}\) and \(\mathbf{S}\)}

For the distribution of \(\overline{\mathbf{y}}=\sum_{i=1}^{n} \mathbf{y}_{i} / n\), we can distinguish two cases:
(a) When \(\overline{\mathbf{y}}\) is based on a random sample \(\mathbf{y}_{1}, \mathbf{y}_{2}, \ldots, \mathbf{y}_{n}\) from a multivariate normal distribution \(N_{p}(\boldsymbol{\mu}, \boldsymbol{\Sigma})\), then \(\overline{\mathbf{y}}\) is \(N_{p}(\boldsymbol{\mu}, \boldsymbol{\Sigma} / n)\).
(b) When \(\overline{\mathbf{y}}\) is based on a random sample \(\mathbf{y}_{1}, \mathbf{y}_{2}, \ldots, \mathbf{y}_{n}\) from a nonnormal multivariate population with mean vector \(\boldsymbol{\mu}\) and covariance matrix \(\boldsymbol{\Sigma}\), then for large \(n, \overline{\mathbf{y}}\) is approximately \(N_{p}(\boldsymbol{\mu}, \boldsymbol{\Sigma} / n)\). More formally, this result is known as the multivariate central limit theorem: If \(\overline{\mathbf{y}}\) is the mean vector of a random sample \(\mathbf{y}_{1}, \mathbf{y}_{2}, \ldots, \mathbf{y}_{n}\) from a population with mean vector \(\boldsymbol{\mu}\) and covariance matrix \(\boldsymbol{\Sigma}\), then as \(n \rightarrow \infty\), the distribution of \(\sqrt{n}(\overline{\mathbf{y}}-\boldsymbol{\mu})\) approaches \(N_{p}(\mathbf{0}, \boldsymbol{\Sigma})\).

There are \(p\) variances in \(\mathbf{S}\) and \(\binom{p}{2}\) covariances, for a total of
\[
p+\binom{p}{2}=p+p(p-1) / 2=p(p+1) / 2
\]
distinct entries. The joint distribution of these \(p(p+1) / 2\) distinct variables in \(\mathbf{W}=\) \((n-1) \mathbf{S}=\sum_{i}\left(\mathbf{y}_{i}-\overline{\mathbf{y}}\right)\left(\mathbf{y}_{i}-\overline{\mathbf{y}}\right)^{\prime}\) is the Wishart distribution, denoted by \(W_{p}(n-1, \boldsymbol{\Sigma})\), where \(n-1\) is the degrees of freedom.

The Wishart distribution is the multivariate analogue of the \(\chi^{2}\)-distribution, and it has similar uses. As noted in property 3 of Section 4.2, a \(\chi^{2}\) random variable is defined formally as the sum of squares of independent standard normal (univariate) random variables:
\[
\sum_{i=1}^{n} z_{i}^{2}=\sum_{i=1}^{n} \frac{\left(y_{i}-\mu\right)^{2}}{\sigma^{2}} \quad \text { is } \quad \chi^{2}(n) .
\]

If \(\bar{y}\) is substituted for \(\mu\), then \(\sum_{i}\left(y_{i}-\bar{y}\right)^{2} / \sigma^{2}=(n-1) s^{2} / \sigma^{2}\) is \(\chi^{2}(n-1)\). Similarly, the formal definition of a Wishart random variable is
\[
\begin{equation*}
\sum_{i=1}^{n}\left(\mathbf{y}_{i}-\boldsymbol{\mu}\right)\left(\mathbf{y}_{i}-\boldsymbol{\mu}\right)^{\prime} \quad \text { is } \quad W_{p}(n, \boldsymbol{\Sigma}) \tag{4.15}
\end{equation*}
\]
where \(\mathbf{y}_{1}, \mathbf{y}_{2}, \ldots, \mathbf{y}_{n}\) are independently distributed as \(N_{p}(\boldsymbol{\mu}, \boldsymbol{\Sigma})\). When \(\overline{\mathbf{y}}\) is substituted for \(\mu\), the distribution remains Wishart with one less degree of freedom:
\[
\begin{equation*}
(n-1) \mathbf{S}=\sum_{i=1}^{n}\left(\mathbf{y}_{i}-\overline{\mathbf{y}}\right)\left(\mathbf{y}_{i}-\overline{\mathbf{y}}\right)^{\prime} \quad \text { is } \quad W_{p}(n-1, \boldsymbol{\Sigma}) \tag{4.16}
\end{equation*}
\]

Finally, we note that when sampling from a multivariate normal distribution, \(\overline{\mathbf{y}}\) and \(\mathbf{S}\) are independent.

\subsection*{4.4 ASSESSING MULTIVARIATE NORMALITY}

Many tests and graphical procedures have been suggested for evaluating whether a data set likely originated from a multivariate normal population. One possibility is to check each variable separately for univariate normality. Excellent reviews for both the univariate and multivariate cases have been given by Gnanadesikan (1997, pp. 178-220) and Seber (1984, pp. 141-155). We give a representative sample of univariate and multivariate methods in Sections 4.4.1 and 4.4.2, respectively.

\subsection*{4.4.1 Investigating Univariate Normality}

When we have several variables, checking each for univariate normality should not be the sole approach, because (1) the variables are correlated and (2) normality of the individual variables does not guarantee joint normality. On the other hand, multivariate normality implies individual normality. Hence, if even one of the separate variables is not normal, the vector is not multivariate normal. An initial check on the individual variables may therefore be useful.

A basic graphical approach for checking normality is the \(Q-Q\) plot comparing quantiles of a sample against the population quantiles of the univariate normal. If the points are close to a straight line, there is no indication of departure from normality. Deviation from a straight line indicates nonnormality (at least for a large sample). In

Figure 4.5 Typical \(Q-Q\) plots for nonnormal data.
fact, the type of nonlinear pattern may reveal the type of departure from normality. Some possibilities are illustrated in Figure 4.5.

Quantiles are similar to the more familiar percentiles, which are expressed in terms of percent; a test score at the 90 th percentile, for example, is above \(90 \%\) of the test scores and below \(10 \%\) of them. Quantiles are expressed in terms of fractions or proportions. Thus the 90 th percentile score becomes the .9 quantile score.

The sample quantiles for the \(Q-Q\) plot are obtained as follows. First we rank the observations \(y_{1}, y_{2}, \ldots, y_{n}\) and denote the ordered values by \(y_{(1)}, y_{(2)}, \ldots, y_{(n)}\); thus \(y_{(1)} \leq y_{(2)} \leq \cdots \leq y_{(n)}\). Then the point \(y_{(i)}\) is the \(i / n\) sample quantile. For example, if \(n=20, y_{(7)}\) is the \(\frac{7}{20}=.35\) quantile, because .35 of the sample is less than or equal to \(y_{(7)}\). The fraction \(i / n\) is often changed to \(\left(i-\frac{1}{2}\right) / n\) as a continuity correction. If \(n=20,\left(i-\frac{1}{2}\right) / n\) ranges from .025 to .975 and more evenly covers the interval from 0 to 1 . With this convention, \(y_{(i)}\) is designated as the \(\left(i-\frac{1}{2}\right) / n\) sample quantile.

The population quantiles for the \(Q-Q\) plot are similarly defined corresponding to \(\left(i-\frac{1}{2}\right) / n\). If we denote these by \(q_{1}, q_{2}, \ldots, q_{n}\), then \(q_{i}\) is the value below which a proportion \(\left(i-\frac{1}{2}\right) / n\) of the observations in the population lie; that is, \(\left(i-\frac{1}{2}\right) / n\) is the probability of getting an observation less than or equal to \(q_{i}\). Formally, \(q_{i}\) can be found for the standard normal random variable \(y\) with distribution \(N(0,1)\) by solving
\[
\begin{equation*}
\Phi\left(q_{i}\right)=P\left(y<q_{i}\right)=\frac{i-\frac{1}{2}}{n} \tag{4.17}
\end{equation*}
\]
which would require numerical integration or tables of the cumulative standard normal distribution, \(\Phi(x)\). Another benefit of using \(\left(i-\frac{1}{2}\right) / n\) instead of \(i / n\) is that \(n / n=1\) would make \(q_{n}=\infty\).

The population need not have the same mean and variance as the sample, since changes in mean and variance merely change the slope and intercept of the plotted line in the \(Q-Q\) plot. Therefore, we use the standard normal distribution, and the \(q_{i}\) values can easily be found from a table of cumulative standard normal probabilities. We then plot the pairs ( \(q_{i}, y_{(i)}\) ) and examine the resulting \(Q-Q\) plot for linearity.

Special graph paper, called normal probability paper, is available that eliminates the need to look up the \(q_{i}\) values. We need only plot \(\left(i-\frac{1}{2}\right) / n\) in place of \(q_{i}\), that is, plot the pairs \(\left[\left(i-\frac{1}{2}\right) / n, y_{(i)}\right]\) and look for linearity as before. As an even easier alternative, most general-purpose statistical software programs provide normal probability plots of the pairs \(\left(q_{i}, y_{(i)}\right)\).

The \(Q-Q\) plots provide a good visual check on normality and are considered to be adequate for this purpose by many researchers. For those who desire a more objective procedure, several hypothesis tests are available. We give three of these that have good properties and are computationally tractable.

We discuss first a classical approach based on the following measures of skewness and kurtosis:
\[
\begin{align*}
\sqrt{b_{1}} & =\frac{\sqrt{n} \sum_{i=1}^{n}\left(y_{i}-\bar{y}\right)^{3}}{\left[\sum_{i=1}^{n}\left(y_{i}-\bar{y}\right)^{2}\right]^{3 / 2}},  \tag{4.18}\\
b_{2} & =\frac{n \sum_{i=1}^{n}\left(y_{i}-\bar{y}\right)^{4}}{\left[\sum_{i=1}^{n}\left(y_{i}-\bar{y}\right)^{2}\right]^{2}} \tag{4.19}
\end{align*}
\]

These are sample estimates of the population skewness and kurtosis parameters \(\sqrt{\beta_{1}}\) and \(\beta_{2}\), respectively. When the population is normal, \(\sqrt{\beta_{1}}=0\) and \(\beta_{2}=3\). If

Figure 4.6 A distribution with positive skewness.
\(\sqrt{\beta_{1}}<0\), we have negative skewness; if \(\sqrt{\beta_{1}}>0\), the skewness is positive. Positive skewness is illustrated in Figure 4.6. If \(\beta_{2}<3\), we have negative kurtosis, and if \(\beta_{2}>3\), there is positive kurtosis. A distribution with negative kurtosis is characterized by being flatter than the normal distribution, that is, less peaked, with heavier flanks and thinner tails. A distribution with positive kurtosis has a higher peak than the normal, with an excess of values near the mean and in the tails but with thinner flanks. Positive and negative kurtosis are illustrated in Figure 4.7.

The test of normality can be carried out using the exact percentage points for \(\sqrt{b_{1}}\) in Table A. 1 for \(4 \leq n \leq 25\), as given by Mulholland (1977). Alternatively, for \(n \geq 8\) the function \(g\) as defined by
\[
\begin{equation*}
g\left(\sqrt{b_{1}}\right)=\delta \sinh ^{-1}\left(\frac{\sqrt{b_{1}}}{\lambda}\right) \tag{4.20}
\end{equation*}
\]
is approximately \(N(0,1)\), where
\[
\begin{equation*}
\sinh ^{-1}(x)=\ln \left(x+\sqrt{x^{2}+1}\right) \tag{4.21}
\end{equation*}
\]

Table A.2, from D'Agostino and Pearson (1973), gives values for \(\delta\) and \(1 / \lambda\). To use \(b_{2}\) as a test of normality, we can use Table A.3, from D'Agostino and Tietjen (1971), which gives simulated percentiles of \(b_{2}\) for selected values of \(n\) in the range \(7 \leq n \leq 50\). Charts of percentiles of \(b_{2}\) for \(20 \leq n \leq 200\) can be found in D'Agostino and Pearson (1973).

Figure 4.7 Distributions with positive and negative kurtosis compared to the normal.

Our second test for normality was given by D'Agostino (1971). The observations \(y_{1}, y_{2}, \ldots, y_{n}\) are ordered as \(y_{(1)} \leq y_{(2)} \leq \cdots \leq y_{(n)}\), and we calculate
\[
\begin{align*}
& D=\frac{\sum_{i=1}^{n}\left[i-\frac{1}{2}(n+1)\right] y_{(i)}}{\sqrt{n^{3} \sum_{i=1}^{n}\left(y_{i}-\bar{y}\right)^{2}}}  \tag{4.22}\\
& Y=\frac{\sqrt{n}\left[D-(2 \sqrt{\pi})^{-1}\right]}{.02998598} \tag{4.23}
\end{align*}
\]

A table of percentiles for \(Y\), given by D'Agostino (1972) for \(10 \leq n \leq 250\), is provided in Table A.4.

The final test we report is by Lin and Mudholkar (1980). The test statistic is
\[
\begin{equation*}
z=\tanh ^{-1}(r)=\frac{1}{2} \ln \left(\frac{1+r}{1-r}\right) \tag{4.24}
\end{equation*}
\]
where \(r\) is the sample correlation of the \(n\) pairs \(\left(y_{i}, x_{i}\right), i=1,2, \ldots, n\), with \(x_{i}\) defined as
\[
\begin{equation*}
x_{i}=\frac{1}{n}\left[\sum_{j \neq i} y_{j}^{2}-\frac{\left(\sum_{j \neq i} y_{j}\right)^{2}}{n-1}\right]^{1 / 3} \tag{4.25}
\end{equation*}
\]

If the y's are normal, \(z\) is approximately \(N(0,3 / n)\). A more accurate upper \(100 \alpha\) percentile is given by
\[
\begin{equation*}
z_{\alpha}=\sigma_{n}\left[u_{\alpha}+\frac{1}{24}\left(u_{\alpha}^{3}-3 u_{\alpha}\right) \gamma_{2 n}\right], \tag{4.26}
\end{equation*}
\]
with
\[
\begin{aligned}
\sigma_{n}^{2} & =\frac{3}{n}-\frac{7.324}{n^{2}}+\frac{53.005}{n^{3}}, \quad u_{\alpha}=\Phi^{-1}(\alpha) \\
\gamma_{2 n} & =-\frac{11.70}{n}+\frac{55.06}{n^{2}}
\end{aligned}
\]
where \(\Phi\) is the distribution function of the \(N(0,1)\) distribution; that is, \(\Phi(x)\) is the probability of an observation less than or equal to \(x\), as in (4.17). The inverse function \(\Phi^{-1}\) is essentially a quantile. For example, \(u_{.05}=-1.645\) and \(u .95=1.645\).

\subsection*{4.4.2 Investigating Multivariate Normality}

Checking for multivariate normality is conceptually not as straightforward as assessing univariate normality, and consequently the state of the art is not as well developed. The complexity of this issue can be illustrated in the context of a goodness-of-fit test for normality. For a goodness-of-fit test in the univariate case, the range covered by a sample \(y_{1}, y_{2}, \ldots, y_{n}\) is divided into several intervals, and we count how many \(y\) 's fall into each interval. These observed frequencies (counts) are compared to the expected frequencies under the assumption that the sample came from a normal distribution with the same mean and variance as the sample. If the \(n\) observations \(\mathbf{y}_{1}, \mathbf{y}_{2}, \ldots, \mathbf{y}_{n}\) are multivariate, however, the procedure is not so simple. We now have a \(p\)-dimensional region that would have to be divided into many more subregions than in the univariate case, and the expected frequencies for these subregions would be less easily obtained. With so many subregions, relatively few would contain observations.

Thus because of the inherent "sparseness" of multivariate data, a goodness-of-fit test would be impractical. The points \(\mathbf{y}_{1}, \mathbf{y}_{2}, \ldots, \mathbf{y}_{n}\) are more distant from each other in \(p\)-space than in any one of the \(p\) individual dimensions. Unless \(n\) is very large, a multivariate sample may not provide a very complete picture of the distribution from which it was taken.

As a consequence of the sparseness of the data in \(p\)-space, the tests for multivariate normality may not be very powerful. However, some check on the distribution is often desirable. Numerous procedures have been proposed for assessing multivariate normality. We now discuss three of these.

The first procedure is based on the standardized distance from each \(\mathbf{y}_{i}\) to \(\overline{\mathbf{y}}\),
\[
\begin{equation*}
D_{i}^{2}=\left(\mathbf{y}_{i}-\overline{\mathbf{y}}\right)^{\prime} \mathbf{S}^{-1}\left(\mathbf{y}_{i}-\overline{\mathbf{y}}\right), \quad i=1,2, \ldots, n \tag{4.27}
\end{equation*}
\]

Gnanadesikan and Kettenring (1972) showed that if the \(\mathbf{y}_{i}\) 's are multivariate normal, then
\[
\begin{equation*}
u_{i}=\frac{n D_{i}^{2}}{(n-1)^{2}} \tag{4.28}
\end{equation*}
\]
has a beta distribution, which is related to the \(F\). To obtain a \(Q-Q\) plot, the values \(u_{1}, u_{2}, \ldots, u_{n}\) are ranked to give \(u_{(1)} \leq u_{(2)} \leq \cdots \leq u_{(n)}\), and we plot \(\left(u_{(i)}, v_{i}\right)\), where the quantiles \(v_{i}\) of the beta are given by the solution to
\[
\begin{equation*}
\int_{0}^{v_{i}} \frac{\Gamma(a+b)}{\Gamma(a) \Gamma(b)} x^{a-1}(1-x)^{b-1} d x=\frac{i-\alpha}{n-\alpha-\beta+1} \tag{4.29}
\end{equation*}
\]
where \(a=\frac{1}{2} p, b=\frac{1}{2}(n-p-1)\),
\[
\begin{align*}
\alpha & =\frac{p-2}{2 p}  \tag{4.30}\\
\beta & =\frac{n-p-3}{2(n-p-1)} \tag{4.31}
\end{align*}
\]

A nonlinear pattern in the plot would indicate a departure from normality. The quantities of the beta are easily obtained in many software packages. A formal significance test is also available for \(D_{(n)}^{2}=\max _{i} D_{i}^{2}\). Table A. 6 gives the upper \(5 \%\) and \(1 \%\) critical values for \(p=2,3,4,5\) from Barnett and Lewis (1978).

Some writers have suggested that the distribution of \(D_{i}^{2}\) in (4.27) can be adequately approximated by a \(\chi_{p}^{2}\) since \((\mathbf{y}-\boldsymbol{\mu})^{\prime} \boldsymbol{\Sigma}^{-1}(\mathbf{y}-\boldsymbol{\mu})\) is \(\chi_{p}^{2}\) [see (4.6)]. However, in Section 5.3.2, it is shown that this approximation is very poor for even moderate values of \(p\). Small (1978) showed that plots of \(D_{i}^{2}\) vs. \(\chi^{2}\) quantiles are misleading.

The second procedure involves scatterplots in two dimensions. If \(p\) is not too high, the bivariate plots of each pair of variables are often reduced in size and shown on one page, arranged to correspond to the entries in a correlation matrix. In this visual matrix, the eye readily picks out those pairs of variables that show a curved trend, outliers, or other nonnormal appearance. This plot is illustrated in Example 4.6.2 in Section 4.6.2. The procedure is based on properties 4 and 6 of Section 4.2, from which we infer that (1) each pair of variables has a bivariate normal distribution and (2) bivariate normal variables follow a straight-line trend.

An extension of this method for assessing multivariate normality is the use of the grand tour discussed in Section 3.5. In the grand tour, we consider a series of random two-dimensional projections of the \(p\)-variate data. For the purposes of normality assessment, properties 1 and 6 from Section 4.2 imply that each projection viewed during the grand tour should exhibit bivariate normality, with no indications of nonlinearity in the projected data. Any deviation from elliptical clouds of points is an indication of potential nonnormality.

The third procedure for assessing multivariate normality is a generalization of the univariate test based on the skewness and kurtosis measures \(\sqrt{b_{1}}\) and \(b_{2}\) as given by (4.18) and (4.19). The test is due to Mardia (1970). Let \(y\) and \(x\) be independent and identically distributed with mean vector \(\boldsymbol{\mu}\) and covariance matrix \(\boldsymbol{\Sigma}\). Then skewness and kurtosis for multivariate populations are defined by Mardia as
\[
\begin{align*}
& \beta_{1, p}=E\left[(\mathbf{y}-\boldsymbol{\mu})^{\prime} \boldsymbol{\Sigma}^{-1}(\mathbf{x}-\boldsymbol{\mu})\right]^{3}  \tag{4.32}\\
& \beta_{2, p}=E\left[(\mathbf{y}-\boldsymbol{\mu})^{\prime} \boldsymbol{\Sigma}^{-1}(\mathbf{y}-\boldsymbol{\mu})\right]^{2} \tag{4.33}
\end{align*}
\]

Since third-order central moments for the multivariate normal distribution are zero, \(\beta_{1, p}=0\) when \(\mathbf{y}\) is \(N_{p}(\boldsymbol{\mu}, \boldsymbol{\Sigma})\). It can also be shown that if \(\mathbf{y}\) is \(N_{p}(\boldsymbol{\mu}, \boldsymbol{\Sigma})\), then
\[
\begin{equation*}
\beta_{2, p}=p(p+2) \tag{4.34}
\end{equation*}
\]

To estimate \(\beta_{1, p}\) and \(\beta_{2, p}\) using a sample \(\mathbf{y}_{1}, \mathbf{y}_{2}, \ldots, \mathbf{y}_{p}\), we first define
\[
\begin{equation*}
g_{i j}=\left(\mathbf{y}_{i}-\overline{\mathbf{y}}\right)^{\prime} \hat{\boldsymbol{\Sigma}}^{-1}\left(\mathbf{y}_{j}-\overline{\mathbf{y}}\right) \tag{4.35}
\end{equation*}
\]
where \(\hat{\boldsymbol{\Sigma}}=\sum_{i=1}^{n}\left(\mathbf{y}_{i}-\overline{\mathbf{y}}\right)\left(\mathbf{y}_{i}-\overline{\mathbf{y}}\right)^{\prime} / n\) is the maximum likelihood estimator (4.12). Then estimates of \(\beta_{1, p}\) and \(\beta_{2, p}\) are given by
\[
\begin{align*}
& b_{1, p}=\frac{1}{n^{2}} \sum_{i=1}^{n} \sum_{j=1}^{n} g_{i j}^{3}  \tag{4.36}\\
& b_{2, p}=\frac{1}{n} \sum_{i=1}^{n} g_{i i}^{2} \tag{4.37}
\end{align*}
\]

Table A. 5 (Mardia 1970, 1974) gives percentage points of \(b_{1, p}\) and \(b_{2, p}\) for \(p=\) \(2,3,4\), which can be used in testing for multivariate normality. For other values of \(p\) or when \(n \geq 50\), the following approximate tests are available. For \(b_{1, p}\), the statistic
\[
\begin{equation*}
z_{1}=\frac{(p+1)(n+1)(n+3)}{6[(n+1)(p+1)-6]} b_{1, p} \tag{4.38}
\end{equation*}
\]
is approximately \(\chi^{2}\) with \(\frac{1}{6} p(p+1)(p+2)\) degrees of freedom. Reject the hypothesis of multivariate normality if \(z_{1} \geq \chi_{.05}^{2}\). With \(b_{2, p}\), on the other hand, we wish to reject for large values (distribution too peaked) or small values (distribution too flat). For the upper \(2.5 \%\) points of \(b_{2, p}\) use
\[
\begin{equation*}
z_{2}=\frac{b_{2, p}-p(p+2)}{\sqrt{8 p(p+2) / n}} \tag{4.39}
\end{equation*}
\]
which is approximately \(N(0,1)\). For the lower \(2.5 \%\) points we have two cases: (1) when \(50 \leq n \leq 400\), use
\[
\begin{equation*}
z_{3}=\frac{b_{2, p}-p(p+2)(n+p+1) / n}{\sqrt{8 p(p+2) /(n-1)}} \tag{4.40}
\end{equation*}
\]
which is approximately \(N(0,1)\); (2) when \(n \geq 400\), use \(z_{2}\) as given by (4.39).

\subsection*{4.5 TRANSFORMATIONS TO NORMALITY}

As noted in Section 4.3.2, the asymptotic distribution of \(\overline{\mathbf{y}}\) is normal, regardless of the distribution of \(\mathbf{y}\). However, there are many scenarios in which we wish to
draw inferences about statistics other than the mean, and/or we do not have a large enough sample size to appeal to the central limit theorem. For such situations, it is often useful to consider transformations of the data that exhibit greater normality than the original data. In many cases, transformations will be very natural from a phenomenological standpoint. For example, log abundance of bacteria in a replicated experiment may not only appear more normal, but will often be a more natural way of quantifying the growth process of interest.

Although our aim here is to find a multivariate transformation \(g(\cdot)\) that makes \(g(\mathbf{y})\) look as close to \(p\)-variate normality as possible, it is often the case that transforming each of the \(p\) variables to a marginal normal distribution will yield a multivariate transformation that is close to optimal. Because univariate transformations are much less complicated, we primarily focus on the univariate approach developed by Box and Cox (1964). We then briefly consider an extension for multivariate transformations based on Andrews, Gnanadesikan, and Warner (1971).

\subsection*{4.5.1 Univariate Transformations to Normality}

When the histogram or normal probability plot for a variable \(y\) exhibits skewness, a transformation will usually yield a modified distribution that is more normal in appearance. For increasingly right-skewed observations, it is useful to use transformations such as \(\log (y), y^{-1}, y^{-2}\), etc. For increasingly left-skewed observations, it is useful to use transformations such as \(y^{2}, y^{3}, y^{4}\), etc. One can choose an appropriate transformation "by eye" using the trial-and-error approach of choosing a transformation \(g(\cdot)\), evaluating the histogram of \(g(y)\), and repeating the process until the "best" transformation has been obtained. Because this process is neither systematic nor objective, Box and Cox (1964) present the family of transformations defined by
\[
y^{(\lambda)}= \begin{cases}\frac{y^{\lambda}-1}{\lambda} & \text { for } \lambda \neq 0  \tag{4.41}\\ \ln (y) & \text { for } \lambda=0\end{cases}
\]

The value of \(\lambda\) is chosen by maximizing
\[
\begin{equation*}
\ell(\lambda)=-\frac{n}{2} \ln s_{\lambda}^{2}+(\lambda-1) \sum_{i=1}^{n} \ln \left(y_{i}\right) \tag{4.42}
\end{equation*}
\]
where
\[
s_{\lambda}^{2}=1 / n \sum_{i=1}^{n}\left(y_{i}^{(\lambda)}-\overline{y^{(\lambda)}}\right)^{2}
\]
is the maximum likelihood estimate of the variance of \(y^{(\lambda)}\) and \(\overline{y^{(\lambda)}}\) is the sample mean of the \(n\) transformed observations. Note that although the transformations ( \(y^{1}\), \(y^{2}, y^{3}, \ldots\) ) are not substantively different from the Box-Cox transformations ( \(y^{(1)}\), \(y^{(2)}, y^{(3)}, \ldots\) ) defined by (4.41), we use the Box-Cox transformations because the criterion to be maximized \([\ell(\lambda)]\) is continuous in \(\lambda\), even when \(\lambda\) approaches 0 . Thus, the Box-Cox transformations allow us to objectively evaluate the comparative utility
of any possible transform \(y^{(\lambda)}\). The optimal \(\lambda\) can be found by explicitly maximizing the function in (4.42), but it is more common that \(\ell(\lambda)\) is calculated for a wide range of values for \(\lambda\), and then \(\lambda\) is plotted against \(\ell(\lambda)\) to find the optimal value.

\subsection*{4.5.2 Multivariate Transformations to Normality}

An extension of the Box-Cox method for transforming to \(p\)-variate normality was proposed by Andrews, Gnanadesikan, and Warner (1971). The multivariate approach is motivated by the fact that the optimal transformation to \(p\)-variate normality is not necessarily based on the collection of \(p\) transformations obtained when targeting marginal normality for each of the \(p\) variables. In practice, the collection of univariately transformed variables will often be very close to the optimal \(p\)-variate transformation, but a more precise criterion for transforming to multivariate normality is to find the collection of transformations \(\boldsymbol{\lambda}=\left(\lambda_{1}, \ldots, \lambda_{p}\right)\) such that the function
\[
\begin{equation*}
\ell(\boldsymbol{\lambda})=-\frac{n}{2} \ln \left|\mathbf{S}_{\boldsymbol{\lambda}}\right|+\sum_{j=1}^{p}\left[\left(\lambda_{j}-1\right) \sum_{i=1}^{n} \ln \left(y_{i j}\right)\right] \tag{4.43}
\end{equation*}
\]
is maximized. In (4.43), \(y_{i j}\) is the \(i\) th measurement on the \(j\) th variable, \(\mathbf{S}_{\boldsymbol{\lambda}}\) is the maximum likelihood estimate of the covariance matrix for the transformed data with its \((j, k)\) element equal to
\[
\frac{1}{n} \sum_{i=1}^{n}\left(y_{i j}^{\left(\lambda_{j}\right)}-\overline{y_{j}^{\left(\lambda_{j}\right)}}\right)\left(y_{i k}^{\left(\lambda_{k}\right)}-\overline{y_{k}^{\left(\lambda_{k}\right)}}\right)
\]
and \(\overline{y_{k}^{\left(\lambda_{k}\right)}}\) is the sample mean of the \(n\) transformed observations on the \(k\) th variable. As in the univariate case in Section 4.5.1, the optimal value for \(\lambda\) can be found by explicitly maximizing the function in (4.43), or the value of \(\ell(\boldsymbol{\lambda})\) can be found for every choice of \(\lambda\) within a \(p\)-dimensional array of candidate values.

\section*{EXAMPLE 4.5.2}

We use the soil richness data in Table 3.3 to illustrate the process of transforming data to appear more normal. The top row of Figure 4.8 illustrates distributions for the concentrations of \(\mathrm{Fe}, \mathrm{K}\), and Mg . Note that Fe appears relatively normal, with Mg exhibiting moderate right-skewness and K exhibiting extreme right-skewness. Applying the Box-Cox approach discussed in Section 4.5.1, we obtain \(\lambda\) values of \(1.0,-0.3\), and 0.1 , respectively. The middle row of Figure 4.8 shows the plot of \(\ell(\lambda)\) versus \(\lambda\) for each variable. The distribution for iron ( Fe ) concentrations is at the near-optimal transformation for appearing normal. Potassium ( K ) requires a transformation that is more extreme than the log transformation, while magnesium ( Mg ) needs a transformation that is slightly less extreme than the log transformation. The bottom row of Figure 4.8 shows the distributions of the three elements after applying the optimal univariate Box-Cox transformation.

Figure 4.8 Transforming data from Table 3.3 to near-normality. Top row: histograms for concentrations of \(\mathrm{Fe}, \mathrm{K}\), and Mg . Middle row: plot of \(\lambda\) against \(\ell(\lambda)\) for \(\mathrm{Fe}, \mathrm{K}\), and Mg . Bottom row: histograms for the transformed concentrations of \(\mathrm{Fe}, \mathrm{K}\), and Mg when using \(\lambda\) values of 1.0 (no transformation), -0.3 , and 0.1 , respectively.

We apply the multivariate Box-Cox approach discussed in Section 4.5.2 by considering an array of values for \(\boldsymbol{\lambda}=\left(\lambda_{\mathrm{Fe}}, \lambda_{\mathrm{K}}, \lambda_{\mathrm{Mg}}\right)\) such that \(\lambda_{\mathrm{Fe}} \in(0.5\), \(0.6, \ldots, 1.5), \lambda_{\mathrm{K}} \in(-0.8,-0.7, \ldots, 0.2)\), and \(\lambda_{\mathrm{Mg}} \in(-0.4,-0.3, \ldots, 0.6)\). The value of \(\boldsymbol{\lambda}\) that maximizes \(\ell(\boldsymbol{\lambda})\) in (4.43) is \(\boldsymbol{\lambda}=(1.0,-0.4,0.2)\), which is predictably similar to the transformation obtained by applying the optimal univariate transformation to each of the three variables.

\subsection*{4.6 OUTLIERS}

The detection of outliers has been of concern to statisticians and other scientists for over a century. Some authors have claimed that the researcher can typically expect
up to \(10 \%\) of the observations to have errors in measurement or recording. Occasional stray observations from a different population than the target population are also fairly common. We review some major concepts and suggested procedures for univariate outliers in Section 4.6 .1 before moving to the multivariate case in Section 4.6.2. An alternative to detection of outliers is to use robust estimators of \(\boldsymbol{\mu}\) and \(\boldsymbol{\Sigma}\) (see Rencher 1998, Section 1.10) that are less sensitive to extreme observations than are the standard estimators \(\overline{\mathbf{y}}\) and \(\mathbf{S}\).

\subsection*{4.6.1 Outliers in Univariate Samples}

Excellent treatments of outliers have been given by Beckman and Cook (1983), Hawkins (1980), and Barnett and Lewis (1978). We abstract a few highlights from Beckman and Cook. Many techniques have been proposed for detecting outliers in the residuals from regression or designed experiments, but we will be concerned only with simple random samples from the normal distribution.

There are two principal approaches for dealing with outliers. The first is identification, which usually involves deletion of the outlier(s) but may also provide important information about the model or the data. The second method is accommodation, in which the method of analysis or the model is modified. Robust methods, in which the influence of outliers is reduced, provide an example of modification of the analysis. An example of a correction to the model is a mixture model that combines two normals with different variances. For example, Marks and Rao (1978) accommodated a particular type of outlier by a mixture of two normal distributions.

In small or moderate-sized univariate samples, visual methods of identifying outliers are the most frequently used. Tests are also available if a less subjective approach is desired.

Two types of slippage models have been proposed to account for outliers. Under the mean slippage model, all observations have the same variance, but one or more of the observations arise from a distribution with a different (population) mean. In the variance slippage model, one or more of the observations arise from a model with larger (population) variance but the same mean. Thus in the mean slippage model, the bulk of the observations arise from \(N\left(\mu, \sigma^{2}\right)\), whereas the outliers originate from \(N\left(\mu+\theta, \sigma^{2}\right)\). For the variance slippage model, the main distribution would again be \(N\left(\mu, \sigma^{2}\right)\), with the outliers coming from \(N\left(\mu, a \sigma^{2}\right)\) where \(a>1\). These models have led to the development of tests for rejection of outliers. We now briefly discuss some of these tests.

For a single outlier in a sample \(y_{1}, y_{2}, \ldots, y_{n}\), most tests are based on the maximum studentized residual,
\[
\begin{equation*}
\max _{i} \tau_{i}=\max _{i}\left|\frac{y_{i}-\bar{y}}{s}\right| . \tag{4.44}
\end{equation*}
\]

If the largest or smallest observation is rejected, one could then examine the \(n-1\) remaining observations for another possible outlier, and so on. This procedure is called a consecutive test. However, if there are two or more outliers, the less extreme
ones will often make it difficult to detect the most extreme one, due to inflation of both mean and variance. This effect is called masking.

Ferguson (1961) showed that the maximum studentized residual (4.44) is more powerful than most other techniques for detecting intermediate or large shifts in the mean and gave the following guidelines for small shifts:
1. For outliers with small positive shifts in the mean, tests based on sample skewness are best.
2. For outliers with small shifts in the mean in either direction, tests based on the sample kurtosis are best.
3. For outliers with small positive shifts in the variance, tests based on the sample kurtosis are best.

Because of the masking problem in consecutive tests, block tests have been proposed for simultaneous rejection of \(k>1\) outliers. These tests work well if \(k\) is known, but in practice, \(k\) is usually not known. If the value we conjecture for \(k\) is too small, we incur the risk of failing to detect any outliers because of masking. If we set \(k\) too large, there is a high risk of rejecting more outliers than there really are, an effect known as swamping.

\subsection*{4.6.2 Outliers in Multivariate Samples}

In the case of multivariate data, the problems in detecting outliers are intensified for several reasons:
1. For \(p>2\) the data cannot be readily plotted to pinpoint the outliers.
2. Multivariate data cannot be ordered as can a univariate sample, where extremes show up readily on either end.
3. An observation vector may have a large recording error in one of its components or smaller errors in several components.
4. A multivariate outlier may reflect slippage in mean, variance, or correlation. This is illustrated in Figure 4.9. Observation 1 causes a small shift in means and variances of both \(y_{1}\) and \(y_{2}\) but has little effect on the correlation. Observation 2 has little effect on means and variances, but it reduces the correlation somewhat. Observation 3 has a major effect on means, variances, and correlation.

One approach to multivariate outlier identification or accommodation is to use robust methods of estimation. Such methods minimize the influence of outliers in estimation or model fitting. However, an outlier sometimes furnishes valuable information, and the specific pursuit of outliers can be very worthwhile.

We present two methods of multivariate outlier identification, both of which are related to methods of assessing multivariate normality. (A third approach based

Figure 4.9 Bivariate sample showing three types of outliers.
on principal components is given in Section 12.4.) The first method, due to Wilks (1963), is designed for detection of a single outlier. Wilks' statistic is
\[
\begin{equation*}
w=\min _{i} \frac{\left|(n-2) \mathbf{S}_{-i}\right|}{|(n-1) \mathbf{S}|}, \tag{4.45}
\end{equation*}
\]
where \(\mathbf{S}\) is the usual sample covariance matrix and \(\mathbf{S}_{-i}\) is obtained from the same sample with the \(i\) th observation deleted. The statistic \(w\) can also be expressed in terms of \(D_{(n)}^{2}=\max _{i}\left(\mathbf{y}_{i}-\overline{\mathbf{y}}\right)^{\prime} \mathbf{S}^{-1}\left(\mathbf{y}_{i}-\overline{\mathbf{y}}\right)\) as
\[
\begin{equation*}
w=1-\frac{n D_{(n)}^{2}}{(n-1)^{2}} \tag{4.46}
\end{equation*}
\]
thus basing a test for an outlier on the distances \(D_{i}^{2}\) used in Section 4.4.2 in a graphical procedure for checking multivariate normality. Table A. 6 gives the upper 5\% and \(1 \%\) critical values for \(D_{(n)}^{2}\) from Barnett and Lewis (1978).

Yang and Lee (1987) provide an \(F\)-test of \(w\) as given by (4.46). Define
\[
\begin{equation*}
F_{i}=\frac{n-p-1}{p}\left[\frac{1}{1-n D_{i}^{2} /(n-1)^{2}}-1\right], \quad i=1,2, \ldots, n . \tag{4.47}
\end{equation*}
\]

Then the \(F_{i}\) 's are independently and identically distributed as \(F_{p, n-p-1}\), and a test can be constructed in terms of \(\max _{i} F_{i}\) :
\[
P\left(\max _{i} F_{i}>f\right)=1-P\left(\text { all } F_{i} \leq f\right)=1-[P(F \leq f)]^{n}
\]

Therefore, the test can be carried out using an \(F\)-table. Note that
\[
\begin{equation*}
\max _{i} F_{i}=F_{(n)}=\frac{n-p-1}{p}\left(\frac{1}{w}-1\right) \tag{4.48}
\end{equation*}
\]
where \(w\) is given in (4.46).
The second test we discuss is designed for detection of several outliers. Schwager and Margolin (1982) showed that the locally best invariant test for mean slippage is based on Mardia's (1970) sample kurtosis \(b_{2, p}\) as defined by (4.35) and (4.37). To be more specific, among all tests invariant to a class of transformations of the type \(\mathbf{z}=\mathbf{A y}+\mathbf{b}\), where \(\mathbf{A}\) is nonsingular (see Problem 4.8), the test using \(b_{2, p}\) is most powerful for small shifts in the mean vector. This result holds if the proportion of outliers is no more than \(21.13 \%\). With some restrictions on the pattern of the outliers, the permissible fraction of outliers can go as high as \(33 \frac{1}{3} \%\). The hypothesis is \(H_{0}\) : no outliers are present. This hypothesis is rejected for large values of \(b_{2, p}\).

A table of critical values of \(b_{2, p}\) and some approximate tests were described in Section 4.4.2 following (4.37). Thus the test doubles as a check for multivariate normality and for the presence of outliers. One advantage of this test for outliers is that we do not have to specify the number of outliers and run the attendant risk of masking or swamping. Schwager and Margolin (1982) pointed out that this feature "increases the importance of performing an overall test that is sensitive to a broad range of outlier configurations. There is also empirical evidence that the kurtosis test performs well in situations of practical interest when compared with other inferential outlier procedures."

Sinha (1984) extended the result of Schwager and Margolin to cover the general case of elliptically symmetric distributions. An elliptically symmetric distribution is one in which \(f(\mathbf{y})=|\boldsymbol{\Sigma}|^{-1 / 2} g\left[(\mathbf{y}-\boldsymbol{\mu})^{\prime} \boldsymbol{\Sigma}^{-1}(\mathbf{y}-\boldsymbol{\mu})\right]\). By varying the function \(g\), distributions with shorter or longer tails than the normal can be obtained. The critical value of \(b_{2, p}\) must be adjusted to correspond to the distribution, but rejection for large values would be a locally best invariant test.

\section*{■ EXAMPLE 4.6.2}

We use the ramus bone data set of Table 3.7 to illustrate a search for multivariate outliers, while at the same time checking for multivariate normality. An examination of each column of Table 3.7 does not reveal any apparent univariate outliers. To check for multivariate outliers, we first calculate \(D_{i}^{2}\) in (4.27) for each observation vector. The results are given in Table 4.1. We see that \(D_{9}^{2}\), \(D_{12}^{2}\), and \(D_{20}^{2}\) seem to stand out as possible outliers. In Table A.6, the upper \(5 \%\) critical value for the maximum value, \(D_{(20)}^{2}\), is given as 11.63 . In our case, the largest \(D_{i}^{2}\) is \(D_{9}^{2}=11.03\), which does not exceed the critical value. This does not surprise us, since the test was designed to detect a single outlier, and we may have as many as three.

We compute \(u_{i}\) and \(v_{i}\) in (4.28) and (4.29) and plot them in Figure 4.10. The figure shows a departure from linearity due to three values and possibly a fourth.

Table 4.1 Values of \(D_{i}^{2}\) for the Ramus Bone Data in Table 3.7
\begin{tabular}{lr|lr}
\hline \begin{tabular}{l} 
Observation \\
Number
\end{tabular} & \(D_{i}^{2}\) & \begin{tabular}{l} 
Observation \\
Number
\end{tabular} & \(D_{i}^{2}\) \\
\hline 1 & 0.7588 & 11 & 2.8301 \\
2 & 1.2980 & 12 & 10.5718 \\
3 & 1.7591 & 13 & 2.5941 \\
4 & 3.8539 & 14 & 0.6594 \\
5 & 0.8706 & 15 & 0.3246 \\
6 & 2.8106 & 16 & 0.8321 \\
7 & 4.2915 & 17 & 1.1083 \\
8 & 7.9897 & 18 & 4.3633 \\
9 & 11.0301 & 19 & 2.1088 \\
10 & 5.3519 & 20 & 10.0931 \\
\hline
\end{tabular}

Figure 4.10 \(Q-Q\) plot of \(u_{i}\) and \(v_{i}\) for the ramus bone data of Table 3.7.

We next calculate \(b_{1, p}\) and \(b_{2, p}\) as given by (4.36) and (4.37):
\[
b_{1, p}=11.338, \quad b_{2, p}=28.884
\]

In Table A.5, the upper . 01 critical value for \(b_{1, p}\) is 9.9 ; the upper .005 critical value for \(b_{2, p}\) is 27.1. Thus both \(b_{1, p}\) and \(b_{2, p}\) exceed their critical values, and we have significant skewness and kurtosis, apparently caused by the three observations with large values of \(D_{i}^{2}\).

Figure 4.11 Scatterplots for the ramus bone data in Table 3.7, with density curves for each variable.

The bivariate scatterplots are given in Figure 4.11. Three values are clearly separate from the other observations in the plot of \(y_{1}\) versus \(y_{4}\). In Table 3.7, the 9 th, 12 th, and 20 th values of \(y_{4}\) are not unusual, nor are the 9 th, 12 th, and 20th values of \(y_{1}\). However, the increase from \(y_{1}\) to \(y_{4}\) is exceptional in each case. If these values are not due to errors in recording the data and if this sample is representative, then we appear to have a mixture of two populations. This should be taken into account in making inferences.

\section*{PROBLEMS}
4.1 Consider the two covariance matrices
\[
\boldsymbol{\Sigma}_{\mathbf{1}}=\left(\begin{array}{rrr}
14 & 8 & 3 \\
8 & 5 & 2 \\
3 & 2 & 1
\end{array}\right), \quad \boldsymbol{\Sigma}_{2}=\left(\begin{array}{lll}
6 & 6 & 1 \\
6 & 8 & 2 \\
1 & 2 & 1
\end{array}\right)
\]

Show that \(\left|\boldsymbol{\Sigma}_{2}\right|>\left|\boldsymbol{\Sigma}_{1}\right|\) and that \(\operatorname{tr}\left(\boldsymbol{\Sigma}_{2}\right)<\operatorname{tr}\left(\boldsymbol{\Sigma}_{\mathbf{1}}\right)\). Thus the generalized variance of population 2 is greater than the generalized variance of population 1 , even though the total variance is less. Comment on why this is true in terms of the variances and correlations.
4.2 \(\operatorname{For} \mathbf{z}=\left(\mathbf{T}^{\prime}\right)^{-1}(\mathbf{y}-\boldsymbol{\mu})\) in (4.4), show that \(E(\mathbf{z})=\mathbf{0}\) and \(\operatorname{cov}(\mathbf{z})=\mathbf{I}\).
4.3 Show that the form of the likelihood function in (4.13) follows from the previous expression.
4.4 For \((\mathbf{y}-\boldsymbol{\mu})^{\prime} \boldsymbol{\Sigma}^{-1}(\mathbf{y}-\boldsymbol{\mu})\) in (4.3) and (4.6), show that \(E\left[(\mathbf{y}-\boldsymbol{\mu})^{\prime} \boldsymbol{\Sigma}^{-1}(\mathbf{y}-\right.\) \(\boldsymbol{\mu})]=p\). Assume \(E(\mathbf{y})=\boldsymbol{\mu}\) and \(\operatorname{cov}(\mathbf{y})=\boldsymbol{\Sigma}\). Normality is not required.
4.5 Show that by adding and subtracting \(\overline{\mathbf{y}}\), the exponent of (4.13) has the form given in (4.14), that is,
\[
\begin{aligned}
& \frac{1}{2} \sum_{i=1}^{n}\left(\mathbf{y}_{i}-\overline{\mathbf{y}}+\overline{\mathbf{y}}-\boldsymbol{\mu}\right)^{\prime} \boldsymbol{\Sigma}^{-1}\left(\mathbf{y}_{i}-\overline{\mathbf{y}}+\overline{\mathbf{y}}-\boldsymbol{\mu}\right) \\
& \quad=\frac{1}{2} \sum_{i=1}^{n}\left(\mathbf{y}_{i}-\overline{\mathbf{y}}\right)^{\prime} \boldsymbol{\Sigma}^{-1}\left(\mathbf{y}_{i}-\overline{\mathbf{y}}\right)+\frac{n}{2}(\overline{\mathbf{y}}-\boldsymbol{\mu})^{\prime} \boldsymbol{\Sigma}^{-1}(\overline{\mathbf{y}}-\boldsymbol{\mu})
\end{aligned}
\]
4.6 Show that \(\sqrt{b_{1}}\) and \(b_{2}\), as given in (4.18) and (4.19), are invariant to the transformation \(z_{i}=a y_{i}+b\).
4.7 Show that if \(\mathbf{y}\) is \(N_{p}(\boldsymbol{\mu}, \boldsymbol{\Sigma})\), then \(\beta_{2, p}=p(p+2)\) as in (4.34).
4.8 Show that \(b_{1, p}\) and \(b_{2, p}\), as given by (4.36) and (4.37), are invariant under the transformation \(\mathbf{z}_{i}=\mathbf{A} \mathbf{y}_{i}+\mathbf{b}\), where \(\mathbf{A}\) is nonsingular. Thus \(b_{1, p}\) and \(b_{2, p}\) do not depend on the units of measurement.
4.9 Show that \(F_{(n)}=[(n-p-1) / p](1 / w-1)\) as in (4.48).
4.10 Suppose \(y\) is \(N_{3}(\boldsymbol{\mu}, \boldsymbol{\Sigma})\), where
\[
\boldsymbol{\mu}=\left(\begin{array}{l}
3 \\
1 \\
4
\end{array}\right), \quad \boldsymbol{\Sigma}=\left(\begin{array}{rrr}
6 & 1 & -2 \\
1 & 13 & 4 \\
-2 & 4 & 4
\end{array}\right)
\]
(a) Find the distribution of \(z=2 y_{1}-y_{2}+3 y_{3}\).
(b) Find the joint distribution of \(z_{1}=y_{1}+y_{2}+y_{3}\) and \(z_{2}=y_{1}-y_{2}+2 y_{3}\).
(c) Find the distribution of \(y_{2}\).
(d) Find the joint distribution of \(y_{1}\) and \(y_{3}\).
(e) Find the joint distribution of \(y_{1}, y_{3}\), and \(\frac{1}{2}\left(y_{1}+y_{2}\right)\).
4.11 Suppose \(\mathbf{y}\) is \(N_{3}(\boldsymbol{\mu}, \boldsymbol{\Sigma})\), with \(\boldsymbol{\mu}\) and \(\boldsymbol{\Sigma}\) given in Problem 4.10.
(a) Find a vector \(\mathbf{z}\) such that \(\mathbf{z}=\left(\mathbf{T}^{\prime}\right)^{-1}(\mathbf{y}-\boldsymbol{\mu})\) is \(N_{3}(\mathbf{0}, \mathbf{I})\) as in (4.4).
(b) Find a vector \(\mathbf{z}\) such that \(\mathbf{z}=\left(\boldsymbol{\Sigma}^{1 / 2}\right)^{-1}(\mathbf{y}-\boldsymbol{\mu})\) is \(N_{3}(\mathbf{0}, \mathbf{I})\) as in (4.5).
(c) What is the distribution of \((\mathbf{y}-\boldsymbol{\mu})^{\prime} \boldsymbol{\Sigma}^{-1}(\mathbf{y}-\boldsymbol{\mu})\) ?
4.12 Suppose \(\mathbf{y}\) is \(N_{4}(\boldsymbol{\mu}, \boldsymbol{\Sigma})\), where
\[
\boldsymbol{\mu}=\left(\begin{array}{r}
-2 \\
3 \\
-1 \\
5
\end{array}\right), \quad \boldsymbol{\Sigma}=\left(\begin{array}{rrrr}
11 & -8 & 3 & 9 \\
-8 & 9 & -3 & -6 \\
3 & -3 & 2 & 3 \\
9 & -6 & 3 & 9
\end{array}\right)
\]
(a) Find the distribution of \(z=4 y_{1}-2 y_{2}+y_{3}-3 y_{4}\).
(b) Find the joint distribution of \(z_{1}=y_{1}+y_{2}+y_{3}+y_{4}\) and \(z_{2}=-2 y_{1}+\) \(3 y_{2}+y_{3}-2 y_{4}\).
(c) Find the joint distribution of \(z_{1}=3 y_{1}+y_{2}-4 y_{3}-y_{4}, z_{2}=-y_{1}-\) \(3 y_{2}+y_{3}-2 y_{4}\), and \(z_{3}=2 y_{1}+2 y_{2}+4 y_{3}-5 y_{4}\).
(d) What is the distribution of \(y_{3}\) ?
(e) What is the joint distribution of \(y_{2}\) and \(y_{4}\) ?
(f) Find the joint distribution of \(y_{1}, \frac{1}{2}\left(y_{1}+y_{2}\right), \frac{1}{3}\left(y_{1}+y_{2}+y_{3}\right)\), and \(\frac{1}{4}\left(y_{1}+\right.\) \(\left.y_{2}+y_{3}+y_{4}\right)\).
4.13 Suppose \(\mathbf{y}\) is \(N_{4}(\boldsymbol{\mu}, \boldsymbol{\Sigma})\) with \(\boldsymbol{\mu}\) and \(\boldsymbol{\Sigma}\) given in Problem 4.12.
(a) Find a vector \(\mathbf{z}\) such that \(\mathbf{z}=\left(\mathbf{T}^{\prime}\right)^{-1}(\mathbf{y}-\boldsymbol{\mu})\) is \(N_{4}(\mathbf{0}, \mathbf{I})\) as in (4.4).
(b) Find a vector \(\mathbf{z}\) such that \(\mathbf{z}=\left(\boldsymbol{\Sigma}^{1 / 2}\right)^{-1}(\mathbf{y}-\boldsymbol{\mu})\) is \(N_{4}(\mathbf{0}, \mathbf{I})\) as in (4.5).
(c) What is the distribution of \((\mathbf{y}-\boldsymbol{\mu})^{\prime} \boldsymbol{\Sigma}^{-1}(\mathbf{y}-\boldsymbol{\mu})\) ?
4.14 Suppose \(y\) is \(N_{3}(\boldsymbol{\mu}, \boldsymbol{\Sigma})\), with
\[
\boldsymbol{\mu}=\left(\begin{array}{r}
2 \\
-3 \\
4
\end{array}\right), \quad \boldsymbol{\Sigma}=\left(\begin{array}{rrr}
4 & -3 & 0 \\
-3 & 6 & 0 \\
0 & 0 & 5
\end{array}\right)
\]

Which of the following random variables are independent?
(a) \(y_{1}\) and \(y_{2}\)
(d) \(\left(y_{1}, y_{2}\right)\) and \(y_{3}\)
(b) \(y_{1}\) and \(y_{3}\)
(e) \(\left(y_{1}, y_{3}\right)\) and \(y_{2}\)
(c) \(y_{2}\) and \(y_{3}\)
4.15 Suppose \(y\) is \(N_{4}(\boldsymbol{\mu}, \boldsymbol{\Sigma})\), with
\[
\boldsymbol{\mu}=\left(\begin{array}{r}
-4 \\
2 \\
5 \\
-1
\end{array}\right), \quad \boldsymbol{\Sigma}=\left(\begin{array}{rrrr}
8 & 0 & -1 & 0 \\
0 & 3 & 0 & 2 \\
-1 & 0 & 5 & 0 \\
0 & 2 & 0 & 7
\end{array}\right)
\]

Which of the following random variables are independent?
(a) \(y_{1}\) and \(y_{2}\)
(f) \(y_{3}\) and \(y_{4}\)
(k) \(y_{1}\) and \(y_{2}\) and \(y_{3}\)
(b) \(y_{1}\) and \(y_{3}\)
(g) \(\left(y_{1}, y_{2}\right)\) and \(y_{3}\)
(l) \(y_{1}\) and \(y_{2}\) and \(y_{4}\)
(c) \(y_{1}\) and \(y_{4}\)
(h) \(\left(y_{1}, y_{2}\right)\) and \(y_{4}\)
(m) \(\left(y_{2}, y_{2}\right)\) and \(\left(y_{3}, y_{4}\right)\)
(d) \(y_{2}\) and \(y_{3}\)
(i) \(\left(y_{1}, y_{3}\right)\) and \(y_{4}\)
(n) \(\left(y_{1}, y_{3}\right)\) and \(\left(y_{2}, y_{4}\right)\)
(e) \(y_{2}\) and \(y_{4}\)
(j) \(y_{1}\) and \(\left(y_{2}, y_{4}\right)\)
4.16 Assume \(\mathbf{y}\) and x are subvectors, each \(2 \times 1\), where \(\binom{\mathbf{y}}{\mathbf{x}}\) is \(N_{4}(\boldsymbol{\mu}, \boldsymbol{\Sigma})\) with
\[
\boldsymbol{\mu}=\left(\begin{array}{r}
2 \\
-1 \\
\hline 3 \\
1
\end{array}\right), \quad \boldsymbol{\Sigma}=\left(\begin{array}{rr|rr}
7 & 3 & -3 & 2 \\
3 & 6 & 0 & 4 \\
\hline-3 & 0 & 5 & -2 \\
2 & 4 & -2 & 4
\end{array}\right)
\]
(a) Find \(E(\mathbf{y} \mid \mathbf{x})\) by (4.7).
(b) Find \(\operatorname{cov}(\mathbf{y} \mid \mathbf{x})\) by (4.8).
4.17 Suppose \(\mathbf{y}\) and \(\mathbf{x}\) are subvectors, such that \(\mathbf{y}\) is \(2 \times 1\) and \(\mathbf{x}\) is \(3 \times 1\), with \(\mu\) and \(\boldsymbol{\Sigma}\) partitioned accordingly:
\[
\boldsymbol{\mu}=\left(\begin{array}{r}
3 \\
-2 \\
\hline 4 \\
-3 \\
5
\end{array}\right), \quad \boldsymbol{\Sigma}=\left(\begin{array}{rr|rrr}
14 & -8 & 15 & 0 & 3 \\
-8 & 18 & 8 & 6 & -2 \\
\hline 15 & 8 & 50 & 8 & 5 \\
0 & 6 & 8 & 4 & 0 \\
3 & -2 & 5 & 0 & 1
\end{array}\right)
\]

Assume that \(\binom{\mathbf{y}}{\mathbf{x}}\) is distributed as \(N_{5}(\boldsymbol{\mu}, \boldsymbol{\Sigma})\).
(a) Find \(E(\mathbf{y} \mid \mathbf{x})\) by (4.7).
(b) Find \(\operatorname{cov}(\mathbf{y} \mid x)\) by (4.8).
4.18 Suppose that \(\mathbf{y}_{1}, \mathbf{y}_{2}, \ldots, \mathbf{y}_{n}\) is a random sample from a nonnormal multivariate population with mean \(\boldsymbol{\mu}\) and covariance matrix \(\boldsymbol{\Sigma}\). If \(n\) is large, what is the approximate distribution of each of the following?
(a) \(\sqrt{n}(\overline{\mathbf{y}}-\boldsymbol{\mu})\)
(b) \(\overline{\mathbf{y}}\)
4.19 For the ramus bone data treated in Example 4.6.2, check each of the four variables for univariate normality using the following techniques:
(a) \(Q-Q\) plots
(b) \(\sqrt{b_{1}}\) and \(b_{2}\) as given by (4.18) and (4.19)
(c) D'Agostino's test using \(D\) and \(Y\) given in (4.22) and (4.23)
(d) The test by Lin and Mudholkar using \(z\) defined in (4.24)
4.20 For the calcium data in Table 3.4, check for multivariate normality and outliers using the following tests:
(a) Calculate \(D_{i}^{2}\) as in (4.27) for each observation.
(b) Compare the largest value of \(D_{i}^{2}\) with the critical value in Table A. 6 .
(c) Compute \(u_{i}\) and \(v_{i}\) in (4.28) and (4.29) and plot them. Is there an indication of nonlinearity or outliers?
(d) Calculate \(b_{1, p}\) and \(b_{2, p}\) in (4.36) and (4.37) and compare them with critical values in Table A.5.
4.21 For the probe word data in Table 3.6, check each of the five variables for univariate normality and outliers using the following tests:
(a) \(Q-Q\) plots
(b) \(\sqrt{b_{1}}\) and \(b_{2}\) as given by (4.18) and (4.19)
(c) D'Agostino's test using \(D\) and \(Y\) given in (4.22) and (4.23)
(d) The test by Lin and Mudholkar using \(z\) defined in (4.24)
4.22 For the probe word data in Table 3.6, check for multivariate normality and outliers using the following tests:
(a) Calculate \(D_{i}^{2}\) as in (4.27) for each observation.
(b) Compare the largest value of \(D_{i}^{2}\) with the critical value in Table A. 6 .
(c) Compute \(u_{i}\) and \(v_{i}\) in (4.28) and (4.29) and plot them. Is there an indication of nonlinearity or outliers?
(d) Calculate \(b_{1, p}\) and \(b_{2, p}\) in (4.36) and (4.37) and compare them with critical values in Table A. 5 .
4.23 Six hematology variables were measured on 51 workers (Royston 1983):
\[
\begin{array}{ll}
y_{1}=\text { hemoglobin concentration } & y_{4}=\text { lymphocyte count } \\
y_{2}=\text { packed cell volume } & y_{5}=\text { neutrophil count } \\
y_{3}=\text { white blood cell count } & y_{6}=\text { serum lead concentration }
\end{array}
\]

Table 4.2 Hematology Data
\begin{tabular}{rlllrll}
\hline \begin{tabular}{r} 
Observation \\
Number
\end{tabular} & \(y_{1}\) & \(y_{2}\) & \(y_{3}\) & \(y_{4}\) & \(y_{5}\) & \(y_{6}\) \\
\hline 1 & 13.4 & 39 & 4100 & 14 & 25 & 17 \\
2 & 14.6 & 46 & 5000 & 15 & 30 & 20 \\
3 & 13.5 & 42 & 4500 & 19 & 21 & 18 \\
4 & 15.0 & 46 & 4600 & 23 & 16 & 18 \\
5 & 14.6 & 44 & 5100 & 17 & 31 & 19 \\
6 & 14.0 & 44 & 4900 & 20 & 24 & 19 \\
7 & 16.4 & 49 & 4300 & 21 & 17 & 18 \\
8 & 14.8 & 44 & 4400 & 16 & 26 & 29 \\
9 & 15.2 & 46 & 4100 & 27 & 13 & 27 \\
10 & 15.5 & 48 & 8400 & 34 & 42 & 36 \\
11 & 15.2 & 47 & 5600 & 26 & 27 & 22 \\
12 & 16.9 & 50 & 5100 & 28 & 17 & 23 \\
13 & 14.8 & 44 & 4700 & 24 & 20 & 23 \\
14 & 16.2 & 45 & 5600 & 26 & 25 & 19 \\
15 & 14.7 & 43 & 4000 & 23 & 13 & 17 \\
16 & 14.7 & 42 & 3400 & 9 & 22 & 13 \\
17 & 16.5 & 45 & 5400 & 18 & 32 & 17 \\
18 & 15.4 & 45 & 6900 & 28 & 36 & 24 \\
19 & 15.1 & 45 & 4600 & 17 & 29 & 17 \\
20 & 14.2 & 46 & 4200 & 14 & 25 & 28 \\
21 & 15.9 & 46 & 5200 & 8 & 34 & 16 \\
22 & 16.0 & 47 & 4700 & 25 & 14 & 18 \\
23 & 17.4 & 50 & 8600 & 37 & 39 & 17 \\
24 & 14.3 & 43 & 5500 & 20 & 31 & 19 \\
25 & 14.8 & 44 & 4200 & 15 & 24 & 29 \\
26 & 14.9 & 43 & 4300 & 9 & 32 & 17 \\
27 & 15.5 & 45 & 5200 & 16 & 30 & 20 \\
28 & 14.5 & 43 & 3900 & 18 & 18 & 25 \\
29 & 14.4 & 45 & 6000 & 17 & 37 & 23 \\
30 & 14.6 & 44 & 4700 & 23 & 21 & 27 \\
31 & 15.3 & 45 & 7900 & 43 & 23 & 23 \\
\(\vdots\) & \(\vdots\) & \(\vdots\) & \(\vdots\) & \(\vdots\) & \(\vdots\) & \(\vdots\) \\
51 & 14.7 & 44 & 7800 & 38 & 34 & 16 \\
\hline & & & & & &
\end{tabular}

The data are given in Table 4.2. Check each of the six variables for univariate normality using the following tests:
(a) \(Q-Q\) plots
(b) \(\sqrt{b_{1}}\) and \(b_{2}\) as given by (4.18) and (4.19)
(c) D'Agostino's test using \(D\) and \(Y\) given in (4.22) and (4.23)
(d) The test by Lin and Mudholkar using \(z\) defined in (4.24)
4.24 For the hematology data in Table 4.2, check for multivariate normality using the following techniques:
(a) Calculate \(D_{i}^{2}\) as in (4.27) for each observation.
(b) Compare the largest value of \(D_{i}^{2}\) with the critical value in Table A. 6 (extrapolate).
(c) Compute \(u_{i}\) and \(v_{i}\) in (4.28) and (4.29) and plot them. Is there an indication of nonlinearity or outliers?
(d) Calculate \(b_{1, p}\) and \(b_{2, p}\) in (4.36) and (4.37) and compare them with critical values in Table A. 5 .
4.25 Use the glucose data in Table 3.9.
(a) Use the methods in Section 4.5 .1 to find the optimal univariate transformation to normality for each of the glucose measurements obtained one hour after sugar intake ( \(x_{1}, x_{2}\), and \(x_{3}\) ).
(b) Use the methods in Section 4.5.2 to find the optimal multivariate transformation to 3 -variate normality for the glucose measurements obtained one hour after sugar intake ( \(x_{1}, x_{2}\), and \(x_{3}\) ).
(c) How do the transformations obtained from the two approaches compare?
4.26 Use the Baker corn field data in Table 3.3.
(a) Use the methods in Section 4.5 .1 to find the optimal univariate transformation to normality for the \(\mathrm{B}, \mathrm{Ca}\), and Cu measurements.
(b) Use the methods in Section 4.5 .2 to find the optimal multivariate transformation to 3 -variate normality for the \(\mathrm{B}, \mathrm{Ca}\), and Cu measurements.
(c) How do the transformations obtained from the two approaches compare?

\section*{CHAPTER 5}

\section*{TESTS ON ONE OR TWO MEAN VECTORS}

\subsection*{5.1 MULTIVARIATE VERSUS UNIVARIATE TESTS}

Hypothesis testing in a multivariate context is more complex than in a univariate setting. The number of parameters may be staggering. The \(p\)-variate normal distribution, for example, has \(p\) means, \(p\) variances, and \(\binom{p}{2}\) covariances, where \(\binom{p}{2}\) represents the number of pairs among the \(p\) variables. The total number of parameters is
\[
p+p+\binom{p}{2}=\frac{1}{2} p(p+3) .
\]

For \(p=10\), for example, the number of parameters is 65 , for each of which a hypothesis could be formulated. Additionally, we might be interested in testing hypotheses about subsets of these parameters or about functions of them. In some cases, we have the added dilemma of choosing among competing test statistics (see Chapter 6).

We first discuss the motivation for testing \(p\) variables multivariately rather than (or in addition to) univariately, as for example, in hypotheses about \(\mu_{1}, \mu_{2}, \ldots, \mu_{p}\) in \(\mu\). There are at least four arguments for a multivariate approach to hypothesis testing:
1. The use of \(p\) univariate tests inflates the Type I error rate, \(\alpha\), whereas the multivariate test preserves the exact \(\alpha\) level. For example, if we do \(p=10\) separate univariate tests at the .05 level, the probability of at least one false rejection is greater than .05 . If the variables were independent (they rarely are), we would have (under \(H_{0}\) )
\[
\begin{aligned}
P(\text { at least one rejection }) & =1-P\left(\text { all } 10 \text { tests accept } H_{0}\right) \\
& =1-(.95)^{10}=.40 .
\end{aligned}
\]

The resulting overall \(\alpha\) of .40 is not an acceptable error rate. Typically, the 10 variables are correlated, and the overall \(\alpha\) would lie somewhere between . 05 and 40 .
2. The univariate tests completely ignore the correlations among the variables, whereas the multivariate tests make direct use of the correlations.
3. The multivariate test is more powerful in many cases. The power of a test is the probability of rejecting \(H_{0}\) when it is false. In some cases, all \(p\) of the univariate tests fail to reach significance, but the multivariate test is significant because small effects on some of the variables combine to jointly indicate significance. However, for a given sample size, there is a limit to the number of variables a multivariate test can handle without losing power. This is discussed further in Section 5.3.2.
4. Many multivariate tests involving means have as a by-product the construction of a linear combination of variables that reveals more about how the variables unite to reject the hypothesis.

\subsection*{5.2 TESTS ON \(\mu\) WITH \(\Sigma\) KNOWN}

The test on a mean vector assuming a known \(\boldsymbol{\Sigma}\) is introduced to illustrate the issues involved in multivariate testing and to serve as a foundation for the unknown \(\boldsymbol{\Sigma}\) case. We first review the univariate case, in which we work with a single variable \(y\) that is distributed as \(N\left(\mu, \sigma^{2}\right)\).

\subsection*{5.2.1 Review of Univariate Test for \(H_{0}: \mu=\mu_{0}\) with \(\sigma\) Known}

The hypothesis of interest is that the mean of \(y\) is equal to a given value, \(\mu_{0}\), versus the alternative that it is not equal to \(\mu_{0}\) :
\[
H_{0}: \mu=\mu_{0} \quad \text { vs. } \quad H_{1}: \mu \neq \mu_{0}
\]

We do not consider one-sided alternative hypotheses because they do not readily generalize to multivariate tests. We assume a random sample of \(n\) observations
\(y_{1}, y_{2}, \ldots, y_{n}\) from \(N\left(\mu, \sigma^{2}\right)\) with \(\sigma^{2}\) known. We calculate \(\bar{y}=\boldsymbol{\Sigma}_{i=1}^{n} y_{i} / n\) and compare it to \(\mu_{0}\) using the test statistic
\[
\begin{equation*}
z=\frac{\bar{y}-\mu_{0}}{\sigma_{\bar{y}}}=\frac{\bar{y}-\mu_{0}}{\sigma / \sqrt{n}}, \tag{5.1}
\end{equation*}
\]
which is distributed as \(N(0,1)\) if \(H_{0}\) is true. For \(\alpha=.05\), we reject \(H_{0}\) if \(|z| \geq 1.96\). Equivalently, we can use \(z^{2}\), which is distributed as \(\chi^{2}\) with one degree of freedom, and reject \(H_{0}\) if \(z^{2} \geq(1.96)^{2}=3.84\). If \(n\) is large, we are assured by the central limit theorem that \(z\) is approximately normal, even if the observations are not from a normal distribution.

\subsection*{5.2.2 Multivariate Test for \(\boldsymbol{H}_{\mathbf{0}}: \mu=\mu_{0}\) with \(\boldsymbol{\Sigma}\) Known}

In the multivariate case we have several variables measured on each sampling unit, and we wish to hypothesize a value for the mean of each variable, \(H_{0}: \boldsymbol{\mu}=\boldsymbol{\mu}_{0}\) vs. \(H_{1}: \boldsymbol{\mu} \neq \boldsymbol{\mu}_{0}\). More explicitly, we have
\[
H_{0}:\left(\begin{array}{c}
\mu_{1} \\
\mu_{2} \\
\vdots \\
\mu_{p}
\end{array}\right)=\left(\begin{array}{c}
\mu_{01} \\
\mu_{02} \\
\vdots \\
\mu_{0 p}
\end{array}\right), \quad H_{\mathbf{1}}:\left(\begin{array}{c}
\mu_{1} \\
\mu_{2} \\
\vdots \\
\mu_{p}
\end{array}\right) \neq\left(\begin{array}{c}
\mu_{01} \\
\mu_{02} \\
\vdots \\
\mu_{0 p}
\end{array}\right)
\]
where each \(\mu_{0 j}\) is specified from previous experience or is a target value. The vector equality in \(H_{0}\) implies \(\mu_{j}=\mu_{0 j}\) for all \(j=1,2, \ldots, p\). The vector inequality in \(H_{1}\) implies at least one \(\mu_{j} \neq \mu_{0 j}\). Thus, for example, if \(\mu_{j}=\mu_{0 j}\) for all \(j\) except 2 , for which \(\mu_{2} \neq \mu_{02}\), then we wish to reject \(H_{0}\).

To test \(H_{0}\), we use a random sample of \(n\) observation vectors \(\mathbf{y}_{1}, \mathbf{y}_{2}, \ldots, \mathbf{y}_{n}\) from \(N_{p}(\boldsymbol{\mu}, \boldsymbol{\Sigma})\), with \(\boldsymbol{\Sigma}\) known, and calculate \(\overline{\mathbf{y}}=\sum_{i=1}^{n} \mathbf{y}_{i} / n\). The test statistic is
\[
\begin{equation*}
Z^{2}=n\left(\overline{\mathbf{y}}-\boldsymbol{\mu}_{0}\right)^{\prime} \boldsymbol{\Sigma}^{-1}\left(\overline{\mathbf{y}}-\boldsymbol{\mu}_{0}\right) . \tag{5.2}
\end{equation*}
\]

If \(H_{0}\) is true, \(Z^{2}\) is distributed as \(\chi_{p}^{2}\) by (4.6), and we therefore reject \(H_{0}\) if \(Z^{2}>\) \(\chi_{\alpha, p}^{2}\). Note that for one variable, \(z^{2}\) [the square of (5.1)] has a chi-square distribution with one degree of freedom, whereas for \(p\) variables, \(Z^{2}\) in (5.2) is distributed as a chi-square with \(p\) degrees of freedom.

If \(\boldsymbol{\Sigma}\) is unknown, we could use \(\mathbf{S}\) in its place in (5.2), and \(Z^{2}\) would have an approximate \(\chi^{2}\)-distribution. But \(n\) would have to be larger than in the analogous univariate situation, in which \(t=\left(\bar{y}-\mu_{0}\right) /(s / \sqrt{n})\) is approximately \(N(0,1)\) for \(n>30\). The value of \(n\) needed for \(n\left(\overline{\mathbf{y}}-\boldsymbol{\mu}_{0}\right)^{\prime} \mathbf{S}^{-1}\left(\overline{\mathbf{y}}-\boldsymbol{\mu}_{0}\right)\) to have an approximate \(\chi^{2}\)-distribution depends on \(p\). This is clarified further in Section 5.3.2.

\section*{■ EXAMPLE 5.2.2}

In Table 3.1, height and weight were given for a sample of 20 college-age males. Let us assume that this sample originated from the bivariate normal

Figure 5.1 Elliptical acceptance region.
\(N_{2}(\boldsymbol{\mu}, \boldsymbol{\Sigma})\), where
\[
\boldsymbol{\Sigma}=\left(\begin{array}{rr}
20 & 100 \\
100 & 1000
\end{array}\right)
\]

Suppose we wish to test \(H_{0}: \boldsymbol{\mu}=(70,170)^{\prime}\). From Example 3.2.1, \(\bar{y}_{1}=\) 71.45 and \(\bar{y}_{2}=164.7\). We thus have
\[
\begin{aligned}
Z^{2} & =n\left(\overline{\mathbf{y}}-\boldsymbol{\mu}_{0}\right)^{\prime} \boldsymbol{\Sigma}^{-1}\left(\overline{\mathbf{y}}-\boldsymbol{\mu}_{0}\right) \\
& =(20)\binom{71.45-70}{164.7-170}^{\prime}\left(\begin{array}{rr}
20 & 100 \\
100 & 1000
\end{array}\right)^{-1}\binom{71.45-70}{164.7-170} \\
& =(20)(1.45,-5.3)\left(\begin{array}{rr}
.1 & -.01 \\
-.01 & .002
\end{array}\right)\binom{1.45}{-5.3}=8.4026 .
\end{aligned}
\]

Using \(\alpha=.05, \chi_{.05,2}^{2}=5.99\), and we therefore reject \(H_{0}: \mu=(70,170)^{\prime}\) because \(Z^{2}=8.4026>5.99\).

The rejection region for \(\overline{\mathbf{y}}=\left(\bar{y}_{1}, \bar{y}_{2}\right)^{\prime}\) is on or outside the ellipse in Figure 5.1 ; that is, the test statistic \(Z^{2}\) is greater than 5.99 if and only if \(\overline{\mathbf{y}}\) is outside the ellipse. If \(\overline{\mathbf{y}}\) falls inside the ellipse, \(H_{0}\) is accepted. Thus distance from \(\mu_{0}\) as well as direction must be taken into account. When the distance is standardized by \(\boldsymbol{\Sigma}^{-1}\), all points on the curve are "statistically equidistant" from the center.

Note that the test is sensitive to the covariance structure. If \(\operatorname{cov}\left(y_{1}, y_{2}\right)\) were negative, \(y_{2}\) would tend to decrease as \(y_{1}\) increases, and the ellipse would be tilted in the other direction. In this case, \(\overline{\mathbf{y}}\) would be in the acceptance region.

Figure 5.2 Acceptance and rejection regions for univariate and multivariate tests.

Let us now investigate the consequence of testing each variable separately. Using \(z_{\alpha / 2}=1.96\) for \(\alpha=.05\), we have
\[
\begin{aligned}
& z_{1}=\frac{\bar{y}_{1}-\mu_{01}}{\sigma_{1} / \sqrt{n}}=1.450<1.96 \\
& z_{2}=\frac{\bar{y}_{2}-\mu_{02}}{\sigma_{2} / \sqrt{n}}=-.7495>-1.96
\end{aligned}
\]

Thus both tests accept the hypothesis. In this case neither of the \(\bar{y}\) 's is far enough from the hypothesized value to cause rejection. But when the positive correlation between \(y_{1}\) and \(y_{2}\) is taken into account in the multivariate test, the two evidences against \(\mu_{0}\) combine to cause rejection. This illustrates the third advantage of multivariate tests given in Section 5.1.

Figure 5.2 shows the rectangular acceptance region for the univariate tests superimposed on the elliptical multivariate acceptance region. The rectangle was obtained by calculating the two acceptance regions
\[
\begin{aligned}
& \mu_{01}-1.96 \frac{\sigma_{1}}{\sqrt{n}}<\bar{y}_{1}<\mu_{01}+1.96 \frac{\sigma_{1}}{\sqrt{n}} \\
& \mu_{02}-1.96 \frac{\sigma_{2}}{\sqrt{n}}<\bar{y}_{2}<\mu_{02}+1.96 \frac{\sigma_{2}}{\sqrt{n}} .
\end{aligned}
\]

Points inside the ellipse but outside the rectangle will be rejected in at least one univariate dimension but will be accepted multivariately. This illustrates the inflation of \(\alpha\) resulting from univariate tests, as discussed in the first motive
for multivariate testing in Section 5.1. This phenomenon has been referred to as Rao's paradox. For further discussion see Rao (1966), Healy (1969), and Morrison (1990, p. 174). Points outside the ellipse but inside the rectangle will be rejected multivariately but accepted univariately in both dimensions. This illustrates the third reason for multivariate testing given in Section 5.1, namely, that the multivariate test is more powerful in some situations.

Thus in either case represented by the shaded areas, we should use the multivariate test result, not the univariate results. In the one case, the multivariate test is more powerful than the univariate tests; in the other case, the multivariate test preserves \(\alpha\) whereas the univariate tests inflate \(\alpha\). Consequently, when the multivariate and univariate results disagree, our tendency is to trust the multivariate result. In Section 5.5, we discuss various procedures for ascertaining the contribution of the individual variables after the multivariate test has rejected the hypothesis.

\subsection*{5.3 TESTS ON \(\mu\) WHEN \(\Sigma\) IS UNKNOWN}

In Section 5.2, we said little about properties of the tests, because the tests discussed were of slight practical consequence because of the assumption that \(\Sigma\) is known. We will be more concerned with test properties in Sections 5.3 and 5.4, first in the one-sample case and then in the two-sample case. The reader may wonder why we include one-sample tests, since we seldom, if ever, have need of a test for \(H_{0}: \boldsymbol{\mu}=\) \(\mu_{0}\). However, we will cover this case for two reasons:
1. Many general principles are more easily illustrated in the one-sample framework than in the two-sample case.
2. Some very useful tests can be cast in the one-sample framework. Two examples are (1) \(H_{0}: \boldsymbol{\mu}_{d}=\mathbf{0}\) used in the paired comparison test covered in Section 5.7 and (2) \(H_{0}: \mathbf{C} \boldsymbol{\mu}=\mathbf{0}\) used in profile analysis in Section 5.9, in analysis of repeated measures in Section 6.9, and in growth curves in Section 6.10.

\subsection*{5.3.1 Review of Univariate \(t\)-Test for \(H_{0}: \mu=\mu_{0}\) with \(\sigma\) Unknown}

We first review the familiar one-sample \(t\)-test in the univariate case, with only one variable measured on each sampling unit. We assume that a random sample \(y_{1}, y_{2}\), \(\ldots, y_{n}\) is available from \(N\left(\mu, \sigma^{2}\right)\). We estimate \(\mu\) by \(\bar{y}\) and \(\sigma^{2}\) by \(s^{2}\), where \(\bar{y}\) and \(s^{2}\) are given by (3.1) and (3.4). To test \(H_{0}: \mu=\mu_{0}\) vs. \(H_{1}: \mu \neq \mu_{0}\), we use
\[
\begin{equation*}
t=\frac{\bar{y}-\mu_{0}}{s / \sqrt{n}}=\frac{\sqrt{n}\left(\bar{y}-\mu_{0}\right)}{s} \tag{5.3}
\end{equation*}
\]

If \(H_{0}\) is true, \(t\) is distributed as \(t_{n-1}\), where \(n-1\) is the degrees of freedom. We reject \(H_{0}\) if \(\left|\sqrt{n}\left(\bar{y}-\mu_{0}\right) / s\right| \geq t_{\alpha / 2, n-1}\), where \(t_{\alpha / 2, n-1}\) is a critical value from the \(t\)-table.

The first expression in (5.3), \(t=\left(\bar{y}-\mu_{0}\right) /(s / \sqrt{n})\), is the characteristic form of the \(t\)-statistic, which represents a sample standardized distance between \(\bar{y}\) and \(\mu_{0}\). In this form, the hypothesized mean is subtracted from \(\bar{y}\) and the difference is divided by \(s_{\bar{y}}=s / \sqrt{n}\). Since \(y_{1}, y_{2}, \ldots, y_{n}\) is a random sample from \(N\left(\mu, \sigma^{2}\right)\), the random variables \(\bar{y}\) and \(s\) are independent. We will see an analogous characteristic form for the \(T^{2}\)-statistic in the multivariate case in Section 5.3.2.

\subsection*{5.3.2 Hotelling's \(T^{2}\)-Test for \(H_{0}: \mu=\mu_{0}\) with \(\Sigma\) Unknown}

We now move to the multivariate case in which \(p\) variables are measured on each sampling unit. We assume that a random sample \(\mathbf{y}_{1}, \mathbf{y}_{2}, \ldots, \mathbf{y}_{n}\) is available from \(N_{p}(\boldsymbol{\mu}, \boldsymbol{\Sigma})\), where \(\mathbf{y}_{i}\) contains the \(p\) measurements on the \(i\) th sampling unit (subject or object). We estimate \(\boldsymbol{\mu}\) by \(\overline{\mathbf{y}}\) and \(\boldsymbol{\Sigma}\) by \(\mathbf{S}\), where \(\overline{\mathbf{y}}\) and \(\mathbf{S}\) are given by (3.16), (3.19), (3.22), (3.27), and (3.29). In order to test \(H_{0}: \boldsymbol{\mu}=\boldsymbol{\mu}_{0}\) versus \(H_{1}: \boldsymbol{\mu} \neq \boldsymbol{\mu}_{0}\), we use an extension of the univariate \(t\)-statistic in (5.3). In squared form, the univariate \(t\) can be rewritten as
\[
\begin{equation*}
t^{2}=\frac{n\left(\bar{y}-\mu_{0}\right)^{2}}{s^{2}}=n\left(\bar{y}-\mu_{0}\right)\left(s^{2}\right)^{-1}\left(\bar{y}-\mu_{0}\right) \tag{5.4}
\end{equation*}
\]

When \(\bar{y}-\mu_{0}\) and \(s^{2}\) are replaced by \(\overline{\mathbf{y}}-\boldsymbol{\mu}_{0}\) and \(\mathbf{S}\), we obtain the test statistic
\[
\begin{equation*}
T^{2}=n\left(\overline{\mathbf{y}}-\boldsymbol{\mu}_{0}\right)^{\prime} \mathbf{S}^{-1}\left(\overline{\mathbf{y}}-\boldsymbol{\mu}_{0}\right) . \tag{5.5}
\end{equation*}
\]

Alternatively, \(T^{2}\) can be obtained from \(Z^{2}\) in (5.2) by replacing \(\boldsymbol{\Sigma}\) with \(\mathbf{S}\).
The distribution of \(T^{2}\) was obtained by Hotelling (1931), assuming \(H_{0}\) is true and sampling is from \(N_{p}(\boldsymbol{\mu}, \boldsymbol{\Sigma})\). The distribution is indexed by two parameters, the dimension \(p\) and degrees of freedom \(\nu=n-1\). We reject \(H_{0}\) if \(T^{2}>T_{\alpha, p, n-1}^{2}\) and accept \(H_{0}\) otherwise. Critical values of the \(T^{2}\)-distribution are found in Table A.7, taken from Kramer and Jensen (1969a).

Note that the terminology "accept \(H_{0}\) " is used for expositional convenience to describe our decision when we do not reject the hypothesis. Strictly speaking, we do not accept \(H_{0}\) in the sense of actually believing it is true. If the sample size were extremely large and we accepted \(H_{0}\), we could be reasonably certain that the true \(\mu\) is close to the hypothesized value \(\mu_{0}\). Otherwise, "accepting \(H_{0}\) " means only that we have failed to reject \(H_{0}\).

The \(T^{2}\)-statistic can be viewed as the sample standardized distance between the observed sample mean vector and the hypothetical mean vector. If the sample mean vector is notably distant from the hypothetical mean vector, we become suspicious of the hypothetical mean vector and wish to reject \(H_{0}\).

The test statistic is a scalar quantity, since \(T^{2}=n\left(\overline{\mathbf{y}}-\boldsymbol{\mu}_{0}\right)^{\prime} \mathbf{S}^{-1}\left(\overline{\mathbf{y}}-\boldsymbol{\mu}_{0}\right)\) is a quadratic form. As with the \(\chi^{2}\)-distribution of \(Z^{2}\), the density of \(T^{2}\) is skewed because the lower limit is zero and there is no upper limit.

The characteristic form of the \(T^{2}\)-statistic (5.5) is
\[
\begin{equation*}
T^{2}=\left(\overline{\mathbf{y}}-\boldsymbol{\mu}_{0}\right)^{\prime}\left(\frac{\mathbf{S}}{n}\right)^{-1}\left(\overline{\mathbf{y}}-\boldsymbol{\mu}_{0}\right) . \tag{5.6}
\end{equation*}
\]

The characteristic form has two features:
1. \(\mathrm{S} / n\) is the sample covariance matrix of \(\overline{\mathrm{y}}\) and serves as a standardizing matrix in the distance function.
2. Since \(\mathbf{y}_{1}, \mathbf{y}_{2}, \ldots, \mathbf{y}_{n}\) are distributed as \(N_{p}(\boldsymbol{\mu}, \boldsymbol{\Sigma})\), it follows that \(\overline{\mathbf{y}}\) is \(N_{p}(\boldsymbol{\mu}\), \(\left.\frac{1}{n} \boldsymbol{\Sigma}\right),(n-1) \mathbf{S}\) is \(W(n-1, \boldsymbol{\Sigma})\), and \(\overline{\mathbf{y}}\) and \(\mathbf{S}\) are independent (see Section 4.3.2).

In (5.3), the univariate \(t\)-statistic represents the number of standard deviations \(\bar{y}\) is separated from \(\mu_{0}\). In appearance, the \(T^{2}\)-statistic (5.6) is similar, but no such simple interpretation is possible. If we add a variable, the distance in (5.6) increases. (By analogy, the hypotenuse of a right triangle is longer than either of the legs.) Thus we need a test statistic that indicates the significance of the distance from \(\overline{\mathbf{y}}\) to \(\mu_{0}\), while allowing for the number of dimensions (see comment 3 below about the \(T^{2}\) table). Since the resulting \(T^{2}\)-statistic cannot be readily interpreted in terms of the number of standard deviations \(\overline{\mathbf{y}}\) is from \(\mu_{0}\), we do not have an intuitive feel for its significance as we do with the univariate \(t\). We must compare the calculated value of \(T^{2}\) with the table value. In addition, the \(T^{2}\)-table provides some insights into the behavior of the \(T^{2}\)-distribution. Four of these insights are noted at the end of this section.

If a test leads to rejection of \(H_{0}: \boldsymbol{\mu}=\boldsymbol{\mu}_{0}\), the question arises as to which variable or variables contributed most to the rejection. This issue is discussed in Section 5.5 for the two-sample \(T^{2}\)-test of \(H_{0}: \mu_{1}=\mu_{2}\), and the results there can be easily adapted to the one-sample test of \(H_{0}: \mu=\mu_{0}\). For confidence intervals on the individual \(\mu_{j}\) 's in \(\boldsymbol{\mu}\), see Rencher (1998, Section 3.4).

The following are some key properties of the \(T^{2}\)-test:
1. We must have \(n>p\). Otherwise, \(\mathbf{S}\) is singular and \(T^{2}\) cannot be computed.
2. In both the one-sample and two-sample cases, the degrees of freedom for the \(T^{2}\)-statistic will be the same as for the analogous univariate \(t\)-test, that is, \(\nu=n-1\) for one sample and \(\nu=n_{1}+n_{2}-2\) for two samples (see Section 5.4.2).
3. The alternative hypothesis is two-sided. Because the space is multidimensional, we do not consider one-sided alternative hypotheses, such as \(\mu>\mu_{0}\). However, even though the alternative hypothesis \(H_{1}: \mu \neq \mu_{0}\) is essentially two-sided, the critical region is one-tailed (we reject for large values of \(T^{2}\) ). This is typical of many multivariate tests.
4. In the univariate case, \(t_{n-1}^{2}=F_{1, n-1}\). The statistic \(T^{2}\) can also be converted to an \(F\)-statistic as follows:
\[
\begin{equation*}
\frac{\nu-p+1}{\nu p} T_{p, \nu}^{2}=F_{p, \nu-p+1} . \tag{5.7}
\end{equation*}
\]

Note that the dimension \(p\) (number of variables) of the \(T^{2}\)-statistic becomes the first of the two degrees-of-freedom parameters of the \(F\). The degrees of
freedom for \(T^{2}\) is denoted by \(\nu\), and the \(F\)-transformation is given in terms of a general \(\nu\), since other applications of \(T^{2}\) will have \(\nu\) different from \(n-1\) (see, for example, Sections 5.4.2 and 6.3.2).

Equation (5.7) gives an easy way to find critical values for the \(T^{2}\)-test. However, we have provided critical values of \(T^{2}\) in Table A. 7 because of the insights they provide into the behavior of the \(T^{2}\)-distribution in particular and multivariate tests in general. The following are some insights that can readily be gleaned from the \(T^{2}\)-tables:
1. The first column of Table A. 7 contains squared values from the \(t\) table; that is, \(T_{\alpha, 1, \nu}^{2}=t_{\alpha / 2, \nu}^{2}\). (We use \(t_{\alpha / 2}^{2}\) because the univariate test of \(H_{0}: \mu=\mu_{0}\) versus \(H_{1}: \mu \neq \mu_{0}\) is two-tailed.) Thus for \(p=1, T^{2}\) reduces to \(t^{2}\). This can easily be seen by comparing (5.5) with (5.4).
2. The last row of each page of Table A. 7 contains \(\chi^{2}\) critical values, that is, \(T_{p, \infty}^{2}=\chi_{p}^{2}\). Thus as \(n\) increases, \(\mathbf{S}\) approaches \(\boldsymbol{\Sigma}\), and
\[
T^{2}=n\left(\overline{\mathbf{y}}-\boldsymbol{\mu}_{0}\right)^{\prime} \mathbf{S}^{-1}\left(\overline{\mathbf{y}}-\boldsymbol{\mu}_{0}\right)
\]
approaches \(Z^{2}=n\left(\overline{\mathbf{y}}-\boldsymbol{\mu}_{0}\right)^{\prime} \boldsymbol{\Sigma}^{-1}\left(\overline{\mathbf{y}}-\boldsymbol{\mu}_{0}\right)\) in (5.2), which is distributed as \(\chi_{p}^{2}\).
3. The values increase along each row of Table A.7; that is, for a fixed \(\nu\), the critical value \(T_{\alpha, p, \nu}^{2}\) increases with \(p\). It was noted above that in any given sample, the calculated value of \(T^{2}\) increases if a variable is added. However, since the critical value also increases, a variable should not be added unless it adds a significant amount to \(T^{2}\).
4. As \(p\) increases, larger values of \(\nu\) are required for the distribution of \(T^{2}\) to approach \(\chi^{2}\). In the univariate case, \(t\) in (5.3) is considered a good approximation to the standard normal \(z\) in (5.1) when \(\nu=n-1\) is at least 30 . In the first column ( \(p=1\) ) of Table A.7, we see \(T_{.05,1,30}^{2}=4.171\) and \(T_{.05,1, \infty}^{2}=3.841\), with a ratio of \(4.171 / 3.841=1.086\). For \(p=5, \nu\) must be 100 to obtain the same ratio: \(T_{.05,5,100}^{2} / T_{.05,5, \infty}^{2}=1.086\). For \(p=10\), we need \(\nu=200\) to obtain a similar value of the ratio: \(T_{.05,10,200}^{2} / T_{.05,10, \infty}^{2}=1.076\). Thus one must be very cautious in stating that \(T^{2}\) has an approximate \(\chi^{2}\)-distribution for large \(n\). The \(\alpha\) level (Type I error rate) could be substantially inflated. For example, suppose \(p=10\) and we assume that \(n=30\) is sufficiently large for a \(\chi^{2}\)-approximation to hold. Then we would reject \(H_{0}\) for \(T^{2} \geq 18.307\) with a target \(\alpha\)-level of . 05 . However, the correct critical value is 34.044 , and the misuse of 18.307 would yield an actual \(\alpha\) of \(P\left(T_{10,29}^{2} \geq 18.307\right)=.314\).

\section*{- EXAMPLE 5.3.2}

In Table 3.4 we have \(n=10\) observations on \(p=3\) variables. Desirable levels for \(y_{1}\) and \(y_{2}\) are 15.0 and 6.0 , respectively, and the expected level of \(y_{3}\) is
2.85. We can, therefore, test the hypothesis
\[
H_{0}: \boldsymbol{\mu}=\left(\begin{array}{r}
15.0 \\
6.0 \\
2.85
\end{array}\right)
\]

In Examples 3.6 and 3.7, \(\bar{y}\) and \(\mathbf{S}\) were obtained as
\[
\overline{\mathbf{y}}=\left(\begin{array}{c}
28.1 \\
7.18 \\
3.09
\end{array}\right), \quad \mathbf{S}=\left(\begin{array}{rrr}
140.54 & 49.68 & 1.94 \\
49.68 & 72.25 & 3.68 \\
1.94 & 3.68 & .25
\end{array}\right)
\]

To test \(H_{0}\), we use (5.5):
\[
\begin{aligned}
T^{2} & =n\left(\overline{\mathbf{y}}-\boldsymbol{\mu}_{0}\right)^{\prime} \mathbf{S}^{-1}\left(\overline{\mathbf{y}}-\boldsymbol{\mu}_{0}\right) \\
& =10\left(\begin{array}{r}
28.1-15.0 \\
7.18-6.0 \\
3.09-2.85
\end{array}\right)^{\prime}\left(\begin{array}{rrr}
140.54 & 49.68 & 1.94 \\
49.68 & 72.25 & 3.68 \\
1.94 & 3.68 & .25
\end{array}\right)^{-1}\left(\begin{array}{l}
28.1-15.0 \\
7.18-6.0 \\
3.09-2.85
\end{array}\right) \\
& =24.559 .
\end{aligned}
\]

From Table A.7, we obtain the critical value \(T_{.05,3,9}^{2}=16.766\). Since the observed value of \(T^{2}\) exceeds the critical value, we reject the hypothesis.

\subsection*{5.4 COMPARING TWO MEAN VECTORS}

We first review the univariate two-sample \(t\)-test and then proceed with the analogous multivariate test.

\subsection*{5.4.1 Review of Univariate Two-Sample \(t\)-Test}

In the one-variable case we obtain a random sample \(y_{11}, y_{12}, \ldots, y_{1_{n_{1}}}\) from \(N\left(\mu_{1}\right.\), \(\left.\sigma_{1}^{2}\right)\) and a second random sample \(y_{21}, y_{22}, \ldots, y_{2 n_{2}}\) from \(N\left(\mu_{2}, \sigma_{2}^{2}\right)\). We assume that the two samples are independent and that \(\sigma_{1}^{2}=\sigma_{2}^{2}=\sigma^{2}\), say, with \(\sigma^{2}\) unknown. [The assumptions of independence and equal variances are necessary in order for the \(t\)-statistic below in (5.8) to have a \(t\)-distribution.] From the two samples we calculate \(\bar{y}_{1}, \bar{y}_{2}, \mathrm{SS}_{1}=\sum_{i=1}^{n_{1}}\left(y_{1 i}-\bar{y}_{1}\right)^{2}=\left(n_{1}-1\right) s_{1}^{2}, \mathrm{SS}_{2}=\sum_{i=1}^{n_{2}}\left(y_{2 i}-\bar{y}_{2}\right)^{2}=\left(n_{2}-1\right) s_{2}^{2}\), and the pooled variance
\[
s_{\mathrm{pl}}^{2}=\frac{\mathrm{SS}_{1}+\mathrm{SS}_{2}}{n_{1}+n_{2}-2}=\frac{\left(n_{1}-1\right) s_{1}^{2}+\left(n_{2}-1\right) s_{2}^{2}}{n_{1}+n_{2}-2}
\]
where \(n_{1}+n_{2}-2\) is the sum of the weights \(n_{1}-1\) and \(n_{2}-1\) in the numerator. With this denominator, \(s_{\mathrm{pl}}^{2}\) is an unbiased estimator for the common variance, \(\sigma^{2}\), that is, \(E\left(s_{\mathrm{pl}}^{2}\right)=\sigma^{2}\).

To test
\[
H_{0}: \mu_{1}=\mu_{2} \quad \text { vs. } \quad H_{1}: \mu_{1} \neq \mu_{2}
\]
we use
\[
\begin{equation*}
t=\frac{\bar{y}_{1}-\bar{y}_{2}}{s_{\mathrm{pl}} \sqrt{\frac{1}{n_{1}}+\frac{1}{n_{2}}}} \tag{5.8}
\end{equation*}
\]
which has a \(t\)-distribution with \(n_{1}+n_{2}-2\) degrees of freedom when \(H_{0}\) is true. We therefore reject \(H_{0}\) if \(|t| \geq t_{\alpha / 2, n_{1}+n_{2}-2}\).

Note that (5.8) exhibits the characteristic form of a \(t\)-statistic. In this form, the denominator is the sample standard deviation of the numerator, that is,
\[
s_{\mathrm{pl}} \sqrt{1 / n_{1}+1 / n_{2}}
\]
is an estimate of
\[
\begin{aligned}
\sigma_{\bar{y}_{1}-\bar{y}_{2}} & =\sqrt{\operatorname{var}\left(\bar{y}_{1}-\bar{y}_{2}\right)}=\sqrt{\frac{\sigma_{1}^{2}}{n_{1}}+\frac{\sigma_{2}^{2}}{n_{2}}} \\
& =\sqrt{\frac{\sigma^{2}}{n_{1}}+\frac{\sigma^{2}}{n_{2}}}=\sigma \sqrt{\frac{1}{n_{1}}+\frac{1}{n_{2}}}
\end{aligned}
\]

\subsection*{5.4.2 Multivariate Two-Sample \(T^{2}\)-Test}

We now consider the case where \(p\) variables are measured on each sampling unit in two samples. We wish to test
\[
H_{0}: \boldsymbol{\mu}_{1}=\boldsymbol{\mu}_{2} \quad \text { vs. } \quad H_{1}: \boldsymbol{\mu}_{\mathbf{1}} \neq \boldsymbol{\mu}_{2}
\]

We obtain a random sample \(\mathbf{y}_{11}, \mathbf{y}_{12}, \ldots, \mathbf{y}_{1 n_{1}}\) from \(N_{p}\left(\boldsymbol{\mu}_{1}, \boldsymbol{\Sigma}_{1}\right)\) and a second random sample \(\mathbf{y}_{21}, \mathbf{y}_{22}, \ldots, \mathbf{y}_{2 n_{2}}\) from \(N_{p}\left(\boldsymbol{\mu}_{2}, \boldsymbol{\Sigma}_{2}\right)\). We assume that the two samples are independent and that \(\boldsymbol{\Sigma}_{1}=\boldsymbol{\Sigma}_{2}=\boldsymbol{\Sigma}\), say, with \(\boldsymbol{\Sigma}\) unknown. These assumptions are necessary in order for the \(T^{2}\)-statistic in (5.9) to have a \(T^{2}\)-distribution. A test of \(H_{0}: \boldsymbol{\Sigma}_{1}=\boldsymbol{\Sigma}_{2}\) is given in Section 7.3.2. For an approximate test of \(H_{0}: \boldsymbol{\mu}_{1}=\boldsymbol{\mu}_{2}\) that can be used when \(\boldsymbol{\Sigma}_{1} \neq \boldsymbol{\Sigma}_{2}\), see Rencher (1998, Section 3.10).

The sample mean vectors are \(\overline{\mathbf{y}}_{1}=\sum_{i=1}^{n_{1}} \mathbf{y}_{1 i} / n_{1}\) and \(\overline{\mathbf{y}}_{2}=\sum_{i=1}^{n_{2}} \mathbf{y}_{2 i} / n_{2}\). Define \(\mathbf{W}_{1}\) and \(\mathbf{W}_{2}\) to be the matrices of sums of squares and cross products for the two samples:
\[
\begin{aligned}
& \mathbf{W}_{1}=\sum_{i=1}^{n_{1}}\left(\mathbf{y}_{1 i}-\overline{\mathbf{y}}_{1}\right)\left(\mathbf{y}_{1 i}-\overline{\mathbf{y}}_{1}\right)^{\prime}=\left(n_{1}-1\right) \mathbf{S}_{1} \\
& \mathbf{W}_{2}=\sum_{i=1}^{n_{2}}\left(\mathbf{y}_{2 i}-\overline{\mathbf{y}}_{2}\right)\left(\mathbf{y}_{2 i}-\overline{\mathbf{y}}_{2}\right)^{\prime}=\left(n_{2}-1\right) \mathbf{S}_{2}
\end{aligned}
\]

Since \(\left(n_{1}-1\right) \mathbf{S}_{1}\) is an unbiased estimator of \(\left(n_{1}-1\right) \boldsymbol{\Sigma}\) and \(\left(n_{2}-1\right) \mathbf{S}_{2}\) is an unbiased estimator of \(\left(n_{2}-1\right) \boldsymbol{\Sigma}\), we can pool them to obtain an unbiased estimator of the
common population covariance matrix, \(\boldsymbol{\Sigma}\) :
\[
\begin{aligned}
\mathbf{S}_{\mathrm{pl}} & =\frac{1}{n_{1}+n_{2}-2}\left(\mathbf{W}_{1}+\mathbf{W}_{2}\right) \\
& =\frac{1}{n_{1}+n_{2}-2}\left[\left(n_{1}-1\right) \mathbf{S}_{1}+\left(n_{2}-1\right) \mathbf{S}_{2}\right]
\end{aligned}
\]

Thus \(E\left(\mathbf{S}_{\mathrm{pl}}\right)=\boldsymbol{\Sigma}\).
The square of the univariate \(t\)-statistic (5.8) can be expressed as
\[
t^{2}=\frac{n_{1} n_{2}}{n_{1}+n_{2}}\left(\bar{y}_{1}-\bar{y}_{2}\right)\left(s_{\mathrm{pl}}^{2}\right)^{-1}\left(\bar{y}_{1}-\bar{y}_{2}\right) .
\]

This can be generalized to \(p\) variables by substituting \(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\) for \(\bar{y}_{1}-\bar{y}_{2}\) and \(\mathbf{S}_{\mathrm{pl}}\) for \(s_{\mathrm{pl}}^{2}\) to obtain
\[
\begin{equation*}
T^{2}=\frac{n_{1} n_{2}}{n_{1}+n_{2}}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)^{\prime} \mathbf{S}_{\mathrm{pl}}^{-1}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right) \tag{5.9}
\end{equation*}
\]
which is distributed as \(T_{p, n_{1}+n_{2}-2}^{2}\) when \(H_{0}: \mu_{1}=\mu_{2}\) is true. To carry out the test, we collect the two samples, calculate \(T^{2}\) by (5.9), and reject \(H_{0}\) if \(T^{2} \geq\) \(T_{\alpha, p, n_{1}+n_{2}-2}^{2}\). Critical values of \(T^{2}\) are found in Table A.7. For tables of the power of the \(T^{2}\)-test (probability of rejecting \(H_{0}\) when it is false) and illustrations of their use, see Rencher (1998, Section 3.11).

The \(T^{2}\)-statistic (5.9) can be expressed in characteristic form as the standardized distance between \(\overline{\mathbf{y}}_{1}\) and \(\overline{\mathbf{y}}_{2}\) :
\[
\begin{equation*}
T^{2}=\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)^{\prime}\left[\left(\frac{1}{n_{1}}+\frac{1}{n_{2}}\right) \mathbf{S}_{\mathrm{pl}}\right]^{-1}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right) \tag{5.10}
\end{equation*}
\]
where \(\left(1 / n_{1}+1 / n_{2}\right) \mathbf{S}_{\mathrm{pl}}\) is the sample covariance matrix for \(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\) and \(\mathbf{S}_{\mathrm{pl}}\) is independent of \(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\) because of sampling from the multivariate normal. For a discussion of robustness of \(T^{2}\) to departures from the assumptions of multivariate normality and homogeneity of covariance matrices ( \(\boldsymbol{\Sigma}_{1}=\boldsymbol{\Sigma}_{2}\) ), see Rencher (1998, Section 3.8).

Some key properties of the two-sample \(T^{2}\)-test are given in the following list:
1. It is necessary that \(n_{1}+n_{2}-2>p\) for \(\mathbf{S}_{\mathrm{pl}}\) to be nonsingular.
2. The statistic \(T^{2}\) is, of course, a scalar. The \(3 p+p(p-1) / 2\) quantities in \(\overline{\mathbf{y}}_{1}, \overline{\mathbf{y}}_{2}\), and \(\mathbf{S}_{\mathrm{pl}}\) have been reduced to a single scale on which \(T^{2}\) is large if the sample evidence favors \(H_{1}: \boldsymbol{\mu}_{1} \neq \boldsymbol{\mu}_{2}\) and small if the evidence supports \(H_{0}: \boldsymbol{\mu}_{1}=\boldsymbol{\mu}_{2}\); we reject \(H_{0}\) if the standardized distance between \(\overline{\mathbf{y}}_{1}\) and \(\overline{\mathbf{y}}_{2}\) is large.
3. Since the lower limit of \(T^{2}\) is zero and there is no upper limit, the density is skewed. In fact, as noted in (5.11) below, \(T^{2}\) is directly related to \(F\), which is a well-known skewed distribution.
4. For degrees of freedom of \(T^{2}\) we have \(n_{1}+n_{2}-2\), which is the same as for the corresponding univariate \(t\)-statistic (5.8).
5. The alternative hypothesis \(H_{1}: \boldsymbol{\mu}_{1} \neq \boldsymbol{\mu}_{2}\) is two sided. The critical region \(T^{2}>T_{\alpha}^{2}\) is one-tailed, however, as is typical of many multivariate tests.
6. The \(T^{2}\)-statistic can be readily transformed to an \(F\)-statistic using (5.7):
\[
\begin{equation*}
\frac{n_{1}+n_{2}-p-1}{\left(n_{1}+n_{2}-2\right) p} T^{2}=F_{p, n_{1}+n_{2}-p-1}, \tag{5.11}
\end{equation*}
\]
where again the dimension \(p\) of the \(T^{2}\)-statistic becomes the first degree-offreedom parameter for the \(F\)-statistic.

\section*{EXAMPLE 5.4.2}

Four psychological tests were given to 32 men and 32 women. The data are recorded in Table 5.1 (Beall 1945). The variables are
\[
\begin{array}{ll}
y_{1}=\text { pictorial inconsistencies } & y_{3}=\text { tool recognition } \\
y_{2}=\text { paper form board } & y_{4}=\text { vocabulary }
\end{array}
\]

The mean vectors and covariance matrices of the two samples are
\[
\begin{aligned}
& \overline{\mathbf{y}}_{1}=\left(\begin{array}{l}
15.97 \\
15.91 \\
27.19 \\
22.75
\end{array}\right), \quad \overline{\mathbf{y}}_{2}=\left(\begin{array}{l}
12.34 \\
13.91 \\
16.66 \\
21.94
\end{array}\right), \\
& \mathbf{S}_{1}=\left(\begin{array}{llll}
5.192 & 4.545 & 6.522 & 5.250 \\
4.545 & 13.18 & 6.760 & 6.266 \\
6.522 & 6.760 & 28.67 & 14.47 \\
5.250 & 6.266 & 14.47 & 16.65
\end{array}\right), \\
& \mathbf{S}_{2}=\left(\begin{array}{llll}
9.136 & 7.549 & 4.864 & 4.151 \\
7.549 & 18.60 & 10.22 & 5.446 \\
4.864 & 10.22 & 30.04 & 13.49 \\
4.151 & 5.446 & 13.49 & 28.00
\end{array}\right) .
\end{aligned}
\]

The sample covariance matrices do not appear to indicate a disparity in the population covariance matrices. (A significance test to check this assumption is carried out in Example 7.3.2, and the hypothesis \(H_{0}: \boldsymbol{\Sigma}_{1}=\boldsymbol{\Sigma}_{2}\) is not rejected.) The pooled covariance matrix is
\[
\begin{aligned}
\mathbf{S}_{\mathrm{pl}} & =\frac{1}{32+32-2}\left[(32-1) \mathbf{S}_{1}+(32-1) \mathbf{S}_{2}\right] \\
& =\left(\begin{array}{llll}
7.164 & 6.047 & 5.693 & 4.701 \\
6.047 & 15.89 & 8.492 & 5.856 \\
5.693 & 8.492 & 29.36 & 13.98 \\
4.701 & 5.856 & 13.98 & 22.32
\end{array}\right)
\end{aligned}
\]

Table 5.1 Four Psychological Test Scores on 32 Males and 32 Females
\begin{tabular}{|c|c|c|c|c|c|c|c|}
\hline \multicolumn{4}{|c|}{Males} & \multicolumn{4}{|c|}{Females} \\
\hline \(y_{1}\) & \(y_{2}\) & \(y_{3}\) & \(y_{4}\) & \(y_{1}\) & \(y_{2}\) & \(y_{3}\) & \(y_{4}\) \\
\hline 15 & 17 & 24 & 14 & 13 & 14 & 12 & 21 \\
\hline 17 & 15 & 32 & 26 & 14 & 12 & 14 & 26 \\
\hline 15 & 14 & 29 & 23 & 12 & 19 & 21 & 21 \\
\hline 13 & 12 & 10 & 16 & 12 & 13 & 10 & 16 \\
\hline 20 & 17 & 26 & 28 & 11 & 20 & 16 & 16 \\
\hline 15 & 21 & 26 & 21 & 12 & 9 & 14 & 18 \\
\hline 15 & 13 & 26 & 22 & 10 & 13 & 18 & 24 \\
\hline 13 & 5 & 22 & 22 & 10 & 8 & 13 & 23 \\
\hline 14 & 7 & 30 & 17 & 12 & 20 & 19 & 23 \\
\hline 17 & 15 & 30 & 27 & 11 & 10 & 11 & 27 \\
\hline 17 & 17 & 26 & 20 & 12 & 18 & 25 & 25 \\
\hline 17 & 20 & 28 & 24 & 14 & 18 & 13 & 26 \\
\hline 15 & 15 & 29 & 24 & 14 & 10 & 25 & 28 \\
\hline 18 & 19 & 32 & 28 & 13 & 16 & 8 & 14 \\
\hline 18 & 18 & 31 & 27 & 14 & 8 & 13 & 25 \\
\hline 15 & 14 & 26 & 21 & 13 & 16 & 23 & 28 \\
\hline 18 & 17 & 33 & 26 & 16 & 21 & 26 & 26 \\
\hline 10 & 14 & 19 & 17 & 14 & 17 & 14 & 14 \\
\hline 18 & 21 & 30 & 29 & 16 & 16 & 15 & 23 \\
\hline 18 & 21 & 34 & 26 & 13 & 16 & 23 & 24 \\
\hline 13 & 17 & 30 & 24 & 2 & 6 & 16 & 21 \\
\hline 16 & 16 & 16 & 16 & 14 & 16 & 22 & 26 \\
\hline 11 & 15 & 25 & 23 & 17 & 17 & 22 & 28 \\
\hline 16 & 13 & 26 & 16 & 16 & 13 & 16 & 14 \\
\hline 16 & 13 & 23 & 21 & 15 & 14 & 20 & 26 \\
\hline 18 & 18 & 34 & 24 & 12 & 10 & 12 & 9 \\
\hline 16 & 15 & 28 & 27 & 14 & 17 & 24 & 23 \\
\hline 15 & 16 & 29 & 24 & 13 & 15 & 18 & 20 \\
\hline 18 & 19 & 32 & 23 & 11 & 16 & 18 & 28 \\
\hline 18 & 16 & 33 & 23 & 7 & 7 & 19 & 18 \\
\hline 17 & 20 & 21 & 21 & 12 & 15 & 7 & 28 \\
\hline 19 & 19 & 30 & 28 & 6 & 5 & 6 & 13 \\
\hline
\end{tabular}

By (5.9), we obtain
\[
T^{2}=\frac{n_{1} n_{2}}{n_{1}+n_{2}}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)^{\prime} \mathbf{S}_{\mathrm{pl}}^{-1}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)=97.6015
\]

From interpolation in Table A.7, we obtain \(T_{.01,4,62}^{2}=15.373\), and we therefore reject \(H_{0}: \mu_{1}=\mu_{2}\). See Example 5.5 for a discussion of which variables contribute most to separation of the two groups.

\subsection*{5.4.3 Likelihood Ratio Tests}

The maximum likelihood approach to estimation was introduced in Section 4.3.1. As noted there, the likelihood function is the joint density of \(\mathbf{y}_{1}, \mathbf{y}_{2}, \ldots, \mathbf{y}_{n}\). The values of the parameters that maximize the likelihood function are the maximum likelihood estimators.

The likelihood ratio method of test construction uses the ratio of the maximum value of the likelihood function assuming \(H_{0}\) is true to the maximum under \(H_{1}\), which is essentially unrestricted. Likelihood ratio tests usually have good power and sometimes have optimum power over a wide class of alternatives.

When applied to multivariate normal samples and \(H_{0}: \mu_{1}=\mu_{2}\), the likelihood ratio approach leads directly to Hotelling's \(T^{2}\)-test in (5.9). Similarly, in the onesample case, the \(T^{2}\)-statistic in (5.5) is the likelihood ratio test. Thus the \(T^{2}\)-test, which we introduced rather informally, is the best test according to certain criteria.

\subsection*{5.5 TESTS ON INDIVIDUAL VARIABLES CONDITIONAL ON REJECTION OF \(H_{0}\) BY THE \(T^{2}\)-TEST}

If the hypothesis \(H_{0}: \boldsymbol{\mu}_{1}=\boldsymbol{\mu}_{2}\) is rejected, the implication is that \(\mu_{1 j} \neq \mu_{2 j}\) for at least one \(j=1,2, \ldots, p\). But there is no guarantee that \(H_{0}: \mu_{1 j}=\mu_{2 j}\) will be rejected for some \(j\) by a univariate test. However, if we consider a linear combination of the variables, \(z=\mathbf{a}^{\prime} \mathbf{y}\), then there is at least one coefficient vector \(\mathbf{a}\) for which
\[
\begin{equation*}
t(\mathbf{a})=\frac{\bar{z}_{1}-\bar{z}_{2}}{\sqrt{\left(1 / n_{1}+1 / n_{2}\right) s_{z}^{2}}} \tag{5.12}
\end{equation*}
\]
will reject the corresponding hypothesis \(H_{0}: \mu_{z_{1}}=\mu_{z_{2}}\) or \(H_{0}: \mathbf{a}^{\prime} \boldsymbol{\mu}_{1}=\mathbf{a}^{\prime} \boldsymbol{\mu}_{2}\). By (3.54), \(\bar{z}_{1}=\mathbf{a}^{\prime} \overline{\mathbf{y}}_{1}\) and \(\bar{z}_{2}=\mathbf{a}^{\prime} \overline{\mathbf{y}}_{2}\), and from (3.55) the variance estimator \(s_{z}^{2}\) is the pooled estimator \(\mathbf{a}^{\prime} \mathbf{S}_{\mathrm{pl}} \mathbf{a}\). Thus (5.12) can be written as
\[
\begin{equation*}
t(\mathbf{a})=\frac{\mathbf{a}^{\prime} \overline{\mathbf{y}}_{1}-\mathbf{a}^{\prime} \overline{\mathbf{y}}_{2}}{\sqrt{\left[\left(n_{1}+n_{2}\right) / n_{1} n_{2}\right] \mathbf{a}^{\prime} \mathbf{S}_{\mathrm{pl}} \mathbf{a}}} \tag{5.13}
\end{equation*}
\]

Since \(t(\mathbf{a})\) can be negative, we work with \(t^{2}(\mathbf{a})\). The linear function \(z=\mathbf{a}^{\prime} \mathbf{y}\) is a projection of \(\mathbf{y}\) onto a line through the origin. We seek the line (direction) on which the difference \(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\) is maximized when projected. The projected difference \(\mathbf{a}^{\prime}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)\) [standardized by \(\mathbf{a}^{\prime} \mathbf{S}_{\mathrm{pl}} \mathbf{a}\) as in (5.13)] will be less in any other direction than that parallel to the line joining \(\overline{\mathbf{y}}_{1}\) and \(\overline{\mathbf{y}}_{2}\). The value of a that projects onto this line, or equivalently, maximizes \(t^{2}(\mathbf{a})\) in (5.13), is (any multiple of)
\[
\begin{equation*}
\mathbf{a}=\mathbf{S}_{\mathrm{pl}}^{-1}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right) \tag{5.14}
\end{equation*}
\]

Since a in (5.14) projects \(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\) onto a line parallel to the line joining \(\overline{\mathbf{y}}_{1}\) and \(\overline{\mathbf{y}}_{2}\), we would expect that \(t^{2}(\mathbf{a})=T^{2}\), and this is indeed the case (see Problem 5.3).

When \(\mathbf{a}=\mathbf{S}_{\mathrm{pl}}^{-1}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)\), then \(z=\mathbf{a}^{\prime} \mathbf{y}\) is called the discriminant function. Sometimes the vector a itself in (5.14) is loosely referred to as the discriminant function.

If \(H_{0}: \boldsymbol{\mu}_{1}=\boldsymbol{\mu}_{2}\) is rejected by \(T^{2}\) in (5.9), the discriminant function \(\mathbf{a}^{\prime} \mathbf{y}\) will lead to rejection of \(H_{0}: \mathbf{a}^{\prime} \boldsymbol{\mu}_{1}=\mathbf{a}^{\prime} \boldsymbol{\mu}_{2}\) using (5.13), with \(\mathbf{a}=\mathbf{S}_{\mathrm{pl}}^{-1}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)\). We can then examine each \(a_{j}\) in a for an indication of the contribution of the corresponding \(y_{j}\) to rejection of \(H_{0}\). This follow-up examination of each \(a_{j}\) should be done only if \(H_{0}: \boldsymbol{\mu}_{1}=\boldsymbol{\mu}_{2}\) is rejected by \(T^{2}\). The discriminant function will appear again in Section 5.6.2 and in Chapters 8 and 9.

We list these and other procedures that could be used to check each variable following rejection of \(H_{0}\) by a two-sample \(T^{2}\)-test:
1. Univariate \(t\)-tests, one for each variable,
\[
\begin{equation*}
t_{j}=\frac{\bar{y}_{1 j}-\bar{y}_{2 j}}{\sqrt{\left[\left(n_{1}+n_{2}\right) / n_{1} n_{2}\right] s_{j j}}}, \quad j=1,2, \ldots, p \tag{5.15}
\end{equation*}
\]
where \(s_{j j}\) is the \(j\) th diagonal element of \(\mathbf{S}_{\mathrm{pl}}\). Reject \(H_{0}: \mu_{1 j}=\mu_{2 j}\) if \(\left|t_{j}\right|>t_{\alpha / 2, n_{1}+n_{2}-2}\). For confidence intervals on \(\mu_{1 j}-\mu_{2 j}\), see Rencher (1998, Section 3.7).
2. To adjust the \(\alpha\)-level resulting from performing the \(p\) tests in (5.15), we could use a Bonferroni critical value \(t_{\alpha / 2 p, n_{1}+n_{2}-2}\) for (5.15) (Bonferroni 1936). A critical value \(t_{\alpha / 2 p}\) is much greater than the corresponding \(t_{\alpha / 2}\), and the resulting overall \(\alpha\)-level is conservative. Bonferroni critical values \(t_{\alpha / 2 p, \nu}\) are given in Table A.8, from Bailey (1977).
3. Another critical value that could be used with (5.15) is \(T_{\alpha, p, n_{1}+n_{2}-2}\), where \(T_{\alpha}\) is the square root of \(T_{\alpha}^{2}\) from Table A.7; that is,
\[
T_{\alpha, p, n_{1}+n_{2}-2}=\sqrt{T_{\alpha, p, n_{1}+n_{2}-2}^{2}}
\]

This allows for all \(p\) variables to be tested as well as all possible linear combinations, as in (5.13), even linear combinations chosen after seeing the data. Consequently, the use of \(T_{\alpha}\) is even more conservative than using \(t_{\alpha / 2 p}\); that is, \(T_{\alpha, p, n_{1}+n_{2}-2}>t_{\alpha / 2 p, n_{1}+n_{2}-2}\).
4. Partial \(F\) - or \(t\)-tests [test of each variable adjusted for the other variables; see (5.32) in Section 5.8]
5. Standardized discriminant function coefficients (see Section 8.5)
6. Correlations between the variables and the discriminant function (see Section 8.7.3)
7. Stepwise discriminant analysis (see Section 8.9)

The first three methods are univariate approaches that do not use covariances or correlations among the variables in the computation of the test statistic. The last four methods are multivariate in the sense that the correlation structure is explicitly taken into account in the computation.

Method 6, involving the correlation between each variable and the discriminant function, is recommended in many texts and software packages. However, Rencher (1988) has shown that these correlations are proportional to individual \(t\) - or \(F\)-tests (see Section 8.7.3). Thus this method is equivalent to method 1 and is a univariate rather than a multivariate approach. Method 7 is often used to identify a subset of important variables or even to rank the variables according to order of entry. But Rencher and Larson (1980) have shown that stepwise methods have a high risk of selecting spurious variables, unless the sample size is very large.

We now consider the univariate procedures 1,2 , and 3 . The probability of rejecting one or more of the \(p\) univariate tests when \(H_{0}\) is true is called the overall \(\alpha\) or experimentwise error rate. If we do univariate tests only, with no \(T^{2}\)-test, then the tests based on \(t_{\alpha / 2 p}\) and \(T_{\alpha}\) in procedures 2 and 3 are conservative (overall \(\alpha\) too low), and tests based on \(t_{\alpha / 2}\) in procedure 1 are liberal (overall \(\alpha\) too high). However, when these tests are carried out only after rejection by the \(T^{2}\)-test (such tests are sometimes called protected tests), the experimentwise error rates change. Obviously the tests will reject less often (under \(H_{0}\) ) if they are carried out only if \(T^{2}\) rejects. Thus the tests using \(t_{\alpha / 2 p}\) and \(T_{\alpha}\) become even more conservative, and the test using \(t_{\alpha / 2}\) becomes more acceptable.

Hummel and Sligo (1971) studied the experimentwise error rate for univariate \(t\) tests following rejection of \(H_{0}\) by the \(T^{2}\)-test (protected tests). Using \(\alpha=.05\), they found that using \(t_{\alpha / 2}\) for a critical value yields an overall \(\alpha\) acceptably close to the nominal .05. In fact, it is slightly conservative, making this the preferred univariate test (within the limits of their study). They also compared this procedure with that of performing univariate tests without a prior \(T^{2}\)-test (unprotected tests). For this case, the overall \(\alpha\) is too high, as expected. Table 5.2 gives an excerpt of Hummel and Sligo's results. The sample size is for each of the two samples; the \(r^{2}\) in common is for every pair of variables.

Hummel and Sligo therefore recommended performing the multivariate \(T^{2}\)-test followed by univariate \(t\)-tests. This procedure appears to have the desired overall \(\alpha\) level and will clearly have better power than tests using \(T_{\alpha}\) or \(t_{\alpha / 2 p}\) as a critical value. Table 5.2 also highlights the importance of using univariate \(t\)-tests only if the multivariate \(T^{2}\)-test is significant. The inflated \(\alpha\) 's resulting if \(t\)-tests are used without regard to the outcome of the \(T^{2}\)-test are clearly evident. Thus among the three univariate procedures (procedures 1, 2, and 3 above), the first appears to be preferred.

Among the multivariate approaches (procedures 4,5, and 7 above), we prefer the fifth procedure, which compares the (absolute value of) coefficients in the discriminant function to find the effect of each variable in separating the two groups of observations. These coefficients will often tell a different story from the univariate tests, because the univariate tests do not take into account the correlations among the variables or the effect of each variable on \(T^{2}\) in the presence of the other variables. A variable will typically have a different effect in the presence of other variables than it has by itself. In the discriminant function \(z=\mathbf{a}^{\prime} \mathbf{y}=a_{1} y_{1}+a_{2} y_{2}+\cdots+a_{p} y_{p}\), where \(\mathbf{a}=\mathbf{S}_{\mathrm{pl}}^{-1}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)\), the coefficients \(a_{1}, a_{2}, \ldots, a_{p}\) indicate the relative importance of the variables in a multivariate context, something the univariate \(t\)-tests

Table 5.2 Comparison of Experimentwise Error Rates (Nominal \(\alpha=0.05\) )

cannot do. If the variables are not commensurate (similar in scale and variance), the coefficients should be standardized, as in Section 8.5; this allows for more valid comparisons among the variables. Rencher and Scott (1990) provide a decomposition of the information in the standardized discriminant function coefficients. For a detailed analysis of the effect of each variable in the presence of the other variables, see Rencher (1993; 1998, Sections 3.3.5 and 3.5.3).

\section*{- EXAMPLE 5.5}

For the psychological data in Table 5.1, we obtained \(\overline{\mathbf{y}}_{1}, \overline{\mathbf{y}}_{2}\), and \(\mathbf{S}_{\mathrm{pl}}\) in Example 5.4.2. The discriminant function coefficient vector is obtained from (5.14) as
\[
\mathbf{a}=\mathbf{S}_{\mathrm{pl}}^{-1}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)=\left(\begin{array}{r}
.5104 \\
-.2033 \\
.4660 \\
-.3097
\end{array}\right)
\]

Thus the linear combination that best separates the two groups is
\[
\mathbf{a}^{\prime} \mathbf{y}=.5104 y_{1}-.2033 y_{2}+.4660 y_{3}-.3097 y_{4}
\]
in which \(y_{1}\) and \(y_{3}\) appear to contribute most to separation of the two groups. (After standardization, the relative contribution of the variables changes somewhat; see the answer to Problem 8.7 in Appendix B.)

\subsection*{5.6 COMPUTATION OF \(T^{2}\)}

If one has a program available with matrix manipulation capability, it is a simple matter to compute \(T^{2}\) using (5.9). However, this approach is somewhat cumbersome for those not accustomed to the use of such a programming language, and many would prefer a more automated procedure. But very few general-purpose statistical programs provide for direct calculation of the two-sample \(T^{2}\)-statistic, perhaps because it is so easy to obtain from other procedures. We will discuss two types of widely available procedures that can be used to compute \(T^{2}\).

\subsection*{5.6.1 Obtaining \(T^{2}\) from a MANOVA Program}

Multivariate analysis of variance (MANOVA) is discussed in Chapter 6, and the reader may wish to return to the present section after becoming familiar with that material. One-way MANOVA involves a comparison of mean vectors from several samples. Typically, the number of samples is three or more, but the procedure will also accommodate two samples. The two-sample \(T^{2}\) test is thus a special case of MANOVA.

Four common tests of significance are defined in Section 6.1: Wilks' \(\Lambda\), the Lawley-Hotelling \(U^{(s)}\), Pillai's \(V^{(s)}\), and Roy's largest root \(\theta\). Without concerning ourselves here with how these are defined or calculated, we show how to use each to obtain the two-sample \(T^{2}\) :
\[
\begin{align*}
& T^{2}=\left(n_{1}+n_{2}-2\right) \frac{1-\Lambda}{\Lambda}  \tag{5.16}\\
& T^{2}=\left(n_{1}+n_{2}-2\right) U^{(s)}  \tag{5.17}\\
& T^{2}=\left(n_{1}+n_{2}-2\right) \frac{V^{(s)}}{1-V^{(s)}}  \tag{5.18}\\
& T^{2}=\left(n_{1}+n_{2}-2\right) \frac{\theta}{1-\theta} \tag{5.19}
\end{align*}
\]
(For the special case of two groups, \(V^{(s)}=\theta\).) These relationships are demonstrated in Section 6.1.7. If the MANOVA program gives eigenvectors of \(\mathbf{E}^{-1} \mathbf{H}(\mathbf{E}\) and \(\mathbf{H}\) are defined in Section 6.1.2), the eigenvector corresponding to the largest eigenvalue will be equal to (a constant multiple of) the discriminant function \(\mathbf{S}_{\mathrm{pl}}^{-1}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)\).

\subsection*{5.6.2 Obtaining \(T^{\mathbf{2}}\) from Multiple Regression}

In this section, the \(y\) 's become independent variables in a regression model. For each observation vector \(\mathbf{y}_{1 i}\) and \(\mathbf{y}_{2 i}\) in a two-sample \(T^{2}\), define a "dummy" group variable as
\[
\begin{aligned}
w_{i} & =\frac{n_{2}}{n_{1}+n_{2}} \text { for each of } \mathbf{y}_{11}, \mathbf{y}_{12}, \ldots, \mathbf{y}_{1 n_{1}} \text { in sample } 1 \\
& =-\frac{n_{1}}{n_{1}+n_{2}} \text { for each of } \mathbf{y}_{21}, \mathbf{y}_{22}, \ldots, \mathbf{y}_{2 n_{2}} \text { in sample } 2
\end{aligned}
\]

Then \(\bar{w}=0\) for all \(n_{1}+n_{2}\) observations. The prediction equation for the regression of \(w\) on the \(y\) 's can be written as
\[
\hat{w}_{i}=b_{0}+b_{1} y_{i 1}+b_{2} y_{i 2}+\cdots+b_{p} y_{i p}
\]
where \(i\) ranges over all \(n_{1}+n_{2}\) observations and the least squares estimate \(b_{0}\) is [see (10.15)]
\[
b_{0}=\bar{w}-b_{1} \bar{y}_{1}-b_{2} \bar{y}_{2}-\cdots-b_{p} \bar{y}_{p} .
\]

Substituting this into the regression equation, we obtain
\[
\begin{aligned}
\hat{w}_{i} & =\bar{w}+b_{1}\left(y_{i 1}-\bar{y}_{1}\right)+b_{2}\left(y_{i 2}-\bar{y}_{2}\right)+\cdots+b_{p}\left(y_{i p}-\bar{y}_{p}\right) \\
& =b_{1}\left(y_{i 1}-\bar{y}_{1}\right)+b_{2}\left(y_{i 2}-\bar{y}_{2}\right)+\cdots+b_{p}\left(y_{i p}-\bar{y}_{p}\right) \quad(\text { since } \bar{w}=0)
\end{aligned}
\]

Let \(\mathbf{b}^{\prime}=\left(b_{1}, b_{2}, \ldots, b_{p}\right)\) be the vector of regression coefficients and \(R^{2}\) the squared multiple correlation. Then we have the following relationships:
\[
\begin{align*}
T^{2} & =\left(n_{1}+n_{2}-2\right) \frac{R^{2}}{1-R^{2}}  \tag{5.20}\\
\mathbf{a} & =\mathbf{S}_{\mathrm{pl}}^{-1}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)=\left[\frac{n_{1}+n_{2}}{n_{1} n_{2}}\left(n_{1}+n_{2}-2+T^{2}\right)\right] \mathbf{b} \tag{5.21}
\end{align*}
\]

Thus with ordinary multiple regression, one can easily obtain \(T^{2}\) and the discriminant function \(\mathbf{S}_{\mathbf{p l}}^{-1}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)\). We simply define \(w_{i}\) as above for each of the \(n_{1}+n_{2}\) observations, regress the \(w\) 's on the \(y\) 's, and use the resulting \(R^{2}\) in (5.20). For \(\mathbf{b}\), delete the intercept from the regression coefficients for use in (5.21). Actually, since only the relative values of the elements of \(\mathbf{a}=\mathbf{S}_{\mathrm{pl}}^{-1}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)\) are of interest, it is not necessary to convert from \(\mathbf{b}\) to \(\mathbf{a}\) in (5.21). We can use \(\mathbf{b}\) directly or standardize the values \(b_{1}, b_{2}, \ldots, b_{p}\) as in Section 8.5.

\section*{들 EXAMPLE 5.6.2}

We illustrate the regression approach to computation of \(T^{2}\) using the psychological data in Table 5.1. We set \(w=n_{2} /\left(n_{1}+n_{2}\right)=\frac{32}{64}=\frac{1}{2}\) for each observation in the first group (males) and equal to \(-n_{1} /\left(n_{1}+n_{2}\right)=-\frac{1}{2}\) in
the second group (females). When \(w\) is regressed on the \(64 y\) 's, we obtain
\[
\left(\begin{array}{l}
b_{0} \\
b_{1} \\
b_{2} \\
b_{3} \\
b_{4}
\end{array}\right)=\left(\begin{array}{r}
-.751 \\
.051 \\
-.020 \\
.047 \\
-.031
\end{array}\right), \quad R^{2}=.6115
\]

By (5.20),
\[
T^{2}=\left(n_{1}+n_{2}-2\right) \frac{R^{2}}{1-R^{2}}=\frac{62(.6115)}{1-.6115}=97.601
\]
as was obtained before in Example 5.4.2. Note that \(\mathbf{b}^{\prime}=\left(b_{1}, b_{2}, b_{3}, b_{4}\right)=\) (.051, -.020,.047, -.031), with the intercept deleted, is proportional to the discriminant function vector a from Example 5.5, as we would expect from (5.21).

\subsection*{5.7 PAIRED OBSERVATIONS TEST}

As usual, we begin with the univariate case to set the stage for the multivariate presentation.

\subsection*{5.7.1 Univariate Case}

Suppose two samples are not independent because there exists a natural pairing between the \(i\) th observation \(y_{i}\) in the first sample and the \(i\) th observation \(x_{i}\) in the second sample for all \(i\), as, for example, when a treatment is applied twice to the same individual or when subjects are matched according to some criterion, such as IQ or family background. With such pairing, the samples are often referred to as paired observations or matched pairs. The two samples thus obtained are correlated, and the two-sample test statistic in (5.8) is not appropriate because the samples must be independent in order for (5.8) to have a \(t\)-distribution. [The two-sample test in (5.8) is somewhat robust to heterogeneity of variances and to lack of normality but not to dependence.] We reduce the two samples to one by working with the differences between the paired observations, as in the following layout for two treatments applied to the same subject:
\begin{tabular}{cccc} 
Pair Number & Treatment 1 & Treatment 2 & \begin{tabular}{c} 
Difference \\
\(d_{i}=y_{i}-x_{i}\)
\end{tabular} \\
\hline 1 & \(y_{1}\) & \(x_{1}\) & \(d_{1}\) \\
2 & \(y_{2}\) & \(x_{2}\) & \(d_{2}\) \\
\(\vdots\) & \(\vdots\) & \(\vdots\) & \(\vdots\) \\
\(n\) & \(y_{n}\) & \(x_{n}\) & \(d_{n}\)
\end{tabular}

To obtain a \(t\)-test, it is not sufficient to assume individual normality for each of \(y\) and \(x\). To allow for the covariance between \(y\) and \(x\), we need the additional assumption that \(y\) and \(x\) have a bivariate normal distribution with
\[
\boldsymbol{\mu}=\binom{\mu_{y}}{\mu_{x}}, \quad \boldsymbol{\Sigma}=\left(\begin{array}{cc}
\sigma_{y}^{2} & \sigma_{y x} \\
\sigma_{y x} & \sigma_{x}^{2}
\end{array}\right)
\]

It then follows by property la in Section 4.2 that \(d_{i}=y_{i}-x_{i}\) is \(N\left(\mu_{y}-\mu_{x}, \sigma_{d}^{2}\right)\), where \(\sigma_{d}^{2}=\sigma_{y}^{2}-2 \sigma_{y x}+\sigma_{x}^{2}\). From \(d_{1}, d_{2}, \ldots, d_{n}\) we calculate
\[
\bar{d}=\frac{1}{n} \sum_{i=1}^{n} d_{i} \quad \text { and } \quad s_{d}^{2}=\frac{1}{n-1} \sum_{i=1}^{n}\left(d_{i}-\bar{d}\right)^{2} .
\]

To test \(H_{0}: \mu_{y}=\mu_{x}\), that is, \(H_{0}: \mu_{d}=0\), we use the one-sample statistic
\[
\begin{equation*}
t=\frac{\bar{d}}{s_{d} / \sqrt{n}} \tag{5.22}
\end{equation*}
\]
which is distributed as \(t_{n-1}\) if \(H_{0}\) is true. We reject \(H_{0}\) in favor of \(H_{1}: \mu_{d} \neq 0\) if \(|t|>t_{\alpha / 2, n-1}\). It is not necessary to assume \(\sigma_{y}^{2}=\sigma_{x}^{2}\) because there are no restrictions on \(\boldsymbol{\Sigma}\).

This test has only \(n-1\) degrees of freedom compared with \(2(n-1)\) for the two independent sample \(t\)-test (5.8). In general, the pairing reduces the within-sample variation \(s_{d}\) and thereby increases the power.

If we mistakenly treated the two samples as independent and used (5.8) with \(n_{1}=\) \(n_{2}=n\), we would have
\[
t=\frac{\bar{y}-\bar{x}}{s_{\mathrm{pl}} \sqrt{2 / n}}=\frac{\bar{y}-\bar{x}}{\sqrt{2 s_{\mathrm{pl}}^{2} / n}}
\]

However,
\[
E\left(\frac{2 s_{\mathrm{pl}}^{2}}{n}\right)=2 E\left[\frac{(n-1) s_{y}^{2}+(n-1) s_{x}^{2}}{(n+n-2) n}\right]=\left(\sigma_{y}^{2}+\sigma_{x}^{2}\right) / n
\]
whereas \(\operatorname{var}(\bar{y}-\bar{x})=\left(\sigma_{y}^{2}+\sigma_{x}^{2}-2 \sigma_{y x}\right) / n\). Thus if the test for independent samples (5.8) is used for paired data, it does not have a \(t\)-distribution, and in fact underestimates the true average \(t\)-value (assuming \(H_{0}\) is false), since \(\sigma_{y}^{2}+\sigma_{x}^{2}>\sigma_{y}^{2}+\sigma_{x}^{2}-2 \sigma_{y x}\) if \(\sigma_{y x}>0\), which would be typical in this situation. One could therefore use
\[
\begin{equation*}
t=\frac{\bar{y}-\bar{x}}{\sqrt{\left(s_{y}^{2}+s_{x}^{2}-2 s_{y x}\right) / n}} \tag{5.23}
\end{equation*}
\]
but \(t=\sqrt{n} \bar{d} / s_{d}\) in (5.22) is equal to it and somewhat simpler to use.

\subsection*{5.7.2 Multivariate Case}

Here we assume the same natural pairing of sampling units as in the univariate case, but we measure \(p\) variables on each sampling unit. Thus \(\mathbf{y}_{i}\) from the first sample is paired with \(\mathbf{x}_{i}\) from the second sample, \(i=1,2, \ldots, n\). In terms of two treatments applied to each sampling unit, this situation is as follows:
\begin{tabular}{cccc} 
Pair Number & Treatment 1 & Treatment 2 & \begin{tabular}{c} 
Difference \\
\(\mathbf{d}_{i}=\mathbf{y}_{\mathbf{i}}-\mathbf{x}_{i}\)
\end{tabular} \\
\hline \(\mathbf{1}\) & \(\mathbf{y}_{\mathbf{1}}\) & \(\mathbf{x}_{\mathbf{1}}\) & \(\mathbf{d}_{1}\) \\
2 & \(\mathbf{y}_{2}\) & \(\mathbf{x}_{2}\) & \(\mathbf{d}_{2}\) \\
\(\vdots\) & \(\vdots\) & \(\vdots\) & \(\vdots\) \\
\(n\) & \(\mathbf{y}_{n}\) & \(\mathbf{x}_{n}\) & \(\mathbf{d}_{n}\)
\end{tabular}

In Section 5.7.1, we made the assumption that \(y\) and \(x\) have a bivariate normal distribution, in which \(y\) and \(x\) are correlated. Here we assume \(\mathbf{y}\) and \(\mathbf{x}\) are correlated and have a multivariate normal distribution:
\[
\binom{\mathbf{y}}{\mathbf{x}} \text { is } N_{2 p}\left[\binom{\boldsymbol{\mu}_{y}}{\boldsymbol{\mu}_{x}},\left(\begin{array}{ll}
\boldsymbol{\Sigma}_{y y} & \boldsymbol{\Sigma}_{y x} \\
\boldsymbol{\Sigma}_{x y} & \boldsymbol{\Sigma}_{x x}
\end{array}\right)\right]
\]

To test \(H_{0}: \boldsymbol{\mu}_{d}=\mathbf{0}\), which is equivalent to \(H_{0}: \boldsymbol{\mu}_{y}=\boldsymbol{\mu}_{x}\) since \(\boldsymbol{\mu}_{d}=E(\mathbf{y}-\mathbf{x})=\) \(\mu_{y}-\mu_{x}\), we calculate
\[
\overline{\mathbf{d}}=\frac{1}{n} \sum_{i=1}^{n} \mathbf{d}_{i} \quad \text { and } \quad \mathbf{S}_{d}=\frac{1}{n-1} \sum_{i=1}^{n}\left(\mathbf{d}_{i}-\overline{\mathbf{d}}\right)\left(\mathbf{d}_{i}-\overline{\mathbf{d}}\right)^{\prime}
\]

We then have
\[
\begin{equation*}
T^{2}=\overline{\mathbf{d}}^{\prime}\left(\frac{\mathbf{S}_{d}}{n}\right)^{-1} \overline{\mathbf{d}}=n \overline{\mathbf{d}}^{\prime} \mathbf{S}_{d}^{-1} \overline{\mathbf{d}} \tag{5.24}
\end{equation*}
\]

Under \(H_{0}\), this paired comparison \(T^{2}\)-statistic is distributed as \(T_{p, n-1}^{2}\). We reject \(H_{0}\) if \(T^{2}>T_{\alpha, p, n-1}^{2}\). Note that \(\mathbf{S}_{d}\) estimates \(\operatorname{cov}(\mathbf{y}-\mathbf{x})=\boldsymbol{\Sigma}_{y y}-\boldsymbol{\Sigma}_{y x}-\boldsymbol{\Sigma}_{x y}+\boldsymbol{\Sigma}_{x x}\), for which an equivalent estimator would be \(\mathbf{S}_{y y}-\mathbf{S}_{y x}-\mathbf{S}_{x y}+\mathbf{S}_{x x}\) [see (3.42)].

The cautions expressed in Section 5.7.I for univariate paired observation data also apply here. If the two samples of multivariate observations are correlated because of a natural pairing of sampling units, the test in (5.24) should be used rather than the two-sample \(T^{2}\)-test in (5.9), which assumes two independent samples. Misuse of (5.9) in place of (5.24) will lead to loss of power

Since the assumption \(\boldsymbol{\Sigma}_{y y}=\boldsymbol{\Sigma}_{x x}\) is not needed for (5.24) to have a \(T^{2}\)-distribution, this test can be used for independent samples when \(\Sigma_{1} \neq \Sigma_{2}\) (as long as \(n_{1}=n_{2}\) ). The observations in the two samples would be paired in the order they were obtained or in an arbitrary order. However, in the case of independent samples, the pairing achieves no gain in power to offset the loss of \(n-1\) degrees of freedom.

By analogy with (5.14), the discriminant function for paired observation data becomes
\[
\begin{equation*}
\mathbf{a}=\mathbf{S}_{d}^{-1} \overline{\mathbf{d}} \tag{5.25}
\end{equation*}
\]

Table 5.3 Maximum Depth of Pits and Number of Pits of Coated Pipes
\begin{tabular}{cccccrr}
\hline & \multicolumn{2}{c}{ Coating 1 } & \multicolumn{2}{c}{ Coating 2 } & \multicolumn{2}{c}{ Difference } \\
\cline { 2 - 7 } & Depth & Number & Depth & Number & Depth & Number \\
Location & \(y_{1}\) & \(y_{2}\) & \(x_{1}\) & \(x_{2}\) & \(d_{1}\) & \(d_{2}\) \\
\hline 1 & 73 & 31 & 51 & 35 & 22 & -4 \\
2 & 43 & 19 & 41 & 14 & 2 & 5 \\
3 & 47 & 22 & 43 & 19 & 4 & 3 \\
4 & 53 & 26 & 41 & 29 & 12 & -3 \\
5 & 58 & 36 & 47 & 34 & 11 & 2 \\
6 & 47 & 30 & 32 & 26 & 15 & 4 \\
7 & 52 & 29 & 24 & 19 & 28 & 10 \\
8 & 38 & 36 & 43 & 37 & -5 & -1 \\
9 & 61 & 34 & 53 & 24 & 8 & 10 \\
10 & 56 & 33 & 52 & 27 & 4 & 6 \\
11 & 56 & 19 & 57 & 14 & -1 & 5 \\
12 & 34 & 19 & 44 & 19 & -10 & 0 \\
13 & 55 & 26 & 57 & 30 & -2 & -4 \\
14 & 65 & 15 & 40 & 7 & 25 & 8 \\
15 & 75 & 18 & 68 & 13 & 7 & 5 \\
\hline
\end{tabular}

For tests on individual variables, we have
\[
\begin{equation*}
t_{j}=\frac{\bar{d}_{j}}{\sqrt{s_{d, j j} / n}}, \quad j=1,2, \ldots, p \tag{5.26}
\end{equation*}
\]

The critical value for \(t_{j}\) is \(t_{\alpha / 2 p, n-1}\) or \(t_{\alpha / 2, n-1}\) depending on whether a \(T^{2}\)-test is carried out first (see Section 5.5).

\section*{- EXAMPLE 5.7.2}

To compare two types of coating for resistance to corrosion, 15 pieces of pipe were coated with each type of coating (Kramer and Jensen 1969b). Two pipes, one with each type of coating, were buried together and left for the same length of time at 15 different locations, providing a natural pairing of the observations. Corrosion for the first type of coating was measured by two variables,
\[
\begin{aligned}
& y_{1}=\text { maximum depth of pit in thousandths of an inch } \\
& y_{2}=\text { number of pits }
\end{aligned}
\]
with \(x_{1}\) and \(x_{2}\) defined analogously for the second coating. The data and differences are given in Table 5.3. Thus we have, for example, \(\mathbf{y}_{1}^{\prime}=(73,31), \mathbf{x}_{1}^{\prime}=\) \((51,35)\), and \(\mathbf{d}_{1}^{\prime}=\mathbf{y}_{1}^{\prime}-\mathbf{x}_{1}^{\prime}=(22,-4)\). For the 15 difference vectors, we obtain
\[
\overline{\mathbf{d}}=\binom{8.000}{3.067}, \quad \mathbf{S}_{d}=\left(\begin{array}{rr}
121.571 & 17.071 \\
17.071 & 21.781
\end{array}\right)
\]

By (5.24),
\[
T^{2}=(15)(8.000,3.067)\left(\begin{array}{rr}
121.571 & 17.071 \\
17.071 & 21.781
\end{array}\right)^{-1}\binom{8.000}{3.067}=10.819
\]

Since \(T^{2}=10.819>T_{.05,2,14}^{2}=8.197\), we reject \(H_{0}: \boldsymbol{\mu}_{d}=\mathbf{0}\) and conclude that the two coatings differ in their effect on corrosion.

\subsection*{5.8 TEST FOR ADDITIONAL INFORMATION}

In this section, we are again considering two independent samples as in Section 5.4.2. We start with a basic \(p \times 1\) vector \(\mathbf{y}\) of measurements on each sampling unit and ask whether a \(q \times 1\) subvector \(\mathbf{x}\) measured in addition to \(\mathbf{y}\) (on the same unit) will significantly increase the separation of the two samples as shown by \(T^{2}\). It is not necessary that we add new variables. We may be interested in determining whether some of the variables we already have are redundant in the presence of other variables in terms of separating the groups. We have designated the subset of interest by \(\mathbf{x}\) for notational convenience.

It is assumed that the two samples are from multivariate normal populations with a common covariance matrix, that is,
\[
\begin{aligned}
& \binom{\mathbf{y}_{11}}{\mathbf{x}_{11}},\binom{\mathbf{y}_{12}}{\mathbf{x}_{12}}, \ldots,\binom{\mathbf{y}_{1 n_{1}}}{\mathbf{x}_{1 n_{1}}} \quad \text { are from } N_{p+q}\left(\boldsymbol{\mu}_{1}, \boldsymbol{\Sigma}\right), \\
& \binom{\mathbf{y}_{21}}{\mathbf{x}_{21}},\binom{\mathbf{y}_{22}}{\mathbf{x}_{22}}, \ldots,\binom{\mathbf{y}_{2 n_{2}}}{\mathbf{x}_{2 n_{2}}} \quad \text { are from } N_{p+q}\left(\boldsymbol{\mu}_{2}, \boldsymbol{\Sigma}\right),
\end{aligned}
\]
where
\[
\begin{aligned}
& \boldsymbol{\mu}_{1}=E\binom{\mathbf{y}_{1 i}}{\mathbf{x}_{1 i}}=\binom{\boldsymbol{\mu}_{1 y}}{\boldsymbol{\mu}_{1 x}}, \quad \boldsymbol{\mu}_{2}=E\binom{\mathbf{y}_{2 i}}{\mathbf{x}_{2 i}}=\binom{\boldsymbol{\mu}_{2 y}}{\boldsymbol{\mu}_{2 x}}, \\
& \boldsymbol{\Sigma}=\operatorname{cov}\binom{\mathbf{y}_{1 i}}{\mathbf{x}_{1 i}}=\operatorname{cov}\binom{\mathbf{y}_{2 i}}{\mathbf{x}_{2 i}}=\left(\begin{array}{ll}
\boldsymbol{\Sigma}_{y y} & \boldsymbol{\Sigma}_{y x} \\
\boldsymbol{\Sigma}_{x y} & \boldsymbol{\Sigma}_{x x}
\end{array}\right) .
\end{aligned}
\]

We partition the sample mean vectors and covariance matrix accordingly:
\[
\binom{\overline{\mathbf{y}}_{1}}{\overline{\mathbf{x}}_{1}},\binom{\overline{\mathbf{y}}_{2}}{\overline{\mathbf{x}}_{2}}, \quad \mathbf{S}_{\mathrm{pl}}=\left(\begin{array}{cc}
\mathbf{S}_{y y} & \mathbf{S}_{y x} \\
\mathbf{S}_{x y} & \mathbf{S}_{x x}
\end{array}\right)
\]
where \(\mathbf{S}_{\mathrm{pl}}\) is the pooled sample covariance matrix from the two samples.
We wish to test the hypothesis that \(\mathbf{x}_{1}\) and \(\mathbf{x}_{2}\) are redundant for separating the two groups, that is, that the extra \(q\) variables do not contribute anything significant beyond the information already available in \(\mathbf{y}_{1}\) and \(\mathbf{y}_{2}\) for separating the groups. This is in the spirit of a full and reduced model test in regression [see (5.31) and Section 10.2.5b]. However, here we are working with a subset of dependent variables as contrasted to the subset of independent variables in the regression setting. Thus
both \(\mathbf{y}\) and x are subvectors of dependent variables. In this setting, the independent variables would be grouping variables 1 and 2 corresponding to \(\mu_{1}\) and \(\mu_{2}\).

We are not asking whether the \(x\) 's can significantly separate the two groups by themselves, but whether they provide additional separation beyond the separation already achieved by the \(y\) 's. If the \(x\) 's were independent of the \(y\) 's, we would have \(T_{p+q}^{2}=T_{p}^{2}+T_{q}^{2}\), but this does not hold, because they are correlated. We must compare \(T_{p+q}^{2}\) for the full set of variables ( \(y_{1}, \ldots, y_{p}, x_{1}, \ldots, x_{q}\) ) with \(T_{p}^{2}\) based on the reduced set \(\left(y_{1}, \ldots, y_{p}\right)\). We are inquiring whether the increase from \({ }_{p}^{2}\) to \(T_{p+q}^{2}\) is significant.

By definition, the \(T^{2}\)-statistic based on the full set of \(p+q\) variables is given by
\[
\begin{equation*}
T_{p+q}^{2}=\frac{n_{1} n_{2}}{n_{1}+n_{2}}\left[\binom{\overline{\mathbf{y}}_{1}}{\overline{\mathbf{x}}_{1}}-\binom{\overline{\mathbf{y}}_{2}}{\overline{\mathbf{x}}_{2}}\right]^{\prime} \mathbf{S}_{\mathrm{pl}}^{-1}\left[\binom{\overline{\mathbf{y}}_{1}}{\overline{\mathbf{x}}_{1}}-\binom{\overline{\mathbf{y}}_{2}}{\overline{\mathbf{x}}_{2}}\right] \tag{5.27}
\end{equation*}
\]
whereas \(T^{2}\) for the reduced set of \(p\) variables is
\[
\begin{equation*}
T_{p}^{2}=\frac{n_{1} n_{2}}{n_{1}+n_{2}}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)^{\prime} \mathbf{S}_{y y}^{-1}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right) \tag{5.28}
\end{equation*}
\]

Then the test statistic for the significance of the increase from \(T_{p}^{2}\) to \(T_{p+q}^{2}\) is given by
\[
\begin{equation*}
T^{2}(\mathbf{x} \mid \mathbf{y})=(\nu-p) \frac{T_{p+q}^{2}-T_{p}^{2}}{\nu+T_{p}^{2}} \tag{5.29}
\end{equation*}
\]
which is distributed as \(T_{q, \nu-p}^{2}\). We reject the hypothesis of redundancy of \(\mathbf{x}\) if \(T^{2}(\mathbf{x} \mid \mathbf{y}) \geq T_{\alpha, q, \nu-p}^{2}\).

By (5.7), \(T^{2}(\mathbf{x} \mid \mathrm{y})\) can be converted to an \(F\)-statistic:
\[
\begin{equation*}
F=\frac{\nu-p-q+1}{q} \frac{T_{p+q}^{2}-T_{p}^{2}}{\nu+T_{p}^{2}} \tag{5.30}
\end{equation*}
\]
which is distributed as \(F_{q, \nu-p-q+1}\), and we reject the hypothesis of redundancy if \(F \geq F_{\alpha, q, \nu-p-q+1}\).

In both cases \(\nu=n_{1}+n_{2}-2\). Note that the first degrees-of-freedom parameter in both (5.29) and (5.30) is \(q\), the number of \(x\) 's. The second parameter in (5.29) is \(\nu-p\) because the statistic is adjusted for the \(p\) variables in \(\mathbf{y}\).

To prove directly that the statistic defined in (5.30) has an \(F\)-distribution, we can use a basic relationship from multiple regression [see (10.33)]:
\[
\begin{equation*}
F_{q, \nu-p-q+1}=\frac{\left(R_{p+q}^{2}-R_{p}^{2}\right)(\nu-p-q+1)}{\left(1-R_{p+q}^{2}\right) q} \tag{5.31}
\end{equation*}
\]
where \(R_{p+q}^{2}\) is the squared multiple correlation from the full model with \(p+q\) independent variables and \(R_{p}^{2}\) is from the reduced model with \(p\) independent variables. If we solve for \(R^{2}\) in terms of \(T^{2}\) from (5.20) and substitute this into (5.31), we readily obtain the test statistic in (5.30).

If we are interested in the effect of adding a single \(x\), then \(q=1\), and both (5.29) and (5.30) reduce to
\[
\begin{equation*}
t^{2}(x \mid \mathbf{y})=(\nu-p) \frac{T_{p+1}^{2}-T_{p}^{2}}{\nu+T_{p}^{2}} \tag{5.32}
\end{equation*}
\]
and we reject the hypothesis of redundancy of \(x\) if \(t^{2}(x \mid \mathbf{y}) \geq t_{\alpha / 2, \nu-p}^{2}=F_{\alpha, 1, \nu-p}\).

\section*{■ EXAMPLE 5.8}

We use the psychological data of Table 5.1 to illustrate tests on subvectors. We begin by testing the significance of \(y_{3}\) and \(y_{4}\) above and beyond \(y_{1}\) and \(y_{2}\). (In the notation of the present section, \(y_{3}\) and \(y_{4}\) become \(x_{1}\) and \(x_{2}\).) For these subvectors, \(p=2\) and \(q=2\). The value of \(T_{p+q}^{2}\) for all four variables as given by (5.27) was obtained in Example 5.4.2 as 97.6015 . For \(y_{1}\) and \(y_{2}\), we obtain, by (5.28),
\[
\begin{aligned}
T_{p}^{2} & =\frac{n_{1} n_{2}}{n_{1}+n_{2}}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)^{\prime} \mathbf{S}_{y y}^{-1}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right) \\
& =\frac{(32)^{2}}{32+32}\binom{15.97-12.34}{15.91-13.91}^{\prime}\left(\begin{array}{rr}
7.16 & 6.05 \\
6.05 & 15.89
\end{array}\right)^{-1}\binom{15.97-12.34}{15.91-13.91} \\
& =31.0126 .
\end{aligned}
\]

By (5.29), the test statistic is
\[
\begin{aligned}
T^{2}\left(y_{3}, y_{4} \mid y_{1}, y_{2}\right) & =(\nu-p) \frac{T_{p+q}^{2}-T_{p}^{2}}{\nu+T_{p}^{2}} \\
& =(62-2) \frac{97.6015-31.0126}{62+31.0126}=42.955 .
\end{aligned}
\]

We reject the hypothesis that \(\mathbf{x}=\left(y_{3}, y_{4}\right)^{\prime}\) is redundant, since \(42.955>\) \(T_{.01,2,60}^{2}=10.137\). We conclude that \(\mathbf{x}=\left(y_{3}, y_{4}\right)^{\prime}\) adds a significant amount of separation to \(\mathbf{y}=\left(y_{1}, y_{2}\right)^{\prime}\).

To test the effect of each variable adjusted for the other three, we use (5.32). In this case, \(p=3, \nu=62\), and \(\nu-p=59\). The results are given below, where \(T_{p+1}^{2}=97.6015\) and \(T_{p}^{2}\) in each case is based on the three variables, excluding the variable in question. For example, \(T_{p}^{2}=90.8348\) for \(y_{2}\) is based on \(y_{1}, y_{3}\), and \(y_{4}\), and \(t^{2}\left(y_{2} \mid y_{1}, y_{2}, y_{3}\right)=2.612\) :
\begin{tabular}{ccr} 
Variable & \(T_{p}^{2}\) & \((\nu-p) \frac{T_{p+1}^{2}-T_{p}^{2}}{\nu+T_{p}^{2}}\) \\
\hline\(y_{1}\) & 78.8733 & 7.844 \\
\(y_{2}\) & 90.8348 & 2.612 \\
\(y_{3}\) & 32.6253 & 40.513 \\
\(y_{4}\) & 74.5926 & 9.938
\end{tabular}

When we compare these four test statistic values with the critical value \(t_{.025,59}^{2}\) \(=4.002\), we see that each variable makes a significant contribution to \(T^{2}\) except \(y_{2}\). Note that \(y_{3}\) contributes most, followed by \(y_{4}\) and then \(y_{1}\). This order
differs from that given by the raw discriminant function in Example 5.5 but agrees with the order for the standardized discriminant function given in the answer to Problem 8.7 in Appendix B.

\subsection*{5.9 PROFILE ANALYSIS}

If \(\mathbf{y}\) is \(N_{p}(\boldsymbol{\mu}, \mathbf{\Sigma})\) and the variables in \(\mathbf{y}\) are commensurate (measured in the same units and with approximately equal variances as, for example, in the probe word data in Table 3.6), we may wish to compare the means \(\mu_{1}, \mu_{2}, \ldots, \mu_{p}\) in \(\mu\). This might be of interest when a measurement is taken on the same research unit at \(p\) successive times. Such situations are often referred to as repeated measures designs or growth curves, which are discussed in some generality in Sections 6.9 and 6.10. In the present section, we discuss one- and two-sample profile analysis. Profile analysis for several samples is covered in Section 6.8.

The pattern obtained by plotting \(\mu_{1}, \mu_{2}, \ldots, \mu_{p}\) as ordinates and connecting the points is called a profile; we usually draw straight lines connecting the points \(\left(1, \mu_{1}\right)\), \(\left(2, \mu_{2}\right), \ldots,\left(p, \mu_{p}\right)\). Profile analysis is an analysis of the profile or a comparison of two or more profiles. Profile analysis is often discussed in the context of administering a battery of \(p\) psychological or other tests.

In growth curve analysis where the variables are measured at time intervals, the responses have a natural order. In profile analysis where the variables arise from test scores, there is ordinarily no natural order. A distinction is not always made between repeated measures of the same variable through time and profile analysis of several different commensurate variables on the same individual.

\subsection*{5.9.1 One-Sample Profile Analysis}

We begin with a discussion of the profile of the mean vector \(\boldsymbol{\mu}\) from a single sample. A plot of \(\boldsymbol{\mu}\) might appear as in Figure 5.3, where we plot \(\left(1, \mu_{1}\right),\left(2, \mu_{2}\right), \ldots,\left(p, \mu_{p}\right)\) and connect the points.

In order to compare the means \(\mu_{1}, \mu_{2}, \ldots, \mu_{p}\) in \(\boldsymbol{\mu}\), the basic hypothesis is that the profile is level or flat:
\[
H_{0}: \mu_{1}=\mu_{2}=\cdots=\mu_{p} \quad \text { vs. } \quad H_{1}: \mu_{j} \neq \mu_{k} \quad \text { for some } j \neq k .
\]

The data matrix \(\mathbf{Y}\) is given in (3.17). We cannot use univariate analysis of variance to test \(H_{0}\) because the columns in \(\mathbf{Y}\) are not independent. For a multivariate approach that allows for correlated variables, we first express \(H_{0}\) as \(p-1\) comparisons,
\[
H_{0}:\left(\begin{array}{c}
\mu_{1}-\mu_{2} \\
\mu_{2}-\mu_{3} \\
\vdots \\
\mu_{p-1}-\mu_{p}
\end{array}\right)=\left(\begin{array}{c}
0 \\
0 \\
\vdots \\
0
\end{array}\right)
\]

Figure 5.3 Profile of a mean vector.
or as
\[
H_{0}:\left(\begin{array}{c}
\mu_{1}-\mu_{2} \\
\mu_{1}-\mu_{3} \\
\vdots \\
\mu_{1}-\mu_{p}
\end{array}\right)=\left(\begin{array}{c}
0 \\
0 \\
\vdots \\
0
\end{array}\right)
\]

These two expressions can be written in the form \(H_{0}: \mathbf{C}_{1} \boldsymbol{\mu}=\mathbf{0}\) and \(H_{0}: \mathbf{C}_{2} \boldsymbol{\mu}=\mathbf{0}\), where \(\mathbf{C}_{1}\) and \(\mathbf{C}_{2}\) are the \((p-1) \times p\) matrices:
\[
\mathbf{C}_{1}=\left(\begin{array}{rrrrr}
1 & -1 & 0 & \cdots & 0 \\
0 & 1 & -1 & \cdots & 0 \\
\vdots & \vdots & \vdots & & \vdots \\
0 & 0 & 0 & \cdots & -1
\end{array}\right), \quad \mathbf{C}_{2}=\left(\begin{array}{rrrrr}
1 & -1 & 0 & \cdots & 0 \\
1 & 0 & -1 & \cdots & 0 \\
\vdots & \vdots & \vdots & & \vdots \\
1 & 0 & 0 & \cdots & -1
\end{array}\right)
\]

In fact, any \((p-1) \times p\) matrix \(\mathbf{C}\) of rank \(p-1\) such that \(\mathbf{C j}=\mathbf{0}\) can be used in \(H_{0}: \mathbf{C} \boldsymbol{\mu}=\mathbf{0}\) to produce \(H_{0}: \mu_{1}=\mu_{2}=\cdots=\mu_{p}\). If \(\mathbf{C j}=\mathbf{0}\), each row \(\mathbf{c}_{i}^{\prime}\) of \(\mathbf{C}\) sums to zero by (2.38), and \(\mathbf{C} \boldsymbol{\mu}\) is a set of \(p-1\) contrasts in the \(\mu\) 's. A linear combination \(\mathbf{c}_{i}^{\prime} \boldsymbol{\mu}=c_{i 1} \mu_{1}+c_{i 2} \mu_{2}+\cdots+c_{i p} \mu_{p}\) is called a contrast in the \(\mu\) 's if the coefficients sum to zero, that is, if \(\sum_{j} c_{i j}=0\). The contrasts in \(\mathbf{C} \mu\) must be linearly independent in order to express \(H_{0}: \mu_{1}=\mu_{2}=\cdots=\mu_{p}\) as \(H_{0}: \mathbf{C} \boldsymbol{\mu}=\mathbf{0}\). Thus \(\operatorname{rank}(\mathbf{C})=p-1\).

From a sample \(\mathbf{y}_{1}, \mathbf{y}_{2}, \ldots, \mathbf{y}_{n}\), we obtain estimates \(\overline{\mathbf{y}}\) and \(\mathbf{S}\) of population parameters \(\boldsymbol{\mu}\) and \(\boldsymbol{\Sigma}\). To test \(H_{0}: \mathbf{C} \boldsymbol{\mu}=\mathbf{0}\), we transform each \(\mathbf{y}_{i}, i=1,2, \ldots, n\), to \(\mathbf{z}_{i}=\mathbf{C} \mathbf{y}_{i}\), which is \((p-1) \times 1\). By (3.62) and (3.64), the sample mean vector

(a) Hypothesis is true

(b) Hypothesis is false
\[
\left(\mu_{14}-\mu_{13} \neq \mu_{24}-\mu_{23}\right)
\]

Figure 5.4 Comparison of two profiles under the hypothesis of parallelism.
and covariance matrix of \(\mathbf{z}_{i}=\mathbf{C y} y_{i}, i=1,2, \ldots, n\), are \(\overline{\mathbf{z}}=\mathbf{C y}\) and \(\mathbf{S}_{z}=\mathbf{C S C}^{\prime}\), respectively. If \(\mathbf{y}\) is \(N_{p}(\boldsymbol{\mu}, \boldsymbol{\Sigma})\), then by property \(\mathbf{l b}\) in Section \(4.2, \mathbf{z}=\mathbf{C y}\) is \(N_{p-1}\left(\mathbf{C} \boldsymbol{\mu}, \mathbf{C} \boldsymbol{\Sigma} \mathbf{C}^{\prime}\right)\). Thus when \(H_{0}: \mathbf{C} \boldsymbol{\mu}=\mathbf{0}\) is true, \(\mathbf{C} \overline{\mathbf{y}}\) is \(N_{p-1}\left(\mathbf{0}, \mathbf{C} \boldsymbol{\Sigma} \mathbf{C}^{\prime} / n\right)\), and
\[
\begin{equation*}
T^{2}=(\mathbf{C} \overline{\mathbf{y}})^{\prime}\left(\mathbf{C S C}^{\prime} / n\right)^{-1}(\mathbf{C} \overline{\mathbf{y}})=n(\mathbf{C} \overline{\mathbf{y}})^{\prime}\left(\mathbf{C S C}^{\prime}\right)^{-1}(\mathbf{C} \overline{\mathbf{y}}) \tag{5.33}
\end{equation*}
\]
is distributed as \(T_{p-1, n-1}^{2}\). We reject \(H_{0}: \mathbf{C} \boldsymbol{\mu}=\mathbf{0}\) if \(T^{2} \geq T_{\alpha, p-1, n-1}^{2}\). The dimension \(p-1\) corresponds to the number of rows of \(\mathbf{C}\). Thus \(\overline{\mathbf{z}}=\mathbf{C} \overline{\mathbf{y}}\) is \((p-1) \times 1\) and \(\mathbf{S}_{z}=\mathbf{C S C}\) ' is \((p-1) \times(p-1)\). Note that the C's in (5.33) don't "cancel" because \(\mathbf{C}\) is \((p-1) \times p\) and does not have an inverse. In fact, \(T^{2}\) in (5.33) is less than \(T^{2}=n \overline{\mathbf{y}}^{\prime} \mathbf{S}^{-1} \overline{\mathbf{y}}\) [see Rencher (1998, p. 84)].

If the variables have a natural ordering, as, for example, in the ramus bone data in Table 3.7, we could test for a linear trend or polynomial curve in the means by suitably choosing the rows of \(\mathbf{C}\). This is discussed in connection with growth curves in Section 6.10. Otherwise, any comparisons of interest can be made as long as they are linearly independent.

\subsection*{5.9.2 Two-Sample Profile Analysis}

Suppose two independent groups or samples receive the same set of \(p\) tests or measurements. If these tests are comparable, for example, all on a scale of 0 to 100 , the variables will often be commensurate.

Rather than testing the hypothesis that \(\mu_{1}=\mu_{2}\), we wish to be more specific in comparing the profiles obtained by connecting the points \(\left(j, \mu_{1 j}\right), j=1,2, \ldots, p\), and \(\left(j, \mu_{2 j}\right), j=1,2, \ldots, p\). There are three hypotheses of interest in comparing the profiles of two samples. The first of these hypotheses addresses the question "Are the two profiles similar in appearance, or more precisely, are they parallel?" We illustrate this hypothesis in Figure 5.4. If the two profiles are parallel, then one group scored uniformly better than the other group on all \(p\) tests.

The parallelism hypothesis can be defined in terms of the slopes. The two profiles are parallel if the two slopes for each segment are the same. If the two profiles are parallel, the two increments for each segment are the same, and it is not necessary to use the actual slopes to express the hypothesis. We can simply compare the increase from one point to the next. The hypothesis can thus be expressed as \(H_{01}: \mu_{1 j}-\) \(\mu_{1, j-1}=\mu_{2 j}-\mu_{2, j-1}\) for \(j=2,3, \ldots, p\), or
\[
H_{01}:\left(\begin{array}{c}
\mu_{12}-\mu_{11} \\
\mu_{13}-\mu_{12} \\
\vdots \\
\mu_{1 p}-\mu_{1, p-1}
\end{array}\right)=\left(\begin{array}{c}
\mu_{22}-\mu_{21} \\
\mu_{23}-\mu_{22} \\
\vdots \\
\mu_{2 p}-\mu_{2, p-1}
\end{array}\right)
\]
which can be written as \(H_{01}: \mathbf{C} \boldsymbol{\mu}_{1}=\mathbf{C} \boldsymbol{\mu}_{2}\), using the contrast matrix
\[
\mathbf{C}=\left(\begin{array}{rrrrr}
-1 & 1 & 0 & \cdots & 0 \\
0 & -1 & 1 & \cdots & 0 \\
\vdots & \vdots & \vdots & & \vdots \\
0 & 0 & 0 & \cdots & 1
\end{array}\right)
\]

From two samples, \(\mathbf{y}_{11}, \mathbf{y}_{12}, \ldots, \mathbf{y}_{1 n_{1}}\) and \(\mathbf{y}_{21}, \mathbf{y}_{22}, \ldots, \mathbf{y}_{2 n_{2}}\), we obtain \(\overline{\mathbf{y}}_{1}, \overline{\mathbf{y}}_{2}\), and \(\mathbf{S}_{\mathrm{pl}}\) as estimates of \(\boldsymbol{\mu}_{1}, \boldsymbol{\mu}_{2}\), and \(\boldsymbol{\Sigma}\). As in the two-sample \(T^{2}\)-test, we assume that each \(\mathbf{y}_{1 i}\) in the first sample is \(N_{p}\left(\mu_{1}, \mathbf{\Sigma}\right)\), and each \(\mathbf{y}_{2 i}\) in the second sample is \(N_{p}\left(\boldsymbol{\mu}_{2}, \boldsymbol{\Sigma}\right)\). If \(\mathbf{C}\) is a \((p-1) \times p\) contrast matrix as before, then \(\mathbf{C y} \mathbf{y}_{1 i}\) and \(\mathbf{C y} \mathbf{y}_{2 i}\) are distributed as \(N_{p-1}\left(\mathbf{C} \boldsymbol{\mu}_{1}, \mathbf{C} \boldsymbol{\Sigma} \mathbf{C}^{\prime}\right)\) and \(N_{p-1}\left(\mathbf{C} \boldsymbol{\mu}_{2}, \mathbf{C} \boldsymbol{\Sigma} \mathbf{C}^{\prime}\right)\), respectively. Under \(H_{01}: \mathbf{C} \boldsymbol{\mu}_{1}-\mathbf{C} \boldsymbol{\mu}_{2}=\mathbf{0}\), the random vector \(\mathbf{C} \overline{\mathbf{y}}_{1}-\mathbf{C} \overline{\mathbf{y}}_{2}\) is \(N_{p-1}\left[\mathbf{0}, \mathbf{C} \mathbf{\Sigma} \mathbf{C}^{\prime}\left(1 / n_{1}+\right.\right.\) \(\left.1 / n_{2}\right)\) ] and
\[
\begin{align*}
T^{2} & =\left(\mathbf{C} \overline{\mathbf{y}}_{1}-\mathbf{C} \overline{\mathbf{y}}_{2}\right)^{\prime}\left[\left(\frac{1}{n_{1}}+\frac{1}{n_{2}}\right) \mathbf{C S}_{\mathrm{pl}} \mathbf{C}^{\prime}\right]^{-1}\left(\mathbf{C} \overline{\mathbf{y}}_{1}-\mathbf{C} \overline{\mathbf{y}}_{2}\right) \\
& =\frac{n_{1} n_{2}}{n_{1}+n_{2}}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)^{\prime} \mathbf{C}^{\prime}\left[\mathbf{C S}_{\mathrm{pl}} \mathbf{C}^{\prime}\right]^{-1} \mathbf{C}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right) \tag{5.34}
\end{align*}
\]
is distributed as \(T_{p-1, n_{1}+n_{2}-2}^{2}\). Note that the dimension \(p-1\) is the number of rows of \(\mathbf{C}\).

By analogy with the discussion in Section 5.5, if \(H_{01}\) is rejected, we can follow up with univariate tests on the individual components of \(\mathbf{C}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)\). Or alternatively we can calculate the discriminant function
\[
\begin{equation*}
\mathbf{a}=\left(\mathbf{C S}_{\mathrm{p} 1} \mathbf{C}^{\prime}\right)^{-1} \mathbf{C}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right) \tag{5.35}
\end{equation*}
\]
as an indication of which slope differences contributed most to rejection of \(H_{01}\) in the presence of the other components of \(\mathbf{C}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)\). There should be less need in this case to standardize the components of a as suggested in Section 5.5, because the variables are assumed to be commensurate. The vector a is \((p-1) \times 1\), corresponding to the \(p-1\) segments of the profile. Thus if the second component of a, for example,

Table 5.4 Data Layout for Two-Sample Profile Analysis
\begin{tabular}{cccccc}
\hline \multicolumn{6}{c}{ Tests (variables) } \\
\hline & 1 & 2 & \(\cdots\) & \(p\) \\
\hline \multicolumn{6}{c}{ Group 1 } \\
\(\mathbf{y}_{11}^{\prime}\) & \(=\) & \(\left(y_{111}\right.\) & \(y_{112}\) & \(\cdots\) & \(\left.y_{11 p}\right)\) \\
\(\mathbf{y}_{12}^{\prime}\) & \(=\) & \(\left(y_{121}\right.\) & \(y_{122}\) & \(\cdots\) & \(\left.y_{12 p}\right)\) \\
\(\vdots\) & & \(\vdots\) & \(\vdots\) & & \(\vdots\) \\
\(\mathbf{y}_{1 n_{1}}^{\prime}\) & \(=\) & \(\left(y_{1 n_{11}}\right.\) & \(y_{1 n_{1} 2}\) & \(\cdots\) & \(\left.y_{1 n_{1 p} p}\right)\) \\
\hline \multicolumn{6}{c}{ Group 2 } \\
\(\mathbf{y}_{21}^{\prime}\) & \(=\) & \(\left(y_{211}\right.\) & \(y_{212}\) & \(\cdots\) & \(\left.y_{21 p}\right)\) \\
\(\mathbf{y}_{22}^{\prime}\) & \(=\) & \(\left(y_{221}\right.\) & \(y_{222}\) & \(\cdots\) & \(\left.y_{22 p}\right)\) \\
\(\vdots\) & & \(\vdots\) & \(\vdots\) & & \(\vdots\) \\
\(\mathbf{y}_{2 n_{2}}^{\prime}\) & \(=\) & \(\left(y_{2 n_{21}}\right.\) & \(y_{2 n_{2} 2}\) & \(\cdots\) & \(\left.y_{2 n_{2} p}\right)\) \\
\hline
\end{tabular}
is largest in absolute value, the divergence in slopes between the two profiles on the second segment contributes most to rejection of \(H_{01}\).

If the data are arranged as in Table 5.4, we see an analogy to a two-way ANOVA model. A plot of the means is often made in a two-way ANOVA; a lack of parallelism corresponds to interaction between the two factors. Thus the hypothesis \(H_{01}\) is analogous to the group by test (variable) interaction hypothesis.

However, the usual ANOVA assumption of independence of observations does not hold here because the variables (tests) are correlated. The ANOVA assumption of independence and homogeneity of variances would require \(\operatorname{cov}(\mathbf{y})=\boldsymbol{\Sigma}=\sigma^{2} \mathbf{I}\). Hence the test of \(H_{01}\) cannot be carried out using a univariate ANOVA approach, since \(\boldsymbol{\Sigma} \neq \sigma^{2} \mathbf{I}\). We therefore proceed with the multivariate approach using \(T^{2}\).

The second hypothesis of interest in comparing two profiles is "Are the two populations or groups at the same level?" This hypothesis corresponds to a group (population) main effect in the ANOVA analogy. We can express this hypothesis in terms of the average level of group 1 compared to the average level of group 2 :
\[
H_{02}: \frac{\mu_{11}+\mu_{12}+\cdots+\mu_{1 p}}{p}=\frac{\mu_{21}+\mu_{22}+\cdots+\mu_{2 p}}{p} .
\]

By (2.37), this can be expressed as
\[
H_{02}: \mathbf{j}^{\prime} \mu_{1}=\mathbf{j}^{\prime} \boldsymbol{\mu}_{2} .
\]

If \(H_{01}\) is true, \(H_{02}\) can be pictured as in Figure 5.5(a). If \(H_{02}\) is false, then the two profiles differ by a constant (given that \(H_{01}\) is true), as in Figure 5.5(b).

The hypothesis \(H_{02}\) can be true when \(H_{01}\) does not hold. Thus the average level of population 1 can equal the average level of population 2 without the two profiles being parallel, as illustrated in Figure 5.6. In this case, the "group main effect" is

Figure 5.5 Hypothesis \(H_{02}\) of equal group effect, assuming parallelism.

Figure 5.6 Hypothesis \(H_{02}\) of equal group effect without parallelism.
somewhat harder to interpret, as is the case in the analogous two-way ANOVA, where main effects are more difficult to describe in the presence of significant interaction. However, the test may still furnish useful information if a careful description of the results is provided.

To test \(H_{02}: \mathbf{j}^{\prime}\left(\boldsymbol{\mu}_{1}-\boldsymbol{\mu}_{2}\right)=0\), we estimate \(\mathbf{j}^{\prime}\left(\boldsymbol{\mu}_{1}-\boldsymbol{\mu}_{2}\right)\) by \(\mathbf{j}^{\prime}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)\), which is \(N\left[0, \mathbf{j}^{\prime} \boldsymbol{\Sigma} \mathbf{j}\left(1 / n_{1}+1 / n_{2}\right)\right]\) when \(H_{02}\) is true. We can therefore use
\[
\begin{equation*}
t=\frac{\mathbf{j}^{\prime}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)}{\sqrt{\mathbf{j}^{\prime} \mathbf{S}_{\mathrm{p} \mathbf{j}} \mathbf{j}\left(1 / n_{1}+1 / n_{2}\right)}} \tag{5.36}
\end{equation*}
\]

Figure 5.7 Hypothesis \(H_{03}\) of equal tests (variables) assuming parallelism.
and reject \(H_{02}\) if \(|t| \geq t_{\alpha / 2, n_{1}+n_{2}-2}\).
The third hypothesis of interest, corresponding to the test (or variable) main effect, is "Are the profiles flat?" Assuming parallelism (assuming \(H_{01}\) is true), the "flatness" hypothesis can be pictured as in Figure 5.7. If \(H_{01}\) is not true, the test could be carried out separately for each group using the test in Section 5.9.1. If \(H_{01}\) and \(H_{02}\) are true, the two profiles in Figure 5.7(a) and Figure 5.7(b) will be coincident.

To express the third hypothesis in a form suitable for testing, we note from Figure 5.7(a) that the average of the two group means is the same for each test:
\[
\begin{equation*}
H_{03}: \frac{1}{2}\left(\mu_{11}+\mu_{21}\right)=\frac{1}{2}\left(\mu_{12}+\mu_{22}\right)=\cdots=\frac{1}{2}\left(\mu_{1 p}+\mu_{2 p}\right) \tag{5.37}
\end{equation*}
\]
or
\[
\begin{equation*}
H_{03}: \frac{1}{2} \mathbf{C}\left(\boldsymbol{\mu}_{1}+\boldsymbol{\mu}_{2}\right)=\mathbf{0}, \tag{5.38}
\end{equation*}
\]
where \(\mathbf{C}\) is a \((p-1) \times p\) matrix such that \(\mathbf{C j}=\mathbf{0}\). From Figure 5.7(a), we see that if \(H_{01}\) is true, \(H_{03}\) could also be expressed as \(\mu_{11}=\mu_{12}=\cdots=\mu_{1 p}\) and \(\mu_{21}=\mu_{22}=\cdots=\mu_{2 p}\) or
\[
H_{03}: \mathbf{C} \boldsymbol{\mu}_{1}=\mathbf{0} \quad \text { and } \quad \mathbf{C} \mu_{2}=\mathbf{0} .
\]

To estimate \(\frac{1}{2}\left(\boldsymbol{\mu}_{1}+\boldsymbol{\mu}_{2}\right)\), we use the sample grand mean vector based on a weighted average:
\[
\overline{\mathbf{y}}=\frac{n_{1} \overline{\mathbf{y}}_{1}+n_{2} \overline{\mathbf{y}}_{2}}{n_{1}+n_{2}} .
\]

It can easily be shown that under \(H_{03}, E(\mathbf{C} \overline{\mathbf{y}})=\mathbf{0}\) and \(\operatorname{cov}(\overline{\mathbf{y}})=\boldsymbol{\Sigma} /\left(n_{1}+n_{2}\right)\). Therefore, \(\mathbf{C y}\) is \(N_{p-1}\left[\mathbf{0}, \mathbf{C} \boldsymbol{\Sigma} \mathbf{C}^{\prime} /\left(n_{1}+n_{2}\right)\right]\), and
\[
\begin{align*}
T^{2} & =(\mathbf{C} \overline{\mathbf{y}})^{\prime}\left(\frac{\mathbf{C S}_{\mathrm{p} 1} \mathbf{C}^{\prime}}{n_{1}+n_{2}}\right)^{-1}(\mathbf{C} \overline{\mathbf{y}}) \\
& =\left(n_{1}+n_{2}\right)(\mathbf{C} \overline{\mathbf{y}})^{\prime}\left(\mathbf{C S}_{\mathrm{p} 1} \mathbf{C}^{\prime}\right)^{-1} \mathbf{C} \overline{\mathbf{y}} \tag{5.39}
\end{align*}
\]
is distributed as \(T_{p-1, n_{1}+n_{2}-2}^{2}\) when \(H_{03}\) is true. It can be readily shown that \(H_{03}\) is unaffected by a difference in the profile levels (unaffected by the status of \(H_{02}\) ).

Figure 5.8 Profiles for the psychological data in Table 5.1.

\section*{EXAMPLE 5.9.2}

We use the psychological data in Table 5.1 to illustrate two-sample profile analysis. The values of \(\overline{\mathbf{y}}_{1}, \overline{\mathbf{y}}_{2}\), and \(\mathbf{S}_{\mathrm{pl}}\) are given in Example 5.4.2. The profiles of the two mean vectors \(\overline{\mathbf{y}}_{1}\) and \(\overline{\mathbf{y}}_{2}\) are plotted in Figure 5.8. There appears to be a lack of parallelism.

To test for parallelism, \(H_{01}: \mathbf{C} \boldsymbol{\mu}_{1}=\mathbf{C} \boldsymbol{\mu}_{2}\), we use the matrix
\[
\mathbf{C}=\left(\begin{array}{rrrr}
-1 & 1 & 0 & 0 \\
0 & -1 & 1 & 0 \\
0 & 0 & -1 & 1
\end{array}\right)
\]
and obtain
\(\mathbf{C}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)=\left(\begin{array}{r}-1.62 \\ 8.53 \\ -9.72\end{array}\right), \quad \mathbf{C S}_{\mathrm{pl}} \mathbf{C}^{\prime}=\left(\begin{array}{rrr}10.96 & -7.05 & -1.64 \\ -7.05 & 27.26 & -12.74 \\ -1.64 & -12.74 & 23.72\end{array}\right)\).
Then, by (5.34),
\[
T^{2}=\frac{(32)(32)}{32+32}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)^{\prime} \mathbf{C}^{\prime}\left(\mathbf{C S}_{\mathrm{pl}} \mathbf{C}^{\prime}\right)^{-1} \mathbf{C}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)=74.240
\]

Upon comparison of this value with \(T_{.01,3,62}^{2}=12.796\) (obtained by interpolation in Table A.7), we reject the hypothesis of parallelism.

In Figure 5.8 the lack of parallelism is most notable in the second and third segments. This can also be seen in the relatively large values of the second and
third components of
\[
\mathbf{C}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)=\left(\begin{array}{r}
-1.62 \\
8.53 \\
-9.72
\end{array}\right)
\]

To see which of these made the greatest statistical contribution, we can examine the discriminant function coefficient vector given in (5.35) as
\[
\mathbf{a}=\left(\mathbf{C S}_{\mathrm{p}} \mathbf{C}^{\prime}\right)^{-1} \mathbf{C}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)=\left(\begin{array}{r}
-.136 \\
.104 \\
-.363
\end{array}\right)
\]

Thus the third segment contributed most to rejection in the presence of the other two segments.

To test for equal levels, \(H_{02}: \mathbf{j}^{\prime} \boldsymbol{\mu}_{1}=\mathbf{j}^{\prime} \boldsymbol{\mu}_{2}\), we use (5.36),
\[
\begin{aligned}
t & =\frac{\mathbf{j}^{\prime}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)}{\sqrt{\mathbf{j}^{\prime} \mathbf{S}_{\mathrm{p} \mathbf{j}} \mathbf{j}\left(1 / n_{1}+1 / n_{2}\right)}} \\
& =\frac{16.969}{\sqrt{(164.276)(1 / 32+1 / 32)}}=5.2957
\end{aligned}
\]

Comparing this with \(t_{.005,62}=2.658\), we reject the hypothesis of equal levels.
To test the flatness hypothesis, \(H_{03}: \frac{1}{2} \mathbf{C}\left(\boldsymbol{\mu}_{1}+\boldsymbol{\mu}_{2}\right)=\mathbf{0}\), we first calculate
\[
\overline{\mathbf{y}}=\frac{32 \overline{\mathbf{y}}_{1}+32 \overline{\mathbf{y}}_{2}}{32+32}=\frac{\overline{\mathbf{y}}_{1}+\overline{\mathbf{y}}_{2}}{2}=\left(\begin{array}{l}
14.16 \\
14.91 \\
21.92 \\
22.34
\end{array}\right)
\]

Using
\[
\mathbf{C}=\left(\begin{array}{rrrr}
1 & -1 & 0 & 0 \\
0 & 1 & -1 & 0 \\
0 & 0 & 1 & -1
\end{array}\right)
\]
we obtain, by (5.39),
\[
T^{2}=(32+32)(\mathbf{C} \overline{\mathbf{y}})^{\prime}\left(\mathbf{C S}_{\mathrm{pl}} \mathbf{C}^{\prime}\right)^{-1} \mathbf{C} \overline{\mathbf{y}}=254.004
\]
which exceeds \(T_{.01,3,62}^{2}=12.796\), so we reject the hypothesis of flatness. However, since the parallelism hypothesis was rejected, a more appropriate approach would be to test each of the two groups separately for flatness using the test of Section 5.9.1. By (5.33), we obtain
\[
\begin{aligned}
& T^{2}=n_{1}\left(\mathbf{C} \overline{\mathbf{y}}_{1}\right)^{\prime}\left(\mathbf{C S}_{1} \mathbf{C}^{\prime}\right)^{-1}\left(\mathbf{C} \overline{\mathbf{y}}_{1}\right)=221.126 \\
& T^{2}=n_{2}\left(\mathbf{C} \overline{\mathbf{y}}_{2}\right)^{\prime}\left(\mathbf{C S}_{2} \mathbf{C}^{\prime}\right)^{-1}\left(\mathbf{C} \overline{\mathbf{y}}_{2}\right)=103.483
\end{aligned}
\]

Both of these exceed \(T_{.01,3.31}^{2}=14.626\), and we have significant lack of flatness.

\section*{PROBLEMS}
5.1 Show that the characteristic form of \(T^{2}\) in (5.6) is the same as the original form in (5.5).
5.2 Show that the \(T^{2}\)-statistic in (5.9) can be expressed in the characteristic form given in (5.10).
5.3 Show that \(t^{2}(\mathbf{a})=T^{2}\), where \(t(\mathbf{a})\) is given by (5.13), \(T^{2}\) is given by (5.9), and \(\mathbf{a}=\mathbf{S}_{\mathrm{pl}}^{-1}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)\) as in (5.14).
5.4 Show that the paired observation \(t\)-test in (5.22), \(t=\bar{d} /\left(s_{d} / \sqrt{n}\right)\), has the \(t_{n-1}\) distribution.
5.5 Show that \(s_{d}^{2}=\sum_{i=1}^{n}\left(d_{i}-\bar{d}\right)^{2} /(n-1)=s_{y}^{2}+s_{x}^{2}-2 s_{y x}\), as in a comparison of (5.22) and (5.23).
5.6 Show that \(T^{2}=n \overline{\mathbf{d}}^{\prime} \mathbf{S}_{d}^{-1} \overline{\mathbf{d}}\) in (5.24) has the characteristic form given by \(T^{2}=\) \(\overline{\mathbf{d}}^{\prime}\left(\mathbf{S}_{d} / n\right)^{-1} \overline{\mathbf{d}}\).
5.7 Use (5.7) to show that \(T^{2}(\mathbf{x} \mid \mathrm{y})\) in (5.29) can be converted to \(F\) as in (5.30).
5.8 Show that the test statistic in (5.30) for additional information in \(\mathbf{x}\) above and beyond \(\mathbf{y}\) has an \(F\)-distribution by solving for \(R^{2}\) in terms of \(T^{2}\) from (5.20) and substituting this into (5.31).
5.9 In Section 5.9.2, show that under \(H_{03}\) and \(H_{01}, E(\mathbf{C} \overline{\mathbf{y}})=\mathbf{0}\) and \(\operatorname{cov}(\overline{\mathbf{y}})=\) \(\boldsymbol{\Sigma} /\left(n_{1}+n_{2}\right)\), where \(\overline{\mathbf{y}}=\left(n_{1} \overline{\mathbf{y}}_{1}+n_{2} \overline{\mathbf{y}}_{2}\right) /\left(n_{1}+n_{2}\right)\) and \(\boldsymbol{\Sigma}\) is the common covariance matrix of the two populations from which \(\overline{\mathbf{y}}_{1}\) and \(\overline{\mathbf{y}}_{2}\) are sampled.
5.10 Verify that \(T^{2}=\left(n_{1}+n_{2}\right)(\mathbf{C y})^{\prime}\left(\mathbf{C S}_{\mathrm{pl}} \mathbf{C}^{\prime}\right)^{-1} \mathbf{C} \overline{\mathbf{y}}\) in (5.39) is distributed as \(T_{p-1, n_{1}+n_{2}-2}^{2}\).
5.11 Test \(H_{0}: \boldsymbol{\mu}^{\prime}=(6,11)\) using the data
\[
\mathbf{Y}=\left(\begin{array}{rr}
3 & 10 \\
6 & 12 \\
5 & 14 \\
10 & 9
\end{array}\right)
\]
5.12 Use the probe word data in Table 3.6:
(a) Test \(H_{0}: \boldsymbol{\mu}=(30,25,40,25,30)^{\prime}\).
(b) If \(H_{0}\) is rejected, test each variable separately, using (5.3).
5.13 For the probe word data in Table 3.6, test \(H_{0}: \mu_{1}=\mu_{2}=\cdots=\mu_{5}\), using \(T^{2}\) in (5.33).
5.14 Use the ramus bone data in Table 3.7:

\hline
\end{tabular}
(a) Test \(H_{0}: \boldsymbol{\mu}=(48,49,50,51)^{\prime}\).
(b) If \(H_{0}\) is rejected, test each variable separately, using (5.3).
5.15 For the ramus bone data in Table 3.7, test \(H_{0}: \mu_{1}=\mu_{2}=\mu_{3}=\mu_{4}\), using \(T^{2}\) in (5.33).
5.16 Four measurements were made on two species of flea beetles (Lubischew 1962). The variables were
\(y_{1}=\) distance of transverse groove from posterior border of prothorax ( \(\mu \mathrm{m}\) )
\(y_{2}=\) length of elytra (in 0.01 mm )
\(y_{3}=\) length of second antennal joint \((\mu \mathbf{m})\)
\(y_{4}=\) length of third antennal joint ( \(\mu \mathrm{m}\) )
The data are given in Table 5.5.
(a) Test \(H_{0}: \mu_{1}=\boldsymbol{\mu}_{2}\) using \(T^{2}\).

\hline 141 & 42 & 80 & 195 & 36 & 241 & 153 & 27 & 89 & 283 & 66 & 291 \\
\hline 135 & 49 & 73 & 152 & 42 & 249 & 136 & 31 & 83 & 257 & 31 & 311 \\
\hline 151 & 37 & 76 & 223 & 74 & 268 & 97 & 36 & 100 & 252 & 30 & 225 \\
\hline 97 & 46 & 83 & 164 & 31 & 243 & 141 & 37 & 105 & 250 & 27 & 243 \\
\hline 109 & 42 & 82 & 188 & 57 & 267 & 164 & 32 & 76 & 187 & 30 & 264 \\
\hline
\end{tabular}
(b) If the \(T^{2}\)-test in part (a) rejects \(H_{0}\), carry out a \(t\)-test on each variable, as in \((5,15)\).
(c) Calculate the discriminant function coefficient vector \(\mathbf{a}=\mathrm{S}_{\mathrm{pl}}^{-1}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)\).
(d) Show that if the vector a found in part (c) is substituted into \(t^{2}\) (a) from (5.13), the result is the same as the value of \(T^{2}\) found in part (a).
(e) Obtain \(T^{2}\) using the regression approach in Section 5.6.2.
(f) Test the significance of each variable adjusted for the other three.
(g) Test the significance of \(y_{3}\) and \(y_{4}\) adjusted for \(y_{1}\) and \(y_{2}\).
5.17 Carry out a profile analysis on the beetle data in Table 5.5.
5.18 Twenty engineer apprentices and 20 pilots were given six tests (Travers 1939). The variables were
\[
\begin{array}{ll}
y_{1}=\text { intelligence } & y_{4}=\text { dotting } \\
y_{2}=\text { form relations } & y_{5}=\text { sensory motor coordination } \\
y_{3}=\text { dynamometer } & y_{6}=\text { perseveration }
\end{array}
\]

The data are given in Table 5.6.
(a) Test \(H_{0}: \mu_{1}=\mu_{2}\).
(b) If the \(T^{2}\)-test in part (a) rejects \(H_{0}\), carry out a \(t\)-test for each variable, as in (5.15).
(c) Test each variable adjusted for the other five.
(d) Test the significance of \(y_{4}, y_{5}, y_{6}\) adjusted for \(y_{1}, y_{2}, y_{3}\).
5.19 Data were collected in an attempt to find a screening procedure to detect carriers of Duchenne muscular dystrophy, a disease transmitted from female carriers to some of their male offspring (Andrews and Herzberg 1985, pp. 223228). The following variables were measured on a sample of noncarriers and a sample of carriers:
\[
\begin{aligned}
& y_{1}=\text { age } \\
& y_{2}=\text { month in which measurements are taken } \\
& y_{3}=\text { creatine kinase } \\
& y_{4}=\text { hemopexin } \\
& y_{5}=\text { lactate dehydrogenase } \\
& y_{6}=\text { pyruvate kinase }
\end{aligned}
\]

The data are given in Table 5.7.
(a) Test \(H_{0}: \boldsymbol{\mu}_{1}=\boldsymbol{\mu}_{2}\) using \(y_{3}, y_{4}, y_{5}\), and \(y_{6}\).
(b) The variables \(y_{3}\) and \(y_{4}\) are relatively inexpensive to measure compared to \(y_{5}\) and \(y_{6}\). Do \(y_{5}\) and \(y_{6}\) contribute an important amount to \(T^{2}\) above and beyond \(y_{3}\) and \(y_{4}\) ?
(c) The levels of \(y_{3}, y_{4}, y_{5}\), and \(y_{6}\) may depend on age and season, \(y_{1}\) and \(y_{2}\). Do \(y_{1}\) and \(y_{2}\) contribute a significant amount to \(T^{2}\) when adjusted for \(y_{3}, y_{4}, y_{5}\), and \(y_{6}\) ?
5.20 Various aspects of economic cycles were measured for consumer goods and producer goods by Tintner (1946). The variables are
\[
\begin{aligned}
& y_{1}=\text { length of cycle } \\
& y_{2}=\text { percentage of rising prices } \\
& y_{3}=\text { cyclical amplitude } \\
& y_{4}=\text { rate of change }
\end{aligned}
\]

The data for several items are given in Table 5.8.
(a) Test \(H_{0}: \boldsymbol{\mu}_{1}=\boldsymbol{\mu}_{2}\) using \(T^{2}\).
(b) Calculate the discriminant function coefficient vector.
(c) Test for significance of each variable adjusted for the other three.

Table 5.7 Comparison of Carriers and Noncarriers of Muscular Dystrophy
\begin{tabular}{|c|c|c|c|c|c|c|c|c|c|c|c|}
\hline \multicolumn{6}{|c|}{Noncarriers} & \multicolumn{6}{|c|}{Carriers} \\

\end{tabular}
5.21 Each of 15 students wrote an informal and a formal essay Kramer (1972, p. 100 ). The variables recorded were the number of words and the number of verbs:
\[
\begin{aligned}
& y_{1}=\text { number of words in the informal essay } \\
& y_{2}=\text { number of verbs in the informal essay } \\
& x_{1}=\text { number of words in the formal essay } \\
& x_{2}=\text { number of verbs in the formal essay }
\end{aligned}
\]

The data are given in Table 5.9. Since each student wrote both types of essays, the observation vectors are paired, and we use the paired comparison test.
(a) Test \(H_{0}: \boldsymbol{\mu}_{d}=\mathbf{0}\).
(b) Find the discriminant function coefficient vector.
(c) Do a univariate \(t\)-test on each \(d_{j}\).
5.22 A number of patients with bronchus cancer were treated with ascorbate and compared with matched patients who received no ascorbate (Cameron and Pauling 1978). The data are given in Table 5.10. The variables measured were
\(y_{1}, x_{1}=\) survival time (days) from date of first hospital admission
\(y_{2}, x_{2}=\) survival time from date of untreatability
Compare \(y_{1}\) and \(y_{2}\) with \(x_{1}\) and \(x_{2}\) using a paired comparison \(T^{2}\)-test.
5.23 Use the glucose data in Table 3.9:
(a) Test \(H_{0}: \boldsymbol{\mu}_{y}=\boldsymbol{\mu}_{x}\) using a paired comparison test.
(b) Test the significance of each variable adjusted for the other two.

\section*{CHAPTER 6}

\section*{MULTIVARIATE ANALYSIS OF VARIANCE}

In this chapter we extend univariate analysis of variance to multivariate analysis of variance, in which we measure more than one variable on each experimental unit. For multivariate analysis of covariance, see Rencher (1998, Section 4.10).

\subsection*{6.1 ONE-WAY MODELS}

We begin with a review of univariate analysis of variance (ANOVA) before covering multivariate analysis of variance (MANOVA) with several dependent variables.

\subsection*{6.1.1 Univariate One-Way Analysis of Variance (ANOVA)}

In the balanced one-way ANOVA, we have a random sample of \(n\) observations from each of \(k\) normal populations with equal variances, as in the following layout:
\begin{tabular}{lcccc} 
& \begin{tabular}{c} 
Sample 1 \\
from \(N\left(\mu_{1}, \sigma^{2}\right)\)
\end{tabular} & \begin{tabular}{c} 
Sample 2 \\
from \(N\left(\mu_{2}, \sigma^{2}\right)\)
\end{tabular} & \(\ldots\) & from \(N\left(\mu_{k}, \sigma^{2}\right)\)
\end{tabular}

The \(k\) samples or the populations from which they arise are sometimes referred to as groups. The groups may correspond to treatments applied by the researcher in an experiment. We have used the "dot" notation for totals and means for each group:
\[
\begin{equation*}
y_{i .}=\sum_{j=1}^{n} y_{i j}, \quad \bar{y}_{i .}=\sum_{j=1}^{n} \frac{y_{i j}}{n} . \tag{6.1}
\end{equation*}
\]

The \(k\) samples are assumed to be independent. The assumptions of independence and common variance are necessary to obtain an \(F\)-test.

The model for each observation is
\[
\begin{align*}
y_{i j} & =\mu+\alpha_{i}+\varepsilon_{i j}  \tag{6.2}\\
& =\mu_{i}+\varepsilon_{i j}, \quad i=1,2, \ldots, k ; j=1,2, \ldots, n ;
\end{align*}
\]
where \(\mu_{i}=\mu+\alpha_{i}\) is the mean of the \(i\) th population. We wish to compare the sample means \(\bar{y}_{i,}, i=1,2, \ldots, k\), to see if they are sufficiently different to lead us to believe the population means differ. The hypothesis can be expressed as \(H_{0}: \mu_{1}=\mu_{2}=\) \(\cdots=\mu_{k}\). Note that the notation for subscripts differs from that of previous chapters, in which the subscript \(i\) represented the observation. In this chapter, we use the last subscript in a model such as (6.2) to represent the observation.

If the hypothesis is true, all \(y_{i j}\) are from the same population, \(N\left(\mu, \sigma^{2}\right)\), and we can obtain two estimates of \(\sigma^{2}\), one based on the sample variances \(s_{1}^{2}, s_{2}^{2}, \ldots, s_{k}^{2}\) [see (3.4) and (3.5)] and the other based on the sample means \(\bar{y}_{1,}, \bar{y}_{2}, \ldots, \bar{y}_{k}\). The pooled "within-sample" estimator of \(\sigma^{2}\) is
\[
\begin{equation*}
s_{e}^{2}=\frac{1}{k} \sum_{i=1}^{k} s_{i}^{2}=\frac{\sum_{i=1}^{k} \sum_{j=1}^{n}\left(y_{i j}-\bar{y}_{i .}\right)^{2}}{k(n-1)}=\frac{\sum_{i j} y_{i j}^{2}-\sum_{i} y_{i .}^{2} / n}{k(n-1)} \tag{6.3}
\end{equation*}
\]

Our second estimate of \(\sigma^{2}\) (under \(H_{0}\) ) is based on the variance of the sample means,
\[
\begin{equation*}
s_{\bar{y}}^{2}=\frac{\sum_{i=1}^{k}\left(\bar{y}_{i .}-\bar{y}_{. .}\right)^{2}}{k-1} \tag{6.4}
\end{equation*}
\]
where \(\bar{y}_{. .}=\sum_{i=1}^{k} \bar{y}_{i .} / k\) is the overall mean. If \(H_{0}\) is true, \(s_{\bar{y}}^{2}\) estimates \(\sigma_{\bar{y}}^{2}=\sigma^{2} / n\) [see remarks following (3.1) in Section 3.1], and therefore \(E\left(n s \frac{2}{y}\right)=n\left(\sigma^{2} / n\right)=\)
\(\sigma^{2}\), from which the estimate of \(\sigma^{2}\) is
\[
\begin{equation*}
n s_{\bar{y}}^{2}=\frac{n \sum_{i=1}^{k}\left(\bar{y}_{i .}-\bar{y}_{. .}\right)^{2}}{k-1}=\frac{\sum_{i} y_{i .}^{2} / n-y_{. .}^{2} / k n}{k-1}, \tag{6.5}
\end{equation*}
\]
where \(y . .=\sum_{i} y_{i .}=\sum_{i j} y_{i j}\) is the overall total. If \(H_{0}\) is false, \(E\left(n s_{\bar{y}}^{2}\right)=\sigma^{2}+\) \(n \sum_{i} \alpha_{i}^{2} /(k-1)\), and \(n s \frac{2}{\bar{y}}\) will tend to reflect a larger spread in \(\bar{y}_{1 .}, \bar{y}_{2 .}, \ldots, \bar{y}_{k}\). Since \(s_{e}^{2}\) is based on variability within each sample, it estimates \(\sigma^{2}\) whether or not \(H_{0}\) is true; thus \(E\left(s_{e}^{2}\right)=\sigma^{2}\) in either case.

When sampling from normal distributions, \(s_{e}^{2}\), a pooled estimator based on the \(k\) values of \(s_{i}^{2}\), is independent of \(s_{\bar{y}}^{2}\), which is based on the \(\bar{y}_{i}\).'s. We can justify this assertion by noting that \(\bar{y}_{i}\). and \(s_{i}^{2}\) are independent in each sample (when sampling from the normal distribution) and that the \(k\) samples are independent of each other. Since \(n s_{\bar{y}}^{2}\) and \(s_{e}^{2}\) are independent and both estimate \(\sigma^{2}\), their ratio forms an \(F\) statistic (see Section 7.3.1):
\[
\begin{align*}
F & =\frac{n s_{\frac{2}{y}}^{2}}{s_{e}^{2}}=\frac{\left(\sum_{i} y_{i .2}^{2} / n-y_{. .}^{2} / k n\right) /(k-1)}{\left(\sum_{i j} y_{i j}^{2}-\sum_{i} y_{i .}^{2} / n\right) /[k(n-1)]} \\
& =\frac{\operatorname{SSH} /(k-1)}{\operatorname{SSE} /[k(n-1)]}  \tag{6.6}\\
& =\frac{\mathrm{MSH}}{\mathrm{MSE}}, \tag{6.7}
\end{align*}
\]
where \(\mathrm{SSH}=\sum_{i} y_{i .}^{2} / n-y_{. .}^{2} / k n\) and \(\mathrm{SSE}=\sum_{i j} y_{i j}^{2}-\sum_{i} y_{i .}^{2} / n\) are the "between"sample sum of squares (due to the means) and "within"-sample sum of squares, respectively, and MSH and MSE are the corresponding sample mean squares. The \(F\)-statistic (6.6) is distributed as \(F_{k-1, k(n-1)}\) when \(H_{0}\) is true. We reject \(H_{0}\) if \(F>F_{\alpha}\). The \(F\)-statistic (6.6) can be shown to be a simple function of the likelihood ratio.

\subsection*{6.1.2 Multivariate One-Way Analysis of Variance Model (MANOVA)}

We often measure several dependent variables on each experimental unit instead of just one variable. In the multivariate case, we assume that \(k\) independent random samples of size \(n\) are obtained from \(p\)-variate normal populations with equal covariance matrices, as in the following layout for balanced one-way multivariate analysis of variance (MANOVA). (In practice, the observation vectors \(\mathbf{y}_{i j}\) would ordinarily be listed in row form, and sample 2 would appear below sample 1, and so on. See, for example, Table 6.2.)
\(\left.\left.\begin{array}{cccc} & \begin{array}{c}\text { Sample 1 } \\
\text { from } N_{p}\left(\boldsymbol{\mu}_{1}, \boldsymbol{\Sigma}\right)\end{array} & \begin{array}{c}\text { Sample 2 } \\
\text { from } N_{p}\left(\boldsymbol{\mu}_{2}, \boldsymbol{\Sigma}\right)\end{array} & \ldots\end{array}\right] \begin{array}{c}\text { Sample } k \\
\text { from } N_{p}\left(\boldsymbol{\mu}_{k}, \boldsymbol{\Sigma}\right)\end{array}\right]\)\begin{tabular}{l}
\(\mathbf{y}_{11}\) \\
\(\mathbf{y}_{12}\)
\end{tabular}

Totals and means are defined as follows:
Total of the \(i\) th sample: \(\mathbf{y}_{i .}=\sum_{j=1}^{n} \mathbf{y}_{i j}\).
Overall total: \(\mathbf{y}_{. .}=\sum_{i=1}^{k} \sum_{j=1}^{n} \mathbf{y}_{i j}\).
Mean of the \(i\) th sample: \(\overline{\mathbf{y}}_{i .}=\mathbf{y}_{i .} / n\).
Overall mean: \(\overline{\mathbf{y}}_{. .}=\mathbf{y}_{\text {.. }} / \mathrm{kn}\).
The model for each observation vector is
\[
\begin{align*}
\mathbf{y}_{i j} & =\boldsymbol{\mu}+\boldsymbol{\alpha}_{i}+\varepsilon_{i j} \\
& =\boldsymbol{\mu}_{i}+\varepsilon_{i j}, i=1,2, \ldots, k ; \quad j=1,2, \ldots, n \tag{6.8}
\end{align*}
\]

In terms of the \(p\) variables in \(\mathbf{y}_{i j}\), (6.8) becomes
\[
\left(\begin{array}{c}
y_{i j 1} \\
y_{i j 2} \\
\vdots \\
y_{i j p}
\end{array}\right)=\left(\begin{array}{c}
\mu_{1} \\
\mu_{2} \\
\vdots \\
\mu_{p}
\end{array}\right)+\left(\begin{array}{c}
\alpha_{i 1} \\
\alpha_{i 2} \\
\vdots \\
\alpha_{i p}
\end{array}\right)+\left(\begin{array}{c}
\varepsilon_{i j 1} \\
\varepsilon_{i j 2} \\
\vdots \\
\varepsilon_{i j p}
\end{array}\right)=\left(\begin{array}{c}
\mu_{i 1} \\
\mu_{i 2} \\
\vdots \\
\mu_{i p}
\end{array}\right)+\left(\begin{array}{c}
\varepsilon_{i j 1} \\
\varepsilon_{i j 2} \\
\vdots \\
\varepsilon_{i j p}
\end{array}\right),
\]
so that the model for the \(r\) th variable \((r=1,2, \ldots, p)\) in each vector \(\mathbf{y}_{i j}\) is
\[
y_{i j r}=\mu_{r}+\alpha_{i r}+\varepsilon_{i j r}=\mu_{i r}+\varepsilon_{i j r}
\]

We wish to compare the mean vectors of the \(k\) samples for significant differences. The hypothesis is therefore
\[
H_{0}: \boldsymbol{\mu}_{1}=\boldsymbol{\mu}_{2}=\cdots=\boldsymbol{\mu}_{k} \quad \text { vs. } \quad H_{1}: \text { at least two } \boldsymbol{\mu}^{\prime} \text { 's are unequal. }
\]

Equality of the mean vectors implies that the \(k\) means are equal for each variable; that is, \(\mu_{1 r}=\mu_{2 r}=\cdots=\mu_{k r}\) for \(r=1,2, \ldots, p\). If two means differ for just one variable, for example, \(\mu_{23} \neq \mu_{43}\), then \(H_{0}\) is false and we wish to reject it. We can see this by examining the elements of the population mean vectors:
\[
H_{0}:\left(\begin{array}{c}
\mu_{11} \\
\mu_{12} \\
\vdots \\
\mu_{1 p}
\end{array}\right)=\left(\begin{array}{c}
\mu_{21} \\
\mu_{22} \\
\vdots \\
\mu_{2 p}
\end{array}\right)=\cdots=\left(\begin{array}{c}
\mu_{k 1} \\
\mu_{k 2} \\
\vdots \\
\mu_{k p}
\end{array}\right)
\]

Thus \(H_{0}\) implies \(p\) sets of equalities:
\[
\begin{aligned}
\mu_{11} & =\mu_{21}=\cdots=\mu_{k 1} \\
\mu_{12} & =\mu_{22}=\cdots=\mu_{k 2} \\
& \vdots \\
& \vdots \\
& \\
\mu_{1 p} & =\mu_{2 p}=\cdots \\
& =\mu_{k p} .
\end{aligned}
\]

All \(p(k-1)\) equalities must hold for \(H_{0}\) to be true; failure of only one equality will falsify the hypothesis.

In the univariate case, we have "between" and "within" sums of squares SSH and SSE. By (6.3), (6.5), and (6.6), these are given by
\[
\begin{aligned}
& \mathrm{SSH}=n \sum_{i=1}^{k}\left(\bar{y}_{i .}-\bar{y}_{. .}\right)^{2}=\sum_{i=1}^{k} \frac{y_{i .}^{2}}{n}-\frac{y_{.}^{2}}{k n}, \\
& \mathrm{SSE}=\sum_{i=1}^{k} \sum_{j=1}^{n}\left(y_{i j}-\bar{y}_{i .}\right)^{2}=\sum_{i j} y_{i j}^{2}-\sum_{i} \frac{y_{i .}^{2}}{n} .
\end{aligned}
\]

By analogy, in the multivariate case, we have "between" and "within" matrices \(\mathbf{H}\) and \(\mathbf{E}\), defined as
\[
\begin{align*}
\mathbf{H} & =n \sum_{i=1}^{k}\left(\overline{\mathbf{y}}_{i .}-\overline{\mathbf{y}}_{. .}\right)\left(\overline{\mathbf{y}}_{i .}-\overline{\mathbf{y}}_{. .}\right)^{\prime}  \tag{6.9}\\
& =\sum_{i=1}^{k} \frac{1}{n} \mathbf{y}_{i . \mathbf{y}_{i .}^{\prime}}-\frac{1}{k n} \mathbf{y}_{. . \mathbf{y}_{. .}^{\prime}} \\
\mathbf{E} & =\sum_{i=1}^{k} \sum_{j=1}^{n}\left(\mathbf{y}_{i j}-\overline{\mathbf{y}}_{i .}\right)\left(\mathbf{y}_{i j}-\overline{\mathbf{y}}_{i .}\right)^{\prime}  \tag{6.10}\\
& =\sum_{i j} \mathbf{y}_{i j} \mathbf{y}_{i j}^{\prime}-\sum_{i} \frac{1}{n} \mathbf{y}_{i . \mathbf{y}_{i .}^{\prime}} .
\end{align*}
\]

The \(p \times p\) "hypothesis" matrix \(\mathbf{H}\) has a "between" sum of squares on the diagonal for each of the \(p\) variables. Off-diagonal elements are analogous sums of products for each pair of variables. Assuming there are no linear dependencies in the variables, the rank of \(\mathbf{H}\) is the smaller of \(p\) and \(\nu_{H}, \min \left(p, \nu_{H}\right)\), where \(\nu_{H}\) represents the degrees of freedom for hypothesis; in the one-way case \(\nu_{H}=k-1\). Thus \(\mathbf{H}\) can be singular. The \(p \times p\) "error" matrix \(\mathbf{E}\) has a "within" sum of squares for each variable on the diagonal with analogous sums of products off-diagonal. The rank of \(\mathbf{E}\) is \(p\), unless \(\nu_{E}\) is less than \(p\).

Thus \(\mathbf{H}\) has the form
\[
\mathbf{H}=\left(\begin{array}{cccc}
\mathrm{SSH}_{11} & \mathrm{SPH}_{12} & \cdots & \mathrm{SPH}_{1 p}  \tag{6.11}\\
\mathrm{SPH}_{12} & \mathrm{SSH}_{22} & \cdots & \mathrm{SPH}_{2 p} \\
\vdots & \vdots & & \vdots \\
\mathrm{SPH}_{1 p} & \mathrm{SPH}_{2 p} & \cdots & \mathrm{SSH}_{p p}
\end{array}\right)
\]
where, for example,
\[
\begin{gathered}
\mathrm{SSH}_{22}=n \sum_{i=1}^{k}\left(\bar{y}_{i .2}-\bar{y}_{. .2}\right)^{2}=\sum_{i} \frac{y_{i .2}^{2}}{n}-\frac{y_{. .2}^{2}}{k n} \\
\mathrm{SPH}_{12}=n \sum_{i=1}^{k}\left(\bar{y}_{i .1}-\bar{y}_{. .1}\right)\left(\bar{y}_{i .2}-\bar{y}_{. .2}\right)=\sum_{i} \frac{y_{i .1} y_{i .2}}{n}-\frac{y_{. .1} y_{. .2}}{k n} .
\end{gathered}
\]

In these expressions, the subscript 1 or 2 indicates the first or second variable. Thus, for example, \(\bar{y}_{i .2}\) is the second element in \(\overline{\mathbf{y}}_{i .}\) :
\[
\overline{\mathbf{y}}_{i .}=\left(\begin{array}{c}
\bar{y}_{i .1} \\
\bar{y}_{i .2} \\
\vdots \\
\bar{y}_{i . p}
\end{array}\right)
\]

The matrix \(E\) can be expressed in a form similar to (6.11):
\[
\mathbf{E}=\left(\begin{array}{cccc}
\mathrm{SSE}_{11} & \mathrm{SPE}_{12} & \cdots & \mathrm{SPE}_{1 p}  \tag{6.12}\\
\mathrm{SPE}_{12} & \mathrm{SSE}_{22} & \cdots & \mathrm{SPE}_{2 p} \\
\vdots & \vdots & & \vdots \\
\mathrm{SPE}_{1 p} & \mathrm{SPE}_{2 p} & \cdots & \mathrm{SSE}_{p p}
\end{array}\right)
\]
where, for example,
\[
\begin{gathered}
\operatorname{SSE}_{22}=\sum_{i=1}^{k} \sum_{j=1}^{n}\left(y_{i j 2}-\bar{y}_{i .2}\right)^{2}=\sum_{i j} y_{i j 2}^{2}-\sum_{i} \frac{y_{i .2}^{2}}{n} \\
\operatorname{SPE}_{12}=\sum_{i=1}^{k} \sum_{j=1}^{n}\left(y_{i j 1}-\bar{y}_{i .1}\right)\left(y_{i j 2}-\bar{y}_{i .2}\right)=\sum_{i j} y_{i j 1} y_{i j 2}-\sum_{i} \frac{y_{i .1} y_{i .2}}{n} .
\end{gathered}
\]

Note that the elements of \(\mathbf{E}\) are sums of squares and products, not variances and covariances. To estimate \(\boldsymbol{\Sigma}\), we use \(\mathbf{S}_{\mathrm{p} 1}=\mathbf{E} /(n k-k)\), so that
\[
E\left(\frac{\mathbf{E}}{n k-k}\right)=\mathbf{\Sigma}
\]

\subsection*{6.1.3 Wilks' Test Statistic}

The likelihood ratio test of \(H_{0}: \mu_{1}=\mu_{2}=\cdots=\mu_{k}\) is given by
\[
\begin{equation*}
\Lambda=\frac{|\mathbf{E}|}{|\mathbf{E}+\mathbf{H}|}, \tag{6.13}
\end{equation*}
\]
which is known as Wilks' \(\Lambda\). (It has also been called Wilks' \(U\).) We reject \(H_{0}\) if \(\Lambda \leq \Lambda_{\alpha, p, \nu_{H}, \nu_{E}}\). Note that rejection is for small values of \(\Lambda\). Exact critical values \(\Lambda_{\alpha, p, \nu_{H}, \nu_{E}}\) for Wilks' \(\Lambda\) are found in Table A.9, taken from Wall (1967). The parameters in Wilks' \(\Lambda\) distribution are
\[
\begin{aligned}
p & =\text { number of variables (dimension) } \\
\nu_{H} & =\text { degrees of freedom for hypothesis }, \\
\nu_{E} & =\text { degrees of freedom for error } .
\end{aligned}
\]

Wilks' \(\Lambda\) compares the "within" sum of squares and products matrix \(\mathbf{E}\) to the "total" sum of squares and products matrix \(\mathbf{E}+\mathbf{H}\). This is similar to the univariate \(F\)-statistic in (6.6) that compares the between sum of squares to the within sum of squares. By using determinants, the test statistic \(\Lambda\) is reduced to a scalar. Thus the multivariate information in \(\mathbf{E}\) and \(\mathbf{H}\) about separation of mean vectors \(\overline{\mathbf{y}}_{1 .}, \overline{\mathbf{y}}_{2,}, \ldots, \overline{\mathbf{y}}_{k}\) is channeled into a single scale, on which we can determine whether the separation of mean vectors is significant. This is typical of multivariate tests in general.

The mean vectors occupy a space of dimension \(s=\min \left(p, \nu_{H}\right)\), and within this space various configurations of these mean vectors are possible. This suggests the possibility that another test statistic may be more powerful than Wilks' \(\Lambda\). Competing test statistics are discussed in Sections 6.1.4 and 6.1.5.

Some of the properties and characteristics of Wilks' \(\Lambda\) are as follows:
1. In order for the determinants in (6.13) to be positive, it is necessary that \(\nu_{E} \geq\) \(p\).
2. For any MANOVA model, the degrees of freedom \(\nu_{H}\) and \(\nu_{E}\) are always the same as in the analogous univariate case. In the balanced one-way model, for example, \(\nu_{H}=k-1\) and \(\nu_{E}=k(n-1)\).
3. The parameters \(p\) and \(\nu_{H}\) can be interchanged; the distribution of \(\Lambda_{p, \nu_{H}, \nu_{E}}\) is the same as that of \(\Lambda_{\nu_{H}, p, \nu_{E}+\nu_{H}-p}\).
4. Wilks' \(\Lambda\) in (6.13) can be expressed in terms of the eigenvalues \(\lambda_{1}, \lambda_{2}, \ldots, \lambda_{s}\) of \(\mathbf{E}^{-1} \mathbf{H}\), as follows:
\[
\begin{equation*}
\Lambda=\prod_{i=1}^{s} \frac{1}{1+\lambda_{i}} \tag{6.14}
\end{equation*}
\]

The number of nonzero eigenvalues of \(\mathbf{E}^{-1} \mathbf{H}\) is \(s=\min \left(p, \nu_{H}\right)\), which is the rank of \(\mathbf{H}\). The matrix \(\mathbf{H E} \mathbf{E}^{-1}\) has the same eigenvalues as \(\mathbf{E}^{-1} \mathbf{H}\) (see Section 2.11.5) and could be used in its place to obtain \(\Lambda\). However, we prefer \(\mathbf{E}^{-1} \mathbf{H}\) because we will use its eigenvectors later.
5. The range of \(\Lambda\) is \(0 \leq \Lambda \leq 1\), and the test based on Wilks' \(\Lambda\) is an inverse test in the sense that we reject \(H_{0}\) for small values of \(\Lambda\). If the sample mean

Table 6.1 Transformations of Wilks' \(\Lambda\) to Exact Upper Tail F-Tests
\begin{tabular}{lcc}
\hline \begin{tabular}{l} 
Parameters \\
\(p, \nu_{H}\)
\end{tabular} & \begin{tabular}{c} 
Statistic Having \\
\(F\)-Distribution
\end{tabular} & \begin{tabular}{c} 
Degrees of \\
Freedom
\end{tabular} \\
\hline Any \(p, \nu_{H}=1\) & \(\frac{1-\Lambda}{\Lambda} \frac{\nu_{E}-p+1}{p}\) & \(p, \nu_{E}-p+1\) \\
Any \(p, \nu_{H}=2\) & \(\frac{1-\sqrt{\Lambda}}{\sqrt{\Lambda}} \frac{\nu_{E}-p+1}{p}\) & \(2 p, 2\left(\nu_{E}-p+1\right)\) \\
\(p=1\), any \(\nu_{H}\) & \(\frac{1-\Lambda}{\Lambda} \frac{\nu_{E}}{\nu_{H}}\) & \(\nu_{H}, \nu_{E}\) \\
\(p=2\), any \(\nu_{H}\) & \(\frac{1-\sqrt{\Lambda}}{\sqrt{\Lambda}} \frac{\nu_{E}-1}{\nu_{H}}\) & \(2 \nu_{H}, 2\left(\nu_{E}-1\right)\) \\
\hline
\end{tabular}
vectors were equal, we would have \(\mathbf{H}=\mathbf{O}\) and \(\Lambda=|\mathbf{E}| /|\mathbf{E}+\mathbf{O}|=1\). On the other hand, as the sample mean vectors become more widely spread apart compared to the within-sample variation, \(\mathbf{H}\) becomes much "larger" than \(\mathbf{E}\), and \(\Lambda\) approaches zero.
6. In Table A.9, the critical values decrease for increasing \(p\). Thus the addition of variables will reduce the power unless the variables contribute to rejection of the hypothesis by causing a significant reduction in \(\Lambda\).
7. When \(\nu_{H}=1\) or 2 or when \(p=1\) or 2 , Wilks' \(\Lambda\) transforms to an exact \(F\)-statistic. The transformations from \(\Lambda\) to \(F\) for these special cases are given in Table 6.1. The hypothesis is rejected when the transformed value of \(\Lambda\) exceeds the upper \(\alpha\)-level percentage point of the \(F\)-distribution, with degrees of freedom as shown.
8. For values of \(p\) and \(\nu_{H}\) other than those in Table 6.1, an approximate \(F\)-statistic is given by
\[
\begin{equation*}
F=\frac{1-\Lambda^{1 / t}}{\Lambda^{1 / t}} \frac{\mathrm{df}_{2}}{\mathrm{df}_{1}} \tag{6.15}
\end{equation*}
\]
with \(\mathrm{df}_{1}\) and \(\mathrm{df}_{2}\) degrees of freedom, where
\[
\begin{aligned}
\mathrm{df}_{1} & =p \nu_{H}, \quad \mathrm{df}_{2}=w t-\frac{1}{2}\left(p \nu_{H}-2\right), \\
w & =\nu_{E}+\nu_{H}-\frac{1}{2}\left(p+\nu_{H}+1\right), \quad t=\sqrt{\frac{p^{2} \nu_{H}^{2}-4}{p^{2}+\nu_{H}^{2}-5}} .
\end{aligned}
\]

When \(p \nu_{H}=2, t\) is set equal to 1 . The approximate \(F\) in (6.15) reduces to the exact \(F\)-values given in Table 6.1, when either \(\nu_{H}\) or \(p\) is 1 or 2 .
A (less accurate) approximate test is given by
\[
\begin{equation*}
\chi^{2}=-\left[\nu_{E}-\frac{1}{2}\left(p-\nu_{H}+1\right)\right] \ln \Lambda, \tag{6.16}
\end{equation*}
\]

Figure 6.1 Three samples with significant Wilks' \(\Lambda\) but nonsignificant \(F\) 's.
which has an approximate \(\chi^{2}\)-distribution with \(p \nu_{H}\) degrees of freedom. We reject \(H_{0}\) if \(\chi^{2}>\chi_{\alpha}^{2}\). This approximation is accurate to three decimal places when \(p^{2}+\nu_{H}^{2} \leq \frac{1}{3} f\), where \(f=\nu_{E}-\frac{1}{2}\left(p-\nu_{H}+1\right)\).

Although it is more expensive computationally, there is also a method for obtaining exact \(p\)-values for \(\Lambda\). This exact method is due to Lee (1972) and Davis (1979) and is available in modern statistical computing packages. For example, in SAS Version 9 (SAS Institute Inc., 2009) exact tests can be requested using the "MSTAT = EXACT" option of the MANOVA statement in PROC GLM.
9. If the multivariate test based on \(\Lambda\) rejects \(H_{0}\), it could be followed by an \(F\)-test as in (6.6) on each of the \(p\) individual \(y\) 's. We can formulate a hypothesis comparing the means across the \(k\) groups for each variable, namely, \(H_{0 r}: \mu_{1 r}=\mu_{2 r}=\cdots=\mu_{k r}, r=1,2, \ldots, p\). It does not necessarily follow that any of the \(F\)-tests on the \(p\) individual variables will reject the corresponding \(H_{0 r}\). Conversely, it is possible that one or more of the \(F\) 's will reject \(H_{0 r}\) when the \(\Lambda\)-test accepts \(H_{0}\). In either case, where the multivariate test and the univariate tests disagree, we use the multivariate test result rather than the univariate results. This is similar to the relationship between \(Z^{2}\)-tests and \(z\)-tests shown in Figure 5.2.

In the three bivariate samples plotted in Figure 6.1, we illustrate the case where \(\Lambda\) rejects \(H_{0}: \boldsymbol{\mu}_{1}=\boldsymbol{\mu}_{2}=\boldsymbol{\mu}_{3}\) but the \(F\) 's accept both of \(H_{0 r}: \mu_{1 r}=\mu_{2 r}=\) \(\mu_{3 r}, r=1,2\), that is, for \(y_{1}\) and \(y_{2}\). There is no significant separation of the
three samples in either the \(y_{1}\) or \(y_{2}\) direction alone. Other follow-up procedures are given in Sections 6.1.4 and 6.4.
10. The Wilks' \(\Lambda\)-test is the likelihood ratio test. Other approaches to test construction lead to different tests. Three such tests are given in Sections 6.1.4 and 6.1.5.

\subsection*{6.1.4 Roy's Test}

In the union-intersection approach, we seek the linear combination \(z_{i j}=\mathbf{a}^{\prime} \mathbf{y}_{i j}\) that maximizes the spread of the transformed means \(\bar{z}_{i}=\mathbf{a}^{\prime} \overline{\mathbf{y}}_{i}\). relative to the withinsample spread of points. Thus we seek the vector a that maximizes
\[
\begin{equation*}
F=\frac{n \sum_{i=1}^{k}\left(\bar{z}_{i .}-\bar{z}_{. .}\right)^{2} /(k-1)}{\sum_{i=1}^{k} \sum_{j=1}^{n}\left(z_{i j}-\bar{z}_{i .}\right)^{2} /(k n-k)}, \tag{6.17}
\end{equation*}
\]
which, by analogy to \(s_{z}^{2}=\mathbf{a}^{\prime} \mathbf{S a}\) in (3.55), can be written as
\[
\begin{equation*}
F=\frac{\mathbf{a}^{\prime} \mathbf{H a} /(k-1)}{\mathbf{a}^{\prime} \mathbf{E a} /(k n-k)} \tag{6.18}
\end{equation*}
\]

This is maximized by \(\mathbf{a}_{1}\), the eigenvector corresponding to \(\lambda_{1}\), the largest eigenvalue of \(\mathbf{E}^{-1} \mathbf{H}\) (see Section 8.4.1), and we have
\[
\begin{equation*}
\max _{\mathbf{a}} F=\frac{\mathbf{a}_{1}^{\prime} \mathbf{H} \mathbf{a}_{1} /(k-1)}{\mathbf{a}_{1}^{\prime} \mathbf{E} \mathbf{a}_{1} /(k n-k)}=\frac{k(n-1)}{k-1} \lambda_{1} \tag{6.19}
\end{equation*}
\]

Since \(\max _{\mathbf{a}} F\) in (6.19) is maximized over all possible linear functions, it no longer has an \(F\)-distribution. To test \(H_{0}: \boldsymbol{\mu}_{1}=\boldsymbol{\mu}_{2}=\cdots=\boldsymbol{\mu}_{k}\) based on \(\lambda_{1}\), we use Roy's union-intersection test, also called Roy's largest root test. The test statistic is given by
\[
\begin{equation*}
\theta=\frac{\lambda_{1}}{1+\lambda_{1}} \tag{6.20}
\end{equation*}
\]

Critical values for \(\theta\) are given in Table A. 10 (Pearson and Hartley 1972, Pillai 1964, 1965). We reject \(H_{0}: \boldsymbol{\mu}_{1}=\boldsymbol{\mu}_{2}=\cdots=\boldsymbol{\mu}_{k}\) if \(\theta \geq \theta_{\alpha, s, m, N}\). The parameters \(s, m\), and \(N\) are defined as
\[
s=\min \left(\nu_{H}, p\right), \quad m=\frac{1}{2}\left(\left|\nu_{H}-p\right|-1\right), \quad N=\frac{1}{2}\left(\nu_{E}-p-1\right)
\]

For \(s=1\), use (6.33) and (6.36) in Section 6.1.7 to obtain an \(F\)-test.
The eigenvector \(\mathbf{a}_{1}\) corresponding to \(\lambda_{1}\) is used in the discriminant function, \(z=\mathbf{a}_{1}^{\prime} \mathbf{y}\). Since this is the function that best separates the transformed means \(\bar{z}_{i .}=\mathbf{a}^{\prime} \overline{\mathbf{y}}_{i .}, i=1,2, \ldots, k\) [relative to the within-sample spread, see (6.17)], the coefficients \(a_{11}, a_{12}, \ldots, a_{1 p}\) in the linear combination \(z=\mathbf{a}_{1}^{\prime} \mathbf{y}\) can be examined for an indication of which variables contribute most to separating the means. The discriminant function is discussed further in Sections 6.1.8 and 6.4 and in Chapter 8.

We do not have a satisfactory \(F\)-approximation for \(\theta\) or \(\lambda_{1}\), but an "upper bound" on \(F\) that is provided in some software programs is given by
\[
\begin{equation*}
F=\frac{\left(\nu_{E}-d-1\right) \lambda_{1}}{d} \tag{6.21}
\end{equation*}
\]
with degrees of freedom \(d\) and \(\nu_{E}-d-1\), where \(d=\max \left(p, \nu_{H}\right)\). The term "upper bound" indicates that the \(F\) in (6.21) is greater than the "true \(F\) "; that is, \(F>F_{d, \nu_{E}-d-1}\). Therefore, we feel safe if \(H_{0}\) is accepted by (6.21), but if rejection of \(H_{0}\) is indicated, the information is virtually worthless.

Fortunately, there exists a method due to Davis (1972) and Pillai and Flury (1984) that allows us to calculate an exact \(p\)-value associated with Roy's largest root. This exact method has been implemented in SAS Version 9 (SAS Institute Inc., 2009) by using the "MSTAT = EXACT" option of the MANOVA statement in PROC GLM.

Some computer programs do not provide eigenvalues of nonsymmetric matrices, such as \(\mathbf{E}^{-1} \mathbf{H}\). However, the eigenvalues of \(\mathbf{E}^{-1} \mathbf{H}\) are the same as the eigenvalues of the symmetric matrices \(\left(\mathbf{E}^{1 / 2}\right)^{-1} \mathbf{H}\left(\mathbf{E}^{1 / 2}\right)^{-1}\) and \(\left(\mathbf{U}^{\prime}\right)^{-1} \mathbf{H} \mathbf{U}^{-1}\), where \(\mathbf{E}^{1 / 2}\) is the square root matrix of \(\mathbf{E}\) given in (2.112) and \(\mathbf{U}^{\prime} \mathbf{U}=\mathbf{E}\) is the Cholesky factorization of \(\mathbf{E}\) (Section 2.7). We demonstrate this for the Cholesky approach. We first multiply the defining relationship \(\left(\mathbf{E}^{-1} \mathbf{H}-\lambda \mathbf{I}\right) \mathbf{a}=\mathbf{0}\) by \(\mathbf{E}\) to obtain
\[
\begin{equation*}
(\mathbf{H}-\lambda \mathbf{E}) \mathbf{a}=\mathbf{0} \tag{6.22}
\end{equation*}
\]

Then substituting \(\mathbf{E}=\mathbf{U}^{\prime} \mathbf{U}\) into (6.22), multiplying by \(\left(\mathbf{U}^{\prime}\right)^{-1}\), and inserting \(\mathbf{U}^{-1} \mathbf{U}=\mathbf{I}\), we have
\[
\begin{align*}
& \left(\mathbf{H}-\lambda \mathbf{U}^{\prime} \mathbf{U}\right) \mathbf{a}=\mathbf{0} \\
& \left(\mathbf{U}^{\prime}\right)^{-1}\left(\mathbf{H}-\lambda \mathbf{U}^{\prime} \mathbf{U}\right) \mathbf{a}=\left(\mathbf{U}^{\prime}\right)^{-1} \mathbf{0}=\mathbf{0} \\
& {\left[\left(\mathbf{U}^{\prime}\right)^{-1} \mathbf{H}-\lambda \mathbf{U}\right] \mathbf{U}^{-1} \mathbf{U} \mathbf{a}=\mathbf{0}} \\
& {\left[\left(\mathbf{U}^{\prime}\right)^{-1} \mathbf{H} \mathbf{U}^{-1}-\lambda \mathbf{I}\right] \mathbf{U} \mathbf{a}=\mathbf{0}} \tag{6.23}
\end{align*}
\]

Thus \(\left(\mathbf{U}^{\prime}\right)^{-1} \mathbf{H} \mathbf{U}^{-1}\) has the same eigenvalues as \(\mathbf{E}^{-1} \mathbf{H}\) and has eigenvectors of the form \(\mathbf{U a}\), where \(\mathbf{a}\) is an eigenvector of \(\mathbf{E}^{-1} \mathbf{H}\). Note that \(\left(\mathbf{U}^{\prime}\right)^{-1} \mathbf{H} \mathbf{U}^{-1}\) is positive semidefinite, and thus \(\lambda_{i} \geq 0\) for all eigenvalues of \(\mathbf{E}^{-1} \mathbf{H}\).

\subsection*{6.1.5 Pillai and Lawley-Hotelling Tests}

There are two additional test statistics for \(H_{0}: \mu_{1}=\mu_{2}=\cdots=\mu_{k}\) based on the eigenvalues \(\lambda_{1}, \lambda_{2}, \ldots, \lambda_{s}\) of \(\mathbf{E}^{-1} \mathbf{H}\). The Pillai statistic is given by
\[
\begin{equation*}
V^{(s)}=\operatorname{tr}\left[(\mathbf{E}+\mathbf{H})^{-1} \mathbf{H}\right]=\sum_{i=1}^{s} \frac{\lambda_{i}}{1+\lambda_{i}} . \tag{6.24}
\end{equation*}
\]

We reject \(H_{0}\) for \(V^{(s)} \geq V_{\alpha}^{(s)}\). The upper percentage points, \(V_{\alpha}^{(s)}\), are given in Table A. 11 (Schuurmann et al. 1975), indexed by \(s, m\), and \(N\), which are defined as in

Section 6.1.4 for Roy's test. For \(s=1\), use (6.33) and (6.36) in Section 6.1.7 to obtain an \(F\)-test.

Pillai's test statistic in (6.24) is an extension of Roy's statistic \(\theta=\lambda_{1} /\left(1+\lambda_{1}\right)\). If the mean vectors do not lie in one dimension, the information in the additional terms \(\lambda_{i} /\left(1+\lambda_{i}\right), i=2,3, \ldots, s\), may be helpful in rejecting \(H_{0}\).

For parameter values not included in Table A.11, we can use an approximate \(F\) statistic:
\[
\begin{equation*}
F_{1}=\frac{(2 N+s+1) V^{(s)}}{(2 m+s+1)\left(s-V^{(s)}\right)} \tag{6.25}
\end{equation*}
\]
which is approximately distributed as \(F_{s(2 m+s+1), s(2 N+s+1)}\). The approximation in (6.25) can also be given as
\[
\begin{equation*}
F_{2}=\frac{\left(\nu_{E}-p+s\right) V^{(s)}}{d\left(s-V^{(s)}\right)} \tag{6.26}
\end{equation*}
\]
with \(s d\) and \(s\left(\nu_{E}-p+s\right)\) degrees of freedom, where \(d=\max \left(p, \nu_{H}\right)\). A more recent \(F\)-approximation due to Muller (1998) has been shown to yield better properties than \(F_{1}\) and \(F_{2}\), but is more computationally expensive. Although it is too complicated to present in detail here, it has been implemented in software packages such as SAS Version 9 (SAS Institute Inc., 2009).

The Lawley-Hotelling statistic (Lawley 1938, Hotelling 1951) is defined as
\[
\begin{equation*}
U^{(s)}=\operatorname{tr}\left(\mathbf{E}^{-1} \mathbf{H}\right)=\sum_{i=1}^{s} \lambda_{i} \tag{6.27}
\end{equation*}
\]
and is also known as Hotelling's generalized \(T^{2}\)-statistic (see a comment at the end of Section 6.1.7). Table A. 12 (Davis 1970a,b, 1980) gives upper percentage points of the test statistic
\[
\frac{\nu_{E}}{\nu_{H}} U^{(s)}
\]

We reject \(H_{0}\) for large values of the test statistic. Note that in Table A.12, \(p \leq \nu_{H}\) and \(p \leq \nu_{E}\). If \(p>\nu_{H}\), use ( \(\left.\nu_{H}, p, \nu_{E}+\nu_{H}-p\right)\) in place of \(\left(p, \nu_{H}, \nu_{E}\right)\). (This same pattern in the parameters is found in Wilks' \(\Lambda\); see property 3 in Section 6.1.3) If \(\nu_{H}=1\) and \(p>1\), use the relationship \(U^{(1)}=T^{2} / \nu_{E}\) [see (6.38) in Section 6.1.7]. For other values of the parameters not included in Table A.12, we can use an approximate \(F\)-statistic:
\[
\begin{equation*}
F_{1}=\frac{U^{(s)}}{c} \tag{6.28}
\end{equation*}
\]
which is approximately distributed as \(F_{a, b}\), where
\[
\begin{aligned}
a & =p \nu_{H}, \quad b=4+\frac{a+2}{B-1}, \quad c=\frac{a(b-2)}{b\left(\nu_{E}-p-1\right)} \\
B & =\frac{\left(\nu_{E}+\nu_{H}-p-1\right)\left(\nu_{E}-1\right)}{\left(\nu_{E}-p-3\right)\left(\nu_{E}-p\right)}
\end{aligned}
\]

An alternative \(F\)-approximation is given by
\[
\begin{equation*}
F_{2}=\frac{2(s N+1) U^{(s)}}{s^{2}(2 m+s+1)} \tag{6.29}
\end{equation*}
\]
with \(s(2 m+s+1)\) and \(2(s N+1)\) degrees of freedom. The approximation in (6.29) can also be given by
\[
\begin{equation*}
F_{3}=\frac{\left[s\left(\nu_{E}-p-1\right)+2\right] U^{(s)}}{s p \nu_{H}} \tag{6.30}
\end{equation*}
\]
with \(p \nu_{H}\) and \(s\left(\nu_{E}-p-1\right)+2\) degrees of freedom.
An exact \(p\)-value based on \(U^{(s)}\) has been given by Davis (1970c, 1980) and has been implemented with the other multivariate exact tests in SAS Version 9 (SAS Institute Inc., 2009).

\subsection*{6.1.6 Unbalanced One-Way MANOVA}

The balanced one-way model can be easily extended to the unbalanced case, in which there are \(n_{i}\) observation vectors in the \(i\) th group. The model in (6.8) becomes
\[
\mathbf{y}_{i j}=\boldsymbol{\mu}+\boldsymbol{\alpha}_{i}+\varepsilon_{i j}=\boldsymbol{\mu}_{i}+\varepsilon_{i j}, \quad i=1,2, \ldots, k ; j=1,2, \ldots, n_{i} .
\]

The mean vectors become \(\overline{\mathbf{y}}_{i .}=\sum_{j=1}^{n_{i}} \mathbf{y}_{i j} / n_{i}\) and \(\overline{\mathbf{y}}_{. .}=\sum_{i=1}^{k} \sum_{j=1}^{n_{i}} \mathbf{y}_{i j} / N\), where \(N=\sum_{i=1}^{k} n_{i}\). Similarly, the total vectors are defined as \(\mathbf{y}_{i .}=\sum_{j=1}^{n_{i}} \mathbf{y}_{i j}\) and \(\mathbf{y}_{. .}=\sum_{i j} \mathbf{y}_{i j}\). The \(\mathbf{H}\) and \(\mathbf{E}\) matrices are calculated as
\[
\begin{align*}
\mathbf{H} & =\sum_{i=1}^{k} n_{i}\left(\overline{\mathbf{y}}_{i .}-\overline{\mathbf{y}}_{. .}\right)\left(\overline{\mathbf{y}}_{i .}-\overline{\mathbf{y}}_{. .}\right)^{\prime}=\sum_{i=1}^{k} \frac{1}{n_{i}} \mathbf{y}_{i .} . \mathbf{y}_{i .}^{\prime}-\frac{1}{N} \mathbf{y}_{. .} \mathbf{y}_{. .}^{\prime},  \tag{6.31}\\
\mathbf{E} & =\sum_{i=1}^{k} \sum_{j=1}^{n_{i}}\left(\mathbf{y}_{i j}-\overline{\mathbf{y}}_{i .}\right)\left(\mathbf{y}_{i j}-\overline{\mathbf{y}}_{i .}\right)^{\prime}=\sum_{i=1}^{k} \sum_{j=1}^{n_{i}} \mathbf{y}_{i j} \mathbf{y}_{i j}^{\prime}-\sum_{i=1}^{k} \frac{1}{n_{i}} \mathbf{y}_{i . \mathbf{y}_{i .}^{\prime}} . \tag{6.32}
\end{align*}
\]

Wilks' \(\Lambda\) and the other tests have the same form as in Sections 6.1.3-6.1.5 using H and \(\mathbf{E}\) from (6.31) and (6.32). In each test we have
\[
\nu_{H}=k-1, \quad \nu_{E}=N-k=\sum_{i=1}^{k} n_{i}-k .
\]

Note that \(N=\sum_{i} n_{i}\) differs from \(N\) used as a parameter in Roy's and Pillai's tests in Sections 6.1.4 and 6.1.5.

\subsection*{6.1.7 Summary of the Four Tests and Relationship to \(\boldsymbol{T}^{\mathbf{2}}\)}

We compare the four test statistics in terms of the eigenvalues \(\lambda_{1}>\lambda_{2}>\ldots>\lambda_{s}\) of \(\mathbf{E}^{-1} \mathbf{H}\), where \(s=\min \left(\nu_{H}, p\right)\) :
\[
\begin{aligned}
\text { Pillai } V^{(s)} & =\sum_{i=1}^{s} \frac{\lambda_{i}}{1+\lambda_{i}} \\
\text { Lawley-Hotelling } U^{(s)} & =\sum_{i=1}^{s} \lambda_{i} \\
\text { Wilks' lambda } \Lambda & =\prod_{i=1}^{s} \frac{1}{1+\lambda_{i}} \\
\text { Roy's largest root } \theta & =\frac{\lambda_{1}}{1+\lambda_{1}}
\end{aligned}
\]

Note that for all four tests we must have \(\nu_{E} \geq p\). As noted in Section 6.1.3 and elsewhere, \(p\) is the number of variables, \(\nu_{H}\) is the degrees of freedom for the hypothesis, and \(\nu_{E}\) is the degrees of freedom for error.

Why do we use four different tests? All four are exact tests; that is, when \(H_{0}\) is true, each test has probability \(\alpha\) of rejecting \(H_{0}\). However, the tests are not equivalent, and in a given sample they may lead to different conclusions even when \(H_{0}\) is true; some may reject \(H_{0}\) while others accept \(H_{0}\). This is due to the multidimensional nature of the space in which the mean vectors \(\boldsymbol{\mu}_{1}, \boldsymbol{\mu}_{2}, \ldots, \boldsymbol{\mu}_{k}\) lie. A comparison of power and other properties of the tests is given in Section 6.2.

When \(\nu_{H}=1\), then \(s\) is also equal to 1 , and there is only one nonzero eigenvalue \(\lambda_{1}\). In this case, all four test statistics are functions of each other and give equivalent results. In terms of \(\theta\), for example, the other three become
\[
\begin{align*}
U^{(1)} & =\lambda_{1}=\frac{\theta}{1-\theta},  \tag{6.33}\\
V^{(1)} & =\theta  \tag{6.34}\\
\Lambda & =1-\theta . \tag{6.35}
\end{align*}
\]

In the case of \(\nu_{H}=1\), all four statistics can be transformed to an exact \(F\) using
\[
\begin{equation*}
F=\frac{\nu_{E}-p+1}{p} U^{(1)} \tag{6.36}
\end{equation*}
\]
which is distributed as \(F_{p, \nu_{E}-p+1}\).
The equivalence of all four test statistics to Hotelling's \(T^{2}\) when \(\nu_{H}=1\) was noted in Section 5.6.1. We now demonstrate the relationship \(T^{2}=\left(n_{1}+n_{2}-\right.\) \(2) U^{(1)}\) in (5.17). For \(\mathbf{H}\) and \(\mathbf{E}\), we use (6.31) and (6.32), which allow unequal \(n_{i}\), since we do not require \(n_{1}=n_{2}\) in \(T^{2}\). In this case, with only two groups, \(\mathbf{H}=\sum_{i=1}^{2} n_{i}\left(\overline{\mathbf{y}}_{i .}-\overline{\mathbf{y}}_{. .}\right)\left(\overline{\mathbf{y}}_{i .}-\overline{\mathbf{y}}_{. .}\right)^{\prime}\) can be expressed as
\[
\begin{equation*}
\mathbf{H}=\frac{n_{1} n_{2}}{n_{1}+n_{2}}\left(\overline{\mathbf{y}}_{1 .}-\overline{\mathbf{y}}_{2 .}\right)\left(\overline{\mathbf{y}}_{1 .}-\overline{\mathbf{y}}_{2 .}\right)^{\prime}=c\left(\overline{\mathbf{y}}_{1 .}-\overline{\mathbf{y}}_{2 .}\right)\left(\overline{\mathbf{y}}_{1 .}-\overline{\mathbf{y}}_{2 .}\right)^{\prime} \tag{6.37}
\end{equation*}
\]
where \(c=n_{1} n_{2} /\left(n_{1}+n_{2}\right)\). Then by (6.33) and (6.27), \(U^{(1)}\) becomes
\[
\begin{align*}
U^{(1)} & =\lambda_{1}=\operatorname{tr}\left(\mathbf{E}^{-1} \mathbf{H}\right) \\
& =\operatorname{tr}\left[c \mathbf{E}^{-1}\left(\overline{\mathbf{y}}_{1 .}-\overline{\mathbf{y}}_{2 .}\right)\left(\overline{\mathbf{y}}_{1 .}-\overline{\mathbf{y}}_{2 .}\right)^{\prime}\right] \quad[\mathbf{b y}(6.37)] \\
& =c \operatorname{tr}\left[\left(\overline{\mathbf{y}}_{1 .}-\stackrel{\overline{\mathbf{y}}}{2 .} 5^{\prime} \mathbf{E}^{-1}\left(\overline{\mathbf{y}}_{1 .}-\overline{\mathbf{y}}_{2 .}\right)\right] \quad[\mathbf{b y}(2.97)]\right. \\
& =\frac{c}{n_{1}+n_{2}-2}\left(\overline{\mathbf{y}}_{1 .}-\overline{\mathbf{y}}_{2 .}\right)^{\prime}\left(\frac{\mathbf{E}}{n_{1}+n_{2}-2}\right)^{-1}\left(\overline{\mathbf{y}}_{1 .}-\overline{\mathbf{y}}_{2 .}\right) \\
& =\frac{T^{2}}{n_{1}+n_{2}-2}, \tag{6.38}
\end{align*}
\]
since \(\mathbf{E} /\left(n_{1}+n_{2}-2\right)=\mathbf{S}_{\mathrm{pl}}\) (see Section 5.4.2). From this result, (5.16), (5.18), and (5.19) follow immediately using (6.33)-(6.35).

Because of the direct relationship in (6.38) between \(U^{(1)}\) and \(T^{2}\) for the case of two groups, the Lawley-Hotelling statistic \(U^{(s)}\) is often called the generalized \(T^{2}\)-statistic.

\section*{EXAMPLE 6.1.7}

In a classical experiment carried out from 1918 to 1934, apple trees of different rootstocks were compared (Andrews and Herzberg 1985, pp. 357-360). The data for eight trees from each of six rootstocks are given in Table 6.2. The variables are
\[
\begin{aligned}
& y_{1}=\text { trunk girth at } 4 \text { years }(\mathrm{mm} \times 100) \\
& y_{2}=\text { extension growth at } 4 \text { years }(\mathrm{m}) \\
& y_{3}=\text { trunk girth at } 15 \text { years }(\mathrm{mm} \times 100) \\
& y_{4}=\text { weight of tree above ground at } 15 \text { years }(\mathrm{lb} \times 1000)
\end{aligned}
\]

The matrices \(\mathbf{H}, \mathbf{E}\), and \(\mathbf{E}+\mathbf{H}\) are given by
\[
\begin{aligned}
\mathbf{H} & =\left(\begin{array}{rrrr}
.074 & .537 & .332 & .208 \\
.537 & 4.200 & 2.355 & 1.637 \\
.332 & 2.355 & 6.114 & 3.781 \\
.208 & 1.637 & 3.781 & 2.493
\end{array}\right), \\
\mathbf{E} & =\left(\begin{array}{rrrr}
.320 & 1.697 & .554 & .217 \\
1.697 & 12.143 & 4.364 & 2.110 \\
.554 & 4.364 & 4.291 & 2.482 \\
.217 & 2.110 & 2.482 & 1.723
\end{array}\right), \\
\mathbf{E}+\mathbf{H} & =\left(\begin{array}{rrrr}
.394 & 2.234 & .886 & .426 \\
2.234 & 16.342 & 6.719 & 3.747 \\
.886 & 6.719 & 10.405 & 6.263 \\
.426 & 3.747 & 6.263 & 4.216
\end{array}\right) .
\end{aligned}
\]

In this case, the mean vectors represent six points in four-dimensional space. We can compare the mean vectors for significant differences using Wilks' \(\Lambda\) as

Table 6.2 Rootstock Data
\begin{tabular}{crrrr}
\hline Rootstock & \(y_{1}\) & \(y_{2}\) & \(y_{3}\) & \(y_{4}\) \\
\hline 1 & 1.11 & 2.569 & 3.58 & .760 \\
1 & 1.19 & 2.928 & 3.75 & .821 \\
1 & 1.09 & 2.865 & 3.93 & .928 \\
1 & 1.25 & 3.844 & 3.94 & 1.009 \\
1 & 1.11 & 3.027 & 3.60 & .766 \\
1 & 1.08 & 2.336 & 3.51 & .726 \\
1 & 1.11 & 3.211 & 3.98 & 1.209 \\
1 & 1.16 & 3.037 & 3.62 & .750 \\
2 & 1.05 & 2.074 & 4.09 & 1.036 \\
2 & 1.17 & 2.885 & 4.06 & 1.094 \\

2 & 1.25 & 3.906 & 4.98 & 1.517 \\
2 & 1.17 & 2.782 & 4.38 & 1.197 \\
2 & 1.15 & 3.018 & 4.65 & 1.244 \\
2 & 1.17 & 3.383 & 4.69 & 1.495 \\
2 & 1.19 & 3.447 & 4.40 & 1.026 \\
3 & 1.07 & 2.505 & 3.76 & .912 \\
3 & .99 & 2.315 & 4.44 & 1.398 \\
3 & 1.06 & 2.667 & 4.38 & 1.197 \\
3 & 1.02 & 2.390 & 4.67 & 1.613 \\
3 & 1.15 & 3.021 & 4.48 & 1.476 \\
3 & 1.20 & 3.085 & 4.78 & 1.571 \\
3 & 1.20 & 3.308 & 4.57 & 1.506 \\
3 & 1.17 & 3.231 & 4.56 & 1.458 \\
4 & 1.22 & 2.838 & 3.89 & .944 \\
4 & 1.03 & 2.351 & 4.05 & 1.241 \\
4 & 1.14 & 3.001 & 4.05 & 1.023 \\
4 & 1.01 & 2.439 & 3.92 & 1.067 \\
4 & .99 & 2.199 & 3.27 & .693 \\
4 & 1.11 & 3.318 & 3.95 & 1.085 \\
4 & 1.20 & 3.601 & 4.27 & 1.242 \\
4 & 1.08 & 3.291 & 3.85 & 1.017 \\
5 & .91 & 1.532 & 4.04 & 1.084 \\
5 & 1.15 & 2.552 & 4.16 & 1.151 \\
5 & 1.14 & 3.083 & 4.79 & 1.381 \\
5 & 1.05 & 2.330 & 4.42 & 1.242 \\
5 & .99 & 2.079 & 3.47 & .673 \\
5 & 1.22 & 3.366 & 4.41 & 1.137 \\
6 & 1.05 & 2.416 & 4.64 & 1.455 \\
6 & 1.11 & 2.469 & 3.95 & .952 \\
6 & 1.07 & 2.251 & 3.21 & .562 \\
5 & 1.13 & 3.100 & 4.57 & 1.325 \\
6 & 1.11 & 2.813 & 3.76 & .800 \\
6 & .75 & .840 & 3.14 & .606 \\
6 & 1.05 & 2.199 & 3.75 & .790 \\
6 & 1.02 & 2.132 & 3.99 & .853 \\
\hline & 1.05 & 1.949 & 3.34 & .610 \\
\hline & & &
\end{tabular}
given by (6.13):
\[
\Lambda=\frac{|\mathbf{E}|}{|\mathbf{E}+\mathbf{H}|}=\frac{.6571}{4.2667}=.154
\]

In this case, the parameters of the Wilks' \(\Lambda\) distribution are \(p=4, \nu_{H}=\) \(6-1=5\), and \(\nu_{E}=6(8-1)=42\). We reject \(H_{0}: \mu_{1}=\mu_{2}=\cdots=\mu_{6}\) because
\[
\Lambda=.154<\Lambda_{.05,4,5,40}=.455 .
\]

Note the use of \(\nu_{E}=40\) in place of \(\nu_{E}=42\). This is a conservative approach that allows a table value to be used without interpolation.

To obtain an approximate \(F\), we first calculate
\[
\begin{aligned}
t & =\sqrt{\frac{p^{2} \nu_{H}^{2}-4}{p^{2}+\nu_{H}^{2}-5}}=\sqrt{\frac{4^{2} 5^{2}-4}{4^{2}+5^{2}-5}}=3.3166, \\
w & =\nu_{E}+\nu_{H}-\frac{1}{2}\left(p+\nu_{H}+1\right)=42+5-\frac{1}{2}(4+5+1)=42 \\
\mathrm{df}_{1} & =p \nu_{H}=4(5)=20, \mathrm{df}_{2}=w t-\frac{1}{2}\left(p \nu_{H}-2\right)=130.3
\end{aligned}
\]

Then the approximate \(F\) is given by (6.15),
\[
F=\frac{1-\Lambda^{1 / t}}{\Lambda^{1 / t}} \frac{\mathrm{df}_{2}}{\mathrm{df}_{1}}=\frac{1-(.154)^{1 / 3.3166}}{(.154)^{1 / 3.3166}} \frac{130.3}{20}=4.937,
\]
which exceeds \(F_{.001,20,120}=2.53\), and we reject \(H_{0}\).
The four eigenvalues of \(\mathbf{E}^{-1} \mathbf{H}\) are 1.876, .791, .229 , and .026 . With these we can calculate the other three test statistics. For Pillai's statistic we have, by (6.24),
\[
V^{(s)}=\sum_{i=1}^{4} \frac{\lambda_{i}}{1+\lambda_{i}}=1.305 .
\]

To find a critical value for \(V^{(s)}\) in Table A.11, we need
\[
\begin{aligned}
s & =\min \left(\nu_{H}, p\right)=4, \quad m=\frac{1}{2}\left(\left|\nu_{H}-p\right|-1\right)=0, \\
N & =\frac{1}{2}\left(\nu_{E}-p-1\right)=18.5
\end{aligned}
\]

Then \(V_{.05}^{(s)}=.645\) (by interpolation). Since \(1.305>.645\), we reject \(H_{0}\).
For the Lawley-Hotelling statistic we obtain, by (6.27),
\[
U^{(s)}=\sum_{i=1}^{s} \lambda_{i}=2.921
\]

To make the test, we calculate the test statistic
\[
\frac{\nu_{E}}{\nu_{H}} U^{(s)}=\frac{42}{5}(2.921)=24.539 .
\]

The .05 critical value for \(\nu_{E} U^{(s)} / \nu_{H}\) is given in Table A. 12 as 7.6188 (using \(\nu_{E}=40\) ), and we therefore reject \(H_{0}\).

Roy's test statistic is given by (6.20) as
\[
\theta=\frac{\lambda_{1}}{1+\lambda_{1}}=\frac{1.876}{1+1.876}=.652
\]
which exceeds the .05 critical value .377 obtained (by interpolation) from Table A. 10 , and we reject \(H_{0}\).

\subsection*{6.1.8 Measures of Multivariate Association}

In multiple regression, a measure of association between the dependent variable \(y\) and the independent variables \(x_{1}, x_{2}, \ldots, x_{q}\) is given by the squared multiple correlation
\[
\begin{equation*}
R^{2}=\frac{\text { regression sum of squares }}{\text { total sum of squares }} \tag{6.39}
\end{equation*}
\]

Similarly, in one-way univariate ANOVA, Fisher's correlation ratio \(\eta^{2}\) is defined as
\[
\eta^{2}=\frac{\text { between sum of squares }}{\text { total sum of squares }}
\]

This is a measure of model fit similar to \(R^{2}\) and gives the proportion of variation in the dependent variable \(y\) attributable to differences among the means of the groups. It answers the question "How well can we predict \(y\) by knowing what group it is from?" Thus \(\eta^{2}\) can be considered to be a measure of association between the dependent variable \(y\) and the grouping variable \(i\) associated with \(\mu_{i}\) or \(\alpha_{i}\) in the model (6.2). In fact, if the grouping variable is represented by \(k-1\) dummy variables (also called indicator or categorical variables), then we have a dependent variable related to several independent variables as in multiple regression.

A dummy variable takes on the value 1 for sampling units in a group (sample) and 0 for all other sampling units. (Values other than 0 and 1 could be used.) Thus for \(k\) samples (groups), the \(k-1\) dummy variables are
\[
x_{i}=\left\{\begin{array}{ll}
1 & \text { if sampling unit is in } i \text { th group } \\
0 & \text { otherwise }
\end{array} \quad i=1,2, \ldots, k-1 .\right.
\]

Only \(k-1\) dummy variables are needed because if \(x_{1}=x_{2}=\cdots=x_{k-1}=0\), the sampling unit must be from the \(k\) th group (see Section 11.6 .2 for an illustration). The dependent variable \(y\) can be regressed on the \(k-1\) dummy variables \(x_{1}, x_{2}, \ldots, x_{k-1}\) to produce results equivalent to the usual ANOVA calculations.

In (one-way) MANOVA, we need to measure the strength of the association between several dependent variables and several independent (grouping) variables. Various measurements of multivariate association have been proposed. Wilks (1932) suggested a "generalized \(\eta^{2}\) ":
\[
\begin{equation*}
\operatorname{MANOVA} \eta^{2}=\eta_{\Lambda}^{2}=1-\Lambda \tag{6.40}
\end{equation*}
\]
based on the use of \(|\mathbf{E}|\) and \(|\mathbf{E}+\mathbf{H}|\) as generalizations of sums of squares. We use \(1-\Lambda\) because \(\Lambda\) is small if the spread in the means is large.

We now consider an \(\eta^{2}\) based on Roy's statistic, \(\theta\). We noted in Section 6.1.4 that the discriminant function is the linear function \(z=\mathbf{a}_{1}^{\prime} \mathbf{y}\) that maximizes the spread of the means \(\bar{z}_{i}\). \(=\mathbf{a}_{1}^{\prime} \overline{\mathbf{y}}_{i}, i=1,2, \ldots, k\), where \(\mathbf{a}_{\mathbf{1}}\) is the eigenvector of \(\mathbf{E}^{-1} \mathbf{H}\) corresponding to the largest eigenvalue \(\lambda_{1}\). We measure the spread among the means by \(\mathrm{SSH}=n \sum_{i=1}^{k}\left(\bar{z}_{i} .-\bar{z}_{.}\right)^{2}\), divided by the within-sample spread SSE \(=\sum_{i j}\left(z_{i j}-\bar{z}_{i .}\right)^{2}\). The maximum value of this ratio is given by \(\lambda_{1}\) [see (6.19)]. Thus
\[
\lambda_{1}=\frac{\operatorname{SSH}(z)}{\operatorname{SSE}(z)}
\]
and by (6.20),
\[
\begin{equation*}
\theta=\frac{\lambda_{1}}{1+\lambda_{1}}=\frac{\operatorname{SSH}(z)}{\operatorname{SSE}(z)+\operatorname{SSH}(z)} \tag{6.41}
\end{equation*}
\]

Hence \(\theta\) serves directly as a measure of multivariate association:
\[
\begin{equation*}
\eta_{\theta}^{2}=\theta=\frac{\lambda_{1}}{1+\lambda_{1}} \tag{6.42}
\end{equation*}
\]

It can be shown that the square root of this quantity,
\[
\begin{equation*}
\eta_{\theta}=\sqrt{\frac{\lambda_{1}}{1+\lambda_{1}}}, \tag{6.43}
\end{equation*}
\]
is the maximum correlation between a linear combination of the \(p\) dependent variables and a linear combination of the \(k-1\) dummy group variables (see Section 11.6.2). This type of correlation is often called a canonical correlation (see Chapter 11) and is defined for each eigenvalue \(\lambda_{1}, \lambda_{2}, \ldots, \lambda_{s}\) as \(r_{i}=\sqrt{\lambda_{i} /\left(1+\lambda_{i}\right)}\).

We now consider some measures of multivariate association suggested by Cramer and Nicewander (1979) and Muller and Peterson (1984). It is easily shown (Section 11.6.2) that \(\Lambda\) can be expressed as
\[
\begin{equation*}
\Lambda=\prod_{i=1}^{s} \frac{1}{1+\lambda_{i}}=\prod_{i=1}^{s}\left(1-r_{i}^{2}\right) \tag{6.44}
\end{equation*}
\]
where \(r_{i}^{2}=\lambda_{i} /\left(1+\lambda_{i}\right)\) is the \(i\) th squared canonical correlation described above. The geometric mean of a set of positive numbers \(a_{1}, a_{2}, \ldots, a_{n}\) is defined as \(\left(a_{1} a_{2} \ldots a_{n}\right)^{1 / n}\). Thus \(\Lambda^{1 / s}\) is the geometric mean of the \(\left(1-r_{i}^{2}\right)\) 's, and another measure of multivariate association based on \(\Lambda\), in addition to that in (6.40), is
\[
\begin{equation*}
A_{\Lambda}=1-\Lambda^{1 / s} \tag{6.45}
\end{equation*}
\]

In fact, as noted by Muller and Peterson, the \(F\)-approximation given in (6.15),
\[
F=\frac{1-\Lambda^{1 / t}}{\Lambda^{1 / t}} \frac{\mathrm{df}_{2}}{\mathrm{df}_{1}}
\]
is very similar to the univariate \(F\)-statistic (10.31) for testing significance in multiple regression,
\[
\begin{equation*}
F=\frac{R^{2} /(\text { df model })}{\left(1-R^{2}\right) /(\text { df error })}, \tag{6.46}
\end{equation*}
\]
based on \(R^{2}\) in (6.39).
Pillai's statistic is easily expressible as the sum of the squared canonical correlations:
\[
\begin{equation*}
V^{(s)}=\sum_{i=1}^{s} \frac{\lambda_{i}}{1+\lambda_{i}}=\sum_{i=1}^{s} r_{i}^{2} \tag{6.47}
\end{equation*}
\]
and the average of the \(r_{i}^{2}\) can be used as a measure of multivariate association:
\[
\begin{equation*}
A_{P}=\frac{\sum_{i=1}^{s} r_{i}^{2}}{s}=\frac{V^{(s)}}{s} \tag{6.48}
\end{equation*}
\]

In terms of \(A_{P}\) the \(F\)-approximation given in (6.26) becomes
\[
\begin{equation*}
F_{2}=\frac{A_{p} / p \nu_{H}}{\left(1-A_{p}\right) / s\left(\nu_{E}-\nu_{H}+s\right)}, \tag{6.49}
\end{equation*}
\]
which has an obvious parallel to (6.46).
For the Lawley-Hotelling statistic \(U^{(s)}\), a multivariate measure of association can be defined as
\[
\begin{equation*}
A_{\mathrm{LH}}=\frac{U^{(s)} / s}{1+U^{(s)} / s} \tag{6.50}
\end{equation*}
\]

If \(s=1,(6.50)\) reduces to (6.42). In fact, (6.42) is a special case of (6.50) because \(U^{(s)} / s=\sum_{i=1}^{s} \lambda_{i} / s\) is the arithmetic average of the \(\lambda_{i}\) 's. It is easily seen that the \(F\)-approximation \(F_{3}\) for the Lawley-Hotelling statistic given in (6.30) can be expressed in terms of \(A_{\mathrm{LH}}\) as
\[
\begin{equation*}
F_{3}=\frac{A_{\mathrm{LH}} / p \nu_{H}}{\left(1-A_{\mathrm{LH}}\right) /\left[s\left(\nu_{E}-p-1\right)+2\right]} \tag{6.51}
\end{equation*}
\]
which resembles (6.46).

\section*{■ EXAMPLE 6.1.8}

We illustrate some measures of association for the rootstock data in Table 6.2:
\[
\begin{aligned}
\eta_{\Lambda}^{2} & =1-\Lambda=.846 \\
\eta_{\theta}^{2} & =\theta=.652 \\
A_{\Lambda} & =1-\Lambda^{1 / 4}=1-(.154)^{1 / 4}=.374 \\
A_{P} & =V^{(s)} / s=1.305 / 4=.326 \\
A_{\mathrm{LH}} & =\frac{U^{(s)} / s}{1+U^{(s)} / s}=\frac{2.921 / 4}{1+2.921 / 4}=.422
\end{aligned}
\]

There is a wide range of values among these measures of association.

Figure 6.2 Two possible configurations for three mean vectors in 3-space.

\subsection*{6.2 COMPARISON OF THE FOUR MANOVA TEST STATISTICS}

When \(H_{0}: \mu_{1}=\mu_{2}=\cdots=\mu_{k}\) is true, all the mean vectors are at the same point. Therefore, all four MANOVA test statistics have the same Type I error rate, \(\alpha\), as noted in Section 6.1.7; that is, all have the same probability of rejection when \(H_{0}\) is true. However, when \(H_{0}\) is false, the four tests have different probabilities of rejection. We noted in Section 6.1.7 that in a given sample the four tests need not agree, even if \(H_{0}\) is true. One test could reject \(H_{0}\) and the others accept \(H_{0}\), for example.

Historically, Wilks' \(\Lambda\) has played the dominant role in MANOVA significance tests because it was the first to be derived and has well-known \(\chi^{2}\) - and \(F\)-approximations. It can also be partitioned in certain ways we will find useful later. However, it is not always the most powerful among the four tests. The probability of rejecting \(H_{0}\) when it is false is known as the power of the test.

In univariate ANOVA with \(p=1\), the means \(\mu_{1}, \mu_{2}, \ldots, \mu_{k}\) can be uniquely ordered along a line in one dimension, and the usual \(F\)-test is uniformly most powerful. In the multivariate case, on the other hand, with \(p>1\), the mean vectors are points in \(s=\min \left(p, \nu_{H}\right)\) dimensions. We have four tests, not one of which is uniformly most powerful. The relative powers of the four test statistics depend on the configuration of the mean vectors \(\boldsymbol{\mu}_{1}, \boldsymbol{\mu}_{2}, \ldots, \boldsymbol{\mu}_{k}\) in the \(s\)-dimensional space. A given test will be more powerful for one configuration of mean vectors than another.

If \(\nu_{H}<p\), then \(s=\nu_{H}\) and the mean vectors lie in an \(s\)-dimensional subspace of the \(p\)-dimensional space of the observations. The points may, in fact, occupy a subspace of the \(s\) dimensions. For example, they may be confined to a line (one dimension) or a plane (two dimensions). This is illustrated in Figure 6.2.

An indication of the pattern of the mean vectors is given by the eigenvalues of \(\mathbf{E}^{-1} \mathbf{H}\). If there is one large eigenvalue and the others are small, the mean vectors lie close to a line. If there are two large eigenvalues, the mean vectors lie mostly in two dimensions, and so on.

Because Roy's test uses only the largest eigenvalue of \(\mathbf{E}^{-1} \mathbf{H}\), it is more powerful than the others if the mean vectors are collinear. The other three tests have greater power than Roy's when the mean vectors are diffuse (spread out in several dimensions).

In terms of power, the tests are ordered \(\theta \geq U^{(s)} \geq \Lambda \geq V^{(s)}\) for the collinear case. In the diffuse case and for intermediate structure between collinear and diffuse, the ordering of power is reversed, \(V^{(s)} \geq \Lambda \geq U^{(s)} \geq \theta\). The latter ordering also holds for accuracy of the Type I error rate when the population covariance matrices \(\boldsymbol{\Sigma}_{\mathbf{1}}, \boldsymbol{\Sigma}_{2}, \ldots, \boldsymbol{\Sigma}_{k}\) are not equal. These orderings are comparisons of power. For actual computation of power in a given experimental setting or to find the sample size needed to yield a desired level of power, see Rencher (1998, Section 4.4).

Generally, if group sizes are equal, the tests are sufficiently robust with respect to heterogeneity of covariance matrices so that we need not worry. If the \(n_{i}\) 's are unequal and we have heterogeneity, then the \(\alpha\)-level of the MANOVA test may be affected as follows. If the larger variances and covariances are associated with the larger samples, the true \(\alpha\)-level is reduced and the tests become conservative. On the other hand, if the larger variances and covariances come from the smaller samples, \(\alpha\) is inflated, and the tests become liberal. Box's \(M\)-test in Section 7.3.2 can be used to test for homogeneity of covariance matrices.

In conclusion, the use of Roy's \(\theta\) is not recommended in any situation except the collinear case under standard assumptions. In the diffuse case its performance is inferior to that of the other three tests, both when the assumptions hold and when they do not. If the data come from nonnormal populations exhibiting skewness or positive kurtosis, any of the other three tests perform acceptably well. Among these three, \(V^{(s)}\) is superior to the other two when there is heterogeneity of covariance matrices. Indeed \(V^{(s)}\) is first in all rankings except those for the collinear case. However, \(\Lambda\) is not far behind, except when there is severe heterogeneity of covariance matrices. It seems likely that Wilks' \(\Lambda\) will continue its dominant role because of its flexibility and historical precedence.

In practice, most MANOVA software programs routinely calculate all four test statistics, and they usually reach the same conclusion. In those cases when they differ as to acceptance or rejection of the hypothesis, one can examine the eigenvalues and covariance matrices and evaluate the conflicting conclusions in light of the test properties discussed previously.

\section*{EXAMPLE 6.2}

We inspect the eigenvalues of \(\mathbf{E}^{-1} \mathbf{H}\) for the rootstock data of Table 6.2 for an indication of the configuration of the six mean vectors in a four-dimensional space. The eigenvalues are \(1.876, .791, .229, .026\). The first eigenvalue 1.876 constitutes a proportion
\[
\frac{1.876}{1.876+.791+.229+.026}=.642
\]
of the sum of the eigenvalues. Therefore, the first eigenvalue does not dominate the others and the mean vectors are not collinear. The first two eigenvalues account for a proportion
\[
\frac{1.876+.791}{1.876+\cdots+.026}=.913
\]
of the sum of the eigenvalues, and thus the six mean vectors lie largely in two dimensions. Since the mean vectors are not collinear, the test statistics \(\Lambda, V^{(s)}\), and \(U^{(s)}\) will be more appropriate than \(\theta\) in this case.

\subsection*{6.3 CONTRASTS}

As in Sections 6.1.1-6.1.5, we consider only the balanced model where \(n_{1}=n_{2}=\) \(\cdots=n_{k}=n\). We begin with a review of contrasts in the univariate setting before moving to the multivariate case.

\subsection*{6.3.1 Univariate Contrasts}

A contrast in the population means is defined as a linear combination
\[
\begin{equation*}
\delta=c_{1} \mu_{1}+c_{2} \mu_{2}+\cdots+c_{k} \mu_{k} \tag{6.52}
\end{equation*}
\]
where the coefficients satisfy
\[
\begin{equation*}
\sum_{i=1}^{k} c_{i}=0 \tag{6.53}
\end{equation*}
\]

An unbiased estimator of \(\delta\) is given by
\[
\begin{equation*}
\hat{\delta}=c_{1} \bar{y}_{1 .}+c_{2} \bar{y}_{2}+\cdots+c_{k} \bar{y}_{k .} \tag{6.54}
\end{equation*}
\]

The sample means \(\bar{y}_{i \text {. }}\) were defined in (6.1). Since the \(\bar{y}_{i}\) 's are independent with variance \(\sigma^{2} / n\), the variance of \(\hat{\delta}\) is
\[
\operatorname{var}(\hat{\delta})=\frac{\sigma^{2}}{n} \sum_{i=1}^{k} c_{i}^{2}
\]
which can be estimated by
\[
\begin{equation*}
s_{\hat{\delta}}^{2}=\frac{\mathrm{MSE}}{n} \sum_{i=1}^{k} c_{i}^{2} \tag{6.55}
\end{equation*}
\]
where MSE was defined in (6.6) and (6.7) as SSE \(/ k(n-1)\).
The usual hypothesis to be tested by a contrast is
\[
H_{0}: \delta=c_{1} \mu_{1}+c_{2} \mu_{2}+\cdots+c_{k} \mu_{k}=0
\]

For example, suppose \(k=4\) and that a contrast of interest to the researcher is \(3 \mu_{1}-\) \(\mu_{2}-\mu_{3}-\mu_{4}\). If this contrast is set equal to zero, we have
\[
3 \mu_{1}=\mu_{2}+\mu_{3}+\mu_{4} \quad \text { or } \quad \mu_{1}=\frac{1}{3}\left(\mu_{2}+\mu_{3}+\mu_{4}\right)
\]
and the experimenter is comparing the first mean with the average of the other three. A contrast is often called a comparison among the treatment means.

Assuming normality, \(H_{0}: \delta=0\) can be tested by
\[
\begin{equation*}
t=\frac{\hat{\delta}-0}{s_{\hat{\delta}}}, \tag{6.56}
\end{equation*}
\]
which is distributed as \(t_{\nu_{E}}\). Alternatively, since \(t^{2}=F\), we can use
\[
\begin{align*}
F & =\frac{\hat{\delta}^{2}}{s_{\hat{\delta}}^{2}}=\frac{\left(\sum_{i=1}^{k} c_{i} \bar{y}_{i .}\right)^{2}}{\operatorname{MSE} \sum_{i=1}^{k} c_{i}^{2} / n} \\
& =\frac{n\left(\sum_{i} c_{i} \bar{y}_{i .}\right)^{2} / \sum_{i} c_{i}^{2}}{\operatorname{MSE}} \tag{6.57}
\end{align*}
\]
which is distributed as \(F_{1, \nu_{E}}\). The numerator of (6.57) is often referred to as the sum of squares for the contrast.

If two contrasts \(\delta=\sum_{i} a_{i} \mu_{i}\) and \(\gamma=\sum_{i} b_{i} \mu_{i}\) are such that \(\sum_{i} a_{i} b_{i}=0\), the contrasts are said to be orthogonal. The two estimated contrasts can be written in the form \(\sum_{i} a_{i} \bar{y}_{i .}=\mathbf{a}^{\prime} \overline{\mathbf{y}}\) and \(\sum_{i} b_{i} \bar{y}_{i .}=\mathbf{b}^{\prime} \overline{\mathbf{y}}\), where \(\overline{\mathbf{y}}=\left(\bar{y}_{1 .}, \bar{y}_{2 .}, \ldots, \bar{y}_{k .}\right)^{\prime}\). Then \(\sum_{i} a_{i} b_{i}=\mathbf{a}^{\prime} \mathbf{b}=0\), and by the discussion following (3.14), the coefficient vectors \(\mathbf{a}\) and \(b\) are perpendicular.

When two contrasts are orthogonal, the two corresponding sums of squares are independent. In fact, for \(k\) treatments, we can find \(k-1\) orthogonal contrasts that partition the treatment sum of squares SSH into \(k-1\) independent sums of squares, each with one degree of freedom. In the unbalanced case (Section 6.1.6), orthogonal contrasts such that \(\sum_{i} a_{i} b_{i}=0\) no longer partition SSH into \(k-1\) independent sums of squares. For a discussion of contrasts in the unbalanced case, see Rencher (1998, Sections 4.8.2 and 4.8.3) or Rencher and Schaalje (2008, Section 15.2.2).

\subsection*{6.3.2 Multivariate Contrasts}

There are two usages of contrasts in a multivariate setting. We have previously encountered one use in Section 5.9.1, where we considered the hypothesis \(H_{0}: \mathbf{C} \boldsymbol{\mu}=\) \(\mathbf{0}\) with \(\mathbf{C j}=\mathbf{0}\). Each row of \(\mathbf{C}\) sums to zero, and \(\mathbf{C} \boldsymbol{\mu}\) is therefore a set of contrasts comparing the elements \(\mu_{1}, \mu_{2}, \ldots, \mu_{p}\) of \(\boldsymbol{\mu}\) with each other. In this section, on the other hand, we consider contrasts comparing several mean vectors, not the elements within a vector.

A contrast among the population mean vectors is defined as
\[
\begin{equation*}
\boldsymbol{\delta}=c_{1} \boldsymbol{\mu}_{1}+c_{2} \boldsymbol{\mu}_{2}+\cdots+c_{k} \boldsymbol{\mu}_{k}, \tag{6.58}
\end{equation*}
\]
where \(\sum_{i=1}^{k} c_{i}=0\). An unbiased estimator of \(\delta\) is given by the corresponding contrast in the sample mean vectors:
\[
\begin{equation*}
\hat{\boldsymbol{\delta}}=c_{1} \overline{\mathbf{y}}_{1 .}+c_{2} \overline{\mathbf{y}}_{2 .}+\cdots+c_{k} \overline{\mathbf{y}}_{k} . \tag{6.59}
\end{equation*}
\]

The sample mean vectors \(\overline{\mathbf{y}}_{1}, \overline{\mathbf{y}}_{2,}, \ldots, \overline{\mathbf{y}}_{k}\). as defined in Section 6.1 .2 were assumed to be independent and to have common covariance matrix, \(\operatorname{cov}\left(\overline{\mathbf{y}}_{i .}\right)=\boldsymbol{\Sigma} / n\). Thus the covariance matrix for \(\hat{\delta}\) is given by
\[
\begin{equation*}
\operatorname{cov}(\hat{\boldsymbol{\delta}})=c_{1}^{2} \frac{\boldsymbol{\Sigma}}{n}+c_{2}^{2} \frac{\boldsymbol{\Sigma}}{n}+\cdots+c_{k}^{2} \frac{\boldsymbol{\Sigma}}{n}=\frac{\boldsymbol{\Sigma}}{n} \sum_{i=1}^{k} c_{i}^{2} \tag{6.60}
\end{equation*}
\]
which can be estimated by
\[
\frac{\mathbf{S}_{\mathrm{pl}}}{n} \sum_{i=1}^{k} c_{i}^{2}=\left(\frac{\mathbf{E}}{\nu_{E}}\right)\left(\frac{\sum_{i=1}^{k} c_{i}^{2}}{n}\right)
\]
where \(\mathbf{S}_{\mathrm{pl}}=\mathbf{E} / \nu_{E}\) is an unbiased estimator of \(\boldsymbol{\Sigma}\).
The hypothesis \(H_{0}: \boldsymbol{\delta}=\mathbf{0}\) or \(H_{0}: c_{1} \boldsymbol{\mu}_{1}+c_{2} \boldsymbol{\mu}_{2}+\cdots+c_{k} \boldsymbol{\mu}_{k}=\mathbf{0}\) makes comparisons among the population mean vectors. For example, \(\boldsymbol{\mu}_{1}-2 \boldsymbol{\mu}_{2}+\boldsymbol{\mu}_{3}=\mathbf{0}\) is equivalent to
\[
\boldsymbol{\mu}_{2}=\frac{1}{2}\left(\boldsymbol{\mu}_{1}+\boldsymbol{\mu}_{3}\right),
\]
and we are comparing \(\mu_{2}\) to the average of \(\mu_{1}\) and \(\mu_{3}\). Of course, this implies that every element of \(\boldsymbol{\mu}_{2}\) must equal the corresponding element of \(\frac{1}{2}\left(\boldsymbol{\mu}_{1}+\boldsymbol{\mu}_{3}\right)\) :
\[
\left(\begin{array}{c}
\mu_{21} \\
\mu_{22} \\
\vdots \\
\mu_{2 p}
\end{array}\right)=\left(\begin{array}{c}
\frac{1}{2}\left(\mu_{11}+\mu_{31}\right) \\
\frac{1}{2}\left(\mu_{12}+\mu_{32}\right) \\
\vdots \\
\frac{1}{2}\left(\mu_{1 p}+\mu_{3 p}\right)
\end{array}\right) .
\]

Under appropriate multivariate normality assumptions, \(H_{0}: c_{1} \mu_{1}+c_{2} \mu_{2}+\cdots+\) \(c_{k} \mu_{k}=\mathbf{0}\) or \(H_{0}: \boldsymbol{\delta}=\mathbf{0}\) can be tested with the one-sample \(T^{2}\)-statistic
\[
\begin{align*}
T^{2} & =\hat{\boldsymbol{\delta}}^{\prime}\left(\frac{\mathbf{S}_{\mathrm{p}}}{n} \sum_{i=1}^{k} c_{i}^{2}\right)^{-1} \hat{\boldsymbol{\delta}} \\
& =\frac{n}{\sum_{i=1}^{k} c_{i}^{2}}\left(\sum_{i=1}^{k} c_{i} \overline{\mathbf{y}}_{i .}\right)^{\prime}\left(\frac{\mathbf{E}}{\nu_{E}}\right)^{-1}\left(\sum_{i=1}^{k} c_{i} \overline{\mathbf{y}}_{i .}\right), \tag{6.61}
\end{align*}
\]
which is distributed as \(T_{p, \nu_{E}}^{2}\). In the one-way model under discussion here, \(\nu_{E}=\) \(k(n-1)\).

An equivalent test of \(H_{0}\) can be made with Wilks' \(\Lambda\). By analogy with the numerator of (6.57), the hypothesis matrix due to the contrast is given by
\[
\begin{equation*}
\mathbf{H}_{1}=\frac{n}{\sum_{i=1}^{k} c_{i}^{2}}\left(\sum_{i=1}^{k} c_{i} \overline{\mathbf{y}}_{i .}\right)\left(\sum_{i=1}^{k} c_{i} \overline{\mathbf{y}}_{i .}\right)^{\prime} . \tag{6.62}
\end{equation*}
\]

The rank of \(\mathbf{H}_{1}\) is 1, and the test statistic is
\[
\begin{equation*}
\Lambda=\frac{|\mathbf{E}|}{\left|\mathbf{E}+\mathbf{H}_{1}\right|} \tag{6.63}
\end{equation*}
\]
which is distributed as \(\Lambda_{p, 1, \nu_{E}}\). The other three MANOVA test statistics can also be applied here using the single nonzero eigenvalue of \(\mathbf{E}^{-1} \mathbf{H}_{1}\). Because \(\nu_{H}=1\) in this case, all four MANOVA statistics and \(T^{2}\) give the same results; that is, all five transform to the same \(F\)-value using the formulations in Section 6.1.7. If \(k-1\) orthogonal contrasts are used, they partition the \(\mathbf{H}\) matrix into \(k-1\) independent matrices \(\mathbf{H}_{1}, \mathbf{H}_{2}, \ldots, \mathbf{H}_{k-1}\). Each \(\mathbf{H}_{i}\) matrix has one degree of freedom because rank \(\left(\mathbf{H}_{i}\right)=1\).

\section*{EXAMPLE 6.3.2}

We consider the following two orthogonal contrasts for the rootstock data in Table 6.2:
\[
\begin{array}{rrrrrr}
2 & -1 & -1 & -1 & -1 & 2 \\
1 & 0 & 0 & 0 & 0 & -1 .
\end{array}
\]

The first compares \(\mu_{1}\) and \(\mu_{6}\) with the other four mean vectors. The second compares \(\mu_{1}\) vs. \(\mu_{6}\). Thus \(H_{01}: 2 \mu_{1}-\mu_{2}-\mu_{3}-\mu_{4}-\mu_{5}+2 \mu_{6}=\mathbf{0}\) can be written as
\[
H_{01}: 2 \mu_{1}+2 \mu_{6}=\mu_{2}+\mu_{3}+\mu_{4}+\mu_{5}
\]

Dividing both sides by 4 so as to express this in terms of averages, we obtain
\[
H_{01}: \frac{1}{2}\left(\boldsymbol{\mu}_{1}+\boldsymbol{\mu}_{6}\right)=\frac{1}{4}\left(\boldsymbol{\mu}_{2}+\boldsymbol{\mu}_{3}+\boldsymbol{\mu}_{4}+\boldsymbol{\mu}_{5}\right)
\]

Similarly, the hypothesis for the second contrast can be expressed as
\[
H_{02}: \boldsymbol{\mu}_{1}=\boldsymbol{\mu}_{6}
\]

The mean vectors are given by
\begin{tabular}{rccccc}
\(\overline{\mathbf{y}}_{1 .}\) & \(\overline{\mathbf{y}}_{2 .}\) & \(\overline{\mathbf{y}}_{3 .}\) & \(\overline{\mathbf{y}}_{4 .}\) & \(\overline{\mathbf{y}}_{5 .}\) & \(\overline{\mathbf{y}}_{6 .}\) \\
\hline 1.14 & 1.16 & 1.11 & 1.10 & 1.08 & 1.04 \\
2.98 & 3.11 & 2.82 & 2.88 & 2.56 & 2.21 \\
3.74 & 4.52 & 4.46 & 3.91 & 4.31 & 3.60 \\
.87 & 1.28 & 1.39 & 1.04 & 1.18 & .74
\end{tabular}

For the first contrast, we obtain \(\mathbf{H}_{1}\) from (6.62) as
\[
\begin{aligned}
\mathbf{H}_{1} & =\frac{n}{\sum_{i} c_{i}^{2}}\left(\sum_{i} c_{i} \overline{\mathbf{y}}_{i .}\right)\left(\sum_{i} c_{i} \overline{\mathbf{y}}_{i} .\right)^{\prime} \\
& =\frac{8}{12}\left(2 \overline{\mathbf{y}}_{1 .}-\overline{\mathbf{y}}_{2 .}-\cdots+2 \overline{\mathbf{y}}_{6 .}\right)\left(2 \overline{\mathbf{y}}_{1 .}-\overline{\mathbf{y}}_{2 .}-\cdots+2 \overline{\mathbf{y}}_{6 .}\right)^{\prime} \\
& =\frac{8}{12}\left(\begin{array}{c}
-.095 \\
-.978 \\
-2.519 \\
-1.680
\end{array}\right)(-.095,-.978,-2.519,-1.680)
\end{aligned}
\]
\[
=\left(\begin{array}{rrrr}
.006 & .062 & .160 & .106 \\
.062 & .638 & 1.642 & 1.095 \\
.160 & 1.642 & 4.229 & 2.820 \\
.106 & 1.095 & 2.820 & 1.881
\end{array}\right)
\]

Then
\[
\Lambda=\frac{|\mathbf{E}|}{\left|\mathbf{E}+\mathbf{H}_{1}\right|}=\frac{.6571}{1.4824}=.443
\]
which is less than \(\Lambda_{.05,4,1,40}=.779\) from Table A.9. We therefore reject \(H_{01}\).
To test the significance of the second contrast, we have
\[
\begin{aligned}
\mathbf{H}_{2} & =\frac{8}{2}\left(\overline{\mathbf{y}}_{1 .}-\overline{\mathbf{y}}_{6 .}\right)\left(\overline{\mathbf{y}}_{1 .}-\overline{\mathbf{y}}_{6 .}\right)^{\prime} \\
& =\frac{8}{2}\left(\begin{array}{c}
.101 \\
.762 \\
.142 \\
.136
\end{array}\right)(.101, .762, .142, .136) \\
& =\left(\begin{array}{rrrr}
.041 & .309 & .058 & .055 \\
.309 & 2.326 & .435 & .415 \\
.058 & .435 & .081 & .078 \\
.055 & .415 & .078 & .074
\end{array}\right)
\end{aligned}
\]

Then
\[
\Lambda=\frac{|\mathbf{E}|}{\left|\mathbf{E}+\mathbf{H}_{2}\right|}=\frac{.6571}{.8757}=.750
\]
which is less than \(\Lambda_{.05,4,1,40}=.779\), and we reject \(H_{02}\).

\subsection*{6.4 TESTS ON INDIVIDUAL VARIABLES FOLLOWING REJECTION OF \(H_{0}\) BY THE OVERALL MANOVA TEST}

In Section 6.1, we considered tests of equality of mean vectors, \(H_{0}: \boldsymbol{\mu}_{1}=\boldsymbol{\mu}_{2}=\) \(\cdots=\mu_{k}\), which implies equality of means for each of the \(p\) variables:
\[
H_{0 r}: \mu_{1 r}=\mu_{2 r}=\cdots=\mu_{k r}, \quad r=1,2, \ldots, p
\]

This hypothesis could be tested for each variable by itself with an ordinary univariate ANOVA \(F\)-test, as noted in property 9 in Section 6.1.3. For example, if there are three mean vectors,
\[
\boldsymbol{\mu}_{1}=\left(\begin{array}{c}
\mu_{11} \\
\mu_{12} \\
\vdots \\
\mu_{1 p}
\end{array}\right), \quad \boldsymbol{\mu}_{2}=\left(\begin{array}{c}
\mu_{21} \\
\mu_{22} \\
\vdots \\
\mu_{2 p}
\end{array}\right), \quad \boldsymbol{\mu}_{3}=\left(\begin{array}{c}
\mu_{31} \\
\mu_{32} \\
\vdots \\
\mu_{3 p}
\end{array}\right)
\]
we have \(H_{01}: \mu_{11}=\mu_{21}=\mu_{31}, H_{02}: \mu_{12}=\mu_{22}=\mu_{32}, \ldots, H_{0 p}: \mu_{1 p}=\mu_{2 p}=\) \(\mu_{3 p}\). Each of these \(p\) hypotheses can be tested with a simple ANOVA \(F\)-test.

If an \(F\)-test is made on each of the \(p\) variables regardless of whether the overall MANOVA test of \(H_{0}: \mu_{1}=\mu_{2}=\mu_{3}\) rejects \(H_{0}\), then the overall \(\alpha\)-level will increase beyond the nominal value because we are making \(p\) tests. As in Section 5.5, we define the overall \(\alpha\) or experimentwise error rate as the probability of rejecting one or more of the \(p\) univariate tests when \(H_{0}: \mu_{1}=\mu_{2}=\mu_{3}\) is true. We could "protect" against inflation of the experimentwise error rate by performing tests on individual variables only if the overall MANOVA test of \(H_{0}: \boldsymbol{\mu}_{1}=\boldsymbol{\mu}_{2}=\boldsymbol{\mu}_{3}\) is rejected. In this procedure, the probability of rejection for the tests on individual variables is reduced, and these tests become more conservative.

Rencher and Scott (1990) compared the above two procedures for testing the individual variables in a one-way MANOVA model. Since the focus was on \(\alpha\)-levels, only the case where \(H_{0}\) is true was considered. Specifically, the two procedures were as follows:
1. A univariate \(F\)-test is made on each variable, testing \(H_{0 r}: \mu_{1 r}=\mu_{2 r}=\) \(\cdots=\mu_{k r}, r=1,2, \ldots, p\). In this context, the \(p\) univariate tests constitute an experiment and one or more rejections are counted as one experimentwise error. No multivariate test is made.
2. The overall MANOVA hypothesis \(H_{0}: \boldsymbol{\mu}_{1}=\boldsymbol{\mu}_{2}=\cdots=\boldsymbol{\mu}_{k}\) is tested with Wilks' \(\Lambda\), and if \(H_{0}\) is rejected, \(p\) univariate \(F\)-tests on \(H_{01}, H_{02}, \ldots, H_{0 p}\) are carried out. Again, one or more rejections among the \(F\)-tests are counted as one experimentwise error.

The amount of intercorrelation among the multivariate normal variables was indicated by \(\sum_{i=1}^{p}\left(1 / \lambda_{i}\right) / p\), where \(\lambda_{1}, \lambda_{2}, \ldots, \lambda_{p}\) are the eigenvalues of the population correlation matrix \(\mathbf{P}_{\rho}\). Note that \(\sum_{i}\left(1 / \lambda_{i}\right) / p=1\) for the uncorrelated case \(\left(\mathbf{P}_{\rho}=\mathbf{I}\right)\) and \(\sum_{i}\left(1 / \lambda_{i}\right) / p>1\) for the correlated case \(\left(\mathbf{P}_{\rho} \neq \mathbf{I}\right)\). When the variables are highly intercorrelated, one or more of the eigenvalues will be near zero (see Section 4.1.3), and \(\sum_{i}\left(1 / \lambda_{i}\right) / p\) will be large.

The error rates of these two procedures were investigated for several values of \(p, n, k\), and \(\sum_{i}\left(1 / \lambda_{i}\right) / p\), where \(p\) is the number of variables, \(n\) is the number of observation vectors in each group, \(k\) is the number of groups, and \(\sum_{i}\left(1 / \lambda_{i}\right) / p\) is the measure of intercorrelation defined above. In procedure 1 , the probability of rejecting one or more univariate tests when \(H_{0}\) is true varied from .09 to .31 ( \(\alpha\) was .05 in each test). Such experimentwise error rates are clearly unacceptable when the nominal value of \(\alpha\) is .05 . However, this approach is commonly used when the researcher is not familiar with the MANOVA approach or does not have access to appropriate software.

Table 6.3 contains the error rates for procedure 2, univariate \(F\)-tests following a rejection by Wilks' \(\Lambda\). The values range from .022 to .057 , comfortably close to the target value of .05 . No apparent trends or patterns are seen; the values do not seem to depend on \(p, k, n\), or amount of intercorrelation as measured by \(\sum_{i}\left(1 / \lambda_{i}\right) / p\). Thus when univariate tests are made only following a rejection of the overall test, the experimentwise error rate is about right.

Table 6.3 Experimentwise Error Rates for Procedure 2: Univariate F-Tests Following Rejection by Wilks' \(\Lambda\)
\begin{tabular}{|c|c|c|c|c|c|c|c|c|c|}
\hline \multirow[b]{3}{*}{\(n\)} & \multirow[b]{3}{*}{\(p\)} & \multicolumn{8}{|c|}{\(\sum_{i}\left(1 / \lambda_{i}\right) / p\)} \\
\hline & & \multicolumn{2}{|c|}{1} & \multicolumn{2}{|c|}{10} & \multicolumn{2}{|c|}{100} & \multicolumn{2}{|c|}{1000} \\
\hline & & \(k=3\) & \(k=5\) & \(k=3\) & \(k=5\) & \(k=3\) & \(k=5\) & \(k=3\) & \(k=5\) \\
\hline 5 & 3 & . 043 & . 037 & . 022 & . 035 & . 046 & . 039 & . 022 & . 029 \\
\hline 5 & 5 & . 041 & . 037 & . 039 & . 057 & . 038 & . 035 & . 027 & . 039 \\
\hline 5 & 7 & . 030 & . 042 & . 035 & . 045 & . 039 & . 037 & . 026 & . 048 \\
\hline 10 & 3 & . 047 & . 041 & . 030 & . 033 & . 043 & . 045 & . 026 & . 032 \\
\hline 10 & 5 & . 047 & . 037 & . 026 & . 049 & . 041 & . 026 & . 027 & . 029 \\
\hline 10 & 7 & . 034 & . 054 & . 037 & . 047 & . 047 & . 040 & . 040 & . 044 \\
\hline 20 & 3 & . 050 & . 043 & . 032 & . 054 & . 048 & . 039 & . 040 & . 032 \\
\hline 20 & 5 & . 045 & . 055 & . 042 & . 051 & . 037 & . 044 & . 050 & . 043 \\
\hline 20 & 7 & . 055 & . 051 & . 029 & . 040 & . 033 & . 051 & . 039 & . 033 \\
\hline
\end{tabular}

Based on these results, we recommend making an overall MANOVA test followed by \(F\)-tests on the individual variables (at the same \(\alpha\)-level as the MANOVA test) only if the MANOVA test leads to rejection of \(H_{0}\).

Another procedure that can be used following rejection of the MANOVA test is an examination of the discriminant function coefficients. The discriminant function was defined in Section 6.1.4 as \(z=\mathbf{a}_{1}^{\prime} \mathbf{y}\), where \(\mathbf{a}_{1}\) is the eigenvector associated with the largest eigenvalue \(\lambda_{1}\) of \(\mathbf{E}^{-1} \mathbf{H}\). Additionally, there are other discriminant functions using eigenvectors corresponding to the other eigenvalues. Since the first discriminant function maximally separates the groups, we can examine its coefficients for the contribution of each variable to group separation. Thus in \(z=a_{11} y_{1}+a_{12} y_{2}+\cdots+a_{1 p} y_{p}\), if \(a_{12}\) is larger than the other \(a_{1 r}\) 's, we believe \(y_{2}\) contributes more than any of the other variables to separation of groups. A method of standardization of the \(a_{1 r}\) 's to adjust for differences in the scale among the variables is given in Section 8.5.

The information in \(a_{1 r}\) (from \(z=\mathbf{a}_{1}^{\prime} \mathbf{y}\) ) about the contribution of \(y_{r}\) to separation of the groups is fundamentally different from the information provided in a univariate \(F\)-test that considers \(y_{r}\) alone (see property 9 in Section 6.1.3). The relative size of \(a_{1 r}\) shows the contribution of \(y_{r}\) in the presence of the other variables and takes into account (1) the correlation of \(y_{r}\) with the others \(y\) 's and (2) the contribution of \(y_{r}\) to Wilks' \(\Lambda\) above and beyond the contribution of the other \(y\) 's. In contrast, the individual \(F\)-test on \(y_{r}\) ignores the presence of the other variables. Because we are primarily interested in the collective behavior of the variables, the discriminant function coefficients provide more pertinent information than the tests on individual variables. For a detailed analysis of the effect of each variable in the presence of other variables, see Rencher (1993; 1998, Section 4.1.6).

Huberty (1975) compared the standardized coefficients to some correlations that can be shown to be related to individual variable tests (see Section 8.7.3). In a limited simulation, the discriminant coefficients were found to be more valid than the univariate tests in identifying those variables that contribute least to separation of groups. Considerable variation was found from sample to sample in ranking the relative potency of the variables.

\section*{■ EXAMPLE 6.4}

In Example 6.1.7, the hypothesis \(H_{0}: \mu_{1}=\mu_{2}=\cdots=\mu_{6}\) was rejected for the rootstock data of Table 6.2. We can therefore test the four individual variables using the .05 level of significance. For the first variable, \(y_{1}=4\)-year trunk girth, we obtain the following ANOVA table:
\begin{tabular}{lcrcc} 
Source & Sum of Squares & df & Mean Square & \(F\) \\
\hline Rootstocks & .073560 & 5 & .014712 & 1.93 \\
Error & .319988 & 42 & .007619 & \\
Total & .393548 & 47 & &
\end{tabular}

For \(F=1.93\) the \(p\)-value is .1094 , and we do not reject \(H_{0}\). For the other three variables we have
\begin{tabular}{lrr} 
Variable & \multicolumn{1}{c}{\(F\)} & \(p\)-Value \\
\hline\(y_{2}=4\)-year extension growth & 2.91 & .024 \\
\(y_{3}=15\)-year trunk girth & 11.97 & \(<.0001\) \\
\(y_{4}=15\)-year weight & 12.16 & \(<.0001\)
\end{tabular}

Thus for three of the four variables, the six means differ significantly. We examine the standardized discriminant function coefficients for this set of data in Chapter 8 (Problem 8.12).

\subsection*{6.5 TWO-WAY CLASSIFICATION}

We consider only balanced models, where each cell in the model has the same number of observations, \(n\). For the unbalanced case with unequal cell sizes, see Rencher (1998, Section 4.8).

\subsection*{6.5.1 Review of Univariate Two-Way ANOVA}

In the univariate two-way model, we measure one dependent variable \(y\) on each experimental unit. The balanced two-way fixed-effects model with factors \(A\) and \(B\) is
\[
\begin{align*}
y_{i j k} & =\mu+\alpha_{i}+\beta_{j}+\gamma_{i j}+\varepsilon_{i j k}  \tag{6.64}\\
& =\mu_{i j}+\varepsilon_{i j k}  \tag{6.65}\\
i & =1,2, \ldots, a, \quad j=1,2, \ldots, b, \quad k=1,2, \ldots, n
\end{align*}
\]
where \(\alpha_{i}\) is the effect (on \(y_{i j k}\) ) of the \(i\) th level of \(A, \beta_{j}\) is the effect of the \(j\) th level of \(B, \gamma_{i j}\) is the corresponding interaction effect, and \(\mu_{i j}\) is the population mean for the \(i\) th level of \(A\) and the \(j\) th level of \(B\). In order to obtain \(F\)-tests, we further assume that the \(\varepsilon_{i j k}\) are independently distributed as \(N\left(0, \sigma^{2}\right)\).

Let \(\bar{\mu}_{i .}=\sum_{j} \mu_{i j} / b\) be the mean at the \(i\) th level of \(A\) and define \(\bar{\mu}_{. j}\) and \(\bar{\mu}_{\text {. }}\) similarly. Then if we use side conditions \(\sum_{i} \alpha_{i}=\sum_{j} \beta_{j}=\sum_{i} \gamma_{i j}=\sum_{j} \gamma_{i j}=0\), the effect of the \(i\) th level of \(A\) can be defined as \(\alpha_{i}=\bar{\mu}_{i}-\bar{\mu}_{. .}\), with similar definitions of \(\beta_{j}\) and \(\gamma_{i j}\). We can show that \(\sum_{i} \alpha_{i}=0\) if \(\alpha_{i}=\bar{\mu}_{i .}-\bar{\mu}_{\text {.. }}\) as follows:
\[
\begin{aligned}
\sum_{i=1}^{a} \alpha_{i} & =\sum_{i=1}^{a}\left(\bar{\mu}_{i .}-\bar{\mu}_{. .}\right)=\sum_{i} \bar{\mu}_{i .}-a \bar{\mu}_{. .} \\
& =a \bar{\mu}_{. .}-a \bar{\mu}_{. .}=0 .
\end{aligned}
\]

Many texts recommend that the interaction \(A B\) be tested first, and if it is found to be significant, then the main effects should not be tested. However, with the side conditions imposed above (side conditions are not necessary in order to obtain tests), the effect of \(A\) is defined as the average effect over the levels of \(B\) and similarly for the effect of \(B\). With this definition of main effects, the tests for \(A\) and \(B\) make sense even if \(A B\) is significant. Admittedly, interpretation requires more care, and the effect of a factor may vary if the number of levels of the other factor is altered. But in many cases, useful information can be gained about the main effects in the presence of interaction.

We illustrate the preceding statement that \(\alpha_{i}=\bar{\mu}_{i .}-\bar{\mu}_{\text {.. }}\) represents the effect of the \(i\) th level of \(A\) averaged over the levels of \(B\). Suppose \(A\) has two levels and \(B\) has three. We represent the means of the six cells as follows:
\begin{tabular}{|c|c|c|c|c|}
\hline \multirow[b]{5}{*}{\(\begin{array}{cc}A & \begin{array}{c}2 \\ \text { Mean }\end{array}\end{array}\)} & \multicolumn{4}{|c|}{\(B\)} \\
\hline & 1 & 2 & 3 & Mean \\
\hline & \(\mu_{11}\) & \(\mu_{12}\) & \(\mu_{13}\) & \(\bar{\mu}_{1}\). \\
\hline & \(\mu_{21}\) & \(\mu_{22}\) & \(\mu_{23}\) & \(\bar{\mu}_{2}\). \\
\hline & \(\bar{\mu}_{.1}\) & \(\bar{\mu}_{.2}\) & \(\overline{\bar{\mu}} .3\) & \(\bar{\mu}\) \\
\hline
\end{tabular}

The means of the rows (corresponding to levels of \(A\) ) and columns (levels of \(B\) ) are also given. Then \(\alpha_{i}=\bar{\mu}_{i .}-\bar{\mu}_{\text {.. }}\) can be expressed as the average of the effect of the \(i t h\) level of \(A\) at the three levels of \(B\). For example,
\[
\begin{aligned}
\alpha_{1} & =\frac{1}{3}\left[\left(\mu_{11}-\bar{\mu}_{.1}\right)+\left(\mu_{12}-\bar{\mu}_{.2}\right)+\left(\mu_{13}-\bar{\mu}_{.3}\right)\right] \\
& =\frac{1}{3}\left(\mu_{11}+\mu_{12}+\mu_{13}\right)-\frac{1}{3}\left(\bar{\mu}_{.1}+\bar{\mu}_{.2}+\bar{\mu}_{.3}\right)=\bar{\mu}_{1 .}-\bar{\mu}_{. .} .
\end{aligned}
\]

To estimate \(\alpha_{i}\), we can use \(\hat{\alpha}_{i}=\bar{y}_{i . .}-\bar{y}_{. . .}\), with similar estimates for \(\beta_{j}\) and \(\gamma_{i j}\). The notation \(\bar{y}_{i . .}\) indicates that \(y_{i j k}\) is averaged over the levels of \(j\) and \(k\) to obtain the mean of all \(n b\) observations at the \(i\) th level of \(A\), namely, \(\bar{y}_{i . .}=\sum_{j k} y_{i j k} / n b\). The means \(\bar{y}_{. j,}, \bar{y}_{i j}\), and \(\bar{y}_{\ldots}\) have analogous definitions.

To construct tests for the significance of factors \(A\) and \(B\) and the interaction \(A B\), we use the usual sums of squares and degrees of freedom in Table 6.4. Computational forms of the sums of squares can be found in many standard (univariate) methods texts.

Table 6.4 Univariate Two-Way Analysis of Variance
\begin{tabular}{llc}
\hline Source & Sum of Squares & df \\
\hline\(A\) & \(\mathrm{SSA}=n b \sum_{i}\left(\bar{y}_{i . .}-\bar{y}_{\ldots}\right)^{2}\) & \(a-1\) \\
\(B\) & \(\mathrm{SSB}=n a \sum_{j}\left(\bar{y}_{. j .}-\bar{y}_{\ldots}\right)^{2}\) & \(b-1\) \\
\(A B\) & \(\left.\mathrm{SSAB}=n \sum_{i j} \bar{y}_{i j .}-\bar{y}_{i . .}-\bar{y}_{. j .}+\bar{y}_{\ldots .}\right)^{2}\) & \((a-\mathbf{1})(b-1)\) \\
Error & \(\mathrm{SSE}=\sum_{i j k}\left(y_{i j k}-\bar{y}_{i j j}\right)^{2}\) & \(a b(n-1)\) \\
Total & \(\mathrm{SST}=\sum_{i j k}\left(y_{i j k}-\bar{y}_{. \ldots}\right)^{2}\) & \(a b n-1\) \\
\hline
\end{tabular}

The sums of squares in Table 6.4 (for the balanced model) have the relationship
\[
\mathrm{SST}=\mathrm{SSA}+\mathrm{SSB}+\mathrm{SSAB}+\mathrm{SSE}
\]
and the four sums of squares on the right are independent. The sums of squares are divided by their corresponding degrees of freedom to obtain mean squares MSA, MSB, MSAB, and MSE. For the fixed-effects model, each of MSA, MSB, and MSAB is divided by MSE to obtain an \(F\)-test. In the case of factor \(A\), for example, the hypothesis can be expressed as
\[
H_{0 A}: \alpha_{1}=\alpha_{2}=\cdots=\alpha_{a}=0
\]
and the test statistic is \(F=\) MSA/MSE, which is distributed as \(F_{a-1, a b(n-1)}\).
In order to define contrasts among the levels of each main effect, we can conveniently use the model in the form given in (6.65),
\[
y_{i j k}=\mu_{i j}+\varepsilon_{i j k}
\]

A contrast among the levels of \(A\) is defined as \(\sum_{i=1}^{a} c_{i} \bar{\mu}_{i,}\), where \(\sum_{i} c_{i}=0\). An estimate of the contrast is given by \(\sum_{i} c_{i} \bar{y}_{i . .}\), with variance \(\sigma^{2} \sum_{i} c_{i}^{2} / n b\), since each \(\bar{y}_{i .}\) is based on \(n b\) observations and the \(\bar{y}_{i . .}\) 's are independent. To test \(H_{0}: \sum_{i} c_{i} \bar{\mu}_{i .}=0\), we can use an \(F\)-statistic corresponding to (6.57),
\[
\begin{equation*}
F=\frac{n b\left(\sum_{i=1}^{a} c_{i} \bar{y}_{i . .}\right)^{2} / \sum_{i=1}^{a} c_{i}^{2}}{\mathrm{MSE}} \tag{6.66}
\end{equation*}
\]
with 1 and \(\nu_{E}\) degrees of freedom. To preserve the experimentwise error rate, significance tests for more than one contrast could be carried out in the spirit of Section 6.4; that is, contrasts should be chosen prior to seeing the data and tests should be made only if the overall \(F\)-test for factor \(A\) rejects \(H_{0 A}\).

Contrasts \(\sum_{j} c_{j} \bar{\mu}_{. j}\) among the levels of \(B\) are tested in an entirely analogous manner.

Table 6.5 Multivariate Two-Way Analysis of Variance
\begin{tabular}{|c|c|c|}
\hline Source & Sum of Squares and Products Matrix & df \\
\hline A & \(\mathbf{H}_{A}=n b \sum_{i}\left(\overline{\mathbf{y}}_{i . .}-\overline{\mathbf{y}}_{\ldots}\right)\left(\overline{\mathbf{y}}_{i \ldots .}-\overline{\mathbf{y}}_{\ldots}\right)^{\prime}\) & \(a-1\) \\
\hline \(B\) & \(\mathbf{H}_{B}=n a \sum_{j}\left(\overline{\mathbf{y}}_{. j .}-\overline{\mathbf{y}}_{\ldots}\right)\left(\overline{\mathbf{y}}_{. j .}-\overline{\mathbf{y}}_{\ldots} .\right)^{\prime}\) & \(b-1\) \\
\hline \(A B\) & \[
\begin{aligned}
\mathbf{H}_{A B}=n & \sum_{i j}\left(\overline{\mathbf{y}}_{i j .}-\overline{\mathbf{y}}_{i .}-\overline{\mathbf{y}}_{. j}+\overline{\mathbf{y}}_{\ldots .}\right) \\
& \times\left(\overline{\mathbf{y}}_{i j .}-\overline{\mathbf{y}}_{i, \ldots}-\overline{\mathbf{y}}_{. j .}+\overline{\mathbf{y}}_{\ldots . .}\right)^{\prime}
\end{aligned}
\] & \((a-1)(b-1)\) \\
\hline Error & \(\mathbf{E}=\sum_{i j k}\left(\mathbf{y}_{i j k}-\overline{\mathbf{y}}_{i j}\right)\left(\overline{\mathbf{y}}_{i j k}-\overline{\mathbf{y}}_{i j}\right)^{\prime}\) & \(a b(n-1)\) \\
\hline Total & \(\mathbf{T}=\sum_{i j k}\left(\mathbf{y}_{i j k}-\overline{\mathbf{y}}_{\ldots}\right)\left(\mathbf{y}_{i j k}-\overline{\mathbf{y}}_{\ldots} \ldots\right)^{\prime}\) & \(a b n-1\) \\
\hline
\end{tabular}

\subsection*{6.5.2 Multivariate Two-Way MANOVA}

A balanced two-way fixed-effects MANOVA model for \(p\) dependent variables can be expressed in vector form analogous to (6.64) and (6.65):
\[
\begin{align*}
\mathbf{y}_{i j k} & =\boldsymbol{\mu}+\boldsymbol{\alpha}_{i}+\boldsymbol{\beta}_{j}+\gamma_{i j}+\boldsymbol{\varepsilon}_{i j k}=\boldsymbol{\mu}_{i j}+\boldsymbol{\varepsilon}_{i j k}  \tag{6.67}\\
i & =1,2, \ldots, a, \quad j=1,2, \ldots, b, \quad k=1,2, \ldots, n
\end{align*}
\]
where \(\boldsymbol{\alpha}_{i}\) is the effect of the \(i\) th level of \(A\) on each of the \(p\) variables in \(\mathbf{y}_{i j k}, \boldsymbol{\beta}_{j}\) is the effect of the \(j\) th level of \(B\), and \(\gamma_{i j}\) is the \(A B\) interaction effect. We use side conditions \(\sum_{i} \boldsymbol{\alpha}_{i}=\sum_{j} \boldsymbol{\beta}_{j}=\sum_{i} \gamma_{i j}=\sum_{j} \gamma_{i j}=\mathbf{0}\) and assume the \(\varepsilon_{i j k}\) 's are independently distributed as \(N_{p}(\mathbf{0}, \boldsymbol{\Sigma})\). Under the side condition \(\sum_{i} \boldsymbol{\alpha}_{i}=\mathbf{0}\), the effect of \(A\) is averaged over the levels of \(B\); that is, \(\boldsymbol{\alpha}_{i}=\bar{\mu}_{i .}-\bar{\mu}_{. .}\), where \(\overline{\boldsymbol{\mu}}_{i .}=\sum_{j} \boldsymbol{\mu}_{i j} / b\) and \(\overline{\boldsymbol{\mu}}_{. .}=\sum_{i j} \boldsymbol{\mu}_{i j} / a b\). There are similar definitions for \(\boldsymbol{\beta}_{j}\) and \(\gamma_{i j}\).

As in the univariate usage, the mean vector \(\overline{\mathbf{y}}_{i . .}\) indicates an average over the subscripts replaced by dots, that is, \(\overline{\mathbf{y}}_{i . .}=\sum_{j k} \mathbf{y}_{i j k} / n b\). The means \(\overline{\mathbf{y}}_{. j,} \overline{\mathbf{y}}_{i j .}\), and \(\overline{\mathbf{y}}_{\ldots}\) have analogous definitions: \(\overline{\mathbf{y}}_{. j}=\sum_{i k} \mathbf{y}_{i j k} / n a, \overline{\mathbf{y}}_{i j .}=\sum_{k} \mathbf{y}_{i j k} / n, \overline{\mathbf{y}}_{\ldots}=\) \(\sum_{i j k} \mathbf{y}_{i j k} / n a b\). The sum of squares and products matrices are given in Table 6.5. Note that the degrees of freedom in Table 6.5 are the same as in the univariate case in Table 6.4. For the two-way model with balanced data, the total sum of squares and products matrix is partitioned as
\[
\begin{equation*}
\mathbf{T}=\mathbf{H}_{A}+\mathbf{H}_{B}+\mathbf{H}_{A B}+\mathbf{E} \tag{6.68}
\end{equation*}
\]

The structure of any of the hypothesis matrices is similar to that of \(\mathbf{H}\) in (6.11). For example, \(\mathbf{H}_{A}\) has on the diagonal the sum of squares for factor \(A\) for each of the \(p\) variables. The off-diagonal elements of \(\mathbf{H}_{A}\) are corresponding sums of products for all pairs of variables. Thus the \(r\) th diagonal element of \(\mathbf{H}_{A}\) corresponding to the \(r\) th variable, \(r=1,2, \ldots, p\), is given by
\[
\begin{equation*}
h_{A r r}=n b \sum_{i=1}^{a}\left(\bar{y}_{i . . r}-\bar{y}_{\ldots r}\right)^{2}=\sum_{i=1}^{a} \frac{y_{i \ldots r}^{2}}{n b}-\frac{y_{\ldots r}^{2}}{n a b}, \tag{6.69}
\end{equation*}
\]
where \(\bar{y}_{i . . r}\) and \(\bar{y}_{\ldots r}\) represent the \(r\) th components of \(\overline{\mathbf{y}}_{i . .}\) and \(\overline{\mathbf{y}}_{\ldots . .}\), respectively, and \(y_{i . . r}\) and \(y_{\ldots r}\) are totals corresponding to \(\bar{y}_{i . . r}\) and \(\bar{y} \ldots r\). The ( \(r s\) )th off-diagonal element of \(\mathbf{H}_{A}\) is
\[
\begin{equation*}
h_{A r s}=n b \sum_{i=1}^{a}\left(\bar{y}_{i . . r}-\bar{y}_{\ldots r}\right)\left(\bar{y}_{i \ldots s}-\bar{y}_{\ldots s}\right)=\sum_{i=1}^{a} \frac{y_{i . . r} y_{i \ldots s}}{n b}-\frac{y_{\ldots r} y_{\ldots s}}{n a b} . \tag{6.70}
\end{equation*}
\]

From (6.68) and Table 6.5, we obtain
\[
\begin{align*}
& h_{A B r r}=\sum_{i j} \frac{y_{i j . r}^{2}}{n}-\frac{y_{\ldots . r}^{2}}{n a b}-h_{A r r}-h_{B r r}  \tag{6.71}\\
& h_{A B r s}=\sum_{i j} \frac{y_{i j . r} y_{i j . s}}{n}-\frac{y_{\ldots . r} y_{\ldots s}}{n a b}-h_{A r s}-h_{B r s}
\end{align*}
\]

For the \(\mathbf{E}\) matrix, computational formulas are based on (6.68):
\[
\mathbf{E}=\mathbf{T}-\mathbf{H}_{A}-\mathbf{H}_{B}-\mathbf{H}_{A B}
\]

Thus the elements of \(\mathbf{E}\) have the form
\[
\begin{align*}
& e_{r r}=\sum_{i j k} y_{i j k r}^{2}-\frac{y_{\ldots r}^{2}}{n a b}-h_{A r r}-h_{B r r}-h_{A B r r}  \tag{6.72}\\
& e_{r s}=\sum_{i j k} y_{i j k r} y_{i j k s}-\frac{y_{\ldots r} y_{\ldots s}}{n a b}-h_{A r s}-h_{B r s}-h_{A B r s}
\end{align*}
\]

The hypotheses matrices for interaction and main effects in this fixed-effects model can be compared to \(\mathbf{E}\) to make a test. Thus for Wilks' \(\Lambda\), we use \(\mathbf{E}\) to test each of \(A, B\), and \(A B\) :
\[
\begin{aligned}
\Lambda_{A} & =\frac{|\mathbf{E}|}{\left|\mathbf{E}+\mathbf{H}_{A}\right|} \text { is } \Lambda_{p, a-1, a b(n-1)} \\
\Lambda_{B} & =\frac{|\mathbf{E}|}{\left|\mathbf{E}+\mathbf{H}_{B}\right|} \text { is } \Lambda_{p, b-1, a b(n-1)}, \\
\Lambda_{A B} & =\frac{|\mathbf{E}|}{\left|\mathbf{E}+\mathbf{H}_{A B}\right|} \text { is } \Lambda_{p,(a-1)(b-1), a b(n-1)}
\end{aligned}
\]

In each case, the indicated distribution holds when \(H_{0}\) is true. To calculate the other three MANOVA test statistics for \(A, B\), and \(A B\), we use the eigenvalues of \(\mathbf{E}^{-\mathbf{1}} \mathbf{H}_{A}\), \(\mathbf{E}^{-1} \mathbf{H}_{B}\), and \(\mathbf{E}^{-1} \mathbf{H}_{A B}\).

If the interaction is not significant, interpretation of the main effects is simpler. However, the comments in Section 6.5.1 about testing main effects in the presence of interaction apply to the multivariate model as well. If we define each main effect as the average effect over the levels of the other factor, then main effects can be tested even if the interaction is significant. One must be more careful with the interpretation in case of a significant interaction, but there is information to be gained.

By analogy with the univariate two-way ANOVA in Section 6.5.1, a contrast among the levels of factor \(A\) can be defined in terms of the mean vectors as follows: \(\sum_{i=1}^{a} c_{i} \overline{\boldsymbol{\mu}}_{i}\), where \(\sum_{i} c_{i}=0\) and \(\overline{\boldsymbol{\mu}}_{i .}=\sum_{j} \boldsymbol{\mu}_{i j} / b\). Similarly, \(\sum_{j=1}^{b} c_{j} \overline{\boldsymbol{\mu}}_{. j}\) represents a contrast among the levels of \(B\). The hypothesis that these contrasts are 0 can be tested by \(T^{2}\) or any of the four MANOVA test statistics, as in (6.61), (6.62), and (6.63). To test \(H_{0}: \sum_{i} c_{i} \overline{\boldsymbol{\mu}}_{i}=\mathbf{0}\), for example, we can use
\[
\begin{equation*}
T^{2}=\frac{n b}{\sum_{i=1}^{a} c_{i}^{2}}\left(\sum_{i=1}^{a} c_{i} \overline{\mathbf{y}}_{i . .}\right)^{\prime}\left(\frac{\mathbf{E}}{\nu_{E}}\right)^{-1}\left(\sum_{i=1}^{a} c_{i} \overline{\mathbf{y}}_{i . .}\right) \tag{6.73}
\end{equation*}
\]
which is distributed as \(T_{p, \nu_{E}}^{2}\) when \(H_{0}\) is true. Alternatively, the hypothesis matrix
\[
\begin{equation*}
\mathbf{H}_{1}=\frac{n b}{\sum_{i=1}^{a} c_{i}^{2}}\left(\sum_{i=1}^{a} c_{i} \overline{\mathbf{y}}_{i . .}\right)\left(\sum_{i=1}^{a} c_{i} \overline{\mathbf{y}}_{i . .}\right)^{\prime} \tag{6.74}
\end{equation*}
\]
can be used in
\[
\Lambda=\frac{|\mathbf{E}|}{\left|\mathbf{E}+\mathbf{H}_{1}\right|},
\]
which, under \(H_{0}\), is \(\Lambda_{p, 1, \nu_{E}}\), with \(\nu_{E}=a b(n-1)\) in the two-way model. The other three MANOVA test statistics can also be constructed from \(\mathbf{E}^{-1} \mathbf{H}_{1}\). All five test statistics will give equivalent results because \(\nu_{H}=1\).

If follow-up tests on individual variables are desired, we can infer from Rencher and Scott (1990), as reported in Section 6.4, that if the MANOVA test on factor \(A\) or \(B\) leads to rejection of \(H_{0}\), then we can proceed with the univariate \(F\)-tests on the individual variables with assurance that the experimentwise error rate will be close to \(\alpha\).

To determine the contribution of each variable in the presence of the others, we can examine the first discriminant function obtained from eigenvectors of \(\mathbf{E}^{-1} \mathbf{H}_{A}\) or \(\mathbf{E}^{-1} \mathbf{H}_{B}\), as in Section 6.4 for one-way MANOVA. The first discriminant function for \(\mathbf{E}^{-1} \mathbf{H}_{A}\), for example, is \(z=\mathbf{a}^{\prime} \mathbf{y}\), where \(\mathbf{a}\) is the eigenvector associated with the largest eigenvalue of \(\mathbf{E}^{-1} \mathbf{H}_{A}\). In \(z=a_{1} y_{1}+a_{2} y_{2}+\cdots+a_{p} y_{p}\), if \(a_{r}\) is larger than the other \(a\) 's, then \(y_{r}\) contributes more than the other variables to the significance of \(\Lambda_{A}\). (In many cases, the \(a_{r}\) 's should be standardized as in Section 8.5.) Note that the first discriminant function obtained from \(\mathbf{E}^{-1} \mathbf{H}_{A}\) will not have the same pattern as the first discriminant function from \(\mathbf{E}^{-1} \mathbf{H}_{B}\). This is not surprising since we expect that the relative contribution of the variables to separating the levels of factor \(A\) will be different from the relative contribution to separating the levels of \(B\).

A randomized block design or a two-way MANOVA without replication can easily be analyzed in a manner similar to that for the two-way model with replication given here; therefore, no specific details will be given.

\section*{■ EXAMPLE 6.5.2}

Table 6.6 contains data reported by Posten (1962) and analyzed by Kramer and Jensen (1970). The experiment involved a \(2 \times 4\) design with 4 replications, for

Table 6.6 Two-Way Classification of Measurements on Bar Steel
\begin{tabular}{cccccc}
\hline & \multicolumn{2}{c}{\(A_{1}\)} & & \multicolumn{2}{c}{\(A_{2}\)} \\
\cline { 2 - 3 } Lubricant & \(y_{1}\) & \(y_{2}\) & & \(y_{1}\) & \(y_{2}\) \\
\hline\(B_{1}\) & 7.80 & 90.4 & & 7.12 & 85.1 \\
& 7.10 & 88.9 & & 7.06 & 89.0 \\
& 7.89 & 85.9 & & 7.45 & 75.9 \\
& 7.82 & 88.8 & & 7.45 & 77.9 \\

& 7.00 & 86.6 & & 7.04 & 79.9 \\
& 7.82 & 85.9 & & 7.52 & 86.4 \\
& 7.80 & 88.8 & & 7.70 & 76.4 \\
\hline
\end{tabular}
a total of 32 observation vectors. The factors were rotational velocity [ \(A_{1}\) (fast) and \(A_{2}\) (slow)] and lubricants (four types). The experimental units were 32 homogeneous pieces of bar steel. Two variables were measured on each piece of bar steel:
\[
\begin{aligned}
& y_{1}=\text { ultimate torque }, \\
& y_{2}=\text { ultimate strain }
\end{aligned}
\]

We display the totals for each variable for use in computations. The numbers inside the box are cell totals (over the four replications), and the marginal totals are for each level of \(A\) and \(B\) :
\begin{tabular}{l|cc|cc|cc|c}
\multicolumn{4}{c}{\begin{tabular}{c}
\multicolumn{2}{c}{ Totals for \(y_{1}\)} & & \multicolumn{4}{c}{ Totals for \(y_{2}\)} \\
\(A_{1}\)
\end{tabular}\(A_{2}\)} & & \multicolumn{3}{c}{\(A_{1}\)} \\
\(B_{1}\) & 30.61 & 29.08 & 59.69 & \(B_{1}\) & 354.0 & 327.9 & 681.9 \\
\(B_{2}\) & 32.61 & 31.34 & 64.12 & \(B_{2}\) & 344.7 & 310.0 & 654.7 \\
\(B_{3}\) & 31.79 & 29.45 & 61.24 & \(B_{3}\) & 352.9 & 305.0 & 657.9 \\
\(B_{4}\) & 30.22 & 29.32 & 59.54 & \(B_{4}\) & 355.4 & 323.9 & 679.3 \\
\cline { 2 - 8 } & 125.40 & 119.19 & 244.59 & & 1407.0 & 1266.8 & 2673.8
\end{tabular}

Using computational forms for \(h_{A r r}\) in (6.69), the (1,1) element of \(\mathbf{H}_{A}\) (corresponding to \(y_{1}\) ) is given by
\[
h_{A 11}=\frac{(125.40)^{2}+(119.19)^{2}}{(4)(4)}-\frac{(244.59)^{2}}{(4)(4)(2)}=1.205
\]

For the (2,2) element of \(\mathbf{H}_{A}\) (corresponding to \(y_{2}\) ), we have
\[
h_{A 22}=\frac{(1407.0)^{2}+(1266.8)^{2}}{16}-\frac{(2673.8)^{2}}{32}=614.25 .
\]

For the (1,2) element of \(\mathbf{H}_{A}\) (corresponding to \(y_{1} y_{2}\) ), we use (6.70) for \(h_{A r s}\) to obtain
\[
\begin{aligned}
h_{A 12} & =\frac{(125.40)(1407.0)+(119.19)(1266.8)}{16}-\frac{(244.59)(2673.8)}{32} \\
& =27.208 .
\end{aligned}
\]

Thus
\[
\mathbf{H}_{A}=\left(\begin{array}{rr}
1.205 & 27.208 \\
27.208 & 614.251
\end{array}\right) .
\]

We obtain \(\mathbf{H}_{B}\) similarly:
\[
\begin{aligned}
h_{B 11} & =\frac{(59.69)^{2}+\cdots+(59.54)^{2}}{(4)(2)}-\frac{(244.59)^{2}}{32}=1.694, \\
h_{B 22} & =\frac{(681.9)^{2}+\cdots+(679.3)^{2}}{8}-\frac{(2673.8)^{2}}{32}=74.874, \\
h_{B 12} & =\frac{(59.69)(681.9)+\cdots+(59.54)(679.3)}{8}-\frac{(244.59)(2673.8)}{32} \\
& =-9.862, \\
\mathbf{H}_{B} & =\left(\begin{array}{rr}
1.694 & -9.862, \\
-9.862 & 74.874
\end{array}\right) .
\end{aligned}
\]

For \(\mathbf{H}_{A B}\) we have by (6.71)
\[
\begin{aligned}
h_{A B 11}= & \frac{(30.61)^{2}+\cdots+(29.32)^{2}}{4}-\frac{(244.59)^{2}}{32}-1.205-1.694=.132 \\
h_{A B 22}= & \frac{(354.0)^{2}+\cdots+(323.9)^{2}}{4}-\frac{(2673.8)^{2}}{32}-614.25-74.874 \\
= & 32.244, \\
h_{A B 12}= & \frac{(30.61)(354.0)+\cdots+(29.32)(323.9)}{4}-\frac{(244.59)(2673.8)}{32} \\
& -27.208-(-9.862)=1.585 \\
\mathbf{H}_{A B}= & \left(\begin{array}{rr}
.132 & 1.585 \\
1.585 & 32.244
\end{array}\right) .
\end{aligned}
\]

The error matrix \(\mathbf{E}\) is obtained using the computational forms given for \(e_{r r}\) and \(e_{r s}\) in (6.72). For example, \(e_{11}\) and \(e_{12}\) are computed as
\[
\begin{aligned}
e_{11}= & (7.80)^{2}+(7.10)^{2}+\cdots+(7.70)^{2}-\frac{(244.59)^{2}}{32}-1.205 \\
& -1.694-.132=4.897 \\
e_{12}= & (7.80)(90.4)+\cdots+(7.70)(76.4)-\frac{(244.59)(2673.8)}{32}-27.208 \\
& -(-9.862)-1.585=-1.890
\end{aligned}
\]

Proceeding in this fashion, we obtain
\[
\mathbf{E}=\left(\begin{array}{rr}
4.897 & -1.890 \\
-1.890 & 736.390
\end{array}\right)
\]
with \(\nu_{E}=a b(n-1)=(2)(4)(4-1)=24\).
To test the main effect of \(A\) with Wilks' \(\Lambda\), we compute
\[
\Lambda_{A}=\frac{|\mathbf{E}|}{\left|\mathbf{E}+\mathbf{H}_{A}\right|}=\frac{3602.2}{7600.2}=.474<\Lambda_{.05,2,1,24}=.771,
\]
and we conclude that velocity has a significant effect on \(y_{1}\) or \(y_{2}\) or both.
For the \(B\) main effect, we have
\[
\Lambda_{B}=\frac{|\mathbf{E}|}{\left|\mathbf{E}+\mathbf{H}_{B}\right|}=\frac{3602.2}{5208.6}=.6916>\Lambda_{.05,2,3,24}=.591 .
\]

We conclude that the effect of lubricants is not significant.
For the \(A B\) interaction, we obtain
\[
\Lambda_{A B}=\frac{|\mathbf{E}|}{\left|\mathbf{E}+\mathbf{H}_{A B}\right|}=\frac{3602.2}{3865.3}=.932>\Lambda_{.05,2,3,24}=.591 .
\]

Hence we conclude that the interaction effect is not significant.
We now obtain the other three MANOVA test statistics for each test. For \(A\), the only nonzero eigenvalue of \(\mathbf{E}^{-1} \mathbf{H}_{A}\) is 1.110. Thus
\[
\begin{aligned}
V^{(s)} & =\frac{\lambda_{1}}{1+\lambda_{1}}=.526, \quad U^{(s)}=\lambda_{1}=1.110 \\
\theta & =\frac{\lambda_{1}}{1+\lambda_{1}}=.526 .
\end{aligned}
\]

In this case, all three tests give results equivalent to that of \(\Lambda_{A}\) because \(\nu_{H}=\) \(s=1\).

For \(B, \nu_{H}=3\) and \(p=s=2\). The eigenvalues of \(\mathbf{E}^{-1} \mathbf{H}_{B}\) are .418 and .020, and we obtain
\[
\begin{aligned}
V^{(s)} & =\sum_{i=1}^{s} \frac{\lambda_{i}}{1+\lambda_{i}}=.314, \\
U^{(s)} & =\sum_{i=1}^{s} \lambda_{i}=.438, \quad \frac{\nu_{E}}{\nu_{H}} U^{(s)}=3.502, \\
\theta & =\frac{\lambda_{1}}{1+\lambda_{1}}=.295 .
\end{aligned}
\]

With \(s=2, m=0\), and \(N=10.5\), we have \(V^{(s)}=.439\) and \(\theta .05=.364\). The .05 critical value of \(\nu_{E} U^{(s)} / \nu_{H}\) is 5.1799. Thus \(V^{(s)}, U^{(s)}\), and \(\theta\) lead to acceptance of \(H_{0}\), as does \(\Lambda\). Of the four tests, \(\theta\) appears to be closer to rejection. This is because \(\lambda_{1} /\left(\lambda_{1}+\lambda_{2}\right)=.418 /(.418+.020)=.954\), indicating that the mean vectors for factor \(B\) are essentially collinear, in which case Roy's test is more powerful. If the mean vectors \(\overline{\mathbf{y}}_{.1}, \overline{\mathbf{y}}_{.2}, \overline{\mathbf{y}}_{.3}\), and \(\overline{\mathbf{y}}_{.4}\). for the four levels of \(B\) were a little further apart, we would have a situation in which the four MANOVA tests do not lead to the same conclusion.

For \(A B\), the eigenvalues of \(\mathbf{E}^{-1} \mathbf{H}_{A B}\) are .0651 and .0075 , from which
\[
\begin{aligned}
V^{(s)} & =\sum_{i=1}^{s} \frac{\lambda_{i}}{1+\lambda_{i}}=.0685, \quad U^{(s)}=.0726, \quad \frac{\nu_{E}}{\nu_{H}} U^{(s)}=.580 \\
\theta & =\frac{\lambda_{1}}{1+\lambda_{1}}=.0611
\end{aligned}
\]

The critical values remain the same as for factor \(B\), and all three tests accept \(H_{0}\), as does Wilks' \(\Lambda\). With a nonsignificant interaction, interpretation of the main effects is simplified.

\subsection*{6.6 OTHER MODELS}

\subsection*{6.6.1 Higher-Order Fixed Effects}

A higher-order (balanced) fixed-effects model or factorial experiment presents no new difficulties. As an illustration, consider a three-way classification with three factors \(A, B\), and \(C\) and all interactions \(A B, A C, B C\), and \(A B C\). The observation vector \(\mathbf{y}\) has \(p\) variables as usual. The MANOVA model allowing for main effects and interactions can be written as
\[
\begin{equation*}
\mathbf{y}_{i j k l}=\mu+\alpha_{i}+\boldsymbol{\beta}_{j}+\gamma_{k}+\delta_{i j}+\eta_{i k}+\tau_{j k}+\phi_{i j k}+\varepsilon_{i j k l}, \tag{6.75}
\end{equation*}
\]
where, for example, \(\boldsymbol{\alpha}_{i}\) is the effect of the \(i\) th level of factor \(A\) on each of the \(p\) variables in \(\mathbf{y}_{i j k l}\) and \(\delta_{i j}\) is the \(A B\) interaction effect on each of the \(p\) variables. Similarly, \(\boldsymbol{\eta}_{i k}, \tau_{j k}\), and \(\phi_{i j k}\) represent the \(A C, B C\), and \(A B C\) interactions on each of the \(p\) variables.

The matrices of sums of squares and products for main effects, interactions, and error are defined in a manner similar to that for the matrices detailed for the twoway model in Section 6.5.2. The sum of squares (on the diagonal) for each variable is calculated exactly the same as in a univariate ANOVA for a three-way model. The sums of products (off-diagonal) are obtained analogously. Test construction parallels that for the two-way model, using the matrix for error to test all factors and interactions.

Degrees of freedom for each factor are the same as in the corresponding threeway univariate model. All four MANOVA test statistics can be computed for each test. Contrasts can be defined and tested in a manner similar to that in Section 6.5.2. Follow-up procedures on the individual variables ( \(F\)-tests and discriminant functions) can be used as discussed for the one-way or two-way models in Sections 6.4 and 6.5.2.

\subsection*{6.6.2 Mixed Models}

There is a MANOVA counterpart for every univariate ANOVA design. This applies to fixed, random, and mixed models and to experimental structures that are crossed, nested, or a combination. Roebruck (1982) has provided a formal proof that univariate mixed models can be generalized to multivariate mixed models. Schott and Saw (1984) have shown that for the one-way multivariate random-effects model, the approach leads to the same test statistics involving the eigenvalues of \(\mathbf{E}^{-1} \mathbf{H}\) as in the fixed-effects model.

In the (balanced) MANOVA mixed model, the expected mean square matrices have exactly the same pattern as expected mean squares for the corresponding univariate ANOVA model. Thus a table of expected mean squares for the terms in the corresponding univariate model provides direction for choosing the appropriate error matrix to test each term in the MANOVA model. However, if the matrix indicated for "error" has fewer degrees of freedom than \(p\), it will not have an inverse and the test cannot be made.

To illustrate, suppose we have a (balanced) two-way MANOVA model with \(A\) fixed and \(B\) random. Then the (univariate) expected mean squares (EMS) and Wilks' \(\Lambda\)-tests are as follows:
\begin{tabular}{lll} 
Source & EMS & \(\Lambda\) \\
\hline\(A\) & \(\sigma^{2}+n \sigma_{A B}^{2}+n b \sigma_{A}^{* 2}\) & \(\left|\mathbf{H}_{A B}\right| /\left|\mathbf{H}_{A B}+\mathbf{H}_{A}\right|\) \\
\(B\) & \(\sigma^{2}+n a \sigma_{B}^{2}\) & \(|\mathbf{E}| /\left|\mathbf{E}+\mathbf{H}_{B}\right|\) \\
\(A B\) & \(\sigma^{2}+n \sigma_{A B}^{2}\) & \(|\mathbf{E}| /\left|\mathbf{E}+\mathbf{H}_{A B}\right|\) \\
Error & \(\sigma^{2}\) &
\end{tabular}

In the expected mean square for factor \(A\), we have used the notation \(\sigma_{A}^{* 2}\) in place of \(\sum_{i=1}^{a} \alpha_{i}^{2} /(a-1)\). The test for \(A\) using \(\mathbf{H}_{A B}\) for error matrix will be indeterminate (of the form \(0 / 0\) ) if \(\nu_{A B} \leq p\), where \(\nu_{A B}=(a-1)(b-1)\). In this case, \(\nu_{A B}\) will often fail to exceed \(p\). For example, suppose \(A\) has two levels and \(B\) has three. Then \(\nu_{A B}=2\), which will ordinarily be less than \(p\). In such a case, we would have little recourse except to compute univariate tests on the \(p\) individual variables.

Table 6.7 Wilks' \(\Lambda\) Tests for a Typical Split-Plot Design
\begin{tabular}{lcll}
\hline Source & df & Expected Mean Squares & Wilks' \(\Lambda\) \\
\hline\(A\) & \(a-1\) & \(\sigma^{2}+c e \sigma_{B}^{2}+b c e \sigma_{A}^{* 2}\) & \(\left|\mathbf{H}_{B}\right| /\left|\mathbf{H}_{A}+\mathbf{H}_{B}\right|\) \\
\(B\) & \(a(b-1)\) & \(\sigma^{2}+c e \sigma_{B}^{2}\) & \(|\mathbf{E}| /\left|\mathbf{H}_{B}+\mathbf{E}\right|\) \\
\(C\) & \(c-1\) & \(\sigma^{2}+e \sigma_{B C}^{2}+a b e \sigma_{C}^{* 2}\) & \(\left|\mathbf{H}_{B C}\right| /\left|\mathbf{H}_{C}+\mathbf{H}_{B C}\right|\) \\
\(A C\) & \((a-1)(c-1)\) & \(\sigma^{2}+e \sigma_{B C}^{2}+b e \sigma_{A C}^{* 2}\) & \(\left|\mathbf{H}_{B C}\right| /\left|\mathbf{H}_{A C}+\mathbf{H}_{B C}\right|\) \\
\(B C\) & \(a(b-1)(c-1)\) & \(\sigma^{2}+e \sigma_{B C}^{2}\) & \(|\mathbf{E}| /\left|\mathbf{H}_{B C}+\mathbf{E}\right|\) \\
Error & \(a b c(e-1)\) & \(\sigma^{2}\) & \\
\hline
\end{tabular}

However, we would not have the multivariate test to protect against carrying out too many univariate tests and thereby inflating the experimentwise \(\alpha\) (see Section 6.4). To protect against inflation of \(\alpha\) when making \(p\) tests, we could use a Bonferroni correction, as in procedure 2 in Section 5.5. In the case of \(F\)-tests, we do not have a table of Bonferroni critical values, as we do for \(t\)-tests (Table A.8), but we can achieve an equivalent result by comparing the \(p\)-values for the \(F\)-tests against \(\alpha / p\) instead of against \(\alpha\).

As another illustration, consider the analysis for a (balanced) multivariate splitplot design. For simplicity, we show the associated univariate model in place of the multivariate model. We use the factor names \(A, B, A C, \ldots\) to indicate parameters in the model:
\[
y_{i j k l}=\mu+A_{i}+B_{(i) j}+C_{k}+A C_{i k}+B C_{(i) j k}+\varepsilon_{(i j k) l}
\]
where \(A\) and \(C\) are fixed and \(B\) is random. Nesting is indicated by bracketed subscripts; for example, \(B\) and \(B C\) are nested in \(A\). Table 6.7 shows the expected mean squares and corresponding Wilks tests.

Since we use \(\mathbf{H}_{B}\) and \(\mathbf{H}_{B C}\), as well as \(\mathbf{E}\), to make tests, the following must hold:
\[
a(b-1) \geq p, \quad a(b-1)(c-1) \geq p, \quad a b c(e-1) \geq p
\]

To construct the other three MANOVA tests, we use eigenvalues of the following matrices:
\begin{tabular}{ll} 
Source & Matrix \\
\hline\(A\) & \(\mathbf{H}_{B}^{-1} \mathbf{H}_{A}\) \\
\(B\) & \(\mathbf{E}^{-1} \mathbf{H}_{B}\) \\
\(C\) & \(\mathbf{H}_{B C}^{-1} \mathbf{H}_{C}\) \\
\(A C\) & \(\mathbf{H}_{B C}^{-1} \mathbf{H}_{A C}\) \\
\(B C\) & \(\mathbf{E}^{-1} \mathbf{H}_{B C}\) \\
\hline
\end{tabular}

With a table of expected mean squares, such as those in Table 6.7, it is a simple matter to determine the error matrix in each case. For a given factor or interaction, such as \(A, B\), or \(A C\), the appropriate error matrix is ordinarily the one whose expected mean square matches that of the given factor except for the last term. For
example, factor \(C\), with expected mean square \(\sigma^{2}+e \sigma_{B C}^{2}+a b e \sigma_{C}^{* 2}\), is tested by \(B C\), whose expected mean square is \(\sigma^{2}+e \sigma_{B C}^{2}\). If \(H_{0}: \sigma_{C}^{* 2}=0\) is true, then \(C\) and \(B C\) have the same expected mean square.

In some mixed and random models, certain terms have no available error term. When this happens in the univariate case, we can construct an approximate test using Satterthwaites' (1941) or other synthetic mean square approach. For a similar approach in the multivariate case, see Khuri, Mathew, and Nel (1994).

\subsection*{6.7 CHECKING ON THE ASSUMPTIONS}

In Section 6.2 we discussed the robustness of the four MANOVA test statistics to nonnormality and heterogeneity of covariance matrices. The MANOVA tests (except for Roy's) are rather robust to these departures from the assumptions, although, in general, as dimensionality increases, robustness decreases.

Even though MANOVA procedures are fairly robust to departures from multivariate normality, we may want to check for gross violations of this assumption. Any of the tests or plots from Section 4.4 could be used. For a two-way design, for example, the tests could be applied separately to the \(n\) observations in each individual cell (if \(n\) is sufficiently large) or to all the residuals. The residual vectors after fitting the model \(\mathbf{y}_{i j k}=\mu_{i j}+\varepsilon_{i j k}\) would be
\[
\hat{\varepsilon}_{i j k}=\mathbf{y}_{i j k}-\overline{\mathbf{y}}_{i j,}, \quad i=1,2, \ldots, a, \quad j=1,2, \ldots, b \quad k=1,2, \ldots, n .
\]

It is also advisable to check for outliers, which can lead to either a Type I or a Type II error. The tests of Section 4.6 can be run separately for each cell (for sufficiently large \(n\) ) or for all of the \(a b n\) residuals, \(\hat{\varepsilon}_{i j k}=\mathbf{y}_{i j k}-\overline{\mathbf{y}}_{i j .}\).

A test of the equality of covariance matrices can be made using Box's \(M\)-test given in Section 7.3.2. Note the cautions expressed there about the sensitivity of this test to nonnormality and unequal sample sizes.

The assumption of independence of the observation vectors \(\mathbf{y}_{i j k}\) is even more important than the assumptions of normality and equality of covariance matrices. We are referring, of course, to independence from one observation vector to another. The variables within a vector are assumed to be correlated, as usual. In the univariate case, Barcikowski (1981) showed that a moderate amount of dependence among the observations produces an actual \(\alpha\) much greater than the nominal \(\alpha\). This effect is to be expected, since the dependence leads to an underestimate of the variance, so that MSE is reduced and the \(F\)-statistic is inflated. We can assume that this effect on error rates carries over to MANOVA.

In univariate ANOVA, a simple measure of dependence among the \(k n\) observations in a one-way model is the so-called intraclass correlation:
\[
\begin{equation*}
r_{c}=\frac{\mathrm{MSB}-\mathrm{MSE}}{\mathrm{MSB}+(n-1) \mathrm{MSE}} \tag{6.76}
\end{equation*}
\]
where MSB and MSE are the between and within mean squares for the variable and \(n\) is the number of observations per group. This could be calculated for each variable in a MANOVA to check for independence.

In many experimental settings, we do not anticipate a lack of independence. But in certain cases the observations are dependent. For example, if the sampling units are people, they may influence each other as they interact together. In some educational studies, researchers must use entire classrooms as sampling units rather than individual students. Another example of dependence is furnished by observations that are serially correlated, as in a time series, for example. Each observation depends to a certain extent on the preceding one, and its random movement is somewhat dampened as a result.

\subsection*{6.8 PROFILE ANALYSIS}

The two-sample profile analysis of Section 5.9.2 can be extended to \(k\) groups. Again we assume that the variables are commensurate, as, for example, when each subject is given a battery of tests. Other assumptions, cautions, and comments expressed in Section 5.9.2 apply here as well.

The basic model is the balanced one-way MANOVA:
\[
\mathbf{y}_{i j}=\boldsymbol{\mu}_{i}+\varepsilon_{i j}, \quad i=1,2, \ldots, k, \quad j=1,2, \ldots, n .
\]

To test \(H_{0}: \boldsymbol{\mu}_{1}=\boldsymbol{\mu}_{2}=\cdots=\boldsymbol{\mu}_{k}\), we use the usual \(\mathbf{H}\) and \(\mathbf{E}\) matrices given in (6.9) and (6.10). If the variables are commensurate, we can be more specific and extend \(H_{0}\) to an examination of the \(k\) profiles obtained by plotting the \(p\) values \(\mu_{i 1}, \mu_{i 2}, \ldots, \mu_{i p}\) in each \(\mu_{i}\), as was done with two \(\mu_{i}\) 's in Section 5.9.2. We are interested in the same three hypotheses as before:
\(H_{01}\) : The \(k\) profiles are parallel.
\(H_{02}\) : The \(k\) profiles are all at the same level.
\(H_{03}\) : The \(k\) profiles are flat.
The hypothesis of parallelism for two groups was expressed in Section 5.9.2 as \(H_{01}: \mathbf{C} \boldsymbol{\mu}_{1}=\mathbf{C} \mu_{2}\), where \(\mathbf{C}\) is any \((p-1) \times p\) matrix of rank \(p-1\) such that \(\mathbf{C j}=\mathbf{0}\), for example,
\[
\mathbf{C}=\left(\begin{array}{rrrrr}
1 & -1 & 0 & \cdots & 0 \\
0 & 1 & -1 & \cdots & 0 \\
\vdots & \vdots & \vdots & & \vdots \\
0 & 0 & 0 & \cdots & -1
\end{array}\right)
\]

For \(k\) groups, the analogous hypothesis of parallelism is
\[
\begin{equation*}
H_{01}: \mathbf{C} \boldsymbol{\mu}_{1}=\mathbf{C} \boldsymbol{\mu}_{2}=\cdots=\mathbf{C} \boldsymbol{\mu}_{k} . \tag{6.77}
\end{equation*}
\]

The hypothesis (6.77) is equivalent to the hypothesis \(H_{0}: \boldsymbol{\mu}_{z 1}=\boldsymbol{\mu}_{z 2}=\cdots=\boldsymbol{\mu}_{z k}\) in a one-way MANOVA on the transformed variables \(\mathbf{z}_{i j}=\mathbf{C} \mathbf{y}_{i j}\). Since \(\mathbf{C}\) has \(p-1\) rows, \(\mathbf{C} \mathbf{y}_{i j}\) is \((p-1) \times 1, \mathbf{C} \boldsymbol{\mu}_{i}\) is \((p-1) \times 1\), and \(\mathbf{C} \Sigma \mathbf{C}^{\prime}\) is \((p-1) \times(p-1)\). By property 1 b in Section 4.2, \(\mathbf{z}_{i j}\) is distributed as \(N_{p-1}\left(\mathbf{C} \boldsymbol{\mu}_{i}, \mathbf{C \Sigma} \mathbf{C}^{\prime}\right)\).

By analogy with (3.64), the hypothesis and error matrices for testing \(H_{01}\) in (6.77) are
\[
\mathbf{H}_{z}=\mathbf{C H C}^{\prime}, \quad \mathbf{E}_{z}=\mathbf{C E C}^{\prime}
\]

We thus have
\[
\begin{equation*}
\Lambda=\frac{\left|\mathbf{C E C}^{\prime}\right|}{\left|\mathbf{C E C}^{\prime}+\mathbf{C H C}\right|}=\frac{\left|\mathbf{C E C}^{\prime}\right|}{\left|\mathbf{C}(\mathbf{E}+\mathbf{H}) \mathbf{C}^{\prime}\right|}, \tag{6.78}
\end{equation*}
\]
which is distributed as \(\Lambda_{p-1, \nu_{H}, \nu_{E}}\), where \(\nu_{H}=k-1\) and \(\nu_{E}=k(n-1)\). The other three MANOVA test statistics can be obtained from the eigenvalues of \(\left(\mathbf{C E C}^{\prime}\right)^{-1}\left(\mathbf{C H C}^{\prime}\right)\). The test for \(H_{01}\) can easily be adjusted for unbalanced data, as in Section 6.1.6. We would calculate \(\mathbf{H}\) and \(\mathbf{E}\) by (6.31) and (6.32) and use \(\nu_{E}=\sum_{i} n_{i}-k\).

The hypothesis that two profiles are at the same level is \(H_{02}: \mathbf{j}^{\prime} \boldsymbol{\mu}_{1}=\mathbf{j}^{\prime} \boldsymbol{\mu}_{2}\) (see Section 5.9.2), which generalizes immediately to \(k\) profiles at the same level,
\[
\begin{equation*}
H_{02}: \mathbf{j}^{\prime} \boldsymbol{\mu}_{1}=\mathbf{j}^{\prime} \boldsymbol{\mu}_{2}=\cdots=\mathbf{j}^{\prime} \boldsymbol{\mu}_{k} . \tag{6.79}
\end{equation*}
\]

For two groups we used a univariate \(t\), as defined in (5.36), to test \(H_{02}\). Similarly, for \(k\) groups we can employ an \(F\)-test for one-way ANOVA comparing \(k\) groups with observations \(\mathbf{j}^{\prime} \mathbf{y}_{i j}\). Alternatively, we can utilize (6.78) with \(\mathbf{C}=\mathbf{j}^{\prime}\),
\[
\begin{equation*}
\Lambda=\frac{\mathbf{j}^{\prime} \mathbf{E} \mathbf{j}}{\mathbf{j}^{\prime} \mathbf{E} \mathbf{j}+\mathbf{j}^{\prime} \mathbf{H} \mathbf{j}}, \tag{6.80}
\end{equation*}
\]
which is distributed as \(\Lambda_{1, \nu_{H}, \nu_{E}}\left(p=1\right.\) because \(\mathbf{j}^{\prime} \mathbf{y}_{i j}\) is a scalar). This is, of course, equivalent to the \(F\)-test on \(\mathbf{j}^{\prime} \mathbf{y}_{i j}\), since by Table 6.1 in Section 6.1.3,
\[
\begin{equation*}
F=\frac{1-\Lambda}{\Lambda} \frac{\nu_{E}}{\nu_{H}} \tag{6.81}
\end{equation*}
\]
is distributed as \(F_{\nu_{H}, \nu_{E}}\).
The third hypothesis, that of "flatness," essentially states that the average of the \(k\) group means is the same for each variable [see (5.37)]:
\[
\begin{aligned}
H_{03}: \frac{\mu_{11}+\mu_{21}+\cdots+\mu_{k 1}}{k} & =\frac{\mu_{12}+\mu_{22}+\cdots+\mu_{k 2}}{k} \\
& =\cdots=\frac{\mu_{1 p}+\mu_{2 p}+\cdots+\mu_{k p}}{k},
\end{aligned}
\]
or by analogy with (5.38),
\[
\begin{equation*}
H_{03}: \frac{\mathbf{C}\left(\boldsymbol{\mu}_{1}+\boldsymbol{\mu}_{2}+\cdots+\boldsymbol{\mu}_{k}\right)}{k}=\mathbf{0} \tag{6.82}
\end{equation*}
\]
where \(\mathbf{C}\) is a \((p-1) \times p\) matrix of rank \(p-1\) such that \(\mathbf{C} \mathbf{j}=\mathbf{0}\) [see (6.77)]. If \(H_{01}\) is true, the flatness hypothesis can also be stated as, the means of all \(p\) variables in each group are the same, or \(\mu_{i 1}=\mu_{i 2}=\cdots=\mu_{i p}, i=1,2, \ldots, k\). This can be expressed as \(H_{03}: \mathbf{C} \boldsymbol{\mu}_{1}=\mathbf{C} \boldsymbol{\mu}_{2}=\cdots=\mathbf{C} \boldsymbol{\mu}_{k}=\mathbf{0}\).

Table 6.8 Weight of Guinea Pigs Under 3 Levels of Vitamin E Supplements
\begin{tabular}{crcccccc}
\hline Group & Animal & Week 1 & Week 3 & Week 4 & Week 5 & Week 6 & Week 7 \\
\hline 1 & 1 & 455 & 460 & 510 & 504 & 436 & 466 \\
1 & 2 & 467 & 565 & 610 & 596 & 542 & 587 \\
1 & 3 & 445 & 530 & 580 & 597 & 582 & 619 \\
1 & 4 & 485 & 542 & 594 & 583 & 611 & 612 \\
1 & 5 & 480 & 500 & 550 & 528 & 562 & 576 \\
2 & 6 & 514 & 560 & 565 & 524 & 552 & 597 \\
2 & 7 & 440 & 480 & 536 & 484 & 567 & 569 \\
2 & 8 & 495 & 570 & 569 & 585 & 576 & 677 \\
2 & 9 & 520 & 590 & 610 & 637 & 671 & 702 \\
2 & 10 & 503 & 555 & 591 & 605 & 649 & 675 \\
3 & 11 & 496 & 560 & 622 & 622 & 632 & 670 \\
3 & 12 & 498 & 540 & 589 & 557 & 568 & 609 \\
3 & 13 & 478 & 510 & 568 & 555 & 576 & 605 \\
3 & 14 & 545 & 565 & 580 & 601 & 633 & 649 \\
3 & 15 & 472 & 498 & 540 & 524 & 532 & 583 \\
\hline
\end{tabular}

To test \(H_{03}\) as given by (6.82), we can extend the \(T^{2}\)-test in (5.39). The grand mean vector \(\left(\mu_{1}+\mu_{2}+\cdots+\mu_{k}\right) / k\) in (6.82) can be estimated as in Section 6.1.2 by
\[
\overline{\mathbf{y}}_{. .}=\sum_{i j} \frac{\mathbf{y}_{i j}}{k n} .
\]

Under \(H_{03}, \mathbf{C} \overline{\mathbf{y}}_{. .}\)is \(N_{p-1}\left(\mathbf{0}, \mathbf{C} \boldsymbol{\Sigma} \mathbf{C}^{\prime} / k n\right)\), and \(H_{03}\) can be tested by
\[
\begin{equation*}
T^{2}=k n\left(\mathbf{C} \overline{\mathbf{y}}_{. .}\right)^{\prime}\left(\mathbf{C E C}^{\prime} / \nu_{E}\right)^{-1} \mathbf{C} \overline{\mathbf{y}}_{. .}, \tag{6.83}
\end{equation*}
\]
where \(\mathbf{E} / \nu_{E}\) is an estimate of \(\boldsymbol{\Sigma}\). As in the two-sample case, \(H_{03}\) is unaffected by the status of \(H_{02}\). When \(H_{03}\) is true, \(T^{2}\) in (6.83) is distributed as \(T_{p-1, \nu_{E}}^{2}\).

\section*{EXAMPLE 6.8}

Three vitamin E diet supplements with levels zero, low, and high were compared for their effect on growth of guinea pigs (Crowder and Hand 1990, pp. 21-29). Five guinea pigs received each supplement level, and their weights were recorded at the end of weeks \(1,3,4,5,6\), and 7 . These weights are given in Table 6.8.

The three mean vectors are
\[
\begin{aligned}
& \overline{\mathbf{y}}_{1}^{\prime}=(466.4,519.4,568.8,561.6,546.6,572.0) \\
& \overline{\mathbf{y}}_{2 .}^{\prime}=(494.4,551.0,574.2,567.0,603.0,644.0) \\
& \overline{\mathbf{y}}_{3 .}^{\prime}=(497.8,534.6,579.8,571.8,588.2,623.2)
\end{aligned}
\]
and the overall mean vector is
\[
\overline{\mathbf{y}}_{. .}^{\prime}=(486.2,535.0,574.3,566.8,579.3,613.1) .
\]

Figure 6.3 Profile of the three groups for the guinea pig data of Table 6.8.

A profile plot of the means \(\overline{\mathbf{y}}_{1 .}, \overline{\mathbf{y}}_{2}\), and \(\overline{\mathbf{y}}_{3}\) is given in Figure 6.3. There is a high degree of parallelism in the three profiles, with the possible exception of week 6 for group 1.

The \(\mathbf{E}\) and \(\mathbf{H}\) matrices are as follows:
\[
\begin{aligned}
& \mathbf{E}=\left(\begin{array}{rrrrrr}
8481.2 & 8538.8 & 4819.8 & 8513.6 & 8710.0 & 8468.2 \\
8538.8 & 17170.4 & 13293.0 & 19476.4 & 17034.2 & 20035.4 \\
4819.8 & 13293.0 & 12992.4 & 17077.4 & 17287.8 & 17697.2 \\
8513.6 & 19476.4 & 17077.4 & 28906.0 & 26226.4 & 28625.2 \\
8710.0 & 17034.2 & 17287.8 & 26226.4 & 36898.0 & 31505.8 \\
8468.2 & 20035.4 & 17697.2 & 28625.2 & 31505.8 & 33538.8
\end{array}\right), \\
& \mathbf{H}=\left(\begin{array}{rrrrrr}
2969.2 & 2177.2 & 859.4 & 813.0 & 4725.2 & 5921.6 \\
2177.2 & 2497.6 & 410.0 & 411.6 & 4428.8 & 5657.6 \\
859.4 & 410.0 & 302.5 & 280.4 & 1132.1 & 1392.5 \\
813.0 & 411.6 & 280.4 & 260.4 & 1096.4 & 1352.0 \\
4725.2 & 4428.8 & 1132.1 & 1096.4 & 8550.9 & 10830.9 \\
5921.6 & 5657.6 & 1392.5 & 1352.0 & 10830.9 & 13730.1
\end{array}\right) .
\end{aligned}
\]

Using
\[
\mathbf{C}=\left(\begin{array}{rrrrrr}
1 & -1 & 0 & 0 & 0 & 0 \\
0 & 1 & -1 & 0 & 0 & 0 \\
0 & 0 & 1 & -1 & 0 & 0 \\
0 & 0 & 0 & 1 & -1 & 0 \\
0 & 0 & 0 & 0 & 1 & -1
\end{array}\right)
\]
in the test statistic (6.78), we have, as a test for parallelism,
\[
\begin{aligned}
\Lambda & =\frac{\left|\mathbf{C E C}^{\prime}\right|}{\left|\mathbf{C}(\mathbf{E}+\mathbf{H}) \mathbf{C}^{\prime}\right|}=\frac{3.8238 \times 10^{18}}{2.1355 \times 10^{19}} \\
& =.1791>\Lambda_{.05,5,2,12}=.153
\end{aligned}
\]

Thus we do not reject the parallelism hypothesis.
To test the hypothesis that the three profiles are at the same level, we use (6.80),
\[
\begin{aligned}
\Lambda & =\frac{\mathbf{j}^{\prime} \mathbf{E} \mathbf{j}}{\mathbf{j}^{\prime} \mathbf{E} \mathbf{j}+\mathbf{j}^{\prime} \mathbf{H j}}=\frac{632,605.2}{632,605.2+111,288.1} \\
& =.8504>\Lambda_{.05,1,2,12}=.607
\end{aligned}
\]

Hence we do not reject the levels hypothesis. This can also be seen by using (6.81) to transform \(\Lambda\) to \(F\),
\[
F=\frac{(1-\Lambda) \nu_{E}}{\Lambda \nu_{H}}=\frac{(1-.8504) 12}{(.8504) 2}=1.0555
\]

Which is clearly nonsignificant ( \(p=.378\) ).
To test the flatness hypothesis, we use (6.83):
\[
\begin{aligned}
T^{2}= & k n\left(\mathbf{C} \overline{\mathbf{y}}_{. .}\right)^{\prime}\left(\mathbf{C E C} \mathbf{C}^{\prime} / \nu_{E}\right)^{-1} \mathbf{C} \overline{\mathbf{y}} . . \\
= & 15\left(\begin{array}{r}
-48.80 \\
-39.27 \\
7.47 \\
-12.47 \\
-33.80
\end{array}\right)\left(\begin{array}{rrrrr}
714.5 & -13.2 & 207.5 & -219.9 & 270.2 \\
-13.2 & 298.1 & -174.9 & 221.0 & -216.0 \\
207.5 & -174.9 & 645.3 & -240.8 & 165.8 \\
-219.9 & 221.0 & -240.8 & 1112.6 & -649.2 \\
270.2 & -216.0 & 165.8 & -649.2 & 618.8
\end{array}\right)^{-1} \\
& \times\left(\begin{array}{r}
-48.80 \\
-39.27 \\
7.47 \\
-12.47 \\
-33.80
\end{array}\right) \\
& =297.13>T_{.01,5,12}^{2}=49.739 .
\end{aligned}
\]

Thus only the flatness hypothesis is rejected in this case.

\subsection*{6.9 REPEATED MEASURES DESIGNS}

\subsection*{6.9.1 Multivariate Versus Univariate Approach}

In repeated measures designs, the research unit is typically a human or animal subject. Each subject is measured under several treatments or at different points of time.

Table 6.9 Data Layout for \(k\)-Groups Repeated Measures Experiment
\begin{tabular}{ccccccl}
\hline & & \multicolumn{4}{c}{ Factor \(A\) (Repeated Measures) } \\
\cline { 3 - 7 } \begin{tabular}{c} 
Factor \(B\) \\
(Group)
\end{tabular} & Subjects & \(A_{1}\) & \(A_{2}\) & \(\cdots\) & \(A_{p}\) & \\
\hline\(B_{1}\) & \(S_{11}\) & \(\left(y_{111}\right.\) & \(y_{112}\) & \(\cdots\) & \(\left.y_{11 p}\right)\) & \(=\mathbf{y}_{11}^{\prime}\) \\
& \(S_{12}\) & \(\left(y_{121}\right.\) & \(y_{122}\) & \(\cdots\) & \(\left.y_{12 p}\right)\) & \(=\mathbf{y}_{12}^{\prime}\) \\
& \(\vdots\) & \(\vdots\) & \(\vdots\) & & \(\vdots\) & \\
& \(S_{1 n}\) & \(\left(y_{1 n 1}\right.\) & \(y_{1 n 2}\) & \(\cdots\) & \(\left.y_{1 n p}\right)\) & \(=\mathbf{y}_{1 n}^{\prime}\) \\
\hline\(B_{2}\) & \(S_{21}\) & \(\left(y_{211}\right.\) & \(y_{212}\) & \(\cdots\) & \(\left.y_{21 p}\right)\) & \(=\mathbf{y}_{21}^{\prime}\) \\
& \(S_{22}\) & \(\left(y_{221}\right.\) & \(y_{222}\) & \(\cdots\) & \(\left.y_{22 p}\right)\) & \(=\mathbf{y}_{22}^{\prime}\) \\
& \(\vdots\) & \(\vdots\) & \(\vdots\) & & \(\vdots\) & \\
& \(S_{2 n}\) & \(\left(y_{2 n 1}\right.\) & \(y_{2 n 2}\) & \(\cdots\) & \(\left.y_{2 n p}\right)\) & \(=\mathbf{y}_{2 n}^{\prime}\) \\
\hline\(\vdots\) & \(\vdots\) & \(\vdots\) & \(\vdots\) & & \(\vdots\) & \\
\hline\(B_{k}\) & \(S_{k 1}\) & \(\left(y_{k 11}\right.\) & \(y_{k 12}\) & \(\cdots\) & \(\left.y_{k 1 p}\right)\) & \(=\mathbf{y}_{k 1}^{\prime}\) \\
& \(S_{k 2}\) & \(\left(y_{k 21}\right.\) & \(y_{k 22}\) & \(\cdots\) & \(\left.y_{k 2 p}\right)\) & \(=\mathbf{y}_{k 2}^{\prime}\) \\
& \(\vdots\) & \(\vdots\) & \(\vdots\) & & \(\vdots\) & \\
& \(S_{k n}\) & \(\left(y_{k n 1}\right.\) & \(y_{k n 2}\) & \(\cdots\) & \(\left.y_{k n p}\right)\) & \(=\mathbf{y}_{k n}^{\prime}\) \\
\hline
\end{tabular}

The treatments might be tests, drug levels, various kinds of stimuli, and so on. If the treatments are such that the order of presentation to the various subjects can be varied, then the order should be randomized to avoid an ordering bias. If subjects are measured at successive time points, it may be of interest to determine the degree of polynomial required to fit the curve. This is treated in Section 6.10 as part of an analysis of growth curves.

When comparing means of the treatments applied to each subject, we are examining the within-subjects factor. There will also be a between-subjects factor if there are several groups of subjects that we wish to compare. In Sections 6.9.2-6.9.6, we consider designs up to a complexity level of two within-subjects factors and two between-subjects factors.

We now discuss univariate and multivariate approaches to hypothesis testing in repeated measures designs. As a framework for this discussion, consider the layout in Table 6.9 for a repeated measures design with one repeated measures (withinsubjects) factor, \(A\), and one grouping (between-subjects) factor, \(B\).

This design has often been analyzed as a univariate mixed-model nested design, also called a split-plot design, with subjects nested in factor \(B\) (whole-plot), which is crossed with factor \(A\) (repeated measures or split-plot). The univariate model for each \(y_{i j r}\) would be
\[
\begin{equation*}
y_{i j r}=\mu+B_{i}+S_{(i) j}+A_{r}+B A_{i r}+\varepsilon_{i j r} \tag{6.84}
\end{equation*}
\]
where the factor level designations ( \(B, S, A\), and \(B A\) ) from (6.84) and Table 6.9 are used as parameter values, and the subscript \((i) j\) on \(S\) indicates that subjects are nested in factor \(B\). In Table 6.9 , the observations \(y_{i j r}\) for \(r=1,2, \ldots, p\) are enclosed in parentheses and denoted by \(\mathbf{y}_{i j}^{\prime}\) to emphasize that these \(p\) variables are measured on one subject and thus constitute a vector of correlated variables. The ranges of the subscripts can be seen in Table 6.9: \(i=1,2, \ldots, k ; j=1,2, \ldots, n\); and \(r=1,2, \ldots, p\). With factors \(A\) and \(B\) fixed and subjects random, the univariate ANOVA is given in Table 6.10.

However, our initial reaction would be to rule out the univariate ANOVA because the \(y\) 's in each row are correlated and the assumption of independence is critical, as noted in Section 6.7. We will discuss below some assumptions under which the univariate analysis would be appropriate.

In the multivariate approach, the \(p\) responses \(y_{i j 1}, y_{i j 2}, \ldots, y_{i j p}\) (repeated measures) for subject \(S_{i j}\) constitute a vector \(\mathbf{y}_{i j}\), as shown in Table 6.9. The multivariate model for \(\mathbf{y}_{i j}\) is a simple one-way MANOVA model,
\[
\begin{equation*}
\mathbf{y}_{i j}=\boldsymbol{\mu}+\boldsymbol{\beta}_{i}+\varepsilon_{i j} \tag{6.85}
\end{equation*}
\]
where \(\boldsymbol{\beta}_{i}\) is a vector of \(p\) main effects (corresponding to the \(p\) variables in \(\mathbf{y}_{i j}\) ) for factor \(B\), and \(\varepsilon_{i j}\) is an error vector for subject \(S_{i j}\). This model seems to include only factor \(B\), but we show in Section 6.9.3 how to use an approach similar to profile analysis in Section 6.8 to obtain tests on factor \(A\) and the \(B A\) interaction. The MANOVA assumption that \(\operatorname{cov}\left(\mathbf{y}_{i j}\right)=\boldsymbol{\Sigma}\) for all \(i\) and \(j\) allows the \(p\) repeated measures to be correlated in any pattern, since \(\boldsymbol{\Sigma}\) is completely general. On the other hand, the ANOVA assumptions of independence and homogeneity of variances can be expressed as \(\operatorname{cov}\left(\mathbf{y}_{i j}\right)=\sigma^{2} \mathbf{I}\). We would be very surprised if repeated measurements on the same subject were independent.

The univariate ANOVA approach has been found to be appropriate under less stringent conditions than \(\boldsymbol{\Sigma}=\sigma^{2} \mathbf{I}\). Wilks (1946) showed that the ordinary \(F\)-tests of ANOVA remain valid for a covariance structure of the form
\[
\begin{align*}
\operatorname{cov}\left(\mathbf{y}_{i j}\right)=\boldsymbol{\Sigma} & =\sigma^{2}\left(\begin{array}{ccccc}
1 & \rho & \rho & \cdots & \rho \\
\rho & 1 & \rho & \cdots & \rho \\
\vdots & \vdots & \vdots & & \vdots \\
\rho & \rho & \rho & \cdots & 1
\end{array}\right) \\
& =\sigma^{2}[(1-\rho) \mathbf{I}+\rho \mathbf{J}] \tag{6.86}
\end{align*}
\]
where \(\mathbf{J}\) is a square matrix of 1 's, as defined in (2.12) [see Rencher and Schaalje (2008, pp. 166-167)]. The covariance pattern (6.86) is variously known as uniformity, compound symmetry, or the intraclass correlation model. It allows for the variables to be correlated but restricts every variable to have the same variance and every pair of variables to have the same covariance. In a carefully designed experiment with appropriate randomization, this assumption may hold under the hypothesis of no \(A\) effect. Alternatively, we could use a test of the hypothesis that \(\boldsymbol{\Sigma}\) has the pattern (6.86) (see Section 7.2.3). If this hypothesis is accepted, one could proceed with the usual ANOVA \(F\)-tests.

Table 6.10 Univariate ANOVA for Data Layout in Table 6.9
\begin{tabular}{lclc}
\hline Source & df & MS & \(F\) \\
\hline\(B\) (between) & \(k-1\) & MSB & MSB/MSS \\
\(S\) (subjects) & \(k(n-1)\) & MSS & \\
\(A\) (within or repeated) & \(p-1\) & MSA & MSA/MSE \\
\(B A\) & \((k-1)(p-1)\) & MSBA & MSBA/MSE \\
Error \((S A\) interaction) & \(k(n-1)(p-1)\) & MSE & \\
\hline
\end{tabular}

Bock (1963) and Huynh and Feldt (1970) showed that the most general condition under which univariate \(F\)-tests remain valid is that
\[
\begin{equation*}
\mathbf{C} \boldsymbol{\Sigma} \mathbf{C}^{\prime}=\sigma^{2} \mathbf{I} \tag{6.87}
\end{equation*}
\]
where \(\mathbf{C}\) is a \((p-1) \times p\) matrix whose rows are orthonormal contrasts (orthogonal contrasts that have been normalized to unit length). We can construct \(\mathbf{C}\) by choosing any \(p-1\) orthogonal contrasts among the means \(\mu_{1}, \mu_{2}, \ldots, \mu_{p}\) of the repeated measures factor and dividing each contrast by \(\sqrt{\sum_{r=1}^{p} c_{r}^{2}}\). (This matrix \(\mathbf{C}\) is different from \(\mathbf{C}\) used in Section 6.8 and in the remainder of Section 6.9, whose rows are contrasts that are not normalized to unit length.) It can be shown that (6.86) is a special case of (6.87). The condition (6.87) is sometimes referred to as sphericity, although this term can also refer to the covariance pattern \(\boldsymbol{\Sigma}=\sigma^{2} \mathbf{I}\) on the untransformed \(\mathbf{y}_{i j}\) (see Section 7.2.2).

A simple way to test the hypothesis that (6.87) holds is to transform the data by \(\mathbf{z}_{i j}=\mathbf{C} \mathbf{y}_{i j}\) and test \(H_{0}: \boldsymbol{\Sigma}_{z}=\sigma^{2} \mathbf{I}\), as in Section 7.2.2, using \(\mathbf{C S}_{\mathrm{p} 1} \mathbf{C}^{\prime}\) in place of \(\mathbf{S}_{\mathrm{p} 1}=\mathbf{E} / \nu_{E}\).

Thus one procedure for repeated measures designs is to make a preliminary test for \((6.86)\) or (6.87) and, if the hypothesis is accepted, use univariate \(F\)-tests, as in Table 6.10. Fehlberg (1980) investigated the use of larger \(\alpha\)-values with a preliminary test of structure of the covariance matrix, as in (6.87). He concludes that using \(\alpha=.40\) sufficiently controls the problem of falsely accepting sphericity so as to justify the use of a preliminary test.

If the univariate test for the repeated measures factor \(A\) is appropriate, it is more powerful because it has more degrees of freedom for error than the corresponding multivariate test. However, even mild departures from (6.87) seriously inflate the Type 1 error rate of the univariate test for factor \(A\) (Box 1954, Davidson 1972, Boik 1981). Because such departures can be easily missed in a preliminary test, Boik (1981) concludes that "on the whole, the ordinary \(F\) tests have nothing to recommend them" (p. 248) and emphasized that "there is no justification for employing ordinary univariate \(F\) tests for repeated measures treatment contrasts" (p. 254).

Another approach to analysis of repeated measures designs is to adjust the univariate \(F\)-test for the amount of departure from sphericity. Box (1954) and Greenhouse and Geisser (1959) showed that when \(\boldsymbol{\Sigma} \neq \sigma^{2} \mathbf{I}\), an approximate \(F\)-test for effects involving the repeated measures is obtained by reducing the degrees of freedom for

Table 6.11 Data Layout for a Single-Sample Repeated Measures Design
\begin{tabular}{cccccc}
\hline & \multicolumn{5}{c}{ Factor \(A\) (Repeated Measures) } \\
\cline { 2 - 6 } Subjects & \(A_{1}\) & \(A_{2}\) & \(A_{3}\) & \(A_{4}\) & \\
\hline\(S_{1}\) & \(\left(y_{11}\right.\) & \(y_{12}\) & \(y_{13}\) & \(\left.y_{14}\right)\) & \(=\mathbf{y}_{1}^{\prime}\) \\
\(S_{2}\) & \(\left(y_{21}\right.\) & \(y_{22}\) & \(y_{23}\) & \(\left.y_{24}\right)\) & \(=\mathbf{y}_{2}^{\prime}\) \\
\(\vdots\) & \(\vdots\) & \(\vdots\) & \(\vdots\) & \(\vdots\) & \(\vdots\) \\
\(S_{n}\) & \(\left(y_{n 1}\right.\) & \(y_{n 2}\) & \(y_{n 3}\) & \(\left.y_{n 4}\right)\) & \(=\mathbf{y}_{n}^{\prime}\) \\
\hline
\end{tabular}
both numerator and denominator by a factor of
\[
\begin{equation*}
\varepsilon=\frac{[\operatorname{tr}(\boldsymbol{\Sigma}-\mathbf{J} \boldsymbol{\Sigma} / p)]^{2}}{(p-\mathbf{1}) \operatorname{tr}(\boldsymbol{\Sigma}-\mathbf{J} \boldsymbol{\Sigma} / p)^{2}}, \tag{6.88}
\end{equation*}
\]
where \(\mathbf{J}\) is a \(p \times p\) matrix of 1 's defined in (2.12). For example, in Table 6.10 the \(F\)-value for the \(B A\) interaction would be compared to \(F_{\alpha}\) with \(\varepsilon(k-1)(p-1)\) and \(\varepsilon k(n-1)(p-1)\) degrees of freedom. An estimate \(\hat{\varepsilon}\) can be obtained by substituting \(\hat{\boldsymbol{\Sigma}}=\mathbf{E} / \nu_{E}\) in (6.88). Greenhouse and Geisser (1959) showed that \(\varepsilon\) and \(\hat{\varepsilon}\) vary between \(1 /(p-1)\) and 1 , with \(\varepsilon=1\) when sphericity holds and \(\varepsilon \geq 1 /(p-1)\) for other values of \(\boldsymbol{\Sigma}\). Thus \(\varepsilon\) is a measure of nonsphericity. For a conservative test, Greenhouse and Geisser recommend dividing numerator and denominator degrees of freedom by \(p-1\). Huynh and Feldt (1976) provided an improved estimator of \(\varepsilon\).

The behavior of the approximate univariate \(F\)-test with degrees of freedom adjusted by \(\hat{\varepsilon}\) has been investigated by Collier et al. (1967), Huynh (1978), Davidson (1972), Rogan et al. (1979), and Maxwell and Avery (1982). In these studies, the true \(\alpha\) level turned out to be close to the nominal \(\alpha\), and the power was close to that of the multivariate test. However, since the \(\varepsilon\)-adjusted \(F\)-test is only approximate and has no power advantage over the exact multivariate test, there appears to be no compelling reason to use it. The only case in which we need to fall back on a univariate test is when there are insufficient degrees of freedom to perform a multivariate test, that is, when \(p>\nu_{E}\).

In Sections 6.9.2-6.9.6, we discuss the multivariate approach to repeated measures. We will cover several models, beginning with the simple one-sample design.

\subsection*{6.9.2 One-Sample Repeated Measures Model}

We illustrate some of the procedures in this section with \(p=4\). A one-sample design with four repeated measures on \(n\) subjects would appear as in Table 6.11. There is a superficial resemblance to a univariate randomized block design. However, in the repeated measures design, the observations \(y_{i 1}, y_{i 2}, y_{i 3}\), and \(y_{i 4}\) are correlated because they are measured on the same subject (experimental unit), whereas in a randomized block design \(y_{i 1}, y_{i 2}, y_{i 3}\), and \(y_{i 4}\) would be measured on four different experimental units. Thus we have a single sample of \(n\) observation vectors \(\mathbf{y}_{1}, \mathbf{y}_{2}, \ldots, \mathbf{y}_{n}\).

To test for significance of factor \(A\), we compare the means of the four variables in \(\mathbf{y}_{i}\),
\[
E\left(\mathbf{y}_{i}\right)=\boldsymbol{\mu}=\left(\begin{array}{c}
\mu_{1} \\
\mu_{2} \\
\mu_{3} \\
\mu_{4}
\end{array}\right)
\]

The hypothesis is \(H_{0}: \mu_{1}=\mu_{2}=\mu_{3}=\mu_{4}\), which can be reexpressed as \(H_{0}: \mu_{1}-\) \(\mu_{2}=\mu_{2}-\mu_{3}=\mu_{3}-\mu_{4}=0\) or \(\mathbf{C}_{1} \boldsymbol{\mu}=\mathbf{0}\), where
\[
\mathbf{C}_{1}=\left(\begin{array}{rrrr}
1 & -1 & 0 & 0 \\
0 & 1 & -1 & 0 \\
0 & 0 & 1 & -1
\end{array}\right)
\]

To test \(H_{0}: \mathbf{C}_{1} \boldsymbol{\mu}=\mathbf{0}\) for a general \(p\) ( \(p\) repeated measures on \(n\) subjects), we calculate \(\overline{\mathbf{y}}\) and \(\mathbf{S}\) from \(\mathbf{y}_{1}, \mathbf{y}_{2}, \ldots, \mathbf{y}_{n}\) and extend \(\mathbf{C}_{1}\) to \(p-1\) rows. Then when \(H_{0}\) is true, \(\mathbf{C}_{1} \overline{\mathbf{y}}\) is \(N_{p-1}\left(\mathbf{0}, \mathbf{C}_{1} \boldsymbol{\Sigma} \mathbf{C}_{1}^{\prime} / n\right)\), and
\[
\begin{equation*}
T^{2}=n\left(\mathbf{C}_{1} \overline{\mathbf{y}}\right)^{\prime}\left(\mathbf{C}_{1} \mathbf{S C}_{1}^{\prime}\right)^{-1}\left(\mathbf{C}_{1} \overline{\mathbf{y}}\right) \tag{6.89}
\end{equation*}
\]
is distributed as \(T_{p-1, n-1}^{2}\). We reject \(H_{0}: \mathbf{C}_{1} \boldsymbol{\mu}=0\) if \(T^{2} \geq T_{\alpha, p-1, n-1}^{2}\). Note that the dimension is \(p-1\) because \(\mathbf{C}_{1} \overline{\mathbf{y}}\) is \((p-1) \times 1\) [see (5.33)].

The multivariate approach involving transformed observations \(\mathbf{z}_{i}=\mathbf{C}_{1} \mathbf{y}_{i}\) was first suggested by Hsu (1938) and has been discussed further by Williams (1970) and Morrison (1972). Note that in \(\mathbf{C}_{1} \overline{\mathbf{y}}\) (for \(p=4\) ), we work with contrasts on the elements \(\bar{y}_{1}, \bar{y}_{2}, \bar{y}_{3}\), and \(\bar{y}_{4}\) within the vector
\[
\overline{\mathbf{y}}=\left(\begin{array}{c}
\bar{y}_{1} \\
\bar{y}_{2} \\
\bar{y}_{3} \\
\bar{y}_{4}
\end{array}\right)
\]
as opposed to the contrasts involving comparisons of several mean vectors themselves, as, for example, in Section 6.3.2.

The hypothesis \(H_{0}: \mu_{1}=\mu_{2}=\mu_{3}=\mu_{4}\) can also be expressed as \(H_{0}: \mu_{1}-\mu_{4}=\) \(\mu_{2}-\mu_{4}=\mu_{3}-\mu_{4}=0\), or \(\mathbf{C}_{2} \boldsymbol{\mu}=\mathbf{0}\), where
\[
\mathbf{C}_{2}=\left(\begin{array}{cccc}
1 & 0 & 0 & -1 \\
0 & 1 & 0 & -1 \\
0 & 0 & 1 & -1
\end{array}\right)
\]

The matrix \(\mathbf{C}_{1}\) can be obtained from \(\mathbf{C}_{2}\) by simple row operations, for example, subtracting the second row from the first and the third row from the second. Hence, \(\mathbf{C}_{1}=\mathbf{A C} \mathbf{C}_{2}\), where
\[
\mathbf{A}=\left(\begin{array}{rrr}
1 & -1 & 0 \\
0 & 1 & -1 \\
0 & 0 & 1
\end{array}\right)
\]

In fact, \(H_{0}: \mu_{1}=\mu_{2}=\cdots=\mu_{p}\) can be expressed as \(\mathbf{C} \boldsymbol{\mu}=\mathbf{0}\) for any full-rank \((p-1) \times p\) matrix \(\mathbf{C}\) such that \(\mathbf{C j}=\mathbf{0}\), and the same value of \(T^{2}\) in (6.89) will result. The contrasts in \(\mathbf{C}\) can be either linearly independent or orthogonal.

The hypothesis \(H_{0}: \mu_{1}=\mu_{2}=\cdots=\mu_{p}=\mu\), say, can also be expressed as
\[
H_{0}: \boldsymbol{\mu}=\mu \mathbf{j},
\]
where \(\mathbf{j}=(1,1, \ldots, 1)^{\prime}\). The maximum likelihood estimate of \(\mu\) is
\[
\begin{equation*}
\hat{\mu}=\frac{\overline{\mathbf{y}}^{\prime} \mathbf{S}^{-\mathbf{1}} \mathbf{j}}{\mathbf{j}^{\prime} \mathbf{S}^{-1} \mathbf{j}} \tag{6.90}
\end{equation*}
\]

The likelihood ratio test of \(H_{0}\) is a function of
\[
\overline{\mathbf{y}}^{\prime} \mathbf{S}^{-1} \overline{\mathbf{y}}-\frac{\left(\overline{\mathbf{y}}^{\prime} \mathbf{S}^{-1} \mathbf{j}\right)^{2}}{\mathbf{j}^{\prime} \mathbf{S}^{-1} \mathbf{j}}
\]

Williams (1970) showed that for any \((p-1) \times p\) matrix \(\mathbf{C}\) of \(\operatorname{rank} p-1\) such that \(\mathbf{C j}=\mathbf{0}\),
\[
\overline{\mathbf{y}}^{\prime} \mathbf{S}^{-1} \overline{\mathbf{y}}-\frac{\left(\overline{\mathbf{y}}^{\prime} \mathbf{S}^{-1} \mathbf{j}\right)^{2}}{\mathbf{j}^{\prime} \mathbf{S}^{-1} \mathbf{j}}=(\mathbf{C} \overline{\mathbf{y}})^{\prime}\left(\mathbf{C S C}^{\prime}\right)^{-1}(\mathbf{C} \overline{\mathbf{y}})
\]
and thus the \(T^{2}\)-test in (6.89) is equivalent to the likelihood ratio test.

\section*{■ EXAMPLE 6.9.2}

The data in Table 6.12 were given by Cochran and Cox (1957, p. 130). As rearranged by Timm (1980), the observations constitute a one-sample repeated measures design with two within-subjects factors. Factor \(A\) is a comparison of two tasks; factor \(B\) is a comparison of two types of calculators. The measurements are speed of calculation.

To test the hypothesis \(H_{0}: \mu_{1}=\mu_{2}=\mu_{3}=\mu_{4}\), we use the contrast matrix
\[
\mathbf{C}=\left(\begin{array}{rrrr}
1 & 1 & -1 & -1 \\
1 & -1 & 1 & -1 \\
1 & -1 & -1 & 1
\end{array}\right)
\]
where the first row compares the two levels of \(A\), the second row compares the two levels of \(B\), and the third row corresponds to the \(A B\) interaction. From the five observation vectors in Table 6.12, we obtain
\[
\overline{\mathbf{y}}=\left(\begin{array}{r}
23.2 \\
15.6 \\
20.0 \\
11.6
\end{array}\right), \quad \mathbf{S}=\left(\begin{array}{rrrr}
51.7 & 29.8 & 9.2 & 7.4 \\
29.8 & 46.8 & 16.2 & -8.7 \\
9.2 & 16.2 & 8.5 & -10.5 \\
7.4 & -8.7 & -10.5 & 24.3
\end{array}\right)
\]

For the overall test of equality of means, we have, by (6.89),
\[
T^{2}=n(\mathbf{C} \overline{\mathbf{y}})^{\prime}\left(\mathbf{C S C}^{\prime}\right)^{-1}(\mathbf{C} \overline{\mathbf{y}})=29.736<T_{.05,3,4}^{2}=114.986
\]

Table 6.12 Calculator Speed Data
\begin{tabular}{crrllr}
\hline & \multicolumn{2}{c}{\(A_{1}\)} & & \multicolumn{2}{c}{\(A_{2}\)} \\
\cline { 2 - 3 } \cline { 5 - 6 } Subjects & \(B_{1}\) & \(B_{2}\) & & \(B_{1}\) & \(B_{2}\) \\
\hline\(S_{1}\) & 30 & 21 & & 21 & 14 \\
\(S_{2}\) & 22 & 13 & & 22 & 5 \\
\(S_{3}\) & 29 & 13 & & 18 & 17 \\
\(S_{4}\) & 12 & 7 & & 16 & 14 \\
\(S_{5}\) & 23 & 24 & & 23 & 8 \\
\hline
\end{tabular}

Since the \(T^{2}\)-test is not significant, we would ordinarily not proceed with tests based on the individual rows of \(\mathbf{C}\). We will do so, however, for illustrative purposes. (Note that the \(T^{2}\)-test has very low power in this case, because \(n-1=4\) is very small.)

To test \(A, B\), and \(A B\), we test each row of \(\mathbf{C}\), in which case
\[
T^{2}=n\left(\mathbf{c}_{i}^{\prime} \overline{\mathbf{y}}\right)^{\prime}\left(\mathbf{c}_{i}^{\prime} \mathbf{S} \mathbf{c}_{i}\right)^{-\mathbf{1}} \mathbf{c}_{i}^{\prime} \overline{\mathbf{y}}
\]
is the square of the \(t\)-statistic
\[
t_{i}=\frac{\sqrt{n} \mathbf{c}_{i}^{\prime} \overline{\mathbf{y}}}{\sqrt{\mathbf{c}_{i}^{\prime} \mathbf{S} \mathbf{c}_{i}}}, \quad i=1,2,3
\]
where \(\mathbf{c}_{i}^{\prime}\) is the \(i\) th row of \(\mathbf{C}\).
The three results are as follows:
\[
\begin{aligned}
\text { Factor } A & t_{1}=1.459<t .025,4=2.776 \\
\text { Factor } B & t_{2}=5.247>t .005,4=4.604 \\
\text { Interaction } A B & t_{3}=-.152
\end{aligned}
\]

Thus only the main effect for \(B\) is significant. Note that in all but one case in Table 6.12, the value for \(B_{1}\) is greater than that for \(B_{2}\).

\subsection*{6.9.3 \(k\)-Sample Repeated Measures Model}

We turn now to the \(k\)-sample repeated measures design depicted in Table 6.9. As noted in Section 6.9.1, the multivariate approach to this repeated measures design uses the one-way MANOVA model \(\mathbf{y}_{i j}=\boldsymbol{\mu}+\boldsymbol{\beta}_{i}+\varepsilon_{i j}=\boldsymbol{\mu}_{i}+\varepsilon_{i j}\). From the \(k\) groups of \(n\) observation vectors each, we calculate \(\overline{\mathbf{y}}_{1,}, \overline{\mathbf{y}}_{2 .}, \ldots, \overline{\mathbf{y}}_{k}\). and the error matrix \(\mathbf{E}\).

The layout in Table 6.9 is similar to that of a \(k\)-sample profile analysis in Section 6.8. To test (the within-subjects) factor \(A\), we need to compare the means of the variables \(y_{1}, y_{2}, \ldots, y_{p}\) within \(y\) averaged across the levels of factor \(B\). The \(p\) variables correspond to the levels of factor \(A\). In the model \(\mathbf{y}_{i j}=\mu_{i}+\varepsilon_{i j}\), the
mean vectors \(\mu_{1}, \mu_{2}, \ldots \mu_{k}\) correspond to the levels of factor \(B\) and are estimated by \(\overline{\mathbf{y}}_{1,}, \overline{\mathbf{y}}_{2} \ldots, \overline{\mathbf{y}}_{k .}\). To compare the means of \(y_{1}, y_{2}, \ldots, y_{p}\) averaged across the levels of \(B\), we use \(\overline{\boldsymbol{\mu}} .=\sum_{i=1}^{k} \boldsymbol{\mu}_{i} / k\), which is estimated by \(\overline{\mathbf{y}}_{. .}=\sum_{i=1}^{k} \overline{\mathbf{y}}_{i .} / k\). The hypothesis \(H_{0}: \bar{\mu}_{.1}=\bar{\mu}_{.2}=\cdots=\bar{\mu}_{. p}\) comparing the means of \(y_{1}, y_{2}, \ldots, y_{p}\) (for factor \(A\) ) can be expressed using contrasts:
\[
\begin{equation*}
H_{0}: \mathbf{C} \overline{\boldsymbol{\mu}}=\mathbf{0}, \tag{6.91}
\end{equation*}
\]
where \(\mathbf{C}\) is any \((p-1) \times p\) full-rank contrast matrix with \(\mathbf{C} \mathbf{j}=\mathbf{0}\). This is equivalent to the "flatness" test of profile analysis, the third test in Section 6.8. Under \(H_{0}\), the vector \(\mathbf{C} \overline{\mathbf{y}}_{\text {.. }}\) is distributed as \(N_{p-1}\left(\mathbf{0}, \mathbf{C} \boldsymbol{\Sigma} \mathbf{C}^{\prime} / N\right)\), where \(N=\sum_{i} n_{i}\) for an unbalanced design and \(N=k n\) in the balanced case. We can therefore test \(H_{0}\) with
\[
\begin{equation*}
T^{2}=N\left(\mathbf{C} \overline{\mathbf{y}}_{. .}\right)^{\prime}\left(\mathbf{C S}_{\mathrm{pl}} \mathbf{C}^{\prime}\right)^{-1}(\mathbf{C} \overline{\mathbf{y}} . .) \tag{6.92}
\end{equation*}
\]
where \(\mathbf{S}_{\mathrm{pl}}=\mathbf{E} / \nu_{E}\). The \(T^{2}\)-statistic in (6.92) is distributed as \(T_{p-1, \nu_{E}}^{2}\) when \(H_{0}\) is true, where \(\nu_{E}=N-k\) [see (6.83) and the comments following]. Note that the dimension of \(T^{2}\) is \(p-1\) because \(\mathbf{C} \overline{\mathbf{y}}_{\text {.. }}\) is \((p-1) \times 1\).

For the grouping or between-subjects factor \(B\), we wish to compare the means for the \(k\) levels of \(B\). The mean response for the \(i\) th level of \(B\) (averaged over the levels of \(A\) ) is \(\sum_{r=1}^{p} \mu_{i r} / p=\mathbf{j}^{\prime} \boldsymbol{\mu}_{i} / p\). The hypothesis can be expressed as
\[
\begin{equation*}
H_{0}: \mathbf{j}^{\prime} \boldsymbol{\mu}_{1}=\mathbf{j}^{\prime} \boldsymbol{\mu}_{2}=\cdots=\mathbf{j}^{\prime} \boldsymbol{\mu}_{k}, \tag{6.93}
\end{equation*}
\]
which is analogous to (6.79), the "levels" hypothesis in profile analysis. This is easily tested by calculating a univariate \(F\)-statistic for a one-way ANOVA on \(z_{i j}=\) \(\mathbf{j}^{\prime} \mathbf{y}_{i j}, i=1,2, \ldots, k ; j=1,2, \ldots, n_{i}\). There is a \(z_{i j}\) corresponding to each subject, \(S_{i j}\). The observation vector for each subject is thus reduced to a single scalar observation, and we have a one-way ANOVA comparing the means \(\mathbf{j}^{\prime} \overline{\mathbf{y}}_{1,}, \mathbf{j}^{\prime} \overline{\mathbf{y}}_{2,}, \ldots, \mathbf{j}^{\prime} \overline{\mathbf{y}}_{k \text {. }}\). (Note that \(\mathrm{j}^{\prime} \overline{\mathbf{y}}_{i .} / p\) is an average over the \(p\) levels of \(A\).)

The \(A B\) interaction hypothesis is equivalent to the parallelism hypothesis in profile analysis [see (6.77)],
\[
\begin{equation*}
H_{0}: \mathbf{C} \boldsymbol{\mu}_{1}=\mathbf{C} \boldsymbol{\mu}_{2}=\cdots=\mathbf{C} \boldsymbol{\mu}_{k} . \tag{6.94}
\end{equation*}
\]

In other words, differences or contrasts among the levels of factor \(A\) are the same across all levels of factor \(B\). This is easily tested by performing a one-way MANOVA on \(\mathbf{z}_{i j}=\mathbf{C} \mathbf{y}_{i j}\) or directly by
\[
\begin{equation*}
\Lambda=\frac{\left|\mathbf{C E C}^{\prime}\right|}{\left|\mathbf{C}(\mathbf{E}+\mathbf{H}) \mathbf{C}^{\prime}\right|} \tag{6.95}
\end{equation*}
\]
[see (6.77)], which is distributed as \(\Lambda_{p-1, \nu_{H}, \nu_{E}}\), with \(\nu_{H}=k-1\) and \(\nu_{E}=N-k\); that is, \(\nu_{E}=\sum_{i}\left(n_{i}-1\right)\) for the unbalanced model or \(\nu_{E}=k(n-1)\) in the balanced model.

\subsection*{6.9.4 Computation of Repeated Measures Tests}

Some statistical software packages have automated repeated measures procedures that are easily implemented. However, if one is unsure as to how the resulting tests correspond to the tests in Section 6.9.3, there are two ways to obtain the tests directly. One approach is to calculate (6.92) and (6.95) outright using a matrix manipulation routine. We would need to have available the \(\mathbf{E}\) and \(\mathbf{H}\) matrices of a one-way MANOVA using a data layout as in Table 6.9.

The second approach uses simple data transformations available in virtually all programs. To test (6.91) for factor \(A\), we would transform each \(\mathbf{y}_{i j}\) to \(\mathbf{z}_{i j}=\mathbf{C} \mathbf{y}_{i j}\) by using the rows of \(\mathbf{C}\). For example, if
\[
\mathbf{C}=\left(\begin{array}{rrrr}
1 & -1 & 0 & 0 \\
0 & 1 & -1 & 0 \\
0 & 0 & 1 & -1
\end{array}\right)
\]
then each \(\mathbf{y}^{\prime}=\left(y_{1}, y_{2}, y_{3}, y_{4}\right)\) becomes \(\mathbf{z}^{\prime}=\left(y_{1}-y_{2}, y_{2}-y_{3}, y_{3}-y_{4}\right)\). We then test \(H_{0}: \boldsymbol{\mu}_{z}=\mathbf{0}\) using a one-sample \(T^{2}\) on all \(N\) of the \(\mathbf{z}_{i j}\) 's,
\[
T^{2}=N \overline{\mathbf{z}}^{\prime} \mathbf{S}_{z} \overline{\mathbf{z}}
\]
where \(N=\sum_{i} n_{i}, \overline{\mathbf{z}}=\sum_{i j} \mathbf{z}_{i j} / N\), and \(\mathbf{S}_{z}=\mathbf{E}_{z} / \nu_{E}\) is the pooled covariance matrix. Reject \(H_{0}\) if \(T^{2} \geq T_{\alpha, p-1, \nu_{E}}^{2}\).

To test (6.93) for factor \(B\), we sum the components of each observation vector to obtain \(z_{i j}=\mathbf{j}^{\prime} \mathbf{y}_{i j}=y_{i j 1}+y_{i j 2}+\cdots+y_{i j p}\) and compare the means \(\bar{z}_{1,}, \bar{z}_{2,}, \ldots, \bar{z}_{k}\). by an \(F\)-test as in one-way ANOVA.

To test the interaction hypothesis (6.94), we transform each \(\mathbf{y}_{i j}\) to \(\mathbf{z}_{i j}=\mathbf{C} \mathbf{y}_{i j}\) using the rows of \(\mathbf{C}\) as above. Note that \(\mathbf{z}_{i j}\) is \((p-1) \times 1\). We then do a one-way MANOVA on \(\mathbf{z}_{i j}\) to obtain
\[
\begin{equation*}
\Lambda=\frac{\left|\mathbf{E}_{z}\right|}{\left|\mathbf{E}_{z}+\mathbf{H}_{z}\right|} \tag{6.96}
\end{equation*}
\]

\subsection*{6.9.5 Repeated Measures with Two Within-Subjects Factors and One Between-Subjects Factor}

The repeated measures model with two within-subjects factors \(A\) and \(B\) and one between-subjects factor \(C\) corresponds to a one-way MANOVA design in which each observation vector includes measurements on a two-way factorial arrangement of treatments. Thus each subject receives all treatment combinations of the two factors \(A\) and \(B\). As usual, the sequence of administration of treatment combinations should be randomized for each subject. A design of this type is illustrated in Table 6.13.

Each \(\mathbf{y}_{i j}\) in Table 6.13 has nine elements, consisting of responses to the nine treatment combinations \(A_{1} B_{1}, A_{1} B_{2}, \ldots, A_{3} B_{3}\). We are interested in the same hypotheses as in a univariate split-plot design, but we use a multivariate approach to allow

Table 6.13 Data Layout for Repeated Measures with Two Within-Subjects Factors and One Between-Subjects Factor
\begin{tabular}{|c|c|c|c|c|c|c|c|c|c|c|}
\hline \multirow[t]{3}{*}{\begin{tabular}{l}

Subjects \\
Factor
\end{tabular}} & \multirow[b]{3}{*}{Subjects} & \multicolumn{9}{|c|}{Within-Subjects Factors} \\
\hline & & \multicolumn{3}{|c|}{\(A_{1}\)} & \multicolumn{3}{|c|}{\(A_{2}\)} & \multicolumn{3}{|c|}{\(A_{3}\)} \\
\hline & & \(B_{1}\) & \(B_{2}\) & \(B_{3}\) & \(B_{1}\) & \(B_{2}\) & \(B_{3}\) & \(B_{1}\) & \(B_{2}\) & \(B_{3}\) \\
\hline \multirow[t]{4}{*}{\(C_{1}\)} & \(S_{11}\) & \multirow[t]{4}{*}{( \(y_{111}\)} & \multirow[t]{4}{*}{\(y_{112}\)} & \multirow[t]{4}{*}{\(y_{113}\)} & \multirow[t]{4}{*}{\(y_{114}\)} & \(y_{115}\) & \multirow[t]{4}{*}{\(y_{116}\)} & \multirow[t]{4}{*}{\(y_{117}\)} & \multirow[t]{4}{*}{\(y_{118}\)} & \multirow[t]{4}{*}{\(\left.y_{119}\right)=y_{11}^{\prime}\)} \\
\hline & \(S_{12}\) & & & & & \(\mathrm{y}_{12}^{\prime}\) & & & & \\
\hline & \(\vdots\) & & & & & : & & & & \\
\hline & \(S_{1 n_{1}}\) & & & & & \(\mathrm{y}_{1 n_{1}}^{\prime}\) & & & & \\
\hline \multirow[t]{4}{*}{\(C_{2}\)} & \(S_{21}\) & & & & & \(\mathbf{y}_{21}^{\prime}\) & & & & \\
\hline & \(S_{22}\) & & & & & \(\mathbf{y}_{22}^{\prime}\) & & & & \\
\hline & & & & & & \(\vdots\) & & & & \\
\hline & \(S_{2 n_{2}}\) & & & & & \(\mathbf{y}_{2 n_{2}}^{\prime}\) & & & & \\
\hline \(C_{3}\) & \(S_{31}\) & & & & & \(\mathrm{y}_{31}^{\prime}\) & & & & \\
\hline & \(S_{32}\) & & & & & \(\mathbf{y}_{32}^{\prime}\) & & & & \\
\hline & \(\vdots\) & & & & & ! & & & & \\
\hline & \(S_{3 n_{3}}\) & & & & & \(\mathrm{y}_{3 n_{3}}^{\prime}\) & & & & \\
\hline
\end{tabular}
for correlated \(y\) 's. The model for the observation vectors is the one-way MANOVA model
\[
\mathbf{y}_{i j}=\boldsymbol{\mu}+\gamma_{i}+\varepsilon_{i j}=\mu_{i}+\varepsilon_{i j}
\]
where \(\gamma_{i}\) is the \(C\) effect.
To test factors \(A, B\), and \(A B\) in Table 6.13, we use contrasts in the \(y\) 's. An example of contrast matrices would be
\[
\begin{align*}
\mathbf{A} & =\left(\begin{array}{rrrrrrrrr}
2 & 2 & 2 & -1 & -1 & -1 & -1 & -1 & -1 \\
0 & 0 & 0 & 1 & 1 & 1 & -1 & -1 & -1
\end{array}\right),  \tag{6.97}\\
\mathbf{B} & =\left(\begin{array}{rrrrrrrrr}
2 & -1 & -1 & 2 & -1 & -1 & 2 & -1 & -1 \\
0 & 1 & -1 & 0 & 1 & -1 & 0 & 1 & -1
\end{array}\right),  \tag{6.98}\\
\mathbf{G} & =\left(\begin{array}{rrrrrrrr}
4 & -2 & -2 & -2 & 1 & 1 & -2 & 1 \\
0 & 2 & -2 & 0 & -1 & 1 & 0 & -1 \\
1 \\
0 & 0 & 0 & 2 & -1 & -1 & -2 & 1 \\
1 \\
0 & 0 & 0 & 0 & 1 & -1 & 0 & -1 \\
1
\end{array}\right) . \tag{6.99}
\end{align*}
\]

Note that the matrices \(\mathbf{A}, \mathbf{B}\), and \(\mathbf{G}\) can be formed by turning the desired comparisons for each \(k\)-level factor into a \((k-1) \times k\) contrast matrix and then using Kronecker products (see Section 2.12). For example, the rows of \(\mathbf{A}\) are orthogonal
contrasts with two comparisons:
\[
\begin{array}{r}
A_{1} \text { vs. } A_{2} \text { and } A_{3}, \\
A_{2} \text { vs. } A_{3} .
\end{array}
\]

Similarly, B compares
\(B_{1}\) vs. \(B_{2}\) and \(B_{3}\),
\(B_{2}\) vs. \(B_{3}\).

So if factor \(A\) has \(a\) levels and factor \(B\) has \(b\) levels, we obtain A, B, and G by constructing matrices \(\mathbf{A}^{*}\) and \(\mathbf{B}^{*}\)
\[
\mathbf{A}^{*}=\left(\begin{array}{rrr}
-2 & 1 & 1 \\
0 & -1 & 1
\end{array}\right) \quad \text { and } \quad \mathbf{A}^{*}=\left(\begin{array}{rrr}
-2 & 1 & 1 \\
0 & -1 & 1
\end{array}\right)
\]
and defining \(\mathbf{A}=\mathbf{A}^{*} \otimes \mathbf{1}_{b}^{\prime}, \mathbf{B}=\mathbf{1}_{a}^{\prime} \otimes \mathbf{B}^{*}\), and \(\mathbf{G}=\mathbf{A}^{*} \otimes \mathbf{B}^{*}\). Other orthogonal (or linearly independent) contrasts could be used for \(A\) and \(B\). Note that the matrix \(\mathbf{G}\) is for the \(A B\) interaction and can also be obtained from products of the corresponding elements of the rows of \(\mathbf{A}\) and the rows of \(\mathbf{B}\).

As before, we define \(\overline{\mathbf{y}} . .=\sum_{i j} \mathbf{y}_{i j} / N, \mathbf{S}_{\mathrm{pl}}=\mathbf{E} / \nu_{E}\), and \(N=\sum_{i} n_{i}\). If there were \(k\) levels of \(C\) in Table 6.13 with mean vectors \(\mu_{1}, \boldsymbol{\mu}_{2}, \ldots, \boldsymbol{\mu}_{k}\), then \(\overline{\boldsymbol{\mu}} .=\) \(\sum_{i=1}^{k} \boldsymbol{\mu}_{i} / k\), and the \(A\) main effect corresponding to \(H_{0}: \mathbf{A} \overline{\boldsymbol{\mu}} .=\mathbf{0}\) could be tested with
\[
\begin{equation*}
T^{2}=N\left(\mathbf{A} \overline{\mathbf{y}}_{. .}\right)^{\prime}\left(\mathbf{A} \mathbf{S}_{\mathrm{pl}} \mathbf{A}^{\prime}\right)^{-1}(\mathbf{A} \overline{\mathbf{y}} . .) \tag{6.100}
\end{equation*}
\]
which is distributed as \(T_{2, \nu_{E}}^{2}\) under \(H_{0}\), where \(\nu_{E}=\sum_{i=1}^{k}\left(n_{i}-1\right)\). The dimension is 2 , corresponding to the two rows of \(\mathbf{A}\).

Similarly, to test \(H_{0}: \mathbf{B} \overline{\boldsymbol{\mu}}=\mathbf{0}\) and \(H_{0}: \mathbf{G} \overline{\boldsymbol{\mu}}=\mathbf{0}\) for the \(B\) main effect and the \(A B\) interaction, respectively, we have
\[
\begin{align*}
& T^{2}=N\left(\mathbf{B} \overline{\mathbf{y}}_{. .}\right)^{\prime}\left(\mathbf{B} \mathbf{S}_{\mathrm{pl}} \mathbf{B}^{\prime}\right)^{-1}\left(\mathbf{B} \overline{\mathbf{y}}_{. .}\right)  \tag{6.101}\\
& T^{2}=N\left(\mathbf{G} \overline{\mathbf{y}}_{. .}\right)^{\prime}\left(\mathbf{G S}_{\mathrm{p} 1} \mathbf{G}^{\prime}\right)^{-1}\left(\mathbf{G} \overline{\mathbf{y}}_{. .}\right) \tag{6.102}
\end{align*}
\]
which are distributed as \(T_{2, \nu_{E}}^{2}\) and \(T_{4, \nu_{E}}^{2}\), respectively. In general, if factor \(A\) has \(a\) levels and factor \(B\) has \(b\) levels, then \(\mathbf{A}\) has \(a-1\) rows, \(\mathbf{B}\) has \(b-1\) rows, and \(\mathbf{G}\) has \((a-1)(b-1)\) rows. The \(T^{2}\)-statistics are then distributed as \(T_{a-1, \nu_{E}}^{2}, T_{b-1, \nu_{E}}^{2}\), and \(T_{(a-1)(b-1), \nu_{E}}^{2}\), respectively.

Factors \(A, B\), and \(A B\) can be tested with Wilks' \(\Lambda\) as well as \(T^{2}\). Define \(\mathbf{H}^{*}=\) \(N \overline{\mathbf{y}} . . \overline{\mathbf{y}}_{\text {.. }}^{\prime}\) from the partitioning \(\sum_{i j} \mathbf{y}_{i j} \mathbf{y}_{i j}^{\prime}=\mathbf{E}+\mathbf{H}+N \overline{\mathbf{y}} . . \overline{\mathbf{y}}_{\text {.. }}^{\prime}\). This can be used to test \(H_{0}: \overline{\boldsymbol{\mu}}=\mathbf{0}\) (not usually a hypothesis of interest) by means of
\[
\begin{equation*}
\Lambda=\frac{|\mathbf{E}|}{\left|\mathbf{E}+\mathbf{H}^{*}\right|}, \tag{6.103}
\end{equation*}
\]
which is \(\Lambda_{p, 1, \nu_{E}}\) if \(H_{0}\) is true. Then the hypothesis of interest, \(H_{0}: \mathbf{A} \overline{\boldsymbol{\mu}} .=\mathbf{0}\) for factor \(A\), can be tested with
\[
\begin{equation*}
\Lambda=\frac{\left|\mathbf{A E} \mathbf{A}^{\prime}\right|}{\left|\mathbf{A}\left(\mathbf{E}+\mathbf{H}^{*}\right) \mathbf{A}^{\prime}\right|}, \tag{6.104}
\end{equation*}
\]
which is distributed as \(\Lambda_{a-1,1, \nu_{E}}\) when \(H_{0}\) is true, where \(a\) is the number of levels of factor \(A\). There are similar expressions for testing factors \(B\) and \(A B\). Note that the dimension of \(\Lambda\) in (6.104) is \(a-1\), because \(\mathbf{A E A}^{\prime}\) is \((a-1) \times(a-1)\).

The \(T^{2}\) and Wilks' \(\Lambda\) expressions in (6.100) and (6.104) are related by
\[
\begin{align*}
\Lambda & =\frac{\nu_{E}}{\nu_{E}+T^{2}}  \tag{6.105}\\
T^{2} & =\nu_{E} \frac{1-\Lambda}{\Lambda} \tag{6.106}
\end{align*}
\]

We can establish (6.105) as follows. By (6.27),
\[
\begin{aligned}
U^{(s)} & =\sum_{i=1}^{s} \lambda_{i}=\operatorname{tr}\left[\left(\mathbf{A E A} \mathbf{A}^{\prime}\right)^{-1}\left(\mathbf{A} \mathbf{H}^{*} \mathbf{A}^{\prime}\right)\right] \\
& =\operatorname{tr}\left[\left(\mathbf{A E A} \mathbf{A}^{\prime}\right)^{-1} \mathbf{A} N \overline{\mathbf{y}} . . \overline{\mathbf{y}}_{. .}^{\prime} \mathbf{A}^{\prime}\right] \\
& =N \operatorname{tr}\left[\left(\mathbf{A E} \mathbf{A}^{\prime}\right)^{-1} \mathbf{A} \overline{\mathbf{y}}_{. .}\left(\mathbf{A} \overline{\mathbf{y}}_{. .}\right)^{\prime}\right] \\
& =N \operatorname{tr}\left[\left(\mathbf{A} \overline{\mathbf{y}}_{. .}\right)^{\prime}\left(\mathbf{A E} \mathbf{A}^{\prime}\right)^{-1} \mathbf{A} \overline{\mathbf{y}}_{. .}\right] \\
& =\frac{N}{\nu_{E}}\left(\mathbf{A} \overline{\mathbf{y}}_{. .}\right)^{\prime}\left(\mathbf{A} \mathbf{S}_{\mathrm{pl}} \mathbf{A}^{\prime}\right)^{-1} \mathbf{A} \overline{\mathbf{y}}_{. .} \\
& =\frac{T^{2}}{\nu_{E}}
\end{aligned}
\]

Since \(\operatorname{rank}\left(\mathbf{H}^{*}\right)=1\), only \(\lambda_{1}\) is nonzero, and
\[
U^{(1)}=\sum_{i=1}^{s} \lambda_{i}=\lambda_{1}
\]

By (6.14),
\[
\Lambda=\frac{1}{1+\lambda_{1}}=\frac{1}{1+U^{(1)}}=\frac{1}{1+T^{2} / \nu_{E}}
\]
which is the same as (6.105).
Factor \(C\) is tested exactly as factor \(B\) in Section 6.9.3. The hypothesis is
\[
H_{0}: \mathbf{j}^{\prime} \boldsymbol{\mu}_{1}=\mathbf{j}^{\prime} \boldsymbol{\mu}_{2}=\cdots=\mathbf{j}^{\prime} \boldsymbol{\mu}_{k}
\]
as in (6.93), and we perform a univariate \(F\)-test on \(z_{i j}=\mathbf{j}^{\prime} \mathbf{y}_{i j}\) in a one-way ANOVA layout.

The \(A C, B C\), and \(A B C\) interactions are tested as follows:
\(A C\) Interaction. The \(A C\) interaction hypothesis is
\[
H_{0}: \mathbf{A} \boldsymbol{\mu}_{1}=\mathbf{A} \boldsymbol{\mu}_{2}=\cdots=\mathbf{A} \boldsymbol{\mu}_{k}
\]
which states that contrasts in factor \(A\) are the same across all levels of factor \(C\). This can be tested by
\[
\begin{equation*}
\Lambda=\frac{\left|\mathbf{A E A}^{\prime}\right|}{\left|\mathbf{A}(\mathbf{E}+\mathbf{H}) \mathbf{A}^{\prime}\right|}, \tag{6.107}
\end{equation*}
\]
which is distributed as \(\Lambda_{2, \nu_{H}, \nu_{E}}\), where \(a-1=2\) is the number of rows of \(\mathbf{A}\) and \(\nu_{H}\) and \(\nu_{E}\) are from the multivariate one-way model. Alternatively, the test can be carried out by transforming \(\mathbf{y}_{i j}\) to \(\mathbf{z}_{i j}=\mathbf{A} \mathbf{y}_{i j}\) and doing a one-way MANOVA on \(\mathbf{z}_{i j}\).
\(B C\) Interaction. The \(B C\) interaction hypothesis
\[
H_{0}: \mathbf{B} \boldsymbol{\mu}_{1}=\mathbf{B} \boldsymbol{\mu}_{2}=\cdots=\mathbf{B} \boldsymbol{\mu}_{k}
\]
is tested by
\[
\Lambda=\frac{\left|\mathbf{B E B}^{\prime}\right|}{\left|\mathbf{B}(\mathbf{E}+\mathbf{H}) \mathbf{B}^{\prime}\right|},
\]
which is \(\Lambda_{2, \nu_{H}, \nu_{E}}\), where \(b-1=2 ; H_{0}\) can also be tested by doing MANOVA on \(\mathbf{z}_{i j}=\mathbf{B} \mathbf{y}_{i j}\).
\(A B C\) Interaction. The \(A B C\) interaction hypothesis
\[
H_{0}: \mathbf{G} \boldsymbol{\mu}_{1}=\mathbf{G} \boldsymbol{\mu}_{2}=\cdots=\mathbf{G} \boldsymbol{\mu}_{k}
\]
is tested by
\[
\Lambda=\frac{\left|\mathbf{G} \mathbf{E G}^{\prime}\right|}{\left|\mathbf{G}(\mathbf{E}+\mathbf{H}) \mathbf{G}^{\prime}\right|}
\]
which is \(\Lambda_{4, \nu_{H}, \nu_{E}}\), or by doing MANOVA on \(\mathbf{z}_{i j}=\mathbf{G} \mathbf{y}_{i j}\). In this case the dimension is \((a-1)(b-1)=4\).

The above tests for \(A C, B C\), or \(A B C\) can be also carried out with the other three MANOVA test statistics using eigenvalues of the appropriate matrices. For example, for \(A C\) we would use ( \(\mathbf{A E A})^{-1}\) ( \(\mathbf{A H A}^{\prime}\) ).

\section*{EXAMPLE 6.9 .5}

The data in Table 6.14 represent a repeated measures design with two withinsubjects factors and one between-subjects factor (Timm 1980). Since \(A\) and \(B\) have three levels each, as in the illustration in this section, we will use the \(\mathbf{A}, \mathbf{B}\), and \(\mathbf{G}\) matrices in (6.97), (6.98), and (6.99). The \(\mathbf{E}\) and \(\mathbf{H}\) matrices are \(9 \times 9\) and will not be shown. The overall mean vector is given by
\[
\overline{\mathbf{y}}_{. .}^{\prime}=(46.45,39.25,31.70,38.85,45.40,40.15,34.55,36.90,39.15)
\]

By (6.100), the test for factor \(A\) is
\[
\begin{aligned}
T^{2} & =N\left(\mathbf{A} \overline{\mathbf{y}}_{. .}\right)^{\prime}\left(\mathbf{A} \mathbf{S}_{\mathrm{pl}} \mathbf{A}^{\prime}\right)^{-1}\left(\mathbf{A} \overline{\mathbf{y}}_{. .}\right) \\
& =20(-.20,13.80)\left(\begin{array}{rr}
2138.4 & 138.6 \\
138.6 & 450.4
\end{array}\right)^{-1}\binom{-.20}{13.80} \\
& =8.645>T_{.05,2,18}^{2}=7.606 .
\end{aligned}
\]

\hline & \(S_{16}\) & 39 & 39 & 38 & 46 & 54 & 43 & 31 & 29 & 28 \\
\hline & \(S_{17}\) & 43 & 32 & 20 & 33 & 46 & 44 & 42 & 37 & 31 \\
\hline & \(S_{18}\) & 35 & 34 & 34 & 39 & 43 & 39 & 35 & 39 & 42 \\
\hline & \(S_{19}\) & 41 & 32 & 23 & 37 & 51 & 39 & 27 & 28 & 30 \\
\hline & \(S_{1,10}\) & 39 & 32 & 24 & 30 & 35 & 31 & 26 & 29 & 32 \\
\hline \multirow[t]{10}{*}{\(C_{2}\)} & \(S_{21}\) & 47 & 36 & 25 & 31 & 36 & 29 & 21 & 24 & 27 \\
\hline & \(S_{22}\) & 53 & 43 & 32 & 40 & 48 & 47 & 46 & 50 & 54 \\
\hline & \(S_{23}\) & 38 & 35 & 33 & 38 & 42 & 45 & 48 & 48 & 49 \\
\hline & \(S_{24}\) & 60 & 51 & 41 & 54 & 67 & 60 & 53 & 52 & 50 \\
\hline & \(S_{25}\) & 37 & 36 & 35 & 40 & 45 & 40 & 34 & 40 & 46 \\
\hline & \(S_{26}\) & 59 & 48 & 37 & 45 & 52 & 44 & 36 & 44 & 52 \\
\hline & \(S_{27}\) & 67 & 50 & 33 & 47 & 61 & 46 & 31 & 41 & 50 \\
\hline & \(S_{28}\) & 43 & 35 & 27 & 32 & 36 & 35 & 33 & 33 & 32 \\
\hline & \(S_{29}\) & 64 & 59 & 53 & 58 & 62 & 51 & 40 & 42 & 43 \\
\hline & \(S_{2,10}\) & 41 & 38 & 34 & 41 & 47 & 42 & 37 & 41 & 46 \\
\hline
\end{tabular}

For factor \(B\), we use (6.101) to obtain
\[
\begin{aligned}
T^{2} & =N(\mathbf{B} \overline{\mathbf{y}} . .)^{\prime}\left(\mathbf{B S}_{\mathrm{pl}} \mathbf{B}^{\prime}\right)^{-1}\left(\mathbf{B} \overline{\mathbf{y}}_{. .}\right) \\
& =20(7.15,10.55)\left(\begin{array}{rr}
305.7 & 94.0 \\
94.0 & 69.8
\end{array}\right)^{-1}\binom{7.15}{10.55} \\
& =37.438>T_{.01,2,18}^{2}=12.943
\end{aligned}
\]

By (6.102), the test for the \(A B\) interaction is given by
\[
\begin{aligned}
T^{2} & =N\left(\mathbf{G} \overline{\mathbf{y}}_{. .}\right)^{\prime}\left(\mathbf{G} \mathbf{S}_{\mathrm{p} \mathbf{l}} \mathbf{G}^{\prime}\right)^{-1}\left(\mathbf{G} \overline{\mathbf{y}}_{. .}\right) \\
& =61.825>T_{.01,4,18}^{2}=23.487
\end{aligned}
\]

To test factor \(C\), we carry out a one-way ANOVA on \(z_{i j}=\mathbf{j}^{\prime} \mathbf{y}_{i j} / 9\) :
\begin{tabular}{lcrrc} 
Source & Sum of Squares & df & Mean Square & \(F\) \\
\hline Between & 3042.22 & 1 & 3042.22 & 8.54 \\
Error & 6408.98 & 18 & 356.05 &
\end{tabular}

The observed \(F, 8.54\), has a \(p\)-value of .0091 and is therefore significant. The \(A C\) interaction is tested by (6.107) as
\[
\begin{aligned}
\Lambda & =\frac{\left|\mathbf{A E A}^{\prime}\right|}{\left|\mathbf{A}(\mathbf{E}+\mathbf{H}) \mathbf{A}^{\prime}\right|}=\frac{3.058 \times 10^{8}}{3.092 \times 10^{8}} \\
& =.9889>\Lambda_{.05,2,1,18}=.703
\end{aligned}
\]

For the \(B C\) interaction, we have
\[
\begin{aligned}
\Lambda & =\frac{\left|\mathbf{B E B}^{\prime}\right|}{\left|\mathbf{B}(\mathbf{E}+\mathbf{H}) \mathbf{B}^{\prime}\right|}=\frac{4.053 \times 10^{6}}{4.170 \times 10^{6}} \\
& =.9718>\Lambda_{.05,2,1,18}=.703
\end{aligned}
\]

For \(A B C\), we obtain
\[
\begin{aligned}
\Lambda & =\frac{\left|\mathbf{G E G} \mathbf{G}^{\prime}\right|}{\left|\mathbf{G}(\mathbf{E}+\mathbf{H}) \mathbf{G}^{\prime}\right|}=\frac{2.643 \times 10^{12}}{2.927 \times 10^{12}} \\
& =.9029>\Lambda_{.05,4,1,18}=.551
\end{aligned}
\]

In summary, factors \(A, B\), and \(C\) and the \(A B\) interaction are significant.

\subsection*{6.9.6 Repeated Measures with Two Within-Subjects Factors and Two Between-Subjects Factors}

In this section we consider a balanced two-way MANOVA design in which each observation vector arises from a two-way factorial arrangement of treatments. This is illustrated in Table 6.15 for a balanced design with three levels of all factors. Each \(\mathbf{y}_{i j k}\) has nine elements, consisting of responses to the nine treatment combinations \(A_{1} B_{1}, A_{2} B_{2}, \ldots, A_{3} B_{3}\) (see Table 6.13).

To test \(A, B\), and \(A B\), we can use the same contrast matrices \(\mathbf{A}, \mathbf{B}\), and \(\mathbf{G}\) as in (6.97)-(6.99). We define a grand mean vector \(\overline{\mathbf{y}}_{\ldots}=\sum_{i j k} \mathbf{y}_{i j k} / N\), where \(N\) is the total number of observation vectors; in this illustration, \(N=27\). In general, \(N=c d n\), where \(c\) and \(d\) are the number of levels of factors \(C\) and \(D\) and \(n\) is the number of replications in each cell (in the illustration, \(n=3\) ). The test statistics for \(A, B\), and \(A B\) are as follows, where \(\mathbf{S}_{\mathrm{pl}}=\mathbf{E} / \nu_{E}\) and the \(\mathbf{E}\) matrix is obtained from the two-way MANOVA with \(\nu_{E}=c d(n-1)\) degrees of freedom.

\section*{Factor \(A\)}
\[
T^{2}=N\left(\mathbf{A} \overline{\mathbf{y}}_{\ldots}\right)^{\prime}\left(\mathbf{A} \mathbf{S}_{\mathrm{pl}} \mathbf{A}^{\prime}\right)^{-1}\left(\mathbf{A} \overline{\mathbf{y}}_{\ldots}\right)
\]
is distributed as \(T_{a-1, \nu_{E}}^{2}\).
Factor B
\[
T^{2}=N\left(\mathbf{B}_{\mathbf{y}}^{\ldots}\right)^{\prime}\left(\mathbf{B} \mathbf{S}_{\mathrm{p} \mathbf{1}} \mathbf{B}^{\prime}\right)^{-1}\left(\mathbf{B} \overline{\mathbf{y}}_{\ldots}\right)
\]
is distributed as \(T_{b-1, \nu_{E}}^{2}\).

Table 6.15 Data Layout for Repeated Measures with Two Within-Subjects Factors and Two Between-Subjects Factors
\begin{tabular}{|c|c|c|c|c|c|c|c|c|c|c|c|}

\hline \multirow[t]{5}{*}{\(C_{2}\)} & \multirow[t]{3}{*}{\(D_{1}\)} & \(S_{211}\) & & & & & \(\mathrm{y}_{211}^{\prime}\) & & & & \\
\hline & & \(S_{212}\) & & & & & \(\mathrm{y}_{212}^{\prime}\) & & & & \\
\hline & & \(S_{213}\) & & & & & \(\mathrm{y}_{213}^{\prime}\) & & & & \\
\hline & \(D_{2}\) & \(S_{221}\) & & & & & \(\mathrm{y}_{221}^{\prime}\) & & & & \\
\hline & \(D_{3}\) & : & & & & & \(\vdots\) & & & & \\
\hline \multirow[t]{3}{*}{\(C_{3}\)} & \(D_{1}\) & : & & & & & ! & & & & \\
\hline & \(D_{2}\) & \(\vdots\) & & & & & : & & & & \\
\hline & \(D_{3}\) & \(S_{333}\) & & & & & \(\mathrm{y}_{333}^{\prime}\) & & & & \\
\hline
\end{tabular}

\section*{\(A B\) Interaction}
\[
T^{2}=N\left(\mathbf{G} \overline{\mathbf{y}}_{\ldots}\right)^{\prime}\left(\mathbf{G} \mathbf{S}_{\mathrm{pl}} \mathbf{G}^{\prime}\right)^{-1}\left(\mathbf{G} \overline{\mathbf{y}}_{\ldots}\right)
\]
is distributed as \(T_{(a-1)(b-1), \nu_{E}}^{2}\).
To test factors \(C, D\), and \(C D\), we transform to \(z_{i j k}=\mathbf{j}^{\prime} \mathbf{y}_{i j k}\) and carry out univariate \(F\)-tests on a two-way ANOVA design.

To test factors \(A C, A D\), and \(A C D\), we perform a two-way MANOVA on \(\mathbf{A y}_{i j k}\). Then, the \(C\) main effect on \(\mathbf{A y}_{i j k}\) compares the levels of \(C\) on \(\mathbf{A y}_{i j k}\), which is an effective description of the \(A C\) interaction. Similarly, the \(D\) main effect on \(\mathbf{A y}_{i j k}\) yields the \(A D\) interaction, and the \(C D\) interaction on \(\mathbf{A y}_{i j k}\) gives the \(A C D\) interaction.

To test factors \(B C, B D\), and \(B C D\), we carry out a two-way MANOVA on \(\mathbf{B} \mathbf{y}_{i j k}\). The \(C\) main effect on \(\mathbf{B} \mathbf{y}_{i j k}\) gives the \(B C\) interaction, the \(D\) main effect on \(\mathbf{B} \mathbf{y}_{i j k}\) yields the \(B D\) interaction, and the \(C D\) interaction on \(\mathbf{B} \mathbf{y}_{i j k}\) corresponds to the \(B C D\) interaction.

Finally, to test factors \(A B C, A B D\), and \(A B C D\), we perform a two-way MANOVA on \(\mathbf{G} \mathbf{y}_{i j k}\). Then the \(C\) main effect on \(\mathbf{G y}_{i j k}\) gives the \(A B C\) interaction, the \(D\) main
effect on \(\mathbf{G} \mathbf{y}_{i j k}\) yields the \(A B D\) interaction, and the \(C D\) interaction on \(\mathbf{G y}_{i j k}\) corresponds to the \(A B C D\) interaction.

\subsection*{6.9.7 Additional Topics}

Wang (1983) and Timm (1980) give a method for obtaining univariate mixed-model sums of squares from the multivariate \(\mathbf{E}\) and \(\mathbf{H}\) matrices. Crepeau et al. (1985) consider repeated measures experiments with missing data. Federer (1986) discusses the planning of repeated measures designs, emphasizing such aspects as determining the length of treatment period, eliminating carry-over effects, the nature of pre- and posttreatment, the nature of a response to a treatment, treatment sequences, and the choice of a model. Vonesh (1986) discusses sample size requirements to achieve a given power level in repeated measures designs. Patel (1986) presents a model that accommodates both within- and between-subjects covariates in repeated measures designs. Jensen (1982) compares the efficiency and robustness of various procedures.

A multivariate or multiresponse repeated measurement design will result if more than one variable is measured on each subject at each treatment combination. Such designs are discussed by Timm (1980), Reinsel (1982), Wang (1983), and Thomas (1983). Bock (1975) refers to observations of this type as doubly multivariate data.

\subsection*{6.10 GROWTH CURVES}

When the subject responds to a treatment or stimulus at successive time periods, the pattern of responses is often referred to as a growth curve. As in repeated measures experiments, subjects are usually human or animal. We consider estimation and testing hypotheses about the form of the response curve for a single sample in Section 6.10.1 and extend to growth curves for several samples in Section 6.10.2.

\subsection*{6.10.1 Growth Curve for One Sample}

The data layout for a single sample growth curve experiment is analogous to Table 6.11, with the levels of factor \(A\) representing time periods. Thus we have a sample of \(n\) observation vectors \(\mathbf{y}_{1}, \mathbf{y}_{2}, \ldots, \mathbf{y}_{n}\), for which we compute \(\overline{\mathbf{y}}\) and \(\mathbf{S}\). The usual approach is to approximate the shape of the growth curve by a polynomial function of time. If the time points are equally spaced, we can use orthogonal polynomials. This approach will be described first, followed by a method suitable for unequal time intervals.

Orthogonal polynomials are special contrasts that are often used in testing for linear, quadratic, cubic, and higher-order trends in quantitative factors. For a more complete description and derivation see Guttman (1982, pp. 194-207), Morrison (1983, pp. 182-188), or Rencher and Schaalje (2008, pp. 363-371). Here we give only a heuristic introduction to the use of these contrasts.

Suppose we administer a drug to some subjects and measure a certain reaction at 3-minute intervals. Let \(\mu_{1}, \mu_{2}, \mu_{3}, \mu_{4}\), and \(\mu_{5}\) designate the average responses at 0 , \(3,6,9\), and 12 minutes, respectively. To test the hypothesis that there are no trends in the \(\mu_{j}\) 's, we could test \(H_{0}: \mu_{1}=\mu_{2}=\cdots=\mu_{5}\) or \(H_{0}: \mathbf{C} \boldsymbol{\mu}=\mathbf{0}\) using the contrast matrix
\[
\mathbf{C}=\left(\begin{array}{rrrrr}
-2 & -1 & 0 & 1 & 2  \tag{6.108}\\
2 & -1 & -2 & -1 & 2 \\
-1 & 2 & 0 & -2 & 1 \\
1 & -4 & 6 & -4 & 1
\end{array}\right)
\]
in \(T^{2}=n(\mathbf{C} \overline{\mathbf{y}})^{\prime}\left(\mathbf{C S C}^{\prime}\right)^{-1}(\mathbf{C} \overline{\mathbf{y}})\) as in (6.89). The four rows of \(\mathbf{C}\) are orthogonal polynomials that test for linear, quadratic, cubic, and quartic trends in the means. As noted in Section 6.9.2, any set of orthogonal contrasts in \(\mathbf{C}\) will give the same value of \(T^{2}\) to test \(H_{0}: \mu_{1}=\mu_{2}=\cdots=\mu_{5}\). However, in this case we will be interested in using a subset of the rows of \(\mathbf{C}\) to determine the shape of the response curve.

Table A. 13 (Kleinbaum, Kupper, and Muller 1988) gives orthogonal polynomials for \(p=3,4, \ldots, 10\). The \(p-1\) entries for each value of \(p\) constitute the matrix \(\mathbf{C}\). Some software programs will generate these automatically.

As with all orthogonal contrasts, the rows of \(C\) in (6.108) sum to zero and are mutually orthogonal. It is also apparent that the coefficients in each row increase and decrease in conformity with the desired pattern. Thus the entries in the first row, \((-2,-1,0,1,2)\), increase steadily in a straight-line trend. The values in the second row dip down and back up in a quadratic-type bend. The third row entries increase, decrease, then increase in a cubic pattern with two bends. The fourth row bends three times in a quartic curve.

To further illustrate how the orthogonal polynomials pinpoint trends in the means when testing \(H_{0}: \mathbf{C} \boldsymbol{\mu}=\mathbf{0}\), consider the three different patterns for \(\boldsymbol{\mu}\) depicted in Figure 6.4 , where \(\boldsymbol{\mu}^{\prime}{ }_{a}=(8,8,8,8,8), \boldsymbol{\mu}_{b}^{\prime}=(20,16,12,8,4)\), and \(\boldsymbol{\mu}_{c}^{\prime}{ }_{c}=\) \((5,12,15,12,5)\). Let us denote the rows of \(\mathbf{C}\) in (6.108) as \(\mathbf{c}_{1}^{\prime}, \mathbf{c}_{2}^{\prime}, \mathbf{c}_{3}^{\prime}\), and \(\mathbf{c}_{4}^{\prime}\). It is clear that \(\mathbf{c}_{i}^{\prime} \boldsymbol{\mu}_{a}=0\) for \(i=1,2,3,4\); that is, when \(H_{0}: \mu_{1}=\cdots=\mu_{5}\) is true, all four comparisons confirm it. If \(\boldsymbol{\mu}\) has the pattern \(\boldsymbol{\mu}_{b}\), only \(\mathbf{c}_{1}^{\prime} \boldsymbol{\mu}_{b}\) is nonzero. The other rows are not sensitive to a linear pattern. We illustrate this for \(\mathbf{c}_{1}^{\prime}\) and \(\mathbf{c}_{2}^{\prime}\) :
\[
\begin{aligned}
& \mathbf{c}_{1}^{\prime} \boldsymbol{\mu}_{b}=(-2)(20)+(-1)(16)+(0)(12)+(1)(8)+(2)(4)=-44, \\
& \mathbf{c}_{2}^{\prime} \boldsymbol{\mu}_{b}=2(20)-16-2(12)-8+2(4)=0
\end{aligned}
\]

For \(\boldsymbol{\mu}_{c}\), only \(\mathbf{c}_{2}^{\prime} \boldsymbol{\mu}_{c}\) is nonzero. For example,
\[
\begin{aligned}
& \mathbf{c}_{1}^{\prime} \boldsymbol{\mu}_{c}=-2(5)-12+12+2(5)=0 \\
& \mathbf{c}_{2}^{\prime} \boldsymbol{\mu}_{c}=2(5)-12-2(15)-12+2(5)=-19 .
\end{aligned}
\]

Thus each orthogonal polynomial independently detects the type of curvature it is designed for and ignores other types. Of course, real curves generally exhibit a mixture of more than one type of curvature, and in practice more than one orthogonal polynomial contrast may be significant.

Figure 6.4 Three different patterns for \(\boldsymbol{\mu}\).

To test hypotheses about the shape of the curve, we therefore use the appropriate rows of \(\mathbf{C}\) in (6.108). Suppose we suspected a priori that there would be a combined linear and quadratic trend. Then we would partition \(\mathbf{C}\) as follows:
\[
\begin{aligned}
& \mathbf{C}_{1}=\left(\begin{array}{rrrrr}
-2 & -1 & 0 & 1 & 2 \\
2 & -1 & -2 & -1 & 2
\end{array}\right), \\
& \mathbf{C}_{2}=\left(\begin{array}{rrlll}
-1 & 2 & 0 & -2 & 1 \\
1 & -4 & 6 & -4 & 1
\end{array}\right) .
\end{aligned}
\]

We would test \(H_{0}: \mathbf{C}_{1} \boldsymbol{\mu}=\mathbf{0}\) by
\[
T^{2}=n\left(\mathbf{C}_{1} \overline{\mathbf{y}}\right)^{\prime}\left(\mathbf{C}_{1} \mathbf{S C}_{1}^{\prime}\right)^{-1}\left(\mathbf{C}_{1} \overline{\mathbf{y}}\right)
\]
which is distributed as \(T_{2, n-1}^{2}\), where 2 is the number of rows of \(\mathbf{C}_{1}, n\) is the number of subjects in the sample, and \(\overline{\mathbf{y}}\) and \(\mathbf{S}\) are the mean vector and covariance matrix for the sample. Similarly, \(H_{0}: \mathbf{C}_{2} \boldsymbol{\mu}=\mathbf{0}\) is tested by
\[
T^{2}=n\left(\mathbf{C}_{2} \overline{\mathbf{y}}\right)^{\prime}\left(\mathbf{C}_{2} \mathbf{S} \mathbf{C}_{2}^{\prime}\right)^{-1}\left(\mathbf{C}_{2} \overline{\mathbf{y}}\right)
\]
which is \(T_{2, n-1}^{2}\). In this case we might expect the first to reject \(H_{0}\) and the second to accept \(H_{0}\).

If we have no a priori expectations as to the shape of the curve, we could proceed as follows. Test the overall hypothesis \(H_{0}: \mathbf{C} \boldsymbol{\mu}=\mathbf{0}\), and if \(H_{0}\) rejected, use each of the rows of \(\mathbf{C}\) separately to test \(H_{0}: \mathbf{c}_{i}^{\prime} \boldsymbol{\mu}=0, i=1,2,3,4\). The respective test statistics are
\[
T^{2}=n(\mathbf{C} \overline{\mathbf{y}})^{\prime}\left(\mathbf{C S C}^{\prime}\right)^{-1}(\mathbf{C} \overline{\mathbf{y}})
\]
which is \(T_{4, n-1}^{2}\), and
\[
t_{i}=\frac{\mathbf{c}_{i}^{\prime} \tilde{\mathbf{y}}}{\sqrt{\mathbf{c}_{i}^{\prime} \mathbf{S c}_{i} / n}}, \quad i=1,2,3,4
\]
each of which is distributed as \(t_{n-1}\) (see Example 6.9.2).
In a case where \(p\) is large so that \(\mu\) has a large number of levels, say 10 or more, we would likely want to stop testing after the first four or five rows of \(\mathbf{C}\) and test the remaining rows in one group. However, for larger values of \(p\), most tables of orthogonal polynomials give only the first few rows and omit those corresponding to higher degrees of curvature. We can find a matrix whose rows are orthogonal to the rows of a given matrix as follows. Suppose \(p=11\) so that \(\mathbf{C}\) is \(10 \times 11\) and \(\mathbf{C}_{1}\) contains the first five orthogonal polynomials. Then a matrix \(\mathbf{C}_{2}\), with rows orthogonal to those of \(\mathbf{C}_{1}\), can be obtained by selecting five linearly independent rows of
\[
\begin{equation*}
\mathbf{B}=\mathbf{I}-\mathbf{C}_{1}^{\prime}\left(\mathbf{C}_{1} \mathbf{C}_{1}^{\prime}\right)^{-1} \mathbf{C}_{1} \tag{6.109}
\end{equation*}
\]
whose rows can easily be shown to be orthogonal to those of \(\mathbf{C}_{1}\). The matrix \(\mathbf{B}\) is not full rank, and some care must be exercised in choosing linearly independent rows. However, if an incorrect choice of \(\mathrm{C}_{2}\) is made, the computer algorithm should indicate this as it attempts to invert \(\mathbf{C}_{2} \mathbf{S C}_{2}^{\prime}\) in \(T^{2}=n\left(\mathbf{C}_{2} \overline{\mathbf{y}}\right)^{\prime}\left(\mathbf{C}_{2} \mathbf{S C}_{2}^{\prime}\right)^{-1}\left(\mathbf{C}_{2} \overline{\mathbf{y}}\right)\).

Alternatively, to check for significant curvature beyond the rows of \(\mathrm{C}_{1}\) without finding \(\mathbf{C}_{2}\), we can use the test for additional information in a subset of variables in Section 5.8. We need not find \(\mathbf{C}_{2}\) in order to find the overall \(T^{2}\), since, as noted in Section 6.9.2, any full rank \((p-1) \times p\) matrix \(\mathbf{C}\) such that \(\mathbf{C j}=\mathbf{0}\) will give the same value in the overall \(T^{2}\)-test of \(H_{0}: \mathbf{C} \boldsymbol{\mu}=\mathbf{0}\). We can conveniently use a simple contrast matrix such as
\[
\mathbf{C}=\left(\begin{array}{rrrrr}
1 & -1 & 0 & \cdots & 0 \\
0 & 1 & -1 & \cdots & 0 \\
\vdots & \vdots & \vdots & & \vdots \\
0 & 0 & 0 & \cdots & -1
\end{array}\right)
\]
in
\[
\begin{equation*}
T^{2}=n(\mathbf{C} \overline{\mathbf{y}})^{\prime}\left(\mathbf{C S C}^{\prime}\right)^{-1}(\mathbf{C} \overline{\mathbf{y}}) \tag{6.110}
\end{equation*}
\]
which is \(T_{p-1, n-1}^{2}\). Let \(p_{1}\) be the number of orthogonal polynomials in \(\mathbf{C}_{1}\) and \(p_{2}\) be the number of rows of \(\mathbf{C}_{2}\) if it were available; that is \(p_{1}+p_{2}=p-1\). Then the test statistic for the \(p_{1}\) orthogonal polynomials in \(\mathbf{C}_{1}\) is
\[
\begin{equation*}
T_{1}^{2}=n\left(\mathbf{C}_{1} \overline{\mathbf{y}}\right)^{\prime}\left(\mathbf{C}_{1} \mathbf{S C}_{1}^{\prime}\right)^{-1}\left(\mathbf{C}_{1} \overline{\mathbf{y}}\right) \tag{6.111}
\end{equation*}
\]
which is \(T_{p_{1}, n-1}^{2}\). We wish to compare \(T_{1}^{2}\) in (6.111) to \(T^{2}\) in (6.110) to check for significant curvature beyond the rows of \(\mathbf{C}_{1}\). However, the test for additional information in a subset of variables in Section 5.8 was for the two-sample case. We can adapt (5.29) for use with the one-sample case as follows. The test for significance of any curvature remaining after that accounted for in \(\mathbf{C}_{1}\) is made by comparing
\[
\left(n-p_{1}-1\right) \frac{T^{2}-T_{\mathbf{1}}^{2}}{n-1+T_{1}^{2}}
\]
with the critical value \(T_{\alpha, p_{2}, n-p_{1}-1}^{2}\).
We now describe an approach that can be used when the time points are not equally spaced. It may also be of interest in the equal-time-increment case because it provides an estimate of the response function.

Suppose we observe the response of the subject at \(p\) time points \(t_{1}, t_{2}, \ldots, t_{p}\) and that the average response \(\mu\) at any time point \(t\) is a polynomial in \(t\) of degree \(k<p\) :
\[
\mu=\beta_{0}+\beta_{1} t+\beta_{2} t^{2}+\cdots+\beta_{k} t^{k}
\]

This holds for each point \(t_{r}\) and the corresponding average response \(\mu_{r}\). Thus our hypothesis becomes
\[
H_{0}:\left[\begin{array}{c}
\mu_{1}=\beta_{0}+\beta_{1} t_{1}+\beta_{2} t_{1}^{2}+\cdots+\beta_{k} t_{1}^{k}  \tag{6.112}\\
\mu_{2}=\beta_{0}+\beta_{1} t_{2}+\beta_{2} t_{2}^{2}+\cdots+\beta_{k} t_{2}^{k} \\
\vdots \\
\mu_{p}=\beta_{0}+\beta_{1} t_{p}+\beta_{2} t_{p}^{2}+\cdots+\beta_{k} t_{p}^{k}
\end{array}\right]
\]
which can be expressed in matrix notation as
\[
\begin{equation*}
H_{0}: \boldsymbol{\mu}=\mathbf{A} \boldsymbol{\beta} \tag{6.113}
\end{equation*}
\]
where
\[
\mathbf{A}=\left(\begin{array}{ccccc}
1 & t_{\mathbf{1}} & t_{1}^{2} & \cdots & t_{1}^{k} \\
1 & t_{2} & t_{2}^{2} & \cdots & t_{2}^{k} \\
\vdots & \vdots & \vdots & & \vdots \\
1 & t_{p} & t_{p}^{2} & \cdots & t_{p}^{k}
\end{array}\right) \quad \text { and } \quad \boldsymbol{\beta}=\left(\begin{array}{c}
\beta_{0} \\
\beta_{\mathbf{1}} \\
\vdots \\
\beta_{k}
\end{array}\right)
\]

In practice, it may be useful to transform the \(t_{r}\) 's by subtracting the mean or the smallest value in order to reduce their size for computational purposes.

The following method of testing \(H_{0}\) is due to Rao (1959, 1973). The model \(\boldsymbol{\mu}=\) \(\mathbf{A} \boldsymbol{\beta}\) is similar to a regression model \(E(\mathbf{y})=\mathbf{X} \boldsymbol{\beta}\) (see Section 10.2.1). However, in this case, we have \(\operatorname{cov}(\mathbf{y})=\Sigma \mathbf{~ r a t h e r ~ t h a n ~} \sigma^{2} \mathbf{I}\), as in the standard regression assumption. In place of the usual regression approach of seeking \(\hat{\boldsymbol{\beta}}\) to minimize \(\operatorname{SSE}=(\mathbf{y}-\mathbf{X} \hat{\boldsymbol{\beta}})^{\prime}(\mathbf{y}-\mathbf{X} \hat{\boldsymbol{\beta}})\) [see (10.4) and (10.6)], we use a standardized distance as in \((3.80),(\overline{\mathbf{y}}-\mathbf{A} \hat{\boldsymbol{\beta}})^{\prime} \mathbf{S}^{-1}(\overline{\mathbf{y}}-\mathbf{A} \hat{\boldsymbol{\beta}})\). The value of \(\hat{\boldsymbol{\beta}}\) that minimizes \((\overline{\mathbf{y}}-\mathbf{A} \hat{\boldsymbol{\beta}})^{\prime} \mathbf{S}^{-1}(\overline{\mathbf{y}}-\) \(\mathbf{A} \hat{\boldsymbol{\beta}})\) is
\[
\begin{equation*}
\hat{\boldsymbol{\beta}}=\left(\mathbf{A}^{\prime} \mathbf{S}^{-1} \mathbf{A}\right)^{-1} \mathbf{A}^{\prime} \mathbf{S}^{-1} \overline{\mathbf{y}} \tag{6.114}
\end{equation*}
\]
[see Rencher and Schaalje (2008, Section 7.8.1)], and \(H_{0}: \boldsymbol{\mu}=\mathbf{A} \boldsymbol{\beta}\) can be tested by
\[
\begin{equation*}
T^{2}=n(\overline{\mathbf{y}}-\mathbf{A} \hat{\boldsymbol{\beta}})^{\prime} \mathbf{S}^{-1}(\overline{\mathbf{y}}-\mathbf{A} \hat{\boldsymbol{\beta}}), \tag{6.115}
\end{equation*}
\]
which is distributed as \(T_{p-k-1, n-1}^{2}\). The dimension of \(T^{2}\) is reduced from \(p\) to \(p-k-1\) because \(k+1\) parameters have been estimated in \(\hat{\boldsymbol{\beta}}\). The \(T^{2}\)-statistic in (6.115) is usually given in the equivalent form
\[
\begin{equation*}
T^{2}=n\left(\overline{\mathbf{y}}^{\prime} \mathbf{S}^{-1} \overline{\mathbf{y}}-\overline{\mathbf{y}}^{\prime} \mathbf{S}^{-1} \mathbf{A} \hat{\boldsymbol{\beta}}\right) \tag{6.116}
\end{equation*}
\]

The mean response at the \(r\) th time point,
\[
\begin{aligned}
\mu_{r} & =\beta_{0}+\beta_{1} t_{r}+\beta_{2} t_{r}^{2}+\cdots+\beta_{k} t_{r}^{k} \\
& =\left(1, t_{r}, t_{r}^{2}, \ldots, t_{r}^{k}\right) \boldsymbol{\beta}=\mathbf{a}_{r}^{\prime} \boldsymbol{\beta}
\end{aligned}
\]
can be estimated by
\[
\begin{equation*}
\hat{\mu}_{r}=\mathbf{a}_{r}^{\prime} \hat{\boldsymbol{\beta}} \tag{6.117}
\end{equation*}
\]

Simultaneous confidence intervals for all possible \(\mathbf{a}^{\boldsymbol{\prime}} \boldsymbol{\beta}\) are given by
\[
\begin{equation*}
\mathbf{a}^{\prime} \hat{\boldsymbol{\beta}} \pm \frac{T_{\alpha}}{\sqrt{n}} \sqrt{\mathbf{a}^{\prime}\left(\mathbf{A}^{\prime} \mathbf{S}^{-1} \mathbf{A}\right)^{-1} \mathbf{a}\left(1+\frac{T^{2}}{n-1}\right)} \tag{6.118}
\end{equation*}
\]
where \(T_{\alpha}=\sqrt{T_{\alpha, k+1, n-1}^{2}}\) is from Table A. 7 and \(T^{2}\) is given by (6.115) or (6.116). The intervals in (6.118) for \(\mathbf{a}^{\prime} \boldsymbol{\beta}\) include, of course, \(\mathbf{a}_{r}^{\prime} \boldsymbol{\beta}\) for the \(p\) rows of \(\mathbf{A}\), that is, confidence intervals for the \(p\) time points. If \(\mathbf{a}_{r}^{\prime} \boldsymbol{\beta}, r=1,2, \ldots, p\), are the only values of interest, we can shorten the intervals in (6.118) by using a Bonferroni coefficient \(t_{\alpha / 2 p}\) in place of \(T_{\alpha}\) :
\[
\begin{equation*}
\mathbf{a}_{r}^{\prime} \hat{\boldsymbol{\beta}} \pm \frac{t_{\alpha / 2 p}}{\sqrt{n}} \sqrt{\mathbf{a}_{r}^{\prime}\left(\mathbf{A}^{\prime} \mathbf{S}^{-1} \mathbf{A}\right)^{-1} \mathbf{a}_{r}\left(1+\frac{T^{2}}{n-1}\right)} \tag{6.119}
\end{equation*}
\]
where \(t_{\alpha / 2 p}=t_{\alpha / 2 p, n-1}\). Bonferroni critical values \(t_{\alpha / 2 p, \nu}\) are given in Table A.8. See procedures 2 and 3 in Section 5.5 for additional comments on the use of \(t_{\alpha / 2 p}\) and \(T_{\alpha}\).

\section*{- EXAMPLE 6.10.1}

Potthoff and Roy (1964) reported measurements in a dental study on boys and girls from ages 8 to 14. The data are given in Table 6.16.

To illustrate the methods of this section, we use the data for the boys alone. In Example 6.10 .2 we will compare the growth curves of the boys with those of

Table 6.16 Dental Measurements
\begin{tabular}{cccccccccccc}

10 & 16.5 & 19.0 & 19.0 & 19.5 & & 10 & 27.5 & 28.0 & 31.0 & 31.5 \\
11 & 24.5 & 25.0 & 28.0 & 28.0 & 11 & 23.0 & 23.0 & 23.5 & 25.0 \\
& & & & & 12 & 21.5 & 23.5 & 24.0 & 28.0 \\
& & & & & 13 & 17.0 & 24.5 & 26.0 & 29.5 \\
& & & & & 14 & 22.5 & 25.5 & 25.5 & 26.0 \\
& & & & & 15 & 23.0 & 24.5 & 26.0 & 30.0 \\
& & & & & 16 & 22.0 & 21.5 & 23.5 & 25.0 \\
\hline
\end{tabular}
the girls. We first test the overall hypothesis \(H_{0}: \mathbf{C} \boldsymbol{\mu}=\mathbf{0}\), where \(\mathbf{C}\) contains orthogonal polynomials for linear, quadratic, and cubic effects:
\[
\mathbf{C}=\left(\begin{array}{rrrr}
-3 & -1 & 1 & 3  \tag{6.120}\\
1 & -1 & -1 & 1 \\
-1 & 3 & -3 & 1
\end{array}\right)
\]

From the 16 observation vectors we obtain
\[
\overline{\mathbf{y}}=\left(\begin{array}{l}
22.88 \\
23.81 \\
25.72 \\
27.47
\end{array}\right), \quad \mathbf{S}=\left(\begin{array}{cccc}
6.02 & 2.29 & 3.63 & 1.61 \\
2.29 & 4.56 & 2.19 & 2.81 \\
3.63 & 2.19 & 7.03 & 3.24 \\
1.61 & 2.81 & 3.24 & 4.35
\end{array}\right)
\]

To test \(H_{0}: \mathbf{C} \boldsymbol{\mu}=\mathbf{0}\), we calculate
\[
T^{2}=n(\mathbf{C} \overline{\mathbf{y}})^{\prime}\left(\mathbf{C S C}^{\prime}\right)^{-1}(\mathbf{C} \overline{\mathbf{y}})=77.957
\]
which exceeds \(T_{.01,3,15}^{2}=19.867\). We now test \(H_{0}: \mathbf{c}_{i}^{\prime} \boldsymbol{\mu}=0\) for each row of \(\mathbf{C}\) to determine the shape of the growth curve. For the linear effect, using the first row, \(\mathbf{c}_{1}^{\prime}\), we obtain
\[
t_{1}=\frac{\mathbf{c}_{1}^{\prime} \overline{\mathbf{y}}}{\sqrt{\mathbf{c}_{1}^{\prime} \mathbf{S c}_{1} / n}}=7.722>t_{.005,15}=2.947
\]

The test of significance of the quadratic component using the second row yields
\[
t_{2}=\frac{\mathbf{c}_{2}^{\prime} \overline{\mathbf{y}}}{\sqrt{\mathbf{c}_{2}^{\prime} \mathbf{S c}_{2} / n}}=1.370<t_{.025,15}=2.131
\]

To test for a cubic trend, we use the third row of \(\mathbf{C}\) :
\[
t_{3}=\frac{\mathbf{c}_{3}^{\prime} \overline{\mathbf{y}}}{\sqrt{\mathbf{c}_{3}^{\prime} \mathbf{S c}_{3} / n}}=-.511>-t_{.025,15}=-2.131
\]

Thus only the linear trend is needed to describe the growth curve.
To model the curve for each variable, we use (6.112),
\[
\begin{gathered}
\mu_{r}=\beta_{0}+\beta_{1} t_{r}, r=1,2,3,4, \text { or } \\
\boldsymbol{\mu}=\mathbf{A} \boldsymbol{\beta},
\end{gathered}
\]
where
\[
\mathbf{A}=\left(\begin{array}{rr}
1 & -3 \\
1 & -1 \\
1 & 1 \\
1 & 3
\end{array}\right), \quad \boldsymbol{\beta}=\binom{\beta_{0}}{\beta_{1}}
\]

The values in the second column of \(\mathbf{A}\) are obtained as \(t=\) age -11 . By (6.114), we obtain
\[
\hat{\boldsymbol{\beta}}=\left(\mathbf{A}^{\prime} \mathbf{S}^{-1} \mathbf{A}\right)^{-1} \mathbf{A}^{\prime} \mathbf{S}^{-1} \overline{\mathbf{y}}=\binom{25.002}{.834}
\]
and our prediction equation is
\[
\begin{aligned}
\hat{\mu} & =25.002+.834 t=25.002+.834(\text { age }-11) \\
& =15.828+.834(\text { age }) .
\end{aligned}
\]

\subsection*{6.10.2 Growth Curves for Several Samples}

For the case of several samples or groups, the data layout would be similar to that in Table 6.9, where the \(p\) levels of factor \(A\) represent time points. Assuming the time points are equally spaced, we can use orthogonal polynomials in the \((p-1) \times p\) contrast matrix \(\mathbf{C}\) and express the basic hypothesis in the form \(H_{0}: \mathbf{C} \bar{\mu} .=\mathbf{0}\), where \(\overline{\boldsymbol{\mu}} .=\sum_{i=1}^{k} \boldsymbol{\mu}_{i} / k\). This is equivalent to \(H_{0}: \bar{\mu}_{.1}=\bar{\mu}_{.2}=\cdots=\bar{\mu}_{. p}\), which compares the means of the \(p\) time points averaged across groups. As in Section 6.9.3, let us denote the sample mean vectors for the \(k\) groups as \(\overline{\mathbf{y}}_{1 .}, \overline{\mathbf{y}}_{2,}, \ldots, \overline{\mathbf{y}}_{k \text {, }}\), with grand mean \(\overline{\mathbf{y}}_{\text {.. }}\) and pooled covariance matrix \(\mathbf{S}_{\mathrm{pl}}=\mathrm{E} / \nu_{E}\). For the overall test of \(H_{0}: \mathbf{C} \overline{\boldsymbol{\mu}} .=\mathbf{0}\) we use the test statistic
\[
\begin{equation*}
T^{2}=N\left(\mathbf{C y}_{\mathbf{y}}^{.}\right)^{\prime}\left(\mathbf{C S}_{\mathrm{pl}} \mathbf{C}^{\prime}\right)^{-1}\left(\mathbf{C} \overline{\mathbf{y}}_{. .}\right), \tag{6.121}
\end{equation*}
\]
which is \(T_{p-1, \nu_{E}}^{2}\) as in (6.92), where \(N=\sum_{i=1}^{k} n_{i}\) for unbalanced data or \(N=k n\) for balanced data. The corresponding degrees of freedom for error is \(\nu_{E}=N-k\) or \(\nu_{E}=k(n-1)\). A test that the average growth curve (averaged over groups) has a particular form can be tested with \(\mathbf{C}_{1}\), containing a subset of the rows of \(\mathbf{C}\) :
\[
\begin{equation*}
T^{2}=N\left(\mathbf{C}_{1} \overline{\mathbf{y}}_{.}\right)^{\prime}\left(\mathbf{C}_{1} \mathbf{S}_{\mathrm{pl}} \mathbf{C}_{1}^{\prime}\right)^{-1}\left(\mathbf{C}_{1} \overline{\mathbf{y}}_{. .}\right), \tag{6.122}
\end{equation*}
\]
which is distributed as \(T_{p_{1}, \nu_{E}}^{2}\), where \(p_{1}\) is the number of rows in \(\mathbf{C}_{1}\).
The growth curves for the \(k\) groups can be compared by the interaction or parallelism test of Section 6.9 .3 using either \(\mathbf{C}\) or \(\mathbf{C}_{1}\). We do a one-way MANOVA on \(\mathbf{C y}{ }_{i j}\) or \(\mathbf{C}_{1} \mathbf{y}_{i j}\), or equivalently calculate by (6.95),
\[
\begin{equation*}
\Lambda=\frac{\left|\mathbf{C E C}^{\prime}\right|}{\left|\mathbf{C}(\mathbf{E}+\mathbf{H}) \mathbf{C}^{\prime}\right|} \quad \text { or } \quad \Lambda=\frac{\left|\mathbf{C}_{1} \mathbf{E C}_{1}^{\prime}\right|}{\left|\mathbf{C}_{1}(\mathbf{E}+\mathbf{H}) \mathbf{C}_{1}^{\prime}\right|}, \tag{6.123}
\end{equation*}
\]
which are distributed as \(\Lambda_{p-1, k-1, \nu_{E}}\) and \(\Lambda_{p_{1}, k-1, \nu_{E}}\), respectively.

\section*{EXAMPLE 6.10.2}

In Example 6.10.1, we found a linear trend for the growth curve for dental measurements of boys in Table 6.16. We now consider the growth curve for the combined group and also compare the girls' group with the boys' group.

The two sample sizes are unequal and we use (6.32) to calculate the \(\mathbf{E}\) matrix for the two groups,
\[
\mathbf{E}=\left(\begin{array}{rrrr}
135.39 & 67.88 & 97.76 & 67.76 \\
67.88 & 103.76 & 72.86 & 82.71 \\
97.76 & 72.86 & 161.39 & 103.27 \\
67.76 & 82.71 & 103.27 & 124.64
\end{array}\right)
\]
from which we obtain \(\mathbf{S}_{\mathrm{pl}}=\mathbf{E} / \nu_{E}\). Using the \(\mathbf{C}\) matrix in (6.120), we can test the basic hypothesis of equal means for the combined samples, \(H_{0}: \mathbf{C} \overline{\boldsymbol{\mu}}=\mathbf{0}\), using (6.121):
\[
\begin{aligned}
T^{2} & =N\left(\mathbf{C} \overline{\mathbf{y}}_{. .}\right)^{\prime}\left(\mathbf{C S}_{\mathrm{pl}} \mathbf{C}^{\prime}\right)^{-1}\left(\mathbf{C} \overline{\mathbf{y}}_{. .}\right) \\
& =118.322>T_{.01,3,25}^{2}=15.538 .
\end{aligned}
\]

To test for a linear trend, we use the first row of \(\mathbf{C}\) in (6.122):
\[
\begin{aligned}
T^{2} & =N\left(\mathbf{c}_{1}^{\prime} \overline{\mathbf{y}} . .\right)^{\prime}\left(\mathbf{c}_{1}^{\prime} \mathbf{S}_{\mathrm{pl}} \mathbf{c}_{1}\right)^{-1}\left(\mathbf{c}_{1}^{\prime} \overline{\mathbf{y}} . .\right) \\
& =99.445>T_{.01,1,25}^{2}=7.770 .
\end{aligned}
\]

This is, of course, the square of a \(t\)-statistic, but in the \(T^{2}\) form it can readily be compared with the \(T^{2}\) above using all three rows of \(\mathbf{C}\). The linear trend is seen to dominate the relationship among the means.

We now compare the growth curves of the two groups using (6.123). For C, we obtain
\[
\begin{aligned}
\Lambda & =\frac{\left|\mathbf{C E C}^{\prime}\right|}{\left|\mathbf{C}(\mathbf{E}+\mathbf{H}) \mathbf{C}^{\prime}\right|}=\frac{1.3996 \times 10^{8}}{1.9025 \times 10^{8}} \\
& =.736>\Lambda_{.05,3,1,25}=.717
\end{aligned}
\]

For the linear trend, we have
\[
\begin{aligned}
\Lambda & =\frac{\left|\mathbf{c}_{1}^{\prime} \mathbf{E} \mathbf{c}_{1}\right|}{\left|\mathbf{c}_{1}^{\prime}(\mathbf{E}+\mathbf{H}) \mathbf{c}_{1}\right|}=\frac{1184.2}{1427.9} \\
& =.829<\Lambda .05,1,1,25
\end{aligned}=.855 .
\]

Thus the overall comparison does not reach significance, but the more specific comparison of linear trends does give a significant result.

\subsection*{6.10.3 Additional Topics}

Jackson and Bryce (1981) presented methods of analyzing growth curves based on univariate linear models. Snee (1972) and Snee et al. (1979) proposed the use of eigenvalues and eigenvectors of a matrix derived from residuals after fitting the model. If one of the eigenvalues is dominant, certain simplifications result. Bryce (1980) discussed a similar simplification for the two-group case. Geisser (1980) and Fearn \((1975,1977)\) gave the Bayesian approach to growth curves, including estimation and prediction. Zerbe ( \(1979 \mathrm{a}, \mathrm{b}\) ) provided a randomization test requiring fewer assumptions than normal-based tests.

\subsection*{6.11 TESTS ON A SUBVECTOR}

\subsection*{6.11.1 Test for Additional Information}

In Section 5.8, we considered tests of significance of the additional information in a subvector when comparing two groups. We now extend these concepts to several groups and use similar notation.

Let \(\mathbf{y}\) be a \(p \times 1\) vector of measurements and \(\mathbf{x}\) be a \(q \times 1\) vector measured in addition to \(\mathbf{y}\). We are interested in determining whether \(\mathbf{x}\) makes a significant contribution to the test of \(H_{0}: \mu_{1}=\mu_{2}=\cdots=\mu_{k}\) above and beyond \(\mathbf{y}\). Another way to phrase the question is: Can the separation of groups achieved by \(\mathbf{x}\) be predicted from the separation achieved by \(\mathbf{y}\) ? It is not necessary, of course, that \(x\) represent new variables. It may be that \(\binom{y}{x}\) is a partitioning of the present variables, and we wish to know if the variables in \(\mathbf{x}\) can be deleted because they do not contribute to rejecting \(H_{0}\).

We consider here only the one-way MANOVA, but the results could be extended to higher-order designs, where various possibilities arise. In a two-way context, for
example, it may happen that \(\mathbf{x}\) contributes nothing to the \(A\) main effect but does contribute significantly to the \(B\) main effect.

It is assumed that we have \(k\) samples,
\[
\binom{\mathbf{y}_{i j}}{\mathbf{x}_{i j}}, \quad i=1,2, \ldots, k ; j=1,2, \ldots, n
\]
from which we calculate
\[
\mathbf{E}=\left(\begin{array}{cc}
\mathbf{E}_{y y} & \mathbf{E}_{y x} \\
\mathbf{E}_{x y} & \mathbf{E}_{x x}
\end{array}\right), \quad \mathbf{H}=\left(\begin{array}{cc}
\mathbf{H}_{y y} & \mathbf{H}_{y x} \\
\mathbf{H}_{x y} & \mathbf{H}_{x x}
\end{array}\right)
\]
where \(\mathbf{E}\) and \(\mathbf{H}\) are \((p+q) \times(p+q)\) and \(\mathbf{E}_{y y}\) and \(\mathbf{H}_{y y}\) are \(p \times p\).
Then
\[
\begin{equation*}
\Lambda(\mathbf{y}, \mathbf{x})=\frac{|\mathbf{E}|}{|\mathbf{E}+\mathbf{H}|} \tag{6.124}
\end{equation*}
\]
is distributed as \(\Lambda_{p+q, \nu_{H}, \nu_{E}}\) and tests the significance of group separation using the full vector \(\binom{\mathbf{y}}{\mathbf{x}}\). In the balanced one-way model, the degrees of freedom are \(\nu_{H}=\) \(k-1\) and \(\nu_{E}=k(n-1)\). To test group separation using the reduced vector \(\mathbf{y}\), we can compute
\[
\begin{equation*}
\Lambda(\mathbf{y})=\frac{\left|\mathbf{E}_{y y}\right|}{\left|\mathbf{E}_{y y}+\mathbf{H}_{y y}\right|}, \tag{6.125}
\end{equation*}
\]
which is distributed as \(\Lambda_{p, \nu_{H}, \nu_{E}}\).
To test the hypothesis that the extra variables in \(\mathbf{x}\) do not contribute anything significant to separating the groups beyond the information already available in \(\mathbf{y}\), we calculate
\[
\begin{equation*}
\Lambda(\mathbf{x} \mid \mathbf{y})=\frac{\Lambda(\mathbf{y}, \mathbf{x})}{\Lambda(\mathbf{y})} \tag{6.126}
\end{equation*}
\]
which is distributed as \(\Lambda_{q, \nu_{G}, \nu_{E}-p}\). Note that the dimension of \(\Lambda(\mathbf{x} \mid \mathbf{y})\) is \(q\), the number of \(x\) 's. The error degrees of freedom \(\nu_{E}-p\) has been adjusted for the \(p y\) 's. Thus to test for the contribution of additional variables to separation of groups, we take the ratio of Wilks' \(\Lambda\) for the full set of variables in (6.124) to Wilks' \(\Lambda\) for the reduced set in (6.125). If the addition of \(\mathbf{x}\) makes \(\Lambda(\mathbf{y}, \mathbf{x})\) sufficiently smaller than \(\Lambda(\mathbf{y})\), then \(\Lambda(\mathbf{x} \mid \mathbf{y})\) in (6.126) will be small enough to reject the hypothesis.

If we are interested in the effect of adding a single \(x\), then \(q=1\), and (6.126) becomes
\[
\begin{equation*}
\Lambda\left(x \mid y_{1}, \ldots, y_{p}\right)=\frac{\Lambda\left(y_{1}, \ldots, y_{p}, x\right)}{\Lambda\left(y_{1}, \ldots, y_{p}\right)} \tag{6.127}
\end{equation*}
\]
which is distributed as \(\Lambda_{1, \nu_{H}, \nu_{E}-p}\). In this test we are inquiring whether \(x\) reduces the overall \(\Lambda\) by a significant amount. With a dimension of 1 , the \(\Lambda\)-statistic in (6.127) has an exact \(F\)-transformation from Table 6.1,
\[
\begin{equation*}
F=\frac{1-\Lambda}{\Lambda} \frac{\nu_{E}-p}{\nu_{H}}, \tag{6.128}
\end{equation*}
\]
which is distributed as \(F_{\nu_{H}, \nu_{E}-p}\). The statistic (6.127) is often referred to as a partial \(\Lambda\)-statistic, and correspondingly, (6.128) is called a partial \(F\)-statistic.

In (6.127) and (6.128), we have a test of the significance of a variable in the presence of the other variables. For a breakdown of precisely how the contribution of a variable depends on the other variables, see Rencher (1993; 1998, Section 4.1.6).

We can rewrite (6.127) as
\[
\begin{equation*}
\Lambda\left(y_{1}, \ldots, y_{p}, x\right)=\Lambda\left(x \mid y_{1}, \ldots, y_{p}\right) \Lambda\left(y_{1}, \ldots, y_{p}\right) \leq \Lambda\left(y_{1}, \ldots, y_{p}\right) \tag{6.129}
\end{equation*}
\]
which shows that Wilks' \(\Lambda\) can only decrease with an additional variable.

\section*{- EXAMPLE 6.11.1}

We use the rootstock data of Table 6.2 to illustrate tests on subvectors. From Example 6.1.7, we have, for all four variables, \(\Lambda\left(y_{1}, y_{2}, y_{3}, y_{4}\right)=.1540\). For the first two variables, we obtain \(\Lambda\left(y_{1}, y_{2}\right)=.6990\). Then to test the significance of \(y_{3}\) and \(y_{4}\) adjusted for \(y_{1}\) and \(y_{2}\), we have by (6.126),
\[
\Lambda\left(y_{3}, y_{4} \mid y_{1}, y_{2}\right)=\frac{\Lambda\left(y_{1}, y_{2}, y_{3}, y_{4}\right)}{\Lambda\left(y_{1}, y_{2}\right)}=\frac{.1540}{.6990}=.2203
\]
which is less than the critical value \(\Lambda_{.05,2,5,40}=.639\).
Similarly, the test for \(y_{4}\) adjusted for \(y_{1}, y_{2}\), and \(y_{3}\) is given by (6.127) as
\[
\begin{aligned}
\Lambda\left(y_{4} \mid y_{1}, y_{2}, y_{3}\right) & =\frac{\Lambda\left(y_{1}, y_{2}, y_{3}, y_{4}\right)}{\Lambda\left(y_{1}, y_{2}, y_{3}\right)}=\frac{.1540}{.2460} \\
& =.6261<\Lambda_{.05,1,5,39}=.759
\end{aligned}
\]

For each of the other variables, we have a similar test:
\[
\begin{array}{ll}
y_{3}: & \Lambda\left(y_{3} \mid y_{1}, y_{2}, y_{4}\right)=\frac{.1540}{.2741}=.5618<\Lambda_{.05,1,5,39}=.759 \\
y_{2}: & \Lambda\left(y_{2} \mid y_{1}, y_{3}, y_{4}\right)=\frac{.1540}{.1922}=.8014>\Lambda_{.05,1,5,39}=.759 \\
y_{1}: & \Lambda\left(y_{1} \mid y_{2}, y_{3}, y_{4}\right)=\frac{.1540}{.1599}=.9630>\Lambda_{.05,1,5,39}=.759
\end{array}
\]

Thus the two variables \(y_{3}\) and \(y_{4}\), either individually or together, contribute a significant amount to separation of the six groups.

\subsection*{6.11.2 Stepwise Selection of Variables}

If there are no variables for which we have a priori interest in testing for significance, we can do a data-directed search for the variables that best separate the groups. Such a strategy is often called stepwise discriminant analysis, although it could more aptly be called stepwise MANOVA. The procedure appears in many software packages.

We first describe an approach that is usually called forward selection. At the first step calculate \(\Lambda\left(y_{i}\right)\) for each individual variable and choose the one with minimum \(\Lambda\left(y_{i}\right)\) (or maximum associated \(F\) ). At the second step calculate \(\Lambda\left(y_{i} \mid y_{1}\right)\) for each of
the \(p-1\) variables not entered at the first step, where \(y_{1}\) indicates the first variable entered. For the second variable we choose the one with minimum \(\Lambda\left(y_{i} \mid y_{1}\right)\) (or maximum associated partial \(F\) ), that is, the variable that adds the maximum separation to the one entered at step 1 . Denote the variable entered at step 2 by \(y_{2}\). At the third step calculate \(\Lambda\left(y_{i} \mid y_{1}, y_{2}\right)\) for each of the \(p-2\) remaining variables and choose the one that minimizes \(\Lambda\left(y_{i} \mid y_{1}, y_{2}\right)\) (or maximizes the associated partial \(F\) ). Continue this process until the \(F\) falls below some predetermined threshold value, say \(F_{\text {in }}\).

A stepwise procedure follows a similar sequence, except that after a variable has entered, the variables previously selected are reexamined to see if each still contributes a significant amount. The variable with smallest partial \(F\) will be removed if the partial \(F\) is less than a second threshold value, \(F_{\text {out }}\). If \(F_{\text {out }}\) is the same as \(F_{\text {in }}\), there is a very small possibility that the procedure will cycle continuously without stopping. This possibility can be eliminated by using a value of \(F_{\text {out }}\) slightly less than \(F_{\mathrm{in}}\). For an illustration of the stepwise procedure, see Example 8.9.

\section*{PROBLEMS}
6.1 Verify the computational forms given in (6.3) and (6.5); that is, show that
(a) \(\sum_{i j}\left(y_{i j}-\bar{y}_{i .}\right)^{2}=\sum_{i j} y_{i j}^{2}-\sum_{i} y_{i .}^{2} / n\)
(b) \(n \sum_{i}\left(\bar{y}_{i .}-\bar{y}_{. .}\right)^{2}=\sum_{i} y_{i .}^{2} / n-y_{. .}^{2} / k n\)
6.2 Show that Wilks' \(\Lambda\) can be expressed in terms of the eigenvalues of \(\mathbf{E}^{-1} \mathbf{H}\) as in (6.14).
6.3 Show that the eigenvalues of the matrices \(\mathbf{E}^{-1} \mathbf{H}\) and \(\left(\mathbf{E}^{1 / 2}\right)^{-1} \mathbf{H}\left(\mathbf{E}^{1 / 2}\right)^{-1}\) are the same, as noted in Section 6.1.4, where \(\mathbf{E}^{1 / 2}\) is the square root matrix defined in (2.112).
6.4 Show that \(F_{2}\) in (6.26) is the same as \(F_{1}\) in (6.25).
6.5 Show that \(F_{3}\) in (6.30) is the same as \(F_{2}\) in (6.29).
6.6 Show that if there is only one nonzero eigenvalue \(\lambda_{1}\), then \(U^{(1)}, V^{(1)}\), and \(\Lambda\) can be expressed in terms of \(\theta\), as in (6.33)-(6.35).
6.7 Show that (5.16), (5.18), and (5.19), which relate \(T^{2}\) to \(\Lambda, V^{(s)}\), and \(\theta\), follow from (6.33)-(6.35) and (6.38), \(U^{(1)}=T^{2} /\left(n_{1}+n_{2}-2\right)\).
6.8 Verify the computational forms of \(\mathbf{H}\) and \(\mathbf{E}\) in (6.31) and (6.32); that is, show that
(a) \(\sum_{i=1}^{k} n_{i}\left(\overline{\mathbf{y}}_{i .}-\overline{\mathbf{y}}_{. .}\right)\left(\overline{\mathbf{y}}_{i .}-\overline{\mathbf{y}}_{. .}\right)^{\prime}=\sum_{i=1}^{k} \mathbf{y}_{i .} \mathbf{y}_{i .}^{\prime} / n_{i}-\mathbf{y} . . \mathbf{y}^{\prime} . . / N\)
(b) \(\sum_{i=1}^{k} \sum_{j=1}^{n_{i}}\left(\mathbf{y}_{i j}-\overline{\mathbf{y}}_{i .}\right)\left(\mathbf{y}_{i j}-\overline{\mathbf{y}}_{i .}\right)^{\prime}=\sum_{i=1}^{k} \sum_{j=1}^{n_{i}} \mathbf{y}_{i j} \mathbf{y}_{i j}^{\prime}-\sum_{i=1}^{k} \mathbf{y}_{i .} \mathbf{y}_{i .}^{\prime} / n_{i}\)
6.9 Show that for two groups, \(\mathbf{H}=\sum_{i=1}^{2} n_{i}\left(\overline{\mathbf{y}}_{i .}-\overline{\mathbf{y}}_{. .}\right)\left(\overline{\mathbf{y}}_{i .}-\overline{\mathbf{y}}_{. .}\right)^{\prime}\) can be expressed as \(\mathbf{H}=\left[n_{1} n_{2} /\left(n_{1}+n_{2}\right)\right]\left(\overline{\mathbf{y}}_{1 .}-\overline{\mathbf{y}}_{2}\right)\left(\overline{\mathbf{y}}_{1 .}-\overline{\mathbf{y}}_{2}\right)^{\prime}\), thus verifying (6.37). Note that
\[
\overline{\mathbf{y}}_{. .}=\frac{n_{1} \overline{\mathbf{y}}_{1 .}+n_{2} \overline{\mathbf{y}}_{2 .}}{n_{1}+n_{2}}
\]
6.10 Show that \(\theta\) can be expressed as \(\theta=\operatorname{SSH}(z) /[\operatorname{SSE}(z)+\operatorname{SSH}(z)]\) as in (6.41).
6.11 Show that
\[
\prod_{i=1}^{s} \frac{1}{1+\lambda_{i}}=\prod_{i=1}^{s}\left(1-r_{i}^{2}\right)
\]
as in (6.44), where \(r_{i}^{2}=\lambda_{i} /\left(1+\lambda_{i}\right)\).
6.12 Show that the \(F\)-approximation based on \(A_{P}\) in (6.49) reduces to (6.26) if \(A_{P}=V^{(s)} / s\), as in (6.48).
6.13 Show that if \(s=1, A_{\mathrm{LH}}\) in (6.50) reduces to (6.42).
6.14 Show that the \(F\)-approximation denoted by \(F_{3}\) in (6.30) is equivalent to (6.51).
6.15 Show that \(\operatorname{cov}(\hat{\boldsymbol{\delta}})=\frac{\boldsymbol{\Sigma}}{n} \sum_{i=1}^{k} c_{i}^{2}\) as in (6.60).
6.16 If \(\mathbf{z}_{i j}=\mathbf{C} \mathbf{y}_{i j}\), where \(\mathbf{C}\) is \((p-1) \times p\), show that \(\mathbf{H}_{z}=\mathbf{C H C} \mathbf{C}^{\prime}\) and \(\mathbf{E}_{z}=\) CEC', as used in (6.78).
6.17 Why do \(\mathbf{C}\) and \(\mathbf{C}^{\prime}\) not "cancel out" of Wilks' \(\Lambda\) in (6.78)?
6.18 Show that under \(H_{03}\) and \(H_{01}, \mathbf{C} \overline{\mathbf{y}} .\). is \(N_{p-1}\left(\mathbf{0}, \mathbf{C} \boldsymbol{\Sigma} \mathbf{C}^{\prime} / k n\right)\), as noted preceding (6.83).
6.19 Show that \(T^{2}=k n\left(\mathbf{C} \overline{\mathbf{y}}_{. .}\right)^{\prime}\left(\mathbf{C E C} \mathbf{C}^{\prime} / \nu_{E}\right)^{-1} \mathbf{C} \overline{\mathbf{y}}_{\text {.. }}\) in (6.83) is distributed as \(T_{p-1, \nu_{E}}^{2}\)
6.20 For \(\varepsilon\) defined by (6.88), show that \(\varepsilon=1\) when \(\boldsymbol{\Sigma}=\sigma^{2} \mathbf{I}\).
6.21 Give a justification of the Wilks' \(\Lambda\) test of \(H_{0}: \bar{\mu}\). \(=0\) in (6.103).
6.22 Provide an alternative derivation of (6.105), \(\Lambda=\nu_{E} /\left(\nu_{E}+T^{2}\right)\), starting with (6.104).
6.23 Obtain \(T^{2}\) in terms of \(\Lambda\) in (6.106) from (6.105).
6.24 Show that the rows of \(\mathbf{C}_{1}\) are orthogonal to those of \(\mathbf{B}=\mathbf{I}-\mathbf{C}_{1}^{\prime}\left(\mathbf{C}_{1} \mathbf{C}_{1}^{\prime}\right)^{-1} \mathbf{C}_{1}\) in (6.109).
6.25 Show that \(\hat{\boldsymbol{\beta}}\) in (6.114) minimizes \((\overline{\mathbf{y}}-\mathbf{A} \hat{\boldsymbol{\beta}})^{\prime} \mathbf{S}^{-1}(\overline{\mathbf{y}}-\mathbf{A} \hat{\boldsymbol{\beta}})\).
6.26 Show that \(T^{2}\) in (6.116) is equivalent to \(T^{2}\) in (6.115).
6.27 Baten, Tack, and Baeder (1958) compared judges' scores on fish prepared by three methods. Twelve fish were cooked by each method, and several judges

Table 6.17 Judges' Scores on Fish Prepared by Three Methods
\begin{tabular}{|c|c|c|c|c|c|c|c|c|c|c|c|}

Source: Baten, Tack, and Baeder (1958, p. 8).
tasted fish samples and rated each on four variables: \(y_{1}=\) aroma, \(y_{2}=\) flavor, \(y_{3}=\) texture, and \(y_{4}=\) moisture. The data are in Table 6.17. Each entry is an average score for the judges on that fish.
(a) Compare the three methods using all four MANOVA tests.
(b) Compute the following measures of multivariate association from Section 6.1.8: \(\eta_{\Lambda}^{2}, \eta_{\theta}^{2}, A_{\Lambda}, A_{\mathrm{LH}}, A_{P}\).
(c) Based on the eigenvalues, is the essential dimensionality of the space containing the mean vectors equal to 1 or 2 ?
(d) Using contrasts, test the following two comparisons: 1 and 2 vs. 3 , and 1 vs. 2.
(e) If any of the four tests in (a) is significant, run an ANOVA \(F\)-test on each \(y_{i}\) and examine the discriminant function \(z=\mathbf{a}^{\prime} \mathbf{y}\) (Section 6.4).
(f) Test the significance of \(y_{3}\) and \(y_{4}\) adjusted for \(y_{1}\) and \(y_{2}\).
(g) Test the significance of each variable adjusted for the other three.
6.28 Table 6.18 from Keuls et al. (1984) gives data from a two-way (fixed-effects) MANOVA on snap beans showing the results of four variables: \(y_{1}=\) yield earliness, \(y_{2}=\) specific leaf area (SLA) earliness, \(y_{3}=\) total yield, and \(y_{4}=\) average SLA. The factors are sowing date \((S)\) and variety \((V)\).
(a) Test for main effects and interaction using all four MANOVA statistics.
(b) In previous experiments, the second variety gave higher yields. Compare variety 2 with varieties 1 and 3 by means of a test on a contrast.

\end{tabular}
6.29 The bar steel data in Table 6.6 was analyzed in Example 6.5 .2 as a two-way fixed-effects design. Consider lubricants to be random so that we have a mixed model. Test for main effects and interaction.
6.30 In Table 6.19, we have a comparison of four reagents (Burdick 1979). The first reagent is the one presently in use and the other three are less expensive reagents that we wish to compare with the first. All four reagents are used with a blood sample from each patient. The three variables measured for each reagent are \(y_{1}=\) white blood count, \(y_{2}=\) red blood count, and \(y_{3}=\) hemoglobin count.
(a) Analyze as a randomized block design with subjects as blocks.
(b) Compare the first reagent with the other three using a contrast.
6.31 The data in Table 6.20 from Box (1950) show the amount of fabric wear \(y_{1}, y_{2}\), and \(y_{3}\) in three successive periods: (1) the first 1000 revolutions, (2) the second 1000 revolutions, and (3) the third 1000 revolutions of the abrasive wheel. There were three factors: type of abrasive surface, type of filler, and proportion of filler. There were two replications. Carry out a three-way MANOVA, testing for main effects and interactions. (Ignore the repeated measures aspects of the data.)

Table 6.20 Wear of Coated Fabrics in Three Periods (mg)

\hline
\end{tabular}
6.32 The fabric wear data in Table 6.20 can be considered to be a growth curve model, with the three periods ( \(y_{1}, y_{2}, y_{3}\) ) representing repeated measurements on the same specimen. We thus have one within-subjects factor, to which we should assign polynomial contrasts \((-1,0,1)\) and \((-1,2,-1)\), and a threeway between-subjects classification. Test for period and the interaction of period with the between-subjects factors and interactions.
6.33 Carry out a profile analysis on the fish data in Table 6.17, testing for parallelism, equal levels, and flatness.
6.34 Rao (1948) measured the weight of cork borings taken from the north ( N ), east ( E ), south ( S ), and west (W) directions of 28 trees. The data are given in Table 6.21. It is of interest to compare the bark thickness (and hence weight) in the four directions. This can be done by analyzing the data as a one-sample repeated measures design. Since the primary comparison of interest is north and south vs. east and west, use the contrast matrix
\[
\mathbf{C}=\left(\begin{array}{rrrr}
1 & -1 & 1 & -1 \\
1 & 0 & -1 & 0 \\
0 & 1 & 0 & -1
\end{array}\right)
\]
(a) Test \(H_{0}: \mu_{N}=\mu_{E}=\mu_{S}=\mu_{W}\) using the entire matrix C.
(b) If the test in (a) rejects \(H_{0}\), test each row of \(\mathbf{C}\).
6.35 Analyze the glucose data in Table 3.9 as a one-sample repeated measures design with two within-subjects factors. Factor \(A\) is a comparison of fasting test vs. 1 hour posttest. The three levels of factor \(B\) are \(y_{1}\) (and \(x_{1}\) ), \(y_{2}\) (and \(x_{2}\) ), and \(y_{3}\) (and \(x_{3}\) ).
6.36 Table 6.22 gives survival times for cancer patients (Cameron and Pauling 1978; see also Andrews and Herzberg 1985, pp. 203-206). The factors in this two-way design are gender ( \(1=\) male, \(2=\) female \()\) and type of cancer ( \(1=\) stomach, \(2=\) bronchus, \(3=\) colon, \(4=\) rectum, \(5=\) bladder, \(6=\) kidney). The variables (repeated measures) are \(y_{1}=\) survival time (days) of patient treated with ascorbate measured from date of first hospital attendance, \(y_{2}=\) mean survival time for the patient's 10 matched controls (untreated with ascorbate), \(y_{3}=\) survival time after ascorbate treatment ceased, and \(y_{4}=\) mean survival time after all treatment ceased for the patient's 10 matched controls. Analyze as a repeated measures design with one within-subjects factor ( \(y_{1}, y_{2}, y_{3}, y_{4}\) ) and a two-way (unbalanced) design between subjects. Since the two-way classification of subjects is unbalanced, you will need to use a program that allows for this or delete some observations to achieve a balanced design.
6.37 Analyze the ramus bone data of Table 3.9 as a one-sample growth curve design.
(a) Using a matrix \(\mathbf{C}\) of orthogonal polynomial contrasts, test the hypothesis of overall equality of means, \(H_{0}: \mathbf{C} \boldsymbol{\mu}=\mathbf{0}\).
(b) If the overall hypothesis in (a) is rejected, find the degree of growth curve by testing each row of \(\mathbf{C}\).
6.38 Table 6.23 contains the weights of 13 male mice measured every 3 days from birth to weaning. The data set was reported and analyzed by Williams and Izenman (1981) and by Izenman and Williams (1989) and has been further analyzed by Rao \((1984,1987)\) and by Lee (1988). Analyze as a one-sample growth curve design.

\end{tabular}
6.44 Consider the complete data from Table 6.28 including the observations corresponding to \(\frac{1}{2}\) and \(1 \frac{1}{2}\) hours. Use the methods in (6.112)-(6.117) for unequally spaced time points to analyze each group separately and the combined groups.
6.45 Table 6.29 contains mandible measurements (Timm 1980). There were two groups of subjects. Each subject was measured at three time points \(y_{1}, y_{2}\), and \(y_{3}\) for each of three types of activator treatment. Analyze as a repeated measures design with two within-subjects factors and one between-subjects factor. Use linear and quadratic contrasts for time (growth curve).

\section*{CHAPTER 7}

\section*{TESTS ON COVARIANCE MATRICES}

\subsection*{7.1 INTRODUCTION}

We now consider tests of hypotheses involving the variance-covariance structure. These tests are often carried out to check assumptions pertaining to other tests. In Sections 7.2-7.4, we cover three basic types of hypotheses: (1) the covariance matrix has a particular structure, (2) two or more covariance matrices are equal, and (3) certain elements of the covariance matrix are zero, thus implying independence of the corresponding (multivariate normal) random variables. In most cases we use the likelihood ratio approach (Section 5.4.3). The resulting test statistics often involve the ratio of the determinants of the sample covariance matrix under the null hypothesis and under the alternative hypothesis.

\subsection*{7.2 TESTING A SPECIFIED PATTERN FOR \(\boldsymbol{\Sigma}\)}

In this section, the discussion is in terms of a sample covariance matrix \(\mathbf{S}\) from a single sample. However, the tests can be applied to a sample covariance matrix \(\mathbf{S}_{\mathrm{pl}}=\) \(\mathrm{E} / \nu_{E}\) obtained by pooling across several samples. To allow for either possibility,
the degrees-of-freedom parameter has been indicated by \(\nu\). For a single sample, \(\nu=\) \(n-1\); for a pooled covariance matrix, \(\nu=\sum_{i=1}^{k}\left(n_{i}-1\right)=\sum_{i=1}^{k} n_{i}-k=N-k\).

\subsection*{7.2.1 Testing \(H_{0}: \Sigma=\Sigma_{0}\)}

We begin with the basic hypothesis \(H_{0}: \boldsymbol{\Sigma}=\boldsymbol{\Sigma}_{0}\) versus \(H_{1}: \boldsymbol{\Sigma} \neq \boldsymbol{\Sigma}_{0}\). The hypothesized covariance matrix \(\boldsymbol{\Sigma}_{0}\) is a target value for \(\boldsymbol{\Sigma}\) or a nominal value from previous experience. Note that \(\boldsymbol{\Sigma}_{0}\) is completely specified in \(H_{0}\), whereas \(\boldsymbol{\mu}\) is not specified.

To test \(H_{0}\), we obtain a random sample of \(n\) observation vectors \(\mathbf{y}_{1}, \mathbf{y}_{2}, \ldots, \mathbf{y}_{n}\) from \(N_{p}(\boldsymbol{\mu}, \boldsymbol{\Sigma})\) and calculate \(\mathbf{S}\). To see if \(\mathbf{S}\) is significantly different from \(\boldsymbol{\Sigma}_{0}\), we use the following test statistic, which is a modification of the likelihood ratio (Section 5.4.3):
\[
\begin{equation*}
u=\nu\left[\ln \left|\boldsymbol{\Sigma}_{0}\right|-\ln |\mathbf{S}|+\operatorname{tr}\left(\mathbf{S} \boldsymbol{\Sigma}_{0}^{-1}\right)-p\right], \tag{7.1}
\end{equation*}
\]
where \(\nu\) represents the degrees of freedom of \(\mathbf{S}\) (see comments at the beginning of Section 7.2), In is the natural logarithm (base \(e\) ), and tr is the trace of a matrix (Section 2.9). Note that if \(\mathbf{S}=\boldsymbol{\Sigma}_{0}\), then \(u=0\); otherwise \(u\) increases with the "distance" between \(S\) and \(\boldsymbol{\Sigma}_{0}\) [see (7.4) and the comment following].

When \(\nu\) is large, the statistic \(u\) in (7.1) is approximately distributed as \(\chi^{2}\left[\frac{1}{2} p(p+\right.\) 1)] if \(H_{0}\) is true. For moderate size \(\nu\),
\[
\begin{equation*}
u^{\prime}=\left[1-\frac{1}{6 \nu-1}\left(2 p+1-\frac{2}{p+1}\right)\right] u \tag{7.2}
\end{equation*}
\]
is a better approximation to the \(\chi^{2}\left[\frac{1}{2} p(p+1)\right]\) distribution. We reject \(H_{0}\) if \(u\) or \(u^{\prime}\) is greater than \(\chi^{2}\left[\alpha, \frac{1}{2} p(p+1)\right]\). Note that the degrees of freedom for the \(\chi^{2}\)-statistic, \(\frac{1}{2} p(p+1)\), is the number of distinct parameters in \(\boldsymbol{\Sigma}\).

We can express \(u\) in terms of the eigenvalues \(\lambda_{1}, \lambda_{2}, \ldots, \lambda_{p}\) of \(\mathbf{S} \boldsymbol{\Sigma}_{0}^{-1}\) by noting that \(\operatorname{tr}\left(\mathbf{S} \boldsymbol{\Sigma}_{0}^{-1}\right)\) and \(\ln \left|\boldsymbol{\Sigma}_{0}\right|-\ln |\mathbf{S}|\) become
\[
\begin{align*}
\operatorname{tr}\left(\mathbf{S} \boldsymbol{\Sigma}_{0}^{-1}\right) & =\sum_{i=1}^{p} \lambda_{i} & & {[\mathrm{by}(2.107)] } \\
\ln \left|\boldsymbol{\Sigma}_{0}\right|-\ln |\mathbf{S}| & =-\ln \left|\boldsymbol{\Sigma}_{0}\right|^{-1}-\ln |\mathbf{S}| & & \\
& =-\ln \left|\mathbf{S} \boldsymbol{\Sigma}_{0}^{-1}\right| & & {[\text { by (2.89) and (2.91)] }}  \tag{7.3}\\
& =-\ln \left(\prod_{i=1}^{p} \lambda_{i}\right) & & {[\mathrm{by}(2.108)], }
\end{align*}
\]
from which (7.1) can be written as
\[
\begin{align*}
u & =\nu\left[-\ln \left(\prod_{i=1}^{p} \lambda_{i}\right)+\sum_{i=1}^{p} \lambda_{i}-p\right] \\
& =\nu\left[\sum_{i=1}^{p}\left(\lambda_{i}-\ln \lambda_{i}\right)-p\right] . \tag{7.4}
\end{align*}
\]

A plot of \(y=x-\ln x\) will show that \(x-\ln x \geq 1\) for all \(x>0\), with equality holding only for \(x=1\). Thus \(\sum_{i=1}^{p}\left(\lambda_{i}-\ln \lambda_{i}\right)>p\) and \(u>0\).

The hypothesis that the variables are independent and have unit variance,
\[
H_{0}: \boldsymbol{\Sigma}=\mathbf{I},
\]
can be tested by simply setting \(\boldsymbol{\Sigma}_{0}=\mathbf{I}\) in (7.1).

\subsection*{7.2.2 Testing Sphericity}

The hypothesis that the variables \(y_{1}, y_{2}, \ldots, y_{p}\) in \(\mathbf{y}\) are independent and have the same variance can be expressed as \(H_{0}: \boldsymbol{\Sigma}=\sigma^{2} \mathbf{I}\) versus \(H_{1}: \boldsymbol{\Sigma} \neq \sigma^{2} \mathbf{I}\), where \(\sigma^{2}\) is the unknown common variance. This hypothesis is of interest in repeated measures (see Section 6.9.1). Under \(H_{0}\), the ellipsoid \((\mathbf{y}-\boldsymbol{\mu})^{\prime} \boldsymbol{\Sigma}^{-1}(\mathbf{y}-\boldsymbol{\mu})=c^{2}\) reduces to \((\mathbf{y}-\boldsymbol{\mu})^{\prime}(\mathbf{y}-\boldsymbol{\mu})=\sigma^{2} c^{2}\), the equation of a sphere; hence the term sphericity is applied to the covariance structure \(\boldsymbol{\Sigma}=\sigma^{2} \mathbf{I}\). Another sphericity hypothesis of interest in repeated measures is \(H_{0}: \mathbf{C} \boldsymbol{\Sigma} \mathbf{C}^{\prime}=\sigma^{2} \mathbf{I}\), where \(\mathbf{C}\) is any full-rank \((p-1) \times p\) matrix of orthonormal contrasts (see Section 6.9.1).

For a random sample \(\mathbf{y}_{1}, \mathbf{y}_{2}, \ldots, \mathbf{y}_{n}\) from \(N_{p}(\boldsymbol{\mu}, \boldsymbol{\Sigma})\), the likelihood ratio for testing \(H_{0}: \mathbf{\Sigma}=\sigma^{2} \mathbf{I}\) is
\[
\begin{equation*}
\mathbf{L R}=\left[\frac{|\mathbf{S}|}{(\operatorname{trS} / p)^{p}}\right]^{n / 2} \tag{7.5}
\end{equation*}
\]

In some cases that we have considered previously, the likelihood ratio is a simple function of a test statistic such as \(F, T^{2}\), Wilks' \(\Lambda\), and so on. However, LR in (7.5) does not reduce to a standard statistic, and we resort to an approximation for its distribution. It has been shown that for a general likelihood ratio statistic LR,
\[
\begin{equation*}
-2 \ln (\mathrm{LR}) \text { is approximately } \chi_{\nu}^{2} \tag{7.6}
\end{equation*}
\]
for large \(n\), where \(\nu\) is the total number of parameters minus the number estimated under the restrictions imposed by \(H_{0}\).

For the likelihood ratio statistic in (7.5), we obtain
\[
-2 \ln (\mathbf{L R})=-n \ln \left[\frac{|\mathbf{S}|}{(\operatorname{trS} / p)^{p}}\right]=-n \ln u
\]
where
\[
\begin{equation*}
u=(\mathbf{L R})^{2 / n}=\frac{p^{p}|\mathbf{S}|}{(\operatorname{tr} \mathbf{S})^{p}} \tag{7.7}
\end{equation*}
\]

By (2.107) and (2.108), \(u\) becomes
\[
\begin{equation*}
u=\frac{p^{p} \prod_{i=1}^{p} \lambda_{i}}{\left(\sum_{i=1}^{p} \lambda_{i}\right)^{p}}, \tag{7.8}
\end{equation*}
\]
where \(\lambda_{1}, \lambda_{2}, \ldots, \lambda_{p}\) are the eigenvalues of \(S\). An improvement over \(-n \ln u\) is given by
\[
\begin{equation*}
u^{\prime}=-\left(\nu-\frac{2 p^{2}+p+2}{6 p}\right) \ln u \tag{7.9}
\end{equation*}
\]
where \(\nu\) is the degrees of freedom for \(S\) (see comments at the beginning of Section 7.2). The statistic \(u^{\prime}\) has an approximate \(\chi^{2}\)-distribution with \(\frac{1}{2} p(p+1)-1\) degrees of freedom. We reject \(H_{0}\) if \(u^{\prime} \geq \chi^{2}\left[\alpha, \frac{1}{2} p(p+1)-1\right]\). As noted above, the degrees of freedom in the \(\chi^{2}\) approximation is equal to the total number of parameters minus the number of parameters estimated under \(H_{0}\). The number of parameters in \(\boldsymbol{\Sigma}\) is \(p+\binom{p}{2}=\frac{1}{2} p(p+1)\) and the loss of one degree of freedom is due to estimation of \(\sigma^{2}\).

We see from (7.8) and (7.9) that if the sample \(\lambda_{i}\) 's are all equal, \(u=1\) and \(u^{\prime}=0\). Hence, this statistic also tests the hypothesis of equality of the population eigenvalues.

To test \(H_{0}: \mathbf{C} \boldsymbol{\Sigma} \mathbf{C}^{\prime}=\sigma^{2} \mathbf{I}\), use \(\mathbf{C S C} \mathbf{C}^{\prime}\) in place of \(\mathbf{S}\) in (7.7) and use \(p-1\) in place of \(p\) in (7.7)-(7.9) and in the degrees of freedom for \(\chi^{2}\).

The likelihood ratio (7.5) was first given by Mauchly (1940), and his name is often associated with this test. Nagarsenker and Pillai (1973) gave the exact distribution of \(u\) and provided a table for \(p=4,5, \ldots, 10\). Venables (1976) showed that \(u\) can be obtained by a union-intersection approach (Section 6.1.4).

\section*{- EXAMPLE 7.2.2}

We use the probe word data in Table 3.6 to illustrate tests of sphericity. The five variables appear to be commensurate, and the hypothesis \(H_{0}: \mu_{1}=\mu_{2}=\) \(\cdots=\mu_{5}\) may be of interest. We would expect the variables to be correlated, and \(H_{0}\) would ordinarily be tested using a multivariate approach, as in Sections 5.9.1 and 6.9.2. However, if \(\boldsymbol{\Sigma}=\sigma^{2} \mathbf{I}\) or \(\mathbf{C} \boldsymbol{\Sigma} \mathbf{C}^{\prime}=\sigma^{2} \mathbf{I}\), then the hypothesis \(H_{0}: \mu_{1}=\mu_{2}=\cdots=\mu_{5}\) can be tested with a univariate ANOVA \(F\)-test (see Section 6.9.1).

We first test \(H_{0}: \mathbf{\Sigma}=\sigma^{2} \mathbf{I}\). The sample covariance matrix \(\mathbf{S}\) was obtained in Example 3.10.1. By (7.7),
\[
u=\frac{p^{p}|\mathbf{S}|}{(\operatorname{tr} \mathbf{S})^{p}}=\frac{5^{5}(27,236,586)}{(292.891)^{5}}=.0395
\]

Then by (7.9), with \(n=11\) and \(p=5\), we have
\[
u^{\prime}=-\left(n-1-\frac{2 p^{2}+p+2}{6 p}\right) \ln u=26.177
\]

The approximate \(\chi^{2}\)-test has \(\frac{1}{2} p(p+1)-1=14\) degrees of freedom. We therefore compare \(u^{\prime}=26.177\) with \(\chi_{.05,14}^{2}=23.68\) and reject \(H_{0}: \mathbf{\Sigma}=\sigma^{2} \mathbf{I}\).

To test \(H_{0}: \mathbf{C} \boldsymbol{\Sigma} \mathbf{C}^{\prime}=\sigma^{2} \mathbf{I}\), we use the following matrix of orthonormalized contrasts:
\[
\mathbf{C}=\left(\begin{array}{rrrrr}
4 / \sqrt{20} & -1 / \sqrt{20} & -1 / \sqrt{20} & -1 / \sqrt{20} & -1 / \sqrt{20} \\
0 & 3 / \sqrt{12} & -1 / \sqrt{12} & -1 / \sqrt{12} & -1 / \sqrt{12} \\
0 & 0 & 2 / \sqrt{6} & -1 / \sqrt{6} & -1 / \sqrt{6} \\
0 & 0 & 0 & 1 / \sqrt{2} & -1 / \sqrt{2}
\end{array}\right)
\]

Then using \(\mathbf{C S C}^{\prime}\) in place of \(\mathbf{S}\) and with \(p-1=4\) for the four rows of \(\mathbf{C}\), we obtain
\[
\begin{aligned}
u & =\frac{(p-1)^{p-1}\left|\mathbf{C S C}^{\prime}\right|}{\left[\operatorname{tr}\left(\mathbf{C S C}^{\prime}\right)\right]^{p-1}}=\frac{4^{4}(144039.8)}{(93.6)^{4}}=.480 \\
u^{\prime} & =6.170
\end{aligned}
\]

For degrees of freedom, we now have \(\frac{1}{2}(4)(5)-1=9\), and the critical value is \(\chi_{.05,9}^{2}=16.92\). Hence, we do not reject \(H_{0}: \mathbf{C} \boldsymbol{\Sigma} \mathbf{C}^{\prime}=\sigma^{2} \mathbf{I}\), and a univariate \(F\)-test of \(H_{0}: \mu_{1}=\mu_{2}=\cdots=\mu_{5}\) may be justified.

\subsection*{7.2.3 Testing \(H_{0}: \Sigma=\sigma^{2}[(1-\rho) \mathrm{I}+\rho \mathrm{J}]\)}

In Section 6.9.1, it was noted that univariate ANOVA remains valid if
\[
\begin{align*}
\boldsymbol{\Sigma} & =\sigma^{2}\left(\begin{array}{ccccc}
1 & \rho & \rho & \ldots & \rho \\
\rho & 1 & \rho & \ldots & \rho \\
\vdots & \vdots & \vdots & & \vdots \\
\rho & \rho & \rho & \ldots & 1
\end{array}\right)  \tag{7.10}\\
& =\sigma^{2}[(1-\rho) \mathbf{I}+\rho \mathbf{J}] \tag{7.11}
\end{align*}
\]
where \(\mathbf{J}\) is a square matrix of 1 's, as defined in (2.12), and \(\rho\) is the population correlation between any two variables. This pattern of equal variances and equal covariances in \(\boldsymbol{\Sigma}\) is variously referred to as uniformity, compound symmetry, or the intraclass correlation model.

We now consider the hypothesis that (7.10) holds:
\[
H_{0}: \boldsymbol{\Sigma}=\left(\begin{array}{cccc}
\sigma^{2} & \sigma^{2} \rho & \cdots & \sigma^{2} \rho \\
\sigma^{2} \rho & \sigma^{2} & \cdots & \sigma^{2} \rho \\
\vdots & \vdots & & \vdots \\
\sigma^{2} \rho & \sigma^{2} \rho & \cdots & \sigma^{2}
\end{array}\right)
\]

From a sample we obtain the sample covariance matrix \(\mathbf{S}\). Estimates of \(\sigma^{2}\) and \(\sigma^{2} \rho\) under \(H_{0}\) are given by
\[
\begin{equation*}
s^{2}=\frac{1}{p} \sum_{j=1}^{p} s_{j j} \quad \text { and } \quad s^{2} r=\frac{1}{p(p-1)} \sum_{j \neq k} s_{j k} \tag{7.12}
\end{equation*}
\]
respectively, where \(s_{j j}\) and \(s_{j k}\) are from \(\mathbf{S}\). Thus \(s^{2}\) is an average of the variances on the diagonal of \(\mathbf{S}\) and \(s^{2} r\) is an average of the off-diagonal covariances in \(\mathbf{S}\). An estimate of \(\rho\) can be obtained as \(r=s^{2} r / s^{2}\). Using \(s^{2}\) and \(s^{2} r\) in (7.12), the estimate of \(\boldsymbol{\Sigma}\) under \(H_{0}\) is then
\[
\mathbf{S}_{0}=\left(\begin{array}{cccc}
s^{2} & s^{2} r & \cdots & s^{2} r  \tag{7.13}\\
s^{2} r & s^{2} & \cdots & s^{2} r \\
\vdots & \vdots & & \vdots \\
s^{2} r & s^{2} r & \cdots & s^{2}
\end{array}\right)=s^{2}[(1-r) \mathbf{I}+r \mathbf{J}]
\]

To compare \(S\) and \(S_{0}\), we use the following function of the likelihood ratio:
\[
\begin{equation*}
u=\frac{|\mathbf{S}|}{\left|\mathbf{S}_{\mathbf{0}}\right|}, \tag{7.14}
\end{equation*}
\]
which can be expressed in the alternative form
\[
\begin{equation*}
u=\frac{|\mathbf{S}|}{\left(s^{2}\right)^{p}(1-r)^{p-1}[1+(p-1) r]} \tag{7.15}
\end{equation*}
\]

By analogy with (7.9), the test statistic is given by
\[
\begin{equation*}
u^{\prime}=-\left[\nu-\frac{p(p+1)^{2}(2 p-3)}{6(p-1)\left(p^{2}+p-4\right)}\right] \ln u \tag{7.16}
\end{equation*}
\]
where \(\nu\) is the degrees of freedom of \(S\) (see comments at the beginning of Section 7.2). The statistic \(u^{\prime}\) is approximately \(\chi^{2}\left[\frac{1}{2} p(p+1)-2\right]\), and we reject \(H_{0}\) if \(u^{\prime}>\) \(\chi^{2}\left[\alpha, \frac{1}{2} p(p+1)-2\right]\). Note that two degrees of freedom are lost due to estimation of \(\sigma^{2}\) and \(\rho\).

An alternative approximate test that is more precise when \(p\) is large and \(\nu\) is relatively small is given by
\[
F=\frac{-\left(\gamma_{2}-\gamma_{2} c_{1}-\gamma_{1}\right) \nu}{\gamma_{1} \gamma_{2}} \ln u
\]
where
\[
\begin{aligned}
c_{1} & =\frac{p(p+1)^{2}(2 p-3)}{6 \nu(p-1)\left(p^{2}+p-4\right)}, & c_{2} & =\frac{p\left(p^{2}-1\right)(p+2)}{6 \nu^{2}\left(p^{2}+p-4\right)} \\
\gamma_{1} & =\frac{1}{2} p(p+1)-2, & \gamma_{2} & =\frac{\gamma_{1}+2}{c_{2}-c_{1}^{2}}
\end{aligned}
\]

We reject \(H_{0}: \boldsymbol{\Sigma}=\sigma^{2}[(1-\rho) \mathbf{I}+\rho \mathbf{J}]\) if \(F>F_{\alpha, \gamma_{1}, \gamma_{2}}\).

\section*{ㄷ EXAMPLE 7.2.3}

To illustrate this test, we use the cork data of Table 6.21. In Problem 6.34, a comparison is made of average thickness, and hence weight, in the four directions. A standard ANOVA approach to this repeated measures design would be valid if (7.10) holds. To check this assumption, we test \(H_{0}: \boldsymbol{\Sigma}=\) \(\sigma^{2}[(1-\rho) \mathbf{I}+\rho \mathbf{J}]\). The sample covariance matrix is given by
\[
\mathbf{S}=\left(\begin{array}{llll}
290.41 & 223.75 & 288.44 & 226.27 \\
223.75 & 219.93 & 229.06 & 171.37 \\
288.44 & 229.06 & 350.00 & 259.54 \\
226.27 & 171.37 & 259.54 & 226.00
\end{array}\right)
\]
from which we obtain
\[
\begin{array}{rlrl}
|\mathbf{S}| & =25,617,563.28, & s^{2} & =\frac{1}{p} \sum_{j=1}^{p} s_{j j}=271.586 \\
s^{2} r=\frac{1}{p(p-1)} \sum_{j \neq k} s_{j k}=233.072, & r & =\frac{s^{2} r}{s^{2}}=\frac{233.072}{271.586}=.858
\end{array}
\]

From (7.15) and (7.16), we now have
\[
\begin{aligned}
u & =\frac{25,617,563.28}{(271.586)^{4}(1-.858)^{3}[1+(3)(.858)]}=.461, \\
u^{\prime} & =-\left[\nu-\frac{p(p+1)^{2}(2 p-3)}{6(p-1)\left(p^{2}+p-4\right)}\right] \ln u \\
& =\left[27-\frac{(4)(25)(5)}{(6)(3)(16)}\right] 0.774=19.511
\end{aligned}
\]

Since \(19.511>\chi_{.05,8}^{2}=15.5\), we reject \(H_{0}\) and conclude that \(\boldsymbol{\Sigma}\) does not have the pattern in (7.10).

\subsection*{7.3 TESTS COMPARING COVARIANCE MATRICES}

An assumption for \(T^{2}\) or MANOVA tests comparing two or more mean vectors is that the corresponding population covariance matrices are equal: \(\boldsymbol{\Sigma}_{1}=\boldsymbol{\Sigma}_{2}=\cdots=\) \(\boldsymbol{\Sigma}_{k}\). Under this assumption, the sample covariance matrices \(\mathbf{S}_{1}, \mathbf{S}_{2}, \ldots, \mathbf{S}_{k}\) reflect a common population \(\boldsymbol{\Sigma}\) and are therefore pooled to obtain an estimate of \(\boldsymbol{\Sigma}\). If \(\boldsymbol{\Sigma}_{1}=\boldsymbol{\Sigma}_{2}=\cdots=\boldsymbol{\Sigma}_{k}\) is not true, large differences in \(\mathbf{S}_{1}, \mathbf{S}_{2}, \ldots, \mathbf{S}_{k}\) may possibly lead to rejection of \(H_{0}: \boldsymbol{\mu}_{1}=\boldsymbol{\mu}_{2}=\cdots=\boldsymbol{\mu}_{k}\). However, the \(T^{2}\) and MANOVA tests are fairly robust to heterogeneity of covariance matrices as long as the sample sizes are large and equal. For other cases it is useful to have available a test of equality of covariance matrices. We begin with a review of the univariate case.

\subsection*{7.3.1 Univariate Tests of Equality of Variances}

The two-sample univariate hypothesis \(H_{0}: \sigma_{1}^{2}=\sigma_{2}^{2}\) versus \(H_{1}: \sigma_{1}^{2} \neq \sigma_{2}^{2}\) is tested with
\[
\begin{equation*}
F=\frac{s_{1}^{2}}{s_{2}^{2}} \tag{7.17}
\end{equation*}
\]
where \(s_{1}^{2}\) and \(s_{2}^{2}\) are the variances of the two samples. If \(H_{0}\) is true, \(F\) is distributed as \(F_{\nu_{1}, \nu_{2}}\), where \(\nu_{1}\) and \(\nu_{2}\) are the degrees of freedom of \(s_{1}^{2}\) and \(s_{2}^{2}\) (typically, \(n_{1}-1\) and \(n_{2}-1\) ). Note that \(s_{1}^{2}\) and \(s_{2}^{2}\) must be independent, which will hold if the two samples are independent.

For the several-sample case, various procedures have been proposed. We present Bartlett's (1937) test of homogeneity of variances because it has been extended to
the multivariate case. To test
\[
H_{0}: \sigma_{1}^{2}=\sigma_{2}^{2}=\cdots=\sigma_{k}^{2}
\]
we calculate
\[
\begin{aligned}
c & =1+\frac{1}{3(k-1)}\left[\sum_{i=1}^{k} \frac{1}{\nu_{i}}-\frac{1}{\sum_{i=1}^{k} \nu_{i}}\right], \quad s^{2}=\frac{\sum_{i=1}^{k} \nu_{i} s_{i}^{2}}{\sum_{i=1}^{k} \nu_{i}}, \\
m & =\left(\sum_{i=1}^{k} \nu_{i}\right) \ln s^{2}-\sum_{i=1}^{k} \nu_{i} \ln s_{i}^{2}
\end{aligned}
\]
where \(s_{1}^{2}, s_{2}^{2}, \ldots, s_{k}^{2}\) are independent sample variances with \(\nu_{1}, \nu_{2}, \ldots, \nu_{k}\) degrees of freedom, respectively. Then
\[
\frac{m}{c} \quad \text { is approximately } \quad \chi_{k-1}^{2}
\]

We reject \(H_{0}\) if \(m / c>\chi_{\alpha, k-1}^{2}\).
For an \(F\)-approximation, we use \(c\) and \(m\) above and calculate in addition
\[
a_{1}=k-1, \quad a_{2}=\frac{k+1}{(c-1)^{2}}, \quad b=\frac{a_{2}}{2-c+2 / a_{2}} .
\]

Then
\[
F=\frac{a_{2} m}{a_{1}(b-m)} \quad \text { is approximately } \quad F_{a_{1}, a_{2}}
\]

We reject \(H_{0}\) if \(F>F_{\alpha}\).
Note that an assumption for either form of the above test is independence of \(s_{1}^{2}, s_{2}^{2}, \ldots, s_{k}^{2}\), which will hold for random samples from \(k\) distinct populations. This test would therefore be inappropriate for comparing \(s_{11}, s_{22}, \ldots, s_{p p}\) from the diagonal of \(\mathbf{S}\), since the \(s_{j j}\) 's are correlated.

\subsection*{7.3.2 Multivariate Tests of Equality of Covariance Matrices}

For \(k\) multivariate populations, the hypothesis of equality of covariance matrices is
\[
\begin{equation*}
H_{0}: \boldsymbol{\Sigma}_{1}=\boldsymbol{\Sigma}_{2}=\cdots=\boldsymbol{\Sigma}_{k} \tag{7.18}
\end{equation*}
\]

The test of \(H_{0}: \Sigma_{1}=\Sigma_{2}\) for two groups is easily obtained as a special case by setting \(k=2\). Thus there is no exact test as there is in the analogous univariate case [see (7.17)]. We assume independent samples of size \(n_{1}, n_{2}, \ldots, n_{k}\) from multivariate normal distributions, as in an unbalanced one-way MANOVA, for example. To make the test, we calculate
\[
\begin{equation*}
M=\frac{\left|\mathbf{S}_{1}\right|^{\nu_{1} / 2}\left|\mathbf{S}_{2}\right|^{\nu_{2} / 2} \cdots\left|\mathbf{S}_{k}\right|^{\nu_{k} / 2}}{\left|\mathbf{S}_{\mathrm{p} \mid}\right|^{\sum_{i} \nu_{i} / 2}} \tag{7.19}
\end{equation*}
\]
in which \(\nu_{i}=n_{i}-1, \mathbf{S}_{i}\) is the covariance matrix of the \(i\) th sample, and \(\mathbf{S}_{\mathrm{pl}}\) is the pooled sample covariance matrix
\[
\begin{equation*}
\mathbf{S}_{\mathrm{pl}}=\frac{\sum_{i=1}^{k} \nu_{i} \mathbf{S}_{i}}{\sum_{i=1}^{k} \nu_{i}}=\frac{\mathbf{E}}{\nu_{E}}, \tag{7.20}
\end{equation*}
\]
where \(\mathbf{E}\) is given by (6.32) and \(\nu_{E}=\sum_{i=1}^{k} \nu_{i}=\sum_{i} n_{i}-k\). It is clear that we must have every \(\nu_{i}>p\); otherwise \(M\) would be zero because \(\left|\mathbf{S}_{i}\right|=0\) for some i. Exact upper percentage points of \(-2 \ln M=\nu\left(k \ln \left|\mathbf{S}_{\mathrm{p} \mid}\right|-\sum_{i} \ln \left|\mathbf{S}_{i}\right|\right)\) for the special case of \(\nu_{1}=\nu_{2}=\cdots=\nu_{k}=\nu\) are given in Table A. 14 for \(p=2,3,4,5\) and \(k=2,3, \ldots, 10\) (Lee et al. 1977). We can easily modify (7.19) and (7.20) to compare covariance matrices for the cells of a two-way model using \(\nu_{i j}=n_{i j}-1\).

The statistic \(M\) is a modification of the likelihood ratio and varies between 0 and 1 , with values near 1 favoring \(H_{0}\) in (7.18) and values near 0 leading to rejection of \(H_{0}\). It is not immediately obvious that \(M\) in (7.19) behaves in this way, and we offer the following heuristic argument. First we note that (7.19) can be expressed as
\[
\begin{equation*}
M=\left(\frac{\left|\mathbf{S}_{1}\right|}{\left|\mathbf{S}_{\mathrm{p} \mid}\right|}\right)^{\nu_{1} / 2}\left(\frac{\left|\mathbf{S}_{2}\right|}{\left|\mathbf{S}_{\mathrm{p} \mid}\right|}\right)^{\nu_{2} / 2} \cdots\left(\frac{\left|\mathbf{S}_{k}\right|}{\left|\mathbf{S}_{\mathrm{p} \mid}\right|}\right)^{\nu_{k} / 2} . \tag{7.21}
\end{equation*}
\]

If \(\mathbf{S}_{1}=\mathbf{S}_{2}=\cdots=\mathbf{S}_{k}=\mathbf{S}_{\mathrm{pl}}\), then \(M=1\). As the disparity among \(\mathbf{S}_{1}, \mathbf{S}_{2}, \ldots, \mathbf{S}_{k}\) increases, \(M\) approaches zero. To see this, note that the determinant of the pooled covariance matrix, \(\left|\mathbf{S}_{\mathrm{pl}}\right|\), lies somewhere near the "middle" of the \(\left|\mathbf{S}_{i}\right|\) 's and that as a set of variables \(z_{1}, z_{2}, \ldots, z_{n}\) increases in spread, \(z_{(1)} / \bar{z}\) reduces the product more than \(z_{(n)} / \bar{z}\) increases it, where \(z_{(1)}\) and \(z_{(n)}\) are the minimum and maximum values, respectively. We illustrate this with the two sets of numbers \(4,5,6\) and \(1,5,9\), which have the same mean but different spread. If we assume \(\nu_{1}=\nu_{2}=\nu_{3}=\nu\), then for the first set,
\[
M_{1}=\left[\left(\frac{4}{5}\right)\left(\frac{5}{5}\right)\left(\frac{6}{5}\right)\right]^{\nu / 2}=[(.8)(1)(1.2)]^{\nu / 2}=(.96)^{\nu / 2}
\]
and for the second set,
\[
M_{2}=\left[\left(\frac{1}{5}\right)\left(\frac{5}{5}\right)\left(\frac{9}{5}\right)\right]^{\nu / 2}=[(.2)(1)(1.8)]^{\nu / 2}=(.36)^{\nu / 2}
\]

In \(M_{2}\), the smallest value, .2 , reduces the product proportionally more than the largest value, 1.8 , increases it. Another illustration is found in Problem 7.9.

Box \((1949,1950)\) gave \(\chi^{2}\) - and \(F\)-approximations for the distribution of \(M\). Either of these approximate tests is referred to as Box's \(M\)-test. For the \(\chi^{2}\)-approximation, calculate
\[
\begin{equation*}
c_{1}=\left[\sum_{i=1}^{k} \frac{1}{\nu_{i}}-\frac{1}{\sum_{i=1}^{k} \nu_{i}}\right]\left[\frac{2 p^{2}+3 p-1}{6(p+1)(k-1)}\right] . \tag{7.22}
\end{equation*}
\]

Then
\[
\begin{equation*}
u=-2\left(1-c_{1}\right) \ln M \text { is approximately } \chi^{2}\left[\frac{1}{2}(k-1) p(p+1)\right], \tag{7.23}
\end{equation*}
\]
where \(M\) is defined in (7.19), and
\[
\begin{equation*}
\ln M=\frac{1}{2} \sum_{i=1}^{k} \nu_{i} \ln \left|\mathbf{S}_{i}\right|-\frac{1}{2}\left(\sum_{i=1}^{k} \nu_{i}\right) \ln \left|\mathbf{S}_{\mathbf{p} \mid}\right| \tag{7.24}
\end{equation*}
\]

We reject \(H_{0}\) if \(u>\chi_{\alpha}^{2}\). If \(\nu_{1}=\nu_{2}=\cdots=\nu_{k}=\nu\), then \(c_{1}\) simplifies to
\[
\begin{equation*}
c_{1}=\frac{(k+1)\left(2 p^{2}+3 p-1\right)}{6 k \nu(p+1)} \tag{7.25}
\end{equation*}
\]

To justify the degrees of freedom of the \(\chi^{2}\)-approximation, note that the total number of parameters estimated under \(H_{1}\) is \(k\left[\frac{1}{2} p(p+1)\right]\), whereas under \(H_{0}\) we estimate only \(\boldsymbol{\Sigma}\), which has \(p+\binom{p}{2}=\frac{1}{2} p(p+1)\) parameters. The difference is \((k-1)\left[\frac{1}{2} p(p+1)\right]\). The quantity \(k\left[\frac{1}{2} p(p+1)\right]\) arises from the assumption that all \(\boldsymbol{\Sigma}_{i}, i=1,2, \ldots, k\), are different. Technically, \(H_{1}\) can be stated as \(\boldsymbol{\Sigma}_{i} \neq \boldsymbol{\Sigma}_{j}\) for some \(i \neq j\). However, the most general case is all \(\boldsymbol{\Sigma}_{i}\) different, and the distribution of \(M\) is derived accordingly.

For the \(F\)-approximation, we use \(c_{1}\) from (7.22) and calculate, additionally,
\[
\begin{align*}
& c_{2}=\frac{(p-1)(p+2)}{6(k-1)}\left[\sum_{i=1}^{k} \frac{1}{\nu_{i}^{2}}-\frac{1}{\left(\sum_{i=1}^{k} \nu_{i}\right)^{2}}\right]  \tag{7.26}\\
& a_{1}=\frac{1}{2}(k-1) p(p+1), \quad a_{2}=\frac{a_{1}+2}{\left|c_{2}-c_{1}^{2}\right|} \\
& b_{1}=\frac{1-c_{1}-a_{1} / a_{2}}{a_{1}}, \quad b_{2}=\frac{1-c_{1}-2 / a_{2}}{a_{2}}
\end{align*}
\]

If \(c_{2}>c_{1}^{2}\),
\[
\begin{equation*}
F=-2 b_{1} \ln M \quad \text { is approximately } F_{a_{1}, a_{2}} \tag{7.27}
\end{equation*}
\]

If \(c_{2}<c_{1}^{2}\),
\[
\begin{equation*}
F=-\frac{a_{2} b_{2} \ln M}{a_{1}\left(1+2 b_{2} \ln M\right)} \quad \text { is approximately } F_{a_{1}, a_{2}} \tag{7.28}
\end{equation*}
\]

In either case, we reject \(H_{0}\) if \(F>F_{\alpha}\). If \(\nu_{1}=\nu_{2}=\cdots=\nu_{k}=\nu\), then \(c_{1}\) simplifies as in (7.25) and \(c_{2}\) simplifies to
\[
\begin{equation*}
c_{2}=\frac{(p-1)(p+2)\left(k^{2}+k+1\right)}{6 k^{2} \nu^{2}} . \tag{7.29}
\end{equation*}
\]

Box's \(M\)-test is calculated routinely in many computer programs for MANOVA. However, Olson (1974) showed that the \(M\)-test with equal \(\nu_{i}\) may detect some forms of heterogeneity that have only minor effects on the MANOVA tests. The test is also sensitive to some forms of nonnormality. For example, it is sensitive to kurtosis, for which the MANOVA tests are rather robust. Thus the \(M\)-test may signal covariance heterogeneity in some cases where it is not damaging to the MANOVA tests. Hence we may not wish to automatically rule out standard MANOVA tests if the \(M\)-test leads to rejection of \(H_{0}\). Olson showed that the skewness and kurtosis statistics \(b_{1, p}\) and \(b_{2, p}\) (see Section 4.4.2) have similar shortcomings.

\section*{EXAMPLE 7.3.2}

We test the hypothesis \(H_{0}: \boldsymbol{\Sigma}_{1}=\boldsymbol{\Sigma}_{2}\) for the psychological data of Table 5.1. The covariance matrices \(\mathbf{S}_{1}, \mathbf{S}_{2}\), and \(\mathbf{S}_{\mathrm{pl}}\) were given in Example 5.4.2. Using these, we obtain, by (7.24),
\[
\begin{aligned}
\ln M= & \frac{1}{2}\left[\nu_{1} \ln \left|\mathbf{S}_{1}\right|+\nu_{2} \ln \left|\mathbf{S}_{2}\right|\right]-\frac{1}{2}\left(\nu_{1}+\nu_{2}\right) \ln \left|\mathbf{S}_{\mathrm{pl}}\right| \\
= & \frac{1}{2}[(31) \ln (7917.7)+(31) \ln (58958.1)] \\
& -\frac{1}{2}(31+31) \ln (27325.2)=-7.2803 .
\end{aligned}
\]

For an exact test, we compare
\[
-2 \ln M=14.561
\]
with 19.74, its critical value from Table A.14.
For the \(\chi^{2}\)-approximation, we compute, by (7.25) and (7.23),
\[
\begin{aligned}
c_{1} & =\frac{(2+1)\left[2\left(4^{2}\right)+3(4)-1\right]}{6(2)(31)(4+1)}=.06935 \\
u & =-2\left(1-c_{1}\right) \ln M=13.551<\chi_{.05,10}^{2}=18.307
\end{aligned}
\]

For an approximate \(F\)-test, we first calculate the following:
\[
\begin{aligned}
& c_{2}=\frac{(4-1)(4+2)}{6(2-1)}\left[\frac{1}{31^{2}}+\frac{1}{31^{2}}-\frac{1}{(31+31)^{2}}\right]=.005463 \\
& a_{1}=\frac{1}{2}(2-1)(4)(4+1)=10 \\
& a_{2}=\frac{10+2}{\left|.005463-.06935^{2}\right|}=18377.7 \\
& b_{1}=\frac{1-.06935-10 / 18377.7}{10}=.0930 \\
& b_{2}=\frac{1-.06935-2 / 18377.7}{18377.7}=5.0634 \times 10^{-5}
\end{aligned}
\]

Since \(c_{2}=.005463>c_{1}^{2}=.00481\), we use (7.27) to obtain
\[
F=-2 b_{1} \ln M=1.354<F_{.05,10, \infty}=1.83
\]

Thus all three tests accept \(H_{0}\).

\subsection*{7.4 TESTS OF INDEPENDENCE}

\subsection*{7.4.1 Independence of Two Subvectors}

Suppose the observation vector is partitioned into two subvectors of interest, which we label \(\mathbf{y}\) and \(\mathbf{x}\), as in Section 3.9.1, where \(\mathbf{y}\) is \(p \times 1\) and \(\mathbf{x}\) is \(q \times 1\). By (3.46), the
corresponding partitioning of the population covariance matrix is
\[
\boldsymbol{\Sigma}=\left(\begin{array}{ll}
\boldsymbol{\Sigma}_{y y} & \boldsymbol{\Sigma}_{y x} \\
\boldsymbol{\Sigma}_{x y} & \boldsymbol{\Sigma}_{x x}
\end{array}\right)
\]
with analogous partitioning of \(S\) and \(\mathbf{R}\) as in (3.42):
\[
\mathbf{S}=\left(\begin{array}{ll}
\mathbf{S}_{y y} & \mathbf{S}_{y x} \\
\mathbf{S}_{x y} & \mathbf{S}_{x x}
\end{array}\right), \quad \mathbf{R}=\left(\begin{array}{ll}
\mathbf{R}_{y y} & \mathbf{R}_{y x} \\
\mathbf{R}_{x y} & \mathbf{R}_{x x}
\end{array}\right)
\]

The hypothesis of independence of \(y\) and \(x\) can be expressed as
\[
H_{0}: \boldsymbol{\Sigma}=\left(\begin{array}{cc}
\boldsymbol{\Sigma}_{y y} & \mathbf{O} \\
\mathbf{O} & \boldsymbol{\Sigma}_{x x}
\end{array}\right) \quad \text { or } \quad H_{0}: \boldsymbol{\Sigma}_{y x}=\mathbf{O}
\]

Thus independence of \(y\) and \(x\) means that every variable in \(y\) is independent of every variable in \(\mathbf{x}\). Note that there is no restriction on \(\boldsymbol{\Sigma}_{y y}\) or \(\boldsymbol{\Sigma}_{x x}\).

The likelihood ratio test statistic for \(H_{0}: \Sigma_{y x}=\mathbf{O}\) is given by
\[
\begin{equation*}
\Lambda=\frac{|\mathbf{S}|}{\left|\mathbf{S}_{y y}\right|\left|\mathbf{S}_{x x}\right|}=\frac{|\mathbf{R}|}{\left|\mathbf{R}_{y y}\right|\left|\mathbf{R}_{x x}\right|}, \tag{7.30}
\end{equation*}
\]
which is distributed as \(\Lambda_{p, q, n-1-q}\). We reject \(H_{0}\) if \(\Lambda \leq \Lambda_{\alpha}\). We thus have an exact test for \(H_{0}: \boldsymbol{\Sigma}_{y x}=\mathbf{O}\). Critical values for Wilks' \(\Lambda\) are given in Table A. 9 using \(\nu_{H}=q\) and \(\nu_{E}=n-1-q\). The test statistic in (7.30) is equivalent (when \(H_{0}\) is true) to the \(\Lambda\)-statistic (10.64) in Section 10.5 .1 for testing the significance of the regression of \(\mathbf{y}\) on \(\mathbf{x}\).

By the symmetry of
\[
\frac{|\mathbf{S}|}{\left|\mathbf{S}_{y y}\right|\left|\mathbf{S}_{x x}\right|}=\frac{|\mathbf{S}|}{\left|\mathbf{S}_{x x}\right|\left|\mathbf{S}_{y y}\right|},
\]
\(\Lambda\) in (7.30) is also distributed as \(\Lambda_{q, p, n-1-p}\). This is equivalent to property 3 in Section 6.1.3.

Note that \(\left|\mathbf{S}_{y y}\right|\left|\mathbf{S}_{x x}\right|\) in (7.30) is an estimate of \(\left|\boldsymbol{\Sigma}_{y y}\right|\left|\boldsymbol{\Sigma}_{x x}\right|\), which by (2.92) is the determinant of \(\boldsymbol{\Sigma}\) when \(\boldsymbol{\Sigma}_{y x}=\mathbf{O}\). Thus Wilks' \(\Lambda\) compares an estimate of \(\boldsymbol{\Sigma}\) without restrictions to an estimate of \(\boldsymbol{\Sigma}\) under \(H_{0}: \boldsymbol{\Sigma}_{y x}=\mathbf{O}\). We can see intuitively that \(|\mathbf{S}|<\left|\mathbf{S}_{y y}\right|\left|\mathbf{S}_{x x}\right|\) by noting from (2.94) that \(|\mathbf{S}|=\left|\mathbf{S}_{x x}\right|\left|\mathbf{S}_{y y}-\mathbf{S}_{y x} \mathbf{S}_{x x}^{-1} \mathbf{S}_{x y}\right|\), and since \(\mathbf{S}_{y x} \mathbf{S}_{x x}^{-1} \mathbf{S}_{x y}\) is positive definite, \(\left|\mathbf{S}_{y y}-\mathbf{S}_{y x} \mathbf{S}_{x x}^{-1} \mathbf{S}_{x y}\right|<\left|\mathbf{S}_{y y}\right|\). This can be illustrated for the case \(p=q=1\) :
\[
|\mathbf{S}|=\left|\begin{array}{cc}
s_{y}^{2} & s_{y x} \\
s_{y x} & s_{x}^{2}
\end{array}\right|=s_{y}^{2} s_{x}^{2}-\left(s_{y x}\right)^{2}<s_{y}^{2} s_{x}^{2} .
\]

As \(s_{y x}^{2}\) increases, \(|S|\) decreases.
Wilks' \(\Lambda\) in (7.30) can be expressed in terms of eigenvalues:
\[
\begin{equation*}
\Lambda=\prod_{i=1}^{s}\left(1-r_{i}^{2}\right) \tag{7.31}
\end{equation*}
\]
where \(s=\min (p, q)\) and the \(r_{i}^{2}\) 's are the nonzero eigenvalues of \(\mathbf{S}_{x x}^{-1} \mathbf{S}_{x y} \mathbf{S}_{y y}^{-1} \mathbf{S}_{y x}\). We could also use \(\mathbf{S}_{y y}^{-1} \mathbf{S}_{y x} \mathbf{S}_{x x}^{-1} \mathbf{S}_{x y}\), since the (nonzero) eigenvalues of \(\mathbf{S}_{y y}^{-1} \mathbf{S}_{y x} \mathbf{S}_{x x}^{-1} \mathbf{S}_{x y}\) are the same as those of \(\mathbf{S}_{x x}^{-1} \mathbf{S}_{x y} \mathbf{S}_{y y}^{-1} \mathbf{S}_{y x}\) (these two matrices are of the form AB and BA; see Section 2.11.5). The number of nonzero eigenvalues is \(s=\min (p, q)\), since \(s\) is the rank of both \(\mathbf{S}_{y y}^{-1} \mathbf{S}_{y x} \mathbf{S}_{x x}^{-1} \mathbf{S}_{x y}\) and \(\mathbf{S}_{x x}^{-1} \mathbf{S}_{x y} \mathbf{S}_{y y}^{-1} \mathbf{S}_{y x}\). The eigenvalues are designated \(r_{i}^{2}\) because they are the squared canonical correlations between \(\mathbf{y}\) and \(\mathbf{x}\) (see Chapter 11). In the special case \(p=1\), (7.31) becomes
\[
\Lambda=1-r_{1}^{2}=1-R^{2}
\]
where \(R^{2}\) is the square of the multiple correlation between \(y\) and \(\left(x_{1}, x_{2}, \ldots, x_{q}\right)\).
The other test statistics, \(U^{(s)}, V^{(s)}\), and Roy's \(\theta\), can also be defined in terms of the \(r_{i}^{2}\) 's (see Section 11.4.1).

\section*{E EXAMPLE 7.4.1}

Consider the diabetes data in Table 3.5. There is a natural partitioning in the variables, with \(y_{1}\) and \(y_{2}\) of minor interest and \(x_{1}, x_{2}\), and \(x_{3}\) of major interest. We test independence of the \(y\) 's and the \(x\) 's, that is, \(H_{0}: \boldsymbol{\Sigma}_{y x}=\mathbf{O}\). From Example 3.9.1, the partitioned covariance matrix is
\[
\mathbf{S}=\left(\begin{array}{ll}
\mathbf{S}_{y y} & \mathbf{S}_{y x} \\
\mathbf{S}_{x y} & \mathbf{S}_{x x}
\end{array}\right)=\left(\begin{array}{rr|rrr}
.0162 & .2160 & .7872 & -.2138 & 2.189 \\
.2160 & 70.56 & 26.23 & -23.96 & -20.84 \\
\hline .7872 & 26.23 & 1106 & 396.7 & 108.4 \\
-.2138 & -23.96 & 396.7 & 2382 & 1143 \\
2.189 & -20.84 & 108.4 & 1143 & 2136
\end{array}\right)
\]

To make the test, we compute
\[
\Lambda=\frac{|\mathbf{S}|}{\left|\mathbf{S}_{y y}\right|\left|\mathbf{S}_{x x}\right|}=\frac{3.108 \times 10^{9}}{(1.095)\left(3.920 \times 10^{9}\right)}=.724<\Lambda_{.05,2,3,40}=.730
\]

Thus we reject the hypothesis of independence. Note the use of 40 in \(\Lambda_{.05,2,3,40}\) in place of \(n-1-q=46-1-3=42\). This is a conservative approach that allows the use of a table value without interpolation.

\subsection*{7.4.2 Independence of Several Subvectors}

Let there be \(k\) sets of variates so that \(\mathbf{y}\) and \(\boldsymbol{\Sigma}\) are partitioned as
\[
\mathbf{y}=\left(\begin{array}{c}
\mathbf{y}_{1} \\
\mathbf{y}_{2} \\
\vdots \\
\mathbf{y}_{k}
\end{array}\right) \quad \text { and } \quad \boldsymbol{\Sigma}=\left(\begin{array}{cccc}
\boldsymbol{\Sigma}_{11} & \boldsymbol{\Sigma}_{12} & \cdots & \boldsymbol{\Sigma}_{1 k} \\
\boldsymbol{\Sigma}_{21} & \boldsymbol{\Sigma}_{22} & \cdots & \boldsymbol{\Sigma}_{2 k} \\
\vdots & \vdots & & \vdots \\
\boldsymbol{\Sigma}_{k 1} & \boldsymbol{\Sigma}_{k 2} & \cdots & \boldsymbol{\Sigma}_{k k}
\end{array}\right)
\]
with \(p_{i}\) variables in \(\mathbf{y}_{i}\), where \(p_{1}+p_{2}+\cdots+p_{k}=p\). Note that \(\mathbf{y}_{1}, \mathbf{y}_{2}, \ldots, \mathbf{y}_{k}\) represents a partitioning of \(\mathbf{y}\), not a random sample of independent vectors. The
hypothesis that the subvectors \(\mathbf{y}_{1}, \mathbf{y}_{2}, \ldots, \mathbf{y}_{k}\) are mutually independent can be expressed as \(H_{0}: \boldsymbol{\Sigma}_{i j}=\mathbf{O}\) for all \(i \neq j\), or
\[
H_{0}: \boldsymbol{\Sigma}=\left(\begin{array}{cccc}
\boldsymbol{\Sigma}_{11} & \mathbf{O} & \cdots & \mathbf{O}  \tag{7.32}\\
\mathbf{O} & \boldsymbol{\Sigma}_{22} & \cdots & \mathbf{O} \\
\vdots & \vdots & & \vdots \\
\mathbf{O} & \mathbf{O} & \cdots & \boldsymbol{\Sigma}_{k k}
\end{array}\right)
\]

The likelihood ratio statistic is
\[
\begin{align*}
u & =\frac{|\mathbf{S}|}{\left|\mathbf{S}_{11}\right|\left|\mathbf{S}_{22}\right| \cdots\left|\mathbf{S}_{k k}\right|}  \tag{7.33}\\
& =\frac{|\mathbf{R}|}{\left|\mathbf{R}_{11}\right|\left|\mathbf{R}_{22}\right| \cdots\left|\mathbf{R}_{k k}\right|}, \tag{7.34}
\end{align*}
\]
where \(\mathbf{S}\) and \(\mathbf{R}\) are obtained from a random sample of \(n\) observations and are partitioned as \(\boldsymbol{\Sigma}\) above, conforming to \(\mathbf{y}_{1}, \mathbf{y}_{2}, \ldots, \mathbf{y}_{k}\). Note that the denominator of (7.33) is the determinant of \(\mathbf{S}\) restricted by \(H_{0}\), that is, with \(\mathbf{S}_{i j}=\mathbf{O}\) for all \(i \neq j\) [see (2.92)]. The statistic \(u\) does not have Wilks' \(\Lambda\)-distribution as it does in (7.30) when \(k=2\), but a good \(\chi^{2}\)-approximation to its distribution is given by
\[
\begin{equation*}
u^{\prime}=-\nu c \ln u \tag{7.35}
\end{equation*}
\]
where
\[
\begin{gather*}
c=1-\frac{1}{12 f \nu}\left(2 a_{3}+3 a_{2}\right)  \tag{7.36}\\
f=\frac{1}{2} a_{2}, \quad a_{2}=p^{2}-\sum_{i=1}^{k} p_{i}^{2}, \quad a_{3}=p^{3}-\sum_{i=1}^{k} p_{i}^{3}
\end{gather*}
\]
and \(\nu\) is the degrees of freedom of \(\mathbf{S}\) or \(\mathbf{R}\) (see comments at the beginning of Section 7.2). We reject the independence hypothesis if \(u^{\prime}>\chi_{\alpha, f}^{2}\).

The degrees of freedom, \(f=\frac{1}{2} a_{2}\), arises from the following consideration. The number of parameters in \(\boldsymbol{\Sigma}\) unrestricted by the hypothesis is \(\frac{1}{2} p(p+1)\). Under the hypothesis (7.32), the number of parameters in each \(\boldsymbol{\Sigma}_{i i}\) is \(\frac{1}{2} p_{i}\left(p_{i}+1\right)\), for a total of \(\frac{1}{2} \sum_{i=1}^{k} p_{i}\left(p_{i}+1\right)\). The difference is
\[
\begin{aligned}
f & =\frac{1}{2} p(p+1)-\frac{1}{2} \sum_{i=1}^{k} p_{i}\left(p_{i}+1\right)=\frac{1}{2}\left(p^{2}+p-\sum_{i} p_{i}^{2}-\sum_{i} p_{i}\right) \\
& =\frac{1}{2}\left(p^{2}+p-\sum_{i} p_{i}^{2}-p\right)=\frac{1}{2}\left(p^{2}-\sum_{i} p_{i}^{2}\right)=\frac{a_{2}}{2}
\end{aligned}
\]

\section*{EXAMPLE 7.4.2}

For 30 brands of Japanese Seishu wine, Siotani et al. (1963) studied the relationship between
\[
\begin{aligned}
& y_{1}=\text { taste } \\
& y_{2}=\text { odor }
\end{aligned}
\]
and
\[
\begin{array}{ll}
x_{1}=\mathrm{pH} & x_{5}=\text { direct reducing sugar } \\
x_{2}=\text { acidity } 1 & x_{6}=\text { total sugar } \\
x_{3}=\text { acidity } 2 & x_{7}=\text { alcohol } \\
x_{4}=\text { sake meter } & x_{8}=\text { formyl-nitrogen } .
\end{array}
\]

The data are in Table 7.1.
We test independence of the following four subsets of variables:
\[
\left(y_{1}, y_{2}\right),\left(x_{1}, x_{2}, x_{3}\right),\left(x_{4}, x_{5}, x_{6}\right),\left(x_{7}, x_{8}\right) .
\]

The sample covariance matrix is
\[
\begin{aligned}
\mathbf{S} & =\left(\begin{array}{rrrr}
\mathbf{S}_{11} & \mathbf{S}_{12} & \mathbf{S}_{13} & \mathbf{S}_{14} \\
\mathbf{S}_{21} & \mathbf{S}_{22} & \mathbf{S}_{23} & \mathbf{S}_{24} \\
\mathbf{S}_{31} & \mathbf{S}_{32} & \mathbf{S}_{33} & \mathbf{S}_{34} \\
\mathbf{S}_{41} & \mathbf{S}_{42} & \mathbf{S}_{43} & \mathbf{S}_{44}
\end{array}\right) \\
& =\left(\begin{array}{rrrr|rrrrr}
.16 & .10 & .01 & .006 & .02 & -.04 & .02 & .01 & -.02 \\
\hline .0 & 1.44 \\
.10 & .19 & -.01 & .009 & .02 & -.16 & .03 & .05 & .04 \\
\hline .01 & -.01 & .03 & .004 & .03 & -.11 & -.03 & -.03 & -.01 \\
\hline .006 & .009 & .004 & .024 & .020 & -.012 & -.009 & .0004 & .038 \\
.02 & .02 & .03 & .020 & .07 & -.18 & -.03 & -.03 & .05 \\
\hline-.04 & -.16 & -.11 & -.012 & -.18 & 5.02 & -.35 & -.67 & -.12 \\
\hline .02 & .03 & -.03 & -.009 & -.03 & -.35 & .13 & .15 & .05 \\
\hline .01 & .05 & -.03 & .0004 & -.03 & -.67 & .15 & .26 & .13 \\
\hline-.02 & .04 & -.01 & .038 & .05 & -.12 & .05 & .13 & .35 \\
1.44 & 1.03 & 4.45 & 2.23 & 9.03 & -23.11 & -4.26 & -3.47 & 6.73 \\
\hline 154
\end{array}\right)
\end{aligned}
\]
where \(\mathbf{S}_{11}\) is \(2 \times 2, \mathbf{S}_{22}\) is \(3 \times 3, \mathbf{S}_{33}\) is \(3 \times 3\), and \(\mathbf{S}_{44}\) is \(2 \times 2\). We first obtain
\[
\begin{aligned}
u & =\frac{|\mathbf{S}|}{\left|\mathbf{S}_{11}\right|\left|\mathbf{S}_{22}\right|\left|\mathbf{S}_{33}\right|\left|\mathbf{S}_{44}\right|} \\
& =\frac{2.925 \times 10^{-7}}{(.0210)(.0000158)(.0361)(496.04)}=.01627 .
\end{aligned}
\]

Table 7.1 Seishu Measurements
\begin{tabular}{rrcccccccr}
\hline \multicolumn{1}{c}{\(y_{1}\)} & \multicolumn{1}{c}{\(y_{2}\)} & \(x_{1}\) & \(x_{2}\) & \multicolumn{1}{c}{\(x_{3}\)} & \multicolumn{1}{c}{\(x_{4}\)} & \(x_{5}\) & \(x_{6}\) & \(x_{7}\) & \multicolumn{1}{c}{\(x_{8}\)} \\

.4 & .5 & 4.16 & 1.61 & .91 & -2.1 & 3.93 & 4.35 & 15.70 & 118.0 \\
-.6 & -.3 & 3.85 & 1.32 & .30 & .7 & 3.61 & 4.29 & 15.71 & 48.0 \\
\hline
\end{tabular}

For the \(\chi^{2}\)-approximation, we calculate
\[
\begin{aligned}
a_{2} & =p^{2}-\sum_{i=1}^{4} p_{i}^{2}=10^{2}-\left(2^{2}+3^{2}+3^{2}+2^{2}\right)=74, \\
a_{3} & =p^{3}-\sum_{i=1}^{4} p_{i}^{3}=930, \quad f=\frac{1}{2} a_{2}=37, \\
c & =1-\frac{1}{12 f \nu}\left(2 a_{3}+3 a_{2}\right)=1-\frac{2(930)+3(74)}{12(37)(29)}=.838 .
\end{aligned}
\]

Then,
\[
u^{\prime}=-\nu c \ln u=-(29)(.838) \ln (.01627)=100.122
\]
which exceeds \(\chi_{.001,37}^{2}=69.35\), and we reject the hypothesis of independence of the four subsets.

\subsection*{7.4.3 Test for Independence of All Variables}

If all \(p_{i}=1\) in the hypothesis (7.32) in Section 7.4.2, we have the special case in which all the variables are mutually independent, \(H_{0}: \sigma_{j k}=0\) for \(j \neq k\), or
\[
H_{0}: \boldsymbol{\Sigma}=\left(\begin{array}{cccc}
\sigma_{11} & 0 & \cdots & 0 \\
0 & \sigma_{22} & \cdots & 0 \\
\vdots & \vdots & & \vdots \\
0 & 0 & \cdots & \sigma_{p p}
\end{array}\right)
\]

There is no restriction on the \(\sigma_{j j}\) 's. With \(\sigma_{j k}=0\) for all \(j \neq k\), the corresponding \(\rho_{j k}\) 's are also 0 , and an equivalent form of the hypothesis is \(H_{0}: \mathbf{P}_{\rho}=\mathbf{I}\), where \(\mathbf{P}_{\rho}\) is the population correlation matrix defined in (3.37).

Since all \(p_{i}=1\), the statistics (7.33) and (7.34) reduce to
\[
\begin{equation*}
u=\frac{|\mathbf{S}|}{s_{11} s_{22} \cdots s_{p p}}=|\mathbf{R}| \tag{7.37}
\end{equation*}
\]
and (7.35) becomes
\[
\begin{equation*}
u^{\prime}=-\left[\nu-\frac{1}{6}(2 p+5)\right] \ln u \tag{7.38}
\end{equation*}
\]
which has an approximate \(\chi_{f}^{2}\)-distribution, where \(\nu\) is the degrees of freedom of \(\mathbf{S}\) or \(\mathbf{R}\) (see comments at the beginning of Section 7.2) and \(f=\frac{1}{2} p(p-1)\) is the degrees of freedom of \(\chi^{2}\). We reject \(H_{0}\) if \(u^{\prime}>\chi_{\alpha, f}^{2}\). Exact percentage points of \(u^{\prime}\) for selected values of \(n\) and \(p\) are given in Table A. 15 (Mathai and Katiyar 1979). Percentage points for the limiting \(\chi^{2}\)-distribution are also given for comparison.

Note that \(|\mathbf{R}|\) in (7.37) varies between 0 and 1. If the variables were uncorrelated (in the sample), we would have \(\mathbf{R}=\mathbf{I}\) and \(|\mathbf{R}|=1\). On the other hand, if two or more variables were linearly related, \(\mathbf{R}\) would not be full rank and we would have \(|\mathbf{R}|=0\). If the variables were highly correlated, \(|\mathbf{R}|\) would be close to 0 ; if the correlations were all small, \(|\mathbf{R}|\) would be close to 1 . This can be illustrated for \(p=2\) :
\[
|\mathbf{R}|=\left|\begin{array}{ll}
1 & r \\
r & 1
\end{array}\right|=1-r^{2}
\]

\section*{EXAMPLE 7.4.3}

To test the hypothesis \(H_{0}: \sigma_{j k}=0, j \neq k\), for the probe word data from Table 3.6, we calculate
\[
\mathbf{R}=\left(\begin{array}{rrrrr}
1.000 & .614 & .757 & .575 & .413 \\
.614 & 1.000 & .547 & .750 & .548 \\
.757 & .547 & 1.000 & .605 & .692 \\
.575 & .750 & .605 & 1.000 & .524 \\
.413 & .548 & .692 & .524 & 1.000
\end{array}\right)
\]

Then by (7.37) and (7.38),
\[
\begin{aligned}
u & =|\mathbf{R}|=.0409, \\
u^{\prime} & =-\left[n-1-\frac{1}{6}(2 p+5)\right] \ln u=23.97 .
\end{aligned}
\]

The exact .01 critical value for \(u^{\prime}\) from Table A. 15 is 23.75 , and we therefore reject \(H_{0}\). The approximate \(\chi^{2}\) critical value for \(u^{\prime}\) is \(\chi_{.01,10}^{2}=23.21\), with which we also reject \(H_{0}\).

\section*{PROBLEMS}
7.1 Show that if \(\mathbf{S}=\boldsymbol{\Sigma}_{0}\) in (7.1), then \(u=0\).
7.2 Verify (7.3); that is, show that \(\ln \left|\boldsymbol{\Sigma}_{0}\right|-\ln |\mathbf{S}|=-\ln \left|\mathbf{S} \boldsymbol{\Sigma}_{0}^{-1}\right|\).
7.3 Verify (7.4); that is, show that \(-\ln \left(\prod_{i=1}^{p} \lambda_{i}\right)+\sum_{i=1}^{p} \lambda_{i}=\sum_{i=1}^{p}\left(\lambda_{i}-\ln \lambda_{i}\right)\).
7.4 Show that the likelihood ratio for \(H_{0}: \boldsymbol{\Sigma}=\sigma^{2} \mathbf{I}\) is given by (7.5), \(\mathbf{L R}=\) \(\left[|\mathbf{S}| /(\operatorname{tr} \mathbf{S} / p)^{p}\right]^{n / 2}\).
7.5 Show that \(u=1\) and \(u^{\prime}=0\) if all the \(\lambda_{i}\) 's are equal, as noted in Section 7.2.2, where \(u\) is given by (7.8) and \(u^{\prime}\) by (7.9).
7.6 Show that the covariance matrix in (7.10) can be written in the form \(\sigma^{2}[(1-\) \(\rho) \mathbf{I}+\rho \mathbf{J}]\), as given in (7.11).
7.7 Obtain (7.15) from (7.14) as follows:
(a) Show that the \(p \times p\) matrix \(\mathbf{J}\) has a single nonzero eigenvalue equal to \(p\) and corresponding eigenvector proportional to \(\mathbf{j}\).
(b) Show that \(\mathbf{S}_{0}=s^{2}[(1-r) \mathbf{I}+r \mathbf{J}]\) in (7.13) can be written in the form \(\mathbf{S}_{0}=s^{2}(1-r)\left(\mathbf{I}+\frac{r}{1-r} \mathbf{J}\right)\).
(c) Use Section 2.11.2 and (2.108) to obtain (7.15).
7.8 Show that \(M\) in (7.19) can be expressed in the form given in (7.21).
7.9 (a) Calculate \(M\) as given in (7.21) for
\[
\mathbf{S}_{1}=\left(\begin{array}{cc}
2 & 1 \\
1 & 4
\end{array}\right), \quad \mathbf{S}_{2}=\left(\begin{array}{cc}
4 & 3 \\
3 & 6
\end{array}\right)
\]

Assume \(\nu_{1}=\nu_{2}=5\).
(b) Calculate \(M\) for
\[
\mathbf{S}_{1}=\left(\begin{array}{ll}
2 & 1 \\
1 & 4
\end{array}\right), \quad \mathbf{S}_{2}=\left(\begin{array}{cc}
10 & 15 \\
15 & 30
\end{array}\right) .
\]

Assume \(\nu_{1}=\nu_{2}=5\).
In (b), \(\mathbf{S}_{1}\) and \(\mathbf{S}_{2}\) differ more than in (a) and \(M\) is accordingly much smaller. This illustrates the comments following (7.21).
7.10 Obtain (7.31), \(\Lambda=\prod_{i=1}^{s}\left(1-r_{i}^{2}\right)\), by using (2.94) to write \(|\mathrm{S}|\) in the form \(|\mathbf{S}|=\left|\mathbf{S}_{x x}\right|\left|\mathbf{S}_{y y}-\mathbf{S}_{y x} \mathbf{S}_{x x}^{-1} \mathbf{S}_{x y}\right|\).
7.11 Show that the forms of \(u\) in (7.33) and (7.34) reduce to (7.37) when all \(p_{i}=1\).
7.12 Show that when all \(p_{i}=1, c\) in (7.36) reduces to \(1-(2 p+5) / 6 \nu\), so that (7.35) becomes (7.38).
7.13 Give a justification for the degrees of freedom \(f=\frac{1}{2} p(p-1)\) for the approximate \(\chi^{2}\) test statistic \(u^{\prime}\) in (7.38).
7.14 In Example 5.2.2, we assumed that for the height and weight data of Table 3.1, the population covariance matrix is
\[
\boldsymbol{\Sigma}=\left(\begin{array}{rr}
20 & 100 \\
100 & 1000
\end{array}\right)
\]

Test this as a hypothesis using (7.2).
7.15 Test \(H_{0}: \boldsymbol{\Sigma}=\sigma^{2} \mathbf{I}\) and \(H_{0}: \mathbf{C} \boldsymbol{\Sigma} \mathbf{C}^{\prime}=\sigma^{2} \mathbf{I}\) for the calculator speed data of Table 6.12.
7.16 Test \(H_{0}: \boldsymbol{\Sigma}=\sigma^{2} \mathbf{I}\) and \(H_{0}: \mathbf{C} \boldsymbol{\Sigma} \mathbf{C}^{\prime}=\sigma^{2} \mathbf{I}\) for the ramus bone data of Table 3.7.
7.17 Test \(H_{0}: \boldsymbol{\Sigma}=\sigma^{2} \mathbf{I}\) and \(H_{0}: \mathbf{C} \boldsymbol{\Sigma} \mathbf{C}^{\prime}=\sigma^{2} \mathbf{I}\) for the cork data of Table 6.21.
7.18 Test \(H_{0}: \mathbf{\Sigma}=\sigma^{2}[(1-\rho) \mathbf{I}+\rho \mathbf{J}]\) for the probe word data in Table 3.6. Use both \(\chi^{2}\) - and \(F\)-approximations.
7.19 Test \(H_{0}: \mathbf{\Sigma}=\sigma^{2}[(1-\rho) \mathbf{I}+\rho \mathbf{J}]\) for the calculator speed data in Table 6.12. Use both \(\chi^{2}\) - and \(F\)-approximations.
7.20 Test \(H_{0}: \mathbf{\Sigma}=\sigma^{2}[(1-\rho) \mathbf{I}+\rho \mathbf{J}]\) for the ramus bone data in Table 3.7. Use both \(\chi^{2}\) - and \(F\)-approximations.
7.21 Test \(H_{0}: \boldsymbol{\Sigma}_{1}=\boldsymbol{\Sigma}_{2}\) for the beetles data of Table 5.5. Use an exact critical value from Table A. 14 as well as \(\chi^{2}\) - and \(F\)-approximations.
7.22 Test \(H_{0}: \boldsymbol{\Sigma}_{1}=\boldsymbol{\Sigma}_{2}\) for the engineer data of Table 5.6. Use an exact critical value from Table A. 14 as well as \(\chi^{2}\) - and \(F\)-approximations.
7.23 Test \(H_{0}: \boldsymbol{\Sigma}_{1}=\boldsymbol{\Sigma}_{2}\) for the dystrophy data of Table 5.7. Use an exact critical value from Table A. 14 as well as \(\chi^{2}\) - and \(F\)-approximations.
7.24 Test \(\dot{H_{0}}: \boldsymbol{\Sigma}_{1}=\boldsymbol{\Sigma}_{2}\) for the cyclical data of Table 5.8. Use an exact critical value from Table A. 14 as well as \(\chi^{2}\) - and \(F\)-approximations.
7.25 Test \(H_{0}: \boldsymbol{\Sigma}_{1}=\boldsymbol{\Sigma}_{2}=\boldsymbol{\Sigma}_{3}\) for the fish data of Table 6.17. Use an exact critical value from Table A. 14 as well as \(\chi^{2}\) - and \(F\)-approximations.
7.26 Test \(H_{0}: \boldsymbol{\Sigma}_{1}=\boldsymbol{\Sigma}_{2}=\cdots=\boldsymbol{\Sigma}_{6}\) for the rootstock data in Table 6.2. Use an exact critical value from Table A. 14 as well as \(\chi^{2}\) - and \(F\)-approximations.
7.27 Test \(H_{0}: \boldsymbol{\Sigma}_{11}=\boldsymbol{\Sigma}_{12}=\cdots=\boldsymbol{\Sigma}_{43}\) for the snap bean data in Table 6.18. Use both \(\chi^{2}\) - and \(F\)-approximations.
7.28 Test independence of ( \(y_{1}, y_{2}\) ) and ( \(x_{1}, x_{2}\) ) for the sons data in Table 3.8.
7.29 Test independence of \(\left(y_{1}, y_{2}, y_{3}\right)\) and \(\left(x_{1}, x_{2}, x_{3}\right)\) for the glucose data in Table 3.9.
7.30 Test independence of ( \(y_{1}, y_{2}\) ) and ( \(x_{1}, x_{2}, \ldots, x_{8}\) ) for the Seishu data of Table 7.1.
7.31 The data in Table 7.2 relate temperature, humidity, and evaporation (courtesy of R. J. Freund). The variables are
\[
\begin{aligned}
y_{1}= & \text { maximum daily air temperature } \\
y_{2}= & \text { minimum daily air temperature } \\
y_{3}= & \text { integrated area under daily air temperature curve, that is, } \\
& \quad \text { a measure of average air temperature } \\
y_{4}= & \text { maximum daily soil temperature } \\
y_{5}= & \text { minimum daily soil temperature } \\
y_{6}= & \text { integrated area under soil temperature curve } \\
y_{7}= & \text { maximum daily relative humidity } \\
y_{8}= & \text { minimum daily relative humidity } \\
y_{9}= & \text { integrated area under daily humidity curve } \\
y_{10}= & \text { total wind, measured in miles per day } \\
y_{11}= & \text { evaporation }
\end{aligned}
\]

Test independence of the following five groups of variables: \(\left(y_{1}, y_{2}, y_{3}\right),\left(y_{4}\right.\), \(\left.y_{5}, y_{6}\right),\left(y_{7}, y_{8}, y_{9}\right), y_{10}\), and \(y_{11}\).
7.32 Test the independence of all the variables for the calcium data of Table 3.4.
7.33 Test the independence of all the variables for the calculator speed data of Table 6.12.

Table 7.2 Temperature, Humidity, and Evaporation
\begin{tabular}{|c|c|c|c|c|c|c|c|c|c|c|}
\hline \(y_{1}\) & \(y_{2}\) & \(y_{3}\) & \(y_{4}\) & \(y_{5}\) & \(y_{6}\) & \(y_{7}\) & \(y_{8}\) & \(y_{9}\) & \(y_{10}\) & \(y_{11}\) \\
\hline 84 & 65 & 147 & 85 & 59 & 151 & 95 & 40 & 398 & 273 & 30 \\

\section*{DISCRIMINANT ANALYSIS: DESCRIPTION OF GROUP SEPARATION}

\subsection*{8.1 INTRODUCTION}

We use the term group to represent either a population or a sample from the population. There are two major objectives in separation of groups:
1. Description of group separation, in which linear functions of the variables (discriminant functions) are used to describe or elucidate the differences between two or more groups. The goals of descriptive discriminant analysis include identifying the relative contribution of the \(p\) variables to separation of the groups and finding the optimal plane on which the points can be projected to best illustrate the configuration of the groups.
2. Prediction or allocation of observations to groups, in which linear or quadratic functions of the variables (classification functions) are employed to assign an individual sampling unit to one of the groups. The measured values in the observation vector for an individual or object are evaluated by the classification functions to find the group to which the individual most likely belongs.

For consistency we will use the term discriminant analysis only in connection with objective 1 . We will refer to all aspects of objective 2 as classification analysis, which is the subject of Chapter 9. Unfortunately, there is no general agreement with regard to usage of the terms "discriminant analysis" and "discriminant functions." Many writers, perhaps the majority, use the term "discriminant analysis" in connection with the second objective, prediction or allocation. The linear functions contributing to the first objective, description of group separation, are often referred to as canonical variates or discriminant coordinates. To avoid confusion, we prefer to reserve the term canonical for canonical correlation analysis in Chapter 11.

Discriminant functions are linear combinations of variables that best separate groups. They were introduced in Section 5.5 for two groups and in Sections 6.1.4 and 6.4 for several groups. In those sections, interest was centered on follow-up to Hotelling's \(T^{2}\)-tests and MANOVA tests. In this chapter, we further develop these useful multivariate tools.

\subsection*{8.2 THE DISCRIMINANT FUNCTION FOR TWO GROUPS}

We assume that the two populations to be compared have the same covariance matrix \(\boldsymbol{\Sigma}\) but distinct mean vectors \(\boldsymbol{\mu}_{1}\) and \(\boldsymbol{\mu}_{2}\). We work with samples \(\mathbf{y}_{11}, \mathbf{y}_{12}, \ldots, \mathbf{y}_{1 n_{1}}\) and \(\mathbf{y}_{21}, \mathbf{y}_{22}, \ldots, \mathbf{y}_{2 n_{2}}\) from the two populations. As usual, each vector \(\mathbf{y}_{i j}\) consists of measurements on \(p\) variables. The discriminant function is the linear combination of these \(p\) variables that maximizes the distance between the two (transformed) group mean vectors. A linear combination \(z=\mathbf{a}^{\prime} \mathbf{y}\) transforms each observation vector to a scalar:
\[
\begin{array}{ll}
z_{1 i}=\mathbf{a}^{\prime} \mathbf{y}_{1 i}=a_{1} y_{1 i 1}+a_{2} y_{1 i 2}+\ldots+a_{p} y_{1 i p}, & i=1,2, \ldots, n_{1} \\
z_{2 i}=\mathbf{a}^{\prime} \mathbf{y}_{2 i}=a_{1} y_{2 i 1}+a_{2} y_{2 i 2}+\ldots+a_{p} y_{2 i p}, & i=1,2, \ldots, n_{2}
\end{array}
\]

Hence the \(n_{1}+n_{2}\) observation vectors in the two samples,
\begin{tabular}{cc}
\(\mathbf{y}_{11}\) & \(\mathbf{y}_{21}\) \\
\(\mathbf{y}_{12}\) & \(\mathbf{y}_{22}\) \\
\(\vdots\) & \(\vdots\) \\
\(\mathbf{y}_{1 n_{1}}\) & \(\mathbf{y}_{2 n_{2}}\),
\end{tabular}
are transformed to scalars,
\begin{tabular}{cc}
\(z_{11}\) & \(z_{21}\) \\
\(z_{12}\) & \(z_{22}\) \\
\(\vdots\) & \(\vdots\) \\
\(z_{1 n_{1}}\) & \(z_{2 n_{2}}\).
\end{tabular}

We find the means \(\bar{z}_{1}=\sum_{i=1}^{n_{1}} z_{1 i} / n_{1}=\mathbf{a}^{\prime} \overline{\mathbf{y}}_{1}\) and \(\bar{z}_{2}=\mathbf{a}^{\prime} \overline{\mathbf{y}}_{2}\) by (3.54), where \(\overline{\mathbf{y}}_{1}=\sum_{i=1}^{n_{1}} \mathbf{y}_{1 i} / n_{1}\) and \(\overline{\mathbf{y}}_{2}=\sum_{i=1}^{n_{2}} \mathbf{y}_{2 i} / n_{2}\). We then wish to find the vector a that maximizes the standardized difference \(\left(\bar{z}_{1}-\bar{z}_{2}\right) / s_{z}\). Since \(\left(\bar{z}_{1}-\bar{z}_{2}\right) / s_{z}\) can be
negative, we use the squared distance \(\left(\bar{z}_{1}-\bar{z}_{2}\right)^{2} / s_{z}^{2}\), which, by (3.54) and (3.55), can be expressed as
\[
\begin{equation*}
\frac{\left(\bar{z}_{1}-\bar{z}_{2}\right)^{2}}{s_{z}^{2}}=\frac{\left[\mathbf{a}^{\prime}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)\right]^{2}}{\mathbf{a}^{\prime} \mathbf{S}_{\mathrm{pl}} \mathbf{a}} \tag{8.1}
\end{equation*}
\]

The maximum of (8.1) occurs when
\[
\begin{equation*}
\mathbf{a}=\mathbf{S}_{\mathrm{pl}}^{-1}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right), \tag{8.2}
\end{equation*}
\]
or when \(\mathbf{a}\) is any multiple of \(\mathbf{S}_{\mathrm{pl}}^{-1}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)\). Thus the maximizing vector \(\mathbf{a}\) is not unique. However, its "direction" is unique; that is, the relative values or ratios of \(a_{1}, a_{2}, \ldots, a_{p}\) are unique, and \(z=\mathbf{a}^{\prime} \mathbf{y}\) projects points \(\mathbf{y}\) onto the line on which \(\left(\bar{z}_{1}-\bar{z}_{2}\right)^{2} / s_{z}^{2}\) is maximized. Note that in order for \(\mathbf{S}_{\mathrm{pl}}^{-1}\) to exist, we must have \(n_{1}+n_{2}-2>p\).

The optimum direction given by \(\mathbf{a}=\mathbf{S}_{\mathrm{pl}}^{-1}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)\) is effectively parallel to the line joining \(\overline{\mathbf{y}}_{1}\) and \(\overline{\mathbf{y}}_{2}\), because the squared distance \(\left(\bar{z}_{1}-\bar{z}_{2}\right)^{2} / s_{z}^{2}\) is equivalent to the standardized distance between \(\overline{\mathbf{y}}_{1}\) and \(\overline{\mathbf{y}}_{2}\). This can be seen by substituting (8.2) into (8.1) to obtain
\[
\begin{equation*}
\frac{\left(\bar{z}_{1}-\bar{z}_{2}\right)^{2}}{s_{z}^{2}}=\left(\overline{\mathbf{y}}_{\mathbf{1}}-\overline{\mathbf{y}}_{2}\right)^{\prime} \mathbf{S}_{\mathrm{pl}}^{-1}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right) \tag{8.3}
\end{equation*}
\]
for \(z=\mathbf{a}^{\prime} \mathbf{y}\) with \(\mathbf{a}=\mathbf{S}_{\mathrm{pl}}^{-1}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)\). Since \(\mathbf{a}^{\prime}=\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)^{\prime} \mathbf{S}_{\mathrm{pl}}^{-1}\), (8.3) can be written as \(\left(\bar{z}_{1}-\bar{z}_{2}\right)^{2} / s_{z}^{2}=\mathbf{a}^{\prime}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)\), and any direction other than that represented by \(\mathbf{a}=\mathbf{S}_{\mathrm{pl}}^{-1}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)\) would yield a smaller difference between \(\mathbf{a}^{\prime} \overline{\mathbf{y}}_{1}\) and \(\mathbf{a}^{\prime} \overline{\mathbf{y}}_{2}\) (see Section 5.5).

Figure 8.1 Two-group discriminant analysis.

Figure 8.2 Separation achieved by the discriminant function.

Figure 8.1 illustrates the separation of two bivariate normal ( \(p=2\) ) groups along the single dimension represented by the discriminant function \(z=\mathbf{a}^{\prime} \mathbf{y}\), where \(\mathbf{a}\) is given by (8.2). In this illustration the population covariance matrices are equal. The linear combinations \(z_{1 i}=\mathbf{a}^{\prime} \mathbf{y}_{1 i}=a_{1} y_{1 i 1}+a_{2} y_{1 i 2}\) and \(z_{2 i}=\mathbf{a}^{\prime} \mathbf{y}_{2 i}=a_{1} y_{2 i 1}+\) \(a_{2} y_{2 i 2}\) project the points \(\mathbf{y}_{1 i}\) and \(\mathbf{y}_{2 i}\) onto the line of optimum separation of the two groups. Since the two variables \(y_{1}\) and \(y_{2}\) are bivariate normal, a linear combination \(z=a_{1} y_{1}+a_{2} y_{2}=\mathbf{a}^{\prime} \mathbf{y}\) is univariate normal (see property 1 a in Section 4.2). We have therefore indicated this by two univariate normal densities along the line representing \(z\).

The point where the line joining the points of intersection of the two ellipses intersects the discriminant function line \(z\) is the point of maximum separation (minimum overlap) of points projected onto the line. If the two populations are multivariate normal with common covariance matrix \(\boldsymbol{\Sigma}\), as illustrated in Figure 8.1, it can be shown that all possible group separation is expressed in a single new dimension.

In Figure 8.2, we illustrate the optimum separation achieved by the discriminant function. Projection in another direction denoted by \(z^{\prime}\) gives a smaller standardized distance between the transformed means \(\bar{z}_{1}^{\prime}\) and \(\bar{z}_{2}^{\prime}\) and also a larger overlap between the projected points.

\section*{EXAMPLE 8.2}

Samples of steel produced at two different rolling temperatures are compared in Table 8.1 (Kramer and Jensen 1969a). The variables are \(y_{1}=\) yield point

Table 8.1 Yield Point and Ultimate Strength of Steel Produced at Two Rolling Temperatures
\begin{tabular}{lllll}
\hline \multicolumn{2}{c}{ Temperature 1 } & & \multicolumn{2}{c}{ Temperature 2 } \\
& \(y_{1}\) & \(y_{2}\) & & \(y_{1}\)
\end{tabular}\(y_{2}\).
and \(y_{2}=\) ultimate strength. From the data, we calculate
\[
\overline{\mathbf{y}}_{1}=\binom{36.4}{62.6}, \quad \overline{\mathbf{y}}_{2}=\binom{39.0}{60.4}, \quad \mathbf{S}_{\mathrm{pl}}=\left(\begin{array}{cc}
7.92 & 5.68 \\
5.68 & 6.29
\end{array}\right) .
\]

A plot of the data appears in Figure 8.3. We see that if the points were projected on either the \(y_{1}\) or the \(y_{2}\) axis, there would be considerable overlap. In fact, when the two groups are compared by means of a \(t\)-statistic for each

Figure 8.3 Ultimate strength and yield point for steel rolled at two temperatures.
\begin{tabular}{lc} 
Table 8.2 Discriminant & Function \(z=\) \\
\(-1.633 y_{1}+1.820 y_{2}\) Evaluated for Data in Ta- \\
ble 8.1 & \\
\hline Temperature 1 & Temperature 2 \\
\hline 55.29 & 46.56 \\
52.20 & 48.57 \\
59.30 & 45.30 \\
52.58 & 47.30 \\
52.95 & 47.68 \\
& 48.05 \\
& 40.40 \\
\hline
\end{tabular}
variable separately, both \(t\) 's are nonsignificant:
\[
\begin{aligned}
& t_{1}=\frac{\bar{y}_{11}-\bar{y}_{21}}{\sqrt{s_{11}\left(1 / n_{1}+1 / n_{2}\right)}}=-1.58, \\
& t_{2}=\frac{\bar{y}_{12}-\bar{y}_{22}}{\sqrt{s_{22}\left(1 / n_{1}+1 / n_{2}\right)}}=1.48 .
\end{aligned}
\]

However, it is clear in Figure 8.3 that the two groups can be separated. If they are projected in an appropriate direction as in Figure 8.1, there will be no overlap. The single dimension onto which the points would be projected is the discriminant function
\[
z=\mathbf{a}^{\prime} \mathbf{y}=a_{1} y_{1}+a_{2} y_{2}=-1.633 y_{1}+1.820 y_{2}
\]
where \(\mathbf{a}\) is obtained as
\[
\mathbf{a}=\mathbf{S}_{\mathrm{pl}}^{-1}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)=\binom{-1.633}{1.820} .
\]

The values of the projected points are found by calculating \(z\) for each observation vector \(y\) in the two groups. The results are given in Table 8.2, where the separation provided by the discriminant function is clearly evident.

\subsection*{8.3 RELATIONSHIP BETWEEN TWO-GROUP DISCRIMINANT ANALYSIS AND MULTIPLE REGRESSION}

The mutual connection between multiple regression and two-group discriminant analysis was introduced as a computational device in Section 5.6.2. The roles of independent and dependent variables are reversed in the two models. The dependent variables ( \(y\) 's) of discriminant analysis become the independent variables in regression.

Let \(w\) be a grouping variable (identifying groups 1 and 2) such that \(\bar{w}=0\) and define \(\mathbf{b}=\left(b_{1}, b_{2}, \ldots, b_{p}\right)^{\prime}\) as the vector of regression coefficients when \(w\) is fit to the \(y\) 's. Then by (5.21), \(\mathbf{b}\) is proportional to the discriminant function coefficient vector \(\mathbf{a}=\mathbf{S}_{\mathrm{pl}}^{-1}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)\) :
\[
\begin{equation*}
\mathbf{b}=\frac{n_{1} n_{2}}{\left(n_{1}+n_{2}\right)\left(n_{1}+n_{2}-2+T^{2}\right)} \mathbf{a}, \tag{8.4}
\end{equation*}
\]
where \(T^{2}=\left[n_{1} n_{2} /\left(n_{1}+n_{2}\right)\right]\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)^{\prime} \mathbf{S}_{\mathrm{pl}}^{-1}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)\) as in (5.9). From (5.20) the squared multiple correlation \(R^{2}\) is related to \(T^{2}\) by
\[
\begin{equation*}
R^{2}=\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)^{\prime} \mathbf{b}=\frac{T^{2}}{n_{1}+n_{2}-2+T^{2}} \tag{8.5}
\end{equation*}
\]

The test statistic (5.29) for the hypothesis that \(q\) of the \(p+q\) variables are redundant for separating the groups can also be obtained in terms of regression by (5.31) as
\[
\begin{equation*}
F=\frac{n_{1}+n_{2}-p-q-1}{q} \frac{R_{p+q}^{2}-R_{p}^{2}}{1-R_{p+q}^{2}} \tag{8.6}
\end{equation*}
\]
where \(R_{p+q}^{2}\) and \(R_{p}^{2}\) are from regressions with \(p+q\) and \(p\) variables, respectively.
The link between two-group discriminant analysis and multiple regression was first noted by Fisher (1936). Flury and Riedwyl (1985) give further insights into the relationship.

\section*{EXAMPLE 8.3}

In Example 5.6.2, the psychological data of Table 5.1 were used in an illustration of the regression approach to computation of a and \(T^{2}\). We use the same data to obtain \(\mathbf{b}\) and \(R^{2}\) from \(\mathbf{a}\) and \(T^{2}\).

From the results of Examples 5.4.2 and 5.5, we have
\[
\begin{aligned}
T^{2} & =97.6015, \\
\mathbf{a} & =\left(\begin{array}{r}
.5104 \\
-.2033 \\
.4660 \\
-.3097
\end{array}\right)
\end{aligned}
\]

To find \(\mathbf{b}\) from \(\mathbf{a}\) and \(T^{2}\), we use (8.4):
\[
\mathbf{b}=\frac{(32)(32)}{(32+32)(32+32-2+97.6015)} \mathbf{a}=\left(\begin{array}{r}
.051 \\
-.020 \\
.047 \\
-.031
\end{array}\right)
\]

To find \(R^{2}\), we use (8.5):
\[
R^{2}=\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)^{\prime} \mathbf{b}=\left(\begin{array}{r}
3.625 \\
2.000 \\
10.531 \\
.812
\end{array}\right)^{\prime}\left(\begin{array}{r}
.051 \\
-.020 \\
.047 \\
-.031
\end{array}\right)=.611
\]

We can also use the relationship with \(T^{2}\) in (8.5):
\[
R^{2}=\frac{T^{2}}{n_{1}+n_{2}-2+T^{2}}=\frac{97.6105}{32+32-2+97.6015}=.611 .
\]

\subsection*{8.4 DISCRIMINANT ANALYSIS FOR SEVERAL GROUPS}

\subsection*{8.4.1 Discriminant Functions}

In discriminant analysis for several groups, we are concerned with finding linear combinations of variables that best separate the \(k\) groups of multivariate observations. Discriminant analysis for several groups may serve any one of various purposes:
1. Examine group separation in a two-dimensional plot. When there are more than two groups, it requires more than one discriminant function to describe group separation. If the points in the \(p\)-dimensional space are projected onto a 2-dimensional space represented by the first two discriminant functions, we obtain the best possible view of how the groups are separated.
2. Find a subset of the original variables that separates the groups almost as well as the original set. This topic was introduced in Section 6.11.2.
3. Rank the variables in terms of their relative contribution to group separation. This use for discriminant functions has been mentioned in Sections 5.5, 6.1.4, 6.1.8, and 6.4. In Section 8.5, we discuss standardized discriminant function coefficients that provide a more valid comparison of the variables.
4. Interpret the new dimensions represented by the discriminant functions.
5. Follow up to fixed-effects MANOVA.

Purposes 3 and 4 are closely related. Any of the first four goals can be used to accomplish purpose 5. Methods of achieving these five goals of discriminant analysis are discussed in subsequent sections. In the present section we review discriminant functions for the several-group case and discuss attendant assumptions. For alternative estimators of discriminant functions that may be useful in the presence of multicollinearity or outliers, see Rencher (1998, Section 5.11).

For \(k\) groups (samples) with \(n_{i}\) observations in the \(i\) th group, we transform each observation vector \(\mathbf{y}_{i j}\) to obtain \(z_{i j}=\mathbf{a}^{\prime} \mathbf{y}_{i j}, i=1,2, \ldots, k ; j=1,2, \ldots, n_{i}\), and find the means \(\bar{z}_{i}=\mathbf{a}^{\prime} \overline{\mathbf{y}}_{i}\), where \(\overline{\mathbf{y}}_{i}=\sum_{j=1}^{n_{i}} \mathbf{y}_{i j} / n_{i}\). As in the two-group case, we seek the vector a that maximally separates \(\bar{z}_{1}, \bar{z}_{2}, \ldots, \bar{z}_{k}\). To express separation among \(\bar{z}_{1}, \bar{z}_{2}, \ldots, \bar{z}_{k}\), we extend the separation criterion (8.1) to the \(k\)-group case. Since \(\mathbf{a}^{\prime}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)=\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)^{\prime} \mathbf{a}\), we can express (8.1) in the form
\[
\begin{equation*}
\frac{\left(\bar{z}_{1}-\bar{z}_{2}\right)^{2}}{s_{z}^{2}}=\frac{\left[\mathbf{a}^{\prime}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)\right]^{2}}{\mathbf{a}^{\prime} \mathbf{S}_{\mathrm{p} \mathbf{1}} \mathbf{a}}=\frac{\mathbf{a}^{\prime}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)^{\prime} \mathbf{a}}{\mathbf{a}^{\prime} \mathbf{S}_{\mathrm{p} \mathbf{1}} \mathbf{a}} \tag{8.7}
\end{equation*}
\]

To extend (8.7) to \(k\) groups, we use the \(\mathbf{H}\) matrix from MANOVA in place of \(\left(\overline{\mathbf{y}}_{1}-\right.\) \(\left.\overline{\mathbf{y}}_{2}\right)\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)^{\prime}\left[\right.\) see (6.37)] and \(\mathbf{E}\) in place of \(\mathbf{S}_{\mathrm{pl}}\) to obtain
\[
\begin{equation*}
\lambda=\frac{\mathbf{a}^{\prime} \mathbf{H a}}{\mathbf{a}^{\prime} \mathbf{E a}} \tag{8.8}
\end{equation*}
\]
which can also be expressed as
\[
\begin{equation*}
\lambda=\frac{\operatorname{SSH}(z)}{\operatorname{SSE}(z)}, \tag{8.9}
\end{equation*}
\]
where \(\operatorname{SSH}(z)\) and \(\operatorname{SSE}(z)\) are the between and within sums of squares for \(z\).
We can write (8.8) in the form
\[
\begin{gather*}
\mathbf{a}^{\prime} \mathbf{H a}=\lambda \mathbf{a}^{\prime} \mathbf{E a}, \\
\mathbf{a}^{\prime}(\mathbf{H a}-\lambda \mathbf{E a})=0 . \tag{8.10}
\end{gather*}
\]

We examine values of \(\lambda\) and a that are solutions of (8.10) in a search for the value of a that results in maximum \(\lambda\). The solution \(\mathbf{a}^{\prime}=\mathbf{0}^{\prime}\) is not permissible because it gives \(\lambda=0 / 0\) in (8.8). Other solutions are found from
\[
\begin{equation*}
\mathbf{H a}-\lambda \mathbf{E a}=\mathbf{0}, \tag{8.11}
\end{equation*}
\]
which can be written in the form
\[
\begin{equation*}
\left(\mathbf{E}^{-1} \mathbf{H}-\lambda \mathbf{I}\right) \mathbf{a}=\mathbf{0} . \tag{8.12}
\end{equation*}
\]

The solutions of (8.12) are the eigenvalues \(\lambda_{1}, \lambda_{2}, \ldots, \lambda_{s}\) and associated eigenvectors \(\mathbf{a}_{1}, \mathbf{a}_{2}, \ldots, \mathbf{a}_{s}\) of \(\mathbf{E}^{-1} \mathbf{H}\). As in previous discussions of eigenvalues, we consider them to be ranked \(\lambda_{1}>\lambda_{2}>\ldots>\lambda_{s}\). The number of (nonzero) eigenvalues \(s\) is the rank of \(\mathbf{H}\), which can be found as the smaller of \(k-1\) or \(p\). Thus the largest eigenvalue \(\lambda_{1}\) is the maximum value of \(\lambda=\mathbf{a}^{\prime} \mathbf{H a} / \mathbf{a}^{\prime} \mathbf{E a}\) in (8.8), and the coefficient vector that produces the maximum is the corresponding eigenvector \(\mathbf{a}_{1}\). (This can be verified using calculus.) Hence the discriminant function that maximally separates the means is \(z_{1}=\mathbf{a}_{1}^{\prime} \mathbf{y}\); that is, \(z_{1}\) represents the dimension or direction that maximally separates the means.

From the \(s\) eigenvectors \(\mathbf{a}_{1}, \mathbf{a}_{2}, \ldots, \mathbf{a}_{s}\) of \(\mathbf{E}^{-1} \mathbf{H}\) corresponding to \(\lambda_{1}, \lambda_{2}, \ldots, \lambda_{s}\), we obtain \(s\) discriminant functions \(z_{1}=\mathbf{a}_{1}^{\prime} \mathbf{y}, z_{2}=\mathbf{a}_{2}^{\prime} \mathbf{y}, \ldots, z_{s}=\mathbf{a}_{s}^{\prime} \mathbf{y}\), which show the dimensions or directions of differences among \(\overline{\mathbf{y}}_{1}, \overline{\mathbf{y}}_{2}, \ldots, \overline{\mathbf{y}}_{k}\). These discriminant functions are uncorrelated but are not orthogonal [see Rencher (1998, pp. 203204)]. These discriminant functions are uncorrelated, but they are not orthogonal \(\left(\mathbf{a}_{i}^{\prime} \mathbf{a}_{j}=0\right.\) for \(i \neq j\) ) because \(\mathbf{E}^{-1} \mathbf{H}\) is not symmetric. Note that the numbering \(z_{1}, z_{2}, \ldots, z_{s}\) corresponds to the eigenvalues, not to the \(k\) groups as was done earlier in this section.

The relative importance of each discriminant function \(z_{i}\) can be assessed by considering its eigenvalue as a proportion of the total:
\[
\begin{equation*}
\frac{\lambda_{i}}{\sum_{j=1}^{s} \lambda_{j}} . \tag{8.13}
\end{equation*}
\]

By this criterion, two or three discriminant functions will often suffice to describe the group differences. The discriminant functions associated with small eigenvalues can be neglected. A test of significance for each discriminant function is also available (see Section 8.6).

The matrix \(\mathbf{E}^{-1} \mathbf{H}\) is not symmetric. Many algorithms for computation of eigenvalues and eigenvectors accept only symmetric matrices. In Section 6.1.4, it was shown that the eigenvalues of the symmetric matrix \(\left(\mathbf{U}^{-1}\right)^{\prime} \mathbf{H} \mathbf{U}^{-1}\) are the same as those of \(\mathbf{E}^{-1} \mathbf{H}\), where \(\mathbf{E}=\mathbf{U}^{\prime} \mathbf{U}\) is the Cholesky factorization of \(\mathbf{E}\). However, an adjustment is needed for the eigenvectors. If \(\mathbf{b}\) is an eigenvector of \(\left(\mathbf{U}^{-1}\right)^{\prime} \mathbf{H} \mathbf{U}^{-1}\), then \(\mathbf{a}=\mathbf{U}^{-1} \mathbf{b}\) is an eigenvector of \(\mathbf{E}^{-1} \mathbf{H}\).

The discussion above was presented in terms of unequal sample sizes \(n_{1}, n_{2}, \ldots\), \(n_{k}\). In applications, this situation is common and can be handled with no difficulty. Ideally, the smallest \(n_{i}\) should exceed the number of variables, \(p\). This is not required mathematically, but will lead to more stable discriminant functions.

\section*{- EXAMPLE 8.4.1}

The data in Table 8.3 were collected by G. R. Bryce and R. M. Barker (Brigham Young University) as part of a preliminary study of a possible link between football helmet design and neck injuries.

Six head measurements were made on each subject. There were 30 subjects in each of three groups: high school football players (group 1), college football players (group 2), and non-football players (group 3). The six variables are
\[
\begin{aligned}
\text { WDIM } & =\text { head width at widest dimension } \\
\text { CIRCUM } & =\text { head circumference } \\
\text { FBEYE } & =\text { front-to-back measurement at eye level } \\
\text { EYEHD } & =\text { eye-to-top-of-head measurement } \\
\text { EARHD } & =\text { ear-to-top-of-head measurement } \\
\text { JAW } & =\text { jaw width }
\end{aligned}
\]

The eigenvalues of \(\mathbf{E}^{-1} \mathbf{H}\) are \(\lambda_{1}=1.9178\) and \(\lambda_{2}=.1159\). The corresponding eigenvectors are
\[
\mathbf{a}_{1}=\left(\begin{array}{r}
-.948 \\
.004 \\
.006 \\
.647 \\
.504 \\
.829
\end{array}\right), \quad \mathbf{a}_{2}=\left(\begin{array}{r}
-1.407 \\
.001 \\
.029 \\
-.540 \\
.384 \\
1.529
\end{array}\right)
\]

The first eigenvalue accounts for a substantial proportion of the total:
\[
\frac{\lambda_{1}}{\lambda_{1}+\lambda_{2}}=\frac{1.9178}{1.9178+.1159}=.94 .
\]

Table 8.3 Head Measurements for Three Groups
\begin{tabular}{ccccccc}
\hline Group & WDIM & CIRCUM & FBEYE & EYEHD & EARHD & JAW \\
\hline 1 & 13.5 & 57.2 & 19.5 & 12.5 & 14.0 & 11.0 \\
1 & 15.5 & 58.4 & 21.0 & 12.0 & 16.0 & 12.0 \\
1 & 14.5 & 55.9 & 19.0 & 10.0 & 13.0 & 12.0 \\
1 & 15.5 & 58.4 & 20.0 & 13.5 & 15.0 & 12.0 \\
1 & 14.5 & 58.4 & 20.0 & 13.0 & 15.5 & 12.0 \\
1 & 14.0 & 61.0 & 21.0 & 12.0 & 14.0 & 13.0 \\
1 & 15.0 & 58.4 & 19.5 & 13.5 & 15.5 & 13.0 \\
1 & 15.0 & 58.4 & 21.0 & 13.0 & 14.0 & 13.0 \\
1 & 15.5 & 59.7 & 20.5 & 13.5 & 14.5 & 12.5 \\
1 & 15.5 & 59.7 & 20.5 & 13.0 & 15.0 & 13.0 \\
1 & 15.0 & 57.2 & 19.0 & 14.0 & 14.5 & 11.5 \\
1 & 15.5 & 59.7 & 21.0 & 13.0 & 16.0 & 12.5 \\
1 & 16.0 & 57.2 & 19.0 & 14.0 & 14.5 & 12.0 \\
1 & 15.5 & 62.2 & 21.5 & 14.0 & 16.0 & 12.0 \\
1 & 15.5 & 57.2 & 19.5 & 13.5 & 15.0 & 12.0 \\
1 & 14.0 & 61.0 & 20.0 & 15.0 & 15.0 & 12.0 \\
1 & 14.5 & 58.4 & 20.0 & 12.0 & 14.5 & 12.0 \\
1 & 15.0 & 56.9 & 19.0 & 13.0 & 14.0 & 12.5 \\
1 & 15.5 & 59.7 & 20.0 & 12.5 & 14.0 & 12.5 \\
1 & 15.0 & 57.2 & 19.5 & 12.0 & 14.0 & 11.0 \\
1 & 17.3 & 61.7 & 20.7 & 11.9 & 13.3 & 13.3 \\
1 & 15.0 & 56.9 & 19.0 & 12.0 & 13.0 & 12.0 \\
1 & 15.5 & 56.9 & 19.5 & 14.5 & 14.5 & 13.0 \\
1 & 17.5 & 63.5 & 21.5 & 14.0 & 15.5 & 13.5 \\
1 & 15.5 & 57.2 & 19.0 & 13.0 & 15.5 & 12.5 \\
1 & 15.5 & 61.0 & 20.5 & 12.0 & 13.0 & 12.5 \\
1 & 15.5 & 61.0 & 21.0 & 14.5 & 15.5 & 12.5 \\
1 & 15.5 & 63.5 & 21.8 & 14.5 & 16.5 & 13.5 \\
1 & 14.5 & 58.4 & 20.5 & 13.0 & 16.0 & 10.5 \\
1 & 15.5 & 56.9 & 20.0 & 13.5 & 14.0 & 12.0 \\
1 & 16.0 & 61.0 & 20.0 & 12.5 & 14.5 & 12.5 \\
2 & 15.5 & 60.0 & 21.1 & 10.3 & 13.4 & 12.4 \\
2 & 15.4 & 59.7 & 20.0 & 12.8 & 14.5 & 11.3 \\
1 & 15.1 & 59.7 & 20.2 & 11.4 & 14.1 & 12.1 \\
1 & 14.3 & 56.9 & 18.9 & 11.0 & 13.4 & 11.0 \\
1 & 14.8 & 58.0 & 20.1 & 9.6 & 11.1 & 11.7 \\
1 & \(\vdots\) & \(\vdots\) & \(\vdots\) & \(\vdots\) & \(\vdots\) \\
1 & 1 & & & & &
\end{tabular}

Thus the mean vectors lie largely in one dimension, and one discriminant function suffices to describe most of the separation among the three groups.

\subsection*{8.4.2 A Measure of Association for Discriminant Functions}

Measures of association between the dependent variables \(y_{1}, y_{2}, \ldots, y_{p}\) and the independent grouping variable \(i\) associated with \(\mu_{i}, i=1,2, \ldots, k\), were presented in Section 6.1.8. These measures attempt to answer the question, How well do the variables separate the groups? It was noted that Roy's statistic \(\theta\) serves as an \(R^{2}\)-like measure of association, since it is the ratio of between sum of squares to total sum of squares for the first discriminant function, \(z_{1}=\mathbf{a}_{1}^{\prime} \mathbf{y}\) :
\[
\eta_{\theta}^{2}=\theta=\frac{\lambda_{1}}{1+\lambda_{1}}=\frac{\operatorname{SSH}\left(z_{1}\right)}{\operatorname{SSE}\left(z_{1}\right)+\operatorname{SSH}\left(z_{1}\right)}
\]
[see (6.41) and (8.9)]. Another interpretation of \(\eta_{\theta}^{2}\) is the maximum squared correlation between the first discriminant function and the best linear combination of the \(k-1\) (dummy) group membership variables [see comments following (6.39) in Section 6.1.8]. Dummy variables were defined in the first two paragraphs of Section 6.1.8. The maximum correlation is called the (first) canonical correlation (see Chapter 11). The squared canonical correlation can be calculated for each discriminant function:
\[
\begin{equation*}
r_{i}^{2}=\frac{\lambda_{i}}{1+\lambda_{i}}, i=1,2, \ldots, s \tag{8.14}
\end{equation*}
\]

The average squared canonical correlation was used as a measure of association in (6.48).

\section*{■ EXAMPLE 8.4.2}

For the football data of Table 8.3, we obtain the squared canonical correlation between each of the two discriminant functions and the grouping variables,
\[
\begin{aligned}
r_{1}^{2} & =\frac{\lambda_{1}}{1+\lambda_{1}}=\frac{1.9178}{1+1.9178}=.657 \\
r_{2}^{2} & =\frac{\lambda_{2}}{1+\lambda_{2}}=\frac{.1159}{1+.1159}=.104
\end{aligned}
\]

\subsection*{8.5 STANDARDIZED DISCRIMINANT FUNCTIONS}

In Section 5.5, it was noted that in the two-group case the relative contribution of the \(y\) 's to separation of the two groups can best be assessed by comparing the coefficients \(a_{r}, r=1,2, \ldots, p\), in the discriminant function
\[
z=\mathbf{a}^{\prime} \mathbf{y}=a_{1} y_{1}+a_{2} y_{2}+\ldots+a_{p} y_{p}
\]

Similar comments appeared in Section 6.1.4, 6.1.8, and 6.4 concerning the use of discriminant functions to assess contribution of the \(y\) 's to separation of several groups. However, such comparisons are informative only if the \(y\) 's are commensurate, that is, measured on the same scale and with comparable variances. If the \(y\) 's are not commensurate, we need coefficients \(a_{r}^{*}\) that are applicable to standardized variables.

Consider the case of two groups. For the \(i\) th observation vector \(\mathbf{y}_{1 i}\) or \(\mathbf{y}_{2 i}\) in group 1 or 2 , we can express the discriminant function in terms of standardized variables as
\[
\begin{align*}
z_{1 i}= & a_{1}^{*} \frac{y_{1 i 1}-\bar{y}_{11}}{s_{1}}+a_{2}^{*} \frac{y_{1 i 2}-\bar{y}_{12}}{s_{2}}+\cdots+a_{p}^{*} \frac{y_{1 i p}-\bar{y}_{1 p}}{s_{p}},  \tag{8.15}\\
& i=1,2, \ldots, n_{1}, \\
z_{2 i}= & a_{1}^{*} \frac{y_{2 i 1}-\bar{y}_{21}}{s_{1}}+a_{2}^{*} \frac{y_{2 i 2}-\bar{y}_{22}}{s_{2}}+\cdots+a_{p}^{*} \frac{y_{2 i p}-\bar{y}_{2 p}}{s_{p}}, \\
& i=1,2, \ldots, n_{2},
\end{align*}
\]
where \(\overline{\mathbf{y}}_{1}^{\prime}=\left(\bar{y}_{11}, \bar{y}_{12}, \ldots, \bar{y}_{1 p}\right)\) and \(\overline{\mathbf{y}}_{2}^{\prime}=\left(\bar{y}_{21}, \bar{y}_{22}, \ldots, \bar{y}_{2 p}\right)\) are the mean vectors for the two groups and \(s_{r}\) is the within-sample standard deviation of the \(r\) th variable, obtained as the square root of the \(r\) th diagonal element of \(\mathbf{S}_{\mathrm{pl}}\). Clearly, these standardized coefficients must be of the form
\[
\begin{equation*}
a_{r}^{*}=s_{r} a_{r}, \quad r=1,2, \ldots, p . \tag{8.16}
\end{equation*}
\]

In vector form, this becomes
\[
\begin{equation*}
\mathbf{a}^{*}=\left(\operatorname{diag} \mathbf{S}_{\mathrm{pl}}\right)^{1 / 2} \mathbf{a} \tag{8.17}
\end{equation*}
\]

For the several-group case, we can standardize the discriminant functions in an analogous fashion. If we denote the \(r\) th coefficient in the \(m\) th discriminant function by \(a_{m r}, m=1,2, \ldots, s ; r=1,2, \ldots, p\), then the standardized form is
\[
a_{m r}^{*}=s_{r} a_{m r}
\]
where \(s_{r}\) is the within-group standard deviation obtained from the diagonal of \(\mathbf{S}_{\mathrm{pl}}=\) \(\mathbf{E} / \nu_{E}\). Note that \(a_{m r}^{*}\) has two subscripts because there are several discriminant functions, while \(a_{r}^{*}\) in (8.16) above has only the one subscript because there is one discriminant function for two groups.

Alternatively, since the \(m\) th eigenvector is unique only up to multiplication by a scalar, we can simplify the standardization by using
\[
a_{m r}^{*}=\sqrt{e_{r r}} a_{m r}, \quad r=1,2, \ldots, p
\]
where \(e_{r r}\) is the \(r\) th diagonal element of \(\mathbf{E}\). For further discussion of the use of standardized discriminant function coefficients to gauge the relative contribution of the variables to group separation, see Section 8.7.1 [see also Rencher and Scott (1990) and Rencher (1998, Section 5.4)].

\section*{- EXAMPLE 8.5}

In Example 8.4.1, we obtained the discriminant function coefficient vectors \(\mathbf{a}_{1}\) and \(\mathbf{a}_{2}\) for the football data of Table 8.3. Since \(\lambda_{1} /\left(\lambda_{1}+\lambda_{2}\right)=.94\), we concentrate on \(\mathbf{a}_{1}\). To standardize \(\mathbf{a}_{1}\), we need the within-sample standard deviations of the variables. The pooled covariance matrix is given by
\[
\mathbf{S}_{\mathrm{pl}}=\frac{\mathbf{E}}{87}=\left(\begin{array}{rrrrrr}
.428 & .578 & .158 & .084 & .125 & .228 \\
.578 & 3.161 & 1.020 & .653 & .340 & .505 \\
.158 & 1.020 & .546 & .077 & .129 & .159 \\
.084 & .653 & .077 & 1.232 & .315 & .024 \\
.125 & .340 & .129 & .315 & .618 & .009 \\
.228 & .505 & .159 & .024 & .009 & .376
\end{array}\right)
\]

Using the square roots of the diagonal elements of \(S_{p l}\), we obtain
\[
\mathrm{a}_{1}^{*}=\left(\begin{array}{c}
\sqrt{.428}(--.948) \\
\sqrt{3.161}(.004) \\
\vdots \\
\sqrt{.376}(.829)
\end{array}\right)=\left(\begin{array}{r}
-.621 \\
.007 \\
.005 \\
.719 \\
.397 \\
.508
\end{array}\right)
\]

Thus the fourth, first, sixth, and fifth variables contribute most to separating the groups, in that order. The second and third variables are not useful (in the presence of the others) in distinguishing groups.

\subsection*{8.6 TESTS OF SIGNIFICANCE}

In order to test hypotheses, we need the assumption of multivariate normality. This was not explicitly required for the development of discriminant functions.

\subsection*{8.6.1 Tests for the Two-Group Case}

By (8.3) we see that the separation of transformed means, \(\left(\bar{z}_{1}-\bar{z}_{2}\right)^{2} / s_{z}^{2}\), achieved by the discriminant function \(z=\mathbf{a}^{\prime} \mathbf{y}\) is equivalent to the standardized distance between the mean vectors \(\overline{\mathbf{y}}_{1}\) and \(\overline{\mathbf{y}}_{2}\). This standardized distance is proportional to the twogroup \(T^{2}\) in (5.9) in Section 5.4.2. Hence the discriminant function coefficient vector a is significantly different from 0 if \(T^{2}\) is significant. More formally, if the population discriminant function coefficient vector is expressed as \(\boldsymbol{\alpha}=\boldsymbol{\Sigma}^{-1}\left(\boldsymbol{\mu}_{1}-\boldsymbol{\mu}_{2}\right)\), then \(H_{0}: \boldsymbol{\alpha}=\mathbf{0}\) is equivalent to \(H_{0}: \boldsymbol{\mu}_{1}=\boldsymbol{\mu}_{2}\).

To test the significance of a subset of the discriminant function coefficients, we can use the test of the corresponding subset of \(y\) 's given in Section 5.9. To test the hypothesis that the population discriminant function has a specified form \(\mathbf{a}_{0}^{\prime} \mathbf{y}\), see Rencher (1998, Section 5.5.1).

\subsection*{8.6.2 Tests for the Several-Group Case}

In Section 8.4.1 we noted that the discriminant criterion \(\lambda=\mathbf{a}^{\prime} \mathbf{H a} / \mathbf{a}^{\prime} \mathbf{E a}\) is maximized by \(\lambda_{1}\), the largest eigenvalue of \(\mathbf{E}^{-1} \mathbf{H}\), and that the remaining eigenvalues \(\lambda_{2}, \ldots, \lambda_{s}\) correspond to other discriminant dimensions. These eigenvalues are the same as those in the Wilks' \(\Lambda\)-test in (6.14) for significant differences among mean vectors,
\[
\begin{equation*}
\Lambda_{1}=\prod_{i=1}^{s} \frac{1}{1+\lambda_{i}} \tag{8.18}
\end{equation*}
\]
which is distributed as \(\Lambda_{p, k-1, N-k}\), where \(N=\sum_{i} n_{i}\) for an unbalanced design or \(N=k n\) in the balanced case. Since \(\Lambda_{1}\) is small if one or more \(\lambda_{i}\) 's are large, Wilks' \(\Lambda\) will test for significance of the eigenvalues and thereby for the discriminant functions. The \(s\) eigenvalues represent \(s\) dimensions of separation of the mean vectors \(\overline{\mathbf{y}}_{1}, \overline{\mathbf{y}}_{2}, \ldots, \overline{\mathbf{y}}_{k}\). We are interested in which, if any, of these dimensions are significant. In the context of discriminant functions, Wilks' \(\Lambda\) is more useful than the other three MANOVA test statistics, because it can be used on a subset of eigenvalues, as we see below.

In addition to the exact test provided by the critical values for \(\Lambda\) found in Table A. 9 , we can use the \(\chi^{2}\)-approximation for \(\Lambda_{1}\) given in (6.16), with \(\nu_{E}=N-k=\) \(\sum_{i} n_{i}-k\) and \(\nu_{H}=k-1:\)
\[
\begin{align*}
V_{1} & =-\left[\nu_{E}-\frac{1}{2}\left(p-\nu_{H}+1\right)\right] \ln \Lambda_{1} \\
& =-\left[N-1-\frac{1}{2}(p+k)\right] \ln \prod_{i=1}^{s} \frac{1}{1+\lambda_{i}} \\
& =\left[N-1-\frac{1}{2}(p+k)\right] \sum_{i=1}^{s} \ln \left(1+\lambda_{i}\right), \tag{8.19}
\end{align*}
\]
which is approximately \(\chi^{2}\) with \(p(k-1)\) degrees of freedom. The test statistic \(\Lambda_{1}\) and its approximation (8.19) test the significance of all of \(\lambda_{1}, \lambda_{2}, \ldots, \lambda_{s}\). If the test leads to rejection of \(H_{0}\), we conclude that at least one of the \(\lambda\) 's is significantly different from zero, and therefore there is at least one dimension of separation of mean vectors. Since \(\lambda_{1}\) is the largest, we are only sure of its significance, along with that of \(z_{1}=\mathbf{a}_{1}^{\prime} \mathbf{y}\).

To test the significance of \(\lambda_{2}, \lambda_{3}, \ldots, \lambda_{s}\), we delete \(\lambda_{1}\) from Wilks' \(\Lambda\) and the associated \(\chi^{2}\)-approximation to obtain
\[
\begin{align*}
\Lambda_{2} & =\prod_{i=2}^{s} \frac{1}{1+\lambda_{i}},  \tag{8.20}\\
V_{2} & =-\left[N-1-\frac{1}{2}(p+k)\right] \ln \Lambda_{2} \\
& =\left[N-1-\frac{1}{2}(p+k)\right] \sum_{i=2}^{s} \ln \left(1+\lambda_{i}\right) \tag{8.21}
\end{align*}
\]
which is approximately \(\chi^{2}\) with \((p-1)(k-2)\) degrees of freedom. If this test leads to rejection of \(H_{0}\), we conclude that at least \(\lambda_{2}\) is significant along with the associated discriminant function \(z_{2}=\mathbf{a}_{2}^{\prime} \mathbf{y}\). We can continue in this fashion, testing each \(\lambda_{i}\) in turn until a test fails to reject \(H_{0}\). (To compensate for making several tests, an adjustment to the \(\alpha\)-level of each test could be made as in procedure 2, Section 5.5.) The test statistic at the \(m\) th step is
\[
\begin{equation*}
\Lambda_{m}=\prod_{i=m}^{s} \frac{1}{1+\lambda_{i}} \tag{8.22}
\end{equation*}
\]
which is distributed as \(\Lambda_{p-m+1, k-m, N-k-m+1}\). The statistic
\[
\begin{align*}
V_{m} & =-\left[N-1-\frac{1}{2}(p+k)\right] \ln \Lambda_{m} \\
& =\left[N-1-\frac{1}{2}(p+k)\right] \sum_{i=m}^{s} \ln \left(1+\lambda_{i}\right) \tag{8.23}
\end{align*}
\]
has an approximate \(\chi^{2}\)-distribution with \((p-m+1)(k-m)\) degrees of freedom. In some cases, more \(\lambda\) 's will be statistically significant than the researcher considers to be of practical importance. If \(\lambda_{i} / \sum_{j} \lambda_{j}\) is small, the associated discriminant function may not be of interest, even if it is significant.

We can also use an \(F\)-approximation for each \(\Lambda_{i}\). For
\[
\Lambda_{1}=\prod_{i=1}^{s} \frac{1}{1+\lambda_{i}}
\]
we use (6.15), with \(\nu_{E}=N-k\) and \(\nu_{H}=k-1\) :
\[
\begin{equation*}
F=\frac{1-\Lambda_{1}^{1 / t}}{\Lambda_{1}^{1 / t}} \frac{\mathrm{df}_{2}}{\mathrm{df}_{1}} \tag{8.24}
\end{equation*}
\]
where
\[
\begin{aligned}
t & =\sqrt{\frac{p^{2}(k-1)^{2}-4}{p^{2}+(k-1)^{2}-5}}, \quad w=N-1-\frac{1}{2}(p+k), \\
\mathrm{df}_{1} & =p(k-1), \quad \mathrm{df}_{2}=w t-\frac{1}{2}[p(k-1)-2] .
\end{aligned}
\]

For
\[
\Lambda_{m}=\prod_{i=m}^{s} \frac{1}{1+\lambda_{i}}, \quad m=2,3, \ldots, s
\]
we use
\[
\begin{equation*}
F=\frac{1-\Lambda_{m}^{1 / t}}{\Lambda_{m}^{1 / t}} \frac{\mathrm{df}_{2}}{\mathrm{df}_{1}} \tag{8.25}
\end{equation*}
\]
with \(p-m+1\) and \(k-m\) in place of \(p\) and \(k-1\) :
\[
\begin{aligned}
t & =\sqrt{\frac{(p-m+1)^{2}(k-m)^{2}-4}{(p-m+1)^{2}+(k-m)^{2}-5}}, \\
w & =N-1-\frac{1}{2}(p+k) \\
\mathrm{df}_{1} & =(p-m+1)(k-m), \\
\mathrm{df}_{2} & =w t-\frac{1}{2}[(p-m+1)(k-m)-2] .
\end{aligned}
\]

\section*{EXAMPLE 8.6.2}

We test the significance of the two discriminant functions obtained in Example 8.4.1 for the football data. For the overall test we have, by (8.18),
\[
\Lambda_{1}=\prod_{i=1}^{2} \frac{1}{1+\lambda_{i}}=\frac{1}{1+1.9178} \frac{1}{1+.1159}=.307
\]

With \(p=6, k=3\), and \(N-k=87\), the critical value from Table A. 9 is \(\Lambda_{05,6,2,80}=.762 . \mathrm{By}(8.19)\), the \(\chi^{2}\)-approximation is
\[
\begin{aligned}
V_{1} & =-\left[N-1-\frac{1}{2}(p+k)\right] \ln \Lambda_{1} \\
& =-\left[90-1-\frac{1}{2}(6+3)\right] \ln (.307)=99.75
\end{aligned}
\]
which exceeds the critical value \(\chi_{.01,12}^{2}=26.217\). Thus at least the first discriminant function is significant.

To test the second discriminant function, we have, by (8.20),
\[
\Lambda_{2}=\frac{1}{1+.1159}=.896
\]

With \(m=2\), the (conservative) critical value is \(\Lambda_{.05,5,1,80}=.867\). Since this is close to \(\Lambda=.896\), we interpolate in Table A. 9 to obtain \(\Lambda_{.05,5,1,86}=.875\). By (8.21), the \(\chi^{2}\)-approximation is
\[
\begin{aligned}
V_{2} & =-\left[N-1-\frac{1}{2}(p+k)\right] \ln \Lambda_{2} \\
& =-\left[90-1-\frac{1}{2}(6+3)\right] \ln \frac{1}{1+.1159}=9.27<\chi_{.05,5}^{2}=11.070
\end{aligned}
\]

For the \(F\)-approximation for \(\Lambda_{1}\), we obtain by (8.24)
\[
\begin{aligned}
t & =\sqrt{\frac{p^{2}(k-1)^{2}-4}{p^{2}+(k-1)^{2}-5}}=\sqrt{\frac{6^{2} 2^{2}-4}{6^{2}+2^{2}-5}}=2, \\
w & =N-1-\frac{1}{2}(p+k)=90-1-\frac{1}{2}(6+3)=84.5, \\
\mathrm{df}_{1} & =p(k-1)=6(2)=12, \\
\mathrm{df}_{2} & =w t-\frac{1}{2}[p(k-1)-2]=(84.5)(2)-\frac{1}{2}[6(2)-2]=164, \\
F & =\frac{1-\Lambda_{1}^{1 / 2}}{\Lambda_{1}^{1 / 2}} \frac{\mathrm{df}_{2}}{\mathrm{df}_{1}}=\frac{1-.307^{1 / 2}}{.307^{1 / 2}} \frac{164}{12}=10.994
\end{aligned}
\]

The \(p\)-value for \(F=10.994\) is less than .0001 . For the \(F\)-approximation for \(\Lambda_{2}\), we reduce \(p\) and \(k\) by 1 and obtain by (8.25)
\[
\begin{aligned}
t & =\sqrt{\frac{5^{2} 1^{2}-4}{5^{2}+1^{2}-5}}=1, \quad w=90-1-\frac{1}{2}(6+3)=84.5, \\
\mathrm{df}_{1} & =5(1)=5, \quad \mathrm{df}_{2}=84.5(1)-\frac{1}{2}[5(1)-2]=83, \\
F & =\frac{1-\Lambda_{2}}{\Lambda_{2}} \cdot \frac{\mathrm{df}_{2}}{\mathrm{df}_{1}}=\frac{1-.896}{.896} \frac{83}{5}=1.924
\end{aligned}
\]

The \(p\)-value for \(F=1.924\) is .099 . Thus only the first discriminant function significantly separates groups. The exact test above using \(\Lambda_{2}\) appears to be somewhat closer to rejection than the approximate tests.

\subsection*{8.7 INTERPRETATION OF DISCRIMINANT FUNCTIONS}

There is a close correspondence between interpreting discriminant functions and determining the contribution of each variable, and we shall not always make a distinction. In interpretation, the signs of the coefficients are taken into account; in ascertaining the contribution, the signs are ignored and the coefficients are ranked in absolute value. (We discuss this distinction further in Section 8.7.1.) We are more commonly interested in assessing the contribution of the variables than in interpreting the function.

In the next three sections, we cover three common approaches to assessing the contribution of each variable (in the presence of the other variables) to separating the groups. The three methods are (1) examine the standardized discriminant function coefficients, (2) calculate a partial \(F\)-test for each variable, and (3) calculate a correlation between each variable and the discriminant function. The third method is the most widely recommended, but we note in Section 8.7.3 that it is the least useful.

\subsection*{8.7.1 Standardized Coefficients}

To offset differing scales among the variables, the discriminant function coefficients can be standardized using (8.16) or (8.17), in which the coefficients have been adjusted so that they apply to standardized variables. For the observations in the first of two groups, for example, we have by (8.15),
\[
\begin{aligned}
z_{1 i}= & a_{1}^{*} \frac{y_{1 i 1}-\bar{y}_{11}}{s_{1}}+a_{2}^{*} \frac{y_{1 i 2}-\bar{y}_{12}}{s_{2}}+\cdots+a_{p}^{*} \frac{y_{1 i p}-\bar{y}_{1 p}}{s_{p}}, \\
& i=1,2, \ldots, n_{1} .
\end{aligned}
\]

The standardized variables \(\left(y_{1 i r}-\bar{y}_{1 r}\right) / s_{r}\) are scale free, and the standardized coefficients \(a_{r}^{*}=s_{r} a_{r}, r=1,2, \ldots, p\), therefore correctly reflect the joint contribution of the variables to the discriminant function \(z\) as it maximally separates the groups. For the case of several groups, each discriminant function coefficient vector
\(\mathbf{a}=\left(a_{1}, a_{2}, \ldots, a_{p}\right)^{\prime}\) is an eigenvector of \(\mathbf{E}^{-1} \mathbf{H}\), and as such, it takes into account the sample correlations among the variables as well as the influence of each variable in the presence of the others.

As noted in Section 8.5, this standardization is carried out for each of the \(s\) discriminant functions. Typically, each will have a different interpretation; that is, the pattern of the coefficients \(a_{r}^{*}\) will vary from one function to another.

The absolute values of the coefficients can be used to rank the variables in order of their contribution to separating the groups. If we wish to go further and interpret or "name" a discriminant function, the signs can be taken into account. Thus, for example, \(z_{1}=.8 y_{1}-.9 y_{2}+.5 y_{3}\) has a different meaning than \(z_{2}=.8 y_{1}+.9 y_{2}+.5 y_{3}\), since \(z_{1}\) depends on the difference between \(y_{1}\) and \(y_{2}\), while \(z_{2}\) is related to the sum of \(y_{1}\) and \(y_{2}\).

The discriminant function is subject to the same limitations as other linear combinations such as a regression equation: for example, (1) the coefficient for a variable may change notably if variables are added or deleted and (2) the coefficients may not be stable from sample to sample unless the sample size is large relative to the number of variables. With regard to limitation 1, we note that the coefficients reflect the contribution of each variable in the presence of the particular variables at hand. This is, in fact, what we want the coefficients to do. As to limitation 2 , the processing of a substantial number of variables is not "free." More stable estimates will be obtained from 50 observations on 2 variables than from 50 observations on 20 variables. In other words, if \(N / p\) is too small, the variables that rank high in one sample may emerge as less important in another sample.

\subsection*{8.7.2 Partial \(\boldsymbol{F}\)-Values}

For any variable \(y_{r}\) we can calculate a partial \(F\)-test showing the significance of \(y_{r}\) after adjusting for the other variables, that is, the separation provided by \(y_{r}\) in addition to that due to the other variables. After computing the partial \(F\) for each variable, the variables can then be ranked.

In the case of two groups, the partial \(F\) is given by (5.32) as
\[
\begin{equation*}
F=(\nu-p+1) \frac{T_{p}^{2}-T_{p-1}^{2}}{\nu+T_{p-1}^{2}} \tag{8.26}
\end{equation*}
\]
where \(T_{p}^{2}\) is the two-sample Hotelling \(T^{2}\) with all \(p\) variables, \(T_{p-1}^{2}\) is the \(T^{2}\)-statistic with all variables except \(y_{r}\), and \(\nu=n_{1}+n_{2}-2\). The \(F\)-statistic in (8.26) is distributed as \(F_{1, \nu-p+1}\).

For the several-group case, the partial \(\Lambda\) for \(y_{r}\) adjusted for the other \(p-1\) variables is given by (6.127) as
\[
\begin{equation*}
\Lambda\left(y_{r} \mid y_{1}, \ldots, y_{r-1}, y_{r+1}, \ldots, y_{p}\right)=\frac{\Lambda_{p}}{\Lambda_{p-1}} \tag{8.27}
\end{equation*}
\]
where \(\Lambda_{p}\) is Wilks' \(\Lambda\) for all \(p\) variables and \(\Lambda_{p-1}\) involves all variables except \(y_{r}\). The corresponding partial \(F\) is given by (6.128) as
\[
\begin{equation*}
F=\frac{1-\Lambda}{\Lambda} \frac{\nu_{E}-p+1}{\nu_{H}} \tag{8.28}
\end{equation*}
\]
where \(\Lambda\) is defined in (8.27), \(\nu_{E}=N-k\), and \(\nu_{H}=k-1\). The partial \(\Lambda\)-statistic in (8.27) is distributed as \(\Lambda_{1, \nu_{H}, \nu_{E}-p+1}\), and the partial \(F\) in (8.28) is distributed as \(F_{\nu_{H}, \nu_{E}-p+1}\).

The partial \(F\)-values in (8.26) and (8.28) are not associated with a single dimension of group separation as are the standardized discriminant function coefficients. For example, \(y_{2}\) will have a different contribution in each of the \(s\) discriminant functions, but the partial \(F\) for \(y_{2}\) constitutes an overall index of the contribution of \(y_{2}\) to group separation taking into account all dimensions. However, the partial \(F\)-values will often rank the variables in the same order as the standardized coefficients for the first discriminant function, especially if \(\lambda_{1} / \sum_{j} \lambda_{j}\) is very large so that the first function accounts for most of the available separation.

A partial index of association for \(y_{r}\) similar to the overall measure for all \(y\) 's given in (6.40), \(\eta_{\Lambda}^{2}=1-\Lambda\), can be defined by
\[
\begin{equation*}
R_{r}^{2}=1-\Lambda_{r} \quad r=1,2, \ldots, p \tag{8.29}
\end{equation*}
\]
where \(\Lambda_{r}\) is the partial \(\Lambda\) in (8.27) for \(y_{r}\). This partial \(R^{2}\) is a measure of association between the grouping variables and \(y_{i}\) after adjusting for the other \(p-1 y\) 's.

\subsection*{8.7.3 Correlations Between Variables and Discriminant Functions}

Many textbooks and research papers assert that the best measure of variable importance is the correlation between each variable and a discriminant function, \(r_{y_{i} z_{j}}\). It is claimed that these correlations are more informative than standardized coefficients with respect to the joint contribution of the variables to the discriminant functions. The correlations are often referred to as loadings or structure coefficients and are routinely provided in many major programs. However, Rencher (1988; 1992b; 1998, Section 5.7) has shown that the correlations in question show the contribution of each variable in a univariate context rather than in a multivariate one. The correlations actually reproduce the \(t\) or \(F\) for each variable, and consequently they only show how each variable by itself separates the groups, ignoring the presence of the other variables. Hence these correlations provide no information about how the variables contribute jointly to separation of the groups. They become misleading if used for interpretation of discriminant functions.

Upon reflection, we could have anticipated this failure of the correlations to provide multivariate information. The objection to standardized coefficients is based on the argument that they are "unstable" because they change if some variables are deleted and others added. However, we actually want them to behave this way, so as to reflect the mutual influence of the variables on each other. In a multivariate analysis, interest is centered on the joint performance of the set of variables at hand.

To ask for the contribution of each variable independent of all other variables is to request a univariate index that ignores the other variables. The correlations \(r_{y_{i} z_{j}}\) are "stable" and do not change when variables are added or deleted; this should be a clear signal that they are univariate in nature. There is no middle ground between the univariate and multivariate realms.

\subsection*{8.7.4 Rotation}

Rotation of the discriminant function coefficients is sometimes recommended. This is a procedure (see Section 13.5) that attempts to produce a pattern with (absolute values of) coefficients closer to 0 or l. Discriminant functions with such coefficients might be easier to interpret, but they have two deficiencies: they no longer maximize group separation, and they are correlated.

Accordingly, for interpretation of discriminant functions we recommend standardized coefficients rather than correlations or rotated coefficients.

\subsection*{8.8 SCATTERPLOTS}

One benefit of the dimension reduction effected by discriminant analysis is the potential for plotting. It was noted in Section 6.2 that the number of large eigenvalues of \(\mathbf{E}^{-1} \mathbf{H}\) reflects the dimensionality of the space occupied by the mean vectors. In many data sets, the first two discriminant functions account for most of \(\lambda_{1}+\lambda_{2}+\ldots+\lambda_{s}\), and consequently the pattern of the mean vectors can be effectively portrayed in a two-dimensional plot. If the essential dimensionality is greater than 2, there may be some distortion in intergroup configuration in a two-dimensional plot; that is, some groups that overlap in two dimensions may be well separated in a third dimension.

To plot the first two discriminant functions for the individual observation vectors \(\mathbf{y}_{i j}\), simply calculate \(z_{1 i j}=\mathbf{a}_{1}^{\prime} \mathbf{y}_{i j}\) and \(z_{2 i j}=\mathbf{a}_{2}^{\prime} \mathbf{y}_{i j}\) for \(i=1,2, \ldots, k ; j=\) \(1,2, \ldots, n_{i}\), and plot a scatterplot of the \(N=\sum_{i} n_{i}\) values of
\[
\begin{equation*}
\mathbf{z}_{i j}=\binom{z_{1 i j}}{z_{2 i j}}=\binom{\mathbf{a}_{1}^{\prime} \mathbf{y}_{i j}}{\mathbf{a}_{2}^{\prime} \mathbf{y}_{i j}}=\binom{\mathbf{a}_{1}^{\prime}}{\mathbf{a}_{2}^{\prime}} \mathbf{y}_{i j}=\mathbf{A} \mathbf{y}_{i j} \tag{8.30}
\end{equation*}
\]

The transformed mean vectors,
\[
\begin{equation*}
\overline{\mathbf{z}}_{i}=\binom{\bar{z}_{1 i}}{\bar{z}_{2 i}}=\binom{\mathbf{a}_{1}^{\prime}}{\mathbf{a}_{2}^{\prime}} \overline{\mathbf{y}}_{i}=\mathbf{A} \overline{\mathbf{y}}_{i}, \quad i=1,2, \ldots, k \tag{8.31}
\end{equation*}
\]
should be plotted along with the individual values, \(\mathbf{z}_{i j}\). In some cases, a plot would show only the transformed mean vectors \(\overline{\mathbf{z}}_{1}, \overline{\mathbf{z}}_{2}, \ldots, \overline{\mathbf{z}}_{k}\). For confidence regions for \(\boldsymbol{\mu}_{z_{i}}=\mathbf{A} \boldsymbol{\mu}_{i}\), see Rencher (1998, Section 5.8).

We note that the eigenvalues of \(\mathbf{E}^{-1} \mathbf{H}\) reveal the dimensionality of the mean vectors, not of the individual points. The dimensionality of the individual observations is \(p\), although the essential dimensionality may be less because the variables are correlated. (The dimensionality of the observation vectors is the concern of principal

Figure 8.4 Scatterplot of discriminant function values for the football data of Table 8.3.
components; see Chapter 12.) If \(s=2\), for example, so that the mean vectors occupy only two dimensions, the individual observation vectors ordinarily lie in more than two-dimensions, and their inclusion in a plot constitutes a projection onto the two-dimensional plane of the mean vectors.

It was noted in Section 8.4.1 that the discriminant functions are uncorrelated but not orthogonal. Thus the angle between \(\mathbf{a}_{1}\) and \(\mathbf{a}_{2}\) as given by (3.14) is not \(90^{\circ}\) (that is, \(\mathbf{a}_{1}^{\prime} \mathbf{a}_{2} \neq 0\) ). In practice, however, the usual procedure is to plot discriminant functions on a rectangular coordinate system. The resulting distortion is generally not serious.

\section*{EXAMPLE 8.8}

Figure 8.4 contains a scatterplot of \(\left(z_{i}, z_{2}\right)\) for the observations in the football data of Table 8.3. Each observation in group 1 is denoted by a circle, observations in group 2 are denoted by triangles, and observations in group 3 are indicated by + signs. We see that the first discriminant function \(z_{1}\) (the horizontal direction) effectively separates group 1 from groups 2 and 3 , while the second discriminant function \(z_{2}\) (the vertical direction) is less successful in separating group 2 from group 3.

The group mean vectors are indicated by solid circles. They are almost collinear, as we would expect since \(\lambda_{1}=1.92\) dominates \(\lambda_{2}=.12\).

\subsection*{8.9 STEPWISE SELECTION OF VARIABLES}

In many applications, a large number of dependent variables are available and the experimenter would like to discard those that are redundant (in the presence of the other variables) for separating the groups. Our discussion is limited to procedures that delete or add variables one at a time. We emphasize that we are selecting dependent variables ( \(y\) 's) and therefore the basic model (one-way MANOVA) does not change. In subset selection in regression, on the other hand, we select independent variables, with a consequent alteration of the model.

A forward selection method was discussed in Section 6.11.2. We begin with a single variable, the one that maximally separates the groups by itself. Then the variable entered at each step is the one that maximizes the partial \(F\)-statistic based on Wilks' \(\Lambda\), thus obtainig the maximal additional separation of groups above and beyond the separation already attained by the other variables. Since we choose the variable with maximum partial \(F\) at each step, the proportion of these maximum \(F\) 's that exceed \(F_{\alpha}\) is greater than \(\alpha\). This bias is discussed in Rencher and Larson (1980) and Rencher (1998, Section 5.10).

Backward elimination is a similar operation in which we begin with all the variables and then at each step the variable that contributes least is deleted, as indicated by the partial \(F\).

Stepwise selection is a combination of the forward and backward approaches. Variables are added one at a time, and at each step the variables are reexamined to see if any variable that entered earlier has become redundant in the presence of recently added variables. The procedure stops when the largest partial \(F\) among the variables available for entry fails to exceed a preset threshold value. The stepwise procedure has long been popular with practitioners. Some detail about the steps in this procedure was given in Section 6.11.2.

All the preceding procedures are commonly referred to as stepwise discriminant analysis. However, as noted in Section 6.11.2, we are actually doing stepwise MANOVA. No discriminant functions are calculated in the selection process. After the subset selection is completed, we can calculate discriminant functions for the selected variables. We could also use the variables in a classification analysis as described in Chapter 9.

\section*{EXAMPLE 8.9}

We use the football data of Table 8.3 to illustrate the stepwise procedure outlined in this section and in Section 6.11.2. At the first step, we carry out a univariate \(F\) (using ordinary ANOVA) for each variable to determine which variable best separates the three groups by itself:
\begin{tabular}{lrl} 
Variable & \multicolumn{1}{c}{\(F\)} & \(p\)-Value \\
\hline WDIM & 2.550 & .0839 \\
CIRCUM & 6.231 & .0030 \\
FBEYE & 1.668 & .1947 \\
EYEHD & 58.162 & \(1.11 \times 10^{-16}\) \\
EARHD & 22.427 & \(1.40 \times 10^{-8}\) \\
JAW & 4.511 & .0137
\end{tabular}

Thus EYEHD is the first variable to "enter." The Wilks' \(\Lambda\) value equivalent to \(F=58.162\) is \(\Lambda\left(y_{1}\right)=.4279\) (see Table 6.1 with \(p=1\) ). At the second step we calculate a partial \(\Lambda\) and accompanying partial \(F\) using (8.27) and (8.28):
\[
\begin{aligned}
\Lambda\left(y_{r} \mid y_{1}\right) & =\frac{\Lambda\left(y_{1}, y_{r}\right)}{\Lambda\left(y_{1}\right)} \\
F & =\frac{1-\Lambda\left(y_{r} \mid y_{1}\right)}{\Lambda\left(y_{r} \mid y_{1}\right)} \frac{\nu_{E}-1}{\nu_{H}}
\end{aligned}
\]
where \(y_{1}\) indicates the variable selected at step 1 (EYEHD) and \(y_{r}\) represents each of the five variables to be examined at step 2 . The results are
\begin{tabular}{lccc} 
Variable & Partial \(\Lambda\) & Partial \(F\) & \(p\)-Value \\
\hline WDIM & .9355 & 2.964 & .0569 \\
CIRCUM & .9997 & .012 & .9881 \\
FBEYE & .9946 & .235 & .7911 \\
EARHD & .9525 & 2.143 & .1235 \\
JAW & .9540 & 2.072 & .1322
\end{tabular}

The variable WDIM would enter at this step, since it has the largest partial \(F\). With a \(p\)-value of .0569 , entering this variable may be questionable, but we will continue the procedure for illustrative purposes. We next check to see if EYEHD is still significant now that WDIM has entered. The partial \(\Lambda\) and \(F\) for EYEHD adjusted for WDIM are \(\Lambda=.424\) and \(F=58.47\). Thus EYEHD stays "in." The overall Wilks' \(\Lambda\) for EYEHD and WDIM is \(\Lambda\left(y_{1}, y_{2}\right)=.4003\).

At step 3 we check each of the four remaining variables for possible entry using
\[
\begin{aligned}
\Lambda\left(y_{r} \mid y_{1}, y_{2}\right) & =\frac{\Lambda\left(y_{1}, y_{2}, y_{r}\right)}{\Lambda\left(y_{1}, y_{2}\right)}, \\
F & =\frac{1-\Lambda\left(y_{r} \mid y_{1}, y_{2}\right)}{\Lambda\left(y_{r} \mid y_{1}, y_{2}\right)} \frac{\nu_{E}-2}{\nu_{H}},
\end{aligned}
\]
where \(y_{1}=\) EYEHD, \(y_{2}=\) WDIM, and \(y_{r}\) represents each of the other four variables. The results are
\begin{tabular}{lccc} 
Variable & Partial \(\Lambda\) & Partial \(F\) & \(p\)-Value \\
\hline CIRCUM & .9774 & .981 & .3793 \\
FBEYE & .9748 & 1.098 & .3381 \\
EARHD & .9292 & 3.239 & .0441 \\
JAW & .8451 & 7.791 & .0008
\end{tabular}

The indicated variable for entry at this step is JAW. To determine whether one of the first two variables should be removed after JAW has entered, we calculate the partial \(\Lambda\) and \(F\) for each, adjusted for the other two:
\begin{tabular}{lccc} 
Variable & Partial \(\Lambda\) & Partial \(F\) & \(p\)-Value \\
\hline WDIM & .8287 & 8.787 & .0003 \\
EYEHD & .4634 & 49.211 & \(6.33 \times 10^{-15}\)
\end{tabular}

Thus both previously entered variables remain in the model. The overall Wilks' \(\Lambda\) for EYEHD, WDIM, and JAW is \(\Lambda\left(y_{1}, y_{2}, y_{3}\right)=.3383\).

At step 4 there are three candidate variables for entry. The partial \(\Lambda\) - and \(F\)-statistics are
\[
\begin{aligned}
\Lambda\left(y_{r} \mid y_{1}, y_{2}, y_{3}\right) & =\frac{\Lambda\left(y_{1}, y_{2}, y_{3}, y_{r}\right)}{\Lambda\left(y_{1}, y_{2}, y_{3}\right)} \\
F & =\frac{1-\Lambda\left(y_{r} \mid y_{1}, y_{2}, y_{3}\right)}{\Lambda\left(y_{r} \mid y_{1}, y_{2}, y_{3}\right)} \frac{\nu_{E}-3}{\nu_{H}}
\end{aligned}
\]
where \(y_{1}, y_{2}\), and \(y_{3}\) are the three variables already entered and \(y_{r}\) represents each of the other three remaining variables. The results are
\begin{tabular}{lccc} 
Variable & Partial \(\Lambda\) & Partial \(F\) & \(p\)-Value \\
\hline CIRCUM & .9987 & .055 & .9462 \\
FBEYE & .9955 & .189 & .8282 \\
EARHD & .9080 & 4.257 & .0173
\end{tabular}

Hence EARHD enters at this step, and we check to see if any of the three previously entered variables has now become redundant. The partial \(\Lambda\) and partial \(F\) for each of these three are
\begin{tabular}{lccc} 
Variable & Partial \(\Lambda\) & Partial \(F\) & \(p\)-Value \\
\hline WDIM & .7889 & 11.237 & \(4.74 \times 10^{-15}\) \\
EYEHD & .6719 & 20.508 & \(5.59 \times 10^{-8}\) \\
JAW & .8258 & 8.861 & .0003
\end{tabular}

Consequently, all three variables are retained. The overall Wilks' \(\Lambda\) for all four variables is now \(\Lambda\left(y_{1}, y_{2}, y_{3}, y_{4}\right)=.3072\).

At step 5, the partial \(\Lambda\) - and \(F\)-values are
\begin{tabular}{lccc} 
Variable & Partial \(\Lambda\) & Partial \(F\) & \(p\)-Value \\
\hline CIRCUM & .9999 & .003 & .9971 \\
FBEYE & .9999 & .004 & .9965
\end{tabular}

Thus no more variables will enter.
We summarize the selection process as follows:
\begin{tabular}{cl|c|ccc} 
& \begin{tabular}{l} 
Variable \\
Step
\end{tabular} & Entered & Overall \(\Lambda\) & Partial \(\Lambda\) & Partial \(F\)
\end{tabular}\(\overline{p \text {-Value }}\)\begin{tabular}{cl|ccc} 
\\
\hline 1 & EYEHD & .4279 & .4279 & 58.162 \\
\(1.11 \times 10^{-16}\) \\
2 & WDIM & .4003 & .9355 & 2.964 \\
.0569 \\
3 & JAW & .3383 & .8451 & 7.791 \\
4 & EARHD & .3072 & .9080 & 4.257 \\
\hline
\end{tabular}

\section*{PROBLEMS}
8.1 Show that if \(\mathbf{a}=\mathbf{S}_{p 1}^{-1}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)\) is substituted into \(\left[\mathbf{a}^{\prime}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)\right]^{2} / \mathbf{a}^{\prime} \mathbf{S}_{\mathrm{pl}} \mathbf{a}\), the result is (8.3).
8.2 Verify (8.4) for the relationship between \(\mathbf{b}\) and \(\mathbf{a}\).
8.3 Verify the relationship between \(R^{2}\) and \(T^{2}\) shown in (8.5).
8.4 Show that \(\left[\mathbf{a}^{\prime}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)\right]^{2}=\mathbf{a}^{\prime}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)^{\prime} \mathbf{a}\) as in (8.7).
8.5 Show that \(\mathbf{H a}-\lambda \mathbf{E a}=\mathbf{0}\) can be written in the form \(\left(\mathbf{E}^{-1} \mathbf{H}-\lambda \mathbf{I}\right) \mathbf{a}=\mathbf{0}\), as in (8.12).
8.6 Verify (8.16) by substituting \(a_{r}^{*}=s_{r} a_{r}\) into (8.15) to obtain \(z_{1 i}=a_{1} y_{1 i 1}+\) \(a_{2} y_{1 i 2}+\cdots+a_{p} y_{1 i p}-\mathbf{a}^{\prime} \overline{\mathbf{y}}_{1}\).
8.7 For the psychological data in Table 5.1, the discriminant function coefficient vector was given in Example 5.5.
(a) Find the standardized coefficients.
(b) Calculate \(t\)-tests for the individual variables.
(c) Compare the results of (a) and (b) as to the contribution of the variables to separation of the two groups.
(d) Find the partial \(F\) for each variable, as in (8.26), and compare with the standardized coefficients.
8.8 Using the beetle data of Table 5.5, do the following:
(a) Find the discriminant function coefficient vector.
(b) Find the standardized coefficients.
(c) Calculate \(t\)-tests for individual variables.
(d) Compare the results of (b) and (c) as to the contribution of each variable to separation of the groups.
(e) Find the partial \(F\) for each variable, as in (8.26). Do the partial \(F\) 's rank the variables in the same order of importance as the standardized coefficients?
8.9 Using the dystrophy data of Table 5.7, do the following:
(a) Find the discriminant function coefficient vector.
(b) Find the standardized coefficients.
(c) Calculate \(t\)-tests for individual variables.
(d) Compare the results of (b) and (c) as to the contribution of each variable to separation of the groups.
(e) Find the partial \(F\) for each variable, as in (8.26). Do the partial \(F\) 's rank the variables in the same order of importance as the standardized coefficients?
8.10 For the cyclical data of Table 5.8, do the following:
(a) Find the discriminant function coefficient vector.
(b) Find the standardized coefficients.
(c) Calculate \(t\)-tests for individual variables.
(d) Compare the results of (b) and (c) as to the contribution of each variable to separation of the groups.
(e) Find the partial \(F\) for each variable, as in (8.26). Do the partial \(F\) 's rank the variables in the same order of importance as the standardized coefficients?
8.11 Using the fish data in Table 6.17, do the following:
(a) Find the eigenvectors of \(\mathbf{E}^{-1} \mathbf{H}\).
(b) Carry out tests of significance for the discriminant functions and find the relative importance of each as in (8.13), \(\lambda_{i} / \sum_{j} \lambda_{j}\). Do these two procedures agree as to the number of important discriminant functions?
(c) Find the standardized coefficients and comment on the contribution of the variables to separation of groups.
(d) Find the partial \(F\) for each variable, as in (8.28). Do they rank the variables in the same order as the standardized coefficients for the first discriminant function?
(e) Plot the first two discriminant functions for each observation and for the mean vectors.
8.12 For the rootstock data of Table 6.2, do the following:
(a) Find the eigenvalues and eigenvectors of \(\mathbf{E}^{-1} \mathbf{H}\).
(b) Carry out tests of significance for the discriminant functions and find the relative importance of each as in (8.13), \(\lambda_{i} / \sum_{j} \lambda_{j}\). Do these two procedures agree as to the number of important discriminant functions?
(c) Find the standardized coefficients and comment on the contribution of the variables to separation of groups.
(d) Find the partial \(F\) for each variable, as in (8.28). Do they rank the variables in the same order as the standardized coefficients for the first discriminant function?
(e) Plot the first two discriminant functions for each observation and for the mean vectors.
8.13 Carry out a stepwise selection of variables on the rootstock data of Table 6.2.
8.14 Carry out a stepwise selection of variables on the engineer data of Table 5.6.
8.15 Carry out a stepwise selection of variables on the fish data of Table 6.17.

\section*{CHAPTER 9}

\section*{CLASSIFICATION ANALYSIS: ALLOCATION OF OBSERVATIONS TO GROUPS}

\subsection*{9.1 INTRODUCTION}

The descriptive aspect of discriminant analysis, in which group separation is characterized by means of discriminant functions, was covered in Chapter 8 . We turn now to allocation of observations to groups, which is the predictive aspect of discriminant analysis. We prefer to call this classification analysis to clearly distinguish it from the descriptive aspect. However, classification is often referred to simply as discriminant analysis. In engineering and computer science, classification is usually called pattern recognition. Some writers use the term "classification analysis" to describe cluster analysis, in which the observations are clustered according to variable values rather than into predefined groups (see Chapter 15).

In classification, a sampling unit (subject or object) whose group membership is unknown is assigned to a group on the basis of the vector of \(p\) measured values, \(\mathbf{y}\), associated with the unit. To classify the unit, we must have available a previously obtained sample of observation vectors from each group. Then one approach is to compare \(\mathbf{y}\) with the mean vectors \(\overline{\mathbf{y}}_{1}, \overline{\mathbf{y}}_{2}, \ldots, \overline{\mathbf{y}}_{k}\) of the \(k\) samples and assign the unit to the group whose \(\overline{\mathbf{y}}_{i}\) is closest to \(\mathbf{y}\).

In this chapter, the term "groups" may refer to either the \(k\) samples or the \(k\) populations from which they were taken. It should be clear from the context which of the two uses is intended in every case.

We give some examples to illustrate the classification technique:
1. A university admissions committee wants to classify applicants as likely to succeed or likely to fail. The variables available are high school grades in various subject areas, standardized test scores, rating of high school, number of advanced placement courses, etc.
2. A psychiatrist gives a battery of diagnostic tests in order to assign a patient to the appropriate mental illness category.
3. A college student takes aptitude and interest tests in order to determine which vocational area his or her profile best matches.
4. African, or "killer," bees cannot be distinguished visually from ordinary domestic honey bees. Ten variables based on chromatograph peaks can be used to readily identify them (Lavine and Carlson 1987).
5. The Air Force wishes to classify each applicant into the training program where he or she has the most potential.
6. Twelve of the Federalist Papers were claimed by both Madison and Hamilton. Can we identify authorship by measuring frequencies of word usage (Mosteller and Wallace 1984)?
7. Variables such as availability of fingerprints, availability of eyewitnesses, and time until police arrive can be used to classify burglaries into solvable and unsolvable.
8. One approach to speech recognition by computer consists of an attempt to identify phonemes based on the energy levels in speech waves.
9. A number of variables are measured at five weather stations. Based on these variables, we wish to predict the ceiling at a particular airport in 2 hours. The ceiling categories are closed, low instrument, high instrument, low open, and high open (Lachenbruch 1975, p. 2).

\subsection*{9.2 CLASSIFICATION INTO TWO GROUPS}

In the case of two populations, we have a sampling unit (subject or object) to be classified into one of two populations. The information we have available consists of the \(p\) variables in the observation vector \(\mathbf{y}\) measured on the sampling unit. In the first illustration in Section 9.1, for example, we have an applicant with high school grades and various test scores recorded in \(\mathbf{y}\). We do not know whether the applicant will succeed or fail at the university, but we have data on previous students
at the university for whom it is now known whether they succeeded or failed. By comparing \(\mathbf{y}\) with \(\overline{\mathbf{y}}_{1}\) for those who succeeded and \(\overline{\mathbf{y}}_{2}\) for those who failed, we attempt to predict the group the applicant will eventually belong to.

When there are two populations, we can use a classification procedure due to Fisher (1936). The principal assumption for Fisher's procedure is that the two populations have the same covariance matrix. Normality is not required. We obtain a sample from each of the two populations and compute \(\overline{\mathbf{y}}_{1}, \overline{\mathbf{y}}_{2}\), and \(\mathrm{S}_{\mathrm{p} 1}\). A simple procedure for classification can be based on the discriminant function,
\[
\begin{equation*}
z=\mathbf{a}^{\prime} \mathbf{y}=\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)^{\prime} \mathbf{S}_{\mathrm{pl}}^{-1} \mathbf{y} \tag{9.1}
\end{equation*}
\]
(see Sections \(5.5,5.6,8.2\), and 8.5 ), where \(y\) is the vector of measurements on a new sampling unit that we wish to classify into one of the two groups (populations). For convenience we speak of "classifying \(\mathbf{y}\) " rather than classifying the subject or object associated with \(\mathbf{y}\).

To determine whether \(\mathbf{y}\) is closer to \(\overline{\mathbf{y}}_{1}\) or \(\overline{\mathbf{y}}_{2}\), we check to see if \(z\) in (9.1) is closer to the transformed mean \(\bar{z}_{1}\) or to \(\bar{z}_{2}\). We evaluate (9.1) for each observation \(\mathbf{y}_{1 i}\) from the first sample and obtain \(z_{11}, z_{12}, \ldots, z_{1 n_{1}}\), from which, by (3.54), \(\bar{z}_{1}=\) \(\sum_{i=1}^{n_{1}} z_{1 i} / n_{1}=\mathbf{a}^{\prime} \overline{\mathbf{y}}_{1}=\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)^{\prime} \mathbf{S}_{\mathrm{pl}}^{-1} \overline{\mathbf{y}}_{1}\). Similarly, \(\bar{z}_{2}=\mathbf{a}^{\prime} \overline{\mathbf{y}}_{2}\). Denote the two groups by \(G_{1}\) and \(G_{2}\). Fisher's (1936) linear classification procedure assigns y to \(G_{1}\) if \(z=\mathbf{a}^{\prime} \mathbf{y}\) is closer to \(\bar{z}_{1}\) than to \(\bar{z}_{2}\) and assigns \(\mathbf{y}\) to \(G_{2}\) if \(z\) is closer to \(\bar{z}_{2}\). This is illustrated in Figure 9.1.

For the configuration in Figure 9.1, we see that \(z\) is closer to \(\bar{z}_{1}\) if
\[
\begin{equation*}
z>\frac{1}{2}\left(\bar{z}_{1}+\bar{z}_{2}\right) . \tag{9.2}
\end{equation*}
\]

This is true in general because \(\bar{z}_{1}\) is always greater than \(\bar{z}_{2}\), which can easily be shown as follows:
\[
\begin{equation*}
\bar{z}_{1}-\bar{z}_{2}=\mathbf{a}^{\prime}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)=\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)^{\prime} \mathbf{S}_{\mathrm{pl}}^{-1}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)>0, \tag{9.3}
\end{equation*}
\]
because \(\mathbf{S}_{\mathrm{pl}}^{-1}\) is positive definite. Thus \(\bar{z}_{1}>\bar{z}_{2}\). [If a were of the form \(\mathbf{a}^{\prime}=\left(\overline{\mathbf{y}}_{2}-\right.\) \(\left.\overline{\mathbf{y}}_{1}\right)^{\prime} \mathbf{S}_{\mathrm{pl}}^{-1}\), then \(\bar{z}_{2}-\bar{z}_{1}\) would be positive.] Since \(\frac{1}{2}\left(\bar{z}_{1}+\bar{z}_{2}\right)\) is the midpoint, \(z>\) \(\frac{1}{2}\left(\bar{z}_{1}+\bar{z}_{2}\right)\) implies that \(z\) is closer to \(\bar{z}_{1}\). By (9.3) the distance from \(\bar{z}_{1}\) to \(\bar{z}_{2}\) is the same as that from \(\overline{\mathbf{y}}_{1}\) to \(\overline{\mathbf{y}}_{2}\).

To express the classification rule in terms of \(\mathbf{y}\), we first write \(\frac{1}{2}\left(\bar{z}_{1}+\bar{z}_{2}\right)\) in the form
\[
\begin{equation*}
\frac{1}{2}\left(\bar{z}_{1}+\bar{z}_{2}\right)=\frac{1}{2}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)^{\prime} \mathbf{S}_{\mathrm{pl}}^{-1}\left(\overline{\mathbf{y}}_{1}+\overline{\mathbf{y}}_{2}\right) . \tag{9.4}
\end{equation*}
\]

Then the classification rule becomes: Assign y to \(G_{1}\) if
\[
\begin{equation*}
\mathbf{a}^{\prime} \mathbf{y}=\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)^{\prime} \mathbf{S}_{\mathrm{pl}}^{-1} \mathbf{y}>\frac{1}{2}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)^{\prime} \mathbf{S}_{\mathrm{pl}}^{-1}\left(\overline{\mathbf{y}}_{1}+\overline{\mathbf{y}}_{2}\right), \tag{9.5}
\end{equation*}
\]
and assign \(y\) to \(G_{2}\) if
\[
\begin{equation*}
\mathbf{a}^{\prime} \mathbf{y}=\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)^{\prime} \mathbf{S}_{\mathbf{p l}}^{-1} \mathbf{y}<\frac{1}{2}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)^{\prime} \mathbf{S}_{\mathrm{pl}}^{-1}\left(\overline{\mathbf{y}}_{1}+\overline{\mathbf{y}}_{2}\right) . \tag{9.6}
\end{equation*}
\]

Figure 9.1 Fisher's procedure for classification into two groups.

This linear classification rule employs the same discriminant function \(z=\mathbf{a}^{\prime} \mathbf{y}\) used in Section 8.2 in connection with descriptive separation of groups. Thus in the two-group case the discriminant function serves as a linear classification function as well. However, in the several-group case in Section 9.3, we use classification functions that are different from the descriptive discriminant functions in Section 8.4.

Fisher's (1936) approach using (9.5) and (9.6) is essentially nonparametric because no distributional assumptions were made. However, if the two populations are normal with equal covariance matrices, then this method is (asymptotically) optimal; that is, the probability of misclassification is minimized [see comments following (9.9)].

If prior probabilities \(p_{1}\) and \(p_{2}\) are known for the two populations, the classification rule can be modified to exploit this additional information. We define the prior probabilities as follows: \(p_{1}\) is the proportion of observations in \(G_{1}\) and \(p_{2}\) is the proportion in \(G_{2}\), where \(p_{2}=1-p_{1}\). For example, suppose that at a certain university \(70 \%\) of entering freshmen ultimately graduate. Then \(p_{1}=.7\) and \(p_{2}=.3\).

If relative costs of misclassification are known for the two populations, the classification rule can be further modified. Let \(c_{12}\) be the cost of misclassifying an observation from group \(G_{1}\) into group \(G_{2}\), and let \(c_{21}\) be the cost of misclassifying an observation from group \(G_{2}\) into group \(G_{1}\). In practice, all we need to know is the relative costs. For example, it would only be necessary for us to know that \(c_{21}\) is twice the value of \(c_{12}\) (i.e., \(c_{21} / c_{12}=2\) ).

In order to use the prior probabilities and misclassification costs, the density functions for the two populations, \(f\left(\mathbf{y} \mid G_{1}\right)\) and \(f\left(\mathbf{y} \mid G_{2}\right)\), must also be known. Then the
optimal classification rule (Welch 1939) that minimizes the cost of misclassification is: Assign \(y\) to \(G_{1}\) if
\[
\begin{equation*}
p_{1} c_{12} f\left(\mathbf{y} \mid G_{1}\right)>c_{21} p_{2} f\left(\mathbf{y} \mid G_{2}\right) \tag{9.7}
\end{equation*}
\]
and to \(G_{2}\) otherwise. If misclassification costs are unknown or equal, we can say that the rule assigning \(\mathbf{y}\) to \(G_{1}\) when
\[
\begin{equation*}
p_{1} f\left(\mathbf{y} \mid G_{1}\right)>p_{2} f\left(\mathbf{y} \mid G_{2}\right) \tag{9.8}
\end{equation*}
\]
will minimize the probability of misclassification. Note that \(f\left(\mathbf{y} \mid G_{1}\right)\) is a convenient notation for the density when sampling from the population represented by \(G_{1}\). It does not represent a conditional distribution in the usual sense (Section 4.2).

Assuming that the two densities are multivariate normal with equal covariance matrices, namely, \(f\left(\mathbf{y} \mid G_{1}\right)=N_{p}\left(\boldsymbol{\mu}_{1}, \boldsymbol{\Sigma}\right)\) and \(f\left(\mathbf{y} \mid G_{2}\right)=N_{p}\left(\boldsymbol{\mu}_{2}, \boldsymbol{\Sigma}\right)\), then from (9.7) we obtain the following rule (with estimates in place of \(\boldsymbol{\mu}_{1}, \boldsymbol{\mu}_{2}\), and \(\boldsymbol{\Sigma}\) ): Assign y to \(G_{1}\) if
\[
\begin{equation*}
\mathbf{a}^{\prime} \mathbf{y}=\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)^{\prime} \mathbf{S}_{\mathrm{pl}}^{-1} \mathbf{y}>\frac{1}{2}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)^{\prime} \mathbf{S}_{\mathrm{pl}}^{-1}\left(\overline{\mathbf{y}}_{1}+\overline{\mathbf{y}}_{2}\right)+\ln \left(\frac{p_{2} c_{21}}{p_{1} c_{12}}\right) \tag{9.9}
\end{equation*}
\]
and to \(G_{2}\) otherwise [see Rencher (1998, p. 231)]. Because we have substituted estimates for the parameters, the rule in (9.9) is no longer optimal as is (9.7). However, it is asymptotically optimal (approaches optimality as the sample size increases).

If \(p_{1}=p_{2}\) and \(c_{12}=c_{21}\), the normal-based classification rule in (9.9) becomes the same as Fisher's procedure given in (9.5) and (9.6). Thus Fisher's rule, which is not based on a normality assumption, has optimal properties when the data come from multivariate normal populations with \(\boldsymbol{\Sigma}_{1}=\boldsymbol{\Sigma}_{2}, p_{1}=p_{2}\), and \(c_{12}=c_{21}\). [For the case when \(\boldsymbol{\Sigma}_{1} \neq \boldsymbol{\Sigma}_{2}\), see Rencher (1998, Section 6.2.2).] Hence, even though Fisher's method is nonparametric, it works better for normally distributed populations or other populations with linear trends. For example, suppose two populations have \(95 \%\) contours, as in Figure 9.2. If the points are projected in any direction onto a straight line, there will be almost total overlap. A linear discriminant procedure will not successfully separate the two populations.

\section*{EXAMPLE 9.2}

For the psychological data of Table 5.1, \(\overline{\mathbf{y}}_{1}, \overline{\mathbf{y}}_{2}\), and \(\mathbf{S}_{\mathrm{pl}}\) were obtained in Example 5.4.2. The discriminant function coefficients were obtained in Example 5.5 as \(\mathbf{a}^{\prime}=(.5104,-.2032, .4660,-.3097)\). For \(G_{1}\) (the male group), we find
\[
\begin{aligned}
\bar{z}_{1} & =\mathbf{a}^{\prime} \overline{\mathbf{y}}_{1}=.5104(15.97)-.2032(15.91)+.4660(27.19)-.3097(22.75) \\
& =10.5427 .
\end{aligned}
\]

Similarly, for \(G_{2}\) (the female group), \(\bar{z}_{2}=\mathbf{a}^{\prime} \overline{\mathbf{y}}_{2}=4.4426\). Thus we assign an observation vector y to \(G_{1}\) if
\[
z=\mathbf{a}^{\prime} \mathbf{y}>\frac{1}{2}\left(\bar{z}_{1}+\bar{z}_{2}\right)=7.4927
\]

Figure 9.2 Two populations with nonlinear separation.
and assign \(\mathbf{y}\) to \(G_{2}\) if \(z<7.4927\).
There are no new observations available, so we will illustrate the procedure by classifying two of the observations in \(G_{1}\). For \(\mathbf{y}_{11}^{\prime}=(15,17,24,14)\), the first observation in \(G_{1}\), we have \(z_{11}=\mathbf{a}^{\prime} \mathbf{y}_{11}=.5104(15)-.2032(17)+\) \(.4660(24)-.3097(14)=11.0498\), which is greater than 7.4927 , and \(y_{11}\) would be correctly classified as belonging to \(G_{1}\). For \(\mathbf{y}_{14}^{\prime}=(13,12,10,16)\), the fourth observation in \(G_{1}\), we find \(z_{14}=3.9016\), which would misclassify \(\mathbf{y}_{14}\) into \(G_{2}\).

\subsection*{9.3 CLASSIFICATION INTO SEVERAL GROUPS}

In this section we discuss classification rules for several groups. As in the two-group case, we use a sample from each of the \(k\) groups to find the sample mean vectors \(\overline{\mathbf{y}}_{1}, \overline{\mathbf{y}}_{2}, \ldots, \overline{\mathbf{y}}_{k}\). For a vector \(\mathbf{y}\) whose group membership is unknown, one approach is to use a distance function to find the mean vector that \(y\) is closest to and assign \(y\) to the corresponding group.

Note that for the \(k\)-group case with \(k>2\), incorporating misclassification costs into classification rules becomes complicated because there are \(k(k-1)\) different costs to consider. Hence, we assume equal misclassification costs for the discussion in this section.

\subsection*{9.3.1 Equal Population Covariance Matrices: Linear Classification Functions}

In this section we assume \(\boldsymbol{\Sigma}_{1}=\boldsymbol{\Sigma}_{2}=\cdots=\boldsymbol{\Sigma}_{k}\). We can estimate the common population covariance matrix by a pooled sample covariance matrix
\[
\mathbf{S}_{\mathrm{pl}}=\frac{1}{N-k} \sum_{i=1}^{k}\left(n_{i}-1\right) \mathbf{S}_{i}=\frac{\mathbf{E}}{N-k},
\]
where \(n_{i}\) and \(\mathbf{S}_{i}\) are the sample size and covariance matrix of the \(i\) th group, \(\mathbf{E}\) is the error matrix from one-way MANOVA, and \(N=\sum_{i} n_{i}\). We compare y to each \(\overline{\mathbf{y}}_{i}, i=1,2, \ldots, k\), by the distance function
\[
\begin{equation*}
D_{i}^{2}(\mathbf{y})=\left(\mathbf{y}-\overline{\mathbf{y}}_{i}\right)^{\prime} \mathbf{S}_{\mathrm{pl}}^{-1}\left(\mathbf{y}-\overline{\mathbf{y}}_{i}\right) \tag{9.10}
\end{equation*}
\]
and assign \(y\) to the group for which \(D_{i}^{2}(\mathbf{y})\) is smallest.
We can obtain a linear classification rule by expanding (9.10):
\[
\begin{aligned}
D_{i}^{2}(\mathbf{y}) & =\mathbf{y}^{\prime} \mathbf{S}_{\mathrm{pl}}^{-1} \mathbf{y}-\mathbf{y}^{\prime} \mathbf{S}_{\mathrm{pl}}^{-1} \overline{\mathbf{y}}_{i}-\overline{\mathbf{y}}_{i}^{\prime} \mathbf{S}_{\mathrm{pl}}^{-1} \mathbf{y}+\overline{\mathbf{y}}_{i}^{\prime} \mathbf{S}_{\mathrm{pl}}^{-1} \overline{\mathbf{y}}_{i} \\
& =\mathbf{y}^{\prime} \mathbf{S}_{\mathrm{pl}}^{-1} \mathbf{y}-2 \overline{\mathbf{y}}_{i}^{\prime} \mathbf{S}_{\mathrm{pl}}^{-1} \mathbf{y}+\overline{\mathbf{y}}_{i}^{\prime} \mathbf{S}_{\mathrm{pl}}^{-1} \overline{\mathbf{y}}_{i} .
\end{aligned}
\]

The term \(\mathbf{y}^{\prime} \mathbf{S}_{\mathrm{pl}}^{-1} \mathbf{y}\) on the right can be neglected since it is not a function of \(i\) and, consequently, does not change from group to group. The second term is a linear function of \(\mathbf{y}\), and the third does not involve \(\mathbf{y}\). We thus delete \(\mathbf{y}^{\prime} \mathbf{S}_{\mathrm{pl}}^{-1} \mathbf{y}\) and obtain a linear classification function, which we denote by \(L_{i}(\mathbf{y})\). If we multiply by \(-\frac{1}{2}\) so as to agree with the rule based on the normal distribution and prior probabilities given in (9.13) below, our linear classification rule becomes: Assign y to the group for which
\[
\begin{equation*}
L_{i}(\mathbf{y})=\overline{\mathbf{y}}_{i}^{\prime} \mathbf{S}_{\mathrm{pl}}^{-1} \mathbf{y}-\frac{1}{2} \overline{\mathbf{y}}_{i}^{\prime} \mathbf{S}_{\mathrm{pl}}^{-1} \overline{\mathbf{y}}_{i}, \quad i=1,2, \ldots, k \tag{9.11}
\end{equation*}
\]
is a maximum (we reversed the sign when multiplying by \(-\frac{1}{2}\) ). To highlight the linearity of (9.11) as a function of \(y\), we can express it as
\[
L_{i}(\mathbf{y})=\mathbf{c}_{i}^{\prime} \mathbf{y}+c_{i 0}=c_{i 1} y_{1}+c_{i 2} y_{2}+\cdots+c_{i p} y_{p}+c_{i 0}
\]
where \(\mathbf{c}_{i}^{\prime}=\overline{\mathbf{y}}_{i}^{\prime} \mathbf{S}_{\mathrm{pl}}^{-1}\) and \(c_{i 0}=-\frac{1}{2} \overline{\mathbf{y}}_{i}^{\prime} \mathbf{S}_{\mathrm{pl}}^{-1} \overline{\mathbf{y}}_{i}\). To assign \(\mathbf{y}\) to a group using this procedure, we calculate \(\mathbf{c}_{i}\) and \(c_{i 0}\) for each of the \(k\) groups, evaluate \(L_{i}(\mathbf{y}), i=\) \(1,2, \ldots, k\), and allocate \(\mathbf{y}\) to the group for which \(L_{i}(\mathbf{y})\) is largest. This will be the same group for which \(D_{i}^{2}(\mathbf{y})\) in (9.10) is smallest, that is, the group whose mean vector \(\overline{\mathbf{y}}_{i}\) is closest to \(\mathbf{y}\).

For the case of several groups, the optimal rule in (9.8) extends to:
Assign \(\mathbf{y}\) to the group for which \(p_{i} f\left(\mathbf{y} \mid G_{i}\right)\) is maximum.
With this rule, the probability of misclassification is minimized. If we assume normality with equal covariance matrices and with prior probabilities of group membership, \(p_{1}, p_{2}, \ldots, p_{k}\), then \(f\left(\mathbf{y} \mid G_{i}\right)=N_{p}\left(\boldsymbol{\mu}_{i}, \boldsymbol{\Sigma}\right)\), and the rule in (9.12) becomes
(with estimates in place of parameters): Calculate
\[
\begin{equation*}
L_{i}^{\prime}(\mathbf{y})=\ln p_{i}+\overline{\mathbf{y}}_{i}^{\prime} \mathbf{S}_{\mathrm{pl}}^{-1} \mathbf{y}-\frac{1}{2} \overline{\mathbf{y}}_{i}^{\prime} \mathbf{S}_{\mathrm{pl}}^{-1} \overline{\mathbf{y}}_{i}, \quad i=1,2, \ldots, k \tag{9.13}
\end{equation*}
\]
and assign \(\mathbf{y}\) to the group with maximum value of \(L_{i}^{\prime}(\mathbf{y})\). Note that if \(p_{1}=p_{2}=\) \(\cdots=p_{k}\), then (9.13), which optimizes the classification rate for the normal distribution, reduces to ( 9.11 ), which was based on the heuristic approach of minimizing the distance of \(\mathbf{y}\) to \(\overline{\mathbf{y}}_{i}\).

The linear functions \(L_{i}(\mathbf{y})\) defined in (9.11) are called linear classification functions (many writers refer to them as linear discriminant functions). They are different from the linear discriminant functions in Sections 6.1.4, 6.4, and 8.4.1, whose coefficients are eigenvectors of \(\mathbf{E}^{-1} \mathbf{H}\). In fact, there will be \(k\) classification functions and \(s=\min (p, k-1)\) discriminant functions, where \(k\) is the number of groups and \(p\) is the number of variables. In many cases we do not need all \(s\) discriminant functions to effectively describe group differences, whereas all \(k\) classification functions must be used in assigning observations to groups.

\section*{■ EXAMPLE 9.3.1}

For the football data of Table 8.3, the mean vectors for the three groups are as follows:
\[
\begin{aligned}
& \overline{\mathbf{y}}_{1}^{\prime}=(15.2,58.9,20.1,13.1,14.7,12.3) \\
& \overline{\mathbf{y}}_{2}^{\prime}=(15.4,57.4,19.8,10.1,13.5,11.9), \\
& \overline{\mathbf{y}}_{3}^{\prime}=(15.6,57.8,19.8,10.9,13.7,11.8)
\end{aligned}
\]

Using these values of \(\overline{\mathbf{y}}_{i}\) and the pooled covariance matrix \(\mathbf{S}_{\mathrm{pl}}\), given in Example 8.5, the linear classification functions (9.11) become
\[
\begin{aligned}
& L_{1}(\mathbf{y})=7.6 y_{1}+13.3 y_{2}+4.2 y_{3}-1.2 y_{4}+14.6 y_{5}+8.2 y_{6}-641.1 \\
& L_{2}(\mathbf{y})=10.2 y_{1}+13.3 y_{2}+4.2 y_{3}-3.4 y_{4}+13.2 y_{5}+6.1 y_{6}-608.0 \\
& L_{3}(\mathbf{y})=10.9 y_{1}+13.3 y_{2}+4.1 y_{3}-2.7 y_{4}+13.1 y_{5}+5.2 y_{6}-614.6
\end{aligned}
\]

We note that \(y_{2}\) and \(y_{3}\) have essentially the same coefficients in all three functions and hence do not contribute to classification of \(\mathbf{y}\). These same two variables were eliminated in the stepwise discriminant analysis in Example 8.9.

We illustrate the use of these linear functions for the first and third observations in group 1. For the first observation, \(\mathbf{y}_{11}\), we obtain
\[
\begin{aligned}
L_{1}\left(\mathbf{y}_{11}\right)= & 7.6(13.5)+13.3(57.2)+4.2(19.5)-1.2(12.5)+14.6(14.0) \\
& +8.2(11.0)-641.1=582.124, \\
L_{2}\left(\mathbf{y}_{11}\right)= & 10.2(13.5)+13.3(57.2)+4.2(19.5)-3.4(12.5)+13.2(14.0) \\
& +6.1(11.0)-608.0=578.099 \\
L_{3}\left(\mathbf{y}_{11}\right)= & 10.9(13.5)+13.3(57.2)+4.1(19.5)-2.7(12.5)+13.1(14.0) \\
& +5.2(11.0)-614.6=578.760 .
\end{aligned}
\]

We classify \(\mathbf{y}_{11}\) into group 1 since \(L_{1}\left(\mathbf{y}_{11}\right)=582.1\) exceeds \(L_{2}\left(\mathbf{y}_{11}\right)\) and \(L_{3}\left(\mathbf{y}_{11}\right)\).

For the third observation in group \(1, \mathbf{y}_{13}\), we obtain
\[
L_{1}\left(\mathbf{y}_{13}\right)=567.054, \quad L_{2}\left(\mathbf{y}_{13}\right)=570.290, \quad L_{3}\left(\mathbf{y}_{13}\right)=569.137
\]

This observation is misclassified into group 2 since \(L_{2}\left(\mathbf{y}_{13}\right)=570.290\) exceeds \(L_{1}\left(\mathbf{y}_{13}\right)\) and \(L_{3}\left(\mathbf{y}_{13}\right)\).

\subsection*{9.3.2 Unequal Population Covariance Matrices: Quadratic Classification Functions}

The linear classification functions in Section 9.3.1 are based on the assumption \(\boldsymbol{\Sigma}_{1}=\) \(\boldsymbol{\Sigma}_{2}=\cdots=\boldsymbol{\Sigma}_{k}\). The resulting classification rules are sensitive to heterogeneity of covariance matrices. Observations tend to be classified too frequently into groups whose covariance matrices have smaller variances on the diagonal.

As an example, consider a simple case with one \(y\) and two groups, where group \(G_{1}\) has a normal distribution with a mean of -1 with a large standard deviation ( \(\sigma_{1}=2\) ) and group \(G_{2}\) has a normal distribution with a mean of 5 with a small standard deviation ( \(\sigma_{2}=0.8\) ). The proper decision rule would utilize both the means and the standard deviations for the groups, assigning a new observation \(y\) to group \(G_{1}\) if \(y<3.05\) and to group \(G_{2}\) otherwise, where the cutoff at \(y=3.05\) corresponds to the location where \(f_{1}\left(y \mid G_{1}\right)=f_{2}\left(y \mid G_{2}\right)\).

Figure 9.3 shows the distributions for the groups and illustrates the pitfall of erroneously assuming equality of covariance matrices in classification analysis. As illustrated by the hatched areas in Figure 9.3, when using the proper cutoff of roughly \(y=3.05\), about \(2.1 \%\) of the observations from group \(G_{1}\) will be misclassified with group \(G_{2}\) and \(0.7 \%\) of the observations from group \(G_{2}\) will be misclassified with group \(G_{1}\). However, if the classification rules are calculated when erroneously assuming that the variances for the two groups are equal, the decision rule would assign a new observation to \(G_{1}\) if \(y<2\) and to group \(G_{2}\) otherwise, where the cutoff at \(y=2\) corresponds to the midpoint between the two group means. Figure 9.3 illustrates that this erroneous rule would result in \(6.7 \%\) of the observations from group \(G_{1}\) being misclassified with group \(G_{2}\) and \(<0.1 \%\) of the observations from group \(G_{2}\) being misclassified with group \(G_{1}\). Thus, erroneously assuming equality for the population covariance matrices will often result in classification rules that perform relatively poorly.

If \(\boldsymbol{\Sigma}_{1}=\boldsymbol{\Sigma}_{2}=\cdots=\boldsymbol{\Sigma}_{k}\) does not hold, the classification rules can easily be altered to preserve optimality of classification rates. In place of (9.10), we can use
\[
\begin{equation*}
D_{i}^{2}(\mathbf{y})=\left(\mathbf{y}-\overline{\mathbf{y}}_{i}\right)^{\prime} \mathbf{S}_{i}^{-1}\left(\mathbf{y}-\overline{\mathbf{y}}_{i}\right), i=1,2, \ldots, k \tag{9.14}
\end{equation*}
\]
where \(\mathbf{S}_{i}\) is the sample covariance matrix for the \(i\) th group. As before, we would assign \(\mathbf{y}\) to the group for which \(D_{i}^{2}(\mathbf{y})\) is smallest. With \(\mathbf{S}_{i}\) in place of \(\mathbf{S}_{\mathrm{pl}}\), (9.14) cannot be reduced to a linear function of \(y\) as in (9.11) but remains a quadratic function. Hence rules based on \(\mathbf{S}_{i}\) are called quadratic classification rules.

Figure 9.3 Misclassification rates when correctly assuming variances are unequal (hatched area) and when incorrectly assuming variances are equal (gray area).

If we assume normality with unequal covariance matrices and with prior probabilities \(p_{1}, p_{2}, \ldots, p_{k}\), then \(f\left(\mathbf{y} \mid G_{i}\right)=N_{p}\left(\boldsymbol{\mu}_{i}, \boldsymbol{\Sigma}_{i}\right)\), and the optimal rule in (9.12) based on \(p_{i} f\left(\mathbf{y} \mid G_{i}\right)\) becomes: Assign \(\mathbf{y}\) to the group for which
\[
\begin{equation*}
Q_{i}(\mathbf{y})=\ln p_{i}-\frac{1}{2} \ln \left|\mathbf{S}_{i}\right|-\frac{1}{2}\left(\mathbf{y}-\overline{\mathbf{y}}_{i}\right)^{\prime} \mathbf{S}_{i}^{-1}\left(\mathbf{y}-\overline{\mathbf{y}}_{i}\right) \tag{9.15}
\end{equation*}
\]
is maximum. If \(p_{1}=p_{2}=\cdots=p_{k}\) or if the \(p_{i}\) 's are unknown, the term \(\ln p_{i}\) is deleted.

In order to use a quadratic classification rule based on \(\mathbf{S}_{i}\), each \(n_{i}\) must be greater than \(p\) so that \(\mathbf{S}_{i}^{-1}\) will exist. This restriction does not apply to linear classification rules based on \(\mathbf{S}_{\mathrm{pl}}\). Since more parameters are estimated with quadratic classification functions, larger values of the \(n_{i}\) 's are needed for stability of estimates. Note the distinction between \(p\), the number of variables, and \(p_{i}\), the prior probability for the \(i\) th group.

\subsection*{9.4 ESTIMATING MISCLASSIFICATION RATES}

In Chapter 8, we assessed the effectiveness of the discriminant functions in group separation by the use of significance tests or by examining \(\lambda_{i} / \sum_{j} \lambda_{j}\). To judge the ability of classification procedures to predict group membership, we usually use the probability of misclassification, which is known as the error rate. We could also use its complement, the correct classification rate.

A simple estimate of the error rate can be obtained by trying out the classification procedure on the same data set that has been used to compute the classification
functions. This method is commonly referred to as resubstitution. Each observation vector \(\mathbf{y}_{i j}\) is submitted to the classification functions and assigned to a group. We then count the number of correct classifications and the number of misclassifications. The proportion of misclassifications resulting from resubstitution is called the apparent error rate. The results can be conveniently displayed in a classification table or confusion matrix, such as Table 9.1 for two groups.

Among the \(n_{1}\) observations in \(G_{1}, n_{11}\) are correctly classified into \(G_{1}\) and \(n_{12}\) are misclassified into \(G_{2}\), where \(n_{1}=n_{11}+n_{12}\). Similarly, of the \(n_{2}\) observations in \(G_{2}, n_{21}\) are misclassified into \(G_{1}\) and \(n_{22}\) are correctly classified into \(G_{2}\), where \(n_{2}=n_{21}+n_{22}\). Thus
\[
\begin{align*}
\text { Apparent error rate } & =\frac{n_{12}+n_{21}}{n_{1}+n_{2}} \\
& =\frac{n_{12}+n_{21}}{n_{11}+n_{12}+n_{21}+n_{22}} . \tag{9.16}
\end{align*}
\]

Similarly, we can define
\[
\begin{equation*}
\text { Apparent correct classification rate }=\frac{n_{11}+n_{22}}{n_{1}+n_{2}} . \tag{9.17}
\end{equation*}
\]

Clearly,
\[
\text { Apparent error rate }=1-\text { apparent correct classification rate. }
\]

The method of resubstitution can be readily extended to the case of several groups.
The apparent error rate is easily obtained and is routinely provided by most classification software programs. It is an estimate of the probability that our classification functions based on the present sample will misclassify a future observation. This probability is called the actual error rate. Unfortunately, the apparent error rate underestimates the actual error rate because the data set used to compute the classification functions is also used to evaluate them. The classification functions are optimized for the particular sample and may be capitalizing on chance to some degree, especially for small samples. For other estimates of error rates, see Rencher (1998, Section 6.4). In Section 9.5 we consider some approaches to reducing the bias in the apparent error rate.

\end{tabular} Female 0

\section*{- EXAMPLE 9.4(a)}

We use the psychological data of Table 5.1 to illustrate the apparent error rate obtained by the resubstitution method for two groups. The hypothesis \(H_{0}: \boldsymbol{\Sigma}_{1}=\boldsymbol{\Sigma}_{2}\) was not rejected in Example 7.3.2, and we therefore classify each of the 64 observations using the linear classification procedure obtained in Example 9.2: Classify as \(G_{1}\) if \(\mathbf{a}^{\prime} \mathbf{y}>7.4927\) and as \(G_{2}\) otherwise. The resulting classification table is given in Table 9.2. By (9.16),
\[
\text { Apparent error rate }=\frac{n_{12}+n_{21}}{n_{1}+n_{2}}=\frac{4+4}{32+32}=.125 .
\]

\section*{EXAMPLE 9.4(b)}

We use the football data of Table 8.3 to illustrate the use of the resubstitution method for estimating the error rate in the case of more than two groups. The sample covariance matrices for the three groups are almost significantly different, and we will use both linear and quadratic classification functions.

The linear classification functions \(L_{i}(\mathbf{y})\) from (9.11) were given in Example 9.3.1 for the football data. Using these, we classify each of the 90 observations. The results are shown in Table 9.3.

An examination of this data set in Example 8.8 showed that groups 2 and 3 are harder to separate than 1 and 2 or 1 and 3 . This pattern is reflected here in the misclassifications. Only 4 of the observation vectors in group 1 are misclassified, while 10 observations in each of groups 2 and 3 are misclassified.

Using the quadratic classification functions \(Q_{i}(\mathbf{y}), i=1,2,3\), in (9.15) and assuming \(p_{1}=p_{2}=p_{3}\), we obtain the classification results in Table 9.4. There is some improvement in the apparent error rate using quadratic classification functions.

\subsection*{9.5 IMPROVED ESTIMATES OF ERROR RATES}

For large samples, the apparent error rate has only a small amount of bias for estimating the actual error rate and can be used with little concern. For small samples,

Table 9.3 Classification Table for the Football Data of Table 8.3 Using Linear Classification Functions
\begin{tabular}{|c|c|c|c|c|}
\hline \multirow[b]{2}{*}{Actual Group} & \multirow[b]{2}{*}{Number of Observations} & \multicolumn{3}{|c|}{Predicted Group} \\

2 & 30 & 2 & 21 & 7 \\
3 & 30 & 1 & 4 & 25 \\
\hline \multicolumn{4}{c}{ Apparent correct classification rate \(=\)} & \(\frac{27+21+25}{90}=.811\) \\
\multicolumn{4}{c}{ Apparent error rate \(=1\)} & \(-.811=.189\)
\end{tabular}
however, it is overly optimistic (biased downward), as noted above. We discuss two techniques for reducing the bias in the apparent error rate, that is, increasing the apparent error rate to a more realistic level.

\subsection*{9.5.1 Partitioning the Sample}

One way to avoid bias is to split the sample into two parts, a training sample used to construct the classification rule and a validation sample used to evaluate it. With the training sample, we calculate linear or quadratic classification functions. We then submit each observation vector in the validation sample to the classification functions obtained from the training sample. Since these observations are not used in calculating the classification functions, the resulting error rate is unbiased. To increase the information gained, we could also reverse the roles of the two samples so that the classification functions are obtained from the validation sample and evaluated on the training sample. The two estimates of error could then be averaged.

Partitioning the sample has at least two disadvantages:
1. It requires large samples that may not be available.
2. It does not evaluate the classification function we will use in practice. The estimate of error based on half the sample may vary considerably from that based on the entire sample. We prefer to use all or almost all of the data to construct the classification functions so as to minimize the variance of our error rate estimate.

\subsection*{9.5.2 Holdout Method}

The holdout method is an improved version of the sample splitting procedure in Section 9.5.1. In the holdout procedure, all but one observation is used to compute the classification rule, and this rule is then used to classify the omitted observation. We repeat this procedure for each observation, so that, in a sample of size \(N=\sum_{i} n_{i}\), each observation is classified by a function based on the other \(N-1\) observations. The computation load is increased because \(N\) distinct classification procedures have to be constructed. The holdout procedure is also referred to as the leaving-one-out method or as cross-validation. Note that this procedure is used to estimate error rates. The actual classification rule for future observations would be based on all \(N\) observations.

\section*{- EXAMPLE 9.5.2}

We use the football data of Table 8.3 to illustrate the holdout method for estimating the error rate. Each of the 90 observations is classified by linear classification functions based on the other 89 observations. To begin the procedure, the first observation in group \(1\left(\mathbf{y}_{11}\right)\) is held out and the linear classification functions \(L_{i}(\mathbf{y}), i=1,2,3\), in (9.11) are calculated using the remaining 29 observations in group 1 and the 60 observations in groups 2 and 3. The observation \(\mathbf{y}_{11}\) is now classified using \(L_{1}(\mathbf{y}), L_{2}(\mathbf{y})\), and \(L_{3}(\mathbf{y})\). Then \(\mathbf{y}_{11}\) is reinserted in group 1 , and \(\mathbf{y}_{12}\) is held out. The functions \(L_{1}(\mathbf{y}), L_{2}(\mathbf{y})\), and \(L_{3}(\mathbf{y})\) are recomputed and \(\mathbf{y}_{12}\) is then classified. This procedure is followed for each of the 90 observations, and the results are in Table 9.5.

As expected, the holdout error rate has increased somewhat from the apparent error rate based on resubstitution in Tables 9.3 and 9.4 in Example 9.4(b). An error rate of .300 is a less optimistic (more realistic) estimate of what the classification functions can do with future samples.

\subsection*{9.6 SUBSET SELECTION}

The experimenter often has available a large number of variables and wishes to keep any that might aid in predicting group membership, but at the same time to delete any superfluous variables that do not contribute to allocation. A reduction in the number of redundant variables may in fact lead to improved error rates. As an additional con-

Table 9.5 Classification Table for the Football Data of Table 8.3 Using the Holdout Method Based on Linear Classification Functions
\begin{tabular}{ccccr}
\hline & & \multicolumn{3}{c}{ Predicted Group } \\
\cline { 3 - 5 } \begin{tabular}{c}

\text { Correct classification rate }=\frac{26+18+19}{90}=.700 \\
\text { Error rate }=1-.700=.300
\end{gathered}
\]
sideration, there is an increase in robustness to nonnormality of linear and quadratic classification functions as \(p\) (the number of variables) decreases.

The majority of selection schemes for classification analysis are based on stepwise discriminant analysis or a similar approach (Section 8.9). One finds the subset of variables that best separates groups using Wilks' \(\Lambda\), for example, and then uses these variables to construct classification functions. Most of the major statistical software packages offer this method. When the "best" subset is selected in this way, an optimistic bias in error rates is introduced. For a discussion of this bias, see Rencher (1992a; 1998, Section 6.7).

Another link between separation and classification is the use of error rates in an informal stopping rule in a stepwise discriminant analysis. Thus, for example, if a subset of 5 variables out of 10 gives a misclassification rate of \(33 \%\) compared to \(30 \%\) for the full set of variables, we may decide that the 5 variables are adequate for separating the groups. We could try several subsets of decreasing sizes to see when the error rate begins to escalate noticeably.

\section*{■ EXAMPLE 9.6(a)}

In Example 8.9, a stepwise discriminant analysis based on a partial Wilks' \(\Lambda\) (or partial \(F\) ) was carried out for the football data of Table 8.3. Four variables were selected: EYEHD, WDIM, JAW, and EARHD. These same four variables are indicated by the coefficients in the linear classification functions in Example 9.3.1. We now use these four variables to classify the observations using the method of resubstitution to obtain the apparent error rate.

The linear classification functions (9.11) are
\[
\begin{array}{rlrl}
\text { Group 1 } & L_{1}(\mathbf{y}) & =\overline{\mathbf{y}}_{1}^{\prime} \mathbf{S}_{\mathrm{pl}}^{-1} \mathbf{y}-\frac{1}{2} \overline{\mathbf{y}}_{1}^{\prime} \mathbf{S}_{\mathrm{pl}}^{-1} \overline{\mathbf{y}}_{1} \\
& & =18.67 y_{1}+4.13 y_{2}+17.67 y_{3}+20.44 y_{4}-425.50, \\
& \text { Group 2 } & L_{2}(\mathbf{y}) & =21.13 y_{1}+1.96 y_{2}+16.24 y_{3}+18.36 y_{4}-392.75, \\
\text { Group 3 } & L_{3}(\mathbf{y}) & =21.87 y_{1}+2.67 y_{2}+16.13 y_{3}+17.46 y_{4}-399.63 .
\end{array}
\]

Table 9.6 Classification Table for the Football Data of Table 8.3 Using Linear Classification Functions Based on Four Variables Chosen by Stepwise Selection
\begin{tabular}{ccrrr}
\hline & & \multicolumn{3}{c}{ Predicted Group } \\
\cline { 3 - 5 } \begin{tabular}{lc} 
Actual \\
Group
\end{tabular} & \begin{tabular}{c} 
Number of \\
Observations
\end{tabular} & \multicolumn{1}{c}{1} & 2 & 3 \\
\hline 1 & 30 & 26 & 1 & 3 \\
2 & 30 & 1 & 20 & 9 \\
3 & 30 & 2 & 8 & 20 \\
\hline
\end{tabular}
\[
\begin{gathered}
\text { Correct classification rate }=\frac{26+20+20}{90}=.733 \\
\text { Error rate }=1-.733=.267
\end{gathered}
\]

When each observation vector is classified using these linear functions, we obtain the classification results in Table 9.6.

Table 9.6 is identical to Table 9.3 in Example 9.4(b) where all six variables were used. Thus the four selected variables can classify the sample as well as all six variables classify it.

\section*{EXAMPLE 9.6(b)}

We illustrate the use of error rates as an informal stopping rule in a stepwise discriminant analysis. Fifteen teacher and pupil behaviors were observed during 5-minute intervals of reading instruction in elementary school classrooms (Rencher, Wadham, and Young 1978). The observations were recorded in rate of occurrences per minute for each variable. The variables were the following:

\section*{Teacher Behaviors}
1. Explains-Explains the task to learner.
2. Models-Models the task response for the learner.
3. Questions-Asks a question to elicit a task response.
4. Directs-Gives a direct signal to elicit a task response.
5. Controls-Controls management behavior with direction statements or gestures.
6. Positive-Gives a positive (affirmative) statement or gesture.
7. Negative-Gives a negative statement or gesture.

\section*{Pupil Behaviors}
8. Overt delayed-An overt learner response to task signals that cannot be judged correct or incorrect until later.

Table 9.7 Stepwise Selection Statistics for the Teacher Data

\hline 15 & .132 & 77.4 \\
10 & .159 & 72.4 \\
9 & .170 & 73.3 \\
8 & .182 & 70.6 \\
7 & .195 & 72.9 \\
6 & .211 & 70.1 \\
5 & .231 & 70.6 \\
4 & .256 & 65.6 \\
\hline
\end{tabular}
9. Correct-A correct learner response with relationship to task signals.
10. Incorrect-An incorrect learner response with relationship to task signals.
11. No response-Learner gives no response with relationship to task signals.
12. Asks-Learner asks a question about the task.
13. Statement-Learner gives a positive statement or gestures not related to the task.
14. Inappropriate-Learner gives inappropriate management behavior.
15. Other-Other learner than one being observed gives responses as teacher directs task signals.

The teachers were grouped into four categories:
Group 1: Outstanding teachers
Group 2: Poor teachers
Group 3: First-year teachers
Group 4: Teacher aides
The sample sizes in groups 1-4 were \(62,61,57\), and 41 , respectively. Because of the large values of \(N\) and \(p(N=221, p=15)\), the data are not given here.

The stepwise discriminant analysis was run several times with different threshold \(F\)-to-enter values so as to select subsets with different sizes. A classification analysis based on resubstitution was carried out with each of the resulting subsets of variables. In Table 9.7, we compare the overall Wilks' \(\Lambda\) and the apparent correct classification rate.

According to the correct classification rate, we would choose to stop at five variables because of the abrupt change from 5 to 4 . On the other hand, the changes in Wilks' \(\Lambda\) are more gradual, and no clear stopping point is indicated.

\subsection*{9.7 NONPARAMETRIC PROCEDURES}

We have previously discussed both parametric and nonparametric classification procedures. Welch's optional rule in (9.8) and (9.12) is parametric, whereas Fisher's linear classification rule for two groups as given in (9.5) and (9.6) is essentially nonparametric, since no distributional assumptions were involved in its derivation. However, Fisher's procedure also turns out to be equivalent to the optimal normal-based approach in (9.9). Nonparametric procedures for estimating error rate include the resubstitution and holdout methods. In the sections below, we discuss additional nonparametric classification procedures.

\subsection*{9.7.1 Multinomial Data}

We now consider data in which an observation vector consists of responses on each of several categorical variables. The various combinations of categories constitute the possible outcomes of a multinomial random variable. For example, consider the following four categorical variables: gender (male or female), political party (Republican, Democrat, other), size of city of residence (under 10,000 , between 10,000 and 100,000 , over 100,000 ), and education (less than high school graduation, high school graduate, college graduate, advanced degree). An observation vector might be ( \(2,1,3,4\) ), that is, a female Republican who lives in a city of over 100,000 and has an advanced degree. The total number of possible outcomes in this multinomial distribution is the product of the number of states of the individual variables: \(2 \times 3 \times 3 \times 4=72\). We will use this example to illustrate classification procedures for multinomial data. Suppose we are attempting to predict whether or not a person will vote. Then there are two groups, \(G_{1}\) and \(G_{2}\), and we assign a person to one of the groups after observing which of the 72 possible outcomes he or she gives.

Welch's (1939) optimum rule given in (9.8) can be written as: Assign y to \(G_{1}\) if
\[
\begin{equation*}
\frac{f\left(\mathbf{y} \mid G_{1}\right)}{f\left(\mathbf{y} \mid G_{2}\right)}>\frac{p_{2}}{p_{1}} \tag{9.18}
\end{equation*}
\]
and to \(G_{2}\) otherwise. In our categorical example, \(f\left(\mathbf{y} \mid G_{1}\right)\) is represented by \(q_{1 i}, i=\) \(1,2, \ldots, 72\), and \(f\left(\mathbf{y} \mid G_{2}\right)\) becomes \(q_{2 i}, i=1,2, \ldots, 72\), where \(q_{1 i}\) is the probability that a person in group 1 will give the \(i\) th outcome, with an analogous definition for \(q_{2 i}\). In terms of these multinomial probabilities, the classification rule in (9.18) becomes: If a person gives the \(i\) th outcome, assign him or her to \(G_{1}\) if
\[
\begin{equation*}
\frac{q_{1 i}}{q_{2 i}}>\frac{p_{2}}{p_{1}} \tag{9.19}
\end{equation*}
\]
and to \(G_{2}\) otherwise. If the probabilities \(q_{1 i}\) and \(q_{2 i}\) were known, it would be easy to check (9.19) for each \(i\) and partition the 72 possible outcomes into two subsets, those for which the person would be assigned to \(G_{1}\) and those corresponding to \(G_{2}\).

The values of \(q_{1 i}\) and \(q_{2 i}\) are usually unknown and must be estimated from a sample. Let \(n_{1 i}\) and \(n_{2 i}\) be the numbers of persons in groups 1 and 2 who give the \(i\) th outcome, \(i=1,2, \ldots, 72\). Then we estimate \(q_{1 i}\) and \(q_{2 i}\) by
\[
\begin{equation*}
\hat{q}_{1 i}=\frac{n_{1 i}}{N_{1}} \quad \text { and } \quad \hat{q}_{2 i}=\frac{n_{2 i}}{N_{2}}, \quad i=1,2, \ldots, 72 \tag{9.20}
\end{equation*}
\]
where \(N_{1}=\sum_{i} n_{1 i}\) and \(N_{2}=\sum_{i} n_{2 i}\). However, a large sample size would be required for stable estimates; in any given example, some of the \(n\) 's may be zero.

Multinomial data can also be classified by ordinary linear classification functions. We must distinguish between ordered and unordered categories. If all of the variables have ordered categories, the data can be submitted directly to an ordinary classification program. In the above example, city size and education are variables of this type. It is customary to assign ordered categories ranked values such as \(1,2,3,4\). It has been shown that linear classification functions perform reasonably well on (ordered) discrete data of this type [see Lachenbruch (1975, p.45), Titterington et al. (1981), and Gilbert (1968)].

Unordered categorical variables cannot be handled this same way. Thus the political party variable in the example above should not be coded \(1,2,3\) and entered into the computation of the classification functions. However, an unordered categorical variable with \(k\) categories can be replaced by \(k-1\) dummy variables (see Sections 6.1.8 and 11.6.2) for use with linear classification functions. For example, the political preference variable with three categories can be converted to two dummy variables as follows:
\[
y_{1}=\left\{\begin{array}{ll}
1 & \text { if Republican } \\
0 & \text { otherwise }
\end{array} \quad y_{2}= \begin{cases}1 & \text { if Democrat } \\
0 & \text { otherwise } .\end{cases}\right.
\]

Thus the \(\left(y_{1}, y_{2}\right)\) pair takes the value \((1,0)\) for a Republican, \((0,1)\) for a Democrat, and \((0,0)\) for other. Many software programs will create dummy variables automatically. Note that if a subset selection program is used, the dummy variables for a given categorical variable must be kept together; that is, they must all be included in the chosen subset or all excluded, because all are necessary to describe the categorical variable.

In some cases, such as in medical data collection, there is a mixture of continuous and categorical variables. Various approaches to classification with such data have been discussed by Krzanowski (1975, 1976, 1977, 1979, 1980), Lachenbruch and Goldstein (1979), Tu and Han (1982), and Bayne et al. (1983). See Rencher (1998, Section 6.8) for a discussion of logistic and probit classification, which are useful for certain types of continuous and discrete data that are not normally distributed.

\subsection*{9.7.2 Classification Based on Density Estimators}

In (9.9), (9.13), and (9.15) we have linear and quadratic classification rules based on the multivariate normal density and prior probabilities. These normal-based rules
arose from Welch's optimal rule that assigns \(\mathbf{y}\) to the group for which \(p_{i} f\left(\mathbf{y} \mid G_{i}\right)\) is maximum. If the form of \(f\left(\mathbf{y} \mid G_{i}\right)\) is nonnormal and unknown, the density can be estimated directly from the data. The approach we describe is known as the kernel estimator.

We first describe the kernel method for a univariate continuous random variable \(y\). Suppose \(y\) has density \(f(y)\), which we wish to estimate using a sample \(y_{1}, y_{2}, \ldots, y_{n}\). A simple estimate of \(f\left(y_{0}\right)\) for an arbitrary point \(y_{0}\) can be based on the proportion of points in the interval \(\left(y_{0}-h, y_{0}+h\right)\). If the number of points in the interval is denoted by \(N\left(y_{0}\right)\), then the proportion \(N\left(y_{0}\right) / n\) is an estimate of \(P\left(y_{0}-h<y<y_{0}+h\right)\), which is approximately equal to \(2 h f\left(y_{0}\right)\). Thus we estimate \(f\left(y_{0}\right)\) by
\[
\begin{equation*}
\hat{f}\left(y_{0}\right)=\frac{N\left(y_{0}\right)}{2 h n} . \tag{9.21}
\end{equation*}
\]

We can express \(\hat{f}\left(y_{0}\right)\) as a function of all \(y_{i}\) in the sample by defining
\[
K(u)= \begin{cases}\frac{1}{2} & \text { for }|u| \leq 1  \tag{9.22}\\ 0 & \text { for }|u|>1\end{cases}
\]
so that \(N\left(y_{0}\right)=2 \sum_{i=1}^{n} K\left[\left(y_{0}-y_{i}\right) / h\right]\), and (9.21) becomes
\[
\begin{equation*}
\hat{f}\left(y_{0}\right)=\frac{1}{h n} \sum_{i=1}^{n} K\left(\frac{y_{0}-y_{i}}{h}\right) \tag{9.23}
\end{equation*}
\]

The function \(K(u)\) is called the kernel. In (9.23), \(K\left[\left(y_{0}-y_{i}\right) / h\right]\) is \(\frac{1}{2}\) for any point \(y_{i}\) in the interval ( \(y_{0}-h, y_{0}+h\) ) and is zero for points outside the interval. Points in the interval add \(1 / 2 h n\) to the density, and points outside the interval contribute nothing.

Kernel estimators were first proposed by Rosenblatt (1956) and Parzen (1962). A good review of nonparametric density estimation including kernel estimators has been given by Silverman (1986), who noted that classification analysis provided the initial motivation for the development of density estimation.

The kernel defined by (9.22) is rectangular and the graph of \(\hat{f}\left(y_{0}\right)\) plotted as a function of \(y_{0}\) will be a step function, since there will be a jump (or drop) whenever \(y_{0}\) is a distance \(h\) from one of the \(y_{i}\) 's. (A moving average has a similar property.)

To obtain a smooth estimator of \(f(y)\), we must choose a smooth kernel. Two possibilities are
\[
\begin{align*}
& K(u)=\frac{1}{\pi} \frac{\sin ^{2} u}{u^{2}}  \tag{9.24}\\
& K(u)=\frac{1}{\sqrt{2 \pi}} e^{-u^{2} / 2} \tag{9.25}
\end{align*}
\]
which have the property that all \(n\) sample points \(y_{1}, y_{2}, \ldots, y_{n}\) contribute to \(\hat{f}\left(y_{0}\right)\) with the closest points weighted heavier than the more distant points. Even though
\(K(u)\) in (9.25) has the form of the normal distribution, this does not imply any assumption about the density \(f(y)\). We have used the normal density function because it is symmetric and unimodal. Other density functions could be used as kernels.

Cacoullos (1966) provided kernel estimates for multivariate density functions; see also \(\operatorname{Scott}\) (1992). If \(\mathbf{y}_{0}^{\prime}=\left(y_{01}, y_{02}, \ldots, y_{0 p}\right)\) is an arbitrary point whose density we wish to estimate, then the extension of (9.23) is
\[
\begin{equation*}
\hat{f}\left(\mathbf{y}_{0}\right)=\frac{1}{n h_{1} h_{2} \cdots h_{p}} \sum_{i=1}^{n} K\left(\frac{y_{01}-y_{i 1}}{h_{1}}, \ldots, \frac{y_{0 p}-y_{i p}}{h_{p}}\right) . \tag{9.26}
\end{equation*}
\]

An estimate \(\hat{f}\left(\mathbf{y}_{0}\right)\) based on a multivariate normal kernel is given by
\[
\begin{equation*}
\hat{f}\left(\mathbf{y}_{0}\right)=\frac{1}{n h^{p}\left|\mathbf{S}_{\mathrm{pl}}\right|^{1 / 2}} \sum_{i=1}^{n} e^{-\left(\mathbf{y}_{0}-\mathbf{y}_{i}\right)^{\prime} \mathbf{s}_{\mathrm{pl}}^{-1}\left(\mathbf{y}_{0}-\mathbf{y}_{i}\right) / 2 h^{2}} \tag{9.27}
\end{equation*}
\]
where \(h_{1}=h_{2}=\cdots=h_{p}=h\) and \(\mathbf{S}_{\mathrm{pl}}\) is the pooled covariance matrix from the \(k\) groups in the sample. The covariance matrix \(\mathrm{S}_{\mathrm{pl}}\) could be replaced by other forms. Two examples are (1) \(\mathrm{S}_{i}\) for the \(i\) th group and (2) a diagonal matrix.

The choice of the smoothing parameter \(h\) is critical in a kernel density estimator. The size of \(h\) determines how much each \(\mathbf{y}_{i}\) contributes to \(\hat{f}\left(\mathbf{y}_{0}\right)\). If \(h\) is too small, \(\hat{f}\left(\mathbf{y}_{0}\right)\) has a peak at each \(\mathbf{y}_{i}\), and if \(h\) is too large, \(\hat{f}\left(\mathbf{y}_{0}\right)\) is almost uniform (overly smoothed). Therefore, the value chosen for \(h\) must depend on the sample size \(n\) to avoid too much or too little smoothing; the larger the sample size, the smaller \(h\) should be. In practice, we could try several values of \(h\) and check the resulting error rates from the classification analysis.

To use the kernel method of density estimation in classification, we can apply it to each group to obtain \(\hat{f}\left(\mathbf{y}_{0} \mid G_{1}\right), \hat{f}\left(\mathbf{y}_{0} \mid G_{2}\right), \ldots, \hat{f}\left(\mathbf{y}_{0} \mid G_{k}\right)\), where \(\mathbf{y}_{0}\) is the vector of measurements for an individual of unknown group membership. The classification rule then becomes: Assign \(y_{0}\) to the group \(G_{i}\) for which
\[
\begin{equation*}
p_{i} \hat{f}\left(\mathbf{y}_{0} \mid G_{i}\right) \text { is maximum. } \tag{9.28}
\end{equation*}
\]

Habbema et al. (1974) proposed a forward selection method for classification based on density estimation. Wegman (1972) and Habbema et al. (1978) found that the size of the \(h_{i}\) 's is more important than the shape of the kernel. The choice of \(h\) was investigated by Pfeiffer (1985) in a stepwise mode. Remme et al. (1980) compared linear, quadratic, and kernel classification methods for two groups and reported that for multivariate normal data with equal covariance matrices, the linear classifications were clearly superior. For some cases with departures from these assumptions, the kernel methods gave better results.

\section*{- EXAMPLE 9.7.2}

We illustrate the density estimation method of classification for the football data of Table 8.3. We use the multivariate normal kernel estimator in (9.27) with \(h=2\) to obtain \(\hat{f}\left(\mathbf{y}_{0} \mid G_{i}\right), i=1,2,3\), for the three groups. Using

& Apparent error rate \(=1-.711=.289\)
\end{tabular}

Table 9.9 Classification Table for the Football Data of Table 8.3 Using the Holdout Method Based on Density Estimation

\(p_{1}=p_{2}=p_{3}\), the rule in (9.28) becomes: Assign \(\mathbf{y}_{0}\) to the group for which \(\hat{f}\left(\mathbf{y}_{0} \mid G_{i}\right)\) is greatest. To obtain an apparent error rate, we follow this procedure for each of the 90 observations and obtain the classification results in Table 9.8.

Applying a holdout method in which the observation \(\mathbf{y}_{i j}\) being classified is excluded from computation of \(\hat{f}\left(\mathbf{y}_{i j} \mid G_{1}\right), \hat{f}\left(\mathbf{y}_{i j} \mid G_{2}\right)\), and \(\hat{f}\left(\mathbf{y}_{i j} \mid G_{3}\right)\), we obtain the classification results in Table 9.9. As expected, the holdout error rate has increased somewhat from the apparent error rate in Table 9.8.

\subsection*{9.7.3 Nearest Neighbor Classification Rule}

The earliest nonparametric classification method was the nearest neighbor rule of Fix and Hodges (1951), also known as the \(k\) nearest neighbor rule. The procedure is conceptually simple. We compute the distance from an observation \(\mathbf{y}_{i}\) to all other points \(\mathbf{y}_{j}\) using the distance function
\[
\left(\mathbf{y}_{i}-\mathbf{y}_{j}\right)^{\prime} \mathbf{S}_{\mathrm{pl}}^{-1}\left(\mathbf{y}_{i}-\mathbf{y}_{j}\right) \quad j \neq i
\]

To classify \(\mathbf{y}_{i}\) into one of two groups, the \(k\) points nearest to \(\mathbf{y}_{i}\) are examined, and if the majority of the \(k\) points belong to \(G_{1}\), assign \(\mathbf{y}_{i}\) to \(G_{1}\); otherwise assign \(\mathbf{y}_{i}\) to \(G_{2}\). If we denote the number of points from \(G_{1}\) as \(k_{1}\), with the remaining \(k_{2}\) points from \(G_{2}\), where \(k=k_{1}+k_{2}\), then the rule can be expressed as: Assign \(\mathbf{y}_{i}\) to \(G_{1}\) if
\[
\begin{equation*}
k_{1}>k_{2} \tag{9.29}
\end{equation*}
\]
and to \(G_{2}\) otherwise. If the sample sizes \(n_{1}\) and \(n_{2}\) differ, we may wish to use proportions in place of counts: Assign \(\mathbf{y}_{i}\) to \(G_{1}\) if
\[
\begin{equation*}
\frac{k_{1}}{n_{1}}>\frac{k_{2}}{n_{2}} . \tag{9.30}
\end{equation*}
\]

A further refinement can be made by taking into account prior probabilities: Assign \(\mathbf{y}_{i}\) to \(G_{1}\) if
\[
\begin{equation*}
\frac{k_{1} / n_{1}}{k_{2} / n_{2}}>\frac{p_{2}}{p_{1}} \tag{9.31}
\end{equation*}
\]

These rules are easily extended to more than two groups. For example, (9.30) becomes: Assign the observation to the group that has the highest proportion \(k_{i} / n_{i}\), where \(k_{i}\) is the number of observations from \(G_{i}\) among the \(k\) nearest neighbors of the observation in question.

A decision must be made as to the value of \(k\). Loftsgaarden and Quesenberry (1965) suggest choosing \(k\) near \(\sqrt{n}_{i}\) for a typical \(n_{i}\). In practice, one could try several values of \(k\) and use the one with the best error rate.

Reviews and extensions of the nearest neighbor method have been given by Hart (1968), Gates (1972), Hand and Batchelor (1978), Chidananda Gowda and Krishna (1979), Rogers and Wagner (1978), and Brown and Koplowitz (1979).

\section*{EXAMPLE 9.7.3}

We use the football data of Table 8.3 to illustrate the \(k\) nearest neighbor method of estimating error rate, with \(k=5\). Since \(n_{1}=n_{2}=n_{3}=30\) and the \(p_{i}\) 's are also assumed to be equal, we simply examine the five points closest to a point y and classify \(y\) into the group that has the most points among the five points. If there is a tie, we do not classify the point. For example, if the numbers from \(G_{1}, G_{2}\), and \(G_{3}\) were 1,2 , and 2 , respectively, then we do not assign \(y\) to either \(G_{2}\) or \(G_{3}\).

For each point \(\mathbf{y}_{i j}, i=1,2,3 ; j=1,2, \ldots, 30\), we find the five nearest neighbors and classify the point accordingly. Table 9.10 gives the classification results. As can be seen, there were 3 observations in group 1 that were not classified because of ties, 1 in group 2, and 3 in group 3. This left a total of 83 observations classified.

\subsection*{9.7.4 Classification Trees}

Although the notion of using decision trees as a means for classification has been discussed for nearly fifty years, the methodology known as classification and regres-

\]} \\
\hline
\end{tabular}
sion trees received its first complete development by Breiman, Friedman, Olshen, and Stone (1984). Classification trees are used to predict categorial responses, while regression trees are used to predict continuous responses. Because this chapter's focus is on classification of observations into discrete groups, we limit our discussion to a very simple type of classification tree. For a more complete discussion of this rich class of predictive tools, we refer the reader to the aforementioned landmark publication of Breiman, Friedman, Olshen, and Stone (1984), overviews of this class of methods including extensions and more recent developments (e.g., Hastie, Tibshirani, and Friedman, 2009), or documentation associated with the various software implementations of classification trees. We adopt much of our notation and terminology from the primer on the RPART routines by Therneau and Atkinson (1997). RPART comprises a collection of implementations of classification and regression trees within the R statistical computing environment ( R Development Core Team, 2010).

We begin forming a classification tree with all \(n\) observations in one group or root node and seek to find a predictor variable \(x\) and an associated cutoff criterion such that splitting the \(n\) subjects into the two groups will minimize the impurity (diversity) within each of the two child nodes. This involves a consideration of all possible \(x\) variables at all possible split points. The process is then repeated for each of the child nodes. Thus the classification tree is formed by recursive binary splits of the observations in order to form an optimal partitioning of the observations into predictive groups.

The tree grows with child nodes splitting to create new generations of nodes. Of course, the splitting could continue until each observation is its own terminal (final) node, but such overfitting will generally lead to decision trees with poor out-ofsample predictive properties. Various stopping and pruning rules exist for selecting the optimal tree, but most are based on cross-validation. When the final tree is constructed, each observation falls into exactly one terminal node that will be associated with a single predicted group.

There are many ways in which we might split a parent node into two child nodes, and there are several criteria that could influence the way we define an optimal split.

The first criterion is the collection of prior probabilities \(p_{1}, \ldots, p_{k}\) associated with each group. Allowing prior probabilities to influence the decision rules will lead to rules that tend to classify more observations into the more commonly observed groups.

A second criterion is the misclassification cost for classifying an observation from group \(G_{i}\) into group \(G_{j}\) (for \(i, j=1, \ldots, k\) ). As stated previously, this can become extremely complicated for more than two groups, so misclassification costs will not be considered here.

A third criterion affecting the definition of an optimal splitting rule is the measure of impurity chosen for the classification. Employing the oft-used Gini index, we can define the impurity associated with the node \(A\) as
\[
\begin{equation*}
I_{A}=\sum_{i=1}^{k} p_{i \mid A}\left(1-p_{i \mid A}\right) \tag{9.32}
\end{equation*}
\]
where \(p_{i \mid A}\) is the probability that an observation is in group \(G_{i}\) given that it is classified into node \(A\). Note that the impurity of node \(A\) is close to zero when each of \(p_{1 \mid A}, p_{2 \mid A}, \ldots, p_{k \mid A}\) is either near zero or near 1 -that is, when the observations in a node are predominantly from only one group. The probability \(p_{i \mid A}\) is calculated from the data using
\[
\begin{equation*}
p_{i \mid A}=\frac{p_{i}\left(n_{i A} / n_{i}\right)}{\sum_{i=1}^{k} p_{i}\left(n_{i A} / n_{i}\right)}, \tag{9.33}
\end{equation*}
\]
where \(p_{i}\) is the prior probability associated with group \(G_{i}, n_{i}\) is the number of observations in \(G_{i}\), and \(n_{i A}\) is the number of observations from \(G_{i}\) that are in node \(A\). Note that if we assume prior probabilities are proportional to the size of the group \(G_{i}\) in the training data (i.e., if \(p_{1} / n_{1}=p_{2} / n_{2}=\ldots=p_{k} / n_{k}\) ), then (9.33) simplifies to
\[
\begin{equation*}
p_{i \mid A}=\frac{n_{i A}}{n_{A}} \tag{9.34}
\end{equation*}
\]
where \(n_{A}\) is the number of observations in node \(A\).
We quantify the probability of an observation being in node \(A\) using
\[
\begin{equation*}
p_{A}=\sum_{i=1}^{k} p_{i}\left(n_{i A} / n_{i}\right) \tag{9.35}
\end{equation*}
\]

For the case of prior probabilities proportional to the size of the group, (9.35) simplifies to \(p_{A}=n_{A} / n\).

Finally, using the quantities defined above, we can define the quality for the split of a parent node \(A\) into two child nodes \(A_{L}\) and \(A_{R}\) (where \(L\) and \(R\) denote the left and right children from the split). The change in total impurity ( \(\Delta I\) ) associated with the split is defined by
\[
\begin{equation*}
\Delta I=p_{A} I_{A}-\left(p_{A_{L}} I_{A_{L}}+p_{A_{R}} I_{A_{R}}\right) \tag{9.36}
\end{equation*}
\]
with \(\Delta I\) guaranteed to be greater than or equal to 0 . After considering all possible choices for the split of node \(A\) into child nodes \(A_{L}\) and \(A_{R}\), the split at node \(A\) that maximizes \(\Delta I\) is deemed the optimal split.

Figure 9.4 Classification tree for classifying subjects into one of three groups using the football data of Table 8.3

\section*{EXAMPLE 9.7.4}

To explain the basic components of a classification tree, we use the football data in Table 8.3 to illustrate the use of classification trees for classification analysis. For this classification exercise, we use equal prior probabilities for the three groups (college players, high school players, and non-football players). For these data, this is equivalent to assuming priors proportional to size since the training data groups each have 30 subjects. Costs of misclassification are assumed to be equal, and the Gini index is used as the basis for the measure of impurity when selecting optimal splits for nodes. Optimal tree size is chosen based on cross-validation.

In Figure 9.4, we begin with all 90 subjects in the root node and seek to find the head dimension variable and associated cutoff criterion that best separates the three types of football players (college players, high school players, and non-players) into two distinct groups. At the root node the optimal rule was to form groups based on whether or not the eye-to-top-of-head measurement (eyehd) is less than 11.95 cm . Those observations with eyehd \(<11.95 \mathrm{~cm}\) are considered to be in the left child node (denoted \(A_{L}\) ), and all others are in the right child node \(\left(A_{R}\right)\). We say this is the optimal split because \(A_{R}\) consists of mostly high school players ( 2 college, 29 high school, and 6 non-players) and the left node is predominantly college players and non-football players ( 28 college, 1 high school, and 24 non-players).

Table 9.11 Comparison of Classification Error Rates for the Football Data of Table 8.3 Using Several Methods Including the Classification Tree
\begin{tabular}{lr}
\hline Classification Method & \begin{tabular}{r} 
Misclassification Rate \\
(based on cross-validation)
\end{tabular} \\
\hline Linear & 0.300 \\
Quadratic & 0.344 \\
Density Estimation & \\
\(\quad\) normal density, \(h=2\) & 0.333 \\
\(\quad\) normal density, \(h=5\) & 0.367 \\
Nearest Neighbor \\
\(\quad k=5\) & \\
\(k=9\) & 0.278 \\
Classification Tree & 0.367 \\
\hline
\end{tabular}

For each child node, the same process is recursively applied. For example, those observations with eyehd \(<11.95 \mathrm{~cm}\) are then further split into groups based again on eyehd, but this time with a new cutoff of 10.35 cm . This serves to further split this group of 53 subjects into two terminal child nodes. The first contains all subjects with eyehd \(<10.35\) and includes 21 college, 1 high school, and 7 non-players. The second terminal child node formed by this split contains all subjects with eyehd measurements in the range \([10.35,11.95)\) and includes 7 college, 0 high school, and 17 non-players. The set of subjects with eyehd \(\geq 11.95 \mathrm{~cm}\) are also further subdivided, with those having ear-to-top-of-head (earhd) measurements greater than or equal to 13.8 cm placed in a terminal child node with 1 college, 27 high school, and 2 non-players. The complementary terminal node for those with eyehd \(>11.95\) and earhd \(<13.8\) cm contains 1 college, 2 high school, and 4 non-players.

Thus there is one large terminal node associated with each of the college and high school player groups, and there are two smaller terminal nodes associated with the non-football-player group. For some future (unclassified) observation, the classification tree in Figure 9.4 illustrates how one would predict group membership based on the eyehd and earhd variables.

Table 9.11 compares the misclassification rates for several different classification methods using the football data of Table 8.3. For this data set, the misclassification rate for the classification tree is lowest among the competing approaches, but the relative accuracy of the approaches will be different for different data sets.

\section*{PROBLEMS}
9.1 Show that if \(z_{1 i}=\mathbf{a}^{\prime} \mathbf{y}_{1 i}, i=1,2, \ldots, n_{1}\), and \(z_{2 i}=\mathbf{a}^{\prime} \mathbf{y}_{2 i}, i=1,2, \ldots, n_{2}\), where \(z\) is the discriminant function defined in (9.1), then \(\bar{z}_{1}-\bar{z}_{2}=\left(\overline{\mathbf{y}}_{1}-\right.\) \(\left.\overline{\mathbf{y}}_{2}\right)^{\prime} \mathbf{S}_{\mathrm{pl}}^{-1}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)\) as in (9.3).
9.2 With \(z=\mathbf{a}^{\prime} \mathbf{y}\) as in (9.1), and \(\bar{z}_{1}=\mathbf{a}^{\prime} \overline{\mathbf{y}}_{1}, \bar{z}_{2}=\mathbf{a}^{\prime} \overline{\mathbf{y}}_{2}\), show that \(\frac{1}{2}\left(\bar{z}_{1}+\bar{z}_{2}\right)=\) \(\frac{1}{2}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)^{\prime} \mathbf{S}_{\mathrm{pl}}^{-1}\left(\overline{\mathbf{y}}_{1}+\overline{\mathbf{y}}_{2}\right)\) as in (9.4).
9.3 Obtain the normal-based classification rule in (9.9).
9.4 Derive the linear classification rule in (9.13).
9.5 Derive the quadratic classification function in (9.15).
9.6 Show that if we assume prior probabilities are proportional to the size of the group \(G_{i}\) in the training data, then (9.33) simplifies to (9.34).
9.7 Do a classification analysis on the beetle data in Table 5.5 as follows:
(a) Find the classification function \(z=\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)^{\prime} \mathbf{S}_{\mathrm{pl}}^{-1} \mathbf{y}\) and the cutoff point \(\frac{1}{2}\left(\bar{z}_{1}+\bar{z}_{2}\right)\).
(b) Find the classification table using the linear classification function in part (a).
(c) Find the classification table using the nearest neighbor method.
9.8 Do a classification analysis on the dystrophy data of Table 5.7 as follows:
(a) Find the classification function \(z=\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)^{\prime} \mathbf{S}_{\mathrm{pl}}^{-1} \mathbf{y}\) and the cutoff point \(\frac{1}{2}\left(\bar{z}_{1}+\bar{z}_{2}\right)\).
(b) Find the classification table using the linear classification function in part (a).
(c) Repeat part (b) using \(p_{1}\) and \(p_{2}\) proportional to sample sizes.
9.9 Do a classification analysis on the cyclical data of Table 5.8 as follows:
(a) Find the classification function \(z=\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)^{\prime} \mathbf{S}_{\mathrm{pl}}^{-1} \mathbf{y}\) and the cutoff point \(\frac{1}{2}\left(\bar{z}_{1}+\bar{z}_{2}\right)\).
(b) Find the classification table using the linear classification function in part (a).
(c) Find the classification table using the holdout method.
(d) Find the classification table using a kernel density estimator method.
9.10 Using the engineer data of Table 5.6, carry out a classification analysis as follows:
(a) Find the classification table using the linear classification function.
(b) Carry out a stepwise discriminant selection of variables (see Problem 8.14).
(c) Find the classification table for the variables selected in part (b).
9.11 Do a classification analysis on the fish data in Table 6.17 as follows. Assume \(p_{1}=p_{2}=p_{3}\).
(a) Find the linear classification functions.
(b) Find the classification table using the linear classification functions in part (a) (assuming \(\boldsymbol{\Sigma}_{1}=\boldsymbol{\Sigma}_{2}=\boldsymbol{\Sigma}_{3}\) ).
(c) Find the classification table using quadratic classification functions (assuming population covariance matrices are not equal).
(d) Find the classification table using linear classification functions and the holdout method.
(e) Find the classification table using a nearest neighbor method.
9.12 Do a classification analysis on the rootstock data of Table 6.2 as follows:
(a) Find the linear classification functions.
(b) Find the classification table using the linear classification functions in part (a) (assuming \(\boldsymbol{\Sigma}_{1}=\boldsymbol{\Sigma}_{2}=\boldsymbol{\Sigma}_{3}\) ).
(c) Find the classification table using quadratic classification functions (assuming population covariance matrices are not equal).
(d) Find the classification table using the nearest neighbor method.
(e) Find the classification table using a kernel density estimator method.

\section*{CHAPTER 10}

\section*{MULTIVARIATE REGRESSION}

\subsection*{10.1 INTRODUCTION}

In this chapter, we consider the linear relationship between one or more \(y\) 's (the dependent or response variables) and one or more \(x\) 's (the independent or predictor variables). We will use a linear model to relate the \(y\) 's to the \(x\) 's and will be concerned with estimation and testing of the parameters in the model. One aspect of interest will be choosing which variables to include in the model if this is not already known.

We can distinguish three cases according to the number of variables:
1. Simple linear regression: one \(y\) and one \(x\). For example, suppose we wish to predict college grade point average (GPA) based on an applicant's high school GPA.
2. Multiple linear regression: one \(y\) and several \(x\) 's. We could attempt to improve our prediction of college GPA by using more than one independent variable, for example, high school GPA, standardized test scores (such as ACT or SAT), or rating of high school.
3. Multivariate multiple linear regression: several \(y\) 's and several \(x\) 's. In the above illustration, we may wish to predict several \(y\) 's (such as number of
years of college the person will complete or GPA in the sciences, arts, and humanities). As another example, suppose the Air Force wishes to predict several measures of pilot efficiency. These response variables could be regressed against independent variables (such as math and science skills, reaction time, eyesight acuity, and manual dexterity).

To further distinguish case 2 from case 3 , we could designate case 2 as univariate multiple regression because there is only one \(y\). Thus in case 3 , "multivariate" indicates that there are several \(y\) 's and "multiple" implies several \(x\) 's. The term multivariate regression usually refers to case 3 .

There are two basic types of independent variables, fixed and random. In the above illustrations, all \(x\) 's are random variables and are therefore not under the control of the researcher. A person is chosen at random, and all of the \(y\) 's and \(x\) 's are measured, or observed, for that person. In some experimental situations, the \(x\) 's are fixed, that is, under the control of the experimenter. For example, a researcher may wish to relate yield per acre and nutritional value to level of application of various chemical fertilizers. The experimenter can choose the amount of chemicals to be applied and then observe the changes in the yield and nutritional responses.

In order to provide a solid base for multivariate multiple regression, we review several aspects of multiple regression with fixed \(x\) 's in Section 10.2. The random- \(x\) case for multiple regression is discussed briefly in Section 10.3.

\subsection*{10.2 MULTIPLE REGRESSION: FIXED \(x\) 's}

\subsection*{10.2.1 Model for Fixed \(\boldsymbol{x}\) 's}

In the fixed- \(x\) regression model, we express each \(y\) in a sample of \(n\) observations as a linear function of the \(x\) 's plus a random error, \(\varepsilon\) :
\[
\begin{align*}
y_{1} & =\beta_{0}+\beta_{1} x_{11}+\beta_{2} x_{12}+\cdots+\beta_{q} x_{1 q}+\varepsilon_{1} \\
y_{2} & =\beta_{0}+\beta_{1} x_{21}+\beta_{2} x_{22}+\cdots+\beta_{q} x_{2 q}+\varepsilon_{2}  \tag{10.1}\\
& \vdots \\
y_{n} & =\beta_{0}+\beta_{1} x_{n 1}+\beta_{2} x_{n 2}+\cdots+\beta_{q} x_{n q}+\varepsilon_{n}
\end{align*}
\]

The number of \(x\) 's is denoted by \(q\). The \(\beta\) 's in (10.1) are called regression coefficients. Additional assumptions that accompany the equations of the model are as follows:
1. \(E\left(\varepsilon_{i}\right)=0\) for all \(i=1,2, \ldots, n\).
2. \(\operatorname{var}\left(\varepsilon_{i}\right)=\sigma^{2}\) for all \(i=1,2, \ldots, n\).
3. \(\operatorname{cov}\left(\varepsilon_{i}, \varepsilon_{j}\right)=0\) for all \(i \neq j\).

Assumption 1 states that the model is linear and that no additional terms are needed to predict \(y\); all remaining variation in \(y\) is purely random and unpredictable. Thus
if \(E\left(\varepsilon_{i}\right)=0\) and the \(x\) 's are fixed, then \(E\left(y_{i}\right)=\beta_{0}+\beta_{1} x_{i 1}+\beta_{2} x_{i 2}+\cdots+\beta_{q} x_{i q}\), and the mean of \(y\) is expressible in terms of these \(q x\) 's with no others needed. In assumption 2 , the variance of each \(\varepsilon_{i}\) is the same, which also implies that \(\operatorname{var}\left(y_{i}\right)=\) \(\sigma^{2}\), since the \(x\) 's are fixed. Assumption 3 imposes the condition that the error terms be uncorrelated, from which it follows that the \(y\) 's are also uncorrelated, that is, \(\operatorname{cov}\left(y_{i}, y_{j}\right)=0\).

Thus the three assumptions can be restated in terms of \(y\) as follows:
1. \(E\left(y_{i}\right)=\beta_{0}+\beta_{1} x_{i 1}+\beta_{2} x_{i 2}+\cdots+\beta_{q} x_{i q}, i=1,2, \ldots, n\).
2. \(\operatorname{var}\left(y_{i}\right)=\sigma^{2}, i=1,2, \ldots, n\).
3. \(\operatorname{cov}\left(y_{i}, y_{j}\right)=0\), for all \(i \neq j\).

Using matrix notation, the models for the \(n\) observations in (10.1) can be written much more concisely in the form
\[
\left(\begin{array}{c}
y_{1}  \tag{10.2}\\
y_{2} \\
\vdots \\
y_{n}
\end{array}\right)=\left(\begin{array}{ccccc}
1 & x_{11} & x_{12} & \cdots & x_{1 q} \\
1 & x_{21} & x_{22} & \cdots & x_{2 q} \\
\vdots & \vdots & \vdots & & \vdots \\
1 & x_{n 1} & x_{n 2} & \cdots & x_{n q}
\end{array}\right)\left(\begin{array}{c}
\beta_{0} \\
\beta_{1} \\
\vdots \\
\beta_{q}
\end{array}\right)+\left(\begin{array}{c}
\varepsilon_{1} \\
\varepsilon_{2} \\
\vdots \\
\varepsilon_{n}
\end{array}\right)
\]
or
\[
\begin{equation*}
\mathbf{y}=\mathbf{X} \boldsymbol{\beta}+\boldsymbol{\varepsilon} \tag{10.3}
\end{equation*}
\]

With this notation, the above three assumptions become
1. \(E(\varepsilon)=0\)
2. \(\operatorname{cov}(\varepsilon)=\sigma^{2} \mathbf{I}\),
which can be rewritten in terms of \(y\) as
1. \(E(\mathbf{y})=\mathbf{X} \boldsymbol{\beta}\)
2. \(\operatorname{cov}(\mathbf{y})=\sigma^{2} \mathbf{I}\).

Note that the second assumption in matrix form incorporates both the second and third assumptions in univariate form; that is, \(\operatorname{cov}(\mathbf{y})=\sigma^{2} \mathbf{I}\) implies \(\operatorname{var}\left(y_{i}\right)=\sigma^{2}\) and \(\operatorname{cov}\left(y_{i}, y_{j}\right)=0\).

For estimation and testing purposes, we need to have \(n>q+1\). Therefore, the matrix expression (10.3) has the following typical pattern:

\subsection*{10.2.2 Least Squares Estimation in the Fixed- \(\boldsymbol{x}\) Model}

If the first assumption holds, we have \(E\left(y_{i}\right)=\beta_{0}+\beta_{1} x_{i 1}+\beta_{2} x_{i 2}+\cdots+\beta_{q} x_{i q}\). We seek to estimate the \(\beta\) 's and thereby estimate \(E\left(y_{i}\right)\). If the estimates are denoted by \(\hat{\beta}_{0}, \hat{\beta}_{1}, \ldots, \hat{\beta}_{q}\), then \(\hat{E}\left(y_{i}\right)=\hat{\beta}_{0}+\hat{\beta}_{1} x_{i 1}+\hat{\beta}_{2} x_{i 2}+\cdots+\hat{\beta}_{q} x_{i q}\). However, \(\hat{E}\left(y_{i}\right)\) is usually designated \(\hat{y}_{i}\). Thus \(\hat{y}_{i}\) estimates \(E\left(y_{i}\right)\), not \(y_{i}\). We now consider the least squares estimates of the \(\beta\) 's.

The least squares estimates of \(\beta_{0}, \beta_{1}, \ldots, \beta_{q}\) minimize the sum of squares of deviations of the \(n\) observed \(y\) 's from their "modeled" values, that is, from their values \(\hat{y}_{i}\) predicted by the model. Thus we seek \(\hat{\beta}_{0}, \hat{\beta}_{1}, \ldots, \hat{\beta}_{q}\) that minimize
\[
\begin{align*}
\operatorname{SSE} & =\sum_{i=1}^{n} \hat{\varepsilon}_{i}^{2}=\sum_{i=1}^{n}\left(y_{i}-\hat{y}_{i}\right)^{2} \\
& =\sum_{i=1}^{n}\left(y_{i}-\hat{\beta}_{0}-\hat{\beta}_{1} x_{i 1}-\hat{\beta}_{2} x_{i 2}-\cdots-\hat{\beta}_{q} x_{i q}\right)^{2} . \tag{10.4}
\end{align*}
\]

The value of \(\hat{\boldsymbol{\beta}}=\left(\hat{\beta}_{0}, \hat{\beta}_{1}, \ldots, \hat{\beta}_{q}\right)^{\prime}\) that minimizes \(\operatorname{SSE}\) in (10.4) is given by
\[
\begin{equation*}
\hat{\boldsymbol{\beta}}=\left(\mathbf{X}^{\prime} \mathbf{X}\right)^{-1} \mathbf{X}^{\prime} \mathbf{y} \tag{10.5}
\end{equation*}
\]

In (10.5), we assume that \(\mathbf{X}^{\prime} \mathbf{X}\) is nonsingular. This will ordinarily hold if \(n>q+1\) and no \(x_{j}\) is a linear combination of other \(x\) 's.

In expression (10.5), we see a characteristic pattern similar to that for \(\hat{\beta}_{1}\) in simple linear regression given in (3.11), \(\hat{\beta}_{1}=s_{x y} / s_{x}^{2}\). The product \(\mathbf{X}^{\prime} \mathbf{y}\) can be used to compute the covariances of the \(x\) 's with \(y\). The product \(\mathbf{X}^{\prime} \mathbf{X}\) can be used to obtain the covariance matrix of the \(x\) 's, which includes the variances and covariances of the \(x\) 's [see the comment following (10.16) about variances and covariances involving the fixed \(x\) 's]. Since \(\mathbf{X}^{\prime} \mathbf{X}\) is typically not diagonal, each \(\hat{\beta}_{j}\) depends on \(s_{x_{j} y}\) and \(s_{x_{j}}^{2}\) as well as the relationship of \(x_{j}\) to the other \(x\) 's.

We now demonstrate algebraically that \(\hat{\boldsymbol{\beta}}=\left(\mathbf{X}^{\prime} \mathbf{X}\right)^{-1} \mathbf{X}^{\prime} \mathbf{y}\) in (10.5) minimizes SSE (this can also be done readily with calculus). If we designate the \(i\) th row of \(\mathbf{X}\) as \(\mathbf{x}_{i}^{\prime}=\left(1, x_{i 1}, x_{i 2}, \ldots, x_{i q}\right)\), we can write (10.4) as
\[
\mathrm{SSE}=\sum_{i=1}^{n}\left(y_{i}-\mathbf{x}_{i}^{\prime} \hat{\boldsymbol{\beta}}\right)^{2}
\]

The quantity \(y_{i}-\mathbf{x}_{i}^{\prime} \hat{\boldsymbol{\beta}}\) is the \(i\) th element of the vector \(\mathbf{y}-\mathbf{X} \hat{\boldsymbol{\beta}}\). Hence, by (2.33),
\[
\begin{equation*}
\operatorname{SSE}=(\mathbf{y}-\mathbf{X} \hat{\boldsymbol{\beta}})^{\prime}(\mathbf{y}-\mathbf{X} \hat{\boldsymbol{\beta}}) \tag{10.6}
\end{equation*}
\]

Let \(\mathbf{b}\) be an alternative estimate that may lead to a smaller value of SSE than \(\hat{\boldsymbol{\beta}}\). We add \(\mathbf{X}(\hat{\boldsymbol{\beta}}-\mathbf{b})\) to see if this reduces SSE.
\[
\operatorname{SSE}=[(\mathbf{y}-\mathbf{X} \hat{\boldsymbol{\beta}})+\mathbf{X}(\hat{\boldsymbol{\beta}}-\mathbf{b})]^{\prime}[(\mathbf{y}-\mathbf{X} \hat{\boldsymbol{\beta}})+\mathbf{X}(\hat{\boldsymbol{\beta}}-\mathbf{b})] .
\]

We now expand this using the two terms \(\mathbf{y}-\mathbf{X} \hat{\boldsymbol{\beta}}\) and \(\mathbf{X}(\hat{\boldsymbol{\beta}}-\mathbf{b})\) to obtain
\[
\begin{aligned}
\mathbf{S S E} & =(\mathbf{y}-\mathbf{X} \hat{\boldsymbol{\beta}})^{\prime}(\mathbf{y}-\mathbf{X} \hat{\boldsymbol{\beta}})+[\mathbf{X}(\hat{\boldsymbol{\beta}}-\mathbf{b})]^{\prime} \mathbf{X}(\hat{\boldsymbol{\beta}}-\mathbf{b})+2[\mathbf{X}(\hat{\boldsymbol{\beta}}-\mathbf{b})]^{\prime}(\mathbf{y}-\mathbf{X} \hat{\boldsymbol{\beta}}) \\
& =(\mathbf{y}-\mathbf{X} \hat{\boldsymbol{\beta}})^{\prime}(\mathbf{y}-\mathbf{X} \hat{\boldsymbol{\beta}})+(\hat{\boldsymbol{\beta}}-\mathbf{b})^{\prime} \mathbf{X}^{\prime} \mathbf{X}(\hat{\boldsymbol{\beta}}-\mathbf{b})+2(\hat{\boldsymbol{\beta}}-\mathbf{b})^{\prime} \mathbf{X}^{\prime}(\mathbf{y}-\mathbf{X} \hat{\boldsymbol{\beta}}) \\
& =(\mathbf{y}-\mathbf{X} \hat{\boldsymbol{\beta}})^{\prime}(\mathbf{y}-\mathbf{X} \hat{\boldsymbol{\beta}})+(\hat{\boldsymbol{\beta}}-\mathbf{b})^{\prime} \mathbf{X}^{\prime} \mathbf{X}(\hat{\boldsymbol{\beta}}-\mathbf{b})+2(\hat{\boldsymbol{\beta}}-\mathbf{b})^{\prime}\left(\mathbf{X}^{\prime} \mathbf{y}-\mathbf{X}^{\prime} \mathbf{X} \hat{\boldsymbol{\beta}}\right) .
\end{aligned}
\]

The third term vanishes if we substitute \(\hat{\boldsymbol{\beta}}=\left(\mathbf{X}^{\prime} \mathbf{X}\right)^{-1} \mathbf{X}^{\prime} \mathbf{y}\) into \(\mathbf{X}^{\prime} \mathbf{X} \hat{\boldsymbol{\beta}}\). The second term is a positive definite quadratic form, and SSE is therefore minimized when \(\mathbf{b}=\hat{\boldsymbol{\beta}}\). Thus no value of \(\mathbf{b}\) can reduce SSE from the value given by \(\hat{\boldsymbol{\beta}}\).

When \(E(\mathbf{y})=\mathbf{X} \boldsymbol{\beta}\) and \(\operatorname{cov}(\mathbf{y})=\sigma^{2} \mathbf{I}\), it follows that the least squares estimator \(\hat{\boldsymbol{\beta}}=\left(\mathbf{X}^{\prime} \mathbf{X}\right)^{-1} \mathbf{X}^{\prime} \mathbf{y}\) in (10.5) has three important properties. The first property is that \(\hat{\boldsymbol{\beta}}\) is an unbiased estimator for \(\boldsymbol{\beta}\). That is, \(E(\hat{\boldsymbol{\beta}})=\boldsymbol{\beta}\). The second property is that \(\operatorname{cov}(\hat{\boldsymbol{\beta}})=\sigma^{2}\left(\mathbf{X}^{\prime} \mathbf{X}\right)^{-1}\). The third important property is characterized by the Gauss-Markov theorem.

Gauss-Markov Theorem. If \(E(\mathbf{y})=\mathbf{X} \boldsymbol{\beta}\) and \(\operatorname{cov}(\mathbf{y})=\sigma^{2} \mathbf{I}\), the least squares estimators \(\hat{\beta}_{0}, \hat{\beta}_{1}, \ldots, \hat{\beta}_{q}\) have minimum variance among all linear unbiased estimators.

The Gauss-Markov theorem is often simplified to the following statement: If \(E(\mathbf{y})=\mathbf{X} \boldsymbol{\beta}\) and \(\operatorname{cov}(\mathbf{y})=\sigma^{2} \mathbf{I}\), the least squares estimators are "best linear unbiased estimators" (BLUE), where "best" implies "minimum variance" and "linear" indicates that the estimators are linear functions of \(\mathbf{y}\). For a review of properties of \(\hat{\boldsymbol{\beta}}\) and an alternative derivation of \(\hat{\boldsymbol{\beta}}\) based on the assumption that \(\mathbf{y}\) is normally distributed, see Rencher (1998, Chapter 7) or Rencher and Schaalje (2008, Chapter 7).

\subsection*{10.2.3 An Estimator for \(\boldsymbol{\sigma}^{2}\)}

It can be shown that
\[
\begin{equation*}
E(\mathrm{SSE})=\sigma^{2}[n-(q+1)]=\sigma^{2}(n-q-1) \tag{10.7}
\end{equation*}
\]

We can therefore obtain an unbiased estimator of \(\sigma^{2}\) as
\[
\begin{equation*}
s^{2}=\frac{\mathbf{S S E}}{n-q-1}=\frac{1}{n-q-1}(\mathbf{y}-\mathbf{X} \hat{\boldsymbol{\beta}})^{\prime}(\mathbf{y}-\mathbf{X} \hat{\boldsymbol{\beta}}) \tag{10.8}
\end{equation*}
\]

We can also express SSE in the form
\[
\begin{equation*}
\operatorname{SSE}=\mathbf{y}^{\prime} \mathbf{y}-\hat{\boldsymbol{\beta}}^{\prime} \mathbf{X}^{\prime} \mathbf{y} \tag{10.9}
\end{equation*}
\]
and we note that there are \(n\) terms in \(\mathbf{y}^{\prime} \mathbf{y}\) and \(q+1\) terms in \(\hat{\boldsymbol{\beta}}^{\prime} \mathbf{X}^{\prime} \mathbf{y}\). The difference is the denominator of \(s^{2}\) in (10.8). Thus the degrees of freedom (denominator) for SSE is reduced by \(q+1\).

The need for an adjustment of \(q+1\) to the degrees of freedom of SSE can be illustrated with a simple random sample of a random variable \(y\) from a population
with mean \(\mu\) and variance \(\sigma^{2}\). The sum of squares \(\sum_{i}\left(y_{i}-\mu\right)^{2}\) has \(n\) degrees of freedom, while \(\sum_{i}\left(y_{i}-\bar{y}\right)^{2}\) has \(n-1\). It is intuitively clear that
\[
E\left[\sum_{i=1}^{n}\left(y_{i}-\mu\right)^{2}\right]>E\left[\sum_{i=1}^{n}\left(y_{i}-\bar{y}\right)^{2}\right]
\]
because \(\bar{y}\) fits the sample better than \(\mu\), which is the mean of the population but not of the sample. Thus (squared) deviations from \(\bar{y}\) will tend to be smaller than deviations from \(\mu\). In fact, it is easily shown that
\[
\begin{align*}
\sum_{i=1}^{n}\left(y_{i}-\mu\right)^{2} & =\sum_{i=1}^{n}\left(y_{i}-\bar{y}+\bar{y}-\mu\right)^{2} \\
& =\sum_{i}\left(y_{i}-\bar{y}\right)^{2}+n(\bar{y}-\mu)^{2} \tag{10.10}
\end{align*}
\]
whence
\[
\sum_{i}\left(y_{i}-\bar{y}\right)^{2}=\sum_{i}\left(y_{i}-\mu\right)^{2}-n(\bar{y}-\mu)^{2} .
\]

Thus \(\sum_{i}\left(y_{i}-\bar{y}\right)^{2}\) is expressible as a sum of \(n\) squares minus one square, which corresponds to \(n-1\) degrees of freedom. More formally, we have
\[
E\left[\sum_{i}\left(y_{i}-\bar{y}\right)^{2}\right]=n \sigma^{2}-\frac{n \sigma^{2}}{n}=(n-1) \sigma^{2}
\]

\subsection*{10.2.4 The Model Corrected for Means}

It is sometimes convenient to "center" the \(x\) 's by subtracting their means, \(\bar{x}_{1}=\) \(\sum_{i=1}^{n} x_{i 1} / n, \bar{x}_{2}=\sum_{i=1}^{n} x_{i 2} / n\), and so on \(\left[\bar{x}_{1}, \bar{x}_{2}, \ldots, \bar{x}_{q}\right.\) are the means of the columns of \(\mathbf{X}\) in (10.2)]. In terms of centered \(x\) 's, the model for each \(y_{i}\) in (10.1) becomes
\[
\begin{equation*}
y_{i}=\alpha+\beta_{1}\left(x_{i 1}-\bar{x}_{1}\right)+\beta_{2}\left(x_{i 2}-\bar{x}_{2}\right)+\cdots+\beta_{q}\left(x_{i q}-\bar{x}_{q}\right)+\varepsilon_{i}, \tag{10.11}
\end{equation*}
\]
where
\[
\begin{equation*}
\alpha=\beta_{0}+\beta_{1} \bar{x}_{1}+\beta_{2} \bar{x}_{2}+\cdots+\beta_{q} \bar{x}_{q} . \tag{10.12}
\end{equation*}
\]

To estimate
\[
\boldsymbol{\beta}_{1}=\left(\begin{array}{c}
\beta_{1} \\
\beta_{2} \\
\vdots \\
\beta_{q}
\end{array}\right)
\]
we use the centered \(x\) 's in the matrix
\[
\mathbf{X}_{c}=\left(\begin{array}{cccc}
x_{11}-\bar{x}_{1} & x_{12}-\bar{x}_{2} & \cdots & x_{1 q}-\bar{x}_{q}  \tag{10.13}\\
x_{21}-\bar{x}_{1} & x_{22}-\bar{x}_{2} & \cdots & x_{2 q}-\bar{x}_{q} \\
\vdots & \vdots & & \vdots \\
x_{n 1}-\bar{x}_{1} & x_{n 2}-\bar{x}_{2} & \cdots & x_{n q}-\bar{x}_{q}
\end{array}\right)=\left(\begin{array}{c}
\left(\mathbf{x}_{1}-\overline{\mathbf{x}}\right)^{\prime} \\
\left(\mathbf{x}_{2}-\overline{\mathbf{x}}\right)^{\prime} \\
\vdots \\
\left(\mathbf{x}_{n}-\overline{\mathbf{x}}\right)^{\prime}
\end{array}\right)
\]
where \(\mathbf{x}_{i}^{\prime}=\left(x_{i 1}, x_{i 2}, \ldots, x_{i q}\right)\) and \(\overline{\mathbf{x}}^{\prime}=\left(\bar{x}_{1}, \bar{x}_{2}, \ldots, \bar{x}_{q}\right)\). Then by analogy to (10.5), the least squares estimate of \(\boldsymbol{\beta}_{1}\) is
\[
\begin{equation*}
\hat{\boldsymbol{\beta}}_{1}=\left(\mathbf{X}_{c}^{\prime} \mathbf{X}_{c}\right)^{-1} \mathbf{X}_{c}^{\prime} \mathbf{y} \tag{10.14}
\end{equation*}
\]

If \(E(y)=\beta_{0}+\beta_{1} x_{1}+\cdots+\beta_{q} x_{q}\) is evaluated at \(x_{1}=\bar{x}_{1}, x_{2}=\bar{x}_{2}, \ldots, x_{q}=\bar{x}_{q}\), the result is the same as \(\alpha\) in (10.12). Thus, we estimate \(\alpha\) by \(\bar{y}\) :
\[
\hat{\alpha}=\bar{y}
\]

In other words, if the origin of the \(x\) 's is shifted to \(\overline{\mathbf{x}}=\left(\bar{x}_{1}, \bar{x}_{2}, \ldots, \bar{x}_{q}\right)^{\prime}\), then the intercept of the fitted model is \(\bar{y}\). With \(\hat{\alpha}=\bar{y}\), we obtain
\[
\begin{equation*}
\hat{\beta}_{0}=\hat{\alpha}-\hat{\beta}_{1} \bar{x}_{1}-\hat{\beta}_{2} \bar{x}_{2}-\cdots-\hat{\beta}_{q} \bar{x}_{q}=\bar{y}-\hat{\boldsymbol{\beta}}_{1}^{\prime} \overline{\mathbf{x}} \tag{10.15}
\end{equation*}
\]
as an estimate of \(\beta_{0}\) in (10.12). Together, the estimators \(\hat{\beta}_{0}\) and \(\hat{\beta}_{1}\) in (10.15) and (10.14) are the same as the usual least squares estimator \(\hat{\boldsymbol{\beta}}\) in (10.5).

We can express \(\hat{\beta}_{1}\) in (10.14) in terms of sample variances and covariances. The overall sample covariance matrix of \(y\) and the \(x\) 's is
\[
\mathbf{S}=\left(\begin{array}{c|cccc}
s_{y y} & s_{y 1} & s_{y 2} & \cdots & s_{y q}  \tag{10.16}\\
\hline s_{1 y} & s_{11} & s_{12} & \cdots & s_{1 q} \\
\vdots & \vdots & \vdots & & \vdots \\
s_{q y} & s_{q 1} & s_{q 2} & \cdots & s_{q q}
\end{array}\right)=\left(\begin{array}{cc}
s_{y y} & \mathbf{s}_{y x}^{\prime} \\
\mathbf{s}_{y x} & \mathbf{S}_{x x}
\end{array}\right)
\]
where \(s_{y y}\) is the variance of \(y, s_{y j}\) is the covariance of \(y\) and \(x_{j}, s_{j j}\) is the variance of \(x_{j}, s_{j k}\) is the covariance of \(x_{j}\) and \(x_{k}\), and \(\mathbf{s}_{y x}^{\prime}=\left(s_{y 1}, s_{y 2}, \ldots, s_{y q}\right)\). These sample variances and covariances are mathematically equivalent to analogous formulas (3.23) and (3.25) for random variables, where the sample variances and covariances were estimates of population variances and covariances. However, here the \(x\) 's are considered to be constants that remain fixed from sample to sample, and a formula such as \(s_{11}=\sum_{i=1}^{n}\left(x_{i 1}-\bar{x}_{1}\right)^{2} /(n-1)\) summarizes the spread in the \(n\) values of \(x_{1}\) but does not estimate a population variance.

To express \(\hat{\boldsymbol{\beta}}_{1}\) in terms of \(\mathbf{S}_{x x}\) and \(\mathbf{s}_{y x}\) in (10.16), we note first that the diagonal elements of \(\mathbf{X}_{c}^{\prime} \mathbf{X}_{c}\) are corrected sums of squares. For example, in the second diagonal position, we have
\[
\sum_{i=1}^{n}\left(x_{i 2}-\bar{x}_{2}\right)^{2}=(n-1) s_{22}
\]

The off-diagonal elements of \(\mathbf{X}_{c}^{\prime} \mathbf{X}_{c}\) are analogous corrected sums of products; for example, the element in the \((1,2)\) position is
\[
\sum_{i=1}^{n}\left(x_{i 1}-\bar{x}_{1}\right)\left(x_{i 2}-\bar{x}_{2}\right)=(n-1) s_{12}
\]

Thus
\[
\begin{equation*}
\frac{1}{n-1} \mathbf{X}_{c}^{\prime} \mathbf{X}_{c}=\mathbf{S}_{x x} \tag{10.17}
\end{equation*}
\]

Similarly,
\[
\begin{equation*}
\frac{1}{n-1} \mathbf{X}_{c}^{\prime} \mathbf{y}=\mathbf{s}_{y x} \tag{10.18}
\end{equation*}
\]
even though \(\mathbf{y}\) has not been centered. The second element of \(\mathbf{X}_{c}^{\prime} \mathbf{y}\), for example, is \(\sum_{i}\left(x_{i 2}-\bar{x}_{2}\right) y_{i}\), which is equal to \((n-1) s_{2 y}\) :
\[
\begin{aligned}
(n-1) s_{2 y} & =\sum_{i=1}^{n}\left(x_{i 2}-\bar{x}_{2}\right)\left(y_{i}-\bar{y}\right) \\
& =\sum_{i}\left(x_{i 2}-\bar{x}_{2}\right) y_{i}-\sum_{i}\left(x_{i 2}-\bar{x}_{2}\right) \bar{y} \\
& =\sum_{i}\left(x_{i 2}-\bar{x}_{2}\right) y_{i}
\end{aligned}
\]
since
\[
\begin{equation*}
\sum_{i}\left(x_{i 2}-\bar{x}_{2}\right) \bar{y}=0 . \tag{10.19}
\end{equation*}
\]

Now, multiplying and dividing by \(n-1\) in (10.14), we obtain
\[
\begin{align*}
\hat{\boldsymbol{\beta}}_{1} & =(n-1)\left(\mathbf{X}_{c}^{\prime} \mathbf{X}_{c}\right)^{-1} \frac{\mathbf{X}_{c}^{\prime} \mathbf{y}}{n-1}=\left(\frac{\mathbf{X}_{c}^{\prime} \mathbf{X}}{n-1}\right)^{-1} \frac{\mathbf{X}_{c}^{\prime} \mathbf{y}}{n-1} \\
& =\mathbf{S}_{x x}^{-1} \mathbf{s}_{y x} \quad[\mathbf{b y}(10.17) \text { and }(10.18)] \tag{10.20}
\end{align*}
\]
and substituting this in (10.15) gives
\[
\begin{equation*}
\hat{\beta}_{0}=\hat{\alpha}-\hat{\boldsymbol{\beta}}_{1}^{\prime} \overline{\mathbf{x}}=\bar{y}-\overline{\mathbf{s}}_{y x}^{\prime} \mathbf{S}_{x x}^{-1} \overline{\mathbf{x}} \tag{10.21}
\end{equation*}
\]

\subsection*{10.2.5 Hypothesis Tests}

In this section, we review two basic tests on the \(\beta\) 's. For other tests and confidence intervals, see Rencher (1998, Section 7.2.4) and Rencher and Schaalje (2008, Sections 8.4-8.7). In order to obtain \(F\)-tests, we assume that \(\mathbf{y}\) is \(N_{n}\left(\mathbf{X} \boldsymbol{\beta}, \sigma^{2} \mathbf{I}\right)\).

\subsection*{10.2.5a Test of Overall Regression}

The overall regression hypothesis that none of the \(x\) 's predicts \(y\) can be expressed as \(H_{0}: \boldsymbol{\beta}_{1}=\mathbf{0}\), since \(\boldsymbol{\beta}_{1}^{\prime}=\left(\beta_{1}, \beta_{2}, \ldots, \beta_{q}\right)\). We do not include \(\beta_{0}=0\) in the hypothesis so as not to restrict \(y\) to have an intercept of zero.

We can write \(\operatorname{SSE}=\mathbf{y}^{\prime} \mathbf{y}-\boldsymbol{\beta}^{\prime} \mathbf{X}^{\prime} \mathbf{y}\) in (10.9) in the form
\[
\begin{equation*}
\mathbf{y}^{\prime} \mathbf{y}=\left(\mathbf{y}^{\prime} \mathbf{y}-\hat{\boldsymbol{\beta}}^{\prime} \mathbf{X}^{\prime} \mathbf{y}\right)+\hat{\boldsymbol{\beta}}^{\prime} \mathbf{X}^{\prime} \mathbf{y} \tag{10.22}
\end{equation*}
\]
which partitions \(\mathbf{y}^{\prime} \mathbf{y}\) into a part due to \(\boldsymbol{\beta}\) and a part due to deviations from the fitted model.

To correct \(\mathbf{y}\) for its mean and thereby avoid inclusion of \(\beta_{0}=0\), we subtract \(n \bar{y}^{2}\) from both sides to obtain
\[
\begin{align*}
\mathbf{y}^{\prime} \mathbf{y}-n \bar{y}^{2} & =\left(\mathbf{y}^{\prime} \mathbf{y}-\hat{\boldsymbol{\beta}}^{\prime} \mathbf{X}^{\prime} \mathbf{y}\right)+\left(\hat{\boldsymbol{\beta}}^{\prime} \mathbf{X}^{\prime} \mathbf{y}-n \bar{y}^{2}\right)  \tag{10.23}\\
& =\mathbf{S S E}+\mathbf{S S R}
\end{align*}
\]
where \(\mathbf{y}^{\prime} \mathbf{y}-n \bar{y}^{2}=\sum_{i}\left(y_{i}-\bar{y}\right)^{2}\) is the total sum of squares adjusted for the mean and SSR \(=\boldsymbol{\beta}^{\prime} \mathbf{X}^{\prime} \mathbf{y}-n \bar{y}^{2}\) is the overall regression sum of squares adjusted for the intercept.

We can test \(H_{0}: \boldsymbol{\beta}_{1}=\mathbf{0}\) by means of
\[
\begin{equation*}
F=\frac{\mathrm{SSR} / q}{\operatorname{SSE} /(n-q-1)}, \tag{10.24}
\end{equation*}
\]
which is distributed as \(F_{q, n-q-1}\) when \(H_{0}: \boldsymbol{\beta}_{1}=\mathbf{0}\) is true. We reject \(H_{0}\) if \(F>\) \(F_{\alpha, h, n-q-1}\).

\subsection*{10.2.5b Test on a Subset of the \(\beta\) 's}

In an attempt to simplify the model, we may wish to test the hypothesis that some of the \(\beta\) 's are zero. For example, in the model
\[
y=\beta_{0}+\beta_{1} x_{1}+\beta_{2} x_{2}+\beta_{3} x_{1}^{2}+\beta_{4} x_{2}^{2}+\beta_{5} x_{1} x_{2}+\varepsilon,
\]
we may be interested in the hypothesis \(H_{0}: \beta_{3}=\beta_{4}=\beta_{5}=0\). If \(H_{0}\) is true, the model is linear in \(x_{1}\) and \(x_{2}\). In other cases, we may want to ascertain whether a single \(\beta_{j}\) can be deleted.

For convenience of exposition, let the \(\beta\) 's that are candidates for deletion be rearranged to appear last in \(\boldsymbol{\beta}\) and denote this subset of \(\beta\) 's by \(\boldsymbol{\beta}_{d}\), where \(d\) reminds us that these \(\beta\) 's are to be deleted if \(H_{0}: \boldsymbol{\beta}_{d}=\mathbf{0}\) is accepted. Let the subset to be retained in the reduced model be denoted by \(\boldsymbol{\beta}_{r}\). Thus \(\boldsymbol{\beta}\) is partitioned into
\[
\boldsymbol{\beta}=\binom{\boldsymbol{\beta}_{r}}{\boldsymbol{\beta}_{d}}
\]

Let \(h\) designate the number of parameters in \(\boldsymbol{\beta}_{d}\). Then there are \(q+1-h\) parameters in \(\boldsymbol{\beta}_{r}\).

To test the hypothesis \(H_{0}: \boldsymbol{\beta}_{d}=\mathbf{0}\), we fit the full model containing all the \(\beta\) 's in \(\boldsymbol{\beta}\) and then fit the reduced model containing only the \(\beta\) 's in \(\boldsymbol{\beta}_{r}\). Let \(\mathbf{X}_{r}\) be the columns of \(\mathbf{X}\) corresponding to \(\boldsymbol{\beta}_{r}\). Then the reduced model can be written as
\[
\begin{equation*}
\mathbf{y}=\mathbf{X}_{r} \boldsymbol{\beta}_{r}+\varepsilon \tag{10.25}
\end{equation*}
\]
and \(\hat{\boldsymbol{\beta}}_{r}=\left(\mathbf{X}_{r}^{\prime} \mathbf{X}_{r}\right)^{-1} \mathbf{X}_{r}^{\prime} \mathbf{y}\). To compare the fit of the full model and the reduced model, we calculate
\[
\begin{equation*}
\hat{\boldsymbol{\beta}}^{\prime} \mathbf{X}^{\prime} \mathbf{y}-\hat{\boldsymbol{\beta}}_{r}^{\prime} \mathbf{X}_{r}^{\prime} \mathbf{y} \tag{10.26}
\end{equation*}
\]
where \(\hat{\boldsymbol{\beta}}^{\prime} \mathbf{X}^{\prime} \mathbf{y}\) is the regression sum of squares from the full model and \(\hat{\boldsymbol{\beta}}_{r}^{\prime} \mathbf{X}_{r}^{\prime} \mathbf{y}\) is the regression sum of squares for the reduced model. The difference in (10.26) shows what \(\boldsymbol{\beta}_{d}\) contributes "above and beyond" \(\boldsymbol{\beta}_{r}\). We can test \(H_{0}: \boldsymbol{\beta}_{\boldsymbol{d}}=\mathbf{0}\) with an \(F\)-statistic:
\[
\begin{align*}
F & =\frac{\left(\hat{\boldsymbol{\beta}}^{\prime} \mathbf{X}^{\prime} \mathbf{y}-\hat{\boldsymbol{\beta}}_{r}^{\prime} \mathbf{X}_{r}^{\prime} \mathbf{y}\right) / h}{\left(\mathbf{y}^{\prime} \mathbf{y}-\hat{\boldsymbol{\beta}}^{\prime} \mathbf{X}^{\prime} \mathbf{y}\right) /(n-q-1)}  \tag{10.27}\\
& =\frac{\left(\operatorname{SSR}_{f}-\mathbf{S S R}_{r}\right) / h}{\mathbf{S S E}_{f} /(n-q-1)}=\frac{\mathbf{M S R}}{\mathrm{MSE}} \tag{10.28}
\end{align*}
\]
where \(\mathrm{SSR}_{f}=\hat{\boldsymbol{\beta}}^{\prime} \mathbf{X}^{\prime} \mathbf{y}\) and \(\mathrm{SSR}_{r}=\hat{\boldsymbol{\beta}}_{r}^{\prime} \mathbf{X}_{r}^{\prime} \mathbf{y}\). The \(F\)-statistic in (10.27) and (10.28) is distributed as \(F_{h, n-q-1}\) if \(H_{0}\) is true. We reject \(H_{0}\) if \(F>F_{\alpha, h, n-q-1}\).

The test in (10.27) is easy to carry out in practice. We fit the full model and obtain the regression and error sums of squares \(\hat{\boldsymbol{\beta}}^{\prime} \mathbf{X}^{\prime} \mathbf{y}\) and \(\mathbf{y}^{\prime} \mathbf{y}-\hat{\boldsymbol{\beta}}^{\prime} \mathbf{X}^{\prime} \mathbf{y}\), respectively. We then fit the reduced model and obtain its regression sum of squares \(\hat{\boldsymbol{\beta}}_{r}^{\prime} \mathbf{X}_{r}^{\prime} \mathbf{y}\) to be subtracted from \(\hat{\boldsymbol{\beta}}^{\prime} \mathbf{X}^{\prime} \mathbf{y}\). If a software package gives the regression sum of squares in corrected form, this can readily be used to obtain \(\hat{\boldsymbol{\beta}}^{\prime} \mathbf{X}^{\prime} \mathbf{y}-\hat{\boldsymbol{\beta}} \mathbf{X}_{r}^{\prime} \mathbf{y}\), since
\[
\hat{\boldsymbol{\beta}}^{\prime} \mathbf{X}^{\prime} \mathbf{y}-n \bar{y}^{2}-\left(\hat{\boldsymbol{\beta}}_{r}^{\prime} \mathbf{X}_{r}^{\prime} \mathbf{y}-n \bar{y}^{2}\right)=\hat{\boldsymbol{\beta}}^{\prime} \mathbf{X}^{\prime} \mathbf{y}-\hat{\boldsymbol{\beta}}_{r}^{\prime} \mathbf{X}_{r}^{\prime} \mathbf{y}
\]

Alternatively, we can obtain \(\hat{\boldsymbol{\beta}}^{\prime} \mathbf{X}^{\prime} \mathbf{y}-\hat{\boldsymbol{\beta}}_{r}^{\prime} \mathbf{X}_{r}^{\prime} \mathbf{y}\) as the difference between error sums of squares for the two models:
\[
\begin{aligned}
\mathbf{S S E}_{r}-\mathrm{SSE}_{f} & =\mathbf{y}^{\prime} \mathbf{y}-\hat{\boldsymbol{\beta}}_{r}^{\prime} \mathbf{X}_{r}^{\prime} \mathbf{y}-\left(\mathbf{y}^{\prime} \mathbf{y}-\hat{\boldsymbol{\beta}}^{\prime} \mathbf{X}^{\prime} \mathbf{y}\right) \\
& =\hat{\boldsymbol{\beta}}^{\prime} \mathbf{X}^{\prime} \mathbf{y}-\hat{\boldsymbol{\beta}}_{r}^{\prime} \mathbf{X}_{r}^{\prime} \mathbf{y}
\end{aligned}
\]

A test for an individual \(\beta_{j}\) above and beyond the other \(\beta\) 's is readily obtained using (10.27). To test \(H_{0}: \beta_{j}=0\), we arrange \(\beta_{j}\) last in \(\boldsymbol{\beta}\),
\[
\boldsymbol{\beta}=\binom{\boldsymbol{\beta}_{r}}{\beta_{j}}
\]
where \(\boldsymbol{\beta}_{r}=\left(\beta_{0}, \beta_{1}, \ldots, \beta_{q-1}\right)^{\prime}\) contains all the \(\beta\) 's except \(\beta_{j}\). By (10.27), the test statistic is
\[
\begin{equation*}
F=\frac{\hat{\boldsymbol{\beta}}^{\prime} \mathbf{X}^{\prime} \mathbf{y}-\hat{\boldsymbol{\beta}}_{r}^{\prime} \mathbf{X}_{r}^{\prime} \mathbf{y}}{\mathbf{S S E}_{f} /(n-q-1)} \tag{10.29}
\end{equation*}
\]
which is \(F_{1, n-q-1}\). Note that \(h=1\). The test of \(H_{0}: \beta_{j}=0\) made by the \(F\) statistic in (10.29) is called a partial \(F\)-test. A detailed breakdown of the effect of each variable in the presence of the others is given by Rencher (1993) and Rencher and Schaalje (2008, Section 10.6).

Since the \(F\)-statistic in (10.29) has 1 and \(n-q-1\) degrees of freedom, it is the square of a \(t\)-statistic. The \(t\)-statistic equivalent to (10.29) is
\[
t=\frac{\hat{\beta}_{j}}{s \sqrt{g_{j j}}}
\]
where \(g_{j j}\) is the \(j\) th diagonal element of \(\left(\mathbf{X}^{\prime} \mathbf{X}\right)^{-1}\) and \(s=\sqrt{\operatorname{SSE}_{f} /(n-q-1)}\) (Rencher and Schaalje 2008, Section 8.5.1).

\subsection*{10.2.6 \(R^{\mathbf{2}}\) in Fixed- \(x\) Regression}

The proportion of the (corrected) total variation in the \(y\) 's that can be attributed to regression on the \(x\) 's is denoted by \(R^{2}\) :
\[
\begin{align*}
R^{2} & =\frac{\text { regression sum of squares }}{\text { total sum of squares }} \\
& =\frac{\hat{\boldsymbol{\beta}}^{\prime} \mathbf{X}^{\prime} \mathbf{y}-n \bar{y}^{2}}{\mathbf{y}^{\prime} \mathbf{y}-n \bar{y}^{2}} . \tag{10.30}
\end{align*}
\]

The ratio \(R^{2}\) is called the coefficient of multiple determination, or more commonly the squared multiple correlation. The multiple correlation \(R\) is defined as the positive square root of \(R^{2}\).

The \(F\)-test for overall regression in (10.24) can be expressed in terms of \(R^{2}\) as
\[
\begin{equation*}
F=\frac{n-q-1}{q} \frac{R^{2}}{1-R^{2}} . \tag{10.31}
\end{equation*}
\]

For the reduced model (10.25), \(R^{2}\) can be written as
\[
\begin{equation*}
R_{r}^{2}=\frac{\hat{\boldsymbol{\beta}}_{r}^{\prime} \mathbf{X}_{r}^{\prime} \mathbf{y}-n \bar{y}^{2}}{\mathbf{y}^{\prime} \mathbf{y}-n \bar{y}^{2}} \tag{10.32}
\end{equation*}
\]

Then in terms of \(R^{2}\) and \(R_{r}^{2}\), the full and reduced model test in (10.27) for \(H_{0}: \boldsymbol{\beta}_{d}=\mathbf{0}\) becomes
\[
\begin{equation*}
F=\frac{\left(R^{2}-R_{r}^{2}\right) / h}{\left(1-R^{2}\right) /(n-q-1)} \tag{10.33}
\end{equation*}
\]
[see (11.36)].
We can express \(R^{2}\) in terms of sample variances, covariances, and correlations:
\[
\begin{equation*}
R^{2}=\frac{\mathbf{s}_{y x}^{\prime} \mathbf{S}_{x x}^{-1} \mathbf{s}_{y x}}{s_{y y}}=\mathbf{r}_{y x}^{\prime} \mathbf{R}_{x x}^{-1} \mathbf{r}_{y x}, \tag{10.34}
\end{equation*}
\]
where \(s_{y y}, \mathbf{s}_{y x}\), and \(\mathbf{S}_{x x}\) are defined in (10.16) and \(\mathbf{r}_{y x}\) and \(\mathbf{R}_{x x}\) are from an analogous partitioning of the sample correlation matrix of \(y\) and the \(x\) 's:
\[
\mathbf{R}=\left(\begin{array}{c|cccc}
1 & r_{y 1} & r_{y 2} & \cdots & r_{y q}  \tag{10.35}\\
\hline r_{1 y} & 1 & r_{12} & \cdots & r_{1 q} \\
\vdots & \vdots & \vdots & & \vdots \\
r_{q y} & r_{q 1} & r_{q 2} & \cdots & 1
\end{array}\right)=\left(\begin{array}{cc}
\mathbf{1} & \mathbf{r}_{y x}^{\prime} \\
\mathbf{r}_{y x} & \mathbf{R}_{x x}
\end{array}\right)
\]

\subsection*{10.2.7 Subset Selection}

In practice, one often has more \(x\) 's than are needed for predicting \(y\). Some of them may be redundant and could be discarded. In addition to logistical motivations for deleting variables, there are statistical incentives; for example, if an \(x\) is deleted from the fitted model, the variances of the \(\hat{\beta}_{j}\) 's and of the \(\hat{y}_{i}\) 's are reduced. Various aspects of model validation are reviewed by Rencher and Schaalje (2008, Section 7.9 and Chapter 9).

The two most popular approaches to subset selection are to (1) examine all possible subsets and (2) use a stepwise technique. We discuss these in the next two sections.

\subsection*{10.2.7a All Possible Subsets}

The optimal approach to subset selection is to examine all possible subsets of the \(x\) 's. This may not be computationally feasible if the sample size and number of variables are large. Some programs take advantage of algorithms that find the optimum subset of each size without examining all of the subsets [see, for example, Furnival and Wilson (1974)].

We discuss three criteria for comparing subsets when searching for the best subset. To conform with established notation in the literature, the number of variables in a subset is denoted by \(p-1\), so that with the inclusion of an intercept, there are \(p\) parameters in the model. The corresponding total number of available variables from which a subset is to be selected is denoted by \(k-1\), with \(k\) parameters in the model.
1. \(R_{p}^{2}\). By its definition in ( 10.30 ) as the proportion of total (corrected) sum of squares accounted for by regression, \(R^{2}\) is clearly a measure of model fit. The subscript \(p\) is an index of the subset size, since it indicates the number of parameters in the model, including an intercept. However, \(R_{p}^{2}\) does not reach a maximum for any value of \(p\) less than \(k\) because it cannot decrease when a variable is added to the model. The usual procedure is to find the subset with largest \(R_{p}^{2}\) for each of \(p=2,3, \ldots, k\) and then choose a value of \(p\) beyond which the increases in \(R^{2}\) appear to be unimportant. This judgment is, of course, subjective.
2. \(s_{p}^{2}\). Another useful criterion is the variance estimator for each subset as defined in (10.8):
\[
\begin{equation*}
s_{p}^{2}=\frac{\mathrm{SSE}_{p}}{n-p} \tag{10.36}
\end{equation*}
\]

For each of \(p=2,3, \ldots, k\), we find the subset with smallest \(s_{p}^{2}\). If \(k\) is fairly large, a typical pattern as \(p\) approaches \(k\) is for the minimal \(s_{p}^{2}\) to decrease to an overall minimum less than \(s_{k}^{2}\) and then increase. The minimum value of \(s_{p}^{2}\) can be less than \(s_{k}^{2}\) if the decrease in \(\mathrm{SSE}_{p}\) with an additional variable does not offset the loss of a degree of freedom in the denominator. It is often suggested that the researcher choose the subset with absolute minimum \(s_{p}^{2}\). However, as Hocking (1976, p.19) notes, this procedure may fit some noise unique to the sample and thereby include one or more extraneous predictor variables. An alternative suggestion is to choose \(p\) such that \(\min _{p} s_{p}^{2}=s_{k}^{2}\), or more precisely, choose the smallest value of \(p\) such that \(\min _{p} s_{p}^{2}<s_{k}^{2}\), since there will not be a \(p<k\) such that \(\min _{p} s_{p}^{2}\) is exactly equal to \(s_{k}^{2}\).
3. \(C_{p}\). The \(C_{p}\) criterion is due to Mallows (1964, 1973). In the following development, we follow Myers (1990, pp. 180-182). The expected squared error, \(E\left[\hat{y}_{i}-E\left(y_{i}\right)\right]^{2}\), is used in formulating the \(C_{p}\) criterion because it incorporates a variance component and a bias component. The goal is to find a model that achieves a good balance between the bias and variance of the fitted values, \(\hat{y}_{i}\). Bias arises when the \(\hat{y}_{i}\) values are based on an incorrect model, in which \(E\left(\hat{y}_{i}\right) \neq E\left(y_{i}\right)\). If \(\hat{y}_{i}\) were based on the correct model, so that \(E\left(\hat{y}_{i}\right)=E\left(y_{i}\right)\), then \(E\left[\hat{y}_{i}-E\left(y_{i}\right)\right]^{2}\) would be equal to \(\operatorname{var}\left(\hat{y}_{i}\right)\). In general, however, as we examine many competing models, for various values of \(p, \hat{y}_{i}\) is not based on the correct model, and we have (see Problem 10.4)
\[
\begin{align*}
E\left[\hat{y}_{i}-E\left(y_{i}\right)\right]^{2} & =E\left[\hat{y}_{i}-E\left(\hat{y}_{i}\right)+E\left(\hat{y}_{i}\right)-E\left(y_{i}\right)\right]^{2} \\
& =E\left[\hat{y}_{i}-E\left(\hat{y}_{i}\right)\right]^{2}+\left[E\left(\hat{y}_{i}\right)-E\left(y_{i}\right)\right]^{2}  \tag{10.37}\\
& =\operatorname{var}\left(\hat{y}_{i}\right)+\left(\text { bias in } \hat{y}_{i}\right)^{2} . \tag{10.38}
\end{align*}
\]

For a given value of \(p\), the total expected squared error for the \(n\) observations in the sample, standardized by dividing by \(\sigma^{2}\), becomes
\[
\begin{equation*}
\frac{1}{\sigma^{2}} \sum_{i=1}^{n}\left[\hat{y}_{i}-E\left(y_{i}\right)\right]^{2}=\frac{1}{\sigma^{2}} \sum_{i=1}^{n} \operatorname{var}\left(\hat{y}_{i}\right)+\frac{1}{\sigma^{2}} \sum_{i=1}^{n}\left(\text { bias in } \hat{y}_{i}\right)^{2} . \tag{10.39}
\end{equation*}
\]

Before defining \(C_{p}\) as an estimate of (10.39), we can achieve some simplification. We first show that \(\sum_{i} \operatorname{var}\left(\hat{y}_{i}\right) / \sigma^{2}\) is equal to \(p\). Let the model for all \(n\) observations be designated by
\[
\mathbf{y}=\mathbf{X}_{p} \boldsymbol{\beta}_{p}+\varepsilon
\]

We assume that, in general, this prospective model is underspecified and that the true model (which produces \(\sigma^{2}\) ) contains additional \(\beta\) 's and additional columns of the \(\mathbf{X}\) matrix. If we designate the \(i\) th row of \(\mathbf{X}_{p}\) by \(\mathbf{x}_{p i}^{\prime}\), then the first term on the right side
of (10.39) becomes (see also Problem 10.5)
\[
\begin{array}{rlrl}
\frac{1}{\sigma^{2}} \sum_{i=1}^{n} \operatorname{var}\left(\hat{y}_{i}\right) & =\frac{1}{\sigma^{2}} \sum_{i=1}^{n} \operatorname{var}\left(\mathbf{x}_{p i}^{\prime} \hat{\boldsymbol{\beta}}_{p}\right) & \\
& =\frac{1}{\sigma^{2}} \sum_{i} \mathbf{x}_{p i}^{\prime}\left[\sigma^{2}\left(\mathbf{X}_{p}^{\prime} \mathbf{X}_{p}\right)^{-1}\right] \mathbf{x}_{p i} & & {[\mathrm{by}(3.70)]} \\
& =\operatorname{tr}\left[\mathbf{X}_{p}\left(\mathbf{X}_{p}^{\prime} \mathbf{X}_{p}\right)^{-1} \mathbf{X}_{p}^{\prime}\right] & & {[\mathrm{by}(3.65)]} \\
& =\operatorname{tr}\left[\left(\mathbf{X}_{p}^{\prime} \mathbf{X}_{p}\right)^{-1} \mathbf{X}_{p}^{\prime} \mathbf{X}_{p}\right] & & {[\mathrm{by}(2.97)]} \\
& =\operatorname{tr}\left(\mathbf{I}_{p}\right)=p . & \tag{10.41}
\end{array}
\]

It can be shown (Myers 1990, pp. 178-179) that
\[
\begin{equation*}
\sum_{i=1}^{n}\left(\text { bias in } \hat{y}_{i}\right)^{2}=(n-p) E\left(s_{p}^{2}-\sigma^{2}\right) \tag{10.42}
\end{equation*}
\]

Using (10.41) and (10.42), the final simplified form of the (standardized) total expected squared error in (10.39) is
\[
\begin{equation*}
\frac{1}{\sigma^{2}} \sum_{i=1}^{n}\left[\hat{y}_{i}-E\left(y_{i}\right)\right]^{2}=p+\frac{n-p}{\sigma^{2}} E\left(s_{p}^{2}-\sigma^{2}\right) \tag{10.43}
\end{equation*}
\]

In practice, \(\sigma^{2}\) is usually estimated by \(s_{k}^{2}\), the MSE from the full model. We thus estimate (10.43) by
\[
\begin{equation*}
C_{p}=p+(n-p) \frac{s_{p}^{2}-s_{k}^{2}}{s_{k}^{2}} \tag{10.44}
\end{equation*}
\]

An alternative form is
\[
\begin{equation*}
C_{p}=\frac{\mathbf{S S E}_{p}}{s_{k}^{2}}-(n-2 p) \tag{10.45}
\end{equation*}
\]

In (10.44), we see that if the bias is small for a particular model, \(C_{p}\) will be close to \(p\). For this reason, the line \(C_{p}=p\) is commonly plotted along with the \(C_{p}\) values of several candidate models. We look for small values of \(C_{p}\) that are near this line.

In a Monte Carlo study, Hilton (1983) compared several subset selection criteria based on \(\mathrm{MSE}_{p}\) and \(C_{p}\). The three best procedures were to choose (1) the subset with the smallest \(p\) such that \(C_{p}<p\), (2) the subset with the smallest \(p\) such that \(s_{p}^{2}<s_{k}^{2}\), and (3) the subset with minimum \(s_{p}^{2}\). The first of these was found to give best results overall, with the second method close behind. The third method performed best in some cases where \(k\) was small.

\subsection*{10.2.7b Stepwise Selection}

For many data sets, it may be impractical to examine all possible subsets, even with an efficient algorithm such as that of Furnival and Wilson (1974). In such cases, we can use the familiar stepwise approach, which is widely available and has virtually no limit as to the number of variables or observations. A related stepwise technique
was discussed in Sections 6.11 .2 and 8.9 in connection with selection of dependent variables to separate groups in a MANOVA or discriminant analysis setting. In this section, we are concerned with selecting the independent variables ( \(x\) 's) that best predict the dependent variable ( \(y\) ) in regression.

We first review the forward selection procedure, which typically uses an \(F\)-test at each step. At the first step, \(y\) is regressed on each \(x_{j}\) alone and the \(x\) with the largest \(F\)-value is "entered" into the model. At the second step, we search for the variable with the largest partial \(F\)-value for testing the significance of each variable in the presence of the variable first entered. Thus, if we denote the first variable to enter as \(x_{1}\), then at the second step we calculate the partial \(F\)-statistic
\[
F=\frac{\operatorname{MSR}\left(x_{j} \mid x_{1}\right)}{\operatorname{MSE}\left(x_{j}, x_{1}\right)}
\]
for each \(j \neq 1\) and choose the variable that maximizes \(F\), where \(\mathrm{MSR}=\left(\mathrm{SSR}_{f}-\right.\) \(\left.\mathrm{SSR}_{r}\right) / h\) and \(\mathrm{MSE}=\mathrm{SSE}_{f} /(n-q-1)\) are the mean squares for regression and error, respectively, as in (10.28). In this case, \(\operatorname{SSR}_{f}=\operatorname{SSR}\left(x_{1}, x_{j}\right)\) and \(\operatorname{SSR}_{r}=\operatorname{SSR}\left(x_{1}\right)\). Note also that \(h=1\) because only one variable is being added, and MSE is calculated using only the variable already entered plus the candidate variable. This procedure continues at each step until the largest partial \(F\) for an entering variable falls below a preselected threshold \(F\)-value or until the corresponding \(p\)-value exceeds some predetermined level.

The stepwise selection procedure similarly seeks the best variable to enter at each step. Then after a variable has entered, each of the variables previously entered is examined by a partial \(F\)-test to see if it is no longer significant and can be dropped from the model.

The backward elimination procedure begins with all \(x\) 's in the model and deletes one at a time. The partial \(F\)-statistic for each variable in the presence of the others is calculated, and the variable with smallest \(F\) is eliminated. This continues until the smallest \(F\) at some step exceeds a preselected threshold value.

Since these sequential methods do not examine all subsets, they will often fail to find the optimum subset, especially if \(k\) is large. However, \(R_{p}^{2}, s_{p}^{2}\), or \(C_{p}\) may not differ substantially between the optimum subset and the one found by stepwise selection. These sequential methods have been popular for at least a generation, and it is very likely they will continue to be used, even though increased computing power has put the optimal methods within reach for larger data sets.

There are some possible risks in the use of stepwise methods. The stepwise procedure may fail to detect a true predictor (an \(x_{j}\) for which \(\beta_{j} \neq 0\) ) because \(s_{p}^{2}\) is biased upward in an underspecified model, thus artificially reducing the partial \(F\)-value. On the other hand, a variable that is not a true predictor of \(y\) (an \(x_{j}\) for which \(\beta_{j}=0\) ) may enter because of chance correlations in a particular sample. In the presence of such "noise" variables, the partial \(F\)-statistic for the entering variable does not have an \(F\)-distribution because it is maximized at each step. The calculated \(p\)-values become optimistic. This problem intensifies when the sample size is relatively small compared to the number of variables. Rencher and Pun (1980) found that in such cases some surprisingly large values of \(R^{2}\) can occur, even when there is no relation-
ship between \(y\) and the \(x\) 's in the population. In a related study, Flack and Chang (1987) included \(x\) 's that were authentic contributors as well as noise variables. They found that "for most samples, a large percentage of the selected variables is noise, particularly when the number of candidate variables is large relative to the number of observations. The adjusted \(R^{2}\) of the selected variables is highly inflated" (p. 84).

\subsection*{10.3 MULTIPLE REGRESSION: RANDOM \(x\) 's}

In Section 10.2, it was assumed that the \(x\) 's were fixed and would have the same values if another sample were taken; that is, the same \(\mathbf{X}\) matrix would be used each time a y vector was observed. However, many regression applications involve \(x\) 's that are random variables.

Thus in the random- \(x\) case, the values of \(x_{1}, x_{2}, \ldots, x_{q}\) are not under the control of the experimenter. They occur randomly along with \(y\). On each subject we observe \(y, x_{1}, x_{2}, \ldots, x_{q}\).

If we assume that \(\left(y, x_{1}, x_{2}, \ldots, x_{q}\right)\) has a multivariate normal distribution, then \(\hat{\boldsymbol{\beta}}, R^{2}\), and the \(F\)-tests have the same formulation as in the fixed- \(x\) case [for details, see Rencher (1998, Section 7.3) or Rencher and Schaalje (2008, Section 10.5)]. Thus with the multivariate normal assumption, we can proceed with estimation and testing the same way in the random- \(x\) case as with fixed \(x\) 's.

\subsection*{10.4 MULTIVARIATE MULTIPLE REGRESSION: ESTIMATION}

In this section we extend the estimation results of Sections 10.2.2-10.2.4 to the multivariate \(y\) case. We assume the \(x\) 's are fixed.

\subsection*{10.4.1 The Multivariate Linear Model}

We turn now to the multivariate multiple regression model, where multivariate refers to the dependent variables and multiple pertains to the independent variables. In this case, several \(y\) 's are measured corresponding to each set of \(x\) 's. Each of \(y_{1}, y_{2}, \ldots, y_{p}\) is to be predicted by all of \(x_{1}, x_{2}, \ldots, x_{q}\).

The \(n\) observed values of the vector of \(y\) 's can be listed as rows in the following matrix:
\[
\mathbf{Y}=\left(\begin{array}{cccc}
y_{11} & y_{12} & \cdots & y_{1 p} \\
y_{21} & y_{22} & \cdots & y_{2 p} \\
\vdots & \vdots & & \vdots \\
y_{n 1} & y_{n 2} & \cdots & y_{n p}
\end{array}\right)=\left(\begin{array}{c}
\mathbf{y}_{1}^{\prime} \\
\mathbf{y}_{2}^{\prime} \\
\vdots \\
\mathbf{y}_{n}^{\prime}
\end{array}\right)
\]

Thus each row of \(\mathbf{Y}\) contains the values of the \(p\) dependent variables measured on a subject. Each column of \(\mathbf{Y}\) consists of the \(n\) observations on one of the \(p\) variables and therefore corresponds to the \(\mathbf{y}\) vector in the (univariate) regression model (10.3).

The \(n\) values of \(x_{1}, x_{2}, \ldots, x_{q}\) can be placed in a matrix that turns out to be the same as the \(\mathbf{X}\) matrix in the multiple regression formulation in Section 10.2.1:
\[
\mathbf{X}=\left(\begin{array}{ccccc}
1 & x_{11} & x_{12} & \cdots & x_{1 q} \\
1 & x_{21} & x_{22} & \cdots & x_{2 q} \\
\vdots & \vdots & \vdots & & \vdots \\
1 & x_{n 1} & x_{n 2} & \cdots & x_{n q}
\end{array}\right)
\]

We assume that \(\mathbf{X}\) is fixed from sample to sample.
Since each of the \(p y\) 's will depend on the \(x\) 's in its own way, each column of \(\mathbf{Y}\) will need different \(\beta\) 's. Thus we have a column of \(\beta\) 's for each column of \(\mathbf{Y}\), and these columns form a matrix \(\mathbf{B}=\left(\boldsymbol{\beta}_{1}, \boldsymbol{\beta}_{2}, \ldots, \boldsymbol{\beta}_{p}\right)\). Our multivariate model is therefore
\[
\begin{equation*}
\mathbf{Y}=\mathbf{X B}+\boldsymbol{\Xi} \tag{10.46}
\end{equation*}
\]
where \(\mathbf{Y}\) is \(n \times p, \mathbf{X}\) is \(n \times(q+1)\), and \(\mathbf{B}\) is \((q+1) \times p\). The notation \(\boldsymbol{\Xi}\) (the uppercase version of \(\boldsymbol{\xi}\) ) is adopted here because of its resemblance to \(\varepsilon\).

We illustrate the multivariate model with \(p=2, q=3\) :
\[
\left(\begin{array}{cc}
y_{11} & y_{12} \\
y_{21} & y_{22} \\
\vdots & \vdots \\
y_{n 1} & y_{n 2}
\end{array}\right)=\left(\begin{array}{cccc}
1 & x_{11} & x_{12} & x_{13} \\
1 & x_{21} & x_{22} & x_{23} \\
\vdots & \vdots & \vdots & \vdots \\
1 & x_{n 1} & x_{n 2} & x_{n 3}
\end{array}\right)\left(\begin{array}{cc}
\beta_{01} & \beta_{02} \\
\beta_{11} & \beta_{12} \\
\beta_{21} & \beta_{22} \\
\beta_{31} & \beta_{32}
\end{array}\right)+\left(\begin{array}{cc}
\varepsilon_{11} & \varepsilon_{12} \\
\varepsilon_{21} & \varepsilon_{22} \\
\vdots & \vdots \\
\varepsilon_{n 1} & \varepsilon_{n 2}
\end{array}\right)
\]

The model for the first column of \(\mathbf{Y}\) is
\[
\left(\begin{array}{c}
y_{11} \\
y_{21} \\
\vdots \\
y_{n 1}
\end{array}\right)=\left(\begin{array}{cccc}
1 & x_{11} & x_{12} & x_{13} \\
1 & x_{21} & x_{22} & x_{23} \\
\vdots & \vdots & \vdots & \vdots \\
1 & x_{n 1} & x_{n 2} & x_{n 3}
\end{array}\right)\left(\begin{array}{c}
\beta_{01} \\
\beta_{11} \\
\beta_{21} \\
\beta_{31}
\end{array}\right)+\left(\begin{array}{c}
\varepsilon_{11} \\
\varepsilon_{21} \\
\vdots \\
\varepsilon_{n 1}
\end{array}\right)
\]
and for the second column, we have
\[
\left(\begin{array}{c}
y_{12} \\
y_{22} \\
\vdots \\
y_{n 2}
\end{array}\right)=\left(\begin{array}{cccc}
1 & x_{11} & x_{12} & x_{13} \\
1 & x_{21} & x_{22} & x_{23} \\
\vdots & \vdots & \vdots & \vdots \\
1 & x_{n 1} & x_{n 2} & x_{n 3}
\end{array}\right)\left(\begin{array}{c}
\beta_{02} \\
\beta_{12} \\
\beta_{22} \\
\beta_{32}
\end{array}\right)+\left(\begin{array}{c}
\varepsilon_{12} \\
\varepsilon_{22} \\
\vdots \\
\varepsilon_{n 2}
\end{array}\right)
\]

By analogy with the univariate case in Section 10.2.1, additional assumptions that lead to good estimates are as follows:
1. \(E(\mathbf{Y})=\mathbf{X B}\) or \(E(\boldsymbol{\Xi})=\mathbf{O}\).
2. \(\operatorname{cov}\left(\mathbf{y}_{i}\right)=\boldsymbol{\Sigma}\) for all \(i=1,2, \ldots, n\), where \(\mathbf{y}_{i}^{\prime}\) is the \(i\) th row of \(\mathbf{Y}\).
3. \(\operatorname{cov}\left(\mathbf{y}_{i}, \mathbf{y}_{j}\right)=\mathbf{O}\) for all \(i \neq j\).

Assumption 1 states that the linear model is correct and that no additional \(x\) 's are needed to predict the \(y\) 's. Assumption 2 asserts that each of the \(n\) observation vectors (rows) in \(\mathbf{Y}\) has the same covariance matrix. Assumption 3 declares that observation vectors (rows of \(\mathbf{Y}\) ) are uncorrelated with each other. Thus we assume that the \(y\) 's within an observation vector (row of \(\mathbf{Y}\) ) are correlated with each other but independent of the \(y\) 's in any other observation vector.

The covariance matrix \(\Sigma\) in assumption 2 contains the variances and covariances of \(y_{i 1}, y_{i 2}, \ldots, y_{i p}\) in any \(\mathbf{y}_{i}\) :
\[
\operatorname{cov}\left(\mathbf{y}_{i}\right)=\boldsymbol{\Sigma}=\left(\begin{array}{cccc}
\sigma_{11} & \sigma_{12} & \cdots & \sigma_{1 p} \\
\sigma_{21} & \sigma_{22} & \cdots & \sigma_{2 p} \\
\vdots & \vdots & & \vdots \\
\sigma_{p 1} & \sigma_{p 2} & \cdots & \sigma_{p p}
\end{array}\right)
\]

The covariance matrix \(\mathbf{O}\) in assumption 3 contains the covariances of each of \(y_{i 1}\), \(y_{i 2}, \ldots, y_{i p}\) with each of \(y_{j 1}, y_{j 2}, \ldots, y_{j p}\) :
\[
\left(\begin{array}{cccc}
\operatorname{cov}\left(y_{i 1}, y_{j 1}\right) & \operatorname{cov}\left(y_{i 1}, y_{j 2}\right) & \cdots & \operatorname{cov}\left(y_{i 1}, y_{j p}\right) \\
\operatorname{cov}\left(y_{i 2}, y_{j 1}\right) & \operatorname{cov}\left(y_{i 2}, y_{j 2}\right) & \cdots & \operatorname{cov}\left(y_{i 2}, y_{j p}\right) \\
\vdots & \vdots & & \vdots \\
\operatorname{cov}\left(y_{i p}, y_{j 1}\right) & \operatorname{cov}\left(y_{i p}, y_{j 2}\right) & \cdots & \operatorname{cov}\left(y_{i p}, y_{j p}\right)
\end{array}\right)=\left(\begin{array}{cccc}
0 & 0 & \cdots & 0 \\
0 & 0 & \cdots & 0 \\
\vdots & \vdots & & \vdots \\
0 & 0 & \cdots & 0
\end{array}\right) .
\]

To aid in the discussion of properties of multivariate multiple regression, we will often choose to consider the multivariate model (10.46) re-expressed in a form that is more directly analogous to the univariate model in (10.3). Using Kronecker and vec notation and property (2.122) discussed in Section 2.12, we re-write the model as
\[
\begin{align*}
\operatorname{vec} \mathbf{Y} & =\operatorname{vec} \mathbf{X B}+\operatorname{vec} \boldsymbol{\Xi} \\
& =\left(\mathbf{I}_{p} \otimes \mathbf{X}\right) \operatorname{vec} \mathbf{B}+\operatorname{vec} \boldsymbol{\Xi} \\
& =\mathbf{X}^{*} \boldsymbol{\beta}^{*}+\boldsymbol{\varepsilon}^{*} \tag{10.47}
\end{align*}
\]
where \(\mathbf{X}^{*}=\mathbf{I}_{p} \otimes \mathbf{X}\) is a \(p n \times p(q+1)\) block-diagonal matrix, \(\boldsymbol{\beta}^{*}=\operatorname{vec} \mathbf{B}\) is a vector of length \(p(q+1)\), and \(\boldsymbol{\varepsilon}^{*}=\mathrm{vec} \boldsymbol{\Xi}\) is a vector of length \(p n\). Note that model (10.47) resembles the univariate model presented in (10.3), with vec \(\mathbf{Y}\) as our vector of responses, \(\mathbf{X}^{*}\) as our full-column-rank matrix of predictors, \(\boldsymbol{\beta}^{*}\) as our vector of regression coefficients, and \(\varepsilon^{*}\) as our vector of random errors.

\subsection*{10.4.2 Least Squares Estimation in the Multivariate Model}

By analogy with the univariate case in (10.5), we estimate \(\mathbf{B}\) with
\[
\begin{equation*}
\hat{\mathbf{B}}=\left(\mathbf{X}^{\prime} \mathbf{X}\right)^{-1} \mathbf{X}^{\prime} \mathbf{Y} \tag{10.48}
\end{equation*}
\]

We call \(\hat{\mathbf{B}}\) the least squares estimator for \(\mathbf{B}\) because it "minimizes" \(\mathbf{E}=\hat{\boldsymbol{\Xi}}^{\prime} \hat{\boldsymbol{E}}\), a matrix analogous to SSE:
\[
\mathbf{E}=\hat{\boldsymbol{\Xi}}^{\prime} \hat{\boldsymbol{\Xi}}=(\mathbf{Y}-\mathbf{X} \hat{\mathbf{B}})^{\prime}(\mathbf{Y}-\mathbf{X} \hat{\mathbf{B}})
\]

The matrix \(\hat{\mathbf{B}}\) minimizes \(\mathbf{E}\) in the following sense. If we let \(\mathbf{B}_{0}\) be an estimate that may possibly be better than \(\hat{\mathbf{B}}\) and add \(\mathbf{X B}-\mathbf{X B}_{0}\) to \(\mathbf{Y}-\mathbf{X B}\), we find that this adds a positive definite matrix to \(\mathbf{E}=(\mathbf{Y}-\mathbf{X} \hat{\mathbf{B}})^{\prime}(\mathbf{Y}-\mathbf{X} \hat{\mathbf{B}})\) (Rencher 1998, Section 7.4.2). Thus we cannot improve on \(\hat{\mathbf{B}}\). The least squares estimate \(\hat{\mathbf{B}}\) also minimizes the scalar quantities \(\operatorname{tr}(\mathbf{Y}-\mathbf{X} \hat{\mathbf{B}})^{\prime}(\mathbf{Y}-\mathbf{X} \hat{\mathbf{B}})\) and \(\left|(\mathbf{Y}-\mathbf{X} \hat{\mathbf{B}})^{\prime}(\mathbf{Y}-\mathbf{X} \hat{\mathbf{B}})\right|\). Note that by (2.98) \(\operatorname{tr}(\mathbf{Y}-\mathbf{X} \hat{\mathbf{B}})^{\prime}(\mathbf{Y}-\mathbf{X B})=\sum_{i=1}^{n} \sum_{j=1}^{p} \hat{\varepsilon}_{i j}^{2}\).

We noted earlier that in the model \(\mathbf{Y}=\mathbf{X B}+\boldsymbol{\Xi}\), there is a column of \(\mathbf{B}\) corresponding to each column of \(\mathbf{Y}\); that is, each \(y_{j}, j=1,2, \ldots, p\), is predicted differently by \(x_{1}, x_{2}, \ldots, x_{q}\). (This is illustrated in Section 10.4.1 for \(p=2\) ). In the estimate \(\hat{\mathbf{B}}=\left(\mathbf{X}^{\prime} \mathbf{X}\right)^{-1} \mathbf{X}^{\prime} \mathbf{Y}\), we have a similar pattern. The matrix product \(\left(\mathbf{X}^{\prime} \mathbf{X}\right)^{-1} \mathbf{X}^{\prime}\) is multiplied by each column of \(\mathbf{Y}\) [see (2.48)]. Thus the \(j\) th column of \(\hat{\mathbf{B}}\) is the usual least squares estimate \(\hat{\boldsymbol{\beta}}\) for the \(j\) th dependent variable \(y_{j}\). To give this a more precise expression, let us denote the \(p\) columns of \(\mathbf{Y}\) by \(\mathbf{y}_{(1)}, \mathbf{y}_{(2)}, \ldots, \mathbf{y}_{(p)}\) to distinguish them from the \(n\) rows \(\mathbf{y}_{i}^{\prime}, i=1,2, \ldots, n\), Then
\[
\begin{align*}
\hat{\mathbf{B}} & =\left(\mathbf{X}^{\prime} \mathbf{X}\right)^{-1} \mathbf{X}^{\prime} \mathbf{Y}=\left(\mathbf{X}^{\prime} \mathbf{X}\right)^{-1} \mathbf{X}^{\prime}\left(\mathbf{y}_{(1)}, \mathbf{y}_{(2)}, \ldots, \mathbf{y}_{(p)}\right) \\
& =\left[\left(\mathbf{X}^{\prime} \mathbf{X}\right)^{-1} \mathbf{X}^{\prime} \mathbf{y}_{(1)},\left(\mathbf{X}^{\prime} \mathbf{X}\right)^{-1} \mathbf{X}^{\prime} \mathbf{y}_{(2)}, \ldots,\left(\mathbf{X}^{\prime} \mathbf{X}\right)^{-1} \mathbf{X}^{\prime} \mathbf{y}_{(p)}\right] \\
& =\left[\hat{\boldsymbol{\beta}}_{(1)}, \hat{\boldsymbol{\beta}}_{(2)}, \ldots, \hat{\boldsymbol{\beta}}_{(p)}\right] . \tag{10.49}
\end{align*}
\]

\section*{EXAMPLE 10.4.2}

The results of a planned experiment involving a chemical reaction are given in Table 10.1 (Box and Youle 1955).

The input (independent) variables are
\[
x_{1}=\text { temperature }, \quad x_{2}=\text { concentration }, \quad x_{3}=\text { time } .
\]

The yield (dependent) variables are
\(y_{1}=\) percentage of unchanged starting material,
\(y_{2}=\) percentage converted to the desired product,
\(y_{3}=\) percentage of unwanted by-product.

Using (10.48), the least squares estimator \(\hat{\mathbf{B}}\) for the regression of ( \(y_{1}, y_{2}, y_{3}\) ) on ( \(x_{1}, x_{2}, x_{3}\) ) is given by
\[
\begin{aligned}
\hat{\mathbf{B}} & =\left(\mathbf{X}^{\prime} \mathbf{X}\right)^{-1} \mathbf{X}^{\prime} \mathbf{Y} \\
& =\left(\begin{array}{rrr}
332.11 & -26.04 & -164.08 \\
-1.55 & .40 & .91 \\
-1.42 & .29 & .90 \\
-2.24 & 1.03 & 1.15
\end{array}\right) .
\end{aligned}
\]

Note that the first column of \(\hat{\mathbf{B}}\) gives \(\hat{\beta}_{0}, \hat{\beta}_{1}, \hat{\beta}_{2}, \hat{\beta}_{3}\) for regression of \(y_{1}\) on \(x_{1}\), \(x_{2}, x_{3}\); the second column of \(\hat{\mathbf{B}}\) gives \(\hat{\beta}_{0}, \hat{\beta}_{1}, \hat{\beta}_{2}, \hat{\beta}_{3}\) for regression of \(y_{2}\) on \(x_{1}\), \(x_{2}, x_{3}\), and so on.

\hline
\end{tabular}

\subsection*{10.4.3 Properties of Least Squares Estimator \(\hat{\mathrm{B}}\)}

The least squares estimator \(\hat{\mathbf{B}}\) can be obtained without imposing the assumptions \(E(\mathbf{y})=\mathbf{X B}, \operatorname{cov}\left(\mathbf{y}_{i}\right)=\boldsymbol{\Sigma}\), and \(\operatorname{cov}\left(\mathbf{y}_{i}, \mathbf{y}_{j}\right)=\mathbf{O}\). However, when these assumptions hold, \(\hat{\mathbf{B}}\) has the following properties:
1. The estimator \(\hat{\mathbf{B}}\) is unbiased, that is, \(E(\hat{\mathbf{B}})=\mathbf{B}\). This means that if we took repeated random samples from the same population, the average value of \(\hat{\mathbf{B}}\) would be \(\mathbf{B}\).
2. All \(\hat{\beta}_{j k}\) 's in \(\hat{\mathbf{B}}\) are correlated with each other. This is due to the correlations among the \(x\) 's and among the \(y\) 's. The \(\hat{\beta}\) 's within a given column of \(\hat{\mathbf{B}}\) are correlated because \(x_{1}, x_{2}, \ldots, x_{q}\) are correlated. If \(x_{1}, x_{2}, \ldots, x_{q}\) were orthogonal to each other, the \(\hat{\beta}\) 's within each column of \(\hat{\mathbf{B}}\) would be uncorrelated. Thus the relationship of the \(x\) 's to each other affects the relationship of the \(\hat{\beta}\) 's within each column to each other. On the other hand, the \(\hat{\beta}\) 's in each column are correlated with \(\hat{\beta}\) 's in other columns because \(y_{1}, y_{2}, \ldots, y_{p}\) are correlated.

Because of the correlations among the columns of \(\hat{\mathbf{B}}\), we need multivariate tests for hypotheses about B. We cannot use an \(F\)-test from Section 10.2.5 on each column of \(\mathbf{B}\), because these \(F\)-tests would not take into account the
correlations or preserve the \(\alpha\)-level. Some appropriate multivariate tests are given in Section 10.5.
3. The least squares estimators \(\hat{\beta}_{j k}\) in \(\hat{\mathbf{B}}\) have minimum variance among all possible linear unbiased estimators. In other words, \(\hat{\mathbf{B}}\) is the best linear unbiased estimator (BLUE) for B. This result is an extension of the Gauss-Markov theorem discussed in Section 10.2.2. The restriction to unbiased estimators is necessary to exclude trivial estimators such as a constant, which has variance equal to zero, but is of no interest. This minimum variance property of least squares estimators is remarkable for its distributional generality; normality of the \(y\) 's is not required. Equally remarkable is the fact that the BLUE for \(\mathbf{B}\) is not a function of \(\boldsymbol{\Sigma}\), the common covariance matrix for the observation vector \(\mathbf{y}_{i}, i=1,2, \ldots, n\).

To demonstrate that the least squares estimator \(\hat{\mathbf{B}}\) is the BLUE for \(\mathbf{B}\), we consider the multivariate multiple regression model (10.46) as written in the alternative form in (10.47). The least squares estimator of \(\boldsymbol{\beta}^{*}\) in (10.47) is \(\hat{\boldsymbol{\beta}}^{*}=\left(\mathbf{X}^{* \prime} \mathbf{X}^{*}\right)^{-1} \mathbf{X}^{* \prime}\) vec \(\mathbf{Y}\), but it is not readily apparent that \(\hat{\boldsymbol{\beta}}^{*}\) is the best linear unbiased estimator of \(\boldsymbol{\beta}^{*}\) because one of the conditions for the GaussMarkov theorem does not hold for model (10.47). Specifically, the \(p n \times p n\) covariance matrix for vec \(\mathbf{Y}\) is not equal to \(\sigma^{2} \mathbf{I}_{p n}\), but rather
\[
\begin{aligned}
\operatorname{cov}(\operatorname{vec} \mathbf{Y}) & =\operatorname{cov}\left(\begin{array}{c}
\mathbf{y}_{(1)} \\
\mathbf{y}_{(2)} \\
\vdots \\
\mathbf{y}_{(p)}
\end{array}\right)=\left(\begin{array}{cccc}
\sigma_{11} \mathbf{I}_{n} & \sigma_{12} \mathbf{I}_{n} & \cdots & \sigma_{1 p} \mathbf{I}_{n} \\
\sigma_{21} \mathbf{I}_{n} & \sigma_{22} \mathbf{I}_{n} & \cdots & \sigma_{2 p} \mathbf{I}_{n} \\
\vdots & \vdots & \ddots & \vdots \\
\sigma_{p 1} \mathbf{I}_{n} & \sigma_{p 2} \mathbf{I}_{n} & \cdots & \sigma_{p p} \mathbf{I}_{n}
\end{array}\right) \\
& =\mathbf{\Sigma} \otimes \mathbf{I}_{n}=\mathbf{\Sigma}^{*} .
\end{aligned}
\]

The generalized least squares (GLS) estimator of \(\boldsymbol{\beta}^{*}\) can be obtained by noting that there exists a nonsingular \(p n \times p n\) matrix \(\mathbf{P}\) such that the positive definite covariance matrix \(\boldsymbol{\Sigma}^{*}\) is equal to \(\mathbf{P} \mathbf{P}^{\prime}\). (One such matrix \(\mathbf{P}\) is the squareroot matrix of \(\boldsymbol{\Sigma}^{*}\), as described in Section 2.11.8.) Multiplying vec \(\mathbf{Y}=\) \(\mathbf{X}^{*} \boldsymbol{\beta}^{*}+\boldsymbol{\varepsilon}^{*}\) by \(\mathbf{P}^{-1}\), we obtain the model
\[
\begin{equation*}
\mathbf{P}^{-1} \operatorname{vec} \mathbf{Y}=\mathbf{P}^{-1} \mathbf{X}^{*} \boldsymbol{\beta}^{*}+\mathbf{P}^{-1} \varepsilon^{*} \tag{10.50}
\end{equation*}
\]

Note that \(E\left(\mathbf{P}^{-1} \varepsilon^{*}\right)=\mathbf{P}^{-1} E\left(\varepsilon^{*}\right)=\mathbf{0}\) and
\[
\begin{aligned}
\operatorname{cov}\left(\mathbf{P}^{-1} \boldsymbol{\varepsilon}^{*}\right) & =\mathbf{P}^{-1} \operatorname{cov}\left(\varepsilon^{*}\right)\left(\mathbf{P}^{-1}\right)^{\prime} \\
& =\mathbf{P}^{-1} \boldsymbol{\Sigma}^{*}\left(\mathbf{P}^{-1}\right)^{\prime} \\
& =\mathbf{P}^{-1} \mathbf{P} \mathbf{P}^{\prime}\left(\mathbf{P}^{-1}\right)^{\prime}=\mathbf{I}_{p n} .
\end{aligned}
\]

Thus, the conditions for the Gauss-Markov theorem discussed in Section 10.2.2 are satisfied for model (10.50), and the least squares estimator
\[
\hat{\boldsymbol{\beta}}^{*}=\left[\left(\mathbf{P}^{-1} \mathbf{X}^{*}\right)^{\prime}\left(\mathbf{P}^{-1} \mathbf{X}^{*}\right)\right]^{-1}\left(\mathbf{P}^{-1} \mathbf{X}^{*}\right)^{\prime} \mathbf{P}^{-1} \operatorname{vec} \mathbf{Y}
\]
is BLUE. This estimator can be reduced to the more commonly used form
\[
\begin{equation*}
\hat{\boldsymbol{\beta}}^{*}=\left[\mathbf{X}^{* \prime} \boldsymbol{\Sigma}^{*-1} \mathbf{X}^{*}\right]^{-1} \mathbf{X}^{* \prime} \boldsymbol{\Sigma}^{*-1} \operatorname{vec} \mathbf{Y} \tag{10.51}
\end{equation*}
\]
which is called the generalized least squares (GLS) estimator of \(\boldsymbol{\beta}^{*}\). However, using properties (2.121) - (2.124), we can show that the GLS estimator (10.51) can be simplified to the least squares estimator (10.48). That is,
\[
\begin{aligned}
\hat{\boldsymbol{\beta}}^{*} & =\left[\left(\mathbf{I}_{p} \otimes \mathbf{X}\right)^{\prime}\left(\boldsymbol{\Sigma} \otimes \mathbf{I}_{n}\right)^{-\mathbf{1}}\left(\mathbf{I}_{p} \otimes \mathbf{X}\right)\right]^{-1}\left(\mathbf{I}_{p} \otimes \mathbf{X}\right)^{\prime}\left(\boldsymbol{\Sigma} \otimes \mathbf{I}_{n}\right)^{-1} \operatorname{vec} \mathbf{Y} \\
& =\left[\left(\boldsymbol{\Sigma}^{-1} \otimes \mathbf{X}^{\prime}\right)\left(\mathbf{I}_{p} \otimes \mathbf{X}\right)\right]^{-\mathbf{1}}\left(\mathbf{I}_{p} \otimes \mathbf{X}^{\prime}\right)\left(\boldsymbol{\Sigma}^{-1} \otimes \mathbf{I}_{n}\right) \operatorname{vec} \mathbf{Y} \\
& =\left[\boldsymbol{\Sigma}^{-1} \otimes\left(\mathbf{X}^{\prime} \mathbf{X}\right)\right]^{-\mathbf{1}}\left(\boldsymbol{\Sigma}^{-1} \otimes \mathbf{X}^{\prime}\right) \operatorname{vec} \mathbf{Y} \\
& =\left(\boldsymbol{\Sigma} \otimes\left(\mathbf{X}^{\prime} \mathbf{X}\right)^{-1}\right)\left(\boldsymbol{\Sigma}^{-1} \otimes \mathbf{X}^{\prime}\right) \operatorname{vec} \mathbf{Y} \\
& =\left(\mathbf{I}_{p} \otimes\left(\mathbf{X}^{\prime} \mathbf{X}\right)^{-\mathbf{1}} \mathbf{X}^{\prime}\right) \operatorname{vec} \mathbf{Y}
\end{aligned}
\]
which implies that by (2.122), the GLS estimator is equivalent to the least squares estimator \(\hat{\mathbf{B}}=\left(\mathbf{X}^{\prime} \mathbf{X}\right)^{-1} \mathbf{X}^{\prime} \mathbf{Y}\) from (10.48). Thus, the ordinary least squares estimator-which is not a function of \(\boldsymbol{\Sigma}\)-is in fact the BLUE for \(\mathbf{B}\).
4. The covariances among the elements of \(\hat{\mathbf{B}}\) can be characterized using the alternative form of the multivariate regression model given in (10.47). The covariance matrix for \(\hat{\boldsymbol{\beta}}^{*}=\operatorname{vec} \hat{\mathbf{B}}\) is
\[
\begin{align*}
\operatorname{cov}\left(\hat{\boldsymbol{\beta}}^{*}\right) & =\operatorname{cov}\left(\left(\mathbf{X}^{* \prime} \mathbf{X}^{*}\right)^{-1} \mathbf{X}^{* \prime} \operatorname{vec} \mathbf{Y}\right) \\
& =\operatorname{cov}\left(\left[\left(\mathbf{I}_{p} \otimes \mathbf{X}\right)^{\prime}\left(\mathbf{I}_{p} \otimes \mathbf{X}\right)\right]^{-1}\left(\mathbf{I}_{p} \otimes \mathbf{X}\right)^{\prime} \operatorname{vec} \mathbf{Y}\right) \\
& =\left[\mathbf{I}_{p} \otimes\left(\mathbf{X}^{\prime} \mathbf{X}\right)^{-1} \mathbf{X}^{\prime}\right] \operatorname{cov}(\mathrm{vec} \mathbf{Y})\left[\mathbf{I}_{p} \otimes\left(\mathbf{X}^{\prime} \mathbf{X}\right)^{-1} \mathbf{X}^{\prime}\right]^{\prime} \\
& =\left[\mathbf{I}_{p} \otimes\left(\mathbf{X}^{\prime} \mathbf{X}\right)^{-1} \mathbf{X}^{\prime}\right]\left(\mathbf{\Sigma} \otimes \mathbf{I}_{n}\right)\left[\mathbf{I}_{p} \otimes \mathbf{X}\left(\mathbf{X}^{\prime} \mathbf{X}\right)^{-1}\right] \\
& =\mathbf{\Sigma} \otimes\left[\left(\mathbf{X}^{\prime} \mathbf{X}\right)^{-1} \mathbf{X}^{\prime} \mathbf{I}_{n} \mathbf{X}\left(\mathbf{X}^{\prime} \mathbf{X}\right)^{-1}\right] \\
& =\mathbf{\Sigma} \otimes\left(\mathbf{X}^{\prime} \mathbf{X}\right)^{-1} \tag{10.52}
\end{align*}
\]

The variances and covariances in \(\operatorname{cov}\left(\hat{\boldsymbol{\beta}}^{*}\right)\) can be used to calculate standard errors for individual partial slopes in \(\hat{\boldsymbol{\beta}}^{*}\) or for linear combinations of the form \(\mathbf{a}^{\prime} \hat{\boldsymbol{\beta}}^{*}\).

\subsection*{10.4.4 An Estimator for \(\Sigma\)}

By analogy with (10.8) and (10.9), an unbiased estimator of \(\operatorname{cov}\left(\mathbf{y}_{i}\right)=\boldsymbol{\Sigma}\) is given by
\[
\begin{align*}
\mathbf{S}_{e}=\frac{\mathbf{E}}{n-q-1} & =\frac{(\mathbf{Y}-\mathbf{X} \hat{\mathbf{B}})^{\prime}(\mathbf{Y}-\mathbf{X} \hat{\mathbf{B}})}{n-q-1}  \tag{10.53}\\
& =\frac{\mathbf{Y}^{\prime} \mathbf{Y}-\hat{\mathbf{B}}^{\prime} \mathbf{X}^{\prime} \mathbf{Y}}{n-q-1} \tag{10.54}
\end{align*}
\]

To demonstrate the unbiasedness of \(\mathbf{S}_{e}\), we first note that
\[
\begin{aligned}
E(\mathbf{Y}-\mathbf{X} \hat{\mathbf{B}}) & =E\left\{\left[\mathbf{I}_{n}-\mathbf{X}\left(\mathbf{X}^{\prime} \mathbf{X}\right)^{-1} \mathbf{X}^{\prime}\right] \mathbf{Y}\right\} \\
& =\left[\mathbf{I}_{n}-\mathbf{X}\left(\mathbf{X}^{\prime} \mathbf{X}\right)^{-1} \mathbf{X}^{\prime}\right] E(\mathbf{X B}+\boldsymbol{\Xi}) \\
& =\left[\mathbf{X}-\mathbf{X}\left(\mathbf{X}^{\prime} \mathbf{X}\right)^{-1} \mathbf{X}^{\prime} \mathbf{X}\right] \mathbf{B}+\left[\mathbf{I}_{n}-\mathbf{X}\left(\mathbf{X}^{\prime} \mathbf{X}\right)^{-1} \mathbf{X}^{\prime}\right] E(\boldsymbol{\Xi}) \\
& =\left[\mathbf{I}_{n}-\mathbf{X}\left(\mathbf{X}^{\prime} \mathbf{X}\right)^{-1} \mathbf{X}^{\prime}\right] E(\boldsymbol{\Xi})=\mathbf{O}
\end{aligned}
\]

Then, denoting the columns of \(\mathbf{Y}-\mathbf{X} \hat{\mathbf{B}}\) with \(\hat{\varepsilon}_{(1)}, \ldots, \hat{\varepsilon}_{(p)}\), we can define the expectation of the \((i, j)\) element of \((n-q-1) \mathbf{S}_{e}\) as
\[
\begin{aligned}
E\left(\hat{\varepsilon}_{(i)}^{\prime} \hat{\varepsilon}_{(j)}\right) & =E\left(\left\{\left[\mathbf{I}_{n}-\mathbf{X}\left(\mathbf{X}^{\prime} \mathbf{X}\right)^{-1} \mathbf{X}^{\prime}\right] \mathbf{y}_{(i)}\right\}^{\prime}\left\{\left[\mathbf{I}_{n}-\mathbf{X}\left(\mathbf{X}^{\prime} \mathbf{X}\right)^{-1} \mathbf{X}^{\prime}\right] \mathbf{y}_{(j)}\right\}\right) \\
& =E\left(\left\{\left[\mathbf{I}_{n}-\mathbf{X}\left(\mathbf{X}^{\prime} \mathbf{X}\right)^{-1} \mathbf{X}^{\prime}\right] \boldsymbol{\varepsilon}_{(i)}\right\}^{\prime}\left\{\left[\mathbf{I}_{n}-\mathbf{X}\left(\mathbf{X}^{\prime} \mathbf{X}\right)^{-1} \mathbf{X}^{\prime}\right] \boldsymbol{\varepsilon}_{(j)}\right\}\right) \\
& =E\left(\boldsymbol{\varepsilon}_{(i)}^{\prime}\left[\mathbf{I}_{n}-\mathbf{X}\left(\mathbf{X}^{\prime} \mathbf{X}\right)^{-1} \mathbf{X}^{\prime}\right]\left[\mathbf{I}_{n}-\mathbf{X}\left(\mathbf{X}^{\prime} \mathbf{X}\right)^{-1} \mathbf{X}^{\prime}\right] \boldsymbol{\varepsilon}_{(j)}\right) \\
& =E\left(\varepsilon_{(i)}^{\prime}\left[\mathbf{I}_{n}-\mathbf{X}\left(\mathbf{X}^{\prime} \mathbf{X}\right)^{-1} \mathbf{X}^{\prime}\right] \boldsymbol{\varepsilon}_{(j)}\right) \\
& =E\left(\operatorname{tr}\left\{\left[\mathbf{I}_{n}-\mathbf{X}\left(\mathbf{X}^{\prime} \mathbf{X}\right)^{-1} \mathbf{X}^{\prime}\right] \boldsymbol{\varepsilon}_{(j)} \boldsymbol{\varepsilon}_{(i)}^{\prime}\right\}\right) \\
& =\operatorname{tr}\left\{\left[\mathbf{I}_{n}-\mathbf{X}\left(\mathbf{X}^{\prime} \mathbf{X}\right)^{-1} \mathbf{X}^{\prime}\right] E\left(\boldsymbol{\varepsilon}_{(j)} \boldsymbol{\varepsilon}_{(i)}^{\prime}\right)\right\} \\
& =\sigma_{i j} \operatorname{tr}\left\{\left[\mathbf{I}_{n}-\mathbf{X}\left(\mathbf{X}^{\prime} \mathbf{X}\right)^{-1} \mathbf{X}^{\prime}\right]\right\} \\
& =\sigma_{i j}\left[\operatorname{tr}\left\{\mathbf{I}_{n}\right\}-\operatorname{tr}\left\{\mathbf{X}^{\prime} \mathbf{X}\left(\mathbf{X}^{\prime} \mathbf{X}\right)^{-1}\right\}\right] \\
& =\sigma_{i j}[n-(q+\mathbf{1})] .
\end{aligned}
\]

Thus,
\[
E\left(\mathbf{S}_{e}\right)=E\left[\frac{1}{n-q-1}(\mathbf{Y}-\mathbf{X} \hat{\mathbf{B}})^{\prime}(\mathbf{Y}-\mathbf{X} \hat{\mathbf{B}})\right]=\boldsymbol{\Sigma}
\]

\subsection*{10.4.5 Model Corrected for Means}

If the \(x\) 's are centered by subtracting their means, we have the centered \(\mathbf{X}\) matrix as in (10.13),
\[
\mathbf{X}_{c}=\left(\begin{array}{cccc}
x_{11}-\bar{x}_{1} & x_{12}-\bar{x}_{2} & \cdots & x_{1 q}-\bar{x}_{q} \\
x_{21}-\bar{x}_{1} & x_{22}-\bar{x}_{2} & \cdots & x_{2 q}-\bar{x}_{q} \\
\vdots & \vdots & & \vdots \\
x_{n 1}-\bar{x}_{1} & x_{n 2}-\bar{x}_{2} & \cdots & x_{n q}-\bar{x}_{q}
\end{array}\right)
\]

The \(\mathbf{B}\) matrix can be partitioned as
\[
\mathbf{B}=\binom{\boldsymbol{\beta}_{0}^{\prime}}{\mathbf{B}_{1}}=\left(\begin{array}{cccc}
\beta_{01} & \beta_{02} & \cdots & \beta_{0 p} \\
\hline \beta_{11} & \beta_{12} & \cdots & \beta_{1 p} \\
\vdots & \vdots & & \vdots \\
\beta_{q 1} & \beta_{q 2} & \cdots & \beta_{q p}
\end{array}\right)
\]

By analogy with (10.14) and (10.15), the estimates are
\[
\begin{align*}
& \hat{\mathbf{B}}_{1}=\left(\mathbf{X}_{c}^{\prime} \mathbf{X}_{c}\right)^{-1} \mathbf{X}_{c}^{\prime} \mathbf{Y},  \tag{10.55}\\
& \hat{\boldsymbol{\beta}}_{0}^{\prime}=\overline{\mathbf{y}}^{\prime}-\overline{\mathbf{x}}^{\prime} \hat{\mathbf{B}}_{1} \tag{10.56}
\end{align*}
\]
where \(\overline{\mathbf{y}}^{\prime}=\left(\bar{y}_{1}, \bar{y}_{2}, \ldots, \bar{y}_{p}\right)\) and \(\overline{\mathbf{x}}^{\prime}=\left(\bar{x}_{1}, \bar{x}_{2}, \ldots, \bar{x}_{q}\right)\). These estimates give the same results as \(\hat{\mathbf{B}}=\left(\mathbf{X}^{\prime} \mathbf{X}\right)^{-1} \mathbf{X}^{\prime} \mathbf{Y}\) in (10.48).

As in (10.20), the estimate \(\hat{\mathbf{B}}_{1}\) in (10.55) can be expressed in terms of sample covariance matrices. We multiply and divide (10.55) by \(n-1\) to obtain
\[
\begin{align*}
\hat{\mathbf{B}}_{1} & =(n-1)\left(\mathbf{X}_{c}^{\prime} \mathbf{X}_{c}\right)^{-1} \frac{\mathbf{X}_{c}^{\prime} \mathbf{Y}}{n-1}=\left(\frac{\mathbf{X}_{c}^{\prime} \mathbf{X}_{c}}{n-1}\right)^{-1} \frac{\mathbf{X}_{c}^{\prime} \mathbf{Y}}{n-1} \\
& =\mathbf{S}_{x x}^{-1} \mathbf{S}_{x y} \tag{10.57}
\end{align*}
\]
where \(\mathbf{S}_{x x}\) and \(\mathbf{S}_{x y}\) are blocks from the overall sample covariance matrix of the vector \(\left(y_{1}, y_{2}, \ldots, y_{p}, x_{1}, x_{2}, \ldots, x_{q}\right)^{\prime}\) :
\[
\mathbf{S}=\left(\begin{array}{ll}
\mathbf{S}_{y y} & \mathbf{S}_{y x}  \tag{10.58}\\
\mathbf{S}_{x y} & \mathbf{S}_{x x}
\end{array}\right)
\]

\subsection*{10.4.6 Estimation in the Seemingly Unrelated Regressions (SUR) Model}

In (10.47) we give an alternative version of the multivariate regression model (10.46). The alternative version can also be written
\[
\begin{aligned}
\operatorname{vec} \mathbf{Y}=\left(\begin{array}{c}
\mathbf{y}_{(1)} \\
\mathbf{y}_{(2)} \\
\vdots \\
\mathbf{y}_{(p)}
\end{array}\right) & =\left(\begin{array}{cccc}
\mathbf{X} & \mathbf{0} & \cdots & \mathbf{0} \\
\mathbf{0} & \mathbf{X} & \cdots & \mathbf{0} \\
\vdots & \vdots & \ddots & \vdots \\
\mathbf{0} & \mathbf{0} & \cdots & \mathbf{X}
\end{array}\right)\left(\begin{array}{c}
\boldsymbol{\beta}_{(1)} \\
\boldsymbol{\beta}_{(2)} \\
\vdots \\
\boldsymbol{\beta}_{(p)}
\end{array}\right)+\left(\begin{array}{c}
\boldsymbol{\varepsilon}_{(1)} \\
\boldsymbol{\varepsilon}_{(2)} \\
\vdots \\
\boldsymbol{\varepsilon}_{(p)}
\end{array}\right) \\
& =\mathbf{X}^{*} \boldsymbol{\beta}^{*}+\boldsymbol{\varepsilon}^{*}
\end{aligned}
\]
where \(\boldsymbol{\beta}^{*}=\) vec \(B\). As noted in Section 10.4.2, the estimates of the \(\boldsymbol{\beta}_{(i)}\) values are equivalent to those that would be obtained by running a separate regression for each \(\mathbf{y}_{(i)}\), without having to adjust the estimates with the covariance matrix \(\boldsymbol{\Sigma}\). That is,
even though \(\operatorname{cov}\left(\varepsilon^{*}\right)=\mathbf{\Sigma} \otimes \mathbf{I}\), the ordinary least squares estimate \(\hat{\mathbf{B}}=\left(\mathbf{X}^{\prime} \mathbf{X}\right)^{-1} \mathbf{X Y}\) is the best linear unbiased estimate (BLUE) for \(\mathbf{B}\).

Suppose, however, that the model for each \(\mathbf{y}_{(i)}\) has a potentially unique predictor variable matrix \(\mathbf{X}_{i}\) of size \(n \times\left(q_{i}+1\right)\). In this case, we have a set of \(p\) seemingly unrelated regressions, except that the responses \(\mathbf{y}_{i}=\left(y_{i 1}, \ldots, y_{i p}\right)^{\prime}\) are measurements of the same observational unit with covariance matrix \(\boldsymbol{\Sigma}\). The seemingly unrelated regressions (SUR) model is then:
\[
\begin{aligned}
\operatorname{vec} \mathbf{Y}=\left(\begin{array}{c}
\mathbf{y}_{(1)} \\
\mathbf{y}_{(2)} \\
\vdots \\
\mathbf{y}_{(p)}
\end{array}\right) & =\left(\begin{array}{cccc}
\mathbf{X}_{1} & \mathbf{0} & \cdots & \mathbf{0} \\
\mathbf{0} & \mathbf{X}_{2} & \cdots & \mathbf{0} \\
\vdots & \vdots & \ddots & \vdots \\
\mathbf{0} & \mathbf{0} & \cdots & \mathbf{X}_{p}
\end{array}\right)\left(\begin{array}{c}
\boldsymbol{\beta}_{(1)} \\
\boldsymbol{\beta}_{(2)} \\
\vdots \\
\boldsymbol{\beta}_{(p)}
\end{array}\right)+\left(\begin{array}{c}
\boldsymbol{\varepsilon}_{(1)} \\
\boldsymbol{\varepsilon}_{(2)} \\
\vdots \\
\boldsymbol{\varepsilon}_{(p)}
\end{array}\right) \\
& =\mathbf{X}^{\mathrm{SUR}} \boldsymbol{\beta}^{\mathrm{SUR}}+\boldsymbol{\varepsilon}^{*} .
\end{aligned}
\]

In general, the ordinary least squares estimate
\[
\tilde{\boldsymbol{\beta}}^{\mathrm{SUR}}=\left(\begin{array}{c}
\left(\mathbf{X}_{1}^{\prime} \mathbf{X}_{1}\right)^{-1} \mathbf{X}_{1} \mathbf{y}_{(1)}  \tag{10.59}\\
\left(\mathbf{X}_{2}^{\prime} \mathbf{X}_{2}\right)^{-1} \mathbf{X}_{2} \mathbf{y}_{(2)} \\
\vdots \\
\left(\mathbf{X}_{p}^{\prime} \mathbf{X}_{p}\right)^{-1} \mathbf{X}_{p} \mathbf{y}_{(p)}
\end{array}\right)
\]
is not the BLUE for \(\beta^{\text {SUR }}\). Following the argument in Section 10.4.3, the generalized least squares approach can be used to obtain the BLUE for \(\boldsymbol{\beta}^{\text {SUR }}\) :
\[
\begin{equation*}
\hat{\boldsymbol{\beta}}^{\mathrm{SUR}}=\left[\mathbf{X}^{\mathrm{SUR}^{\prime}}(\boldsymbol{\Sigma} \otimes \mathbf{I})^{-1} \mathbf{X}^{\mathrm{SUR}}\right]^{-1} \mathbf{X}^{\mathrm{SUR}}(\boldsymbol{\Sigma} \otimes \mathbf{I})^{-1} \operatorname{vec} \mathbf{Y} . \tag{10.60}
\end{equation*}
\]

If \(\boldsymbol{\Sigma}\) is not known, an estimate \(\hat{\boldsymbol{\Sigma}}\) can be calculated by first obtaining the ordinary least squares estimate for each \(\mathbf{y}_{(i)}\) :
\[
\hat{\boldsymbol{\beta}}_{(i)}=\left(\mathbf{X}_{i}^{\prime} \mathbf{X}_{i}\right)^{-1} \mathbf{X}_{i} \mathbf{y}_{(i)} .
\]

Next, the errors associated with each of the vectors \(\mathbf{y}_{(i)}\) are estimated using
\[
\begin{equation*}
\hat{\boldsymbol{\varepsilon}}_{(i)}=\mathbf{y}_{(i)}-\mathbf{X}_{i} \hat{\boldsymbol{\beta}}_{(i)} . \tag{10.61}
\end{equation*}
\]

Finally, let the \((i, j)\) element of \(\hat{\boldsymbol{\Sigma}}\) equal
\[
\begin{equation*}
\hat{\sigma}_{i j}=\frac{1}{\sqrt{\left(n-q_{i}\right)\left(n-q_{j}\right)}} \hat{\varepsilon}_{(i)}^{\prime} \hat{\varepsilon}_{(j)} . \tag{10.62}
\end{equation*}
\]

Using \(\dot{\boldsymbol{\Sigma}}\), the estimate of \(\boldsymbol{\beta}\) in (10.60) can be obtained, from which a new estimate of \(\hat{\boldsymbol{\Sigma}}\) in (10.62) can be obtained. The calculations associated with equations (10.60) and (10.62) can then be repeated until the estimate \(\hat{\boldsymbol{\beta}}^{\text {SUR }}\) is not changing by a meaningful amount. Note that the BLUE in (10.60) reduces to the ordinary least squares estimate in (10.59) if (i) \(\mathbf{X}_{1}=\mathbf{X}_{2}=\ldots=\mathbf{X}_{p}\), or (ii) the off-diagonal elements of \(\boldsymbol{\Sigma}\) are all equal to 0 (i.e., \(\sigma_{i j}=0\) for \(i \neq j\) ).

\subsection*{10.5 MULTIVARIATE MULTIPLE REGRESSION: HYPOTHESIS TESTS}

In this section we extend the two tests of Section 10.2 .5 to the multivariate \(y\) case. We assume the \(x\) 's are fixed and the \(y\) 's are multivariate normal. For other tests and confidence intervals, see Rencher (1998, Chapter 7).

\subsection*{10.5.1 Test of Overall Regression}

We first consider the hypothesis that none of the \(x\) 's predicts any of the \(y\) 's, which can be expressed as \(H_{0}: \mathbf{B}_{1}=\mathbf{O}\), where \(\mathbf{B}_{1}\) includes all rows of \(\mathbf{B}\) except the first:
\[
\mathbf{B}=\binom{\boldsymbol{\beta}_{0}^{\prime}}{\mathbf{B}_{1}}=\left(\begin{array}{cccc}
\beta_{01} & \beta_{02} & \cdots & \beta_{0 p} \\
\hline \beta_{11} & \beta_{12} & \cdots & \beta_{1 p} \\
\vdots & \vdots & & \vdots \\
\beta_{q 1} & \beta_{q 2} & \cdots & \beta_{q p}
\end{array}\right) .
\]

We do not wish to include \(\boldsymbol{\beta}_{0}^{\prime}=\mathbf{0}^{\prime}\) in the hypothesis, because this would restrict all \(y\) 's to have intercepts of zero. The alternative hypothesis is \(H_{1}: \mathbf{B}_{1} \neq \mathbf{0}\), which implies that we want to know if even one \(\beta_{j k} \neq 0, j=1,2, \ldots, q ; k=1,2, \ldots, p\).

The numerator of (10.54) suggests a partitioning of the total sum of squares and products matrix \(\mathbf{Y}^{\prime} \mathbf{Y}\),
\[
\mathbf{Y}^{\prime} \mathbf{Y}=\left(\mathbf{Y}^{\prime} \mathbf{Y}-\hat{\mathbf{B}}^{\prime} \mathbf{X}^{\prime} \mathbf{Y}\right)+\hat{\mathbf{B}}^{\prime} \mathbf{X}^{\prime} \mathbf{Y}
\]

By analogy to (10.23), we subtract \(n \overline{\mathbf{y}} \overline{\mathbf{y}}^{\prime}\) from both sides to avoid inclusion of \(\boldsymbol{\beta}_{0}^{\prime}=\) \(\mathbf{0}^{\prime}\) :
\[
\begin{align*}
\mathbf{Y}^{\prime} \mathbf{Y}-n \overline{\mathbf{y}} \overline{\mathbf{y}}^{\prime} & =\left(\mathbf{Y}^{\prime} \mathbf{Y}-\hat{\mathbf{B}}^{\prime} \mathbf{X}^{\prime} \mathbf{Y}\right)+\left(\hat{\mathbf{B}}^{\prime} \mathbf{X}^{\prime} \mathbf{Y}-n \overline{\mathbf{y}} \overline{\mathbf{y}}^{\prime}\right) \\
& =\mathbf{E}+\mathbf{H} \tag{10.63}
\end{align*}
\]

The overall regression sum of squares and products matrix \(\mathbf{H}=\hat{\mathbf{B}}^{\prime} \mathbf{X}^{\prime} \mathbf{Y}-n \overline{\mathbf{y}} \overline{\mathbf{y}}^{\prime}\) can be used to test \(H_{0}: \mathbf{B}_{1}=\mathbf{O}\). The notation \(\mathbf{E}=\mathbf{Y}^{\prime} \mathbf{Y}-\hat{\mathbf{B}}^{\prime} \mathbf{X}^{\prime} \mathbf{Y}\) and \(\mathbf{H}=\) \(\hat{\mathbf{B}}^{\prime} \mathbf{X}^{\prime} \mathbf{Y}-n \overline{\mathbf{y}} \overline{\mathbf{y}}^{\prime}\) conforms with usage of \(\mathbf{E}\) and \(\mathbf{H}\) in Chapter 6.

As in Chapter 6, we can test \(H_{0}: \mathbf{B}_{1}=\mathbf{O}\) by means of
\[
\begin{equation*}
\Lambda=\frac{|\mathbf{E}|}{|\mathbf{E}+\mathbf{H}|}=\frac{\left|\mathbf{Y}^{\prime} \mathbf{Y}-\hat{\mathbf{B}}^{\prime} \mathbf{X}^{\prime} \mathbf{Y}\right|}{\left|\mathbf{Y}^{\prime} \mathbf{Y}-n \overline{\mathbf{Y}} \overline{\mathbf{y}}^{\prime}\right|} \tag{10.64}
\end{equation*}
\]
which is distributed as \(\Lambda_{p, q, n-q-1}\) when \(H_{0}: \mathbf{B}_{1}=\mathbf{O}\) is true, where \(p\) is the number of \(y\) 's and \(q\) is the number of \(x\) 's. We reject \(H_{0}\) if \(\Lambda \leq \Lambda_{\alpha, p, q, n-q-1}\). The likelihood ratio approach leads to the same test statistic. If \(\mathbf{H}\) is "large" because of large values of the \(\hat{\beta}_{j k}\) 's, then \(|\mathbf{E}+\mathbf{H}|\) would be expected to be sufficiently greater than \(|\mathbf{E}|\) so that \(\Lambda\) would lead to rejection. By \(\mathbf{H}\) "large," we mean that the regression sums of squares on the diagonal are large. Critical values for \(\Lambda\) are available in Table A. 9 using \(\nu_{H}=q\) and \(\nu_{E}=n-q-1\). Note that these degrees of freedom are the same
as in the univariate test for regression of \(y\) on \(x_{1}, x_{2}, \ldots, x_{q}\) in (10.24). The \(F\) - and \(\chi^{2}\)-approximations for \(\Lambda\) in (6.15) and (6.16) can also be used, or the exact \(p\)-values described in Section 6.1.3 can be used to evaluate the significance of \(\Lambda\).

There are two alternative expressions for Wilks' \(\Lambda\) in (10.64). We can express \(\Lambda\) in terms of the eigenvalues \(\lambda_{1}, \lambda_{2}, \ldots, \lambda_{s}\) of \(\mathbf{E}^{-1} \mathbf{H}\) :
\[
\begin{equation*}
\Lambda=\prod_{i=1}^{s} \frac{1}{1+\lambda_{i}} \tag{10.65}
\end{equation*}
\]
where \(s=\min (p, q)\). Wilks' \(\Lambda\) can also be written in the form
\[
\begin{equation*}
\Lambda=\frac{|\mathbf{S}|}{\left|\mathbf{S}_{x x}\right|\left|\mathbf{S}_{y y}\right|} \tag{10.66}
\end{equation*}
\]
where \(S\) is partitioned as in (10.58):
\[
\mathbf{S}=\left(\begin{array}{ll}
\mathbf{S}_{y y} & \mathbf{S}_{y x} \\
\mathbf{S}_{x y} & \mathbf{S}_{x x}
\end{array}\right)
\]

The form of \(\Lambda\) in (10.66) is the same as in the test for independence of \(y\) and \(x\) given in (7.30), where \(y\) and \(x\) are both random vectors. In the present section, the \(y\) 's are random variables and the \(x\) 's are fixed. Thus \(\mathbf{S}_{y y}\) is the sample covariance matrix of the \(y\) 's in the usual sense, while \(\mathbf{S}_{x x}\) consists of an analogous mathematical expression involving the constant \(x\) 's (see comments about \(\mathbf{S}_{x x}\) in Section 10.2.4).

By the symmetry of (10.66) in \(x\) and \(y, \Lambda\) is distributed as \(\Lambda_{q, p, n-p-1}\) as well as \(\Lambda_{p, q, n-q-1}\). This is equivalent to property 3 in Section 6.1.3. Hence, if we regressed the \(x\) 's on the \(y\) 's, we would get a different \(\hat{\mathbf{B}}\) but would have the same value of \(\Lambda\) for the test.

The union-intersection test of \(H_{0}: \mathbf{B}_{1}=\mathbf{O}\) uses Roy's test statistic analogous to (6.20),
\[
\begin{equation*}
\theta=\frac{\lambda_{1}}{1+\lambda_{1}} \tag{10.67}
\end{equation*}
\]
where \(\lambda_{1}\) is the largest eigenvalue of \(\mathbf{E}^{-1} \mathbf{H}\). Upper percentage points \(\theta_{\alpha}\) are given in Table A.10. The accompanying parameters are
\[
s=\min (p, q), \quad m=\frac{1}{2}(|q-p|-1), \quad N=\frac{1}{2}(n-q-p-2) .
\]

The hypothesis is rejected if \(\theta>\theta_{\alpha}\). The exact \(p\)-value for Roy's test can also be obtained using the approach discussed in Section 10.2.4.

As in Section 6.1.5, Pillai's test statistic is defined as
\[
\begin{equation*}
V^{(s)}=\sum_{i=1}^{s} \frac{\lambda_{i}}{1+\lambda_{i}} \tag{10.68}
\end{equation*}
\]
and the Lawley-Hotelling test statistic is given by
\[
\begin{equation*}
U^{(s)}=\sum_{i=1}^{s} \lambda_{i} \tag{10.69}
\end{equation*}
\]
where \(\lambda_{1}, \lambda_{2}, \ldots, \lambda_{s}\) are the eigenvalues of \(\mathbf{E}^{-1} \mathbf{H}\). For \(V^{(s)}\), upper percentage points are found in Table A.11, indexed by \(s, m\), and \(n\) as defined above in connection with Roy's test. Upper percentage points for \(\nu_{E} U^{(s)} / \nu_{H}\) (see Section 6.1.5) are provided in Table A.12, where \(\nu_{H}=q\) and \(\nu_{E}=n-q-1\). Alternatively, we can use the \(F\)-approximations or exact tests for \(V^{(s)}\) and \(U^{(s)}\) in Section 6.1.5.

When \(H_{0}\) is true, all four test statistics have probability \(\alpha\) of rejecting; that is, they all have the same probability of a type I error. When \(H_{0}\) is false, the power ranking of the tests depends on the configuration of the population eigenvalues, as was noted in Section 6.2. (The sample eigenvalues \(\lambda_{1}, \lambda_{2}, \ldots, \lambda_{s}\) from \(\mathbf{E}^{-1} \mathbf{H}\) are estimates of the population eigenvalues.) If the population eigenvalues are equal or nearly equal, the power ranking of the tests is \(V^{(s)} \geq \Lambda \geq U^{(s)} \geq \theta\). If only one population eigenvalue is nonzero, the powers are reversed: \(\theta \geq U^{(s)} \geq \Lambda \geq V^{(s)}\).

In the case of a single nonzero population eigenvalue, the rank of \(\mathbf{B}_{1}\) is 1 . There are various ways this could occur; for example, \(\mathbf{B}_{1}\) could have only one nonzero row, which would indicate that only one of the \(x\) 's predicts the \(y\) 's. On the other hand, a single nonzero column implies that only one of the \(y\) 's is predicted by the \(x\) 's. Alternatively, \(\mathbf{B}_{1}\) would have rank 1 if all rows were equal or linear combinations of each other, manifesting that all \(x\) 's act alike in predicting the \(y\) 's. Similarly, all columns equal to each other or linear functions of each other would signify only one dimension in the \(y\) 's as they relate to the \(x\) 's.

\section*{EXAMPLE 10.5.1}

For the chemical data of Table 10.1, we test the overall regression hypothesis \(H_{0}: \mathbf{B}_{1}=\mathbf{O}\). The \(\mathbf{E}\) and \(\mathbf{H}\) matrices are given by
\[
\begin{aligned}
\mathbf{E} & =\left(\begin{array}{rrr}
80.174 & -21.704 & -65.923 \\
-21.704 & 249.462 & -179.496 \\
-65.923 & -179.496 & 231.197
\end{array}\right), \\
\mathbf{H} & =\left(\begin{array}{rrr}
1707.158 & -492.532 & -996.584 \\
-492.532 & 151.002 & 283.607 \\
-996.584 & 283.607 & 583.688
\end{array}\right) .
\end{aligned}
\]

The eigenvalues of \(\mathbf{E}^{-1} \mathbf{H}\) are 26.3183, .1004, and .0033 . The parameters for use in obtaining critical values of the four test statistics are
\[
\begin{aligned}
\nu_{H} & =q=3, \quad \nu_{E}=n-q-1=19-3-1=15 \\
s & =\min (3,3)=3, \quad m=\frac{1}{2}(|q-p|-1)=-\frac{1}{2} \\
N & =\frac{1}{2}(n-q-p-2)=5.5
\end{aligned}
\]

Using the eigenvalues, we obtain the test statistics
\[
\begin{aligned}
\Lambda & =\prod_{i=1}^{3} \frac{1}{1+\lambda_{i}}=\frac{1}{1+26.3183} \frac{1}{1+.1004} \frac{1}{1+.0033} \\
& =.0332<\Lambda_{.05,3,3,15}=.309, \\
\theta & =\frac{\lambda_{1}}{1+\lambda_{1}}=.963>\theta(.05,3,0,5)=.669, \\
V^{(s)} & =\sum_{i=1}^{3} \frac{\lambda_{i}}{1+\lambda_{i}}=1.058>V_{.05,3,0,5}^{(s)}=1.040, \\
U^{(s)} & =\sum_{i=1}^{3} \lambda_{i}=26.422, \quad \frac{\nu_{E} U^{(s)}}{\nu_{H}}=132.11,
\end{aligned}
\]
which exceeds the .05 critical value, 8.427 (interpolated), from Table A. 12 (see Section 6.1.5). Thus all four tests reject \(H_{0}\). Note that the critical values given for \(\theta\) and \(V^{(s)}\) are conservative, since 0 was used in place of -.5 for \(m\).

In this case, the first eigenvalue, 26.3183, completely dominates the other two. In Example 10.4.2, we obtained
\[
\hat{\mathbf{B}}_{1}=\left(\begin{array}{rrr}
-1.55 & .40 & .91 \\
-1.42 & .29 & .90 \\
-2.24 & 1.03 & 1.15
\end{array}\right)
\]

The columns are approximately proportional to each other, indicating that there is essentially only one dimension in the \(y\) 's as they are predicted by the \(x\) 's. A similar statement can be made about the rows and the dimensionality of the \(x\) 's as they predict the \(y\) 's.

\subsection*{10.5.2 Test on a Subset of the \(x\) 's}

We consider the hypothesis that the \(y\) 's do not depend on the last \(h\) of the \(x\) 's, \(x_{q-h+1}, x_{q-h+2}, \ldots, x_{q}\). By this we mean that none of the \(p y\) 's is predicted by any of these \(h x\) 's. To express this hypothesis, write the \(\mathbf{B}\) matrix in partitioned form,
\[
\mathbf{B}=\binom{\mathbf{B}_{r}}{\mathbf{B}_{d}}
\]
where, as in Section 10.2.5b, the subscript \(r\) denotes the subset of \(\beta_{j k}\) 's to be retained in the reduced model and \(d\) represents the subset of \(\beta_{j k}\) 's to be deleted if they are not significant predictors of the \(y\) 's. Thus \(\mathbf{B}_{d}\) has \(h\) rows. The hypothesis can be expressed as
\[
H_{0}: \mathbf{B}_{d}=\mathbf{O}
\]

If \(\mathbf{X}_{r}\) contains the columns of \(\mathbf{X}\) corresponding to \(\mathbf{B}_{r}\), then the reduced model is
\[
\begin{equation*}
\mathbf{Y}=\mathbf{X}_{r} \mathbf{B}_{r}+\boldsymbol{\Xi} \tag{10.70}
\end{equation*}
\]

To compare the fit of the full model and the reduced model, we use the difference between the regression sum of squares and products matrix for the full model, \(\hat{\mathbf{B}}^{\prime} \mathbf{X}^{\prime} \mathbf{Y}\), and the regression sum of squares and products matrix for the reduced model, \(\hat{\mathbf{B}}_{r}^{\prime} \mathbf{X}_{r}^{\prime} \mathbf{Y}\). By analogy to (10.26), this difference becomes our \(\mathbf{H}\) matrix:
\[
\begin{equation*}
\mathbf{H}=\hat{\mathbf{B}}^{\prime} \mathbf{X}^{\prime} \mathbf{Y}-\hat{\mathbf{B}}_{r}^{\prime} \mathbf{X}_{r}^{\prime} \mathbf{Y} . \tag{10.71}
\end{equation*}
\]

Thus the test of \(H_{0}: \mathbf{B}_{d}=\mathbf{O}\) is a full and reduced model test of the significance of \(x_{q-h+1}, x_{q-h+2}, \ldots, x_{q}\) above and beyond \(x_{1}, x_{2}, \ldots, x_{q-h}\).

To make the test, we use the \(\mathbf{E}\) matrix based on the full model, \(\mathbf{E}=\mathbf{Y}^{\prime} \mathbf{Y}-\) \(\hat{\mathbf{B}}^{\prime} \mathbf{X}^{\prime} \mathbf{Y}\). Then
\[
\begin{aligned}
\mathbf{E}+\mathbf{H} & =\left(\mathbf{Y}^{\prime} \mathbf{Y}-\hat{\mathbf{B}}^{\prime} \mathbf{X}^{\prime} \mathbf{Y}\right)+\left(\hat{\mathbf{B}}^{\prime} \mathbf{X}^{\prime} \mathbf{Y}-\hat{\mathbf{B}}_{r}^{\prime} \mathbf{X}_{r}^{\prime} \mathbf{Y}\right) \\
& =\mathbf{Y}^{\prime} \mathbf{Y}-\hat{\mathbf{B}}_{r}^{\prime} \mathbf{X}_{r}^{\prime} \mathbf{Y}
\end{aligned}
\]
and Wilks' \(\Lambda\)-statistic is given by
\[
\begin{align*}
\Lambda\left(x_{q-h+1}, \ldots, x_{q} \mid x_{1}, \ldots, x_{q-h}\right) & =\frac{|\mathbf{E}|}{|\mathbf{E}+\mathbf{H}|} \\
& =\frac{\left|\mathbf{Y}^{\prime} \mathbf{Y}-\hat{\mathbf{B}}^{\prime} \mathbf{X}^{\prime} \mathbf{Y}\right|}{\left|\mathbf{Y}^{\prime} \mathbf{Y}-\hat{\mathbf{B}}_{r}^{\prime} \mathbf{X}_{r}^{\prime} \mathbf{Y}\right|} \tag{10.72}
\end{align*}
\]
which is distributed as \(\Lambda_{p, h, n-q-1}\) when \(H_{0}: \mathbf{B}_{d}=\mathbf{O}\) is true. Critical values are available in Table A. 9 with \(\nu_{H}=h\) and \(\nu_{E}=n-q-1\). Note that these degrees of freedom for the multivariate \(y\) case are the same as for the univariate \(y\) case (multiple regression) in Section 10.2.5b. The \(F\) - and \(\chi^{2}\)-approximations for \(\Lambda\) in (6.15) and (6.16) can also be used.

As implied in the notation \(\Lambda\left(x_{q-h+1}, \ldots, x_{q} \mid x_{1}, \ldots, x_{q-h}\right)\), Wilks' \(\Lambda\) in (10.72) provides a full and reduced model test. We can express it in terms of \(\Lambda\) for the full model and a similar \(\Lambda\) for the reduced model. In the denominator of (10.72), we have \(\mathbf{Y}^{\prime} \mathbf{Y}-\hat{\mathbf{B}}_{r}^{\prime} \mathbf{X}_{r}^{\prime} \mathbf{Y}\), which is the error matrix for the reduced model \(\mathbf{Y}=\mathbf{X}_{r} \mathbf{B}_{r}+\boldsymbol{\Xi}\) in (10.70). This error matrix could be used in a test for the significance of overall regression in the reduced model, as in (10.64),
\[
\begin{equation*}
\Lambda_{r}=\frac{\left|\mathbf{Y}^{\prime} \mathbf{Y}-\hat{\mathbf{B}}_{r}^{\prime} \mathbf{X}_{r}^{\prime} \mathbf{Y}\right|}{\left|\mathbf{Y}^{\prime} \mathbf{Y}-n \overline{\mathbf{y}} \overline{\mathbf{y}}^{\prime}\right|} \tag{10.73}
\end{equation*}
\]

Since \(\Lambda_{r}\) in (10.73) has the same denominator as \(\Lambda\) in (10.64), we recognize (10.72) as the ratio of Wilks' \(\Lambda\) for the overall regression test in the full model to Wilks' \(\Lambda\) for the overall regression test in the reduced model,
\[
\begin{align*}
\Lambda\left(x_{q-n+1}, \ldots, x_{q} \mid x_{1}, \ldots, x_{q-h}\right) & =\frac{\left|\mathbf{Y}^{\prime} \mathbf{Y}-\hat{\mathbf{B}}^{\prime} \mathbf{X}^{\prime} \mathbf{Y}\right|}{\left|\mathbf{Y}^{\prime} \mathbf{Y}-\hat{\mathbf{B}}_{r}^{\prime} \mathbf{X}_{r}^{\prime} \mathbf{Y}\right|} \\
& =\frac{\frac{\left|\mathbf{Y}^{\prime} \mathbf{Y}-\hat{\mathbf{B}}^{\prime} \mathbf{X}^{\prime} \mathbf{Y}\right|}{\left|\mathbf{Y}^{\prime} \mathbf{Y}-n \overline{\mathbf{y}} \overline{\mathbf{y}}^{\prime}\right|}}{\frac{\left|\mathbf{Y}^{\prime} \mathbf{Y}-\hat{\mathbf{B}}_{r}^{\prime} \mathbf{X}_{r}^{\prime} \mathbf{Y}\right|}{\left|\mathbf{Y}^{\prime} \mathbf{Y}-n \overline{\mathbf{Y}} \overline{\mathbf{y}}^{\prime}\right|}} \\
& =\frac{\Lambda_{f}}{\Lambda_{r}} \tag{10.74}
\end{align*}
\]
where \(\Lambda_{f}\) is given by (10.64). In (10.74), we have a convenient computational device. We run the overall regression test for the full model and again for the reduced model and take the ratio of the resulting \(\Lambda\) values.

The Wilks' \(\Lambda\) in (10.74), comparing the full and reduced models, is similar in appearance to (6.126). However, in (6.126), the full and reduced models involve the dependent variables \(y_{1}, y_{2}, \ldots, y_{p}\) in MANOVA, whereas in (10.74), the reduced model is obtained by deleting a subset of the independent variables \(x_{1}, x_{2}, \ldots, x_{q}\) in regression. The parameters of the Wilks' \(\Lambda\) distribution are different in the two cases. Note that in (6.126), some of the dependent variables were denoted by \(x_{1}, \ldots, x_{q}\) for convenience.

Test statistics due to Roy, Pillai, and Lawley-Hotelling can be obtained from the eigenvalues of \(\mathbf{E}^{-1} \mathbf{H}=\left(\mathbf{Y}^{\prime} \mathbf{Y}-\hat{\mathbf{B}}^{\prime} \mathbf{X}^{\prime} \mathbf{Y}\right)^{-1}\left(\hat{\mathbf{B}}^{\prime} \mathbf{X}^{\prime} \mathbf{Y}-\hat{\mathbf{B}}_{r}^{\prime} \mathbf{X}_{r}^{\prime} \mathbf{Y}\right)\). Critical values or approximate tests for these three test statistics are based on \(\nu_{H}=h, \nu_{E}=n-q-1\), and
\[
s=\min (p, h), \quad m=\frac{1}{2}(|h-p|-1), \quad N=\frac{1}{2}(n-p-h-2)
\]

\section*{EXAMPLE 10.5.2}

The chemical data in Table 10.1 originated from a response surface experiment seeking to locate optimum operating conditions. Therefore, a second-order model is of interest, and we add \(x_{1}^{2}, x_{2}^{2}, x_{3}^{2}, x_{1} x_{2}, x_{1} x_{3}, x_{2} x_{3}\) to the variables \(x_{1}, x_{2}, x_{3}\) considered in Example 10.5.1. There are now \(q=9\) independent variables, and we obtain an overall Wilks' \(\Lambda\) of
\[
\Lambda=.00145<\Lambda_{.05,3,9,9}=.024
\]
where \(\nu_{H}=q=9\) and \(\nu_{E}=n-q-1=19-9-1=9\). To see whether the six second-order variables add a significant amount to \(x_{1}, x_{2}, x_{3}\) for predicting the \(y\) 's, we calculate
\[
\Lambda=\frac{\Lambda_{f}}{\Lambda_{r}}=\frac{.00145}{.0332}=.0438<\Lambda_{.05,3,6,9}=.049
\]
where \(\nu_{H}=h=6\) and \(\nu_{E}=n-q-1=19-9-1=9\). In this case, \(\Lambda_{r}=.0332\) is from Example 10.5.1, in which we considered the model with
\(x_{1}, x_{2}\), and \(x_{3}\). Thus we reject \(H_{0}: \mathbf{B}_{d}=\mathbf{O}\) and conclude that the secondorder terms add significant predictability to the model.

\subsection*{10.6 MULTIVARIATE MULTIPLE REGRESSION: PREDICTION}

In this section we consider the problem of predicting the response variables \(y_{0}\) associated with a known vector of predictor variables \(\mathbf{x}_{0}\). Assuming that model (10.46) holds, we first consider a confidence interval for the expected value of \(\mathbf{y}_{0}\) given \(\mathbf{x}_{0}\) and then we discuss a prediction interval for a future observation \(y_{0}\) based on \(\mathbf{x}_{0}\).

\subsection*{10.6.1 Confidence Interval for \(\boldsymbol{E}\left(\mathrm{y}_{0}\right)\)}

Under model (10.46), the expected value of \(\mathbf{y}_{0}\) given \(\mathbf{x}_{0}=\left(1, x_{01}, x_{01}, \ldots, x_{0 q}\right)^{\prime}\) is
\[
E\left(\mathbf{y}_{0}\right)=E\left(\mathbf{B}^{\prime} \mathbf{x}_{0}+\varepsilon_{0}\right)=\mathbf{B}^{\prime} \mathbf{x}_{0}+E\left(\varepsilon_{0}\right)=\mathbf{B}^{\prime} \mathbf{x}_{0}
\]

To construct a confidence interval for \(E\left(\mathbf{y}_{0}\right)\), we first need an estimate of the covariance of the error associated with \(\hat{\mathbf{B}}^{\prime} \mathbf{x}_{0}\) when estimating \(E\left(\mathbf{y}_{0}\right)\). Using (10.52) and properties (2.121) - (2.123) and (3.68),
\[
\begin{aligned}
\operatorname{cov}\left(\hat{\mathbf{B}}^{\prime} \mathbf{x}_{0}-\mathbf{B}^{\prime} \mathbf{x}_{0}\right) & =\operatorname{cov}\left(\hat{\mathbf{B}}^{\prime} \mathbf{x}_{0}\right) \\
& =\operatorname{cov}\left[\left(\mathbf{x}_{0}^{\prime} \otimes \mathbf{I}_{p}\right) \operatorname{vec} \hat{\mathbf{B}}^{\prime}\right] \\
& =\left(\mathbf{x}_{0}^{\prime} \otimes \mathbf{I}_{p}\right)\left[\left(\mathbf{X}^{\prime} \mathbf{X}\right)^{-1} \otimes \mathbf{\Sigma}\right]\left(\mathbf{x}_{0} \otimes \mathbf{I}_{p}\right) \\
& =\left[\mathbf{x}_{0}^{\prime}\left(\mathbf{X}^{\prime} \mathbf{X}\right)^{-1} \mathbf{x}_{0}\right] \otimes \boldsymbol{\Sigma} \\
& =\left[\mathbf{x}_{0}^{\prime}\left(\mathbf{X}^{\prime} \mathbf{X}\right)^{-1} \mathbf{x}_{0}\right] \mathbf{\Sigma}
\end{aligned}
\]
and a useful estimate of \(\operatorname{cov}\left(\hat{\mathbf{B}}^{\prime} \mathbf{x}_{0}\right)\) is
\[
\begin{equation*}
\widehat{\operatorname{cov}}\left(\hat{\mathbf{B}}^{\prime} \mathbf{x}_{0}\right)=\left[\mathbf{x}_{0}^{\prime}\left(\mathbf{X}^{\prime} \mathbf{X}\right)^{-1} \mathbf{x}_{0}\right] \mathbf{S}_{e} \tag{10.75}
\end{equation*}
\]
with \(S_{e}\) defined in (10.53).
The estimated covariance matrix in (10.75) can be used to create a \(p\)-dimensional confidence region for \(E\left(\mathbf{y}_{0}\right)\). More commonly, interest is in individual confidence intervals for the elements of \(E\left(\mathbf{y}_{0}\right)\). The \((i, i)\) element of \(\widehat{\operatorname{cov}}\left(\hat{\mathbf{B}}^{\prime} \mathbf{x}_{0}\right)\) can be used to create a \(100(1-\alpha) \%\) confidence interval for the \(i\) th component of \(E\left(y_{0}\right)\) with
\[
\begin{equation*}
\hat{\boldsymbol{\beta}}_{(i)}^{\prime} \mathbf{x}_{0} \pm t_{\alpha / 2, n-q-1} \sqrt{s_{i i}\left[\mathbf{x}_{0}^{\prime}\left(\mathbf{X}^{\prime} \mathbf{X}\right)^{-1} \mathbf{x}_{0}\right]} \tag{10.76}
\end{equation*}
\]
where \(\hat{\boldsymbol{\beta}}_{(i)}\) is the \(i\) th column of \(\hat{\mathbf{B}}\) and \(s_{i i}\) is the \(i\) th diagonal element of \(\mathbf{S}_{e}\). If \(100(1-\alpha) \%\) simultaneous confidence intervals for all \(p\) components of \(E\left(\mathbf{y}_{0}\right)\) are desired without inflating the experimentwise Type I error rate [i.e., the probability of obtaining at least one confidence interval that does not contain \(\left.E\left(y_{0 i}\right)\right]\), then the Hotelling's \(T^{2}\)-based intervals can be used:
\[
\begin{equation*}
\hat{\boldsymbol{\beta}}_{(i)}^{\prime} \mathbf{x}_{0} \pm \sqrt{T_{\alpha, p, n-q-1}^{2} s_{i i}\left[\mathbf{x}_{0}^{\prime}\left(\mathbf{X}^{\prime} \mathbf{X}\right)^{-1} \mathbf{x}_{0}\right]} . \tag{10.77}
\end{equation*}
\]

Although the \(T^{2}\)-intervals obtained using (10.77) are more conservative than the \(t\) intervals of (10.76), the probability that at least one of the \(p\) confidence intervals does not contain \(E\left(y_{0 i}\right)\) is bounded above by \(\alpha\).

\subsection*{10.6.2 Prediction Interval for a Future Observation yo}

We are often interested in obtaining a range of reasonable values for a future observation \(\mathbf{y}_{0}\) associated with \(\mathbf{x}_{0}\). Notice that we use the same point estimate for \(\mathbf{y}_{0}\) that we use for \(E\left(\mathbf{y}_{0}\right)\). However, the covariance of the error associated with \(\hat{\mathbf{B}}^{\prime} \mathbf{x}_{0}\) in estimating \(\mathbf{y}_{0}\) is different from the error covariance (10.75) that is used when estimating \(E\left(\mathbf{y}_{0}\right)\). Using (10.75) and the independence of \(\varepsilon_{0}\) and \(\mathbf{y}_{i}, i=1, \ldots, n\), the covariance of the error associated with \(\hat{\mathbf{B}}^{\prime} \mathbf{x}_{0}\) when predicting \(E\left(\mathbf{y}_{0}\right)=\mathbf{B}^{\prime} \mathbf{x}_{0}+\varepsilon_{0}\) is
\[
\begin{aligned}
\operatorname{cov}\left(\hat{\mathbf{B}}^{\prime} \mathbf{x}_{0}-\left[\mathbf{B}^{\prime} \mathbf{x}_{0}+\varepsilon_{0}\right]\right) & =\operatorname{cov}\left(\hat{\mathbf{B}}^{\prime} \mathbf{x}_{0}-\boldsymbol{\varepsilon}_{0}\right) \\
& =\operatorname{cov}\left(\hat{\mathbf{B}}^{\prime} \mathbf{x}_{0}\right)+\operatorname{cov}\left(\boldsymbol{\varepsilon}_{0}\right) \\
& =\left[\mathbf{x}_{0}^{\prime}\left(\mathbf{X}^{\prime} \mathbf{X}\right)^{-1} \mathbf{x}_{0}\right] \boldsymbol{\Sigma}+\boldsymbol{\Sigma}
\end{aligned}
\]
and a useful estimate of \(\operatorname{cov}\left(\hat{\mathbf{B}}^{\prime} \mathbf{x}_{0}-\boldsymbol{\varepsilon}_{0}\right)\) is
\[
\begin{equation*}
\widehat{\operatorname{cov}}\left(\hat{\mathbf{B}}^{\prime} \mathbf{x}_{0}-\boldsymbol{\varepsilon}_{0}\right)=\left[1+\mathbf{x}_{0}^{\prime}\left(\mathbf{X}^{\prime} \mathbf{X}\right)^{-1} \mathbf{x}_{0}\right] \mathbf{S}_{e} \tag{10.78}
\end{equation*}
\]
with \(\mathbf{S}_{e}\) defined in (10.53).
The covariance matrix in (10.78) can be used to construct a \(p\)-dimensional prediction region, but similar to inference associated with \(E\left(\mathbf{y}_{0}\right)\), the more common inferential procedure associated with the predicted observation \(\mathbf{y}_{0}\) is a prediction interval for an individual element of \(\mathbf{y}_{0}\). The ( \(\left.i, i\right)\) element of \(\widehat{\operatorname{cov}}\left(\hat{\mathbf{B}}^{\prime} \mathbf{x}_{0}-\varepsilon_{0}\right)\) can be used to create a \(100(1-\alpha) \%\) prediction interval for the \(i\) th component of \(y_{0}\) with
\[
\begin{equation*}
\hat{\boldsymbol{\beta}}_{(i)}^{\prime} \mathbf{x}_{0} \pm t_{\alpha / 2, n-q-1} \sqrt{s_{i i}\left[1+\mathbf{x}_{0}^{\prime}\left(\mathbf{X}^{\prime} \mathbf{X}\right)^{-1} \mathbf{x}_{0}\right]} \tag{10.79}
\end{equation*}
\]
where \(\hat{\boldsymbol{\beta}}_{(i)}\) is the \(i\) th column of \(\hat{\mathbf{B}}\) and \(s_{i i}\) is the \(i\) th diagonal element of \(\mathbf{S}_{e}\). Similar to the simultaneous confidence intervals in (10.77), the \(100(1-\alpha) \%\) simultaneous prediction intervals for all \(p\) components of \(\mathbf{y}_{0}\) are:
\[
\begin{equation*}
\hat{\boldsymbol{\beta}}_{(i)}^{\prime} \mathbf{x}_{0} \pm \sqrt{T_{\alpha, p, n-q-1}^{2} s_{i i}\left[1+\mathbf{x}_{0}^{\prime}\left(\mathbf{X}^{\prime} \mathbf{X}\right)^{-1} \mathbf{x}_{0}\right]} \tag{10.80}
\end{equation*}
\]

\section*{© EXAMPLE 10.6.2}

For the chemical data of Table 10.1, we obtain confidence intervals for the three elements of \(E\left(\mathbf{y}_{0}\right)\) and prediction intervals for the three elements of a new observation \(\mathbf{y}_{0}\) when \(\mathbf{x}_{0}=(1,160,25,5)\). The value \(\mathbf{x}_{0}^{\prime}\left(\mathbf{X}^{\prime} \mathbf{X}\right)^{-1} \mathbf{x}_{0}\) is equal to \(0.2386, \hat{\mathbf{B}}^{\prime} \mathbf{x}_{0}=(37.96,51.19,10.40)^{\prime}\), the diagonal elements of \(\mathbf{S}_{e}\)
in (10.53) are \((5.35,16.63,15.41)^{\prime}\), and \(t_{\alpha / 2,15}=2.13\). So, using (10.76), the confidence intervals for \(E\left(y_{01}\right), E\left(y_{02}\right)\), and \(E\left(y_{03}\right)\) are
(46.94, 55.43),
and (6.32, 14.49).
Using (10.79), the prediction intervals for \(y_{01}, y_{02}\), and \(y_{03}\) are
\[
(32.47,43.44)
\]
\[
(41.51,60.86),
\]
\[
\text { and }(1.09,19.72)
\]

\subsection*{10.7 MEASURES OF ASSOCIATION BETWEEN THE \(y\) 's AND THE \(x\) 's}

The most widely used measures of association between two sets of variables are the canonical correlations, which are treated in Chapter 11. In this section, we review other measures of association that have been proposed.

In (10.34), we have \(R^{2}=\mathbf{s}_{y x}^{\prime} \mathbf{S}_{x x}^{-1} \mathbf{s}_{y x} / s_{y y}\) for the univariate \(y\) case. By analogy, we define an \(R^{2}\)-like measure of association between \(y_{1}, y_{2}, \ldots, y_{p}\) and \(x_{1}, x_{2}, \ldots, x_{q}\) as
\[
\begin{equation*}
R_{M}^{2}=\frac{\left|\mathbf{S}_{y x} \mathbf{S}_{x x}^{-1} \mathbf{S}_{x y}\right|}{\left|\mathbf{S}_{y y}\right|}, \tag{10.81}
\end{equation*}
\]
where \(\mathbf{S}_{y x}, \mathbf{S}_{x y}, \mathbf{S}_{x x}\), and \(\mathbf{S}_{y y}\) are defined in (10.58) and the subscript \(M\) indicates multivariate \(y\) 's.

By analogy to \(r_{x y}=s_{x y} / s_{x} s_{y}\) in (3.13), Robert and Escoufier (1976) suggested
\[
\begin{equation*}
\mathrm{RV}=\frac{\operatorname{tr}\left(\mathbf{S}_{x y} \mathbf{S}_{y x}\right)}{\sqrt{\operatorname{tr}\left(\mathbf{S}_{x x}^{2}\right) \operatorname{tr}\left(\mathbf{S}_{y y}^{2}\right)}} \tag{10.82}
\end{equation*}
\]

Kabe (1985) discussed the generalized correlation determinant
\[
\mathbf{G C D}=\frac{\left|\mathbf{L}^{\prime} \mathbf{S}_{x y} \mathbf{M M}^{\prime} \mathbf{S}_{y x} \mathbf{L}\right|}{\left|\mathbf{L}^{\prime} \mathbf{S}_{x x} \mathbf{L}\right|\left|\mathbf{M}^{\prime} \mathbf{S}_{y y} \mathbf{M}\right|}
\]
for various choices of the transformation matrices \(\mathbf{L}\) and \(\mathbf{M}\).
In Section 6.1.8, we introduced several measures of association that quantify the amount of relationship between the \(y\) 's and the dummy grouping variables in a MANOVA context. These are even more appropriate here in the multivariate regression setting, where both the \(x\) 's and the \(y\) 's are continuous variables. The \(R^{2}\)-like indices given in (6.40), (6.42), (6.45), (6.48), and (6.50) range between 0 and 1 and
will be briefly reviewed in the remainder of this section. For more complete commentary, see Section 6.1.8.

The two measures based on Wilks' \(\Lambda\) are
\[
\begin{aligned}
\eta_{\Lambda}^{2} & =1-\Lambda \\
A_{\Lambda} & =1-\Lambda^{1 / s}
\end{aligned}
\]
where \(s=\min (p, q)\). A measure based on Roy's \(\theta\) is provided by \(\theta\) itself,
\[
\eta_{\theta}^{2}=\frac{\lambda_{1}}{1+\lambda_{1}}=\theta
\]
where \(\lambda_{1}\) is the largest eigenvalue of \(\mathbf{E}^{-1} \mathbf{H}\). This was identified in Section 6.1.8 as the square of the first canonical correlation (see Chapter 11) between the \(y\) 's and the grouping variables in MANOVA. In the multivariate regression setting, \(\theta\) is the square of the first canonical correlation, \(r_{1}^{2}\), between the \(y\) 's and the \(x\) 's.

Measures of association based on the Lawley-Hotelling and Pillai statistics are given by
\[
\begin{align*}
A_{L H} & =\frac{U^{(s)} / s}{1+U^{(s)} / s} \\
A_{P} & =\frac{V^{(s)}}{s} \tag{10.83}
\end{align*}
\]

By (6.47) and (6.48), \(A_{P}\) in (10.83) is the average of the \(s\) squared canonical correlations, \(r_{1}^{2}, r_{2}^{2}, \ldots, r_{s}^{2}\).

\section*{EXAMPLE 10.7}

We use the chemical data of Table 10.1 to illustrate some measures of association. For the three dependent variables \(y_{1}, y_{2}\), and \(y_{3}\) and the three independent variables \(x_{1}, x_{2}\), and \(x_{3}\), the partitioned covariance matrix is
\[
\begin{aligned}
\mathbf{S} & =\left(\begin{array}{ll}
\mathbf{S}_{y y} & \mathbf{S}_{y x} \\
\mathbf{S}_{x y} & \mathbf{S}_{x x}
\end{array}\right) \\
& =\left(\begin{array}{rrr|rrr}
99.30 & -28.57 & -59.03 & -41.95 & -9.49 & -7.37 \\
-28.57 & 22.25 & 5.78 & 11.85 & 1.60 & 3.03 \\
-59.03 & 5.78 & 45.27 & 24.14 & 6.43 & 3.97 \\
\hline-41.95 & 11.85 & 24.14 & 38.67 & -12.17 & -.22 \\
-9.49 & 1.60 & 6.43 & -12.17 & 17.95 & 1.22 \\
-7.36 & 3.03 & 3.97 & -.22 & 1.22 & 2.67
\end{array}\right),
\end{aligned}
\]
from which we obtain \(R_{M}^{2}\) and RV directly using (10.81) and (10.82),
\[
\begin{aligned}
R_{M}^{2} & =\frac{\left|\mathbf{S}_{y x} \mathbf{S}_{x x}^{-1} \mathbf{S}_{x y}\right|}{\left|\mathbf{S}_{y y}\right|}=.00029 \\
\mathrm{RV} & =\frac{\operatorname{tr}\left(\mathbf{S}_{x y} \mathbf{S}_{y x}\right)}{\sqrt{\operatorname{tr}\left(\mathbf{S}_{x x}^{2}\right) \operatorname{tr}\left(\mathbf{S}_{y y}^{2}\right)}}=.403 .
\end{aligned}
\]

Using the results in Example 10.5.1, we obtain
\[
\begin{aligned}
\eta_{\Lambda}^{2} & =1-\Lambda=1-.0332=.967 \\
A_{\Lambda} & =1-\Lambda^{1 / s}=1-\Lambda^{1 / 3}=.679 \\
\eta_{\theta}^{2} & =\frac{\lambda_{1}}{1+\lambda_{1}}=.963 \\
A_{\mathrm{LH}} & =\frac{U^{(s)} / s}{1+U^{(s)} / s}=\frac{26.422 / 3}{1+26.422 / 3}=.898 \\
A_{p} & =\frac{V^{(s)}}{s}=\frac{1.058}{3}=.352
\end{aligned}
\]

We have general agreement among \(\eta_{\Lambda}^{2}, A_{\Lambda}, \eta_{\theta}^{2}\), and \(A_{\mathrm{LH}}\). But \(R_{M}^{2}\), RV, and \(A_{p}\) do not appear to be measuring the same level of association, especially \(R_{M}^{2}\). It appears that more study is needed before one or more of these measures can be universally recommended.

\subsection*{10.8 SUBSET SELECTION}

As in the univariate \(y\) case in Section 10.2.7, there may be more potential predictor variables ( \(x\) 's) than are useful in a given situation. Some of the \(x\) 's may be redundant in the presence of the other \(x\) 's.

We may also be interested in deleting some of the \(y\) 's if they are not well predicted by any of the \(x\) 's. This would lead to further simplification of the model.

We present two approaches to subset selection: stepwise procedures and methods involving all possible subsets.

\subsection*{10.8.1 Stepwise Procedures}

Subset selection among the \(x\) 's is discussed in Section 10.8.1 a, followed by selection among the \(y\) 's in Section 10.8.1b.

\subsection*{10.8.1a Finding a Subset of the \(x\) 's}

We begin with the forward selection procedure based on Wilks' \(\Lambda\). At the first step, we test the regression of the \(p y\) 's on each \(x_{j}\). There will be two rows in the \(\hat{\mathbf{B}}\) matrix, a row containing the intercepts and a row corresponding to \(x_{j}\) :
\[
\hat{\mathbf{B}}_{j}=\left(\begin{array}{llll}
\hat{\beta}_{01} & \hat{\beta}_{02} & \cdots & \hat{\beta}_{0 p} \\
\hat{\beta}_{j 1} & \hat{\beta}_{j 2} & \cdots & \hat{\beta}_{j p}
\end{array}\right) .
\]

We use the overall regression test statistic (10.64),
\[
\Lambda\left(x_{j}\right)=\frac{\left|\mathbf{Y}^{\prime} \mathbf{Y}-\hat{\mathbf{B}}_{j}^{\prime} \mathbf{X}_{j}^{\prime} \mathbf{Y}\right|}{\left|\mathbf{Y}^{\prime} \mathbf{Y}-n \overline{\mathbf{y}} \overline{\mathbf{y}}^{\prime}\right|}
\]
which is distributed as \(\Lambda_{p, 1, n-2}\), since \(\hat{\mathbf{B}}_{j}\) has two rows and \(\mathbf{X}_{j}\) has two columns. After calculating \(\Lambda\left(x_{j}\right)\) for each \(j\), we choose the variable with minimum \(\Lambda\left(x_{j}\right)\). Note that at the first step, we are not testing each variable in the presence of the others. We search for the variable \(x_{j}\) that best predicts the \(p y\) 's by itself, not above and beyond the other \(x\) 's.

At the second step, we seek the variable yielding the smallest partial \(\Lambda\) for each \(x\) adjusted for the variable first entered, where the partial \(\Lambda\)-statistic is given by (10.74). After one variable has entered, (10.74) becomes
\[
\begin{equation*}
\Lambda\left(x_{j} \mid x_{1}\right)=\frac{\Lambda\left(x_{1}, x_{j}\right)}{\Lambda\left(x_{1}\right)} \tag{10.84}
\end{equation*}
\]
where \(x_{1}\) denotes the variable entered at the first step. We calculate (10.84) for each \(x_{j} \neq x_{1}\) and choose the variable that minimizes \(\Lambda\left(x_{j} \mid x_{1}\right)\).

If we denote the second variable to enter by \(x_{2}\), then at the third step we seek the \(x_{j}\) that minimizes
\[
\begin{equation*}
\Lambda\left(x_{j} \mid x_{1}, x_{2}\right)=\frac{\Lambda\left(x_{1}, x_{2}, x_{j}\right)}{\Lambda\left(x_{1}, x_{2}\right)} \tag{10.85}
\end{equation*}
\]

By property 7 in Section 6.1.3, the partial Wilks' \(\Lambda\)-statistic transforms to an exact \(F\) since \(\nu_{H}=h=1\) at each step.

After \(m\) variables have been selected, the partial \(\Lambda\) would have the following form at the next step:
\[
\begin{equation*}
\Lambda\left(x_{j} \mid x_{1}, x_{2}, \ldots, x_{m}\right)=\frac{\Lambda\left(x_{1}, x_{2}, \ldots, x_{m}, x_{j}\right)}{\Lambda\left(x_{1}, x_{2}, \ldots, x_{m}\right)} \tag{10.86}
\end{equation*}
\]
where the first \(m\) variables to enter are denoted \(x_{1}, x_{2}, \ldots, x_{m}\) and \(x_{j}\) is a candidate variable from among the \(q--m\) remaining variables. At this step, we would choose the \(x_{j}\) that minimizes (10.86). The partial Wilks' \(\Lambda\) in (10.86) is distributed as \(\Lambda_{p, 1, n-m-1}\) and, by Table 6.1, transforms to a partial \(F\)-statistic distributed as \(F_{p, n-m-p}\). [These distributions hold for a variable \(x_{j}\) chosen before seeing the data but not for the \(x_{j}\) that minimizes (10.86) or maximizes the corresponding partial \(F\).]

The procedure continues, bringing in the "best" variable at each step, until a step is reached at which the minimum partial \(\Lambda\) exceeds a predetermined threshold value or, equivalently, the associated partial \(F\) falls below a preselected value. Alternatively, the stopping rule can be cast in terms of the \(p\)-value of the partial \(\Lambda\) or \(F\). If the smallest \(p\)-value at some step exceeds a predetermined value, the procedure stops.

For each \(x_{j}\), there corresponds an entire row of the \(\hat{\mathbf{B}}\) matrix because \(x_{j}\) has a coefficient for each of the \(p y\) 's. Thus if a certain \(x\) significantly predicts even one of the \(y\) 's, it should be retained.

The stepwise procedure is an extension of forward selection. Each time a variable enters, all the variables that have entered previously are checked by a partial \(\Lambda\) or \(F\) to see if the least "significant" one is now redundant and can be deleted.

The backward elimination procedure begins with all \(x\) 's (all rows of \(\hat{\mathbf{B}}\) ) included in the model and deletes one at a time, using a partial \(\Lambda\) or \(F\). At the first step, the
partial \(\Lambda\) for each \(x_{j}\) is
\[
\begin{equation*}
\Lambda\left(x_{j} \mid x_{1}, \ldots, x_{j-1}, x_{j+1}, \ldots, x_{q}\right)=\frac{\Lambda\left(x_{1}, \ldots, x_{q}\right)}{\Lambda\left(x_{1}, \ldots, x_{j-1}, x_{j+1}, \ldots, x_{q}\right)} \tag{10.87}
\end{equation*}
\]
which is distributed as \(\Lambda_{p, 1, n-q-1}\) and can be converted to \(F_{p, n-q-p}\) by Table 6.1. The variable with largest \(\Lambda\) or smallest \(F\) is deleted. At the second step, a partial \(\Lambda\) or \(F\) is calculated for each of the \(q-1\) remaining variables, and again the least important variable in the presence of the others is eliminated. This process continues until a step is reached at which the largest \(\Lambda\) or smallest \(F\) is "significant," indicating that the corresponding variable is apparently not redundant in the presence of its fellows. Some preselected \(p\)-value or threshold value of \(\Lambda\) or \(F\) is used to determine a stopping rule.

If no automated program is available for subset selection in the multivariate case, a forward selection or backward elimination procedure could be carried out by means of a rather simple set of commands based on (10.86) or (10.87).

A sequential procedure such as stepwise selection will often fail to find the optimum subset, especially if a large pool of predictor variables is involved. However, the value of Wilks' \(\Lambda\) found by stepwise selection may not be far from that for the optimum subset.

The remarks in the final paragraph of Section 10.2 .7b are pertinent in the multivariate context as well. True predictors of the \(y\) 's in the population may be overlooked because of inflated error variances, or, on the other hand, \(x\) 's that are not true predictors may appear to be so in the sample. The latter problem can be severe for small sample sizes (Rencher and Pun 1980).

\subsection*{10.8.1b Finding a Subset of the \(y\) 's}

After a subset of \(x\) 's has been found, the researcher may wish to know if these \(x\) 's predict all \(p\) of the \(y\) 's. If some of the \(y\) 's do not relate to any of the \(x\) 's, they could be deleted from the model to achieve a further simplification. The \(y\) 's can be checked for redundancy in a manner analogous to the stepwise discriminant approach presented in Sections 6.11.2 and 8.9, which finds subsets of dependent variables, using a full and reduced model Wilks' \(\Lambda\) for the \(y\) 's. The partial \(\Lambda\)-statistic for adding or deleting a \(y\) is similar to (10.84), (10.85), or (10.86), except that dependent variables are involved rather than independent variables. Thus to add a \(y\) at the third step of a forward selection procedure, for example, where the first two variables already entered are denoted as \(y_{1}\) and \(y_{2}\), we use (6.127) to obtain
\[
\begin{equation*}
\Lambda\left(y_{j} \mid y_{1}, y_{2}\right)=\frac{\Lambda\left(y_{1}, y_{2}, y_{j}\right)}{\Lambda\left(y_{1}, y_{2}\right)} \tag{10.88}
\end{equation*}
\]
for each \(y_{j} \neq y_{1}\) or \(y_{2}\), and we choose the \(y_{j}\) that minimizes \(\Lambda\left(y_{j} \mid y_{1}, y_{2}\right)\). [ In (6.127) the dependent variable of interest was denoted by \(x\) instead of \(y_{j}\) as here.]

Similarly, if three \(y\) 's, designated as \(y_{1}, y_{2}\), and \(y_{3}\), were "in the model" and we were checking the feasibility of adding \(y_{j}\), the partial \(\Lambda\)-statistic would be
\[
\begin{equation*}
\Lambda\left(y_{j} \mid y_{1}, y_{2}, y_{3}\right)=\frac{\Lambda\left(y_{1}, y_{2}, y_{3}, y_{j}\right)}{\Lambda\left(y_{1}, y_{2}, y_{3}\right)} \tag{10.89}
\end{equation*}
\]
which is distributed as \(\Lambda_{1, q, n-q-4}\), where \(q\) is the number of \(x\) 's presently in the model and 4 is the number of \(y\) 's presently in the model. The two Wilks' \(\Lambda\) values in the numerator and denominator of the right side of (10.89), \(\Lambda\left(y_{1}, y_{2}, y_{3}, y_{j}\right)\) and \(\Lambda\left(y_{1}, y_{2}, y_{3}\right)\), are obtained from (10.64). Since \(p=1, \Lambda_{1, q, n-q-4}\) in (10.89) transforms to \(F_{q, n-q-4}\) (see Table 6.1).

In the first step of a backward elimination procedure, we would delete the \(y_{j}\) that maximizes
\[
\begin{equation*}
\Lambda\left(y_{j} \mid y_{1}, \ldots, y_{j-1}, y_{j+1}, \ldots, y_{p}\right)=\frac{\Lambda\left(y_{1}, \ldots, y_{p}\right)}{\Lambda\left(y_{1}, \ldots, y_{j-1}, y_{j+1}, \ldots, y_{p}\right)} \tag{10.90}
\end{equation*}
\]
which is distributed as \(\Lambda_{1, \nu_{H}, \nu_{E}-p+1}\). In this case, \(\nu_{H}=q\) and \(\nu_{E}=n-q-1\) so that the distribution of (10.90) is \(\Lambda_{1, q, n-q-p}\), which can be transformed to an exact \(F\). Note that \(q\), the number of \(x\) 's, may have been reduced in a subset selection on the \(x\) 's as in Section 10.8.1a. Similarly, \(p\) is the number of \(y\) 's and will decrease in subsequent steps.

Stopping rules for either the forward or backward approach could be defined in terms of \(p\)-values or threshold values of \(\Lambda\) or the equivalent \(F\). A stepwise procedure could be devised as a modification of the forward approach.

If a software program is available that tests the significance of one \(x\) as in (10.87), it can be adapted to test one \(y\) as in (10.90) by use of property 3 of Section 6.1.3: The distribution of \(\Lambda_{p, \nu_{H}, \nu_{E}}\) is the same as that of \(\Lambda_{\nu_{H}, p, \nu_{E}+\nu_{H}-p}\), which can also be seen from the symmetry of \(\Lambda\) in (10.66),
\[
\Lambda=\frac{|\mathbf{S}|}{\left|\mathbf{S}_{x x}\right|\left|\mathbf{S}_{y y}\right|},
\]
which is distributed as \(\Lambda_{p, q, n-q-1}\) or equivalently as \(\Lambda_{q, p, n-p-1}\). Thus we can reverse the \(y\) 's and \(x\) 's; we list the \(x\) 's as dependent variables in the program and the \(y\) 's as independent variables. Then the test of a single \(y\) in (10.89) or (10.90) can be carried out using (10.87) without any adjustment. The partial \(\Lambda\)-statistic in (10.87) is distributed as \(\Lambda_{p, 1, n-q-1}\). If we interchange \(p\) and \(q\), because the \(y\) 's and \(x\) 's are interchanged as dependent and independent variables, this becomes \(\Lambda_{q, 1, n-p-1}\). By property 3 of Section 6.1.3 (repeated above), this is equivalent to \(\Lambda_{1, q, n-p-1+1-q}=\Lambda_{1, q, n-p-q}\), which is the distribution of (10.90).

\subsection*{10.8.2 All Possible Subsets}

In Section 10.2.7a, we discussed the criteria \(R_{p}^{2}, s_{p}^{2}\), and \(C_{p}\) for comparing all possible subsets of \(x\) 's to predict a univariate \(y\) in multiple regression, where \(p-1\) denotes the number of \(x\) 's in a subset selected from a pool of \(k-1\) available independent variables. We now discuss some matrix analogues of these criteria for the multivariate \(y\) case, as suggested by Mallows (1973) and Sparks et al. (1983).

In this section, in order to conform with notation in the literature, we will use \(p\) for the number of columns in \(\mathbf{X}\) (and the number of rows in \(\mathbf{B}\) ), rather than for the number of \(y\) 's. The number of \(y\) 's will be indicated by \(m\).

We now extend the three criteria \(R_{p}^{2}, s_{p}^{2}\), and \(C_{p}\) to analogous matrix expressions \(\mathbf{R}_{p}^{2}, \mathbf{S}_{p}\), and \(\mathbf{C}_{p}\). These can be reduced to scalar form using trace or determinant.
1. \(\mathbf{R}_{p}^{2}\). In the univariate \(y\) case, \(R_{p}^{2}\) for a ( \(p-1\) )-variable subset of \(x\) 's is defined by (10.32) as
\[
R_{p}^{2}=\frac{\hat{\boldsymbol{\beta}}_{p}^{\prime} \mathbf{X}_{p}^{\prime} \mathbf{y}-n \bar{y}^{2}}{\mathbf{y}^{\prime} \mathbf{y}-n \bar{y}^{2}}
\]

A direct extension of \(R_{p}^{2}\) for the multivariate \(y\) case is given by the matrix
\[
\begin{equation*}
\mathbf{R}_{p}^{2}=\left(\mathbf{Y}^{\prime} \mathbf{Y}-n \overline{\mathbf{y}} \overline{\mathbf{y}}^{\prime}\right)^{-1}\left(\hat{\mathbf{B}}_{p}^{\prime} \mathbf{X}_{p}^{\prime} \mathbf{Y}-n \overline{\mathbf{y}} \overline{\mathbf{y}}^{\prime}\right) \tag{10.91}
\end{equation*}
\]
where \(p-1\) is the number of \(x\) 's selected from the \(k-1\) available \(x\) 's. To convert \(\mathbf{R}_{p}^{2}\) to scalar form, we can use \(\operatorname{tr}\left(\mathbf{R}_{p}^{2}\right) / m\), in which we divide by \(m\), the number of \(y\) 's, so that \(0 \leq \operatorname{tr}\left(\mathbf{R}_{p}^{2}\right) / m \leq 1\). As in the univariate case, we identify the subset that maximizes \(\operatorname{tr}\left(\mathbf{R}_{p}^{2}\right) / m\) for each value of \(p=2,3, \ldots, k\). The criterion \(\operatorname{tr}\left(\mathbf{R}_{p}^{2}\right) / m\) does not attain its maximum until \(p\) reaches \(k\), but we look for the value of \(p\) at which further increases are deemed unimportant. We could also use \(\left|\mathbf{R}_{p}^{2}\right|\) in place of \(\operatorname{tr}\left(\mathbf{R}_{p}^{2}\right) / m\).
2. \(\mathbf{S}_{p}\). A direct extension of the univariate criterion \(s_{p}^{2}=\operatorname{MSE}_{p}=\operatorname{SSE}_{p} /(n-p)\) is provided by
\[
\begin{equation*}
\mathbf{S}_{p}=\frac{\mathbf{E}_{p}}{n-p} \tag{10.92}
\end{equation*}
\]
where \(\mathbf{E}_{p}=\mathbf{Y}^{\prime} \mathbf{Y}-\hat{\mathbf{B}}_{p}^{\prime} \mathbf{X}_{p}^{\prime} \mathbf{Y}\). To convert to a scalar, we can use \(\operatorname{tr}\left(\mathbf{S}_{p}\right)\) or \(\left|\mathbf{S}_{p}\right|\), either of which will behave in an analogous fashion to \(s_{p}^{2}\) in the univariate case. The remarks in Section 10.2.7a apply here as well; one may wish to select the subset with minimum value of \(\operatorname{tr}\left(\mathbf{S}_{p}\right)\) or perhaps the subset with smallest \(p\) such that \(\operatorname{tr}\left(\mathbf{S}_{p}\right)<\) \(\operatorname{tr}\left(\mathbf{S}_{k}\right)\). A similar application could be made with \(\left|\mathbf{S}_{p}\right|\).
3. \(\mathbf{C}_{p}\). To extend the \(C_{p}\) criterion to the multivariate \(y\) case, we write the model under consideration as
\[
\mathbf{Y}=\mathbf{X}_{p} \mathbf{B}_{p}+\boldsymbol{\Xi}
\]
where \(p-1\) is the number of \(x\) 's in the subset and \(k-1\) is the number of \(x\) 's in the "full model." The predicted values of the \(y\) 's are given by
\[
\hat{\mathbf{Y}}=\mathbf{X}_{p} \hat{\mathbf{B}}_{p}
\]

We are interested in predicted values of the observation vectors, \(\hat{\mathbf{y}}_{1}, \hat{\mathbf{y}}_{2}, \ldots, \hat{\mathbf{y}}_{n}\), which are given by the rows of \(\hat{\mathbf{Y}}\) :
\[
\left(\begin{array}{c}
\hat{\mathbf{y}}_{1}^{\prime} \\
\hat{\mathbf{y}}_{2}^{\prime} \\
\vdots \\
\hat{\mathbf{y}}_{n}^{\prime}
\end{array}\right)=\left(\begin{array}{c}
\mathbf{x}_{p 1}^{\prime} \\
\mathbf{x}_{p 2}^{\prime} \\
\vdots \\
\mathbf{x}_{p n}^{\prime}
\end{array}\right) \hat{\mathbf{B}}_{p}=\left(\begin{array}{c}
\mathbf{x}_{p 1}^{\prime} \hat{\mathbf{B}}_{p} \\
\mathbf{x}_{p 2}^{\prime} \hat{\mathbf{B}}_{p} \\
\vdots \\
\mathbf{x}_{p n}^{\prime} \hat{\mathbf{B}}_{p}
\end{array}\right) .
\]

In general, the predicted vectors \(\hat{\mathbf{y}}_{i}\) are biased estimators of \(E\left(\mathbf{y}_{i}\right)\) in the correct model, because we are examining many competing models for which \(E\left(\hat{\mathbf{y}}_{i}\right) \neq\)
\(E\left(\mathbf{y}_{i}\right)\). In place of the univariate expected squared error in (10.37) and (10.38), we define a matrix of expected squares and products of errors, \(E\left[\hat{\mathbf{y}}_{i}-E\left(\mathbf{y}_{i}\right)\right]\left[\hat{\mathbf{y}}_{i}-\right.\) \(\left.E\left(\mathbf{y}_{i}\right)\right]^{\prime}\). We then add and subtract \(E\left(\hat{\mathbf{y}}_{i}\right)\) to obtain (see Problem 10.8)
\[
\begin{align*}
E\left[\hat{\mathbf{y}}_{i}\right. & \left.-E\left(\mathbf{y}_{i}\right)\right]\left[\hat{\mathbf{y}}_{i}-E\left(\mathbf{y}_{i}\right)\right]^{\prime} \\
& =E\left[\hat{\mathbf{y}}_{i}-E\left(\hat{\mathbf{y}}_{i}\right)+E\left(\hat{\mathbf{y}}_{i}\right)-E\left(\mathbf{y}_{i}\right)\right]\left[\hat{\mathbf{y}}_{i}-E\left(\hat{\mathbf{y}}_{i}\right)+E\left(\hat{\mathbf{y}}_{i}\right)-E\left(\mathbf{y}_{i}\right)\right]^{\prime} \\
& =E\left[\hat{\mathbf{y}}_{i}-E\left(\hat{\mathbf{y}}_{i}\right)\right]\left[\hat{\mathbf{y}}_{i}-E\left(\hat{\mathbf{y}}_{i}\right)\right]^{\prime}+\left[E\left(\hat{\mathbf{y}}_{i}\right)-E\left(\mathbf{y}_{i}\right)\right]\left[E\left(\hat{\mathbf{y}}_{i}\right)-E\left(\mathbf{y}_{i}\right)\right]^{\prime} \\
& =\operatorname{cov}\left(\hat{\mathbf{y}}_{i}\right)+\left(\operatorname{bias} \text { in } \hat{\mathbf{y}}_{i}\right)\left(\text { bias in } \hat{\mathbf{y}}_{i}\right)^{\prime} . \tag{10.93}
\end{align*}
\]

By analogy to (10.39), our \(\mathrm{C}_{p}\) matrix will be an estimate of the sum of (10.93), multiplied by \(\boldsymbol{\Sigma}^{-1}\) for standardization.

We first find an expression for \(\operatorname{cov}\left(\hat{\mathbf{y}}_{i}\right)\), which for convenience we write in row form,
\[
\operatorname{cov}\left(\hat{\mathbf{y}}_{i}^{\prime}\right)=\operatorname{cov}\left(\mathbf{x}_{p i}^{\prime} \hat{\mathbf{B}}_{p}\right)=\operatorname{cov}\left(\mathbf{x}_{p i}^{\prime} \hat{\boldsymbol{\beta}}_{p(1)}, \mathbf{x}_{p i}^{\prime} \hat{\boldsymbol{\beta}}_{p(2)}, \ldots, \mathbf{x}_{p i}^{\prime} \hat{\boldsymbol{\beta}}_{p(m)}\right)
\]
where \(\hat{\mathbf{B}}=\left(\hat{\boldsymbol{\beta}}_{(1)}, \hat{\boldsymbol{\beta}}_{(2)}, \ldots, \hat{\boldsymbol{\beta}}_{(m)}\right)\), as in (10.49). This can be written as
\[
\begin{align*}
\operatorname{cov}\left(\hat{\mathbf{y}}_{i}^{\prime}\right) & =\left(\begin{array}{ccc}
\sigma_{11} \mathbf{x}_{p i}^{\prime}\left(\mathbf{X}_{p}^{\prime} \mathbf{X}_{p}\right)^{-1} \mathbf{x}_{p i} & \cdots & \sigma_{1 m} \mathbf{x}_{p i}^{\prime}\left(\mathbf{X}_{p}^{\prime} \mathbf{X}_{p}\right)^{-1} \mathbf{x}_{p i} \\
\vdots & & \vdots \\
\sigma_{m 1} \mathbf{x}_{p i}^{\prime}\left(\mathbf{X}_{p}^{\prime} \mathbf{X}_{p}\right)^{-1} \mathbf{x}_{p i} & \cdots & \sigma_{m m} \mathbf{x}_{p i}^{\prime}\left(\mathbf{X}_{p}^{\prime} \mathbf{X}_{p}\right)^{-1} \mathbf{x}_{p i}
\end{array}\right)  \tag{10.94}\\
& =\mathbf{x}_{p i}^{\prime}\left(\mathbf{X}_{p}^{\prime} \mathbf{X}_{p}\right)^{-1} \mathbf{x}_{p i} \mathbf{\Sigma},
\end{align*}
\]
where \(m\) is the number of \(y\) 's and \(\boldsymbol{\Sigma}=\operatorname{cov}\left(\mathbf{y}_{i}\right)\) (see Problem 10.9). As in (10.41) (see also Problem 10.5), we can sum over the \(n\) observations and use (3.65) to obtain
\[
\begin{align*}
\sum_{i=1}^{n} \operatorname{cov}\left(\hat{\mathbf{y}}_{i}^{\prime}\right) & =\sum_{i=1}^{n} \mathbf{x}_{p i}^{\prime}\left(\mathbf{X}_{p}^{\prime} \mathbf{X}_{p}\right)^{-1} \mathbf{x}_{p i} \mathbf{\Sigma} \\
& =\boldsymbol{\Sigma} \sum_{i=1}^{n} \mathbf{x}_{p i}^{\prime}\left(\mathbf{X}_{p}^{\prime} \mathbf{X}_{p}\right)^{-1} \mathbf{x}_{p i}=p \mathbf{\Sigma} \tag{10.95}
\end{align*}
\]

To sum the second term on the right of (10.93), we have, by analogy to (10.42),
\[
\begin{equation*}
\sum_{i=1}^{n}\left(\operatorname{bias} \text { in } \hat{\mathbf{y}}_{i}\right)\left(\text { bias in } \hat{\mathbf{y}}_{i}\right)^{\prime}=(n-p) E\left(\mathbf{S}_{p}-\boldsymbol{\Sigma}\right) \tag{10.96}
\end{equation*}
\]
where \(\mathbf{S}_{p}\) is given by (10.92).
Now by (10.95) and (10.96), we can sum (10.93) and multiply by \(\boldsymbol{\Sigma}^{-1}\) to obtain the matrix of total expected squares and products of error standardized by \(\boldsymbol{\Sigma}^{-1}\),
\[
\begin{align*}
\boldsymbol{\Sigma}^{-1} & \sum_{i=1}^{n} E\left[\hat{\mathbf{y}}_{i}-E\left(\hat{\mathbf{y}}_{i}\right)\right]\left[\hat{\mathbf{y}}_{i}-E\left(\hat{\mathbf{y}}_{i}\right)\right]^{\prime} \\
& =\boldsymbol{\Sigma}^{-1}\left[p \boldsymbol{\Sigma}+(n-p) E\left(\mathbf{S}_{p}-\boldsymbol{\Sigma}\right)\right] \\
& =p \mathbf{I}+(n-p) \boldsymbol{\Sigma}^{-1} E\left(\mathbf{S}_{p}-\boldsymbol{\Sigma}\right) \tag{10.97}
\end{align*}
\]

Using \(\mathbf{S}_{k}=\mathbf{E}_{k} /(n-k)\), the sample covariance matrix based on all \(k-1\) variables, as an estimate of \(\Sigma\), we can estimate (10.97) by
\[
\begin{align*}
\mathbf{C}_{p} & =p \mathbf{I}+(n-p) \mathbf{S}_{k}^{-1}\left(\mathbf{S}_{p}-\mathbf{S}_{k}\right)  \tag{10.98}\\
& =\mathbf{S}_{k}^{-1} \mathbf{E}_{p}+(2 p-n) \mathbf{I} \quad[\mathbf{b y}(10.92)] \tag{10.99}
\end{align*}
\]
which is the form suggested by Mallows (1973). We can use \(\operatorname{tr}\left(\mathbf{C}_{p}\right)\) or \(\left|\mathbf{C}_{p}\right|\) to reduce this to a scalar. But if \(2 p-n\) is negative, \(\left|\mathbf{C}_{p}\right|\) can be negative, and Sparks et al. (1983) suggested a modification of \(\left|\mathbf{C}_{p}\right|\),
\[
\begin{equation*}
\left|\mathbf{C}_{p}\right|=\left|\mathbf{E}_{k}^{-1} \mathbf{E}_{p}\right| \tag{10.100}
\end{equation*}
\]
which is always positive.
To find the optimal subset of \(x\) 's for each value of \(p\), we could examine all possible subsets [or use a computational scheme such as that of Furnival and Wilson (1974)] and look for the "smallest" \(\mathbf{C}_{p}\) matrix for each \(p\). In (10.97), we see that when the bias is \(\mathbf{O}\), the "population \(\mathbf{C}_{p}\) " is equal to \(p \mathbf{I}\). Thus we seek a \(\mathbf{C}_{p}\) that is "small" and near \(p \mathbf{I}\). In terms of trace, we seek \(\operatorname{tr}\left(\mathbf{C}_{p}\right)\) close to \(p m\), where \(m\) is the number of \(y\) 's in the vector of measurements; that is, \(\operatorname{tr}(\mathbf{I})=m\).

To find a "target" value for (10.100), we write \(\mathbf{E}_{k}^{-1} \mathbf{E}_{p}\) in terms of \(\mathbf{C}_{p}\) from (10.99),
\[
\begin{equation*}
\mathbf{E}_{k}^{-1} \mathbf{E}_{p}=\frac{\mathbf{C}_{p}+(n-2 p) \mathbf{I}}{n-k} \tag{10.101}
\end{equation*}
\]

When the bias is \(\mathbf{O}\), we have \(\mathbf{C}_{p}=p \mathbf{I}\), and (10.101) becomes
\[
\begin{equation*}
\mathbf{E}_{k}^{-1} \mathbf{E}_{p}=\frac{n-p}{n-k} \mathbf{I}, \tag{10.102}
\end{equation*}
\]
whence, by (2.85),
\[
\begin{equation*}
\left|\mathbf{E}_{k}^{-1} \mathbf{E}_{p}\right|=\left(\frac{n-p}{n-k}\right)^{m} \tag{10.103}
\end{equation*}
\]

Thus we seek subsets such that
\[
\operatorname{tr}\left(\mathbf{C}_{p}\right) \leq p m \quad \text { or } \quad\left|\mathbf{E}_{k}^{-1} \mathbf{E}_{p}\right| \leq\left(\frac{n-p}{n-k}\right)^{m}
\]

In summary, when examining all possible subsets, any or all of the following criteria may be useful in finding the single best subset or the best subset for each \(p\) :
\[
\operatorname{tr}\left(\mathbf{R}_{p}^{2}\right) / m, \quad\left|\mathbf{R}_{p}^{2}\right|, \quad \operatorname{tr}\left(\mathbf{S}_{p}\right), \quad\left|\mathbf{S}_{p}\right|, \quad \operatorname{tr}\left(\mathbf{C}_{p}\right), \quad\left|\mathbf{E}_{k}^{-1} \mathbf{E}_{p}\right|
\]

\subsection*{10.9 MULTIVARIATE REGRESSION: RANDOM \(\boldsymbol{x}\) 's}

In Sections 10.4 and 10.5 , it was assumed that the \(x\) 's were fixed and would have the same values in repeated sampling. In many applications, the \(x\) 's are random
variables. In such a case, the values of \(x_{1}, x_{2}, \ldots, x_{q}\) are not under the control of the experimenter but occur randomly along with \(y_{1}, y_{2}, \ldots, y_{p}\). On each subject, we observe \(p+q\) values in the vector \(\left(y_{1}, y_{2}, \ldots, y_{p}, x_{1}, x_{2}, \ldots, x_{q}\right)\).

If we assume that \(\left(y_{1}, y_{2}, \ldots, y_{p}, x_{1}, x_{2}, \ldots, x_{q}\right)\) has a multivariate normal distribution, then all estimates and tests have the same formulation as in the fixed- \(x\) case [for details, see Rencher (1998, Section 7.7)]. Thus there is no essential difference in our procedures between the fixed- \(x\) case and the random- \(x\) case.

\section*{PROBLEMS}
10.1 Show that \(\sum_{i=1}^{n}\left(y_{i}-\mathbf{x}_{i}^{\prime} \hat{\boldsymbol{\beta}}\right)^{2}=(\mathbf{y}-\mathbf{X} \hat{\boldsymbol{\beta}})^{\prime}(\mathbf{y}-\mathbf{X} \hat{\boldsymbol{\beta}})\) as in (10.6).
10.2 Show that \(\sum_{i=1}^{n}\left(y_{i}-\mu\right)^{2}=\sum_{i=1}^{n}\left(y_{i}-\bar{y}\right)^{2}+n(\bar{y}-\mu)^{2}\) as in (10.10).
10.3 Show that \(\sum_{i=1}^{n}\left(x_{i 2}-\bar{x}_{2}\right) \bar{y}=0\) as in (10.19).
10.4 Show that \(E\left[\hat{y}_{i}-E\left(y_{i}\right)\right]^{2}=E\left[\hat{y}_{i}-E\left(\hat{y}_{i}\right)\right]^{2}+\left[E\left(\hat{y}_{i}\right)-E\left(y_{i}\right)\right]^{2}\) as in (10.37).
10.5 Show that \(\sum_{i=1}^{n} \operatorname{var}\left(\hat{y}_{i}\right) / \sigma^{2}=\operatorname{tr}\left[\mathbf{X}_{p}\left(\mathbf{X}_{p}^{\prime} \mathbf{X}_{p}\right)^{-1} \mathbf{X}_{p}^{\prime}\right]\) as in (10.40).
10.6 Show that the alternative form of \(C_{p}\) in (10.45) is equal to the original form in (10.44).
10.7 Show that (10.53) is the same as (10.54), that is, \((\mathbf{Y}-\mathbf{X B})^{\prime}(\mathbf{Y}-\mathbf{X B})=\) \(\mathbf{Y}^{\prime} \mathbf{Y}-\hat{\mathbf{B}}^{\prime} \mathbf{X}^{\prime} \mathbf{Y}\).
10.8 Show that
\[
\begin{aligned}
E\left[\hat{\mathbf{y}}_{i}\right. & \left.-E\left(\mathbf{y}_{i}\right)\right]\left[\hat{\mathbf{y}}_{i}-E\left(\mathbf{y}_{i}\right)\right]^{\prime} \\
& \left.=E\left[\hat{\mathbf{y}}_{i}-E\left(\hat{\mathbf{y}}_{i}\right)\right]\left[\hat{\mathbf{y}}_{i}-E\left(\hat{\mathbf{y}}_{i}\right)\right]^{\prime}+\left[E\left(\hat{\mathbf{y}}_{i}\right)-E\left(\mathbf{y}_{i}\right)\right]\left[E\left(\hat{\mathbf{y}}_{i}\right)-E\left(\mathbf{y}_{i}\right)\right]^{\prime}\right]
\end{aligned}
\] thus verifying (10.93).
10.9 Show that \(\operatorname{cov}\left(\hat{\mathbf{y}}_{i}^{\prime}\right)\) has the form given in (10.94).
10.10 Show that the two forms of \(\mathbf{C}_{p}\) in (10.98) and (10.99) are equal.
10.11 Explain why \(\left|\mathbf{E}_{k}^{-1} \mathbf{E}_{p}\right|>0\), as claimed following (10.100).
10.12 Show that \(\mathbf{E}_{k}^{-1} \mathbf{E}_{p}=\left[\mathbf{C}_{p}+(n-2 p) \mathbf{I}\right] /(n-k)\), as in (10.101), where \(\mathbf{C}_{p}\) is given in (10.98).
10.13 Show that if \(\mathbf{C}_{p}=p \mathbf{I}\), then \(\mathbf{E}_{k}^{-1} \mathbf{E}_{p}=[(n-p) /(n-k)] \mathbf{I}\) as in (10.102).
10.14 One way to show that the ordinary least squares estimate is the best linear unbiased estimator (BLUE) is to verify that the condition of Zyskind (1967) applies. The Zyskind condition states that for a model \(\mathbf{y}=\mathbf{X} \boldsymbol{\beta}+\varepsilon\) with \(E(\varepsilon)=\mathbf{0}\) and \(\operatorname{cov}(\varepsilon)=\mathbf{V}\), the ordinary least squares estimate \(\left(\mathbf{X}^{\prime} \mathbf{X}\right)^{-1} \mathbf{X}^{\prime} \mathbf{y}\) is BLUE if and only if there exists a matrix \(\mathbf{Q}\) such that \(\mathbf{V X}=\mathbf{X Q}\).
(a) Use the Zyskind condition to show that the ordinary least squares estimate in (10.59) is BLUE when \(\mathbf{X}_{1}=\mathbf{X}_{2}=\ldots=\mathbf{X}_{p}\). [Note that this is equivalent to showing that (10.48) is BLUE, because \(\mathbf{X}_{1}=\mathbf{X}_{2}=\ldots=\) \(\mathbf{X}_{p}\) implies that model (10.47) holds.]
(b) Use the Zyskind condition to show that the ordinary least squares estimate ( 10.59 ) is BLUE when the off-diagonal elements of \(\Sigma\) are all equal to 0 (i.e., \(\sigma_{i j}=0\) for \(i \neq j\) ).
10.15 Use the diabetes data of Table 3.5.
(a) Find the least squares estimate \(\hat{\mathbf{B}}\) for the regression of ( \(y_{1}, y_{2}\) ) on ( \(x_{1}\), \(x_{2}, x_{3}\) ).
(b) Test the significance of overall regression using all four test statistics.
(c) Determine what the eigenvalues of \(\mathbf{E}^{-1} \mathbf{H}\) reveal about the essential rank of \(\hat{\mathbf{B}}_{1}\) and the implications of this rank, such as the relative power of the four tests.
(d) Test the significance of each of \(x_{1}, x_{2}\), and \(x_{3}\) adjusted for the other two \(x\) 's.
(e) Calculate simultaneous \(95 \%\) confidence intervals for the elements of \(E\left(\mathbf{y}_{0}\right)\) given that \(\mathbf{x}_{0}=(1,350,200,100)^{\prime}\).
(f) Calculate simultaneous \(95 \%\) prediction intervals for the elements of \(\mathbf{y}_{0}\) given that \(\mathbf{x}_{0}=(1,350,200,100)^{\prime}\). Compare with part (e).
10.16 Use the sons data of Table 3.8.
(a) Find the least squares estimate \(\hat{\mathbf{B}}\) for the regression of \(\left(y_{1}, y_{2}\right)\) on \(\left(x_{1}\right.\), \(x_{2}\) ).
(b) Test the significance of overall regression using all four test statistics.
(c) Determine what the eigenvalues of \(\mathbf{E}^{-1} \mathbf{H}\) reveal about the essential rank of \(\hat{\mathbf{B}}_{1}\) and the implications of this rank, such as the relative power of the four tests.
(d) Test the significance of \(x_{1}\) adjusted for \(x_{2}\) and of \(x_{2}\) adjusted for \(x_{1}\).
(e) Calculate simultaneous \(95 \%\) confidence intervals for the elements of \(E\left(\mathbf{y}_{0}\right)\) given that \(\mathbf{x}_{0}=(1,170,140)^{\prime}\).
(f) Calculate simultaneous \(95 \%\) prediction intervals for the elements of \(\mathbf{y}_{0}\) given that \(\mathbf{x}_{0}=(1,170,140)^{\prime}\). Compare with part (e).
10.17 Use the glucose data of Table 3.9.
(a) Find the least squares estimate \(\hat{\mathbf{B}}\) for the regression of \(\left(y_{1}, y_{2}, y_{3}\right)\) on \(\left(x_{1}, x_{2}, x_{3}\right)\).
(b) Test the significance of overall regression using all four test statistics.
(c) Determine what the eigenvalues of \(\mathbf{E}^{-1} \mathbf{H}\) reveal about the essential rank of \(\hat{\mathbf{B}}_{1}\) and the implications of this rank, such as the relative power of the four tests.
(d) Test the significance of each of \(x_{1}, x_{2}\), and \(x_{3}\) adjusted for the other two \(x\) 's.
(e) Test the significance of each \(y\) adjusted for the other two by using (10.90).
(f) Calculate simultaneous \(95 \%\) confidence intervals for the elements of \(E\left(\mathbf{y}_{0}\right)\) given that \(\mathbf{x}_{0}=(1,100,100,100)^{\prime}\).
(g) Calculate simultaneous \(95 \%\) prediction intervals for the elements of \(\mathbf{y}_{0}\) given that \(\mathbf{x}_{0}=(1,100,100,100)^{\prime}\). Compare with part (f).
10.18 Use the Seishu data of Table 7.1.
(a) Find the least squares estimate \(\hat{\mathbf{B}}\) for the regression of \(\left(y_{1}, y_{2}\right)\) on ( \(x_{1}\), \(x_{2}, \ldots, x_{8}\) ) and test for significance.
(b) Test the significance of \(\left(x_{7}, x_{8}\right)\) adjusted for the other \(x\) 's.
(c) Test the significance of \(\left(x_{4}, x_{5}, x_{6}\right)\) adjusted for the other \(x\) 's.
(d) Test the significance of \(\left(x_{1}, x_{2}, x_{3}\right)\) adjusted for the other \(x\) 's.
10.19 Use the Seishu data of Table 7.1.
(a) Do a stepwise regression to select a subset of \(x_{1}, x_{2}, \ldots, x_{8}\) that adequately predicts \(\left(y_{1}, y_{2}\right)\).
(b) After selecting a subset of \(x\) 's, use the methods of Section 10.8 .1 b to check if either of the \(y\) 's can be deleted.
10.20 Use the temperature data of Table 7.2.
(a) Find the least squares estimate \(\hat{\mathbf{B}}\) for the regression of \(\left(y_{4}, y_{5}, y_{6}\right)\) on \(\left(y_{1}\right.\), \(y_{2}, y_{3}\) ) and test for significance.
(b) Find the least squares estimate \(\hat{\mathbf{B}}\) for the regression of \(\left(y_{7}, y_{8}, y_{9}\right)\) on ( \(y_{1}, \ldots, y_{6}\) ) and test for significance.
(c) Find the least squares estimate \(\hat{\mathbf{B}}\) for the regression of \(\left(y_{10}, y_{11}\right)\) on ( \(y_{1}, \ldots, y_{9}\) ) and test for significance.
10.21 Using the temperature data of Table 7.2, carry out a stepwise regression to select a subset of \(y_{1}, y_{2}, \ldots, y_{9}\) that adequately predicts ( \(y_{10}, y_{11}\) ).

\section*{CHAPTER 11}

\section*{CANONICAL CORRELATION}

\subsection*{11.1 INTRODUCTION}

Canonical correlation analysis is concerned with the amount of (linear) relationship between two sets of variables. We often measure two types of variables on each research unit, for example, a set of aptitude variables and a set of achievement variables, a set of personality variables and a set of ability measures, a set of price indices and a set of production indices, a set of student behaviors and a set of teacher behaviors, a set of psychological attributes and a set of physiological attributes, a set of ecological variables and a set of environmental variables, a set of academic achievement variables and a set of measures of job success, a set of closed-book exam scores and a set of open-book exam scores, and a set of personality variables of freshmen students and the same variables on the same students as seniors.

\subsection*{11.2 CANONICAL CORRELATIONS AND CANONICAL VARIATES}

We assume that two sets of variables \(\mathbf{y}^{\prime}=\left(y_{1}, y_{2}, \ldots, y_{p}\right)\) and \(\mathbf{x}^{\prime}=\left(x_{1}, x_{2}, \ldots, x_{q}\right)\) are measured on the same sampling unit. We denote the two sets of variables as \(y\)
and \(x\) to conform to notation in Chapters 3, 7, and 10. In Section 7.4.1, we discussed the hypothesis that \(y\) and \(x\) were independent. In this chapter, we consider a measure of overall correlation between \(\mathbf{y}\) and x .

Canonical correlation is an extension of multiple correlation, which is the correlation between one \(y\) and several \(x\) 's. Canonical correlation analysis is often a useful complement to a multivariate regression analysis.

We first review multiple correlation. The sample covariances and correlations among \(y, x_{1}, x_{2}, \ldots, x_{q}\) can be summarized in the matrices
\[
\begin{align*}
\mathbf{S} & =\left(\begin{array}{cc}
s_{y}^{2} & \mathbf{s}_{y x}^{\prime} \\
\mathbf{s}_{y x} & \mathbf{S}_{x x}
\end{array}\right),  \tag{11.1}\\
\mathbf{R} & =\left(\begin{array}{cc}
1 & \mathbf{r}_{y x}^{\prime} \\
\mathbf{r}_{y x} & \mathbf{R}_{x x}
\end{array}\right), \tag{11.2}
\end{align*}
\]
where \(\mathbf{s}_{y x}^{\prime}=\left(s_{y 1}, s_{y 2}, \ldots, s_{y q}\right)\) contains the sample covariances of \(y\) with \(x_{1}\), \(x_{2}, \ldots, x_{q}\) and \(\mathbf{S}_{x x}\) is the sample covariance matrix of the \(x\) 's [see(10.16)]. The partitioned matrix \(\mathbf{R}\) is defined analogously; \(\mathbf{r}_{y x}^{\prime}=\left(r_{y 1}, r_{y 2}, \ldots, r_{y q}\right)\) contains the sample correlations of \(y\) with \(x_{1}, x_{2}, \ldots, x_{q}\), and \(\mathbf{R}_{x x}\) is the sample correlation matrix of the \(x\) 's [see (10.35)].

By (10.34), the squared multiple correlation between \(y\) and the \(x\) 's can be computed from the partitioned covariance matrix (11.1) or correlation matrix (11.2) as follows:
\[
\begin{equation*}
R^{2}=\frac{\mathbf{s}_{y x}^{\prime} \mathbf{S}_{x x}^{-1} \mathbf{s}_{y x}}{s_{y}^{2}}=\mathbf{r}_{y x}^{\prime} \mathbf{R}_{x x}^{-1} \mathbf{r}_{y x} \tag{11.3}
\end{equation*}
\]

In \(R^{2}\), the \(q\) covariances between \(y\) and the \(x\) 's in \(\mathrm{s}_{y x}\) or the \(q\) correlations between \(y\) and the \(x\) 's in \(r_{y x}\) are channeled into a single measure of linear relationship between \(y\) and the \(x\) 's. The multiple correlation \(R\) can be defined alternatively as the maximum correlation between \(y\) and a linear combination of the \(x\) 's; that is, \(R=\max _{\mathbf{b}} r_{y, \mathbf{b}^{\prime} \mathbf{x}}\).

We now return to the case of several \(y\) 's and several \(x\) 's. The covariance structure associated with two subvectors \(\mathbf{y}\) and \(\mathbf{x}\) was first discussed in Section 3.9.1. By (3.42), the overall sample covariance matrix for \(\left(y_{1}, \ldots, y_{p}, x_{1}, \ldots, x_{q}\right)\) can be partitioned as
\[
\mathbf{S}=\left(\begin{array}{ll}
\mathbf{S}_{y y} & \mathbf{S}_{y x} \\
\mathbf{S}_{x y} & \mathbf{S}_{x x}
\end{array}\right)
\]
where \(\mathbf{S}_{y y}\) is the \(p \times p\) sample covariance matrix of the \(y\) 's, \(\mathbf{S}_{y x}\) is the \(p \times q\) matrix of sample covariances between the \(y\) 's and the \(x\) 's, and \(\mathbf{S}_{x x}\) is the \(q \times q\) sample covariance matrix of the \(x\) 's.

In Section 10.7, we discussed several measures of association between the \(y\) 's and the \(x\) 's. The first of these is defined in (10.81) as \(R_{M}^{2}=\left|\mathbf{S}_{y x} \mathbf{S}_{x x}^{-1} \mathbf{S}_{x y}\right| /\left|\mathbf{S}_{y y}\right|\), which is analogous to \(R^{2}=\mathbf{s}_{y x}^{\prime} \mathbf{S}_{x x}^{-1} \mathbf{S}_{y x} / s_{y}^{2}\) in (11.3). By (2.89) and (2.91), \(R_{M}^{2}\) can be rewritten as \(R_{M}^{2}=\left|\mathbf{S}_{y y}^{-1} \mathbf{S}_{y x} \mathbf{S}_{x x}^{-1} \mathbf{S}_{x y}\right|\). By (2.108), \(R_{M}^{2}\) can be expressed as
\[
R_{M}^{2}=\left|\mathbf{S}_{y y}^{-1} \mathbf{S}_{y x} \mathbf{S}_{x x}^{-1} \mathbf{S}_{x y}\right|=\prod_{i=1}^{s} r_{i}^{2},
\]
where \(s=\min (p, q)\) and \(r_{1}^{2}, r_{2}^{2}, \ldots, r_{s}^{2}\) are the eigenvalues of \(\mathbf{S}_{y y}^{-1} \mathbf{S}_{y x} \mathbf{S}_{x x}^{-1} \mathbf{S}_{x y}\). When written in this form, \(R_{M}^{2}\) is seen to be a poor measure of association because \(0 \leq r_{i}^{2} \leq 1\) for all \(i\), and the product will usually be too small to meaningfully reflect the amount of association. (In Example 10.7, \(R_{M}^{2}=.00029\) was a tiny fraction of the other measures of association.) The eigenvalues themselves, on the other hand, provide meaningful measures of association between the \(y\) 's and the \(x\) 's. The square roots of the eigenvalues, \(r_{1}, r_{2}, \ldots, r_{s}\), are called canonical correlations.

The best overall measure of association is the largest squared canonical correlation (maximum eigenvalue) \(r_{1}^{2}\) of \(\mathbf{S}_{y y}^{-1} \mathbf{S}_{y x} \mathbf{S}_{x x}^{-1} \mathbf{S}_{x y}\), but the other eigenvalues (squared canonical correlations) of \(\mathbf{S}_{y y}^{-1} \mathbf{S}_{y x} \mathbf{S}_{x x}^{-1} \mathbf{S}_{x y}\) provide measures of supplemental dimensions of (linear) relationship between \(\mathbf{y}\) and x . As an alternative approach, it can be shown that \(r_{1}^{2}\) is the maximum squared correlation between a linear combination of the \(y\) 's, \(u=\mathbf{a}^{\prime} \mathbf{y}\), and a linear combination of the \(x ' s, v=\mathbf{b}^{\prime} \mathbf{x}\); that is,
\[
\begin{equation*}
r_{1}=\max _{\mathbf{a}, \mathbf{b}} r_{\mathbf{a}^{\prime} \mathbf{y}, \mathbf{b}^{\prime} \mathbf{x}} . \tag{11.4}
\end{equation*}
\]

We denote the coefficient vectors that yield the maximum correlation as \(\mathbf{a}_{1}\) and \(\mathbf{b}_{1}\). Thus \(r_{1}\) (the positive square root of \(r_{1}^{2}\) ) is the correlation between \(u_{1}=\mathbf{a}_{1}^{\prime} \mathbf{y}\) and \(v_{1}=\) \(\mathbf{b}_{1}^{\prime} \mathbf{x}\). The coefficient vectors \(\mathbf{a}_{1}\) and \(\mathbf{b}_{1}\) can be found as eigenvectors, see (11.7) and (11.8) below. The linear functions \(u_{1}\) and \(v_{1}\) are called the first canonical variates. There are additional canonical variates \(u_{i}=\mathbf{a}_{i}^{\prime} \mathbf{y}\) and \(v_{i}=\mathbf{b}_{i}^{\prime} \mathbf{x}\) corresponding to \(r_{2}, r_{3}, \ldots, r_{s}\).

It was noted in Section 2.11 .5 that the (nonzero) eigenvalues of \(\mathbf{A B}\) are the same as those of \(\mathbf{B A}\) as long as \(\mathbf{A B}\) and \(\mathbf{B A}\) are square, but that the eigenvectors of \(\mathbf{A B}\) and \(\mathbf{B A}\) are not the same. If we let \(\mathbf{A}=\mathbf{S}_{y y}^{-1} \mathbf{S}_{y x}\) and \(\mathbf{B}=\mathbf{S}_{x x}^{-1} \mathbf{S}_{x y}\), then \(r_{1}^{2}, r_{2}^{2}, \ldots, r_{s}^{2}\) can also be obtained from \(\mathbf{B A}=\mathbf{S}_{x x}^{-1} \mathbf{S}_{x y} \mathbf{S}_{y y}^{-1} \mathbf{S}_{y x}\), as well as from \(\mathbf{A B}=\mathbf{S}_{y y}^{-1} \mathbf{S}_{y x} \mathbf{S}_{x x}^{-1} \mathbf{S}_{x y}\). Thus the eigenvalues can be obtained from either of the characteristic equations
\[
\begin{align*}
& \left|\mathbf{S}_{y y}^{-1} \mathbf{S}_{y x} \mathbf{S}_{x x}^{-1} \mathbf{S}_{x y}-r^{2} \mathbf{I}\right|=0  \tag{11.5}\\
& \left|\mathbf{S}_{x x}^{-1} \mathbf{S}_{x y} \mathbf{S}_{y y}^{-1} \mathbf{S}_{y x}-r^{2} \mathbf{I}\right|=0 \tag{11.6}
\end{align*}
\]

The coefficient vectors \(\mathbf{a}_{i}\) and \(\mathbf{b}_{i}\) in the canonical variates \(u_{i}=\mathbf{a}_{i}^{\prime} \mathbf{y}\) and \(v_{i}=\mathbf{b}_{i}^{\prime} \mathbf{x}\) are the eigenvectors of these same two matrices:
\[
\begin{align*}
\left(\mathbf{S}_{y y}^{-1} \mathbf{S}_{y x} \mathbf{S}_{x x}^{-1} \mathbf{S}_{x y}-r^{2} \mathbf{I}\right) \mathbf{a} & =\mathbf{0}  \tag{11.7}\\
\left(\mathbf{S}_{x x}^{-1} \mathbf{S}_{x y} \mathbf{S}_{y y}^{-1} \mathbf{S}_{y x}-r^{2} \mathbf{I}\right) \mathbf{b} & =\mathbf{0} \tag{11.8}
\end{align*}
\]

Thus the two matrices \(\mathbf{S}_{y y}^{-1} \mathbf{S}_{y x} \mathbf{S}_{x x}^{-1} \mathbf{S}_{x y}\) and \(\mathbf{S}_{x x}^{-1} \mathbf{S}_{x y} \mathbf{S}_{y y}^{-1} \mathbf{S}_{y x}\) have the same (nonzero) eigenvalues, as indicated in (11.5) and (11.6), but different eigenvectors, as in (11.7) and (11.8). Since \(\mathbf{y}\) is \(p \times 1\) and \(\mathbf{x}\) is \(q \times 1\), the \(\mathbf{a}_{i}\) 's are \(p \times 1\) and the \(\mathbf{b}_{i}\) 's are \(q \times 1\). This can also be seen in the sizes of the matrices in (11.7) and (11.8); that is, \(\mathbf{S}_{y y}^{-1} \mathbf{S}_{y x} \mathbf{S}_{x x}^{-1} \mathbf{S}_{x y}\) is \(p \times p\) and \(\mathbf{S}_{x x}^{-1} \mathbf{S}_{x y} \mathbf{S}_{y y}^{-1} \mathbf{S}_{y x}\) is \(q \times q\). Since \(p\) is typically not equal to \(q\), the matrix that is larger in size will be singular, and the smaller one will be nonsingular. We illustrate for \(p<q\). In this case \(\mathbf{S}_{x x}^{-1} \mathbf{S}_{x y} \mathbf{S}_{y y}^{-1} \mathbf{S}_{y x}\) has the form

With \(p<q\), the rank of \(\mathbf{S}_{x x}^{-1} \mathbf{S}_{x y} \mathbf{S}_{y y}^{-1} \mathbf{S}_{y x}\) is \(p\), because \(\mathbf{S}_{x x}^{-1}\) has rank \(q\) and \(\mathbf{S}_{x y} \mathbf{S}_{y y}^{-1} \mathbf{S}_{y x}\) has rank \(p\). In this case \(p\) eigenvalues are nonzero and the remaining \(q-p\) eigenvalues are equal to zero. In general, there are \(s=\min (p, q)\) values of the squared canonical correlation \(r_{i}^{2}\) with \(s\) corresponding pairs of canonical variates \(u_{i}=\mathbf{a}_{i}^{\prime} \mathbf{y}\) and \(v_{i}=\mathbf{b}_{i}^{\prime} \mathbf{x}\). For example, if \(p=3\) and \(q=7\), there will be three canonical correlations, \(r_{1}, r_{2}\), and \(r_{3}\).

Thus we have \(s\) canonical correlations \(r_{1}, r_{2}, \ldots, r_{s}\) corresponding to the \(s\) pairs of canonical variates \(u_{i}\) and \(v_{i}\) :
\[
\begin{array}{ccc}
r_{1} & u_{1}=\mathbf{a}_{1}^{\prime} \mathbf{y} & v_{1}=\mathbf{b}_{1}^{\prime} \mathbf{x} \\
r_{2} & u_{2}=\mathbf{a}_{2}^{\prime} \mathbf{y} & v_{2}=\mathbf{b}_{2}^{\prime} \mathbf{x} \\
\vdots & \vdots & \vdots \\
r_{s} & u_{s}=\mathbf{a}_{s}^{\prime} \mathbf{y} & v_{s}=\mathbf{b}_{s}^{\prime} \mathbf{x}
\end{array}
\]

For each \(i, r_{i}\) is the (sample) correlation between \(u_{i}\) and \(v_{i}\); that is, \(r_{i}=r_{u_{i} v_{i}}\). The pairs \(\left(u_{i}, v_{i}\right), i=1,2, \ldots, s\), provide the \(s\) dimensions of relationship. For simplicity, we would prefer only one dimension of relationship, but this occurs only when \(s=1\), that is, when \(p=1\) or \(q=1\).

The \(s\) dimensions of relationship \(\left(u_{i}, v_{i}\right), i=1,2, \ldots, s\), are nonredundant. The information each pair provides is unavailable in the other pairs because \(u_{1}, u_{2}, \ldots, u_{s}\) are uncorrelated. They are not orthogonal because \(\mathbf{a}_{1}, \mathbf{a}_{2}, \ldots, \mathbf{a}_{s}\) are eigenvectors of \(\mathbf{S}_{y y}^{-1} \mathbf{S}_{y x} \mathbf{S}_{x x}^{-1} \mathbf{S}_{x y}\), which is nonsymmetric. Similarly, each \(u_{i}\) is uncorrelated with all \(v_{j}, j \neq i\), except, of course, \(v_{i}\).

We examine the elements of the coefficient vectors \(\mathbf{a}_{i}\) and \(\mathbf{b}_{i}\) for the information they provide about the contribution of the \(y\) 's and \(x\) 's to \(r_{i}\). These coefficients can be standardized, as noted in the last paragraph in the present section and in Section 11.5.1.

As noted, the matrix \(\mathbf{S}_{y y}^{-1} \mathbf{S}_{y x} \mathbf{S}_{x x}^{-1} \mathbf{S}_{x y}\) is not symmetric. Many algorithms for computation of eigenvalues and eigenvectors accept only symmetric matrices. Since \(\mathbf{S}_{y y}^{-1} \mathbf{S}_{y x} \mathbf{S}_{x x}^{-1} \mathbf{S}_{x y}\) is the product of the two symmetric matrices \(\mathbf{S}_{y y}^{-1}\) and \(\mathbf{S}_{y x} \mathbf{S}_{x x}^{-1} \mathbf{S}_{x y}\), we can proceed as in (6.23) and work with \(\left(\mathbf{U}^{\prime}\right)^{-1} \mathbf{S}_{y x} \mathbf{S}_{x x}^{-1} \mathbf{S}_{x y} \mathbf{U}^{-1}\), where \(\mathbf{U}^{\prime} \mathbf{U}=\) \(\mathbf{S}_{y y}\) is the Cholesky factorization of \(\mathbf{S}_{y y}\) (see Section 2.7). The symmetric matrix \(\left(\mathbf{U}^{\prime}\right)^{-1} \mathbf{S}_{y x} \mathbf{S}_{x x}^{-1} \mathbf{S}_{x y} \mathbf{U}^{-1}\) has the same eigenvalues as \(\mathbf{S}_{y y}^{-1} \mathbf{S}_{y x} \mathbf{S}_{x x}^{-1} \mathbf{S}_{x y}\) but has eigenvectors \(\mathbf{U a}_{i}\), where \(\mathbf{a}_{i}\) is given in (11.7).

In effect, the \(p q\) covariances between the \(y\) 's and \(x\) 's in \(\mathbf{S}_{y x}\) have been replaced by \(s=\min (p, q)\) canonical correlations. These succinctly summarize the relationships between \(\mathbf{y}\) and \(\mathbf{x}\). In fact, in a typical study, we do not need all \(s\) canonical correlations. The smallest eigenvalues can be disregarded to achieve even more simplification. As in (8.13) for discriminant functions, we can judge the importance of each eigenvalue by its relative size:
\[
\begin{equation*}
\frac{r_{i}^{2}}{\sum_{j=1}^{s} r_{j}^{2}} \tag{11.9}
\end{equation*}
\]

The canonical correlations can also be obtained from the partitioned correlation matrix of the \(y\) 's and \(x\) 's,
\[
\mathbf{R}=\left(\begin{array}{ll}
\mathbf{R}_{y y} & \mathbf{R}_{y x} \\
\mathbf{R}_{x y} & \mathbf{R}_{x x}
\end{array}\right)
\]
where \(\mathbf{R}_{y y}\) is the \(p \times p\) sample correlation matrix of the \(y\) 's, \(\mathbf{R}_{y x}\) is the \(p \times q\) matrix of sample correlations between the \(y\) 's and the \(x\) 's, and \(\mathbf{R}_{x x}\) is the \(q \times q\) sample correlation matrix of the \(x\) 's. The matrix \(\mathbf{R}_{y y}^{-1} \mathbf{R}_{y x} \mathbf{R}_{x x}^{-1} \mathbf{R}_{x y}\) is analogous to \(R^{2}=\) \(\mathbf{r}_{y x}^{\prime} \mathbf{R}_{x x}^{-1} \mathbf{r}_{y x}\) in the univariate \(y\) case. The characteristic equations corresponding to (11.5) and (11.6),
\[
\begin{align*}
& \left|\mathbf{R}_{y y}^{-1} \mathbf{R}_{y x} \mathbf{R}_{x x}^{-1} \mathbf{R}_{x y}-r^{2} \mathbf{I}\right|=0,  \tag{11.10}\\
& \left|\mathbf{R}_{x x}^{-1} \mathbf{R}_{x y} \mathbf{R}_{y y}^{-1} \mathbf{R}_{y x}-r^{2} \mathbf{I}\right|=0, \tag{11.11}
\end{align*}
\]
yield the same eigenvalues \(r_{1}^{2}, r_{2}^{2}, \ldots, r_{s}^{2}\) as (11.5) and (11.6) (the canonical correlations are scale invariant; see property 1 in Section 11.3).

If we use the partitioned correlation matrix in place of the covariance matrix in (11.7) and (11.8), we obtain the same eigenvalues (squared canonical correlations) but different eigenvectors:
\[
\begin{align*}
\left(\mathbf{R}_{y y}^{-1} \mathbf{R}_{y x} \mathbf{R}_{x x}^{-1} \mathbf{R}_{x y}-r^{2} \mathbf{I}\right) \mathbf{c} & =\mathbf{0}  \tag{11.12}\\
\left(\mathbf{R}_{x x}^{-1} \mathbf{R}_{x y} \mathbf{R}_{y y}^{-1} \mathbf{R}_{y x}-r^{2} \mathbf{I}\right) \mathbf{d} & =\mathbf{0} \tag{11.13}
\end{align*}
\]

The relationship between the eigenvectors \(\mathbf{c}\) and \(\mathbf{d}\) in (11.12) and (11.13) and the eigenvectors \(\mathbf{a}\) and \(\mathbf{b}\) in (11.7) and (11.8) is
\[
\begin{equation*}
\mathbf{c}=\mathbf{D}_{y} \mathbf{a} \text { and } \quad \mathbf{d}=\mathbf{D}_{x} \mathbf{b} \tag{11.14}
\end{equation*}
\]
where \(\mathbf{D}_{y}=\operatorname{diag}\left(s_{y_{1}}, s_{y_{2}}, \ldots, s_{y_{p}}\right)\) and \(\mathbf{D}_{x}=\operatorname{diag}\left(s_{x_{1}}, s_{x_{2}}, \ldots, s_{x_{q}}\right)\).
The eigenvectors \(\mathbf{c}\) and d in (11.12), (11.13), and (11.14) are standardized coefficient vectors. By analogy to (8.15), they would be applied to standardized variables. To show this, note that in terms of centered variables \(\mathbf{y}-\overline{\mathbf{y}}\), we have
\[
\begin{align*}
u & =\mathbf{a}^{\prime}(\mathbf{y}-\overline{\mathbf{y}})=\mathbf{a}^{\prime} \mathbf{D}_{y} \mathbf{D}_{y}^{-1}(\mathbf{y}-\overline{\mathbf{y}}) \\
& =\mathbf{c}^{\prime} \mathbf{D}_{y}^{-1}(\mathbf{y}-\overline{\mathbf{y}}) \quad[\mathrm{by}(11.14)] \\
& =c_{1} \frac{y_{1}-\bar{y}_{1}}{s_{y_{1}}}+c_{2} \frac{y_{2}-\bar{y}_{2}}{s_{y_{2}}}+\cdots+c_{p} \frac{y_{p}-\bar{y}_{p}}{s_{y_{p}}} . \tag{11.15}
\end{align*}
\]

Hence \(\mathbf{c}\) and \(\mathbf{d}\) are preferred to \(\mathbf{a}\) and \(\mathbf{b}\) for interpretation of the canonical variates \(u_{i}\) and \(v_{i}\).

\subsection*{11.3 PROPERTIES OF CANONICAL CORRELATIONS}

Two interesting properties of canonical correlations are the following [for other properties, see Rencher (1998, Section 8.3)]:
1. Canonical correlations are invariant to changes of scale on either the \(y\) 's or the \(x\) 's. For example, if the measurement scale is changed from inches to centimeters, the canonical correlations will not change (the corresponding eigenvectors will change). This property holds for simple and multiple correlations as well.
2. The first canonical correlation \(r_{1}\) is the maximum correlation between linear functions of \(\mathbf{y}\) and \(\mathbf{x}\). Therefore, \(r_{1}\) exceeds (the absolute value of) the simple correlation between any \(y\) and any \(x\) or the multiple correlation between any \(y\) and all the \(x\) 's or between any \(x\) and all the \(y\) 's.

\section*{EXAMPLE 11.3}

For the chemical data of Table 10.1, we obtain the canonical correlations and illustrate property 2 above. We consider the extended set of nine \(x\) 's, as in Example 10.5.2. The matrix \(\mathbf{R}_{y x}\) of correlations between the \(y\) 's and the \(x\) 's is
\begin{tabular}{r|rrrrrrrrr} 
& \(x_{1}\) & \multicolumn{1}{c}{\(x_{2}\)} & \(x_{3}\) & \(x_{1} x_{2}\) & \(x_{1} x_{3}\) & \(x_{2} x_{3}\) & \multicolumn{1}{c}{\(x_{1}^{2}\)} & \multicolumn{1}{c}{\(x_{2}^{2}\)} & \multicolumn{1}{c}{\(x_{3}^{2}\)} \\
\hline\(y_{1}\) & -.68 & -.22 & -.45 & -.41 & -.55 & -.45 & -.68 & -.23 & -.42 \\
\(y_{2}\) & .40 & .08 & .39 & .16 & .44 & .33 & .40 & .12 & .33 \\
\(y_{3}\) & .58 & .23 & .36 & .40 & .45 & .39 & .58 & .22 & .36
\end{tabular}

The three canonical correlations and their squares are
\[
\begin{array}{ll}
r_{1}=.9899 & r_{1}^{2}=.9800 \\
r_{2}=.9528 & r_{2}^{2}=.9078 \\
r_{3}=.4625 & r_{3}^{2}=.2139
\end{array}
\]

From the relative sizes of the squared canonical correlations, we would consider only the first two to be important. A hypothesis test for the significance of each is carried out in Example 11.4.2.

To confirm that property 2 holds in this case, we compare \(r_{1}=.9899\) to the individual correlations and the multiple correlations. We first note that .9899 is greater than individual correlations, since (the absolute value of) the largest correlation in \(\mathbf{R}_{y x}\) is .68 . The multiple correlation \(R_{y_{j} \mid \mathrm{x}}\) of each \(y_{j}\) with the \(x\) 's is given by
\[
R_{y_{1} \mid \mathbf{x}}=.987, \quad R_{y_{2} \mid \mathbf{x}}=.921, \quad R_{y_{3} \mid \mathbf{x}}=.906
\]
and for the multiple correlation of each \(x\) with the \(y\) 's we have
\[
\begin{aligned}
& R_{x_{1} \mid \mathrm{y}}=.691, \quad R_{x_{2} \mid \mathbf{y}}=.237, \quad \quad R_{x_{3} \mid y}=.507, \\
& R_{x_{1} x_{2} \mid \mathrm{y}}=.432, \quad R_{x_{1} x_{3} \mid \mathrm{y}}=.585, \quad R_{x_{2} x_{3} \mid \mathrm{y}}=.482, \\
& R_{x_{1}^{2} \mid y}=.690, \quad R_{x_{2}^{2} \mid y}=.234, \quad \quad R_{x_{3}^{2} \mid y}=.466 .
\end{aligned}
\]

The first canonical correlation \(r_{1}=.9899\) exceeds all multiple correlations, and property 2 is satisfied.

\subsection*{11.4 TESTS OF SIGNIFICANCE}

In the following two sections we discuss basic tests of significance associated with canonical correlations. For other aspects of model validation for canonical correlations and variates, see Rencher (1998, Section 8.5).

\subsection*{11.4.1 Tests of No Relationship Between the \(y\) 's and the \(x\) 's}

In Section 7.4.1, we considered the hypothesis of independence, \(H_{0}: \boldsymbol{\Sigma}_{y x}=\mathbf{O}\). If \(\boldsymbol{\Sigma}_{y x}=\mathbf{O}\), the covariance of every \(y_{i}\) with every \(x_{j}\) is zero, and all corresponding correlations are likewise zero. Hence, under \(H_{0}\), there is no (linear) relationship between the \(y\) 's and the \(x\) 's, and \(H_{0}\) is equivalent to the statement that all canonical correlations \(r_{1}, r_{2}, \ldots, r_{s}\) are nonsignificant. Furthermore, \(H_{0}\) is equivalent to the overall regression hypothesis in Section 10.5.1, \(H_{0}: \mathbf{B}_{1}=\mathbf{O}\), which also relates all the \(y\) 's to all the \(x\) 's. Thus by (7.30) or (10.66), the significance of \(r_{1}, r_{2}, \ldots, r_{s}\) can be tested by
\[
\begin{equation*}
\Lambda_{1}=\frac{|\mathbf{S}|}{\left|\mathbf{S}_{y y}\right|\left|\mathbf{S}_{x x}\right|}=\frac{|\mathbf{R}|}{\left|\mathbf{R}_{y y}\right|\left|\mathbf{R}_{x x}\right|} \tag{11.16}
\end{equation*}
\]
which is distributed as \(\Lambda_{p, q, n-1-q}\). We reject \(H_{0}\) if \(\Lambda_{1} \leq \Lambda_{\alpha}\). Critical values \(\Lambda_{\alpha}\) are available in Table A. 9 using \(\nu_{H}=q\) and \(\nu_{E}=n-1-q\). The statistic \(\Lambda_{1}\) in (11.16) is also distributed as \(\Lambda_{q, p, n-1-p}\). As in (7.31), \(\Lambda_{1}\) is expressible in terms of the squared canonical correlations:
\[
\begin{equation*}
\Lambda_{1}=\prod_{i=1}^{s}\left(1-r_{i}^{2}\right) \tag{11.17}
\end{equation*}
\]

In this form, we can see that if one or more \(r_{i}^{2}\) is large, \(\Lambda_{1}\) will be small. We have used the notation \(\Lambda_{1}\) in (11.16) and (11.17) because in Section 11.4 .2 we will define \(\Lambda_{2}, \Lambda_{3}\) and so on to test the significance of \(r_{2}\) and succeeding \(r_{i}\) 's after the first.

If the parameters exceed the range of critical values for Wilks' \(\Lambda\) in Table A.9, we can use the \(\chi^{2}\)-approximation in (6.16),
\[
\begin{equation*}
\chi^{2}=-\left[n-\frac{1}{2}(p+q+3)\right] \ln \Lambda_{1}, \tag{11.18}
\end{equation*}
\]
which is approximately distributed as \(\chi^{2}\) with \(p q\) degrees of freedom. We reject \(H_{0}\) if \(\chi^{2} \geq \chi_{\alpha}^{2}\). Alternatively, we can use the \(F\)-approximation given in (6.15):
\[
\begin{equation*}
F=\frac{1-\Lambda_{1}^{1 / t}}{\Lambda_{1}^{1 / t}} \frac{\mathrm{df}_{2}}{\mathrm{df}_{1}}, \tag{11.19}
\end{equation*}
\]
which has an approximate \(F\)-distribution with \(\mathrm{df}_{1}\) and \(\mathrm{df}_{2}\) degrees of freedom, where
\[
\begin{aligned}
\mathrm{df}_{1} & =p q, \quad \mathrm{df}_{2}=w t-\frac{1}{2} p q+1 \\
w & =n-\frac{1}{2}(p+q+3), \quad t=\sqrt{\frac{p^{2} q^{2}-4}{p^{2}+q^{2}-5}}
\end{aligned}
\]

We reject \(H_{0}\) if \(F>F_{\alpha}\). When \(p q=2, t\) is set equal to 1 . If \(s=\min (p, q)\) is equal to either 1 or 2 , then the \(F\)-approximation in (11.19) has an exact \(F\)-distribution. For example, if one of the two sets consists of only two variables, an exact test is afforded by the \(F\)-approximation in (11.19). In contrast, the \(\chi^{2}\)-approximation in (11.18) does not reduce to an exact test for any parameter values.

The other three multivariate test statistics in Sections 6.1.4, 6.1.5, and 10.5.1 can also be used. Pillai's test statistic for the significance of canonical correlations is
\[
\begin{equation*}
V^{(s)}=\sum_{i=1}^{s} r_{i}^{2} \tag{11.20}
\end{equation*}
\]

Upper percentage points of \(V^{(s)}\) are found in Table A.11, indexed by
\[
s=\min (p, q), \quad m=\frac{1}{2}(|q-p|-1), \quad N=\frac{1}{2}(n-q-p-2) .
\]

For \(F\)-approximations for \(V^{(s)}\), see Section 6.1.5.
The Lawley-Hotelling statistic for canonical correlations is
\[
\begin{equation*}
U^{(s)}=\sum_{i=1}^{s} \frac{r_{i}^{2}}{1-r_{i}^{2}} \tag{11.21}
\end{equation*}
\]

Upper percentage points for \(\nu_{E} U^{(s)} / \nu_{H}\) (see Section 6.1.5) are given in Table A.12, which is entered with \(p, \nu_{H}=q\), and \(\nu_{E}=n-q-1\). For \(F\)-approximations, see Section 6.1.5.

Roy's largest root statistic is given by
\[
\begin{equation*}
\theta=r_{1}^{2} \tag{11.22}
\end{equation*}
\]

Upper percentage points are found in Table A.10, with \(s, m\), and \(N\) defined as above for Pillai's test. An "upper bound" on \(F\) for Roy's test is given in (6.21). Even though this "upper bound" is routinely calculated in many software packages, it is not a valid approximation.

As noted at the beginning of this section, the following three tests are equivalent:
1. Test of \(H_{0}: \boldsymbol{\Sigma}_{y x}=\mathbf{O}\), independence of two sets of variables
2. Test of \(H_{0}: \mathbf{B}_{1}=\mathbf{O}\), significance of overall multivariate multiple regression
3. Test of significance of the canonical correlations

Even though these tests are equivalent, we have discussed them separately because each has an extension that is different from the others. The respective extensions are
1. Test of independence of three or more sets of variables (Section 7.4.2)
2. Test of full vs. reduced model in multivariate multiple regression (Section 10.5.2)
3. Test of significance of succeeding canonical correlations after the first (Section 11.4.2)

\section*{EXAMPLE 11.4.1}

For the chemical data of Table 10.1 , with the extended set of nine \(x\) 's, we obtained canonical correlations .9899 , 9528 , and .4625 in Example 11.3. To test the significance of these, we calculate the following four test statistics and associated approximate \(F\) 's.
\begin{tabular}{lcrlr} 
& \begin{tabular}{c} 
Approximate \\
Statistic
\end{tabular} & \(F\) & \(\mathrm{df}_{1}\) & \(\mathrm{df}_{2}\)
\end{tabular} \begin{tabular}{r}
\(p\)-Value \\
for \(F\) \\
\hline Wilks' \(\Lambda=.00145\) \\
6.537 \\
27 \\
\hline
\end{tabular}

The \(F\)-approximation for Roy's test is, of course, an "upper bound." Rejection of \(H_{0}\) in these tests implies that at least \(r_{1}^{2}\) is significantly different from zero. The question of how many \(r_{i}^{2}\),s are significant is treated in the next section.

\subsection*{11.4.2 Test of Significance of Succeeding Canonical Correlations After the First}

If the test in (11.17) based on all \(s\) canonical correlations rejects \(H_{0}\), we are not sure if the canonical correlations beyond the first are significant. To test the significance of \(r_{2}, \ldots, r_{s}\), we delete \(r_{1}^{2}\) from \(\Lambda_{1}\) in (11.17) to obtain
\[
\begin{equation*}
\Lambda_{2}=\prod_{i=2}^{s}\left(1-r_{i}^{2}\right) \tag{11.23}
\end{equation*}
\]

Table 11.1 Tests of Three Canonical Correlations of the Chemical Data
\begin{tabular}{ccccccc}
\hline\(k\) & \(\Lambda_{k}\) & \(\Lambda_{.05}\) & Approximate \(F\) & \(\mathrm{df}_{1}\) & \(\mathrm{df}_{2}\) & \(p\)-Value for \(F\) \\
\hline 1 & .00145 & .024 & 6.537 & 27 & 21.1 & \(<.0001\) \\
2 & .0725 & .069 & 2.714 & 16 & 16 & .0269 \\
3 & .786 & .209 & .350 & 7 & 9 & .91 \\
\hline
\end{tabular}

If this test rejects the hypothesis, we conclude that at least \(r_{2}\) is significantly different from zero. We can continue in this manner, testing each \(r_{i}\) in turn, until a test fails to reject the hypothesis. At the \(k\) th step, the test statistic is
\[
\begin{equation*}
\Lambda_{k}=\prod_{i=k}^{s}\left(1-r_{i}^{2}\right) \tag{11.24}
\end{equation*}
\]
which is distributed as \(\Lambda_{p-k+1, q-k+1, n-k-q}\) and tests the significance of \(r_{k}, r_{k+1}, \ldots\), \(r_{s}\). (These test statistics are analogous to those for discriminant functions in Section 8.6.2.) Note that each parameter is reduced by \(k-1\) from the parameter values \(p, q\), and \(n-1-q\) for \(\Lambda_{1}\) in (11.16) or (11.17).

The usual \(\chi^{2}\) - and \(F\)-approximations can also be applied to \(\Lambda_{k}\). The \(\chi^{2}\)-approximation analogous to (11.18) is given by
\[
\begin{equation*}
\chi^{2}=-\left[n-\frac{1}{2}(p+q+3)\right] \ln \Lambda_{k}, \tag{11.25}
\end{equation*}
\]
which has \((p-k+1)(q-k+1)\) degrees of freedom. The \(F\)-approximation for \(\Lambda_{k}\) is a simple modification of (11.19) and the accompanying parameter definitions. In place of \(p, q\), and \(n\), we use \(p-k+1, q-k+1\), and \(n-k+1\) to obtain
\[
F=\frac{1-\Lambda_{k}^{1 / t}}{\Lambda_{k}^{1 / t}} \frac{\mathrm{df}_{2}}{\mathrm{df}_{1}}
\]
where
\[
\begin{aligned}
\mathrm{df}_{1} & =(p-k+1)(q-k+1), \\
\mathrm{df}_{2} & =w t-\frac{1}{2}[(p-k+1)(q-k+1)]+1, \\
w & =n-\frac{1}{2}(p+q+3), \\
t & =\sqrt{\frac{(p-k+1)^{2}(q-k+1)^{2}-4}{(p-k+1)^{2}+(q-k+1)^{2}-5}} .
\end{aligned}
\]

\section*{■ EXAMPLE 11.4.2}

We continue our analysis of the canonical correlations for the chemical data in Table 10.1 with three \(y\) 's and nine \(x\) 's. The tests are summarized in Table 11.1.

In the case of \(\Lambda_{2}\), we have a discrepancy between the exact Wilks' \(\Lambda\)-test and the approximate \(F\)-test. The test based on \(\Lambda\) is not significant, while the \(F\)-test does reach significance. This illustrates the need to check critical values for exact tests whenever \(p\)-values for approximate tests are close to the nominal value of \(\alpha\). From the test using \(\Lambda\), we conclude that only \(r_{1}=.9899\) is significant. The relative sizes of the squared canonical correlations, \(.980, .908\), and .214 , would indicate two dimensions of relationship, but this is not confirmed by the Wilks' test, perhaps because of the small sample size relative to the number of variables ( \(p+q=12\) and \(n=19\) ).

To illustrate the computations, we obtain the values in Table 11.1 for \(k=2\). Using (11.24), the computation for \(\Lambda_{2}\) is
\[
\Lambda_{2}=\prod_{i=2}^{3}\left(1-r_{i}^{2}\right)=(1-.908)(1-.214)=.0725
\]

With \(k=2, p=3, q=9\), and \(n=19\), the critical value for \(\Lambda_{2}\) is obtained from Table A. 9 as
\[
\Lambda_{.05, p-k+1, q-k+1, n-k-q}=\Lambda_{.05,2,8,8}=.069 .
\]

For the approximate \(F\) for \(\Lambda_{2}\), we have
\[
\begin{aligned}
t & =\sqrt{\frac{(3-2+1)^{2}(9-2+1)^{2}-4}{(3-2+1)^{2}+(9-2+1)^{2}-5}}=2, \\
w & =19-\frac{1}{2}(3+9+3)=11.5, \\
\mathrm{df}_{1} & =(3-2+1)(9-2+1)=16, \\
\mathrm{df}_{2} & =(11.5)(2)-\frac{1}{2}[(3-2+1)(9-2+1)]+1=16, \\
F & =\frac{1-(.0725)^{1 / 2}}{(0.725)^{1 / 2}} \frac{16}{16}=2.714 .
\end{aligned}
\]

\subsection*{11.5 INTERPRETATION}

We now turn to an assessment of the information contained in the canonical correlations and canonical variates. As was done for discriminant functions in Section 8.7, a distinction can be made between interpretation of the canonical variates and assessing the contribution of each variable. In the former, the signs of the coefficients are considered; in the latter, the signs are ignored and the coefficients are ranked in order of absolute value.

In Sections 11.5.1-11.5.3, we discuss three common tools for interpretation of canonical variates: (1) standardized coefficients, (2) the correlation between each
variable and the canonical variate, and (3) rotation of the canonical variate coefficients. The second of these is the most widely recommended, but we note in Section 11.5.2 that it is the least useful. In fact, for reasons to be outlined, we recommend only the first, standardized coefficients. In Section 11.5.4, we describe redundancy analysis and discuss its shortcomings as a measure of association between two sets of variables.

\subsection*{11.5.1 Standardized Coefficients}

The coefficients in the canonical variates \(u_{i}=\mathbf{a}_{i}^{\prime} \mathbf{y}\) and \(v_{i}=\mathbf{b}_{i}^{\prime} \mathbf{x}\) reflect differences in scaling of the variables as well as differences in contribution of the variables to canonical correlation. To remove the effect of scaling, \(\mathbf{a}_{i}\) and \(\mathbf{b}_{i}\) can be standardized by multiplying by the standard deviations of the corresponding variables as in (11.14):
\[
\mathbf{c}_{i}=\mathbf{D}_{y} \mathbf{a}_{i}, \quad \mathbf{d}_{i}=\mathbf{D}_{x} \mathbf{b}_{i}
\]
where \(\mathbf{D}_{y}=\operatorname{diag}\left(s_{y_{1}}, s_{y_{2}}, \ldots, s_{y_{p}}\right)\) and \(\mathbf{D}_{x}=\operatorname{diag}\left(s_{x_{1}}, s_{x_{2}}, \ldots, s_{x_{q}}\right)\). Alternatively, \(\mathbf{c}_{i}\) and \(\mathbf{d}_{i}\) can be obtained directly from (11.12) and (11.13) as eigenvectors of \(\mathbf{R}_{y y}^{-1} \mathbf{R}_{y x} \mathbf{R}_{x x}^{-1} \mathbf{R}_{x y}\) and \(\mathbf{R}_{x x}^{-1} \mathbf{R}_{x y} \mathbf{R}_{y y}^{-1} \mathbf{R}_{y x}\), respectively. It was noted at the end of Section 11.2 that the coefficients in \(\mathbf{c}_{i}\) are applied to standardized variables [see (11.15)]. Thus the effect of differences in size or scaling of the variables is removed, and the coefficients \(c_{i 1}, c_{i 2}, \ldots, c_{i p}\) in \(\mathbf{c}_{i}\) reflect the relative contribution of each of \(y_{1}, y_{2}, \ldots, y_{p}\) to \(u_{i}\). A similar statement can be made about \(\mathbf{d}_{i}\).

The standardized coefficients show the contribution of the variables in the presence of each other. Thus if some of the variables are deleted and others added, the coefficients will change. This is precisely the behavior we desire from the coefficients in a multivariate setting.

\section*{EXAMPLE 11.5.1}

For the chemical data in Table 10.1 with the extended set of nine \(x\) 's, we obtain the following standardized coefficients for the three canonical variates:
\begin{tabular}{c|rrr} 
& \multicolumn{1}{c}{\(\mathbf{c}_{1}\)} & \multicolumn{1}{c}{\(\mathbf{c}_{2}\)} & \multicolumn{1}{c}{\(\mathbf{c}_{3}\)} \\
\hline\(y_{1}\) & 1.5360 & 4.4704 & 5.7961 \\
\(y_{2}\) & .2108 & 2.8291 & 2.2280 \\
\(y_{3}\) & .4676 & 3.1309 & 5.1442 \\
& \multicolumn{1}{|c}{\(\mathbf{d}_{1}\)} & \multicolumn{1}{c}{\(\mathbf{d}_{2}\)} & \multicolumn{1}{c}{\(\mathbf{d}_{3}\)} \\
\hline\(x_{1}\) & 5.0125 & -38.3053 & -12.5072 \\
\(x_{2}\) & 5.8551 & -17.7390 & -24.2290 \\
\(x_{3}\) & 1.6500 & -7.9699 & -32.7392 \\
\(x_{1} x_{2}\) & -3.9209 & 19.2937 & 11.6420 \\
\(x_{1} x_{3}\) & -2.2968 & 6.4001 & 31.2189 \\
\(x_{2} x_{3}\) & .5316 & .8096 & 1.2988 \\
\(x_{1}^{2}\) & -2.6655 & 32.7933 & 4.8454 \\
\(x_{2}^{2}\) & -1.2346 & -3.3641 & 10.7979 \\
\(x_{3}^{2}\) & .5703 & .8733 & .9706
\end{tabular}

Thus
\[
\begin{aligned}
& u_{1}=1.54 \frac{y_{1}-\bar{y}_{1}}{s_{y_{1}}}+.21 \frac{y_{2}-\bar{y}_{2}}{s_{y_{2}}}+.47 \frac{y_{3}-\bar{y}_{3}}{s_{y_{3}}} \\
& v_{1}=5.01 \frac{x_{1}-\bar{x}_{1}}{s_{x_{1}}}+5.86 \frac{x_{2}-\bar{x}_{2}}{s_{x_{2}}}+\cdots+.57 \frac{x_{3}^{2}-\bar{x}_{3}^{2}}{s_{x_{3}^{2}}} .
\end{aligned}
\]

The variables that contribute most to the correlation between \(u_{1}\) and \(v_{1}\) are \(y_{1}\) and \(x_{1}, x_{2}, x_{1} x_{2}, x_{1} x_{3}, x_{1}^{2}\). The correlation between \(u_{2}\) and \(v_{2}\) is due largely to all three \(y\) 's and \(x_{1}, x_{2}, x_{1} x_{2}, x_{1}^{2}\).

\subsection*{11.5.2 Correlations between Variables and Canonical Variates}

Many writers recommend the additional step of converting the standardized coefficients to correlations. Thus, for example, in \(\mathbf{c}_{1}^{\prime}=\left(c_{11}, c_{12}, \ldots, c_{1 p}\right)\), instead of the second coefficient \(c_{12}\) we could examine \(r_{y_{2} u_{1}}\), the correlation between \(y_{2}\) and the first canonical variate \(u_{1}\). Such correlations are sometimes referred to as loadings or structure coefficients, and it is widely claimed that they provide a more valid interpretation of the canonical variates. Rencher (1988; 1992b; 1998, Section 8.6.3) has shown, however, that a weighted sum of the correlations between \(y_{j}\) and the canonical variates \(u_{1}, u_{2}, \ldots, u_{s}\) is equal to \(R_{y_{j} \mid \mathbf{x}}^{2}\), the squared multiple correlation between \(y_{j}\) and the \(x\) 's. There is no information about how the \(y\) 's contribute jointly to canonical correlation with the \(x\) 's. Therefore, the correlations are useless in gauging the importance of a given variable in the context of the others. The researcher who uses these correlations for interpretation is unknowingly reducing the multivariate setting to a univariate one.

\subsection*{11.5.3 Rotation}

In an attempt to improve interpretability, the canonical variate coefficients can be rotated (see Section 13.5) to increase the number of high and low coefficients and reduce the number of intermediate ones.

We do not recommend rotation of the canonical variate coefficients for two reasons [for proof and further discussion, see Rencher (1992b)]:
1. Rotation destroys the optimality of the canonical correlations. For example, the first canonical correlation is reduced and is no longer equal to \(\max _{\mathbf{a}, \mathbf{b}} r_{\mathbf{a}^{\prime} \mathbf{y}, \mathbf{b}^{\prime} \mathbf{x}}\) as in (11.4).
2. Rotation introduces correlations among succeeding canonical variates. Thus, for example, \(u_{1}\) and \(u_{2}\) are correlated after rotation. Hence even though the resulting coefficients may offer a subjectively more interpretable pattern, this gain is offset by the increased complexity due to interrelationships among the canonical variates. For example, \(u_{2}\) and \(v_{2}\) no longer offer a new dimension of relationship uncorrelated with \(u_{1}\) and \(v_{1}\). The dimensions now overlap, and some of the information in \(u_{2}\) and \(v_{2}\) is already available in \(u_{1}\) and \(v_{1}\).

\subsection*{11.5.4 Redundancy Analysis}

The redundancy is a measure of association between the \(y\) 's and the \(x\) 's based on the correlations between variables and canonical variates discussed in Section 11.5.2. Since these correlations provide only univariate information, the redundancy turns out to be a univariate rather than a multivariate measure of relationship. If the squared multiple correlation of \(y_{j}\) regressed on the \(x\) 's is denoted by \(R_{\left.y_{j}\right|_{x}}^{2}\), then the redundancy of the \(y\) 's given the \(v\) 's is the average squared multiple correlation:
\[
\begin{equation*}
\operatorname{Rd}(\mathbf{y} \mid \mathbf{v})=\frac{\sum_{j=1}^{p} R_{y_{j} \mid \mathbf{x}}^{2}}{p} \tag{11.26}
\end{equation*}
\]

Similarly, the redundancy of the \(x\) 's given the \(u\) 's is the average
\[
\begin{equation*}
\operatorname{Rd}(\mathbf{x} \mid \mathbf{u})=\frac{\sum_{j=1}^{q} R_{x_{j} \mid \mathbf{y}}^{2}}{q} \tag{11.27}
\end{equation*}
\]
where \(R_{x_{j} \mid y}^{2}\) is the squared multiple correlation of \(x_{j}\) regressed on the \(y\) 's. Since \(\operatorname{Rd}(\mathbf{y} \mid \mathbf{v})\) in (11.26) is the average squared multiple correlation of each \(y_{j}\) regressed on the \(x\) 's, it does not take into account the correlations among the \(y\) 's. It is thus an average univariate measure of relationship between the \(y\) 's and the \(x\) 's, not a multivariate measure at all. The two redundancy measures in (11.26) and (11.27) are not symmetric; that is, \(\operatorname{Rd}(\mathbf{y} \mid \mathbf{v}) \neq \operatorname{Rd}(\mathbf{x} \mid \mathbf{u})\).

Thus the so-called redundancy does not really quantify the redundancy among the \(y\) 's and \(x\) 's and is, therefore, not a useful measure of association between two sets of variables. For a measure of association we recommend \(r_{1}^{2}\) itself.

\subsection*{11.6 RELATIONSHIPS OF CANONICAL CORRELATION ANALYSIS TO OTHER MULTIVARIATE TECHNIQUES}

In Section 11.4.1, we noted the equivalence of the test for significance of the canonical correlations and the test for significance of overall regression, \(H_{0}: \mathbf{B}_{1}=\mathbf{O}\). Additional relationships between canonical correlation and multivariate regression are developed in Section 11.6.1. The relationship of canonical correlation analysis to MANOVA and discriminant analysis is discussed in Section 11.6.2.

\subsection*{11.6.1 Regression}

There is a direct link between canonical variate coefficients and multivariate multiple regression coefficients. The matrix of regression coefficients of the \(y\) 's regressed on the \(x\) 's (corrected for their means) is given in (10.57) as \(\hat{\mathbf{B}}_{1}=\mathbf{S}_{x x}^{-1} \mathbf{S}_{x y}\). This matrix can be used to relate \(\mathbf{a}_{i}\) and \(\mathbf{b}_{i}\) :
\[
\begin{equation*}
\mathbf{b}_{i}=\hat{\mathbf{B}}_{1} \mathbf{a}_{i} \tag{11.28}
\end{equation*}
\]
[Since \(\mathbf{a}_{i}\) and \(\mathbf{b}_{i}\) are eigenvectors, (11.28) can be written as \(\mathbf{b}_{i}=c \hat{\mathbf{B}}_{1} \mathbf{a}_{i}\), where \(c\) is an arbitrary scale factor.] By (2.67) and (11.28), the canonical variate coefficient vector \(\mathbf{b}_{i}\) is expressible as a linear combination of the columns of \(\hat{\mathbf{B}}_{1}\). A similar expression for \(\mathbf{a}_{i}\) can be obtained from the regression of x on \(\mathbf{y}: \mathbf{a}_{i}=\mathbf{S}_{y y}^{-1} \mathbf{S}_{y x} \mathbf{b}_{i}\).

In Section 11.2, canonical correlation was defined as an extension of multiple correlation. Correspondingly, canonical correlation reduces to multiple correlation when one of the two sets of variables has only one variable. When \(p=1\), for example, \(\mathbf{R}_{y y}\) becomes 1, and by (11.10), the single squared canonical correlation reduces to \(r^{2}=\mathbf{r}_{y x}^{\prime} \mathbf{R}_{x x}^{-1} \mathbf{r}_{y x}\), which we recognize from (10.34) as \(R^{2}\).

The two Wilks test statistics in multivariate regression in Sections 10.5.1 and 10.5.2, namely, the test for overall regression and the test on a subset of the \(x\) 's, can both be expressed in terms of canonical correlations. By (10.64) and (11.17), the test statistic for the overall regression hypothesis \(H_{0}: \mathbf{B}_{1}=\mathbf{O}\) can be written as
\[
\begin{align*}
\Lambda_{f} & =\frac{\left|\mathbf{Y}^{\prime} \mathbf{Y}-\hat{\mathbf{B}}^{\prime} \mathbf{X}^{\prime} \mathbf{Y}\right|}{\left|\mathbf{Y}^{\prime} \mathbf{Y}-n \overline{\mathbf{Y}} \overline{\mathbf{y}}^{\prime}\right|}  \tag{11.29}\\
& =\prod_{i=1}^{s}\left(1-r_{i}^{2}\right), \tag{11.30}
\end{align*}
\]
where \(r_{i}^{2}\) is the \(i\) th squared canonical correlation.
A test statistic for \(H_{0}: \mathbf{B}_{d}=\mathbf{O}\), the hypothesis that the \(y\) 's do not depend on the last \(h\) of the \(x\) 's, is given by (10.74) as
\[
\begin{equation*}
\Lambda\left(x_{q-h+1}, \ldots, x_{q} \mid x_{1}, \ldots, x_{q-h}\right)=\frac{\Lambda_{f}}{\Lambda_{r}} \tag{11.31}
\end{equation*}
\]
where \(\Lambda_{f}\) is given in (11.29) and \(\Lambda_{r}\) is given in (10.73) as
\[
\begin{equation*}
\Lambda_{r}=\frac{\left|\mathbf{Y}^{\prime} \mathbf{Y}-\hat{\mathbf{B}}_{r}^{\prime} \mathbf{X}_{r}^{\prime} \mathbf{Y}\right|}{\left|\mathbf{Y}^{\prime} \mathbf{Y}-n \overline{\mathbf{y}} \overline{\mathbf{y}}^{\prime}\right|} . \tag{11.32}
\end{equation*}
\]

By analogy with (11.30), \(\Lambda_{r}\) can be expressed in terms of the squared canonical correlations \(c_{1}^{2}, c_{2}^{2}, \ldots, c_{t}^{2}\) between \(y_{1}, y_{2}, \ldots, y_{p}\) and \(x_{1}, x_{2}, \ldots, x_{q-h}\) :
\[
\begin{equation*}
\Lambda_{r}=\prod_{i=1}^{t}\left(1-c_{i}^{2}\right) \tag{11.33}
\end{equation*}
\]
where \(t=\min (p, q-h)\). We have used the notation \(c_{i}^{2}\) instead of \(r_{i}^{2}\) to emphasize that the canonical correlations in the reduced model differ from those in the full model. By (11.30) and (11.33), the full and reduced model test of \(H_{0}: \mathbf{B}_{d}=\mathbf{O}\) in (11.31) can now be expressed in terms of canonical correlations as
\[
\begin{equation*}
\Lambda\left(x_{q-h+1}, \ldots, x_{q} \mid x_{1}, \ldots, x_{q-h}\right)=\frac{\prod_{i=1}^{s}\left(1-r_{i}^{2}\right)}{\prod_{i=1}^{t}\left(1-c_{i}^{2}\right)} \tag{11.34}
\end{equation*}
\]

If \(p=1\), as in multiple regression, then \(s=t=1\), and (11.34) reduces to
\[
\begin{equation*}
\Lambda=\frac{1-R_{f}^{2}}{1-R_{r}^{2}} \tag{11.35}
\end{equation*}
\]
where \(R_{f}^{2}\) and \(R_{r}^{2}\) are the squared multiple correlations for the full model and for the reduced model. The distribution of \(\Lambda\) in (11.35) is \(\Lambda_{1, h, n-q-1}\) when \(H_{0}\) is true. Since \(p=1\), there is an exact \(F\)-transformation from Table 6.1,
\[
F=\frac{(1-\Lambda)(n-q-1)}{\Lambda h}
\]
which is distributed as \(F_{h, n-q-1}\) when \(H_{0}\) is true. Substitution of \(\Lambda=\left(1-R_{f}^{2}\right) /(1-\) \(R_{r}^{2}\) ) from (11.35) yields the \(F\)-statistic expressed in terms of \(R^{2}\),
\[
\begin{equation*}
F=\frac{\left(R_{f}^{2}-R_{r}^{2}\right)(n-q-1)}{\left(1-R_{f}^{2}\right) h}, \tag{11.36}
\end{equation*}
\]
as given in (10.33).
Subset selection in canonical correlation analysis can be handled by the methods for multivariate regression given in Section 10.8. A subset of \(x\) 's can be found by the procedure of Section 10.8.1a. After a subset of \(x\) 's is found, the approach in Section 10.8.1b can be used to select a subset of \(y\) 's.

Muller (1982) discussed the relationship of canonical correlation analysis to multivariate regression and principal components. (Principal components are treated in Chapter 12.)

\subsection*{11.6.2 MANOVA and Discriminant Analysis}

In Sections 6.1.8 and 8.4.2, it was noted that in a one-way MANOVA or discriminant analysis setting, \(\lambda_{i} /\left(1+\lambda_{i}\right)\) is equal to \(r_{i}^{2}\), where \(\lambda_{i}\) is the \(i\) th eigenvalue of \(\mathbf{E}^{-1} \mathbf{H}\) and \(r_{i}^{2}\) is the \(i\) th squared canonical correlation between the \(p\) dependent variables and the \(k-1\) grouping variables. We now give a justification of this assertion.

Let the dependent variables be denoted by \(y_{1}, y_{2}, \ldots, y_{p}\) as usual. We represent the \(k\) groups by \(k-1\) dummy variables, \(x_{1}, x_{2}, \ldots, x_{k-1}\), defined for each member of the \(i\) th group, \(i \leq k-1\), as \(x_{1}=0, \ldots, x_{i-1}=0, x_{i}=1, x_{i+1}=0, \ldots, x_{k-1}=0\). For the \(k\) th group, all \(x\) 's are zero. (See Section 6.1 .8 for an introduction to dummy variables.) To illustrate with \(k=4\), the \(x\) 's are defined as follows in each group:
\begin{tabular}{cccc} 
Group & \(x_{1}\) & \(x_{2}\) & \(x_{3}\) \\
\hline 1 & 1 & 0 & 0 \\
2 & 0 & 1 & 0 \\
3 & 0 & 0 & 1 \\
4 & 0 & 0 & 0
\end{tabular}

The MANOVA model is equivalent to multivariate regression of \(y_{1}, y_{2}, \ldots, y_{p}\) on the dummy grouping variables \(x_{1}, x_{2}, \ldots, x_{k-1}\). The MANOVA test of \(H_{0}: \boldsymbol{\mu}_{1}=\)
\(\boldsymbol{\mu}_{2}=\cdots=\boldsymbol{\mu}_{k}\) is equivalent to the multivariate regression test of \(H_{0}: \mathbf{B}_{1}=\mathbf{O}\), as given by (11.17),
\[
\begin{equation*}
\Lambda=\prod_{i=1}^{s}\left(1-r_{i}^{2}\right) \tag{11.37}
\end{equation*}
\]

When we compare this form of \(\Lambda\) to the MANOVA test statistic (6.14),
\[
\begin{equation*}
\Lambda=\prod_{i=1}^{s} \frac{1}{1+\lambda_{i}} \tag{11.38}
\end{equation*}
\]
we obtain the relationships
\[
\begin{align*}
r_{i}^{2} & =\frac{\lambda_{i}}{1+\lambda_{i}}  \tag{11.39}\\
\lambda_{i} & =\frac{r_{i}^{2}}{1-r_{i}^{2}} \tag{11.40}
\end{align*}
\]

To establish this relationship more formally, we write (6.22) as
\[
\begin{equation*}
\mathbf{H a}=\lambda \mathbf{E a}, \tag{11.41}
\end{equation*}
\]
and (11.7) as
\[
\begin{equation*}
\mathbf{S}_{y y}^{-1} \mathbf{S}_{y x} \mathbf{S}_{x x}^{-1} \mathbf{S}_{x y} \mathbf{a}=r^{2} \mathbf{a} \tag{11.42}
\end{equation*}
\]

We multiply (11.42) on the left by \(\mathrm{S}_{y y}\) to obtain
\[
\begin{equation*}
\mathbf{S}_{y x} \mathbf{S}_{x x}^{-1} \mathbf{S}_{x y} \mathbf{a}=r^{2} \mathbf{S}_{y y} \mathbf{a} . \tag{11.43}
\end{equation*}
\]

Using the centered matrix \(\mathbf{X}_{c}\) in (10.14), with an analogous definition for \(\mathbf{Y}_{c}\), we can write \(B_{1}\) in the form [see (10.57)]
\[
\hat{\mathbf{B}}_{1}=\left(\frac{\mathbf{X}_{c}^{\prime} \mathbf{X}_{c}}{n-1}\right)^{-1} \frac{\mathbf{X}_{c}^{\prime} \mathbf{Y}_{c}}{n-1}=\mathbf{S}_{x x}^{-1} \mathbf{S}_{x y} .
\]

In terms of centered matrices, \(\mathbf{E}=\mathbf{Y}^{\prime} \mathbf{Y}-\hat{\mathbf{B}}^{\prime} \mathbf{X}^{\prime} \mathbf{Y}\) in (10.54) can be written as
\[
\begin{align*}
\frac{\mathbf{E}}{n-1} & =\frac{\mathbf{Y}_{c}^{\prime} \mathbf{Y}_{c}}{n-1}-\hat{\mathbf{B}}_{1}^{\prime} \frac{\mathbf{X}_{c}^{\prime} \mathbf{Y}_{c}}{n-1} \\
& =\mathbf{S}_{y y}-\mathbf{S}_{x y}^{\prime} \mathbf{S}_{x x}^{-1} \mathbf{S}_{x y}=\mathbf{S}_{y y}-\mathbf{S}_{y x} \mathbf{S}_{x x}^{-1} \mathbf{S}_{x y} \tag{11.44}
\end{align*}
\]
since \(\mathbf{S}_{x y}^{\prime}=\mathbf{S}_{y x}\). Similarly,
\[
\begin{equation*}
\frac{\mathbf{H}}{n-1}=\frac{\hat{\mathbf{B}}_{1}^{\prime} \mathbf{X}_{c}^{\prime} \mathbf{Y}_{c}}{n-1}=\mathbf{S}_{y x} \mathbf{S}_{x x}^{-1} \mathbf{S}_{x y} \tag{11.45}
\end{equation*}
\]

Since MANOVA is equivalent to multivariate regression on dummy grouping variables, we can substitute these values of \(\mathbf{E}\) and \(\mathbf{H}\) into (11.41) to obtain
\[
\begin{equation*}
\mathbf{S}_{y x} \mathbf{S}_{x x}^{-1} \mathbf{S}_{x y} \mathbf{a}=\lambda\left(\mathbf{S}_{y y}-\mathbf{S}_{y x} \mathbf{S}_{x x}^{-1} \mathbf{S}_{x y}\right) \mathbf{a} \tag{11.46}
\end{equation*}
\]

Subtracting \(r^{2} \mathbf{S}_{y x} \mathbf{S}_{x x}^{-1} \mathbf{S}_{x y} \mathbf{a}\) from both sides of (11.43) gives
\[
\begin{equation*}
\mathbf{S}_{y x} \mathbf{S}_{x x}^{-1} \mathbf{S}_{x y} \mathbf{a}=\frac{r^{2}}{1-r^{2}}\left(\mathbf{S}_{y y}-\mathbf{S}_{y x} \mathbf{S}_{x x}^{-1} \mathbf{S}_{x y}\right) \mathbf{a} \tag{11.47}
\end{equation*}
\]

A comparison of (11.46) and (11.47) shows that
\[
\lambda=\frac{r^{2}}{1-r^{2}}
\]
as in (11.40). Lindsey et al. (1985) discussed some advantages of using canonical correlation analysis in place of discriminant analysis in the several-group case.

\section*{PROBLEMS}
11.1 Show that the expression for canonical correlations in (11.12) can be obtained from the analogous expression in terms of variances and covariances in (11.7).
11.2 Verify (11.28), \(\mathbf{b}_{i}=\hat{\mathbf{B}}_{1} \mathbf{a}_{i}\).
11.3 Verify (11.35) for \(\Lambda\) when \(p=s=t=1\).
11.4 Verify the expression in (11.36) for \(F\) in terms of \(R_{f}^{2}\) and \(R_{r}^{2}\).
11.5 Solve (11.39), \(r_{i}^{2}=\lambda_{i} /\left(1+\lambda_{i}\right)\), for \(\lambda_{i}\) to obtain (11.40).
11.6 Verify (11.46), \(\mathbf{S}_{y x} \mathbf{S}_{x x}^{-1} \mathbf{S}_{x y} \mathbf{a}=\lambda\left(\mathbf{S}_{y y}-\mathbf{S}_{y x} \mathbf{S}_{x x}^{-1} \mathbf{S}_{x y}\right) \mathbf{a}\).
11.7 Show that (11.47) can be obtained by subtracting \(r^{2} \mathbf{S}_{y x} \mathbf{S}_{x x}^{-1} \mathbf{S}_{x y}\) a from both sides of (11.43).
11.8 Use the diabetes data of Table 3.5.
(a) Find the canonical correlations between \(\left(y_{1}, y_{2}\right)\) and \(\left(x_{1}, x_{2}, x_{3}\right)\).
(b) Find the standardized coefficients for the canonical variates.
(c) Test the significance of each canonical correlation.
11.9 Use the sons data of Table 3.8.
(a) Find the canonical correlations between \(\left(y_{1}, y_{2}\right)\) and \(\left(x_{1}, x_{2}\right)\).
(b) Find the standardized coefficients for the canonical variates.
(c) Test the significance of each canonical correlation.
11.10 Use the glucose data of Table 3.9.
(a) Find the canonical correlations between \(\left(y_{1}, y_{2}, y_{3}\right)\) and \(\left(x_{1}, x_{2}, x_{3}\right)\).
(b) Find the standardized coefficients for the canonical variates.
(c) Test the significance of each canonical correlation.
11.11 Use the Seishu data of Table 7.1.
(a) Find the canonical correlations between \(\left(y_{1}, y_{2}\right)\) and \(\left(x_{1}, x_{2}, \ldots, x_{8}\right)\).
(b) Find the standardized coefficients for the canonical variates.
(c) Test the significance of each canonical correlation.
11.12 Use canonical correlation to carry out the tests in parts (b), (c), and (d) of Problem 10.17, using the Seishu data. You will need to find the canonical correlations between ( \(y_{1}, y_{2}\) ) and the \(x\) 's in the indicated reduced models and use (11.34).
11.13 Using the temperature data of Table 7.2, find the canonical correlations and the standardized coefficients and carry out significance tests for the following:
(a) \(\left(y_{1}, y_{2}, y_{3}\right)\) and \(\left(y_{4}, y_{5}, y_{6}\right)\)
(b) \(\left(y_{1}, y_{2}, \ldots, y_{6}\right)\) and \(\left(y_{7}, y_{8}, y_{9}\right)\)
(c) \(\left(y_{1}, y_{2}, \ldots, y_{9}\right)\) and \(\left(y_{10}, y_{11}\right)\)
(d) \(\left(y_{1}, y_{2}, \ldots, y_{6}\right)\) and \(\left(y_{7}, y_{8}, \ldots, y_{11}\right)\).

\section*{CHAPTER 12}

\section*{PRINCIPAL COMPONENT ANALYSIS}

\subsection*{12.1 INTRODUCTION}

In principal component analysis, we seek to maximize the variance of a linear combination of the variables. For example, we might want to rank students on the basis of their scores on achievement tests in English, mathematics, reading, and so on. An average score would provide a single scale on which to compare the students, but with unequal weights we can spread the students out further on the scale and obtain a better ranking.

Essentially, principal component analysis is a one-sample technique applied to data with no groupings among the observations as in Chapters 8 and 9 and no partitioning of the variables into subsets \(\mathbf{y}\) and x as in Chapters 10 and 11. All the linear combinations that we have considered previously were related to other variables or to the data structure. In regression, we have linear combinations of the independent variables that best predict the dependent variable(s); in canonical correlation, we have linear combinations of a subset of variables that maximally correlate with linear combinations of another subset of variables; and discriminant analysis involves linear combinations that maximally separate groups of observations. Principal components, on the other hand, are concerned only with the core structure of a single
sample of observations on \(p\) variables. None of the variables is designated as dependent, and no grouping of observations is assumed. [For a discussion of the use of principal components with data consisting of several samples or groups, see Rencher (1998, Section 9.9)].

The first principal component is the linear combination with maximal variance; we are essentially searching for a dimension along which the observations are maximally separated or spread out. The second principal component is the linear combination with maximal variance in a direction orthogonal to the first principal component, and so on. In general, the principal components define dimensions that are different from those defined by discriminant functions or canonical variates.

In some applications, the principal components are an end in themselves and may be amenable to interpretation. More often they are obtained for use as input to another analysis. For example, two situations in regression where principal components may be useful are (1) if the number of independent variables is large relative to the number of observations, a test may be ineffective or even impossible; and (2) if the independent variables are highly correlated, the estimates of regression coefficients may be unstable. In such cases, the independent variables can be reduced to a smaller number of principal components that will yield a better test or more stable estimates of the regression coefficients. For details of this application, see Rencher (1998, Section 9.8).

As another illustration, suppose that in a MANOVA application \(p\) is close to \(\nu_{E}\), so that a test has low power, or that \(p>\nu_{E}\), in which case we have so many dependent variables that a test cannot be made. In such cases, we can replace the dependent variables with a smaller set of principal components and then carry out the test.

In these illustrations, principal components are used to reduce the number of dimensions. A useful dimension reduction device is to evaluate the first two principal components for each observation vector and construct a scatterplot to check for multivariate normality, outliers, and so on.

Finally, we note that in the term principal components we use the adjective principal, describing what kind of components-main, primary, fundamental, major, and so on. We do not use the noun principle as a modifier for components.

\subsection*{12.2 GEOMETRIC AND ALGEBRAIC BASES OF PRINCIPAL COMPONENTS}

\subsection*{12.2.1 Geometric Approach}

As noted in Section 12.1, principal components analysis deals with a single sample of \(n\) observation vectors \(\mathbf{y}_{1}, \mathbf{y}_{2}, \ldots, \mathbf{y}_{n}\) that form a swarm of points in a \(p\)-dimensional space. Principal component analysis can be applied to any distribution of \(\mathbf{y}\), but it will be easier to visualize geometrically if the swarm of points is ellipsoidal.

If the variables \(y_{1}, y_{2}, \ldots, y_{p}\) in \(y\) are correlated, the ellipsoidal swarm of points is not oriented parallel to any of the axes represented by \(y_{1}, y_{2}, \ldots, y_{p}\). We wish to find the natural axes of the swarm of points (the axes of the ellipsoid) with origin at
\(\overline{\mathbf{y}}\), the mean vector of \(\mathbf{y}_{1}, \mathbf{y}_{2}, \ldots, \mathbf{y}_{n}\). This is done by translating the origin to \(\overline{\mathbf{y}}\) and then rotating the axes. After rotation so that the axes become the natural axes of the ellipsoid, the new variables (principal components) will be uncorrelated.

We could indicate the translation of the origin to \(\overline{\mathbf{y}}\) by writing \(\mathbf{y}_{i}-\overline{\mathbf{y}}\) but will not usually do so for economy of notation. We will write \(\mathbf{y}_{i}-\overline{\mathbf{y}}\) when there is an explicit need; otherwise we assume that \(\mathbf{y}_{i}\) has been centered.

The axes can be rotated by multiplying each \(\mathbf{y}_{i}\) by an orthogonal matrix \(\mathbf{A}\) [see (2.101), where the orthogonal matrix was denoted by C]:
\[
\begin{equation*}
\mathbf{z}_{i}=\mathbf{A} \mathbf{y}_{i} \tag{12.1}
\end{equation*}
\]

Since \(\mathbf{A}\) is orthogonal, \(\mathbf{A}^{\prime} \mathbf{A}=\mathbf{I}\), and the distance to the origin is unchanged:
\[
\mathbf{z}_{i}^{\prime} \mathbf{z}_{i}=\left(\mathbf{A} \mathbf{y}_{i}\right)^{\prime}\left(\mathbf{A} \mathbf{y}_{i}\right)=\mathbf{y}_{i}^{\prime} \mathbf{A}^{\prime} \mathbf{A} \mathbf{y}_{i}=\mathbf{y}_{i}^{\prime} \mathbf{y}_{i}
\]
[see (2.103)]. Thus an orthogonal matrix transforms \(\mathbf{y}_{i}\) to a point \(\mathbf{z}_{i}\) that is the same distance from the origin, and the axes are effectively rotated.

Finding the axes of the ellipsoid is equivalent to finding the orthogonal matrix \(\mathbf{A}\) that rotates the axes to line up with the natural extensions of the swarm of points so that the new variables (principal components) \(z_{1}, z_{2}, \ldots, z_{p}\) in \(\mathbf{z}=\mathbf{A y}\) are uncorrelated. Thus we want the sample covariance matrix of \(\mathbf{z}, \mathbf{S}_{z}=\mathbf{A S A}^{\prime}\) [see (3.64)], to be diagonal,
\[
\mathbf{S}_{z}=\mathbf{A S A}^{\prime}=\left(\begin{array}{cccc}
s_{z_{1}}^{2} & 0 & \cdots & 0  \tag{12.2}\\
0 & s_{z_{2}}^{2} & \cdots & 0 \\
\vdots & \vdots & & \vdots \\
0 & 0 & \cdots & s_{z_{p}}^{2}
\end{array}\right)
\]
where \(\mathbf{S}\) is the sample covariance matrix of \(\mathbf{y}_{1}, \mathbf{y}_{2}, \ldots, \mathbf{y}_{n}\). By (2.111), \(\mathbf{C}^{\prime} \mathbf{S C}=\) \(\mathbf{D}=\operatorname{diag}\left(\lambda_{1}, \lambda_{2}, \ldots, \lambda_{p}\right)\), where the \(\lambda_{i}\) 's are eigenvalues of \(\mathbf{S}\) and \(\mathbf{C}\) is an orthogonal matrix whose columns are normalized eigenvectors of \(\mathbf{S}\). Thus the orthogonal matrix \(\mathbf{A}\) that diagonalizes \(\mathbf{S}\) is the transpose of the matrix \(\mathbf{C}\) :
\[
\mathbf{A}=\mathbf{C}^{\prime}=\left(\begin{array}{c}
\mathbf{a}_{1}^{\prime}  \tag{12.3}\\
\mathbf{a}_{2}^{\prime} \\
\vdots \\
\mathbf{a}_{p}^{\prime}
\end{array}\right)
\]
where \(\mathbf{a}_{i}\) is the \(i\) th normalized ( \(\mathbf{a}_{i}^{\prime} \mathbf{a}_{i}=1\) ) eigenvector of \(\mathbf{S}\). The principal components are the transformed variables \(z_{1}=\mathbf{a}_{1}^{\prime} \mathbf{y}, z_{2}=\mathbf{a}_{2}^{\prime} \mathbf{y}, \ldots, z_{p}=\mathbf{a}_{p}^{\prime} \mathbf{y}\) in \(\mathbf{z}=\mathbf{A} \mathbf{y}\). For example, \(z_{1}=a_{11} y_{1}+a_{12} y_{2}+\cdots+a_{1 p} y_{p}\).

By (2.111), the diagonal elements of \(\mathbf{A S A}^{\prime}\) on the right side of (12.2) are eigenvalues of \(\mathbf{S}\). Hence the eigenvalues \(\lambda_{1}, \lambda_{2}, \ldots, \lambda_{p}\) of \(\mathbf{S}\) are the (sample) variances of the principal components \(z_{i}=\mathbf{a}_{i}^{\prime} \mathbf{y}\) :
\[
\begin{equation*}
s_{z_{i}}^{2}=\lambda_{i} \tag{12.4}
\end{equation*}
\]

Since the rotation lines up with the natural extensions of the swarm of points, \(z_{1}=\) \(\mathbf{a}_{\mathbf{1}}^{\prime} \mathbf{y}\) has the largest (sample) variance and \(z_{p}=\mathbf{a}_{p}^{\prime} \mathbf{y}\) has the smallest variance. This also follows from (12.4), because the variance of \(z_{1}\) is \(\lambda_{1}\), the largest eigenvalue, and the variance of \(z_{p}\) is \(\lambda_{p}\), the smallest eigenvalue. If some of the eigenvalues are small, we can neglect them and represent the points fairly well with fewer than \(p\) dimensions. For example, if \(p=3\) and \(\lambda_{3}\) is small, then the swarm of points is an "elliptical pancake" and a two-dimensional representation will adequately portray the configuration of points.

Because the eigenvalues are variances of the principal components, we can speak of "the proportion of variance explained" by the first \(k\) components:
\[
\begin{align*}
\text { Proportion of variance } & =\frac{\lambda_{1}+\lambda_{2}+\cdots+\lambda_{k}}{\lambda_{1}+\lambda_{2}+\cdots+\lambda_{p}} \\
& =\frac{\lambda_{1}+\lambda_{2}+\cdots+\lambda_{k}}{\sum_{j=1}^{p} s_{j j}} \tag{12.5}
\end{align*}
\]
since \(\sum_{i=1}^{p} \lambda_{i}=\operatorname{tr}(\mathbf{S})\) by (2.107). Thus we try to represent the \(p\)-dimensional points \(\left(y_{i 1}, y_{i 2}, \ldots, y_{i p}\right)\) with a few principal components \(\left(z_{i 1}, z_{i 2}, \ldots, z_{i k}\right)\) that account for a large proportion of the total variance. If a few variables have relatively large variances, they will figure disproportionately in \(\sum_{j} s_{j j}\) and in the principal components. For example, if \(s_{22}\) is strikingly larger than the other variances, then in \(z_{1}=a_{11} y_{1}+a_{12} y_{2}+\cdots+a_{1 p} y_{p}\), the coefficient \(a_{12}\) will be large and all other \(a_{1 j}\) will be small.

When a ratio analogous to (12.5) is used for discriminant functions and canonical variates [see (8.13) and (11.9)], it is frequently referred to as percent of variance. However, in the case of discriminant functions and canonical variates, the eigenvalues are not variances, as they are in principal components.

If the variables are highly correlated, the essential dimensionality is much smaller than \(p\). In this case, the first few eigenvalues will be large, and (12.5) will be close to 1 for a small value of \(k\). On the other hand, if the correlations among the variables are all small, the dimensionality is close to \(p\) and the eigenvalues will be nearly equal. In this case, no useful reduction in dimension is achieved, because the principal components essentially duplicate the variables.

Any two principal components \(z_{i}=\mathbf{a}_{i}^{\prime} \mathbf{y}\) and \(z_{j}=\mathbf{a}_{j}^{\prime} \mathbf{y}\) are orthogonal for \(i \neq j\), that is, \(\mathbf{a}_{i}^{\prime} \mathbf{a}_{j}=0\), because \(\mathbf{a}_{i}\) and \(\mathbf{a}_{j}\) are eigenvectors of the symmetric matrix \(\mathbf{S}\) (see Section 2.11.6). Principal components also have the secondary property of being uncorrelated in the sample [see (12.2) and (3.63)]; that is, the covariance of \(z_{i}\) and \(z_{j}\) is zero:
\[
\begin{equation*}
s_{z_{i} z_{j}}=\mathbf{a}_{i}^{\prime} \mathbf{S} \mathbf{a}_{j}=0 \quad \text { for } \quad i \neq j \tag{12.6}
\end{equation*}
\]

Discriminant functions and canonical variates, on the other hand, have the weaker property of being uncorrelated but not the stronger property of orthogonality. Thus when we plot the first two discriminant functions or canonical variates on perpendicular coordinate axes, there is some distortion of their true relationship because the actual angle between their axes is not \(90^{\circ}\).

If we change the scale on one or more of the \(y\) 's, the shape of the swarm of points will change, and we will need different components to represent the new points. Hence the principal components are not scale invariant. We therefore need to be concerned with the units in which the variables are measured. If possible, all variables should be expressed in the same units. If the variables have widely disparate variances, we could standardize them before extracting eigenvalues and eigenvectors. This is equivalent to finding principal components of the correlation matrix \(\mathbf{R}\) and is treated in Section 12.5.

If one variable has a much greater variance than the other variables, the swarm of points will be elongated and will be nearly parallel to the axis corresponding to the variable with large variance. The first principal component will largely represent that variable, and the other principal components will have negligibly small variances. Such principal components (based on \(\mathbf{S}\) ) do not involve the other \(p-1\) variables, and we may prefer to analyze the correlation matrix \(\mathbf{R}\).

\section*{EXAMPLE 12.2.1}

To illustrate principal components as a rotation when \(p=2\), we use two variables from the sons data of Table 3.8: \(y_{1}\) is head length and \(y_{2}\) is head width for the first son. The mean vector and covariance matrix are
\[
\overline{\mathbf{y}}=\binom{185.7}{151.1}, \quad \mathbf{S}=\left(\begin{array}{cc}
95.29 & 52.87 \\
52.87 & 54.36
\end{array}\right)
\]

The eigenvalues and eigenvectors of \(\mathbf{S}\) are
\[
\begin{aligned}
& \lambda_{1}=131.52, \quad \lambda_{2}=18.14 \\
& \mathbf{a}_{\mathbf{1}}^{\prime}=\left(a_{11}, a_{12}\right)=(.825, .565), \quad \mathbf{a}_{2}^{\prime}=\left(a_{21}, a_{22}\right)=(-.565, .825)
\end{aligned}
\]

The symmetric pattern in the eigenvectors is due to their orthogonality: \(\mathbf{a}_{1}^{\prime} \mathbf{a}_{2}=\) \(a_{11} a_{21}+a_{12} a_{22}=0\).

The observations are plotted in Figure 12.1, along with the (translated and) rotated axes. The major axis is the line passing through \(\overline{\mathbf{y}}^{\prime}=(185.7,151.1)\) in the direction determined by \(\mathbf{a}_{1}^{\prime}=(.825, .565)\); the slope is \(a_{12} / a_{11}=\) \(.565 / .825\). Alternatively, the equation of the major axis can be obtained by setting \(z_{2}=0\) :
\[
\begin{aligned}
z_{2}=0 & =a_{21}\left(y_{1}-\bar{y}_{1}\right)+a_{22}\left(y_{2}-\bar{y}_{2}\right) \\
& =-.565\left(y_{1}-185.7\right)+.825\left(y_{2}-151.1\right)
\end{aligned}
\]

Note that the line formed by the major axis can be considered to be a regression line. It is fit to the points so that the perpendicular distance of the points to the line is minimized, rather than the usual vertical distance (see Section 12.3).

Figure 12.1 Principal component transformation for the sons data.

\subsection*{12.2.2 Algebraic Approach}

An algebraic approach to principal components can be briefly described as follows. As noted in Section 12.1, we seek a linear combination with maximal variance. By (3.55), the sample variance of \(z=\mathbf{a}^{\prime} \mathbf{y}\) is \(\mathbf{a}^{\prime} \mathbf{S a}\). Since \(\mathbf{a}^{\prime} \mathbf{S a}\) has no maximum if \(\mathbf{a}\) is unrestricted, we seek the maximum of
\[
\begin{equation*}
\lambda=\frac{\mathbf{a}^{\prime} \mathbf{S a}}{\mathbf{a}^{\prime} \mathbf{a}} . \tag{12.7}
\end{equation*}
\]

By an argument similar to that used in (8.8)-(8.12), the maximum value of \(\lambda\) is given by the largest eigenvalue in the expression
\[
\begin{equation*}
(\mathbf{S}-\lambda \mathbf{I}) \mathbf{a}=\mathbf{0} \tag{12.8}
\end{equation*}
\]
(see Problem 12.1). The eigenvector \(\mathbf{a}_{1}\) corresponding to the largest eigenvalue \(\lambda_{1}\) is the coefficient vector in \(z_{1}=\mathbf{a}_{1}^{\prime} \mathbf{y}\), the linear combination with maximum variance.

Unlike discriminant analysis or canonical correlation, there is no inverse involved before obtaining eigenvectors for principal components. Therefore, \(\mathbf{S}\) can be singular, in which case some of the eigenvalues are zero and can be ignored. A singular \(S\) would arise, for example, when \(n<p\), that is, when the sample size is less than the number of variables.

This tolerance of principal component analysis for a singular \(\mathbf{S}\) is important in certain research situations. For example, suppose that one has a one-way MANOVA with 10 observations in each of three groups and that \(p=50\), so that there are 50 variables in each of these 30 observation vectors. A MANOVA test involving \(\mathbf{E}^{-1} \mathbf{H}\) cannot be carried out directly in this case because \(\mathbf{E}\) is singular, but we could reduce
the 50 variables to a small number of principal components and then do a MANOVA test on the components. The principal components would be based on \(\mathbf{S}\) obtained from the 30 observations (ignoring groups). For entry into the MANOVA program, we would evaluate the principal components for each observation vector. If we are retaining \(k\) components, we calculate
\[
\begin{align*}
& z_{1 i}=\mathbf{a}_{1}^{\prime} \mathbf{y}_{i} \\
& z_{2 i}=\mathbf{a}_{2}^{\prime} \mathbf{y}_{i} \\
& \vdots  \tag{12.9}\\
& z_{k i}=\mathbf{a}_{k}^{\prime} \mathbf{y}_{i}
\end{align*}
\]
for \(i=1,2, \ldots, 30\). These are sometimes referred to as component scores. In vector form, (12.9) can be rewritten as
\[
\begin{equation*}
\mathbf{z}_{i}=\mathbf{A}_{k} \mathbf{y}_{i} \tag{12.10}
\end{equation*}
\]
where
\[
\mathbf{z}_{i}=\left(\begin{array}{c}
z_{1 i} \\
z_{2 i} \\
\vdots \\
z_{k i}
\end{array}\right) \quad \text { and } \quad \mathbf{A}_{k}=\left(\begin{array}{c}
\mathbf{a}_{1}^{\prime} \\
\mathbf{a}_{2}^{\prime} \\
\vdots \\
\mathbf{a}_{k}^{\prime}
\end{array}\right)
\]

We then use \(\mathbf{z}_{1}, \mathbf{z}_{2}, \ldots, \mathbf{z}_{30}\) as input to the MANOVA program.
Note that in this case with \(p>n\), the \(k\) components would not likely be stable; that is, they would be different in a new sample. However, this is of no concern here because we are using the components only to extract information from the sample at hand in order to compare the three groups.

\section*{- EXAMPLE 12.2.2}

Consider the football data of Table 8.3. In Example 8.8, we saw that high school football players (group 1) differed from the other two groups, college football players and college-age non-football players. Therefore, to obtain a homogeneous group of observations, we delete group 1 and use groups 2 and 3 combined. The covariance matrix is as follows:
\[
\mathbf{S}=\left(\begin{array}{rrrrrr}
.370 & .602 & .149 & .044 & .107 & .209 \\
.602 & 2.629 & .801 & .666 & .103 & .377 \\
.149 & .801 & .458 & .011 & -.013 & .120 \\
.044 & .666 & .011 & 1.474 & .252 & -.054 \\
.107 & .103 & -.013 & .252 & .488 & -.036 \\
.209 & .377 & .120 & -.054 & -.036 & .324
\end{array}\right)
\]

The total variance is
\[
\sum_{j=1}^{6} s_{j j}=\sum_{i=1}^{6} \lambda_{i}=5.743
\]

The eigenvalues of \(\mathbf{S}\) are as follows:
\begin{tabular}{rrr} 
Eigenvalue & \begin{tabular}{r} 
Proportion \\
of Variance
\end{tabular} & \begin{tabular}{c} 
Cumulative \\
Proportion
\end{tabular} \\
\hline 3.323 & .579 & .579 \\
1.374 & .239 & .818 \\
.476 & .083 & .901 \\
.325 & .057 & .957 \\
.157 & .027 & .985 \\
.088 & .015 & 1.000
\end{tabular}

The first two principal components account for \(81.8 \%\) of the total variance. The corresponding eigenvectors are as follows:
\begin{tabular}{lrr} 
& \(\mathbf{a}_{1}\) & \(\mathbf{a}_{2}\) \\
\hline WDIM & .207 & -.142 \\
CIRCUM & .873 & -.219 \\
FBEYE & .261 & -.231 \\
EYEHD & .326 & .891 \\
EARHD & .066 & .222 \\
JAW & .128 & -.187
\end{tabular}

Thus the first two principal components are
\[
\begin{aligned}
& z_{1}=\mathbf{a}_{1}^{\prime} \mathbf{y}=.207 y_{1}+.873 y_{2}+.261 y_{3}+.326 y_{4}+.066 y_{5}+.128 y_{6} \\
& z_{2}=\mathbf{a}_{2}^{\prime} \mathbf{y}=-.142 y_{1}-.219 y_{2}-.231 y_{3}+.891 y_{4}+.222 y_{5}-.187 y_{6} .
\end{aligned}
\]

Notice that the large coefficient in \(z_{1}\) and the large coefficient in \(z_{2}, .873\) and .891, respectively, correspond to the two largest variances on the diagonal of \(\mathbf{S}\). The two variables with large variances, \(y_{2}\) and \(y_{4}\), have a notable influence on the first two principal components. However, \(z_{1}\) and \(z_{2}\) are still meaningful linear functions. If the six variances were closer in size, the six variables would enter more evenly into the first two principal components. On the other hand, if the variances of \(y_{2}\) and \(y_{4}\) were substantially larger, \(z_{1}\) and \(z_{2}\) would be essentially equal to \(y_{2}\) and \(y_{4}\), respectively.

Note that \(y_{2}\) and \(y_{3}\) did not contribute at all when this data set was used to separate groups in Examples 8.5, 8.9, 9.3.1, and 9.6(a). However, these two variables are very useful here in the first two dimensions showing the spread of individual observations.

\subsection*{12.3 PRINCIPAL COMPONENTS AND PERPENDICULAR REGRESSION}

It was noted in Section 12.2.1 that principal components constitute a rotation of axes. Another geometric property of the line formed by the first principal component is

Figure 12.2 The first principal component as a perpendicular regression line.
that it minimizes the total sum of squared perpendicular distances from the points to the line. This is easily demonstrated in the bivariate case. The first principal component line is plotted in Figure 12.2 for the first two variables of the sons data, as in Example 12.2.1. The perpendicular distance from each point to the line is simply \(z_{2}\), the second coordinate in the transformed coordinates \(\left(z_{1}, z_{2}\right)\). Hence the sum of squares of perpendicular distances is
\[
\begin{equation*}
\sum_{i=1}^{n} z_{2 i}^{2}=\sum_{i=1}^{n}\left[\mathbf{a}_{2}^{\prime}\left(\mathbf{y}_{i}-\overline{\mathbf{y}}\right)\right]^{2} \tag{12.11}
\end{equation*}
\]
where \(\mathbf{a}_{2}\) is the second eigenvector of \(\mathbf{S}\) and we use \(\mathbf{y}_{i}-\overline{\mathbf{y}}\) because the axes have been translated to the new origin \(\overline{\mathbf{y}}\). Since \(\mathbf{a}_{2}^{\prime}\left(\mathbf{y}_{i}-\overline{\mathbf{y}}\right)=\left(\mathbf{y}_{i}-\overline{\mathbf{y}}\right)^{\prime} \mathbf{a}_{2}\), we can write (12.11) in the form
\[
\begin{array}{rlr}
\sum_{i=1}^{n} z_{2 i}^{2} & =\sum_{i=1}^{n} \mathbf{a}_{2}^{\prime}\left(\mathbf{y}_{i}-\overline{\mathbf{y}}\right)\left(\mathbf{y}_{i}-\overline{\mathbf{y}}\right)^{\prime} \mathbf{a}_{2} & \\
& =\mathbf{a}_{2}^{\prime}\left[\sum_{i}\left(\mathbf{y}_{i}-\overline{\mathbf{y}}\right)\left(\mathbf{y}_{i}-\overline{\mathbf{y}}\right)^{\prime}\right] \mathbf{a}_{2} & {[\mathbf{b y}(2.44)]} \\
& =(n-1) \mathbf{a}_{2}^{\prime} \mathbf{S} \mathbf{a}_{2}=(n-1) \lambda_{2} & {[\text { by }(3.27)]} \tag{12.12}
\end{array}
\]
which is a minimum [see remarks following (12.4)].
For the two variables \(y_{1}\) and \(y_{2}\), as plotted in Figure 12.2, the ordinary regression line of \(y_{2}\) on \(y_{1}\) minimizes the sum of squares of vertical distances from the points to the line. Similarly, the regression of \(y_{1}\) on \(y_{2}\) minimizes the sum of squares of

Figure 12.3 Regression lines compared with first principal component (P.C.) line.
horizontal distances from the points to the line. The first principal component line represents a "perpendicular" regression line that lies between the other two. The three lines are compared in Figure 12.3 for the partial sons data. The equation of the first principal component line is easily obtained by setting \(z_{2}=0\) :
\[
\begin{array}{r}
z_{2}=\mathbf{a}_{2}^{\prime}(\mathbf{y}-\overline{\mathbf{y}})=0, \\
a_{21}\left(y_{1}-\bar{y}_{1}\right)+a_{22}\left(y_{2}-\bar{y}_{2}\right)=0, \\
-.565\left(y_{1}-\bar{y}_{1}\right)+.825\left(y_{2}-\bar{y}_{2}\right)=0 .
\end{array}
\]

\subsection*{12.4 PLOTTING OF PRINCIPAL COMPONENTS}

The plots in Figures 12.1 and 12.2 were illustrations of principal components as a rotation of axes when \(p=2\). When \(p>2\), we can plot the first two components as a dimension reduction device. We simply evaluate the first two components \(\left(z_{1}, z_{2}\right)\) for each observation vector and plot these \(n\) points. The plot is equivalent to a projection of the \(p\)-dimensional data swarm onto the plane that shows the greatest spread of the points.

The plot of the first two components may reveal some important features of the data set. In Example 12.4(a), we show a principal component plot that exhibits a pattern typical of a sample from a multivariate normal distribution. One of the objectives of plotting is to check for departures from normality, such as outliers or nonlinearity. In Examples 12.4(b) and 12.4(c), we illustrate principal component plots showing a nonnormal pattern characterized by the presence of outliers. Jackson

Table 12.1 Principal Components for the Ramus Bone Data of Table 3.7
\begin{tabular}{crllrr}
\hline \multicolumn{2}{c}{ Eigenvalues } & & \multicolumn{3}{c}{ First Two Eigenvectors } \\
\cline { 5 - 6 } \cline { 4 - 6 } Number & Value & & Variable & \(\mathbf{a}_{1}\) & \(\mathbf{a}_{2}\) \\
\hline 1 & 25.05 & & AGE 8 & .474 & .592 \\
2 & 1.74 & & AGE 8.5 & .492 & .406 \\
3 & .22 & & AGE 9 & .515 & -.304 \\
4 & .11 & & AGE 9.5 & .517 & -.627 \\
\hline
\end{tabular}
(1980) provided a test for adequacy of representation of observation vectors in terms of principal components.

Gnanadesikan (1997, p. 308) pointed out that, in general, the first few principal components are sensitive to outliers that inflate variances or distort covariances, and the last few are sensitive to outliers that introduce artificial dimensions or mask singularities. We could examine the bivariate plots of at least the first two and the last two principal components in a search for outliers that may exert undue influence.

Devlin et al. (1981) recommended the extraction of principal components from robust estimates of \(\mathbf{S}\) or \(\mathbf{R}\) that reduce the influence of outliers. Campbell (1980) and Ruymgaart (1981) discussed direct robust estimation of principal components. Critchley (1985) developed methods for detection of influential observations in principal component analysis.

Another feature of the data that a plot of the first two components may reveal is a tendency of the points to cluster. The plot may reveal groupings of points; this is illustrated in Example 12.4(d).
- EXAMPLE 12.4(a)

For the modified football data in Example 12.2.2, the first two principal components were given as follows:
\[
\begin{aligned}
& z_{1}=\mathbf{a}_{1}^{\prime} \mathbf{y}=.207 y_{1}+.873 y_{2}+.261 y_{3}+.326 y_{4}+.066 y_{5}+.128 y_{6} \\
& z_{2}=\mathbf{a}_{2}^{\prime} \mathbf{y}=-.142 y_{1}-.219 y_{2}-.231 y_{3}+.891 y_{4}+.222 y_{5}-.187 y_{6}
\end{aligned}
\]

These are evaluated for each observation vector and plotted in Figure 12.4. (For convenience in scaling, \(\mathbf{y}-\overline{\mathbf{y}}\) was used in the computations.) The pattern is typical of that from a multivariate normal distribution. Note that the variance along the \(z_{1}\) axis is greater than the variance in the \(z_{2}\) direction, as expected.

\section*{EXAMPLE 12.4(b)}

In Figures 4.10 and 4.11, the \(Q-Q\) plot and bivariate scatterplots for the ramus bone data of Table 3.7 exhibit a nonnormal pattern. A principal component analysis using the covariance matrix is given in Table 12.1, and the first two

Figure 12.4 Plot of first two components for the modified football data.
principal components are plotted in Figure 12.5. The presence of three outliers that cause a nonnormal pattern is evident. These outliers do not appear when the four variables are examined individually.

Figure 12.5 First two principal components for the ramus bone data in Table 3.7.

Figure 12.6 First two principal components for economics data.

A rather extreme example of the effect of an outlier is given by Devlin et al. (1981). The data set involved \(p=14\) economic variables for \(n=29\) chemical companies. The first two principal components are plotted in Figure 12.6. The sample correlation \(r_{z_{1} z_{2}}\) is indeed zero for all 29 points, as it must be [see (12.6)], but if the apparent outlier is excluded from the computation, then \(r_{z_{1} z_{2}}=.99\) for the remaining 28 points. If the outlier were deleted from the data set, the axes of the principal components would pass through the natural extensions of the data swarm.

■ EXAMPLE 12.4(d)
Jeffers (1967) applied principal component analysis to a sample of 40 alate adelges (winged aphids) on which the following 19 variables had been measured:
\begin{tabular}{rl} 
LENGTH & body length \\
WIDTH & body width \\
FORWING & forewing length \\
HINWING & hindwing length \\
SPIRAC & number of spiracles \\
ANTSEG 1 & length of antennal segment I \\
ANTSEG 2 & length of antennal segment II
\end{tabular}
\begin{tabular}{rl} 
ANTSEG 3 & length of antennal segment III \\
ANTSEG 4 & length of antennal segment IV \\
ANTSEG 5 & length of antennal segment V \\
ANTSPIN & number of antennal spines \\
TARSUS 3 & leg length, tarsus III \\
TIBIA 3 & leg length, tibia III \\
FEMUR 3 & leg length, femur III \\
ROSTRUM & rostrum \\
OVIPOS & ovipositor \\
OVSPIN & number of ovipositor spines \\
FOLD & anal fold \\
HOOKS & number of hindwing hooks
\end{tabular}

\end{tabular}

An objective in the study was to determine the number of distinct taxa present in the habitat where the sample was taken. Since adelges are difficult to identify by the usual taxonomic methods, principal component analysis was used to search for groupings among the 40 individuals in the sample.

The correlation matrix is given in Table 12.2, and the eigenvalues and first four eigenvectors are in Tables 12.3 and 12.4, respectively. The eigenvectors are scaled so that the largest value in each is 1 . The first principal component is largely an index of size. The second component is associated with SPIRAC, OVIPOS, OVSPIN, and FOLD.

The first two components were computed for each of the 40 individuals and plotted in Figure 12.7. Since the first two components account for \(85 \%\) of the total variance, the plot represents the data with very little distortion. There are four major groups, apparently corresponding to species. The groupings form an interesting S-shape.

\subsection*{12.5 PRINCIPAL COMPONENTS FROM THE CORRELATION MATRIX}

Generally, extracting components from \(\mathbf{S}\) rather than \(\mathbf{R}\) remains closer to the spirit and intent of principal component analysis, especially if the components are to be

Table 12.4 Eigenvectors for the First Four Components of the Winged Aphid Data
\begin{tabular}{lrrrr}
\hline & \multicolumn{4}{c}{ Eigenvectors } \\
\cline { 2 - 5 } Variable & \multicolumn{1}{c}{1} & \multicolumn{1}{c}{2} & \multicolumn{1}{c}{3} & \multicolumn{1}{c}{4} \\
\hline LENGTH & .96 & -.06 & .03 & -.12 \\

FOLD & -.71 & .64 & .04 & -.80 \\
HOOKS & .76 & -.52 & .06 & .72 \\
\hline
\end{tabular}
used in further computations. However, in some cases, the principal components will be more interpretable if \(\mathbf{R}\) is used. For example, if the variances differ widely or if the measurement units are not commensurate, the components of \(S\) will be dominated by the variables with large variances. The other variables will contribute very little. For a more balanced representation in such cases, components of \(\mathbf{R}\) may be used (see, for example, Problem 12.9).

As with any change of scale, when the variables are standardized in transforming from \(\mathbf{S}\) to \(\mathbf{R}\), the shape of the swarm of points will change. Note, however, that after transforming to \(\mathbf{R}\), any further changes of scale on the variables would not affect the components because changes of scale do not change \(\mathbf{R}\). Thus the principal components from \(\mathbf{R}\) are scale invariant.

To illustrate how the eigenvalues and eigenvectors change when converting from \(\mathbf{S}\) to \(\mathbf{R}\), we use a simple bivariate example in which one variance is substantially larger than the other. Suppose that \(\mathbf{S}\) and the corresponding \(\mathbf{R}\) have the values
\[
\mathbf{S}=\left(\begin{array}{cc}
1 & 4 \\
4 & 25
\end{array}\right), \quad \mathbf{R}=\left(\begin{array}{cc}
1 & .8 \\
.8 & 1
\end{array}\right) .
\]

The eigenvalues and eigenvectors from \(\mathbf{S}\) are

Figure 12.7 Plotted values of the first two components for individual insects.
\[
\begin{array}{ll}
\lambda_{1}=25.65, & \mathbf{a}_{1}^{\prime}=(.160, .987) \\
\lambda_{2}=.35, & \mathbf{a}_{2}^{\prime}=(.987,-.160)
\end{array}
\]

The patterns we see in \(\lambda_{1}, \lambda_{2}, \mathbf{a}_{1}\), and \(\mathbf{a}_{2}\) are quite predictable. The symmetry in \(\mathbf{a}_{1}\) and \(\mathbf{a}_{2}\) is due to their orthogonality, \(\mathbf{a}_{1}^{\prime} \mathbf{a}_{2}=0\). The large variance of \(y_{2}\) in \(\mathbf{S}\) is reflected in the first principal component \(z_{1}=.160 y_{1}+.987 y_{2}\), where \(y_{2}\) is weighted heavily. Thus the first principal component \(z_{1}\) essentially duplicates \(y_{2}\) and does not show the mutual effect of \(y_{1}\) and \(y_{2}\). As expected, \(z_{1}\) accounts for virtually all of the total variance:
\[
\frac{\lambda_{1}}{\lambda_{1}+\lambda_{2}}=\frac{25.65}{26}=.9865
\]

The eigenvalues and eigenvectors of \(\mathbf{R}\) are
\[
\begin{aligned}
& \lambda_{1}=1.8, \quad \mathbf{a}_{1}^{\prime}=(.707, .707) \\
& \lambda_{2}=.2, \quad \mathbf{a}_{2}^{\prime}=(.707,-.707)
\end{aligned}
\]

The first principal component of \(\mathbf{R}\),
\[
z_{1}=.707 \frac{y_{1}-\bar{y}_{1}}{1}+.707 \frac{y_{2}-\bar{y}_{2}}{5}
\]
accounts for a high proportion of variance,
\[
\frac{\lambda_{1}}{\lambda_{1}+\lambda_{2}}=\frac{1.8}{2}=.9
\]
because the variables are fairly highly correlated ( \(r=.8\) ). But the standardized variables \(\left(y_{1}-\bar{y}_{1}\right) / 1\) and \(\left(y_{2}-\bar{y}_{2}\right) / 5\) are equally weighted in \(z_{1}\), due to the equality of the diagonal elements ("variances") of \(\mathbf{R}\).

We now list some general comparisons of principal components from \(\mathbf{R}\) with those from \(S\) :
1. The percent of variance in (12.5) accounted for by the components of \(\mathbf{R}\) will differ from the percent for \(S\), as illustrated above.
2. The coefficients of the principal components from \(\mathbf{R}\) differ from those obtained from \(S\), as illustrated above.
3. If we express the components from \(\mathbf{R}\) in terms of the original variables, they still will not agree with the components from \(\mathbf{S}\). By transforming the standardized variables back to the original variables in the above illustration, the components of \(\mathbf{R}\) become
\[
\begin{aligned}
z_{1} & =.707 \frac{y_{1}-\bar{y}_{1}}{1}+.707 \frac{y_{2}-\bar{y}_{2}}{5} \\
& =.707 y_{1}+.141 y_{2}+\text { const } \\
z_{2} & =.707 \frac{y_{1}-\bar{y}_{1}}{1}-.707 \frac{y_{2}-\bar{y}_{2}}{5} \\
& =.707 y_{1}-.141 y_{2}+\text { const. }
\end{aligned}
\]

As expected, these are very different from the components extracted directly from \(\mathbf{S}\). This problem arises, of course, because of the lack of scale invariance of the components of \(S\).
4. The principal components from \(\mathbf{R}\) are scale invariant, because \(\mathbf{R}\) itself is scale invariant.
5. The components from a given matrix \(\mathbf{R}\) are not unique to that \(\mathbf{R}\). For example, in the bivariate case, the eigenvalues of
\[
\mathbf{R}=\left(\begin{array}{ll}
\mathbf{1} & r \\
r & 1
\end{array}\right)
\]
are given by
\[
\begin{equation*}
\lambda_{1}=1+r, \quad \lambda_{2}=1-r \tag{12.13}
\end{equation*}
\]
and the eigenvectors are \(\mathbf{a}_{1}^{\prime}=(.707, .707)\) and \(\mathbf{a}_{2}^{\prime}=(.707,-.707)\), which give principal components
\[
\begin{align*}
& z_{1}=.707 \frac{y_{1}-\bar{y}_{1}}{s_{1}}+.707 \frac{y_{2}-\bar{y}_{2}}{s_{2}}  \tag{12.14}\\
& z_{2}=.707 \frac{y_{1}-\bar{y}_{1}}{s_{1}}-.707 \frac{y_{2}-\bar{y}_{2}}{s_{2}}
\end{align*}
\]

The components in (12.14) do not depend on \(r\). For example, they serve equally well for \(r=.01\) and for \(r=.99\). For \(r=.01\), the proportion of variance explained by \(z_{1}\) is \(\lambda_{1} /\left(\lambda_{1}+\lambda_{2}\right)=(1+.01) /(1+.01+1-.01)=\) \(1.01 / 2=.505\). For \(r=.99\), the ratio is \(1.99 / 2=.995\). Thus the statement that the first component from a correlation matrix accounts for, say, \(90 \%\) of the variance is not very meaningful. In general, for \(p>2\), the components from \(\mathbf{R}\) depend only on the ratios (relative values) of the correlations, not on their actual values, and components of a given \(\mathbf{R}\) matrix will serve for other \(\mathbf{R}\) matrices [see Rencher (1998, Section 9.4)].

\subsection*{12.6 DECIDING HOW MANY COMPONENTS TO RETAIN}

In every application, a decision must be made on how many principal components should be retained in order to effectively summarize the data. The following guidelines have been proposed:
1. Retain sufficient components to account for a specified percentage of the total variance, say \(80 \%\).
2. Retain the components whose eigenvalues are greater than the average of the eigenvalues, \(\sum_{i=1}^{p} \lambda_{i} / p\). For a correlation matrix, this average is 1 .
3. Use the scree graph, a plot of \(\lambda_{i}\) versus \(i\), and look for a natural break between the "large" eigenvalues and the "small" eigenvalues.
4. Test the significance of the "larger" components, that is, the components corresponding to the larger eigenvalues.

We now discuss the above four criteria for choosing the components to keep. Note, however, that the smallest components may carry valuable information that should not be routinely ignored (see Section 12.7).

In method 1, the challenge lies in selecting an appropriate threshold percentage. If we aim too high, we run the risk of including components that are either sample specific or variable specific. By sample specific we mean that a component may not generalize to the population or to other samples. A variable specific component is dominated by a single variable and does not represent a composite summary of several variables.

Method 2 is widely used and is the default in many software packages. By (2.107), \(\sum_{i} \lambda_{i}=\operatorname{tr}(\mathbf{S})\), and the average eigenvalue is also the average variance of the individual variables. Thus method 2 retains those components that account for more variance than the average variance of the variables. In cases where the data can be successfully summarized in a relatively small number of dimensions, there is often a wide gap between the two eigenvalues that fall on both sides of the average. In Example 12.2.2, the average eigenvalue (of \(\mathbf{S}\) ) for the football data is .957 , which is

Figure 12.8 Scree graph for eigenvalues of modified football data.
amply bracketed by \(\lambda_{2}=1.37\) and \(\lambda_{3}=.48\). In the winged aphid data in Example \(12.4(\mathrm{~d})\), the second and third eigenvalues (of \(\mathbf{R}\) ) are 2.370 and .748 , leaving a comfortable margin on both sides of 1 . In some cases, one may wish to move the cutoff point slightly to accommodate a visible gap in eigenvalues.

The scree graph in method 3 is named for its similarity in appearance to a cliff with rocky debris at its bottom. The scree graph for the modified football data of Example 12.2.2 exhibits an ideal pattern, as shown in Figure 12.8. The first two eigenvalues form a steep curve, followed by a bend and then a straight-line trend with shallow slope. The recommendation is to retain those eigenvalues in the steep curve before the first one on the straight line. Thus in Figure 12.8, two components would be retained. In practice, the turning point between the steep curve and the straight line may not be as distinct as this or there may be more than one discernible bend. In such cases, this approach is not as conclusive. The scree graph for the winged aphid data in Example 12.4(d) is plotted in Figure 12.9. The plot would suggest that two components be retained (possibly four).

The remainder of this section is devoted to method 4 , tests of significance. The tests assume multivariate normality, which is not required for estimation of principal components.

It may be useful to make a preliminary test of complete independence of the variables, as in Section 7.4.3: \(H_{0}: \boldsymbol{\Sigma}=\operatorname{diag}\left(\sigma_{11}, \sigma_{22}, \ldots, \sigma_{p p}\right)\), or equivalently, \(H_{0}: \mathbf{P}_{\rho}=\mathbf{I}\). The test statistic is given in (7.37) and (7.38). If the results indicate that the variables are independent, there is no point in extracting principal components, since (except for sampling fluctuation) the variables themselves already form the principal components.

Figure 12.9 Scree graph for eigenvalues of winged aphid data.

To test the significance of the "larger" components, we test the hypothesis that the last \(k\) population eigenvalues are small and equal, \(H_{0 k}: \gamma_{p-k+1}=\gamma_{p-k+2}=\cdots=\) \(\gamma_{p}\), where \(\gamma_{1}, \gamma_{2}, \ldots, \gamma_{p}\) denote the population eigenvalues, namely, the eigenvalues of \(\boldsymbol{\Sigma}\). The implication is that the first sample components capture all the essential dimensions, while the last components reflect noise. If \(H_{0}\) is true, the last \(k\) sample eigenvalues will tend to have the pattern shown by the straight line with small slope in the ideal scree graph, such as in Figure 12.8 or 12.9.

To test \(H_{0 k}: \gamma_{p-k+1}=\cdots=\gamma_{p}\) using a likelihood ratio approach, we calculate the average of the last \(k\) eigenvalues of \(\mathbf{S}\),
\[
\bar{\lambda}=\sum_{i=p-k+1}^{p} \frac{\lambda_{i}}{k}
\]
and use the test statistic
\[
\begin{equation*}
u=\left(n-\frac{2 p+11}{6}\right)\left(k \ln \bar{\lambda}-\sum_{i=p-k+1}^{p} \ln \lambda_{i}\right) \tag{12.15}
\end{equation*}
\]
which has an approximate \(\chi^{2}\)-distribution. We reject \(H_{0}\) if \(u \geq \chi_{\alpha, \nu}^{2}\), where \(\nu=\) \(\frac{1}{2}(k-1)(k+2)\).

To carry out this procedure, we could begin by testing \(H_{02}: \gamma_{p-1}=\gamma_{p}\). If this is accepted, we could then test \(H_{03}: \gamma_{p-2}=\gamma_{p-1}=\gamma_{p}\) and continue testing in this fashion until \(H_{0 k}\) is rejected for some value of \(k\).

In practice, when the variables are fairly highly correlated and the data can be successfully represented by a small number of principal components, the first three
methods will typically agree on the number of components to retain, and the test in method 4 will often indicate a larger number of components.

\section*{- EXAMPLE 12.6}

We apply the above four criteria to the modified football data of Example 12.2.2.
For method 1, we simply examine the eigenvalues and their proportion of variance explained, as obtained in Example 12.2.2:
\begin{tabular}{ccc} 
Eigenvalue & \begin{tabular}{c} 
Proportion \\
of Variance
\end{tabular} & \begin{tabular}{c} 
Cumulative \\
Proportion
\end{tabular} \\
\hline 3.323 & .579 & .579 \\
1.374 & .239 & .818 \\
.476 & .083 & .901 \\
.325 & .057 & .957 \\
.157 & .027 & .985 \\
.088 & .015 & 1.000
\end{tabular}

To account for \(82 \%\) of the variance, we would keep two components. This percent of variance is high enough for most descriptive purposes. For certain other applications, such as input to another analysis, we might wish to retain three components, which would account for \(90 \%\) of the variance.

To apply method 2, we find the average eigenvalue to be
\[
\bar{\lambda}=\sum_{i=1}^{6} \frac{\lambda_{i}}{6}=\frac{5.742824}{6}=.957
\]

Since only \(\lambda_{1}\) and \(\lambda_{2}\) exceed .957 , we would retain two components.
For method 3, the scree graph in Figure 12.8 indicates conclusively that two components should be retained.

To implement method 4, we carry out the significance tests in (12.15). The values of the test statistic \(u\) for \(k=2,3, \ldots, 6\) are as follows:
\begin{tabular}{rrrrr} 
Eigenvalue & \(k\) & \multicolumn{1}{c}{\(u\)} & df & \(\chi_{.05}^{2}\) \\
\hline 3.32341 & 6 & 245.57 & 20 & 31.41 \\
1.37431 & 5 & 123.93 & 14 & 23.68 \\
.47607 & 4 & 44.10 & 9 & 16.92 \\
.32468 & 3 & 23.84 & 5 & 11.07 \\
.15650 & 2 & 4.62 & 2 & 5.99 \\
.08785 & 1 & & &
\end{tabular}

The tests indicate that only the last two (population) eigenvalues are equal and we should retain the first four. This differs from the results of the other three criteria, which are in close agreement that two components should be retained.

\subsection*{12.7 INFORMATION IN THE LAST FEW PRINCIPAL COMPONENTS}

Up to this point, we have focused on using the first few principal components to summarize and simplify the data. However, the last few components may carry useful information in some applications.

Since the eigenvalues serve as variances of the principal components, the last few principal components have smaller variances. If the variance of a component is zero or close to zero, the component represents a linear relationship among the variables that is essentially constant; that is, the relationship holds for all \(\mathbf{y}_{i}\) 's in the sample. Thus if the last eigenvalue is near zero, it signifies the presence of a collinearity that may provide new information for the researcher. Suppose, for example, that there are five variables and \(y_{5}=\sum_{j=1}^{4} y_{j} / 4\). Then S is singular, and barring round-off error, \(\lambda_{5}\) will be zero. Thus \(s_{z_{5}}^{2}=0\), and \(z_{5}\) is constant. As noted early in Section 12.2, the \(\mathbf{y}_{i}\) 's are centered, because the origin of the principal components is translated to \(\overline{\mathbf{y}}\). Hence the constant value of \(z_{5}\) is its mean, which is zero:
\[
z_{5}=\mathbf{a}_{5}^{\prime} \mathbf{y}=a_{51} y_{1}+a_{52} y_{2}+\cdots+a_{55} y_{5}=0
\]

Since this must reflect the dependency of \(y_{5}\) on \(y_{1}, y_{2}, y_{3}\), and \(y_{4}\), the eigenvector \(\mathbf{a}_{5}^{\prime}\) will be proportional to ( \(1,1,1,1,-4\) ).

\subsection*{12.8 INTERPRETATION OF PRINCIPAL COMPONENTS}

In Section 12.5, we noted that principal components obtained from \(\mathbf{R}\) are not compatible with those obtained from \(S\). Because of this lack of scale invariance of principal components from \(S\), the coefficients cannot be converted to standardized form, as can be done with coefficients in discriminant functions in Chapter 8 and canonical variates in Chapter 11. Hence interpretation of principal components is not as clear-cut as with previous linear functions that we have discussed. We must choose between components of \(\mathbf{S}\) or \(\mathbf{R}\), knowing they will have a different interpretation. If the variables have widely disparate variances, we can use \(\mathbf{R}\) instead of \(\mathbf{S}\) to improve interpretation.

For certain patterns of elements in \(\mathbf{S}\) or \(\mathbf{R}\), the form of the principal components can be predicted. This aid to interpretation is discussed in Section 12.8.1. As with discriminant functions and canonical variates, some writers have advocated rotation and the use of correlations between the variables and the principal components. We argue against the use of these two approaches to interpretation in Sections 12.8.2 and 12.8.3.

\subsection*{12.8.1 Special Patterns in \(S\) or \(R\)}

In the covariance or correlation matrix, we may recognize a distinguishing pattern from which the structure of the principal components can be deduced. For example, we noted in Section 12.2 that if one variable has a much larger variance than
the other variables, this variable will dominate the first component, which will account for most of the variance. Another case in which a component will duplicate a variable occurs when the variable is uncorrelated with the other variables. We now demonstrate this by showing that if all \(p\) variables are uncorrelated, the variables themselves are the principal components. If the variables were uncorrelated (orthogonal), \(\mathbf{S}\) would have the form
\[
\mathbf{S}=\left(\begin{array}{cccc}
s_{11} & 0 & \cdots & 0  \tag{12.16}\\
0 & s_{22} & \cdots & 0 \\
\vdots & \vdots & & \vdots \\
0 & 0 & \cdots & s_{p p}
\end{array}\right)
\]
and the characteristic equation would be
\[
0=|\mathbf{S}-\lambda \mathbf{I}|=\prod_{i=1}^{p}\left(s_{i i}-\lambda\right) \quad[\mathbf{b y}(2.83)],
\]
which has solutions
\[
\begin{equation*}
\lambda_{i}=s_{i i}, \quad i=1,2, \ldots, p \tag{12.17}
\end{equation*}
\]

The corresponding normalized eigenvectors have a 1 in the \(i\) th position and 0 's elsewhere:
\[
\begin{equation*}
\mathbf{a}_{i}^{\prime}=(0, \ldots, 0,1,0, \ldots, 0) \tag{12.18}
\end{equation*}
\]

Thus the \(i\) th component is
\[
z_{i}=\mathbf{a}_{i}^{\prime} \mathbf{y}=y_{i}
\]

In practice, the sample correlations (of continuous random variables) will not be zero, but if the correlations are all small, the principal components will largely duplicate the variables.

By the Perron-Frobenius theroem in Section 2.11.4, if all correlations or covariances are positive, all elements of the first eigenvector \(\mathbf{a}_{1}\) are positive. Since the remaining eigenvectors \(\mathbf{a}_{2}, \mathbf{a}_{3}, \ldots, \mathbf{a}_{p}\) are orthogonal to \(\mathbf{a}_{1}\), they must have both positive and negative elements. When all elements of \(a_{1}\) are positive, the first component is a weighted average of the variables and is sometimes referred to as a measure of size. Likewise, the positive and negative coefficients in subsequent components may be regarded as defining shape. This pattern is often seen when the variables are various measurements of an organism.

■ EXAMPLE 12.8.1
In the modified football data of Example 12.2.2, there are a few negative covariances in \(\mathbf{S}\), but they are small, and all elements of the first eigenvector remain positive. The second eigenvector therefore has positive and negative elements:
\begin{tabular}{lcr}
\multicolumn{3}{c}{ First Two Eigenvectors } \\
& \(\mathbf{a}_{1}\) & \(\mathbf{a}_{2}\) \\
\hline WDIM & .207 & -.142 \\
CIRCUM & .873 & -.219 \\
FBEYE & .261 & -.231 \\
EYEHD & .326 & .891 \\
EARHD & .066 & .222 \\
JAW & .128 & -.187
\end{tabular}

With all positive coefficients, the first component \(z_{1}\) is an overall measure of head size ( \(z_{1}\) increases if all six variables increase). The second component \(z_{2}\) is a shape component that contrasts the vertical measurements EYEHD and EARHD with the three lateral measurements and CIRCUM ( \(z_{2}\) increases if EYEHD and EARHD increase and the other four variables decrease).

\subsection*{12.8.2 Rotation}

The principal components are initially obtained by rotating axes in order to line up with the natural extensions of the system, whereupon the new variables become uncorrelated and reflect the directions of maximum variance. If the resulting components do not have a satisfactory interpretation, they can be further rotated, seeking dimensions in which many of the coefficients of the linear combinations are near zero to simplify interpretation.

However, the new rotated components are correlated, and they do not successively account for maximum variance. They are therefore no longer principal components in the usual sense, and their routine use is questionable. For improved interpretation, one may wish to try factor analysis (Chapter 13), in which rotation does not destroy any properties. (In factor analysis, the rotation does not involve the variables \(y_{1}, y_{2}, \ldots, y_{p}\), but another space, that of the factor loadings.)

\subsection*{12.8.3 Correlations Between Variables and Principal Components}

The use of correlations between variables and principal components is widely recommended as an aid to interpretation. It was noted in Sections 8.7.3 and 11.5.2 that analogous correlations for discriminant functions and canonical variates are not useful in a multivariate context because they provide only univariate information about how each variable operates by itself, ignoring the other variables. Rencher (1992b) obtained a similar result for principal components.

We denote the correlation between the \(i\) th variable \(y_{i}\) and the \(j\) th principal component \(z_{j}\) by \(r_{y_{i} z_{j}}\). Because of the orthogonality of the \(z_{j}\) 's, we have the simple relationship
\[
\begin{equation*}
r_{y_{i} z_{1}}^{2}+r_{y_{i} z_{2}}^{2}+\cdots+r_{y_{i} z_{k}}^{2}=R_{y_{i} \mid z_{1}, \ldots, z_{k}}^{2}, \tag{12.19}
\end{equation*}
\]
where \(k\) is the number of components retained and \(R_{y_{i} \mid z_{1}, \ldots, z_{k}}^{2}\) is the squared multiple correlation of \(y_{i}\) with the \(z_{j}\) 's. Thus \(r_{y_{i} z_{j}}^{2}\) forms part of \(R_{y_{i} \mid z_{1}, \ldots, z_{k}}^{2}\), which shows how \(y_{i}\) relates to the \(z\) 's by itself, not what it contributes in the presence of the other

Table 12.5 Eigenvectors Obtained from S, Correlations Between Variables and Principal Components, and \(R^{2}\) for the First Two Principal Components
\begin{tabular}{|c|c|c|c|c|c|}
\hline \multirow[b]{2}{*}{Variable} & \multicolumn{2}{|l|}{Eigenvectors from \(S\)} & \multicolumn{2}{|l|}{Correlations} & \multirow[b]{2}{*}{\(R_{y_{i} \mid z_{1}, z_{2}}^{2}\)} \\
\hline & \(\mathbf{a}_{1}\) & \(\mathrm{a}_{2}\) & \(r_{y_{i} z_{1}}\) & \(r_{y_{i} z_{2}}\) & \\
\hline 1 & . 21 & --. 14 & . 62 & -. 27 & . 46 \\
\hline 2 & . 87 & -. 22 & . 98 & -. 16 & . 99 \\
\hline 3 & . 26 & -. 23 & . 70 & -. 40 & . 66 \\
\hline 4 & . 33 & . 89 & . 49 & . 86 & . 98 \\
\hline 5 & . 07 & . 22 & . 17 & . 37 & . 17 \\
\hline 6 & . 13 & -. 19 & . 41 & \(-.39\) & . 32 \\
\hline
\end{tabular}
\(y\) 's. The correlations are therefore not informative about the joint contribution of the \(y\) 's in a principal component.

Note that the simple partitioning of \(R^{2}\) into the sum of squares of correlations in (12.19) does not happen in practice when the independent variables ( \(x\) 's) are correlated. However, here the \(z\) 's are principal components and are therefore orthogonal.

Since we do not recommend rotation or correlations for interpretation, we are left with the coefficients themselves, obtained from the eigenvectors of either \(\mathbf{S}\) or \(\mathbf{R}\).

\section*{EXAMPLE 12.8.3}

In Example 12.8.1, the eigenvectors of \(\mathbf{S}\) from the modified football data gave a satisfactory interpretation of the first two principal components as head size and shape. We give these in Table 12.5, along with the correlations between each of the variables \(y_{1}, y_{2}, \ldots, y_{6}\) and the first two principal components \(z_{1}\) and \(z_{2}\). For comparison we also give \(R_{y_{i} \mid z_{1}, z_{2}}^{2}\) for each variable.

The correlations rank the variables somewhat differently in their contribution to the components, since they form part of the univariate information provided by \(R^{2}\) for each variable by itself. For example, for the first component, the correlations rank the variables in the order \(2,3,1,4,6,5\), whereas the coefficients (eigenvectors) from \(S\) rank them in the order \(2,4,3,1,6,5\).

\subsection*{12.9 SELECTION OF VARIABLES}

We have previously discussed subset selection in connection with Wilks' \(\Lambda\) (Section 6.11.2), discriminant analysis (Section 8.9), classification analysis (Section 9.6), and regression (Sections 10.2.7 and 10.8). In each case the criterion for selection of variables was the relationship of the variables to some external factor, such as dependent variable(s), separation of groups, or correct classification rates. In the context of principal components, we have no dependent variable, as in regression, and no groupings among the observations, as in discriminant analysis. With no external in-
fluence, we simply wish to find the subset that best captures the internal variation (and covariation) of the variables.

Jolliffe (1972, 1973) discussed eight selection methods and referred to the process as discarding variables. The eight methods were based on three basic approaches: multiple correlation, clustering of variables, and principal components. One of the correlation methods, for example, proceeds in a stepwise fashion, deleting at each step the variable that has the largest multiple correlation with the other variables. The clustering methods partition the variables into groups or clusters and select a variable from each cluster.

We describe Jolliffe's principal component methods in the context of selecting a subset of 10 variables out of 50 variables. One of his techniques associates a variable with each of the first 10 principal components and retains these 10 variables. Another approach is to associate a variable with each of the last 40 principal components and delete the 40 variables. To associate a variable with a principal component, we choose the variable corresponding to the largest coefficient (in absolute value) in the component, providing the variable has not previously been selected. We can use components extracted from either \(\mathbf{S}\) or \(\mathbf{R}\). For example, in the two principal components for the football data in Example 12.2.2, we would choose variables 2 and 4, which clearly have the largest coefficients in the two components. Jolliffe's methods could also be applied iteratively, with the principal components being recomputed after a variable is retained or deleted.

Jolliffe (1972) compared the eight methods using both real and simulated data and found that the methods based on principal components performed well in comparison to the regression and cluster-based methods. But he concluded that no single method was uniformly best.

McCabe (1984) suggested several criteria for selection, most of which are based on the conditional covariance matrix of the variables not selected, given those selected. He denoted the selected variables as principal variables. Let \(y\) be partitioned as
\[
\mathbf{y}=\binom{\mathbf{y}_{1}}{\mathbf{y}_{2}}
\]
where \(y_{1}\) contains the selected variables and \(y_{2}\) consists of the variables not selected. The corresponding covariance matrix is
\[
\operatorname{cov}(\mathbf{y})=\boldsymbol{\Sigma}=\left(\begin{array}{ll}
\boldsymbol{\Sigma}_{11} & \boldsymbol{\Sigma}_{12} \\
\boldsymbol{\Sigma}_{21} & \boldsymbol{\Sigma}_{22}
\end{array}\right) .
\]

By (4.8), the conditional covariance matrix is given by (assuming normality)
\[
\operatorname{cov}\left(\mathbf{y}_{2} \mid \mathbf{y}_{1}\right)=\boldsymbol{\Sigma}_{22}-\boldsymbol{\Sigma}_{21} \boldsymbol{\Sigma}_{\mathbf{1 1}}^{-1} \boldsymbol{\Sigma}_{12}
\]
which is estimated by \(\mathbf{S}_{22}-\mathbf{S}_{21} \mathbf{S}_{11}^{-1} \mathbf{S}_{12}\). To find a subset \(\mathbf{y}_{1}\) of size \(m\), two of McCabe's criteria are to choose the subset \(\mathbf{y}_{1}\) that
1. Minimizes \(\left|\mathbf{S}_{22}-\mathbf{S}_{21} \mathbf{S}_{11}^{-1} \mathbf{S}_{12}\right|\) and
2. Maximizes \(\sum_{i=1}^{m^{*}} r_{i}^{2}\), where \(r_{i}, i=1,2, \ldots, m^{*}=\min (m, p-m)\) are the canonical correlations between the \(m\) selected variables in \(\mathbf{y}_{1}\) and the \(p-m\) deleted variables in \(\mathbf{y}_{2}\).

Ideally, these criteria would be evaluated for all possible subsets so as to obtain the best subset of each size. McCabe suggested a regression approach for obtaining a percent of variance explained by a subset of variables to be compared with the percent of variance accounted for by the same number of principal components.

\section*{PROBLEMS}
12.1 Show that the solutions to \(\lambda=\mathbf{a}^{\prime} \mathbf{S a} / \mathbf{a}^{\prime} \mathbf{a}\) in (12.7) are given by the eigenvalues and eigenvectors in (12.8), so that \(\lambda\) in (12.7) is maximized by the largest eigenvalue of \(S\).
12.2 Show that the eigenvalues of
\[
\mathbf{R}=\left(\begin{array}{ll}
1 & r \\
r & 1
\end{array}\right)
\]
are \(1 \pm r\), as in (12.13), and that the eigenvectors are as given in (12.14).
12.3 (a) Give a justification based on the likelihood ratio for the test statistic \(u\) in (12.15).
(b) Give a justification for the degrees of freedom \(\nu=\frac{1}{2}(k-1)(k+2)\) for the test statistic in (12.15).
12.4 Show that when \(\mathbf{S}\) is diagonal as in (12.16), the eigenvectors have the form \(\mathbf{a}_{i}^{\prime}=(0, \ldots, 0,1,0, \ldots, 0)\), as given in (12.18).
12.5 Show that \(r_{y_{i} z_{1}}^{2}+r_{y_{i} z_{2}}^{2}+\cdots+r_{y_{i} z_{k}}^{2}=R_{y_{i} \mid z_{1}, \ldots, z_{k}}^{2}\), as in (12.19).
12.6 Carry out a principal component analysis of the diabetes data of Table 3.5. Use all five variables, including \(y\) 's and \(x\) 's. Use both \(\mathbf{S}\) and \(\mathbf{R}\). Which do you think is more appropriate here? Show the percent of variance explained. Based on the average eigenvalue or a scree plot, decide how many components to retain. Can you interpret the components of either \(\mathbf{S}\) or \(\mathbf{R}\) ?
12.7 Do a principal component analysis of the probe word data of Table 3.6. Use both \(S\) and \(\mathbf{R}\). Which do you think is more appropriate here? Show the percent of variance explained. Based on the average eigenvalue or a scree plot, decide how many components to retain. Can you interpret the components of either \(\mathbf{S}\) or \(\mathbf{R}\) ?
12.8 Carry out a principal component analysis on all six variables of the glucose data of Table 3.9. Use both \(\mathbf{S}\) and \(\mathbf{R}\). Which do you think is more appropriate here? Show the percent of variance explained. Based on the average
eigenvalue or a scree plot, decide how many components to retain. Can you interpret the components of either \(\mathbf{S}\) or \(\mathbf{R}\) ?
12.9 Carry out a principal component analysis on the hematology data of Table 4.2. Use both \(\mathbf{S}\) and \(\mathbf{R}\). Which do you think is more appropriate here? Show the percent of variance explained. Based on the average eigenvalue or a scree plot, decide how many components to retain. Can you interpret the components of either \(\mathbf{S}\) or \(\mathbf{R}\) ? Does the large variance of \(y_{3}\) affect the pattern of the components of \(S\) ?
12.10 Carry out a principal component analysis separately for males and females in the psychological data of Table 5.1. Compare the results for the two groups. Use \(\mathbf{S}\).
12.11 Carry out a principal component analysis separately for the two species in the beetle data of Table 5.5. Compare the results for the two groups. Use S.
12.12 Carry out a principal component analysis on the engineer data of Table 5.6 as follows:
(a) Use the pooled covariance matrix.
(b) Ignore groups and use a covariance matrix based on all 40 observations.
(c) Which of the approaches in (a) or (b) appears to be more successful?
12.13 Repeat the previous problem for the dystrophy data of Table 5.7.
12.14 Carry out a principal component analysis on all 10 variables of the Seishu data of Table 7.1. Use both \(\mathbf{S}\) and \(\mathbf{R}\). Which do you think is more appropriate here? Show the percent of variance explained. Based on the average eigenvalue or a scree plot, decide how many components to retain. Can you interpret the components of either \(\mathbf{S}\) or \(\mathbf{R}\) ?
12.15 Carry out a principal component analysis on the temperature data of Table 7.2. Use both \(\mathbf{S}\) and \(\mathbf{R}\). Which do you think is more appropriate here? Show the percent of variance explained. Based on the average eigenvalue or a scree plot, decide how many components to retain. Can you interpret the components of either \(\mathbf{S}\) or \(\mathbf{R}\) ?

\section*{CHAPTER 13}

\section*{EXPLORATORY FACTOR ANALYSIS}

\subsection*{13.1 INTRODUCTION}

In factor analysis we represent the variables \(y_{1}, y_{2}, \ldots, y_{p}\) as linear combinations of a few random variables \(f_{1}, f_{2}, \ldots, f_{m}(m<p)\) called factors. The factors are underlying constructs or latent variables that "generate" the \(y\) 's. Like the original variables, the factors vary from individual to individual; but unlike the variables, the factors cannot be measured or observed. The existence of these hypothetical variables is therefore open to question.

If the original variables \(y_{1}, y_{2}, \ldots, y_{p}\) are at least moderately correlated, the basic dimensionality of the system is less than \(p\). The goal of factor analysis is to reduce the redundancy among the variables by using a smaller number of factors.

Suppose the pattern of the high and low correlations in the correlation matrix is such that the variables in a particular subset have high correlations among themselves but low correlations with all the other variables. Then there may be a single underlying factor that gave rise to the variables in the subset. If the other variables can be similarly grouped into subsets with a like pattern of correlations, then a few factors can represent these groups of variables. In this case the pattern in the correlation ma-
trix corresponds directly to the factors. For example, suppose the correlation matrix has the form
\[
\left(\begin{array}{rrrrr}
1 & .9 & .05 & .05 & .05 \\
.9 & 1 & .05 & .05 & .05 \\
.05 & .05 & 1 & .9 & .9 \\
.05 & .05 & .9 & 1 & .9 \\
.05 & .05 & .9 & .9 & 1
\end{array}\right)
\]

Then variables 1 and 2 correspond to a factor and variables 3,4 , and 5 correspond to another factor. In some cases where the correlation matrix does not have such a simple pattern, factor analysis will still partition the variables into clusters.

Factor analysis is related to principal component analysis in that both seek a simpler structure in a set of variables, but they differ in many respects (see Section 13.8). For example, two differences in basic approach are as follows:
1. Principal components are defined as linear combinations of the original variables. In factor analysis, the original variables are expressed as linear combinations of the factors.
2. In principal component analysis, we explain a large part of the total variance of the variables, \(\sum_{i} s_{i i}\). In factor analysis, we seek to account for the covariances or correlations among the variables.

Although we have thus far compared principal component analysis with "factor analysis," we can draw further distinctions between the exploratory factor analysis described in this chapter and the confirmatory factor analysis that will be discussed in Chapter 14. Exploratory factor analysis (or EFA) is most often used to explore multivariate data to identify possible latent structure. In EFA, the number of latent factors is not determined before the analysis. In contrast, confirmatory factor analysis (or CFA) allows the researcher to hypothesize the number of latent factors and the specific nature of the latent structure in the data, and then test the hypotheses that have been formulated. Thus the objectives and methods of EFA are more closely related to those of principal component analysis, while CFA uses the more traditional statistical notions of model formulation, parameter estimation, model evaluation, and statistical inference. Because of the subjectivity and relative lack of formal statistical inference associated with EFA, it is considered by some to be controversial or of limited utility. Regardless, EFA has proven to be a useful tool in many settings, particularly as a technique for simplifying complex multivariate data and formulating hypotheses that can be later verified by using a CFA on an independently obtained data set (see Gerbing and Hamilton, 1996).

For either type of factor analysis, there will be some data sets for which the factor analysis model does not provide a satisfactory fit. Sometimes a few easily interpretable factors emerge, but for other data sets neither the number of factors nor the interpretation is clear. Some possible reasons for these failures are discussed in Section 13.7.

In this chapter, we describe the methods associated with exploratory factor analysis. Throughout this chapter, we will use "exploratory factor analysis" and "factor analysis" interchangeably.

\subsection*{13.2 ORTHOGONAL FACTOR MODEL}

\subsection*{13.2.1 Model Definition and Assumptions}

Factor analysis is basically a one-sample procedure [for possible applications to data with groups, see Rencher (1998, Section 10.8)]. We assume a random sample \(\mathbf{y}_{1}, \mathbf{y}_{2}, \ldots, \mathbf{y}_{n}\) from a homogeneous population with mean vector \(\boldsymbol{\mu}\) and covariance matrix \(\boldsymbol{\Sigma}\).

The factor analysis model expresses each variable as a linear combination of underlying common factors \(f_{1}, f_{2}, \ldots, f_{m}\), with an accompanying error term to account for that part of the variable that is unique (not in common with the other variables). For \(y_{1}, y_{2}, \ldots, y_{p}\) in any observation vector \(\mathbf{y}\), the model is as follows:
\[
\begin{align*}
y_{1}-\mu_{1} & =\lambda_{11} f_{1}+\lambda_{12} f_{2}+\cdots+\lambda_{1 m} f_{m}+\varepsilon_{1} \\
y_{2}-\mu_{2} & =\lambda_{21} f_{1}+\lambda_{22} f_{2}+\cdots+\lambda_{2 m} f_{m}+\varepsilon_{2}  \tag{13.1}\\
& \vdots \\
y_{p}-\mu_{p} & =\lambda_{p 1} f_{1}+\lambda_{p 2} f_{2}+\cdots+\lambda_{p m} f_{m}+\varepsilon_{p}
\end{align*}
\]

Ideally, \(m\) should be substantially smaller than \(p\); otherwise we have not achieved a parsimonious description of the variables as functions of a few underlying factors. We might regard the \(f\) 's in (13.1) as random variables that engender the \(y\) 's. The coefficients \(\lambda_{i j}\) are called loadings and serve as weights, showing how each \(y_{i}\) individually depends on the \(f\) 's. (In this chapter, we defer to common usage in the factor analysis literature and use the notation \(\lambda_{i j}\) for loadings rather than eigenvalues.) With appropriate assumptions, \(\lambda_{i j}\) indicates the importance of the \(j\) th factor \(f_{j}\) to the \(i\) th variable \(y_{i}\) and can be used in interpretation of \(f_{j}\). We describe or interpret \(f_{2}\), for example, by examining its coefficients, \(\lambda_{12}, \lambda_{22}, \ldots, \lambda_{p 2}\). The larger loadings relate \(f_{2}\) to the corresponding \(y\) 's. From these \(y\) 's, we infer a meaning or description of \(f_{2}\). After estimating the \(\lambda_{i j}\) 's (and rotating them, see Sections 13.2.2 and 13.5), they will hopefully partition the variables into groups corresponding to factors.

The system of equations (13.1) bears a superficial resemblance to the multiple regression model (10.1), but there are fundamental differences. For example, (1) the \(f\) 's are unobserved and (2) the model in (13.1) represents only one observation vector, while (10.1) depicts all \(n\) observations.

It is assumed that for \(j=1,2, \ldots, m, E\left(f_{j}\right)=0, \operatorname{var}\left(f_{j}\right)=1\), and \(\operatorname{cov}\left(f_{j}, f_{k}\right)=\) \(0, j \neq k\). The assumptions for \(\varepsilon_{i}, i=1,2, \ldots, p\), are similar, except that we must allow each \(\varepsilon_{i}\) to have a different variance, since it shows the residual part of \(y_{i}\) that is not in common with the other variables. Thus we assume that \(E\left(\varepsilon_{i}\right)=0, \operatorname{var}\left(\varepsilon_{i}\right)=\) \(\psi_{i}\), and \(\operatorname{cov}\left(\varepsilon_{i}, \varepsilon_{k}\right)=0, i \neq k\). In addition, we assume that \(\operatorname{cov}\left(\varepsilon_{i}, f_{j}\right)=0\) for all \(i\) and \(j\). We refer to \(\psi_{i}\) as the specific variance.

These assumptions are natural consequences of the basic model (13.1) and the goals of factor analysis. Since \(E\left(y_{i}-\mu_{i}\right)=0\), we need \(E\left(f_{j}\right)=0, j=1,2, \ldots, m\). The assumption \(\operatorname{cov}\left(f_{j}, f_{k}\right)=0\) is made for parsimony in expressing the \(y\) 's as functions of as few factors as possible. The assumptions \(\operatorname{var}\left(f_{j}\right)=1, \operatorname{var}\left(\varepsilon_{i}\right)=\psi_{i}\), \(\operatorname{cov}\left(f_{j}, f_{k}\right)=0\), and \(\operatorname{cov}\left(\varepsilon_{i}, f_{j}\right)=0\) yield a simple expression for the variance of \(y_{i}\),
\[
\begin{equation*}
\operatorname{var}\left(y_{i}\right)=\lambda_{i 1}^{2}+\lambda_{i 2}^{2}+\cdots+\lambda_{i m}^{2}+\psi_{i} \tag{13.2}
\end{equation*}
\]
which plays an important role in our development. The assumption \(\operatorname{cov}\left(\varepsilon_{i}, \varepsilon_{k}\right)=0\) implies that the factors account for all the correlations among the \(y\) 's, that is, all that the \(y\) 's have in common. Thus the emphasis in factor analysis is on modeling the covariances or correlations among the \(y\) 's.

Model (13.1) can be written in matrix notation as
\[
\begin{equation*}
\mathbf{y}-\boldsymbol{\mu}=\mathbf{\Lambda f}+\boldsymbol{\varepsilon} \tag{13.3}
\end{equation*}
\]
where \(\mathbf{y}=\left(y_{1}, y_{2}, \ldots, y_{p}\right)^{\prime}, \boldsymbol{\mu}=\left(\mu_{1}, \mu_{2}, \ldots, \mu_{p}\right)^{\prime}, \mathbf{f}=\left(f_{1}, f_{2}, \ldots, f_{m}\right)^{\prime}, \boldsymbol{\varepsilon}=\) \(\left(\varepsilon_{1}, \varepsilon_{2}, \ldots, \varepsilon_{p}\right)^{\prime}\), and
\[
\boldsymbol{\Lambda}=\left(\begin{array}{cccc}
\lambda_{11} & \lambda_{12} & \cdots & \lambda_{1 m}  \tag{13.4}\\
\lambda_{21} & \lambda_{22} & \cdots & \lambda_{2 m} \\
\vdots & \vdots & & \vdots \\
\lambda_{p 1} & \lambda_{p 2} & \cdots & \lambda_{p m}
\end{array}\right)
\]

We illustrate the model in (13.1) and (13.3) with \(p=5\) and \(m=2\). The model for each variable in (13.1) becomes
\[
\begin{aligned}
y_{1}-\mu_{1} & =\lambda_{11} f_{1}+\lambda_{12} f_{2}+\varepsilon_{1} \\
y_{2}-\mu_{2} & =\lambda_{21} f_{1}+\lambda_{22} f_{2}+\varepsilon_{2} \\
y_{3}-\mu_{3} & =\lambda_{31} f_{1}+\lambda_{32} f_{2}+\varepsilon_{3} \\
y_{4}-\mu_{4} & =\lambda_{41} f_{1}+\lambda_{42} f_{2}+\varepsilon_{4} \\
y_{5}-\mu_{5} & =\lambda_{51} f_{1}+\lambda_{52} f_{2}+\varepsilon_{5} .
\end{aligned}
\]

In matrix notation as in (13.3), this becomes
\[
\left(\begin{array}{c}
y_{1}-\mu_{1}  \tag{13.5}\\
y_{2}-\mu_{2} \\
y_{3}-\mu_{3} \\
y_{4}-\mu_{4} \\
y_{5}-\mu_{5}
\end{array}\right)=\left(\begin{array}{cc}
\lambda_{11} & \lambda_{12} \\
\lambda_{21} & \lambda_{22} \\
\lambda_{31} & \lambda_{32} \\
\lambda_{41} & \lambda_{42} \\
\lambda_{51} & \lambda_{52}
\end{array}\right)\binom{f_{1}}{f_{2}}+\left(\begin{array}{l}
\varepsilon_{1} \\
\varepsilon_{2} \\
\varepsilon_{3} \\
\varepsilon_{4} \\
\varepsilon_{5}
\end{array}\right),
\]
or \(\mathbf{y}-\boldsymbol{\mu}=\boldsymbol{\Lambda} \mathbf{f}+\boldsymbol{\varepsilon}\).
The assumptions described above between (13.1) and (13.2) can be expressed concisely using vector and matrix notation:
\(E\left(f_{j}\right)=0, j=1,2, \ldots, m\), becomes
\[
\begin{equation*}
E(\mathbf{f})=\mathbf{0} \tag{13.6}
\end{equation*}
\]
\(\operatorname{var}\left(f_{j}\right)=1, j=1,2, \ldots, m\), and \(\operatorname{cov}\left(f_{j}, f_{k}\right)=0, j \neq k\), become
\[
\begin{equation*}
\operatorname{cov}(\mathbf{f})=\mathbf{I}, \tag{13.7}
\end{equation*}
\]
\(E\left(\varepsilon_{i}\right)=0, i=1,2, \ldots, p\), becomes
\[
\begin{equation*}
E(\varepsilon)=\mathbf{0} \tag{13.8}
\end{equation*}
\]
\(\operatorname{var}\left(\varepsilon_{i}\right)=\psi_{i}, i=1,2, \ldots, p\), and \(\operatorname{cov}\left(\varepsilon_{i}, \varepsilon_{k}\right)=0, i \neq k\), become
\[
\operatorname{cov}(\varepsilon)=\boldsymbol{\Psi}=\left(\begin{array}{cccc}
\psi_{1} & 0 & \cdots & 0  \tag{13.9}\\
0 & \psi_{2} & \cdots & 0 \\
\vdots & \vdots & & \vdots \\
0 & 0 & \cdots & \psi_{p}
\end{array}\right)
\]
and \(\operatorname{cov}\left(\varepsilon_{i}, f_{j}\right)=0\) for all \(i\) and \(j\) becomes
\[
\begin{equation*}
\operatorname{cov}(\mathbf{f}, \boldsymbol{\varepsilon})=\mathbf{O} \tag{13.10}
\end{equation*}
\]

The notation \(\operatorname{cov}(\mathbf{f}, \varepsilon)\) indicates a rectangular matrix containing the covariances of the \(f\) 's with the \(\varepsilon\) 's:
\[
\operatorname{cov}(\mathbf{f}, \boldsymbol{\varepsilon})=\left(\begin{array}{cccc}
\sigma_{f_{1} \varepsilon_{1}} & \sigma_{f_{1} \varepsilon_{2}} & \cdots & \sigma_{f_{1} \varepsilon_{p}} \\
\sigma_{f_{2} \varepsilon_{1}} & \sigma_{f_{2} \varepsilon_{2}} & \cdots & \sigma_{f_{2} \varepsilon_{p}} \\
\vdots & \vdots & & \vdots \\
\sigma_{f_{m} \varepsilon_{1}} & \sigma_{f_{m} \varepsilon_{2}} & \cdots & \sigma_{f_{m} \varepsilon_{p}}
\end{array}\right)
\]

It was noted following (13.2) that the emphasis in factor analysis is on modeling the covariances among the \(y\) 's. We wish to express the \(\frac{1}{2} p(p-1)\) covariances (and the \(p\) variances) of the variables \(y_{1}, y_{2}, \ldots, y_{p}\) in terms of a simplified structure involving the \(p m\) loadings \(\lambda_{i j}\) and the \(p\) specific variances \(\psi_{i}\); that is, we wish to express \(\boldsymbol{\Sigma}\) in terms of \(\boldsymbol{\Lambda}\) and \(\boldsymbol{\Psi}\). We can do this using the model (13.3) and the assumptions (13.7), (13.9), and (13.10). Since \(\mu\) does not affect variances and covariances of \(y\), we have from (13.3)
\[
\boldsymbol{\Sigma}=\operatorname{cov}(\mathbf{y})=\operatorname{cov}(\boldsymbol{\Lambda f}+\boldsymbol{\varepsilon})
\]

By (13.10), \(\boldsymbol{\Lambda f}\) and \(\varepsilon\) are uncorrelated; therefore, the covariance matrix of their sum is the sum of their covariance matrices:
\[
\begin{align*}
\boldsymbol{\Sigma} & =\operatorname{cov}(\boldsymbol{\Lambda} \mathbf{f})+\operatorname{cov}(\boldsymbol{\varepsilon}) \\
& =\boldsymbol{\Lambda} \operatorname{cov}(\mathbf{f}) \boldsymbol{\Lambda}^{\prime}+\boldsymbol{\Psi} \quad[\text { by }(3.74) \text { and (13.9) }] \\
& =\boldsymbol{\Lambda I} \mathbf{\Lambda}^{\prime}+\boldsymbol{\Psi} \quad[\text { by }(\mathbf{1 3 . 7})] \\
& =\boldsymbol{\Lambda} \mathbf{\Lambda}^{\prime}+\mathbf{\Psi} . \tag{13.11}
\end{align*}
\]

If \(\boldsymbol{\Lambda}\) has only a few columns, say two or three, then \(\boldsymbol{\Sigma}=\boldsymbol{\Lambda} \boldsymbol{\Lambda}^{\prime}+\boldsymbol{\Psi}\) in (13.11) represents a simplified structure for \(\boldsymbol{\Sigma}\), in which the covariances are modeled by the
\(\lambda_{i j}\) 's alone since \(\Psi\) is diagonal. For example, in the above illustration in (13.5) with \(m=2\) factors, \(\sigma_{12}\) would be the product of the first two rows of \(\boldsymbol{\Lambda}\), that is,
\[
\sigma_{12}=\operatorname{cov}\left(y_{1}, y_{2}\right)=\lambda_{11} \lambda_{21}+\lambda_{12} \lambda_{22},
\]
where \(\left(\lambda_{11}, \lambda_{12}\right)\) is the first row of \(\boldsymbol{\Lambda}\) and \(\left(\lambda_{21}, \lambda_{22}\right)\) is the second row of \(\boldsymbol{\Lambda}\). If \(y_{1}\) and \(y_{2}\) have a great deal in common, they will have similar loadings on the common factors \(f_{1}\) and \(f_{2}\); that is, \(\left(\lambda_{11}, \lambda_{12}\right)\) will be similar to \(\left(\lambda_{21}, \lambda_{22}\right)\). In this case, either \(\lambda_{11} \lambda_{21}\) or \(\lambda_{12} \lambda_{22}\) is likely to be high. On the other hand, if \(y_{1}\) and \(y_{2}\) have little in common, then their loadings \(\lambda_{11}\) and \(\lambda_{21}\) on \(f_{1}\) will be different and their loadings \(\lambda_{12}\) and \(\lambda_{22}\) on \(f_{2}\) will likewise differ. In this case, the products \(\lambda_{11} \lambda_{21}\) and \(\lambda_{12} \lambda_{22}\) will tend to be small.

We can also find the covariances of the \(y\) 's with the \(f\) 's in terms of the \(\lambda\) 's. Consider, for example, \(\operatorname{cov}\left(y_{1}, f_{2}\right)\). By (13.1), \(y_{1}-\mu_{1}=\lambda_{11} f_{1}+\lambda_{12} f_{2}+\cdots+\lambda_{1 m} f_{m}+\) \(\varepsilon_{1}\). From (13.7), \(f_{2}\) is uncorrelated with all other \(f_{j}\) 's, and by (13.10), \(f_{2}\) is uncorrelated with \(\varepsilon_{1}\). Thus
\[
\begin{aligned}
\operatorname{cov}\left(y_{1}, f_{2}\right) & =E\left[\left(y_{1}-\mu_{1}\right)\left(f_{2}-\mu_{f_{2}}\right)\right] \\
& =E\left[\left(\lambda_{11} f_{1}+\lambda_{12} f_{2}+\cdots+\lambda_{1 m} f_{m}\right) f_{2}\right] \\
& =E\left(\lambda_{11} f_{1} f_{2}+\lambda_{12} f_{2}^{2}+\cdots+\lambda_{1 m} f_{m} f_{2}\right) \\
& =\lambda_{11} \operatorname{cov}\left(f_{1}, f_{2}\right)+\lambda_{12} \operatorname{var}\left(f_{2}\right)+\cdots+\lambda_{1 m} \operatorname{cov}\left(f_{m}, f_{2}\right) \\
& =\lambda_{12}
\end{aligned}
\]
since \(\operatorname{var}\left(f_{2}\right)=1\). Hence the loadings themselves represent covariances of the variables with the factors. In general,
\[
\begin{equation*}
\operatorname{cov}\left(y_{i}, f_{j}\right)=\lambda_{i j}, \quad i=1,2, \ldots, p, \quad j=1,2, \ldots, m \tag{13.12}
\end{equation*}
\]

Since \(\lambda_{i j}\) is the \((i j)\) th element of \(\boldsymbol{\Lambda}\), we can write (13.12) in the form
\[
\begin{equation*}
\operatorname{cov}(\mathbf{y}, \mathbf{f})=\mathbf{\Lambda} \tag{13.13}
\end{equation*}
\]

If standardized variables are used, (13.11) is replaced by \(\mathbf{P}_{\rho}=\boldsymbol{\Lambda} \mathbf{\Lambda}^{\prime}+\boldsymbol{\Psi}\), and the loadings become correlations:
\[
\begin{equation*}
\operatorname{corr}\left(y_{i}, f_{j}\right)=\lambda_{i j} \tag{13.14}
\end{equation*}
\]

In (13.2), we have a partitioning of the variance of \(y_{i}\) into a component due to the common factors, called the communality, and a component unique to \(y_{i}\), called the specific variance:
\[
\begin{aligned}
\sigma_{i i}=\operatorname{var}\left(y_{i}\right) & =\left(\lambda_{i 1}^{2}+\lambda_{i 2}^{2}+\cdots+\lambda_{i m}^{2}\right)+\psi_{i} \\
& =h_{i}^{2}+\psi_{i} \\
& =\text { communality }+ \text { specific variance },
\end{aligned}
\]
where
\[
\begin{align*}
\text { Communality } & =h_{i}^{2}=\lambda_{i 1}^{2}+\lambda_{i 2}^{2}+\cdots+\lambda_{i m}^{2},  \tag{13.15}\\
\text { Specific variance } & =\psi_{i} .
\end{align*}
\]

The communality \(h_{i}^{2}\) is also referred to as common variance, and the specific variance \(\psi_{i}\) has been called specificity, unique variance, or residual variance.

Assumptions (13.6)-(13.10) lead to the simple covariance structure of (13.11), \(\boldsymbol{\Sigma}=\boldsymbol{\Lambda} \mathbf{\Lambda}^{\prime}+\boldsymbol{\Psi}\), which is an essential part of the factor analysis model. In schematic form, \(\boldsymbol{\Sigma}=\mathbf{\Lambda} \mathbf{\Lambda}^{\prime}+\boldsymbol{\Psi}\) has the following appearance:

The diagonal elements of \(\boldsymbol{\Sigma}\) can be easily modeled by adjusting the diagonal elements of \(\boldsymbol{\Psi}\), but \(\boldsymbol{\Lambda} \mathbf{\Lambda}^{\prime}\) is a simplified configuration for the off-diagonal elements. Hence the critical aspect of the model involves the covariances, and this is the major emphasis of factor analysis, as noted in Section 13.1 and in comments following (13.2) and (13.10).

It is a rare population covariance matrix \(\boldsymbol{\Sigma}\) that can be expressed exactly as \(\boldsymbol{\Sigma}=\boldsymbol{\Lambda} \mathbf{\Lambda}^{\prime}+\mathbf{\Psi}\), where \(\boldsymbol{\Psi}\) is diagonal and \(\boldsymbol{\Lambda}\) is \(p \times m\), with \(m\) relatively small. In practice, many sample covariance matrices do not come satisfactorily close to this ideal pattern. However, we do not relax the assumptions because the structure \(\boldsymbol{\Sigma}=\boldsymbol{\Lambda} \boldsymbol{\Lambda}^{\prime}+\boldsymbol{\Psi}\) is essential for estimation of \(\boldsymbol{\Lambda}\).

One advantage of the factor analysis model is that when it does not fit the data, the estimate of \(\boldsymbol{\Lambda}\) clearly reflects this failure. In such cases, there are two problems in the estimates: (1) it is unclear how many factors there should be, and (2) it is unclear what the factors are. In other statistical procedures, failure of assumptions may not lead to such obvious consequences in the estimates or tests. In factor analysis, the assumptions are essentially self-checking, whereas in other procedures, we typically have to check the assumptions with residual plots, tests, and so on.

\subsection*{13.2.2 Nonuniqueness of Factor Loadings}

The loadings in the model (13.3) can be multiplied by an orthogonal matrix without impairing their ability to reproduce the covariance matrix in \(\boldsymbol{\Sigma}=\boldsymbol{\Lambda} \boldsymbol{\Lambda}^{\prime}+\boldsymbol{\Psi}\). To see this, let \(\mathbf{T}\) be an arbitrary orthogonal matrix. Then by (2.102), \(\mathbf{T \mathbf { T } ^ { \prime }}=\mathbf{I}\), and we can insert \(\mathbf{T T}^{\prime}\) into the basic model (13.3) to obtain
\[
\mathbf{y}-\boldsymbol{\mu}=\boldsymbol{\Lambda} \mathbf{T} \mathbf{T}^{\prime} \mathbf{f}+\boldsymbol{\varepsilon}
\]

We then associate \(\mathbf{T}\) with \(\boldsymbol{\Lambda}\) and associate \(\mathbf{T}^{\prime}\) with \(\mathbf{f}\) so that the model becomes
\[
\begin{equation*}
\mathbf{y}-\boldsymbol{\mu}=\mathbf{\Lambda}^{*} \mathbf{f}^{*}+\varepsilon \tag{13.16}
\end{equation*}
\]
where
\[
\begin{align*}
\mathbf{\Lambda}^{*} & =\mathbf{\Lambda} \mathbf{T}  \tag{13.17}\\
\mathbf{f}^{*} & =\mathbf{T}^{\prime} \mathbf{f} \tag{13.18}
\end{align*}
\]

If \(\boldsymbol{\Lambda}\) in \(\boldsymbol{\Sigma}=\boldsymbol{\Lambda} \boldsymbol{\Lambda}^{\prime}+\boldsymbol{\Psi}\) is replaced by \(\boldsymbol{\Lambda}^{*}=\boldsymbol{\Lambda} \mathbf{T}\), we have
\[
\begin{aligned}
\boldsymbol{\Sigma} & =\boldsymbol{\Lambda}^{*} \boldsymbol{\Lambda}^{*^{\prime}}+\boldsymbol{\Psi}=\mathbf{\Lambda} \mathbf{T}(\mathbf{\Lambda} \mathbf{T})^{\prime}+\boldsymbol{\Psi} \\
& =\boldsymbol{\Lambda} \mathbf{T} \mathbf{T}^{\prime} \boldsymbol{\Lambda}^{\prime}+\boldsymbol{\Psi}=\boldsymbol{\Lambda} \mathbf{\Lambda}^{\prime}+\boldsymbol{\Psi}
\end{aligned}
\]
since \(\mathbf{T T} \mathbf{T}^{\prime}=\mathbf{I}\). Thus the new loadings \(\boldsymbol{\Lambda}^{*}=\boldsymbol{\Lambda T}\) in (13.17) reproduce the covariance matrix, just as \(\boldsymbol{\Lambda}\) does in (13.11):
\[
\begin{equation*}
\boldsymbol{\Sigma}=\mathbf{\Lambda}^{*} \boldsymbol{\Lambda}^{*^{\prime}}+\boldsymbol{\Psi}=\boldsymbol{\Lambda} \mathbf{\Lambda}^{\prime}+\boldsymbol{\Psi} \tag{13.19}
\end{equation*}
\]

The new factors \(\mathbf{f}^{*}=\mathbf{T}^{\prime} \mathbf{f}\) in (13.18) satisfy the assumptions (13.6), (13.7), and (13.10); that is, \(E\left(\mathbf{f}^{*}\right)=\mathbf{0}, \operatorname{cov}\left(\mathbf{f}^{*}\right)=\mathbf{I}\), and \(\operatorname{cov}\left(\mathbf{f}^{*}, \boldsymbol{\varepsilon}\right)=\mathbf{O}\).

The communalities \(h_{i}^{2}=\lambda_{i 1}^{2}+\lambda_{i 2}^{2}+\cdots+\lambda_{i m}^{2}, i=1,2, \ldots, p\), as defined in (13.15), are also unaffected by the transformation \(\boldsymbol{\Lambda}^{*}=\Lambda \mathbf{T}\). This can be seen as follows. The communality \(h_{i}^{2}\) is the sum of squares of the \(i\) th row of \(\Lambda\). If we denote the \(i\) th row of \(\boldsymbol{\Lambda}\) by \(\boldsymbol{\lambda}_{i}^{\prime}\), then the sum of squares in vector notation is \(h_{i}^{2}=\boldsymbol{\lambda}_{i}^{\prime} \boldsymbol{\lambda}_{i}\). The \(i\) th row of \(\Lambda^{*}=\Lambda \mathbf{T}\) is \(\lambda_{i}^{*^{\prime}}=\lambda_{i}^{\prime} \mathbf{T}\), and the corresponding communality is
\[
h_{i}^{* 2}=\boldsymbol{\lambda}_{i}^{*^{\prime}} \boldsymbol{\lambda}_{i}^{*}=\boldsymbol{\lambda}_{i}^{\prime} \mathbf{T} \mathbf{T}^{\prime} \boldsymbol{\lambda}_{i}=\boldsymbol{\lambda}_{i}^{\prime} \boldsymbol{\lambda}_{i}=h_{i}^{2}
\]

Thus the communalities remain the same for the new loadings. Note that \(h_{i}^{2}=\) \(\lambda_{i 1}^{2}+\lambda_{i 2}^{2}+\cdots+\lambda_{i m}^{2}=\boldsymbol{\lambda}_{i}^{\prime} \boldsymbol{\lambda}_{i}\) is the distance from the origin to the point \(\boldsymbol{\lambda}_{i}^{\prime}=\) \(\left(\lambda_{i 1}, \lambda_{i 2}, \ldots, \lambda_{i m}\right)\) in the \(m\)-dimensional space of the factor loadings. Since the distance \(\boldsymbol{\lambda}_{i}^{\prime} \boldsymbol{\lambda}_{i}\) is the same as \(\boldsymbol{\lambda}_{i}^{*^{\prime}} \boldsymbol{\lambda}_{i}^{*}\), the points \(\boldsymbol{\lambda}_{i}^{*}\) are rotated from the points \(\boldsymbol{\lambda}_{i}\). [This also follows because \(\boldsymbol{\lambda}_{i}^{*^{\prime}}=\boldsymbol{\lambda}_{i}^{\prime} \mathbf{T}\), where T is orthogonal. Multiplication of a vector by an orthogonal matrix is equivalent to a rotation of axes; see (2.103).]

The inherent potential to rotate the loadings to a new frame of reference without affecting any assumptions or properties is very useful in interpretation of the factors and will be exploited in Section 13.5.

Note that the coefficients (loadings) in (13.1) are applied to the factors, not to the variables, as they are in discriminant functions and principal components. Thus in factor analysis the observed variables are not involved in the rotation as they are in discriminant functions and principal components.

\subsection*{13.3 ESTIMATION OF LOADINGS AND COMMUNALITIES}

In Sections 13.3.1-13.3.4, we discuss four approaches to estimation of loadings and communalities.

\subsection*{13.3.1 Principal Component Method}

The first technique we consider is commonly called the principal component method. This name is perhaps unfortunate in that it adds to the confusion between factor analysis and principal component analysis. In the principal component method for estimation of loadings, we do not actually calculate any principal components. The reason for the name is given following (13.25).

From a random sample \(\mathbf{y}_{1}, \mathbf{y}_{2}, \ldots, \mathbf{y}_{n}\), we obtain the sample covariance matrix \(\mathbf{S}\) and then attempt to find an estimator \(\hat{\boldsymbol{\Lambda}}\) that will approximate the fundamental expression (13.11) with \(\mathbf{S}\) in place of \(\boldsymbol{\Sigma}\) :
\[
\begin{equation*}
\mathbf{S} \cong \hat{\boldsymbol{\Lambda}} \hat{\boldsymbol{\Lambda}}^{\prime}+\hat{\mathbf{\Psi}} \tag{13.20}
\end{equation*}
\]

In the principal component approach, we neglect \(\hat{\Psi}\) and factor \(\mathbf{S}\) into \(\mathbf{S}=\hat{\boldsymbol{\Lambda}} \hat{\boldsymbol{\Lambda}}^{\prime}\).
In order to factor \(\mathbf{S}\), we use the spectral decomposition in (2.109),
\[
\begin{equation*}
\mathbf{S}=\mathbf{C D C}^{\prime} \tag{13.21}
\end{equation*}
\]
where \(\mathbf{C}\) is an orthogonal matrix constructed with normalized eigenvectors ( \(\mathbf{c}_{i}^{\prime} \mathbf{c}_{i}=\) 1 ) of \(\mathbf{S}\) as columns and \(\mathbf{D}\) is a diagonal matrix with the eigenvalues \(\theta_{1}, \theta_{2}, \ldots, \theta_{p}\) of \(\mathbf{S}\) on the diagonal:
\[
\mathbf{D}=\left(\begin{array}{cccc}
\theta_{1} & 0 & \cdots & 0  \tag{13.22}\\
0 & \theta_{2} & \cdots & 0 \\
\vdots & \vdots & & \vdots \\
0 & 0 & \cdots & \theta_{p}
\end{array}\right)
\]

We use the notation \(\theta_{i}\) for eigenvalues instead of the usual \(\lambda_{i}\) in order to avoid confusion with the notation \(\lambda_{i j}\) used for the loadings.

To finish factoring \(\mathbf{C D C}^{\prime}\) in (13.21) into the form \(\hat{\boldsymbol{\Lambda}} \hat{\boldsymbol{\Lambda}}^{\prime}\), we observe that since the eigenvalues \(\theta_{i}\) of the positive semidefinite matrix \(\mathbf{S}\) are all positive or zero, we can factor \(\mathbf{D}\) into
\[
\mathbf{D}=\mathbf{D}^{1 / 2} \mathbf{D}^{1 / 2}
\]
where
\[
\mathbf{D}^{1 / 2}=\left(\begin{array}{cccc}
\sqrt{\theta_{1}} & 0 & \cdots & 0 \\
0 & \sqrt{\theta_{2}} & \cdots & 0 \\
\vdots & \vdots & & \vdots \\
0 & 0 & \cdots & \sqrt{\theta_{p}}
\end{array}\right)
\]

With this factoring of \(\mathbf{D}\), (13.21) becomes,
\[
\begin{align*}
\mathbf{S} & =\mathbf{C D C}^{\prime}=\mathbf{C D}^{1 / 2} \mathbf{D}^{1 / 2} \mathbf{C}^{\prime} \\
& =\left(\mathbf{C D}^{1 / 2}\right)\left(\mathbf{C D}^{1 / 2}\right)^{\prime} \tag{13.23}
\end{align*}
\]

This is of the form \(\mathbf{S}=\hat{\boldsymbol{\Lambda}} \hat{\boldsymbol{\Lambda}}^{\prime}\), but we do not define \(\hat{\boldsymbol{\Lambda}}\) to be \(\mathbf{C D}{ }^{1 / 2}\) because \(\mathbf{C D}{ }^{1 / 2}\) is \(p \times p\), and we are seeking a \(\hat{\boldsymbol{\Lambda}}\) that is \(p \times m\) with \(m<p\). We therefore define
\(\mathbf{D}_{1}=\operatorname{diag}\left(\theta_{1}, \theta_{2}, \ldots, \theta_{m}\right)\) with the \(m\) largest eigenvalues \(\theta_{1}>\theta_{2}>\cdots>\theta_{m}\) and \(\mathbf{C}_{1}=\left(\mathbf{c}_{1}, \mathbf{c}_{2}, \ldots, \mathbf{c}_{m}\right)\) containing the corresponding eigenvectors. We then estimate \(\boldsymbol{\Lambda}\) by the first \(m\) columns of \(\mathbf{C D}^{1 / 2}\),
\[
\begin{equation*}
\hat{\boldsymbol{\Lambda}}=\mathbf{C}_{1} \mathbf{D}_{1}^{1 / 2}=\left(\sqrt{\theta_{1}} \mathbf{c}_{1}, \sqrt{\theta_{2}} \mathbf{c}_{2}, \ldots, \sqrt{\theta_{m}} \mathbf{c}_{m}\right) \tag{13.24}
\end{equation*}
\]
by (2.56), where \(\hat{\boldsymbol{\Lambda}}\) is \(p \times m, \mathbf{C}_{1}\) is \(p \times m\), and \(\mathbf{D}_{1}^{1 / 2}\) is \(m \times m\).
We illustrate the structure of the \(\hat{\lambda}_{i j}\) in (13.24) for \(p=5\) and \(m=2\) :
\[
\begin{align*}
\left(\begin{array}{ll}
\hat{\lambda}_{11} & \hat{\lambda}_{12} \\
\hat{\lambda}_{21} & \hat{\lambda}_{22} \\
\hat{\lambda}_{31} & \hat{\lambda}_{32} \\
\hat{\lambda}_{41} & \hat{\lambda}_{42} \\
\hat{\lambda}_{51} & \hat{\lambda}_{52}
\end{array}\right) & =\left(\begin{array}{ll}
c_{11} & c_{12} \\
c_{21} & c_{22} \\
c_{31} & c_{32} \\
c_{41} & c_{42} \\
c_{51} & c_{52}
\end{array}\right)\left(\begin{array}{cc}
\sqrt{\theta_{1}} & 0 \\
0 & \sqrt{\theta_{2}}
\end{array}\right) \\
& =\left(\begin{array}{cc}
\sqrt{\theta_{1}} c_{11} & \sqrt{\theta_{2}} c_{12} \\
\sqrt{\theta_{1}} c_{21} & \sqrt{\theta_{2}} c_{22} \\
\sqrt{\theta_{1}} c_{31} & \sqrt{\theta_{2}} c_{32} \\
\sqrt{\theta_{1}} c_{41} & \sqrt{\theta_{2}} c_{42} \\
\sqrt{\theta_{1}} c_{51} & \sqrt{\theta_{2}} c_{52}
\end{array}\right) \quad[\mathrm{by}(2.56)] . \tag{13.25}
\end{align*}
\]

We can see in (13.25) the source of the term principal component solution. The columns of \(\hat{\Lambda}\) are proportional to the eigenvectors of \(\mathbf{S}\), so that the loadings on the \(j\) th factor are proportional to coefficients in the \(j\) th principal component. The factors are thus related to the first \(m\) principal components, and it would seem that interpretation would be the same as for principal components. But after rotation of the loadings, the interpretation of the factors is usually different. The researcher will ordinarily prefer the rotated factors for reasons to be treated in Section 13.5.

By (2.52), the \(i\) th diagonal element of \(\hat{\Lambda} \hat{\Lambda}^{\prime}\) is the sum of squares of the \(i\) th row of \(\hat{\boldsymbol{\Lambda}}\), or \(\hat{\boldsymbol{\lambda}}_{i}^{\prime} \hat{\boldsymbol{\lambda}}_{i}=\sum_{j=1}^{m} \hat{\lambda}_{i j}^{2}\). Hence to complete the approximation of \(\mathbf{S}\) in (13.20), we define
\[
\begin{equation*}
\hat{\psi}_{i}=s_{i i}-\sum_{j=1}^{m} \hat{\lambda}_{i j}^{2} \tag{13.26}
\end{equation*}
\]
and write
\[
\begin{equation*}
\mathbf{S} \cong \hat{\boldsymbol{\Lambda}} \hat{\mathbf{\Lambda}}^{\prime}+\hat{\mathbf{\Psi}} \tag{13.27}
\end{equation*}
\]
where \(\hat{\boldsymbol{\Psi}}=\operatorname{diag}\left(\hat{\psi}_{1}, \hat{\psi}_{2}, \ldots, \hat{\psi}_{p}\right)\). Thus in (13.27) the variances on the diagonal of \(\mathbf{S}\) are modeled exactly, but the off-diagonal covariances are only approximate. Again, this is the challenge of factor analysis.

In this method of estimation, the sums of squares of the rows and columns of \(\hat{\boldsymbol{\Lambda}}\) are equal to communalities and eigenvalues, respectively. This is easily shown. By (13.26) and by analogy with (13.15), the \(i\) th communality is estimated by
\[
\begin{equation*}
\hat{h}_{i}^{2}=\sum_{j=1}^{m} \hat{\lambda}_{i j}^{2} \tag{13.28}
\end{equation*}
\]
which is the sum of squares of the \(i\) th row of \(\hat{\boldsymbol{\Lambda}}\). The sum of squares of the \(j\) th column of \(\hat{\Lambda}\) is the \(j\) th eigenvalue of \(S\) :
\[
\begin{align*}
\sum_{i=1}^{p} \hat{\lambda}_{i j}^{2} & =\sum_{i=1}^{p}\left(\sqrt{\theta_{j}} c_{i j}\right)^{2} \quad[\text { by }(13.25)] \\
& =\theta_{j} \sum_{i=1}^{p} c_{i j}^{2} \\
& =\theta_{j} \tag{13.29}
\end{align*}
\]
since the normalized eigenvectors (columns of \(\mathbf{C}\) ) have length 1.
By (13.26) and (13.28), the variance of the \(i\) th variable is partitioned into a part due to the factors and a part due uniquely to the variable:
\[
\begin{align*}
s_{i i} & =\hat{h}_{i}^{2}+\hat{\psi}_{i} \\
& =\hat{\lambda}_{i 1}^{2}+\hat{\lambda}_{i 2}^{2}+\cdots+\hat{\lambda}_{i m}^{2}+\hat{\psi}_{i} \tag{13.30}
\end{align*}
\]

Thus the \(j\) th factor contributes \(\hat{\lambda}_{i j}^{2}\) to \(s_{i i}\). The contribution of the \(j\) th factor to the total sample variance, \(\operatorname{tr}(\mathbf{S})=s_{11}+s_{22}+\cdots+s_{p p}\), is therefore
\[
\begin{equation*}
\text { variance due to } j \text { th factor }=\sum_{i=1}^{p} \hat{\lambda}_{i j}^{2}=\hat{\lambda}_{1 j}^{2}+\hat{\lambda}_{2 j}^{2}+\cdots+\hat{\lambda}_{p j}^{2} \text {, } \tag{13.31}
\end{equation*}
\]
which is the sum of squares of loadings in the \(j\) th column of \(\hat{\boldsymbol{\Lambda}}\). By (13.29), this is equal to the \(j\) th eigenvalue, \(\theta_{j}\). The proportion of total sample variance due to the \(j\) th factor is
\[
\begin{equation*}
\frac{\sum_{i=1}^{p} \hat{\lambda}_{i j}^{2}}{\operatorname{tr}(\mathbf{S})}=\frac{\theta_{j}}{\operatorname{tr}(\mathbf{S})} . \tag{13.32}
\end{equation*}
\]

If the variables are not commensurate, we can use standardized variables and work with the correlation matrix \(\mathbf{R}\). The eigenvalues and eigenvectors of \(\mathbf{R}\) are then used in place of those of \(\mathbf{S}\) in (13.24) to obtain estimates of the loadings. In practice, \(\mathbf{R}\) is used more often than \(\mathbf{S}\) and is the default in most software packages. Since the emphasis in factor analysis is on reproducing the covariances or correlations rather than the variances, use of \(\mathbf{R}\) is more appropriate in factor analysis than in principal components. In applications, \(\mathbf{R}\) often gives better results than \(\mathbf{S}\).

If we are factoring \(\mathbf{R}\), the proportion corresponding to (13.32) is
\[
\begin{equation*}
\frac{\sum_{i=1}^{p} \hat{\lambda}_{i j}^{2}}{\operatorname{tr}(\mathbf{R})}=\frac{\theta_{j}}{p} \tag{13.33}
\end{equation*}
\]
where \(p\) is the number of variables.
We can assess the fit of the factor analysis model by comparing the left and right sides of (13.27). The error matrix
\[
\mathbf{E}=\mathbf{S}-\left(\hat{\boldsymbol{\Lambda}} \hat{\mathbf{\Lambda}}^{\prime}+\hat{\mathbf{\Psi}}\right)
\]

Table 13.1 Perception Data: Ratings on Five Adjectives for Seven People
\begin{tabular}{lccccc}
\hline People & Kind & Intelligent & Happy & Likeable & Just \\
\hline FSM1 \(^{a}\) & 1 & 5 & 5 & 1 & 1 \\
SISTER & 8 & 9 & 7 & 9 & 8 \\
FSM2 & 9 & 8 & 9 & 9 & 8 \\
FATHER & 9 & 9 & 9 & 9 & 9 \\
TEACHER & 1 & 9 & 1 & 1 & 9 \\
MSM \(^{b}\) & 9 & 7 & 7 & 9 & 9 \\
FSM3 \(^{3}\) & 9 & 7 & 9 & 9 & 7 \\
\hline
\end{tabular}
\({ }^{a}\) Female schoolmate 1.
\({ }^{b}\) Male schoolmate.
has zeros on the diagonal but nonzero off-diagonal elements. The following inequality gives a bound on the size of the elements in \(\mathbf{E}=\mathbf{S}-\left(\hat{\boldsymbol{\Lambda}} \hat{\boldsymbol{\Lambda}}^{\prime}+\hat{\mathbf{\Psi}}\right)\) :
\[
\begin{equation*}
\sum_{i j} e_{i j}^{2} \leq \theta_{m+1}^{2}+\theta_{m+2}^{2}+\cdots+\theta_{p}^{2} \tag{13.34}
\end{equation*}
\]
that is, the sum of squared entries in the matrix \(\mathbf{E}=\mathbf{S}-\left(\hat{\mathbf{\Lambda}} \hat{\mathbf{\Lambda}}^{\prime}+\hat{\mathbf{\Psi}}\right)\) is at most equal to the sum of squares of the deleted eigenvalues of \(\mathbf{S}\). If the eigenvalues are small, the residuals in the error matrix \(\mathbf{S}-\left(\hat{\mathbf{\Lambda}} \hat{\mathbf{\Lambda}}^{\prime}+\hat{\mathbf{\Psi}}\right)\) are small and the fit is good.

\section*{■ EXAMPLE 13.3.1}

To illustrate the principal component method of estimation, we use a simple data set collected by Brown et al. (1984). A 12-year-old girl made five ratings on a nine-point semantic differential scale for each of seven of her acquaintances. The ratings were based on the five adjectives "kind," "intelligent," "happy," "likeable," and "just." Her ratings are given in Table 13.1.

The correlation matrix for the five variables (adjectives) is as follows, with the larger values bolded:
\[
\mathbf{R}=\left(\begin{array}{rrrrr}
1.000 & .296 & . \mathbf{8 8 1} & \mathbf{. 9 9 5} & .545  \tag{13.35}\\
.296 & 1.000 & -.022 & .326 & . \mathbf{8 3 7} \\
. \mathbf{8 8 1} & -.022 & 1.000 & . \mathbf{8 6 7} & .130 \\
. \mathbf{9 9 5} & .326 & . \mathbf{8 6 7} & 1.000 & .544 \\
.545 & . \mathbf{8 3 7} & .130 & .544 & 1.000
\end{array}\right)
\]

The boldface values indicate two groups of variables: \(\{1,3,4\}\) and \(\{2,5\}\). We would therefore expect that the correlations among the variables can be explained fairly well by two factors.

The eigenvalues of \(\mathbf{R}\) are \(3.263,1.538, .168, .031\), and 0 . Thus \(\mathbf{R}\) is singular, which is possible in a situation such as this with only seven observations on five variables recorded in a single-digit scale. The multicollinearity among

Table 13.2 Factor Loadings by the Principal Component Method for the Perception Data of Table 13.1
\begin{tabular}{|c|c|c|c|c|}
\hline \multirow[b]{2}{*}{Variables} & \multicolumn{2}{|c|}{Loadings} & \multirow[t]{2}{*}{Communalities, \(\hat{h}_{i}^{2}\)} & \multirow[t]{2}{*}{Specific Variances, \(\hat{\psi}_{i}\)} \\
\hline & \(\hat{\lambda}_{1 j}\) & \(\hat{\lambda}_{2 j}\) & & \\
\hline Kind & . 969 & \(-.231\) & . 993 & . 007 \\
\hline Intelligent & . 519 & . 807 & . 921 & . 079 \\
\hline Happy & . 785 & \(-.587\) & . 960 & . 040 \\
\hline Likeable & . 971 & -. 210 & . 987 & . 013 \\
\hline Just & . 704 & . 667 & . 940 & . 060 \\
\hline Variance accounted for & 3.263 & 1.538 & 4.802 & \\
\hline Proportion of total variance & . 653 & . 308 & . 960 & \\
\hline Cumulative proportion & . 653 & . 960 & . 960 & \\
\hline
\end{tabular}
the variables induced by the fifth eigenvalue, 0 , could be ascertained from the corresponding eigenvector, as noted in Section 12.7 (see Problem 13.6).

By (13.33), the first two factors account for \((3.263+1.538) / 5=.96\) of the total sample variance. We therefore extract two factors. The first two eigenvectors are
\[
\mathbf{c}_{1}=\left(\begin{array}{l}
.537 \\
.288 \\
.434 \\
.537 \\
.390
\end{array}\right) \quad \text { and } \quad \mathbf{c}_{2}=\left(\begin{array}{r}
-.186 \\
.651 \\
-.473 \\
-.169 \\
.538
\end{array}\right)
\]

When these are multiplied by the square roots of the respective eigenvalues 3.263 and 1.538 as in (13.25), we obtain the loadings in Table 13.2.

The communalities in Table 13.2 are obtained from the sum of squares of the rows of the loadings, as in (13.28). The first one, for example, is \((.969)^{2}+(-.231)^{2}=.993\). The specific variances are obtained from (13.26) as \(\hat{\psi}_{i}=1-\hat{h}_{i}^{2}\) using 1 in place of \(s_{i i}\) because we are factoring \(\mathbf{R}\) rather than \(\mathbf{S}\). The variance accounted for by each factor is the sum of squares of the corresponding column of the loadings, as in (13.31). By (13.29), the variance accounted for is also equal to the eigenvalue in each case. Note that the variance accounted for by the two factors adds to the sum of the communalities, since the latter is the sum of all squared loadings. By (13.33), the proportion of total variance for each factor is the variance accounted for divided by 5 .

The two factors account for \(96 \%\) of the total variance and therefore represent the five variables very well. To see how well the two-factor model reproduces the correlation matrix, we examine
\[
\begin{aligned}
\hat{\mathbf{\Lambda}} \hat{\mathbf{\Lambda}}^{\prime}+\hat{\mathbf{\Psi}}= & \left(\begin{array}{rr}
.969 & -.231 \\
.519 & .807 \\
.785 & -.587 \\
.971 & -.210 \\
.704 & .667
\end{array}\right)\left(\begin{array}{rrrrr}
.969 & .519 & .785 & .971 & .704 \\
-.231 & .807 & -.587 & -.210 & .667
\end{array}\right) \\
& +\left(\begin{array}{rrrrr}
.007 & 0 & 0 & 0 & 0 \\
0 & .079 & 0 & 0 & 0 \\
0 & 0 & .040 & 0 & 0 \\
0 & 0 & 0 & .013 & 0 \\
0 & 0 & 0 & 0 & .060
\end{array}\right) \\
= & \left(\begin{array}{rrrrr}
1.000 & .317 & .896 & .990 & .528 \\
.317 & 1.000 & -.066 & .335 & .904 \\
.896 & -.066 & 1.000 & .885 & .161 \\
.990 & .335 & .885 & 1.000 & .543 \\
.528 & .904 & .161 & .543 & 1.000
\end{array}\right)
\end{aligned}
\]
which is very close to the original \(\mathbf{R}\). We will not attempt to interpret the factors at this point but will wait until they have been rotated in Section 13.5.2.

\subsection*{13.3.2 Principal Factor Method}

In the principal component approach to estimation of the loadings, we neglected \(\Psi\) and factored \(\mathbf{S}\) or \(\mathbf{R}\). The principal factor method (also called the principal axis method) uses an initial estimate \(\hat{\mathbf{\Psi}}\) and factors \(\mathbf{S}-\hat{\mathbf{\Psi}}\) or \(\mathbf{R}-\hat{\mathbf{\Psi}}\) to obtain
\[
\begin{align*}
& \mathbf{S}-\hat{\mathbf{\Psi}} \cong \hat{\boldsymbol{\Lambda}} \hat{\boldsymbol{\Lambda}}^{\prime}  \tag{13.36}\\
& \mathbf{R}-\hat{\mathbf{\Psi}} \cong \hat{\boldsymbol{\Lambda}} \hat{\boldsymbol{\Lambda}}^{\prime} \tag{13.37}
\end{align*}
\]
where \(\hat{\Lambda}\) is \(p \times m\) and is calculated as in (13.24) using eigenvalues and eigenvectors of \(\mathbf{S}-\hat{\mathbf{\Psi}}\) or \(\mathbf{R}-\hat{\mathbf{\Psi}}\).

The \(i\) th diagonal element of \(\mathbf{S}-\hat{\mathbf{\Psi}}\) is given by \(s_{i i}-\hat{\psi}_{i}\), which is the \(i\) th communality, \(\hat{h}_{i}^{2}=s_{i i}-\hat{\psi}_{i}\) [see (13.30)]. Likewise, the diagonal elements of \(\mathbf{R}-\hat{\mathbf{\Psi}}\) are the communalities \(\hat{h}_{i}^{2}=1-\hat{\psi}_{i}\). (Obviously, \(\hat{\psi}_{i}\) and \(\hat{h}_{i}^{2}\) have different values for \(\mathbf{S}\)
than for \(\mathbf{R}\).) With these diagonal values, \(\mathbf{S}-\hat{\mathbf{\Psi}}\) and \(\mathbf{R}-\hat{\mathbf{\Psi}}\) have the form
\[
\begin{align*}
& \mathbf{S}-\hat{\mathbf{\Psi}}=\left(\begin{array}{cccc}
\hat{h}_{1}^{2} & s_{12} & \cdots & s_{1 p} \\
s_{21} & \hat{h}_{2}^{2} & \cdots & s_{2 p} \\
\vdots & \vdots & & \vdots \\
s_{p 1} & s_{p 2} & \cdots & \hat{h}_{p}^{2}
\end{array}\right),  \tag{13.38}\\
& \mathbf{R}-\hat{\mathbf{\Psi}}=\left(\begin{array}{cccc}
\hat{h}_{1}^{2} & r_{12} & \cdots & r_{1 p} \\
r_{21} & \hat{h}_{2}^{2} & \cdots & r_{2 p} \\
\vdots & \vdots & & \vdots \\
r_{p 1} & r_{p 2} & \cdots & \hat{h}_{p}^{2}
\end{array}\right) . \tag{13.39}
\end{align*}
\]

A popular initial estimate for a communality in \(\mathbf{R}-\hat{\mathbf{\Psi}}\) is \(\hat{h}_{i}^{2}=R_{i}^{2}\), the squared multiple correlation between \(y_{i}\) and the other \(p-1\) variables. This can be found as
\[
\begin{equation*}
\hat{h}_{i}^{2}=R_{i}^{2}=1-\frac{1}{r^{i i}}, \tag{13.40}
\end{equation*}
\]
where \(r^{i i}\) is the \(i\) th diagonal element of \(\mathbf{R}^{-1}\).
For \(\mathbf{S}-\hat{\Psi}\), an initial estimate of communality analogous to (13.40) is
\[
\begin{equation*}
\hat{h}_{i}^{2}=s_{i i}-\frac{1}{s^{i i}}, \tag{13.41}
\end{equation*}
\]
where \(s_{i i}\) is the \(i\) th diagonal element of \(\mathbf{S}\) and \(s^{i i}\) is the \(i\) th diagonal element of \(\mathbf{S}^{-1}\). It can be shown that (13.41) is equivalent to
\[
\begin{equation*}
\hat{h}_{i}^{2}=s_{i i}-\frac{1}{s^{i i}}=s_{i i} R_{i}^{2} \tag{13.42}
\end{equation*}
\]
which is a reasonable estimate of the amount of variance that \(y_{i}\) has in common with the other \(y\) 's.

To use (13.40) or (13.41), \(\mathbf{R}\) or \(\mathbf{S}\) must be nonsingular. If \(\mathbf{R}\) is singular we can use the absolute value or the square of the largest correlation in the \(i\) th row of \(\mathbf{R}\) as an estimate of communality.

After obtaining communality estimates, we calculate eigenvalues and eigenvectors of \(S-\hat{\Psi}\) or \(\mathbf{R}-\hat{\Psi}\) and use (13.24) to obtain estimates of factor loadings, \(\hat{\boldsymbol{\Lambda}}\). Then the columns and rows of \(\hat{\boldsymbol{\Lambda}}\) can be used to obtain new eigenvalues (variance explained) and communalities, respectively. The sum of squares of the \(j\) th column of \(\hat{\boldsymbol{\Lambda}}\) is the \(j\) th eigenvalue of \(\mathbf{S}-\hat{\mathbf{\Psi}}\) or \(\mathbf{R}-\hat{\mathbf{\Psi}}\), and the sum of squares of the \(i\) th row of \(\hat{\Lambda}\) is the communality of \(y_{i}\). The proportion of variance explained by the \(j\) th factor is
\[
\frac{\theta_{j}}{\operatorname{tr}(\mathbf{S}-\hat{\mathbf{\Psi}})}=\frac{\theta_{j}}{\sum_{i=1}^{p} \theta_{i}}
\]
or
\[
\frac{\theta_{j}}{\operatorname{tr}(\mathbf{R}-\hat{\mathbf{\Psi}})}=\frac{\theta_{j}}{\sum_{i=1}^{p} \theta_{i}},
\]
where \(\theta_{j}\) is the \(j\) th eigenvalue of \(\mathbf{S}-\hat{\boldsymbol{\Psi}}\) or \(\mathbf{R}-\hat{\boldsymbol{\Psi}}\). The matrices \(\mathbf{S}-\hat{\mathbf{\Psi}}\) and \(\mathbf{R}-\hat{\boldsymbol{\Psi}}\) are not necessarily positive semidefinite and will often have some small negative eigenvalues. In such a case, the cumulative proportion of variance will exceed 1 and then decline to 1 as the negative eigenvalues are added. [Note that loadings cannot be obtained by (13.24) for the negative eigenvalues.]

\section*{■ EXAMPLE 13.3.2}

To illustrate the principal factor method, we use the perception data from Table 13.1. The correlation matrix as given in Example 13.3.1 is singular. Hence in place of multiple correlations as communality estimates, we use the (absolute value of) the largest correlation in each row of \(\mathbf{R}\). [The multiple correlation of \(y\) with several variables is greater than the simple correlation of \(y\) with any of the individual variables; see, for example, Rencher and Schaalje (2008, p. 257).] The diagonal elements of \(\mathbf{R}-\hat{\Psi}\) as given by (13.39) are therefore \(.995, .837, .881, .995\), and .837 , which are obtained from \(\mathbf{R}\) in (13.35). The eigenvalues of \(\mathbf{R}-\hat{\boldsymbol{\Psi}}\) are \(3.202,1.395, .030,-.0002\), and -.080 , whose sum is 4.546. The first two eigenvectors of \(\mathbf{R}-\hat{\mathbf{\Psi}}\) are
\[
\mathbf{c}_{1}=\left(\begin{array}{l}
.548 \\
.272 \\
.431 \\
.549 \\
.373
\end{array}\right) \quad \text { and } \quad \mathbf{c}_{2}=\left(\begin{array}{r}
-.178 \\
.656 \\
-.460 \\
-.159 \\
.549
\end{array}\right)
\]

When these are multiplied by the square roots of the respective eigenvalues, we obtain the principal factor loadings. In Table 13.3, these are compared with the loadings obtained by the principal component method in Example 13.3.1. The two sets of loadings are very similar, as we would have expected because of the large size of the communalities. The communalities in Table 13.3 are for the principal factor loadings, as noted above. The proportion of variance in each case for the principal factor loadings is obtained by dividing the variance accounted for (eigenvalue) by the sum of the eigenvalues, 4.546; for example, \(3.202 / 4.546=.704\).

\subsection*{13.3.3 Iterated Principal Factor Method}

The principal factor method can easily be iterated to improve the estimates of communality. After obtaining \(\hat{\boldsymbol{\Lambda}}\) from \(\mathbf{S}-\hat{\mathbf{\Psi}}\) or \(\mathbf{R}-\hat{\boldsymbol{\Psi}}\) in (13.36) or (13.37) using initial communality estimates, we can obtain new communality estimates from the loadings in \(\hat{\boldsymbol{\Lambda}}\) using (13.28),
\[
\hat{h}_{i}^{2}=\sum_{j=1}^{m} \hat{\lambda}_{i j}^{2} .
\]

These values of \(\hat{h}_{i}^{2}\) are substituted into the diagonal of \(\mathbf{S}-\hat{\mathbf{\Psi}}\) or \(\mathbf{R}-\hat{\mathbf{\Psi}}\), from which we obtain a new value of \(\hat{\boldsymbol{\Lambda}}\) using (13.24). This process is continued until the

Table 13.3 Loadings Obtained by Two Different Methods for Perception Data of Table 13.1
\begin{tabular}{|c|c|c|c|c|c|}
\hline \multirow[b]{2}{*}{Variables} & \multicolumn{2}{|l|}{Principal Component Loadings} & \multicolumn{2}{|r|}{Principal Factor Loadings} & \multirow[b]{2}{*}{Communalities} \\
\hline & \(f_{1}\) & \(f_{2}\) & \(f_{1}\) & \(f_{2}\) & \\
\hline Kind & . 969 & \(-.231\) & . 981 & -. 210 & . 995 \\
\hline Intelligent & . 519 & . 807 & . 487 & . 774 & . 837 \\
\hline Happy & . 785 & -. 587 & . 771 & -. 544 & . 881 \\
\hline Likeable & . 971 & -. 210 & . 982 & -. 188 & . 995 \\
\hline Just & . 704 & . 667 & . 667 & . 648 & . 837 \\
\hline Variance accounted for & 3.263 & 1.538 & 3.202 & 1.395 & \\
\hline Proportion of total variance & . 653 & . 308 & . 704 & . 307 & \\
\hline Cumulative proportion & . 653 & . 960 & . 704 & 1.01 & \\
\hline
\end{tabular}
communality estimates converge. (For some data sets, the iterative procedure does not converge.) Then the eigenvalues and eigenvectors of the final version of \(S-\hat{\Psi}\) or \(R-\hat{\Psi}\) are used in (13.24) to obtain the loadings.

The principal factor method and the iterated principal factor method will typically yield results very close to those from the principal component method when either of the following is true.
1. The correlations are fairly large, with a resulting small value of \(m\).
2. The number of variables, \(p\), is large.

A shortcoming of the iterative approach is that sometimes it leads to a communality estimate \(\hat{h}_{i}^{2}\) exceeding 1 (when factoring \(\mathbf{R}\) ). Such a result is known as a Heywood case (Heywood 1931). If \(\hat{h}_{i}^{2}>1\), then \(\hat{\psi}_{i}<0\) by (13.26) and (13.28), which is clearly improper, since we cannot have a negative specific variance. Thus when a communality exceeds 1 , the iterative process should stop, with the program reporting that a solution cannot be reached. Some software programs have an option of continuing the iterations by setting the communality equal to 1 in all subsequent iterations. The resulting solution with \(\hat{\psi}_{i}=0\) is somewhat questionable because it implies exact dependence of a variable on the factors, a possible but unlikely outcome.

\section*{- EXAMPLE 13.3.3}

We illustrate the iterated principal factor method using the Seishu data in Table 7.1. The correlation matrix is given below:
\[
\mathbf{R}=\left(\begin{array}{rrrrrrrrrr}
1.00 & .56 & .22 & .10 & .20 & -.04 & .13 & .03 & -.07 & .09 \\
.56 & 1.00 & -.09 & .13 & .20 & -.17 & .17 & .24 & .16 & .06 \\
.22 & -.09 & 1.00 & .16 & .70 & -.31 & -.45 & -.34 & -.11 & .68 \\
.10 & .13 & .16 & 1.00 & .49 & -.03 & -.16 & .01 & .42 & .37 \\
.20 & .20 & .70 & .49 & 1.00 & -.32 & -.34 & -.19 & .30 & .87 \\
-.04 & -.17 & -.31 & -.03 & -.32 & 1.00 & -.42 & -.57 & -.11 & -.26 \\
.13 & .17 & -.45 & -.16 & -.34 & -.42 & 1.00 & .82 & .23 & -.30 \\
.03 & .24 & -.34 & .01 & -.19 & -.57 & .82 & 1.00 & .45 & -.17 \\
-.07 & .16 & -.11 & .42 & .30 & -.11 & .23 & .45 & 1.00 & .29 \\
.09 & .06 & .68 & .37 & .87 & -.26 & -.30 & -.17 & .29 & 1.00
\end{array}\right) .
\]

The eigenvalues of \(\mathbf{R}\) are \(3.17,2.56,1.43,1.28, .54, .47, .25, .12, .10\), and .06. There is a notable gap between 1.28 and .54 , and we therefore extract four factors (see Section 13.4). The first four eigenvalues account for a proportion
\[
\frac{3.17+2.56+1.43+1.28}{10}=.84
\]
of \(\operatorname{tr}(R)\).
For initial communality estimates, we use the squared multiple correlation between each variable and the other nine variables. These are given in Table 13.4 , along with the final communalities after iteration. We multiply the first four eigenvectors of the final iterated version of \(\mathbf{R}-\hat{\Psi}\) by the square roots of the respective eigenvalues, as in (13.24), to obtain the factor loadings given in Table 13.4. We will not attempt to interpret the factors until after they have been rotated in Example 13.5.2b(b).

\subsection*{13.3.4 Maximum Likelihood Method}

If we assume that the observations \(y_{1}, y_{2}, \ldots, y_{n}\) constitute a random sample from \(N_{p}(\boldsymbol{\mu}, \boldsymbol{\Sigma})\), then \(\boldsymbol{\Lambda}\) and \(\Psi\) can be estimated by the method of maximum likelihood. It can be shown that the estimates \(\hat{\boldsymbol{\Lambda}}\) and \(\hat{\boldsymbol{\Psi}}\) satisfy the following:
\[
\begin{align*}
& \mathbf{S} \hat{\Psi} \hat{\boldsymbol{\Lambda}}=\hat{\boldsymbol{\Lambda}}\left(\mathbf{I}+\hat{\boldsymbol{\Lambda}}^{\prime} \hat{\Psi}^{-1} \hat{\boldsymbol{\Lambda}}\right)  \tag{13.43}\\
& \hat{\mathbf{\Psi}}=\operatorname{diag}\left(\mathbf{S}-\hat{\boldsymbol{\Lambda}} \hat{\mathbf{\Lambda}}^{\prime}\right)  \tag{13.44}\\
& \hat{\boldsymbol{\Lambda}}^{\prime} \hat{\Psi}^{-1} \hat{\boldsymbol{\Lambda}} \text { is diagonal. } \tag{13.45}
\end{align*}
\]

These equations must be solved iteratively, and in practice the procedure may fail to converge or may yield a Heywood case (Section 13.3.3).

We note that the proportion of variance accounted for by the factors, as given by (13.32) or (13.33), will not necessarily be in descending order for maximum likelihood factors, as it is for factors obtained from the principal component or principal factor method.

\text { Communalities }\end{array}\right]\)

\section*{- EXAMPLE 13.3.4}

We illustrate the maximum likelihood method with the Seishu data of Table 7.1. The correlation matrix and its eigenvalues were given in Example 13.3.3. We extract four factors, as in Example 13.3.3. The iterative solution of (13.43), (13.44), and (13.45) yielded the loadings and communalities given in Table 13.5.

The pattern of the loadings is different from that obtained using the iterated principal factor method in Example 13.3.3, but we will not compare them until after rotation in Example 13.5 .2 b (b). Note that the four values of variance accounted for are not in descending order.

\subsection*{13.4 CHOOSING THE NUMBER OF FACTORS, \(m\)}

Several criteria have been proposed for choosing \(m\), the number of factors. We consider four criteria, which are similar to those given in Section 12.6 for choosing the number of principal components to retain.
1. Choose \(m\) equal to the number of factors necessary for the variance accounted for to achieve a predetermined percentage, say \(80 \%\), of the total variance \(\operatorname{tr}(\mathbf{S})\) or \(\operatorname{tr}(\mathbf{R})\).
2. Choose \(m\) equal to the number of eigenvalues greater than the average eigenvalue. For \(\mathbf{R}\) the average is 1 ; for \(\mathbf{S}\) it is \(\sum_{j=1}^{p} \theta_{j} / p\).
3. Use the scree test based on a plot of the eigenvalues of \(\mathbf{S}\) or \(\mathbf{R}\). If the graph drops sharply, followed by a straight line with much smaller slope, choose \(m\) equal to the number of eigenvalues before the straight line begins.

Table 13.5 Maximum Likelihood Loadings and Communalities for the Seishu Data
\begin{tabular}{lrrrrc}
\hline & \multicolumn{4}{c}{ Loadings } & \\
\cline { 2 - 5 } Variables & \multicolumn{1}{c}{\(f_{1}\)} & \multicolumn{1}{c}{\(f_{2}\)} & \multicolumn{1}{c}{\(f_{3}\)} & \multicolumn{1}{c}{\(f_{4}\)} & Communalities \\
\hline \multicolumn{1}{c}{ Taste } & 1.00 & 0 & 0 & 0 & 1.00 \\
Odor & .45 & -.05 & .22 & .19 & .29 \\
pH & .22 & .68 & -.20 & -.40 & .71 \\
Acidity 1 & .10 & .47 & .10 & .37 & .38 \\
Acidity 2 & .20 & .98 & .02 & .00 & 1.00 \\
Sake meter & -.04 & -.31 & -.68 & .55 & .86 \\
Reducing sugar & .13 & -.39 & .76 & -.02 & .75 \\
\(\quad\) Total sugar & .03 & -.22 & .96 & .02 & .98 \\
\(\quad\) Alcohol & -.07 & .31 & .52 & .60 & .72 \\
\(\quad\) Formyl-nitrogen & .02 & .79 & -.05 & -.10 & .63 \\
Variance & & & & & \\
accounted for & 1.33 & 2.66 & 2.34 & 1.00 & 7.32 \\
\hline
\end{tabular}
4. Test the hypothesis that \(m\) is the correct number of factors, \(H_{0}: \mathbf{\Sigma}=\mathbf{\Lambda \Lambda}^{\prime}+\) \(\boldsymbol{\Psi}\), where \(\boldsymbol{\Lambda}\) is \(p \times m\).

Method 1 applies particularly to the principal component method. By (13.32), the proportion of total sample variance (variance accounted for) due to the \(j\) th factor from \(\mathbf{S}\) is \(\sum_{i=1}^{p} \hat{\lambda}_{i j}^{2} / \operatorname{tr}(\mathbf{S})\). The corresponding proportion from \(\mathbf{R}\) is \(\sum_{i=1}^{p} \hat{\lambda}_{i j}^{2} / p\), as in (13.33). The contribution of all \(m\) factors to \(\operatorname{tr}(\mathbf{S})\) or \(p\) is therefore \(\sum_{i=1}^{p} \sum_{j=1}^{m} \hat{\lambda}_{i j}^{2}\), which is the sum of squares of all elements of \(\hat{\Lambda}\). For the principal component method, we see by (13.28) and (13.29) that this sum is also equal to the sum of the first \(m\) eigenvalues or to the sum of all \(p\) communalities:
\[
\begin{equation*}
\sum_{i=1}^{p} \sum_{j=1}^{m} \hat{\lambda}_{i j}^{2}=\sum_{i=1}^{p} \hat{h}_{i}^{2}=\sum_{j=1}^{m} \theta_{j} . \tag{13.46}
\end{equation*}
\]

Thus we choose \(m\) sufficiently large so that the sum of the communalities or the sum of the eigenvalues (variance accounted for) constitutes a relatively large portion of \(\operatorname{tr}(\mathbf{S})\) or \(p\).

Method 1 can be extended to the principal factor method, where prior estimates of communalities are used to form \(\mathbf{S}-\hat{\boldsymbol{\Psi}}\) or \(\mathbf{R}-\hat{\mathbf{\Psi}}\). However, \(\mathbf{S}-\hat{\mathbf{\Psi}}\) or \(\mathbf{R}-\hat{\mathbf{\Psi}}\) will often have some negative eigenvalues. Therefore, as values of \(m\) range from 1 to \(p\), the cumulative proportion of eigenvalues, \(\sum_{j=1}^{m} \theta_{j} / \sum_{j=1}^{p} \theta_{j}\), will exceed 1.0 and then reduce to 1.0 as the negative eigenvalues are added. Hence a percentage such as \(80 \%\) will be reached for a lower value of \(m\) than would be the case for \(\mathbf{S}\) or \(\mathbf{R}\), and a better strategy might be to choose \(m\) equal to the value for which the percentage first exceeds \(100 \%\).

In the iterated principal factor method, \(m\) is specified before iteration, and \(\sum_{i} \hat{h}_{i}^{2}\) is obtained after iteration as \(\sum_{i} \hat{h}_{i}^{2}=\operatorname{tr}(\mathbf{S}-\hat{\Psi})\). To choose \(m\) before iterating, one could use a priori considerations or the eigenvalues of \(\mathbf{S}\) or \(\mathbf{R}\), as in the principal component method.

Method 2 is a popular criterion of long standing and is the default in many software packages. Although heuristically based, it often works well in practice. A variation to method 2 that has been suggested for use with \(\mathbf{R}-\hat{\Psi}\) is to let \(m\) equal the number of positive eigenvalues. (There will typically be some negative eigenvalues of \(\mathbf{R}-\hat{\mathbf{\Psi}}\).) However, this criterion will often result in too many factors, since the sum of the positive eigenvalues will exceed the sum of the communalities.

The scree test in method 3 was named after the geological term scree, referring to the debris at the bottom of a rocky cliff. It also performs well in practice.

In method 4 we wish to test
\[
H_{0}: \boldsymbol{\Sigma}=\boldsymbol{\Lambda} \mathbf{\Lambda}^{\prime}+\boldsymbol{\Psi} \quad \text { vs. } \quad H_{1}: \boldsymbol{\Sigma} \neq \boldsymbol{\Lambda} \boldsymbol{\Lambda}^{\prime}+\boldsymbol{\Psi},
\]
where \(\boldsymbol{\Lambda}\) is \(p \times m\). The test statistic, a function of the likelihood ratio, is
\[
\begin{equation*}
\left(n-\frac{2 p+4 m+11}{6}\right) \ln \left(\frac{\left|\hat{\mathbf{\Lambda}} \hat{\mathbf{\Lambda}}^{\prime}+\hat{\mathbf{\Psi}}\right|}{|\mathbf{S}|}\right), \tag{13.47}
\end{equation*}
\]
which is approximately \(\chi_{\nu}^{2}\) when \(H_{0}\) is true, where \(\nu=\frac{1}{2}\left[(p-m)^{2}-p-m\right]\) and \(\hat{\boldsymbol{\Lambda}}\) and \(\hat{\boldsymbol{\Psi}}\) are the maximum likelihood estimators. Rejection of \(H_{0}\) implies that \(m\) is too small and more factors are needed.

In practice, when \(n\) is large, the test in method 4 often shows more factors to be significant than do the other three methods. We may therefore consider the value of \(m\) indicated by the test to be an upper bound on the number of factors with practical importance.

For many data sets, the choice of \(m\) will not be obvious. This indeterminacy leaves many statisticians skeptical as to the validity of factor analysis. A researcher may begin with one of the methods (say method 2 ) for an initial choice of \(m\), will inspect the resulting percent of \(\operatorname{tr}(\mathbf{R})\) or \(\operatorname{tr}(\mathbf{S})\), and will then examine the rotated loadings for interpretability. If the percent of variance or interpretation does not seem satisfactory, the experimenter will try other values of \(m\) in a search for an acceptable compromise between percent of \(\operatorname{tr}(\mathbf{R})\) and interpretability of the factors. Admittedly, this is a subjective procedure, and for such data sets one could well question the outcome (see Section 13.7).

When a data set is successfully fitted by a factor analysis model, the first three methods will almost always give the same value of \(m\), and there will be little question as to what this value should be. Thus for a "good" data set, the entire procedure becomes much more objective.

\section*{\(\square\) EXAMPLE 13.4(a)}

We compare the four methods of choosing \(m\) for the perception data used in Examples 13.3.1 and 13.3.2.

Figure 13.1 Scree graph for the perception data.

Method 1 gives \(m=2\), because one eigenvalue accounts for \(65 \%\) of \(\operatorname{tr}(\mathbf{R})\), while two eigenvalues account for \(96 \%\).

Method 2 gives \(m=2\), since \(\lambda_{2}=1.54\) and \(\lambda_{3}=.17\).
For method 3, we examine the scree plot in Figure 13.1. It is clear that \(m=2\) is indicated.

Method 4 is not available for the perception data because \(\mathbf{R}\) is singular (fifth eigenvalue is zero), and the test involves \(|\mathbf{R}|\).

Hence for the perception data, all three available methods agree on \(m=2\).

\section*{EXAMPLE 13.4(b)}

We compare the four methods of choosing \(m\) for the Seishu data used in Examples 13.3.3 and 13.3.4.

Method 1 gives \(m=4\) for the principal component method, because four eigenvalues of \(\mathbf{R}\) account for \(82 \%\) of \(\operatorname{tr}(\mathbf{R})\). For the principal factor method with initial communality estimates \(R_{i}^{2}\), the eigenvalues of \(\mathbf{R}-\hat{\mathbf{\Psi}}\) and corresponding proportions are as follows:
\begin{tabular}{lrrrrrrrrrr} 
Eigenvalues & 2.86 & 2.17 & .94 & .88 & .12 & .08 & .01 & -.06 & -.13 & -.22 \\
Proportions & .43 & .33 & .14 & .16 & .02 & .01 & .00 & -.01 & -.02 & -.03 \\
\begin{tabular}{c} 
Cumulative \\
proportions
\end{tabular} & .43 & .76 & .90 & 1.03 & 1.05 & 1.06 & 1.06 & 1.06 & 1.03 & 1.00
\end{tabular}

Figure 13.2 Scree graph for the Seishu data.

The proportions are obtained by dividing the eigenvalues by their sum, 6.63. Thus the cumulative proportion first exceeds 1.00 for \(m=4\).

Method 2 gives \(m=4\), since \(\lambda_{4}=1.31\) and \(\lambda_{5}=.61\), where \(\lambda_{4}\) and \(\lambda_{5}\) are eigenvalues of \(\mathbf{R}\).

For method 3, we examine the scree plot in Figure 13.2. There is a discernible bend in slope at the fifth eigenvalue.

For method 4, we use \(m=4\) in the approximate chi-squared statistic in (13.47) and obtain \(\chi^{2}=9.039\), with degrees of freedom
\[
\nu=\frac{1}{2}\left[(p-m)^{2}-p-m\right]=\frac{1}{2}\left[(10-4)^{2}-10-4\right]=11 .
\]

Since \(9.039<\chi_{.05,11}^{2}=19.68\), we do not reject the hypothesis that four factors are adequate.

Thus for the Seishu data, all four methods agree on \(m=4\).

\subsection*{13.5 ROTATION}

\subsection*{13.5.1 Introduction}

As noted in Section 13.2.2, the factor loadings (rows of \(\boldsymbol{\Lambda}\) ) in the population model are unique only up to multiplication by an orthogonal matrix that rotates the loadings. The rotated loadings preserve the essential properties of the original loadings; they reproduce the covariance matrix and satisfy all basic assumptions. The estimated loading matrix \(\hat{\boldsymbol{\Lambda}}\) can likewise be rotated to obtain \(\hat{\boldsymbol{\Lambda}}^{*}=\hat{\boldsymbol{\Lambda}} \mathbf{T}\), where \(\mathbf{T}\) is orthogonal.

Since \(\mathbf{T T}^{\prime}=\mathbf{I}\) by (2.102), the rotated loadings provide the same estimate of the covariance matrix as before:
\[
\begin{equation*}
\mathbf{S} \cong \hat{\boldsymbol{\Lambda}}^{*} \hat{\boldsymbol{\Lambda}}^{* \prime}+\hat{\mathbf{\Psi}}=\hat{\boldsymbol{\Lambda}} \mathbf{T} \mathbf{T}^{\prime} \hat{\boldsymbol{\Lambda}}^{\prime}+\hat{\mathbf{\Psi}}=\hat{\boldsymbol{\Lambda}} \hat{\boldsymbol{\Lambda}}^{\prime}+\hat{\mathbf{\Psi}} \tag{13.48}
\end{equation*}
\]

Geometrically, the loadings in the \(i\) th row of \(\hat{\boldsymbol{\Lambda}}\) constitute the coordinates of a point in the loading space corresponding to \(y_{i}\). Rotation of the \(p\) points gives their coordinates with respect to new axes (factors) but otherwise leaves their basic geometric configuration intact. We hope to find a new frame of reference in which the factors are more interpretable. To this end, the goal of rotation is to place the axes close to as many points as possible. If there are clusters of points (corresponding to groupings of \(y\) 's), we seek to move the axes so as to pass through or near these clusters. This would associate each group of variables with a factor (axis) and make interpretation more objective. The resulting axes then represent the natural factors.

If we can achieve a rotation in which every point is close to an axis, then each variable loads highly on the factor corresponding to the axis and has small loadings on the remaining factors. In this case, there is no ambiguity. Such a happy state of affairs is called simple structure, and interpretation is greatly simplified. We merely observe which variables are associated with each factor, and the factor is defined or named accordingly.

In order to identify the natural groupings of variables, we seek a rotation to an interpretable pattern for the loadings, in which the variables load highly on only one factor. The number of factors on which a variable has moderate or high loadings is called the complexity of the variable. In the ideal situation referred to above as simple structure, the variables all have a complexity of 1 . In this case, the variables have been clearly clustered into groups corresponding to the factors.

We consider two basic types of rotation: orthogonal and oblique. The rotation in (13.48) involving an orthogonal matrix is an orthogonal rotation; the original perpendicular axes are rotated rigidly and remain perpendicular. In an orthogonal rotation, angles and distances are preserved, communalities are unchanged, and the basic configuration of the points remains the same. Only the reference axes differ. In an oblique "rotation" (transformation), the axes are not required to remain perpendicular and are thus free to pass closer to clusters of points.

In Sections 13.5.2 and 13.5.3, we discuss orthogonal and oblique rotations, followed by some guidelines for interpretation in Section 13.5.4.

\subsection*{13.5.2 Orthogonal Rotation}

It was noted above in Section 13.5.1 that orthogonal rotations preserve communalities. This is because the rows of \(\hat{\boldsymbol{\Lambda}}\) are rotated, and the distance to the origin is unchanged, which, by (13.28), is the communality. However, the variance accounted for by each factor as given in (13.31) will change, as will the corresponding proportion in (13.32) or (13.33). The proportions due to the rotated loadings will not necessarily be in descending order.

In Sections 13.5.2a and 13.5.2b, we consider two approaches to orthogonal rotation.

\subsection*{13.5.2a Graphical Approach}

If there are only two factors ( \(m=2\) ), we can use a graphical rotation based on a visual inspection of a plot of factor loadings. In this case, the rows of \(\hat{\boldsymbol{\Lambda}}\) are pairs of loadings, \(\left(\hat{\lambda}_{i 1}, \hat{\lambda}_{i 2}\right), i=1,2, \ldots, p\), corresponding to \(y_{1}, y_{2}, \ldots, y_{p}\). We choose an angle \(\phi\) through which the axes can be rotated to move them closer to groupings of points. The new rotated loadings ( \(\hat{\lambda}_{i 1}^{*}, \hat{\lambda}_{i 2}^{*}\) ) can be measured directly on the graph as coordinates of the axes or calculated from \(\hat{\boldsymbol{\Lambda}}^{*}=\hat{\boldsymbol{\Lambda}} \mathbf{T}\) using
\[
\mathbf{T}=\left(\begin{array}{rr}
\cos \phi & -\sin \phi  \tag{13.49}\\
\sin \phi & \cos \phi
\end{array}\right)
\]

\section*{EXAMPLE 13.5.2a}

In Example 13.3.1, the initial factor loadings for the perception data did not provide an interpretation consistent with the two groupings of variables apparent in the pattern of correlations in \(\mathbf{R}\). The five pairs of loadings ( \(\hat{\lambda}_{i 1}, \hat{\lambda}_{i 2}\) ) corresponding to the five variables are plotted in Figure 13.3. An orthogonal rotation through \(-35^{\circ}\) would bring the axes (factors) closer to the two clusters of points (variables) identified in Example 13.3.1. With the rotation, each cluster of variables corresponds much more closely to a factor. Using \(\hat{\boldsymbol{\Lambda}}\) from Example 13.3.1 and \(-35^{\circ}\) in T as given in (13.49), we obtain the following rotated loadings:
\[
\begin{aligned}
\hat{\boldsymbol{\Lambda}}^{*}=\hat{\boldsymbol{\Lambda}} \mathbf{T} & =\left(\begin{array}{rr}
.969 & -.231 \\
.519 & .807 \\
.785 & -.587 \\
.971 & -.210 \\
.704 & .667
\end{array}\right)\left(\begin{array}{rr}
.819 & .574 \\
-.574 & .819
\end{array}\right) \\
& =\left(\begin{array}{rr}
.927 & .367 \\
-.037 & .959 \\
.980 & -.031 \\
.916 & .385 \\
.194 & .950
\end{array}\right)
\end{aligned}
\]

In Table 13.6, we compare the rotated loadings in \(\hat{\boldsymbol{\Lambda}}^{*}\) with the original loadings in \(\hat{\boldsymbol{\Lambda}}\).

The interpretation of the rotated loadings is clear. As indicated by the boldface loadings in Table 13.6, the first factor is associated with variables 1, 3, and 4: kind, happy, and likeable. The second factor is associated with the other two variables: intelligent and just. This same grouping of variables is indicated by the pattern in the correlation matrix in (13.35) and can also be seen in the two clusters of points in Figure 13.3. The first factor might be described as representing a person's perceived humanity or amiability, while the second involves more logical or rational practices.

Figure 13.3 Plot of the two loadings for each of the five variables in the perception data of Table 13.1.

Note that if the angle between the rotated axes was allowed to be less than \(90^{\circ}\) (an oblique rotation), the lower axis representing \(f_{1}^{*}\) could come closer to the points corresponding to variables 1 and 4 so that the coordinates on \(f_{2}^{*}\), .367 and .385 , could be reduced. However, the basic interpretation would not change; variables 1 and 4 would still be associated with \(f_{1}^{*}\).

\subsection*{13.5.2b Varimax Rotation}

The graphical approach to rotation is generally limited to \(m=2\). For \(m>2\), various analytical methods have been proposed. The most popular of these is the varimax technique, which seeks rotated loadings that maximize the variance of the squared loadings in each column of \(\hat{\boldsymbol{\Lambda}}^{*}\). If the loadings in a column were nearly equal, the variance would be close to 0 . As the squared loadings approach 0 and 1 (for factoring \(\mathbf{R}\) ), the variance will approach a maximum. Thus the varimax method attempts to make the loadings either large or small to facilitate interpretation.

The varimax procedure cannot guarantee that all variables will load highly on only one factor. In fact, no procedure could do this for all possible data sets. The configuration of the points in the loading space remains fixed; we merely rotate the

Table 13.6 Graphically Rotated Loadings for the Perception Data of Table 13.1
\begin{tabular}{lrrrrrl}
\hline & \multicolumn{2}{c}{\begin{tabular}{c} 
Principal \\
Component \\
Loadings
\end{tabular}} & & \multicolumn{2}{c}{\begin{tabular}{c} 
Graphically \\
Rotated \\
Loadings
\end{tabular}} &
\end{tabular} Communalities,
axes to be as close to as many points as possible. In many cases, the points are not well clustered, and the axes simply cannot be rotated so as to be near all of them. This problem is compounded by having to choose \(m\). If \(m\) is changed, the coordinates ( \(\hat{\lambda}_{i 1}, \hat{\lambda}_{i 2}, \ldots, \hat{\lambda}_{i m}\) ) change, and the relative position of the points is altered.

The varimax rotation is available in virtually all factor analysis software programs. The output typically includes the rotated loading matrix \(\hat{\Lambda}^{*}\), the variance accounted for (sum of squares of each column of \(\hat{\Lambda}^{*}\) ), the communalities (sum of squares of each row of \(\hat{\Lambda}^{*}\) ), and the orthogonal matrix \(\mathbf{T}\) used to obtain \(\hat{\Lambda}^{*}=\hat{\Lambda} \mathbf{T}\).

\section*{EXAMPLE 13.5.2b(a)}

In Example 13.5.2a, a graphical rotation was devised visually to achieve interpretable loadings for the perception data of Table 13.1. As we would expect, the varimax method yields a similar result. The varimax rotated loadings are given in Table 13.7. For comparison, we have included the original unrotated loadings from Table 13.3 and the graphically rotated loadings from Table 13.6.

The orthogonal matrix T for the varimax rotation is
\[
\mathbf{T}=\left(\begin{array}{rr}
.859 & .512 \\
-.512 & .859
\end{array}\right)
\]

By (13.49), \(-\sin \phi=.512\), and the angle of rotation is \(\phi=-\sin ^{-1}(.512)=\) \(-30.8^{\circ}\). Thus the varimax rotation chose an angle of rotation of \(-30.8^{\circ}\) as compared to the \(-35^{\circ}\) we selected visually, but the results are very close and the interpretation is exactly the same.

Table 13.7 Varimax Rotated Factor Loadings for the Perception Data of Table 13.1

\hline Proportion of total variance & . 653 & . 308 & . 539 & . 421 & . 562 & . 398 & . 960 \\
\hline Cumulative proportion & . 653 & . 960 & . 539 & . 960 & . 562 & . 960 & . 960 \\
\hline
\end{tabular}

\section*{■ EXAMPLE 13.5.2b(b)}

In Examples 13.3.3 and 13.3.4, we obtained the iterated principal factor loadings and maximum likelihood loadings for the Seishu data. In Table 13.8, we show the varimax rotation of these two sets of loadings. The similarities in the two sets of rotated loadings are striking. The interpretation in each case is the same. The variances accounted for are virtually identical.

The rotation in each case has achieved a satisfactory simple structure, and most variables show a complexity of 1 . The boldface loadings indicate the variables associated with each factor for interpretation purposes. These may be meaningful to the researcher. For example, factor 2 is associated with sake meter, reducing sugar, and total sugar, while factor 3 is aligned with taste and odor.

\subsection*{13.5.3 Oblique Rotation}

The term oblique rotation refers to a transformation in which the axes do not remain perpendicular. Technically, the term oblique rotation is a misnomer, since rotation implies an orthogonal transformation that preserves distances. A more accurate characterization would be oblique transformation, but the term oblique rotation is well established in the literature.

Instead of the orthogonal transformation matrix \(T\) used in (13.16), (13.17), and (13.18), an oblique rotation uses a general nonsingular transformation matrix \(\mathbf{Q}\) to obtain \(\mathbf{f}^{*}=\mathbf{Q}^{\prime} \mathbf{f}\), and by (3.74),
\[
\begin{equation*}
\operatorname{cov}\left(\mathbf{f}^{*}\right)=\mathbf{Q}^{\prime} \mathbf{I} \mathbf{Q}=\mathbf{Q}^{\prime} \mathbf{Q} \neq \mathbf{I} . \tag{13.50}
\end{equation*}
\]

Table 13.8 Varimax Rotated Loadings for the Seishu Data
\begin{tabular}{|c|c|c|c|c|c|c|c|c|}
\hline \multirow[b]{2}{*}{Variables} & \multicolumn{4}{|r|}{Iterated Principal Factor Rotated Loadings} & \multicolumn{4}{|c|}{Maximum Likelihood Rotated Loadings} \\
\hline & \(f_{1}\) & \(f_{2}\) & \(f_{3}\) & \(f_{4}\) & \(f_{1}\) & \(f_{2}\) & \(f_{3}\) & \(f_{4}\) \\
\hline Taste & . 16 & -. 01 & . 99 & -. 09 & . 16 & -. 00 & . 98 & -. 10 \\
\hline Odor & -. 11 & . 14 & . 48 & . 14 & -. 07 & . 14 & . 49 & . 17 \\
\hline pH & . 88 & -. 12 & . 02 & \(-.13\) & . 82 & -. 10 & . 08 & -. 15 \\
\hline Acidity 1 & . 26 & -. 09 & . 09 & . 54 & . 29 & -. 08 & . 11 & . 53 \\
\hline Acidity 2 & . 89 & -. 06 & . 10 & . 43 & . 91 & -. 06 & . 10 & . 39 \\
\hline Sake meter & -. 43 & -. 76 & . 01 & . 07 & -. 46 & -. 80 & . 04 & . 10 \\
\hline Reducing sugar & -. 37 & . 76 & . 18 & . 03 & -. 37 & . 75 & . 20 & . 08 \\
\hline Total sugar & -. 26 & . 92 & . 10 & . 25 & -. 27 & . 91 & . 11 & . 26 \\
\hline Alcohol & -. 01 & . 25 & . 00 & . 80 & -. 00 & . 25 & . 01 & . 81 \\
\hline Formyl-nitrogen & . 74 & -. 07 & -. 08 & . 20 & . 76 & -. 07 & -. 08 & . 22 \\
\hline Variance accounted for & 2.62 & 2.12 & 1.27 & 1.27 & 2.61 & 2.14 & 1.29 & 1.28 \\
\hline
\end{tabular}

Thus the new factors are correlated. Since distances and angles are not preserved, the communalities for \(\mathbf{f}^{*}\) are different from those for \(\mathbf{f}\). Some program packages report communalities obtained from the original loadings, rather than the oblique loadings.

When the axes are not required to be perpendicular, they can more easily pass through the major clusters of points in the loading space (assuming there are such clusters). For example, in Figure 13.4, we have plotted the varimax rotated loadings for two factors extracted from the sons data of Table 3.8 (see Example 13.5.3 at the end of this section). Oblique axes with an angle of \(38^{\circ}\) would pass much closer to the points, and the resulting loadings would be very close to 0 and 1 . However, the interpretation would not change, since the same points (variables) would be associated with the oblique axes as with the orthogonal axes.

Various analytical methods for achieving oblique rotations have been proposed and are available in program packages. Typically, the output of one of these procedures includes a pattern matrix, a structure matrix, and a matrix of correlations among the oblique factors. For interpretation, we would usually prefer the pattern matrix rather than the structure matrix. The loadings in a row of the pattern matrix are the natural coordinates of the point (variable) on the oblique axes and serve as coefficients in the model relating the variable to the factors.

One use for an oblique rotation is to check on the orthogonality of the factors. The orthogonality in the original factors is imposed by the model and maintained by an orthogonal rotation. If an oblique rotation produces a correlation matrix that is nearly diagonal, we can be more confident that the factors are indeed orthogonal.

Figure 13.4 Orthogonal and oblique rotations for the sons data.

\section*{EXAMPLE 13.5.3}

The correlation matrix for the sons data of Table 3.8 is given below:
\[
\mathbf{R}=\left(\begin{array}{rrrr}
1.000 & .735 & .711 & .704 \\
.735 & 1.000 & .693 & .709 \\
.711 & .693 & 1.000 & .839 \\
.704 & .709 & .839 & 1.000
\end{array}\right)
\]

The varimax rotated loadings for two factors obtained by the principal component method are given in Table 13.9 and plotted in Figure 13.4. An analytical oblique rotation (Harris-Kaiser orthoblique method in SAS) produced oblique axes with an angle of \(38^{\circ}\), the same as obtained by a graphical approach. The correlation between the two factors is .79 [obtained from \(Q^{\prime} Q\) in (13.50)], which is related to the angle by (3.15), .79 \(=\cos 38^{\circ}\). The pattern loadings are given in Table 13.9.

The oblique loadings give a much cleaner simple structure than the varimax loadings, but the interpretation is essentially the same if we neglect loadings below .45 on the varimax rotation.

Table 13.9 Varimax and Orthoblique Loadings for the Sons Data
\begin{tabular}{ccrrrr}
\hline & \multicolumn{2}{c}{\begin{tabular}{c} 
Varimax \\
Loadings
\end{tabular}} & & \multicolumn{2}{c}{\begin{tabular}{c} 
Orthoblique \\
Pattern Matrix
\end{tabular}} \\
\cline { 2 - 3 } \cline { 5 - 6 } Variable & \(f_{1}\) & \(f_{2}\) & & \(f_{1}\) & \(f_{2}\) \\
\hline 1 & .42 & \(\mathbf{. 8 2}\) & & .03 & \(\mathbf{. 9 0}\) \\
2 & .40 & \(\mathbf{8 5}\) & & -.03 & \(\mathbf{. 9 6}\) \\
3 & \(\mathbf{8 7}\) & .41 & & \(\mathbf{9 7}\) & -.01 \\
4 & \(\mathbf{. 8 6}\) & .43 & \(\mathbf{. 9 5}\) & .01 \\
\hline
\end{tabular}

In Figure 13.4, it is evident that a single factor would be adequate since the angle between axes is less than \(45^{\circ}\). The suggestion to let \(m=1\) is also supported by the first three criteria in Section 13.4: the eigenvalues of \(\mathbf{R}\) are \(3.20, .38, .27\), and .16 . The first accounts for \(80 \%\), the second for an additional \(9 \%\). The large correlation, .79 , between the two oblique factors constitutes additional evidence that a single factor model would suffice here. In fact, the pattern in \(\mathbf{R}\) itself indicates the presence of only one factor. The four variables form only one cluster, since all are highly correlated. There are no small correlations between groupings of variables.

\subsection*{13.5.4 Interpretation}

In Sections 13.5.1, 13.5.2, and 13.5.3, we have discussed the usefulness of rotation as an aid to interpretation. Our goal is to achieve a simple structure in which each variable loads highly on only one factor, with small loadings on all other factors. In practice, we often fail to achieve this goal, but rotation usually produces loadings that are closer to the desired simple structure.

We now suggest general guidelines for interpreting the factors by examination of the matrix of rotated factor loadings. Moving horizontally from left to right across the \(m\) loadings in each row, identify the highest loading (in absolute value). If the highest loading is of a significant size (a subjective determination, see the next paragraph), circle or underline it. This is done for each of the \(p\) variables. There may be other significant loadings in a row besides the one circled. If these are considered, the interpretation is less simple. On the other hand, there may be variables with such small communalities that no significant loading appears on any factor. In this case, the researcher may wish to increase the number of factors and run the program again so that these variables might associate with a new factor.

To assess significance of factor loadings \(\hat{\lambda}_{i j}\) obtained from \(\mathbf{R}\), a threshold value of .3 has been advocated by many writers. For most successful applications, however, a critical value of .3 is too low and will result in variables of complexity greater than 1. A target value of .5 or .6 is typically more useful. The .3 criterion is loosely based on the critical value for significance of an ordinary correlation coefficient, \(r\). However, the distribution of the sample loadings is not the same as that of \(r\) arising
from the bivariate normal. In addition, the critical value should be increased because \(m p\) values of \(\hat{\lambda}_{i j}\) are being tested. On the other hand, if \(m\) is large, the critical value might possibly need to be reduced somewhat. Since \(\hat{h}_{i}^{2}=\sum_{j=1}^{m} \hat{\lambda}_{i j}^{2}\) is bounded by 1 , an increase in \(m\) reduces the average squared loading in a row.

After identifying potentially significant loadings, the experimenter then attempts to discover some meaning in the factors and, ideally, to label or name them. This can readily be done if the group of variables associated with each factor makes sense to the researcher. But in many situations, the groupings are not so logical, and a revision can be tried, such as adjusting the size of loading deemed to be important, changing \(m\), using a different method of estimating the loadings, or employing another type of rotation.

\subsection*{13.6 FACTOR SCORES}

In many applications, the researcher wishes only to ascertain whether a factor analysis model fits the data and to identify the factors. In other applications, the experimenter wishes to obtain factor scores \(\hat{\mathbf{f}}_{i}=\left(\hat{f}_{i 1}, \hat{f}_{i 2}, \ldots, \hat{f}_{i m}\right)^{\prime}, i=1,2, \ldots, n\), which are defined as estimates of the underlying factor values for each observation. There are two potential uses for such scores: (1) the behavior of the observations in terms of the factors may be of interest and (2) we may wish to use the factor scores as input to another analysis, such as MANOVA. The latter usage resembles a similar application of principal components.

Since the \(f\) 's are not observed, we must estimate them as functions of the observed \(y\) 's. The most popular approach to estimating the factors is based on regression (Thompson 1951). We will discuss this method and also briefly describe an informal technique that can be used when \(\mathbf{R}\) (or \(\mathbf{S}\) ) is singular. For other approaches see Harman (1976, Chapter 16).

Since \(E\left(f_{i}\right)=0\), we relate the \(f\) 's to the \(y\) 's by a centered regression model
\[
\begin{align*}
f_{1} & =\beta_{11}\left(y_{1}-\bar{y}_{1}\right)+\beta_{12}\left(y_{2}-\bar{y}_{2}\right)+\cdots+\beta_{1 p}\left(y_{p}-\bar{y}_{p}\right)+\epsilon_{1} \\
f_{2} & =\beta_{21}\left(y_{1}-\bar{y}_{1}\right)+\beta_{22}\left(y_{2}-\bar{y}_{2}\right)+\cdots+\beta_{2 p}\left(y_{p}-\bar{y}_{p}\right)+\epsilon_{2} \\
& \vdots  \tag{13.51}\\
f_{m} & =\beta_{m 1}\left(y_{1}-\bar{y}_{1}\right)+\beta_{m 2}\left(y_{2}-\bar{y}_{2}\right)+\cdots+\beta_{m p}\left(y_{p}-\bar{y}_{p}\right)+\epsilon_{m}
\end{align*}
\]
which can be written in matrix form as
\[
\begin{equation*}
\mathbf{f}=\mathbf{B}_{1}^{\prime}(\mathbf{y}-\overline{\mathbf{y}})+\boldsymbol{\epsilon} \tag{13.52}
\end{equation*}
\]

We have used the notation \(\epsilon\) to distinguish this error from \(\varepsilon\) in the original factor model \(\mathbf{y}-\boldsymbol{\mu}=\boldsymbol{\Lambda f}+\varepsilon\) given in (13.3). Our approach is to estimate \(\mathbf{B}_{1}\) and use the predicted value \(\hat{\mathbf{f}}=\hat{\mathbf{B}}_{1}^{\prime}(\mathbf{y}-\overline{\mathbf{y}})\) to estimate \(\mathbf{f}\).

The model (13.52) holds for each observation:
\[
\mathbf{f}_{i}=\mathbf{B}_{1}^{\prime}\left(\mathbf{y}_{i}-\overline{\mathbf{y}}\right)+\boldsymbol{\epsilon}_{i}, \quad i=1,2, \ldots, n
\]

In transposed form, the model becomes
\[
\mathbf{f}_{i}^{\prime}=\left(\mathbf{y}_{i}-\overline{\mathbf{y}}\right)^{\prime} \mathbf{B}_{1}+\epsilon_{i}^{\prime}, \quad i=1,2, \ldots, n
\]
and these \(n\) equations can be combined into a single model,
\[
\begin{align*}
\mathbf{F}=\left(\begin{array}{c}
\mathbf{f}_{1}^{\prime} \\
\mathbf{f}_{2}^{\prime} \\
\vdots \\
\mathbf{f}_{n}^{\prime}
\end{array}\right) & =\left(\begin{array}{c}
\left(\mathbf{y}_{1}-\overline{\mathbf{y}}\right)^{\prime} \mathbf{B}_{1} \\
\left(\mathbf{y}_{2}-\overline{\mathbf{y}}\right)^{\prime} \mathbf{B}_{1} \\
\vdots \\
\left(\mathbf{y}_{n}-\overline{\mathbf{y}}\right)^{\prime} \mathbf{B}_{1}
\end{array}\right)+\left(\begin{array}{c}
\epsilon_{1}^{\prime} \\
\epsilon_{2}^{\prime} \\
\vdots \\
\epsilon_{n}^{\prime}
\end{array}\right) \\
& =\left(\begin{array}{c}
\left(\mathbf{y}_{1}-\overline{\mathbf{y}}\right)^{\prime} \\
\left(\mathbf{y}_{2}-\overline{\mathbf{y}}\right)^{\prime} \\
\vdots \\
\left(\mathbf{y}_{n}-\overline{\mathbf{y}}\right)^{\prime}
\end{array}\right) \mathbf{B}_{1}+\boldsymbol{\Xi} \\
& =\mathbf{Y}_{c} \mathbf{B}_{1}+\boldsymbol{\Xi} \quad[\mathrm{by}(10.11)] \tag{13.53}
\end{align*}
\]

The model (13.53) has the appearance of a centered multivariate multiple regression model as in Section 10.4.5, with \(\mathbf{Y}_{c}\) in place of \(\mathbf{X}_{c}\). By (10.55), the estimate for \(B_{1}\) would be
\[
\begin{equation*}
\hat{\mathbf{B}}_{1}=\left(\mathbf{Y}_{c}^{\prime} \mathbf{Y}_{c}\right)^{-1} \mathbf{Y}_{c}^{\prime} \mathbf{F} \tag{13.54}
\end{equation*}
\]

However, \(\mathbf{F}\) is unobserved. To evaluate \(\hat{\mathbf{B}}_{1}\) in spite of this, we first use (10.57) to rewrite (13.54) in terms of covariance matrices,
\[
\begin{equation*}
\hat{\mathbf{B}}_{1}=\mathbf{S}_{y y}^{-1} \mathbf{S}_{y f} \tag{13.55}
\end{equation*}
\]

In the notation of the present chapter, \(\mathbf{S}_{y y}\) is represented by \(\mathbf{S}\); for \(\mathbf{S}_{y f}\) we use \(\hat{\boldsymbol{\Lambda}}\), since \(\hat{\boldsymbol{\Lambda}}\) estimates \(\operatorname{cov}(\mathbf{y}, \mathbf{f})=\boldsymbol{\Lambda}\) in (13.13). Thus, based on the assumptions in Section 13.2.1, we can write (13.55) as
\[
\begin{equation*}
\hat{\mathbf{B}}_{1}=\mathbf{S}^{-1} \hat{\boldsymbol{\Lambda}} \tag{13.56}
\end{equation*}
\]

Then from model (13.53), the estimated (predicted) \(\mathbf{f}_{i}\) values are given by
\[
\begin{align*}
\hat{\mathbf{F}}=\left(\begin{array}{c}
\hat{\mathbf{f}}_{1}^{\prime} \\
\hat{\mathbf{f}}_{2}^{\prime} \\
\vdots \\
\hat{\mathbf{f}}_{n}^{\prime}
\end{array}\right) & =\mathbf{Y}_{c} \hat{\mathbf{B}}_{1} \\
& =\mathbf{Y}_{c} \mathbf{S}^{-1} \hat{\mathbf{\Lambda}} \tag{13.57}
\end{align*}
\]

If \(\mathbf{R}\) is factored instead of \(\mathbf{S}\), (13.56) and (13.57) become
\[
\begin{align*}
\hat{\mathbf{B}}_{1} & =\mathbf{R}^{-1} \boldsymbol{\Lambda}  \tag{13.58}\\
\hat{\mathbf{F}} & =\mathbf{Y}_{s} \mathbf{R}^{-1} \hat{\boldsymbol{\Lambda}} \tag{13.59}
\end{align*}
\]
respectively, where \(\mathbf{Y}_{s}\) is the observed matrix of standardized variables, \(\left(y_{i j}-\right.\) \(\left.\bar{y}_{j}\right) / s_{j}\).

We would ordinarily obtain factor scores for the rotated factors rather than the original factors. Thus \(\hat{\Lambda}\) in (13.57) or (13.59) would be replaced by \(\hat{\Lambda}^{*}\).

In order to obtain factor scores by (13.57) or (13.59), \(\mathbf{S}\) or \(\mathbf{R}\) must be nonsingular. When \(\mathbf{R}\) (or \(\mathbf{S}\) ) is singular, we can obtain factor scores by a simple method based directly on the rotated loadings. We cluster the variables into groups (factors) according to the loadings and find a score for each factor by averaging the variables associated with the factor. If the variables are not commensurate, the variables should be standardized before averaging. An alternative approach would be to weight the variables by their loadings when averaging.

\section*{- EXAMPLE 13.6}

The speaking rate of four voices was artificially manipulated by means of a rate changer without altering the pitch (Brown, Strong, and Rencher 1973). There were five rates for each voice:
\[
\begin{aligned}
\mathrm{FF} & =45 \% \text { faster } \\
\mathrm{F} & =25 \% \text { faster } \\
\mathrm{N} & =\text { normal rate } \\
\mathrm{S} & =22 \% \text { slower } \\
\mathrm{SS} & =42 \% \text { slower }
\end{aligned}
\]

The resulting 20 voices were played to 30 judges who rated them on 15 paired-opposite adjectives (variables) with a 14 -point scale between poles. The following adjectives were used: intelligent, ambitious, polite, active, confident, happy, just, likeable, kind, sincere, dependable, religious, good-looking, sociable, and strong. The results were averaged over the 30 judges to produce 20 observation vectors of 15 variables each. The averaging produced very reliable data so that even though there were only 20 observations on 15 variables, the factor analysis model fit very well. The correlation matrix is as follows:
\[
\mathbf{R}=\left(\begin{array}{rrrrrrrrrrrrr}
1.00 & .90 & -.17 & .88 & .92 & .88 & .15 & .39 & -.02 & -.16 & .52 & -.15 & -.79 \\
.90 & 1.00 & -.46 & .93 & .87 & .79 & -.16 & .10 & -.35 & -.42 & .25 & -.40 & .68 \\
\hline . .60 & .72 \\
-.17 & -.46 & 1.00 & -.56 & -.13 & .07 & .85 & .75 & .88 & .91 & .68 & .88 & .21 \\
.31 & .25 \\
.88 & .93 & -.56 & 1.00 & .85 & .73 & -.25 & -.02 & -.45 & -.57 & .10 & -.53 & .58 \\
.84 & .50 \\
.92 & .87 & -.13 & .85 & 1.00 & .91 & .20 & .39 & -.09 & -.16 & .49 & -.10 & .85 \\
.80 & .81 \\
.88 & .79 & .07 & .73 & .91 & 1.00 & .27 & .53 & .12 & .06 & .66 & .08 & .90 \\
.85 & .78 \\
.15 & -.16 & .85 & -.25 & .20 & .27 & 1.00 & .85 & .81 & .79 & .79 & .81 & .43 \\
.54 & .53 \\
.39 & .10 & .75 & -.02 & .39 & .53 & .85 & 1.00 & .84 & .79 & .93 & .77 & .71 \\
.69 & .76 \\
-.02 & -.35 & .88 & -.45 & -.09 & .12 & .81 & .84 & 1.00 & .91 & .76 & .85 & .28 \\
.36 & .35 \\
-.16 & -.42 & .91 & -.57 & -.16 & .06 & .79 & .79 & .91 & 1.00 & .72 & .96 & .26 \\
.28 & .29 \\
.52 & .25 & .67 & .10 & .49 & .66 & .79 & .93 & .76 & .72 & 1.00 & .72 & .75 \\
\hline .77 & .78 \\
-.15 & -.40 & .88 & -.53 & -.10 & .08 & .81 & .77 & .85 & .96 & .72 & 1.00 & .33 \\
.32 & .34 \\
.79 & .68 & .21 & .58 & .85 & .90 & .43 & .71 & .28 & .26 & .75 & .33 & 1.00 \\
.86 & .92 \\
.78 & .60 & .31 & .54 & .80 & .85 & .54 & .69 & .36 & .28 & .77 & .32 & .86 \\
.73 & .62 & .25 & .50 & .81 & .78 & .53 & .76 & .35 & .29 & .78 & .34 & .92 \\
& .82 & 1.00
\end{array}\right)
\]

Figure 13.5 Scree graph for voice data.

The eigenvalues of \(\mathbf{R}\) are \(7.91,5.85, .31, .26, \cdots, .002\), with the scree plot in Figure 13.5. Clearly, by any criterion for choosing \(m\), there are two factors.

All four major methods of factor extraction discussed in Section 13.3 produced nearly identical results (after rotation). We give the initial and rotated loadings obtained from the principal component method in Table 13.10.

The two rotated factors were labeled "competence" and "benevolence." The same two factors emerged consistently in similar studies with different voices and different judges.

The two groupings of variables can also be seen in the correlation matrix. For example, in the first row, the large correlations correspond to the boldface rotated loadings for \(f_{1}\), while in the third row, the large correlations correspond to the boldface rotated loadings for \(f_{2}\).

The factor scores were of primary interest in this study. The goal was to ascertain the effect of the rate manipulations on the two factors, that is, to determine the perceived change in competence and benevolence when the speaking rate is increased or decreased.

The two factor scores were obtained for each of the 20 voices; these are plotted in Figure 13.6, where a consistent effect of the manipulation of speaking rate on all four voices can clearly be seen. Decreasing the speaking rate causes the speaker to be rated less competent; increasing the rate causes the speaker to be rated less benevolent. The mean vectors (centroids) are also given in Figure 13.6 for the four speakers.

Table 13.10 Initial and Varimax Rotated Loadings for the Voice Data
\begin{tabular}{|c|c|c|c|c|c|}
\hline \multirow[b]{2}{*}{Variable} & \multicolumn{2}{|l|}{Initial Loadings} & \multicolumn{2}{|l|}{Rotated Loadings} & \multirow[b]{2}{*}{Communalities} \\
\hline & \(f_{1}\) & \(f_{2}\) & \(f_{1}\) & \(f_{2}\) & \\
\hline Intelligent & 71 & -. 65 & . 96 & -. 06 & . 93 \\
\hline Ambitious & . 48 & -. 84 & . 90 & -. 36 & . 94 \\
\hline Polite & . 50 & . 81 & -. 12 & . 95 & . 92 \\
\hline Active & . 37 & -. 91 & . 86 & -. 48 & . 97 \\
\hline Confident & . 73 & -. 64 & . 97 & -. 04 & . 95 \\
\hline Happy & . 83 & -. 47 & . 94 & . 15 & . 91 \\
\hline Just & . 71 & . 58 & . 20 & . 89 & . 84 \\

\hline Proportion of total variance & . 53 & . 39 & . 47 & . 44 & . 92 \\
\hline Cumulative proportion & . 53 & . 92 & . 47 & . 92 & . 92 \\
\hline
\end{tabular}

\subsection*{13.7 VALIDITY OF THE FACTOR ANALYSIS MODEL}

For many statisticians, factor analysis is controversial and does not belong in a tool kit of legitimate multivariate techniques. The reasons for this mistrust include the following: the difficulty in choosing \(m\), the many methods of extracting factors, the many rotation techniques, and the subjectivity in interpretation. Some statisticians also criticize factor analysis because of the indeterminacy of the factor loading matrix \(\boldsymbol{\Lambda}\) or \(\hat{\boldsymbol{\Lambda}}\), first noted in Section 13.2.2. However, it is the ability to rotate that gives factor analysis its utility, if not its charm.

The basic question is whether the factors really exist. The model (13.11) for the covariance matrix is \(\boldsymbol{\Sigma}=\boldsymbol{\Lambda} \mathbf{\Lambda}^{\prime}+\boldsymbol{\Psi}\) or \(\boldsymbol{\Sigma}-\boldsymbol{\Psi}=\boldsymbol{\Lambda} \boldsymbol{\Lambda}^{\prime}\), where \(\boldsymbol{\Lambda} \mathbf{\Lambda}^{\prime}\) is of rank \(m\). Many populations have covariance matrices that do not approach this pattern unless \(m\) is large. Thus the model will not fit data from such a population when we try to impose a small value of \(m\). On the other hand, for a population in which \(\Sigma\) is reasonably close to \(\mathbf{\Lambda} \mathbf{\Lambda}^{\prime}+\boldsymbol{\Psi}\) for small \(m\), the sampling procedure leading to \(\mathbf{S}\) may obscure this pattern. The researcher may believe there are underlying factors but has difficulty collecting data that will reveal them. In many cases, the basic problem is

Figure 13.6 Factor scores of adjective rating of voices with five levels of manipulated rate.
that \(\mathbf{S}\) (or \(\mathbf{R}\) ) contains both structure and error, and the methods of factor analysis cannot separate the two.

A statistical consultant in a university setting or elsewhere all too often sees the following scenario. A researcher designs a long questionnaire, with answers to be given in, say, a five-point semantic differential scale or Likert scale. The respondents, who vary in attitude from uninterested to resentful, hurriedly mark answers that in many cases are not even good subjective responses to the questions. Then the researcher submits the results to a handy factor analysis program. Being disappointed in the results, he or she appeals to a statistician for help. They attempt to improve the results by trying different methods of extraction, different rotations, different values of \(m\), and so on. But it is all to no avail. The scree plot looks more like foothills than a steep cliff with gently sloping debris at the bottom. There is no clear value of \(m\). They have to extract 10 or 12 factors to account for, say, \(60 \%\) of the variance, and interpretation of this large number of factors is hopeless. If a few underlying dimensions exist, they are totally obscured by both systematic and random errors in marking the questionnaire. A factor analysis model simply does not fit such a data set, unless a large value of \(m\) is used, which gives useless results.

It is not necessarily the "discreteness" of the data that causes the problem, but the "noisiness" of the data. The specified variables are not measured accurately. In some cases, discrete variables yield satisfactory results, such as in Examples 13.3.1, 13.3.2, 13.5.2a, and \(13.5 .2 \mathrm{~b}(\mathrm{a})\), where a 12 -year-old girl, responding carefully to a semantic
differential scale, produced data leading to an unambiguous factor analysis. On the other hand, continuous variables do not guarantee good results [see Example 13.7(a) below].

In cases in which some factors are found that provide a satisfactory fit to the data, we should still be tentative in interpretation until we can independently establish the existence of the factors. If the same factors emerge in repeated sampling from the same population or a similar one, then we can have confidence that application of the model has uncovered some real factors. Thus it is good practice to repeat the experiment to check the stability of the factors. If the data set is large enough, it could be split in half and a factor analysis performed on each half. The two solutions could be compared with each other and with that for the complete set.

If there is replication in the data set, it may be helpful to average over the replications. This was done to great advantage in Example 13.6, where several judges rated the same voices. Averaging over the judges produced variables that apparently possessed very low noise. Similar experimentation with different judges always produced the same factors. Unfortunately, replication of this type is unavailable in most situations.

As with other techniques in this book, factor analysis assumes that the variables are at least approximately linearly related to each other. We could make bivariate scatterplots to check this assumption.

A basic prerequisite for a factor analysis application is that the variables not be independent. To check this requirement, we could test \(H_{0}: \mathbf{P}_{\rho}=\mathbf{I}\) by using the test in Section 7.4.3.

Some writers have suggested that \(\mathbf{R}^{-1}\) should be a near-diagonal matrix in order to successfully fit a factor analysis model. To assess how close \(\mathbf{R}^{-1}\) is to a diagonal matrix, Kaiser (1970) proposed a measure of sampling adequacy,
\[
\begin{equation*}
\mathrm{MSA}=\frac{\sum_{i \neq j} r_{i j}^{2}}{\sum_{i \neq j} r_{i j}^{2}+\sum_{i \neq j} q_{i j}^{2}}, \tag{13.60}
\end{equation*}
\]
where \(r_{i j}^{2}\) is the square of an element from \(\mathbf{R}\) and \(q_{i j}^{2}\) is the square of an element from \(\mathbf{Q}=\mathbf{D} \mathbf{R}^{-1} \mathbf{D}\), with \(\mathbf{D}=\left[\left(\operatorname{diag} \mathbf{R}^{-1}\right)^{1 / 2}\right]^{-1}\). As \(\mathbf{R}^{-1}\) approaches a diagonal matrix, MSA approaches 1. Kaiser and Rice (1974) suggest that MSA should exceed .8 for satisfactory results to be expected. We show some results for MSA in Example 13.7(b).

In summary, there are many data sets to which factor analysis should not be applied. One indication that \(\mathbf{R}\) is inappropriate for factoring is the failure of the methods in Section 13.4 to clearly and rather objectively choose a value for \(m\). If the scree plot does not have a pronounced bend or the eigenvalues do not show a large gap around 1 , then \(\mathbf{R}\) is likely to be unsuitable for factoring. In addition, the communality estimates after factoring should be fairly large.

To balance the "good" examples in this chapter, we now give an example involving a data set that cannot be successfully modeled by factor analysis. Likewise, the problems at the end of the chapter include both "good" and "bad" data sets.

Figure 13.7 Scree graph for diabetes data.

\section*{EXAMPLE 13.7(a)}

As an illustration of an application of factor analysis that is less successful than previous examples in this chapter, we consider the diabetes data of Table 3.4. The correlation matrix for the five variables is as follows:
\[
\mathbf{R}=\left(\begin{array}{rrrrr}
1.00 & .05 & -.13 & .07 & .21 \\
.05 & 1.00 & -0.1 & .01 & -.10 \\
-.13 & -.01 & 1.00 & .29 & .05 \\
.07 & .01 & .29 & 1.00 & .21 \\
.21 & -.10 & .05 & .21 & 1.00
\end{array}\right)
\]

The correlations are all small, and the variables do not appear to have much in common. The MSA value is .49 . The eigenvalues are \(1.40,1.21,1.04, .71\), and .65 . Three factors would be required to account for \(73 \%\) of the variance and four factors to reach \(87 \%\). This is not a useful reduction in dimensionality. The eigenvalues are plotted in a scree graph in Figure 13.7. The lack of a clear value of \(m\) is apparent.

It is evident from the small correlations in \(\mathbf{R}\) that the communalities of the variables will not be large. The principal component method, which essentially estimates the initial communalities as 1 , gave very different final communality estimates than did the iterated principal factor method:

Communalities
Principal component method \(\quad .71 \quad .91 \quad .71 \quad .67 \quad .64\)
Iterated principal factor method \(\quad .31\). 16 . 35 . 37 . 33

Table 13.11 Varimax Rotated Factor Loadings for Iterated Principal Factors from the Diabetes Data
\begin{tabular}{lrrrc}
\hline & \multicolumn{2}{c}{ Rotated Loadings } & \\
\cline { 2 - 4 } Variable & \multicolumn{1}{c}{\(f_{1}\)} & \multicolumn{1}{c}{\(f_{2}\)} & \multicolumn{1}{c}{\(f_{3}\)} & Communalities \\
\hline 1 & -.08 & \(\mathbf{. 5 4}\) & .12 & .31 \\
2 & .01 & .01 & \(\mathbf{. 4 0}\) & .16 \\
3 & \(\mathbf{5 7}\) & -.15 & -.03 & .35 \\
4 & \(\mathbf{5 7}\) & .22 & .02 & .37 \\
5 & .19 &. \(\mathbf{4 7}\) & -.27 & .33 \\
Variance & & & & \\
accounted for & .69 & .59 & .24 & 1.52 \\
\hline
\end{tabular}

The communalities obtained by the iterated approach reflect more accurately the small correlations among the variables.

The varimax rotated factor loadings for three factors extracted by the iterated principal factor method are given in Table 13.11. The first factor is associated with variables 3 and 4, the second factor with variables 1 and 5, and the third with variable 2 . This clustering of variables can be seen in \(\mathbf{R}\), where variables 1 and 5 have a correlation of .21, variables 3 and 4 have a correlation of .29 , and variable 2 has very low correlations with all other variables. However, these correlations (.21 and .29) are small, and in this case the collapsing of five variables to three factors is not a useful reduction in dimensionality, especially since the first three eigenvalues account for only \(73 \%\) of \(\operatorname{tr}(\mathbf{R})\). The \(73 \%\) is not convincingly greater than \(60 \%\), which we would expect from three original variables picked at random. This conclusion is borne out by a test of \(H_{0}: \mathbf{P}_{\rho}=\mathbf{I}\). Using (7.37) and (7.38), we obtain
\[
\begin{aligned}
u & =|\mathbf{R}|=.80276, \quad \nu=20-1=19, \quad p=5 \\
u^{\prime} & =-\left[\nu-\frac{1}{6}(2 p+5)\right] \ln u=-\left(19-\frac{15}{6}\right)(-.2197)=3.625 .
\end{aligned}
\]

With \(\frac{1}{2} p(p-1)=10\) degrees of freedom, the .05 critical value for this approximate \(\chi^{2}\) test is 18.31 , and we have no basis to question the independence of the five variables. Thus the three factors we obtained are very likely an artifact of the present sample and would not reappear in another sample from the same population.

\section*{EXAMPLE 13.7(b)}

For data sets used in previous examples in this chapter, the values of MSA from (13.60) are calculated as follows:
\[
\begin{aligned}
\text { Seishu data: } \mathrm{MSA} & =.53 \\
\text { Sons data: } \mathrm{MSA} & =.82 \\
\text { Voice data: } \mathrm{MSA} & =.73 \\
\text { Diabetes data: } \mathrm{MSA} & =.49
\end{aligned}
\]

The MSA value cannot be computed for the perception data, because \(\mathbf{R}\) is singular.

These results do not suggest great confidence in the MSA index as a sole guide to the suitability of \(\mathbf{R}\) for factoring. We see a wide disparity in the MSA values for the first three data sets. Yet all three yielded successful factor analyses. These three MSA values seem to be inversely related to the number of factors: In the sons data, there were indications that one factor would suffice; the voice data clearly had two factors; and for the Seishu data, there were four factors.

The MSA for the diabetes data is close to that of the Seishu data. Yet the diabetes data are totally unsuitable for factor analysis, while the factor analysis of the Seishu data is very convincing.

\subsection*{13.8 RELATIONSHIP OF FACTOR ANALYSIS TO PRINCIPAL COMPONENT ANALYSIS}

Both factor analysis and principal component analysis have the goal of reducing dimensionality. Because the objectives are similar, many authors discuss principal component analysis as another type of factor analysis. This can be confusing, and we wish to underscore the distinguishing characteristics of the two techniques.

Two of the differences between factor analysis and principal component analysis were mentioned in Section 13.1: (1) In factor analysis, the variables are expressed as linear combinations of the factors, whereas the principal components are linear functions of the variables, and (2) in principal component analysis, the emphasis is on explaining the total variance \(\sum_{i} s_{i i}\), as contrasted with the attempt to explain the covariances in factor analysis.

Additional differences are that (3) principal component analysis requires essentially no assumptions, while factor analysis makes several key assumptions; (4) the principal components are unique (assuming distinct eigenvalues of \(\mathbf{S}\) ), whereas the factors are subject to an arbitrary rotation; and (5) if we change the number of factors, the (estimated) factors change. This does not happen in principal components.

The ability to rotate to improve interpretability is one of the advantages of factor analysis over principal components. If finding and describing some underlying factors is the goal, factor analysis may prove more useful than principal components; we would prefer factor analysis if the factor model fits the data well and we like the interpretation of the rotated factors. On the other hand, if we wish to define a smaller number of variables for input into another analysis, we would ordinarily pre-
fer principal components, although this can sometimes be accomplished with factor scores. Occasionally, principal components are interpretable, as in the size and shape components in Example 12.8.1.

\section*{PROBLEMS}
13.1 Show that the assumptions lead to (13.2), \(\operatorname{var}\left(y_{i}\right)=\lambda_{i 1}^{2}+\lambda_{i 2}^{2}+\cdots+\lambda_{i m}^{2}+\psi_{i}\).
13.2 Verify directly that \(\operatorname{cov}(\mathbf{y}, \mathbf{f})=\boldsymbol{\Lambda}\) as in (13.13).
13.3 Show that \(\mathbf{f}^{*}=\mathbf{T}^{\prime} \mathbf{f}\) in (13.18) satisfies the assumptions (13.6) and (13.7), \(E\left(\mathbf{f}^{*}\right)=\mathbf{0}\) and \(\operatorname{cov}\left(\mathbf{f}^{*}\right)=\mathbf{I}\).
13.4 Show that \(\sum_{i j} e_{i j}^{2} \leq \theta_{m+1}^{2}+\theta_{m+2}^{2}+\cdots+\theta_{p}^{2}\) as in (13.34), where the \(e_{i j}\) 's are the elements of \(\mathbf{E}=\mathbf{S}-\left(\hat{\boldsymbol{\Lambda}} \hat{\boldsymbol{\Lambda}}^{\prime}+\hat{\mathbf{\Psi}}\right)\) and the \(\theta_{i}\) 's are eigenvalues of \(\mathbf{S}\).
13.5 Show that \(\sum_{i=1}^{p} \sum_{j=1}^{m} \hat{\lambda}_{i j}^{2}\) is equal to the sum of the first \(m\) eigenvalues and also equal to the sum of all \(p\) communalities, as in (13.46).
13.6 In Example 13.3.2, the correlation matrix for the perception data was shown to have an eigenvalue equal to 0 . Find the multicollinearity among the five variables that this implies.
13.7 Use the words data of Table 5.9.
(a) Obtain principal component loadings for two factors.
(b) Do a graphical rotation of the two factors.
(c) Do a varimax rotation and compare the results with those in part (b).
13.8 Use the ramus bone data of Table 3.7.
(a) Extract loadings by the principal component method and do a varimax rotation. Use two factors.
(b) Do all variables have a complexity of 1 ? Carry out an oblique rotation to improve the loadings.
(c) What is the angle between the oblique axes? Would a single factor ( \(m=\) 1) be more appropriate here?
13.9 Carry out a factor analysis of the rootstock data of Table 6.2. Combine the six groups into a single sample.
(a) Estimate the loadings for two factors by the principal component method and do a varimax rotation.
(b) Did the rotation improve the loadings?
13.10 Use the fish data of Table 6.17. Combine the three groups into a single sample.
(a) Obtain loadings on two factors by the principal component method and do a varimax rotation.
(b) Note the similarity of loadings for \(y_{1}\) and \(y_{2}\). Is there any indication in the correlation matrix as to why this is so?
(c) Compute factor scores.
(d) Using the factor scores, carry out a MANOVA comparing the three groups.
13.11 Carry out a factor analysis of the flea data in Table 5.5. Combine the two groups into a single sample.
(a) From an examination of the eigenvalues greater than 1, the scree plot, and the percentages, is there a clear choice of \(m\) ?
(b) Extract two factors by the principal component method and carry out a varimax rotation.
(c) Is the rotation an improvement? Try an oblique rotation.
13.12 Use the engineer data of Table 5.6. Combine the two groups into a single sample.
(a) Using a scree plot, the number of eigenvalues greater than 1 , and the percentages, is there a clear choice of \(m\) ?
(b) Extract three factors by the principal component method and carry out a varimax rotation.
(c) Extract three factors by the principal factor method and carry out a varimax rotation.
(d) Compare the results of parts (b) and (c).
13.13 Use the probe word data of Table 3.6.
(a) Obtain loadings for two factors by the principal component method and carry out a varimax rotation.
(b) Note the near duplication of loadings for \(y_{2}\) and \(y_{4}\). Is there any indication in the correlation matrix as to why this is so?
(c) Is the rotation satisfactory? Try an oblique rotation.

\section*{CHAPTER 14}

\section*{CONFIRMATORY FACTOR ANALYSIS}

\subsection*{14.1 INTRODUCTION}

In Chapter 13, we emphasized that exploratory factor analysis (EFA) is used to give a low-dimensional description of high-dimensional data, but is not based on a uniquely identifiable model. That is, no sample of data-regardless of how large-will yield a scenario in which the "true" values of the EFA model can be identified. This is due to the over-parameterized nature of the EFA model, as described in Sections 13.2.2 and 13.7. Because of the nonuniqueness of the factor loadings and other model parameters, practitioners of EFA typically find a solution to the model and then rotate the factor loadings to find a more interpretable or convenient definition of the latent factors (see Section 13.5).

As in the EFA model (13.1), the factors \(f_{j}\) in the confirmatory factor analysis (CFA) model are used to represent underlying latent variables that are of principal interest but are difficult or impossible to measure. For example, an educational researcher may be interested in a students' attitudes about facets of their class experience, or a physician may be interested in assessing various dimensions of quality of life for patients being treated for cancer. In such cases where primary interest is in attitudes, ideas, or other hard-to-measure variables, the factor analysis approach will
be of particular utility. Thus, along with item response theory, CFA is a frequently used tool in the development and analysis of assessment tests and questionnaires. In fact, many item response theory models are special cases of confirmatory factor analysis.

What sets CFA apart from EFA (Chapter 13) is that constraints will be incorporated into the model to ensure a uniquely identifiable set of model parameters. Thus, CFA will follow the usual statistical paradigm-hypothesizing an identifiable model, fitting model parameters, assessing the goodness of model fit, and performing statistical inference for model parameters using conventional tools such as hypothesis tests and confidence intervals. CFA is often considered to be a subset or special case of structural equation modeling, wherein unobserved factors can have structural relationships. For example, a structural equation model might posit that one factor is predicted by another factor in a manner analogous to the way a response (dependent) variable \(y\) is affected by a predictor (independent) variable \(x\) in the simple linear regression model: \(y=\beta_{0}+\beta_{1} x+\varepsilon\). In contrast, CFA allows the estimation of multiple correlated factors but does not allow the factors to have predictor/response relationships.

Throughout our discussion, we emphasize facets of CFA that are most directly useful to the practitioner. Readers interested in technical details, derivations, or extensions to structural equation modeling should refer to the excellent treatments of CFA found in Fuller (1987; Sections 1.5 and 4.3) and Bollen (1989).

\subsection*{14.2 MODEL SPECIFICATION AND IDENTIFICATION}

\subsection*{14.2.1 Confirmatory Factor Analysis Model}

When employing confirmatory factor analysis, we use an alternative approach for fitting the general factor analysis model that was first introduced as (13.1):
\[
\begin{align*}
& y_{1}=\mu_{1}+\lambda_{11} f_{1}+\lambda_{12} f_{2}+\cdots+\lambda_{1 m} f_{m}+\varepsilon_{1} \\
& y_{2}=\mu_{2}+\lambda_{21} f_{1}+\lambda_{22} f_{2}+\cdots+\lambda_{2 m} f_{m}+\varepsilon_{2} \\
& \quad \vdots  \tag{14.1}\\
& y_{p}=\mu_{p}+\lambda_{p 1} f_{1}+\lambda_{p 2} f_{2}+\cdots+\lambda_{p m} f_{m}+\varepsilon_{p} .
\end{align*}
\]

In matrix form, we write the model:
\[
\begin{equation*}
\mathbf{y}=\boldsymbol{\mu}+\mathbf{\Lambda f}+\boldsymbol{\varepsilon} \tag{14.2}
\end{equation*}
\]

As in the EFA setting, the factor loading \(\lambda_{i j}\) in (14.1) quantifies the influence of the factor \(f_{j}\) on the observed variable \(y_{i}\), and the mean and specific factor (or error) components for \(y_{i}\) are still defined as \(\mu_{i}\) and \(\varepsilon_{i}\), respectively. The factor vector
\(\mathbf{f}=\left(f_{1}, \ldots, f_{m}\right)^{\prime}\) has mean \(\mathbf{0}\) and covariance matrix
\[
\operatorname{cov}(\mathbf{f})=\boldsymbol{\Phi}=\left(\begin{array}{cccc}
\phi_{11} & \phi_{12} & \cdots & \phi_{1 m}  \tag{14.3}\\
\phi_{21} & \phi_{22} & \cdots & \phi_{2 m} \\
\vdots & \vdots & \ddots & \vdots \\
\phi_{m 1} & \phi_{m 2} & \cdots & \phi_{m m}
\end{array}\right)
\]
and the error vector \(\varepsilon=\left(\varepsilon_{1}, \ldots, \varepsilon_{p}\right)^{\prime}\) has mean \(\mathbf{0}\) and diagonal covariance matrix
\[
\operatorname{cov}(\varepsilon)=\boldsymbol{\Psi}=\left(\begin{array}{cccc}
\psi_{11} & 0 & \cdots & 0  \tag{14.4}\\
0 & \psi_{22} & \cdots & 0 \\
\vdots & \vdots & \ddots & \vdots \\
0 & 0 & \cdots & \psi_{p p}
\end{array}\right)
\]

The vectors f and \(\varepsilon\) are independent. The diagonality assumption for \(\Psi\) can be relaxed in more general forms of the model, but we focus here on the classical model, which assumes that all of the correlation among the observed variables is due to the factors.

Note that model (14.2) implies a specific structure for the covariance matrix for \(y\). When the model holds, we can define the population covariance matrix for \(y\) to be
\[
\begin{equation*}
\boldsymbol{\Sigma}(\boldsymbol{\theta})=\boldsymbol{\Lambda} \boldsymbol{\Phi} \boldsymbol{\Lambda}^{\prime}+\boldsymbol{\Psi} \tag{14.5}
\end{equation*}
\]
where \(\boldsymbol{\Lambda}, \boldsymbol{\Phi}\), and \(\boldsymbol{\Psi}\) are defined in (14.2), (14.3), and (14.4), and \(\boldsymbol{\theta}\) is the collection of the unique parameters in the model. For the unconstrained model (14.2),
\[
\begin{equation*}
\boldsymbol{\theta}=\left(\boldsymbol{\lambda}^{\prime}, \boldsymbol{\phi}^{\prime}, \boldsymbol{\psi}^{\prime}\right)^{\prime} \tag{14.6}
\end{equation*}
\]
where \(\boldsymbol{\lambda}\) contains the \(p m\) factor loadings in \(\boldsymbol{\Lambda}, \phi\) contains the \(m(m+1) / 2\) factor variances and covariances in the symmetric matrix \(\Phi\), and \(\psi\) contains the \(p\) error variances in the diagonal matrix \(\Psi\). When model (14.2) holds, \(\Sigma(\theta)\) is completely specified by the parameter vector \(\boldsymbol{\theta}\).

A model formulation such as (14.1) or (14.2) is one way of describing the relationships between observed and latent variables. Equally popular is the use of the path diagram, wherein a latent variable model such as those described above is illustrated graphically. In a path diagram, observed variables are denoted with rectangles and latent variables (factors) are denoted with ovals. For example, Figure 14.1 illustrates the path diagram for the multiple regression model \(y=\beta_{1} x_{1}+\beta_{2} x_{2}+\varepsilon\), with \(\operatorname{var}(\varepsilon)=\sigma^{2}\). Note that a one-headed arrow denotes a structural or unidirectional relationship, while a two-headed arrow denotes a covariance among variables. A two-headed arrow pointing from one variable and back to itself is used to specify the variance of the variable, which is usually an error or "disturbance" variable. As CFA models become increasingly complex, the use of path diagrams becomes increasingly attractive for efficiently communicating the hypothesized model.

Figure 14.1 Path diagram for multiple regression model \(y=\beta_{1} x_{1}+\beta_{2} x_{2}+\varepsilon\), with \(\operatorname{var}(\varepsilon)=\) \(\sigma^{2}\).

\subsection*{14.2.2 Identified Models}

As discussed in Sections 13.2.2 and 14.1, the unconstrained factor analysis model (14.1) is (in general) underidentified. That is, there is no unique solution for the parameter vector \(\theta\) in (14.5). More specifically, we say that a model is underidentified if it is possible to find two different vectors \(\boldsymbol{\theta}_{1}\) and \(\boldsymbol{\theta}_{2}\) such that \(\boldsymbol{\Sigma}\left(\boldsymbol{\theta}_{1}\right)=\boldsymbol{\Sigma}\left(\boldsymbol{\theta}_{2}\right)\). Identification problems often occur when there are so many free parameters in \(\theta\) that there are many different values for the vector \(\boldsymbol{\theta}\) that provide a solution to the equations. Every two-factor EFA model is underidentified because the factor loadings can be rotated without affecting the implied covariance matrix \(\boldsymbol{\Sigma}(\boldsymbol{\theta})\). In the CFA setting, our intent is to impose phenomenologically based constraints on the model in order to ensure that the model is identified. That is, we wish to guarantee that there exists a unique solution for the parameter vector \(\boldsymbol{\theta}\).

A necessary but not sufficient condition for a model to be identified is that the number of unique statistics in the sample covariance matrix is at least as large as the number of parameters needed to specify the population covariance matrix under the hypothesized model. This is sometimes called the order condition. Within a \(p \times p\) covariance matrix \(\mathbf{S}\), there are \(p(p+1) / 2\) unique statistics-the variances and covariances. Given the unconstrained model (14.2), the parameter vector \(\theta\) described in (14.5) has \(p m\) factor loadings, \(m(m+1) / 2\) factor variances and covariances, and \(p\) error variances. Thus, for the unconstrained model, the order condition is met when
\[
\frac{p(p+1)}{2} \geq p m+\frac{m(m+1)}{2}+p
\]

However, even when the order condition is met, say when \(p=9\) and \(m=3\) in model (14.1), we are still not guaranteed identifiability because of the way the model parameters interact. For example, the model will have equivalent goodness of fit ( \(i\) ) when \(\phi_{11}\) is large and the loadings \(\lambda_{11}, \ldots, \lambda_{p 1}\) are small and ( \(i i\) ) when \(\phi_{11}\) is small and the loadings \(\lambda_{11}, \ldots, \lambda_{p 1}\) are large. This indeterminacy associated with the scale of the latent factors is one cause of the nonidentifiability in the unconstrained model, even when the order condition is met.

There are many different ways that one can constrain model (14.1) to ensure that the parameters are uniquely identified. One widely used approach for obtaining an identified factor analysis model is to rewrite model (14.2) using the parameterization:
\[
\left(\begin{array}{c}
\mathbf{y}_{0}  \tag{14.7}\\
m \times 1 \\
\mathbf{y}_{1} \\
(p-m) \times \mathbf{1}
\end{array}\right)=\left(\begin{array}{c}
\mathbf{0} \\
m \times 1 \\
\boldsymbol{\mu}_{1} \\
(p-m) \times \mathbf{1}
\end{array}\right)+\left(\begin{array}{c}
\underset{\mathbf{I}}{m \times m} \\
\boldsymbol{\Lambda}_{1} \\
(p-m) \times m
\end{array}\right) \mathbf{f}+\left(\begin{array}{c}
\boldsymbol{\varepsilon}_{0} \\
m \times 1 \\
\boldsymbol{\varepsilon}_{1} \\
(p-m) \times 1
\end{array}\right)
\]

Note that this reparameterization of (14.2) constrains the first \(m\) rows of \(\Lambda\) in (14.2) to be equal to the identity matrix, and the first \(m\) elements of \(\boldsymbol{\mu}\) to be 0 . This implies that each of the first \(m\) elements of \(\mathbf{y}\) in (14.2) is equal to one of the \(m\) factors plus error. Specifically, \(y_{i}=f_{i}+\varepsilon_{i}, i=1, \ldots, m\). Equation (14.7) is called the errors-in-variables or measurement error parameterization because it is analogous to the errors-in-variables regression problem where the linear model of interest is \(\mathbf{y}_{1}=\) \(\boldsymbol{\mu}_{1}+\Lambda_{\mathbf{1}} \mathbf{f}+\varepsilon_{1}\) but the predictor variables \(\mathbf{f}\) are only observable in their measurement-error-contaminated form: \(\mathbf{y}_{0}=\mathbf{f}+\varepsilon_{0}\) (see Fuller, 1987, Section 1.3.1).

Although \(\mathbf{f}\) is related to all \(p\) of the observed variables, (14.7) effectively constrains \(f_{1}, \ldots, f_{m}\) to have the same means as \(y_{1}, \ldots, y_{m}\), respectively. Further, the variances of \(f_{1}, \ldots, f_{m}\) are bounded above by the variances of \(y_{1}, \ldots, y_{m}\), respectively. In practice, the modeler uses her a priori hypothesis about the nature of the multivariate structure in \(y\) to select which observed variables should be the indicator variables \(\mathbf{y}_{0}\) that are most closely associated with the factors \(f\). As we will show in Section 14.3, the validity of the hypothesis-driven model will be formally evaluated for goodness of fit before it is abandoned or tentatively accepted.

The order condition for model (14.7) is satisfied when
\[
\begin{equation*}
\frac{p(p+1)}{2} \geq(p-m) m+\frac{m(m+1)}{2}+p \tag{14.8}
\end{equation*}
\]
or, equivalently (see Problem 14.1), when
\[
(p-m)^{2} \geq p+m
\]

For example, the errors-in-variables parameterization of the CFA model satisfies the order condition for one factor when \(p \geq 3\), for two factors when \(p \geq 5\), for three factors when \(p \geq 6\), and so forth. However, an even more general criterion for satisfying the model's order condition [regardless of whether (14.7) is satisfied] is simply that
\[
\begin{equation*}
\frac{p(p+1)}{2} \geq q \tag{14.9}
\end{equation*}
\]
where \(q\) is the total number of unique parameters to be estimated in \(\boldsymbol{\Lambda}, \boldsymbol{\Phi}\), and \(\boldsymbol{\Psi}\). That is, \(q\) is the dimension of the parameter vector \(\theta\).

The indeterminacy in the unconstrained version of (14.2) is eliminated in model (14.7) by ( \(i\) ) satisfying the order condition in (14.8) or (14.9) and (ii) replacing an \(m \times m\) submatrix of \(\boldsymbol{\Lambda}\) with the rank \(m\) matrix \(\mathbf{I}_{m}\). However, model (14.2) will in fact be identified as long as the order condition in (14.9) is satisfied and any \(m\) rows
of \(\boldsymbol{\Lambda}\) are replaced by any full-rank \(m \times m\) matrix of constants \(\mathbf{K}\). Assuming that inference on \(\boldsymbol{\mu}\) is not of direct interest (which is usually the case), a more general model is:
\[
\begin{equation*}
\mathbf{y}=\boldsymbol{\mu}+\binom{\underset{m \times m}{\mathbf{K}}}{\underset{(p-m) \times m}{\boldsymbol{\Lambda}_{1}}} \mathbf{f}+\boldsymbol{\varepsilon} \tag{14.10}
\end{equation*}
\]

Additional constants can be included in \(\boldsymbol{\Lambda}_{1}\) and still have an identified model. Further, constraints such as setting some factor loadings equal to each other can often be accommodated in an identified model. A careful review of a variety of identifiability conditions for CFA can be found in the latent variable modeling literature (e.g., Bollen, 1987, Chapter 7). For our present purposes, it suffices to conclude that the modeler can fix the physical meaning of the factors in any desired way that satisfies the order condition along with some other identifiability-inducing constraint of the model, with the parameterizations in models (14.7) and (14.10) being examples of such acceptable constraints. As with the modeling choices associated with model (14.7), the nature of the imposed constraints utilized in model (14.10) will depend on the phenomenology under consideration and the a priori hypothesis about the nature of the covariances among the observed variables.

\section*{- EXAMPLE 14.2.2}

To illustrate the formulation of a CFA model, we use the grade data given in Table 14.1, which were obtained from a university business statistics class. As shown in Table 14.1, each of the 94 students in the class received scores for laboratory assignments (Lab), homework assignments (HW), pop quizzes (PopQuiz), midterm exam \#1 (Exam1), midterm exam \#2 (Exam2), and the final exam (FinalExam). The instructor might hypothesize that the 6 -dimensional measure of performance in the class is being driven by an underlying 2-dimensional factor process, with the first factor associated with daily effort and the second factor associated with knowledge mastery. Consequently, we might express the model using the parameterization in (14.10):
\[
\begin{align*}
\text { Lab } & =\mu_{1}+\lambda_{11} f_{1}+\lambda_{12} f_{2}+\varepsilon_{1} \\
\text { HW } & =\mu_{2}+f_{1} \\
\text { PopQuiz } & =\mu_{3}+\lambda_{31} f_{1}+\lambda_{32} f_{2}+\varepsilon_{3}  \tag{14.11}\\
\text { Exam1 } & =\mu_{4}+\lambda_{41} f_{1}+\lambda_{42} f_{2}+\varepsilon_{4} \\
\text { Exam } 2 & =\mu_{5}+\lambda_{51} f_{1}+\lambda_{52} f_{2}+\varepsilon_{5} \\
\text { FinalExam } & =\mu_{6} \quad+\quad f_{2}+\varepsilon_{6}
\end{align*}
\]

The order condition is satisfied for model (14.11) because the number of statistics in the sample covariance matrix \(S\) [the left side of the inequality in (14.8) and (14.9)] is 21 and the number of parameters ( \(q\) ) in the model [the right side of the inequality in (14.8) and (14.9)] is 17 . Additionally, the second and sixth rows of the model's \(\boldsymbol{\Lambda}\) matrix form an identity matrix of rank 2. Thus,

Table 14.1 Statistics Course Grade Measurements
\begin{tabular}{rrrrrr}
\hline Lab & HW & PopQuiz & Exam1 & Exam2 & FinalExam \\
\hline 9.95 & 9.40 & 8.13 & 72 & 90 & 62 \\
7.71 & 0.00 & 8.00 & 63 & 26 & 78 \\
10.00 & 9.50 & 8.13 & 79 & 55 & 80 \\
9.95 & 9.40 & 8.88 & 89 & 77 & 79 \\

Figure 14.2 Path diagram for the grade data model.
model (14.11) is identified. The choice to constrain the HW and FinalExam variables as in model (14.11) was based on a priori expectations about the nature of these measures roughly corresponding to the effort and mastery factors, respectively. While choices about how to specify model structure are largely subject to the discretion of the modeler, the choice of which variables are constrained in the model does not generally affect goodness-of-fit considerations (see Problem 14.4).

In this study however, the theory we wish to test is that most variables load on only one of the two factors, with the pop quiz score being the only course component that is influenced by both daily effort and knowledge mastery. That is, the model we wish to test is
\[
\begin{array}{rlrl}
\text { Lab } & =\mu_{1}+\lambda_{11} f_{1} & +\varepsilon_{1} \\
\text { HW } & =\mu_{2}+\quad f_{1} & +\varepsilon_{2} \\
\text { PopQuiz } & =\mu_{3}+\lambda_{31} f_{1} & +\lambda_{32} f_{2}+\varepsilon_{3}  \tag{14.12}\\
\text { Exam1 } & =\mu_{4} & & +\lambda_{42} f_{2}+\varepsilon_{4} \\
\text { Exam2 } & =\mu_{5} & & +\lambda_{52} f_{2}+\varepsilon_{5} \\
\text { FinalExam } & =\mu_{6} & & +\quad f_{2}+\varepsilon_{6}
\end{array}
\]

The path diagram associated with model (14.12) is shown in Figure 14.2. The number of statistics in the sample covariance matrix \(S\) is still 21 as it was for model (14.11), but there are fewer parameters in model (14.12). There are 5 unconstrained factor loadings in \(\Lambda, m(m+1) / 2=3\) elements in the covariance matrix for \(\mathbf{f}\), and \(p=6\) diagonal elements in \(\boldsymbol{\Psi}\), for a total of \(q=14\) parameters in the model. Because the order condition in (14.9) is satisfied, and because the second and sixth rows of the model's \(\boldsymbol{\Lambda}\) matrix still form an identity matrix of rank 2 , model (14.12) is also identified.

\subsection*{14.3 PARAMETER ESTIMATION AND MODEL ASSESSMENT}

At an intuitive level, our approach for estimating the model parameters \(\boldsymbol{\theta}\) is to find a \(\boldsymbol{\theta}\) within a parameter space \(\boldsymbol{\Theta}\) such that the difference between \(\mathbf{S}\) and \(\boldsymbol{\Sigma}(\boldsymbol{\theta})\) from (14.5) is minimized. The parameter space \(\Theta\) represents the collection of \(\theta\) values that yield matrices \(\boldsymbol{\Sigma}(\boldsymbol{\theta})\) that are nonnegative definite. We note here that a careful definition of the parameter space \(\Theta\) is not merely a mathematical formality but an essential part of the parameter estimation and model assessment process. For example, proper parameter estimation will involve software that constrains factor and error variances to be nonnegative. In other settings, factor loadings or other parameters may be constrained to be equal. Such constraints will be illustrated in Example 14.3.3.

We begin by assuming that \(y\) follows a multivariate normal distribution with a mean \(\boldsymbol{\mu}\) and a covariance matrix \(\boldsymbol{\Sigma}(\boldsymbol{\theta})\). We will then apply the results of Anderson and Amemiya (1988) and Amemiya and Anderson (1990) to argue that as the sample size becomes large, the normality-based parameter estimators and associated inferential tools are valid, even for nonnormal data.

\subsection*{14.3.1 Maximum Likelihood Estimation}

In Sections 4.3.1 and 5.4.3 we introduced the notions of maximum likelihood estimation and likelihood ratio tests, respectively. In this section, we introduce maximum likelihood estimates for the \(q\) factor analysis model parameters \(\boldsymbol{\theta}\). Throughout the discussion, we use the maximum likelihood estimate of the covariance matrix for \(\mathbf{y}\), denoted \(\mathbf{S}_{n}=1 / n \sum_{i=1}^{n}\left(\mathbf{y}_{i}-\overline{\mathbf{y}}\right)^{\prime}\left(\mathbf{y}_{i}-\overline{\mathbf{y}}\right)\).

If we assume that the factor analysis model (14.2) holds and that \(y\) follows a multivariate normal distribution, then \(\mathbf{S}_{n}\) follows a Wishart distribution and it can be shown that the likelihood for \(\boldsymbol{\Sigma}(\boldsymbol{\theta})\) given \(\mathbf{S}_{n}\) is
\[
L\left[\boldsymbol{\Sigma}(\boldsymbol{\theta}) ; \mathbf{S}_{n}\right]=c \times|\boldsymbol{\Sigma}(\boldsymbol{\theta})|^{-n / 2} \exp \left(-\frac{1}{2} \operatorname{tr}\left\{n \mathbf{S}_{n}[\boldsymbol{\Sigma}(\boldsymbol{\theta})]^{-1}\right\}\right)
\]
where \(c\) is a constant that is unaffected by \(\boldsymbol{\theta}\) or \(\boldsymbol{\Sigma}(\boldsymbol{\theta})\). The value of \(\boldsymbol{\theta}\) that maximizes \(L\left(\boldsymbol{\Sigma}(\boldsymbol{\theta}) ; \mathbf{S}_{n}\right)\) is called the maximum likelihood estimator for \(\boldsymbol{\theta}\) and is denoted \(\hat{\boldsymbol{\theta}}_{\mathrm{ML}}\).

The likelihood ratio statistic associated with the hypothesized factor analysis model is
\[
L R\left(\hat{\boldsymbol{\theta}}_{\mathrm{ML}}\right)=\frac{L\left[\boldsymbol{\Sigma}\left(\hat{\boldsymbol{\theta}}_{\mathrm{ML}}\right) ; \mathbf{S}_{n}\right]}{L\left[\mathbf{S}_{n} ; \mathbf{S}_{n}\right]}
\]
where the numerator is the likelihood evaluated with \(\boldsymbol{\Sigma}\) at its maximum under the hypothesized model and the denominator is the likelihood evaluated with \(\Sigma\) at its unrestricted maximum (i.e., \(\boldsymbol{\Sigma}=\mathbf{S}_{n}\) ). Taking \(-2 \log L R(\boldsymbol{\theta})\), we obtain
\[
\begin{equation*}
\ell\left(\boldsymbol{\theta} ; \mathbf{S}_{n}\right)=n\left(\log |\boldsymbol{\Sigma}(\boldsymbol{\theta})|+\operatorname{tr}\left\{\mathbf{S}_{n}[\boldsymbol{\Sigma}(\boldsymbol{\theta})]^{-1}\right\}-\log \left|\mathbf{S}_{n}\right|-p\right) \tag{14.13}
\end{equation*}
\]

It can be shown that \(\hat{\boldsymbol{\theta}}_{\text {ML }}\) minimizes \(\ell(\boldsymbol{\theta} ; \mathbf{S})\) over the parameter space \(\Theta\) and thatregardless of the actual distribution of the data-the statistic \(\ell\left(\hat{\boldsymbol{\theta}}_{\mathrm{ML}} ; \mathbf{S}_{n}\right)\) has an
asymptotic distribution of \(\chi_{p(p+1) / 2-q}^{2}\). Further, under some fairly tractable conditions, the factor loading estimates \(\hat{\boldsymbol{\lambda}}_{\text {ML }}\) converge to \(\boldsymbol{\lambda}\) [as defined in (14.6)] when \(n \rightarrow \infty\). As we will discuss in Section 14.3.3, the statistic \(\ell\left(\boldsymbol{\theta} ; \mathbf{S}_{n}\right)\) plays a central role in the assessment of the factor analysis model's goodness of fit.

\subsection*{14.3.2 Least Squares Estimation}

As an alternative to maximum likelihood estimation, we consider here a computational approach based on least squares estimation under the assumption that \(y\) in model (14.2) is distributed normally with mean \(\boldsymbol{\mu}\) and covariance matrix \(\boldsymbol{\Sigma}[\theta]\). In this scenario, \((n-1) \mathbf{S} \sim W_{p}(n-1, \boldsymbol{\Sigma}[\boldsymbol{\theta}])\), where \(W_{p}\) denotes the Wishart distribution introduced in Section 4.3.2. Note that we are interested in the distribution of \(\mathbf{S}\) because we wish to make inferences about the \(q\) elements of \(\boldsymbol{\theta}\), which are functions of second moments. Thus, just as carrying out inferences about means (first moments) requires information about second moments (variances and covariances), carrying out inferences associated with second moments will require fourth moments for the data. Although the normality assumption is not required for least squares estimation, it is a substantial benefit to assume normality because higher-order moments will always be simple functions of first and second moments. We will later argue that normality-based approaches are asymptotically valid even when the normal assumptions are violated.

Given the assumption of normality of the data, we can show that the \(p(p+1) / 2 \times\) \(p(p+1) / 2\) covariance matrix for the unique elements of \(\mathbf{S}\) is:
\[
\operatorname{cov}(\operatorname{vech} \mathbf{S})=\frac{2}{n-1} \mathbf{H}_{p}^{+}[\boldsymbol{\Sigma}(\boldsymbol{\theta}) \otimes \boldsymbol{\Sigma}(\boldsymbol{\theta})] \mathbf{H}_{p}^{+^{\prime}}
\]

The matrices \(\mathbf{H}_{p}\) and \(\mathbf{H}_{p}^{+}\)are defined as in (2.125) and (2.126), respectively, so that for any \(p \times p\) matrix \(\mathbf{A}, \mathbf{H}_{p}\) vech \(\mathbf{A}=\operatorname{vec} \mathbf{A}\) and \(\mathbf{H}_{p}^{+}\)vec \(\mathbf{A}=\) vech \(\mathbf{A}\). Further, the normality assumption implies that if \(\boldsymbol{\Sigma}(\boldsymbol{\theta})\) is positive definite, then
\[
\begin{equation*}
[\operatorname{cov}(\operatorname{vech} \mathbf{S})]^{-1}=\frac{n-1}{2} \mathbf{H}_{p}^{\prime}\left\{[\boldsymbol{\Sigma}(\boldsymbol{\theta})]^{-1} \otimes[\boldsymbol{\Sigma}(\boldsymbol{\theta})]^{-1}\right\} \mathbf{H}_{p} \tag{14.14}
\end{equation*}
\]

In practice, we will estimate \(\operatorname{cov}(\) vech \(\mathbf{S})\) with either
\[
\begin{equation*}
\hat{\mathbf{V}}=\frac{2}{n-1} \mathbf{H}_{p}^{+}(\mathbf{S} \otimes \mathbf{S}) \mathbf{H}_{p}^{+^{\prime}} \tag{14.15}
\end{equation*}
\]
or
\[
\begin{equation*}
\mathbf{V}(\hat{\boldsymbol{\theta}})=\frac{2}{n-1} \mathbf{H}_{p}^{+}[\boldsymbol{\Sigma}(\hat{\boldsymbol{\theta}}) \otimes \boldsymbol{\Sigma}(\hat{\boldsymbol{\theta}})] \mathbf{H}_{p}^{+^{\prime}} \tag{14.16}
\end{equation*}
\]

The least squares estimator \(\hat{\boldsymbol{\theta}}_{\mathrm{LS}}\) is the value of \(\boldsymbol{\theta}\) that minimizes the weighted sum of squares
\[
\begin{equation*}
q(\boldsymbol{\theta} ; \mathbf{S})=[\operatorname{vech} \mathbf{S}-\operatorname{vech} \boldsymbol{\Sigma}(\boldsymbol{\theta})]^{\prime} \hat{\mathbf{V}}^{-1}[\operatorname{vech} \mathbf{S}-\operatorname{vech} \boldsymbol{\Sigma}(\boldsymbol{\theta})] \tag{14.17}
\end{equation*}
\]
over the parameter space \(\Theta\), with \(\hat{\mathbf{V}}^{-1}\) defined using (14.14) and (14.15). Evaluating (14.17) at the value \(\boldsymbol{\theta}_{\mathrm{LS}}\) yields the goodness-of-fit statistic \(q(\hat{\boldsymbol{\theta}} ; \mathbf{S})\). Regardless of the actual distribution of the data, \(q(\hat{\boldsymbol{\theta}} ; \mathbf{S})\) has an asymptotic distribution of \(\chi_{p(p+1) / 2-q}^{2}\) and the factor loading estimates \(\hat{\boldsymbol{\lambda}}_{\mathrm{LS}}\) converge to \(\boldsymbol{\lambda}\) as defined in (14.6).

Use of \(\mathbf{V}(\hat{\boldsymbol{\theta}})\) as an estimate of \(\operatorname{cov}(\) vech \(\mathbf{S})\) implies an iteratively reweighted least squares procedure beginning with an initial estimate of \(\boldsymbol{\theta}\) such as \(\hat{\boldsymbol{\theta}}^{(0)}=\hat{\boldsymbol{\theta}}_{\mathrm{LS}}\). Then, in the \(i\) th iteration of the procedure \((i=1,2, \ldots), \hat{\boldsymbol{\theta}}^{(i)}\) is the value of \(\boldsymbol{\theta}\) that minimizes
\[
\begin{align*}
& w\left(\boldsymbol{\theta} ; \hat{\boldsymbol{\theta}}^{(i-1)}, \mathbf{S}\right)= \\
& \quad[\operatorname{vech} \mathbf{S}-\operatorname{vech} \boldsymbol{\Sigma}(\boldsymbol{\theta})]^{\prime}\left[\mathbf{V}\left(\hat{\boldsymbol{\theta}}^{(i-1)}\right)\right]^{-1}[\operatorname{vech} \mathbf{S}-\operatorname{vech} \boldsymbol{\Sigma}(\boldsymbol{\theta})] \tag{14.18}
\end{align*}
\]
with \(\mathbf{V}\left(\hat{\boldsymbol{\theta}}^{(i-1)}\right)\) defined using (14.14) and (14.16). The procedure is continued until \(\hat{\boldsymbol{\theta}}^{(i)}\) has converged, with the final estimate denoted \(\hat{\boldsymbol{\theta}}_{\text {IRLS }}\). Each of the estimates \(\hat{\boldsymbol{\theta}}_{\mathrm{LS}}\) and \(\hat{\boldsymbol{\theta}}_{\text {IRLS }}\) has the same asymptotic distribution as \(\hat{\boldsymbol{\theta}}_{\text {ML }}\), although the procedure used to obtain \(\hat{\boldsymbol{\theta}}_{\text {IRLS }}\) may require a simple modification in rare instances to achieve the desired result (see Fuller, 1987, Section 4.2.2).

\subsection*{14.3.3 Model Assessment}

As noted in Sections 14.3.1 and 14.3.2, each of the statistics \(\ell\left(\hat{\boldsymbol{\theta}}_{\mathrm{ML}} ; \mathbf{S}\right), q\left(\hat{\boldsymbol{\theta}}_{\mathrm{LS}} ; \mathbf{S}\right)\), and \(w\left(\hat{\boldsymbol{\theta}}_{\text {IRLS }} ; \hat{\boldsymbol{\theta}}_{\text {IRLS }}, \mathbf{S}\right)\) [described in (14.13), (14.17), and (14.18), respectively] has an asymptotic \(\chi_{p(p+1) / 2-q}^{2}\) distribution. Thus, each can be used used as a goodness-of-fit statistic where the degrees of freedom for the asymptotic \(\chi^{2}\) distribution is the difference between the number of unique statistics in \(\mathbf{S}[p(p+1) / 2]\) and the number of parameters in \(\boldsymbol{\theta}(q)\). The hypotheses being compared are
\(H_{0}\) : the hypothesized model is correct.
\(H_{1}\) : the hypothesized model is incorrect (more factors are needed).
For example, if maximum likelihood is used to estimate the model parameters, then a value of \(\ell\left(\hat{\boldsymbol{\theta}}_{\mathrm{ML}} ; \mathbf{S}\right)\) that exceeds the \(100(1-\alpha)\) percentile of the \(\chi_{p(p+1) / 2-q}^{2}\) distribution would indicate that we reject \(H_{0}\) at level \(\alpha\) and conclude that the hypothesized model is incorrect. Obtaining a statistic whose value is less than said percentile would indicate the opposite conclusion-that is, we would fail to reject \(H_{0}\) and proceed with statistical inference for the model parameters under the presumption that the model is an adequate characterization of the phenomenology associated with the data. We note that the degrees of freedom for the \(\chi^{2}\) test will usually be increased by 1 for every parameter that is constrained at the solution. For example, if we constrain an error variance to be nonnegative and that constraint is imposed on the solution (i.e., the error variance is set to 0 ), then \(q\) is decreased by 1 and the degrees of freedom is increased by 1 .

One of the commonly cited limitations of the \(\chi^{2}\) goodness-of-fit test is that the probability of rejecting \(H_{0}\) (i.e., rejecting the proposed model) increases as the sample size gets larger. Additionally, the test may reject for slight deviations from
normality such as the presence of kurtosis. Consequently, there are many other goodness-of-fit criteria that have been proposed and evaluated (see Bollen, 1989, Chapter 7; Hu and Bentler, 1999). In this section, we discuss three additional goodness-of-fit assessment tools that have become widely used and recommended in the literature: the comparative fit index (CFI) of Bentler (1989), the root mean square error approximation (RMSEA) index of Steiger and Lind (1980), and the standardized root mean square residual (SRMR) of Jöreskog and Sörbom (1985). None of these supplementary goodness-of-fit statistics is associated with a formal statistical test [as are the \(\chi^{2}\) statistics in (14.13), (14.17), and (14.18)], but each can be helpful for assessing model fit when used with an associated rule of thumb.

Bentler's CFI is a measure of the scaled reduction of lack of fit when using the specified model instead of a baseline model such as the independence model:
\[
\begin{equation*}
\mathbf{y}=\boldsymbol{\mu}+\varepsilon . \tag{14.19}
\end{equation*}
\]

For a specified model, let \(\chi_{M}^{2}\) be one of the goodness-of-fit statistics described in (14.13), (14.17), or (14.18), with the degrees of freedom associated with the statistic denoted \(d f_{M}\). Further, let \(\chi_{\mathrm{B}}^{2}\) and \(d f_{B}\) be the corresponding statistic and degrees of freedom when fitting a baseline model such as (14.19). Then, CFI is calculated using
\[
\begin{equation*}
\mathrm{CFI}=1-\frac{\max \left(\chi_{M}^{2}-d f_{M}, 0\right)}{\max \left(\chi_{B}^{2}-d f_{B}, \chi_{M}^{2}-d f_{M}, 0\right)} \tag{14.20}
\end{equation*}
\]

Because the expected value of a \(\chi^{2}\) random variable is equal to the degrees of freedom for the variable's distribution, the quantity \(\chi_{M}^{2}-d f_{M}\) represents excess lack of fit for the hypothesized model. The CFI statistic has range \(0 \leq \mathrm{CFI} \leq 1\), with values near 1 indicating that the excess lack of fit associated with the hypothesized model is much smaller than that associated with the baseline model. Values of CFI near zero imply that the increased complexity of the proposed model (relative to the baseline model) yields no additional explanatory ability. Hu and Bentler (1999) recommend that CFI values greater than 0.95 indicate a good fit, although other authors argue that values greater than 0.90 are acceptable.

The RMSEA index is another measure of excess lack of fit associated with the hypothesized model. It is calculated using
\[
\begin{equation*}
\text { RMSEA }=\sqrt{\frac{1}{n-1} \frac{\max \left(\chi_{M}^{2}-d f_{M}, 0\right)}{d f_{M}}} \tag{14.21}
\end{equation*}
\]
where \(n\) is the sample size and the other quantities are as described in (14.20). Hu and Benter recommend that an RMSEA value less than 0.06 indicates a good fit.

The final goodness-of-fit measure considered here, SRMR, is not a function of the \(\chi^{2}\) statistic, but rather quantifies the difference between the sample covariance matrix for the data ( \(\mathbf{S}\) ) and the model-constructed estimates of the covariance matrix [ \(\Sigma(\hat{\theta})\) ]. The SRMR value is calculated using
\[
\begin{equation*}
\mathrm{SRMR}=\sqrt{\frac{2}{p(p+1)} \sum_{i=1}^{p} \sum_{j=1}^{i} \frac{\left(s_{i j}-\sigma_{i j}\right)^{2}}{s_{i i} s_{j j}}} \tag{14.22}
\end{equation*}
\]
where \(s_{i j}\) and \(\sigma_{i j}\) are the \((i, j)\) elements of \(\mathbf{S}\) and \(\boldsymbol{\Sigma}(\hat{\boldsymbol{\theta}})\), respectively. Hu and Bentler (1999) recommend that SRMR values less than 0.08 indicate a good fit, although other authors argue that values less than 0.10 imply an adequate fit of the model.

\section*{- EXAMPLE 14.3.3}

We illustrate model fitting and model assessment using the business statistics class data given in Table 14.1 and the CFA model given in (14.12). In specifying the model, we note that the factor variances and error variances must be constrained to be nonnegative. Using maximum likelihood ("method=ML" in SAS), the the parameter estimates in \(\hat{\boldsymbol{\theta}}_{\mathrm{ML}}\) are:
\[
\begin{aligned}
&\left(\begin{array}{l}
\hat{\lambda}_{11} \\
\hat{\lambda}_{31} \\
\hat{\lambda}_{32} \\
\hat{\lambda}_{42} \\
\hat{\lambda}_{52}
\end{array}\right)=\left(\begin{array}{l}
0.356 \\
0.123 \\
0.061 \\
0.884 \\
1.416
\end{array}\right),\left(\begin{array}{l}
\hat{\phi}_{11} \\
\hat{\phi}_{21} \\
\hat{\phi}_{22}
\end{array}\right)=\left(\begin{array}{r}
3.162 \\
10.267 \\
123.947
\end{array}\right) \\
& \text { and }\left(\begin{array}{l}
\hat{\psi}_{11} \\
\hat{\psi}_{22} \\
\hat{\psi}_{33} \\
\hat{\psi}_{44} \\
\hat{\psi}_{55} \\
\hat{\psi}_{66}
\end{array}\right)=\left(\begin{array}{r}
0.547 \\
0 \\
1.667 \\
67.006 \\
139.496 \\
81.423
\end{array}\right)
\end{aligned}
\]

Note that \(\hat{\psi}_{22}\) is a parameter estimate that lies at a boundary of a specified parameter space. Consequently, statistical inference procedures typically treat this scenario as if \(\psi_{22}\) were constrained to equal 0 a priori, with the number of free parameters reduced from 14 to 13 and the degrees of freedom increased from 7 to 8 . We focus on \(\hat{\boldsymbol{\theta}}_{\text {ML }}\) in this example, but the least squares estimates \(\hat{\boldsymbol{\theta}}_{\mathrm{LS}}\) found by minimizing (14.17) (using "method=GLS" in SAS) are very similar.

To assess model fit, we consider the diagnostics discussed in Section 14.3.3. The \(\chi^{2}\) statistic in (14.13) is equal to 12.371 with a degrees of freedom of 8 , based on 21 unique elements in \(S\) with 13 unconstrained parameters fit in the model. Thus, the \(p\)-value associated with the hypothesis
\[
H_{0}: \text { the hypothesized model is correct }
\]
is 0.135 , and we determine that we have insufficient evidence to declare lack of fit. The additional diagnostic metrics yield a mixed verdict about the goodness of fit for the proposed model. Bentler's CFI in (14.20) is 0.978 (greater than the recommended lower cutoff of 0.95 ) and the SRMR value in (14.22) is 0.039 (less than the recommended upper cutoff of 0.08 ). On the other hand, the RMSEA index in (14.21) is 0.0767 (greater than the recommended upper
cutoff of 0.06 ). In practice, the quality of fit of a latent variable model is determined using an ensemble of fit indexes. On balance, it appears that model (14.12) has reasonably good fit.

\subsection*{14.4 INFERENCE FOR MODEL PARAMETERS}

We previously noted that normality-based methods for parameter estimation are still of practical value when data are not normally distributed. However, when conducting inference about the \(q\)-dimensional parameter vector \(\boldsymbol{\theta}\) using \(\hat{\boldsymbol{\theta}}_{\mathrm{ML}}, \hat{\boldsymbol{\theta}}_{\mathrm{LS}}\), or \(\hat{\boldsymbol{\theta}}_{\text {IRLS }}\), we need an estimate of the covariance matrix for the vector of parameter estimates that properly accounts for the potential nonnormality of the data. Because \(\boldsymbol{\theta}\) is based on the second moments of the data found in the covariance matrix, inference about \(\boldsymbol{\theta}\) requires a fourth-moment matrix. Thus, we first define an estimated covariance matrix for vech \(S\).

Let \(\mathbf{z}_{i}\) be the vector of length \(p(p+1) / 2\) that is associated with the \(i\) th observation and defined by
\[
\mathbf{z}_{i}=\operatorname{vech}\left(\mathbf{y}_{i}-\overline{\mathbf{y}}\right)\left(\mathbf{y}_{i}-\overline{\mathbf{y}}\right)^{\prime},
\]
so that
\[
\operatorname{vech} \mathbf{S}=\frac{1}{n-1} \sum_{i=1}^{n} \mathbf{z}_{i}
\]

We can then define the covariance matrix for vech S as
\[
\boldsymbol{\Gamma}=\operatorname{cov}(\operatorname{vech} \mathbf{S})
\]
which can be estimated using
\[
\begin{equation*}
\hat{\boldsymbol{\Gamma}}=\frac{1}{(n-1)^{2}} \sum_{i=1}^{n}\left(\mathbf{z}_{i}-\overline{\mathbf{z}}\right)\left(\mathbf{z}_{i}-\overline{\mathbf{z}}\right)^{\prime} \tag{14.23}
\end{equation*}
\]
where \(\overline{\mathbf{z}}=\frac{1}{n} \sum_{i=1}^{n} \mathbf{z}_{i}\). When \(\hat{\boldsymbol{\theta}}\) is \(\hat{\boldsymbol{\theta}}_{\mathrm{ML}}, \hat{\boldsymbol{\theta}}_{\mathrm{LS}}\), or \(\hat{\boldsymbol{\theta}}_{\text {IRLS }}\), the covariance matrix for the estimated model parameters is
\[
\begin{equation*}
\widehat{\operatorname{cov}}(\hat{\boldsymbol{\theta}})=\left\{\hat{\mathbf{F}}^{\prime}[\mathbf{V}(\hat{\boldsymbol{\theta}})]^{-1} \hat{\mathbf{F}}\right\}^{-1} \hat{\mathbf{F}}^{\prime}[\mathbf{V}(\hat{\boldsymbol{\theta}})]^{-1} \hat{\boldsymbol{\Gamma}}[\mathbf{V}(\hat{\boldsymbol{\theta}})]^{-1} \hat{\mathbf{F}}\left\{\hat{\mathbf{F}}^{\prime}[\mathbf{V}(\hat{\boldsymbol{\theta}})]^{-1} \hat{\mathbf{F}}\right\}^{-1}, \tag{14.24}
\end{equation*}
\]
where \(\mathbf{V}(\hat{\boldsymbol{\theta}})\) is defined in (14.16), \(\mathbf{F}\) is the \(p(p+1) / 2 \times q\) matrix of partial derivatives defined by
\[
\mathbf{F}=\frac{\partial \mathrm{vech} \boldsymbol{\Sigma}(\boldsymbol{\theta})}{\partial \boldsymbol{\theta}^{\prime}}
\]
and \(\hat{\mathbf{F}}\) is the matrix \(\mathbf{F}\) when evaluated at \(\boldsymbol{\theta}=\hat{\boldsymbol{\theta}}\).
As noted previously, Anderson and Amemiya (1988) and Amemiya and Anderson (1990) show that given general identification conditions and a large sample size, a wide array of statistical inferences about \(\boldsymbol{\theta}\) can be carried out, regardless of the
actual distribution of \(\mathbf{y}\). Specifically, the parameter estimates \(\hat{\boldsymbol{\theta}}_{\mathrm{ML}}, \hat{\boldsymbol{\theta}}_{\text {LS }}\), and \(\hat{\boldsymbol{\theta}}_{\text {IRLS }}\) are asymptotically unbiased, and the subset of \(\widehat{\operatorname{cov}}(\hat{\boldsymbol{\theta}})\) corresponding to \(\widehat{\operatorname{cov}}(\hat{\boldsymbol{\lambda}})\) (the variances and covariances among the factor loadings) are also unbiased.

The square roots of the diagonal elements of (14.24) corresponding to the estimated factor loadings \(\left(\hat{\lambda}_{i j}\right)\) are their associated standard errors [s.e. \(\left.\left(\hat{\lambda}_{i j}\right)\right]\). Thus, the standard error s.e. \(\left(\hat{\lambda}_{i j}\right)\) can be used to construct the asymptotically normal test statistic
\[
\begin{equation*}
z_{i j}=\frac{\hat{\lambda}_{i j}}{\text { s.e. }\left(\hat{\lambda}_{i j}\right)} \tag{14.25}
\end{equation*}
\]
which is suitable for testing the hypothesis \(H_{0}: \lambda_{i j}=0\). The \(z_{i j}\) statistics associated with the various factor loadings can then be used to evaluate the relative statistical evidence for relationships among observed and latent variables. Using similar logic, a \(100(1-\alpha) \%\) confidence interval for \(\lambda_{i j}\) can be constructed using
\[
\begin{equation*}
\hat{\lambda}_{i j} \pm z_{\alpha / 2} \text { s.e. }\left(\hat{\lambda}_{i j}\right) \tag{14.26}
\end{equation*}
\]

Because \(\hat{\boldsymbol{\theta}}\) and \(\widehat{\operatorname{cov}}(\hat{\boldsymbol{\theta}})\) are valid in large samples regardless of the distribution of the data, the associated hypothesis tests and confidence intervals for \(\boldsymbol{\theta}\) are valuable tools for evaluating and refining the proposed factor analysis model. A typical process for model refinement first uses the model assessment tools discussed in Section 14.3.3, then uses parameter assessment tools based on \(\hat{\boldsymbol{\theta}}\) and \(\widehat{\operatorname{cov}}(\hat{\boldsymbol{\theta}})\) to fine-tune the model. For example, if a model exhibits adequate goodness of fit, we might then determine which if any of the model parameter estimates are nonsignificant, dropping any that are deemed extraneous and then refitting the model to ensure that the goodness of overall model fit has not been substantially reduced. As with any exploratory model-building exercise, there is a delicate balance between parsimony and goodness of fit. Further, such iterative model-selection procedures are subject to the overly optimistic assessments of model fit that are associated with the subset selection problem in regression analysis (see discussion in Section 10.2.7b). Thus, analyses that require several iterations of model refinement should be interpreted as exploratory in nature and used with caution.

\section*{■ EXAMPLE 14.4}

In this example, we continue the analysis of the business statistics class data given in Table 14.1 with the intent of evaluating and refining the CFA model given in (14.12) and fitted in Example 14.3.3. Table 14.2 gives the test statistic \(z_{i j}\) and other pertinent inferential quantities for each of the factor loadings in the model. Note that all but \(\lambda_{31}\) appear to be significantly different from 0 . In an effort to obtain a more parsimonious model with good fit, we consider the

Table 14.2 Factor Loading Estimates for Statistics Course Grade Data of Table 14.I When Using Model (14.12)
\begin{tabular}{rrrcr}
\hline Parameter & Estimate & Standard Error & \(z_{i j}\) & \(p\)-value \\
\hline\(\lambda_{11}\) & 0.356 & 0.043 & 8.254 & \(<0.0001\) \\
\(\lambda_{31}\) & 0.123 & 0.094 & 1.307 & 0.0957 \\
\(\lambda_{32}\) & 0.061 & 0.017 & 3.487 & 0.0002 \\
\(\lambda_{42}\) & 0.884 & 0.127 & 6.985 & \(<0.0001\) \\
\(\lambda_{52}\) & 1.416 & 0.197 & 7.185 & \(<0.0001\) \\
\hline
\end{tabular}

Table 14.3 Factor Loading Estimates for Statistics Course Grade Data of Table 14.1 When Using Model (14.27)
\begin{tabular}{rrrcc}
\hline Parameter & Estimate & Standard Error & \(z_{i j}\) & \(p\)-value \\
\hline\(\lambda_{11}\) & 0.376 & 0.088 & 4.274 & \(<0.0001\) \\
\(\lambda_{32}\) & 0.073 & 0.015 & 4.814 & \(<0.0001\) \\
\(\lambda_{42}\) & 0.882 & 0.128 & 6.916 & \(<0.0001\) \\
\(\lambda_{52}\) & 1.435 & 0.199 & 7.211 & \(<0.0001\) \\
\hline
\end{tabular}
revised model for the data:
\[
\begin{array}{rlrl}
\text { Lab } & =\mu_{1}+\lambda_{11} f_{1} & +\varepsilon_{1} \\
\text { HW } & =\mu_{2}+ & f_{1} & +\varepsilon_{2} \\
\text { PopQuiz } & =\mu_{3} & & +\lambda_{32} f_{2}+\varepsilon_{3}  \tag{14.27}\\
\text { Exam1 } & =\mu_{4} & & +\lambda_{42} f_{2}+\varepsilon_{4} \\
\text { Exam } 2 & =\mu_{5} & & +\lambda_{52} f_{2}+\varepsilon_{5} \\
\text { FinalExam } & =\mu_{6} & & +\quad f_{2}+\varepsilon_{6}
\end{array}
\]

The goodness-of-fit statistics associated with the revised model given in (14.27) are: \(\chi^{2}=13.945\) (degrees of freedom \(=8\) and \(p\)-value \(=0.083\) ), Bentler's CFI \(=0.970\), RMSEA \(=0.0894\), and \(\operatorname{SRMR}=0.039\). Thus, all measures indicate an adequate fit of the model to the data except for RMSEA, which exceeds the recommended upper cutoff of 0.06 . We determine that the use of the revised model in (14.27) is an improvement over the use of (14.12). Table 14.3 gives the factor loading estimates and associated inferential statistics for the revised model, which now involves only factor loadings that are statistically significant. The revised model indicates that Lab and HW load solely on the effort factor and PopQuiz, Exam1, Exam2, and FinalExam load solely on the knowledge mastery factor.

\subsection*{14.5 FACTOR SCORES}

As discussed in the EFA setting in Section 13.6, it is often the case that we wish to obtain factor scores-estimates of the underlying factor values for each observation. In this section, we introduce two common approaches for obtaining such estimates. Factor scores are often used after fitting the factor analysis model in order to understand the underlying characteristics of the observational units.

Using the parameter estimates \(\hat{\boldsymbol{\Lambda}}, \hat{\boldsymbol{\Phi}}\), and \(\hat{\boldsymbol{\Psi}}\), we can form factor score estimates for the \(i\) th observational unit using the so-called regression method formula
\[
\begin{equation*}
\hat{\mathbf{f}}_{i}=\hat{\boldsymbol{\Phi}} \hat{\boldsymbol{\Lambda}}^{\prime}\left(\hat{\boldsymbol{\Lambda}} \hat{\boldsymbol{\Phi}} \hat{\boldsymbol{\Lambda}}^{\prime}+\hat{\mathbf{\Psi}}\right)^{-1}\left(\mathbf{y}_{i}-\hat{\mathbf{y}}\right) \tag{14.28}
\end{equation*}
\]
or the weighted least squares formula
\[
\begin{equation*}
\tilde{\mathbf{f}}_{i}=\left(\hat{\boldsymbol{\Lambda}}^{\prime} \hat{\mathbf{\Psi}}^{-1} \hat{\boldsymbol{\Lambda}}\right)^{-\mathbf{1}} \hat{\boldsymbol{\Lambda}}^{\prime} \hat{\mathbf{\Psi}}^{-1}\left(\mathbf{y}_{i}-\overline{\mathbf{y}}\right) \tag{14.29}
\end{equation*}
\]

Although the two approaches generally yield very similar estimates, the regression method formula in (14.28) is perhaps the most widely used (see Bollen 1989, Chapter 7).

\section*{EXAMPLE 14.5}

In this example, we use the regression method in (14.28) to obtain factor scores for each student in the statistics course grade data set. The data are found in Table 14.1, and the parameter estimates used are based on the revised model (14.27) fit to the data in Example 14.4. The matrices used to calculate the factor scores are:
\[
\begin{aligned}
\hat{\boldsymbol{\Lambda}} & =\left(\begin{array}{rr}
0.376 & 0 \\
1 & 0 \\
0 & 0.073 \\
0 & 0.882 \\
0 & 1.435 \\
0 & 1
\end{array}\right), \hat{\boldsymbol{\Phi}}=\left(\begin{array}{rrrr}
2.992 & 10.542 \\
10.542 & 122.032
\end{array}\right), \\
\text { and } \hat{\boldsymbol{\Psi}} & =\left(\begin{array}{rrrrrr}
0.524 & 0 & 0 & 0 & 0 & 0 \\
0 & 0.170 & 0 & 0 & 0 & 0 \\
0 & 0 & 1.664 & 0 & 0 & 0 \\
0 & 0 & 0 & 68.982 & 0 & 0 \\
0 & 0 & 0 & 0 & 136.699 & 0 \\
0 & 0 & 0 & 0 & 0 & 83.338
\end{array}\right) .
\end{aligned}
\]

Values for \(\hat{f}_{1}\) (estimated effort score) and \(\hat{f}_{2}\) (estimated knowledge mastery score) are calculated and plotted against each other in Figure 14.3. Although we can say nothing about causal influences between the factors, it does appear that the effort score can be used to provide a rough upper bound for the knowledge mastery score.

Figure 14.3 Estimated effort score ( \(\hat{f}_{1}\) ) vs. estimated knowledge mastery score ( \(\hat{f_{2}}\) ) for 94 students in a business statistics course.

\section*{PROBLEMS}
14.1 Show that the order condition given in (14.8) simplifies to \((p-m)^{2} \geq p+m\).
14.2 Consider the confirmatory factor analysis model in (14.2). In the scenarios below, various constrained \(\boldsymbol{\Lambda}\) matrices of dimension \(p \times m\) are proposed. For each proposed model, use the rules presented in Section 14.2.2 to determine whether or not the model is identified. Assume that for each model, \(\boldsymbol{\Phi}=\) \(\operatorname{cov}(\mathbf{f})\) is an \(m \times m\) symmetric matrix containing \(m(m+1) / 2\) unique factor variances and covariances to be estimated. Further, assume that \(\Psi=\operatorname{cov}(\varepsilon)\) is a diagonal matrix with \(p\) unique error variances to be estimated. For each assessment of model identifiability, explain your reasoning.
(a) \(\boldsymbol{\Lambda}=\left[\begin{array}{cc}\lambda_{11} & \lambda_{12} \\ \lambda_{21} & \lambda_{22} \\ \lambda_{31} & \lambda_{32} \\ 0.5 & 0 \\ 0 & 1\end{array}\right]\)
(b) \(\boldsymbol{\Lambda}=\left[\begin{array}{ccc}\lambda_{11} & 0 & 0 \\ 0 & \lambda_{22} & \lambda_{23} \\ 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1\end{array}\right]\)
(c) \(\boldsymbol{\Lambda}=\left[\begin{array}{ccc}\lambda_{11} & \lambda_{12} & \lambda_{13} \\ \lambda_{21} & \lambda_{22} & \lambda_{23} \\ \lambda_{31} & \lambda_{32} & \lambda_{33} \\ \lambda_{41} & \lambda_{42} & \lambda_{43} \\ 1 & 0 & 0 \\ 0 & 1 & 0.5 \\ 0 & 1 & 0.5\end{array}\right]\)
(d) \(\boldsymbol{\Lambda}=\left[\begin{array}{cc}\lambda_{11} & 0 \\ \lambda_{21} & \lambda_{22} \\ 1 & 0 \\ 0 & 1\end{array}\right]\)
14.3 Consider the 1-factor confirmatory factor analysis model in (14.2) with
\[
\boldsymbol{\Lambda}=\left[\begin{array}{c}
1 \\
\lambda_{2} \\
\lambda_{3}
\end{array}\right], \operatorname{var}(f)=\phi, \text { and } \operatorname{cov}(\varepsilon)=\left[\begin{array}{ccc}
\psi_{11} & 0 & 0 \\
0 & \psi_{22} & 0 \\
0 & 0 & \psi_{33}
\end{array}\right]
\]
(a) Use the rules presented in Section 14.2.2 to determine whether or not the model is identified. Explain your reasoning.
(b) How many degrees of freedom will be associated with the \(\chi^{2}\) goodness-of-fit statistic described in (14.13)? What does this imply about the nature of the estimate \(\hat{\boldsymbol{\theta}}\)-that is, how close will \(\boldsymbol{\Sigma}(\hat{\boldsymbol{\theta}})\) be to the sample covariance matrix for the data \(\mathbf{S}\) ?
(c) Find the model covariance matrix \(\boldsymbol{\Sigma}(\boldsymbol{\theta})\), with each element written as a function of \(\lambda_{2}, \lambda_{3}, \phi, \psi_{11}, \psi_{22}\), and \(\psi_{33}\).
(d) Let the sample covariance matrix for the data be denoted
\[
\mathbf{S}=\left[\begin{array}{lll}
s_{11} & s_{12} & s_{13} \\
s_{21} & s_{22} & s_{23} \\
s_{31} & s_{32} & s_{33}
\end{array}\right]
\]

Set the six unique elements of \(S\) equal to the corresponding elements of \(\boldsymbol{\Sigma}(\boldsymbol{\theta})\). With six equations and six parameters to estimate, find estimates of \(\lambda_{2}, \lambda_{3}, \phi, \psi_{11}, \psi_{22}\), and \(\psi_{33}\) as functions of sample variances and covariances ( \(s_{11}, s_{12}, s_{13}, s_{22}, s_{23}\), and \(s_{33}\) ).
14.4 Use the probe word data of Table 3.6. Conduct a confirmatory factor analysis of the covariance matrix for the five variables. Use maximum likelihood to determine if the five word probes can be adequately modeled using a single latent factor. In formulating the model, identifiability can be ensured by letting \(y_{1}=f_{1}+\varepsilon_{1}\) and letting \(y_{i}=\lambda_{i} f_{1}+\varepsilon_{i}(i=2,3,4,5)\).
(a) Assess goodness of fit with the criteria discussed in Section 14.3.3.
(b) Which variables are most significantly related to the latent factor? Which are least significant? Can the model be further simplified?
(c) Fit the model again, this time identifying the model by setting one of the other observed variables equal to \(f_{1}+\varepsilon_{i}\). For example, set \(y_{2}=\) \(f_{1}+\varepsilon_{2}\), with \(y_{i}=\lambda_{i} f_{1}+\varepsilon_{i}\) for \(i=1,3,4,5\). Calculate the goodness of fit statistics discussed in Section 14.3.3 and compare with part (a). Is the goodness of fit for the one-factor model affected by which observed variable is set equal to \(f_{1}+\varepsilon_{i}\) ?
14.5 Use the Seishu data of Table 7.1. Conduct a confirmatory factor analysis of the covariance matrix for all 10 variables. Use maximum likelihood to fit the model and test the hypothesis that the observations are driven by four factors:
\[
\begin{aligned}
& f_{1}=\text { "flavor" } \\
& f_{2}=\text { "acidity" } \\
& f_{3}=\text { "sweetness" } \\
& f_{4}=\text { "alcohol content" }
\end{aligned}
\]

To fit an identifiable model, define the observed variable "Taste" to be equal to \(f_{1}\) plus error, define the observed variable " pH " to be equal to \(f_{2}\) plus error, define the observed variable "Total Sugar" to be equal to \(f_{3}\) plus error, and define the observed variable "Alcohol" to be equal to \(f_{4}\) plus error. In your initial model, allow the other 6 variables to be functions of all 4 factors, for a total of 24 factor loadings to be estimated.
(a) Assess goodness of fit with the criteria discussed in Section 14.3.3.
(b) Using goodness-of-fit statistics and hypothesis tests on each of the factor loadings, conduct an exploratory analysis using the iterative modelselection process discussed at the end of Section 14.5 to identify a simpler model. Specifically, determine whether a model can be specified with fewer factor loadings (i.e., simpler structure) and still exhibit a good fit. Propose a simpler model and appropriately justify your proposal using goodness-of-fit statistics and hypothesis tests.
14.6 Use the football data of Table 8.3, combining the three groups into a single sample. Conduct a confirmatory factor analysis of the covariance matrix using maximum likelihood to fit the model. Test the hypothesis that the observations are driven by two factors related to head size:
\(f_{1}=\) "horizontal dimension"
\(f_{2}=\) "vertical dimension"

To fit an identifiable model, define the observed variable "head circumference" to be equal to \(f_{1}\) plus error, and define the observed variable "eye-to-top-ofhead measurement" to be equal to \(f_{2}\) plus error. In your initial model, allow the other 4 variables to be functions of both factors, for a total of 8 factor loadings to be estimated.
(a) Assess goodness of fit with the criteria discussed in Section 14.3.3.
(b) For comparison, fit the 2 -factor model with simple structure. That is, fit the model with head width, head circumference, front-to-back measurement at eye level, and jaw width loading only on \(f_{1}\). Similarly, let eye-to-top-of-head measurement and ear-to-top-of-head measurement load only on \(f_{2}\). Use goodness-of-fit criteria and hypothesis tests on factor loadings to compare the initial model with this simple-structure model. Which model is preferable?
14.7 Use the engineer data of Table 5.6, combining the two groups into a single sample. Conduct a confirmatory factor analysis of the covariance matrix using maximum likelihood. Test the hypothesis that the observations are driven by two factors related to test performance:
\[
\begin{aligned}
& f_{1}=\text { "aptitude" } \\
& f_{2}=\text { "effort" }
\end{aligned}
\]

To fit an identifiable model, define the observed variable "intelligence" to be equal to \(f_{1}\) plus error, and define the observed variable "perseveration" to be equal to \(f_{2}\) plus error. Allow the other 4 variables to be functions of both factors, for a total of 8 factor loadings to be estimated.
(a) Assess goodness of fit with the criteria discussed in Section 14.3.3.
(b) For each observed \(y_{i}\) (performance test), quantify how much of the variability in \(y_{i}\) can be accounted for by the factors. This can be calculated using
\[
1-\frac{\hat{\psi}_{i i}}{s_{i i}}
\]

Note that if the estimated error variance ( \(\hat{\psi}_{i i}\) ) is greater than the sample variance for the associated observed variable ( \(s_{i i}\) ), the percent of variability explained by the factors is undefined and the quality of the model fit is compromised.
(c) Interpret the results from parts (a) and (b). Does goodness of fit imply that the latent factors can be used as a lower-dimensional replacement for the observed variables? Would you expect that the variance explained by the factors for each \(y_{i}\) would improve substantially with the addition of another factor in the model?
14.8 Use the rootstock data of Table 6.2. Using the covariance matrix, fit a confirmatory factor analysis model using maximum likelihood to determine if the four tree measurements can be adequately modeled using a single latent factor.

To ensure model identifiability, let one of the four variables be modeled with \(y_{i}=f_{1}+\varepsilon_{i}\) and let \(y_{j}=\lambda_{j} f_{1}+\varepsilon_{j}\) for \(j \neq i\). Assess goodness of fit with the criteria discussed in Section 14.3.3. If the model exhibits adequate fit, explain whether or not the model can be further simplified. If the model does not exhibit adequate fit, explain why you would or would not recommend fitting a 2-factor or 3-factor model.

\section*{CHAPTER 15}

\section*{CLUSTER ANALYSIS}

\subsection*{15.1 INTRODUCTION}

In cluster analysis we search for patterns in a data set by grouping the (multivariate) observations into clusters. The goal is to find an optimal grouping for which the observations or objects within each cluster are similar but the clusters are dissimilar to each other. We hope to find the natural groupings in the data, groupings that make sense to the researcher.

Cluster analysis differs fundamentally from classification analysis (Chapter 9). In classification analysis, we allocate the observations to a known number of predefined groups or populations. In cluster analysis, neither the number of groups nor the groups themselves are known in advance.

To group the observations into clusters, many techniques begin with similarities between all pairs of observations. In many cases the similarities are based on some measure of distance. Other cluster methods use a preliminary choice for cluster centers or a comparison of within- and between-cluster variability. It is also possible to cluster the variables, in which case the similarity could be a correlation; see Section 15.7.

We can search for clusters graphically by plotting the observations. If there are only two variables ( \(p=2\) ), this can be done in a scatterplot (see Section 3.3). For \(p>2\), we can plot the data in two dimensions using principal components (see Section 12.4) or biplots (see Section 16.3). For an example of a principal component plot, see Figure 12.7 in Section 12.4, in which four clear groupings of points can be observed. Another approach to plotting is provided by projection pursuit, which seeks two-dimensional projections that reveal clusters [see Friedman and Tukey (1974); Huber (1985); Sibson (1984); Jones and Sibson (1987); Yenyukov (1988); Posse (1990); Nason (1995); Ripley (1996, pp. 296-303)].

Cluster analysis has also been referred to as classification, pattern recognition (specifically, unsupervised learning), and numerical taxonomy. The techniques of cluster analysis have been extensively applied to data in many fields, such as medicine, psychiatry, sociology, criminology, anthropology, archaeology, geology, geography, remote sensing, market research, economics, and engineering.

We shall concentrate largely on quantitative variables [for categorical variables, see Gordon (1999) or Everitt (1993)]. The data matrix [see (3.17)] can be written as
\[
\mathbf{Y}=\left(\begin{array}{c}
\mathbf{y}_{1}^{\prime}  \tag{15.1}\\
\mathbf{y}_{2}^{\prime} \\
\vdots \\
\mathbf{y}_{n}^{\prime}
\end{array}\right)=\left(\mathbf{y}_{(1)}, \mathbf{y}_{(2)}, \cdots, \mathbf{y}_{(p)}\right)
\]
where \(\mathbf{y}_{i}^{\prime}\) is a row (observation vector) and \(\mathbf{y}_{(j)}\) is a column (corresponding to a variable). We generally wish to group the \(n \mathbf{y}_{i}^{\prime}\) 's (rows) into \(g\) clusters. We may also wish to cluster the columns \(\mathbf{y}_{(j)}, j=1,2, \ldots, p\) (see Section 15.7).

Two common approaches to clustering the observation vectors are hierarchical clustering and partitioning. In hierarchical clustering we typically start with \(n\) clusters, one for each observation, and end with a single cluster containing all \(n\) observations. At each step, an observation or a cluster of observations is absorbed into another cluster. We can also reverse this process, that is, start with a single cluster containing all \(n\) observations and end with \(n\) clusters of a single item each (see Section 15.3.10). In partitioning, we simply divide the observations into \(g\) clusters. This can be done by starting with an initial partitioning or with cluster centers and then reallocating the observations according to some optimality criterion. Other clustering methods that we will discuss are based on fitting mixtures of multivariate normal distributions or searching for regions of high density sometimes called modes.

There is an abundant literature on cluster analysis. Useful monographs and reviews have been given by Gordon (1999), Everitt (1993), Khattree and Naik (2000, Chapter 6), Kaufman and Rousseuw (1990), Seber (1984, Chapter 7), Anderberg (1973), and Hartigan (1975a).

\subsection*{15.2 MEASURES OF SIMILARITY OR DISSIMILARITY}

Since cluster analysis attempts to identify the observation vectors that are similar and group them into clusters, many techniques use an index of similarity or proximity
between each pair of observations. A convenient measure of proximity is the distance between two observations. Since distance increases as two units become further apart, distance is actually a measure of dissimilarity.

A common distance function is the Euclidean distance between two vectors \(\mathbf{x}=\) \(\left(x_{1}, x_{2}, \ldots, x_{p}\right)^{\prime}\) and \(\mathbf{y}=\left(y_{1}, y_{2}, \ldots, y_{p}\right)^{\prime}\), defined as
\[
\begin{equation*}
d(\mathbf{x}, \mathbf{y})=\sqrt{(\mathbf{x}-\mathbf{y})^{\prime}(\mathbf{x}-\mathbf{y})}=\sqrt{\sum_{j=1}^{p}\left(x_{j}-y_{j}\right)^{2}} \tag{15.2}
\end{equation*}
\]

To adjust for differing variances and covariances among the \(p\) variables, we could use the statistical distance
\[
\begin{equation*}
d(\mathbf{x}, \mathbf{y})=\sqrt{(\mathbf{x}-\mathbf{y})^{\prime} \mathbf{S}^{-1}(\mathbf{x}-\mathbf{y})} \tag{15.3}
\end{equation*}
\]
[see (3.79)], where \(\mathbf{S}\) is the sample covariance matrix. After the clusters are formed, \(S\) could be computed as the pooled within-cluster covariance matrix, but we do not know beforehand what the clusters will be. If we compute \(\mathbf{S}\) on the unpartitioned sample, there will be distortion of the variances and covariances because of the groups in the data (assuming there really are some natural clusters). We therefore usually use the Euclidean distance given by (15.2). In some clustering procedures, it is not necessary to take the square root in (15.2) or (15.3).

Other distance measures have been suggested, for example, the Minkowski metric
\[
\begin{equation*}
d(\mathbf{x}, \mathbf{y})=\left[\sum_{j=1}^{p}\left|x_{j}-y_{j}\right|^{r}\right]^{1 / r} \tag{15.4}
\end{equation*}
\]

For \(r=2, d(\mathbf{x}, \mathbf{y})\) in (15.4) becomes the Euclidean distance given in (15.2). For \(p=\) 2 and \(r=1\), (15.4) measures the "city block" distance between two observations. There are distance measures for categorical data; see Gordon (1999, Chapter 2).

For the \(n\) observation vectors \(\mathbf{y}_{1}, \mathbf{y}_{2}, \ldots, \mathbf{y}_{n}\), we can compute an \(n \times n\) matrix \(\mathbf{D}=\left(d_{i j}\right)\) of distances (or dissimilarities) where \(d_{i j}=d\left(\mathbf{y}_{i}, \mathbf{y}_{j}\right)\) is usually given by (15.2), \(d\left(\mathbf{y}_{i}, \mathbf{y}_{j}\right)=\sqrt{\left(\mathbf{y}_{i}-\mathbf{y}_{j}\right)^{\prime}\left(\mathbf{y}_{i}-\mathbf{y}_{j}\right)}\). We sometimes use \(\mathbf{D}=\left(d_{i j}^{2}\right)\), where \(d_{i j}^{2}=d^{2}\left(\mathbf{y}_{i}, \mathbf{y}_{j}\right)=\left(\mathbf{y}_{i}-\mathbf{y}_{j}\right)^{\prime}\left(\mathbf{y}_{i}-\mathbf{y}_{j}\right)\) is the square of (15.2). The matrix \(\mathbf{D}\) will typically be symmetric with diagonal elements equal to zero.

The scale of measurement of the variables is an important consideration when using the Euclidean distance measure in (15.2). Changing the scale can affect the relative distances among the items. For example, suppose three items have the following bivariate measurements \(\left(y_{1}, y_{2}\right):(2,5),(4,2),(7,9)\). Using \(d_{i j}\) as given by (15.2), the matrix \(\mathbf{D}=\left(d_{i j}\right)\) for these items is
\[
\mathbf{D}_{1}=\left(\begin{array}{ccc}
0 & 3.6 & 6.4 \\
3.6 & 0 & 7.6 \\
6.4 & 7.6 & 0
\end{array}\right)
\]

However, if we multiply \(y_{1}\) by 100 as , for example, in changing from meters to centimeters, the matrix becomes
\[
\mathbf{D}_{2}=\left(\begin{array}{ccc}
0 & 200 & 500 \\
200 & 0 & 300 \\
500 & 300 & 0
\end{array}\right)
\]
and the largest distance is now \(d_{13}\) instead of \(d_{23}\). The distance rankings have been altered by scaling.

To counter this problem, each variable could be standardized in the usual way by subtracting the mean and dividing by the standard deviation of the variable. However, such scaling would ordinarily be based on the entire data set, that is, on all \(n\) values in each column of Y in (15.1). In this case, the variables that best separate clusters might no longer do so after division by standard deviations that include between-cluster variation. If we use standardized variables, the clusters could be less well separated. The question of scaling is therefore not an easy one. However, standardization of this type is recommended by many authors.

By (15.2), the squared Euclidean distance between two observations \(\mathbf{x}=\left(x_{1}\right.\), \(\left.x_{2}, \ldots, x_{p}\right)^{\prime}\) and \(\mathbf{y}=\left(y_{1}, y_{2}, \ldots, y_{p}\right)^{\prime}\) is \(d^{2}(\mathbf{x}, \mathbf{y})=\sum_{j=1}^{p}\left(x_{j}-y_{j}\right)^{2}\). This can be expressed as
\[
\begin{equation*}
d^{2}(\mathbf{x}, \mathbf{y})=\left(v_{x}-v_{y}\right)^{2}+p(\bar{x}-\bar{y})^{2}+2 v_{x} v_{y}\left(1-r_{x y}\right) \tag{15.5}
\end{equation*}
\]
where \(v_{x}^{2}=\sum_{j=1}^{p}\left(x_{j}-\bar{x}\right)^{2}\) and \(\bar{x}=\sum_{j=1}^{p} x_{j} / p\), with similar expressions for \(v_{y}^{2}\) and \(\bar{y}\). The correlation \(r_{x y}\) in (15.5) is given by
\[
\begin{equation*}
r_{x y}=\frac{\sum_{j=1}^{p}\left(x_{j}-\bar{x}\right)\left(y_{j}-\bar{y}\right)}{\sqrt{\sum_{j=1}^{p}\left(x_{j}-\bar{x}\right)^{2} \sum_{j=1}^{p}\left(y_{j}-\bar{y}\right)^{2}}} \tag{15.6}
\end{equation*}
\]

In Figure 15.1, we illustrate the profile (see Sections 5.9 and 6.8) for each of two observation vectors \(\mathbf{x}\) and \(\mathbf{y}\). The squared Eulcidean distance in (15.5) can be used to compare the profiles of \(\mathbf{x}\) and \(\mathbf{y}\) in terms of levels, variation, and shape, where \(\bar{x}\) and \(\bar{y}\) are the levels of the two profiles, \(v_{x}\) and \(v_{y}\) are the variations of the profiles, and the correlation \(r_{x y}\) is a measure of the closeness of the shapes of the two profiles. The closer \(r_{x y}\) is to 1 , the greater is the similarity in shape of the two profiles. Note that \(\bar{x}\) and \(v_{x}\) are the mean and variation of the \(p\) variables within the observation vector \(x\), not over the \(n\) observations in the data set. A similar comment can be made about \(\bar{y}\) and \(v_{y}\). Likewise, the correlation \(r_{x y}\) is between the two observation vectors \(\mathbf{x}\) and \(\mathbf{y}\), not between two variables. The use of \(r_{x y}\) has been questioned by Jardine and Sibson (1971) and Wishart (1971), but Strauss et al. (1973) found the correlation to be superior to the Euclidean distance for finding the clusters in a particular data set.

Figure 15.1 Profiles for two observation vectors \(\mathbf{x}\) and \(\mathbf{y}\).

\subsection*{15.3 HIERARCHICAL CLUSTERING}

\subsection*{15.3.1 Introduction}

Hierarchical methods and other clustering algorithms represent an attempt to find "good" clusters in the data using a computationally efficient technique. It is not generally feasible to examine all possible clustering possibilities for a data set, especially a large one. The number of ways of partitioning a set of \(n\) items into \(g\) clusters is given by
\[
\begin{equation*}
N(n, g)=\frac{1}{g!} \sum_{k=1}^{g}\binom{g}{k}(-1)^{g-k} k^{n} \tag{15.7}
\end{equation*}
\]
[see Duran and Odell (1974, Chapter 4), Jensen (1969), Seber (1984, p. 379)]. This can be approximated by \(g^{n} / g!\), which is large even for moderate values of \(n\) and \(g\). For example, \(N(25,10) \cong 2.8 \times 10^{18}\). The total possible number of clusters for a set of \(n\) items is \(\sum_{g=1}^{n} N(n, g)\), which, for \(n=25\), is greater than \(10^{19}\). Hence, hierarchical methods and other approaches permit us to search for a reasonable solution without having to look at all possible arrangements.

As noted in Section 15.1, hierarchical clustering algorithms involve a sequential process. In each step of the agglomerative hierarchical approach, an observation or a cluster of observations is merged into another cluster. In this process, the number of clusters shrinks and the clusters themselves grow larger. We start with \(n\) clusters (individual items) and end with one single cluster containing the entire data set. An alternative approach, called the divisive method, starts with a single cluster
containing all \(n\) items and partitions a cluster into two clusters at each step (see Section 15.3.10). The end result of the divisive approach is \(n\) clusters of one item each. Agglomerative methods are more commonly used than divisive methods. In either type of hierarchical clustering, a decision must be made as to the "optimal" number of clusters (see Section 15.5).

At each step of an agglomerative hierarchical approach, the two "closest" clusters are merged into a single new cluster. The process is therefore irreversible in the sense that any two items that are once lumped together in a cluster cannot be separated later in the procedure; any early mistakes cannot be corrected. Similarly, in a divisive hierarchical method, items cannot be moved to other clusters. An optional approach is to carry out a hierarchical procedure followed by a partitioning procedure in which items can be moved from one cluster to another (see Section 15.4.1).

Since an agglomerative hierarchical procedure combines the two "closest" clusters at each step, we must consider the question of measuring the similarity or dissimilarity of two clusters. Different approaches to measuring distance between clusters give rise to different hierarchical methods. Agglomerative techniques are discussed in Sections 15.3.2-15.3.9, and the divisive approach is considered in Section 15.3.10.

\subsection*{15.3.2 Single Linkage (Nearest Neighbor)}

In the single linkage method, the distance between two clusters \(A\) and \(B\) is defined as the minimum distance between a point in \(A\) and a point in \(B\) :
\[
\begin{equation*}
D(A, B)=\min \left\{d\left(\mathbf{y}_{i}, \mathbf{y}_{j}\right), \text { for } \mathbf{y}_{i} \text { in } A \text { and } \mathbf{y}_{j} \text { in } B\right\} \tag{15.8}
\end{equation*}
\]
where \(d\left(\mathbf{y}_{i}, \mathbf{y}_{j}\right)\) is the Euclidean distance in (15.2) or some other distance between the vectors \(\mathbf{y}_{i}\) and \(\mathbf{y}_{j}\). This approach is also called the nearest neighbor method.

At each step in the single linkage method, the distance (15.8) is found for every pair of clusters, and we merge the two clusters with smallest distance. The number of clusters is therefore reduced by one. After two clusters are merged, the procedure is repeated for the next step: the distances between all pairs of clusters are calculated again, and the pair with minimum distance is merged into a single cluster.

The results of a hierarchical clustering procedure can be displayed graphically using a tree diagram, also known as a dendrogram, which shows all the steps in the hierarchical procedure, including the distances at which clusters are merged. Dendrograms are shown in Figures 15.2 and 15.3 in Examples 15.3.2(a) and 15.3.2(b).
- EXAMPLE 15.3.2(a)

Hartigan (1975a, p. 28) compared the crime rates per 100,000 population for various cities. The data are in Table 15.1 (taken from the 1970 US Statistical Abstract). In order to illustrate the use of the distance matrix in single linkage clustering, we use the first six observations in Table 15.1 (Atlanta through Detroit).

Table 15.1 City Crime Rates per 100,000 Population
\begin{tabular}{lrrrrrrr}
\hline City & Murder & Rape & Robbery & Assault & Burglary & Larceny & AutoTheft \\
\hline Atlanta & 16.5 & 24.8 & 106 & 147 & 1112 & 905 & 494 \\
Boston & 4.2 & 13.3 & 122 & 90 & 982 & 669 & 954 \\
Chicago & 11.6 & 24.7 & 340 & 242 & 808 & 609 & 645 \\
Dallas & 18.1 & 34.2 & 184 & 293 & 1668 & 901 & 602 \\
Denver & 6.9 & 41.5 & 173 & 191 & 1534 & 1368 & 780 \\
Detroit & 13.0 & 35.7 & 477 & 220 & 1566 & 1183 & 788 \\
Hartford & 2.5 & 8.8 & 68 & 103 & 1017 & 724 & 468 \\
Honolulu & 3.6 & 12.7 & 42 & 28 & 1457 & 1102 & 637 \\
Houston & 16.8 & 26.6 & 289 & 186 & 1509 & 787 & 697 \\
Kansas City & 10.8 & 43.2 & 255 & 226 & 1494 & 955 & 765 \\
Los Angeles & 9.7 & 51.8 & 286 & 355 & 1902 & 1386 & 862 \\
New Orleans & 10.3 & 39.7 & 266 & 283 & 1056 & 1036 & 776 \\
New York & 9.4 & 19.4 & 522 & 267 & 1674 & 1392 & 848 \\
Portland & 5.0 & 23.0 & 157 & 144 & 1530 & 1281 & 488 \\
Tucson & 5.1 & 22.9 & 85 & 148 & 1206 & 756 & 483 \\
Washington & 12.5 & 27.6 & 524 & 217 & 1496 & 1003 & 793
\end{tabular}

The distance matrix \(\mathbf{D}\) is given by
\begin{tabular}{l|rrrrrr}
\hline CITY & \multicolumn{6}{|c}{ DISTANCE BETWEEN CITIES } \\
\hline Atlanta & 0 & 536.6 & 516.4 & 590.2 & 693.6 & 716.2 \\
Boston & 536.6 & 0 & 447.4 & 833.1 & 915.0 & 881.1 \\
Chicago & 516.4 & 447.4 & 0 & 924.0 & 1073.4 & 971.5 \\
Dallas & 590.2 & 833.1 & 924.0 & 0 & 527.7 & 464.5 \\
Denver & 693.6 & 915.0 & 1073.4 & 527.7 & 0 & 358.7 \\
Detroit & 716.2 & 881.1 & 971.5 & 464.5 & 358.7 & 0
\end{tabular}

The smallest distance is 358.7 between Denver and Detroit, and therefore these two cities are joined at the first step to form \(C_{1}=\{\) Denver, Detroit \(\}\). In the next step, the distance matrix is calculated for Atlanta, Boston, Chicago, Dallas, and \(C_{1}\) :
\begin{tabular}{lrrrrr} 
Atlanta & 0 & 536.6 & 516.4 & 590.2 & 693.6 \\
Boston & 536.6 & 0 & 447.4 & 833.1 & 881.1 \\
Chicago & 516.4 & 447.4 & 0 & 924.0 & 971.5 \\
Dallas & 590.2 & 833.1 & 924.0 & 0 & 464.5 \\
\(C_{1}\) & 693.6 & 881.1 & 971.5 & 464.5 & 0
\end{tabular}

Note that all elements of this distance matrix are contained in the original distance matrix. This same pattern will hold in subsequent distance matrices below and is also characteristic of the complete linkage method [see Example 15.3.3(a)]. The smallest distance is 447.4 between Boston and Chicago. Therefore \(C_{2}=\{\) Boston, Chicago \(\}\). At the next step, the distance matrix is calculated for Atlanta, Dallas, \(C_{1}\), and \(C_{2}\) :
\begin{tabular}{lrrrr} 
Atlanta & 0 & 516.4 & 590.2 & 693.6 \\
\(C_{2}\) & 516.4 & 0 & 833.1 & 881.1 \\
Dallas & 590.2 & 833.1 & 0 & 464.5 \\
\(C_{1}\) & 693.6 & 881.1 & 464.5 & 0
\end{tabular}

The smallest distance is 464.5 between Dallas and \(C_{1}\), so that \(C_{3}=\{\) Dallas, \(\left.C_{1}\right\}\). The distance matrix for Atlanta, \(C_{2}\), and \(C_{3}\) is given by
\begin{tabular}{lrrr} 
Atlanta & 0 & 516.4 & 590.2 \\
\(C_{2}\) & 516.4 & 0 & 833.1 \\
\(C_{3}\) & 590.2 & 833.1 & 0
\end{tabular}

The smallest distance is 516.4 , which defines \(C_{4}=\left\{\right.\) Atlanta, \(\left.C_{2}\right\}\). The distance matrix for \(C_{3}\) and \(C_{4}\) is
\begin{tabular}{lrr}
\(C_{3}\) & 0 & 590.2 \\
\(C_{4}\) & 590.2 & 0
\end{tabular}

The last cluster is given by \(C_{5}=\left\{C_{3}, C_{4}\right\}\). The dendrogram for the steps in this example is given in Figure 15.2. The order in which the clusters were formed and the relative distances at which they formed can all be seen. Note that the distance scale runs from right to left.

\section*{- EXAMPLE 15.3.2(b)}

To further illustrate the single linkage method of clustering, we use the complete city crime data from Table 15.1. The dendrogram in Figure 15.3 shows the cluster groupings attained by the single linkage method.

\subsection*{15.3.3 Complete Linkage (Farthest Neighbor)}

In the complete linkage approach, also called the farthest neighbor method, the distance between two clusters \(A\) and \(B\) is defined as the maximum distance between a point in \(A\) and a point in \(B\) :
\[
\begin{equation*}
D(A, B)=\max \left\{d\left(\mathbf{y}_{i}, \mathbf{y}_{j}\right) \text { for } \mathbf{y}_{i} \text { in } A \text { and } \mathbf{y}_{j} \text { in } B\right\} . \tag{15.9}
\end{equation*}
\]

At each step, the distance (15.9) is found for every pair of clusters, and we merge the two clusters with the smallest distance.

■ EXAMPLE 15.3.3(a)
As in Example 15.3.2(a) for single linkage clustering, we illustrate the use of the distance matrix in complete linkage clustering with the first six observations of the city crime data in Table 15.1. The initial distance matrix is exactly the same as in Example 15.3.2(a):

Figure 15.2 Dendrogram for single linkage of the first six observations in the city crime data in Table 15.1 [See Example 15.3.2(a)].
\begin{tabular}{l|rrrrrr}
\hline CITY & \multicolumn{6}{|c}{ DISTANCE BETWEEN CITIES } \\
\hline Atlanta & 0 & 536.6 & 516.4 & 590.2 & 693.6 & 716.2 \\
Boston & 536.6 & 0 & 447.4 & 833.1 & 915.0 & 881.1 \\
Chicago & 516.4 & 447.4 & 0 & 924.0 & 1073.4 & 971.5 \\
Dallas & 590.2 & 833.1 & 924.0 & 0 & 527.7 & 464.5 \\
Denver & 693.6 & 915.0 & 1073.4 & 527.7 & 0 & 358.7 \\
Detroit & 716.2 & 881.1 & 971.5 & 464.5 & 358.7 & 0
\end{tabular}

The smallest distance is 358.7 between Denver and Detroit, and these two therefore form the first cluster, \(C_{1}=\{\) Denver, Detroit \(\}\). Note that since the first cluster is based on the initial distance matrix, it will be the same regardless of which hierarchical clustering method is used.

Figure 15.3 Dendrogram for single linkage of the complete city crime data from Table 15.1 [see Example 15.3.2(b)].

In the next step, the distance matrix is calculated for Atlanta, Boston, Chicago, Dallas, and \(C_{1}\) :
\begin{tabular}{lrrrrr} 
Atlanta & 0 & 536.6 & 516.4 & 590.2 & 716.2 \\
Boston & 536.6 & 0 & 447.4 & 833.1 & 915.0 \\
Chicago & 516.4 & 447.4 & 0 & 924.0 & 1073.4 \\
Dallas & 590.2 & 833.1 & 924.0 & 0 & 527.7 \\
\(C_{1}\) & 716.2 & 915.0 & 1073.4 & 527.7 & 0
\end{tabular}

Note that this distance matrix differs from its analog for the second step in Example 15.3.2(a) only in the distances between \(C_{1}\) and the other cities. All elements of this matrix and subsequent distance matrices below are contained in the original distance matrix for the six cities. The smallest distance is 447.4 between Boston and Chicago. Therefore, \(C_{2}=\{\) Boston, Chicago \(\}\). At the next step, distances are calculated for Atlanta, Dallas, \(C_{1}\), and \(C_{2}\) :
\begin{tabular}{lrrrr} 
Atlanta & 0 & 536.6 & 590.2 & 716.2 \\
\(C_{2}\) & 536.6 & 0 & 924.0 & 833.1 \\
Dallas & 590.2 & 924.0 & 0 & 527.7 \\
\(C_{1}\) & 693.6 & 881.1 & 527.7 & 0
\end{tabular}

The smallest distance, 527.7, defines \(C_{3}=\left\{\right.\) Dallas, \(\left.C_{1}\right\}\). The distance matrix for Atlanta, \(C_{2}\), and \(C_{3}\) is given by
\begin{tabular}{lrrr} 
Atlanta & 0 & 536.6 & 716.2 \\
\(C_{2}\) & 536.6 & 0 & 1073.4 \\
\(C_{3}\) & 590.2 & 1073.4 & 0
\end{tabular}

The smallest distance is 536.6 between Atlanta and \(C_{3}\), so that \(C_{4}=\{\) Atlanta, \(\left.C_{2}\right\}\). The distance matrix for \(C_{3}\) and \(C_{4}\) is
\[
\begin{array}{rrr}
C_{3} & 0 & 1073.4 \\
C_{4} & 1073.4 & 0
\end{array}
\]

The last cluster is given by \(C_{5}=\left\{C_{3}, C_{4}\right\}\). The dendrogram in Figure 15.4 shows the steps in this example.
- EXAMPLE 15.3.3(b)

To further illustrate the complete linkage method, we use the complete crime data in Table 15.1. The dendrogram in Figure 15.5 shows the clusters found for this data set by the complete linkage approach. There are some differences between these groupings and the groupings from single linkage in Figure 15.3.

\subsection*{15.3.4 Average Linkage}

In the average linkage approach, the distance between two clusters \(A\) and \(B\) is defined as the average of the \(n_{A} n_{B}\) distances between the \(n_{A}\) points in \(A\) and the \(n_{B}\)

Figure 15.4 Dendrogram for complete linkage of the first six observations in the city crime data in Table 15.1 [see Example 15.3.3(a)].

Figure 15.5 Dendrogram for complete linkage of the complete city crime data of Table 15.1 [see Example 15.3.3(b)].
points in \(B\) :
\[
\begin{equation*}
D(A, B)=\frac{1}{n_{A} n_{B}} \sum_{i=1}^{n_{A}} \sum_{j=1}^{n_{B}} d\left(\mathbf{y}_{i}, \mathbf{y}_{j}\right) \tag{15.10}
\end{equation*}
\]
where the sum is over all \(\mathbf{y}_{i}\) in \(A\) and all \(\mathbf{y}_{j}\) in \(B\). At each step, we join the two clusters with the smallest distance, as measured by (15.10).

\section*{E EXAMPLE 15.3.4}

Figure 15.6 shows the dendrogram resulting from the average linkage method applied to the city crime data in Table 15.1. The solution is the same as the complete linkage solution for this data set as given in Example 15.3.3(b) and Figure 15.5.

\subsection*{15.3.5 Centroid}

In the centroid method, the distance between two clusters \(A\) and \(B\) is defined as the Euclidean distance between mean vectors (often called centroids) of the two clusters:
\[
\begin{equation*}
D(A, B)=d\left(\overline{\mathbf{y}}_{A}, \overline{\mathbf{y}}_{B}\right) \tag{15.11}
\end{equation*}
\]
where \(\overline{\mathbf{y}}_{A}\) and \(\overline{\mathbf{y}}_{B}\) are the mean vectors for the observation vectors in \(A\) and the observation vectors in \(B\), respectively, and \(d\left(\overline{\mathbf{y}}_{A}, \overline{\mathbf{y}}_{B}\right)\) is defined in (15.2). We define \(\overline{\mathbf{y}}_{A}\) and \(\overline{\mathbf{y}}_{B}\) in the usual way, that is, \(\overline{\mathbf{y}}_{A}=\sum_{i=1}^{n_{A}} \mathbf{y}_{i} / n_{A}\). The two clusters with the smallest distance between centroids are merged at each step.

After two clusters \(A\) and \(B\) are joined, the centroid of the new cluster \(A B\) is given by the weighted average
\[
\begin{equation*}
\overline{\mathbf{y}}_{A B}=\frac{n_{A} \overline{\mathbf{y}}_{A}+n_{B} \overline{\mathbf{y}}_{B}}{n_{A}+n_{B}} . \tag{15.12}
\end{equation*}
\]

\section*{E EXAMPLE 15.3.5}

Figure 15.7 shows the dendrogram resulting from using the centroid clustering method on the complete city crime data in Table 15.1.

Note the two crossovers in the dendrogram in Figure 15.7. Boston and Chicago join at a distance of 447.4. Then that cluster joins with \{Atlanta, Tucson, Hartford \} at a distance of 441.1. Finally, all five join with New Orleans at a distance of 393.8. Crossovers are discussed in Section 15.3.9a.

\subsection*{15.3.6 Median}

If two clusters \(A\) and \(B\) are combined using the centroid method, and if \(A\) contains a larger number of items than \(B\), then the new centroid \(\overline{\mathbf{y}}_{A B}=\left(n_{A} \overline{\mathbf{y}}_{A}+\right.\) \(\left.n_{B} \overline{\mathbf{y}}_{B}\right) /\left(n_{A}+n_{B}\right)\) may be much closer to \(\overline{\mathbf{y}}_{A}\) than to \(\overline{\mathbf{y}}_{B}\). To avoid weighting the mean vectors according to cluster size, we can use the median (midpoint) of the line

Figure 15.6 Dendrogram for average linkage clustering of the data in Table 15.1 (see Example 15.3.4).
joining \(A\) and \(B\) as the point for computing new distances to other clusters:
\[
\begin{equation*}
\mathbf{m}_{A B}=\frac{1}{2}\left(\overline{\mathbf{y}}_{A}+\overline{\mathbf{y}}_{B}\right) \tag{15.13}
\end{equation*}
\]

The two clusters with the smallest distance between medians are merged at each step.
Note that the "median" in (15.13) is not the ordinary median in the statistical sense. The terminology arises from a median of a triangle, namely, the line from a vertex to the midpoint of the opposite side.

Figure 15.7 Dendrogram for the centroid clustering of the complete city crime data in Table 15.1 (see Example 15.3.5).

EXAMPLE 15.3.6
Figure 15.8 shows the dendrogram resulting from using the median distance clustering method on the complete city crime data in Table 15.1. In Figure 15.8, we see the same two crossovers as in Figure 15.7.

Figure 15.8 Dendrogram for the median clustering method applied to the complete city crime data in Table 15.1 (see Example 15.3.6).

\subsection*{15.3.7 Ward's Method}

Ward's method, also called the incremental sum of squares method, uses the withincluster (squared) distances and the between-cluster (squared) distances (Ward 1963, Wishart 1969a). If \(A B\) is the cluster obtained by combining clusters \(A\) and \(B\), then
the sums of within-cluster distances (of the items from the cluster mean vectors) are
\[
\begin{align*}
\operatorname{SSE}_{A} & =\sum_{i=1}^{n_{A}}\left(\mathbf{y}_{i}-\overline{\mathbf{y}}_{A}\right)^{\prime}\left(\mathbf{y}_{i}-\overline{\mathbf{y}}_{A}\right)  \tag{15.14}\\
\operatorname{SSE}_{B} & =\sum_{i=1}^{n_{B}}\left(\mathbf{y}_{i}-\overline{\mathbf{y}}_{B}\right)^{\prime}\left(\mathbf{y}_{i}-\overline{\mathbf{y}}_{B}\right)  \tag{15.15}\\
\operatorname{SSE}_{A B} & =\sum_{i=1}^{n_{A B}}\left(\mathbf{y}_{i}-\overline{\mathbf{y}}_{A B}\right)^{\prime}\left(\mathbf{y}_{i}-\overline{\mathbf{y}}_{A B}\right) \tag{15.16}
\end{align*}
\]
where \(\overline{\mathbf{y}}_{A B}=\left(n_{A} \overline{\mathbf{y}}_{A}+n_{B} \overline{\mathbf{y}}_{B}\right) /\left(n_{A}+n_{B}\right)\) as in (15.12) and \(n_{A}, n_{B}\), and \(n_{A B}=\) \(n_{A}+n_{B}\) are the numbers of points in \(A, B\), and \(A B\) respectively. Since these sums of distances are equivalent to within-cluster sums of squares, they are denoted by \(\operatorname{SSE}_{A}, \mathrm{SSE}_{B}\), and \(\mathrm{SSE}_{A B}\).

Ward's method joins the two clusters \(A\) and \(B\) that minimize the increase in SSE, defined as
\[
\begin{equation*}
I_{A B}=\operatorname{SSE}_{A B}-\left(\mathrm{SSE}_{A}+\mathrm{SSE}_{B}\right) \tag{15.17}
\end{equation*}
\]

It can be shown that the increase \(I_{A B}\) in (15.17) has the following two equivalent forms:
\[
\begin{align*}
I_{A B}= & n_{A}\left(\overline{\mathbf{y}}_{A}-\overline{\mathbf{y}}_{A B}\right)^{\prime}\left(\overline{\mathbf{y}}_{A}-\overline{\mathbf{y}}_{A B}\right) \\
& \quad+n_{B}\left(\overline{\mathbf{y}}_{B}-\overline{\mathbf{y}}_{A B}\right)^{\prime}\left(\overline{\mathbf{y}}_{B}-\overline{\mathbf{y}}_{A B}\right)  \tag{15.18}\\
= & \frac{n_{A} n_{B}}{n_{A}+n_{B}}\left(\overline{\mathbf{y}}_{A}-\overline{\mathbf{y}}_{B}\right)^{\prime}\left(\overline{\mathbf{y}}_{A}-\overline{\mathbf{y}}_{B}\right) . \tag{15.19}
\end{align*}
\]

Thus by (15.19), minimizing the increase in SSE is equivalent to minimizing the between cluster distances. If \(A\) consists only of \(\mathbf{y}_{i}\) and \(B\) consists only of \(\mathbf{y}_{j}\), then \(\mathrm{SSE}_{A}\) and \(\mathrm{SSE}_{B}\) are zero, and (15.17) and (15.19) reduce to
\[
I_{i j}=\operatorname{SSE}_{A B}=\frac{1}{2}\left(\mathbf{y}_{i}-\mathbf{y}_{j}\right)^{\prime}\left(\mathbf{y}_{i}-\mathbf{y}_{j}\right)=\frac{1}{2} d^{2}\left(\mathbf{y}_{i}, \mathbf{y}_{j}\right)
\]

Ward's method is related to the centroid method in Section 15.3.5. If the distance \(d\left(\overline{\mathbf{y}}_{A}, \overline{\mathbf{y}}_{B}\right)\) in (15.11) is squared and compared to (15.19), the only difference is the coefficient \(n_{A} n_{B} /\left(n_{A}+n_{B}\right)\) for Ward's method. Thus the cluster sizes have an impact on Ward's method but not on the centroid method. Writing \(n_{A} n_{B} /\left(n_{A}+n_{B}\right)\) in (15.19) as
\[
\frac{n_{A} n_{B}}{n_{A}+n_{B}}=\frac{1}{1 / n_{A}+1 / n_{B}}
\]
we see that as \(n_{A}\) and \(n_{B}\) increase, \(n_{A} n_{B} /\left(n_{A}+n_{B}\right)\) increases. Writing the coefficient as
\[
\frac{n_{A} n_{B}}{n_{A}+n_{B}}=\frac{n_{A}}{1+n_{A} / n_{B}},
\]
we see that as \(n_{B}\) increases with \(n_{A}\) fixed, \(n_{A} n_{B} /\left(n_{A}+n_{B}\right)\) increases. Therefore, compared to the centroid method, Ward's method is more likely to join smaller clusters or clusters of equal size.

Figure 15.9 Dendrogram for Ward's method applied to the complete city crime data in Table 15.1 (see Example 15.3.7).

\section*{EXAMPLE 15.3.7}

Figure 15.9 shows the dendrogram resulting from using Ward's clustering method on the complete city crime data in Table 15.1. The vertical axis is \(I_{A B} / \sum_{i=1}^{n}\left(\mathbf{y}_{i}-\overline{\mathbf{y}}\right)^{\prime}\left(\mathbf{y}_{i}-\overline{\mathbf{y}}\right)\), where \(\overline{\mathbf{y}}\) is the overall mean vector for the data.

\subsection*{15.3.8 Flexible Beta Method}

Suppose clusters \(A\) and \(B\) have just been merged to form cluster \(A B\). A general formula for the distance between \(A B\) and any other cluster \(C\) was given by Lance and Williams (1967):
\[
\begin{align*}
D(C, A B)= & \alpha_{A} D(C, A)+\alpha_{B} D(C, B)+\beta D(A, B) \\
& +\gamma|D(C, A)-D(C, B)| \tag{15.20}
\end{align*}
\]

The distances \(D(C, A), D(C, B)\), and \(D(A, B)\) are from the distance matrix before joining \(A\) and \(B\). The distances from \(A B\) to other clusters as given by (15.20) would be used (along with distances between other pairs of clusters) to form the next distance matrix for choosing the pair of clusters with smallest distance. This pair would then be joined at the next step.

To simplify (15.20), Lance and Williams (1967) suggested the following constraints on the parameter values:
\[
\begin{gathered}
\alpha_{A}+\alpha_{B}+\beta=1 \\
\alpha_{A}=\alpha_{B} \\
\gamma=0 \\
\beta<1 .
\end{gathered}
\]

With \(\alpha_{A}=\alpha_{B}\) and \(\gamma=0\), we have \(2 \alpha_{A}=1-\beta\) or \(\alpha_{A}=\alpha_{B}=(1-\beta) / 2\), and we need only choose a value of \(\beta\). The resulting hierarchical clustering procedure is called the flexible beta method.

The choice of \(\beta\) determines the characteristics of the flexible beta clustering procedure. Lance and Williams (1967) suggested the use of a small negative value of \(\beta\), such as \(\beta=-.25\). If there are (or might be) outliers in the data, the use of a smaller value of \(\beta\), such as \(\beta=-.5\), may be more likely to isolate these outliers into simple clusters.

The distances defined for the agglomerative hierarchical methods in Sections \(15.3 .2-15.3 .7\) can all be expressed as special cases of ( 15.20 ). The requisite parameter values are given in Table 15.2. For the centroid, median, and Ward's methods, the distances in (15.20) must be squared distances (assuming Euclidean distances). For the other methods in Table 15.2, the distances may be either squared or unsquared.

We illustrate the choice of parameter values in Table 15.2 for the single linkage method. Using \(\alpha_{A}=\alpha_{B}=\frac{1}{2}, \beta=0\), and \(\gamma=-\frac{1}{2}\) as in the first row of Table 15.2, (15.20) becomes
\[
\begin{equation*}
D(C, A B)=\frac{1}{2} D(C, A)+\frac{1}{2} D(C, B)-\frac{1}{2}|D(C, A)-D(C, B)| . \tag{15.21}
\end{equation*}
\]

If \(D(C, A)>D(C, B)\), then \(|D(C, A)-D(C, B)|=D(C, A)-D(C, B)\), and (15.21) reduces to
\[
\begin{equation*}
D(C, A B)=D(C, B) \tag{15.22}
\end{equation*}
\]

On the other hand, if \(D(C, A)<D(C, B)\), then \(|D(C, A)-D(C, B)|=D(C, B)-\) \(D(C, A)\), and (15.21) reduces to
\[
\begin{equation*}
D(C, A B)=D(C, A) \tag{15.23}
\end{equation*}
\]

Table 15.2 Parameter Values for (15.20)
\begin{tabular}{lcccc}
\hline Cluster Method & \(\alpha_{A}\) & \(\alpha_{B}\) & \(\beta\) & \(\gamma\) \\
\hline Single linkage & \(\frac{1}{2}\) & \(\frac{1}{2}\) & 0 & \(-\frac{1}{2}\) \\
Complete linkage & \(\frac{1}{2}\) & \(\frac{1}{2}\) & 0 & \(\frac{1}{2}\) \\
Average linkage & \(\frac{n_{A}}{n_{A}+n_{B}}\) & \(\frac{n_{B}}{n_{A}+n_{B}}\) & 0 & 0 \\
Centroid & \(\frac{n_{A}}{n_{A}+n_{B}}\) & \(\frac{n_{B}}{n_{A}+n_{B}}\) & \(\frac{-n_{A} n_{B}}{\left(n_{A}+n_{B}\right)^{2}}\) & 0 \\
Median & \(\frac{1}{2}\) & \(\frac{1}{2}\) & \(-\frac{1}{4}\) & 0 \\
Ward's method & \(\frac{n_{A}+n_{C}}{n_{A}+n_{B}+n_{C}}\) & \(\frac{n_{B}+n_{C}}{n_{A}+n_{B}+n_{C}}\) & \(\frac{-n_{C}}{n_{A}+n_{B}+n_{C}}\) & 0 \\
Flexible beta & \((1-\beta) / 2\) & \((1-\beta) / 2\) & \(\beta(<1)\) & 0 \\
\hline
\end{tabular}

Thus, (15.21) can be written as
\[
\begin{equation*}
D(C, A B)=\min [D(C, A), D(C, B)] \tag{15.24}
\end{equation*}
\]
which is equivalent to (15.8), the definition of distance for the single linkage method.

\section*{■ EXAMPLE 15.3.8}

Figures 15.10 and 15.11 show dendrograms produced when using the flexible beta clustering method on the complete city crime data in Table 15.1, with \(\beta=-.25\) and \(\beta=-.75\). The two results are similar.

\subsection*{15.3.9 Properties of Hierarchical Methods}

\subsection*{15.3.9a Monotonicity}

If an item or a cluster joins another cluster at a distance that is less than the distance for the previous merger of two clusters, we say that an inversion or a reversal has occurred. The reversal is represented by a crossover in the dendrogram. Examples of crossovers can be found in Figures 15.7 and 15.8.

A hierarchical method in which reversals cannot occur is said to be monotonic, because the distance at each step is greater than the distance at the previous step. A distance measure or clustering method that is monotonic is also called ultrametric.

We now show that the single linkage and complete linkage methods are monotonic. Let \(d_{k}\) be the distance at which two clusters are joined at the \(k\) th step. We can describe steps \(k\) and \(k+1\) in terms of four clusters \(A, B, C\), and \(D\). Suppose \(D(A, B)\) is less than the distance between any other pair among these four clusters,

Figure 15.10 Dendrogram for the flexible beta method with \(\beta=-.25\) applied to the complete city crime data in Table 15.1(see Example 15.3.8).

Figure 15.11 Dendrogram for the flexible beta method with \(\beta=-.75\) applied to the complete city crime data in Table 15.1 (see Example 15.3.8).
so that \(A\) and \(B\) are joined at step \(k\) to form \(A B\). Then
\[
\begin{equation*}
d_{k}=D(A, B)<\min \{D(A, C), D(B, C), D(C, D)\} \tag{15.25}
\end{equation*}
\]
[If \(D(A, B)\) is less than these three distances, it is less than the other two possible distances, \(D(A, D)\) and \(D(B, D)\).] Suppose at step \(k+1\) we join \(A B\) and \(C\) or we join \(C\) and \(D\). If we merge \(C\) and \(D\), then by (15.25), \(d_{k}=D(A, B)<D(C, D)=\) \(d_{k+1}\). If we join \(A B\) and \(C\), then for single linkage (15.24) gives
\[
d_{k+1}=D(C, A B)=\min \{D(A, C), D(B, C)\}>d_{k}=D(A, B)
\]

By (15.25), both of \(D(A, C)\) and \(D(B, C)\) exceed \(D(A, B)\), and this also holds for complete linkage. Thus, the single linkage and complete linkage methods are monotonic.

For the methods in Table 15.2 other than single linkage and complete linkage, we have \(\gamma=0\) and by (15.20) and (15.25),
\[
\begin{equation*}
D(C, A B)>\left(\alpha_{A}+\alpha_{B}+\beta\right) D(A, B) \tag{15.26}
\end{equation*}
\]

Thus we need \(\alpha_{A}+\alpha_{B}+\beta \geq 1\) for monotonicity. Using this criterion, we see that all methods in Table 15.1 (beyond the first two) are monotonic except the centroid and median methods. (These two methods showed crossovers in the dendrograms in Figures 15.7 and 15.8.) Because of lack of monotonicity, some authors do not recommend the centroid and median methods.

\subsection*{15.3.9b Contraction or Dilation}

We now consider the characteristics of the distances or proximities between the original points. As clusters form, the properties of this space of distances may be altered somewhat. A clustering method that does not alter the spatial properties is referred to by Lance and Williams (1967) as space-conserving. A method that is not spaceconserving may either contract or dilate the space.

A method is space-contracting if newly formed clusters appear to move closer to individual observations, so that an individual item tends to join an existing cluster rather than join with another individual item to form a new cluster. This tendency is also called chaining.

A method is space-dilating if newly formed clusters appear to move away from individual observations, so that individual items tend to form new clusters rather than join existing clusters. In this case, clusters appear to be more distinct than they are.

Dubien and Warde (1979) described the spatial properties as follows. Suppose that the distances among three clusters satisfy
\[
D(A, B)<D(A, C)<D(B, C)
\]

Then a cluster method is space-conserving if
\[
\begin{equation*}
D(A, C)<D(A B, C)<D(B, C) \tag{15.27}
\end{equation*}
\]

A method is space-contracting if the first inequality in (15.27) does not hold and space-dilating if the second inequality does not hold.

The single linkage method is very space-contracting, with marked chaining tendencies. For this reason, single linkage is not recommended by some authors. Complete linkage on the other hand, is very space-dilating, with a tendency to artificially impose cluster boundaries.

Other hierarchical methods fall in between the extremes represented by single linkage and complete linkage. The centroid and average linkage methods are largely space-conserving, while Ward's method is space-contracting. Whenever a method produces reversals for a particular data set, it can be considered to be space-contracting. Thus the centroid method is space-conserving unless it has reversals, whereupon it becomes space-contracting.

The flexible beta method is space-contracting for \(\beta>0\), space-conserving for \(\beta=0\), and space-dilating for \(\beta<0\). A small degree of dilation may help define cluster boundaries, but too much dilation may lead to too many clusters in the early stages. Thus the recommended value of \(\beta=-.25\) may represent a good compromise.

Figure 15.12 Two distinct clusters with intervening individuals.

Figure 15.13 Single linkage clustering of the data in Figure 15.12.

EXAMPLE 15.3.9b
To illustrate chaining in the single linkage method, consider the data plotted in Figure 15.12 (see Everitt 1993, p. 68). Two distinct clusters, \(A\) and \(C\), have points between them labeled \(B\) that do not belong to \(A\) or \(C\).

In Figure 15.13, the two-cluster solution for single linkage clustering places \(C_{1}\) and \(C_{11}\) into one cluster and all other points into another cluster. The threecluster solution has two clusters with \(C\) 's and a cluster with \(A\) 's and \(B\) 's.

Figure 15.14 Average linkage clustering of the data in Figure 15.12.

A dendrogram for average linkage clustering of the data in Figure 15.12 is given in Figure 15.14. For this data set, the average linkage method is more robust to chaining. The two-cluster solution separates the \(C\) 's from the \(A\) 's and \(B\) 's. The three-cluster solution completely separates the three groups, \(A, B\), and \(C\).

\subsection*{15.3.9c Other Properties}

The single linkage method has been criticized by many authors because of its chaining tendencies and because it is sensitive to errors in distances between observations.

Figure 15.15 Clusters in a single dimension.

On the other hand, the single linkage approach is better than the other methods at identifying clusters that have curvy shapes instead of spherical or elliptical shapes, and it is somewhat robust to outliers in the data.

Ward's method and the average linkage method are also relatively insensitive to outliers. For example, in the average linkage method, outliers tend to remain isolated in the early stages and to join with other outliers rather than to join with large clusters or with less compact clusters. This is due to two properties of the average linkage method: (1) the average distance between two groups (squared Euclidean distance) increases as the points in the groups are more spread out, and (2) the average distance increases as the size of the groups increases.

These two properties of the average linkage method are illustrated in one dimension in Figure 15.15 (see Jobson 1992, pp. 524-525), where cluster \(A\) has one point at \(z_{1}\) and cluster \(B\) has two points, \(b_{1}\) and \(b_{2}\), located at \(z_{2}-h\) and \(z_{2}+h\). The average squared distance between \(A\) and \(B\) is
\[
\begin{aligned}
\overline{d^{2}} & =\frac{1}{2}\left[\left(z_{1}-z_{2}+h\right)^{2}+\left(z_{1}-z_{2}-h\right)^{2}\right] \\
& =\frac{1}{2}\left[\left(z_{1}-z_{2}\right)^{2}+h^{2}+2 h\left(z_{1}-z_{2}\right)+\left(z_{1}-z_{2}\right)^{2}+h^{2}-2 h\left(z_{1}-z_{2}\right)\right] \\
& =\left(z_{1}-z_{2}\right)^{2}+h^{2}
\end{aligned}
\]

Thus the average distance between \(A\) and \(B\) increases as the spread of \(b_{1}\) and \(b_{2}\) increases (that is, as \(h\) increases).

To illustrate the second property of the average linkage method, suppose cluster \(B\) in Figure 15.15 consists of a single point located at \(z_{2}\). Then, the distance between \(A\) and \(B\) is \(\left(z_{1}-z_{2}\right)^{2}\), and \(A\) is closer to \(B\) than it is if \(B\) consists of two points.

The centroid method is fairly robust to outliers. Complete linkage is somewhat sensitive to outliers and tends to produce clusters of the same size and shape. Ward's method tends to yield spherical clusters of the same size.

Many studies conclude that the best overall performers are Ward's method and the average linkage method. However, there seems to be an "interaction" between methods and data sets; that is, some methods work better for certain data sets, and other methods work better for other data sets.

A good strategy is to try several methods. If the results agree to some extent, the researcher may have found some natural clusters in the data.

\subsection*{15.3.10 Divisive Methods}

In the agglomerative hierarchical methods covered in Sections 15.3.2-15.3.9, we begin with \(n\) items and end with a single cluster containing all \(n\) items. As noted in the second paragraph of Section 15.3.1, a divisive hierarchical method starts with a single cluster of \(n\) items and divides it into two groups. At each step thereafter, one of the groups is divided into two subgroups. The ultimate result of a divisive algorithm is \(n\) clusters of one item each. The results can be shown in a dendrogram.

Divisive methods suffer from the same potential drawback as the agglomerative methods, namely, that once a partition is made, an item cannot be moved into another group it does not belong to at the time of the partitioning. However, if larger clusters are of interest, then the divisive approach may sometimes be preferred over the agglomerative approach, in which the larger clusters are reached only after a large number of joinings of smaller groups.

Divisive algorithms are generally of two classes: monothetic and polythetic. In a monothetic approach, the division of a group into two subgroups is based on a single variable, whereas the polythetic approach uses all \(p\) variables to make the split.

If the variables are binary (quantitative variables can be converted to binary variables), the monothetic approach can easily be applied. Division into two groups is based on presence or absence of an attribute. The variable (attribute) is chosen which maximizes a chi-square statistic or an information statistic; see Everitt (1993, pp. 87-88) or Gordon (1999, pp. 130-134).

For a monothetic approach using a quantitative variable \(y\), we seek to maximize the between-group sum of squares,
\[
\mathrm{SSB}=n_{1}\left(\bar{y}_{1}-\bar{y}\right)^{2}+n_{2}\left(\bar{y}_{2}-\bar{y}\right)^{2},
\]
where \(n_{1}\) and \(n_{2}\) are the two group sizes (with \(n_{1}+n_{2}=n\) ), \(\bar{y}_{1}\) and \(\bar{y}_{2}\) are the group means, and \(\bar{y}\) is the overall mean based on all \(n\) observations. The sum of squares SSB would be calculated for all possible splits into two groups of sizes \(n_{1}\) and \(n_{2}\) and for each of the \(p\) variables. The final division would be based on the variable that maximizes SSB/ \(\sum_{i=1}^{n}\left(y_{i}-\bar{y}\right)^{2}\).

\hline
\end{tabular}

For a polythetic approach, we consider a technique proposed by MacNaughtonSmith et al. (1964). To divide a group, we work with a splinter group and the remainder. We seek the item in the remainder whose average distance (dissimilarity) from other items in the remainder, minus its average distance from items in the splinter group, is largest. If the largest difference is positive, the item is shifted to the splinter group. If the largest difference is negative, the procedure stops, and the division is complete. We can start the splinter group with the item that has the largest average distance from the other items in the group.

■ EXAMPLE 15.3.10
In Table 15.3 we have the track records of eight countries (Dawkins 1989). Based on the distance matrix for these eight observations, the average distance from each observation to the other seven observations is given in Table 15.4. Since USA has the greatest average distance to the other countries, USA becomes the first observation in the splinter group. Now, the average distance between each observation in the remainder to the other six observations in the remainder is calculated. Then the (average) distance between USA and each

\hline
\end{tabular}
item in the remainder is calculated. (This may be found using the distance matrix since there is only one observation in the splinter group.) Finally, we calculate the difference between the average distance to the remainder and the average distance to the splinter group. The results are in Table 15.5. Because Australia has a positive difference in Table 15.5, it is added to the splinter group with USA. This process is repeated for the six countries in the remainder, and the results are given in Table 15.6. Since no difference in Table 15.6 is positive, the process stops, and we have the following clusters: \(C_{1}=\{\) USA, Australia \(\}, C_{2}=\{\mathrm{GB}, \mathrm{GDR}, \mathrm{USSR}, \mathrm{Canada}\), Kenya, Belgium \(\}\). We could continue and divide \(C_{2}\) into two groups in the same way.

\subsection*{15.4 NONHIERARCHICAL METHODS}

In this section, we discuss three nonhierarchical techniques: partitioning, mixtures of distributions, and density estimation. Among these three methods, partitioning is the most commonly used.

\subsection*{15.4.1 Partitioning}

In the partitioning approach, the observations are separated into \(g\) clusters without using a hierarchical approach based on a matrix of distances or similarities between all pairs of points. The methods described in this section are sometimes called optimization methods rather than partitioning.

An attractive strategy would be to examine all possible ways to partition \(n\) items into \(g\) clusters and find the optimal clustering according to some criterion. However, the number of possible partitions as given by (15.7) is prohibitively large for even moderate values of \(n\) and \(g\). Thus we seek simpler techniques.

\subsection*{15.4.1a k-Means}

We now consider an approach to partitioning that is usually called the \(k\)-means method. (We will continue to use the notation \(g\) rather than \(k\) for the number of clusters.) The method allows the items to be moved from one cluster to another, a reallocation that is not available in the hierarchical methods.

We first select \(g\) items to serve as "seeds." These are later replaced by the centroids (mean vectors) of the clusters. There are various ways we can choose the seeds: select \(g\) items at random (perhaps separated by some minimum distance), choose the first \(g\) points in the data set (again subject to a minimum distance apart), select the \(g\) points that are mutually farthest apart, find the \(g\) points of maximum density, or specify \(g\) regularly spaced points in a grid-like pattern (these would not be actual data points).

For these methods of selecting seeds, the number of clusters, \(g\), must be specified. Alternatively, a minimum distance between seeds may be specified, and then all items that satisfy this criterion are chosen as seeds.

After the seeds are chosen, each remaining point in the data set is assigned to the cluster with the nearest seed (based on Euclidean distance). As soon as a cluster has more than one member, the cluster seed is replaced by the centroid.

After all items are assigned to clusters, each item is examined to see if it is closer to the centroid of another cluster than to the centroid of its own cluster. If so, the item is moved to the new cluster and the two cluster centroids are updated. This process is continued until no further improvement is possible.

The \(k\)-means procedure is somewhat sensitive to the initial choice of seeds. It might be advisable to try the procedure again with a new initial choice of seeds. If different initial choices of seeds produce widely different final clusters, or if convergence is extremely slow, there may be no natural clusters in the data.

The \(k\)-means partitioning method can also be used as a possible improvement on hierarchical techniques. We first cluster the items using a hierarchical method and then use the centroids of these clusters as seeds for a \(k\)-means approach, which will allow points to be reallocated from one cluster to another.

\section*{■ EXAMPLE 15.4.1a}

Protein consumption in twenty-five European countries for nine food groups is given in Table 15.7 (Hand et al. 1994, p. 298). In order to illustrate the

sensitivity of the \(k\)-means clustering method to the initial choice of seeds we use the following four methods of choosing seeds:
1. Select at random \(g\) observations that are at least a distance \(r\) apart.
2. Select the first \(g\) observations that are at least a distance \(r\) apart.
3. Select the \(g\) observations that are mutually farthest apart.
4. Use the \(g\) centroids from the \(g\)-cluster solution from the average linkage (hierarchical) clustering method.

To help choose \(g\), the number of clusters, we plot the first two principal components in Figure 15.16. It appears that there may be at least five clusters. For the first method, we select five observations at random that are at least a distance \(r=1\) from each other. The five chosen seeds are West Germany, Austria, Ireland, France, and Czechoslovakia. Using these seeds, the \(k\)-means

Figure 15.16 First two principal components \(z_{1}\) and \(z_{2}\) for the protein data in Table 15.7.
method produced the clusters identified in Table 15.8 along with the distance of each observation from its cluster centroid.

To view the clusters, we plot the first two discriminant functions (see Section 8.4.1) in Figure 15.17. The first two discriminant functions show good separation among clusters 3,4 and 5 . However, clusters 1 and 2 appear to overlap with the other clusters.

We now select the first five observations as cluster seeds. With these seeds, the \(k\)-means clustering method produced the clusters in Table 15.9. The first two discriminant functions are plotted in Figure 15.18. Good separation of clusters is seen except for clusters 2 and 3.

We next choose as cluster seeds the five observations that are mutually farthest apart. These seeds gave rise to the clusters in Table 15.10. The first two discriminant functions are plotted in Figure 15.19. Clusters 1, 3, and 4 seem very well separated, but clusters 2 and 5 show considerable overlap.

Finally, we obtain a five-cluster solution from average linkage and use the centroids of these clusters as the new seeds. The clusters in Table 15.11 result. The first two discriminant functions are plotted in Figure 15.20. All five clusters are well separated in the first two discriminant functions. These clusters show some resemblance to those in the principal components plot given in Figure 15.16.

\subsection*{15.4.1b Other Partitioning Criteria}

We now consider three partitioning methods that are not based directly on the distance from a point to the centroid of a cluster. These methods are based on the between-cluster and within-cluster sum of squares and products matrices \(\mathbf{H}\) and \(\mathbf{E}\) defined in (6.9) and (6.10) for one-way MANOVA. For well-defined clusters, we would like \(\mathbf{E}\) to be "small" and \(\mathbf{H}\) to be "large."

The three criteria are as follows:
1. Minimize \(\operatorname{tr}(\mathbf{E})\)
2. Minimize \(|\mathbf{E}|\)
3. Maximize \(\operatorname{tr}\left(\mathbf{E}^{-1} \mathbf{H}\right)\).

Using criterion 1, for example, we would move an item with observation vector \(\mathbf{y}\) to the cluster for which \(\operatorname{tr}(\mathbf{E})\) is minimized after the move.

We can express the first criterion in two alternative forms. By (6.10), we have
\[
\begin{align*}
\operatorname{tr}(\mathbf{E}) & =\operatorname{tr}\left[\sum_{i=1}^{g} \sum_{j=1}^{n}\left(\mathbf{y}_{i j}-\overline{\mathbf{y}}_{i .}\right)\left(\mathbf{y}_{i j}-\overline{\mathbf{y}}_{i .}\right)^{\prime}\right]  \tag{15.28}\\
& =\sum_{i} \operatorname{tr}\left[\sum_{j}\left(\mathbf{y}_{i j}-\overline{\mathbf{y}}_{i .}\right)\left(\mathbf{y}_{i j}-\overline{\mathbf{y}}_{i .}\right)^{\prime}\right] \quad[\text { by }(2.96)] \\
& =\sum_{i} \operatorname{tr}\left(\mathbf{E}_{i}\right) \tag{15.29}
\end{align*}
\]
where \(\mathbf{E}_{i}=\sum_{j=1}^{n}\left(\mathbf{y}_{i j}-\overline{\mathbf{y}}_{i .}\right)\left(\mathbf{y}_{i j}-\overline{\mathbf{y}}_{i .}\right)^{\prime}\) is the sum of squares and products matrix of deviations of observations from the mean vector for the \(i\) th cluster. In (15.28) we are using the notation of Section 6.1.2 for a balanced design, in which \(n\) is the number of observations in each cluster.

We can write \(\operatorname{tr}\left(\mathbf{E}_{i}\right)\) in (15.29) in the form
\[
\begin{align*}
\operatorname{tr}\left(\mathbf{E}_{i}\right) & =\operatorname{tr} \sum_{j}\left(\mathbf{y}_{i j}-\overline{\mathbf{y}}_{i .}\right)\left(\mathbf{y}_{i j}-\overline{\mathbf{y}}_{i .}\right)^{\prime} \\
& =\sum_{j} \operatorname{tr}\left(\mathbf{y}_{i j}-\overline{\mathbf{y}}_{i .}\right)\left(\mathbf{y}_{i j}-\overline{\mathbf{y}}_{i .}\right)^{\prime} \quad[\text { by (2.96)] } \\
& =\sum_{j}\left(\mathbf{y}_{i j}-\overline{\mathbf{y}}_{i .}\right)^{\prime}\left(\mathbf{y}_{i j}-\overline{\mathbf{y}}_{i .}\right) \quad[\text { by (2.97)]. } \tag{15.30}
\end{align*}
\]

Thus \(\operatorname{tr}\left(\mathbf{E}_{i}\right)\) is the sum of the (squared) Euclidean distances from the individual points to the centroid of the \(i\) th cluster.

A second form of (15.28) was given by Seber (1984, p. 277) as
\[
\begin{equation*}
\operatorname{tr}(\mathbf{E})=\frac{1}{n} \sum_{i} \sum_{k<m}\left(\mathbf{y}_{i k}-\mathbf{y}_{i m}\right)^{\prime}\left(\mathbf{y}_{i k}-\mathbf{y}_{i m}\right) \tag{15.31}
\end{equation*}
\]

Hence minimizing \(\operatorname{tr}(\mathbf{E})\) is equivalent to minimizing the sum of squared Euclidean distances between all pairs of points in a cluster.

The second criterion, minimizing \(|\mathbf{E}|\), is related to \(\Lambda=|\mathbf{E}| /|\mathbf{E}+\mathbf{H}|\) in (6.13). Minimizing \(|\mathrm{E}|\) is equivalent to minimizing Wilks' \(\Lambda\).

Another way to look at minimizing \(|\mathbf{E}|\) is to consider the effect of adding a point \(\mathbf{y}\) to a cluster with centroid \(\overline{\mathbf{y}}\). Let \(\mathbf{u}=\mathbf{y}-\overline{\mathbf{y}}\). By (15.28), \(\mathbf{E}\) is a sum of terms of the form \(\mathbf{u u}^{\prime}=(\mathbf{y}-\overline{\mathbf{y}})(\mathbf{y}-\overline{\mathbf{y}})^{\prime}\). Thus (ignoring the change in centroid with the added observation \(y\) ), the increase in \(|\mathbf{E}|\) is
\[
\begin{aligned}
\left|\mathbf{E}+\mathbf{u} \mathbf{u}^{\prime}\right|-|\mathbf{E}| & =|\mathbf{E}|\left(\mathbf{1}+\mathbf{u}^{\prime} \mathbf{E}^{-1} \mathbf{u}\right)-|\mathbf{E}| \quad[\text { by (2.95) }] \\
& =|\mathbf{E}| \mathbf{u}^{\prime} \mathbf{E}^{-1} \mathbf{u}
\end{aligned}
\]

Hence, the minimum increase in \(|\mathbf{E}|\) is obtained by adding \(y\) to the cluster for which the standardized distance \(\mathbf{u}^{\prime} \mathbf{E}^{-1} \mathbf{u}\) of \(\mathbf{y}\) from \(\overline{\mathbf{y}}\) is the smallest. By comparison, the \(\operatorname{tr}(\mathbf{E})\) criterion would add \(\mathbf{y}\) to the cluster for which \(\mathbf{u}^{\prime} \mathbf{u}\) is minimum [see (15.30)].

The third criterion, maximizing \(\operatorname{tr}\left(\mathbf{E}^{-1} \mathbf{H}\right)\), is related to the Lawley-Hotelling statistic \(U^{(s)}=\operatorname{tr}\left(\mathbf{E}^{-1} \mathbf{H}\right)=\sum_{i=1}^{s} \lambda_{i}\) in (6.27), where \(\lambda_{1}, \lambda_{2}, \ldots, \lambda_{s}\) are the eigenvalues of \(\mathbf{E}^{-1} \mathbf{H}\) and \(s=\min (p, g-1)\). Associated with each \(\lambda_{i}\) is the eigenvector \(\mathbf{a}_{i}\) and the discriminant function \(z_{i}=\mathbf{a}_{i}^{\prime} \mathbf{y}\) (see Section 8.4). The largest eigenvalue, \(\lambda_{1}\), and the accompanying first discriminant function, \(z_{1}=\mathbf{a}_{\mathbf{1}}^{\prime} \mathbf{y}\), have the greatest influence on \(\operatorname{tr}\left(\mathbf{E}^{-1} \mathbf{H}\right)\). Maximizing \(\operatorname{tr}\left(\mathbf{E}^{-1} \mathbf{H}\right)\) has the inclination to produce elliptical clusters of the same size. These would tend to follow a straight-line trend, especially if the first eigenvalue dominates the others. If the initial clusters or seeds are lined up in a different direction than the "true clusters," maximizing \(\operatorname{tr}\left(\mathbf{E}^{-1} \mathbf{H}\right)\) may not correct the error in subsequent iterations.

Since \(\operatorname{tr}(\mathbf{E})\) involves only the diagonal elements, the first criterion ignores the correlations and tends to yield spherical clusters. The second criterion, minimizing \(|\mathrm{E}|\), takes correlations into account and tends to produce elliptical clusters. These clusters have a tendency to be of the same shape because \(\mathrm{E} / \nu_{E}\) is a pooled estimator of the covariance matrix. A modification that may be useful is \(\prod_{i=1}^{g}\left|\mathbf{E}_{i}\right|\), where \(\mathbf{E}_{i}\) is the error matrix for the \(i\) th cluster [see (15.29)].

Finally, we compare the three criteria in terms of invariance to nonsingular linear transformations \(\mathbf{v}_{i j}=\mathbf{A} \mathbf{y}_{i j}+\mathbf{b}\), where \(\mathbf{A}\) is a constant nonsingular matrix and \(\mathbf{b}\) is a vector of constants. The first criterion, minimizing \(\operatorname{tr}(\mathbf{E})\), is not invariant to such linear transformations, while the other two criteria are invariant to these transformations. Therefore, minimizing \(\operatorname{tr}(\mathbf{E})\) will likely give different partitions for the raw data and standardized data.

\subsection*{15.4.2 Other Methods}

We discuss mixtures of distributions in Section 15.4.2a and density estimation in Section 15.4.2b.

\subsection*{15.4.2a Mixtures of Distributions}

In this method, we assume the existence of \(g\) distributions (usually multivariate normal ), and we wish to assign each of the \(n\) items in the sample to the distribution
it most likely belongs to. Such an approach is related to classification analysis in Chapter 9. Along with partitioning in Section 15.4.1, this method has the property that points can be transferred from one cluster to another, but it requires more assumptions than partitioning.

We define the density of a mixture of \(g\) distributions as the weighted average
\[
\begin{equation*}
h(\mathbf{y})=\sum_{i=1}^{g} \alpha_{i} f\left(\mathbf{y}, \boldsymbol{\mu}_{i}, \boldsymbol{\Sigma}_{i}\right) \tag{15.32}
\end{equation*}
\]
where \(0 \leq \alpha_{i} \leq 1, \sum_{i=1}^{g} \alpha_{i}=1\), and \(f\left(\mathbf{y}, \boldsymbol{\mu}_{i}, \boldsymbol{\Sigma}_{i}\right)\) is the multivariate normal \(N_{p}\left(\boldsymbol{\mu}_{i}, \boldsymbol{\Sigma}_{i}\right)\) given in (4.2).

Clusters could be formed in two ways. The first approach is to assign an item with observation vector \(\mathbf{y}\) to the cluster \(C_{i}\) with largest value of the estimated posterior probability
\[
\begin{equation*}
\hat{P}\left(C_{i} \mid \mathbf{y}\right)=\frac{\hat{\alpha}_{i} f\left(\mathbf{y}, \hat{\boldsymbol{\mu}}_{i}, \hat{\boldsymbol{\Sigma}}_{i}\right)}{h(\mathbf{y})} \tag{15.33}
\end{equation*}
\]
[see Rencher (1998, Sections 6.2.4 and 6.3.1)], where \(\hat{\alpha}_{i}, \hat{\boldsymbol{\mu}}_{i}\), and \(\hat{\boldsymbol{\Sigma}}_{i}\) are maximum likelihood estimates and \(h(\mathbf{y})\) is given by (15.32) with estimates inserted for parameters. The posterior probability (15.33) is an estimate of the probability that an item with observation vector \(y\) belongs to the \(i\) th cluster, \(C_{i}\).

The second approach is to assign an item with observation vector \(y\) to the cluster with largest value of
\[
\begin{equation*}
\ln \hat{\alpha}_{i}-\frac{1}{2} \ln \left|\hat{\boldsymbol{\Sigma}}_{i}\right|-\frac{1}{2}\left(\mathbf{y}-\hat{\boldsymbol{\mu}}_{i}\right)^{\prime} \hat{\boldsymbol{\Sigma}}_{i}^{-1}\left(\mathbf{y}-\hat{\boldsymbol{\mu}}_{i}\right) \tag{15.34}
\end{equation*}
\]
[see (9.15)]. For either of these approaches [based on (15.33) or (15.34)], we need the estimates \(\hat{\alpha}_{i}, \hat{\boldsymbol{\mu}}_{i}\), and \(\hat{\boldsymbol{\Sigma}}_{i}\). These estimates are obtained by maximizing the likelihood function \(L=\prod_{j=1}^{n} h\left(\mathbf{y}_{j}\right)\), where \(h\left(\mathbf{y}_{j}\right)\) is given by (15.32). The results are
\[
\begin{aligned}
\hat{\alpha}_{i} & =\frac{1}{n} \sum_{j=1}^{n} \hat{P}\left(C_{i} \mid \mathbf{y}_{j}\right), \quad i=1,2, \ldots, g-1 \\
\hat{\boldsymbol{\mu}}_{i} & =\frac{1}{n \hat{\alpha}_{i}} \sum_{j=1}^{n} \mathbf{y}_{j} \hat{P}\left(C_{i} \mid \mathbf{y}_{j}\right), \quad i=1,2, \ldots, g \\
\hat{\boldsymbol{\Sigma}}_{i} & =\frac{1}{n \hat{\alpha}_{i}} \sum_{j=1}^{n}\left(\mathbf{y}_{j}-\hat{\boldsymbol{\mu}}_{i}\right)\left(\mathbf{y}_{j}-\hat{\boldsymbol{\mu}}_{i}\right)^{\prime} \hat{P}\left(C_{i} \mid \mathbf{y}_{j}\right), \quad i=1,2, \ldots, g
\end{aligned}
\]
(Everitt 1993, p. 111), where \(\hat{P}\left(C_{i} \mid \mathbf{y}_{j}\right)\) is given by (15.33). These three equations must be solved iteratively. For a given value of \(g\), we can begin with initial estimates or guesses for the parameters and adjust them by iteration (this approach is related to the EM algorithm mentioned in Section 3.11). If \(g\) is not known, we can begin with \(g=1\), then successively try \(g=2, g=3\), and so on, until the results are satisfactory.

The total number of parameters to be estimated is large. There are \(p\) parameters in each \(\boldsymbol{\mu}_{i}, \frac{1}{2} p(p+1)\) unique parameters in each \(\boldsymbol{\Sigma}_{i}\), and \(g-1\) values of \(\alpha_{i}\) (the
remaining \(\hat{\alpha}_{i}\) is found by \(\sum_{i=1}^{g} \hat{\alpha}_{i}=1\) ), for a total of
\[
\begin{equation*}
\frac{1}{2} g(p+1)(p+2)-1 \tag{15.35}
\end{equation*}
\]
parameters. If the sample size \(n\) is not sufficiently large to estimate all of these parameters, we could assume a common covariance matrix \(\boldsymbol{\Sigma}\), which reduces the number of parameters by \(\frac{1}{2}(g-1) p(p+1)\).

The method of mixtures is invariant to full-rank linear transformations and is somewhat robust to the assumption of normality. The technique works better if the \(g\) densities are well separated or the sample sizes are large.

\section*{- EXAMPLE 15.4.2a}

To illustrate the clustering method based on mixtures of distributions, we use the protein consumption data of Table 15.7. Because of the small number of countries in the data set, there are not enough degrees of freedom to estimate a different covariance matrix for each cluster. Hence we assume equal covariance matrices and estimate a pooled covariance matrix \(\hat{\boldsymbol{\Sigma}}\). For illustration purposes, we choose \(g=5\) as in Example 15.4.1a.

We use the five clusters found by Ward's method to obtain initial estimates of \(\alpha_{i}, \boldsymbol{\mu}_{i}\), and \(\boldsymbol{\Sigma}\). Then the maximum likelihood equations are solved iteratively to find the following estimates.
\[
\begin{gathered}
\hat{\alpha}_{1}=0.2801, \hat{\alpha}_{2}=0.3200, \hat{\alpha}_{3}=0.1199, \hat{\alpha}_{4}=0.1600, \hat{\alpha}_{5}=0.1200 \\

\]
\[
\hat{\boldsymbol{\Sigma}}=\left(\begin{array}{rrrrrrrrr}
4.250 & -2.952 & .021 & -.047 & 1.001 & .929 & -.157 & .287 & .035 \\
-2.952 & 9.41 & .963 & .265 & -1.934 & -4.250 & 1.245 & -2.903 & -.319 \\
.021 & .963 & .471 & .552 & -.296 & -.699 & .301 & -.256 & -.008 \\
-.047 & .265 & .552 & 9.706 & -1.254 & .011 & 1.313 & -.801 & .032 \\
1.001 & -1.934 & -.296 & -1.254 & 3.648 & .167 & .111 & .839 & 1.653 \\
.929 & -4.250 & -.699 & -.011 & .167 & 8.412 & -.777 & 1.708 & .137 \\
-.157 & 1.245 & .301 & 1.313 & .111 & -.777 & 1.634 & -.845 & -.208 \\
.287 & -2.903 & -.256 & -.801 & .839 & 1.708 & -.845 & 2.053 & .503 \\
.035 & -.319 & -.008 & .032 & 1.653 & .137 & -.208 & .503 & 1.808
\end{array}\right)
\]

Then assigning each country to the cluster for which it has the highest posterior probability of membership as in (15.33) yields the following clusters:
\begin{tabular}{lllll}
\hline Cluster 1 & Cluster 2 & Cluster 3 & Cluster 4 & Cluster 5 \\
\hline Albania, Czech., & Austria, & Bulgaria, & Denmark, & E. Germany, \\
Greece, & Belgium, France, & Romania, & Finland & Portugal \\
Hungary, Italy, & Ireland, & Yugoslavia & Norway, & Spain \\
Poland, USSR & Netherlands, & & Sweden & \\
& Switzerland, UK, & & & \\
& W. Germany & & & \\
\hline
\end{tabular}

\subsection*{15.4.2b Density Estimation}

In the method of density estimation or density searching, we seek regions of high density sometimes called modes. No assumption is made about the form of the density, as was done in Section 15.4.2a. We could estimate the density using a kernel function as in Section 9.7.2. Alternatively, we simply attempt to separate regions with a high concentration of points from regions with a low density.

To find regions of high density, we first choose a radius \(r\) and a value of \(k\), the number of points in a \(k\)-nearest neighbor scheme. For each of the \(n\) points in the data, the number of points within a sphere of radius \(r\) is found. A point is called a dense point if at least \(k\) other points are contained in its sphere.

If a dense point is more than a distance \(r\) from all other dense points, it becomes the nucleus of a new cluster. If a dense point is within a distance \(r\) from at least one dense point that belongs to a cluster, it is added to the cluster. If the dense point is within a distance \(r\) of two or more clusters, these clusters are combined. Two clusters are also combined if the smallest distance between their dense points is less than the average of the \(2 k\) smallest distances between the original \(n\) points. The value of \(r\) can be gradually increased so that more points become dense. Another option is to begin with the specified value of \(r\) for each point and then gradually increase \(r\) until \(k\) observations are contained in its sphere.

\section*{EXAMPLE 15.4.2b}

To illustrate the density estimation method, we use the protein data. For each pair of values of \(k\) and \(r\), the value of \(r\) was allowed to increase if needed, as described above. For the following values of \(k\) and \(r\), the number of clusters obtained are given.

Figure 15.21 First two discriminant functions for the clusters found in Example 15.4.2b.
\begin{tabular}{cccccccccccccc}
\hline\(k / r\) & 1.6 & 1.7 & 1.8 & 1.9 & 2.0 & 2.1 & 2.2 & 2.3 & 2.4 & 2.5 & 2.6 & 2.7 & 2.8 \\
\hline 2 & 5 & 5 & 5 & 4 & 4 & 4 & 4 & 4 & 3 & 3 & 3 & 3 & 3 \\
3 & 3 & 3 & 3 & 3 & 3 & 3 & 3 & 3 & 2 & 2 & 2 & 2 & 2 \\
4 & 3 & 3 & 3 & 3 & 3 & 3 & 3 & 3 & 2 & 2 & 2 & 2 & 2 \\
\hline
\end{tabular}

The five-cluster solution found by setting \(r=1.8\) and \(k=2\) is
\begin{tabular}{lllll}
\hline Cluster 1 & Cluster 2 & Cluster 3 & Cluster 4 & Cluster 5 \\
\hline Austria, Belgium & Denmark & Albania, & Czech., & Greece, \\
France, Ireland, & Finland, & Bulgaria, & E. Germany, & Italy, \\
Netherlands, & Norway, & Hungary, & Poland, & Portugal, \\
Switzerland, & Sweden & Romania, & USSR & Spain \\
UK, W. Germany & & Yugoslavia & & \\
\hline
\end{tabular}

This partitioning into five clusters is perhaps more reasonable than any of those found in Example 15.4.2a. The first two discriminant functions for these five clusters are plotted in Figure 15.21.

\subsection*{15.5 CHOOSING THE NUMBER OF CLUSTERS}

In hierarchical clustering, we can select \(g\) clusters from the dendrogram by cutting across the branches at a given level of the distance measure used by one of the axes.

Figure 15.22 Cutting the dendrogram to choose the number of clusters.

This is illustrated in Figure 15.22, which is the dendrogram for the average linkage method (Section 15.3.4) applied to the city crime data in Table 15.1. Cutting the dendrogram at a level of 700 yields two clusters. Cutting it at 535 gives three clusters.

We wish to determine the value of \(g\) that provides the best fit to the data. One approach is to look for large changes in distances at which clusters are formed. For example, in Figure 15.22, the largest change in levels occurs in going from two clusters to a single cluster. The change in distance between the two-cluster solution and the three-cluster solution is 82 units-squared. The difference between the three-
cluster solution and the four-cluster solution is 73 units-squared, and the change between the four- and five-cluster solutions is only 26 units-squared. In this case we would choose two clusters.

A formalization of this procedure was proposed by Mojena (1977): Choose the number of groups given by the first stage in the dendrogram at which
\[
\begin{equation*}
\alpha_{j}>\bar{\alpha}+k s_{\alpha}, \quad j=1,2, \ldots, n \tag{15.36}
\end{equation*}
\]
where \(\alpha_{1}, \alpha_{2}, \ldots, \alpha_{n}\) are the distance values for stages with \(n, n-1, \ldots, 1\) clusters, \(\bar{\alpha}\) and \(s_{\alpha}\) are the mean and standard deviation of the \(\alpha\) 's, and \(k\) is a constant. Mojena (1977) suggested using a value of \(k\) in the range 2.75 to 3.5 , but Milligan and Cooper (1985) recommended \(k=1.25\), based on a simulation study.

An index that can be used with either hierarchical or partitioning methods is
\[
\begin{equation*}
c=\frac{\operatorname{tr}(\mathbf{H}) /(g-1)}{\operatorname{tr}(\mathbf{E}) /(n-g)} . \tag{15.37}
\end{equation*}
\]

The value of \(g\) that maximizes \(c\) is chosen. A related approach is to choose the value of \(g\) that minimizes
\[
\begin{equation*}
d=g^{2}|\mathbf{E}| \tag{15.38}
\end{equation*}
\]

To compare two cluster solutions with \(g_{1}\) and \(g_{2}\) clusters where \(g_{2}>g_{1}\), we can use the test statistic
\[
\begin{equation*}
F=\frac{\operatorname{tr}\left(\mathbf{E}_{1}\right)-\operatorname{tr}\left(\mathbf{E}_{2}\right)}{\operatorname{tr}\left(\mathbf{E}_{2}\right)\left[\left(\frac{n-g_{1}}{n-g_{2}}\right)\left(\frac{g_{2}}{g_{1}}\right)^{2 / p}-1\right]}, \tag{15.39}
\end{equation*}
\]
which has an approximate \(F\)-distribution with \(p\left(g_{2}-g_{1}\right)\) and \(p\left(n-g_{2}\right)\) degrees of freedom [Beale (1969)]. The matrices \(\mathbf{E}_{1}\) and \(\mathbf{E}_{2}\) are within-cluster sums of squares and products matrices corresponding to \(g_{1}\) and \(g_{2}\). The hypothesis is that the cluster solutions with \(g_{1}\) and \(g_{2}\) clusters are equally valid, and rejection implies that the cluster solution with \(g_{2}\) clusters is better than the solution with \(g_{1}\) clusters \(\left(g_{2}>g_{1}\right)\). The \(F\)-approximation in (15.39) may not be sufficiently accurate to justify the use of \(p\)-values.

\subsection*{15.6 CLUSTER VALIDITY}

To check the validity of a cluster solution, it may be possible to test the hypothesis that there are no clusters or groups in the population from which the sample at hand was taken. For example, the hypothesis could be that the population represents a single unimodal distribution such as the multivariate normal, or that the observations arose from a uniform distribution. Formal tests of hypotheses of this type concerning cluster validity are reviewed by Gordon (1999, Section 7.2).

A cross-validation approach can also be used to check the validity or stability of a clustering result. The data are randomly divided into two subsets, say \(A\) and \(B\), and
the cluster analysis is carried out separately on each of \(A\) and \(B\). The results should be similar if the clusters are valid. An alternative approach is the following (Gordon 1999, Section 7.1; Milligan 1996):
1. Use some clustering method to partition subset \(A\) into \(g\) clusters.
2. Partition subset \(B\) into \(g\) clusters in two ways:
(a) Assign each item in \(B\) to the cluster in \(A\) that it is closest to by using, for example, the distance to cluster centroids.
(b) Use the same clustering method on \(B\) that was used on \(A\).
3. Compare the results of (a) and (b) in step 2.

\subsection*{15.7 CLUSTERING VARIABLES}

In some cases, it may be of interest to cluster the \(p\) variables rather than the \(n\) observations. For a similarity measure between each pair of variables, we would usually use the correlation. Since most clustering methods use dissimilarities (such as distances), we need to convert the correlation matrix \(\mathbf{R}=\left(r_{i j}\right)\) to a dissimilarity matrix. This can conveniently be done by replacing each \(r_{i j}\) by \(1-\left|r_{i j}\right|\) or \(1-r_{i j}^{2}\). Using the resulting dissimilarity matrix, we can apply a clustering method such as a hierarchical technique to cluster the variables.

Clustering of variables can sometimes be done successfully with factor analysis, which groups the variables corresponding to each factor, see Sections 13.1 and 13.5 .

\section*{E EXAMPLE 15.7}

We illustrate clustering of variables using the city crime data in Table 15.1. We first calculate the correlation matrix \(\mathbf{R}=\left(r_{i j}\right)\) and then transform \(\mathbf{R}\) to a dissimilarity matrix \(\mathbf{D}=\left(1-r_{i j}^{2}\right)\). The variables are then clustered using both average linkage and Ward's clustering methods, and the dendrograms are given in Figures 15.23 and 15.24, respectively. Both clustering methods yield the same solution.

We next carry out a factor analysis of the data and compare the resulting groups of variables with the clusters obtained with the average linkage and Ward's methods. The factor loadings are estimated using the principal factor method (Section 13.3.2) with squared multiple correlations as initial communality estimates, and the loadings are then rotated with a varimax rotation (Section 13.5.2b). The rotated factor pattern is given in Table 15.12. The highest loading in each row is bolded. The first factor deals with crimes associated with the home. The second factor involves crimes that are violent in nature. The third factor consists of crimes of theft outside the home. Note that the three-cluster solutions found by both average linkage and Ward's methods are identical to the grouping of variables in the factor analysis solution, which is

Figure 15.23 Dendrogram for clustering the variables of Table 15.1 using average linkage (see Example 15.7).
(1) murder, rape, and assault, (2) robbery and auto theft, and (3) burglary and larceny. Since all three methods agree, we have some confidence in the validity of the solution.

\section*{PROBLEMS}
15.1 Show that \(d^{2}(\mathbf{x}, \mathbf{y})=\sum_{j=1}^{p}\left(x_{j}-y_{j}\right)^{2}\) from (15.2) is equal to (15.5), \(d^{2}(\mathbf{x}, \mathbf{y})=\) \(\left(v_{x}-v_{y}\right)^{2}+p(\bar{x}-\bar{y})^{2}+2 v_{x} v_{y}\left(1-r_{x y}\right)\), where \(v_{x}^{2}=\sum_{j=1}^{p}\left(x_{j}-\bar{x}\right)^{2}, \bar{x}=\) \(\sum_{j=1}^{p} x_{j} / p\), and \(r_{y x}\) is defined in (15.6).

Figure 15.24 Dendrogram for clustering the variables of Table 15.1 using Ward's method (see Example 15.7).
15.2 (a) Show that \(I_{A B}=n_{A}\left(\overline{\mathbf{y}}_{A}-\overline{\mathbf{y}}_{A B}\right)^{\prime}\left(\overline{\mathbf{y}}_{A}-\overline{\mathbf{y}}_{A B}\right)+n_{B}\left(\overline{\mathbf{y}}_{B}-\overline{\mathbf{y}}_{A B}\right)^{\prime}\left(\overline{\mathbf{y}}_{B}-\right.\) \(\overline{\mathbf{y}}_{A B}\) ) as in (15.18).
(b) Show that (15.18) is equal to (15.19); that is,
\[
\begin{gathered}
n_{A}\left(\overline{\mathbf{y}}_{A}-\overline{\mathbf{y}}_{A B}\right)^{\prime}\left(\overline{\mathbf{y}}_{A}-\overline{\mathbf{y}}_{A B}\right)+n_{B}\left(\overline{\mathbf{y}}_{B}-\overline{\mathbf{y}}_{A B}\right)^{\prime}\left(\overline{\mathbf{y}}_{B}-\overline{\mathbf{y}}_{A B}\right) \\
=\frac{n_{A} n_{B}}{n_{A}+n_{B}}\left(\overline{\mathbf{y}}_{A}-\overline{\mathbf{y}}_{B}\right)^{\prime}\left(\overline{\mathbf{y}}_{A}-\overline{\mathbf{y}}_{B}\right) .
\end{gathered}
\]
15.3 Using the hints provided below, show that the parameter values for (15.20) in Table 15.2 produce appropriate distances for the following cluster methods.

Table 15.12 Rotated Factor Loadings for City Crime Data
\begin{tabular}{lccc}
\hline Variables & Factor \(\mathbf{1}\) & Factor 2 & Factor 3 \\
\hline Murder & -.063 & \(\mathbf{. 7 3 4}\) & .142 \\
Rape & \(\mathbf{5 0 4}\) & \(\mathbf{. 6 5 9}\) & .160 \\
Robbery & .133 & .355 & \(\mathbf{. 7 2 6}\) \\
Burglary & \(\mathbf{7 6 4}\) & .221 & .181 \\
Larceny & \(\mathbf{. 8 4 7}\) & -.014 & .244 \\
Auto theft & .240 & .097 & \(\mathbf{. 5 8 4}\) \\
\hline
\end{tabular}
(a) Complete linkage. Use an approach analogous to that in Section 15.3.8 for the single linkage method.
(b) Average linkage. Write (15.20) in terms of parameter values for average linkage in Table 15.2. Then use (15.9).
(c) Centroid method. Show that
\[
\begin{align*}
\left(\overline{\mathbf{y}}_{C}-\overline{\mathbf{y}}_{A B}\right)^{\prime}\left(\overline{\mathbf{y}}_{C}-\overline{\mathbf{y}}_{A B}\right) & =\frac{n_{A}}{n_{A}+n_{B}}\left(\overline{\mathbf{y}}_{C}-\overline{\mathbf{y}}_{A}\right)^{\prime}\left(\overline{\mathbf{y}}_{C}-\overline{\mathbf{y}}_{A}\right) \\
& +\frac{n_{B}}{n_{A}+n_{B}}\left(\overline{\mathbf{y}}_{C}-\overline{\mathbf{y}}_{B}\right)^{\prime}\left(\overline{\mathbf{y}}_{C}-\overline{\mathbf{y}}_{B}\right) \\
& -\frac{n_{A} n_{B}}{\left(n_{A}+n_{B}\right)^{2}}\left(\overline{\mathbf{y}}_{A}-\overline{\mathbf{y}}_{B}\right)^{\prime}\left(\overline{\mathbf{y}}_{A}-\overline{\mathbf{y}}_{B}\right) \tag{15.40}
\end{align*}
\]
where \(\overline{\mathbf{y}}_{A B}=\left(n_{A} \overline{\mathbf{y}}_{A}+n_{B} \overline{\mathbf{y}}_{B}\right) /\left(n_{A}+n_{B}\right)\).
(d) Median method. Use \(n_{A}=n_{B}\) in (15.12) and (15.40) [see part (c)].
(e) Ward's method. Show that
\[
\begin{aligned}
I_{C(A B)}= & \frac{n_{A}+n_{C}}{n_{A}+n_{B}+n_{C}} I_{A C}+\frac{n_{B}+n_{C}}{n_{A}+n_{B}+n_{C}} I_{B C} \\
& -\frac{n_{C}}{n_{A}+n_{B}+n_{C}} I_{A B},
\end{aligned}
\]
where \(I_{A B}\) is defined in (15.17).
15.4 Show that for all methods in Table 15.2 for which \(\gamma=0\), we have \(D(C, A B)>\) \(\left(\alpha_{A}+\alpha_{B}+\beta\right) D(A, B)\) as in (15.26).
15.5 Verify the statement in the last paragraph of Section 15.4.1b, namely, that the first criterion in Section 15.4.1b is not invariant to nonsingular linear transformations \(\mathbf{v}_{i j}=\mathbf{A} \mathbf{y}_{i j}+\mathbf{b}\), where \(\mathbf{A}\) is a \(p \times p\) nonsingular matrix, and that the other two criteria are invariant to such transformations. Use the following approach:
(a) Show that \(\mathbf{H}_{v}=\mathbf{A} \mathbf{H}_{y} \mathbf{A}^{\prime}\) and \(\mathbf{E}_{v}=\mathbf{A E} \mathbf{E}_{y} \mathbf{A}^{\prime}\).
(b) Show that minimizing \(\operatorname{tr}(\mathbf{E})\) is not invariant.
(c) Show that minimizing \(|\mathbf{E}|\) is invariant.
(d) Show that maximizing \(\operatorname{tr}\left(\mathbf{E}^{-1} \mathbf{H}\right)\) is invariant.
15.6 Verify the statement in Section 15.4.2a that in \(\boldsymbol{\mu}_{i}, i=1,2, \ldots, g ; \boldsymbol{\Sigma}_{i}, i=\) \(1,2, \ldots, g\); and \(\alpha_{i}, i=1,2, \ldots, g-1\); the total number of parameters is given by \(\frac{1}{2} g(p+1)(p+2)-1\) as in (15.35).
15.7 Use the ramus bone date of Table 3.7. Carry out the following cluster methods and compare to the principal component plot in Figure 12.5.
(a) Find a two-cluster solution using the single linkage method.
(b) Find a two-cluster solution using the average linkage method and compare to the result in (a). Which seems better?
(c) Carry out a cluster analysis using the Ward's, complete linkage, centroid, and median methods.
(d) Use the flexible beta method with \(\beta=-0.25, \beta=-0.5\), and \(\beta=\) -0.75 .
15.8 Use the hematology data of Table 4.2.
(a) Carry out a cluster analysis using the centroid method and find the distance between the centroids of the two-cluster solution.
(b) Carry out a cluster analysis using the average linkage method. How many clusters are indicated in the dendrogram?
(c) Using the two-cluster solution from part (b), label observations from one cluster as group 1 and the observations from the other cluster as group 2. Calculate and plot the discriminant function, as in Example 8.2. Do the two clusters overlap?
15.9 Use all of the variables of the Seishu data of Table 7.1.
(a) Find the three-cluster solution using the single linkage, complete linkage, average linkage, centroid, median, and Ward's methods. Which observation appears to be an outlier? Which cluster is the same in all six solutions?
(b) Using the cluster found in part (a) to be common to all solutions as group 1 and the rest of the observations as group 2, calculate and plot the discriminant function, as in Problem 15.8(c). Do the two clusters overlap?
15.10 Use the first 20 observations of the temperature data of Table 7.2. Standardize the variables (columns) before doing the following:
(a) Carry out a \(k\)-means cluster analysis using as initial seeds the five observations that are mutually farthest apart. Plot the first two discriminant functions using the five clusters as groups.
(b) Repeat part (a) using the first five observations as initial seeds.
(c) Repeat part (a) using as initial seeds the centroids of the five-cluster solution found using Ward's method. Plot the dendrogram resulting from Ward's method.
(d) Repeat part (c) using average linkage instead of Ward's method. Compare the results with those in part (c).
(e) Plot the first and second principal components and the second and third components. Which cluster solutions found in parts (a)-(d) seem to agree most with the principal component plots?
(f) Repeat parts (a) and (b) using three initial seeds instead of five. How do the cluster solutions compare?
(g) Repeat part (c) using three initial seeds instead of five. How does the cluster solution compare to your answer in (f)?
15.11 Table 15.13 contains air pollution data from 41 US cities (Sokal and Rohlf 1981, p. 619). The variables are as follows:
\(y_{1}=\mathrm{SO}_{2}\) content of air in micrograms per cubic meter
\(y_{2}=\) Average annual temperature in \({ }^{\circ} \mathrm{F}\)
\(y_{3}=\) Number of manufacturing enterprises employing 20 or more workers
\(y_{4}=\) Population size ( 1970 census) in thousands
\(y_{5}=\) Average annual wind speed in miles per hour
\(y_{6}=\) Average annual precipitation in inches
\(y_{7}=\) Average number of days with precipitation per year
Standardize each variable to mean 0 and standard deviation 1. Carry out a cluster analysis using the density estimation method with \(k\) equal to \(2,3,4,5\), and values of \(r\) ranging from 0.2 to 2 by increments of 0.2 for each value of \(k\). What is the maximum value of \(k\) that produces a two-cluster solution?
15.12 Table 15.14 gives the yields of winter wheat in each of the years 1970-1973 at twelve different sites in England (Hand et al. 1994, p. 31).
(a) Carry out a cluster analysis using the density estimation method with \(k=2,3,4\), and \(r=.2, .4, \ldots, 2.0\).
(b) Plot the first two discriminant functions from the three-cluster solution obtained with \(k=2\) and \(r=1\).
(c) Plot the first two principal components and compare with the plot in part (b).
(d) Repeat part (b) using a two-cluster solution obtained with \(k=3\) and \(r=1\). Which two clusters of the three-cluster solution found in part (b) merged into one cluster?

Table 15.13 Air Pollution Levels in US Cities
\begin{tabular}{|c|c|c|c|c|c|c|c|}
\hline Cities & \(y_{1}\) & \(y_{2}\) & \(y_{3}\) & \(y_{4}\) & \(y_{5}\) & \(y_{6}\) & \(y_{7}\) \\
\hline Phoenix & 10 & 70.3 & 213 & 582 & 6.0 & 7.05 & 36 \\
\hline Little Rock & 13 & 61.0 & 91 & 132 & 8.2 & 48.52 & 100 \\

\section*{CHAPTER 16}

\section*{GRAPHICAL PROCEDURES}

In Sections 16.1, 16.2, and 16.3, we consider three graphical techniques: multidimensional scaling, correspondence analysis, and biplots. These methods are designed to reduce dimensionality and portray relationships among observations or variables.

\subsection*{16.1 MULTIDIMENSIONAL SCALING}

\subsection*{16.1.1 Introduction}

In the dimension reduction technique called multidimensional scaling, we begin with the distances \(\delta_{i j}\) between each pair of items. We wish to represent the \(n\) items in a low-dimensional coordinate system, in which the distances \(d_{i j}\) between items closely match the original distances \(\delta_{i j}\), that is,
\[
d_{i j} \cong \delta_{i j} \text { for all } i, j
\]

The final distances \(d_{i j}\) are usually Euclidean. The original distances \(\delta_{i j}\) may be actual measured distances between observations \(\mathbf{y}_{i}\) and \(\mathbf{y}_{j}\) in \(p\) dimensions, such as
\[
\begin{equation*}
\delta_{i j}=\left[\left(\mathbf{y}_{i}-\mathbf{y}_{j}\right)^{\prime}\left(\mathbf{y}_{i}-\mathbf{y}_{j}\right)\right]^{1 / 2} \tag{16.1}
\end{equation*}
\]

On the other hand, the distances \(\delta_{i j}\) may be only a proximity or similarity based on human judgment, for example, the perceived degree of similarity between all pairs of brands of a certain type of appliance (for a discussion of similarities and dissimilarities, see Section 15.2). The goal of multidimensional scaling is a plot that exhibits information about how the items relate to each other or provides some other meaningful interpretation of the data. For example, the aim may be seriation or ranking; if the points lie close to a curve in two dimensions, then the ordering of points along the curve is used to rank the points.

If the observation vectors \(\mathbf{y}_{i}, i=1,2, \ldots, n\), are available and we calculate distances using (16.1) or a similar measure, or if the original \(y_{i}\) 's are not available but we have actual distances between items, then the process of reduction to a lowerdimensional geometric representation is called metric multidimensional scaling. If the original distances are only similarities based on judgment, the process is called nonmetric multidimensional scaling, and the final spatial representation preserves only the rank order among the similarities. We consider metric scaling in Section 16.1.2 and nonmetric scaling in Section 16.1.3. For useful discussions of various aspects of multidimensional scaling, see Davidson (1983); Gordon (1999, Sections 6.2 and 6.3); Kruskal and Wish (1978); Mardia, Kent, and Bibby (1979, Chapter 14); Seber (1984, Section 5.5); Young (1987); Jobson (1992, Section 10.3); Shepard, Romney, and Nerlove (1972); and Romney, Shepard, and Nerlove (1972).

\subsection*{16.1.2 Metric Multidimensional Scaling}

In this section, we consider metric multidimensional scaling, which is also known as the classical solution and as principal coordinate analysis. We begin with an \(n \times n\) distance matrix \(\mathbf{D}=\left(\delta_{i j}\right)\). Our goal is to find \(n\) points in \(k\) dimensions such that the interpoint distances \(d_{i j}\) in the \(k\) dimensions are approximately equal to the values of \(\delta_{i j}\) in \(\mathbf{D}\). Typically, we use \(k=2\) for plotting purposes, but \(k=1\) or 3 may also be useful.

The points are found as follows:
1. Construct the \(n \times n\) matrix \(\mathbf{A}=\left(a_{i j}\right)=\left(-\frac{1}{2} \delta_{i j}^{2}\right)\), where \(\delta_{i j}\) is the \(i j\) th element of \(\mathbf{D}\).
2. Construct the \(n \times n\) matrix \(\mathbf{B}=\left(b_{i j}\right)\), with elements \(b_{i j}=a_{i j}-\bar{a}_{i .}-\bar{a}_{. j}+\bar{a} .\). , where \(\bar{a}_{i .}=\sum_{j=1}^{n} a_{i j} / n, \bar{a}_{. j}=\sum_{i=1}^{n} a_{i j} / n, \bar{a} . .=\sum_{i j} a_{i j} / n^{2}\). The matrix \(\mathbf{B}\) can be written as
\[
\begin{equation*}
\mathbf{B}=\left(\mathbf{I}-\frac{1}{n} \mathbf{J}\right) \mathbf{A}\left(\mathbf{I}-\frac{1}{n} \mathbf{J}\right) \tag{16.2}
\end{equation*}
\]

It can be shown that there exists a \(q\)-dimensional configuration \(\mathbf{z}_{1}, \mathbf{z}_{2}, \ldots, \mathbf{z}_{n}\) with interpoint distances \(d_{i j}=\left(\mathbf{z}_{i}-\mathbf{z}_{j}\right)^{\prime}\left(\mathbf{z}_{i}-\mathbf{z}_{j}\right)\) such that \(d_{i j}=\delta_{i j}\) if
and only if \(\mathbf{B}\) is positive semidefinite of rank \(q\) (Schoenberg 1935; Young and Householder 1938; Gower 1966; Seber 1984, p. 236).
3. Since \(\mathbf{B}\) is a symmetric matrix, we can use the spectral decomposition in (2.109) to write \(\mathbf{B}\) in the form
\[
\begin{equation*}
\mathbf{B}=\mathbf{V} \boldsymbol{\Lambda} \mathbf{V}^{\prime}, \tag{16.3}
\end{equation*}
\]
where \(\mathbf{V}\) is the matrix of eigenvectors of \(\mathbf{B}\) and \(\boldsymbol{\Lambda}\) is the diagonal matrix of eigenvalues of \(\mathbf{B}\). If \(\mathbf{B}\) is positive semidefinite of rank \(q\), there are \(q\) positive eigenvalues, and the remaining \(n-q\) eigenvalues are zero. If \(\boldsymbol{\Lambda}_{1}=\) \(\operatorname{diag}\left(\lambda_{1}, \lambda_{2}, \ldots, \lambda_{q}\right)\) contains the positive eigenvalues and \(\mathbf{V}_{1}=\left(\mathbf{v}_{1}, \mathbf{v}_{2}, \ldots\right.\), \(\mathbf{v}_{q}\) ) contains the corresponding eigenvectors, then we can express (16.3) in the form
\[
\begin{aligned}
\mathbf{B} & =\mathbf{V}_{\mathbf{1}} \mathbf{\Lambda}_{\mathbf{1}} \mathbf{V}_{1}^{\prime} \\
& =\mathbf{V}_{\mathbf{1}} \mathbf{\Lambda}_{1}^{1 / 2} \boldsymbol{\Lambda}_{1}^{1 / 2} \mathbf{V}_{\mathbf{1}}^{\prime} \\
& =\mathbf{Z} \mathbf{Z}^{\prime},
\end{aligned}
\]
where
\[
\mathbf{Z}=\mathbf{V}_{1} \mathbf{\Lambda}_{1}^{1 / 2}=\left(\sqrt{\lambda_{1}} \mathbf{v}_{1}, \sqrt{\lambda_{2}} \mathbf{v}_{2}, \ldots, \sqrt{\lambda_{q}} \mathbf{v}_{q}\right)=\left(\begin{array}{c}
\mathbf{z}_{1}^{\prime}  \tag{16.4}\\
\mathbf{z}_{2}^{\prime} \\
\vdots \\
\mathbf{z}_{n}^{\prime}
\end{array}\right) .
\]
4. The rows \(\mathbf{z}_{1}^{\prime}, \mathbf{z}_{2}^{\prime}, \ldots, \mathbf{z}_{n}^{\prime}\) of \(\mathbf{Z}\) in (16.4) are the points whose interpoint distances \(d_{i j}=\left(\mathbf{z}_{i}-\mathbf{z}_{j}\right)^{\prime}\left(\mathbf{z}_{i}-\mathbf{z}_{j}\right)\) match the \(\delta_{i j}\) 's in the original distance matrix \(\mathbf{D}\), as noted following (16.2).
5. Since \(q\) in (16.4) will typically be too large to be of practical interest and we would prefer a smaller dimension \(k\) for plotting, we can use the first \(k\) eigenvalues and corresponding eigenvectors in (16.4) to obtain \(n\) points whose interpoint distances \(d_{i j}\) are approximately equal to the corresponding \(\delta_{i j}\) 's.
6. If \(\mathbf{B}\) is not positive semidefinite, but its first \(k\) eigenvalues are positive and relatively large, then these eigenvalues and associated eigenvectors may be used in (16.4) to construct points that give reasonably good approximations to the \(\delta_{i j}\) 's.
Note that the method used to obtain \(\mathbf{Z}\) from \(\mathbf{B}\) closely resembles principal component analysis. Note also that the solution \(\mathbf{Z}\) in (16.4) is not unique, since a shift in origin or a rotation will not change the distances \(d_{i j}\). For example, if \(\mathbf{C}\) is a \(q \times q\) orthogonal matrix producing a rotation [see (2.101)], then
\[
\begin{aligned}
\left(\mathbf{C} \mathbf{z}_{i}-\mathbf{C} \mathbf{z}_{j}\right)^{\prime}\left(\mathbf{C} \mathbf{z}_{i}-\mathbf{C} \mathbf{z}_{j}\right) & =\left(\mathbf{z}_{i}-\mathbf{z}_{j}\right)^{\prime} \mathbf{C}^{\prime} \mathbf{C}\left(\mathbf{z}_{i}-\mathbf{z}_{j}\right) \\
& =\left(\mathbf{z}_{i}-\mathbf{z}_{j}\right)^{\prime}\left(\mathbf{z}_{i}-\mathbf{z}_{j}\right) \quad[\text { see }(2.103)]
\end{aligned}
\]

Thus the rotated points \(\mathbf{C} z_{i}\) have the same interpoint distances \(d_{i j}\).

\section*{EXAMPLE 16.1.2(a)}

To illustrate the first four steps of the above algorithm for metric multidimensional scaling, consider the \(5 \times 5\) distance matrix
\[
\mathbf{D}=\left(\delta_{i j}\right)=\left(\begin{array}{ccccc}
0 & 2 \sqrt{2} & 2 \sqrt{2} & 2 \sqrt{2} & 2 \sqrt{2} \\
2 \sqrt{2} & 0 & 4 & 4 \sqrt{2} & 4 \\
2 \sqrt{2} & 4 & 0 & 4 & 4 \sqrt{2} \\
2 \sqrt{2} & 4 \sqrt{2} & 4 & 0 & 4 \\
2 \sqrt{2} & 4 & 4 \sqrt{2} & 4 & 0
\end{array}\right)
\]

The matrix \(\mathbf{A}=\left(-\frac{1}{2} \delta_{i j}^{2}\right)\) in step 1 is given by
\[
\mathbf{A}=-\left(\begin{array}{ccccc}
0 & 4 & 4 & 4 & 4 \\
4 & 0 & 8 & 16 & 8 \\
4 & 8 & 0 & 8 & 16 \\
4 & 16 & 8 & 0 & 8 \\
4 & 8 & 16 & 8 & 0
\end{array}\right)
\]

For the means, we have \(\bar{a}_{1 .}=\bar{a}_{.1}=-16 / 5, \bar{a}_{i .}=\bar{a}_{. i}=-36 / 5, i=\) \(2, \ldots, 5, \bar{a}_{\text {.. }}=-32 / 5\). With \(n=5\), the matrix \(\mathbf{B}\) in step 2 is given by
\[
\mathbf{B}=\left(\mathbf{I}-\frac{1}{5} \mathbf{J}\right) \mathbf{A}\left(\mathbf{I}-\frac{\mathbf{1}}{5} \mathbf{J}\right)=\left(\begin{array}{rrrrr}
0 & 0 & 0 & 0 & 0 \\
0 & 8 & 0 & -8 & 0 \\
0 & 0 & 8 & 0 & -8 \\
0 & -8 & 0 & 8 & 0 \\
0 & 0 & -8 & 0 & 8
\end{array}\right)
\]

The rank of \(\mathbf{B}\) is clearly 2 . For step 3, the (nonzero) eigenvalues and corresponding eigenvectors of \(\mathbf{B}\) are given by \(\lambda_{1}=16, \lambda_{2}=16\),
\[
\mathbf{v}_{1}=\left(\begin{array}{r}
0 \\
\frac{1}{2} \sqrt{2} \\
0 \\
-\frac{1}{2} \sqrt{2} \\
0
\end{array}\right), \quad \mathbf{v}_{2}=\left(\begin{array}{r}
0 \\
0 \\
\frac{1}{2} \sqrt{2} \\
0 \\
-\frac{1}{2} \sqrt{2}
\end{array}\right)
\]

Then for step 3 we have by (16.4)
\[
\mathbf{Z}=\left(\sqrt{\lambda_{1}} \mathbf{v}_{1}, \sqrt{\lambda_{2}} \mathbf{v}_{2}\right)=\left(\begin{array}{rr}
0 & 0 \\
2 \sqrt{2} & 0 \\
0 & 2 \sqrt{2} \\
-2 \sqrt{2} & 0 \\
0 & -2 \sqrt{2}
\end{array}\right)
\]

It can be shown (step 4) that the distance matrix for these five points is \(\mathbf{D}\). The five points constitute a square with each side of length 4 and a center point at the origin. The five points (rows of \(\mathbf{Z}\) ) are plotted in Figure 16.1.

Dimension 1
Figure 16.1 Plot of the five points found in Example 16.1.2(a).

\section*{- EXAMPLE 16.1.2(b)}

For another example of metric multidemensional scaling, we use airline distances between 10 US cities, as given in Table 16.1 (Kruskal and Wish 1978, pp. 7-9).

Table 16.1 Airline Distances Between Ten US Cities
\begin{tabular}{ccccccccccc}
\hline City & 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 \\
\hline 1 & 0 & 587 & 1212 & 701 & 1936 & 604 & 748 & 2139 & 2182 & 543 \\
2 & 587 & 0 & 920 & 940 & 1745 & 1188 & 713 & 1858 & 1737 & 597 \\
3 & 1212 & 920 & 0 & 879 & 831 & 1726 & 1631 & 949 & 1021 & 1494 \\
4 & 701 & 940 & 879 & 0 & 1374 & 968 & 1420 & 1645 & 1891 & 1220 \\
5 & 1936 & 1745 & 831 & 1374 & 0 & 2339 & 2451 & 347 & 959 & 2300 \\
6 & 604 & 1188 & 1726 & 968 & 2339 & 0 & 1092 & 2594 & 2734 & 923 \\
7 & 748 & 713 & 1631 & 1420 & 2451 & 1092 & 0 & 2571 & 2408 & 205 \\
8 & 2139 & 1858 & 949 & 1645 & 347 & 2594 & 2571 & 0 & 678 & 2442 \\
9 & 2182 & 1737 & 1021 & 1891 & 959 & 2734 & 2408 & 678 & 0 & 2329 \\
10 & 543 & 597 & 1494 & 1220 & 2300 & 923 & 205 & 2442 & 2329 & 0 \\
\hline
\end{tabular}

Cities: (1) Atlanta, (2) Chicago, (3) Denver, (4) Houston, (5) Los Angeles, (6) Miami, (7) New York,
(8) San Francisco, (9) Seattle, (10) Washington, DC.

Figure 16.2 Plot of the points found in Example 16.1.2(b).

The points given by metric multidimensional scaling are plotted in Figure 16.2. Note that in the plot, dimensions 1 and 2 roughly correspond to easting and northing, but the sign for each of these dimensions is arbitrary. That is, the eigenvectors \(\mathbf{v}_{i}\) in (16.4) are normalized but are subject to multiplication by -1 .

\subsection*{16.1.3 Nonmetric Multidimensional Scaling}

Suppose the \(m=n(n-1) / 2\) dissimilarities \(\delta_{i j}\) cannot be measured as in (16.1) but can be ranked in order,
\[
\begin{equation*}
\delta_{r_{1} s_{1}}<\delta_{r_{2} s_{2}}<\cdots<\delta_{r_{m} s_{m}} \tag{16.5}
\end{equation*}
\]
where \(r_{1} s_{1}\) indicates the pair of items with the smallest dissimilarity and \(r_{m} s_{m}\) represents the pair with greatest dissimilarity. In nonmetric multidimensional scaling, we seek a low-dimensional representation of the points such that the rankings of the distances
\[
\begin{equation*}
d_{r_{1} s_{1}}<d_{r_{2} s_{2}}<\cdots<d_{r_{m} s_{m}} \tag{16.6}
\end{equation*}
\]
match exactly the ordering of dissimilarities in (16.5). Thus, while metric scaling uses the magnitudes of the \(\delta_{i j}\) 's, nonmetric scaling is based only on the rank order of the \(\delta_{i j}\) 's.

For a given set of points with distances \(d_{i j}\), a plot of \(d_{i j}\) versus \(\delta_{i j}\) may not be monotonic; that is, the ordering in (16.6) may not match exactly the ordering in (16.5). Suitable \(\hat{d}_{i j}\) 's can be estimated by monotonic regression, in which we seek
values of \(\hat{d}_{i j}\) to minimize the scaled sum of squared differences
\[
\begin{equation*}
S^{2}=\frac{\sum_{i<j}\left(d_{i j}-\hat{d}_{i j}\right)^{2}}{\sum_{i<j} d_{i j}^{2}} \tag{16.7}
\end{equation*}
\]
subject to the constraint
\[
\hat{d}_{r_{1} s_{1}} \leq \hat{d}_{r_{2} s_{2}} \leq \cdots \leq \hat{d}_{r_{m} s_{m}}
\]
where \(r_{1} s_{1}, r_{2} s_{2}, \ldots, r_{m} s_{m}\) are defined as in (16.5) and (16.6) (Kruskal 1964a, 1964b). The minimum value of \(S^{2}\) for a given dimension, \(k\), is called the STRESS. Note that the \(\hat{d}_{i j}\) 's are not distances. They are merely numbers used as a reference to assess the monotonicity of the \(d_{i j}\) 's. The \(\hat{d}_{i j}\) 's are sometimes called disparities.

The minimum value of the STRESS over all possible configurations of points can be found using the following algorithm.
1. Rank the \(m=n(n-1) / 2\) distances or dissimilarities \(\delta_{i j}\) as in (16.5).
2. Choose a value of \(k\) and an initial configuration of points in \(k\) dimensions. The initial configuration could be \(n\) points chosen at random from a uniform or normal distribution, \(n\) evenly spaced points in \(k\)-dimensional space, or the metric solution obtained by treating the ordinal measurements as continuous and using the algorithm in Section 16.1.2.
3. For the initial configuration of points, find the interitem distances \(d_{i j}\). Find the corresponding \(\hat{d}_{i j}\) 's by monotonic regression as defined above using (16.7).
4. Choose a new configuration of points whose distances \(d_{i j}\) minimize \(S^{2}\) in (16.7) with respect to the \(\hat{d}_{i j}\) 's found in step 3 . One approach is to use an iterative gradient technique such as the method of steepest descent or the NewtonRaphson method.
5. Using monotonic regression, find new \(\hat{d}_{i j}\) 's for the \(d_{i j}\) 's found in step 4. This gives a new value of STRESS.
6. Repeat steps 4 and 5 until STRESS converges to a minimum over all possible \(k\)-dimensional configurations of points.
7. Using the preceding six steps, calculate the minimum STRESS for values of \(k\) starting at \(k=1\) and plot these. As \(k\) increases, the curve will decrease, with occasional exceptions due to round off or numerical anomalies in the search procedure for minimum STRESS. We look for a discernible bend in the plot, following which the curve is low and relatively flat. An ideal plot is shown in Figure 16.3. The curve levels off after \(k=2\), which is convenient for plotting the resulting \(n\) points in 2 dimensions.

There is a possibility that the minimum value of STRESS found by the above seven steps for a given value of \(k\) may be a local minimum rather than the global

Figure 16.3 Ideal plot of minimum STRESS versus \(k\).
minimum. Such an anomaly may show up in the plot of minimum STRESS versus \(k\). The possibility of a local minimum can be checked by repeating the procedure, starting with a different initial configuration.

As was the case with metric scaling, the final configuration of points from a nonmetric scaling is invariant to a rotation of axes.

\section*{EXAMPLE 16.1.3}

The voting records for fifteen congressmen from New Jersey on nineteen environmental bills are given in Table 16.2 in the form of a dissimilarity matrix (Hand et al. 1994, p. 235). The congressmen are identified by party: \(R_{1}\) for Republican 1, \(D_{2}\) for Democrat 2, etc. Each entry shows how often the indicated congressman voted differently from each of the other fourteen.

Using an initial configuration of points from a multivariate normal distribution with mean vector \(\boldsymbol{\mu}=\mathbf{0}\) and \(\boldsymbol{\Sigma}=\mathbf{I}\), we find an "optimal" configuration of points for each of \(k=1,2, \ldots, 5\). A plot of the STRESS is given in Figure 16.4.

From the plot of STRESS vs. number of dimensions, we see that either two or three dimensions will be sufficient. For plotting purposes, we choose two dimensions, which has a STRESS value of 0.113 . The plot of the first two dimensions is given in Figure 16.5. It is apparent that the plot separates the Republicans from the Democrats except for Republican 6, who voted much the same as the Democrats.

Table 16.2 Dissimilarity Matrix for Voting Records of 15 Congressmen
\begin{tabular}{lrrrrrrrrrrrrrrr}
\hline & \(R_{1}\) & \(R_{2}\) & \(D_{1}\) & \(D_{2}\) & \(R_{3}\) & \(R_{4}\) & \(R_{5}\) & \(D_{3}\) & \(D_{4}\) & \(D_{5}\) & \(D_{6}\) & \(R_{6}\) & \(R_{7}\) & \(R_{8}\) & \(D_{7}\) \\
\hline\(R_{1}\) & 0 & 8 & 15 & 15 & 10 & 9 & 7 & 15 & 16 & 14 & 15 & 16 & 7 & 11 & 13 \\

\(R_{7}\) & 7 & 13 & 11 & 15 & 10 & 6 & 10 & 12 & 13 & 11 & 12 & 12 & 0 & 9 & 13 \\
\(R_{8}\) & 11 & 12 & 10 & 10 & 11 & 6 & 11 & 7 & 7 & 4 & 5 & 6 & 9 & 0 & 9 \\
\(D_{7}\) & 13 & 16 & 7 & 7 & 11 & 10 & 13 & 6 & 5 & 6 & 5 & 4 & 13 & 9 & 0 \\
\hline
\end{tabular}

We now use a different initial configuration of points drawn from a uniform distribution. The resulting plot is given in Figure 16.6. The approximate orientation of the points in the two-dimensional space is similar, with the exception of the locations of \(R_{2}\) and \(R_{5}\).

Figure 16.4 Plot of STRESS for each value of \(k\) for the voting data in Table 16.2.

Figure 16.5 Plot of points found using initial points from a multivariate normal distribution.

Figure 16.6 Plot of points found using initial points from a uniform distribution.

Figure 16.7 Plot of points found using initial points from a metric solution.

We next use a third initial configuration of points resulting from the metric solution as described in Section 16.1.2. The resulting plot is given in Figure 16.7. All three plots are very similar, indicating a good fit.

\subsection*{16.2 CORRESPONDENCE ANALYSIS}

\subsection*{16.2.1 Introduction}

Correspondence analysis is a graphical technique for representing the information in a two-way contingency table, which contains the counts (frequencies) of items for a cross-classification of two categorical variables. With correspondence analysis, we construct a plot that shows the interaction of the two categorical variables along with the relationship of the rows to each other and the columns to each other. In Sections \(16.2 .2-16.2 .4\), we consider correspondence analysis for ordinary two-way contingency tables. In Section 16.2.5 we consider multiple correspondence analysis for three-way and higher-order contingency tables. Useful treatments of correspondence analysis have been given by Greenacre (1984), Jobson (1992, Section 9.4), Khattree and Naik (1999, Chapter 7), Gower and Hand (1996, Chapters 4 and 9), and Benzécri (1992).

To test for significance of association of the two categorical variables in a contingency table, we can use a chi-square test or a log-linear model, both of which represent an asymptotic approach. Since correspondence analysis is associated with the chi-square approach, we will review it in Section 16.2.3. If a contingency table

Table 16.3 Contingency Table with \(a\) Rows and \(b\) Columns
\begin{tabular}{ccccccc}
\hline & & \multicolumn{5}{c}{ Columns } \\
& & 1 & 2 & \(\cdots\) & \(b\) & Row Total \\
\hline \multirow{4}{*}{ Rows } & 1 & \(n_{11}\) & \(n_{12}\) & \(\cdots\) & \(n_{1 b}\) & \(n_{1 .}\) \\
& 2 & \(n_{21}\) & \(n_{22}\) & \(\cdots\) & \(n_{2 b}\) & \(n_{2 .}\) \\
& \(\vdots\) & \(\vdots\) & \(\vdots\) & & \(\vdots\) & \(\vdots\) \\
\hline & \(a\) & \(n_{a 1}\) & \(n_{a 2}\) & \(\cdots\) & \(n_{a b}\) & \(n_{a .}\) \\
\hline
\end{tabular}
has some cell frequencies that are small or zero, the chi-square approximation is not very satisfactory. In this case, some categories can be combined to increase the cell frequencies. Correspondence analysis may be useful in identifying the categories that are similar, which we may thereby wish to combine.

In correspondence analysis, we plot a point for each row and a point for each column of the contingency table. These points are in effect projections of the rows and columns of the contingency table onto a two-dimensional Euclidean space. The goal is to preserve as far as possible the relationship of the rows (or columns) to each other in a two-dimensional space. If two row points are close together, the profiles of the two rows (across the columns) are similar. Likewise, two column points that are close together represent columns with similar profiles across the rows (see Section 16.2.2 for a definition of profiles). If a row point is close to a column point, this combination of categories of the two variables occurs more frequently than would occur by chance if the two variables were independent. Another output of a correspondence analysis is the inertia or amount of information in each of the two dimensions in the plot (see Section 16.2.4).

\subsection*{16.2.2 Row and Column Profiles}

A contingency table with \(a\) rows and \(b\) columns is represented in Table 16.3. The entries \(n_{i j}\) are the counts or frequencies for every two-way combination of row and column (every cell). The marginal totals are shown using the familiar "dot" notation: \(n_{i .}=\sum_{j=1}^{b} n_{i j}\) and \(n_{. j}=\sum_{i=1}^{a} n_{i j}\). The overall total frequency is denoted by \(n\) instead of \(n_{\text {., }}\) for simplicity: \(n=\sum_{i j} n_{i j}\).

The frequencies \(n_{i j}\) in a contingency table can be converted to relative frequencies \(p_{i j}\) by dividing by \(n\) : \(p_{i j}=n_{i j} / n\). The matrix of relative frequencies is called the correspondence matrix and is denoted by \(\mathbf{P}\) :
\[
\begin{equation*}
\mathbf{P}=\left(p_{i j}\right)=\left(n_{i j} / n\right) \tag{16.8}
\end{equation*}
\]

In Table 16.4 we show the contingency table in Table 16.3 converted to a correspondence matrix.

Table 16.4 Correspondence Matrix of Relative Frequencies
\begin{tabular}{ccccccc}
\hline & & \multicolumn{5}{c}{ Columns } \\
& & 1 & 2 & \(\cdots\) & \(b\) & Row Total \\
\cline { 3 - 6 } & & 1 & \(p_{11}\) & \(p_{12}\) & \(\cdots\) & \(p_{1 b}\) \\
\multirow{4}{*}{ Rows } & 2 & \(p_{21}\) & \(p_{22}\) & \(\cdots\) & \(p_{2 b}\) & \(p_{2 .}\) \\
& \(\vdots\) & \(\vdots\) & \(\vdots\) & & \(\vdots\) & \(\vdots\) \\
& \(a\) & \(p_{a 1}\) & \(p_{a 2}\) & \(\cdots\) & \(p_{a b}\) & \(p_{a .}\) \\
\hline \multirow{7}{*}{ Column Total } & \(p_{.1}\) & \(p_{.2}\) & \(\cdots\) & \(p_{. b}\) & 1 \\
\hline
\end{tabular}

The last column of Table 16.4 contains the row sums \(p_{i .}=\sum_{j=1}^{b} p_{i j}\). This column vector is denoted by \(\mathbf{r}\) and can be obtained as
\[
\begin{equation*}
\mathbf{r}=\mathbf{P} \mathbf{j}=\left(p_{1 .}, p_{2 .}, \ldots, p_{a .}\right)^{\prime}=\left(n_{1 .} / n, n_{2 .} / n, \ldots, n_{a .} / n\right)^{\prime}, \tag{16.9}
\end{equation*}
\]
where \(\mathbf{j}\) is an \(a \times 1\) vector of 1 's. Similarly, the last row of Table 16.4 contains the column sums \(p_{. j}=\sum_{i=1}^{a} p_{i j}\). This row vector is denoted by \(\mathbf{c}^{\prime}\) and can be obtained as
\[
\begin{equation*}
\mathbf{c}^{\prime}=\mathbf{j}^{\prime} \mathbf{P}=\left(p_{.1}, p_{.2}, \ldots, p_{. b}\right)=\left(n_{.1} / n, n_{.2} / n, \ldots, n_{. b} / n\right) \tag{16.10}
\end{equation*}
\]
where \(\mathbf{j}^{\prime}\) is a \(1 \times b\) vector of 1 's. The elements of the vectors \(\mathbf{r}\) and \(\mathbf{c}\) are sometimes referred to as row and column masses. The correspondence matrix and marginal totals in Table 16.4 can be expressed as
\[
\left(\begin{array}{cc}
\mathbf{P} & \mathbf{r}  \tag{16.11}\\
\mathbf{c}^{\prime} & 1
\end{array}\right)=\left(\begin{array}{cccc|c}
p_{11} & p_{12} & \cdots & p_{1 b} & p_{1 .} \\
p_{21} & p_{22} & \cdots & p_{2 b} & p_{2 .} \\
\vdots & \vdots & & \vdots & \vdots \\
p_{a 1} & p_{a 2} & \cdots & p_{a b} & p_{a .} \\
\hline p_{.1} & p_{.2} & \cdots & p_{. b} & 1
\end{array}\right)
\]

We now convert each row and column of \(\mathbf{P}\) to a profile. The \(i\) th row profile \(\mathbf{r}_{i}^{\prime}, i=1,2, \ldots, a\), is defined by dividing the \(i\) th row of either Table 16.3 or Table 16.4 by its marginal total:
\[
\begin{equation*}
\mathbf{r}_{i}^{\prime}=\left(\frac{p_{i 1}}{p_{i .}}, \frac{p_{i 2}}{p_{i .}}, \ldots, \frac{p_{i b}}{p_{i .}}\right)=\left(\frac{n_{i 1}}{n_{i .}}, \frac{n_{i 2}}{n_{i .}}, \ldots, \frac{n_{i b}}{n_{i .}}\right) . \tag{16.12}
\end{equation*}
\]

The elements in each \(\mathbf{r}_{i}^{\prime}\) are relative frequencies, and therefore they sum to 1 :
\[
\begin{equation*}
\mathbf{r}_{i}^{\prime} \mathbf{j}=\sum_{j=1}^{b} \frac{n_{i j}}{n_{i .}}=\frac{n_{i .}}{n_{i .}}=\mathbf{1} \tag{16.13}
\end{equation*}
\]

By defining
\[
\mathbf{D}_{r}=\operatorname{diag}(\mathbf{r})=\left(\begin{array}{cccc}
p_{1 .} & 0 & \cdots & 0  \tag{16.14}\\
0 & p_{2} & \cdots & 0 \\
\vdots & \vdots & & \vdots \\
0 & 0 & \cdots & p_{a .}
\end{array}\right)
\]
and using (2.55), the matrix \(\mathbf{R}\) of row profiles can be expressed as
\[
\mathbf{R}=\mathbf{D}_{r}^{-1} \mathbf{P}=\left(\begin{array}{c}
\mathbf{r}_{1}^{\prime}  \tag{16.15}\\
\mathbf{r}_{2}^{\prime} \\
\vdots \\
\mathbf{r}_{a}^{\prime}
\end{array}\right)=\left(\begin{array}{cccc}
\frac{p_{11}}{p_{1 .}} & \frac{p_{12}}{p_{1 .}} & \ldots & \frac{p_{1 b}}{p_{1 .}} \\
\frac{p_{21}}{p_{2 .}} & \frac{p_{22}}{p_{2 .}} & \ldots & \frac{p_{2 b}}{p_{2 .}} \\
\vdots & \vdots & & \vdots \\
\frac{p_{a 1}}{p_{a .}} & \frac{p_{a 2}}{p_{a .}} & \ldots & \frac{p_{a b}}{p_{a .}}
\end{array}\right) .
\]

Similarly, the \(j\) th column profile \(\mathbf{c}_{j}, j=1,2, \ldots, b\), is defined by dividing the \(j\) th column of either Table 16.3 or Table 16.4 by its marginal total:
\[
\begin{equation*}
\mathbf{c}_{j}=\left(\frac{p_{1 j}}{p_{. j}}, \frac{p_{2 j}}{p_{. j}}, \ldots, \frac{p_{a j}}{p_{. j}}\right)^{\prime}=\left(\frac{n_{1 j}}{n_{. j}}, \frac{n_{2 j}}{n_{. j}}, \ldots, \frac{n_{a j}}{n_{. j}}\right)^{\prime} \tag{16.16}
\end{equation*}
\]

The elements in each \(c_{j}\) are relative frequencies, and therefore they sum to 1 :
\[
\begin{equation*}
\mathbf{j}^{\prime} \mathbf{c}_{j}=\sum_{i=1}^{a} \frac{n_{i j}}{n_{\cdot j}}=\frac{n_{. j}}{n_{\cdot j}}=1 \tag{16.17}
\end{equation*}
\]

By defining
\[
\mathbf{D}_{c}=\operatorname{diag}(\mathbf{c})=\left(\begin{array}{cccc}
p_{.1} & 0 & \cdots & 0  \tag{16.18}\\
0 & p_{.2} & \cdots & 0 \\
\vdots & \vdots & & \vdots \\
0 & 0 & \cdots & p_{. b}
\end{array}\right)
\]
and using (2.56), the matrix \(\mathbf{C}\) of column profiles can be expressed as
\[
\mathbf{C}=\mathbf{P D}_{c}^{-1}=\left(\mathbf{c}_{1}, \mathbf{c}_{2}, \cdots, \mathbf{c}_{b}\right)=\left(\begin{array}{cccc}
\frac{p_{11}}{p_{11}} & \frac{p_{12}}{p_{.2}} & \cdots & \frac{p_{1 a}}{p_{. a}}  \tag{16.19}\\
\frac{p_{21}}{p_{11}} & \frac{p_{22}}{p_{.2}} & \cdots & \frac{p_{2 a}}{p_{. a}} \\
\vdots & \vdots & & \vdots \\
\frac{p_{a 1}}{p_{.1}} & \frac{p_{a 2}}{p_{.2}} & \cdots & \frac{p_{a b}}{p_{. a}}
\end{array}\right)
\]

The vector \(\mathbf{r}\) is defined in (16.9) as the column vector of row sums of \(\mathbf{P}\). It can also be expressed as a weighted average of the column profiles:
\[
\begin{equation*}
\mathbf{r}=\sum_{j=1}^{b} p_{. j} \mathbf{c}_{j} \tag{16.20}
\end{equation*}
\]

Table 16.5 Piston Ring Failures
\begin{tabular}{ccccc}
\hline \multirow{3}{*}{ Compressor } & \multicolumn{3}{c}{ Leg } & \\
\cline { 2 - 4 } & North & Center & South & Row Total \\
\hline 1 & 17 & 17 & 12 & 46 \\
2 & 11 & 9 & 13 & 33 \\
3 & 11 & 8 & 19 & 38 \\
4 & 14 & 7 & 28 & 49 \\
\hline Total & 53 & 41 & 72 & 166 \\
\hline
\end{tabular}

Similarly, \(\mathbf{c}^{\prime}\) in (16.10) is the row vector of column sums of \(\mathbf{P}\) and can be expressed as a weighted average of the row profiles:
\[
\begin{equation*}
\mathbf{c}^{\prime}=\sum_{i=1}^{a} p_{i .} \mathbf{r}_{i}^{\prime} \tag{16.21}
\end{equation*}
\]

Note that \(\sum_{j=1}^{b} p_{. j}=\sum_{i=1}^{a} p_{i .}=1\), or
\[
\begin{equation*}
\mathbf{j}^{\prime} \mathbf{r}=\mathbf{c}^{\prime} \mathbf{j}=1 \tag{16.22}
\end{equation*}
\]
where the first \(\mathbf{j}\) is \(a \times 1\) and the second is \(b \times 1\). Therefore the \(p_{. j}\) 's and \(p_{i}\).'s serve as appropriate weights in the weighted averages (16.20) and (16.21).

\section*{EXAMPLE 16.2.2}

In Table 16.5 (Hand et al. 1994, p. 12) we have the number of piston ring failures in each of three legs in four compressors found in the same building (the four compressors are oriented in the same direction). We obtain the correspondence matrix in Table 16.6 by dividing each element of Table 16.5 by \(n=\sum_{i j} n_{i j}=166\).

The vectors of row and column sums (marginal totals) in Table 16.6 are given by (16.9) and (16.10) as
\[
\begin{gathered}
\mathbf{r}=\left(\begin{array}{l}
.277 \\
.199 \\
.229 \\
.295
\end{array}\right), \\
\mathbf{c}^{\prime}=(.319, \quad .247, \quad .434) .
\end{gathered}
\]

The matrix of row profiles is given by (16.15) as
\[
\mathbf{R}=\mathbf{D}_{r}^{-1} \mathbf{P}=\left(\begin{array}{ccc}
.370 & .370 & .261 \\
.333 & .273 & .394 \\
.290 & .211 & .500 \\
.286 & .143 & .571
\end{array}\right)
\]

Table 16.6 Correspondence Matrix Obtained from Table 16.5
\begin{tabular}{ccccc}
\hline \multirow{2}{*}{ Compressor } & \multicolumn{3}{c}{ Leg } & \\
\cline { 2 - 4 } & North & Center & South & Row Total \\
\hline 1 & .102 & .102 & .072 & .277 \\
2 & .066 & .054 & .078 & .199 \\
3 & .066 & .048 & .114 & .229 \\
4 & .084 & .042 & .169 & .295 \\
\hline Total & .319 & .247 & .434 & 1.000 \\
\hline
\end{tabular}

The matrix of column profiles is given by (16.19) as
\[
\mathbf{C}=\mathbf{P D}_{c}^{-1}=\left(\begin{array}{ccc}
.321 & .415 & .167 \\
.208 & .220 & .181 \\
.208 & .195 & .264 \\
.264 & .171 & .389
\end{array}\right)
\]

\subsection*{16.2.3 Testing Independence}

In Section 16.2.1, we noted that the data in a contingency table are often used to check for association of two categorical variables. If the two variables are denoted by \(x\) and \(y\), then the assumption of independence can be expressed in terms of probabilities as
\[
\begin{equation*}
P\left(x_{i} y_{j}\right)=P\left(x_{i}\right) P\left(y_{j}\right), i=1,2, \ldots, a ; j=1,2, \ldots, b \tag{16.23}
\end{equation*}
\]
where \(x_{i}\) and \(y_{j}\) correspond to the \(i\) th row and \(j\) th column of the contingency table. Using the notation in Table 16.4, we can estimate (16.23) as
\[
\begin{equation*}
p_{i j}=p_{i .} p_{j}, i=1,2, \ldots a ; j=1,2, \ldots, b . \tag{16.24}
\end{equation*}
\]

The usual chi-square statistic for testing independence of \(x\) and \(y\) (comparing \(p_{i j}\) with \(p_{i .} p_{. j}\) for all \(i, j\) ) is given by
\[
\begin{equation*}
\chi^{2}=n \sum_{i=1}^{a} \sum_{j=1}^{b} \frac{\left(p_{i j}-p_{i .} p_{. j}\right)^{2}}{p_{i .} p_{j}}, \tag{16.25}
\end{equation*}
\]
which is approximately (asymptotically) distributed as a chi-square random variable with \((a-1)(b-1)\) degrees of freedom. The statistic in (16.25) can also be written in terms of the frequencies \(n_{i j}\) rather than the relative frequencies \(p_{i j}\) :
\[
\begin{equation*}
\chi^{2}=\sum_{i=1}^{a} \sum_{j=1}^{b} \frac{\left(n_{i j}-\frac{n_{i . n} n_{. j}}{n}\right)^{2}}{\frac{n_{i .} n_{. j}}{n}} \tag{16.26}
\end{equation*}
\]

Two other alternative forms of (16.25) are
\[
\begin{align*}
& \chi^{2}=\sum_{i=1}^{a} n p_{i .} \sum_{j=1}^{b}\left[\left(\frac{p_{i j}}{p_{i .}}-p_{. j}\right)^{2} / p_{. j}\right],  \tag{16.27}\\
& \chi^{2}=\sum_{j=1}^{b} n p_{. j} \sum_{i=1}^{a}\left[\left(\frac{p_{i j}}{p_{. j}}-p_{i .}\right)^{2} / p_{i .}\right] . \tag{16.28}
\end{align*}
\]

In vector and matrix form, (16.27) and (16.28) can be written as
\[
\begin{align*}
& \chi^{2}=\sum_{i=1}^{a} n p_{i .}\left(\mathbf{r}_{i}-\mathbf{c}\right)^{\prime} \mathbf{D}_{c}^{-1}\left(\mathbf{r}_{i}-\mathbf{c}\right)  \tag{16.29}\\
& \chi^{2}=\sum_{j=1}^{b} n p_{. j}\left(\mathbf{c}_{j}-\mathbf{r}\right)^{\prime} \mathbf{D}_{r}^{-1}\left(\mathbf{c}_{j}-\mathbf{r}\right) \tag{16.30}
\end{align*}
\]
where \(\mathbf{r}, \mathbf{c}, \mathbf{r}_{i}, \mathbf{c}_{j}, \mathbf{D}_{r}\), and \(\mathbf{D}_{c}\) are defined in (16.9), (16.10), (16.12), (16.16), (16.14), and (16.18), respectively. Thus, in (16.29) we compare \(\mathbf{r}_{i}\) to \(\mathbf{c}\) for each \(i\), and in (16.30) we compare \(\mathbf{c}_{j}\) to \(\mathbf{r}\) for each \(j\). Either of these is equivalent to testing independence by comparing \(p_{i j}\) to \(p_{i .} p_{. j}\) for all \(i, j\), since the definitions of \(\chi^{2}\) in (16.25)-(16.30) are all equal. Thus, the following three statements of independence are equivalent (for simplicity, we express the three statements in terms of sample quantities rather than their theoretical counterparts):
1. \(p_{i j}=p_{i .} p_{. j}\) for all \(i, j\) (or \(\mathbf{P}=\mathbf{r c}^{\prime}\) ).
2. All rows \(\mathbf{r}_{i}^{\prime}\) of \(\mathbf{R}\) in (16.15) are equal (and equal to their weighted average, \(c^{\prime}\) ).
3. All columns \(\mathbf{c}_{j}\) of \(\mathbf{C}\) in (16.19) are equal (and equal to their weighted average, \(\mathbf{r}\) ).

Thus, if the variables \(x\) and \(y\) were independent, we would expect the rows of the contingency table to have similar profiles, or equivalently, the columns to have similar profiles. We can compare the row profiles to each other by comparing each row profile \(\mathbf{r}_{i}^{\prime}\) to the weighted average \(\mathbf{c}^{\prime}\) of the row profiles defined in (16.21). This comparison is made in the \(\chi^{2}\) statistic (16.29). Similarly, we compare column profiles in (16.30).

The chi-square statistic in (16.25) can be expressed in vector and matrix terms as
\[
\begin{align*}
\chi^{2} & =n \operatorname{tr}\left[\mathbf{D}_{r}^{-1}\left(\mathbf{P}-\mathbf{r c}^{\prime}\right) \mathbf{D}_{c}^{-1}\left(\mathbf{P}-\mathbf{r c}^{\prime}\right)^{\prime}\right]  \tag{16.31}\\
& =n \sum_{i=1}^{k} \lambda_{i}^{2} \quad[\text { by }(2.107)] \tag{16.32}
\end{align*}
\]
where \(\lambda_{1}^{2}, \lambda_{2}^{2}, \ldots, \lambda_{k}^{2}\) are the nonzero eigenvalues of \(\mathbf{D}_{r}^{-1}\left(\mathbf{P}-\mathbf{r c}^{\prime}\right) \mathbf{D}_{c}^{-1}\left(\mathbf{P}-\mathbf{r c}^{\prime}\right)^{\prime}\) and
\[
\begin{equation*}
k=\operatorname{rank}\left[\mathbf{D}_{r}^{-1}\left(\mathbf{P}-\mathbf{r c}^{\prime}\right) \mathbf{D}_{c}^{-1}\left(\mathbf{P}-\mathbf{r c}^{\prime}\right)^{\prime}\right]=\operatorname{rank}\left(\mathbf{P}-\mathbf{r c}^{\prime}\right) \tag{16.33}
\end{equation*}
\]

The rank of \(\mathbf{P}-\mathbf{r c}^{\prime}\) is ordinarily \(k=\min [(a-1),(b-1)]\). It is clear that the rank is less than \(\min (a, b)\) since
\[
\begin{equation*}
\left(\mathbf{P}-\mathbf{r} \mathbf{c}^{\prime}\right) \mathbf{j}=\mathbf{P} \mathbf{j}-\mathbf{r} \mathbf{c}^{\prime} \mathbf{j}=\mathbf{r}-\mathbf{r}=\mathbf{0} \tag{16.34}
\end{equation*}
\]
[see (16.9) and (16.22)].

\section*{- EXAMPLE 16.2.3}

In order to test independence of the rows (compressors) and columns (legs) of Table 16.5 in Example 16.2.2, we perform a chi-square test. Using (16.25) or (16.26), we obtain \(\chi^{2}=11.722\), with 6 degrees of freedom, for which the \(p\)-value is 0.0685 . There is some evidence of lack of independence between leg and compressor.

\subsection*{16.2.4 Coordinates for Plotting Row and Column Profiles}

We now obtain coordinates of the row points and column points for the best twodimensional representation of the data in a contingency table. As we will see, the metric for the row points and column points is the same, and the two sets of points can therefore be superimposed on the same plot.

In multidimensional scaling in Section 16.1, we transformed the distance matrix and then factored it by a spectral decomposition to obtain coordinates for plotting. In correspondence analysis, the matrix \(\mathbf{P}-\mathbf{r c}^{\prime}\) is not symmetric, and we therefore resort to a singular value decomposition to obtain coordinates.

We first scale \(\mathbf{P}-\mathbf{r c}^{\prime}\) to obtain
\[
\begin{equation*}
\mathbf{Z}=\mathbf{D}_{r}^{-1 / 2}\left(\mathbf{P}-\mathbf{r c}^{\prime}\right) \mathbf{D}_{c}^{-1 / 2}, \tag{16.35}
\end{equation*}
\]
whose elements are
\[
\begin{equation*}
z_{i j}=\frac{p_{i j}-p_{i . p_{. j}}}{\sqrt{p_{i .} p_{. j}}} \tag{16.36}
\end{equation*}
\]
as in (16.25). The \(a \times b\) matrix \(\mathbf{Z}\) has rank \(k=\min (a-1, b-1)\), the assumed rank of \(\mathbf{P}-\mathbf{r c}^{\prime}\). We then factor \(\mathbf{Z}\) using the singular value decomposition (2.117):
\[
\begin{equation*}
\mathbf{Z}=\mathbf{U} \boldsymbol{\Lambda} \mathbf{V}^{\prime} \tag{16.37}
\end{equation*}
\]

The columns of the \(a \times k\) matrix \(\mathbf{U}\) are (normalized) eigenvectors of \(\mathbf{Z Z}^{\prime}\); the columns of the \(b \times k\) matrix \(\mathbf{V}\) are (normalized) eigenvectors of \(\mathbf{Z}^{\prime} \mathbf{Z}\); and \(\boldsymbol{\Lambda}=\) \(\operatorname{diag}\left(\lambda_{1}, \lambda_{2}, \ldots, \lambda_{k}\right)\), where \(\lambda_{1}^{2}, \lambda_{2}^{2}, \ldots, \lambda_{k}^{2}\) are the nonzero eigenvalues of \(\mathbf{Z}^{\prime} \mathbf{Z}\) and of \(\mathbf{Z} \mathbf{Z}^{\prime}\). The eigenvectors in \(\mathbf{U}\) and \(\mathbf{V}\) correspond to the eigenvalues \(\lambda_{1}^{2}, \lambda_{2}^{2}, \ldots, \lambda_{k}^{2}\). Since, the columns of \(\mathbf{U}\) and \(\mathbf{V}\) are orthonormal, \(\mathbf{U}^{\prime} \mathbf{U}=\mathbf{V}^{\prime} \mathbf{V}=\mathbf{I}\). The values \(\lambda_{1}, \lambda_{2}, \ldots, \lambda_{k}\) in \(\boldsymbol{\Lambda}\) are called the singular values of \(\mathbf{Z}\). Note that, by (16.35),
\[
\begin{align*}
\mathbf{Z} \mathbf{Z}^{\prime} & =\mathbf{D}_{r}^{-1 / 2}\left(\mathbf{P}-\mathbf{r c}^{\prime}\right) \mathbf{D}_{c}^{-1 / 2} \mathbf{D}_{c}^{-1 / 2}\left(\mathbf{P}-\mathbf{r c}^{\prime}\right)^{\prime} \mathbf{D}_{r}^{-1 / 2} \\
& =\mathbf{D}_{r}^{-1 / 2}\left(\mathbf{P}-\mathbf{r c}^{\prime}\right) \mathbf{D}_{c}^{-1}\left(\mathbf{P}-\mathbf{r c}^{\prime}\right)^{\prime} \mathbf{D}_{r}^{-1 / 2} \tag{16.38}
\end{align*}
\]

The (nonzero) eigenvalues of \(\mathbf{Z Z}{ }^{\prime}\) in (16.38) are the same as those of
\[
\begin{equation*}
\mathbf{D}_{r}^{-1 / 2} \mathbf{D}_{r}^{-1 / 2}\left(\mathbf{P}-\mathbf{r c}^{\prime}\right) \mathbf{D}_{c}^{-1}\left(\mathbf{P}-\mathbf{r c}^{\prime}\right)^{\prime} \tag{16.39}
\end{equation*}
\]
(see Section 2.11.5). The matrix expression in (16.39) is the same as that in (16.31). We have therefore denoted the eigenvalues as \(\lambda_{1}^{2}, \lambda_{2}^{2}, \ldots, \lambda_{k}^{2}\) as in (16.32).

We can obtain a decomposition of \(\mathbf{P}-\mathbf{r c}^{\prime}\) by equating the right-hand sides of (16.35) and (16.37) and solving for \(\mathbf{P}-\mathbf{r c}^{\prime}\) :
\[
\begin{align*}
\mathbf{D}_{r}^{-1 / 2}\left(\mathbf{P}-\mathbf{r c}^{\prime}\right) \mathbf{D}_{c}^{-1 / 2} & =\mathbf{U} \boldsymbol{\Lambda} \mathbf{V}^{\prime} \\
\mathbf{P}-\mathbf{r} \mathbf{c}^{\prime} & =\mathbf{D}_{r}^{1 / 2} \mathbf{U} \boldsymbol{\Lambda} \mathbf{V}^{\prime} \mathbf{D}_{c}^{1 / 2} \\
& =\mathbf{A} \mathbf{\Lambda} \mathbf{B}^{\prime}=\sum_{i=1}^{k} \lambda_{i} \mathbf{a}_{i} \mathbf{b}_{i}^{\prime} \tag{16.40}
\end{align*}
\]
where \(\mathbf{A}=\mathbf{D}_{r}^{1 / 2} \mathbf{U}, \mathbf{B}=\mathbf{D}_{c}^{1 / 2} \mathbf{V}, \mathbf{a}_{i}\) and \(\mathbf{b}_{i}\) are columns of \(\mathbf{A}\) and \(\mathbf{B}\), and \(\boldsymbol{\Lambda}=\) \(\operatorname{diag}\left(\lambda_{1}, \lambda_{2}, \ldots, \lambda_{k}\right)\).

Since \(\mathbf{U}^{\prime} \mathbf{U}=\mathbf{V}^{\prime} \mathbf{V}=\mathbf{I}, \mathbf{A}\) and \(\mathbf{B}\) in (16.40) are scaled so that \(\mathbf{A}^{\prime} \mathbf{D}_{r}^{-1} \mathbf{A}=\) \(\mathbf{B}^{\prime} \mathbf{D}_{c}^{-1} \mathbf{B}=\mathbf{I}\). With this scaling, the decomposition in (16.40) is often called the generalized singular value decomposition.

In (16.40) the rows of \(\mathbf{P}-\mathbf{r c}^{\prime}\) are expressed as linear combinations of the rows of \(\mathbf{B}^{\prime}\), which are the columns of \(\mathbf{B}=\left(\mathbf{b}_{1}, \mathbf{b}_{2}, \ldots, \mathbf{b}_{k}\right)\). The coordinates (coefficients) for the \(i\) th row of \(\mathbf{P}-\mathbf{r c}^{\prime}\) are found in the \(i\) th row of \(\mathbf{A} \boldsymbol{\Lambda}\). In like manner, the coordinates for the columns of \(\mathbf{P}-\mathbf{r c}^{\prime}\) are given by the columns of \(\mathbf{\Lambda B ^ { \prime }}\), since the columns of \(\boldsymbol{\Lambda} \mathbf{B}^{\prime}\) provide coefficients for the columns of \(\mathbf{A}=\left(\mathbf{a}_{1}, \mathbf{a}_{2}, \ldots, \mathbf{a}_{k}\right)\) in (16.40).

To find coordinates for the row deviations \(\mathbf{r}_{i}^{\prime}-\mathbf{c}^{\prime}\) in \(\mathbf{R}-\mathbf{j} \mathbf{c}^{\prime}\) and the column deviations \(\mathbf{c}_{j}-\mathbf{r}\) in \(\mathbf{C}-\mathbf{r j}^{\prime}\), we express the two matrices as functions of \(\mathbf{P}-\mathbf{r} \mathbf{c}^{\prime}\) (see Problem 16.8):
\[
\begin{align*}
\mathbf{R}-\mathbf{j} \mathbf{c}^{\prime} & =\mathbf{D}_{r}^{-1}\left(\mathbf{P}-\mathbf{r c}^{\prime}\right)  \tag{16.41}\\
\mathbf{C}-\mathbf{r j}^{\prime} & =\mathbf{D}_{c}^{-1}\left(\mathbf{P}-\mathbf{r c}^{\prime}\right) \tag{16.42}
\end{align*}
\]

Thus the coordinates for the row deviations in \(\mathbf{R}-\mathbf{j} \mathbf{c}^{\prime}\) with respect to the axes provided by \(\mathbf{b}_{1}, \mathbf{b}_{2}, \ldots, \mathbf{b}_{k}\) are given by the columns of
\[
\begin{equation*}
\mathbf{X}=\mathbf{D}_{r}^{-1} \mathbf{A} \mathbf{\Lambda} \tag{16.43}
\end{equation*}
\]

Similarly, the coordinates for the column deviations in \(\mathbf{C}-\mathbf{r j}^{\prime}\) with respect to the axes \(\mathbf{a}_{1}, \mathbf{a}_{2}, \ldots, \mathbf{a}_{k}\) are given by the columns of
\[
\begin{equation*}
\mathbf{Y}=\mathbf{D}_{c}^{-1} \mathbf{B} \boldsymbol{\Lambda} \tag{16.44}
\end{equation*}
\]

Therefore, to plot the coordinates for the row profile deviations \(\mathbf{r}_{i}^{\prime}-\mathbf{c}^{\prime}, i=1,2, \ldots\), \(a\), in two dimensions, we plot the rows of the first two columns of \(\mathbf{X}\) :
\[
\mathbf{X}_{1}=\left(\begin{array}{cc}
x_{11} & x_{12} \\
x_{21} & x_{22} \\
\vdots & \vdots \\
x_{a 1} & x_{a 2}
\end{array}\right)
\]

Similarly, to plot the coordinates for the column profile deviations \(\mathbf{c}_{j}-\mathbf{r}, j=\) \(1,2, \ldots, b\), in two dimensions, we plot the rows of the first two columns of \(\mathbf{Y}\) :
\[
\mathbf{Y}_{\mathbf{1}}=\left(\begin{array}{cc}
y_{11} & y_{12} \\
y_{21} & y_{22} \\
\vdots & \vdots \\
y_{b 1} & y_{b 2}
\end{array}\right)
\]

Both plots can be superimposed on the same graph because \(\mathbf{A}\) and \(\mathbf{B}\) in (16.40) share the same singular values \(\lambda_{1}, \lambda_{2}, \ldots, \lambda_{k}\) in \(\boldsymbol{\Lambda}\). Distances between row points and distances between column points are meaningful. For example, the distance between two row points is related to the chi-square metric implicit in (16.29). The chi-square distance between two row profiles \(\mathbf{r}_{i}\) and \(\mathbf{r}_{j}\) is given by
\[
d_{i j}^{2}=\left(\mathbf{r}_{i}-\mathbf{r}_{j}\right)^{\prime} \mathbf{D}_{c}^{-1}\left(\mathbf{r}_{i}-\mathbf{r}_{j}\right)
\]

If two row points (or two column points) are close, the two rows (or two columns) could be combined into a single category if necessary to improve the chi-square approximation.

The distance between a row point and a column point is not meaningful, but the proximity of a row point and a column point has meaning as noted in Section 16.2.1, namely that these two categories of the two variables occur more frequently than would be expected to happen by chance if the two variables were independent.

The weighted average (weighted by \(p_{i}\) ) of the distances \(\left(\mathbf{r}_{i}-\mathbf{c}\right)^{\prime} \mathbf{D}_{c}^{-1}\left(\mathbf{r}_{i}-\mathbf{c}\right)\) between the row profiles \(\mathbf{r}_{i}\) and their mean \(\mathbf{c}\) [see (16.21)] weighted by \(p_{i}\). is called the total inertia. By (16.29) this can be expressed as \(\chi^{2} / n\) :
\[
\begin{equation*}
\text { Total inertia }=\frac{\chi^{2}}{n}=\sum_{i=1}^{a} p_{i .}\left(\mathbf{r}_{i}-\mathbf{c}\right)^{\prime} \mathbf{D}_{c}^{-1}\left(\mathbf{r}_{i}-\mathbf{c}\right) \tag{16.45}
\end{equation*}
\]

As noted following (16.21), \(\sum_{i} p_{i .}=1\), and therefore the \(p_{i}\),'s serve as appropriate weights.

By (16.32), we can write (16.45) as
\[
\begin{equation*}
\frac{\chi^{2}}{n}=\sum_{i=1}^{k} \lambda_{i}^{2} \tag{16.46}
\end{equation*}
\]

Therefore, the contribution of each of the first two dimensions (axes) of our plot to the total inertia in (16.45) is \(\lambda_{1}^{2} / \sum_{i} \lambda_{i}^{2}\) and \(\lambda_{2}^{2} / \sum_{i} \lambda_{i}^{2}\). The combined contribution of the two dimensions is
\[
\begin{equation*}
\frac{\lambda_{1}^{2}+\lambda_{2}^{2}}{\sum_{i=1}^{k} \lambda_{i}^{2}} \tag{16.47}
\end{equation*}
\]

If (16.47) is large, then the points in the plane of the first two dimensions account for nearly all the variation in the data, including the associations. The total inertia in

Figure 16.8 Row points (1, 2, 3, 4) and column points (Center, North, South).
(16.45) and (16.46) can also be described in terms of the columns by using (16.30):
\[
\begin{equation*}
\text { Total inertia }=\frac{\chi^{2}}{n}=\sum_{j=1}^{b} p_{. j}\left(\mathbf{c}_{j}-\mathbf{r}\right)^{\prime} \mathbf{D}_{r}^{-1}\left(\mathbf{C}_{j}-\mathbf{r}\right)=\sum_{i=1}^{k} \lambda_{i}^{2} \tag{16.48}
\end{equation*}
\]

Since the inertia associated with the axes for columns is the same as that for rows, the row and column points can be plotted on the same axes.

Some computer programs use a singular value decomposition of \(\mathbf{P}\) rather than of \(\mathbf{P}-\mathbf{r c}^{\prime}\). The results are the same if the first singular value (which is 1 ) is discarded along with the first column of \(\mathbf{A}\) (which is \(\mathbf{r}\) ) and the first column of \(\mathbf{B}\) (which is \(\mathbf{c}\) ).

\section*{EXAMPLE 16.2.4}

We continue the analysis of the piston ring data of Table 16.5. A correspondence analysis is performed, and a plot of the row and column points is given in Figure 16.8. Row points do not lie near other row points and column points do not lie near column points. However, compressor 1 seems to be closely associated with the center leg, compressor 2 with the north leg, and compressor 4 with the south leg. These associations illustrate the lack of independence between compressor and leg position.

Singular values and inertias are given in Table 16.7. Most of the variation is due to the first dimension, and the first two dimensions explain all the variation because \(\operatorname{rank}(\mathbf{Z})=\min (a-1, b-1)=\min (4-1,3-1)=2\), where \(\mathbf{Z}\) is defined in (16.35).

Table 16.7 Singular Values \(\left(\lambda_{i}\right)\), Inertia \(\left(\lambda_{i}^{2}\right)\), Chi-Square \(\left(n \lambda_{i}^{2}\right)\), and Percent \(\left(\lambda_{i}^{2} / \sum_{j} \lambda_{j}^{2}\right)\) for the Data in Table 16.5

\hline Total & .07062 & 11.7223 & 100.00 \\
\hline
\end{tabular}

\subsection*{16.2.5 Multiple Correspondence Analysis}

Correspondence analysis of a two-way contingency table can be extended to a threeway or higher-order multi-way table. By the method of multiple correspondence analysis, we obtain a two-dimensional graphical display of the information in the multi-way contingency table. The method involves a correspondence analysis of an indicator matrix \(\mathbf{G}\). There is a row of \(\mathbf{G}\) for each item; thus the number of rows of \(\mathbf{G}\) is the total number of items in the sample. The number of columns of \(\mathbf{G}\) is the total number of categories in all variables. The elements of \(\mathbf{G}\) are 1's and 0's. In each row, an element is 1 if the item belongs in the corresponding category of the variable; otherwise, the element is 0 . Thus the number of 1 's in a row of \(G\) is the number of variables; for a four-way contingency table, for example, there would be four 1's in each row of G.

We illustrate a four-way classification with the (contrived) data in Table 16.8. There are \(n=12\) items (people) and \(p=4\) categorical variables. The four variables and their categories are listed in Table 16.9. The indicator matrix \(\mathbf{G}\) for the data in Table 16.8 is given in Table 16.10.

Table 16.8 A List of 12 People and Their Categories on Four Variables
\begin{tabular}{lcccc}
\hline Person & Gender & Age & Marital Status & Hair Color \\
\hline 1 & Male & Young & Single & Brown \\
2 & Male & Old & Single & Red \\

\hline
\end{tabular}

Table 16.10 Indicator Matrix \(\mathbf{G}\) for the Data in Table 16.8
\begin{tabular}{|c|c|c|c|c|}
\hline Person & Gender & Age & Marital Status & Hair Color \\
\hline 1 & 10 & 100 & 10 & 0100 \\
\hline 2 & 10 & 001 & 10 & 0001 \\
\hline 3 & 01 & 010 & 01 & 1000 \\
\hline 4 & 10 & 001 & 10 & 0010 \\
\hline 5 & 01 & 010 & 01 & 0010 \\
\hline 6 & 01 & 010 & 10 & 0100 \\
\hline 7 & 10 & 100 & 01 & 0001 \\
\hline 8 & 10 & 001 & 01 & 1000 \\
\hline 9 & 10 & 010 & 10 & 1000 \\
\hline 10 & 01 & 100 & 01 & 0010 \\
\hline 11 & 01 & 001 & 10 & 0100 \\
\hline 12 & 10 & 100 & 01 & 1000 \\
\hline
\end{tabular}

A correspondence analysis on \(\mathbf{G}\) is equivalent to a correspondence analysis on \(\mathbf{G}^{\prime} \mathbf{G}\), which is called the Burt matrix. This equivalence can be justified as follows. In the singular value decomposition \(\mathbf{G}=\mathbf{U} \boldsymbol{\Lambda} \mathbf{V}^{\prime}\), the matrix \(\mathbf{V}\) contains eigenvectors of \(G^{\prime} G\). The same matrix \(V\) would be used in the spectral decomposition of \(G^{\prime} G\). Thus the columns of \(\mathbf{V}\) are used in plotting coordinates for the columns of \(\mathbf{G}\) or the columns of \(\mathbf{G}^{\prime} \mathbf{G}\). If \(\mathbf{G}\) is \(n \times p\) with \(p<n\), then \(\mathbf{G}^{\prime} \mathbf{G}\) would be smaller in size than G.

The Burt matrix \(G^{\prime} G\) has a square block on the diagonal for each variable and a rectangular block off-diagonal for each pair of variables. Each diagonal block is a diagonal matrix showing the frequencies for the categories in the corresponding variable. Each off-diagonal block is a two-way contingency table for the corresponding pair of variables. In Table 16.11, we show the \(\mathbf{G}^{\prime} \mathbf{G}\) matrix for the \(\mathbf{G}\) matrix in Table 16.10.

A correspondence analysis of \(G^{\prime} G\) yields only column coordinates. A point is plotted for each column of \(\mathbf{G}\) (or of \(\mathbf{G}^{\prime} \mathbf{G}\) ). Thus each point represents a category (attribute) of one of the variables.

Distances between points are not as meaningful as in correspondence analysis, but points in the same quadrant or approximate vicinity indicate an association. If

Table 16.11 Burt Matrix \(\mathbf{G}^{\prime} \mathbf{G}\) for the Matrix \(\mathbf{G}\) in Table 16.10

\hline Total & 1.75000 & 116.638 & 100.00 \\
\hline
\end{tabular}
two close points represent attributes of the same variable, the two attributes may be combined into a single attribute.

Since the Burt matrix \(\mathbf{G}^{\prime} \mathbf{G}\) has only two-way contingency tables, three-way and higher-order interactions are not represented in the plot. The various two-way tables are analyzed simultaneously, however.

\section*{■ EXAMPLE 16.2.5(a)}

We continue the illustration in this section. A correspondence analysis of the Burt matrix \(G^{\prime} G\) in Table 16.11 yielded the singular values, inertia, and chisquare values in Table 16.12. The first two singular values account for only \(53.05 \%\) of the total variation. A plot of the first two dimensions for the 11

Figure 16.9 Plot of Points Representing the 11 Columns of Table 16.10 or Table 16.11.
columns in Table 16.10 or Table 16.11 is given in Figure 16.9. It appears that married and blond hair have a greater association than would be expected by chance alone. Another association is that between female and middle age.

\section*{EXAMPLE 16.2.5(b)}

Table 16.13 (Edwards and Kreiner 1983) is a five-way contingency table of employed men between the ages of 18 and 67 who were asked whether they themselves carried out repair work on their home, as opposed to hiring a craftsman to do the job. The five categorical variables are as follows:

Work of respondent: Skilled, Unskilled, Office
Tenure: Rent, Own
Age: Up to 30, 31-45, over 45
Accommodation type: Apartment, House
Response to repair question: Yes, No
A multiple correspondence analysis produced the inertia and singular values in Table 16.14. The plot of the first two dimensions is given in Figure 16.10.

Unskilled employment has a high association with not doing ones own repairs. Doing ones own repairs is associated with owning a house, age between 31 and 45, and doing office work. Living in an apartment is associated with renting.

Table 16.13 Do-It-Yourself Data

\subsection*{16.3 BIPLOTS}

\subsection*{16.3.1 Introduction}

A biplot is a two-dimensional representation of a data matrix \(\mathbf{Y}\) [see (3.17)] showing a point for each of the \(n\) observation vectors (rows of \(\mathbf{Y}\) ) along with a point for each

Figure 16.10 Plot of points representing the 12 categories in Table 16.13.
of the \(p\) variables (columns of \(\mathbf{Y}\) ). The prefix "bi" refers to the two kinds of points, not to the dimensionality of the plot. The method presented here could, in fact, be generalized to a three-dimensional (or higher-order) biplot. Biplots were introduced by Gabriel (1971) and have been discussed at length by Gower and Hand (1996); see also Khattree and Naik (2000), Jacoby (1998, Chapter 7), and Seber (1984, pp. 204-212).

If \(p=2\), a simple scatterplot such as in Section 3.3 has both kinds of information, namely, a point for each observation and the two axes representing the variables. We can see at a glance the placement of the points relative to each other and relative to the variables.

When \(p>2\), we can obtain a two-dimensional plot of the observations by plotting the first two principal components of \(S\) as in Section 12.4. We can then add a representation of the \(p\) variables to the plot of principal components to obtain a biplot. The principal component approach is discussed in Section 16.3.2. A method based on the singular value decomposition is presented in Section 16.3.3, and other methods are reviewed in Section 16.3.5.

\subsection*{16.3.2 Principal Component Plots}

A principal component is given by \(z=\mathbf{a}^{\prime} \mathbf{y}\), where \(\mathbf{a}\) is an eigenvector of \(\mathbf{S}\), the sample covariance matrix, and \(\mathbf{y}\) is a \(p \times 1\) observation vector (see Section 12.2). There are \(p\) eigenvectors \(\mathbf{a}_{1}, \mathbf{a}_{2}, \ldots, \mathbf{a}_{p}\), and thus there are \(p\) principal components \(z_{1}, z_{2}, \ldots, z_{p}\) for each observation vector \(\mathbf{y}_{i}, i=1,2, \ldots, n\). Hence (using the
centered form) the observation vectors are transformed to \(z_{i j}=\mathbf{a}_{j}^{\prime}\left(\mathbf{y}_{i}-\overline{\mathbf{y}}\right)=\) \(\left(\mathbf{y}_{i}-\overline{\mathbf{y}}\right)^{\prime} \mathbf{a}_{j}, i=1,2, \ldots, n ; j=1,2, \ldots, p\). Each \(p \times 1\) observation vector \(\mathbf{y}_{i}\) is transformed to a \(p \times 1\) vector of principal components,
\[
\begin{align*}
\mathbf{z}_{i}^{\prime} & =\left[\left(\mathbf{y}_{i}-\overline{\mathbf{y}}\right)^{\prime} \mathbf{a}_{1},\left(\mathbf{y}_{i}-\overline{\mathbf{y}}\right)^{\prime} \mathbf{a}_{2}, \ldots,\left(\mathbf{y}_{i}-\overline{\mathbf{y}}\right)^{\prime} \mathbf{a}_{p}\right] \\
& =\left(\mathbf{y}_{i}-\overline{\mathbf{y}}\right)^{\prime}\left(\mathbf{a}_{1}, \mathbf{a}_{2}, \ldots, \mathbf{a}_{p}\right) \\
& =\left(\mathbf{y}_{i}-\overline{\mathbf{y}}\right)^{\prime} \mathbf{A}, i=1,2, \ldots, n, \tag{16.49}
\end{align*}
\]
where \(\mathbf{A}=\left(\mathbf{a}_{1}, \mathbf{a}_{2}, \ldots, \mathbf{a}_{p}\right)\) is the \(p \times p\) matrix whose columns are (normalized) eigenvectors of \(S\). [Note that the matrix \(\mathbf{A}\) in (16.49) is the transpose of \(\mathbf{A}\) in (12.3)]. With \(\mathbf{Z}\) and \(\mathbf{Y}_{c}\) defined as
\[
\mathbf{Z}=\left(\begin{array}{c}
\mathbf{z}_{1}^{\prime}  \tag{16.50}\\
\mathbf{z}_{2}^{\prime} \\
\vdots \\
\mathbf{z}_{n}^{\prime}
\end{array}\right), \quad \mathbf{Y}_{c}=\left(\begin{array}{c}
\left(\mathbf{y}_{1}-\overline{\mathbf{y}}\right)^{\prime} \\
\left(\mathbf{y}_{2}-\overline{\mathbf{y}}\right)^{\prime} \\
\vdots \\
\left(\mathbf{y}_{n}-\overline{\mathbf{y}}\right)^{\prime}
\end{array}\right)
\]
[see (10.13)], we can express the principal components in (16.49) as
\[
\begin{equation*}
\mathbf{Z}=\mathbf{Y}_{c} \mathbf{A} \tag{16.51}
\end{equation*}
\]

Since the eigenvectors \(\mathbf{a}_{j}\) of the symmetric matrix \(\mathbf{S}\) are mutually orthogonal (see Section 2.11.6), \(\mathbf{A}=\left(\mathbf{a}_{1}, \mathbf{a}_{2}, \ldots, \mathbf{a}_{p}\right)\) is an orthogonal matrix and \(\mathbf{A A}^{\prime}=\mathbf{I}\). Multiplying ( 16.51 ) on the right by \(\mathbf{A}^{\prime}\), we obtain
\[
\begin{equation*}
\mathbf{Y}_{c}=\mathbf{Z} \mathbf{A}^{\prime} \tag{16.52}
\end{equation*}
\]

The best two-dimensional representation of \(\mathbf{Y}_{c}\) is given by taking the first two columns of \(\mathbf{Z}\) and the first two columns of \(\mathbf{A}\). If the resulting matrices are denoted by \(\mathbf{Z}_{2}\) and \(\mathbf{A}_{2}\), we have
\[
\begin{equation*}
\mathbf{Y}_{c} \cong \mathbf{Z}_{2} \mathbf{A}_{2}^{\prime} \tag{16.53}
\end{equation*}
\]

The fit in (16.53) is best in a least squares sense. If the left side of (16.53) is represented by \(\mathbf{Y}_{c}=\mathbf{B}=\left(b_{i j}\right)\) and the right side by \(\mathbf{Z}_{2} \mathbf{A}_{2}^{\prime}=\mathbf{C}=\left(c_{i j}\right)\), then \(\sum_{i=1}^{n} \sum_{j=1}^{p}\left(b_{i j}-c_{i j}\right)^{2}\) is minimized (Seber 1984, p. 206).

The coordinates for the \(n\) observations are the rows of \(\mathbf{Z}_{2}\) and the coordinates for the \(p\) variables are the rows of \(\mathbf{A}_{2}\) (columns of \(\mathbf{A}_{2}^{\prime}\) ). The coordinates are discussed further in Section 16.3.4.

The adequacy of the fit in (16.53) can be evaluated by examining the first two eigenvalues \(\lambda_{1}\) and \(\lambda_{2}\) of \(\mathbf{S}\). Thus a large value (close to 1 ) of
\[
\frac{\lambda_{1}+\lambda_{2}}{\sum_{i=1}^{p} \lambda_{i}}
\]
would indicate that \(\mathbf{Y}_{c}\) is represented well visually in the plot.

\subsection*{16.3.3 Singular Value Decomposition Plots}

We can obtain \(\mathbf{Y}_{c}=\mathrm{ZA}^{\prime}\) in (16.52) by means of the singular value decomposition of \(\mathbf{Y}_{c}\). By (2.117), we have
\[
\begin{equation*}
\mathbf{Y}_{c}=\mathbf{U} \boldsymbol{\Lambda} \mathbf{V}^{\prime} \tag{16.54}
\end{equation*}
\]
where \(\boldsymbol{\Lambda}=\operatorname{diag}\left(\lambda_{1}, \lambda_{2}, \ldots, \lambda_{p}\right)\) is a diagonal matrix containing square roots of the nonzero eigenvalues \(\lambda_{1}^{2}, \lambda_{2}^{2}, \ldots, \lambda_{p}^{2}\) of \(\mathbf{Y}_{c}^{\prime} \mathbf{Y}_{c}\) (or of \(\mathbf{Y}_{c} \mathbf{Y}_{c}^{\prime}\) ), the columns of \(\mathbf{U}\) are the corresponding eigenvectors of \(\mathbf{Y}_{c} \mathbf{Y}_{c}^{\prime}\), and the columns of \(\mathbf{V}\) are the corresponding eigenvectors of \(\mathbf{Y}_{c}^{\prime} \mathbf{Y}_{c}\).

The product \(\mathbf{U} \boldsymbol{\Lambda}\) in (16.54) is equal to \(\mathbf{Z}\), the matrix of principal component scores in (16.51). To see this we multiply (16.54) by \(\mathbf{V}\), which is orthogonal because it contains the (normalized) eigenvectors of the symmetric matrix \(\mathbf{Y}_{c}^{\prime} \mathbf{Y}_{c}\) (see Section 2.11.6). This gives
\[
\begin{equation*}
\mathbf{Y}_{c} \mathbf{V}=\mathbf{U} \boldsymbol{\Lambda} \mathbf{V}^{\prime} \mathbf{V}=\mathbf{U} \boldsymbol{\Lambda} \tag{16.55}
\end{equation*}
\]

By (10.17), \(\mathbf{Y}_{c}^{\prime} \mathbf{Y}_{c}\) is equal to \((n-1) \mathbf{S}\). By (2.106), eigenvectors of \((n-1) \mathbf{S}\) are also eigenvectors of \(\mathbf{S}\). Thus \(\mathbf{V}\) is the same as \(\mathbf{A}\) in (16.51), which contains eigenvectors of \(\mathbf{S}\). Hence, \(\mathbf{Y}_{c} \mathbf{V}\) in (16.55) becomes
\[
\begin{array}{rlr}
\mathbf{Y}_{c} \mathbf{V} & =\mathbf{Y}_{c} \mathbf{A} \\
& =\mathbf{Z} \quad & {[\text { by }(16.51)]} \\
& =\mathbf{U} \mathbf{\Lambda} & {[\text { by }(16.55)] .}
\end{array}
\]

We can therefore write (16.54) as
\[
\begin{equation*}
\mathbf{Y}_{c}=\mathbf{U} \mathbf{\Lambda} \mathbf{V}^{\prime}=\mathbf{Z} \mathbf{V}^{\prime}=\mathbf{Z} \mathbf{A}^{\prime} \tag{16.56}
\end{equation*}
\]

Thus the singular value decomposition of \(\mathbf{Y}_{c}\) gives the same factoring as the expression in (16.52) based on principal components.

\subsection*{16.3.4 Coordinates}

In this section, we consider the coordinates for the methods of Sections 16.3.2 and 16.3.3. Let us return to (16.53), the two-dimensional representation of \(\mathbf{Y}_{c}\) based on principal components (which is the same representation as that based on the singular value decomposition):
\[
\mathbf{Y}_{c} \cong \mathbf{Z}_{2} \mathbf{A}_{2}^{\prime}=\left(\begin{array}{cc}
z_{11} & z_{12}  \tag{16.57}\\
z_{21} & z_{22} \\
\vdots & \vdots \\
z_{n 1} & z_{n 2}
\end{array}\right)\left(\begin{array}{cccc}
a_{11} & a_{21} & \cdots & a_{p 1} \\
a_{12} & a_{22} & \cdots & a_{p 2}
\end{array}\right)
\]

The elements of (16.57) are of the form
\[
y_{i j}-\bar{y}_{j} \cong z_{i 1} a_{j 1}+z_{i 2} a_{j 2}, \quad i=1,2, \ldots, n ; j=1,2, \ldots, p
\]

Thus each observation is represented as a linear combination, the coordinates (coefficients) being the elements of the vector \(\left(z_{i 1}, z_{i 2}\right)\) and the axes being the elements of the vector \(\left(a_{j 1}, a_{j 2}\right)\). We therefore plot the points \(\left(z_{i 1}, z_{i 2}\right), i=1,2, \ldots, n\), and the points \(\left(a_{j 1}, a_{j 2}\right), j=1,2, \ldots, p\). To distinguish them and to show relationship of the points to the axes, the points \(\left(a_{j 1}, a_{j 2}\right)\) are connected to the origin with a straight line forming an arrow. If necessary, the scale of the points \(\left(a_{j 1}, a_{j 2}\right)\) could be adjusted to be compatible with that of the principal components \(\left(z_{i 1}, z_{i 2}\right)\).

The Euclidean distance between two points \(\left(z_{i 1}, z_{i 2}\right)\) and \(\left(z_{k 1}, z_{k 2}\right)\) is approximately equal to the distance between the corresponding points (rows) \(\mathbf{y}_{i}^{\prime}\) and \(\mathbf{y}_{k}^{\prime}\) in the data matrix \(\mathbf{Y}\). If all of the principal components were used, as in (16.51) and (16.52), the distance would be the same, but with only two principal components, the distance is an approximation.

The cosine of the angle between the arrows (lines) drawn to each pair of axis points \(\left(a_{j 1}, a_{j 2}\right)\) and ( \(a_{k 1}, a_{k 2}\) ) shows the correlation between the two corresponding variables [see (3.14) and (3.15)]. Thus a small angle between two vectors indicates that the two variables are highly correlated, two variables whose vectors form a \(90^{\circ}\) angle are uncorrelated, and an angle greater than \(90^{\circ}\) indicates that the variables are negatively correlated.

The values of the \(p\) variables in the \(i\) th observation vector \(y_{i}\) (corrected for means) are related to the perpendicular projection of the point \(\left(z_{1 i}, z_{2 i}\right)\) on the \(p\) vectors from the origin to the points \(\left(a_{j 1}, a_{j 2}\right)\) representing variables. The further from the origin a projection falls on an arrow, the larger the value of the observation on that variable. Hence the vectors will be oriented toward the observations that have larger values on the corresponding variables.

\section*{- EXAMPLE 16.3.4}

Using the city crime data of Table 15.1, we illustrate the principal components approach. The first two eigenvectors of the sample covariance matrix \(\mathbf{S}\) are given by
\[
\mathbf{A}_{2}=\left(\begin{array}{rr}
.002 & .008 \\
.017 & .014 \\
.182 & .689 \\
.104 & .221 \\
.747 & -.240 \\
.612 & -.109 \\
.153 & .638
\end{array}\right)
\]

The matrix of the first two principal components is given by
\[
\mathbf{Z}_{2}=\mathbf{Y}_{c} \mathbf{A}_{2}=\left(\begin{array}{rr}
-317.2 & -156.1 \\
-491.8 & 192.4 \\
-650.0 & 227.6 \\
141.7 & -133.8 \\
342 & -69.3 \\
312.2 & 164.1 \\
-514.7 & -166.4 \\
58.6 & -239.7 \\
-24.5 & 25.9 \\
75.7 & 40.1 \\
678.2 & 7.1 \\
-192.4 & 163.4 \\
542.7 & 194.8 \\
233.1 & -266.8 \\
-343.8 & -184.3 \\
150.4 & 200.9
\end{array}\right) .
\]

The coordinates for the sixteen cities are found in \(\mathbf{Z}_{2}\), and the coordinates for the seven variables are found in \(\mathbf{A}_{2}\). The plot of the city and variable points could be given, but because of the different scaling for the observation points (spread out) and the variable points (clustered at the origin), the plot is not illuminating. Suitable scaling of the eigenvectors in \(\mathbf{A}_{2}\) would enable the arrows representing the variables to pass through the points (see Example 16.3.5).

\subsection*{16.3.5 Other Methods}

The singular value decomposition of \(\mathbf{Y}_{c}\) is given in (16.54) as
\[
\begin{equation*}
\mathbf{Y}_{c}=\mathbf{U} \boldsymbol{\Lambda} \mathbf{V}^{\prime} \tag{16.58}
\end{equation*}
\]

In Section 16.3.3, it was shown that \(\mathbf{U} \boldsymbol{\Lambda}=\mathbf{Z}\) and \(\mathbf{V}=\mathbf{A}\) [see (16.56)], so that (16.58) can be written as
\[
\mathbf{Y}_{c}=(\mathbf{U} \mathbf{\Lambda}) \mathbf{V}^{\prime}=\mathbf{Z} \mathbf{A}^{\prime}
\]
which is equivalent to the principal component solution \(\mathbf{Y}_{c}=\mathbf{Z} \mathbf{A}^{\prime}\) in (16.52). Alternative factorings may be of interest. Two that have been considered are
\[
\begin{align*}
& \mathbf{Y}_{c}=\mathbf{U}\left(\boldsymbol{\Lambda} \mathbf{V}^{\prime}\right)  \tag{16.59}\\
& \mathbf{Y}_{c}=\left(\mathbf{U} \boldsymbol{\Lambda}^{1 / 2}\right)\left(\boldsymbol{\Lambda}^{\mathbf{1 / 2}} \mathbf{V}^{\prime}\right) \tag{16.60}
\end{align*}
\]

If we denote the submatrices consisting of the first two columns of \(\mathbf{U}\) and \(\mathbf{V}\) as \(\mathbf{U}_{2}\) and \(\mathbf{V}_{2}\), respectively, and define \(\boldsymbol{\Lambda}_{2}=\operatorname{diag}\left(\lambda_{1}, \lambda_{2}\right)\), then the two-dimensional
representations of (16.59) and (16.60) are
\[
\begin{align*}
\mathbf{Y}_{c} & \cong \mathbf{U}_{2}\left(\mathbf{\Lambda}_{2} \mathbf{V}_{2}^{\prime}\right) \\
& =\left(\begin{array}{cc}
u_{11} & u_{12} \\
u_{21} & u_{22} \\
\vdots & \vdots \\
u_{n 1} & u_{n 2}
\end{array}\right)\left(\begin{array}{llll}
\lambda_{1} v_{11} & \lambda_{1} v_{21} & \cdots & \lambda_{1} v_{p 1} \\
\lambda_{2} v_{12} & \lambda_{2} v_{22} & \cdots & \lambda_{2} v_{p 2}
\end{array}\right),  \tag{16.61}\\
\mathbf{Y}_{c} & \cong\left(\mathbf{U}_{2} \mathbf{\Lambda}_{2}^{1 / 2}\right)\left(\mathbf{\Lambda}_{2}^{1 / 2} \mathbf{V}^{\prime}\right) \\
& =\left(\begin{array}{cc}
\sqrt{\lambda_{1}} u_{11} & \sqrt{\lambda_{2}} u_{12} \\
\sqrt{\lambda_{1}} u_{21} & \sqrt{\lambda_{2}} u_{22} \\
\vdots & \vdots \\
\sqrt{\lambda_{1}} u_{n 1} & \sqrt{\lambda_{2}} u_{n 2}
\end{array}\right)\left(\begin{array}{cccc}
\sqrt{\lambda_{1}} v_{11} & \sqrt{\lambda_{1}} v_{21} & \cdots & \sqrt{\lambda_{1}} v_{p 1} \\
\sqrt{\lambda_{2}} v_{12} & \sqrt{\lambda_{2}} v_{22} & \cdots & \sqrt{\lambda_{2}} v_{p 2}
\end{array}\right) . \tag{16.62}
\end{align*}
\]

For the biplot arising from (16.61), we plot the set of points ( \(u_{i 1}, u_{i 2}\) ), \(i=1,2, \ldots\), \(n\), and the set of points \(\left(\lambda_{1} v_{j 1}, \lambda_{2} v_{j 2}\right), j=1,2, \ldots, p\), with the latter points connected to the origin by an arrow to show the axes. For the biplot arising from (16.62), we plot the set of points \(\left(\sqrt{\lambda_{1}} u_{i 1}, \sqrt{\lambda_{2}} u_{i 2}\right), i=1,2, \ldots, n\), and the set of points \(\left(\sqrt{\lambda_{1}} v_{j 1}, \sqrt{\lambda_{2}} v_{j 2}\right), j=1,2, \ldots, p\), with the latter points connected to the origin with an arrow.

The presence of \(\lambda_{1}\) and \(\lambda_{2}\) in (16.61) and (16.62) provides scaling that is absent in (16.57). For many data sets the scaling in (16.62) will be adequate with no further adjustment.

If we write (16.59) in the form
\[
\begin{equation*}
\mathbf{Y}_{c}=\mathbf{U}\left(\mathbf{\Lambda} \mathbf{V}^{\prime}\right)=\mathbf{U}(\mathbf{V} \boldsymbol{\Lambda})^{\prime}=\mathbf{\mathbf { U H } ^ { \prime }} \tag{16.63}
\end{equation*}
\]
then
\[
\begin{gather*}
\mathbf{U} \mathbf{U}^{\prime}=\left(\frac{1}{n-1}\right) \mathbf{Y}_{c} \mathbf{S}^{-1} \mathbf{Y}_{c}^{\prime}  \tag{16.64}\\
\mathbf{H} \mathbf{H}^{\prime}=(n-1) \mathbf{S} \tag{16.65}
\end{gather*}
\]
(see Problem 16.10). With suitable scaling of the eigenvectors in \(\mathbf{U}\) and \(\mathbf{V}\), we could eliminate the coefficients involving \(n-1\) from (16.64) and (16.65).

By (16.64) (with scaling to eliminate \(n-1\) ), the (Euclidean) distance ( \(\mathbf{u}_{i}-\) \(\left.\mathbf{u}_{k}\right)^{\prime}\left(\mathbf{u}_{i}-\mathbf{u}_{k}\right)\) between two points \(\mathbf{u}_{i}\) and \(\mathbf{u}_{k}\) is equal to the Mahalanobis distance \(\left(\mathbf{y}_{i}-\mathbf{y}_{k}\right)^{\prime} \mathbf{S}^{-1}\left(\mathbf{y}_{i}-\mathbf{y}_{k}\right)\) between the corresponding points \(\mathbf{y}_{i}\) and \(\mathbf{y}_{k}\) in the data matrix \(\mathbf{Y}\) :
\[
\begin{equation*}
\left(\mathbf{u}_{i}-\mathbf{u}_{k}\right)^{\prime}\left(\mathbf{u}_{i}-\mathbf{u}_{k}\right)=\left(\mathbf{y}_{i}-\mathbf{y}_{k}\right)^{\prime} \mathbf{S}^{-1}\left(\mathbf{y}_{i}-\mathbf{y}_{k}\right) \tag{16.66}
\end{equation*}
\]
(see Problem 16.11). By (16.65), the covariance \(s_{j k}\) between the \(j\) th and \(k\) th variables (columns of \(\mathbf{Y}\) ) is given by
\[
\begin{equation*}
s_{j k}=\mathbf{h}_{j}^{\prime} \mathbf{h}_{k}, \tag{16.67}
\end{equation*}
\]
where \(\mathbf{h}_{j}^{\prime}\) and \(\mathbf{h}_{k}^{\prime}\) are rows of \(\mathbf{H}\). By (3.14) and (3.15), this can be converted to the correlation
\[
\begin{equation*}
r_{j k}=\cos \theta=\frac{\mathbf{h}_{j}^{\prime} \mathbf{h}_{k}}{\sqrt{\left(\mathbf{h}_{j}^{\prime} \mathbf{h}_{j}\right)\left(\mathbf{h}_{k}^{\prime} \mathbf{h}_{k}\right)}} \tag{16.68}
\end{equation*}
\]
so that the angle between the two vectors \(\mathbf{h}_{j}\) and \(\mathbf{h}_{k}\) is related to the correlation between the \(j\) th and \(k\) th variables.

The two-dimensional representation of \(\mathbf{u}_{i}\) and \(\mathbf{h}_{j}\) in (16.61) has the approximate Mahalanobis distance and correlation properties discussed earlier.

\section*{EXAMPLE 16.3.5}

Using the city crime data of Table 15.1 , we illustrate the singular value decomposition method with the factorings in (16.61) and (16.62). The matrices \(\mathbf{U}_{2}, \boldsymbol{\Lambda}_{2}\), and \(\mathbf{V}_{2}\) are
\[
\begin{aligned}
& \mathbf{U}_{2}=\left(\begin{array}{rr}
-.211 & -.230 \\
-.327 & .284 \\
-.432 & .335 \\
.094 & -.197 \\
.227 & -.102 \\
.208 & .242 \\
-.342 & -.245 \\
.039 & -.353 \\
-.016 & .038 \\
.050 & .059 \\
.451 & .010 \\
-.128 & .241 \\
.361 & .287 \\
.155 & -.393 \\
.229 & -.272 \\
.100 & .296
\end{array}\right), \quad \mathbf{V}_{2}=\left(\begin{array}{rr}
.002 & .008 \\
.017 & .014 \\
.182 & .689 \\
.104 & .221 \\
.747 & -.240 \\
.612 & -.109 \\
.153 & .639
\end{array}\right), \\
& \mathbf{\Lambda}_{\mathbf{2}}=\operatorname{diag}(1503.604,678.615) .
\end{aligned}
\]

By (16.61), the two-dimensional representation is given by plotting the rows of \(\mathbf{U}_{2}\) and the rows of \(\mathbf{V}_{2} \boldsymbol{\Lambda}_{2}\) (or the columns of \(\boldsymbol{\Lambda}_{2} \mathbf{V}_{2}^{\prime}\) ). For \(\mathbf{V}_{2} \boldsymbol{\Lambda}_{2}\) we have
\[
\mathbf{V}_{2} \boldsymbol{\Lambda}_{2}=\left(\begin{array}{rr}
3.0 & 5.2 \\
25.4 & 9.5 \\
273.6 & 467.5 \\
156.3 & 150.1 \\
1123.4 & -162.6 \\
920.0 & -74.1 \\
229.3 & 432.9
\end{array}\right)
\]

As in Example 16.3.4, the plot of the observation points and variable points is not useful, again because the scale for the observation points differs greatly from the scale for the variable points.

For (16.62), we obtain
\[
\mathbf{U}_{2} \mathbf{\Lambda}_{2}^{1 / 2}=\left(\begin{array}{rr}
-8.18 & -5.99 \\
-12.68 & 7.39 \\
-16.76 & 8.74 \\
3.65 & -5.14 \\
8.82 & -2.66 \\
8.05 & 6.30 \\
-13.27 & -6.39 \\
1.51 & -9.20 \\
-.63 & .99 \\
1.95 & 1.54 \\
17.49 & .27 \\
-4.96 & 6.27 \\
13.99 & 7.48 \\
6.01 & -10.24 \\
-8.87 & -7.08 \\
3.88 & 7.71
\end{array}\right), \quad \mathbf{V}_{2} \mathbf{\Lambda}_{2}^{1 / 2}=\left(\begin{array}{rr}
.08 & .20 \\
.66 & .37 \\
7.06 & 17.95 \\
4.03 & 5.76 \\
28.97 & -6.24 \\
23.73 & -2.85 \\
5.91 & 16.62
\end{array}\right) .
\]

The plot of the coordinates is given in Figure 16.11. For this data set, the factoring given by (16.62) and illustrated in Figure 16.11 is preferred because it plots both observation and variable points on the same scale. As previously noted, the factoring discussed in Example 16.3.4 and the factoring discussed at the beginning of this example would need adjustments in scaling in order to yield useful biplots.

\section*{PROBLEMS}
16.1 In step 2 of the algorithm for metric scaling in Section 16.1.2, the matrix \(\mathbf{B}=\) \(\left(b_{i j}\right)\) is defined in terms of \(\mathbf{A}=\left(a_{i j}\right)\) as \(b_{i j}=a_{i j}-\bar{a}_{i .}-\bar{a}_{. j}+\bar{a}_{. .}\). Show that \(b_{i j}\) in \(\mathbf{B}=\left(\mathbf{I}-\frac{1}{n} \mathbf{J}\right) \mathbf{A}\left(\mathbf{I}-\frac{1}{n} \mathbf{J}\right)\) in (16.2) is equivalent to \(b_{i j}=a_{i j}-\bar{a}_{i .}-\) \(\bar{a}_{. j}+\bar{a}_{. .}\).
16.2 Verify the result stated in step 2 of the algorithm in Section 16.1.2, namely, that there exists a \(q\)-dimensional configuration \(\mathbf{z}_{1}, \mathbf{z}_{2}, \ldots, \mathbf{z}_{n}\) such that \(d_{i j}=\delta_{i j}\) if and only if \(\mathbf{B}\) is positive semidefinite of rank \(q\). Use the following approach.
(a) Assuming the existence of \(\mathbf{z}_{1}, \mathbf{z}_{2}, \ldots, \mathbf{z}_{n}\) such that \(\delta_{i j}^{2}=d_{i j}^{2}=\left(\mathbf{z}_{i}-\right.\) \(\left.\mathbf{z}_{j}\right)^{\prime}\left(\mathbf{z}_{i}-\mathbf{z}_{j}\right)\), show that \(\mathbf{B}\) is positive semidefinite.
(b) Assuming \(\mathbf{B}\) is positive semidefinite, show that there exist \(\mathbf{z}_{1}, \mathbf{z}_{2}, \ldots, \mathbf{z}_{n}\) such that \(d_{i j}^{2}=\left(\mathbf{z}_{i}-\mathbf{z}_{j}\right)^{\prime}\left(\mathbf{z}_{i}-\mathbf{z}_{j}\right)=\delta_{i j}^{2}\).

Figure 16.11 Plot of \(\mathbf{U}_{2} \Lambda_{2}^{1 / 2}\) and \(\mathbf{V}_{2} \Lambda_{2}^{1 / 2}\) for the City Crime Data in Table 15.1.
16.3 (a) Show that \(\mathbf{r}=\sum_{j=1}^{b} p_{. j} \mathbf{c}_{j}\) in (16.20) is the same as \(\mathbf{r}=\left(p_{1 .}, p_{2 .}, \ldots\right.\), \(\left.p_{a .}\right)^{\prime}\) in (16.9).
(b) Show that \(\mathbf{c}^{\prime}=\sum_{i=1}^{a} p_{i .} \mathbf{r}_{i}^{\prime}\) in (16.21) is equivalent to \(\mathbf{c}^{\prime}=\left(p_{.1}, p_{.2}, \ldots\right.\), \(p_{. b}\) ) in (16.10).
16.4 Show that \(\mathbf{j}^{\prime} \mathbf{r}=\mathbf{c}^{\prime} \mathbf{j}=1\) as in (16.22).
16.5 Show that the chi-square statistic in (16.26) is equal to that in (16.25).
16.6 (a) Show that the chi-square statistic in (16.27) is equal to that in (16.25).
(b) Show that the chi-square statistic in (16.28) is equal to that in (16.25).
16.7 (a) Show the chi-square statistic in (16.29) is equal to that in (16.27).
(b) Show the chi-square statistic in (16.30) is equal to that in (16.28).
16.8 (a) Show that \(\mathbf{R}-\mathbf{j c}^{\prime}=\mathbf{D}_{r}^{-1}\left(\mathbf{P}-\mathbf{r c}^{\prime}\right)\) as in (16.41).
(b) Show that \(\mathbf{C}-\mathbf{r j}^{\prime}=\mathbf{D}_{c}^{-1}\left(\mathbf{P}-\mathbf{r c}^{\prime}\right)\) as in (16.42).
16.9 Show that if all the principal components were used, the distance between \(\mathbf{z}_{i}\) and \(z_{k}\) would be the same as between \(\mathbf{y}_{i}\) and \(\mathbf{y}_{k}\), as noted in Section 16.3.4.
16.10 (a) Show that \(\mathbf{U U}^{\prime}=\mathbf{Y}_{c} \mathbf{S}^{-1} \mathbf{Y}_{c}^{\prime} /(n-1)\) as in (16.64).
(b) Show that \(\mathbf{H} \mathbf{H}^{\prime}=(n-1) \mathbf{S}\) as in (16.65).
16.11 Show that \(\left(\mathbf{u}_{i}-\mathbf{u}_{k}\right)^{\prime}\left(\mathbf{u}_{i}-\mathbf{u}_{k}\right)=\left(\mathbf{y}_{i}-\mathbf{y}_{k}\right)^{\prime} \mathbf{S}^{-1}\left(\mathbf{y}_{i}-\mathbf{y}_{k}\right)\), as in (16.66).
16.12 In Table 16.15, we have road distances between major UK towns (Hand et al. 1994, p. 346). The towns are as follows:
\(\mathrm{A}=\) Aberdeen, \(\mathrm{B}=\) Birmingham, \(\mathrm{C}=\) Brighton, \(\mathrm{D}=\) Bristol, \(\mathrm{E}=\) Cardiff, F = Carlisle, \(\mathrm{G}=\) Dover, \(\mathrm{H}=\) Edinburgh, \(\mathrm{I}=\) Fort William, \(\mathrm{J}=\) Glasgow, \(\mathrm{K}=\) Holyhead, \(\mathrm{L}=\) Hull, \(\mathrm{M}=\) Inverness, \(\mathrm{N}=\) Leeds, \(\mathrm{O}=\) Liverpool, \(\mathrm{P}=\) London, Q \(=\) Manchester, \(\mathrm{R}=\) Newcastle, \(\mathrm{S}=\) Norwich, \(\mathrm{T}=\) Nottingham, \(\mathrm{U}=\) Penzance, \(\mathrm{V}=\) Plymouth, \(\mathrm{W}=\) Sheffield.
(a) Find the matrix \(\mathbf{B}\) as in (16.2).
(b) Using the spectral decomposition, find the first two columns of the matrix Z as in (16.4).
(c) Create a metric multidimensional scaling plot of the first two dimensions. What do you notice about the positions of the cities?
16.13 Zhang, Helander, and Drury (1996) analyzed a \(43 \times 43\) similarity matrix for 43 descriptors of comfort, such as calm, tingling, restful, etc. For the similarity matrix, see the Wiley ftp site (Appendix C).
(a) Carry out a metric multidimensional scaling analysis and plot the first two dimensions. What pattern is seen in the plot?
(b) For an alternative approach, carry out a cluster analysis of the configuration of points found in part (a), using Ward's method. Create a dendrogram of the cluster solution. How many clusters are indicated?
16.14 Use the politics data of Table 16.16 (Everitt 1987, Table 6.7). Two subjects assessed the degree of dissimilarity between World War II politicians. The data matrix represents the sum of the dissimilarities between the two subjects.
(a) For \(k=6\), create an initial configuration of points by choosing twelve random observations taken from a multivariate normal distribution with mean vector 0 and covariance matrix \(\mathbf{I}_{6}\).
(b) Carry out a nonmetric multidimensional scaling analysis using the seeds found in part (a). Find the value of the STRESS statistic.
(c) Repeat parts (a) and (b) for \(k=1, \ldots, 5\). Plot the STRESS values against the values of \(k\). How many dimensions should be kept? Plot the final configuration of points with two dimensions.

(d) Repeat parts (a)-(c) using an initial configuration of points from a multivariate normal with different mean vector and covariance matrix from those in part (a). How many dimensions should be kept? Plot the final configuration of points with two dimensions. How does this solution compare to that in part (c)?
(e) Repeat parts (a)-(c) using an initial configuration of points from a uniform distribution over \((0,1)\). How many dimensions should be kept? Plot the final configuration of points with two dimensions.
(f) Repeat part (e) using as initial configuration of points the metric multidimensional scaling solution found by treating the ordinal measurements as continuous. How many dimensions should be kept? Plot the final configuration of points with two dimensions.
16.15 In Table 16.17 we have the months of birth and death for 1281 people (Andrews and Herzberg 1985, Table 71.2).
(a) Find the correspondence matrix \(\mathbf{P}\) as in (16.8).
(b) Find the matrices \(\mathbf{R}\) and \(\mathbf{C}\), as in (16.15) and (16.19).
(c) Perform a chi-square test for independence between birth month and death month.
(d) Plot the row and column deviations as in Example 16.2.4.
16.16 In Table 16.18, we have a cross-classification of crimes in Norway in 1984 categorized by type and site (Clausen 1988, p. 9).

Table 16.17 Birth and Death Months of 1281 People
\begin{tabular}{lrrrrrrrrrrrrr}

\end{tabular}
(a) Find the correspondence matrix \(\mathbf{P}\) as in (16.8).
(b) Find the matrices \(\mathbf{R}\) and \(\mathbf{C}\) as in (16.15) and (16.19).
(c) Perform a chi-square test for independence between type of crime and site.
(d) Plot the row and column deviations as in Example 16.2.4.
16.17 In Table 16.19, we have a six-way contingency table (Andrews and Herzberg 1985, Table 34.1). Carry out a multiple correspondence analysis.
(a) Set up an indicator matrix \(G\) and find the Burt matrix \(G^{\prime} G\).
(b) Perform a correspondence analysis on the Burt matrix found in part (a) and plot the coordinates.
(c) What associations are present?
16.18 Use the protein consumption data of Table 15.7.
(a) Create a biplot using the principal components approach in (16.53) or (16.57).
(b) Create a biplot using the singular value decomposition approach with the factoring as in (16.61).
(c) Create a biplot using the singular value decomposition approach with the factoring as in (16.62).
(d) Which of the three biplots best represents the data?
16.19 Use the perception data of Table 13.1.
(a) Create a biplot using the principal components approach in (16.53) or (16.57).
(b) Create a biplot using the singular value decomposition approach with the factoring as in (16.61).
(c) Create a biplot using the singular value decomposition approach with the factoring as in (16.62).
(d) Which of the three biplots best represents the data?

\end{tabular}
16.20 Use the cork data of Table 6.21.
(a) Create a biplot using the principal components approach in (16.53) or (16.57).
(b) Create a biplot using the singular value decomposition approach with the factoring as in (16.61).
(c) Create a biplot using the singular value decomposition approach with the factoring as in (16.62).
(d) Which of the three biplots best represents the data?

\section*{Appendix A}

\section*{Tables}

Table A.1: Upper Percentiles for \(\sqrt{b_{1}}\)
Table A.2: Coefficients for Transforming \(\sqrt{b_{1}}\) to a Standard Normal
Table A.3: Percentiles for \(b_{2}\)
Table A.4: Percentiles for D'Agostino's Test for Normality
Table A.5: Upper Percentiles for \(b_{1, p}\) and Upper and Lower Percentiles for \(b_{2, p}\)
Table A.6: Upper Percentiles for Test of Single Multivariate Normal Outlier
Table A.7: Upper Percentage Points of Hotelling's \(T^{2}\) Distribution
Table A.8: Bonferroni \(t\)-Values, \(t_{\alpha / 2 k, \nu}, \alpha=0.05\)
Table A.9: Lower Critical Values of Wilks' \(\Lambda, \alpha=0.05\)
Table A.10: Upper Critical Values for Roy's Test, \(\alpha=.05\)
Table A.11: Upper Critical Values of Pillai's Statistic \(V^{(s)}, \alpha=.05\)
Table A.12: Upper Critical Values for the Lawley-Hotelling Statistic, \(\alpha=.05\)
Table A.13: Orthogonal Polynomial Contrasts
Table A.14: Test for Equal Covariance Matrices, \(\alpha=0.05\)
Table A.15: Test for Independence of \(p\) Variables

Table A. 1 Upper Percentiles for \(\sqrt{b_{1}}\)
\[
\sqrt{b_{1}}=\frac{\sqrt{n} \sum_{i=1}^{n}\left(y_{i}-\bar{y}\right)^{3}}{\left[\sum_{i=1}^{n}\left(y_{i}-\bar{y}\right)^{2}\right]^{3 / 2}}
\]

The sampling distribution of \(\sqrt{b_{1}}\) is symmetric about zero, and the lower percentage points corresponding to negative skewness are given by the negative of the table values. Reject the hypothesis of normality if \(\sqrt{b_{1}}\) is greater than the table value or less than the negative of the table value.
\begin{tabular}{rcrcccc}

Table A. 6 Upper Percentiles for Test of Single Multivariate Normal Outlier
Upper percentage points for the test statistic
\[
D_{(n)}^{2}=\max _{l \leq i \leq n}\left(\mathbf{y}_{i}-\overline{\mathbf{y}}\right)^{\prime} \mathbf{S}^{-1}\left(\mathbf{y}_{i}-\overline{\mathbf{y}}\right) .
\]

This tests for a single outlier in a sample of size \(n\) from a multivariate normal distribution. Reject and conclude that the outlier is significant if \(D_{(n)}^{2}\) exceeds the table value.

Table A. 10 Upper Critical Values for Roy's Test, \(\alpha=.05\)
Roy's test statistic is given by
\[
\theta=\frac{\lambda_{1}}{1+\lambda_{1}}
\]
where \(\lambda_{1}\) is the largest eigenvalue of \(\mathbf{E}^{-1} \mathbf{H}\). The parameters are
\[
s=\min \left(\nu_{H}, p\right), \quad m=\frac{\left|\nu_{H}-p\right|-1}{2}, \quad N=\frac{\nu_{E}-p-1}{2} .
\]

Reject \(H_{0}\) if \(\theta>\) table value.

\end{tabular}

Note: Table contains upper percentage points for
\[
-2 \ln M=\nu\left(k \ln |\mathbf{S}|-\sum_{i=1}^{k} \ln \left|\mathbf{S}_{i}\right|\right)
\]
for \(k\) samples, each with \(\nu\) degrees of freedom. Reject \(H_{0}: \boldsymbol{\Sigma}_{1}=\boldsymbol{\Sigma}_{2}=\cdots=\boldsymbol{\Sigma}_{k}\) if \(-2 \ln M>\) table value.

Table A. 15 Test for Independence of \(p\) Variables
Upper percentage points for
\[
\boldsymbol{u}^{\prime}=-\left(\nu-\frac{2 p+5}{6}\right) \ln \left(\frac{|\mathbf{S}|}{s_{11} \cdots s_{p p}}\right)=-\left(\nu-\frac{2 p+5}{6}\right) \ln |\mathbf{R}|
\]
where \(\nu\) is the degrees of freedom of \(\mathbf{S}\) or \(\mathbf{R}\). Reject independence if \(u^{\prime}\) is greater than table value. The \(\chi_{\alpha}^{2}\) values are shown for comparison, since \(u^{\prime}\) is approximately \(\chi^{2}\) distributed with \(f=\frac{1}{2} p(p-1)\) degrees of freedom.

(b) \(\mathbf{C}^{\prime} \mathbf{A C}=\left(\begin{array}{rrr}-2 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 4\end{array}\right)\)
(c) \(\mathbf{C D C}^{\prime}=\left(\begin{array}{lll}3 & 1 & 1 \\ 1 & 0 & 2 \\ 1 & 2 & 0\end{array}\right)=\mathbf{A}\)
2.21 Eigenvalues: \(1,3, \mathrm{C}=\left(\begin{array}{rr}-.7071 & -.7071 \\ -.7071 & .7071\end{array}\right)\),
\[
\mathbf{A}^{1 / 2}=\mathbf{C D}^{1 / 2} \mathbf{C}^{\prime}=\left(\begin{array}{rr}
1.3660 & -.3660 \\
-.3660 & 1.3660
\end{array}\right)
\]
2.22 (a) The spectral decomposition of \(\mathbf{A}\) is given by \(\mathbf{A}=\mathbf{C D C}^{\prime}\), where \(\mathbf{C}=\)
\[
\left(\begin{array}{rrr}
.455 & -.580 & .675 \\
.846 & .045 & -.531 \\
.278 & .813 & .511
\end{array}\right) \text { and } \mathbf{D}=\operatorname{diag}(13.542,3.935,-2.477)
\]
(b) The spectral decomposition of \(\mathbf{A}^{2}\) is given by \(\mathbf{A}^{2}=\mathbf{C D C}^{\prime}\), where \(\mathbf{C}\) is the same as in part (a) and \(\mathbf{D}=\operatorname{diag}(183.378,15.486,6.135)\). Note that the diagonal elements of \(\mathbf{D}\) are the squares of the diagonal elements of D in part (a).
(c) The spectral decomposition of \(\mathbf{A}^{-1}\) is given by \(\mathbf{A}^{-1}=\mathbf{C D C}^{\prime}\), where \(\mathbf{C}=\left(\begin{array}{rrr}-.580 & .455 & .675 \\ .045 & .846 & -.531 \\ .813 & .278 & .511\end{array}\right)\) and \(\mathbf{D}=\operatorname{diag}(.254, .074,-.404)\).
The diagonal elements of \(\mathbf{D}\) are the reciprocals of those of \(\mathbf{D}\) in part (a). The first two columns of \(\mathbf{C}\) have been interchanged to match the interchange of the corresponding elements of \(\mathbf{D}\); that is, \(\mathbf{D}=\left(1 / \lambda_{2}, 1 / \lambda_{1}, 1 / \lambda_{3}\right)\).
2.23 \(\mathbf{A}=\mathbf{U D V}^{\prime}\), where \(\mathbf{D}=\operatorname{diag}(13.161,7,000,3.433)\),
\[
\mathbf{U}=\left(\begin{array}{rrr}
.282 & -.730 & .424 \\
.591 & -.146 & .184 \\
-.225 & .404 & .886 \\
.721 & .531 & -.040
\end{array}\right), \quad \mathbf{V}=\left(\begin{array}{rrr}
.856 & -.015 & .517 \\
-.156 & .946 & .284 \\
.494 & .324 & -.807
\end{array}\right)
\]
2.24 (a) \(\mathbf{j}^{\prime} \mathbf{a}=(1) a_{1}+(1) a_{2}+\cdots+(1) a_{n}=\sum_{i} a_{i}=\mathbf{a}^{\prime} \mathbf{j}\)
(b) \(\mathbf{j}^{\mathbf{\prime}} \mathbf{A}=\left[(1) a_{11}+(1) a_{21}+\cdots+(1) a_{n 1}, \ldots,(1) a_{1 p}\right.\) \(\left.+(1) a_{2 p}+\cdots+(1) a_{n p}\right]\) \(=\left(\sum_{i} a_{i 1}, \sum_{i} a_{i 2}, \ldots, \sum_{i} a_{i p}\right)\)
(c) \(\mathbf{A} \mathbf{j}=\left(\begin{array}{rlllll}(1) a_{11} & + & (1) a_{12} & + & \cdots & + \\ (1) a_{1 p} \\ (1) a_{21} & + & (1) a_{22} & + & \cdots & + \\ \vdots & & & \vdots & & \\ (1) a_{2 p} \\ (1) a_{n 1} & + & (1) a_{n 2} & + & \cdots & + \\ & (1) a_{n p}\end{array}\right)=\left(\begin{array}{c}\sum_{j} a_{1 j} \\ \sum_{j} a_{2 j} \\ \vdots \\ \sum_{j} a_{n j}\end{array}\right)\)
\(2.25 \begin{aligned}(x-y)^{\prime}(x-y) & =\left(x^{\prime}-y^{\prime}\right)(x-y)=x^{\prime} x-x^{\prime} y-y^{\prime} x+y^{\prime} y \\ & =x^{\prime} \mathbf{x}-2 \mathbf{x}^{\prime} \mathbf{y}+\mathbf{y}^{\prime} \mathbf{y}\end{aligned}\)

\end{array}\right) \\
& 2.32\left(\mathbf{B}+\mathbf{c c}^{\prime}\right)\left(\mathbf{B}^{-1}-\frac{\mathbf{B}^{-1} \mathbf{c c}^{\prime} \mathbf{B}^{-1}}{1+\mathbf{c}^{\prime} \mathbf{B}^{-1} \mathbf{c}}\right) \\
& =\mathbf{I}-\frac{\mathbf{c c}^{\prime} \mathbf{B}^{-1}}{1+\mathbf{c}^{\prime} \mathbf{B}^{-1} \mathbf{c}}+\mathbf{c c}^{\prime} \mathbf{B}^{-1}-\frac{\mathbf{c}\left(\mathbf{c}^{\prime} \mathbf{B}^{-1} \mathbf{c}\right) \mathbf{c}^{\prime} \mathbf{B}^{-1}}{1+\mathbf{c}^{\prime} \mathbf{B}^{-1} \mathbf{c}} \quad[\mathrm{by}(2.26)] \\
& =\mathbf{I}-\mathbf{c c}^{\prime} \mathbf{B}^{-1}\left(\frac{1+\mathbf{c}^{\prime} \mathbf{B}^{-1} \mathbf{c}}{1+\mathbf{c}^{\prime} \mathbf{B}^{-1} \mathbf{c}}\right)+\mathbf{c c}^{\prime} \mathbf{B}^{-1}=\mathbf{I} \\
& 2.33|c \mathbf{A}|=|c \mathbf{I A}| \\
& =|c \mathbf{I}||\mathbf{A}| \quad[\text { by (2.89) }] \\
& =c^{n}|\mathbf{A}| \quad[\text { by (2.84)] } \\
& 2.34 \mathbf{A A}^{-1}=\mathbf{I} \\
& \left|\mathbf{A} \mathbf{A}^{-1}\right|=|\mathbf{I}| \\
& \left|\mathbf{A} \| \mathbf{A}^{-1}\right|=1 \quad \text { [by (2.83)] } \\
& \left|\mathbf{A}^{-1}\right|=\frac{1}{|\mathbf{A}|}
\end{aligned}
\]
2.35 In (2.93) and (2.94), let \(\mathbf{A}_{11}=\mathbf{B}, \mathbf{A}_{12}=\mathbf{c}, \mathbf{A}_{21}=-\mathbf{c}^{\prime}\), and \(\mathbf{A}_{22}=1\). Then equate the right-hand sides of (2.93) and (2.94) to obtain (2.95).
2.36 \(\operatorname{By}(2.52), \operatorname{tr}\left(\mathbf{A A}^{\prime}\right)=\sum_{i=1}^{n} \mathbf{a}_{i}^{\prime} \mathbf{a}_{i}=\sum_{i=1}^{n}\left(a_{i 1}^{2}+a_{i 2}^{2}+\cdots+a_{i n}^{2}\right)\)
\[
=\sum_{i=1}^{n} \sum_{j=1}^{n} a_{i j}^{2} .
\]
2.37 Show that \(|\mathbf{C}| \neq 0\) by taking the determinant of both sides of \(\mathbf{C}^{\prime} \mathbf{C}=\mathbf{I}\). Thus \(\mathbf{C}\) is nonsingular and \(\mathbf{C}^{-1}\) exists. Multiply \(\mathbf{C}^{\prime} \mathbf{C}=\mathbf{I}\) on the right by \(\mathbf{C}^{-1}\) and on the left by \(\mathbf{C}\).
2.38 Multiply \(\mathbf{A B x}=\lambda \mathbf{x}\) on the left by \(\mathbf{B}\). Then \(\lambda\) is an eigenvalue of \(\mathbf{B A}\) and \(\mathbf{B x}\) is an eigenvector.
2.39
(a) \(\left(\mathbf{A}^{1 / 2}\right)^{2}=\left(\mathbf{C D}^{1 / 2} \mathbf{C}^{\prime}\right)^{2}=\mathbf{C D}^{1 / 2} \mathbf{C}^{\prime} \mathbf{C D}^{1 / 2} \mathbf{C}^{\prime}\)
\[
\begin{aligned}
& =\mathbf{C D C}^{\prime} \quad[\text { by (2.101) }] \\
& =\mathbf{A} \quad[\text { by }(2.109)]
\end{aligned}
\]
(b) By (2.114), \(\mathbf{A}^{1 / 2} \mathbf{A}^{1 / 2}=\mathbf{A}\). By (2.89),
\[
\begin{aligned}
\left|\mathbf{A}^{1 / 2} \mathbf{A}^{1 / 2}\right| & =|\mathbf{A}| \\
\left|\mathbf{A}^{1 / 2}\right|\left|\mathbf{A}^{1 / 2}\right| & =|\mathbf{A}| \\
\left|\mathbf{A}^{1 / 2}\right|^{2} & =|\mathbf{A}|
\end{aligned}
\]
(c) Since \(\mathbf{A}\) is positive definite, we have, from part (b), \(\left|\mathbf{A}^{1 / 2}\right|=|\mathbf{A}|^{1 / 2}\).
2.40 Use properties (2.123) and (2.124). Then use property (2.121) (twice). Finally, use property (2.124).

\section*{CHAPTER 3}
\(3.1 \bar{z}=\sum_{i=1}^{n} z_{i} / n=\sum_{i} a y_{i} / n=\left(a y_{1}+\cdots+a y_{n}\right) / n\). Now factor \(a\) out of the sum.
3.2 The numerator of \(s_{z}^{2}\) is \(\sum_{i=1}^{n}\left(z_{i}-\bar{z}\right)^{2}=\sum_{i}\left(a y_{i}-a \bar{y}\right)^{2}=\sum_{i}\left[a\left(y_{i}-\bar{y}\right)\right]^{2}\).
\(3.3 \bar{x}=4, \bar{y}=4\) :
\begin{tabular}{ccccc}
\(x\) & \(y\) & \(x-\bar{x}\) & \(y-\bar{y}\) & \((x-\bar{x})(y-\bar{y})\) \\
\hline 2 & 2 & -2 & -2 & 4 \\
2 & 4 & -2 & 0 & 0 \\
2 & 6 & -2 & 2 & -4 \\
4 & 2 & 0 & -2 & 0 \\
4 & 4 & 0 & 0 & 0 \\
4 & 6 & 0 & 2 & 0 \\
6 & 2 & 2 & -2 & -4 \\
6 & 4 & 2 & 0 & 0 \\
6 & 6 & 2 & 2 & 4 \\
\cline { 4 - 4 }\(=0\)
\end{tabular}
\(\mathbf{3 . 4} \mathbf{x}-\bar{x} \mathbf{j}=\left(\begin{array}{c}x_{1} \\ x_{2} \\ \vdots \\ x_{n}\end{array}\right)-\bar{x}\left(\begin{array}{c}1 \\ 1 \\ \vdots \\ 1\end{array}\right)=\left(\begin{array}{c}x_{1} \\ x_{2} \\ \vdots \\ x_{n}\end{array}\right)-\left(\begin{array}{c}\bar{x} \\ \bar{x} \\ \vdots \\ \bar{x}\end{array}\right)=\left(\begin{array}{c}x_{1}-\bar{x} \\ x_{2}-\bar{x} \\ \vdots \\ x_{n}-\bar{x}\end{array}\right)\)
\(3.5 \mathbf{y}_{i}-\overline{\mathbf{y}}=\left(\begin{array}{c}y_{i 1} \\ y_{i 2} \\ y_{i 3}\end{array}\right)-\left(\begin{array}{c}\bar{y}_{1} \\ \bar{y}_{2} \\ \bar{y}_{3}\end{array}\right)=\left(\begin{array}{c}y_{i 1}-\bar{y}_{1} \\ y_{i 2}-\bar{y}_{2} \\ y_{i 3}-\bar{y}_{3}\end{array}\right)\)
\[
\begin{aligned}
& \sum_{i=1}^{n}\left(\mathbf{y}_{i}-\overline{\mathbf{y}}\right)\left(\mathbf{y}_{i}-\overline{\mathbf{y}}\right)^{\prime}=\sum_{i=1}^{n}\left(\begin{array}{c}
y_{i 1}-\bar{y}_{1} \\
y_{i 2}-\bar{y}_{2} \\
y_{i 3}-\bar{y}_{3}
\end{array}\right)\left(y_{i 1}-\bar{y}_{1}, y_{i 2}-\bar{y}_{2}, y_{i 3}-\bar{y}_{3}\right) \\
& =\sum_{i=1}^{n}\left(\begin{array}{ccc}
\left(y_{i 1}-\bar{y}_{1}\right)^{2} & \left(y_{i 1}-\bar{y}_{1}\right)\left(y_{i 2}-\bar{y}_{2}\right) & \left(y_{i 1}-\bar{y}_{1}\right)\left(y_{i 3}-\bar{y}_{3}\right) \\
\left(y_{i 2}-\bar{y}_{2}\right)\left(y_{i 1}-\bar{y}_{1}\right) & \left(y_{i 2}-\bar{y}_{2}\right)^{2} & \left(y_{i 2}-\bar{y}_{2}\right)\left(y_{i 3}-\bar{y}_{3}\right) \\
\left(y_{i 3}-\bar{y}_{3}\right)\left(y_{i 1}-\bar{y}_{1}\right) & \left(y_{i 3}-\bar{y}_{3}\right)\left(y_{i 2}-\bar{y}_{2}\right) & \left(y_{i 3}-\bar{y}_{3}\right)^{2}
\end{array}\right)
\end{aligned}
\]
\(3.6 \bar{z}=\sum_{i=1}^{n} z_{i} / n=\sum_{i} \mathbf{a}^{\prime} \mathbf{y}_{i} / n=\left(\mathbf{a}^{\prime} \mathbf{y}_{1}+\cdots+\mathbf{a}^{\prime} \mathbf{y}_{n}\right) / n\). Now factor out \(\mathbf{a}^{\prime}\) on the left. See also (2.42).
3.7 The numerator of \(s_{z}^{2}\) is \(\sum_{i=1}^{n}\left(z_{i}-\bar{z}\right)^{2}=\sum_{i}\left(\mathbf{a}^{\prime} \mathbf{y}_{i}-\mathbf{a}^{\prime} \overline{\mathbf{y}}\right)^{2}=\sum_{i}\left(\mathbf{a}^{\prime} \mathbf{y}_{i}-\right.\) \(\left.\mathbf{a}^{\prime} \overline{\mathbf{y}}\right)\left(\mathbf{a}^{\prime} \mathbf{y}_{i}-\mathbf{a}^{\prime} \overline{\mathbf{y}}\right)\). The scalar \(\mathbf{a}^{\prime} \mathbf{y}_{i}\) is equal to its transpose, as in (2.39). Thus \(\mathbf{a}^{\prime} \mathbf{y}_{i}=\left(\mathbf{a}^{\prime} \mathbf{y}_{i}\right)^{\prime}=\mathbf{y}_{i}^{\prime} \mathbf{a}\), and \(\sum_{i}\left(\mathbf{a}^{\prime} \mathbf{y}_{i}-\mathbf{a}^{\prime} \overline{\mathbf{y}}\right)\left(\mathbf{a}^{\prime} \mathbf{y}_{i}-\mathbf{a}^{\prime} \overline{\mathbf{y}}\right)=\sum_{i}\left(\mathbf{a}^{\prime} \mathbf{y}_{i}-\right.\) \(\left.\mathbf{a}^{\prime} \overline{\mathbf{y}}\right)\left(\mathbf{y}_{i}^{\prime} \mathbf{a}-\overline{\mathbf{y}}^{\prime} \mathbf{a}\right)\). By (2.22) and (2.24), this becomes \(\sum_{i} \mathbf{a}^{\prime}\left(\mathbf{y}_{i}-\overline{\mathbf{y}}\right)\left(\mathbf{y}_{i}-\overline{\mathbf{y}}\right)^{\prime} \mathbf{a}\). Now factor out \(\mathbf{a}^{\prime}\) on the left and \(\mathbf{a}\) on the right. See also (2.44).
3.8 By (3.63) and (3.64),
\[
\mathbf{A S A}^{\prime}=\left(\begin{array}{cccc}
\mathbf{a}_{1}^{\prime} \mathbf{S} \mathbf{a}_{1} & \mathbf{a}_{1}^{\prime} \mathbf{S} \mathbf{a}_{2} & \cdots & \mathbf{a}_{1}^{\prime} \mathbf{S} \mathbf{a}_{k} \\
\mathbf{a}_{2}^{\prime} \mathbf{S} \mathbf{a}_{1} & \mathbf{a}_{2}^{\prime} \mathbf{S} \mathbf{a}_{2} & \cdots & \mathbf{a}_{2}^{\prime} \mathbf{S} \mathbf{a}_{k} \\
\vdots & \vdots & & \vdots \\
\mathbf{a}_{k}^{\prime} \mathbf{S} \mathbf{a}_{1} & \mathbf{a}_{k}^{\prime} \mathbf{S} \mathbf{a}_{2} & \cdots & \mathbf{a}_{k}^{\prime} \mathbf{S} \mathbf{a}_{k}
\end{array}\right)
\]
from which the result follows immediately.
\[
\begin{aligned}
3.9 \operatorname{cov}(\mathbf{z}) & =\operatorname{cov}\left[\left(\boldsymbol{\Sigma}^{1 / 2}\right)^{-1} \overline{\mathbf{y}}-\left(\boldsymbol{\Sigma}^{1 / 2}\right)^{-1} \boldsymbol{\mu}\right] & \\
& =\left(\boldsymbol{\Sigma}^{1 / 2}\right)^{-1} \operatorname{cov}(\overline{\mathbf{y}})\left[\left(\boldsymbol{\Sigma}^{1 / 2}\right)^{-1}\right]^{\prime} & {[\text { by }(3.76)] } \\
& =\left(\boldsymbol{\Sigma}^{1 / 2}\right)^{-1}\left(\frac{\boldsymbol{\Sigma}}{n}\right)\left(\boldsymbol{\Sigma}^{1 / 2}\right)^{-1} & \\
& =\frac{1}{n}\left(\boldsymbol{\Sigma}^{1 / 2}\right)^{-1} \boldsymbol{\Sigma}^{1 / 2} \boldsymbol{\Sigma}^{1 / 2}\left(\boldsymbol{\Sigma}^{1 / 2}\right)^{-1} & {[\text { by }(2.114)] } \\
& =\frac{1}{n} \mathbf{I} &
\end{aligned}
\]

\end{array}\right)
\]

\section*{CHAPTER 4}
\(4.1 \quad\left|\boldsymbol{\Sigma}_{1}\right|=1, \quad \operatorname{tr}\left(\boldsymbol{\Sigma}_{1}\right)=20, \quad\left|\boldsymbol{\Sigma}_{2}\right|=4, \quad \operatorname{tr}\left(\boldsymbol{\Sigma}_{2}\right)=15\). Thus \(\operatorname{tr}\left(\boldsymbol{\Sigma}_{1}\right)>\) \(\operatorname{tr}\left(\boldsymbol{\Sigma}_{2}\right)\), but \(\left|\boldsymbol{\Sigma}_{1}\right|<\left|\boldsymbol{\Sigma}_{2}\right|\). When converted to correlations, we have
\[
\mathbf{P}_{\rho 1}=\left(\begin{array}{rrr}
1 & .96 & .80 \\
.96 & 1 & .89 \\
.80 & .89 & 1
\end{array}\right), \quad \mathbf{P}_{\rho 2}=\left(\begin{array}{rrr}
1 & .87 & .41 \\
.87 & 1 & .71 \\
.41 & .71 & 1
\end{array}\right)
\]

As noted at the end of Section 4.1.3, a decrease in intercorrelations or an increase in the variances will lead to a larger \(|\boldsymbol{\Sigma}|\). In this case, the decrease in correlations from \(\boldsymbol{\Sigma}_{1}\) to \(\boldsymbol{\Sigma}_{2}\) outweighed the increase in the variances (the increase in trace).
4.2 \(E(\mathbf{z})=\left(\mathbf{T}^{\prime}\right)^{-1}[E(\mathbf{y})-\mu] \quad[\) by (3.75)]
\[
=\left(\mathbf{T}^{\prime}\right)^{-1}[\mu-\mu]=0
\]
\(\operatorname{cov}(\mathbf{z})=\left(\mathbf{T}^{\prime}\right)^{-1} \Sigma\left[\left(\mathbf{T}^{\prime}\right)^{-1}\right]^{\prime} \quad[\) by (3.76) \(]\)
\(=\left(\mathbf{T}^{\prime}\right)^{-1} \mathbf{T}^{\prime} \mathbf{T} \mathbf{T}^{-1} \quad[\) by (2.75) and (2.79) \(]\)
\(=\mathbf{I}\)
4.3 By the last expression in Section 2.3.1,
\[
\prod_{i=1}^{n} \frac{1}{(\sqrt{2 \pi})^{p}|\Sigma|^{1 / 2}}=\frac{1}{(\sqrt{2 \pi})^{n p}|\Sigma|^{n / 2}}
\]

The sum in the exponent of (4.13) follows from the basic algebra of exponents.
4.4 Since \((\mathbf{y}-\boldsymbol{\mu})^{\prime} \boldsymbol{\Sigma}^{-1}(\mathbf{y}-\boldsymbol{\mu})\) is a scalar, we have \(E\left[(\mathbf{y}-\boldsymbol{\mu})^{\prime} \boldsymbol{\Sigma}^{-1}(\mathbf{y}-\boldsymbol{\mu})\right]=\) \(E\left\{\operatorname{tr}\left[(\mathbf{y}-\boldsymbol{\mu})^{\prime} \boldsymbol{\Sigma}^{-1}(\mathbf{y}-\boldsymbol{\mu})\right]\right\}=E\left\{\operatorname{tr}\left[\boldsymbol{\Sigma}^{-1}(\mathbf{y}-\boldsymbol{\mu})(\mathbf{y}-\boldsymbol{\mu})^{\prime}\right]\right\}=\operatorname{tr}\left[\boldsymbol{\Sigma}^{-1} E(\mathbf{y}-\right.\) \(\left.\boldsymbol{\mu})(\mathbf{y}-\boldsymbol{\mu})^{\prime}\right]=\operatorname{tr}\left(\boldsymbol{\Sigma}^{-1} \boldsymbol{\Sigma}\right)=\operatorname{tr}\left(\mathbf{I}_{p}\right)=p\).
4.5 The other two terms are of the form \(\frac{1}{2} \sum_{i=1}^{n}(\overline{\mathbf{y}}-\boldsymbol{\mu})^{\prime} \boldsymbol{\Sigma}^{-1}\left(\mathbf{y}_{i}-\overline{\mathbf{y}}\right)\), which is equal to \(\frac{1}{2}\left[(\overline{\mathbf{y}}-\boldsymbol{\mu})^{\prime} \boldsymbol{\Sigma}^{-1}\right] \sum_{i=1}^{n}\left(\overline{\mathbf{y}}_{i}-\overline{\mathbf{y}}\right)\). This vanishes because \(\sum_{i=1}^{n}\left(\mathbf{y}_{i}-\right.\) \(\overline{\mathbf{y}})=n \overline{\mathbf{y}}-n \overline{\mathbf{y}}=\mathbf{0}\).
4.6 We replace \(y_{i}\) in \(\sqrt{b_{1}}\) by \(z_{i}=a y_{i}+b\). By an extension of (3.3), \(\bar{z}=a \bar{y}+b\). Then (4.18) becomes
\[
\begin{aligned}
\frac{\sqrt{n} \sum_{i=1}^{n}\left(z_{i}-\bar{z}\right)^{3}}{\left[\sum_{i=1}^{n}\left(z_{i}-\bar{z}\right)^{2}\right]^{3 / 2}} & =\frac{\sqrt{n} \sum_{i}\left(a y_{i}+b-a \bar{y}-b\right)^{3}}{\left[\sum_{i}\left(a y_{i}+b-a \bar{y}-b\right)^{2}\right]^{3 / 2}} \\
& =\frac{\sqrt{n} a^{3} \sum_{i}\left(y_{i}-\bar{y}\right)^{3}}{\left[a^{2} \sum_{i}\left(y_{i}-\bar{y}\right)^{2}\right]^{3 / 2}}=\frac{\sqrt{n} \sum_{i}\left(y_{i}-\bar{y}\right)^{3}}{\left[\sum_{i}\left(y_{i}-\bar{y}\right)^{2}\right]^{3 / 2}}=\sqrt{b_{1}}
\end{aligned}
\]

Similarly, if (4.19) is expressed in terms of \(z_{i}=a y_{i}+b\), it reduces to \(b_{2}\) in terms of \(y_{i}\).
4.7 \(\beta_{2, p}=E\left[(\mathbf{y}-\boldsymbol{\mu})^{\prime} \boldsymbol{\Sigma}^{-1}(\mathbf{y}-\boldsymbol{\mu})\right]^{2}\) by (4.33). But when \(\mathbf{y}\) is \(N_{p}(\boldsymbol{\mu}, \boldsymbol{\Sigma}), v=\) \((\mathbf{y}-\boldsymbol{\mu})^{\prime} \boldsymbol{\Sigma}^{-1}(\mathbf{y}-\boldsymbol{\mu})\) is distributed as \(\chi^{2}(p)\) by property 3 in Section 4.2. Then \(E\left(v^{2}\right)=\operatorname{var}(v)+[E(v)]^{2}\).
4.8 To show that \(b_{1, p}\) and \(b_{2, p}\) are invariant under the transformation \(\mathbf{z}=\mathbf{A} \mathbf{y}_{i}+\mathbf{b}\), where \(\mathbf{A}\) is nonsingular, it is sufficient to show that \(g_{i j}(\mathbf{z})=\left(\mathbf{y}_{i}-\overline{\mathbf{y}}\right)^{\prime} \hat{\mathbf{\Sigma}}^{-1}\left(\mathbf{y}_{j}-\right.\) \(\overline{\mathbf{y}}\) ). By (3.67) and (3.68), \(\overline{\mathbf{z}}=\mathbf{A} \overline{\mathbf{y}}+\mathbf{b}\) and \(\hat{\boldsymbol{\Sigma}}_{z}=\mathbf{A} \hat{\boldsymbol{\Sigma}} \mathbf{A}^{\prime}\). Then \(g_{i j}\) for \(\mathbf{z}\) becomes
\[
\begin{aligned}
g_{i j}(\mathbf{z}) & =\left(\mathbf{z}_{i}-\overline{\mathbf{z}}\right)^{\prime} \hat{\mathbf{\Sigma}}_{z}^{-1}\left(\mathbf{z}_{j}-\overline{\mathbf{z}}\right) \\
& =\left(\mathbf{A} \mathbf{y}_{i}+\mathbf{b}-\mathbf{A} \overline{\mathbf{y}}-\mathbf{b}\right)^{\prime}\left(\mathbf{A} \hat{\mathbf{\Sigma}} \mathbf{A}^{\prime}\right)^{-1}\left(\mathbf{A} \mathbf{y}_{j}+\mathbf{b}-\mathbf{A} \overline{\mathbf{z}}-\mathbf{b}\right) \\
& =\left(\mathbf{y}_{i}-\overline{\mathbf{y}}\right)^{\prime} \mathbf{A}^{\prime}\left(\mathbf{A}^{\prime}\right)^{-1} \hat{\boldsymbol{\Sigma}}^{-1} \mathbf{A}^{-1} \mathbf{A}\left(\mathbf{y}_{j}-\overline{\mathbf{y}}\right) \\
& =\left(\mathbf{y}_{i}-\overline{\mathbf{y}}\right)^{\prime} \hat{\boldsymbol{\Sigma}}^{-1}\left(\mathbf{y}_{j}-\overline{\mathbf{y}}\right)=g_{i j}(\mathbf{y})
\end{aligned}
\]
4.9 Let \(i=(n)\) in (4.47); then solve for \(D_{(n)}^{2}\) in (4.46) and substitute into (4.47) to obtain \(F_{(n)}\) in terms of \(w\), as in (4.48).
\(4.10 \quad\) (a) \(\quad \mathbf{a}^{\prime}=(2,-1,3), \quad z=\mathbf{a}^{\prime} \mathbf{y}\) is \(N(17,21)\)
(b) \(\mathbf{A}=\left(\begin{array}{rrr}1 & 1 & 1 \\ 1 & -1 & 2\end{array}\right), \quad \mathbf{z}=\mathbf{A y}\) is \(N_{2}\left[\binom{8}{10},\left(\begin{array}{rr}29 & -1 \\ -1 & 9\end{array}\right)\right]\)
(c) By property 4 b in Section \(4.2, y_{2}\) is \(N(1,13)\).
(d) By property 4 a in Section \(4.2,\binom{y_{1}}{y_{3}}\) is \(N_{2}\left[\binom{3}{4},\left(\begin{array}{rr}6 & -2 \\ -2 & 4\end{array}\right)\right]\).
(e) \(\mathbf{A}=\left(\begin{array}{ccc}1 & 0 & 0 \\ 0 & 0 & 1 \\ \frac{1}{2} & \frac{1}{2} & 0\end{array}\right), \quad \mathbf{A y}\) is \(N_{3}\left[\left(\begin{array}{l}3 \\ 4 \\ 2\end{array}\right),\left(\begin{array}{rrr}6 & -2 & 3.5 \\ -2 & 4 & 1 \\ 3.5 & 1 & 5.25\end{array}\right)\right]\)
\(4.11 \quad\) (a) \(\mathbf{z}=\left(\begin{array}{rrr}.408 & 0 & 0 \\ -.047 & .279 & 0 \\ .285 & -.247 & .731\end{array}\right)\left(\begin{array}{l}y-3 \\ y-1 \\ y-4\end{array}\right)\)
(b) \(\mathbf{z}=\left(\begin{array}{rrr}.465 & -.070 & .170 \\ -.070 & .326 & -.166 \\ .170 & -.166 & .692\end{array}\right)\left(\begin{array}{l}y-3 \\ y-1 \\ y-4\end{array}\right)\)
(c) By (4.6), \((\mathbf{y}-\boldsymbol{\mu})^{\prime} \boldsymbol{\Sigma}^{-1}(\mathbf{y}-\boldsymbol{\mu})\) is distributed as \(\chi_{3}^{2}\).
4.12 (a) \(\mathbf{a}^{\prime}=(4,-2,1,-3), \quad z=\mathbf{a}^{\prime} \mathbf{y}\) is \(N(-30,153)\)
(b) \(\mathbf{A}=\left(\begin{array}{rrrr}1 & 1 & 1 & 1 \\ -2 & 3 & 1 & -2\end{array}\right), \mathbf{z}=\mathbf{A y}\) is \(N_{2}\left[\binom{5}{2},\left(\begin{array}{rr}27 & -79 \\ -79 & 361\end{array}\right)\right]\)
(c) \(\mathbf{A}=\left(\begin{array}{rrrr}3 & 1 & -4 & -1 \\ -1 & -3 & 1 & -2 \\ 2 & 2 & 4 & -5\end{array}\right)\),
\[
\mathbf{z}=\mathbf{A} \mathbf{y} \text { is } N_{3}\left[\left(\begin{array}{r}
-4 \\
-18 \\
-27

9 & -6 \\
-6 & 17
\end{array}\right)=\left(\begin{array}{rr}
5 & -2 \\
-2 & 1
\end{array}\right)
\end{aligned}
\]
4.18 (a) By the central limit theorem in Section 4.3.2, \(\sqrt{n}(\overline{\mathbf{y}}-\boldsymbol{\mu})\) is approximately \(N_{p}(\mathbf{0}, \boldsymbol{\Sigma})\).
(b) \(\overline{\mathbf{y}}\) is approximately \(N_{p}(\boldsymbol{\mu}, \boldsymbol{\Sigma} / n)\).
4.19 (a) The plots show almost no deviation from normality.
(b)
\begin{tabular}{c|cccc} 
Variable & \(y_{1}\) & \(y_{2}\) & \(y_{3}\) & \(y_{4}\) \\
\hline\(\sqrt{\overline{b_{1}}}\) & .3069 & .3111 & .0645 & .0637 \\
\(b_{2}\) & 1.932 & 2.107 & 1.792 & 1.570
\end{tabular}

The values of \(\sqrt{b_{1}}\) show a small amount of positive skewness, but none exceeds the upper \(2.5 \%\) critical value for \(\sqrt{b_{1}}\) given in Table A. 1 as .942 . The values of \(b_{2}\) show negative kurtosis. For \(y_{4}\), the kurtosis is significant, since \(b_{2}<1.74\), the lower 2.5 percentile in Table A.3.
(c)
\begin{tabular}{c|cccc} 
Variable & \(y_{1}\) & \(y_{2}\) & \(y_{3}\) & \(y_{4}\) \\
\hline\(D\) & .2848 & .2841 & .2866 & .2851 \\
\(Y\) & .4021 & .2934 & .6730 & .4491
\end{tabular}

From Table A.4, the lower 2.5 percentile for \(Y\) is -3.04 and the upper 97.5 percentile is .628 . We reject the hypothesis of normality only for \(y_{3}\).
(d) \(z\) defined in (4.24) is approximately \(N(0,3 / n)\). To obtain a \(N(0,1)\) statistic, we calculate \(z^{*}=z / \sqrt{3 / n}\).
\begin{tabular}{c|rrrr} 
Variable & \(y_{1}\) & \(y_{2}\) & \(y_{3}\) & \(y_{4}\) \\
\hline\(z^{*}\) & -.3366 & -.3095 & -.0737 & -.0856
\end{tabular}
4.20 (a)
\begin{tabular}{c|cccccccccc}
\(i\) & 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 \\
\hline\(D_{i}^{2}\) & 1.06 & 1.60 & 7.54 & 3.54 & 4.61 & .63 & .81 & 2.47 & .95 & 3.78
\end{tabular}
(b) The .05 critical value from Table A. 6 is \(7.01 . D_{(10)}^{2}=7.54>7.01\).
(c)
\begin{tabular}{c|cccccccccc}
\(i\) & 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 \\
\hline\(u_{(i)}\) & .08 & .10 & .12 & .13 & .20 & .30 & .44 & .47 & .57 & .93 \\
\hline\(v_{i}\) & .07 & .13 & .18 & .23 & .28 & .34 & .40 & .47 & .55 & .68
\end{tabular}

The plot of \(\left(v_{i}, u_{(i)}\right)\) shows some evidence of nonlinearity and an outlier.
(d) \(b_{1, p}=7.255, b_{2, p}=14.406\). Both (barely) exceed upper .05 critical values in Table A.5.
4.21 (b)
\begin{tabular}{c|ccccc} 
Variable & \(y_{1}\) & \(y_{2}\) & \(y_{3}\) & \(y_{4}\) & \(y_{5}\) \\
\hline\(\sqrt{b_{1}}\) & .2176 & .5857 & .7461 & -.3327 & -.1772 \\
\(b_{2}\) & 2.079 & 1.681 & 2.583 & 1.774 & 2.456
\end{tabular}

None of the values of \(\sqrt{b_{1}}\) exceeds 1.134 (from Table A.1) or is less than -1.134 . None of the values of \(b_{2}\) is less than 1.53 (from Table A.3). Thus there is no significant departure from normality.
(c)
\begin{tabular}{c|rrrrr} 
Variable & \multicolumn{1}{|c}{\(y_{1}\)} & \multicolumn{1}{c}{\(y_{2}\)} & \multicolumn{1}{c}{\(y_{3}\)} & \multicolumn{1}{c}{\(y_{4}\)} & \multicolumn{1}{c}{\(y_{5}\)} \\
\hline\(D\) & .279 & .269 & .275 & .281 & .276 \\
\(Y\) & -.305 & -1.399 & -.805 & -.114 & -.669
\end{tabular}
(d) \(z^{*}=z / \sqrt{3 / n}\), where \(z\) is defined in (4.24).
\begin{tabular}{c|ccccc} 
Variable & \(y_{1}\) & \(y_{2}\) & \(y_{3}\) & \(y_{4}\) & \(y_{5}\) \\
\hline\(z^{*}\) & -.4848 & -1.7183 & -1.3627 & .8091 & .3686
\end{tabular}
4.22
\begin{tabular}{c|ccccccccccc}
\(i\) & 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 & 11 \\
\hline\(D_{i}^{2}\) & 5.20 & 2.15 & 7.63 & 5.34 & 5.54 & 1.73 & 5.21 & 5.90 & 2.72 & 6.02 & 2.56
\end{tabular}
(c)
\begin{tabular}{c|ccccccccccc}
\(i\) & 1 & 2 & 3 & 4 & 5 & 6 & 7 & 8 & 9 & 10 & 11 \\
\hline\(u_{(i)}\) & .19 & .24 & .28 & .30 & .57 & .57 & .59 & .61 & .65 & .66 & .84 \\
\hline\(v_{i}\) & .18 & .27 & .34 & .39 & .45 & .50 & .55 & .61 & .66 & .73 & .82
\end{tabular}

The plot shows a sharp break from the fourth to the fifth points.
(d) \(b_{1, p}=12.985, b_{2, p}=29.072\)
4.23 (a) The \(Q-Q\) plots for \(y_{1}\) and \(y_{5}\) show little departure from normality. The \(Q-Q\) plots for \(y_{2}\) and \(y_{3}\) show some evidence of heavier tails than the normal. The \(Q-Q\) plots for \(y_{4}\) and \(y_{6}\) show some evidence of positive skewness.
(b)
\begin{tabular}{c|cccccc} 
Variable & \(y_{1}\) & \(y_{2}\) & \(y_{3}\) & \(y_{4}\) & \(y_{5}\) & \(y_{6}\) \\
\hline\(\sqrt{b_{1}}\) & .5521 & .0302 & .7827 & 1.4627 & .2219 & .9974 \\
\(b_{2}\) & 3.160 & 3.275 & 2.772 & 6.675 & 2.176 & 4.528
\end{tabular}
(c)
\begin{tabular}{c|rrrrrr} 
Variable & \(y_{1}\) & \(y_{2}\) & \(y_{3}\) & \(y_{4}\) & \(y_{5}\) & \(y_{6}\) \\
\hline\(D\) & .276 & .274 & .275 & .260 & .286 & .271 \\
\(Y\) & -1.469 & -1.845 & -1.675 & -5.249 & .889 & -2.741
\end{tabular}
(d)
\begin{tabular}{c|cccccc} 
Variable & \(y_{1}\) & \(y_{2}\) & \(y_{3}\) & \(y_{4}\) & \(y_{5}\) & \(y_{6}\) \\
\hline\(z^{*}\) & -1.640 & -.062 & -2.803 & -2.961 & -.870 & -2.456
\end{tabular}
4.24 (a) \(D_{i}^{2}=7.816,3.640,5.730, \ldots, 6.433\)
(b) \(D_{(51)}^{2}=25.628\). By extrapolation in Table A. 6 , the .05 critical value for \(p=6\) is approximately 19. Thus we reject the hypothesis of multivariate normality.
(c) \(\left(v_{i}, u_{(i)}\right)=(.021, .024),(.029, .028), \ldots,(.306, .523)\). The plot shows nonlinearity for the last four points.
(d) \(b_{1, p}=16.287, b_{2, p}=58.337\). By extrapolation to \(p=6\) in Table A.5, both appear to exceed their critical values.
4.25 (a) \(\lambda_{1}=0.5, \lambda_{2}=-0.3, \lambda_{3}=1.1\)
(b) \(\boldsymbol{\lambda}=(0.7,0,1.1)^{\prime}\)
4.26 (a) \(\lambda_{1}=-0.1, \lambda_{2}=-0.4, \lambda_{3}=0.4\)
(b) \(\boldsymbol{\lambda}=(-0.2,-0.5,0.5)^{\prime}\)

\section*{CHAPTER 5}
5.1 By (5.6), we have
\[
\begin{aligned}
\left(\overline{\mathbf{y}}-\boldsymbol{\mu}_{0}\right)^{\prime}\left(\frac{\mathbf{S}}{n}\right)^{-1}\left(\overline{\mathbf{y}}-\boldsymbol{\mu}_{0}\right) & =\left(\overline{\mathbf{y}}-\boldsymbol{\mu}_{0}\right)^{\prime}\left(\frac{1}{n}\right)^{-1} \mathbf{S}^{-1}\left(\overline{\mathbf{y}}-\boldsymbol{\mu}_{0}\right) \\
& =n\left(\overline{\mathbf{y}}-\boldsymbol{\mu}_{0}\right)^{\prime} \mathbf{S}^{-1}\left(\overline{\mathbf{y}}-\boldsymbol{\mu}_{0}\right)
\end{aligned}
\]
5.2 From (5.9), we have
\[
\begin{aligned}
& \frac{n_{1} n_{2}}{n_{1}+n_{2}}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)^{\prime} \mathbf{S}_{\mathbf{p} 1}^{-1}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right) \\
& \quad=\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)^{\prime}\left(\frac{n_{1}+n_{2}}{n_{1} n_{2}}\right)^{-1} \mathbf{S}_{\mathbf{p} 1}^{-1}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right) \\
& \quad=\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)^{\prime}\left(\frac{n_{1}+n_{2}}{n_{1} n_{2}} \mathbf{S}_{\mathrm{p} 1}\right)^{-1}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right) \\
& \quad=\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)^{\prime}\left[\left(\frac{1}{n_{1}}+\frac{1}{n_{2}}\right) \mathbf{S}_{\mathbf{p} 1}\right]^{-1}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)
\end{aligned}
\]
5.3 By (5.13) and (5.14),
\(t^{2}(\mathbf{a})=\frac{\left[\mathbf{a}^{\prime}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)\right]^{2}}{\left[\left(n_{1}+n_{2}\right) / n_{1} n_{2}\right] \mathbf{a}^{\prime} \mathbf{S}_{\mathrm{pl}} \mathbf{a}}=\frac{n_{1} n_{2}}{n_{1}+n_{2}} \frac{\left[\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)^{\prime} \mathbf{S}_{\mathrm{pl}}^{-1}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)\right]^{2}}{\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)^{\prime} \mathbf{S}_{\mathrm{pl}}^{-1} \mathbf{S}_{\mathrm{pl}} \mathbf{S}_{\mathrm{pl}}^{-1}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)}\).
5.4 It is assumed that \(y\) and \(x\) have a bivariate normal distribution. Let \(\mathbf{y}_{i}=\) \(\binom{y_{i}}{x_{i}}\). Then \(d_{i}\) can be expressed as \(d_{i}=y_{i}-x_{i}=\mathbf{a}^{\prime} \mathbf{y}_{i}\), where \(\mathbf{a}^{\prime}=\) \((1,-1)\). By property 1 a in Section \(4.2, d_{i}\) is \(N\left(\mathbf{a}^{\prime} \boldsymbol{\mu}, \mathbf{a}^{\prime} \boldsymbol{\Sigma} \mathbf{a}\right)\). Show that \(\mathbf{a}^{\prime} \overline{\mathbf{y}}=\) \(\bar{y}-\bar{x}, \mathbf{a}^{\prime} \mathbf{S a}=s_{y}^{2}-2 s_{y x}+s_{x}^{2}=s_{d}^{2}\), and that \(T^{2}=n\left(\mathbf{a}^{\prime} \overline{\mathbf{y}}\right)^{\prime}\left(\mathbf{a}^{\prime} \mathbf{S a}\right)^{-1}\left(\mathbf{a}^{\prime} \overline{\mathbf{y}}\right)\) is the square of \(t=\bar{d} /\left(s_{d} / \sqrt{n}\right)\).
\(5.5 \bar{d}=\frac{1}{n} \sum_{i=1}^{n} d_{i}=\frac{1}{n} \sum_{i=1}^{n}\left(y_{i}-x_{i}\right)=\frac{1}{n} \sum_{i} y_{i}-\frac{1}{n} \sum_{i} x_{i}=\bar{y}-\bar{x}\), \(s_{d}^{2}=\frac{1}{n-1} \sum_{i=1}^{n}\left(d_{i}-\bar{d}\right)^{2}=\frac{1}{n-1} \sum_{i}\left(y_{i}-x_{i}-\bar{y}+\bar{x}\right)^{2}\)
\[
=\frac{1}{n-1} \sum_{i}\left[\left(y_{i}-\bar{y}\right)-\left(x_{i}-\bar{x}\right)\right]^{2}
\]

When this is expanded, we obtain \(s_{d}^{2}=s_{y}^{2}+s_{x}^{2}-2 s_{y x}\).

\subsection*{5.6 Similar to Problem 5.1.}
5.7 By (5.7), \(\left[(\nu-p+1) / \nu_{p}\right] T_{p, \nu}^{2}=F_{p, \nu-p+1}\). By (5.29), \((\nu-q)\left(T_{p+q}^{2}-\right.\) \(\left.T_{p}^{2}\right) /\left(\nu+T^{2}\right)\) is \(T_{q, \nu-p}^{2}\). Replacing \(p\) by \(q\) and \(\nu\) by \(\nu-p\) in (5.7), we obtain \(\frac{(\nu-p)-q+1}{(\nu-p) q}(\nu-p) \frac{T_{p+q}^{2}-T_{p}^{2}}{\nu+T_{p}^{2}}\) is \(F_{q,(\nu-p)-q+1}\).
5.9 Under \(H_{03}\), we have \(\mathbf{C} \boldsymbol{\mu}_{1}=0\) and \(\mathbf{C} \boldsymbol{\mu}_{2}=\mathbf{0}\). Then
\[
E(\mathbf{C} \overline{\mathbf{y}})=\mathbf{C} E(\overline{\mathbf{y}})=\mathbf{C} E\left(\frac{n_{1} \overline{\mathbf{y}}_{1}+n_{2} \overline{\mathbf{y}}_{2}}{n_{1}+n_{2}}\right)=\frac{n_{1} \mathbf{C} \boldsymbol{\mu}_{1}+n_{2} \mathbf{C} \boldsymbol{\mu}_{2}}{n_{1}+n_{2}}=\mathbf{0}
\]

Since \(\overline{\mathbf{y}}_{1}\) and \(\overline{\mathbf{y}}_{2}\) are independent,
\[
\begin{aligned}
\operatorname{cov}(\overline{\mathbf{y}}) & =\operatorname{cov}\left(\frac{n_{1} \overline{\mathbf{y}}_{1}+n_{2} \overline{\mathbf{y}}_{2}}{n_{1}+n_{2}}\right)=\frac{n_{1}^{2} \boldsymbol{\Sigma} / n_{1}+n_{2}^{2} \boldsymbol{\Sigma} / n_{2}}{\left(n_{1}+n_{2}\right)^{2}} \\
& =\frac{\left(n_{1}+n_{2}\right) \boldsymbol{\Sigma}}{\left(n_{1}+n_{2}\right)^{2}}
\end{aligned}
\]
5.10 \(\mathrm{CS}_{\mathrm{p} 1} \mathbf{C}^{\prime} /\left(n_{1}+n_{2}\right)\) is the sample covariance matrix of \(\mathbf{C} \overline{\mathbf{y}}\). Hence the equation immediately above (5.39) exhibits the characteristic form of the \(T^{2}\)-distribution.
\(5.11 T^{2}=.061\)
5.12 (a) \(T^{2}=85.3327\)
(b) \(t_{1}=2.5039, t_{2}=.2665, t_{3}=-2.5157, t_{4}=.9510, t_{5}=.3161\)
\(5.13 T^{2}=30.2860\)
5.14 (a) \(T^{2}=1.8198\)
(b) \(t_{1}=1.1643, t_{2}=1.1006, t_{3}=.9692, t_{4}=.7299\). None of these is significant. In fact, ordinarily they would not have been examined because the \(T^{2}\)-test in part (a) did not reject \(H_{0}\).
\(5.15 T^{2}=79.5510\)
5.16 (a) \(T^{2}=133.4873\)
(b) \(t_{1}=3.8879, t_{2}=-3.8652, t_{3}=-5.6911, t_{4}=-5.0426\)
(c) \(\mathbf{a}^{\prime}=(.345,-.130,-.106,-.143)\)
(d) \(t^{2}(\) a \()=133.4873\)
(e) \(R^{2}=.782975, T^{2}=133.4873\)
(f) \(\operatorname{By}(5.32), t^{2}\left(y_{1} \mid y_{2}, y_{3}, y_{4}\right)=35.9336, t^{2}\left(y_{2} \mid y_{1}, y_{3}, y_{4}\right)=5.7994\), \(t^{2}\left(y_{3} \mid y_{1}, y_{2}, y_{4}\right)=1.7749, t^{2}\left(y_{4} \mid y_{1}, y_{2}, y_{3}\right)=8.2592\)
(g) \(\operatorname{By}(5.29), T^{2}\left(y_{3}, y_{4} \mid y_{1}, y_{2}\right)=12.5206, F\left(y_{3}, y_{4} \mid y_{1}, y_{2}\right)=6.0814\)
5.17 By (5.34), the test for parallelism gives \(T^{2}=132.6863\). The discriminant function coefficient vector is given by (5.35) as \(\mathbf{a}^{\prime}=(-.362,-.223,-.137)\).
5.18 (a) \(T^{2}=66.6604\)
(b) \(t_{1}=-.6556, t_{2}=2.6139, t_{3}-3.2884, t_{4}=-4.6315, t_{5}=1.8873, t_{6}=\) \(-3.2205\)
(c) \(\mathrm{By}(5.32)\),
\[

\section*{CHAPTER 6}
6.1 (a) Using \(\bar{y}_{i .}=y_{i .} / n\), we have
\[
\begin{aligned}
\sum_{i=1}^{k} \sum_{j=1}^{n}\left(y_{i j}-\bar{y}_{i .}\right)^{2} & =\sum_{i j}\left(y_{i j}^{2}-2 y_{i j} \bar{y}_{i .}+\bar{y}_{i .}^{2}\right) \\
& =\sum_{i j} y_{i j}^{2}-\sum_{i} \bar{y}_{i .} \sum_{j} y_{i j}+n \sum_{i} \bar{y}_{i .}^{2} \\
& =\sum_{i j} y_{i j}^{2}-2 \sum_{i} \frac{y_{i .}}{n} y_{i .}+n \sum_{i}\left(\frac{y_{i .}}{n}\right)^{2} \\
& =\sum_{i j} y_{i j}^{2}-2 \sum_{i} \frac{y_{i .}^{2}}{n}+\sum_{i} \frac{y_{i .}^{2}}{n} .
\end{aligned}
\]
6.2 \(\frac{\left|\mathbf{E}^{-1}\right||\mathbf{E}|}{\left|\mathbf{E}^{-1}\right||\mathbf{E}+\mathbf{H}|}=\frac{\left|\mathbf{E}^{-1} \mathbf{E}\right|}{\left|\mathbf{E}^{-1}(\mathbf{E}+\mathbf{H})\right|}=\frac{|\mathbf{I}|}{\left|\mathbf{I}+\mathbf{E}^{-1} \mathbf{H}\right|}=\frac{1}{\prod_{i=1}^{s}\left(1+\lambda_{i}\right)} ;\)
see Section 2.11.2.
\[
\begin{aligned}
6.3 & \left(\mathbf{E}^{-1} \mathbf{H}-\lambda \mathbf{I}\right) \mathbf{a}=\mathbf{0} \\
& {\left[\left(\mathbf{E}^{1 / 2} \mathbf{E}^{1 / 2}\right)^{-1} \mathbf{H}-\lambda \mathbf{I}\right] \mathbf{a}=\mathbf{0} } \\
& {\left[\left(\mathbf{E}^{1 / 2}\right)^{-1}\left(\mathbf{E}^{1 / 2}\right)^{-1} \mathbf{H}-\lambda \mathbf{I}\right] \mathbf{a}=\mathbf{0} } \\
& {\left[\left(\mathbf{E}^{1 / 2}\right)^{-1} \mathbf{H}-\lambda \mathbf{E}^{1 / 2}\right] \mathbf{a}=\mathbf{0} } \\
& {\left[\left(\mathbf{E}^{1 / 2}\right)^{-1} \mathbf{H}-\lambda \mathbf{E}^{1 / 2}\right]\left(\mathbf{E}^{1 / 2}\right)^{-1} \mathbf{E}^{1 / 2} \mathbf{a}=\mathbf{0} } \\
& {\left[\left(\mathbf{E}^{1 / 2}\right)^{-1} \mathbf{H}\left(\mathbf{E}^{1 / 2}\right)^{-1}-\lambda \mathbf{I}\right] \mathbf{E}^{1 / 2} \mathbf{a}=\mathbf{0} }
\end{aligned}
\]
6.4 We need to show that \((2 N+s+1) /(2 m+s+1)=\left(\nu_{E}-p+s\right) / d\). Using the definitions \(N=\frac{1}{2}\left(\nu_{E}-p-1\right), m=\frac{1}{2}\left(\left|\nu_{H}-p\right|-1\right), d=\max \left(p, \nu_{H}\right)\), and \(s=\min \left(p, \nu_{H}\right)\), we have \(2 N+s+1=2\left(\frac{1}{2}\right)\left(\nu_{E}-p-1\right)+s+\) \(1=\nu_{E}-p-1+s+1=\nu_{E}-p+s\). For the denominator, we have \(2 m+s+1=2\left(\frac{1}{2}\right)\left(\left|\nu_{H}-p\right|-1\right)+s+1=\left|\nu_{H}-p\right|+s\). Suppose \(\nu_{H}>p\). Then \(\left|\nu_{H}-p\right|+s=\nu_{H}-p+p=\nu_{H}=d\). On the other hand, if \(\nu_{H}<p\), then \(\left|\nu_{H}-p\right|+s=p-\nu_{H}+\nu_{H}=p=d\).
6.5 If \(p \leq \nu_{H}\), we have \(s=p\) and \(\left|\nu_{H}-p\right|=\nu_{H}-p\). Then (6.29) becomes
\[
\begin{aligned}
\frac{2(s N+1) U^{(s)}}{s^{2}(2 m+s+1)} & =\frac{2\left[p\left(\frac{1}{2}\right)\left(\nu_{E}-p-1\right)+1\right] U^{(s)}}{p^{2}\left[2\left(\frac{1}{2}\right)\left(\nu_{H}-p-1\right)+p+1\right]} \\
& =\frac{\left[p\left(\nu_{E}-p-1\right)+2\right] U^{(s)}}{p^{2}\left(\nu_{H}-p-1+p+1\right)} \\
& =\frac{\left[p\left(\nu_{E}-p-1\right)+2\right] U^{(s)}}{p^{2} \nu_{H}}
\end{aligned}
\]
which is the same as (6.30) because \(p=s\). If \(\nu_{H} \leq p\), then \(s=\nu_{H},\left|\nu_{H}-p\right|=\) \(p-\nu_{H}\), and (6.29) can be shown to equal (6.30) in a similar manner.
6.6 When \(s=1\), we have \(V^{(1)}=\lambda_{1} /\left(1+\lambda_{1}\right), U^{(1)}=\lambda_{1}, \Lambda=1 /\left(1+\lambda_{1}\right)\), and \(\theta=\lambda_{1} /\left(1+\lambda_{1}\right)\). Solving the last of these for \(\lambda_{1}\) gives \(\lambda_{1}=\theta /(1-\theta)\), and the results in (6.33), (6.34), and (6.35) follow immediately.
6.7 With \(T^{2}=\left(n_{1}+n_{2}-2\right) U^{(1)}\) and \(U^{(1)}=\theta /(1-\theta)\), we obtain (5.19). We obtain (5.18) from (5.19) by \(V^{(1)}=\theta\). A similar argument leads to (5.16).
6.8 (a) With \(\overline{\mathbf{y}}_{i .}=\mathbf{y}_{i . /} / n_{i}\) and \(\overline{\mathbf{y}}_{. .}=\mathbf{y} . . / N\), we obtain
\[
\begin{aligned}
& \mathbf{H}=\sum_{i=1}^{k} n_{i}\left(\overline{\mathbf{y}}_{i .}-\overline{\mathbf{y}}_{.}\right)\left(\overline{\mathbf{y}}_{i .}-\overline{\mathbf{y}}_{. .}\right)^{\prime} \\
& =\sum_{i} n_{i}\left(\overline{\mathbf{y}}_{i .} \overline{\mathbf{y}}_{i .}^{\prime}-\overline{\mathbf{y}}_{i .} \overline{\mathbf{y}}_{. .}^{\prime}-\overline{\mathbf{y}}_{. .} \overline{\mathbf{y}}_{i .}^{\prime}+\overline{\mathbf{y}}_{. .} \overline{\mathbf{y}}_{. .}^{\prime}\right) \\
& =\sum_{i} n_{i} \overline{\mathbf{y}}_{i .} \overline{\mathbf{y}}_{i .}^{\prime}-\left(\sum_{i} n_{i} \overline{\mathbf{y}}_{i .}\right) \overline{\mathbf{y}}_{. .}^{\prime}-\overline{\mathbf{y}}_{. .} \sum_{i} n_{i} \overline{\mathbf{y}}_{i .}^{\prime}+\overline{\mathbf{y}}_{. .} \overline{\mathbf{y}}_{. .}^{\prime} \sum_{i} n_{i} \\
& =\sum_{i} n_{i} \frac{\mathbf{y}_{i . .} \mathbf{y}_{i .}^{\prime}}{n_{i}^{2}}-\frac{\left(\sum_{i} \mathbf{y}_{i .}\right) \mathbf{y}_{. .}^{\prime}}{N}-\frac{\mathbf{y}_{. .}}{N} \sum_{i} \mathbf{y}_{i .}^{\prime}+\frac{N \mathbf{y}_{. . \mathbf{y}_{\text {.. }}^{\prime}}^{N^{2}}}{N^{2}}
\end{aligned}
\]
\(6.9 \overline{\mathbf{y}}_{1 .}-\overline{\mathbf{y}}_{\text {.. }}\) becomes
\[
\overline{\mathbf{y}}_{1 .}-\frac{n_{1} \overline{\mathbf{y}}_{1 .}+n_{2} \overline{\mathbf{y}}_{2 .}}{n_{1}+n_{2}}=\frac{n_{1} \overline{\mathbf{y}}_{\mathbf{1}}+n_{2} \overline{\mathbf{y}}_{1 .}-n_{1} \overline{\mathbf{y}}_{1 .}-n_{2} \overline{\mathbf{y}}_{2 .}}{n_{1}+n_{2}}=\frac{n_{2}\left(\overline{\mathbf{y}}_{\mathbf{1}}-\overline{\mathbf{y}}_{2 .}\right)}{n_{1}+n_{2}} .
\]

The first term in the sum is
\[
\frac{n_{1} n_{2}^{2}}{\left(n_{1}+n_{2}\right)^{2}}\left(\overline{\mathbf{y}}_{1 .}-\overline{\mathbf{y}}_{2 .}\right)\left(\overline{\mathbf{y}}_{1 .}-\overline{\mathbf{y}}_{2 .}\right)^{\prime}
\]

The second term in the sum is
\[
\frac{n_{1}^{2} n_{2}}{\left(n_{1}+n_{2}\right)^{2}}\left(\overline{\mathbf{y}}_{1 .}-\overline{\mathbf{y}}_{2 .}\right)\left(\overline{\mathbf{y}}_{1 .}-\overline{\mathbf{y}}_{2 .}\right)^{\prime}
\]
\(6.10 \theta=\frac{\lambda_{1}}{1+\lambda_{1}}=\frac{\operatorname{SSH}(z) / \operatorname{SSE}(z)}{1+\operatorname{SSH}(z) / \operatorname{SSE}(z)}=\frac{\operatorname{SSH}(z)}{\operatorname{SSE}(z)+\operatorname{SSH}(z)}\)
6.11 From \(r_{i}^{2}=\lambda_{i} /\left(1+\lambda_{i}\right)\), obtain \(\lambda_{i}=r_{i}^{2} /\left(1-r_{i}^{2}\right)\). Substitute this into \(1 /\left(1+\lambda_{i}\right)\) to obtain the result.
6.12 Substitute \(A_{p}=V^{(s)} / s\) into (6.49) to obtain (6.26).
6.13 When \(s=1,(6.50)\) becomes
\[
A_{\mathrm{LH}}=\frac{U^{(1)}}{1+U^{(1)}}
\]
\(\operatorname{By}(6.33), U^{(1)}=\lambda_{1}\).
6.14 Substitute \(A_{\mathrm{LH}}=U^{(s)} /\left(s+U^{(s)}\right)\) from (6.50) into (6.51) to obtain \(F_{3}\) in (6.30).
6.15 To show \(\operatorname{cov}\left(c_{i} \overline{\mathbf{y}}_{i .}\right)=c_{i}^{2} \boldsymbol{\Sigma} / n\), use (3.74), \(\operatorname{cov}(\mathbf{A y})=\mathbf{A} \boldsymbol{\Sigma} \mathbf{A}^{\prime}\), with \(\mathbf{A}=c_{i} \mathbf{I}\).
6.16 By (6.9),
\[
\begin{aligned}
\mathbf{H}_{z} & =n \sum_{i=1}^{k}\left(\overline{\mathbf{z}}_{i .}-\overline{\mathbf{z}} . .\right)\left(\overline{\mathbf{z}}_{i .}-\overline{\mathbf{z}}_{. .}\right)^{\prime} \\
& =n \sum_{i}\left(\mathbf{C} \overline{\mathbf{y}}_{i .}-\mathbf{C} \overline{\mathbf{y}} . .\right)\left(\mathbf{C} \overline{\mathbf{y}}_{i .}-\mathbf{C} \overline{\mathbf{y}} . .\right)^{\prime} \\
& =n \sum_{i}\left[\mathbf{C}\left(\overline{\mathbf{y}}_{i .}-\overline{\mathbf{y}} . .\right)\right]\left[\mathbf{C}\left(\overline{\mathbf{y}}_{i .}-\overline{\mathbf{y}} . .\right)^{\prime}\right]^{\prime} \\
& =n \mathbf{C}\left[\sum_{i}\left(\overline{\mathbf{y}}_{i .}-\overline{\mathbf{y}} . .\right)\left(\overline{\mathbf{y}}_{i .}-\overline{\mathbf{y}} . .\right)^{\prime}\right] \mathbf{C}^{\prime} \quad[\mathbf{b y}(2.45)]
\end{aligned}
\]
6.17 C is not square.
6.18 \(E(\mathbf{C} \overline{\mathbf{y}} .)=.\mathbf{C} E(\overline{\mathbf{y}} .)=.\mathbf{C} E\left(\sum_{i=1}^{k} \overline{\mathbf{y}}_{i .} / k\right)\)
\[
\begin{aligned}
& =\mathbf{C} \sum_{i} E\left(\overline{\mathbf{y}}_{i .}\right) / k=\mathbf{C} \sum_{i} \boldsymbol{\mu}_{i} / k \\
& =\mathbf{0} \quad\left[\text { by } H_{03} \text { in (6.82) }\right]
\end{aligned}
\]
\(\operatorname{cov}(\mathbf{C y} .)=.\mathbf{C} \boldsymbol{\Sigma} \mathbf{C}^{\prime} / k n\) if there are no differences in the group means, \(\mathbf{C} \boldsymbol{\mu}_{1}, \mathbf{C} \boldsymbol{\mu}_{2}, \ldots\), This condition is assured by \(H_{01}\) in (6.77).
6.19 For our purposes, it will suffice to show that \(T^{2}\) has the characteristic form of the \(T^{2}\)-distribution in (5.6).
6.20 If \(\boldsymbol{\Sigma}=\sigma^{2} \mathbf{I}\), (6.88) becomes
\[
\varepsilon=\frac{\left[\operatorname{tr}\left(\sigma^{2} \mathbf{I}-\mathbf{J} \sigma^{2} \mathbf{I} / p\right)\right]^{2}}{(p-1) \operatorname{tr}\left(\sigma^{2} \mathbf{I}-\mathbf{J} \sigma^{2} \mathbf{I} / p\right)^{2}}=\frac{\left[\sigma^{2} \operatorname{tr}(\mathbf{I}-\mathbf{J} / p)\right]^{2}}{\sigma^{4}(p-1) \operatorname{tr}(\mathbf{I}-\mathbf{J} / p)^{2}}
\]

Show that \((\mathbf{I}-\mathbf{J} / p)^{2}=\mathbf{I}-\mathbf{J} / p\). Then
\[
\varepsilon=\frac{\sigma^{4}(p-p / p)^{2}}{\sigma^{4}(p-1)(p-p / p)}=\frac{(p-1)^{2}}{(p-1)^{2}}=1
\]
6.21 The (univariate) expected mean square corresponding to \(\bar{\mu}\). in a one-way ANOVA is \(\sigma^{2}+N \mu^{2}\). Thus the mean square for \(\bar{\mu}\). is tested with MSE. The corresponding multivariate test therefore uses \(\mathbf{H}^{*}\) and \(\mathbf{E}\).
6.22 From (6.104) we have
\[
\Lambda=\frac{\left|\mathbf{A E A} \mathbf{A}^{\prime}\right|}{\left|\mathbf{A}\left(\mathbf{E}+\mathbf{H}^{*}\right) \mathbf{A}^{\prime}\right|}=\frac{\left|\mathbf{A E} \mathbf{A}^{\prime}\right|}{\mid \mathbf{A E} \mathbf{A}^{\prime}+\mathbf{\mathbf { A H } ^ { * } \mathbf { A } ^ { \prime } |}} .
\]

Substitute \(\mathbf{H}^{*}=k n \overline{\mathbf{y}} . . \overline{\mathbf{y}}^{\prime}\). to obtain
\[
\Lambda=\frac{\left|\mathbf{A} \mathbf{E} \mathbf{A}^{\prime}\right|}{\left|\mathbf{A} \mathbf{E} \mathbf{A}^{\prime}+\sqrt{k n} \mathbf{A} \overline{\mathbf{y}} . .(\sqrt{k n} \mathbf{A} \overline{\mathbf{y}} . .)^{\prime}\right|}
\]

Now use (2.95) with \(\mathbf{B}=\mathbf{A E A} \mathbf{A}^{\prime}\) and \(\mathbf{c}=\sqrt{k n} \mathbf{A} \overline{\mathbf{y}} .\). to obtain
\[
\Lambda=\frac{1}{\left.1+k n(\mathbf{A} \overline{\mathbf{y}} . .)^{\prime}(\mathbf{A E A})^{\prime}\right)^{-1}(\mathbf{A} \overline{\mathbf{y}} . .)}
\]

Multiply and divide by \(\nu_{E}\) and use (6.100) to obtain (6.105).
6.23 Solve for \(T^{2}\) in (6.105).
6.24 In \(\mathbf{C}_{1} \mathbf{B}^{\prime}\) the rows of \(\mathbf{C}_{1}\) are multiplied by the rows of \(\mathbf{B}\). Show that \(\mathbf{C}_{1} \mathbf{B}^{\prime}=\) O.
6.25 As noted, the function \((\overline{\mathbf{y}}-\mathbf{A} \hat{\boldsymbol{\beta}})^{\prime} \mathbf{S}^{-1}(\overline{\mathbf{y}}-\mathbf{A} \hat{\boldsymbol{\beta}})\) is similar to \(\operatorname{SSE}=(\mathbf{y}-\) \(\mathbf{X} \hat{\boldsymbol{\beta}})^{\prime}(\mathbf{y}-\mathbf{X} \hat{\boldsymbol{\beta}})\) in (10.4) and (10.6). By an argument similar to that used in Section 10.2.2 to obtain \(\hat{\boldsymbol{\beta}}=\left(\mathbf{X}^{\prime} \mathbf{X}\right)^{-1} \mathbf{X}^{\prime} \mathbf{y}\), it follows that \(\hat{\boldsymbol{\beta}}=\left(\mathbf{A}^{\prime} \mathbf{S}^{-1} \mathbf{A}\right)^{-1} \mathbf{A}^{\prime} \mathbf{S}^{-1} \overline{\mathbf{y}}\). An alternative approach (for those familiar with differentiation with respect to a vector) is to expand \((\overline{\mathbf{y}}-\mathbf{A} \hat{\boldsymbol{\beta}})^{\prime} \mathbf{S}^{-1}(\overline{\mathbf{y}}-\mathbf{A} \hat{\boldsymbol{\beta}})\) to four terms, differentiate with respect to \(\hat{\boldsymbol{\beta}}\), and set the result equal to 0 .
6.26 Expand \(n(\overline{\mathbf{y}}-\mathbf{A} \hat{\boldsymbol{\beta}})^{\prime} \mathbf{S}^{-1}(\overline{\mathbf{y}}-\mathbf{A} \hat{\boldsymbol{\beta}})\) to four terms and substitute
\[
\hat{\boldsymbol{\beta}}=\left(\mathbf{A}^{\prime} \mathbf{S}^{-1} \mathbf{A}\right)^{-1} \mathbf{A}^{\prime} \mathbf{S}^{-1} \overline{\mathbf{y}}
\]
into the last one.
\(\mathbf{6 . 2 7} \quad\) (a) \(\mathbf{E}=\left(\begin{array}{rrrr}13.41 & 7.72 & 8.68 & 5.86 \\ 7.72 & 8.48 & 7.53 & 6.21 \\ 8.68 & 7.53 & 11.61 & 7.04 \\ 5.86 & 6.21 & 7.04 & 10.57\end{array}\right)\)
\(\mathbf{H}=\left(\begin{array}{rrrr}1.05 & 2.17 & -1.38 & -.76 \\ 2.17 & 4.88 & -2.37 & -1.26 \\ -1.38 & -2.37 & 2.38 & 1.38 \\ -.76 & -1.26 & 1.38 & .81\end{array}\right)\)
\(\Lambda=.224, V^{(s)}=.860, U^{(s)}=3.08\), and \(\theta=.747 \mathrm{All}\) four are significant.
(b) \(\eta_{\Lambda}^{2}=1-\Lambda=.776, \eta_{\theta}^{2}=\theta=.747, A_{\Lambda}=1-\Lambda^{1 / s}=.526, A_{\mathrm{LH}}=\) \(.606, A_{p}=V^{(s)} / s=.430\)
(c) The eigenvalues of \(\mathbf{E}^{-1} \mathbf{H}\) are 2.9515 and .1273. The essential dimensionality of the space of the mean vectors is 1 .
(d) For 1,2 vs. 3 we have \(\Lambda=.270, V^{(s)}=.730, U^{(s)}=2.702\), and \(\theta=\) 730. All four are significant. For 1 vs. 2 we obtain \(\Lambda=.726, V^{(s)}=\) \(.274, U^{(s)}=.377\), and \(\theta=.274\). All four are significant.
(e)
\begin{tabular}{ccccc} 
Variable & \(y_{1}\) & \(y_{2}\) & \(y_{3}\) & \(y_{4}\) \\
\hline\(F\) & 1.29 & 9.50 & 3.39 & 1.27
\end{tabular}

The \(F\) 's for \(y_{2}\) and \(y_{3}\) are significant. For the discriminant function \(z=\mathbf{a}^{\prime} \mathbf{y}\), where \(\mathbf{a}\) is the first eigenvector of \(\mathbf{E}^{-1} \mathbf{H}\), we have \(\mathbf{a}^{\prime}=\) \((-.032,-.820, .533, .208)\). Again \(y_{2}\) and \(y_{3}\) contribute most to separation of groups.
(f) \(\operatorname{By}(6.126), \Lambda\left(y_{3}, y_{4} \mid y_{1}, y_{2}\right)=\Lambda\left(y_{1}, y_{2}, y_{3}, y_{4}\right) / \Lambda\left(y_{1}, y_{2}\right)=.224 / .568=\) \(.395<\Lambda_{.05}=.725\)
(g) \(\mathrm{By}(6.127)\),
\[
\begin{aligned}
\Lambda\left(y_{1} \mid y_{2}, y_{3}, y_{4}\right) & =\Lambda\left(y_{1}, y_{2}, y_{3}, y_{4}\right) / \Lambda\left(y_{2}, y_{3}, y_{4}\right) \\
& =.224 / .240=.934>\Lambda_{.05}=.819 \\
\Lambda\left(y_{2} \mid y_{1}, y_{3}, y_{4}\right) & =.224 / .538=.417<.819 \\
\Lambda\left(y_{3} \mid y_{1}, y_{2}, y_{4}\right) & =.224 / .369=.609<.819 \\
\Lambda\left(y_{4} \mid y_{1}, y_{2}, y_{3}\right) & =.224 / .243=.924>.819
\end{aligned}
\]
6.28 (a) \(S\) effect: \(\Lambda=.00065, V^{(s)}=2.357, U^{(s)}=142.304, \theta=.993\). All are significant.
\(V\) effect: \(\Lambda=.065, V^{(s)}=1.107, U^{(s)}=11.675, \theta=.920\). All are significant.
\(S V\) interaction: \(\Lambda=.138, V^{(s)}=1.321, U^{(s)}=3.450, \theta=.726\). All are significant.
(b) Contrast on \(V\) comparing 2 vs. \(1,3: \Lambda=.0804, V^{(s)}=.920, U^{(s)}=\) \(11.445, \theta=.920\). All are significant.
(c) Linear contrast for \(S: \Lambda=.0073, V^{(S)}=.993, U^{(s)}=135.273, \theta=\) .993. All are significant.

Quadratic contrast for \(S: \Lambda=.168, V^{(s)}=.832, U^{(s)}=4.956, \theta=\) .832. All are significant.

Cubic contrast for \(S: \Lambda=.325, V^{(s)}=.675, U^{(s)}=2.076, \theta=.675\). All are significant.
(d) The ANOVA \(F\) 's for each variable are as follows:
\begin{tabular}{crrrr} 
Source & \multicolumn{1}{c}{\(y_{1}\)} & \multicolumn{1}{c}{\(y_{2}\)} & \multicolumn{1}{c}{\(y_{3}\)} & \multicolumn{1}{c}{\(y_{4}\)} \\
\hline\(S\) & 980.21 & 214.24 & 876.13 & 73.91 \\
\(V\) & 251.22 & 9.47 & 14.77 & 27.12 \\
\(S V\) & 20.37 & 2.84 & 3.44 & 2.08
\end{tabular}

All \(F\) 's are significant except the last one, 2.08 .
(e) Test of significance of \(y_{3}\) and \(y_{4}\) adjusted for \(y_{1}\) and \(y_{2}\) :
\begin{tabular}{cccc} 
& \(S\) & \(V\) & \(S V\) \\
\hline\(\Lambda\left(y_{3}, y_{4} \mid y_{1}, y_{2}\right)\) & .1226 & .9336 & .6402
\end{tabular}
(f) Test of significance of each variable adjusted for the other three:
\begin{tabular}{cccc} 
& \(S\) & \(V\) & \(S V\) \\
\hline\(\Lambda\left(y_{1} \mid y_{2}, y_{3}, y_{4}\right)\) & .1158 & .2099 & .3082 \\
\(\Lambda\left(y_{2} \mid y_{1}, y_{3}, y_{4}\right)\) & .5586 & .8134 & .7967 \\
\(\Lambda\left(y_{3} \mid y_{1}, y_{2}, y_{4}\right)\) & .2271 & .9627 & .7604 \\
\(\Lambda\left(y_{4} \mid y_{1}, y_{2}, y_{3}\right)\) & .6692 & .9795 & .8683
\end{tabular}
6.29 \(V=\) velocity (fixed), \(L=\) lubricant (random)
\(V\) effect (using \(\mathbf{H}_{V L}\) for error matrix): \(\Lambda=.0492, V^{(s)}=.951, U^{(s)}=\) \(19.315, \theta=.951\). With \(p=2, \nu_{H}=1\), and \(\nu_{E}=3, \Lambda_{.05}=.050, V_{.05}^{(s)}=\) \(.950, U_{.05}^{(s)}=T_{.05}^{2} / \nu_{E}=19.00, \theta_{.05}=.950\). Thus all four test statistics are significant.
\(L\) effect (using \(\mathbf{E}\) for error matrix): \(\Lambda=.692, V^{(s)}=.314, U^{(s)}=.438, \theta=\) .295. None is significant.
\(V L\) interaction (using \(\mathbf{E}\) for error matrix): \(\Lambda=.932, V^{(s)}=.069, U^{(s)}=\) \(.073, \theta=.061\). None is significant.
\begin{tabular}{|c|c|c|c|c|c|c|}
\hline 6.30 & Source & \(\Lambda\) & \(V^{(s)}\) & \(U^{(s)}\) & \(\theta\) & Significant? \\
\hline & (a) Reagent & . 0993 & 1.126 & 6.911 & . 868 & Yes \\
\hline & (b) Contrast 1 vs. 2, 3, 4 & . 146 & . 854 & 5.871 & . 854 & Yes \\
\hline & Subjects & . 00000082 & 2.847 & 1091.127 & . 999 & Yes \\
\hline
\end{tabular}
6.31 \(P=\) proportion of filler, \(T=\) surface treatment, \(F=\) filler:
\begin{tabular}{lcrrcc} 
Source & \multicolumn{1}{c}{\(\Lambda\)} & \multicolumn{1}{c}{\(V^{(s)}\)} & \multicolumn{1}{c}{\(U^{(s)}\)} & \(\theta\) & Significant? \\
\hline\(P\) & .138 & .977 & 5.441 & .841 & Yes \\
\(T\) & .080 & .920 & 11.503 & .920 & Yes \\
\(P T\) & .712 & .295 & .396 & .271 & No \\
\(F\) & .019 & .980 & 51.180 & .981 & Yes \\
\(P F\) & .179 & .958 & 3.835 & .784 & Yes \\
\(T F\) & .355 & .645 & 1.815 & .645 & Yes \\
\(P T F\) & .752 & .264 & .309 & .172 & No
\end{tabular}
6.32 \(A=\) period; \(P, T\), and \(F\) are defined in Problem 6.31:
\begin{tabular}{lcrrrc} 
Source & \(\Lambda\) & \(V^{(s)}\) & \multicolumn{1}{c}{\(U^{(s)}\)} & \multicolumn{1}{c}{\(\theta\)} & Significant? \\
\hline\(A\) & .021 & .979 & 47.099 & .979 & Yes \\
\(A P\) & .475 & .545 & 1.063 & .505 & No \\
\(A T\) & .142 & .858 & 6.049 & .858 & Yes \\
\(A P T\) & .777 & .228 & .282 & .208 & No \\
\(A F\) & .095 & .905 & 9.486 & .905 & Yes \\
\(A P F\) & .622 & .387 & .594 & .363 & No \\
\(A T F\) & .387 & .613 & 1.586 & .613 & Yes \\
\(A P T F\) & .781 & .229 & .267 & .169 & No
\end{tabular}

For the between-subject factors and interactions, we have
\begin{tabular}{lrrr} 
Source & df & \multicolumn{1}{c}{\(F\)} & \(p\)-Value \\
\hline\(P\) & 2 & 21.79 & \(<.0001\) \\
\(T\) & 1 & 78.34 & \(<.0001\) \\
\(P T\) & 2 & 1.28 & .3143 \\
\(F\) & 1 & 345.04 & \(<.0001\) \\
\(P F\) & 2 & 15.79 & .0004 \\
\(T F\) & 1 & 5.36 & .0392 \\
\(P T F\) & 2 & .48 & .6294 \\
Error & 12 & &
\end{tabular}
6.33 For parallelism, we use (6.78) to obtain \(\Lambda=.2397\). For levels, we use (6.80) and (6.81) to obtain \(\Lambda=.9651\) and \(F=.597\). For flatness we use (6.83) to obtain \(T^{2}=110.521\).
6.34 (a) \(\mathrm{By}(6.89), T^{2}=20.7420\). By (6.104) or (6.105), \(\Lambda=.5655\).
(b) For each row \(\mathbf{c}_{i}^{\prime}\) of \(\mathbf{C}\), we use \(T_{i}^{2}=n\left(\mathbf{c}_{i}^{\prime} \overline{\mathbf{y}}\right)^{\prime}\left(\mathbf{c}_{i}^{\prime} \mathbf{S c}_{i}\right)^{-1} \mathbf{c}_{i}^{\prime} \overline{\mathbf{y}}\), as in Example 6.9.2: \(T_{1}^{2}=17.0648, T_{2}^{2}=.3238, T_{3}^{2}=.2714\). This can also be done by Wilks' \(\Lambda\) using \(\Lambda_{i}=\mathbf{c}_{i}^{\prime} \mathbf{E c}_{i} / \mathbf{c}_{i}^{\prime}\left(\mathbf{E}+\mathbf{H}^{*}\right) \mathbf{c}_{i}: \Lambda_{1}=.6127, \Lambda_{2}=\) \(.9882, \Lambda_{3}=.9900\).
6.35 The six variables represent two within-subjects factors: \(y_{1}\) is \(A_{1} B_{1}, y_{2}\) is \(A_{1} B_{2}, y_{3}\) is \(A_{1} B_{3}, x_{1}\) is \(A_{2} B_{1}, x_{2}\) is \(A_{2} B_{2}\), and \(x_{3}\) is \(A_{2} B_{2}\). Using linear and quadratic effects (other orthogonal contrasts could be used), the matrices

A, B, and G in (6.97), (6.98), and (6.99) become
\[
\begin{aligned}
\mathbf{A} & =\left(\begin{array}{llllll}
1 & 1 & 1 & -1 & -1 & -1
\end{array}\right) \\
\mathbf{B} & =\left(\begin{array}{rrrrrr}
1 & 0 & -1 & 1 & 0 & -1 \\
1 & -2 & 1 & 1 & -2 & 1
\end{array}\right) \\
\mathbf{G} & =\left(\begin{array}{rrrrrr}
1 & 0 & -1 & -1 & 0 & 1 \\
1 & -2 & 1 & -1 & 2 & -1
\end{array}\right) .
\end{aligned}
\]

Using these in \(T^{2}\) as given by (6.100), (6.101), and (6.102), we obtain \(T_{A}^{2}=\) 193.0901, \(T_{B}^{2}=2.8000\), and \(T_{A B}^{2}=6.8676\). Using MANOVA tests for the same within-subjects factors, we obtain
\begin{tabular}{lccccc} 
Source & \(\Lambda\) & \(V^{(s)}\) & \(U^{(s)}\) & \(\theta\) & Significant? \\
\hline\(A\) & .202 & .798 & 3.941 & .798 & Yes \\
\(B\) & .946 & .054 & .057 & .054 & No \\
\(A B\) & .877 & .123 & .140 & .123 & Yes
\end{tabular}
6.36 MANOVA tests for the within-subjects effect \(T\) (time), and interactions of time with the between-subjects effects \(C\) (cancer) and \(G\) (gender):
\begin{tabular}{lcccc} 
Source & \(\Lambda\) & \(V^{(s)}\) & \(U^{(s)}\) & \(\theta\) \\
\hline\(T\) & .258 & .742 & 2.874 & .742 \\
\(T C\) & .363 & .809 & 1.299 & .444 \\
\(T G\) & .929 & .071 & .077 & .071 \\
\(T C G\) & .809 & .201 & .225 & .130
\end{tabular}

ANOVA \(F\)-tests for between-subjects factors and interactions:
\begin{tabular}{lrrr} 
Source & df & \(F\) & \(p\)-Value \\
\hline\(C\) & 5 & 4.16 & .003 \\
\(G\) & 1 & 2.69 & .107 \\
\(C G\) & 5 & .37 & .869
\end{tabular}
6.37 (a) \(T^{2}=79.551\)
(b) Using \(t_{i}=\mathbf{c}_{i}^{\prime} \overline{\mathbf{y}} / \sqrt{\mathbf{c}_{i}^{\prime} \mathbf{S \mathbf { c } _ { i } / n}}\), where \(\mathbf{c}_{i}^{\prime}\) is the \(i\) th row of \(\mathbf{C}\), we obtain \(t_{1}=7.155, t_{2}=-.445, t_{3}=-.105\).
6.38 (a) \(T^{2}=1712.2201\)
(b) Using \(t_{i}=\mathbf{c}_{i}^{\prime} \overline{\mathbf{y}} / \sqrt{\mathbf{c}_{i}^{\prime} \mathbf{S c}_{i} / n}\), we obtain \(t_{1}=332.358, t_{2}=54.589, t_{3}=\) \(.056, t_{4}=7.637, t_{5}=4.344, t_{6}=1.968\).
6.39 (a) Using \(T^{2}=N\left(\mathbf{C} \overline{\mathbf{y}}_{. .}\right)^{\prime}\left(\mathbf{C S}_{p 1} \mathbf{C}^{\prime}\right)^{-1}(\mathbf{C} \overline{\mathbf{y}} .\).\() in (6.121), we obtain T^{2}=\) \(17.582<T_{.05,3,9}^{2}=27.202\).
(b) \(t_{1}=.951, t_{2}=1.606, t_{3}=.127\) [Since the \(T^{2}\)-test in part (a) did not reject \(H_{0}\), these would ordinarily not be calculated.]
(c) Using \(\Lambda=\left|\mathbf{C E C}^{\prime}\right| /\left|\mathbf{C}(\mathbf{E}+\mathbf{H}) \mathbf{C}^{\prime}\right|\) in (6.123), we obtain \(\Lambda=.3107>\) \(\Lambda_{.05,3,2,9}=.203\).
(d) To compare groups using each row of \(\mathbf{C}\), we use \(\Lambda_{i}=\mathbf{c}_{i}^{\prime} \mathbf{E} \mathbf{c}_{i} / \mathbf{c}_{i}^{\prime}(\mathbf{E}+\) \(\mathbf{H}) \mathbf{c}_{i}\) to obtain \(\Lambda_{1}=.833, \Lambda_{2}=.988, \Lambda_{3}=.650\). [Since the \(\Lambda\)-test in part (c) did not reject \(H_{0}\), we would ordinarily not have calculated these.]
6.40 (a) Using \(T^{2}=N\left(\mathbf{C} \overline{\mathbf{y}}_{. .}\right)^{\prime}\left(\mathbf{C S}_{\mathrm{p} 1} \mathbf{C}^{\prime}\right)^{-1}\left(\mathbf{C} \overline{\mathbf{y}}_{\text {.. }}\right)\) in (6.121), we obtain \(T^{2}=\) \(33.802>T_{.05,4,24}^{2}=12.983\).
(b) Using \(t_{i}^{2}=N\left(\mathbf{c}_{i}^{\prime} \overline{\mathbf{y}}\right)^{2} / \mathbf{c}_{i}^{\prime} \mathbf{S}_{\mathrm{p} 1} \mathbf{c}_{i}\), we obtain \(t_{1}^{2}=.675, t_{2}^{2}=.393, t_{3}^{2}=\) 32.626. Only the cubic effect is significant.
(c) For an overall test comparing groups, we use (6.123),
\[
\Lambda=\left|\mathbf{C E C}^{\prime}\right| /\left|\mathbf{C}(\mathbf{E}+\mathbf{H}) \mathbf{C}^{\prime}\right|=.4361
\]
(d) To compare groups using each row of \(\mathbf{C}\), we use \(\Lambda_{i}=\mathbf{c}_{i}^{\prime} \mathbf{E} \mathbf{c}_{i} / \mathbf{c}_{i}^{\prime}(\mathbf{E}+\mathbf{H}) \mathbf{c}_{i}\) : \(\Lambda_{1}=.534, \Lambda_{2}=.764, \Lambda_{3}=.941\).
6.41 (a) Using \(T^{2}=N\left(\mathbf{C} \overline{\mathbf{y}}_{. .}\right)^{\prime}\left(\mathbf{C S}_{\mathrm{p} 1} \mathbf{C}^{\prime}\right)^{-1}\left(\mathbf{C} \overline{\mathbf{y}}_{. .}\right)\)in (6.121), we obtain \(T^{2}=\) 45.500 .
(b) Using \(t_{i}^{2}=N\left(\mathbf{c}_{i}^{\prime} \overline{\mathbf{y}}\right)^{2} / \mathbf{c}_{i}^{\prime} \mathbf{S}_{\mathbf{p} 1} \mathbf{c}_{i}\), we obtain \(t_{1}^{2}=18.410, t_{2}^{2}=8.385, t_{3}^{2}=\) \(3.446, t_{4}^{2}=.011, t_{5}^{2}=.098, t_{6}^{2}=2.900\).
(c) For an overall test comparing groups, we use (6.123),
\[
\Lambda=\left|\mathbf{C E} \mathbf{C}^{\prime}\right| /\left|\mathbf{C}(\mathbf{E}+\mathbf{H}) \mathbf{C}^{\prime}\right|=.304
\]
(d) To compare groups using each row of \(\mathbf{C}\), we use \(\Lambda_{i}=\mathbf{c}_{i}^{\prime} \mathbf{E c}_{i} / \mathbf{c}_{i}^{\prime}(\mathbf{E}+\mathbf{H}) \mathbf{c}_{i}\) : \(\Lambda_{1}=.695, \Lambda_{2}=.925, \Lambda_{3}=.731, \Lambda_{4}=.814, \Lambda_{5}=.950, \Lambda_{6}=.894\).
6.42 (a) Combined groups (pooled covariance matrix). Using \(t=\) number of minutes -30 , we obtain, by (6.114),
\[
\hat{\boldsymbol{\beta}}^{\prime}=(98.1, .981, .0418,-.00101,-.000048)
\]

By (6.115), we obtain \(T^{2}=.216\). By (6.117), we have
\[
\hat{\boldsymbol{\mu}}^{\prime}=(95.5,96.7,95.6,93.8,98.1,99.2)
\]
(b) Group 1: \(\hat{\boldsymbol{\beta}}_{1}^{\prime}=(100.7, .819, .040,-.00085,-.000038), T^{2}=.0113\), \(\hat{\mu}_{1}^{\prime}=(105.2,104.4,101.5,98.6,100.6,108.1)\)
(c) Groups 2-4: \(\hat{\boldsymbol{\beta}}_{2}^{\prime}=(97.4,1.010, .0403,-.00103,-.000049), T^{2}=\) \(.2554, \hat{\boldsymbol{\mu}}_{2}^{\prime}=(92.6,94.4,93.8,92.4,97.4,96.6)\)
6.43 (a) For the control group, the overall test is
\[
T^{2}=n_{1}\left(\mathbf{C} \overline{\mathbf{y}}_{1 .}\right)^{\prime}\left(\mathbf{C S}_{1} \mathbf{C}^{\prime}\right)^{-1}\left(\mathbf{C} \overline{\mathbf{y}}_{1 .}\right)=554.749
\]

For each row of \(\mathbf{C}\) (linear, quadratic, etc.), we have
\[
t_{i}^{2}=n_{1}\left(\mathbf{c}_{i}^{\prime} \overline{\mathbf{y}}_{1 .}\right)^{2} / \mathbf{c}_{i}^{\prime} \mathbf{S}_{1} \mathbf{c}_{i}:
\]
\[
t_{1}^{2}=5.714, t_{2}^{2}=50.111, t_{3}^{2}=50.767, t_{4}^{2}=8.011, t_{5}^{2}=.508
\]
(b) For the obese group, we obtain \(T^{2}=n_{2}\left(\mathbf{C} \overline{\mathbf{y}}_{2}\right)^{\prime}\left(\mathbf{C S}_{2} \mathbf{C}^{\prime}\right)^{-1}\left(\mathbf{C} \overline{\mathbf{y}}_{2}\right)=\) 128.552. For the five rows of \(\mathbf{C}\), we obtain \(t_{1}^{2}=4.978, t_{2}^{2}=107.129\), \(t_{3}^{2}=5.225, t_{4}^{2}=10.750, t_{5}^{2}=3.572\).
(c) For the combined groups \(\left(\mathbf{S}_{\mathrm{pl}}=\right.\) pooled covariance matrix), we use \(T^{2}=N\left(\mathbf{C} \overline{\mathbf{y}}_{. .}\right)^{\prime}\left(\mathbf{C S}_{\mathrm{pl}} \mathbf{C}^{\prime}\right)^{-1}\left(\mathbf{C} \overline{\mathbf{y}}_{. .}\right)\)in (6.121) to obtain \(T^{2}=247.0079\). We test for linear, quadratic, etc., trends using the rows of \(\mathbf{C}\) in \(t_{i}^{2}=\) \(N\left(\mathbf{c}_{i}^{\prime} \overline{\mathbf{y}}_{. .}\right)^{2} / \mathbf{c}_{i}^{\prime} \mathbf{S c}_{\dot{z}} t_{1}^{2}=1.162, t_{2}^{2}=155.017, t_{3}^{2}=30.540, t_{4}^{2}=1.319\), \(t_{5}^{2}=.506\). To compare groups, we use \(\Lambda=\left|\mathbf{C E C} \mathbf{C}^{\prime}\right| /\left|\mathbf{C}(\mathbf{E}+\mathbf{H}) \mathbf{C}^{\prime}\right|\) in (6.123) and \(\Lambda_{i}=\mathbf{c}_{i}^{\prime} \mathbf{E c}_{i} / \mathbf{c}_{i}^{\prime}(\mathbf{E}+\mathbf{H}) \mathbf{c}_{i}: \Lambda=.4902, \Lambda_{1}=.7947, \Lambda_{2}=\) \(.9940, \Lambda_{3}=.7987, \Lambda_{4}=.6228, \Lambda_{5}=.9172\).
6.44 Control group: \(B y(6.114), \hat{\boldsymbol{\beta}}_{1}^{\prime}=(3.129, .656,-.283,-.334, .192, .037,-0.20)\).

Вy (6.115), \(T^{2}=.7633\). Вy (6.117), \(\hat{\mu}_{1}^{\prime}=\left(\hat{\mu}_{11}, \hat{\mu}_{12}, \ldots, \hat{\mu}_{18}\right)=(4.11,3.29,2.71\), 2.71, 3.04, 3.39, 3.54, 3.95).

Obese group: \(\hat{\boldsymbol{\beta}}_{2}^{\prime}=(3.207,-.187, .463, .056,-.102,-.010, .010), T^{2}=\) \(.3943, \hat{\mu}_{2}^{\prime}=(4.51,4.12,3.81,3.48,3.24,3.37,3.70,4.02)\)

Combined groups (pooled covariance matrix): \(\hat{\boldsymbol{\beta}}^{\prime}=(3.15, .162, .183,-.115\), \(.012, .010,-.002), T^{2}=.0158, \hat{\mu}^{\prime}=(4.36,3.80,3.36,3.15,3.13,3.37\), \(3.63,3.98)\)
6.45 \(A=\) activator, \(T=\) time, \(C=\) group. In (6.100), (6.101), and (6.102), we use
\[
\begin{aligned}
\mathbf{A} & =\left(\begin{array}{rrrrrrrrr}
2 & 2 & 2 & -1 & -1 & -1 & -1 & -1 & -1 \\
0 & 0 & 0 & 1 & 1 & 1 & -1 & -1 & -1
\end{array}\right) \\
\mathbf{T} & =\left(\begin{array}{rrrrrrrrr}
-1 & 0 & 1 & -1 & 0 & 1 & -1 & 0 & 1 \\
1 & -2 & 1 & 1 & -2 & 1 & 1 & -2 & 1
\end{array}\right) \\
\mathbf{G} & =\left(\begin{array}{rrrrrrrrr}
-2 & 0 & 2 & 1 & 0 & -1 & 1 & 0 & -1 \\
2 & -4 & 2 & -1 & 2 & -1 & -\mathbf{1} & 2 & -1 \\
0 & 0 & 0 & 1 & 0 & -1 & -\mathbf{1} & 0 & 1 \\
0 & 0 & 0 & 1 & -2 & 1 & -1 & 2 & -1
\end{array}\right)
\end{aligned}
\]
\(T_{A}^{2}=5072.579, T_{T}^{2}=268.185, T_{A T}^{2}=143.491\). The same within-sample factors and interaction can be tested with Wilks' \(\Lambda\) using (6.104) and the other three MANOVA tests:
\begin{tabular}{lccrcc} 
Source & \(\Lambda\) & \(V^{(s)}\) & \multicolumn{1}{c}{\(U^{(s)}\)} & \(\theta\) & Significant? \\
\hline\(A\) & .003 & .997 & 317.04 & .997 & Yes \\
\(T\) & .056 & .944 & 16.76 & .944 & Yes \\
\(A T\) & .100 & .900 & 8.97 & .900 & Yes
\end{tabular}

The interactions of the within factors with the between factor \(G\) are tested with Wilks' \(\Lambda\) (Section 6.9.5) and with the other three MANOVA tests:
\begin{tabular}{lccccc} 
Source & \(\Lambda\) & \(V^{(s)}\) & \(U^{(s)}\) & \(\theta\) & Significant? \\
\hline\(A C\) & .884 & .116 & .131 & .116 & No \\
\(T C\) & .889 & .111 & .125 & .111 & No \\
\(A T C\) & .795 & .205 & .258 & .205 & No
\end{tabular}

The between-subjects factor \(C\) is tested with an ANOVA \(F\)-test: \(F=.47, p\)-value \(=\) . 504.

\section*{CHAPTER 7}
7.1 If \(\boldsymbol{\Sigma}_{0}\) is substituted for S in (7.1), we have
\[
u=\nu\left[\ln \left|\boldsymbol{\Sigma}_{0}\right|-\ln \left|\boldsymbol{\Sigma}_{0}\right|+\operatorname{tr}(\mathbf{I})-p\right]=\nu[0+p-p]=0
\]
\(7.2 \ln \left|\Sigma_{0}\right|-\ln |\mathbf{S}|=-\ln \left|\Sigma_{0}\right|^{-1}-\ln |\mathbf{S}|\)
\[
\begin{aligned}
& =-\ln \left|\boldsymbol{\Sigma}_{0}^{-1}\right|-\ln |\mathbf{S}| \quad[\text { by (2.91) }] \\
& =-\left(\ln |\mathbf{S}|+\ln \left|\Sigma_{0}^{-1}\right|\right) \\
& =-\ln \left|\mathbf{S} \Sigma_{0}^{-1}\right| \quad[\text { by }(2.89)]
\end{aligned}
\]
\(7.3-\ln \left(\prod_{i=1}^{p} \lambda_{i}\right)+\sum_{i=1}^{p} \lambda_{i}=-\sum_{i=1}^{p} \ln \lambda_{i}+\sum_{i=1}^{p} \lambda_{i}\)
\[
=\sum_{i=1}^{p}\left(\lambda_{i}-\ln \lambda_{i}\right)
\]
7.4 As noted in Section 7.1, the likelihood ratio in this case involves the ratio of the determinants of the sample covariance matrices under \(H_{0}\) and \(H_{1}\). Under \(H_{1}\), which is essentially unrestricted, the maximum likelihood estimate of \(\boldsymbol{\Sigma}\) (corrected for bias) is given by (4.12) as S . Under \(H_{0}\) it is assumed that each of the \(p y_{i}\) 's in \(\mathbf{y}\) has variance \(\sigma^{2}\) and that all \(y_{i}\) 's are independent. Thus we estimate \(\sigma^{2}\) (unbiasedly) in each of the \(p\) columns of the \(\mathbf{Y}\) matrix [see (3.17) and (3.23)] and pool the \(p\) estimates to obtain
\[
\hat{\sigma}^{2}=\sum_{i=1}^{n} \sum_{j=1}^{p} \frac{\left(y_{i j}-\bar{y}_{j}\right)^{2}}{(n-1) p} .
\]

Show that by (3.22) and (3.23) this is equal to
\[
\hat{\sigma}^{2}=\sum_{j=1}^{p} \frac{s_{j j}}{p}=\frac{\operatorname{tr}(\mathbf{S})}{p}
\]

Thus the likelihood ratio is
\[
\mathbf{L R}=\left(\frac{|\mathbf{S}|}{\left|\hat{\sigma}^{2} \mathbf{I}\right|}\right)^{n / 2}=\left(\frac{|\mathbf{S}|}{|\mathbf{I} \operatorname{tr}(\mathbf{S}) / p|}\right)^{n / 2} .
\]

Show that by (2.85) this becomes
\[
\mathrm{LR}=\left(\frac{|\mathbf{S}|}{(\operatorname{trS} / p)^{p}}\right)^{n / 2}
\]
7.5 If \(\lambda_{1}=\lambda_{2}=\cdots=\lambda_{p}=\lambda\), say, then by (7.5),
\[
u=\frac{p^{p} \prod_{i=1}^{p} \lambda_{i}}{\left(\sum_{i=1}^{p} \lambda_{i}\right)^{p}}=\frac{p^{p} \lambda^{p}}{(p \lambda)^{p}}=1
\]
\(7.6[(1-\rho) \mathbf{I}+\rho \mathbf{J}]=\left(\begin{array}{cccc}1-\rho & 0 & \ldots & 0 \\ 0 & 1-\rho & \ldots & 0 \\ \vdots & \vdots & & \vdots \\ 0 & 0 & \ldots & 1-\rho\end{array}\right)+\left(\begin{array}{cccc}\rho & \rho & \ldots & \rho \\ \rho & \rho & \ldots & \rho \\ \vdots & \vdots & & \vdots \\ \rho & \rho & \ldots & \rho\end{array}\right)\)
\[
=\left(\begin{array}{cccc}
1 & \rho & \ldots & \rho \\
\rho & 1 & \ldots & \rho \\
\vdots & \vdots & & \vdots \\
\rho & \rho & \ldots & 1
\end{array}\right)
\]
7.7 (a) Substitute \(\mathbf{J}=\mathbf{j} \mathbf{j}^{\prime}\) and \(\mathbf{x}=\mathbf{j}\) into \(\mathbf{J x}=\lambda \mathbf{x}\) to obtain \(\mathbf{j} \mathbf{j}^{\prime} \mathbf{j}=\lambda \mathbf{j}\) which gives \(p \mathbf{j}=\lambda \mathbf{j}\).
(b) \(\mathbf{S}_{0}=s^{2}[(1-r) \mathbf{I}+r \mathbf{J}]=s^{2}(1-r)\left(\mathbf{I}+\frac{r}{1-r} \mathbf{J}\right)\)
(c) By (2.85) and (2.108), we have
\[
\begin{aligned}
\left|\mathbf{S}_{0}\right| & =\left|s^{2}(1-r)\left(\mathbf{I}+\frac{r}{1-r} \mathbf{J}\right)\right|=\left(s^{2}\right)^{p}(1-r)^{p}\left|\mathbf{I}+\frac{r}{1-r} \mathbf{J}\right| \\
& =\left(s^{2}\right)^{p}(1-r)^{p} \prod_{i=1}^{p}\left(1+\lambda_{i}\right)=\left(s^{2}\right)^{p}(1-r)^{p}\left(1+\frac{r p}{1-r}\right) \\
& =\left(s^{2}\right)^{p}(1-r)^{p-1}(1-r+r p)=\left(s^{2}\right)^{p}(1-r)^{p-1}[1+(p-1) r]
\end{aligned}
\]
7.8 \(M=\frac{\left|\mathbf{S}_{1}\right|^{\nu_{1} / 2}\left|\mathbf{S}_{2}\right|^{\nu_{2} / 2} \cdots\left|\mathbf{S}_{k}\right|^{\nu_{k} / 2}}{|\mathbf{S}|^{\sum_{i} \nu_{i} / 2}}=\frac{\left|\mathbf{S}_{1}\right|^{\nu_{1} / 2}\left|\mathbf{S}_{2}\right|^{\nu_{2} / 2} \cdots\left|\mathbf{S}_{k}\right|^{\nu_{k} / 2}}{|\mathbf{S}|^{\nu_{1} / 2}|\mathbf{S}|^{\nu_{2} / 2} \cdots|\mathbf{S}|^{\nu_{k} / 2}}\)
7.9 (a) \(M=.7015\)
(b) \(M=.0797\)
\(7.10 \Lambda=\frac{|\mathbf{S}|}{\left|\mathbf{S}_{y y}\right|\left|\mathbf{S}_{x x}\right|}=\frac{\left|\mathbf{S}_{x x}\right|\left|\mathbf{S}_{y y}-\mathbf{S}_{y x} \mathbf{S}_{x x}^{-1} \mathbf{S}_{x y}\right|}{\left|\mathbf{S}_{y y}\right|\left|\mathbf{S}_{x x}\right|}\)
\[
\begin{aligned}
& =\left|\mathbf{S}_{y y}^{-1}\right|\left|\mathbf{S}_{y y}-\mathbf{S}_{y x} \mathbf{S}_{x x}^{-1} \mathbf{S}_{x y}\right| \\
& =\left|\mathbf{S}_{y y}^{-1}\left(\mathbf{S}_{y y}-\mathbf{S}_{y x} \mathbf{S}_{x x}^{-1} \mathbf{S}_{x y}\right)\right| \\
& =\mid \mathbf{I}-91)] \\
& {[\mathbf{S y}(2.89)]} \\
& \left.\mathbf{S}_{y y}^{-1} \mathbf{S}_{y x} \mathbf{S}_{x x}^{-1} \mathbf{S}_{x y}\right) \mid
\end{aligned}
\]
\[
=\prod_{i=1}^{s}\left(1-r_{i}^{2}\right) \quad[\text { by }(2.108)],
\]
where the \(r_{i}^{2}\) 's are the nonzero eigenvalues of \(\mathbf{S}_{y y}^{-1} \mathbf{S}_{y x} \mathbf{S}_{x x}^{-1} \mathbf{S}_{x y}\). It was shown in Section 2.11.2 that \(1-\lambda_{i}\) is an eigenvalue of \(\mathbf{I}-\mathbf{A}\), where \(\lambda_{i}\) is an eigenvalue of \(\mathbf{A}\).
7.11 When all \(p_{i}=1\), we have \(k=p\), and the submatrices in the denominators of (7.33) and (7.34) reduce to \(\mathbf{S}_{j j}=s_{j j}, j=1,2, \ldots, p\), and \(\mathbf{R}_{j j}=1, j=\) \(1,2, \ldots, p\).
7.12 When all \(p_{i}=1\), we have \(k=p\) and
\[
\begin{aligned}
a_{2} & =p^{2}-\sum_{i=1}^{p} p_{i}^{2}=p^{2}-p, \quad a_{3}=p^{3}-p \\
c & =1-\frac{1}{12 f \nu}\left(2 a_{3}+3 a_{2}\right) \\
& =1-\frac{1}{6\left(p^{2}-p\right) \nu}\left[2\left(p^{3}-p\right)+3\left(p^{2}-p\right)\right] \\
& =1-\frac{1}{6(p-1) \nu}\left[2\left(p^{2}-1\right)+3(p-1)\right] \\
& =1-\frac{1}{6(p-1) \nu}[2(p-1)(p+1)+3(p-1)] \\
& =1-\frac{1}{6 \nu}[2 p+5]
\end{aligned}
\]
7.13 As noted below (7.6), the degrees of freedom for the \(\chi^{2}\)-approximation is the total number of parameters minus the number estimated under \(H_{0}\). The number of distinct parameters in \(\boldsymbol{\Sigma}\) is \(p+\binom{p}{2}=\frac{1}{2} p(p+1)\). The number of parameters estimated under \(H_{0}\) is \(p\). The difference is \(\frac{1}{2} p(p+1)-p=\frac{1}{2} p(p-1)\).
7.14 By (7.1) and (7.2), \(u=11.094\) and \(u^{\prime}=10.668\).
7.15 By (7.7), \(u=.0000594\). By (7.9), \(u^{\prime}=23.519\). For \(H_{0}: \mathbf{C} \boldsymbol{\Sigma} \mathbf{C}^{\prime}=\sigma^{2} \mathbf{I}, u=\) .471 and \(u^{\prime}=2.050\).
7.16 For \(H_{0}: \boldsymbol{\Sigma}=\sigma^{2} \mathbf{I}, u=.00513\) and \(u^{\prime}=131.922\). For \(H_{0}: \mathbf{C} \boldsymbol{\Sigma} \mathbf{C}^{\prime}=\) \(\sigma^{2} \mathbf{I}, u=.129\) and \(u^{\prime}=36.278\).
7.17 For \(H_{0}: \boldsymbol{\Sigma}=\sigma^{2} \mathbf{I}, u=.00471\) and \(u^{\prime}=136.190\). For \(H_{0}: \mathbf{C} \boldsymbol{\Sigma} \mathbf{C}^{\prime}=\) \(\sigma^{2} \mathbf{I}, u=.747\) and \(u^{\prime}=7.486\).
7.18 By (7.16), \(u^{\prime}=6.3323\) with 13 degrees of freedom. The \(F\)-approximation is \(F=.4802\) with 13 and 1147 degrees of freedom.
\(7.19 u^{\prime}=21.488, F=2.511\) with 8 and 217 degrees of freedom
\(7.20 u^{\prime}=35.795, F=4.466\) with 8 and 4905 degrees of freedom
\(7.21 u=8.7457, F=.8730\) with 10 and 6502 degrees of freedom
\(7.22\left|\mathbf{S}_{1}\right|=2.620 \times 10^{14},\left|\mathbf{S}_{2}\right|=2.410 \times 10^{14},\left|\mathbf{S}_{\mathrm{p} 1}\right|=4.368 \times 10^{14}, u=\) \(17.502, F=.829\)
\(7.23 \ln M=-85.965, u=156.434, a_{1}=21, a_{2}=17,797, F=7.4396\)
\(7.24 \ln M=-7.082, u=10.565, a_{1}=10, a_{2}=1340, F=1.046\)

\(7.30|\mathbf{S}|=9.676 \times 10^{-8},\left|\mathbf{S}_{y y}\right|=.02097,\left|\mathbf{S}_{x x}\right|=9.94 \times 10^{-6}, \Lambda=.4642\)
\(7.31|\mathbf{S}|=1.7148 \times 10^{16},\left|\mathbf{S}_{11}\right|=11,284.967,\left|\mathbf{S}_{22}\right|=11,891.15,\left|\mathbf{S}_{33}\right|=\) \(25,951.605, s_{44}=22,227.158, s_{55}=214.06, u=.00103, u^{\prime}=274.787, \nu=\) 46
\(7.32|\mathbf{S}|=459.96, s_{11}=140.54, s_{22}=72.25, s_{33}=.250, u=.1811, u^{\prime}=\) \(12.246, f=3\)
\(7.33 u=.0001379, u^{\prime}=16.297\)
\(7.34 u=.0005176, u^{\prime}=127.367\)
\(7.35 u=.005071, u^{\prime}=131.226\)

\section*{CHAPTER 8}
8.1 Using \(\mathbf{a}=\mathbf{S}_{\mathrm{p} 1}^{-1}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)\), we obtain
\[
\begin{aligned}
{\left[\frac{\left[\mathbf{a}^{\prime}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)\right]^{2}}{\mathbf{a}^{\prime} \mathbf{S}_{\mathrm{p} 1} \mathbf{a}}\right.} & =\frac{\left[\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)^{\prime} \mathbf{S}_{\mathrm{p} 1}^{-1}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)\right]^{2}}{\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)^{\prime} \mathbf{S}_{\mathrm{p} 1}^{-1} \mathbf{S}_{\mathrm{p} 1} \mathbf{S}_{\mathrm{p} 1}^{-1}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)} \\
& =\frac{\left[\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)^{\prime} \mathbf{S}_{\mathrm{p} 1}^{-1}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)\right]^{2}}{\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)^{\prime} \mathbf{S}_{\mathrm{p} 1}^{-1}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)}
\end{aligned}
\]
8.2 You may wish to use the following steps:
(i) In Section 5.6.2 the grouping variable \(w\) is defined as \(n_{2} /\left(n_{1}+n_{2}\right)\) for each observation in group 1 and \(-n_{1} /\left(n_{1}+n_{2}\right)\) for group 2 . Show that with this formulation, \(\bar{w}=0\).
(ii) Because \(\bar{w}=0\), there is no intercept and the fitted model becomes
\[
\begin{aligned}
\hat{w}_{i} & =b_{1}\left(y_{i 1}-\bar{y}_{1}\right)+b_{2}\left(y_{i 2}-\bar{y}_{2}\right)+\cdots+b_{p}\left(y_{i p}-\bar{y}_{p}\right), \\
i & =1,2, \ldots, n_{1}+n_{2}
\end{aligned}
\]

Denote the resulting matrix of \(y\)-values corrected for their means as \(\mathbf{Y}_{c}\) and the vector of \(w\) 's as \(\mathbf{w}\). Then the least squares estimate \(\mathbf{b}=\) \(\left(b_{1}, b_{2}, \ldots, b_{p}\right)^{\prime}\) is obtained as
\[
\mathbf{b}=\left(\mathbf{Y}_{c}^{\prime} \mathbf{Y}_{c}\right)^{-1} \mathbf{Y}_{c}^{\prime} \mathbf{w}
\]

Using (2.51), show that
\[
\begin{aligned}
\mathbf{Y}_{c}^{\prime} \mathbf{Y}_{c} & =\sum_{i=1}^{2} \sum_{j=1}^{n_{i}}\left(\mathbf{y}_{i j}-\overline{\mathbf{y}}\right)\left(\mathbf{y}_{i j}-\overline{\mathbf{y}}\right)^{\prime} \\
& =\sum_{i=1}^{2} \sum_{j=1}^{n_{i}}\left(\mathbf{y}_{i j}-\overline{\mathbf{y}}_{i}\right)\left(\mathbf{y}_{i j}-\overline{\mathbf{y}}_{i}\right)^{\prime}+\frac{n_{1} n_{2}}{n_{1}+n_{2}}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)^{\prime}
\end{aligned}
\]
where \(\overline{\mathbf{y}}=\left(n_{1} \overline{\mathbf{y}}_{1}+n_{2} \overline{\mathbf{y}}_{2}\right) /\left(n_{1}+n_{2}\right)\). It will be helpful to write the first sum above as
\[
\sum_{j=1}^{n_{1}}\left(\mathbf{y}_{1 j}-\overline{\mathbf{y}}\right)\left(\mathbf{y}_{1 j}-\overline{\mathbf{y}}\right)^{\prime}+\sum_{j=1}^{n_{2}}\left(\mathbf{y}_{2 j}-\overline{\mathbf{y}}\right)\left(\mathbf{y}_{2 j}-\overline{\mathbf{y}}\right)^{\prime}
\]
and add and subtract \(\overline{\mathbf{y}}_{1}\) in the first term and \(\overline{\mathbf{y}}_{2}\) in the second.
(iii) Show that
\[
\mathbf{Y}_{c}^{\prime} \mathbf{w}=\sum_{i=1}^{2} \sum_{j=1}^{n_{i}}\left(\mathbf{y}_{i j}-\overline{\mathbf{y}}\right) w_{i j}=\frac{n_{1} n_{2}}{n_{2}+n_{2}}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right) .
\]

Again it will be helpful to sum separately over the two groups.
(iv) From (ii) and (iii) we have
\[
\mathbf{b}=\left(\nu \mathbf{S}+k \overline{\mathbf{d}} \overline{\mathbf{d}}^{\prime}\right)^{-\mathbf{1}} k \overline{\mathbf{d}}
\]
where \(\mathbf{S}=\sum_{i j}\left(\mathbf{y}_{i j}-\overline{\mathbf{y}}_{i}\right)\left(\mathbf{y}_{i j}-\overline{\mathbf{y}}_{i}\right)^{\prime} /\left(n_{1}+n_{2}-2\right), \nu=n_{1}+n_{2}-2\), \(k=n_{1} n_{2} /\left(n_{1}+n_{2}\right)\), and \(\overline{\mathbf{d}}=\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\). Use (2.77) for the inverse of a patterned matrix of the type \(\nu \mathbf{S}+k \overline{\mathbf{d}} \overline{\mathbf{d}}^{\prime}\) to obtain (8.4).
8.3 You may want to use the following steps:
(i) \(R^{2}\) is defined as [see (10.30)]
\[
R^{2}=\frac{\mathbf{b}^{\prime} \mathbf{Y}_{c}^{\prime} \mathbf{w}-n \bar{w}^{2}}{\mathbf{w}^{\prime} \mathbf{w}-n \bar{w}^{2}}
\]

In this case the expression simplifies because \(\bar{w}=0\). Using \(\mathbf{Y}_{c}^{\prime} \mathbf{w}\) in Problem 8.2(iii) above, show that \(R^{2}=\mathbf{b}^{\prime}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)\).
(ii) Show that
\[
\mathbf{b}^{\prime}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)=\frac{T^{2}}{n_{1}+n_{2}-2+T^{2}}
\]
\(8.4\left[\mathbf{a}^{\prime}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)\right]^{2}=\mathbf{a}^{\prime}\left(\overline{\mathbf{y}}-\overline{\mathbf{y}}_{2}\right) \mathbf{a}^{\prime}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)=\mathbf{a}^{\prime}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)^{\prime} \mathbf{a}\)
\(8.5 \mathbf{H a}-\lambda \mathbf{E a}=0\)
\(\mathbf{E}^{-1}(\mathbf{H a}-\lambda \mathbf{E a})=\mathbf{E}^{-1} \mathbf{0}\)
\(\mathbf{E}^{-1} \mathbf{H a}-\lambda \mathbf{E}^{-1} \mathbf{E a}=\mathbf{0}\)
\(\left(\mathbf{E}^{-1} \mathbf{H}-\lambda \mathbf{I}\right) \mathbf{a}=\mathbf{0}\)
8.6 Substituting \(a_{r}^{*}=s_{r} a_{r}, r=1,2, \ldots, p\), into (8.15), we obtain
\[
\begin{aligned}
z_{1 i} & =s_{1} a_{1} \frac{y_{1 i 1}-\bar{y}_{11}}{s_{1}}+s_{2} a_{2} \frac{y_{1 i 2}-\bar{y}_{12}}{s_{2}}+\cdots+s_{p} a_{p} \frac{y_{1 i p}-\bar{y}_{1 p}}{s_{p}} \\
& =a_{1} y_{1 i 1}+a_{2} y_{1 i 2}+\cdots+a_{p} y_{1 i p}-a_{1} \bar{y}_{11}-a_{2} \bar{y}_{12}-\cdots-a_{p} \bar{y}_{1 p} \\
& =a_{1} y_{1 i 1}+a_{2} y_{1 i 2}+\cdots+a_{p} y_{1 i p}-\mathbf{a}^{\prime} \overline{\mathbf{y}}_{1}
\end{aligned}
\]
8.7 (a) \(\mathbf{a}^{*^{\prime}}=(1.366,-.810,2.525,-1.463)\)
(b) \(t_{1}=5.417, t_{2}=2.007, t_{3}=7.775, t_{4}=.688\)
(c) The standardized coefficients rank the variables in the order \(y_{3}, y_{4}, y_{1}, y_{2}\). The \(t\)-tests rank them in the order \(y_{3}, y_{1}, y_{2}, y_{4}\).
(d) The partial \(F\) 's calculated by (8.26) are \(F\left(y_{1} \mid y_{2}, y_{3}, y_{4}\right)=7.844\), \(F\left(y_{2} \mid y_{1}, y_{3}, y_{4}\right)=2.612, F\left(y_{3} \mid y_{1}, y_{2}, y_{4}\right)=40.513\), and \(F\left(y_{4} \mid y_{1}, y_{2}, y_{3}\right)=9.938\).
8.8 (a) \(\mathbf{a}^{\prime}=(.345,-.130,-.106,-.143)\)
(b) \(\mathbf{a}^{\mathbf{}^{\prime}}=(4.137,-2.501,-1.158,-2.068)\)
(c) \(t_{1}=3.888, t_{2}=-3.865, t_{3}=-5.691, t_{4}=-5.043\)
(e) \(F\left(y_{1} \mid y_{2}, y_{3}, y_{4}\right)=35.934, F\left(y_{2} \mid y_{1}, y_{3}, y_{4}\right)=5.799\)
\(F\left(y_{3} \mid y_{1}, y_{2}, y_{4}\right)=1.775, F\left(y_{4} \mid y_{1}, y_{2}, y_{3}\right)=8.259\)
8.9 (a) \(\mathbf{a}^{\prime}=(-.145, .052,-.005,-.089,-.007,-.022)\)
(b) \(\mathbf{a}^{*^{\prime}}=(-1.016, .147,-.542,-1.035,-.107,-1.200)\)
(c) \(t_{1}=-4.655, t_{2}=.592, t_{3}=-4.354, t_{4}=-5.257, t_{5}=-4.032, t_{6}=\) \(-6.439\)
(e) \(F\left(y_{1} \mid y_{2}, y_{3}, y_{4}, y_{5}, y_{6}\right)=8.081, F\left(y_{2} \mid y_{1}, y_{3}, y_{4}, y_{5}, y_{6}\right)=.150\),
\(F\left(y_{3} \mid y_{1}, y_{2}, y_{4}, y_{5}, y_{6}\right)=.835, F\left(y_{4} \mid y_{1}, y_{2}, y_{3}, y_{5}, y_{6}\right)=8.503\),
\(F\left(y_{5} \mid y_{1}, y_{2}, y_{3}, y_{4}, y_{6}\right)=.028, F\left(y_{6} \mid y_{1}, y_{2}, y_{3}, y_{4}, y_{5}\right)=9.192\)
8.10 (a) \(\mathbf{a}^{\prime}=(.057, .010, .242, .071)\)
(b) \(\mathbf{a}^{\mathbf{*}^{\prime}}=(1.390, .083,1.025, .032)\)
(c) \(t_{1}=-3.713, t_{2}=.549, t_{3}=-3.262, t_{4}=-.724\)
(e) \(F\left(y_{1} \mid y_{2}, y_{3}, y_{4}\right)=3.332, F\left(y_{2} \mid y_{1}, y_{3}, y_{4}\right)=.010\) \(F\left(y_{3} \mid y_{1}, y_{2}, y_{4}\right)=1.482, F\left(y_{4} \mid y_{1}, y_{2}, y_{3}\right)=.001\)
8.11 (a) \(\mathbf{a}_{1}^{\prime}=(.021, .533,-.347,-.135), \mathbf{a}_{2}^{\prime}=(-.317, .298, .243,-.026)\)
(b) \(\lambda_{1} /\left(\lambda_{1}+\lambda_{2}\right)=.958, \lambda_{2} /\left(\lambda_{1}+\lambda_{2}\right)=.042\). Using the methods of Section 8.6.2, we have two tests, the first for significance of \(\lambda_{1}\) and \(\lambda_{2}\) and the second for significance of \(\lambda_{2}\) :
\begin{tabular}{cccr} 
Test & \(\Lambda\) & \(F\) & \(p\)-Value for \(F\) \\
\hline 1 & .2245 & 8.3294 & \(<.0001\) \\
2 & .8871 & 1.3157 & .2869
\end{tabular}
(c) \(\mathbf{a}_{1}^{*^{\prime}}=(.076,1.553,-1.182,-.439), \mathbf{a}_{2}^{\mathbf{*}^{\prime}}=(-1.162, .869, .828,-.085)\)
(d) \(F\left(y_{1} \mid y_{2}, y_{3}, y_{4}\right)=1.067, F\left(y_{2} \mid y_{1}, y_{3}, y_{4}\right)=20.975\)
\(F\left(y_{3} \mid y_{1}, y_{2}, y_{4}\right)=9.630, F\left(y_{4} \mid y_{1}, y_{2}, y_{3}\right)=1.228\)
(e) In the plot, the first discriminant function separates groups 1 and 2 from group 3, but the second is ineffective in separating group 1 from group 2 .
8.12 (a) \(\lambda_{i} \quad \lambda_{i} / \sum_{j=1}^{4} \lambda_{j} \quad\) Eigenvector
\begin{tabular}{rrl}
\hline 1.8757 & .6421 & \(\mathbf{a}_{1}^{\prime}=(.470,-.263, .653,-.074)\) \\
.7907 & .2707 & \(\mathbf{a}_{2}^{\prime}=(.176, .188,-1.058,1.778)\) \\
.2290 & .0784 & \(\mathbf{a}_{3}^{\prime}=(-.155, .258, .470,-.850)\) \\
.0260 & .0089 & \(\mathbf{a}_{4}^{\prime}=(-3.614, .475, .310,-.479)\)
\end{tabular}
(b) Test of significance of each eigenvalue and those that follow it:
\begin{tabular}{crrr} 
Test & \(\Lambda\) & Approximate \(F\) & \(p\)-Value for \(F\) \\
\hline 1 & .1540 & 4.937 & \(<.0001\) \\
2 & .4429 & 3.188 & .0006 \\
3 & .7931 & 1.680 & .1363 \\
4 & .9747 & .545 & .5839
\end{tabular}
(c) \(\mathbf{a}_{1,}^{x^{\prime}}=(.266,-.915,1.353,-.097), \mathbf{a}_{2}^{*^{\prime}}=(.100, .654,-2.291,2.333)\), \(\mathbf{a}_{3}^{*^{\prime}}=(-.087, .899, .973,-1.115), \mathbf{a}_{4}^{*^{\prime}}=(-2.044,1.654, .643,-.628)\)
(d) \(F\left(y_{1} \mid y_{2}, y_{3}, y_{4}\right)=.299, F\left(y_{2} \mid y_{1}, y_{3}, y_{4}\right)=1.931\) \(F\left(y_{3} \mid y_{1}, y_{2}, y_{4}\right)=6.085, F\left(y_{4} \mid y_{1}, y_{2}, y_{3}\right)=4.659\)
(e) In the plot, the first discriminant function separates groups 1,4 , and 6 from groups 2,3 , and 5 . The second function achieves some separation of group 6 from groups 1 and 4 and some separation of group 3 from groups 2 and 5 .
8.13 Three variables entered the model in the stepwise selection. The summary table is as follows:
\begin{tabular}{cccccrr} 
& \begin{tabular}{c} 
Variable \\
Step
\end{tabular} & Entered & Overall \(\Lambda\) & \(p\)-Value & Partial \(\Lambda\) & Partial \(F\)
\end{tabular}\(\quad p\)-Value \begin{tabular}{cccrrr} 
\\
\hline 1 & \(y_{4}\) & .4086 & \(<.0001\) & .4086 & 12.158 \\
2 & \(y_{3}\) & .2655 & \(<.0001\) & .6499 & 4.418 \\
3 & \(y_{2}\) & .1599 & \(<.0001\) & 6022 & 5.284 \\
\hline
\end{tabular}
8.14 Summary table:
\begin{tabular}{cccccrr} 
Step & \begin{tabular}{c} 
Variable \\
Entered
\end{tabular} & Overall \(\Lambda\) & \(p\)-Value & Partial \(\Lambda\) & Partial \(F\) & \(p\)-Value \\
\hline 1 & \(y_{4}\) & .6392 & \(<.0001\) & .6392 & 21.451 & \(<.0001\) \\
2 & \(y_{3}\) & .5430 & \(<.0001\) & .8495 & 6.554 & .0147 \\
3 & \(y_{6}\) & .4594 & \(<.0001\) & .8461 & 6.549 & .0148 \\
4 & \(y_{2}\) & .4063 & \(<.0001\) & .8843 & 4.578 & .0394 \\
5 & \(y_{5}\) & .3639 & \(<.0001\) & .8957 & 3.959 & .0547
\end{tabular}

In this case, the fifth variable to enter, \(y_{5}\), would not ordinarily be included in the subset. The \(p\)-value of .0547 is large in this setting, where several tests are run at each step and the variable with smallest \(p\)-value is selected.
8.15 Summary table:
\begin{tabular}{cccrcrr} 
Step & \begin{tabular}{c} 
Variable \\
Entered
\end{tabular} & Overall \(\Lambda\) & \(p\)-Value & Partial \(\Lambda\) & Partial \(F\) & \(p\)-Value \\
\hline 1 & \(y_{2}\) & .6347 & .0006 & .6347 & 9.495 & .0006 \\
2 & \(y_{3}\) & .2606 & \(<.0001\) & .4106 & 22.975 & \(<.0001\)
\end{tabular}

\section*{CHAPTER 9}
\(9.1 \bar{z}_{1}-\bar{z}_{2}=\mathbf{a}^{\prime} \overline{\mathbf{y}}_{1}-\mathbf{a}^{\prime} \overline{\mathbf{y}}_{2}=\mathbf{a}^{\prime}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)=\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)^{\prime} \mathbf{S}_{\mathrm{pl}}^{-1}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)\)
\(9.2 \frac{1}{2}\left(\bar{z}_{1}+\bar{z}_{2}\right)=\frac{1}{2}\left(\mathbf{a}^{\prime} \overline{\mathbf{y}}_{1}+\mathbf{a}^{\prime} \overline{\mathbf{y}}_{2}\right)=\frac{1}{2} \mathbf{a}^{\prime}\left(\overline{\mathbf{y}}_{1}+\overline{\mathbf{y}}_{2}\right)\)
\[
=\frac{1}{2}\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)^{\prime} \mathbf{S}_{\mathrm{pl}}^{-1}\left(\overline{\mathbf{y}}_{1}+\overline{\mathbf{y}}_{2}\right)
\]
9.3 Write (9.8) in the form
\[
\frac{f\left(\mathbf{y} \mid G_{1}\right)}{f\left(\mathbf{y} \mid G_{2}\right)}>\frac{p_{2}}{p_{1}}
\]
and substitute \(f\left(\mathbf{y} \mid G_{i}\right)=N_{p}\left(\boldsymbol{\mu}_{i}, \boldsymbol{\Sigma}\right)\) from (4.2) to obtain
\[
\frac{f\left(\mathbf{y} \mid G_{1}\right)}{f\left(\mathbf{y} \mid G_{2}\right)}=e^{\left(\boldsymbol{\mu}_{1}-\boldsymbol{\mu}_{2}\right)^{\prime} \boldsymbol{\Sigma}^{-1} \mathbf{y}-\left(\boldsymbol{\mu}_{1}-\boldsymbol{\mu}_{2}\right)^{\prime} \boldsymbol{\Sigma}^{-1}\left(\boldsymbol{\mu}_{1}+\boldsymbol{\mu}_{2}\right) / 2}>\frac{p_{2}}{p_{1}}
\]

Substitute estimates for \(\boldsymbol{\mu}_{1}, \boldsymbol{\mu}_{2}\), and \(\boldsymbol{\Sigma}\), and take the logarithm of both sides to obtain (9.9). Note that if \(a>b\), then \(\ln a>\ln b\).
9.4 Maximizing \(p_{i} f\left(\mathbf{y}, G_{i}\right)\) is equivalent to maximizing \(\ln \left[p_{i} f\left(\mathbf{y} \mid G_{i}\right)\right]\). Use \(f\left(\mathbf{y} \mid G_{i}\right)=\) \(N_{p}\left(\boldsymbol{\mu}_{i}, \boldsymbol{\Sigma}\right)\) from (4.2) and take the logarithm to obtain
\[
\ln \left[p_{i} f\left(\mathbf{y} \mid G_{i}\right)\right]=\ln p_{i}-\frac{1}{2} p \ln (2 \pi)-\frac{1}{2}|\boldsymbol{\Sigma}|-\frac{1}{2}\left(\mathbf{y}-\boldsymbol{\mu}_{i}\right)^{\prime} \boldsymbol{\Sigma}^{-1}\left(\mathbf{y}-\boldsymbol{\mu}_{i}\right) .
\]

Expand the last term, delete terms common to all groups (terms that do not involve \(i\) ), and substitute estimators of \(\boldsymbol{\mu}_{i}\) and \(\boldsymbol{\Sigma}\) to obtain (9.13).
9.5 Use \(f\left(\mathbf{y} \mid G_{i}\right)=N_{p}\left(\boldsymbol{\mu}_{i}, \boldsymbol{\Sigma}_{i}\right)\) in \(\ln \left[p_{i} f\left(\mathbf{y} \mid G_{i}\right)\right]\), delete \(-(p / 2) \ln (2 \pi)\), and substitute \(\overline{\mathbf{y}}_{i}\) and \(\mathbf{S}_{i}\) for \(\boldsymbol{\mu}_{i}\) and \(\boldsymbol{\Sigma}_{i}\).
9.6 Substitute the constant \(c\) for each occurrence of \(p_{i} / n_{i}\) to obtain the result.
9.7 (a) \(\mathbf{a}^{\prime}=\left(\overline{\mathbf{y}}_{1}-\overline{\mathbf{y}}_{2}\right)^{\prime} \mathbf{S}_{\mathrm{pl}}^{-1}=(.345,-.130,-.106,-.143)\),
\(\frac{1}{2}\left(\bar{z}_{1}+\bar{z}_{2}\right)=-15.8054\)
(b)
\begin{tabular}{ccrr}

Error rate \(=1-.875=.125\)

\section*{CHAPTER 10}
\(\mathbf{1 0 . 1} \mathbf{y}-\mathbf{X} \hat{\boldsymbol{\beta}}=\left(\begin{array}{c}y_{1} \\ y_{2} \\ \vdots \\ y_{n}\end{array}\right)-\left(\begin{array}{c}\mathbf{x}_{1}^{\prime} \\ \mathbf{x}_{2}^{\prime} \\ \vdots \\ \mathbf{x}_{n}^{\prime}\end{array}\right) \hat{\boldsymbol{\beta}}=\left(\begin{array}{c}y_{1} \\ y_{2} \\ \vdots \\ y_{n}\end{array}\right)-\left(\begin{array}{c}\mathbf{x}_{1}^{\prime} \hat{\boldsymbol{\beta}} \\ \mathbf{x}_{2}^{\prime} \hat{\boldsymbol{\beta}} \\ \vdots \\ \mathbf{x}_{n}^{\prime} \hat{\boldsymbol{\beta}}\end{array}\right)=\left(\begin{array}{c}y_{1}-\mathbf{x}_{1}^{\prime} \hat{\boldsymbol{\beta}} \\ y_{2}-\mathbf{x}_{2}^{\prime} \hat{\boldsymbol{\beta}} \\ \vdots \\ y_{n}-\mathbf{x}_{n}^{\prime} \hat{\boldsymbol{\beta}}\end{array}\right)\)
\(\operatorname{By}(2.33), \sum_{i=1}^{n}\left(y_{i}-\mathbf{x}_{i}^{\prime} \hat{\boldsymbol{\beta}}\right)^{2}=(\mathbf{y}-\mathbf{X} \hat{\boldsymbol{\beta}})^{\prime}(\mathbf{y}-\mathbf{X} \hat{\boldsymbol{\beta}})\).
\(10.2 \sum_{i=1}^{n}\left(y_{i}-\mu\right)^{2}=\sum_{i}\left(y_{i}-\bar{y}+\bar{y}-\mu\right)^{2}\)
\[
\begin{aligned}
& =\sum_{i}\left(y_{i}-\bar{y}\right)^{2}+2 \sum_{i}\left(y_{i}-\bar{y}\right)(\bar{y}-\mu)+\sum_{i}(\bar{y}-\mu)^{2} \\
& =\sum_{i}\left(y_{i}-\bar{y}\right)^{2}+(\bar{y}-\mu) \sum_{i}\left(y_{i}-\bar{y}\right)+n(\bar{y}-\mu)^{2} \\
& =\sum_{i}\left(y_{i}-\bar{y}\right)^{2}+n(\bar{y}-\mu)^{2} \quad\left[\text { since } \sum_{i}\left(y_{i}-\bar{y}\right)=0\right]
\end{aligned}
\]
\(10.3 \sum_{i=1}^{n}\left(x_{i 2}-\bar{x}_{2}\right) \bar{y}=\bar{y} \sum_{i}\left(x_{i 2}-\bar{x}_{2}\right)=\bar{y}\left(\sum_{i} x_{i 2}-n \bar{x}_{2}\right)=\bar{y}\left(n \bar{x}_{2}-n \bar{x}_{2}\right)\)
10.4 \(E\left[\hat{y}_{i}-E\left(y_{i}\right)\right]^{2}=E\left[\hat{y}_{i}-E\left(\hat{y}_{i}\right)+E\left(\hat{y}_{i}\right)-E\left(y_{i}\right)\right]^{2}\)
\[
\begin{aligned}
= & E\left[\hat{y}_{i}-E\left(\hat{y}_{i}\right)\right]^{2}+2 E\left[\hat{y}_{i}-E\left(\hat{y}_{i}\right)\right]\left[E\left(\hat{y}_{i}\right)-E\left(y_{i}\right)\right] \\
& +E\left[E\left(\hat{y}_{i}\right)-E\left(y_{i}\right)\right]^{2}
\end{aligned}
\]

The second term on the right vanishes because \(\left[E\left(\hat{y}_{i}\right)-E\left(y_{i}\right)\right]\) is constant and \(E\left[\hat{y}_{i}-E\left(\hat{y}_{i}\right)\right]=E\left(\hat{y}_{i}\right)-E\left(\hat{y}_{i}\right)=0\). For the third term, we have \(E\left[E\left(\hat{y}_{i}\right)-\right.\) \(\left.E\left(y_{i}\right)\right]^{2}=\left[E\left(\hat{y}_{i}\right)-E\left(y_{i}\right)\right]^{2}\), because \(\left[E\left(\hat{y}_{i}\right)-E\left(y_{i}\right)\right]^{2}\) is constant.
10.5 First show that \(\operatorname{cov}\left(\hat{\boldsymbol{\beta}}_{p}\right)=\sigma^{2}\left(\mathbf{X}_{p}^{\prime} \mathbf{X}_{p}\right)^{-1}\). This can be done by noting that \(\hat{\boldsymbol{\beta}}_{p}=\left(\mathbf{X}_{p}^{\prime} \mathbf{X}_{p}\right)^{-1} \mathbf{X}_{p}^{\prime} \mathbf{y}=\mathbf{A y}\), say. Then, by (3.74), \(\operatorname{cov}(\mathbf{A y})=\mathbf{A} \operatorname{cov}(\mathbf{y}) \mathbf{A}^{\prime}=\) \(\mathbf{A}\left(\sigma^{2} \mathbf{I}\right) \mathbf{A}^{\prime}=\sigma^{2} \mathbf{A} \mathbf{A}^{\prime}\). By substituting \(\mathbf{A}=\left(\mathbf{X}_{p}^{\prime} \mathbf{X}_{p}\right)^{-1} \mathbf{X}_{p}^{\prime}\), this becomes \(\operatorname{cov}\left(\hat{\boldsymbol{\beta}}_{p}\right)=\sigma^{2}\left(\mathbf{X}_{p}^{\prime} \mathbf{X}_{p}\right)^{-1}\). Then by (3.70), \(\operatorname{var}\left(\mathbf{x}_{p i}^{\prime} \hat{\boldsymbol{\beta}}_{p}\right)=\mathbf{x}_{p i}^{\prime} \operatorname{cov}\left(\hat{\boldsymbol{\beta}}_{p}\right) \mathbf{x}_{p i}\) and the remaining steps follow as indicated.
10.6 \(\operatorname{By}(10.36), s_{p}^{2}=\operatorname{SSE}_{p} /(n-p)\). Then by (10.44),
\[
\begin{aligned}
C_{p} & =p+(n-p) \frac{s_{p}^{2}-s_{k}^{2}}{s_{k}^{2}}=p+(n-p)\left(\frac{s_{p}^{2}}{s_{k}^{2}}-1\right) \\
& =p+(n-p) \frac{s_{p}^{2}}{s_{k}^{2}}-(n-p)=(n-p) \frac{\operatorname{SSE}_{p} / s_{k}^{2}}{n-p}-n+2 p \\
& =\frac{\operatorname{SSE}_{p}}{s_{k}^{2}}-(n-2 p)
\end{aligned}
\]
\(10.7(\mathbf{Y}-\mathbf{X} \hat{\mathbf{B}})^{\prime}(\mathbf{Y}-\mathbf{X} \hat{\mathbf{B}})=\mathbf{Y}^{\prime} \mathbf{Y}-\mathbf{Y}^{\prime} \mathbf{X} \hat{\mathbf{B}}-\hat{\mathbf{B}}^{\prime} \mathbf{X}^{\prime} \mathbf{Y}-\hat{\mathbf{B}}^{\prime} \mathbf{X}^{\prime} \mathbf{X} \hat{\mathbf{B}}\). Transpose \(\hat{\mathbf{B}}=\left(\mathbf{X}^{\prime} \mathbf{X}\right)^{-1} \mathbf{X}^{\prime} \mathbf{Y}\) from (10.48) and substitute into \(\hat{\mathbf{B}}^{\prime} \mathbf{X}^{\prime} \mathbf{X B}\).
10.8 \(E\left[\hat{\mathbf{y}}_{i}-E\left(\mathbf{y}_{i}\right)\right]\left[\hat{\mathbf{y}}_{i}-E\left(\mathbf{y}_{i}\right)\right]^{\prime}=E\left[\hat{\mathbf{y}}_{i}-E\left(\hat{\mathbf{y}}_{i}\right)+E\left(\hat{\mathbf{y}}_{i}\right)-E\left(\mathbf{y}_{i}\right)\right]\left[\hat{\mathbf{y}}_{i}-E\left(\hat{\mathbf{y}}_{i}\right)\right.\) \(\left.+E\left(\hat{\mathbf{y}}_{i}\right)-E\left(\mathbf{y}_{i}\right)\right]^{\prime}\)
\[
\begin{aligned}
= & E\left[\hat{\mathbf{y}}_{i}-E\left(\hat{\mathbf{y}}_{i}\right)\right]\left[\hat{\mathbf{y}}_{i}-E\left(\hat{\mathbf{y}}_{i}\right)\right]^{\prime} \\
& +E\left[\hat{\mathbf{y}}_{i}-E\left(\hat{\mathbf{y}}_{i}\right)\right]\left[E\left(\hat{\mathbf{y}}_{i}\right)-E\left(\mathbf{y}_{i}\right)\right]^{\prime} \\
& +E\left[E\left(\hat{\mathbf{y}}_{i}\right)-E\left(\mathbf{y}_{i}\right)\right]\left[\hat{\mathbf{y}}_{i}-E\left(\hat{\mathbf{y}}_{i}\right)\right]^{\prime} \\
& +E\left[E\left(\hat{\mathbf{y}}_{i}\right)-E\left(\mathbf{y}_{i}\right)\right]\left[E\left(\hat{\mathbf{y}}_{i}\right)-E\left(\mathbf{y}_{i}\right)\right]^{\prime}
\end{aligned}
\]

The second and third terms are equal to \(\mathbf{O}\) because \(\left[E\left(\hat{\mathbf{y}}_{i}\right)-E\left(\mathbf{y}_{i}\right)\right]\) is a constant vector and \(E\left[\hat{\mathbf{y}}_{i}-E\left(\hat{\mathbf{y}}_{i}\right)\right]=E\left(\hat{\mathbf{y}}_{i}\right)-E\left(\hat{\mathbf{y}}_{i}\right)=\mathbf{0}\). The fourth term is a constant matrix and the first \(E\) can be deleted.
10.9 As in Problem 10.5, we have \(\operatorname{cov}\left(\hat{\boldsymbol{\beta}}_{p(j)}\right)=\sigma_{j j}\left(\mathbf{X}_{p}^{\prime} \mathbf{X}_{p}\right)^{-1}\), where \(\sigma_{j j}=\) \(\operatorname{var}\left(y_{j}\right)\) is the \(j\) th diagonal element of \(\boldsymbol{\Sigma}=\operatorname{cov}(\mathbf{y})\). Similarly, \(\operatorname{cov}\left(\hat{\boldsymbol{\beta}}_{p(j)}\right.\), \(\left.\hat{\boldsymbol{\beta}}_{p(k)}\right)=\sigma_{j k}\left(\mathbf{X}_{p}^{\prime} \mathbf{X}_{p}\right)^{-1}\), where \(\sigma_{j k}=\operatorname{cov}\left(y_{j}, y_{k}\right)\) is the \((j k)\) th element of \(\boldsymbol{\Sigma}\). The notation \(\operatorname{cov}\left(\hat{\boldsymbol{\beta}}_{p(j)}, \hat{\boldsymbol{\beta}}_{p(k)}\right)\) indicates a matrix containing the covariance of each element of \(\hat{\boldsymbol{\beta}}_{p(j)}\) and each element of \(\hat{\boldsymbol{\beta}}_{p(k)}\). Now for the covariance matrix, \(\operatorname{cov}\left(\hat{\mathbf{y}}_{i}^{\prime}\right)=\operatorname{cov}\left(\mathbf{x}_{p i}^{\prime} \hat{\boldsymbol{\beta}}_{p(1)}, \ldots, \mathbf{x}_{p i}^{\prime} \hat{\boldsymbol{\beta}}_{p(m)}\right)\), we need the variance of each of the \(m\) random variables and the covariance of each pair. By Problem 10.5
and (3.70), \(\operatorname{var}\left(\mathbf{x}_{p i}^{\prime} \hat{\boldsymbol{\beta}}_{p(1)}\right)=\mathbf{x}_{p i}^{\prime} \operatorname{cov}\left(\hat{\boldsymbol{\beta}}_{p(1)}\right) \mathbf{x}_{p i}=\sigma_{11} \mathbf{x}_{p i}^{\prime}\left(\mathbf{X}_{p}^{\prime} \mathbf{X}_{p}\right)^{-1} \mathbf{x}_{p i}\). Similarly, \(\operatorname{cov}\left(\mathbf{x}_{p i}^{\prime} \hat{\boldsymbol{\beta}}_{p(1)}, \mathbf{x}_{p i}^{\prime} \hat{\boldsymbol{\beta}}_{p(2)}\right)=\sigma_{12} \mathbf{x}_{p i}^{\prime}\left(\mathbf{X}_{p}^{\prime} \mathbf{X}_{p}\right)^{-1} \mathbf{x}_{p i}\). The other variances and covariances can be obtained in an analogous manner.
10.10 \(\mathrm{By}(10.92), \mathbf{S}_{p}=\mathbf{E}_{p} /(n-p)\). Then by (10.98),
\[
\begin{aligned}
\mathbf{C}_{p} & =p \mathbf{I}+(n-p) \mathbf{S}_{k}^{-1}\left(\mathbf{S}_{p}-\mathbf{S}_{k}\right) \\
& =p \mathbf{I}+(n-p) \mathbf{S}_{k}^{-1} \frac{\mathbf{E}_{p}}{n-p}-(n-p) \mathbf{I} \\
& =\mathbf{S}_{k}^{-1} \mathbf{E}_{p}+(2 p-n) \mathbf{I}
\end{aligned}
\]
10.11 \(\left|\mathbf{E}_{k}^{-1} \mathbf{E}_{p}\right|=\left|\mathbf{E}_{k}^{-1} \|\left|\mathbf{E}_{p}\right|>0\right.\), because both \(\mathbf{E}_{k}^{-1}\) and \(\mathbf{E}_{p}\) are positive definite.
10.12 By (10.99), \(\mathbf{C}_{p}=\mathbf{S}_{k}^{-1} \mathbf{E}_{p}+(2 p-n)\) I. Using \(\mathbf{S}_{k}=\mathbf{E}_{k} /(n-k)\), we obtain
\[
\begin{aligned}
\left(\frac{\mathbf{E}_{k}}{n-k}\right)^{-1} \mathbf{E}_{p} & =\mathbf{C}_{p}-(2 p-n) \mathbf{I} \\
(n-k) \mathbf{E}_{k}^{-1} \mathbf{E}_{p} & =\mathbf{C}_{p}+(n-2 p) \mathbf{I}
\end{aligned}
\]
10.13 If \(\mathbf{C}_{p}\) is replaced by \(p \mathbf{I}\) in (10.101), we obtain
\[
\mathbf{E}_{k}^{-1} \mathbf{E}_{p}=\frac{\mathbf{C}_{p}+(n-2 p) \mathbf{I}}{n-k}=\frac{p \mathbf{I}+n \mathbf{I}-2 p \mathbf{I}}{n-k}=\frac{(n-p) \mathbf{I}}{n-k}
\]
10.14 (a) For this scenario, the Zyskind condition holds if \((\boldsymbol{\Sigma} \otimes I) X^{\text {SUR }}=X^{\text {SUR }} \mathbf{Q}\). Use property (2.121) to find the matrix \(\mathbf{Q}\).
(b) For this scenario, the Zyskind condition holds if \((\boldsymbol{\Sigma} \otimes \mathbf{I}) \mathbf{X}^{\text {SUR }}=\mathbf{X}^{\mathrm{SUR}} \mathbf{Q}\). Use the diagonal property of \(\boldsymbol{\Sigma}\) to find the matrix \(\mathbf{Q}\).
\(\mathbf{1 0 . 1 5} \quad\) (a) \(\hat{\mathbf{B}}=\left(\begin{array}{rr}.6264 & 83.243 \\ .0009 & .029 \\ -.0010 & -.013 \\ .0015 & -.004\end{array}\right)\)
(b) \(\Lambda=.724, V^{(s)}=.280, U^{(s)}=.375, \theta=.264\)
(c) \(\lambda_{1}=.3594, \lambda_{2}=.0160\). The essential rank of \(\hat{\mathbf{B}}_{1}\) is 1 , and the power ranking is \(\theta>U^{(s)}>\Lambda>V^{(s)}\).
(d) The Wilks' \(\Lambda\) test of \(x_{2}\) adjusted for \(x_{1}\) and \(x_{3}\), for example, is given by (10.74) as
\[
\Lambda\left(x_{2} \mid x_{1}, x_{3}\right)=\frac{\Lambda\left(x_{1}, x_{2}, x_{3}\right)}{\Lambda\left(x_{1}, x_{3}\right)}
\]
which is distributed as \(\Lambda_{p, 1, n-4}\) and has an exact \(F\)-transformation. The tests for \(x_{1}\) and \(x_{3}\) are similar. For the three tests we obtain the following:
\begin{tabular}{rrrr} 
& \(\Lambda\) & \(F\) & \(p\)-Value \\
\hline\(x_{1} \mid x_{2}, x_{3}\) & .931 & 1.519 & .231 \\
\(x_{2} \mid x_{1}, x_{3}\) & .887 & 2.606 & .086 \\
\(x_{3} \mid x_{1}, x_{2}\) & .762 & 6.417 & .004
\end{tabular}
(e) Confidence intervals for the two elements of \(E\left(\mathbf{y}_{0}\right)\) are: \((0.86,0.94)\) and (87.20, 93.39).
(f) Prediction intervals for the two elements of \(y_{0}\) are: \((0.67,1.13)\) and (72.63, 107.98).
\(10.16 \quad\) (a) \(\hat{\mathbf{B}}=\left(\begin{array}{rr}34.282 & 35.802 \\ .394 & .245 \\ .529 & .471\end{array}\right)\)
(b) \(\Lambda=.377, V^{(s)}=.625, U^{(s)}=1.647, \theta=.622\)
(c) \(\lambda_{1}=1.644, \lambda_{2}=.0029\). The essential rank of \(\hat{\mathbf{B}}_{1}\) is 1 , and the power ranking is \(\theta>U^{(s)}>\Lambda>V^{(s)}\).
(d)
\begin{tabular}{rrrr} 
& \(\Lambda\) & \(F\) & \(p\)-Value \\
\hline\(x_{1} \mid x_{2}\) & .888 & 1.327 & .287 \\
\(x_{2} \mid x_{1}\) & .875 & 1.506 & .245
\end{tabular}
(e) Confidence intervals for the two elements of \(E\left(\mathrm{y}_{0}\right)\) are: \((170.31,180.44)\) and (139.51, 147.25).
(f) Prediction intervals for the two elements of \(y_{0}\) are: \((160.23,190.52)\) and (131.82, 154.94).
\(10.17 \quad\) (a) \(\hat{\mathbf{B}}=\left(\begin{array}{rrr}54.870 & 65.679 & 58.106 \\ .054 & -.048 & .018 \\ -.024 & .163 & .012 \\ .107 & -.036 & .125\end{array}\right)\)
(b) \(\Lambda=.665, V^{(s)}=.365, U^{(s)}=.458, \theta=.240\)
(c) \(\lambda_{1}=.3159, \lambda_{2}=.1385, \lambda_{3}=.0037\). The essential rank of \(\hat{\mathbf{B}}_{1}\) is 2 , and the power ranking is \(V^{(s)}>\Lambda>U^{(s)}>\theta\).
(d)
\begin{tabular}{rrrr} 
& \(\Lambda\) & \(F\) & \(p\)-Value \\
\hline\(x_{1} \mid x_{2}, x_{3}\) & .942 & .903 & .447 \\
\(x_{2} \mid x_{1}, x_{3}\) & .847 & 2.653 & .060 \\
\(x_{3} \mid x_{1}, x_{2}\) & .829 & 3.020 & .040
\end{tabular}
(e)
\begin{tabular}{rrrr} 
& \(\Lambda\) & \(F\) & \(p\)-Value \\
\hline\(y_{1} \mid y_{2}, y_{3}\) & .890 & 1.804 & .160 \\
\(y_{2}| |_{1}, y_{3}\) & .833 & 2.932 & .044 \\
\(y_{3} \mid y_{1}, y_{2}\) & .872 & 2.159 & .106
\end{tabular}
(f) Confidence intervals for the three elements of \(E\left(\mathbf{y}_{0}\right)\) are: \((65.55,71.62)\), (71.06, 76.27), and (70.96, 76.29).
(g) Prediction intervals for the three elements of \(\mathbf{y}_{0}\) are: \((49.07,88.10)\), (56.92, 90.41), and (56.51, 90.74).
\(\mathbf{1 0 . 1 8} \quad\) (a) \(\hat{\mathbf{B}}=\left(\begin{array}{rr}-4.140 & 4.935 \\ 1.103 & -.955 \\ .231 & -.222 \\ 1.171 & 1.773 \\ .111 & .048 \\ .617 & -.058 \\ .267 & .485 \\ -.263 & -.209 \\ -.004 & -.004\end{array}\right)\)
Test of overall regression of \(\left(y_{1}, y_{2}\right)\) on \(\left(x_{1}, x_{2}, \ldots, x_{8}\right): \Lambda=.4642\) (with \(p=2\), exact \(F=1.169, p\)-value \(=.332\) ). Tests on subsets (the \(F\) 's are exact because \(p=2\) ):
\begin{tabular}{lccc} 
& \(\Lambda\) & \(F\) & \(p\)-Value \\
\hline (b) \(x_{7}, x_{8} \mid x_{1}, x_{2}, \ldots, x_{6}\) & .856 & .808 & .527 \\
(c) \(x_{4}, x_{5}, x_{6} \mid x_{1}, x_{2}, x_{3}, x_{7}, x_{8}\) & .674 & 1.457 & .218 \\
(d) \(x_{1}, x_{2}, x_{3} \mid x_{4}, x_{5}, \ldots, x_{8}\) & .569 & 2.170 & .066
\end{tabular}
10.19 (a) The overall test of \(\left(y_{1}, y_{2}\right)\) on \(\left(x_{1}, x_{2}, \ldots, x_{8}\right)\) gives \(\Lambda=.4642\), with (exact) \(F=1.169\) ( \(p\)-value \(=.332\) ). Even though this test result is not significant, we give the results of a backward elimination for illustrative purposes:

Partial \(\Lambda\)-Test on Each \(x_{i}\) Using (10.87)
\begin{tabular}{crrrrrrrr} 
Step & \(x_{1}\) & \(x_{2}\) & \(x_{3}\) & \(x_{4}\) & \(x_{5}\) & \(x_{6}\) & \(x_{7}\) & \(x_{8}\) \\
\hline 1 & .723 & .969 & .817 & .859 & .821 & .945 & .924 & .943 \\
2 & .741 & & .801 & .851 & .839 & .948 & .927 & .940 \\
3 & .737 & & .837 & .798 & .757 & & .949 & .938 \\
4 & .675 & & .852 & .821 & .794 & & & .925 \\
5 & .680 & & .861 & .835 & .817 & & & \\
6 & .701 & & & .805 & .806 & & & \\
7 & .855 & & & .930 & & & & \\
8 & .891 & & & & & & &
\end{tabular}

At each step, the variable deleted was not significant. In fact, the variable remaining at the last step, \(x_{1}\), is not a significant predictor of \(y_{1}\) and \(y_{2}\).
(b) There were no significant \(x\) 's, but to illustrate, we will use the three \(x\) 's at step 6 above and test for each \(y\) :
\begin{tabular}{rrrr} 
& \(\Lambda\) & \(F\) & \(p\)-Value \\
\hline\(y_{1} \mid y_{2}\) & .701 & 3.548 & .029 \\
\(y_{2} \mid y_{1}\) & .808 & 1.984 & .142
\end{tabular}
\(\mathbf{1 0 . 2 0} \quad\) (a) \(\hat{\mathbf{B}}=\left(\begin{array}{rrr}43.703 & 46.793 & 187.923 \\ .019 & -.098 & 1.016 \\ .139 & .185 & -4.953 \\ .204 & .107 & 1.606\end{array}\right)\)
\[
\Lambda=.167, V^{(s)}=.883, U^{(s)}=4.709, \theta=.823
\]
(b) \(\hat{\mathbf{B}}=\left(\begin{array}{rrr}99.817 & -29.120 & 121.595 \\ -.008 & -.224 & -.027 \\ .097 & 1.252 & 5.775 \\ -.049 & -.442 & -1.768 \\ -.022 & -.631 & -.488 \\ -.159 & 2.128 & 4.387 \\ .054 & -.037 & -.476\end{array}\right)\)
\[
\Lambda=.110, V^{(s)}=1.350, U^{(s)}=4.319, \theta=.769
\]
(c) \(\hat{\mathbf{B}}=\left(\begin{array}{rr}710.236 & 123.403 \\ -1.625 & .055 \\ 24.648 & .094 \\ -8.622 & -.334 \\ -8.224 & .462 \\ 23.626 & -.110 \\ 2.862 & .427 \\ -16.186 & -.267 \\ -.268 & .014 \\ -1.160 & -.336\end{array}\right)\)
\[
\Lambda=.102, V^{(s)}=1.236, U^{(s)}=5.475, \theta=.827
\]
10.21 Using a backward elimination based on (10.87), we obtain the following partial \(\Lambda\)-values:
\begin{tabular}{crrrrrrrrr} 
Step & \(x_{1}\) & \(x_{2}\) & \(x_{3}\) & \(x_{4}\) & \(x_{5}\) & \(x_{6}\) & \(x_{7}\) & \(x_{8}\) & \(x_{9}\) \\
\hline 1 & .993 & .962 & .916 & .958 & .919 & .879 & .981 & .999 & .797 \\
2 & .994 & .962 & .916 & .956 & .099 & .874 & .980 & & .626 \\
3 & & .951 & .883 & .954 & .912 & .873 & .981 & & .626 \\
4 & & .948 & .884 & .955 & .861 & .867 & & & .561 \\
5 & & .953 & .862 & & .840 & .803 & & & .561 \\
6 & & & .830 & & .781 & .783 & & & .535
\end{tabular}

At step 6, we stop and retain all four \(x\) 's because each \(\Lambda\) has a \(p\)-value less than 05.

\section*{CHAPTER 11}
11.1 By (3.38), \(\mathbf{S}_{y y}=\mathbf{D}_{y} \mathbf{R}_{y y} \mathbf{D}_{y}\) and \(\mathbf{S}_{x x}=\mathbf{D}_{x} \mathbf{R}_{x x} \mathbf{D}_{x}\), where \(\mathbf{D}_{y}\) and \(\mathbf{D}_{x}\) are defined below (11.14). Similarly, \(\mathbf{S}_{y x}=\mathbf{D}_{y} \mathbf{R}_{y x} \mathbf{D}_{x}\) and \(\mathbf{S}_{x y}=\mathbf{D}_{x} \mathbf{R}_{x y} \mathbf{D}_{y}\). Substitute these into (11.7), replace I by \(\mathbf{D}_{y}^{-1} \mathbf{D}_{y}\), and factor out \(\mathbf{D}_{y}\) on the right.
11.2 Multiply (11.7) by \(\mathbf{S}_{x x}^{-1} \mathbf{S}_{x y}\) on the left to obtain \(\left(\mathbf{S}_{x x}^{-1} \mathbf{S}_{x y} \mathbf{S}_{y y}^{-1} \mathbf{S}_{y x} \mathbf{S}_{x x}^{-1} \mathbf{S}_{x y}-\right.\) \(\left.r^{2} \mathbf{S}_{x x}^{-1} \mathbf{S}_{x y}\right) \mathbf{a}=\mathbf{0}\). Factor out \(\mathbf{S}_{x x}^{-1} \mathbf{S}_{x y}\) on the right to write this in the form \(\left(\mathbf{S}_{x x}^{-1} \mathbf{S}_{x y} \mathbf{S}_{y y}^{-1} \mathbf{S}_{y x}-r^{2} \mathbf{I}\right) \mathbf{S}_{x x}^{-1} \mathbf{S}_{x y} \mathbf{a}=\mathbf{0}\). Upon comparing this to (11.8), we see that \(\mathbf{b}=\mathbf{S}_{x x}^{-1} \mathbf{S}_{x y} \mathbf{a}\).
11.3 When \(p=1, s\) is also 1 , and there is only one canonical correlation, which is equal to \(R^{2}\) from multiple regression [see comments between (11.28) and (11.29)]. Thus
\[
\Lambda=\frac{1-r_{1}^{2}}{1-c_{1}^{2}}=\frac{1-R_{f}^{2}}{1-R_{r}^{2}}
\]
\(11.4 F=\frac{(1-\Lambda)(n-q-1)}{\Lambda h}=\frac{\left[1-\left(1-R_{f}^{2}\right) /\left(1-R_{r}^{2}\right)\right](n-q-1)}{\left[\left(1-R_{f}^{2}\right) /\left(1-R_{r}^{2}\right)\right] h}\)
\(=\frac{\left[1-R_{r}^{2}-\left(1-R_{f}^{2}\right)\right](n-q-1)}{\left(1-R_{f}^{2}\right) h}\)
\(=\frac{\left(R_{f}^{2}-R_{r}^{2}\right)(n-q-1)}{\left(1-R_{f}^{2}\right) h}\)
\(11.5 \mathrm{By}(11.39)\),
\[
r_{i}^{2}=\frac{\lambda_{i}}{1+\lambda_{i}}, \quad r_{i}^{2}+r_{i}^{2} \lambda_{i}=\lambda_{i}, \quad \lambda_{i}\left(1-r_{i}^{2}\right)=r_{i}^{2}
\]
11.6 Substitute \(\mathbf{E}=(n-1)\left(\mathbf{S}_{y y}-\mathbf{S}_{y x} \mathbf{S}_{x x}^{-1} \mathbf{S}_{x y}\right)\) and \(\mathbf{H}=(n-1) \mathbf{S}_{y x} \mathbf{S}_{x x}^{-1} \mathbf{S}_{x y}\) from (11.44) and (11.45) into (11.37):
\[
\begin{aligned}
\mathbf{H a} & =\lambda \mathbf{E a}, \\
(n-1) \mathbf{S}_{y x} \mathbf{S}_{x x}^{-1} \mathbf{S}_{x y} \mathbf{a} & =(n-1) \lambda\left(\mathbf{S}_{y y}-\mathbf{S}_{y x} \mathbf{S}_{x x}^{-1} \mathbf{S}_{x y}\right) \mathbf{a}, \\
\mathbf{S}_{y x} \mathbf{S}_{x x}^{-1} \mathbf{S}_{x y} \mathbf{a} & =\lambda\left(\mathbf{S}_{y y}-\mathbf{S}_{y x} \mathbf{S}_{x x}^{-1} \mathbf{S}_{x y}\right) \mathbf{a} .
\end{aligned}
\]
11.7 By (11.42), \(\mathbf{S}_{y x} \mathbf{S}_{x x}^{-1} \mathbf{S}_{x y} \mathbf{a}=r^{2} \mathbf{S}_{y y} \mathbf{a}\). Subtracting \(r^{2} \mathbf{S}_{y x} \mathbf{S}_{x x}^{-1} \mathbf{S}_{x y} \mathbf{a}\) from both sides gives
\[
\begin{aligned}
\mathbf{S}_{y x} \mathbf{S}_{x x}^{-1} \mathbf{S}_{x y} \mathbf{a}-r^{2} \mathbf{S}_{y x} \mathbf{S}_{x x}^{-1} \mathbf{S}_{x y} \mathbf{a} & =r^{2} \mathbf{S}_{y y} \mathbf{a}-r^{2} \mathbf{S}_{y x} \mathbf{S}_{x x}^{-1} \mathbf{S}_{x y} \mathbf{a} \\
\left(1-r^{2}\right) \mathbf{S}_{y x} \mathbf{S}_{x x}^{-1} \mathbf{S}_{x y} \mathbf{a} & =r^{2}\left(\mathbf{S}_{y y}-\mathbf{S}_{y x} \mathbf{S}_{x x}^{-1} \mathbf{S}_{x y}\right) \mathbf{a}
\end{aligned}
\]
11.8 (a) \(r_{1}=.5142, \quad r_{2}=.1255\)
(b)

\begin{tabular}{lrr} 
& \(\mathbf{d}_{1}\) & \(\mathbf{d}_{2}\) \\
\hline\(x_{1}\) & .436 & .823 \\
\(x_{2}\) & -.704 & -.455 \\
\(x_{3}\) & 1.081 & -.401
\end{tabular}
(c) \begin{tabular}{cccc}
\(k\) & \(\Lambda\) & Approximate \(F\) & \(p\)-Value \\
\hline 1 & .7240 & 2.395 & .035 \\
2 & .9843 & .336 & .716
\end{tabular}

\section*{CHAPTER 12}
12.1 From \(\lambda=\mathbf{a}^{\prime} \mathbf{S a} / \mathbf{a}^{\prime} \mathbf{a}\) in (12.7), we obtain \(\lambda \mathbf{a}^{\prime} \mathbf{a}=\mathbf{a S a}\), which can be factored as \(\mathbf{a}^{\prime}(\mathbf{S a}-\lambda \mathbf{a})=0\). Since \(\mathbf{a}=\mathbf{0}\) is not a solution to \(\lambda=\mathbf{a}^{\prime} \mathbf{S a} / \mathbf{a}^{\prime} \mathbf{a}\), we have \(\mathbf{S a}-\lambda \mathbf{a}=\mathbf{0}\).
12.2 \(|\mathbf{R}-\lambda \mathbf{I}|=0, \quad\left|\begin{array}{cc}1-\lambda & r \\ r & 1-\lambda\end{array}\right|=(1-\lambda)^{2}-r^{2}=0\),
\((1-\lambda+r)(1-\lambda-r)=0, \quad \lambda=1 \pm r\)
With \(\lambda_{1}=1+r\) in \(\left(\mathbf{R}-\lambda_{1} \mathbf{I}\right) \mathbf{a}_{1}=\mathbf{0}\), we obtain
\[
\left(\begin{array}{rr}
-r & r \\
r & -r
\end{array}\right)\binom{a_{11}}{a_{12}}=\binom{0}{0}
\]
which gives \(a_{11}=a_{12}\) for any \(r\). Normalizing to \(\mathbf{a}_{1}^{\prime} \mathbf{a}_{1}=1\), yields \(a_{11}=\) \(1 / \sqrt{2}\).
12.3 (a) By (4.14) and a comment in Section 7.1, the likelihood ratio is given by \(\mathrm{LR}=\left(|\mathbf{S}| /\left|\mathbf{S}_{0}\right|\right)^{n / 2}\), where \(\mathbf{S}_{0}\) is the estimate of \(\boldsymbol{\Sigma}\) under \(H_{0}\). By (2.108) and (7.6), the test statistic is
\[
\begin{aligned}
-2 \ln \mathrm{LR} & =-2 \ln \left(\frac{|\mathbf{S}|}{\left|\mathbf{S}_{0}\right|}\right)^{n / 2}=-2\left(\frac{n}{2}\right) \ln \frac{\prod_{i=1}^{p-k} \lambda_{i} \prod_{i=p-k+1}^{p} \lambda_{i}}{\prod_{i=1}^{p-k} \lambda_{i} \prod_{i=p-k+1}^{p} \bar{\lambda}} \\
& =-n \ln \frac{\prod_{i=p-k+1}^{p} \lambda_{i}}{\bar{\lambda}^{k}}=n\left(k \ln \bar{\lambda}-\sum_{i=p-k+1}^{p} \lambda_{i}\right)
\end{aligned}
\]

In (12.15), the coefficient \(n\) is modified to give an improved chi-square approximation.
12.4 If \(\mathbf{S}\) is diagonal, then \(\lambda_{i}=s_{i i}\), as in (12.17). Thus
\[
\begin{gathered}
\mathbf{S a}_{i}=\lambda_{i} \mathbf{a}_{i}=s_{i i} \mathbf{a}_{i} \\
\left(\begin{array}{cccc}
s_{11} & 0 & \cdots & 0 \\
0 & s_{22} & \cdots & 0 \\
\vdots & \vdots & & \vdots \\
0 & 0 & \cdots & s_{p p}
\end{array}\right)\left(\begin{array}{c}
a_{i 1} \\
a_{i 2} \\
\vdots \\
a_{i p}
\end{array}\right)=\left(\begin{array}{c}
s_{11} a_{i 1} \\
s_{22} a_{i 2} \\
\vdots \\
s_{p p} a_{i p}
\end{array}\right)=\left(\begin{array}{c}
s_{i i} a_{i 1} \\
s_{i i} a_{i 2} \\
\vdots \\
s_{i i} a_{i p}
\end{array}\right)
\end{gathered}
\]

From the first element, we obtain \(s_{11} a_{i 1}=s_{i i} a_{i 1}\) or \(\left(s_{11}-s_{i i}\right) a_{i 1}=0\). Since \(s_{11}-s_{i i} \neq 0\) (unless \(i=1\) ), we must have \(a_{i 1}=0\). Thus, \(\mathbf{a}_{i}=\) \(\left(0, \ldots, 0, a_{i i}, 0, \ldots, 0\right)^{\prime}\), and normalizing \(\mathbf{a}_{i}\) leads to \(a_{i i}=1\).
12.5 By (10.34) and (12.2),
\[
\begin{aligned}
& \quad R_{y_{i} \mid z_{1}, \ldots, z_{k}}^{2}=\frac{\mathbf{s}_{y_{i} z}^{\prime} \mathbf{S}_{z z}^{-1} \mathbf{s}_{y_{i} z}}{s_{y_{i}}^{2}} \\
& =\left(s_{y_{i} z_{1}}, s_{y_{i} z_{2}}, \ldots, s_{y_{i} z_{k}}\right)\left(\begin{array}{cccc}
s_{z_{1}}^{2} & 0 & \cdots & 0 \\
0 & s_{z_{2}}^{2} & \cdots & 0 \\
\vdots & & & \vdots \\
0 & \cdots & & s_{z_{k}}^{2}
\end{array}\right)^{-1}\left(\begin{array}{c}
s_{y_{i} z_{1}} \\
s_{y_{i} z_{2}} \\
\vdots \\
s_{y_{i} z_{k}}
\end{array}\right) / s_{y_{i}}^{2} .
\end{aligned}
\]

Show that this is equal to
\[
R_{y_{i} \mid z_{1}, \ldots, z_{k}}^{2}=\sum_{j=1}^{k} \frac{s_{y_{i} z_{j}}^{2}}{s_{z_{j}}^{2} s_{y_{i}}^{2}}=\sum_{j=1}^{k} r_{y_{i} z_{j}}^{2}
\]
12.6 The variances of \(y_{1}, y_{2}, x_{1}, x_{2}\), and \(x_{3}\) on the diagonal of \(\mathbf{S}\) are \(.016,70.6\), 1106.4, 2381.9, and 2136.4. The eigenvalues of \(\mathbf{S}\) and \(\mathbf{R}\) are as follows:
\begin{tabular}{rcccccc}
\hline \multicolumn{4}{c}{\(\mathbf{S}\)} & & \multicolumn{4}{c}{\(\mathbf{R}\)} \\
\cline { 1 - 1 } \cline { 5 - 7 } & \multicolumn{8}{c}{\(\lambda_{i}\)} & \(\lambda_{i} / \sum_{j} \lambda_{j}\) & Cumulative & & \(\lambda_{i}\) & \(\lambda_{i} / \sum_{j} \lambda_{j}\) & Cumulative \\
\hline 3466.18 & .608607 & .60861 & & 1.72 & .34 & .34 \\
1264.47 & .222021 & .83063 & & 1.23 & .25 & .59 \\
895.27 & .157195 & .98782 & & .96 & .19 & .78 \\
69.34 & .012174 & .99999 & & .79 & .16 & .94 \\
.01 & .000002 & 1.00000 & & .30 & .06 & 1.00 \\
\hline
\end{tabular}

Two principal components of \(\mathbf{S}\) account for \(83 \%\) of the variance, but it requires three principal components of \(\mathbf{R}\) to reach \(78 \%\). For most purposes we would use two components of S, although with three we could account for \(99 \%\) of the variance. However, we show all five eigenvectors below because of the interesting pattern they exhibit. The first principal component is largely a weighted average of the last two variables, \(x_{2}\) and \(x_{3}\), which have the largest variances. The second and third components represent contrasts in the last three variables and could be described as "shape" components. The fourth and fifth components are associated uniquely with \(y_{2}\) and \(y_{1}\), respectively. These components are "variable specific," as described in the discussion of method 1 in Section 12.6.

As expected, the principal components of \(\mathbf{R}\) show an entirely different pattern. All five variables contribute to the first three components of \(\mathbf{R}\), whereas in \(\mathbf{S}\), \(y_{1}\) and \(y_{2}\) have small variances and contribute almost nothing to the first three components. The eigenvectors of \(\mathbf{S}\) and \(\mathbf{R}\) are as follows:
\begin{tabular}{|c|c|c|c|c|c|c|c|c|c|c|}
\hline \multicolumn{6}{|c|}{S} & \multicolumn{5}{|c|}{R} \\
\hline & \(\mathbf{a}_{1}\) & \(\mathbf{a}_{2}\) & \(\mathbf{a}_{3}\) & \(\mathbf{a}_{4}\) & \(\mathbf{a}_{5}\) & \(\mathrm{a}_{1}\) & \(\mathbf{a}_{2}\) & \(\mathrm{a}_{3}\) & \(\mathbf{a}_{4}\) & \(\mathrm{a}_{5}\) \\
\hline \(y_{1}\) & . 0004 & -. 0008 & . 0018 & . 0029 & . 9999 & . 42 & . 53 & -. 42 & \(-.40\) & . 46 \\
\hline \(y_{2}\) & -. 0080 & . 0166 & . 0286 & . 9994 & -. 0029 & . 07 & . 68 & . 16 & . 70 & \(-.10\) \\
\hline \(x_{1}\) & . 1547 & . 6382 & . 7535 & -. 0309 & -. 0008 & . 36 & . 20 & . 76 & -. 44 & -. 24 \\
\hline \(x_{2}\) & . 7430 & . 4279 & -. 5145 & . 0136 & . 0009 & . 54 & -. 43 & . 25 & . 39 & . 56 \\
\hline \(x_{3}\) & . 6511 & -. 6397 & . 4083 & . 0042 & -. 0015 & . 63 & -. 18 & -. 40 & . 10 & -. 64 \\
\hline
\end{tabular}
\(\mathbf{1 2 . 7} \mathbf{S}=\left(\begin{array}{lllll}65.1 & 33.6 & 47.6 & 36.8 & 25.4 \\ 33.6 & 46.1 & 28.9 & 40.3 & 28.4 \\ 47.6 & 28.9 & 60.7 & 37.4 & 41.1 \\ 36.8 & 40.3 & 37.4 & 62.8 & 31.7 \\ 25.4 & 28.4 & 41.1 & 31.7 & 58.2\end{array}\right)\)
\[
\mathbf{R}=\left(\begin{array}{rrrrr}
1.00 & .61 & .76 & .58 & .41 \\
.61 & 1.00 & .55 & .75 & .55 \\
.76 & .55 & 1.00 & .61 & .69 \\
.58 & .75 & .61 & 1.00 & .52 \\
.41 & .55 & .69 & .52 & 1.00
\end{array}\right)
\]

The eigenvalues of \(S\) and \(\mathbf{R}\) are as follows:
\begin{tabular}{ccccccc}
\hline \multicolumn{3}{c}{\(\mathbf{S}\)} & & \multicolumn{4}{c}{\(\mathbf{R}\)} \\
\cline { 1 - 1 } \cline { 5 - 8 }\(\lambda_{i}\) & \(\lambda_{i} / \sum_{j} \lambda_{j}\) & Cumulative & & \(\lambda_{i}\) & \(\lambda_{i} / \sum_{j} \lambda_{i}\) & Cumulative \\
\hline 200.4 & .684 & .684 & & 3.42 & .683 & .683 \\
36.1 & .123 & .807 & & .61 & .123 & .806 \\
34.1 & .116 & .924 & & .57 & .114 & .921 \\
15.0 & .051 & .975 & & .27 & .054 & .975 \\
7.4 & .025 & 1.000 & & .13 & .025 & 1.000 \\
\hline
\end{tabular}

The first three eigenvectors of \(\mathbf{S}\) and \(\mathbf{R}\) are as follows:
\begin{tabular}{rrrrrrr}
\hline \multicolumn{8}{c}{\(\mathbf{S}\)} & & \multicolumn{3}{c}{\(\mathbf{R}\)} \\
\cline { 1 - 3 } \cline { 5 - 7 } & \(\mathbf{a}_{1}\) & \(\mathbf{a}_{2}\) & \(\mathbf{a}_{3}\) & & \(\mathbf{a}_{1}\) & \(\mathbf{a}_{2}\) \\
\hline .47 & -.58 & -.42 & & .44 & -.20 & -.68 \\
.39 & -.11 & .45 & & .45 & -.43 & .35 \\
.49 & .10 & -.48 & & .47 & .37 & -.38 \\
.47 & -.12 & .62 & & .45 & -.39 & .33 \\
.41 & .80 & -.09 & & .41 & .70 & .41 \\
\hline
\end{tabular}

The variances in \(\mathbf{S}\) are nearly identical, and the covariances are likewise similar in magnitude. Consequently, the percent of variance explained by the eigenvalues of \(\mathbf{S}\) and \(\mathbf{R}\) are indistinguishable. The interpretation of the second principal component from \(S\) is slightly different from that of the second one from \(\mathbf{R}\), but otherwise there is little to choose between them.
12.8 The variances on the diagonal of \(S\) are \(95.5,73.2,76.2,808.6,505.9\), and 508.7. The eigenvalues of \(\mathbf{S}\) and \(\mathbf{R}\) are as follows:
\begin{tabular}{rccccccc}
\hline \multicolumn{3}{c}{\(\mathbf{S}\)} & & \multicolumn{3}{c}{\(\mathbf{R}\)} \\
\cline { 1 - 4 } \cline { 5 - 8 }\(\lambda_{i}\) & \(\lambda_{i} / \sum_{j} \lambda_{j}\) & Cumulative & & \(\lambda_{i}\) & \(\lambda_{i} / \sum_{j} \lambda_{j}\) & Cumulative \\
\hline 1152.0 & .557 & .557 & & 2.17 & .363 & .363 \\
394.1 & .191 & .748 & & 1.08 & .180 & .543 \\
310.8 & .150 & .898 & & .98 & .163 & .706 \\
97.8 & .047 & .945 & & .87 & .144 & .850 \\
68.8 & .033 & .978 & & .55 & .092 & .942 \\
44.6 & .022 & 1.000 & & .35 & .058 & 1.000 \\
\hline
\end{tabular}

We could keep either two or three components from \(\mathbf{S}\). The first three components of \(S\) account for a larger percent of variance than do those from \(R\). The first three eigenvectors of \(\mathbf{S}\) and \(\mathbf{R}\) are as follows:
\begin{tabular}{|c|c|c|c|c|c|}
\hline \multicolumn{3}{|c|}{S} & \multicolumn{3}{|c|}{R} \\
\hline \(\mathbf{a}_{1}\) & \(\mathrm{a}_{2}\) & \(\mathrm{a}_{3}\) & \(\mathrm{a}_{1}\) & \(\mathrm{a}_{2}\) & \(\mathrm{a}_{3}\) \\
\hline . 080 & . 092 & -. 069 & . 336 & . 176 & . 497 \\
\hline . 034 & -. 018 & . 202 & . 258 & . 843 & -. 093 \\
\hline . 076 & . 122 & -. 011 & . 370 & . 049 & . 466 \\
\hline . 758 & -. 446 & -. 469 & . 475 & -. 329 & -. 358 \\
\hline . 493 & -. 081 & . 844 & . 486 & . 079 & -. 567 \\
\hline . 412 & . 878 & -. 147 & . 471 & -. 376 & . 278 \\
\hline
\end{tabular}

As expected, the first three principal components from \(\mathbf{S}\) are heavily influenced by the last three variables because of their relatively large variances.
12.9 The variances on the diagonal of \(S\) are \(.69 ; 5.4 ; 2,006,682.4 ; 90.3 ; 56.4 ; 18.1\). With the large variance of \(y_{3}\), we would expect the first principal component from \(\mathbf{S}\) to account for most of the variance, and \(y_{3}\) would essentially constitute that single component. This is indeed the pattern that emerges in the eigenvalues and eigenvectors of \(\mathbf{S}\). The principal components from \(\mathbf{R}\), on the other hand, are not dominated by \(y_{3}\). The eigenvalues of \(\mathbf{S}\) and \(\mathbf{R}\) are as follows:
\begin{tabular}{rcrrcc}
\hline \multicolumn{2}{c}{\(\mathbf{S}\)} & & \multicolumn{3}{c}{\(\mathbf{R}\)} \\
\hline \multicolumn{1}{c}{\(\lambda_{i}\)} & \(\lambda_{i} / \sum_{j} \lambda_{j}\) & & \(\lambda_{i}\) & \(\lambda_{i} / \sum_{j} \lambda_{j}\) & Cumulative \\
\hline \(2,006,760\) & .999954 & & 2.42 & .404 & .404 \\
65 & .000033 & & 1.40 & .234 & .638 \\
18 & .000009 & & 1.03 & .171 & .809 \\
7 & .000003 & & .92 & .153 & .963 \\
3 & .000001 & & .20 & .033 & .996 \\
0 & .000000 & & .02 & .004 & 1.000 \\
\hline
\end{tabular}

Most of the correlations in \(\mathbf{R}\) are small (only three exceed .3), and its first three principal components account for only \(72 \%\) of the variance. The first three eigenvectors of \(\mathbf{S}\) and \(\mathbf{R}\) are as follows:
\begin{tabular}{rrrrrrr}
\hline \multicolumn{3}{c}{\(\mathbf{S}\)} & & \multicolumn{3}{c}{\(\mathbf{R}\)} \\
\cline { 1 - 3 } \cline { 5 - 7 } & \(\mathbf{a}_{1}\) & \(\mathbf{a}_{2}\) & \(\mathbf{a}_{3}\) & & \(\mathbf{a}_{1}\) & \(\mathbf{a}_{2}\) \\
\hline .00016 & .005 & -.0136 & & .424 & -.561 & -.150 \\
.00051 & .017 & .0787 & & .446 & -.528 & .087 \\
.99998 & -.001 & -.0002 & & .563 & .387 & -.051 \\
.00529 & .698 & .0174 & & .454 & .267 & .166 \\
.00322 & -.716 & .0195 & & .303 & .425 & -.296 \\
.00020 & .025 & .9965 & & .073 & .069 & .923 \\
\hline
\end{tabular}
12.10 Covariance matrix for males:
\[
\mathbf{S}_{M}=\left(\begin{array}{rrrr}
5.19 & 4.55 & 6.52 & 5.25 \\
4.55 & 13.18 & 6.76 & 6.27 \\
6.52 & 6.76 & 28.67 & 14.47 \\
5.25 & 6.27 & 14.47 & 16.65
\end{array}\right)
\]

Covariance matrix for females:
\[
\mathbf{S}_{F}=\left(\begin{array}{rrrr}
9.14 & 7.55 & 4.86 & 4.15 \\
7.55 & 18.60 & 10.22 & 5.45 \\
4.86 & 10.22 & 30.04 & 13.49 \\
4.15 & 5.45 & 13.49 & 28.00
\end{array}\right)
\]

The eigenvalues are as follows:
\begin{tabular}{rccccccc}
\hline \multicolumn{3}{c}{ Males } & & \multicolumn{3}{c}{ Females } \\
\cline { 1 - 1 } \cline { 5 - 7 }\(\lambda_{i}\) & \(\lambda_{i} / \sum_{j} \lambda_{j}\) & Cumulative & & \(\lambda_{i}\) & \(\lambda_{i} / \sum_{j} \lambda_{j}\) & Cumulative \\
\hline 43.56 & .684 & .684 & & 48.96 & .571 & .571 \\
11.14 & .175 & .858 & & 18.46 & .215 & .786 \\
6.47 & .102 & .960 & & 13.54 & .158 & .944 \\
2.52 & .040 & 1.000 & & 4.82 & .056 & 1.000 \\
\hline
\end{tabular}

The first two eigenvectors are as follows:
\begin{tabular}{crlrr}
\hline \multicolumn{2}{c}{ Males } & & \multicolumn{2}{c}{ Females } \\
& \(\mathbf{a}_{1}\) & \(\mathbf{a}_{2}\) & & \(\mathbf{a}_{1}\) \\
\hline .24 & .21 & & \(\mathbf{a}_{2}\) \\
.31 & .85 & & .27 \\
.76 & -.48 & & .68 & .62 \\
.52 & .09 & & .58 & -.72 \\
\hline
\end{tabular}

The variances in \(\mathbf{S}_{M}\) have a slightly wider range ( 5.19 to 28.67 ) than those in \(\mathbf{S}_{F}\) (9.14 to 30.04), and this is reflected in the eigenvalues. The first two components account for \(86 \%\) of the variance from \(S_{M}\), whereas the first two account for \(79 \%\) from \(\mathbf{S}_{F}\).
12.11 Covariance matrix for species 1 :
\[
\mathbf{S}_{1}=\left(\begin{array}{rrrr}
187.6 & 176.9 & 48.4 & 113.6 \\
176.9 & 345.4 & 76.0 & 118.8 \\
48.4 & 76.0 & 66.4 & 16.2 \\
113.6 & 118.8 & 16.2 & 239.9
\end{array}\right)
\]

Covariance matrix for species 2 :
\[
\mathbf{S}_{2}=\left(\begin{array}{rrrr}
101.8 & 128.1 & 37.0 & 32.6 \\
128.1 & 389.0 & 165.4 & 94.4 \\
37.0 & 165.4 & 167.5 & 66.5 \\
32.6 & 94.4 & 66.5 & 177.9
\end{array}\right)
\]

The eigenvalues are as follows:
\begin{tabular}{rccccccc}
\hline \multicolumn{3}{c}{ Species 1 } & & \multicolumn{3}{c}{ Species 2 } \\
\cline { 1 - 2 } \cline { 5 - 7 }\(\lambda_{i}\) & \(\lambda_{i} / \sum_{j} \lambda_{j}\) & Cumulative & & \(\lambda_{i}\) & \(\lambda_{i} / \sum_{j} \lambda_{j}\) & Cumulative \\
\hline 561.3 & .669 & .669 & & 555.7 & .664 & .664 \\
169.0 & .201 & .870 & & 145.4 & .174 & .838 \\
65.3 & .078 & .948 & & 93.5 & .112 & .950 \\
43.7 & .057 & 1.000 & & 41.7 & .050 & 1.000 \\
\hline
\end{tabular}

The first two eigenvectors are as follows:
\begin{tabular}{crlrr}
\hline \multicolumn{2}{c}{ Species 1 } & & \multicolumn{2}{c}{ Species 2 } \\
\cline { 5 - 5 } & & \(\mathbf{a}_{2}\) & & \(\mathbf{a}_{1}\) \\
\hline \(\mathbf{a}_{1}\) & .01 & & \(\mathbf{a}_{2}\) \\
\hline .50 & & .28 & -.20 \\
.72 & -.48 & & .81 & -.34 \\
.17 & -.22 & & .42 & .14 \\
.45 & .85 & & .30 & .91 \\
\hline
\end{tabular}

The variances in \(\mathbf{S}_{1}\) have a wider range than those in \(\mathbf{S}_{2}\), and the first two components of \(S_{1}\) account for a higher percent of variance.
12.12 The variances on the diagonal of \(S\) in each case are:
(a) Pooled: 536.0, 59.9, 116.0, 896.4, 248.1, 862.0
(b) Unpooled: 528.2, 68.9, 145.2, 1366.4, 264.4, 1069.1

The eigenvalues are as follows:
\begin{tabular}{rccccccc}
\hline \multicolumn{3}{c}{ Pooled } & & \multicolumn{4}{c}{ Unpooled } \\
\cline { 1 - 4 } \cline { 5 - 8 } \cline { 5 - 8 }\(\lambda_{i}\) & \(\lambda_{i} / \sum_{j} \lambda_{j}\) & Cumulative & & \multicolumn{1}{c}{\(\lambda_{i}\)} & \(\lambda_{i} / \sum_{j} \lambda_{j}\) & Cumulative \\
\hline 1050.6 & .386 & .386 & & 1722.0 & .500 & .500 \\
858.3 & .316 & .702 & & 878.4 & .255 & .755 \\
398.9 & .147 & .849 & & 401.4 & .117 & .872 \\
259.2 & .095 & .944 & & 261.1 & .076 & .948 \\
108.1 & .040 & .984 & & 128.9 & .037 & .985 \\
43.4 & .016 & 1.000 & & 50.4 & .015 & 1.000 \\
\hline
\end{tabular}

The first three eigenvectors are as follows:
\begin{tabular}{rrrrrrr}
\hline \multicolumn{3}{c}{ Pooled } & & \multicolumn{3}{c}{ Unpooled } \\
\cline { 6 - 8 } \cline { 5 - 7 } & \(\mathbf{a}_{1}\) & \(\mathbf{a}_{2}\) & \(\mathbf{a}_{3}\) & & \(\mathbf{a}_{1}\) & \(\mathbf{a}_{2}\) \\
\hline .441 & -.190 & .864 & & .212 & .389 & .888 \\
.041 & -.038 & .082 & & -.039 & .064 & .096 \\
-.039 & .031 & .143 & & .080 & -.066 & .081 \\
.450 & .892 & -.033 & & .776 & -.608 & .081 \\
-.019 & -.001 & -.054 & & -.096 & .010 & .015 \\
.774 & -.407 & -.471 & & .580 & .686 & -.434 \\
\hline
\end{tabular}
(c) The pattern in both eigenvalues and eigenvectors is similar for the pooled and unpooled cases. The first three principal components account for \(87.2 \%\) of the variance in the unpooled case compared to \(84.9 \%\) for the pooled case.
12.13 The variances on the diagonal of \(S\) in each case are:
(a) Pooled: 49.1, 8.1, 12140.8, 136.2, 210.8, 2983.9
(b) Unpooled: 63.2, 8.0, 15168.9, 186.6, 255.4, 4660.7

The eigenvalues are as follows:
\begin{tabular}{rcccrccc}
\hline \multicolumn{3}{c}{ Pooled } & & \multicolumn{3}{c}{ Unpooled } \\
\cline { 5 - 7 } \multicolumn{1}{c}{\(\lambda_{i}\)} & \(\lambda_{i} / \sum_{j} \lambda_{j}\) & Cumulative & & \multicolumn{1}{c}{\(\lambda_{i}\)} & \(\lambda_{i} / \sum_{j} \lambda_{j}\) & Cumulative \\
\hline \(12,809.0\) & .8249 & .8249 & & \(17,087.0\) & .8400 & .8400 \\
\(2,455.9\) & .1582 & .9830 & & \(2,958.0\) & .1454 & .9854 \\
137.1 & .0088 & .9918 & & 168.6 & .0083 & .9937 \\
77.2 & .0050 & .9968 & & 77.1 & .0038 & .9974 \\
42.2 & .0027 & .9995 & & 44.7 & .0022 & .9996 \\
7.4 & .0005 & 1.0000 & & 7.3 & .0004 & 1.0000 \\
\hline
\end{tabular}

The eigenvectors are as follows:
\begin{tabular}{rrrrr}
\hline \multicolumn{2}{c}{ Pooled } & & \multicolumn{2}{c}{ Unpooled } \\
\cline { 4 - 5 } \(\mathbf{a}_{1}\) & \(\mathbf{a}_{2}\) & & \(\mathbf{a}_{1}\) & \(\mathbf{a}_{2}\) \\
\hline-.004 & -.000 & & .013 & .027 \\
-.005 & .004 & & -.004 & .004 \\
.968 & -.233 & & .931 & -.355 \\
-.002 & .023 & & .028 & .069 \\
.103 & .041 & & .103 & .021 \\
.228 & .971 & .350 & .932 \\
\hline
\end{tabular}
12.14 The variances on the diagonal of \(\mathbf{S}\) are all less than 1 except \(s_{x_{4}}^{2}=5.02\) and \(s_{x_{8}}^{2}=1541.08\). We therefore expect the last variable, \(x_{8}\), to dominate the principal components of \(\mathbf{S}\). This is the case for \(\mathbf{S}\) but not for \(\mathbf{R}\). The eigenvalues of \(\mathbf{S}\) and \(\mathbf{R}\) are as follows:
\begin{tabular}{rcrccc}
\hline \multicolumn{2}{c}{\(\mathbf{S}\)} & & \multicolumn{3}{c}{\(\mathbf{R}\)} \\
\cline { 1 - 2 } \cline { 5 - 6 }\(\lambda_{i}\) & \(\lambda_{i} / \sum_{j} \lambda_{j}\) & & \(\lambda_{i}\) & \(\lambda_{i} / \sum_{j} \lambda_{j}\) & Cumulative \\
\hline 1541.55 & .996273 & & 3.174 & .317 & .317 \\
4.83 & .003123 & & 2.565 & .256 & .574 \\
.44 & .000286 & & 1.432 & .143 & .717 \\
.27 & .000174 & & 1.277 & .128 & .845 \\
.10 & .000066 & & .542 & .054 & .899 \\
.07 & .000043 & & .473 & .047 & .946 \\
.02 & .000014 & & .251 & .025 & .971 \\
.02 & .000011 & & .118 & .012 & .983 \\
.01 & .000005 & & .104 & .010 & .994 \\
.00 & .000003 & & .064 & .006 & 1.000 \\
\hline
\end{tabular}

The eigenvectors of \(\mathbf{S}\) and \(\mathbf{R}\) are as follows:
\begin{tabular}{rrrrrr}
\hline \multicolumn{2}{c}{\(\mathbf{S}\)} & & \multicolumn{4}{c}{\(\mathbf{R}\)} \\
\cline { 5 - 7 } & \(\mathbf{a}_{1}\) & \(\mathbf{a}_{2}\) & & \(\mathbf{a}_{1}\) & \(\mathbf{a}_{2}\) \\
\(\mathbf{a}_{3}\) & \(\mathbf{a}_{4}\) \\
\hline .0009 & -.005 & & .12 & .19 & .69 \\
.0007 & -.034 & & .06 & .32 & .54 \\
.0029 & -.007 & & .46 & -.06 & .07 \\
.0014 & .004 & & .29 & .17 & -.18 \\

\(y_{11}\) & .0034 & .3311 & & .3357 & -.1153 & -.1853 & .4550 \\
\hline
\end{tabular}

For most purposes, one or two principal components would suffice for \(\mathbf{S}\), with \(91 \%\) or \(98 \%\) of the variance explained. For \(\mathbf{R}\), on the other hand, three components are required to explain \(84 \%\) of the variance, and seven components are necessary to reach \(98 \%\). The reduction to one or two components for \(\mathbf{S}\) is due in part to the relatively large variances of \(y_{3}, y_{6}, y_{9}\), and \(y_{10}\). In the eigenvectors of \(\mathbf{S}\), we see that these four variables figure prominently in the first two principal components.

\section*{CHAPTER 13}
\(13.1 \operatorname{var}\left(y_{i}\right)=\operatorname{var}\left(y_{i}-\mu_{i}\right)=\operatorname{var}\left(\lambda_{i 1} f_{1}+\lambda_{i 2} f_{2}+\cdots+\lambda_{i m} f_{m}+\varepsilon_{i}\right)\)
\[
\begin{aligned}
= & \sum_{j=1}^{m} \lambda_{i j}^{2} \operatorname{var}\left(f_{j}\right)+\operatorname{var}\left(\varepsilon_{i}\right)+\sum_{j \neq k} \lambda_{i j} \lambda_{i k} \operatorname{cov}\left(f_{j}, f_{k}\right) \\
& +\sum_{j=1}^{m} \lambda_{i j} \operatorname{cov}\left(f_{j}, \varepsilon_{i}\right) \\
= & \sum_{j=1}^{m} \lambda_{i j}^{2}+\psi_{i} .
\end{aligned}
\]

The last equality follows by the assumptions \(\operatorname{var}\left(f_{j}\right)=1, \operatorname{var}\left(\varepsilon_{i}\right)=\psi_{i}\), \(\operatorname{cov}\left(f_{j}, f_{k}\right)=0\), and \(\operatorname{cov}\left(f_{j}, \varepsilon_{i}\right)=0\).
\[
\begin{aligned}
13.2 \operatorname{cov}(\mathbf{y}, \mathbf{f}) & =\operatorname{cov}(\mathbf{\Lambda f}+\boldsymbol{\varepsilon}, \mathbf{f}) & & {[\text { by }(13.3)] } \\
& =\operatorname{cov}(\mathbf{\Lambda f}, \mathbf{f}) & & {[\text { by (13.10)] }} \\
& =E[\mathbf{\Lambda f}-E(\mathbf{\Lambda f})][\mathbf{f}-E(\mathbf{f})]^{\prime} & & {[\text { by analogy to (3.31)] }} \\
& =E[\boldsymbol{\Lambda} \mathbf{f}-\boldsymbol{\Lambda} E(\mathbf{f})][\mathbf{f}-E(\mathbf{f})]^{\prime} & & \\
& =\boldsymbol{\Lambda} E[\mathbf{f}-E(\mathbf{f})][\mathbf{f}-E(\mathbf{f})]^{\prime} & & \\
& =\boldsymbol{\Lambda} \operatorname{cov}(\mathbf{f})=\boldsymbol{\Lambda} & & {[\text { by (13.7)] }}
\end{aligned}
\]
\(13.3 \quad E\left(\mathbf{f}^{*}\right)=E\left(\mathbf{T}^{\prime} \mathbf{f}\right)=\mathbf{T}^{\prime} E(\mathbf{f})=\mathbf{T}^{\prime} \mathbf{0}=\mathbf{0}\), \(\operatorname{cov}\left(\mathbf{f}^{*}\right)=\operatorname{cov}\left(\mathbf{T}^{\prime} \mathbf{f}\right)=\mathbf{T}^{\prime} \operatorname{cov}(\mathbf{f}) \mathbf{T}=\mathbf{T}^{\prime} \mathbf{I} \mathbf{T}=\mathbf{I}\)
13.4 Let \(\mathbf{E}=\mathbf{S}-\left(\hat{\boldsymbol{\Lambda}} \hat{\boldsymbol{\Lambda}}^{\prime}+\hat{\mathbf{\Psi}}\right)\). Then by (2.98), \(\operatorname{tr}\left(\mathbf{E}^{\prime} \mathbf{E}\right)=\sum_{i j} e_{i j}^{2}\). By (13.26), \(\hat{\mathbf{\Psi}}=\) \(\operatorname{diag}\left(\mathbf{S}-\hat{\boldsymbol{\Lambda}} \hat{\mathbf{\Lambda}}^{\prime}\right)\), and \(\mathbf{E}\) has zeros on the diagonal. This gives the inequality
\[
\sum_{i j} e_{i j}^{2} \leq \text { sum of squared elements of } \mathbf{S}-\hat{\boldsymbol{\Lambda}} \hat{\boldsymbol{\Lambda}}^{\prime} .
\]

By (2.98),
\[
\text { sum of squared elements of } \mathbf{S}-\hat{\boldsymbol{\Lambda}} \hat{\boldsymbol{\Lambda}}^{\prime}=\operatorname{tr}\left(\mathbf{S}-\hat{\boldsymbol{\Lambda}} \hat{\boldsymbol{\Lambda}}^{\prime}\right)^{\prime}\left(\mathbf{S}-\hat{\boldsymbol{\Lambda}} \hat{\boldsymbol{\Lambda}}^{\prime}\right)
\]

Since \(\mathbf{S}-\hat{\boldsymbol{\Lambda}} \hat{\mathbf{\Lambda}}^{\prime}\) is symmetric, we have by (13.20), (13.23), and (13.24),
\[
\begin{aligned}
\mathbf{S}-\hat{\boldsymbol{\Lambda}} \hat{\boldsymbol{\Lambda}}^{\prime} & =\mathbf{C D C}^{\prime}-\mathbf{C}_{1} \mathbf{D}_{1}^{1 / 2} \mathbf{D}_{1}^{1 / 2} \mathbf{C}_{1}^{\prime} \\
& =\mathbf{C D C}^{\prime}-\mathbf{C}_{1} \mathbf{D}_{1} \mathbf{C}_{1}^{\prime},
\end{aligned}
\]
where \(\mathbf{C}=\left(\mathbf{c}_{1}, \mathbf{c}_{2}, \ldots, \mathbf{c}_{p}\right)\) contains normalized eigenvectors of \(\mathbf{S}, \mathbf{D}=\) \(\operatorname{diag}\left(\theta_{1}, \theta_{2}, \ldots, \theta_{p}\right)\) contains eigenvalues of \(\mathbf{S}, \mathbf{C}_{1}=\left(\mathbf{c}_{1}, \mathbf{c}_{2}, \ldots, \mathbf{c}_{m}\right)\), and \(\mathbf{D}_{1}=\operatorname{diag}\left(\theta_{1}, \theta_{2}, \ldots, \theta_{m}\right)\).
Using the partitioned forms \(\mathbf{C}=\left(\mathbf{C}_{1}, \mathbf{C}_{2}\right)\) and \(\mathbf{D}=\left(\begin{array}{ll}\mathbf{D}_{1} & \mathbf{O} \\ \mathbf{O} & \mathbf{D}_{2}\end{array}\right)\), show that \(\mathbf{C}_{1}^{\prime} \mathbf{C}_{1}=\mathbf{I}_{m}, \mathbf{C}_{1}^{\prime} \mathbf{C}_{2}=\mathbf{O}, \mathbf{C}^{\prime} \mathbf{C}_{1}=\binom{\mathbf{I}_{m}}{\mathbf{O}}, \mathbf{D}\binom{\mathbf{I}_{m}}{\mathbf{O}}=\binom{\mathbf{D}_{1}}{\mathbf{O}}, \mathbf{C}\binom{\mathbf{D}_{1}}{\mathbf{O}}=\) \(\mathbf{C}_{1} \mathbf{D}_{1}\), and \(\mathbf{C D C}^{\prime} \mathbf{C}_{1} \mathbf{D}_{1} \mathbf{C}_{1}^{\prime}=\mathbf{C}_{1} \mathbf{D}_{1}^{2} \mathbf{C}_{1}^{\prime}\). Show similarly that \(\mathbf{C}_{1} \mathbf{D}_{1} \mathbf{C}_{1}^{\prime} \mathbf{C D C}^{\prime}=\mathbf{C}_{1} \mathbf{D}_{1}^{2} \mathbf{C}_{1}^{\prime}\) and \(\mathbf{C}_{1} \mathbf{D}_{1} \mathbf{C}_{1}^{\prime} \mathbf{C}_{1} \mathbf{D}_{1} \mathbf{C}_{1}^{\prime}=\mathbf{C}_{1} \mathbf{D}_{1}^{2} \mathbf{C}_{1}^{\prime}\). Now by \((2.97) \operatorname{tr}\left(\mathbf{C D}^{2} \mathbf{C}^{\prime}\right)=\operatorname{tr}\left(\mathbf{C}^{\prime} \mathbf{C D}^{2}\right)=\operatorname{tr}\left(\mathbf{D}^{2}\right)=\sum_{i=1}^{p} \theta_{i}^{2}\). Similarly, \(\operatorname{tr}\left(\mathbf{C}_{1} \mathbf{D}_{1}^{2} \mathbf{C}_{1}^{\prime}\right)=\sum_{i=1}^{m} \theta_{i}^{2}\). Then
\[
\begin{aligned}
\operatorname{tr}\left(\mathbf{S}-\hat{\boldsymbol{\Lambda}} \hat{\mathbf{\Lambda}}^{\prime}\right)^{\prime}\left(\mathbf{S}-\hat{\mathbf{\Lambda}} \hat{\mathbf{\Lambda}}^{\prime}\right)= & \operatorname{tr}\left(\mathbf{C D C}^{\prime}-\mathbf{C}_{1} \mathbf{D}_{1} \mathbf{C}_{1}^{\prime}\right)\left(\mathbf{C D C}^{\prime}-\mathbf{C}_{1} \mathbf{D}_{1} \mathbf{C}_{1}^{\prime}\right) \\
= & \operatorname{tr}\left(\mathbf{C D C}^{\prime} \mathbf{C D C}^{\prime}-\mathbf{C D C}^{\prime} \mathbf{C}_{1} \mathbf{D}_{1} \mathbf{C}_{1}^{\prime}\right. \\
& \left.\quad-\mathbf{C}_{1} \mathbf{D}_{1} \mathbf{C}_{1}^{\prime} \mathbf{C D C}^{\prime}+\mathbf{C}_{1} \mathbf{D}_{1} \mathbf{C}_{1}^{\prime} \mathbf{C}_{1} \mathbf{D}_{1} \mathbf{C}_{1}^{\prime}\right) \\
= & \sum_{i=1}^{p} \theta_{i}^{2}-\sum_{i=1}^{m} \theta_{i}^{2}-\sum_{i=1}^{m} \theta_{i}^{2}+\sum_{i=1}^{m} \theta_{i}^{2} \\
= & \sum_{i=m+1}^{p} \theta_{i}^{2} .
\end{aligned}
\]
13.5 \(\sum_{i=1}^{p} \sum_{j=1}^{m} \hat{\lambda}_{i j}^{2}=\sum_{i=1}^{p}\left[\sum_{j=1}^{m} \hat{\lambda}_{i j}^{2}\right]=\sum_{i=1}^{p} \hat{h}_{i}^{2} \quad\) [by (13.28)]

By interchanging the order of summation, we have
\[
\sum_{i=1}^{p} \sum_{j=1}^{m} \hat{\lambda}_{i j}^{2}=\sum_{j=1}^{m} \sum_{i=1}^{p} \hat{\lambda}_{i j}^{2}=\sum_{j=1}^{m} \theta_{j} \quad[\mathrm{by}(13.29)] .
\]
13.6 We use the covariance matrix to avoid working with standardized variables. The eigenvalues of S are \(39.16,8.78, .66, .30\), and 0 . The eigenvector corresponding to \(\lambda_{5}=0\) is
\[
\mathbf{a}_{5}^{\prime}=(-.75,-.25, .25, .50, .25) .
\]

As noted in Section 12.7, \(s_{z_{5}}^{2}=0\) implies \(z_{5}=0\). Thus
\[
\begin{gathered}
z_{5}=\mathbf{a}_{5}^{\prime} \mathbf{y}=-.75 y_{1}-.25 y_{2}+.25 y_{3}+.50 y_{4}+.25 y_{5}=0, \\
3 y_{1}+y_{2}=y_{3}+2 y_{4}+y_{5} .
\end{gathered}
\]
13.7 Words data of Table 5.9:
\begin{tabular}{|c|c|c|c|c|c|}
\hline \multirow[t]{2}{*}{} & \multicolumn{2}{|l|}{Principal Component Loadings} & \multicolumn{2}{|l|}{\begin{tabular}{l}
Varimax \\
Rotated \\
Loadings
\end{tabular}} & \multirow[b]{2}{*}{Communalities, \(\hat{h}_{i}^{2}\)} \\
\hline & \(f_{1}\) & \(f_{2}\) & \(f_{1}\) & \(f_{2}\) & \\
\hline Variables & & & & & \\
\hline Informal words & . 802 & -. 535 & . 956 & . 129 & . 930 \\
\hline Informal verbs & . 856 & -. 326 & . 858 & . 321 & . 839 \\
\hline Formal words & . 883 & . 270 & . 484 & . 786 & . 853 \\
\hline Formal verbs & . 714 & . 658 & . 101 & . 966 & . 943 \\
\hline Variance & 2.666 & . 899 & 1.894 & 1.671 & 3.565 \\
\hline Proportion & . 666 & . 225 & . 474 & . 418 & . 891 \\
\hline
\end{tabular}

The orthogonal matrix \(\mathbf{T}\) for the varimax rotation as given by (13.49) is
\[
\mathbf{T}=\left(\begin{array}{rr}
.750 & .661 \\
-.661 & .750
\end{array}\right)
\]

Thus \(\sin \phi=-.661\) and \(\phi=-41.4^{\circ}\). A graphical rotation of \(-40^{\circ}\) would produce results very close to the varimax rotation.
13.8 Ramus bone data of Table 3.7:
\begin{tabular}{|c|c|c|c|c|c|c|c|}
\hline \multirow[t]{2}{*}{} & \multicolumn{2}{|l|}{Principal Component Loadings} & \multicolumn{2}{|l|}{\begin{tabular}{l}
Varimax \\

\hline 8 years & . 949 & \(-.295\) & . 884 & . 455 & . 988 & -. 108 & 1.087 \\
\hline \(8 \frac{1}{2}\) years & . 974 & -. 193 & . 830 & . 545 & . 986 & . 106 & . 900 \\
\hline 9 years & . 978 & . 171 & . 578 & . 808 & . 986 & . 825 & . 188 \\
\hline \(9 \frac{1}{2}\) years & . 943 & . 319 & . 449 & . 888 & . 991 & 1.099 & -. 121 \\
\hline Variance & 3.695 & . 255 & 2.005 & 1.946 & 3.951 & & \\
\hline Proportion & . 924 & . 064 & . 501 & . 486 & . 988 & & \\
\hline
\end{tabular}

The Harris-Kaiser orthoblique rotation produced loadings for which the variables have a complexity of 1 . These oblique loadings provide a much cleaner simple structure than the varimax loadings. For interpretation, we see that one factor represents variables 1 and 2 , and the other factor represents variables 3 and 4 . This same clustering of variables can be deduced from the varimax loadings if we simply use the larger of the two loadings for each variable.

The correlation between the two oblique factors is .87 . The angle between the oblique axes is \(\cos ^{-1}(.87)=29.5^{\circ}\). With such a small angle between the axes and a large correlation between the factors, it is clear that a single factor
would better represent the variables. This is also borne out by the eigenvalues of the correlation matrix: \(3.695, .255, .033\), and .017 . The first accounts for \(92 \%\) of the variance and the second for only \(6 \%\).

\subsection*{13.9 Rootstock data of Table 6.2:}
\begin{tabular}{|c|c|c|c|c|c|}
\hline \multirow[t]{2}{*}{} & \multicolumn{2}{|l|}{\begin{tabular}{l}
Principal \\
Component Loadings
\end{tabular}} & \multicolumn{2}{|l|}{\begin{tabular}{l}
Varimax \\
Rotated \\
Loadings
\end{tabular}} & \multirow[b]{2}{*}{\(\underset{\hat{h}_{i}^{2}}{\text { Communalities, }}\)} \\
\hline & \(f_{1}\) & \(f_{2}\) & \(f_{1}\) & \(f_{2}\) & \\
\hline Variables & & & & & \\
\hline Trunk 4 years & . 787 & . 575 & . 167 & . 960 & . 949 \\
\hline Extension 4 years & . 849 & . 467 & . 287 & . 925 & . 939 \\
\hline Trunk 15 years & . 875 & -. 455 & . 946 & . 280 & . 973 \\
\hline Weight 15 years & . 824 & -. 547 & . 973 & . 179 & . 978 \\
\hline Variance & 2.785 & 1.054 & 1.951 & 1.888 & 3.839 \\
\hline Proportion & . 696 & . 264 & . 488 & . 472 & . 960 \\
\hline
\end{tabular}

The rotation was successful in producing variables with a complexity of 1 , that is, partitioning the variables into two groups, each with two variables.
13.10 Fish data of Table 6.17:
\begin{tabular}{|c|c|c|c|c|c|}
\hline \multirow[t]{2}{*}{} & \multicolumn{2}{|l|}{Principal Component Loadings} & \multicolumn{2}{|l|}{\begin{tabular}{l}
Varimax \\
Rotated \\
Loadings
\end{tabular}} & \multirow[b]{2}{*}{\(\underset{\hat{h}_{i}^{2}}{\text { Communalities, }}\)} \\
\hline & \(f_{1}\) & \(f_{2}\) & \(f_{1}\) & \(f_{2}\) & \\
\hline Variables & & & & & \\
\hline \(y_{1}\) & . 830 & -. 403 & . 874 & . 294 & . 851 \\
\hline \(y_{2}\) & . 783 & -. 504 & . 911 & . 189 & . 866 \\
\hline \(y_{3}\) & . 803 & . 432 & . 270 & . 871 & . 831 \\
\hline \(y_{4}\) & . 769 & . 497 & . 200 & . 893 & . 838 \\
\hline Variance & 2.537 & . 850 & 1.709 & 1.678 & 3.386 \\
\hline Proportion & . 634 & . 213 & . 427 & . 420 & . 847 \\
\hline
\end{tabular}
(b) The loadings for \(y_{1}\) and \(y_{2}\) are similar. In \(\mathbf{R}\) below we see some indication of the reason for this; \(y_{1}\) and \(y_{2}\) are more highly correlated than any other pair of variables and their correlations with \(y_{3}\) and \(y_{4}\) are similar:
\[
\mathbf{R}=\left(\begin{array}{rrrr}
1.00 & .71 & .51 & .40 \\
.71 & 1.00 & .38 & .40 \\
.51 & .38 & 1.00 & .67 \\
.40 & .40 & .67 & 1.00
\end{array}\right)
\]
(c) \(\mathrm{By}(13.58)\), the factor score coefficient matrix is
\[
\hat{\mathbf{B}}_{1}=\mathbf{R}^{-1} \hat{\boldsymbol{\Lambda}}=\left(\begin{array}{rr}
.566 & -.109 \\
.636 & -.207 \\
-.130 & .584 \\
-.194 & .630
\end{array}\right)
\]
where \(\hat{\Lambda}\) is the matrix of rotated factor loadings given above in part (a). The factor scores are given by (13.59) as follows:
\begin{tabular}{|c|c|c|c|c|c|}
\hline \multicolumn{2}{|r|}{Method 1} & \multicolumn{2}{|c|}{Method 2} & \multicolumn{2}{|l|}{Method 3} \\
\hline \(\hat{f}_{1}\) & \(\hat{f}_{2}\) & \(\hat{f}_{1}\) & \(\hat{f}_{2}\) & \(\hat{f}_{1}\) & \(\hat{f}_{2}\) \\
\hline . 544 & 1.151 & -. 254 & . 309 & -1.156 & 2.104 \\
\hline 1.250 & -. 254 & -. 309 & -1.534 & -. 321 & . 878 \\
\hline 1.017 & 1.120 & -1.865 & -1.558 & -. 671 & . 947 \\
\hline -. 147 & \(-1.583\) & --. 999 & -. 690 & . 067 & 1.130 \\
\hline . 219 & -. 103 & . 520 & -. 343 & -1.610 & -. 458 \\
\hline 1.007 & . 679 & . 919 & -. 111 & . 557 & . 491 \\
\hline 1.413 & -. 186 & -. 443 & -. 018 & -. 454 & 1.157 \\
\hline -. 666 & -2.279 & \(-.265\) & . 676 & -. 961 & . 063 \\
\hline 1.057 & \(-1.870\) & 1.449 & -. 295 & -. 230 & 1.721 \\
\hline . 388 & -. 440 & 1.371 & . 295 & -1.309 & . 054 \\
\hline 1.328 & -. 298 & 1.260 & -. 027 & -1.766 & -. 111 \\
\hline . 694 & -. 033 & -. 000 & -1.452 & -1.636 & -. 048 \\
\hline
\end{tabular}
(d) A one-way MANOVA on the two factor scores comparing the three methods yielded the following values for \(\mathbf{E}\) and \(\mathbf{H}\) :
\[
\mathbf{E}=\left(\begin{array}{rr}
21.8606 & 10.3073 \\
10.3073 & 25.2081
\end{array}\right), \quad \mathbf{H}=\left(\begin{array}{rr}
13.1394 & -10.3073 \\
-10.3073 & 9.7919
\end{array}\right)
\]

The four MANOVA test statistics are \(\Lambda=.3631, V^{(s)}=.6552, U^{(s)}=\) 1.7035 , and \(\theta=.6259\). All are highly significant.
13.11 (a) For the flea data of Table 5.5, the eigenvalues of \(\mathbf{R}\) are 2.273, 1.081, .450, and .196. There is a noticeable gap between 1,081 and .450 , and the first two factors account for \(83.9 \%\) of the variance. Thus \(m=2\) factors seem to be indicated for this set of data.
(b)
\begin{tabular}{|c|c|c|c|c|c|c|c|}
\hline \multirow[t]{2}{*}{} & \multicolumn{2}{|l|}{Principal Component Loadings} & \multicolumn{2}{|r|}{\begin{tabular}{l}
Varimax \\
Rotated \\
Loadings
\end{tabular}} & \multirow[b]{2}{*}{Communalities, \(\hat{h}_{i}^{2}\)} & \multicolumn{2}{|l|}{\begin{tabular}{l}
Orthoblique \\
Pattern \\
Loadings
\end{tabular}} \\
\hline & \(f_{1}\) & \(f_{2}\) & \(f_{1}\) & \(f_{2}\) & & \(f_{1}\) & \(f_{2}\) \\
\hline Variables & & & & & & & \\
\hline \(y_{1}\) & -. 038 & . 989 & -. 025 & . 990 & . 980 & -. 003 & . 990 \\
\hline \(y_{2}\) & . 889 & . 269 & . 892 & . 256 & . 862 & . 898 & . 253 \\
\hline \(y_{3}\) & . 893 & -. 157 & . 891 & -. 170 & . 823 & . 887 & \(-.173\) \\
\hline \(y_{4}\) & . 827 & \(-.073\) & . 823 & \(-.084\) & . 689 & . 824 & -. 087 \\
\hline Variance & 2.273 & 1.081 & 2.273 & 1.081 & 3.354 & & \\
\hline Proportion & . 568 & . 270 & . 568 & . 270 & . 839 & & \\
\hline
\end{tabular}
(The variance explained by the varimax rotated factors remains the same as for the initial factors when rounded to three decimal places.)
(c) In this case, neither of the rotations changes the initial loadings appreciably. The reason for this unusual outcome can be seen in the correlation matrix:
\[
\mathbf{R}=\left(\begin{array}{rrrr}
1.00 & .18 & -.17 & -.07 \\
.18 & 1.00 & .73 & .59 \\
-.17 & .73 & 1.00 & .59 \\
-.07 & .59 & .59 & 1.00
\end{array}\right)
\]

There are clearly two clusters of variables: \(\left\{y_{1}\right\}\) and \(\left\{y_{2}, y_{3}, y_{4}\right\}\). We would expect two factors corresponding to these groupings to emerge after rotation. That the same pattern surfaces in the initial factor loadings (based on eigenvectors) is due to their affiliation with principal components. As noted in Section 12.8.1, if a variable has small correlations with all other variables, the variable itself will essentially constitute a principal component. In this case, \(y_{1}\) has this property and makes up most of the second principal component. The first component is comprised of the other three variables.
13.12 (a) For the engineer data of Table 5.6, the number of eigenvalues greater than 1 is three, but the three account for only \(70 \%\) of the variance. It requires four eigenvalues to reach \(84 \%\). The scree plot also indicates four eigenvalues.
(b)
\begin{tabular}{|c|c|c|c|c|c|c|c|}
\hline \multirow[t]{2}{*}{} & \multicolumn{3}{|c|}{Principal Component Loadings} & \multicolumn{3}{|c|}{Varimax Rotated Loadings} & \multirow[t]{2}{*}{\[
\begin{aligned}
& \text { Commun- } \\
& \text { alities, } \\
& \hat{h}_{i}^{2}
\end{aligned}
\]} \\
\hline & \(f_{1}\) & \(f_{2}\) & \(f_{3}\) & \(f_{1}\) & \(f_{2}\) & \(f_{3}\) & \\
\hline \multicolumn{8}{|l|}{Variables} \\
\hline \(y_{1}\) & . 536 & . 461 & . 478 & \(-.063\) & . 834 & . 170 & . 729 \\
\hline \(y_{2}\) & -. 129 & . 870 & -. 182 & \(-.357\) & . 100 & . 818 & . 806 \\
\hline \(y_{3}\) & . 514 & -. 254 & -. 448 & . 724 & -. 026 & . 068 & . 529 \\
\hline \(y_{4}\) & . 724 & -. 366 & -. 110 & . 739 & . 295 & -. 193 & . 670 \\
\hline \(y_{5}\) & -. 416 & -. 414 & . 649 & -. 484 & -. 013 & -. 729 & . 766 \\
\hline \(y_{6}\) & . 715 & . 124 & . 420 & . 239 & . 800 & -. 069 & . 702 \\
\hline Variance & 1.775 & 1.354 & 1.073 & 1.493 & 1.435 & 1.275 & 4.202 \\
\hline Proportion & . 296 & . 226 & . 179 & . 249 & . 239 & . 212 & . 700 \\
\hline
\end{tabular}
(c) The initial communality estimates for the six variables are given by (13.36) as \(.215, .225, .113, .255, .161, .248\). With these substituted for the diagonal of \(\mathbf{R}\), the eigenvalues of \(\mathbf{R}-\hat{\Psi}\) are
\begin{tabular}{lrrrrrr} 
Eigenvalue & .994 & .569 & .255 & -.025 & -.237 & -.339 \\
Proportion & .816 & .468 & .209 & -.020 & -.195 & -.278 \\
Cumulative & .816 & 1.284 & 1.493 & 1.473 & 1.278 & 1.000
\end{tabular}

The principal factor loadings and varimax rotation are as follows:
\begin{tabular}{|c|c|c|c|c|c|c|c|}
\hline \multirow[t]{2}{*}{} & \multicolumn{3}{|c|}{Principal Component Loadings} & \multicolumn{3}{|c|}{\begin{tabular}{l}
Varimax \\
Rotated \\
Loadings
\end{tabular}} & \multirow[t]{2}{*}{\[
\begin{gathered}
\text { Commun- } \\
\text { alities, } \\
\hat{h}_{i}^{2}
\end{gathered}
\]} \\
\hline & \(f_{1}\) & \(f_{2}\) & \(f_{3}\) & \(f_{1}\) & \(f_{2}\) & \(f_{3}\) & \\
\hline \multicolumn{8}{|l|}{Variables} \\
\hline \(y_{1}\) & . 403 & . 312 & . 227 & . 030 & . 536 & . 151 & . 311 \\
\hline \(y_{2}\) & -. 106 & . 569 & -. 100 & --. 288 & . 083 & . 505 & . 345 \\
\hline \(y_{3}\) & . 343 & -. 139 & -. 197 & . 413 & . 060 & . 037 & . 176 \\
\hline \(y_{4}\) & . 559 & -. 247 & -. 090 & . 564 & . 233 & -. 094 & . 381 \\
\hline \(y_{5}\) & -. 286 & -. 246 & . 328 & -. 262 & -. 088 & -. 417 & . 250 \\
\hline \(y_{6}\) & . 556 & . 089 & . 197 & . 258 & . 537 & . 003 & . 356 \\
\hline
\end{tabular}
(d) The pattern of loadings is similar in parts (b) and (c), and the interpretation of the three factors would be the same.
13.13 Probe word data of Table 3.6:
\begin{tabular}{|c|c|c|c|c|c|c|c|}
\hline \multirow[t]{2}{*}{} & \multicolumn{2}{|l|}{Principal Component Loadings} & \multicolumn{2}{|l|}{\begin{tabular}{l}
Varimax \\
Rotated \\
Loadings
\end{tabular}} & \multirow[b]{2}{*}{Communalities, \(\hat{h}_{i}^{2}\)} & \multicolumn{2}{|l|}{\begin{tabular}{l}
Orthoblique \\
Pattern \\
Loadings
\end{tabular}} \\
\hline & \(f_{1}\) & \(f_{2}\) & \(f_{1}\) & \(f_{2}\) & & \(f_{1}\) & \(f_{2}\) \\
\hline \multicolumn{8}{|l|}{Variables} \\
\hline \(y_{1}\) & . 817 & -. 157 & . 732 & . 395 & . 692 & . 737 & . 131 \\
\hline \(y_{2}\) & . 838 & -. 336 & . 861 & . 271 & . 815 & . 963 & -. 092 \\
\hline \(y_{3}\) & . 874 & . 288 & . 494 & . 776 & . 847 & . 248 & . 734 \\
\hline \(y_{4}\) & . 838 & -. 308 & . 844 & . 292 & . 798 & . 931 & -. 057 \\
\hline \(y_{5}\) & . 762 & . 547 & . 244 & . 905 & . 879 & -. 134 & 1.023 \\
\hline Variance & 3.416 & . 614 & 2.294 & 1.736 & 4.031 & & \\
\hline Proportion & . 683 & . 123 & . 459 & . 347 & . 806 & & \\
\hline
\end{tabular}

The loadings for \(y_{2}\) are similar to those for \(y_{4}\) in all three sets of loadings. The reason for this can be seen in the correlation matrix
\[
\mathbf{R}=\left(\begin{array}{rrrrr}
1.00 & .61 & .76 & .58 & .41 \\
.61 & 1.00 & .55 & .75 & .55 \\
.76 & .55 & 1.00 & .61 & .69 \\
.58 & .75 & .61 & 1.00 & .52 \\
.41 & .55 & .69 & .52 & 1.00
\end{array}\right)
\]

The correlations of \(y_{2}\) with \(y_{1}, y_{3}\), and \(y_{5}\) are very similar to the correlations of \(y_{4}\) with \(y_{1}, y_{3}\), and \(y_{5}\).

\section*{CHAPTER 14}
14.1 Multiply both sides of the inequality by 2 to obtain:
\[
\begin{aligned}
p^{2}+p & \geq 2 p m-2 m^{2}+m^{2}+m+2 p \\
\Rightarrow p^{2}-2 p m+m^{2} & \geq p+m \\
\Rightarrow(p-m)^{2} & \geq p+m
\end{aligned}
\]
14.2 (a) Identified
(b) Identified
(c) Not identified
(d) Identified
14.3 (a) Identified
(b) 0
(c) Find \(\operatorname{var}\left(y_{1}\right), \operatorname{var}\left(y_{2}\right), \operatorname{var}\left(y_{3}\right), \operatorname{cov}\left(y_{1}, y_{2}\right), \operatorname{cov}\left(y_{1}, y_{3}\right)\), and \(\operatorname{cov}\left(y_{2}, y_{3}\right)\). For example, \(\operatorname{var}\left(y_{1}\right)=\phi+\psi_{1}\) and \(\operatorname{cov}\left(y_{1}, y_{2}\right)=\lambda_{2} \phi\).
(d) \(\hat{\lambda}_{2}=s_{23} / s_{13}, \hat{\lambda}_{3}=s_{23} / s_{12}, \hat{\phi}=s_{12} s_{13} / s_{23}, \hat{\psi}_{11}=s_{11}-s_{12} s_{13} / s_{23}\), \(\hat{\psi}_{22}=s_{22}-s_{12} s_{23} / s_{13}\), and \(\hat{\psi}_{33}=s_{33}-s_{13} s_{23} / s_{12}\).
14.4 (a) \(\chi^{2}=6.5811, \mathrm{df}=5, p\)-value \(=0.2537\)

Bentler's CFI \(=0.9280\)

\section*{CHAPTER 15}
15.1 Adding and subtracting \(\bar{x}\) and \(\bar{y}\) in (15.2) (squared), we obtain
\[
\begin{aligned}
d^{2}(\mathbf{x}, \mathbf{y})= & \sum_{j=1}^{p}\left[\left(x_{j}-\bar{x}\right)-\left(y_{j}-\bar{y}\right)+(\bar{x}-\bar{y})\right]^{2} \\
= & \sum_{j=1}^{p}\left(x_{j}-\bar{x}\right)^{2}+\sum_{j=1}^{p}\left(y_{i}-\bar{y}\right)^{2}+p(\bar{x}-\bar{y})^{2} \\
& \quad-2 \sum_{j=1}^{p}\left(x_{j}-\bar{x}\right)\left(y_{j}-\bar{y}\right)
\end{aligned}
\]

The other two terms vanish because \(\sum_{j}\left(x_{j}-\bar{x}\right)=\sum_{j}\left(y_{j}-\bar{y}\right)=0\). Substituting \(v_{x}^{2}=\sum_{j=1}^{p}\left(x_{j}-\bar{x}\right)^{2}\) and \(v_{y}^{2}=\sum_{j=1}^{p}\left(y_{j}-\bar{y}\right)^{2}\) and adding and subracting \(-2 \sqrt{v_{x}^{2} v_{y}^{2}}=-2 v_{x} v_{y}\), we obtain
\[
\begin{aligned}
d^{2}(\mathbf{x}, \mathbf{y})= & v_{x}^{2}+v_{y}^{2}-2 \sqrt{v_{x}^{2} v_{y}^{2}}+p(\bar{x}-\bar{y})^{2}+2 v_{x} v_{y} \\
& -2 \sqrt{v_{x}^{2} v_{y}^{2}} \frac{\sum_{j=1}^{p}\left(x_{j}-\bar{x}\right)\left(y_{j}-\bar{y}\right)}{\sqrt{v_{x}^{2} v_{y}^{2}}} \\
= & \left(v_{x}-v_{y}\right)^{2}+p(\bar{x}-\bar{y})^{2}+2 v_{x} v_{y}\left(1-r_{x y}\right)
\end{aligned}
\]
15.2 (a) Since \(\overline{\mathbf{y}}_{A B}=\sum_{i=1}^{n_{A B}} \mathbf{y}_{i} / n_{A B}\), we have by (15.16),
\[
\begin{aligned}
\mathrm{SSE}_{A B}= & \sum_{i=1}^{n_{A B}}\left(\mathbf{y}_{i}-\overline{\mathbf{y}}_{A B}\right)^{\prime}\left(\mathbf{y}_{i}-\overline{\mathbf{y}}_{A B}\right) \\
= & \sum_{i=1}^{n_{A B}} \mathbf{y}_{i}^{\prime} \mathbf{y}_{i}-\sum_{i=1}^{n_{A B}} \mathbf{y}_{i}^{\prime} \overline{\mathbf{y}}_{A B}-\sum_{i=1}^{n_{A B}} \overline{\mathbf{y}}_{A B}^{\prime} \mathbf{y}_{i} \\
& +\sum_{i=1}^{n_{A B}} \overline{\mathbf{y}}_{A B}^{\prime} \overline{\mathbf{y}}_{A B} \\
= & \sum_{i=1}^{n_{A B}} \mathbf{y}_{i}^{\prime} \mathbf{y}_{i}-n_{A B} \overline{\mathbf{y}}_{A B}^{\prime} \overline{\mathbf{y}}_{A B}-n_{A B} \overline{\mathbf{y}}_{A B}^{\prime} \overline{\mathbf{y}}_{A B} \\
& +n_{A B} \overline{\mathbf{y}}_{A B}^{\prime} \overline{\mathbf{y}}_{A B} \\
= & \sum_{i=1}^{n_{A B}} \mathbf{y}_{i}^{\prime} \mathbf{y}_{i}-n_{A B} \overline{\mathbf{y}}_{A B}^{\prime} \overline{\mathbf{y}}_{A B}
\end{aligned}
\]

Similarly, \(\operatorname{SSE}_{A}=\sum_{i=1}^{n_{A}} \mathbf{y}_{i}^{\prime} \mathbf{y}_{i}-n_{A} \overline{\mathbf{y}}_{A}^{\prime} \overline{\mathbf{y}}_{A}\) and \(\operatorname{SSE}_{B}=\sum_{i=1}^{n_{B}} \mathbf{y}_{i}^{\prime} \mathbf{y}_{i}-\) \(n_{B} \overline{\mathbf{y}}_{B}^{\prime} \overline{\mathbf{y}}_{B}\). Now
\[
\begin{aligned}
n_{A B} \overline{\mathbf{y}}_{A B}^{\prime} \overline{\mathbf{y}}_{A B} & =\left(n_{A}+n_{B}\right) \frac{\left(n_{A} \overline{\mathbf{y}}_{A}+n_{B} \overline{\mathbf{y}}_{B}\right)^{\prime}}{n_{A}+n_{B}} \frac{\left(n_{A} \overline{\mathbf{y}}_{A}+n_{B} \overline{\mathbf{y}}_{B}\right)}{n_{A}+n_{B}} \\
& =\frac{n_{A}^{2} \overline{\mathbf{y}}_{A}^{\prime} \overline{\mathbf{y}}_{A}+n_{A} n_{B} \overline{\mathbf{y}}_{A}^{\prime} \overline{\mathbf{y}}_{B}+n_{A} n_{B} \overline{\mathbf{y}}_{A}^{\prime} \overline{\mathbf{y}}_{B}+n_{B}^{2} \overline{\mathbf{y}}_{B}^{\prime} \overline{\mathbf{y}}_{B}}{n_{A}+n_{B}} .
\end{aligned}
\]

Thus
\[
\begin{aligned}
\operatorname{SSE}_{A B}-\left(\operatorname{SSE}_{A}+\operatorname{SSE}_{B}\right)= & \sum_{i=1}^{n_{A B}} \mathbf{y}_{i}^{\prime} \mathbf{y}_{i}-\sum_{i=1}^{n_{A}} \mathbf{y}_{i}^{\prime} \mathbf{y}_{i}-\sum_{i=1}^{n_{B}} \mathbf{y}_{i}^{\prime} \mathbf{y}_{i} \\
& +n_{A} \overline{\mathbf{y}}_{A}^{\prime} \overline{\mathbf{y}}_{A}+n_{B} \overline{\mathbf{y}}_{B}^{\prime} \overline{\mathbf{y}}_{B}-n_{A B} \overline{\mathbf{y}}_{A B}^{\prime} \overline{\mathbf{y}}_{A B} \\
= & n_{A} \overline{\mathbf{y}}_{A}^{\prime} \overline{\mathbf{y}}_{A}+n_{B} \overline{\mathbf{y}}_{B}^{\prime} \overline{\mathbf{y}}_{B}-n_{A B} \overline{\mathbf{y}}_{A B}^{\prime} \overline{\mathbf{y}}_{A B}
\end{aligned}
\]

Show that when the right side of (15.16) is expanded, it reduces to this same expression [see Problem 15.3(b) below].
(b) Multiplying out the right side of (15.16), we have
\[
\begin{aligned}
& n_{A} \overline{\mathbf{y}}_{A}^{\prime} \overline{\mathbf{y}}_{A}-n_{A} \overline{\mathbf{y}}_{A}^{\prime} \overline{\mathbf{y}}_{A B}-n_{A} \overline{\mathbf{y}}_{A B}^{\prime} \overline{\mathbf{y}}_{A}+n_{A} \overline{\mathbf{y}}_{A B}^{\prime} \overline{\mathbf{y}}_{A B}+n_{B} \overline{\mathbf{y}}_{B}^{\prime} \overline{\mathbf{y}}_{B} \\
& \quad-n_{B} \overline{\mathbf{y}}_{B}^{\prime} \overline{\mathbf{y}}_{A B}-n_{B} \overline{\mathbf{y}}_{A B}^{\prime} \overline{\mathbf{y}}_{B}+n_{B} \overline{\mathbf{y}}_{A B}^{\prime} \overline{\mathbf{y}}_{A B} \\
& =n_{A} \overline{\mathbf{y}}_{A}^{\prime} \overline{\mathbf{y}}_{A}+n_{B} \overline{\mathbf{y}}_{B}^{\prime} \overline{\mathbf{y}}_{B}-2\left(n_{A} \overline{\mathbf{y}}_{A}^{\prime}+n_{B} \overline{\mathbf{y}}_{B}^{\prime}\right) \overline{\mathbf{y}}_{A B}+\left(n_{A}+n_{B}\right) \overline{\mathbf{y}}_{A B}^{\prime} \overline{\mathbf{y}}_{A B} \\
& =n_{A} \overline{\mathbf{y}}_{A}^{\prime} \overline{\mathbf{y}}_{A}+n_{B} \overline{\mathbf{y}}_{B}^{\prime} \overline{\mathbf{y}}_{B}-2\left(n_{A}+n_{B}\right) \overline{\mathbf{y}}_{A B}^{\prime} \overline{\mathbf{y}}_{A B}+\left(n_{A}+n_{B}\right) \overline{\mathbf{y}}_{A B}^{\prime} \overline{\mathbf{y}}_{A B} \\
& =n_{A} \overline{\mathbf{y}}_{A}^{\prime} \overline{\mathbf{y}}_{A}+n_{B} \overline{\mathbf{y}}_{B}^{\prime} \overline{\mathbf{y}}_{B}-\left(n_{A}+n_{B}\right) \overline{\mathbf{y}}_{A B}^{\prime} \overline{\mathbf{y}}_{A B} . \\
& \text { Substitute } \overline{\mathbf{y}}_{A B}=\left(n_{A} \overline{\mathbf{y}}_{A}+n_{B} \overline{\mathbf{y}}_{B}\right) /\left(n_{A}+n_{B}\right) .
\end{aligned}
\]
15.3 (a) Complete linkage. From Table 15.2, we have
\[
\begin{equation*}
D(C, A B)=\frac{1}{2} D(C, A)+\frac{1}{2} D(C, B)+\frac{1}{2}|D(C, A)-D(C, B)| \tag{1}
\end{equation*}
\]

If \(D(C, A)>D(C, B)\), then \(|D(C, A)-D(C, B)|=D(C, A)-\) \(D(C, B)\), and (l) becomes \(D(C, A B)=D(C, A)\). If \(D(C, A)>\) \(D(C, B)\), then \(|D(C, A)-D(C, B)|=D(C, B)-D(C, A)\) and equation (1) becomes \(D(C, A B)=D(C, B)\). Thus equation (1) can be written as \(D(C, A B)=\max [D(C, A), D(C, B)]\), which is equivalent to (15.9), the definition of distance for the complete linkage method.
(b) Average linkage. From Table 15.2, we have
\[
\begin{equation*}
D(C, A B)=\frac{n_{A}}{n_{A}+n_{B}} D(C, A)+\frac{n_{B}}{n_{A}+n_{B}} D(C, B) \tag{2}
\end{equation*}
\]

By (15.10) equation (2) can be written as
\[
\begin{aligned}
D(C, A B)= & \frac{n_{A}}{n_{A}+n_{B}} \cdot \frac{1}{n_{C} n_{A}} \sum_{i=1}^{n_{C}} \sum_{j=1}^{n_{A}} d\left(\mathbf{y}_{i}, \mathbf{y}_{j}\right) \\
& +\frac{n_{B}}{n_{A}+n_{B}} \cdot \frac{1}{n_{C} n_{B}} \sum_{i=1}^{n_{C}} \sum_{j=1}^{n_{B}} d\left(\mathbf{y}_{i}, \mathbf{y}_{j}\right) \\
= & \frac{1}{n_{C}\left(n_{A}+n_{B}\right)} \sum_{i=1}^{n_{C}}\left[\sum_{j=1}^{n_{A}} d\left(\mathbf{y}_{i}, \mathbf{y}_{j}\right)+\sum_{j=1}^{n_{B}} d\left(\mathbf{y}_{i}, \mathbf{y}_{j}\right)\right] \\
= & \frac{1}{n_{C} n_{A B}} \sum_{i=1}^{n_{C}} \sum_{j=1}^{n_{A B}} d\left(\mathbf{y}_{i}, \mathbf{y}_{j}\right)
\end{aligned}
\]
which, by (15.10), is the definition of distance for the average linkage method.
(c) Substitute \(\overline{\mathbf{y}}_{A B}=\left(n_{A} \overline{\mathbf{y}}_{A}+n_{B} \overline{\mathbf{y}}_{B}\right) /\left(n_{A}+n_{B}\right)\) in the left side of (15.40) in the statement of Problem 15.3(c) and multiply to obtain
\[
\begin{aligned}
& \overline{\mathbf{y}}_{C}^{\prime} \overline{\mathbf{y}}_{C}-\frac{2 n_{A} \overline{\mathbf{y}}_{A}^{\prime} \overline{\mathbf{y}}_{C}}{n_{A}+n_{B}}+\frac{2 n_{A} n_{B} \overline{\mathbf{y}}_{A}^{\prime} \overline{\mathbf{y}}_{B}}{\left(n_{A}+n_{B}\right)^{2}}-\frac{2 n_{B} \overline{\mathbf{y}}_{B}^{\prime} \overline{\mathbf{y}}_{C}}{n_{A}+n_{B}} \\
& \quad+\frac{n_{A}^{2} \overline{\mathbf{y}}_{A}^{\prime} \overline{\mathbf{y}}_{A}}{\left(n_{A}+n_{B}\right)^{2}}+\frac{n_{B}^{2} \overline{\mathbf{y}}_{B}^{\prime} \overline{\mathbf{y}}_{B}}{\left(n_{A}+n_{B}\right)^{2}} .
\end{aligned}
\]

Similarly, multiply on the right side of (15.40) to obtain the same result.
(d) Using \(n_{A}=n_{B}\) in \(\overline{\mathbf{y}}_{A B}=\left(n_{A} \overline{\mathbf{y}}_{A}+n_{B} \overline{\mathbf{y}}_{B}\right) /\left(n_{A}+n_{B}\right)\) in (15.12), we obtain \(\mathbf{m}_{A B}=\frac{1}{2}\left(\overline{\mathbf{y}}_{A}+\overline{\mathbf{y}}_{B}\right)\) in (15.13). Then (15.40) [see part (c)] becomes
\[
\begin{aligned}
\left(\overline{\mathbf{y}}_{C}-\mathbf{m}_{A B}\right)^{\prime}\left(\overline{\mathbf{y}}_{C}-\mathbf{m}_{A B}\right)= & \frac{1}{2}\left(\overline{\mathbf{y}}_{C}-\overline{\mathbf{y}}_{A}\right)^{\prime}\left(\overline{\mathbf{y}}_{C}-\overline{\mathbf{y}}_{A}\right) \\
& +\frac{1}{2}\left(\overline{\mathbf{y}}_{C}-\overline{\mathbf{y}}_{B}\right)^{\prime}\left(\overline{\mathbf{y}}_{C}-\overline{\mathbf{y}}_{B}\right)-\frac{1}{4}\left(\overline{\mathbf{y}}_{A}-\overline{\mathbf{y}}_{B}\right)^{\prime}\left(\overline{\mathbf{y}}_{A}-\overline{\mathbf{y}}_{B}\right)
\end{aligned}
\]
which matches the parameter values for the median method in Table 15.2.
(e) \(\mathrm{By}(15.19)\),
\[
\left(\overline{\mathbf{y}}_{A}-\overline{\mathbf{y}}_{B}\right)^{\prime}\left(\overline{\mathbf{y}}_{A}-\overline{\mathbf{y}}_{B}\right)=\frac{n_{A}+n_{B}}{n_{A} n_{B}} I_{A B}
\]
and we have analogous expressions for \(\left(\overline{\mathbf{y}}_{C}-\overline{\mathbf{y}}_{A B}\right)^{\prime}\left(\overline{\mathbf{y}}_{C}-\overline{\mathbf{y}}_{A B}\right),\left(\overline{\mathbf{y}}_{C}-\right.\) \(\left.\overline{\mathbf{y}}_{A}\right)^{\prime}\left(\overline{\mathbf{y}}_{C}-\overline{\mathbf{y}}_{A}\right)\), and \(\left(\overline{\mathbf{y}}_{C}-\overline{\mathbf{y}}_{B}\right)^{\prime}\left(\overline{\mathbf{y}}_{C}-\overline{\mathbf{y}}_{B}\right)\). Then (15.40) in part (c) becomes
\[
\begin{aligned}
\frac{n_{C}+n_{A B}}{n_{C} n_{A B}} I_{C(A B)}= & \left(\frac{n_{A}}{n_{A}+n_{B}}\right)\left(\frac{n_{C}+n_{A}}{n_{C} n_{A}}\right) I_{C A} \\
& +\left(\frac{n_{B}}{n_{A}+n_{B}}\right)\left(\frac{n_{c}+n_{B}}{n_{C} n_{B}}\right) I_{C B} \\
& -\left[\frac{n_{A} n_{B}}{\left(n_{A}+n_{B}\right)^{2}}\right]\left(\frac{n_{A}+n_{B}}{n_{A} n_{B}}\right) I_{A B} \\
= & \frac{n_{A}+n_{B}}{n_{C} n_{A B}} I_{A C}+\frac{n_{B}+n_{C}}{n_{C} n_{A B}} I_{C B}-\frac{1}{n_{A B}} I_{A B}
\end{aligned}
\]

Solve for \(I_{C(A B)}\).
15.4 If \(\gamma=0\), then (15.20) becomes
\[
\begin{equation*}
D(C, A B)=\alpha_{A} D(C, A)+\alpha_{B} D(C, B)+\beta D(A, B) \tag{1}
\end{equation*}
\]

By (15.25), we have \(D(A, C)>D(A, B)\) and \(D(B, C)>D(A, B)\). Thus, replacing \(D(C, A)\) and \(D(C, B)\) in equation (1) by \(D(A, B)\), we obtain
\[
D(C, A B)>\alpha_{A} D(A, B)+\alpha_{B} D(A, B)+\beta D(A, B)
\]
which is equivalent to (15.26).
15.5
\[
\text { (a) } \begin{aligned}
\overline{\mathbf{v}}_{. .} & =\frac{1}{g n} \sum_{i=1}^{g} \sum_{j=1}^{n} \mathbf{v}_{i j}=\frac{1}{g n} \sum_{i=1}^{g} \sum_{j=1}^{n}\left(\mathbf{A} \mathbf{y}_{i j}+\mathbf{b}\right) \\
& =\frac{1}{g n}\left(\mathbf{A} \sum_{i j} \mathbf{y}_{i j}+g n \mathbf{b}\right)=\mathbf{A}\left(\frac{1}{g n} \sum_{i j} \mathbf{y}_{i j}\right)+\mathbf{b}=\mathbf{A} \overline{\mathbf{y}}_{. .}+\mathbf{b}
\end{aligned}
\]

Show similarly that \(\overline{\mathbf{v}}_{i .}=\mathbf{A} \overline{\mathbf{y}}_{i .}+\mathbf{b}\). Then by (6.9), we have
\[
\begin{aligned}
\mathbf{H}_{v} & =n \sum_{i=1}^{g}\left(\overline{\mathbf{v}}_{i .}-\overline{\mathbf{v}}_{. .}\right)\left(\overline{\mathbf{v}}_{i .}-\overline{\mathbf{v}}_{. .}\right)^{\prime} \\
& =n \sum_{i}\left[\mathbf{A} \overline{\mathbf{y}}_{i .}+\mathbf{b}-\left(\mathbf{A} \overline{\mathbf{y}}_{. .}+\mathbf{b}\right)\right]\left[\mathbf{A} \overline{\mathbf{y}}_{i .}+\mathbf{b}-\left(\mathbf{A} \overline{\mathbf{y}}_{. .}+\mathbf{b}\right)\right]^{\prime} \\
& =n \sum_{i}\left(\mathbf{A} \overline{\mathbf{y}}_{i .}-\mathbf{A} \overline{\mathbf{y}}_{. .}\right)\left(\mathbf{A} \overline{\mathbf{y}}_{i .}-\mathbf{A} \overline{\mathbf{y}}_{. .}\right)^{\prime} \\
& =n \sum_{i} \mathbf{A}\left(\overline{\mathbf{y}}_{i .}-\overline{\mathbf{y}}_{. .}\right)\left(\overline{\mathbf{y}}_{i .}-\overline{\mathbf{y}}_{. .}\right)^{\prime} \mathbf{A}^{\prime} \quad[\mathrm{by}(2.27)] \\
& =n \mathbf{A}\left[\sum_{i}\left(\overline{\mathbf{y}}_{i .}-\overline{\mathbf{y}}_{. .}\right)\left(\overline{\mathbf{y}}_{i .}-\overline{\mathbf{y}}_{. .}\right)^{\prime}\right] \mathbf{A}^{\prime} \quad[\mathrm{by}(2.45)] \\
& =\mathbf{A} \mathbf{H}_{y} \mathbf{A}^{\prime}
\end{aligned}
\]

Show similarly that \(\mathbf{E}_{v}=\mathbf{A} \mathbf{E}_{y} \mathbf{A}^{\prime}\).
(b) \(\operatorname{tr}\left(\mathbf{E}_{v}\right)=\operatorname{tr}\left(\mathbf{A} \mathbf{E}_{y} \mathbf{A}^{\prime}\right)=\operatorname{tr}\left(\mathbf{A}^{\prime} \mathbf{A} \mathbf{E}_{y}\right) \neq \operatorname{tr}\left(\mathbf{E}_{y}\right)\)
(c) \(\left|\mathbf{E}_{v}\right|=\left|\mathbf{A} \mathbf{E}_{y} \mathbf{A}^{\prime}\right|=|\mathbf{A}|\left|\mathbf{E}_{y}\right|\left|\mathbf{A}^{\prime}\right|=|\mathbf{A}|^{2}\left|\mathbf{E}_{y}\right|=c\left|\mathbf{E}_{y}\right|\), where \(c>0\). Thus minimizing \(\left|\mathbf{E}_{v}\right|\) is equivalent to minimizing \(\left|\mathbf{E}_{y}\right|\).
(d) \(\operatorname{tr}\left(\mathbf{E}_{v}^{-1} \mathbf{H}_{v}\right)=\operatorname{tr}\left[\left(\mathbf{A} \mathbf{E}_{y} \mathbf{A}^{\prime}\right)^{-1}\left(\mathbf{A} \mathbf{H}_{y} \mathbf{A}^{\prime}\right)\right]\)
\[
\begin{aligned}
& \left.=\operatorname{tr}\left[\left(\mathbf{A}^{\prime}\right)^{-1} \mathbf{E}_{y}^{-1} \mathbf{A}^{-1} \mathbf{A} \mathbf{H}_{y} \mathbf{A}^{\prime}\right)\right] \\
& =\operatorname{tr}\left[\left(\mathbf{A}^{\prime}\right)^{-1} \mathbf{E}_{y}^{-1} \mathbf{H}_{y} \mathbf{A}^{\prime}\right] \\
& =\operatorname{tr}\left[\mathbf{A}^{\prime}\left(\mathbf{A}^{\prime}\right)^{-1} \mathbf{E}_{y}^{-1} \mathbf{H}_{y}\right] \\
& =\operatorname{tr}\left(\mathbf{E}_{y}^{-1} \mathbf{H}_{y}\right)
\end{aligned}
\]
15.6 There are \(p\) parameters in each \(\boldsymbol{\mu}_{i}, \frac{1}{2} p(p+1)\) unique parameters in each \(\boldsymbol{\Sigma}_{i}\), and \(g-1\) unique parameters \(\alpha_{i}\). Thus the total number is
\[
\begin{aligned}
g p+g\left[\frac{1}{2} p(p+1)\right]+g-1 & =g\left[p+\frac{1}{2} p(p+1)+1\right]-1 \\
& =\frac{1}{2} g\left[2 p+p^{2}+p+2\right]-1 \\
& =\frac{1}{2} g\left(3 p+p^{2}+2\right)-1 \\
& =\frac{1}{2} g(p+1)(p+2)-1 .
\end{aligned}
\]
15.7 (a) The two-cluster solution from single linkage puts boy number 20 in one cluster and the other 19 boys in the other cluster.
(b)-(d) Based on the change in distance, average linkage and the other cluster solutions in parts (c) and (d) clearly indicate two clusters. These solutions generally agree and also correspond to a division into two groups seen in the first principal component in Figure 12.5. The separation of the three apparent outliers from the other 17 observations is less pronounced in the cluster analyses than in Figure 12.5. Note that the scale of the second component in Figure 12.5 is much larger than that of the first component, so the separation of points 9,12 , and 20 from the rest is not as large as it appears in the figure. Of the methods in parts (b), (c), and (d), only flexible beta with \(\beta=-.50\) and -.75 place points 9,12 , and 20 together in one cluster. All others place 9 and 12 in one of the clusters and 20 in the other.
15.8 (a) The distance between centroids of the two clusters is \(\sqrt{2994.9}=54.7\).
(b) From the dendrogram produced by the average linkage method, the largest change in distance corresponds to a two-cluster solution.
(c) The discriminant function completely separates the two clusters, with no overlap.
15.9 (a) Observation 22 seems to be an outlier, because it forms its own cluster in both the single linkage and average linkage methods. The cluster consisting of observations \(2,21,24,26\) and 30 is the same in all six methods.
(b) The discriminant function completely separates the two clusters, with no overlap.
15.10 (a) The following five clusters were found using as seeds the five observations that are mutually farthest apart.
\begin{tabular}{cccccc}
\hline Cluster & 1 & 2 & 3 & 4 & 5 \\
\hline Observation(s) & \(9,15,16\), & \(1,2,3\), & 6,7, & 10,11, & 14 \\
& 18,19 & \(4,5,17\) & 8,20 & 12,13 & \\
\hline
\end{tabular}

In the plot of the first two discriminant functions, observation 14 is relatively far removed from the rest. Clusters 1,2 , and 3 are somewhat closer to each other.
(b) The following five clusters were found using as seeds the first five observations.
\begin{tabular}{cccccc}
\hline Cluster & 1 & 2 & 3 & 4 & 5 \\
\hline Observation(s) & \(1,3,4\) & 2 & 5,17, & \(6,7,8\), & \(9,10,11\), \\
& & & 18,19 & \(15,16,20\) & \(12,13,14\) \\
\hline
\end{tabular}

The plot of the first two discriminant functions shows a pattern different from that in part (a).
(c) The following five clusters were found using as seeds the centroids of the five-cluster solution resulting from Ward's method.
\begin{tabular}{cccccc}
\hline Cluster & 1 & 2 & 3 & 4 & 5 \\
\hline Observation(s) & \(6,7,8,15\) & \(5,9,17\), & 10,11, & 1,2, & 14 \\
& 16,20 & 18,19 & 12,13 & 3,4 & \\
\hline
\end{tabular}

The plot of the first two discriminant functions shows a pattern similar to that found in part (a), with observation 14 isolated.The dendrogram shows that Ward's method gives the same five-cluster solution as the \(k\) means result.
(d) The following five clusters were found using the \(k\)-means method with seeds equal to the centroids of the five clusters from average linkage.
\begin{tabular}{cccccc}
\hline Cluster & 1 & 2 & 3 & 4 & 5 \\
\hline Observation(s) & \(6,7,8,15\), & \(1,2,3,4,5\), & 10,11, & 9 & 14 \\
& 16,20 & \(17,18,19\) & 12,13 & & \\
\hline
\end{tabular}

The plot of the first two discriminant functions shows a pattern somewhat similar to that in part (a). In the dendrogram for average linkage, observations 9 and 14 are isolated clusters in the five-cluster solution, which is identical to the five-cluster solution using \(k\)-means clustering with these seeds.
(e) Observation 14 does not appear as an outlier in the plot of the first two principal compoments, but it does show up as an outlier in the plot of the
second and third components. The solutions found in parts (a) and (c) seem to agree most with the principal component plots. This suggests that a different number of initial cluster seeds be used.
(f) The two clustering solutions are identical. The results are given below.
\begin{tabular}{cccc}
\hline Cluster & 1 & 2 & 3 \\
\hline Observation(s) & \(6,7,8,15,16,20\) & \(9,10,11,12,13,14\) & \(1,2,3,4,5,17,18,19\) \\
\hline
\end{tabular}
(g) The clustering solution is identical to that found in part (e), which indicates that the three-cluster solution is appropriate.
15.11 The numbers of clusters obtained from the indicated combinations of \(k\) and \(r\) are shown in the table below. Note that for each pair of values of \(k\) and \(r\), the value of \(r\) was increased if necessary for each point until \(k\) points were included in the sphere.
\begin{tabular}{ccccccccccc}
\hline\(k / r\) & .2 & .4 & .6 & .8 & 1.0 & 1.2 & 1.4 & 1.6 & 1.8 & 2.0 \\
\hline 2 & 10 & 10 & 10 & 10 & 8 & 6 & 4 & 3 & 3 & 2 \\
3 & 5 & 5 & 5 & 5 & 5 & 3 & 2 & 2 & 2 & 2 \\
4 & 2 & 2 & 2 & 2 & 2 & 2 & 2 & 2 & 2 & 2 \\
5 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\
\hline
\end{tabular}

The maximum value of \(k\) that yields a two-cluster solution is 4 .
15.12 (a) The numbers of clusters obtained from the initial combinations of \(k\) and \(r\) are shown in the table below. The value of \(r\) was variable, as noted in Problem 15.11 above.
\begin{tabular}{ccccccccccc}
\hline\(k / r\) & .2 & .4 & .6 & .8 & 1.0 & 1.2 & 1.4 & 1.6 & 1.8 & 2.0 \\
\hline 2 & 3 & 3 & 3 & 3 & 3 & 3 & 3 & 3 & 3 & 3 \\
3 & 2 & 2 & 2 & 2 & 2 & 2 & 2 & 2 & 2 & 2 \\
4 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\
\hline
\end{tabular}
(b) The plot of the first two discriminant functions for \(k=2\) and \(r=1\) shows the three clusters to be well separated.
(c) The plot of the first two principal components shows the same groupings as in the plot in part (b).
(d) The plot of the discriminant function shows wide separation of the two clusters. The clusters do not overlap. The three-cluster solution found in part (b) is given below
\begin{tabular}{lll}
\hline Cluster 1 & Cluster 2 & Cluster 3 \\
\hline Harpers & Rosemaund & Cambridge \\
Morley & Terrington & Cockle Park \\
Myerscough & Headley & \\
Sparsholt & Seale-Hayne & \\
Sutton Bonington & & \\
Wye & & \\
\hline
\end{tabular}

The two-cluster solution found in part (d) merges clusters two and three of part (b).

\section*{CHAPTER 16}
16.1 \(\mathbf{B}=\left(\mathbf{I}-\frac{1}{n} \mathbf{J}\right) \mathbf{A}\left(\mathbf{I}-\frac{1}{n} \mathbf{J}\right)\)
\[
\begin{equation*}
=\mathbf{A}-\frac{1}{n} \mathbf{A} \mathbf{J}-\frac{1}{n} \mathbf{J} \mathbf{A}+\frac{1}{n^{2}} \mathbf{J} \mathbf{A} \mathbf{J} \tag{1}
\end{equation*}
\]

By (2.38),
\[
\frac{1}{n} \mathbf{A} \mathbf{j}=\frac{1}{n}\left(\begin{array}{c}
\sum_{j} a_{1 j}  \tag{2}\\
\sum_{j} a_{2 j} \\
\vdots \\
\sum_{j} a_{n j}
\end{array}\right)=\left(\begin{array}{c}
\bar{a}_{1 .} \\
\bar{a}_{2 .} \\
\vdots \\
\bar{a}_{n} .
\end{array}\right)
\]

Hence,
\[
\begin{aligned}
\frac{1}{n} \mathbf{A} \mathbf{J} & =\frac{1}{n} \mathbf{A}(\mathbf{j}, \mathbf{j}, \ldots, \mathbf{j})=\left(\frac{1}{n} \mathbf{A} \mathbf{j}, \ldots, \frac{1}{n} \mathbf{A} \mathbf{j}\right) \\
& =\left(\begin{array}{ccc}
\bar{a}_{1 .} & \cdots & \bar{a}_{1 .} \\
\bar{a}_{2 .} & \cdots & \bar{a}_{2 .} \\
\vdots & & \vdots \\
\bar{a}_{n .} & \cdots & \bar{a}_{n .}
\end{array}\right) .
\end{aligned}
\]

Show that
\[
\frac{1}{n} \mathbf{J} \mathbf{A}=\left(\begin{array}{cccc}
\bar{a}_{.1} & \bar{a}_{.2} & \cdots & \bar{a}_{. n} \\
\bar{a}_{.1} & \bar{a}_{.2} & \cdots & \bar{a}_{. n} \\
\vdots & \vdots & & \vdots \\
\bar{a}_{.1} & \bar{a}_{.2} & \cdots & \bar{a}_{. n}
\end{array}\right)
\]

Using equation (2), we obtain
\[
\frac{\mathbf{1}}{n^{2}} \mathbf{j}^{\prime} \mathbf{A} \mathbf{j}=\frac{\mathbf{1}}{n^{2}}(\mathbf{1}, 1, \ldots, 1)\left(\begin{array}{c}
\sum_{j} a_{1 j} \\
\sum_{j} a_{2 j} \\
\vdots \\
\sum_{j} a_{n j}
\end{array}\right)=\frac{1}{n^{2}} \sum_{i j} a_{i j}=\bar{a}_{. .}
\]

By (3.63),
\[
\frac{1}{n^{2}} \mathbf{J} \mathbf{A J}=\frac{1}{n^{2}}\left(\begin{array}{ccc}
\mathbf{j}^{\prime} \mathbf{A} \mathbf{j} & \cdots & \mathbf{j}^{\prime} \mathbf{A} \mathbf{j} \\
\vdots & & \vdots \\
\mathbf{j}^{\prime} \mathbf{A} \mathbf{j} & \cdots & \mathbf{j}^{\prime} \mathbf{A} \mathbf{j}
\end{array}\right)=\left(\begin{array}{ccc}
\bar{a}_{. .} & \cdots & \bar{a}_{. .} \\
\vdots & & \vdots \\
\bar{a}_{. .} & \cdots & \bar{a}_{. .}
\end{array}\right)
\]

Hence the \(i j\) th element of equation (1) is \(b_{i j}=a_{i j}-\bar{a}_{i .}-\bar{a}_{. j}+\bar{a}_{. .}\).
16.2 (a) (Seber 1984, pp. 236-237) The elements of \(\mathbf{B}=\left(b_{i j}\right)\) are defined as \(b_{i j}=a_{i j}-\bar{a}_{i .}-\bar{a}_{. j}+\bar{a}_{. .}\), where \(a_{i j}=-\frac{1}{2} \delta_{i j}^{2}\). Thus
\[
\begin{aligned}
-2 a_{i j} & =\delta_{i j}^{2}=\left(\mathbf{z}_{i}-\mathbf{z}_{j}\right)^{\prime}\left(\mathbf{z}_{i}-\mathbf{z}_{j}\right) \\
& =\mathbf{z}_{i}^{\prime} \mathbf{z}_{i}+\mathbf{z}_{j}^{\prime} \mathbf{z}_{j}-2 \mathbf{z}_{i}^{\prime} \mathbf{z}_{j} .
\end{aligned}
\]

Then
\[
\begin{aligned}
-2 \bar{a}_{i .} & =\frac{1}{n} \sum_{j=1}^{n}\left(-2 a_{i j}\right)=\frac{1}{n} \sum_{j}\left(\mathbf{z}_{i}^{\prime} \mathbf{z}_{i}+\mathbf{z}_{j}^{\prime} \mathbf{z}_{j}-2 \mathbf{z}_{i}^{\prime} \mathbf{z}_{j}\right) \\
& =\mathbf{z}_{i}^{\prime} \mathbf{z}_{i}+\frac{1}{n} \sum_{j} \mathbf{z}_{j}^{\prime} \mathbf{z}_{j}-\frac{2}{n} \mathbf{z}_{i}^{\prime} \sum_{j} \mathbf{z}_{j} \\
& =\mathbf{z}_{i}^{\prime} \mathbf{z}_{i}+\frac{1}{n} \sum_{j} \mathbf{z}_{j}^{\prime} \mathbf{z}_{j}-2 \mathbf{z}_{i}^{\prime} \overline{\mathbf{z}}
\end{aligned}
\]

Similarly, show that
\[
\begin{aligned}
& -2 \bar{a}_{. j}=\mathbf{z}_{j}^{\prime} \mathbf{z}_{j}+\frac{1}{n} \sum_{i} \mathbf{z}_{i}^{\prime} \mathbf{z}_{i}-2 \overline{\mathbf{z}}^{\prime} \mathbf{z}_{j} \\
& -2 \bar{a}_{. .}=\frac{2}{n} \sum_{i} \mathbf{z}_{i}^{\prime} \mathbf{z}_{i}-2 \overline{\mathbf{z}}^{\prime} \overline{\mathbf{z}}
\end{aligned}
\]

Solve for \(a_{i j}, \bar{a}_{i,}, \bar{a}_{. j}\), and \(\bar{a}_{. .}\)and substitute into \(b_{i j}=a_{i j}-\bar{a}_{i .}-\bar{a}_{. j}+\bar{a}_{\text {. }}\) to obtain \(b_{i j}=\mathbf{z}_{i}^{\prime} \mathbf{z}_{j}-\mathbf{z}_{i}^{\prime} \overline{\mathbf{z}}-\overline{\mathbf{z}}^{\prime} \mathbf{z}_{j}+\overline{\mathbf{z}}^{\prime} \overline{\mathbf{z}}\), which can be factored as \(b_{i j}=\) \(\left(\mathbf{z}_{i}-\overline{\mathbf{z}}\right)^{\prime}\left(\mathbf{z}_{j}-\overline{\mathbf{z}}\right)\). Hence
\[
\begin{aligned}
\mathbf{B} & =\left(\begin{array}{ccc}
\left(\mathbf{z}_{1}-\overline{\mathbf{z}}\right)^{\prime}\left(\mathbf{z}_{1}-\overline{\mathbf{z}}\right) & \cdots & \left(\mathbf{z}_{1}-\overline{\mathbf{z}}\right)^{\prime}\left(\mathbf{z}_{n}-\overline{\mathbf{z}}\right) \\
\vdots & & \vdots \\
\left(\mathbf{z}_{n}-\overline{\mathbf{z}}\right)^{\prime}\left(\mathbf{z}_{\mathbf{1}}-\overline{\mathbf{z}}\right) & \cdots & \left(\mathbf{z}_{n}-\overline{\mathbf{z}}\right)^{\prime}\left(\mathbf{z}_{n}-\overline{\mathbf{z}}\right)
\end{array}\right) \\
& =\left(\begin{array}{c}
\left(\mathbf{z}_{1}-\overline{\mathbf{z}}\right)^{\prime} \\
\vdots \\
\left(\mathbf{z}_{n}-\overline{\mathbf{z}}\right)^{\prime}
\end{array}\right)\left(\mathbf{z}_{1}-\overline{\mathbf{z}}, \ldots, \mathbf{z}_{n}-\overline{\mathbf{z}}\right) \\
& =\mathbf{Z}_{c} \mathbf{Z}_{c}^{\prime} \quad[\operatorname{see}(10.13)] .
\end{aligned}
\]

Thus \(\mathbf{B}\) is positive semidefinite (see Section 2.7).
(b) If \(\mathbf{B}\) is positive semidefinite of \(\operatorname{rank} q\), then by (2.109) and Section 2.11.4, \(\mathbf{B}\) can be expressed in the form \(\mathbf{B}=\mathbf{V} \boldsymbol{\Lambda} \mathbf{V}^{\prime}\), where \(\mathbf{V}=\left(\mathbf{v}_{1}, \mathbf{v}_{2}, \ldots, \mathbf{v}_{n}\right)\) is an orthogonal matrix of eigenvectors of \(B\), and \(\boldsymbol{\Lambda}\) is a diagonal matrix of eigenvalues, \(q\) of which are positive, with the rest equal to zero. Letting \(\boldsymbol{\Lambda}_{1}\) be the \(q \times q\) upper left hand block of \(\boldsymbol{\Lambda}\) with positive eigenvalues and \(\mathbf{V}_{1}=\left(\mathbf{v}_{1}, \mathbf{v}_{2}, \ldots, \mathbf{v}_{q}\right)\) be the \(n \times q\) matrix with the corresponding eigenvectors, we can write \(\mathbf{B}=\mathbf{V} \boldsymbol{\Lambda} \mathbf{V}^{\prime}\) as
\[
\begin{align*}
\mathbf{B} & =\left(\mathbf{V}_{1}, \mathbf{V}_{2}\right)\left(\begin{array}{cc}
\boldsymbol{\Lambda}_{1} & \mathbf{O} \\
\mathbf{O} & \mathbf{O}
\end{array}\right)\binom{\mathbf{V}_{1}^{\prime}}{\mathbf{V}_{2}^{\prime}} \\
& =\mathbf{V}_{1} \boldsymbol{\Lambda}_{1} \mathbf{V}_{1}^{\prime}=\mathbf{V}_{1} \boldsymbol{\Lambda}_{1}^{1 / 2} \boldsymbol{\Lambda}_{1}^{1 / 2} \mathbf{V}_{1}^{\prime} \\
& =\mathbf{Z Z} \mathbf{Z}^{\prime}, \tag{1}
\end{align*}
\]
where the \(n \times q\) matrix \(\mathbf{Z}\) is
\[
\begin{aligned}
\mathbf{Z} & =\mathbf{V}_{1} \mathbf{\Lambda}_{1}^{1 / 2}=\left(\sqrt{\lambda_{1}} \mathbf{v}_{1}, \sqrt{\lambda_{2}} \mathbf{v}_{2}, \ldots, \sqrt{\lambda_{q}} \mathbf{v}_{q}\right) \\
& =\left(\begin{array}{c}
\mathbf{z}_{1}^{\prime} \\
\mathbf{z}_{2}^{\prime} \\
\vdots \\
\mathbf{z}_{n}^{\prime}
\end{array}\right)
\end{aligned}
\]

To show that \(\left(\mathbf{z}_{i}-\mathbf{z}_{j}\right)^{\prime}\left(\mathbf{z}_{i}-\mathbf{z}_{j}\right)\) is equal to \(\delta_{i j}^{2}\), we can proceed as follows:
\[
\begin{equation*}
\left(\mathbf{z}_{i}-\mathbf{z}_{j}\right)^{\prime}\left(\mathbf{z}_{i}-\mathbf{z}_{j}\right)=\mathbf{z}_{i}^{\prime} \mathbf{z}_{i}+\mathbf{z}_{j}^{\prime} \mathbf{z}_{j}-2 \mathbf{z}_{i}^{\prime} \mathbf{z}_{j} \tag{2}
\end{equation*}
\]

By equation (1), we have
\[
\begin{aligned}
\mathbf{B}=\mathbf{Z} \mathbf{Z}^{\prime} & =\left(\begin{array}{c}
\mathbf{z}_{1}^{\prime} \\
\mathbf{z}_{2}^{\prime} \\
\vdots \\
\mathbf{z}_{n}^{\prime}
\end{array}\right)\left(\mathbf{z}_{1}, \mathbf{z}_{2}, \ldots, \mathbf{z}_{n}\right) \\
& =\left(\begin{array}{cccc}
\mathbf{z}_{1}^{\prime} \mathbf{z}_{1} & \mathbf{z}_{1}^{\prime} \mathbf{z}_{2} & \cdots & \mathbf{z}_{1}^{\prime} \mathbf{z}_{n} \\
\mathbf{z}_{2}^{\prime} \mathbf{z}_{1} & \mathbf{z}_{2}^{\prime} \mathbf{z}_{2} & \cdots & \mathbf{z}_{2}^{\prime} \mathbf{z}_{n} \\
\vdots & \vdots & & \vdots \\
\mathbf{z}_{n}^{\prime} \mathbf{z}_{1} & \mathbf{z}_{n}^{\prime} \mathbf{z}_{2} & \cdots & \mathbf{z}_{n}^{\prime} \mathbf{z}_{n}
\end{array}\right)
\end{aligned}
\]

Hence equation (2) becomes
\[
\begin{align*}
\left(\mathbf{z}_{i}-\mathbf{z}_{j}\right)^{\prime}\left(\mathbf{z}_{i}-\mathbf{z}_{j}\right) & =\mathbf{z}_{i}^{\prime} \mathbf{z}_{i}+\mathbf{z}_{j}^{\prime} \mathbf{z}_{j}-2 \mathbf{z}_{i}^{\prime} \mathbf{z}_{j} \\
& =b_{i i}+b_{j j}-2 b_{i j} \tag{3}
\end{align*}
\]

Show that substituting \(b_{i j}=a_{i j}-\bar{a}_{i .}-\bar{a}_{. j}+\bar{a}_{. .}\)into equation (3) leads to
\[
\left(\mathbf{z}_{i}-\mathbf{z}_{j}\right)^{\prime}\left(\mathbf{z}_{i}-\mathbf{z}_{j}\right)=a_{i i}+a_{j j}-2 a_{i j}+\bar{a}_{i .}-\bar{a}_{. i}+\bar{a}_{. j}-\bar{a}_{j .} .
\]

Show that the symmetry of \(\mathbf{A}\) implies \(\bar{a}_{i .}=\bar{a}_{i}\) and \(\bar{a}_{j}-\bar{a}_{j .}\). Hence,
\[
\begin{aligned}
& \quad\left(\mathbf{z}_{i}-\mathbf{z}_{j}\right)^{\prime}\left(\mathbf{z}_{i}-\mathbf{z}_{j}\right)=a_{i i}+a_{j j}-2 a_{i j}=-2 a_{i j}=\delta_{i j}^{2}, \\
& \text { since } a_{i i}=-\frac{1}{2} \delta_{i i}^{2}=0 \text { and }-2 a_{i j}=\delta_{i j}^{2} .
\end{aligned}
\]
16.3 (a) \(\quad \mathbf{r}=\sum_{j=1}^{b} p_{. j} \mathbf{c}_{j}=\sum_{j=1}^{b} p_{. j}\left(\frac{p_{1 j}}{p_{\cdot j}}, \frac{p_{2 j}}{p_{\cdot j}}, \ldots, \frac{p_{a j}}{p_{\cdot j}}\right)^{\prime}\)
\[
\begin{aligned}
& =\sum_{j=1}^{b}\left(p_{1 j}, p_{2 j}, \ldots, p_{a j}\right)^{\prime} \quad[\text { by }(2.61)] \\
& =\left(\sum_{j} p_{1 j}, \sum_{j} p_{2 j}, \ldots, \sum_{j} p_{a j}\right)^{\prime} \\
& =\left(p_{1 .}, p_{2 .}, \ldots, p_{a .}\right)^{\prime}
\end{aligned}
\]
(b) \(\quad \mathbf{c}^{\prime}=\sum_{i=1}^{a} p_{i .} \mathbf{r}_{i}^{\prime}=\sum_{i=1}^{a} p_{i .}\left(\frac{p_{i 1}}{p_{i .}}, \frac{p_{i 2}}{p_{i .}}, \ldots, \frac{p_{i b}}{p_{i .}}\right)\)
\[
\begin{aligned}
& =\sum_{i=1}^{a}\left(p_{i 1}, p_{i 2}, \ldots, p_{i b}\right) \quad[\text { by }(2.61)] \\
& =\left(\sum_{i} p_{i 1}, \sum_{i} p_{i 2}, \ldots, \sum_{i} p_{i b}\right) \\
& =\left(p_{.1}, p_{.2}, \ldots, p_{. b}\right)
\end{aligned}
\]
\(16.4 \mathbf{j}^{\prime} \mathbf{r}=\sum_{i=1}^{a} p_{i .}=\sum_{i=1}^{a} \sum_{j=1}^{b} p_{i j}=\sum_{i j} n_{i j} / n=n / n=1\), \(\mathbf{c}^{\prime} \mathbf{j}=\sum_{j=1}^{b} p_{. j}=\sum_{j} n_{. j} / n=\sum_{j} \sum_{i} n_{i j} / n=n / n\)
16.5 By (16.8), (16.9), and (16.10), \(p_{i j}=n_{i j} / n, p_{i .}=n_{i .} / n\), and \(p_{. j}=n_{. j} / n\). Substituting these into (16.25), we obtain
\[
\begin{aligned}
& \chi^{2}=\sum_{i j} \frac{n\left(\frac{n_{i j}}{n}-\frac{n_{i, n} n_{j}}{n^{2}}\right)^{2}}{\frac{n_{i, i} n_{j}}{n^{2}}}=\sum_{i j} \frac{n\left[\frac{1}{n}\left(n_{i j}-\frac{n_{i,} n_{. j}}{n}\right)\right]^{2}}{\frac{n_{i, i} n^{2}}{n^{2}}} \\
& =\sum_{i j} \frac{\frac{n}{n^{2}}\left(n_{i j}-\frac{n_{i .} n_{j}}{n}\right)^{2}}{\frac{n_{i \cdot} \cdot n_{j}}{n^{2}}}=\sum_{i j} \frac{\left(n_{i j}-\frac{n_{i .} n_{. j}}{n}\right)^{2}}{\frac{n_{i \cdot} \cdot n_{. j}}{n}} .
\end{aligned}
\]
16.6 (a) Multiplying numerator and denominator of (16.25) by \(p_{i \text {, }}\), we obtain
\[
\begin{aligned}
\chi^{2} & =\sum_{i} n \sum_{j} \frac{p_{i .}}{p_{i .}^{2} p_{. j}}\left(p_{i j}-p_{i .} p_{. j}\right)^{2} \\
& =\sum_{i} n p_{i .} \sum_{j} \frac{1}{p_{. j}}\left[\frac{1}{p_{i .}}\left(p_{i j}-p_{i .} p_{. j}\right)\right]^{2} \\
& =\sum_{i} n p_{i .} \sum_{j}\left(\frac{p_{i j}}{p_{i .}}-p_{. j}\right)^{2} / p_{. j} .
\end{aligned}
\]
16.7 (a) By (16.29), (16.10), (16.12), and (16.18), we obtain
\[
\begin{aligned}
\chi^{2} & =\sum_{i} n p_{i .}\left(\mathbf{r}_{i}-\mathbf{c}\right)^{\prime} \mathbf{D}_{c}^{-1}\left(\mathbf{r}_{i}-\mathbf{c}\right) \\
& =\sum_{i} n p_{i .}\left(\frac{p_{i 1}}{p_{i .}}-p_{.1}, \ldots, \frac{p_{i b}}{p_{i .}}-p_{. b}\right)\left(\begin{array}{ccc}
p_{.1} & \cdots & 0 \\
\vdots & & \vdots \\
0 & \cdots & p_{. b}
\end{array}\right)^{-1}\left(\begin{array}{c}
\frac{p_{i 1}}{p_{i .}}-p_{.1} \\
\vdots \\
\frac{p_{i b}}{p_{i .}}-p_{. b}
\end{array}\right) \\
& =\sum_{i} n p_{i .}\left(\frac{\frac{p_{i 1}}{p_{i .}}-p_{.1}}{p_{.1}}, \ldots, \frac{\frac{p_{i b}}{p_{i .}}-p_{. b}}{p_{. b}}\right)\left(\begin{array}{c}
\frac{p_{i 1}}{p_{i .}}-p_{.1} \\
\vdots \\
\frac{p_{i b}}{p_{i .}}-p_{. b}
\end{array}\right)
\end{aligned}
\]
16.8 (a) By (16.9) \(\mathbf{r}=\mathbf{P j}\). Then \(\mathrm{D}_{r}^{-1} \mathbf{r}=\mathrm{D}_{r}^{-1} \mathbf{P j}=\mathbf{R j}\) by (16.15). By (16.13) \(\mathbf{r}_{i}^{\prime} \mathbf{j}=1\), and therefore \(\mathbf{R} \mathbf{j}=\mathbf{j}\). Now
\[
\mathbf{D}_{r}^{-1}\left(\mathbf{P}-\mathbf{r} \mathbf{c}^{\prime}\right)=\mathbf{D}_{r}^{-1} \mathbf{P}-\mathbf{D}_{r}^{-1} \mathbf{r c}^{\prime}=\mathbf{R}-\mathbf{R} \mathbf{j} \mathbf{c}^{\prime}=\mathbf{R}-\mathbf{j} \mathbf{c}^{\prime}
\]
16.9 \(\mathrm{By}\left(16.49\right.\) ), \(\mathbf{z}_{i}^{\prime}=\mathbf{y}_{i}^{\prime} \mathbf{A}\) (ignoring the centering on \(\mathbf{y}_{i}\) ). Thus the squared Euclidean distance can be written as
\[
\begin{aligned}
\left(\mathbf{z}_{i}-\mathbf{z}_{k}\right)^{\prime}\left(\mathbf{z}_{i}-\mathbf{z}_{k}\right) & =\left(\mathbf{z}_{i}^{\prime}-\mathbf{z}_{k}^{\prime}\right)\left(\mathbf{z}_{i}-\mathbf{z}_{k}\right) \\
& =\left(\mathbf{y}_{i}^{\prime} \mathbf{A}-\mathbf{y}_{k}^{\prime} \mathbf{A}\right)\left(\mathbf{A}^{\prime} \mathbf{y}_{i}-\mathbf{A}^{\prime} \mathbf{y}_{k}\right) \\
& =\left(\mathbf{y}_{i}^{\prime}-\mathbf{y}_{k}^{\prime}\right) \mathbf{A} \mathbf{A}^{\prime}\left(\mathbf{y}_{i}-\mathbf{y}_{k}\right) \\
& =\left(\mathbf{y}_{i}-\mathbf{y}_{k}\right)^{\prime}\left(\mathbf{y}_{i}-\mathbf{y}_{k}\right),
\end{aligned}
\]
since \(\mathbf{A}\) is orthogonal.
16.10 (a) From \(\mathbf{Y}_{c} \mathbf{V}=\mathbf{U} \boldsymbol{\Lambda}\) in (16.55), we have \(\mathbf{Y}_{c} \mathbf{V} \boldsymbol{\Lambda}^{-1}=\mathbf{U}\). Then
\[
\begin{align*}
\mathbf{U} \mathbf{U}^{\prime} & =\mathbf{Y}_{c} \mathbf{V} \boldsymbol{\Lambda}^{-1} \boldsymbol{\Lambda}^{-1} \mathbf{V}^{\prime} \mathbf{Y}_{c}^{\prime} \\
& =\mathbf{Y}_{c} \mathbf{V}\left(\boldsymbol{\Lambda}^{-1}\right)^{2} \mathbf{V}^{\prime} \mathbf{Y}_{c}^{\prime} \tag{1}
\end{align*}
\]

Since \(\left(\boldsymbol{\Lambda}^{-1}\right)^{2}=\operatorname{diag}\left(1 / \lambda_{1}^{2}, 1 / \lambda_{2}^{2}, \ldots, 1 / \lambda_{p}^{2}\right)\), where the \(\lambda_{i}^{2}\) 's are eivenvalues of \(\mathbf{Y}_{c}^{\prime} \mathbf{Y}_{c}\), the matrix \(\left(\mathbf{\Lambda}^{-1}\right)^{2}\) contains eigenvalues of \(\left(\mathbf{Y}_{c}^{\prime} \mathbf{Y}_{c}\right)^{-1}=\) \([(n-1) \mathbf{S}]^{-1}=\mathbf{S}^{-1} /(n-1)\) [see (2.115) and (2.116)]. The matrix \(\mathbf{V}\) contains eigenvectors of \(\mathbf{Y}_{c}^{\prime} \mathbf{Y}_{c}\) and thereby of \(\left(\mathbf{Y}_{c}^{\prime} \mathbf{Y}_{c}\right)^{-1}\) (see Section 2.11.9). Hence we recognize \(\mathbf{V}\left(\boldsymbol{\Lambda}^{-1}\right)^{2} \mathbf{V}^{\prime}\) as the spectral decomposition of \(\left(\mathbf{Y}_{c}^{\prime} \mathbf{Y}_{c}\right)^{-1}\) [see (2.109), (2.115), and (2.116)]. Therefore, equation (1) can be written as
\[
\begin{aligned}
\mathbf{U} \mathbf{U}^{\prime} & =\mathbf{Y}_{c} \mathbf{V}\left(\mathbf{\Lambda}^{-1}\right)^{2} \mathbf{V}^{\prime} \mathbf{Y}_{c}^{\prime}=\mathbf{Y}_{c}\left(\mathbf{Y}_{c}^{\prime} \mathbf{Y}_{c}\right)^{-1} \mathbf{Y}_{c}^{\prime} \\
& =\mathbf{Y}_{c} \mathbf{S}^{-1} \mathbf{Y}_{c}^{\prime} /(n-1)
\end{aligned}
\]
(b) If \(\mathbf{H}=\mathbf{V} \boldsymbol{\Lambda}\), then \(\mathbf{H} \mathbf{H}^{\prime}=\mathbf{V} \boldsymbol{\Lambda} \boldsymbol{\Lambda} \mathbf{V}^{\prime}=\mathbf{V} \boldsymbol{\Lambda}^{2} \mathbf{V}^{\prime}\). The diagonal matrix \(\boldsymbol{\Lambda}^{2}\) contains the eigenvalues \(\lambda_{i}^{2}\) of the matrix \(\mathbf{Y}_{c}^{\prime} \mathbf{Y}_{c}\). Thus by (2.115), \(\mathbf{V} \boldsymbol{\Lambda}^{2} \mathbf{V}^{\prime}\) is the spectral decomposition of \(\mathbf{Y}_{c}^{\prime} \mathbf{Y}_{c}\), and
\[
\mathbf{H H}^{\prime}=\mathbf{V} \boldsymbol{\Lambda}^{2} \mathbf{V}^{\prime}=\mathbf{Y}_{c}^{\prime} \mathbf{Y}_{c}=(n-1) \mathbf{S}
\]
16.11 By (16.64), (3.63), and (3.64) (ignoring \(n-1\) and assuming the \(y_{i}\) 's are centered),
\[
\begin{aligned}
\left(\mathbf{u}_{i}-\mathbf{u}_{k}\right)^{\prime}\left(\mathbf{u}_{i}-\mathbf{u}_{k}\right) & =\mathbf{u}_{i}^{\prime} \mathbf{u}_{i}+\mathbf{u}_{k}^{\prime} \mathbf{u}_{k}-2 \mathbf{u}_{i}^{\prime} \mathbf{u}_{k} \\
& =\mathbf{y}_{i}^{\prime} \mathbf{S}^{-1} \mathbf{y}_{i}+\mathbf{y}_{k}^{\prime} \mathbf{S}^{-1} \mathbf{y}_{k}-2 \mathbf{y}_{i}^{\prime} \mathbf{S}^{-1} \mathbf{y}_{k} \\
& =\left(\mathbf{y}_{i}-\mathbf{y}_{k}\right)^{\prime} \mathbf{S}^{-1}\left(\mathbf{y}_{i}-\mathbf{y}_{k}\right)
\end{aligned}
\]
16.12 (a) The first ten rows and columns of the matrix \(\mathbf{B}\) are as follows:
\[
\left(\begin{array}{rrrrrrrrrr}
129849 & -26801 & -88750 & -53847 & -59118 & 43583 & -73877 & 81571 & 112101 & 80909 \\
-26801 & 2310 & 17029 & 11125 & 14394 & -1076 & 18149 & -18662 & -21852 & -16306 \\
-88750 & 17029 & 65973 & 32378 & 31044 & -31085 & 68156 & -56671 & -79481 & -54135 \\
-53847 & 11125 & 32378 & 27683 & 31808 & -18550 & 30003 & -34154 & -46882 & -32096 \\
-59118 & 14394 & 31044 & 31808 & 38141 & -19161 & 27269 & -37147 & -51673 & -34687 \\
45383 & -11076 & -31085 & -18550 & -19161 & 14741 & -33620 & 27054 & 45347 & 29211 \\

\end{array}\right)
\]
(b) The first two columns of the matrix \(\mathbf{Z}\) are given by:
\begin{tabular}{crr}
\hline City & \multicolumn{1}{c}{\(z_{1}\)} & \multicolumn{1}{c}{\(z_{2}\)} \\
\hline A & 354.1 & -10.2 \\
B & -77.1 & 25.0 \\
C & -238.2 & -75.7 \\
D & -154.9 & 65.9 \\
E & -163.2 & 72.2 \\
F & 126.0 & 24.9 \\
G & -228.8 & -149.4 \\
H & 223.9 & 1.5 \\
I & 337.7 & 44.8 \\
J & 226.7 & 34.7 \\
K & -33.4 & 22.3 \\
L & 1.1 & -79.4
\end{tabular}
\begin{tabular}{crr}
\hline City & \multicolumn{1}{c}{\(z_{1}\)} & \multicolumn{1}{c}{\(z_{2}\)} \\
\hline M & 391.6 & 47.5 \\
N & 21.0 & -44.7 \\
O & 9.8 & 30.9 \\
P & -173.8 & -78.5 \\
Q & 6.3 & 17.1 \\
R & 117.0 & -48.0 \\
S & -102.3 & -170.2 \\
T & -53.2 & -27.3 \\
U & -315.2 & 190.9 \\
V & -255.7 & 140.2 \\
W & -19.3 & -34.3
\end{tabular}
(c) The metric multidimensional scaling plot shows the relative positions of the cities.
16.13 (a) The multidimensional scaling plot shows two clusters, one for positive values of the first dimension, and one for negative values. The two clusters can be interpreted as comfort (positive values) and discomfort (negative values). Hence, the axis of the first dimension can be interpreted as the level of comfort.
(b) The dendrogram for Ward's method clearly shows two clusters, the same as in part (a).
16.14 (a) The initial configuration of points will vary. One example is as follows:
\begin{tabular}{rrrrrr}
\multicolumn{1}{c}{\(y_{1}\)} & \multicolumn{1}{c}{\(y_{2}\)} & \multicolumn{1}{c}{\(y_{3}\)} & \multicolumn{1}{c}{\(y_{4}\)} & \multicolumn{1}{c}{\(y_{5}\)} & \multicolumn{1}{c}{\(y_{6}\)} \\
\hline 1.458 & .769 & -1.350 & .456 & -1.610 & 1.827 \\
-.598 & -1.069 & -2.667 & .458 & .416 & 1.094 \\
-1.777 & -.409 & .369 & .655 & -.058 & 1.177 \\
.071 & .361 & 1.157 & -.154 & .343 & -.417 \\
-.060 & 1.361 & .743 & 1.436 & .332 & -.894 \\
-.757 & -.432 & -.545 & .233 & .646 & -.102 \\
-1.971 & -.492 & -.461 & .078 & 1.441 & .039 \\
-1.560 & -.173 & .657 & -.528 & 1.001 & 1.030 \\
-.597 & .814 & -.898 & .283 & -.355 & -1.115 \\
1.449 & -.942 & .867 & -.922 & .833 & 1.196 \\
-1.809 & -.093 & -1.762 & -.533 & -1.136 & -.226 \\
1.067 & .199 & .978 & .884 & -1.060 & -.800 \\
\hline
\end{tabular}
(b) Answers will vary. For the seeds given in part (a), STRESS \(=0.0266\).
(c) Answers will vary. The plot of STRESS versus \(k\) for one solution showed that two dimensions should be retained. The nonmetric MDS plot showed that Franco, Mussolini, and Hitler lie closely together, as well as Churchill and De Gaulle, and Eisenhower and Truman.
(d) Answers will vary. One solution gave results similar to part (c).
(e) Answers will vary. One solution showed three dimensions. A plot of two dimensions showed Mussolini and Franco together in the center with the others forming a circle around them almost equally spaced.
(f) Answers will vary. One solution was similar to that in part (c).
16.15 (a) The correspondence matrix \(\mathbf{P}\) is found by dividing each element of Table 16.16 by \(n=1281\) to obtain the following:
\begin{tabular}{llllllllllllll}
\hline \begin{tabular}{l} 
Death \\
Birth
\end{tabular} & Jan & Feb & Mar & Apr & May & Jun & Jul & Aug & Sep & Oct & Nov & Dec & Total \\

.09 & .08 & .07 & .10 & .06 & .05 & .10 & .09 & .08 & .08 & .06 & .12
\end{array}\right) .
\]
(c) The chi-square statistic is 117.7742 with 121 degrees of freedom, which gives a \(p\)-value of .5660. The two variables appear to be independent.
(d) In the correspondence plot, the following associations are seen:
\{November births, June deaths \}, \{March deaths, April deaths, January births \}, \{September births, February deaths\}, \{August births, April births\}, \{May deaths, September deaths, May births \}.
16.16 (a) The correspondence matrix \(\mathbf{P}\) is found by dividing each element of Table 16.17 by 8193 to obtain the following:
\begin{tabular}{lcccr}
\hline Part of Country & Burglary & Fraud & Vandalism & Total \\
\hline Oslo area & .048 & .300 & .215 & .563 \\
Mid-Norway & .018 & .019 & .112 & .148 \\
North Norway & .085 & .040 & .164 & .289 \\
\hline Total & .151 & .358 & .491 & 1.000 \\
\hline
\end{tabular}
(b) The \(\mathbf{R}\) matrix is given by
\begin{tabular}{lccc}
\hline Part of Country & Burglary & Fraud & Vandalism \\
\hline Oslo area & .086 & .533 & .381 \\
Mid-Norway & .121 & .126 & .753 \\
North Norway & .293 & .138 & .569 \\
\hline
\end{tabular}
and the \(\mathbf{C}\) matrix is given by
\begin{tabular}{lccc}
\hline Part of Country & Burglary & Fraud & Vandalism \\
\hline Oslo area & .320 & .837 & .437 \\
Mid-Norway & .119 & .052 & .228 \\
North Norway & .561 & .111 & .335 \\
\hline
\end{tabular}
(c) The chi-square statistic is 1662.6 with 4 degrees of freedom, which gives a \(p\)-value less than .0001 . The two variables are dependent.
(d) In the correspondence plot, North Norway is associated with burglaries, Oslo is associated with fraud, and mid-Norway is associated with vandalism.
16.17 (a) The Burt matrix is given below.
\begin{tabular}{lrr|rrr|rr|rr|rr|rrr}

\hline
\end{tabular}

Variable Points
\begin{tabular}{lrr}
\hline Name & Coordinate 1 & Coordinate 2 \\
\hline RMEAT & -1.177 & .691 \\
W_MEAT & -1.012 & .226 \\
EGGS & -.526 & .109 \\
MILK & -3.323 & 4.329 \\
FISH & -.992 & -1.523 \\
CEREALS & 6.726 & 2.116 \\
STARCHY & -.522 & -.396 \\
NUTS & .890 & -.365 \\
FRUIT_VEG & .158 & -.882 \\
\hline
\end{tabular}

In the biplot, the variable points and observation points are both well spaced. Finland scored high on the milk variable. Yugoslavia and Bulgaria scored high on the cereal variable. Spain and Portugal scored highest on the fish and frut_veg variables.
(d) The biplot from part (c) seems better because the scales on the variables and points are more evenly matched.
16.19 (a) The two-dimensional coordinates of the observation points and variable points are as follows.
\begin{tabular}{lrr}
\multicolumn{3}{c}{ Observation Points } \\
\hline Name & Coordinate 1 & Coordinate 2 \\
\hline FSM1 & -9.535 & -4.752 \\
Sister & 2.705 & .796 \\
FSM2 & 4.043 & -.584 \\
Father & 4.392 & .614 \\
Teacher & -8.708 & 5.008 \\
MSM & 3.409 & .701 \\
FSM3 & 3.694 & -1.782 \\
\hline
\end{tabular}

Variable Points
\begin{tabular}{lrr}
\hline Name & Coordinate 1 & Coordinate 2 \\
\hline KIND & .610 & -.054 \\
INTEL & .085 & .413 \\
HAPPY & .407 & -.456 \\
LIKE & .621 & -.039 \\
JUST & .264 & .785 \\
\hline
\end{tabular}

In the biplot, the arrows for the variables are too short to pass through the points for observations.
(b) The two-dimensional coordinates of the observation points and variable points are given below.
\begin{tabular}{lrr}
\multicolumn{3}{c}{ Observation Points } \\
\hline Name & Coordinate 1 & Coordinate 2 \\
\hline FSM1 & -.622 & -.655 \\
Sister & .176 & .110 \\
FSM2 & .264 & -.080 \\
Father & .287 & .085 \\
Teacher & -.568 & .690 \\
MSM & .222 & .097 \\
FSM3 & .241 & -.246 \\
\hline
\end{tabular}

Variable Points
\begin{tabular}{lrr}
\hline Name & Coordinate 1 & Coordinate 2 \\
\hline KIND & 9.345 & -.391 \\
INTEL & 1.298 & 2.997 \\
HAPPY & 6.235 & -3.313 \\
LIKE & 9.521 & -.282 \\
JUST & 4.054 & 5.700 \\
\hline
\end{tabular}

In the biplot, the observation points are tightly clustered around the point \((0,0)\) making them difficult to distinguish, whereas variable points are well spaced. Just and intelligent are highly positively correlated, as are kind and likeable.
(c) The two-dimensional coordinates of the observation points and variable points are given below.

Observation Points
\begin{tabular}{lrr}
\hline Name & Coordinate 1 & Coordinate 2 \\
\hline FSM1 & -2.435 & -1.764 \\
Sister & .691 & .295 \\
FSM2 & 1.033 & -.217 \\
Father & 1.122 & .228 \\
Teacher & -2.224 & 1.859 \\
MSM & .871 & .260 \\
FSM3 & .943 & -.662 \\
\hline
\end{tabular}

Variable Points
\begin{tabular}{lrr}
\hline Name & Coordinate 1 & Coordinate 2 \\
\hline KIND & 2.387 & -.145 \\
INTEL & .331 & 1.113 \\
HAPPY & 1.593 & -1.230 \\
LIKE & 2.432 & -.105 \\
JUST & 1.036 & 2.116 \\
\hline
\end{tabular}

In the biplot, the variable points and observation points are both well spaced. Father, sister, FSM2 and FSM3 all scored high on the kind, likeable, and happy variables, whereas teacher and FSM1 scored negatively on those variables.
(d) The biplot from part (c) seems better because the scales on the variables and points are more evenly matched.
16.20 (a) The two-dimensional coordinates of the observation points and variable points are given below.
\begin{tabular}{|c|c|c|}
\hline \multicolumn{3}{|c|}{Observation Points} \\
\hline Name & Coordinate 1 & Coordinate 2 \\
\hline 1 & 49.410 & \(-5.832\) \\
\hline 2 & 25.407 & \(-7.658\) \\
\hline 3 & 21.600 & -2.340 \\
\hline 4 & -23.545 & -6.367 \\
\hline 5 & -28.477 & -4.773 \\
\hline 6 & -33.341 & 2.315 \\
\hline 7 & -28.176 & 7.992 \\
\hline 8 & -25.786 & 12.655 \\
\hline 9 & -29.703 & 9.275 \\
\hline 10 & -33.868 & -3.776 \\
\hline 11 & -33.529 & -1.977 \\
\hline 12 & 28.186 & \(-16.031\) \\
\hline 13 & 10.804 & -6.608 \\
\hline 14 & . 566 & 3.021 \\
\hline 15 & 77.970 & . 109 \\
\hline 16 & 12.859 & 16.294 \\
\hline 17 & 41.960 & 5.103 \\
\hline 18 & 46.930 & 19.064 \\
\hline 19 & 34.958 & \(-1.018\) \\
\hline 20 & -16.477 & 1.148 \\
\hline 21 & -23.634 & \(-1.055\) \\
\hline 22 & -34.036 & -2.424 \\
\hline 23 & 20.632 & \(-5.882\) \\
\hline 24 & -15.873 & \(-6.731\) \\
\hline 25 & -23.023 & . 745 \\
\hline 26 & -15.183 & \(-1.942\) \\
\hline 27 & -11.903 & -6.917 \\
\hline 28 & 5.273 & 3.610 \\
\hline
\end{tabular}

Variable Points
\begin{tabular}{lrr}
\hline Name & Coordinate 1 & Coordinate 2 \\
\hline North & .526 & .225 \\
East & .429 & .752 \\
South & .579 & -.379 \\
West & .452 & -.490 \\
\hline
\end{tabular}

In the biplot, the variable points are tightly grouped and the corresponding arrows do not pass through the points for observations.
(b) The two-dimensional coordinates of the observation points and variable points are given below.
\begin{tabular}{crr}
\multicolumn{3}{c}{ Observation Points } \\
\hline Name & Coordinate 1 & Coordinate 2 \\
\hline 1 & .303 & -.145 \\
2 & .156 & -.191 \\
3 & .132 & -.058 \\
4 & -.144 & -.158 \\
5 & -.175 & -.119 \\
6 & -.205 & .058 \\
7 & -.173 & .199 \\
8 & -.158 & .315 \\
9 & -.182 & .231 \\
10 & -.208 & -.094 \\
11 & -.206 & -.049 \\
12 & .173 & -.399 \\
13 & .066 & -.164 \\
14 & .003 & .075 \\
15 & .478 & .003 \\
16 & .079 & .406 \\
17 & .257 & .127 \\
18 & .288 & .474 \\
19 & .214 & -.025 \\
20 & -.101 & .029 \\
21 & -.145 & -.026 \\
22 & -.209 & -.060 \\
23 & .127 & -.146 \\
24 & -.097 & -.168 \\
25 & -.141 & .019 \\
26 & -.093 & -.048 \\
27 & -.073 & -.172 \\
28 & .032 & .090 \\
\hline
\end{tabular}

Variable Points
\begin{tabular}{lrr}
\hline Name & Coordinate 1 & Coordinate 2 \\
\hline North & 85.779 & 9.026 \\
East & 69.899 & 30.223 \\
South & 94.377 & -15.213 \\
West & 73.682 & -19.694 \\
\hline
\end{tabular}

In the biplot, the observation points are tightly clustered around the point \((0,0)\), making them difficult to distinguish, whereas variable points are well spaced. All the variables are positively correlated, with south and west showing the closest relationship.
(c) The two-dimensional coordinates of the observation points and variable points are given below.

Observation Points
\begin{tabular}{crr}
\multicolumn{3}{c}{ Observation Points } \\
\hline Name & Coordinate 1 & Coordinate 2 \\
\hline 1 & 3.870 & -.920 \\
2 & 1.990 & -1.208 \\
3 & 1.692 & -.369 \\
4 & -1.844 & -1.004 \\
5 & -2.230 & -.753 \\
6 & -2.611 & .365 \\
7 & -2.207 & 1.261 \\
8 & -2.020 & 1.996 \\
9 & -2.326 & 1.463 \\
10 & -2.652 & -.596 \\
11 & -2.626 & -.312 \\
12 & 2.207 & -2.529 \\
13 & .846 & -1.042 \\
14 & .044 & .477 \\
15 & 6.106 & .017 \\
16 & 1.007 & 2.571 \\
17 & 3.286 & .805 \\
18 & 3.675 & 3.008 \\
19 & 2.738 & -.161 \\
20 & -1.290 & .181 \\
21 & -1.851 & -.166 \\
22 & -2.666 & -.382 \\
23 & 1.616 & -.928 \\
24 & -1.243 & -1.062 \\
25 & -1.803 & .118 \\
26 & -1.189 & -.306 \\
27 & -.932 & -1.091 \\
28 & .413 & .569 \\
\hline
\end{tabular}

Variable Points
\begin{tabular}{lrr}
\hline Name & Coordinate 1 & Coordinate 2 \\
\hline North & 6.718 & 1.424 \\
East & 5.474 & 4.768 \\
South & 7.391 & -2.400 \\
West & 5.771 & -3.107 \\
\hline
\end{tabular}

In the biplot, the variable points and observation points are both well spaced. Tree 18 is associated with east, 17 with north, 1 and 3 with south, and 2 and 23 with west.
(d) The biplot from part (c) seems better because the scales on the variables and points are more evenly matched.

\section*{Appendix C}

\section*{Data Sets and SAS Files}

Two sets of files are located on the ftp server of John Wiley \& Sons STM (Scientific, Technical, and Medical) Division.

All data sets in the book
SAS command files for nearly all numerical examples

\section*{DOWNLOADING DATA SET FILES FROM FTP SERVER}

The new FTP site for the third edition can be found at:
\(\mathrm{ftp}: / / \mathrm{ftp}\).wiley.com/public/sci_tech_med/multivariate_analysis_3e
The zipped files at this site can be downloaded and extracted. Additional information about the files can be found in the file named README.TXT.

\section*{INDEX}

Additional information, test for, 149-152, 241243
Air pollution data, 553
Airline distance data, 559
Algebra, matrix, see Matrix, algebra
Analysis of variance, multivariate (MANOVA):
additional information, test for, 241-243
association, measures of, 186-188
assumptions, checking on, 210-211
and canonical correlation, 400-402
contrasts, 192-195
orthogonal, 194
discriminant function, 178, 197-198, 203
growth curves, 232-241, see also Growth curves; Repeated measures designs
H and E matrices, 173-174
higher-order models, 207-208
individual variables, tests on, 177-178, 195-198
discriminant function, 178, 197-198, 203
experimentwise error rate, 195-197
protected tests, 196
Lawley-Hotelling test, 180-181
table of critical values, 627-636
likelihood ratio test, 178
mixed models, 208-210
expected mean squares, 208
multivariate association, measures of, 186-188
one-way, 171-174
contrasts, 192-195
model, 172
unbalanced, 181
Pillai's test, 179
table of critical values, 624-626
profile analysis, 211-213
repeated measures, 215-232, see also Repeated measures designs; Growth curves
Roy's test (union-intersection), 178-179
table of critical values, 621-623
stepwise discriminant analysis, 243-244
stepwise selection of variables, 243-244
test for additional information, 241-243
test statistics, 174-186
comparison of, 182-183, 189-190
and eigenvalues, 182
power of, 189-190
and \(T^{2}, 182\)
tests on a subvector, 241-243
tests on individual variables, see indi-
vidual variables, tests on
two-way, 201-207
contrasts, 202-203
discriminant function, 203
interactions, 201-202
main effects, 201-202
model, 201
test statistics, 202
tests on individual variables, 203
unbalanced one-way, 181
union-intersection test, 178-179
Wilks' \(\Lambda\) (likelihood ratio) test, 174178
\(F\) approximation, 176
chi-square approximation, 177
partial \(\Lambda\) statistic, 242
properties of, 175-178
table of critical values, 613-636
transformation to an exact \(F, 176\)
Analysis of variance, univariate (ANOVA):
one-way, 169-171
contrasts, 191-192
SSH, SSE, \(F\)-statistic, 171
two-way, 198-200
\(F\)-test, 200
contrasts, 200
interactions, 199
main effects, 199-200
model, 198
ANOVA, see Analysis of variance, univariate (ANOVA)
Assocation, measures of, 186-188
Association, measures of, 372-374
Athletic record data, 530

Baker corn field data, 61
Bar steel data, 204
Beetles data, 162
Bilinear form, 21
Biplots, 580-588
coordinates of points, 583-585
correlation, 584
cosine, 584, 587
points for observations, 580-585
points for variables, 580-585
principal component approach, 581-582, 585
singular value decomposition, 583, 585
Birth and death data, 593
Bivariate normal distribution, 51, 93, 98-99, 146
Blood data, 248

Blood pressure data, 255
Bonferroni critical values, 140 table, 611
Box's M-test, 267-269
table of exact critical values, 633-636
Box-Cox transformations, 109-111
Bronchus data, 167
Burt matrix, 577-579
Byssinosis data, 594, 595

Calcium data, 66
Calculator speed data, 222
Canonical correlation(s), 187, 271, 385-402
canonical variates, see Canonical variates
definition of, 387
and discriminant analysis, 400-402
and eigenvalues, 387, 400-402
and MANOVA, 400-402
dummy variables, 400
and measures of association, 386, 398
and multiple correlation, 386, 390, 400
properties of, 390-391
redundancy analysis, 398
and regression, 393, 398-400
subset selection, 400
tests of significance, 391-395
subset of canonical correlations, 393395
subset selection, 400
test of a subset in regression, 399400
and test of independence, 391-392
and test of overall regression, 391392
with all canonical correlations, 391393
with grouping variables, 187
with test for independence of two subvectors, 271, 391-392
Canonical variates:
correlations among, 388
definition of, 387
interpretation, 395-398
by correlations (structure coefficients), 397
by rotation, 397
by standardized coefficients, 396-397
redundancy analysis, 398
and regression, 398-400
standardized coefficients, 389, 396-397
Categorical variables, see Dummy variables
Central limit theorem (multivariate), 100, 109
CFA, see Confirmatory factor analysis

Characteristic form:
of \(T^{2}\)-statistic, 131,136
of \(t\)-statistic, 131, 135
Characteristic roots, see Eigenvalues
Chemical data, 358
Chi-square distribution, 96, 101, 127
Cholesky decomposition, 27
City crime data, 507
Classification analysis, 309-337
assigning a sampling unit to a group, 309
asymptotic optimality, 313
classification trees, 331-335
impurity, 332
prior probabilities, 333
correct classification rates, 318-320
error rates, 318-326, see also Error rate(s)
as a stopping rule, 323-326
\(k\)-nearest neighbor rule, 330-331
nonparametric classification procedures, 312, 326-335
classification trees, 331-335
density estimators (kernel), 327-330
multinomial data (categorical variables), 326
nearest neighbor rule, 330-331
several groups, 314-318
linear classification functions, 315
optimal classification rule (Welch), 315
quadratic classification functions, 317

Numerical taxonomy, see Cluster analysis
Objectives of this book, 3
Observations, 1
One-sample test for a mean vector, 130-134
Orthogonal matrix, 31
Orthogonal polynomials, 232-236
table of, 632
Orthogonal vectors, 54
Outliers, multivariate
kurtosis, 115-116
elliptically symmetric distributions, 115
and principal components, 415
slippage in mean, variance, and correlation, 113
Wilks' statistic, 114-115
Outliers, univariate
accomodation, 112
block test, 113
identification, 112
masking, 113
maximum studentized residual, 112
skewness and kurtosis, 113
slippage in mean and variance, 112
swamping, 113
Overall probability, 81-82
Paired observation test, 145-149
Parallel coordinates plot, 59
Partial \(F\)-tests, 140, 151, 242, 303-306
Partitioned matrices, see Matrix (matrices), partitioned matrices
Partitioning, see Cluster analysis, partitioning

Pattern recognition, see Cluster analysis
People data, 576
Perception data, 446
Perron-Frobenius theorem, 35, 428
Pillai's test statistic:
definition of, 179
table of critical values, 624-626
Piston ring data, 569
Plasma data, 256
Plotting multivariate data, 56-58
Politics data, 592
Positive definite matrix, 26
positive definite sample covariance matrix, 76
Prerequisites for this book, 3
Principal components, 405-433
algebra of, 410-412
and biplots, 581-582
and cluster analysis, 415, 417-419, 421, 533, 534
component scores, 411
definition of, 405, 407
dimension reduction, 406-412, 414
eigenvalues and eigenvectors, 407-409, 423
major axis, 409, 414
and factor analysis, 429, 436, 475-476
geometry of, 406-409
interpretation of, 427-430
correlations, 429-430
rotation, 429
special patterns in \(\mathbf{S}\) or \(\mathbf{R}, 427-429\)
large variance of a variable, effect of, 409, 428
last few principal components, 408,415 , 427
maximum variance, 405,410
minimum perpendicular distances to line, 412-414
number of components to retain, 423426
orthogonality of, 406, 408
percent of variance, 408,423
and perpendicular regression, 409, 412414
plotting of, 414-419
assessing normality, 414
detection of outliers, 415
properties of, 406-411
proportion of variance, 408
robust, 415
as rotation of axes, 406-409
from \(\mathbf{S}\) or \(\mathbf{R}, 408-409,419-423\)
nonuniqueness of components from R, 422
sample specific components, 423
scale invariance, lack of, 408
scree graph, 423-424
selection of variables, 430-432
singular matrix and, 410-411
size and shape, 428
smaller principal components, 408,415 , 427
tests of significance for, 423-426
variable specific components, 423
variances of, 408
Probe word data, 79
Product notation (П), 12
Profile, 152
profile of observation vector, 504
Profile analysis, 152-160, 211-215
and contrasts, 155
one-sample, 152-154
and one-way ANOVA, 152
profile, definition of, 152
and repeated measures, 152
several-sample, 211-215
two-sample, 154-160
and two-way ANOVA, 156
Projection pursuit, 502
Protein data, 533
Psychological data, 138
\(Q-Q\) plot, 101-103
Quadratic classification functions, 317-318
Quadratic form, 21
Quantiles, 101-103, 107
\(R^{2}\) (squared multiple correlation), 349-350, 353, 372, 378, 386, 389, 399, 400, 449
Ramus bone data, 87
Random variable(s):

partial \(F\)-tests, 140, 242
protected tests, 141
likelihood ratio test, 139, see also Likelihood ratio tests
for linear combinations:
one sample ( \(H_{0}: \mathbf{C} \boldsymbol{\mu}=\mathbf{0}\) ), 130, 153, 219-222
two samples ( \(H_{0}: \mathbf{C} \mu_{1}=\mathbf{C} \mu_{2}\) ), 155
mean vectors:
likelihood ratio tests, 139
one sample, \(\boldsymbol{\Sigma}\) known, 127-130
one sample, \(\boldsymbol{\Sigma}\) unknown, 131-134
several samples, 171-186
two-sample \(T^{2}\)-test, 135-139
multivariate vs. univariate testing, \(2-3\), 125-130, 140-143
paired observations (matched pairs), 145149
multivariate, 147-149
univariate, 145-146
partial \(F\)-tests, 140, 150, 242
power of a test, 126
protected tests, 141
on regression coefficients, 346-349, 364 370
on a subvector, 149-152, 241-243, 367370, 376-381
univariate tests:
ANOVA \(F\)-test, 169-171, 198-200
one-sample test on a mean, \(\sigma\) known, 126
one-sample test on a mean, \(\sigma\) unknown, 130
paired observation test, 145-146
tests on variance, 265-266
two-sample \(t\)-test, 134-135, 140
variances, equality of, 265-266
Total sample variance, 82, 408, 436, 445, 453
Trace of a matrix, 31, 34, 78
Trout data, 252
Two-sample test for equal mean vectors, 135139

Union-intersection test, 178-179
Unit:
experimental, 1
research, 1
sampling, 1
Univariate normal distribution, 92, 95
Univariate normality, tests for, 101-106
D'Agostino's \(D\)-statistic, 105
table of critical values, 601
goodness-of-fit test, 106
normal probability paper, 103
Q-Q plot, 101-103
quantiles, 101-103
skewness and kurtosis, 103-104
tables of critical values, 598-636
transformation of correlation, 105
Univariate normality, transformations to, 109110

Variables, 1, see also Random variable(s)
commensurate, 2
dummy variables, \(186,292,327,400\)
linear combinations of, 75-81
Variance matrix, see Covariance matrix
Variance-covariance matrix, see Covariance matrix
Variance:
generalized sample variance, 81
pooled variance, 134
population variance ( \(\sigma^{2}\) ), 48
sample variance \(\left(s^{2}\right), 48\)
total sample variance, 82
Varimax rotation, \(460-462\)
Vector(s):
0 vector, 11
definition of, 8
distance:
Mahalanobis, 85
from origin to a point, 16
between two vectors, 85
geometry of, 9
j vector, 11
length of, 16
linear combinations of, 21
linear independence and dependence of, 23
normalized, 32
notation for vector, 8
observation vector, 64
orthogonal, 31, 54
perpendicular, 54
product of, 16
rows and columns of a matrix, 17
standardized, 95
subvectors, 71-75
sum of products, 16
sum of squares, 16
transpose of, 8
zero vector, 11
Voting data, 563
Weight gain data, 253
Wheat data, 554
Wilks' \(\Lambda\) test statistic:
definition of, 174-178
partial \(\Lambda\) statistic, 242
table of critical values, 613-636
Wishart distribution, 100-101
Words data, 167

\title{
WILEY SERIES IN PROBABILITY AND STATISTICS
}

\section*{established by Walter A. Shewhart and Samuel S. Wilks}

Editors: David J. Balding, Noel A. C. Cressie, Garrett M. Fitzmaurice, Harvey Goldstein, Iain M. Johnstone, Geert Molenberghs, David W. Scott, Adrian F. M. Smith, Ruey S. Tsay, Sanford Weisberg Editors Emeriti: Vic Barnett, J. Stuart Hunter, Joseph B. Kadane, Jozef L. Teugels

The Wiley Series in Probability and Statistics is well established and authoritative. It covers many topics of current research interest in both pure and applied statistics and probability theory. Written by leading statisticians and institutions, the titles span both state-of-the-art developments in the field and classical methods.

Reflecting the wide range of current research in statistics, the series encompasses applied, methodological and theoretical statistics, ranging from applications and new techniques made possible by advances in computerized practice to rigorous treatment of theoretical approaches.

This series provides essential and invaluable reading for all statisticians, whether in academia, industry, government, or research.
