**Ultrasonic Fluxless Soldering.**—This more recently introduced method of soldering makes use of ultrasonic vibrations which facilitates the penetration of surface films by the molten solder thus eliminating the need for flux. The equipment offered by one manufacturer consists of an ultrasonic generator, ultrasonic soldering head which includes a transducer coupling, soldering tip, tip heater, and heating platen. Metals that can be soldered by this method include aluminum, copper, brass, silver, magnesium, germanium, and silicon.

### Brazing

Brazing is a metal joining process which uses a non-ferrous filler metal with a melting point below that of the base metals but above 800 degrees F. The filler metal wets the base metal when molten in a manner similar to that of a solder and its base metal. There is a slight diffusion of the filler metal into the hot, solid base metal or a surface alloying of the base and filler metal. The molten metal flows between the close-fitting metals because of capillary forces.

**Filler Metals for Brazing Applications.**—Brazing filler metals have melting points that are lower than those of the base metals being joined and have the ability when molten to flow readily into closely fitted surfaces by capillary action. The commonly used brazing metals may be considered as grouped into the seven standard classifications shown in [Tables 1a](#) and [1b](#). These are aluminum-silicon; copper-phosphorus; silver; nickel; copper and copper-zinc; magnesium; and precious metals.

The solidus and liquidus are given in [Tables 1a](#) and [1b](#) instead of the melting and flow points in order to avoid confusion. The solidus is the highest temperature at which the metal is completely solid or, in other words, the temperature above which the melting starts. The liquidus is the lowest temperature at which the metal is completely liquid, that is, the temperature below which the solidification starts.

**Table 1a. Brazing Filler Metals [ Based on Specification and Appendix of American Welding Society AWS A5.8-81 ]**

| AWS Classification <sup>a</sup> | Nominal Composition, <sup>b</sup> Per Cent |      |      |      |     |                         | Temperature, Degrees F |          |               | Standard Form <sup>c</sup> | Uses  |
|---------------------------------|--|------|------|------|-----|-------------------------|------------------------|----------|---------------|----------------------------|---|
|                                 | Ag   | Cu   | Zn   | Al   | Ni  | Other                   | Solidus                | Liquidus | Brazing Range |                            |   |
| BAISi-2                         | ...  | ...  | ...  | 92.5 | ... | Si, 7.5                 | 1070                   | 1135     | 1110-1150     | 7                          | For joining the following aluminum alloys: 1060, EC, 1100, 3003, 3004, 5005, 5050, 6053, 6061, 6062, 6063, 6951 and cast alloys A612 and C612. All of these filler metals are suitable for furnace and dip brazing. BAISi-3, -4 and -5 are suitable for torch brazing. Used with lap and tee joints rather than butt joints. Joint clearances run from .006 to .025 inch.                                   |
| BAISi-3                         | ...  | 4    | ...  | 86   | ... | Si, 10                  | 970                    | 1085     | 1160-1120     | 2, 3, 5                    |   |
| BAISi-4                         | ...  | ...  | ...  | 88   | ... | Si, 12                  | 1070                   | 1080     | 1080-1120     | 2, 3, 4, 5                 |   |
| BAISi-5                         | ...  | ...  | ...  | 90   | ... | Si, 10                  | 1070                   | 1095     | 1090-1120     | 7                          |   |
| BAISi-6                         | ...  | ...  | ...  | 90   | ... | Si, 7.5; Mg, 2.5        | 1038                   | 1125     | 1110-1150     | 7                          |   |
| BAISi-7                         | ...  | ...  | ...  | 88.5 | ... | Si, 10; Mg, 1.5         | 1038                   | 1105     | 1090-1120     | 7                          | BAISi-6 through -11 are vacuum brazing filler metals. Magnesium is present as an O <sub>2</sub> getter. When used in vacuum, solidus & liquidus temperatures are different from those shown.  |
| BAISi-8                         | ...  | ...  | ...  | 86.5 | ... | Si, 12; Mg, 1.5         | 1038                   | 1075     | 1080-1120     | 2, 7                       |   |

<sup>a</sup>These classifications contain chemical symbols preceded by "B" which stands for brazing filler metal.

<sup>b</sup>These are nominal compositions. Trace elements may be present in small amounts and are not shown. Abbreviations used are: Ag, silver; Cu, copper; Zn, zinc; Al, aluminum; Ni, nickel; Ot, other; Si, silicon; P, phosphorus; Cd, cadmium; Sn, tin; Li, lithium; Cr, chromium; B, boron; Fe, iron; O, oxygen; Mg, magnesium; W, tungsten; Pd, palladium; and Au, gold.

<sup>c</sup>Numbers specify standard forms as follows: 1, strip; 2, wire; 3, rod; 4, powder; 5, sheet; 6, paste; 7, clad sheet or strip; and 8, transfer tape.

**Table 2. Guide to Selection of Brazing Filler Metals and Fluxes**

| Base Metals Being Brazed  | Filler Metals Recommended <sup>a</sup>                               | AWS Brazing Flux Type No. | Effective Temperature Range, Degrees F | Flux Ingredients   | Flux Supplied As         | Flux Method of Use <sup>b</sup> |
|---|--|---------------------------|--|--|--------------------------|---------------------------------|
| All brazeable aluminum alloys   | BA1Si  | 1                         | 700 to 1190                            | Chlorides, Fluorides   | Powder                   | 1, 2, 3, 4                      |
| All brazeable magnesium alloys  | BMg  | 2                         | 900 to 1200                            | Chlorides, Fluorides   | Powder                   | 3, 4                            |
| Alloys such as aluminum-bronze; aluminum-brass containing additions of aluminum of 0.5 per cent or more | BCuZn, BCuP  | 4 <sup>c</sup>            | 1050 to 1800                           | Chlorides, Fluorides, Borates, Wetting agent   | Paste or Powder          | 1, 2, 3                         |
| Titanium and zirconium in base alloys   | BAG  | 6                         | 700 to 1600                            | Chlorides, Fluorides, Wetting agent  | Paste or Powder          | 1, 2, 3                         |
| Any other brazeable alloys not listed above   | All brazing filler metals except BA1Si and BMg                       | 3                         | 700 to 2000                            | Boric acid, Borates, Fluorides, Fluoroates, Wetting agent<br><i>Must contain fluorine compound</i> | Paste, Powder, or Liquid | 1, 2, 3                         |
|   | All brazing filler metals except BA1Si, BMg, and BAG 1 through BAG 7 | 5                         | 1000 to 2200                           | Borax, Boric acid<br>Borates, Wetting agent<br><i>No fluorine in any form</i>                      | Paste, Powder, or Liquid | 1, 2, 3                         |

<sup>a</sup> Abbreviations used in this column are as follows: B, brazing filler metal; Al, aluminum; Si, silicon; Mg, magnesium; Cu, copper; Zn, zinc; P, phosphorus; and Ag, silver.

<sup>b</sup> Explanation of numbering system used is as follows: 1—dry powder is sprinkled in joint region; 2—heated metal filler rod is dipped into powder or paste; 3—flux is mixed with alcohol, water, monochlorobenzene, etc., to form a paste or slurry; 4—flux is used molten in a bath.

<sup>c</sup> Types 1 and 3 fluxes, alone or in combination, may be used with some of these base metals also.

**Fluxes for Brazing.**—In order to obtain a sound joint the surfaces in and adjacent to the joint must be free from dirt, oil, and oxides or other foreign matter at the time of brazing. Cleaning may be achieved by chemical or mechanical means. Some of the mechanical means employed are filing, grinding, scratch brushing and machining. The chemical means include the use of trisodium phosphate, carbon tetrachloride, and trichloroethylene for removing oils and greases.

Fluxes are used mainly to prevent the formation of oxides and to remove any oxides on the base and filler metals. They also promote free flow of the filler metal during the course of the brazing operation.

They are made available in the following forms: powders; pastes or solutions; gases or vapors; and as coatings on the brazing rods.

In the powder form a flux can be sprinkled along the joint, provided that the joint has been preheated sufficiently to permit the sprinkled flux to adhere and not be blown away by the torch flame during brazing. A thin paste or solution is easily applied and when spread on evenly, with no bare spots, gives a very satisfactory flux coating. Gases or vapors are used in controlled atmosphere furnace brazing where large amounts of assemblies are mass-brazed. Coatings on the brazing rods protect the filler metal from becoming oxidized and eliminate the need for dipping rods into the flux, but it is recommended that flux be applied to the base metal since it may become oxidized in the heating operation. No matter which flux is used, it performs its task only if it is chemically active at the brazing temperature.

Chemical compounds incorporated into brazing fluxes include borates (sodium, potassium, lithium, etc.), fused borax, fluoborates (potassium, sodium, etc.), fluorides (sodium,

potassium, lithium, etc.), chlorides (sodium, potassium, lithium), acids (boric, calcined boric acid), alkalis (potassium hydroxide, sodium hydroxide), wetting agents, and water (either as water of crystallization or as an addition for paste fluxes). [Table 2](#) provides a guide which will aid in the selection of brazing fluxes that are available commercially.

**Methods of Steadying Work for Brazing.**—Pieces to be joined by brazing after being properly jointed may be held in a stable position by means of clamping devices, spot welds, or mechanical means such as crimping, staking, or spinning. When using clamping devices care must be taken to avoid the use of devices containing springs for applying pressure because springs tend to lose their properties under the influence of heat. Care must also be taken to be sure that the clamping devices are no larger than is necessary for strength considerations, because a large metal mass in contact with the base metal near the brazing area would tend to conduct heat away from the area too quickly and result in an inefficient braze. Thin sections that are to be brazed are frequently held together by spot welds. It must be remembered that these spot welds may interfere with the flow of the molten brazing alloy and appropriate steps must be taken to be sure that the alloy is placed where it can flow into all portions of the joint.

**Methods of Supplying Heat for Brazing.**—The methods of supplying heat for brazing form the basis of the classification of the different brazing methods and are as follows.

*Torch or Blowpipe Brazing:* Air-gas, oxy-acetylene, air-acetylene, and oxy-other fuel gas blowpipes are used to bring the areas of the joint and the filler material to the proper heat for brazing. The flames should generally be neutral or slightly reducing but in some instances some types of bronze welding require a slightly oxidizing flame.

*Dip Brazing:* Baths of molten alloy, covered with flux, or baths of molten salts are used for dip brazing. The parts to be brazed are first assembled, usually with the aid of jigs, and are dipped into the molten metal, then raised and allowed to drain. The molten alloy enters the joint by capillary action. When the salt bath is used, the filler metal is first inserted between the parts being joined, or, in the form of wire, is wrapped around the area of the joint. The brazing metal melts and flows into the joint, again by capillary action.

*Furnace Brazing:* Furnaces that are heated electrically or by gas or oil with auxiliary equipment that maintains a reducing or protective atmosphere and controlled temperatures therein are used for brazing large numbers of units, usually without flux.

*Resistance Brazing:* Heat is supplied by means of hot or incandescent electrodes. The heat is produced by the resistance of the electrodes to the flow of electricity and the filler metal is frequently used as an insert between the parts being joined.

*Induction Brazing:* Parts to be joined are heated by being placed near a coil carrying an electric current. Eddy current losses of the induced electric current are dissipated in the form of heat raising the temperature of the work to a point higher than the melting point of the brazing alloy. This method is both quick and clean.

*Vacuum Furnace Brazing:* Cold-wall vacuum furnaces, with electrical-resistance radiant heaters, and pumping systems capable of evacuating a conditioned chamber to moderate vacuum (about 0.01 micron) in 5 minutes are recommended for vacuum brazing. Metals commonly brazed in vacuum are the stainless steels, heat-resistant alloys, titanium, refractory metals, and aluminum. Fluxes and filler metals containing alloying elements with low boiling points or high vapor pressure are not used.

**Brazing Symbol Application.**—ANSI/AWS A2.4-79 symbols for brazing are also used for welding with the exception of the symbol for a scarf joint (see the diagram at the top of page [1388](#), and the symbol for a scarf joint in the table *Basic Weld Symbols* on page [1433](#), for applications of brazing symbols). The second, third and fourth figures from the top of the next page show how joint clearances are indicated. If no special joint preparation is required, only the arrow is used with the brazing process indicated in the tail.

BRAZING

Typical Applications of Standard Brazing Symbols

## WELDING

Welding of metals requires that they be heated to a molten state so that they fuse together. A filler wire or rod is held in the heated zone to add material that will replace metal consumed by the process and to produce a slightly raised area that can be dressed down to make a level surface if needed. Most welding operations today use an electric arc, though the autogenous method using a torch that burns a mixture of (usually) acetylene and oxygen gases to heat the components is still used for certain work. Lasers are also used as the heating medium for some welding operations. In arc welding, a low-voltage, high-current arc is struck between the end of an electrode in a holder and the work, generating intense heat that immediately melts the surface.

### Welding Electrodes, Fluxes, and Processes

Electrodes for welding may be made of a tungsten or other alloy that does not melt at welding temperatures (nonconsumable) or of an alloy similar to that of the work so that it melts and acts as the filler wire (consumable). In welding with a nonconsumable electrode, filler metal is added to the pool as welding proceeds. Filler metals that will produce welds having strength properties similar to those of the work are used where high-strength welds are specified.

Briefly, the effects of the main alloying elements in welding filler wires and electrodes are: carbon adds strength but may cause brittle weld metal if cooling is rapid, so low-carbon wire is preferred; silicon adds strength and reduces oxidation, changes fluidity, and gives a flatter weld bead; manganese strengthens and assists deoxidation, plus it reduces effects of sulfur, lowering the risk of hot cracking; sulfur may help form iron sulfide, which increases the risk of hot cracking; and phosphorus, may contribute to hot cracking.

*Fluxes* in (usually) granular form are added to the weld zone, as coatings on the filler wire or as a core in the tube that forms the (consumable) electrode. The flux melts and flows in the weld zone, shielding the arc from the oxygen in the atmosphere, and often contains materials that clean impurities from the molten metal and prevent grain growth during recrystallization.

**Processes.**—There are approximately 100 welding and allied welding processes but the four manual arc welding processes: gas metal arc welding (GMAW) (which is also commonly known as MIG for metal inert gas), flux-cored arc (FCAW), shielded metal arc (SMAW), gas tungsten arc welding (GTAW), account for over 90 per cent of the arc welding used in production, fabrication, structural, and repair applications. FCAW and SMAW use fluxes to shield the arc and FCAW uses fluxes and gases to protect the weld from oxygen and nitrogen. GMAW and GTAW use mixtures of gases to protect the weld.

There are two groups of weld types, groove and fillet, which are self-explanatory. Each type of weld may be made with the work at any angle from horizontal (flat) to inverted (overhead). In a vertical orientation, the electrode tip may move down the groove or fillet (vertical down), or up (vertical up). In any weld other than flat, skill is needed to prevent the molten metal falling from the weld area.

Because of the many variables, such as material to be welded and its thickness, equipment, fluxes, gases, electrodes, degree of skill, and strength requirements for the finished welds, it is not practicable to set up a complete list of welding recommendations that would have general validity. Instead, examples embracing a wide range of typical applications, and assuming common practices, are presented here for the most-used welding processes. The recommendations given are intended as a guide to finding the best approach to any welding job, and are to be varied by the user to fit the conditions encountered in the specific welding situation.

**Gas Metal Arc Welding (GMAW)**

The two most cost-effective manual arc welding processes are GMAW and FCAW. These two welding processes are used with more than 50 per cent of the arc welding consumable electrodes purchased. Gas metal arc welding modes extend from short-circuit welding, where the consumable electrode wire is melted into the molten pool in a rapid succession of short circuits during which the arc is extinguished, to pulsed and regular spray transfer, where a stream of fine drops and vaporized weld metal is propelled across the continuous arc gap by electromagnetic forces in the arc.

GMAW is the most-used welding process and the two most common GMAW low-carbon steel electrodes used for production welding in North America are the E70S-3 and E70S-6 from the ANSI/AWS Standard A5 series of specifications for arc welding. The E70S-3 contains manganese and silicon as deoxidants and is mainly used for welding low-carbon steels, using argon mixtures as shielding gases. The wire used in the E70S-6 electrodes has more silicon than wire used for the E70S-3 electrodes, and is preferred where straight CO<sub>2</sub> or argon mixes are used as the shielding gas or if the metal to be welded is contaminated. The deoxidizing properties of the E70S-6 electrode also may be beneficial for high-current, deep-penetration welds, and welds in which higher than normal impact-strength properties are required.

E80S-D2 wire contains more manganese and silicon, plus 0.5 per cent molybdenum for welding such steels as AISI 4130, and steels for high-temperature service. The argon + CO<sub>2</sub> mixture is preferred to exert the influence of argon's inertness over the oxidizing action of CO<sub>2</sub>. E70S-2 electrodes contain aluminum, titanium, and zirconium to provide greater deoxidation action and are valuable for welding contaminated steel plate.

When the GMAW welding process is used for galvanized steels, minute welding cracks may be caused by the reaction of the zinc coating on the work with silicon in the electrode. Galvanized steel should be welded with an electrode having the lowest possible silicon content such as the E70S-3. For welding low-carbon and low-alloy steels with conventional argon mixture shielding gases, there is little difference between the E70S-3 and E70S-6.

**Electrode Diameters.**—One of the most important welding decisions is selecting the optimum GMAW electrode diameter. Selection of electrode diameters should be based on the material thickness, as shown for carbon and stainless steels in Table 1, the compatibility of the electrode current requirements with the material thickness, the mode of weld metal transfer, and the deposition rate potential shown in Table 2. The two most popular GMAW electrode sizes are 0.035 in. (1.0 mm) and 0.045 in. (1.2 mm). Diameters of electrodes used for GMAW exert a strong influence on cost of welding. Table 2 also shows how the weld deposition rate varies in short-circuit and spray transfer modes in welding carbon and stainless steels.

**Table 1. GMAW Electrode Sizes for Welding Carbon and Stainless Steels**

| Material Thickness                   | Electrode Diameter    |                       |                       |                       |
|--------------------------------------|-----------------------|-----------------------|-----------------------|-----------------------|
|                                      | 0.030 in.<br>(0.8 mm) | 0.035 in.<br>(1.0 mm) | 0.045 in.<br>(1.2 mm) | 0.062 in.<br>(1.6 mm) |
| 25 to 21 gage (0.020 to 0.032 in.)   | yes                   | ...                   | ...                   | ...                   |
| 20 gage to ¼ in. (0.036 to 0.25 in.) | ...                   | yes                   | ...                   | ...                   |
| ⅜ to ⅞ in. flat and horizontal       | ...                   | ...                   | yes                   | ...                   |
| ½ in. and up                         | ...                   | ...                   | ...                   | yes                   |

The table is based on suitability of the electrode size to mode of weld transfer, material thickness, and cost effectiveness. If a smaller electrode size is selected, the lower deposition rates could increase welding costs by 20 to 60 per cent.

**Table 2. Typical Maximum GMAW Deposition Rates for Carbon and Stainless Steels. Constant-Voltage 450-amp Power Source and Standard Wire Feeder**

| Weld transfer mode | Electrode Diameter    |                       |                       |                       |
|--------------------|-----------------------|-----------------------|-----------------------|-----------------------|
|                    | 0.030 in.<br>(0.8 mm) | 0.035 in.<br>(1.0 mm) | 0.045 in.<br>(1.2 mm) | 0.062 in.<br>(1.6 mm) |
| Short circuit      | 5 lb/h<br>(2.3 kg/h)  | 7 lb/h<br>(3.2 kg/h)  | 9 lb/h<br>(4 kg/h)    | ...                   |
| Spray transfer     | 9 lb/h<br>(4 kg/h)    | 11 lb/h<br>(5 kg/h)   | 19 lb/h<br>(8.6 kg/h) | 21 lb/h<br>(9.5 kg/h) |

For the lowest-cost welds with GMAW electrodes larger than 0.030 in. in diameter, the power source should provide a minimum of 350 amps. The compatibility of the optimum current range of the 0.035-in. (1.0-mm) electrode and its deposition potential make it the first choice for welding of 20 gage to  $\frac{1}{4}$  in. (0.88 to 6.4 mm) thicknesses. For welding thinner sheet metals of 25 to 21 gage, the optimum electrode diameter is 0.030 in. (0.8 mm). The 0.045-in. (1.2-mm) electrode is the most practical choice for spray transfer applications on materials over  $\frac{1}{4}$  in. (6.4 mm) thick and thicker.

As an example, when welding  $\frac{1}{4}$ -in. (6.4-mm) thick steel, with 100 per cent arc-on time and a labor cost of \$15/h, the deposition rate with a 0.035-in. (0.9-mm) electrode is approximately 11 lb/h (5 kg/h). The labor cost per lb at \$15/h  $\div$  11 lb/h = \$1.36/lb (\$3.00/kg). If an electrode of 0.045-in. (1.2-mm) diameter is used for the same application, the deposition rate is 16 lb/h (7.2 kg/h) and at a \$15/h labor rate, the cost of weld metal deposited = \$15/h  $\div$  16 lb/h = \$0.93/lb (\$2.00/kg). The 0.045-in. diameter electrode would also cost less per pound than a smaller wire, and the weld time with the 0.045-in. electrode would be reduced, so less shielding gas also would be consumed.

**GMAW Welding of Sheet Steel.**—In GMAW, the short-circuit transfer mode is used to weld carbon steel, low-alloy steel, and stainless steel sheet of 24 gage (0.023 in., or 0.6 mm) to 11 gage (0.12 in., or 3 mm). The most common gage sizes welded with short-circuit transfer are 20 gage to 11 gage (0.88 to 3 mm) and the best GMAW electrode for these thin, sheet metal gages is the 0.035-in. (1-mm) diameter electrode. The short-circuit current requirements for these operations are typically 50 to 200 amps with voltages in the range of 14 to 22 volts. The optimum short-circuit voltage for the majority of applications is 16 to 18 volts.

**Shielding Gases for Welding Carbon and Low-Alloy Steels.**—With more than 40 GMAW gas mixtures available for welding carbon steels, low-alloy steels, and stainless steels, selection is often confusing. Reactive oxygen and carbon dioxide (CO<sub>2</sub>) are added to argon to stabilize the arc and add energy to the weld. CO<sub>2</sub> can provide more energy to the weld than oxygen. As the CO<sub>2</sub> content in a shielding gas mixture is increased to certain levels, the voltage requirements are increased. Argon + oxygen mixtures will require lower voltages than mixtures containing argon with 10 to 25 per cent CO<sub>2</sub>. Helium may also be added to argon if increased weld energy is required.

**Shielding Gases for Short-Circuit Welding of Carbon Steels.**—GMAW short-circuit transfer (SCT) is used mainly for welding thin metals of less than 10 gage, and gaps. With the SCT mode of weld metal transfer, the arc short circuits many times each second. The numerous short circuits switch the arc energy on and off. The short circuits and low current cause the transferred weld to freeze rapidly. Short-circuit transfer on carbon steel gage metals thicker than  $\frac{1}{16}$  in. (1.6 mm) requires a shielding gas that will provide substantial weld energy. For these applications, argon with 15–25 per cent CO<sub>2</sub> is recommended.

If short-circuit transfer is used on metals thinner than 18 gage (0.047 in., 1.2 mm), melt-through and distortion often occur. Melt-through and distortion can be reduced on very thin-gage carbon and low-alloy steels by using a shielding gas that provides less weld energy than argon + 15 to 25 per cent CO<sub>2</sub> mixes. Argon + oxygen mixtures can utilize

lower voltages to sustain the arc. Argon mixed with 2 to 5 per cent oxygen is a practical mixture for thin carbon steel of less than 16 gage, where there is sensitivity to heat.

**Shielding Gases for Spray Transfer Welding of Carbon Steels.**—With GMAW spray transfer, all traditional argon gas mixtures will provide spatter-free spray weld transfer, depending on the electrode diameter and welding parameters used. The electrode diameter and the electrode current density influence the formation of the weld metal to be transferred. For example, with a 0.035-in. diameter electrode using a mixture containing argon 75 + CO<sub>2</sub> 25 per cent, a small globular weld droplet is formed on the end of the electrode tip in the conventional spray transfer parameter range. With the same gas mixture, a 0.045-in. (1.2-mm) diameter electrode, and current above 330 amps, the globular formation disappears and the metal transfers in the spray mode.

Spatter potential stemming from shielding gas, with 0.035-in. (1.0-mm) and smaller diameter electrodes can be controlled by reducing the CO<sub>2</sub> content in the argon mixture to less than 21 per cent. Each different shielding gas will primarily influence the open arc spray transfer mode by variations in the weld energy provided through the welding voltage requirements.

Gas selection in spray transfer must be given careful consideration. In welding of clean cold-rolled carbon steel or low-alloy steel less than  $\frac{3}{8}$  in. (9.5 mm) thick, the energy potential of the arc is less important than it is for welding of steels thicker than  $\frac{1}{4}$  in. (13 mm) or steels with mill scale. The energy level of the arc is also a key factor in welding steels for which higher than normal impact properties are specified.

A simple, practical multipurpose gas mixture for carbon and low-alloy steels is argon + 15 to 20 per cent CO<sub>2</sub>, and a mixture of argon + 17 per cent CO<sub>2</sub> would be ideal. This two-part argon/CO<sub>2</sub> mixture provides higher weld energy than two-component argon + CO<sub>2</sub> mixtures having less than 10 per cent CO<sub>2</sub>, argon + oxygen mixtures, or argon + CO<sub>2</sub> + oxygen tri-component mixtures. The argon + 17 per cent CO<sub>2</sub> mixture will provide an arc slightly less sensitive to mill scale than the other mixtures mentioned.

The argon + 17 per cent CO<sub>2</sub> mixture also has practical benefits in that it provides sufficient weld energy for all GMAW short-circuit and spray transfer applications with cylinder or bulk gases. The argon + 17 per cent CO<sub>2</sub> mixture may also be used for all-position FCAW electrodes in welding carbon steels, low-alloy steels, and stainless steels.

**Shielding Gases for GMAW Welding of Stainless Steels.**—The major problems encountered when using GMAW on stainless steels of thinner than 14 gage include controlling potential melt-through, controlling distortion, and black oxidation on the weld surface. These three welding problems have a common denominator, which is heat. The key to welding thin stainless steel is to minimize the potential heat when welding, by appropriate choice of gas mixture.

A popular gas mixture that is often recommended for GMAW welding of thin-gage stainless steel is the three-part helium gas mixture containing helium 90 + argon 7.5 + CO<sub>2</sub> 2.5 per cent. In contrast to gas mixtures without helium, the helium tri-mixture requires the use of higher voltages to sustain the arc, which adds unnecessary heat to the heat-sensitive thin-gage welds.

A practical and lower-cost alternative for GMAW short-circuit transfer on stainless steels is an argon mixture with 2 to 4 per cent CO<sub>2</sub>. The argon + CO<sub>2</sub> mixture allows use of lower voltages than is practical with argon/helium mixtures, and the lower voltages resulting from the argon + CO<sub>2</sub> mixture will help to reduce distortion and oxidation, and decrease the melt-through potential. The mixture that works with short-circuit transfer is also a logical practical choice for spray transfer welding of stainless steel because it is less oxidizing than argon/oxygen mixtures. [Table 3](#) provides practical gas mixture recommendations for specific applications.

**Table 3. Shielding Gases for Welding Carbon Steels and Stainless Steels**

| Application  | Gas mixtures   |                                  |                              |                               |                                |                             |
|--|----------------|----------------------------------|------------------------------|-------------------------------|--------------------------------|-----------------------------|
|  | Argon + Oxygen | Argon + CO <sub>2</sub> + Oxygen | Argon + 2-4% CO <sub>2</sub> | Argon + 6-10% CO <sub>2</sub> | Argon + 13-20% CO <sub>2</sub> | Argon + 25% CO <sub>2</sub> |
| Short-circuit melt-through problems; less than 20 gage       | 1              | 1                                | 1                            | 1                             | 2                              | 3                           |
| Short-circuit 18 to 11 gage                                  | ...            | ...                              | ...                          | ...                           | 1                              | 1                           |
| Spray if mill scale or surface problems; carbon steels       | ...            | ...                              | ...                          | ...                           | 1                              | 2                           |
| Spray if low energy required; carbon steel                   | 1              | 1                                | 1                            | 1                             | ...                            | ...                         |
| Spray, best impact strengths, lowest porosity; carbon steels | ...            | ...                              | ...                          | ...                           | 1                              | ...                         |
| Best single gas mixture for carbon steels                    | ...            | ...                              | ...                          | ...                           | 1                              | ...                         |
| Short-circuit; stainless steels                              | ...            | ...                              | 1                            | ...                           | ...                            | ...                         |
| Spray; stainless steels                                      | 2              | ...                              | 1                            | ...                           | ...                            | ...                         |
| Best single gas mixture for stainless and duplex steels      | ...            | ...                              | 1                            | ...                           | ...                            | ...                         |

Preferred choice of shielding gas is 1, followed by 2 and 3.

For GMAW spray transfer welding of stainless steels thicker than 11 gage, the traditional GMAW shielding gas has been argon 98 + oxygen 2 per cent. The argon + oxygen mixture provides excellent, stable, spray transfer, but the oxygen promotes oxidation, leaving the weld with a black surface. To reduce the oxidation, the 2 per cent oxygen can be replaced with the less oxidizing 2-4 per cent CO<sub>2</sub>.

**Shielding Gases for GMAW Welding of Aluminum.**—For GMAW welding of aluminum, helium is added to argon to provide additional weld energy, increasing penetration width, and reducing porosity potential. A gas mixture that has worked well in practice and can be used on the majority of aluminum applications is argon + 25 to 35 per cent helium. Mixtures with higher helium content, of 50 to 90 per cent, require voltages and flow rates that may be excessive for many established aluminum applications.

**Welding Controls.**—The two primary controls for welding with GMAW are the electrode wire feed control on the wire feeder and the voltage control on the power source. As shown in Fig. 1, these controls typically consist of switches and knobs but do not have the scales, seen enlarged at the upper left, that indicate combinations of wire feed rate, wire gage, volts, and amps. These scales have been added here to allow clearer explanation of the functioning of the wire feed control.

The typical wire feed unit provides maximum feed rates of 600 to 800 in./min. The scale surrounding the setting knob on a wire feed control unit usually has only 10 unnumbered graduations, somewhat like the hour markers on a clock face. On most machines, each of these graduations represents an adjustment of the feed rate of approximately 70 in./min.

For each increase in the wire feed rate of 70 in./min, depending on the voltage, the welding current increases by approximately 20 to 40 amps, depending on the wire diameter and wire feed positions.

In Fig. 1, a black sector has been drawn in on the wire feed rate adjustment knob to indicate the range of wire feed rates usable with the gas mixture and the electrode diameter (gage) specified. The wire feed and voltage settings shown are for welding thin-gage carbon, low-alloy, or stainless steels with a 0.030- or 0.035-in. (0.8- or 1-mm) diameter electrode. The left edge of the sector on the wire feed knob is set to the eight o'clock position, corresponding to 70 in./min. The optimum voltage for this wire feed rate is 15. If a setting is too low, the knob is turned to the second (nine o'clock) or third (ten o'clock) position to increase the current. The voltage typically increases or decreases by 1 volt for each graduation of the wire feed quadrant.

The short-circuit transfer current range of 50 to 200 amps corresponds to a wire feed rate of 70 to 420 in./min, and is typically found between the eight and one o'clock positions on the scale, as indicated by the black sector on the knob in Fig. 1.

Diagrammatic quadrants have been added at the left in Fig. 1, to show the material thickness, voltage, and current that correspond to the setting of the wire feed rate adjustment knob. Optimum settings are easily made for short-circuit welding of sheet metals. When using a 0.030-in. (0.8-mm) or 0.035-in. (1-mm) diameter GMAW electrode, for instance, to weld 16-gage carbon or stainless steel with a conventional 200-to 450-amp constant-voltage power source and wire feeder, the wire feed control is set to the ten o'clock position for a feed rate of 210 in./min. With digital wire feed units, the short-circuit current range is typically between 100 and 400 in./min, so a good starting point is to set the wire feeder at 210 in./min. The welding voltage is set to 17.

Fig. 1. Wire Feed Settings for Short-Circuit Welding of Carbon, Low-Alloy, and Stainless Steel Sheet.

Many welders set their parameters by an established mark on the equipment or by the sound of the arc as the weld is being made. The sound of the arc, influenced by the optimum current and voltage set, should be a consistent, smooth, crackling noise. If the SCT sound is harsh, the voltage should be increased slightly. If the sound is soft, the voltage should be decreased in volt increments until the sound becomes a smooth crackle. For welding metals thicker than 16 gage but less than 10 gage, the wire feed control should be moved to the eleven o'clock position (280 in./min), and the voltage reset to 18.

Welding of thicknesses less than 16 gage should be started with the wire feed control at the nine o'clock position (140 in./min) and the voltage control set to 16. The parameters discussed above apply when using argon mixtures containing 15 to 25 per cent CO<sub>2</sub>.

**GMAW Spray Transfer.**—In the spray transfer mode, spatter is often caused by the voltage being set so low that the electrode runs into the weld, resulting in expulsion of molten metal from the weld pool. GMAW spray transfer is normally used for welding carbon, low-alloy, and stainless steels of a minimum thickness of  $\frac{1}{8}$  in. (3.2 mm).

In Table 4, typical deposition rates with a 0.045-in. (1.2-mm) carbon steel electrode are compared with rates for larger carbon steel GMAW and flux-cored electrodes. These welds are typically carried out in the flat and horizontal positions. The practical GMAW electrode diameters commonly used for spray transfer are 0.035-in. (1-mm), 0.045-in. (1.2-mm), and 0.062-in. (1.6-mm) diameter. The most cost-effective GMAW electrode that also has the greatest range of applications on metals over  $\frac{3}{16}$  in. thick is the 0.045-in. (1.2-mm) diameter size.

**Table 4. Typical Deposition Rates for Carbon Steel Welding Electrodes**

| Electrode Diameter |       | Electrode Type | Amperage <sup>a</sup> | Deposit Rates |        |
|--------------------|-------|----------------|-----------------------|---------------|--------|
| in.                | (mm)  |                |                       | lb/h          | (kg/h) |
| 0.035              | (1.0) | GMAW           | 350                   | 11            | (5)    |
| 0.045              | (1.2) | GMAW           | 380                   | 13            | (6)    |
| 0.062              | (1.6) | GMAW           | 400                   | 14            | (6.4)  |
| $\frac{1}{16}$     | (1.6) | FCAW           | 350                   | 15            | (7)    |
| $\frac{3}{32}$     | (2.4) | FCAW           | 450                   | 16            | (7.3)  |

<sup>a</sup>The optimum ampere value for the electrode type is shown. The 0.045 GMAW electrode is the most versatile and cost-effective electrode for welding material of 14 gage to 1 in. thick.

**GMAW Spray Transfer Welding of Metal Thicknesses Less than  $\frac{1}{4}$  in. (6.4 mm).—**

The most versatile GMAW electrode for a welding shop that welds carbon, low-alloy, and stainless steels from 20 gage to  $\frac{1}{4}$  in. (6.4 mm) thick is the 0.035-in. (1.0-mm) diameter electrode. The traditional practical spray transfer current range of between 200 and 350 amps for the 0.035-in. electrode is well suited for welding thicknesses from 10 gage to  $\frac{1}{4}$  in. (6.4 mm).

The correct parameters for a 0.035-in. (1-mm) electrode and spray transfer welding are found on the wire feed unit between the one and five o'clock positions, or, on a digital wire feeder, between 420 and 700 in./min. In the drawing at the left in Fig. 2, the spray transfer wire feed range is shaded. When the wire feed rate has been set, the voltage should be fine-tuned so that the electrode wire tip is just touching the weld and a smooth crackling sound without spatter is produced.

An optimum single spray transfer mode current setting for a 0.035-in. (1-mm) diameter electrode for most welding applications is approximately 280 amps with the wire feed set at the three o'clock position for 560 in./min. Manual or high-speed mechanized welds on material of 10 gage to  $\frac{1}{4}$  in. thick can be made at the three o'clock wire feed position with only an adjustment for voltage, which should be set initially at 31 volts, when using an argon + CO<sub>2</sub> mixture.

**GMAW Spray Transfer for Metal Thicknesses  $\frac{1}{4}$  in. (6.4 mm) and Up.**—The 0.045-in. (1.2-mm) diameter is the most cost-effective GMAW electrode for spray transfer welding of carbon, low-alloy, and stainless steels  $\frac{1}{4}$  in. and thicker. A  $\frac{7}{16}$ -in. (11.2-mm) single-pass, no-weave, fillet weld can be produced with this electrode. If larger single-pass welds are required, use of flux-cored electrodes should be considered.

Fig. 2. GMAW Spray Transfer Parameters with 0.035-in. (0.9-mm) Diameter Electrodes

A 400-amp power source is a practical cost-effective unit to use with the 0.045-in. diameter electrode. Globular spray transfer, obtained at the ten o'clock position on the wire feed adjustment knob, starts at current levels of approximately 230 amps and requires a wire feed rate of approximately 210 in./min (90 mm/s). Most spray applications are carried out in the higher-energy, deeper-penetrating 270- to 380-amp range, or between twelve and two o'clock wire feed positions giving 350 to 490 in./min (150 to 210 mm/s). In this range, in which there is minimum weld spatter, the weld deposits are in the form of minute droplets and vaporized weld metal.

The quadrants at the top in Fig. 3 show some typical settings for feed rate, voltage, and current, with different shielding gases. An ideal starting point with a 0.045-in. (1.2-mm) diameter electrode is to set the wire feed rate knob at the one o'clock position, or 420 in./min, at which rate the current drawn, depending on the power source used, should be about 320 to 350 amps. The best starting voltage for the 0.045-in. (1.2-mm) electrode is 30 volts. The arc length should then be set as indicated in Fig. 4. With current over 400 amps at 560 in./min, the 0.045-in. diameter electrode may produce a turbulent weld puddle and a digging arc, which can lead to lack of fusion, porosity, and cracks.

**GMAW Spray Transfer with 0.062-in. (1.6-mm) Diameter Electrodes.**—Electrode wire of 0.062-in. (1.6-mm) diameter is the largest size in normal use and is often chosen for its high deposition rates. Due to the high-current requirements for the spray transfer mode, use of these thicker electrodes is generally restricted to metal thicknesses of  $\frac{1}{2}$  in. (13 mm) and thicker. The high-current requirement reduces ease of welding. This electrode size is suitable for mechanized welding in which fillet welds greater than  $\frac{3}{8}$  in. (9.6 mm) are required.

As indicated at the lower left in Fig. 3, the current range for 0.062-in. (1.6-mm) electrodes is narrow and most welds are made in the range of 360 to 420 amps, or between the ten and eleven o'clock positions on the wire feed control unit for 210 to 280 in./min (90 to 120 mm/s). The quadrants at the lower center and lower right in Fig. 3 show deposition rates in lb/h and kg/h for 0.045-in. (1.2-mm) and 0.062-in. (1.6-mm) diameter electrodes.

Some optimum settings for GMAW welding with a mixture of argon + 15 to 20 per cent  $\text{CO}_2$  gases are given in Table 5.

Fig. 3. GMAW Spray Transfer Parameters for Various Electrodes and Gases.

Table 5. Optimum Settings for GMAW with Argon + 15-20 per cent CO<sub>2</sub>

| Diameters |     | Mode           | Wire Feed Rates |       | Amps | Volts |
|-----------|-----|----------------|-----------------|-------|------|-------|
| in.       | mm  |                | in./min         | m/min |      |       |
| 0.035     | 1.0 | short circuit  | 210             | 5.3   | 140  | 17    |
|           |     | spray transfer | 560             | 14.2  | 280  | 29-30 |
| 0.045     | 1.2 | short circuit  | 210             | 5.3   | 190  | 18    |
|           |     | spray transfer | 420             | 10.7  | 380  | 30-31 |
| 0.052     | 1.4 | spray transfer | 280             | 7.1   | 370  | 31-32 |
| 0.062     | 1.6 | spray transfer | 280             | 7.1   | 410  | 31-32 |

*Note:* If argon + oxygen gas mixtures are used, voltage should be lowered by 1 to 4 volts for the spray transfer mode. The faster the weld travel speed, the lower the voltage required.

**Spray Transfer Voltage.**—The usual setting for spray transfer welding with commonly used electrode diameters is between 25 and 35 volts (see Fig. 4A). To set the optimum voltage for GMAW spray transfer, set the voltage initially so that it is too high, usually between 30 and 35 volts. With excess voltage, there should be a visible gap between the tip of the electrode and the weld, and the arc sound should be free from crackle. With the sequence shown in Fig. 4, the voltage should now be reduced until a consistent smooth crackle sound is produced. If the voltage is lowered too much, the electrode will run into the weld, making a harsh crackling sound, and the resulting weld expulsion will cause spatter.

Fig. 4. Setting Optimum Voltage for GMAW Spray Transfer Welding.

### Flux-Cored Arc Welding

FCAW welding offers unique benefits for specific applications, but flux-cored consumable electrodes cost more than the solid electrodes used in gas metal arc welding, so users need to be aware of FCAW benefits and disadvantages compared with those of GMAW welding. Generally, flux-cored electrodes designed for use without a shielding gas are intended for welding outdoors. Most indoor FCAW welding is done with gas-shielded FCAW welding electrode wire. Some Standards for gas-shielded FCAW electrodes for various countries are listed in [Table 6](#).

**Table 6. Standards for Gas-Shielded, Flux-Cored Welding Electrodes**

| Steel Type        | Country        | Standard    |
|-------------------|----------------|-------------|
| Low-Carbon Steels | USA            | AWS A5.20   |
|                   | Canada         | CSA W48.5   |
|                   | Japan          | JIS Z3313   |
|                   | Germany        | DIN 8559    |
| Low-Alloy Steels  | USA            | AWS A5.29   |
|                   | Canada         | CSA W48.3-M |
|                   | United Kingdom | BS 639-2492 |
| Stainless Steels  | USA            | AWS A5.22   |

**All-Position, Gas-Shielded Electrodes.**—The term “all-position” does not necessarily mean that these electrodes are the best choice for all positions. Also, flux-cored electrodes may meet all standard specifications, but there will inevitably be subtle differences in weld transfer characteristics and recommended current, voltage, and other settings between electrodes made by different manufacturers. The chemistry and slag of the electrodes developed for welding in the flat and horizontal positions (E70T-X) typically provide superior results when they are used for flat and horizontal applications where the surface conditions of the plate are suspect or large, deep-penetrating welds are required. All-posi-

tion electrodes are intended for, and best used in, vertical and overhead welds. For extensive welding in flat or horizontal positions, the welder is better served with the electrodes designed for these specific positions.

All-position, gas-shielded FCAW electrodes provide unique benefits and potential for cost savings. In contrast with short-circuit GMAW, or pulsed GMAW, the all-position FCAW electrodes used for vertical up welding of carbon, low-alloy, or stainless steels are simpler to operate, are capable of greater weld quality, and will provide two to three times the rate of weld deposition. The electrode most commonly used in the USA for vertical up welding on carbon steels is the type E71T-1. The equivalent to the E71T-1 standardized electrode specification now in use in other countries include: Canada, E4801T9; Germany, SGR1; and Japan, YFW 24.

If the end user selects the correct all-position electrode diameter, the routine weaving of the electrode during vertical up and overhead applications may be minimized. Keeping the weld weave to a minimum reduces the skill level needed by the welder and increases the potential for consistent side-wall fusion and minimum porosity. If weaving is necessary, a straight-line oscillation technique is often preferred. Typical settings for welding with various sizes of gas-shielded FCAW electrodes are shown in [Table 7](#).

**Table 7. Typical Settings for Welding with Gas-Shielded FCAW Electrodes**

| Electrode Diameter |       | Vertical Up Welds               |                                 | Flat and Horizontal Welds       |                                 |
|--------------------|-------|---------------------------------|---------------------------------|---------------------------------|---------------------------------|
| in.                | (mm)  |                                 |                                 |                                 |                                 |
| 0.035              | (1)   | Feed rate<br>Current<br>Voltage | 450 ipm<br>165 amps<br>28 volts | Feed rate<br>Current<br>Voltage | 630 ipm<br>250 amps<br>30 volts |
| 0.045              | (1.2) | Feed rate<br>Current<br>Voltage | 350 ipm<br>200 amps<br>25 volts | Feed rate<br>Current<br>Voltage | 560 ipm<br>280 amps<br>26 Volts |

| $\frac{3}{32}$     | (2.4) | ...                             |                                 | Feed rate<br>Current<br>Voltage | 210 ipm<br>460 amps<br>32 volts |

**Material Condition and Weld Requirements.**—Practical considerations for selecting a gas-shielded, flux-cored electrode depend on the material condition and weld requirements. FCAW electrodes are beneficial if the surface of the material to be welded is contaminated with mill scale, rust, oil, or paint; the fillet weld size is to be over  $\frac{3}{8}$  in. (9.6 mm) wide (a GMAW single-pass fillet weld with an electrode size of 0.045 in. is typically  $\frac{3}{8}$  in. wide); the weld is vertical up, or overhead; the required impact strengths and other mechanical properties are above normal levels; crack resistance needs to be high; and increased penetration is required.

**Selecting an FCAW Electrode.**—Selection of FCAW electrodes is simplified by matching the characteristics of flux-cored types with the material and weld requirements listed above. Once the correct electrode type is selected, the next step is to choose the optimum size. In selecting an all-position, flux-cored electrode for vertical up or overhead welding, the steel thickness is the prime consideration. Selecting the optimum electrode diameter allows the high current capability of the electrode to be fully used to attain maximum deposition rates and allows use of the highest penetrating current without concern for excessive heat-related problems during welding. When used in the optimum current range, the

deposited filler metal matches the required amount of filler metal for the specific size of the weld, determined by the plate thickness.

The following suggestions and recommendations are made for FCAW welding of carbon, low-alloy, and stainless steels having flat surfaces. For vertical up welds on steels of thicknesses from  $\frac{1}{8}$  to  $\frac{3}{16}$  in. (3.2 to 4.8 mm) and for vertical up welds on pipe in the thickness range of  $\frac{1}{4}$  to  $\frac{1}{2}$  in. (6.4 to 13 mm), consider the 0.035-in. (1.0-mm) diameter E71T-1 electrode. For vertical up welds on steels in the range of  $\frac{1}{4}$  to  $\frac{3}{8}$  in. (6.4 to 9.6 mm) thickness, consider the 0.045-in. (1.2-mm) diameter E71T-1 electrode or, in nonheat-sensitive applications, the 0.062-in. (1.6-mm) diameter E71T-1 electrode. For vertical up welds on steels of over  $\frac{3}{8}$  in. (9.6 mm) thickness, consider the 0.062-in. (1.6-mm) diameter E71T-1 electrodes for optimum deposition rates. For flat and horizontal welds on steels of  $\frac{3}{8}$  to  $\frac{3}{4}$  in. (9.6 to 19 mm) thickness, consider the  $\frac{1}{16}$ -in. (1.6-mm) diameter E70T-X electrodes. For flat and horizontal welds on steels over  $\frac{3}{4}$  in. (19 mm) in thickness, consider the  $\frac{3}{32}$ -in. (2.4-mm) E70T-X electrodes.

**FCAW Welding of Low-Carbon Steels.**—Low-carbon steel is usually called carbon steel or mild steel. The most-used FCAW electrode for welding carbon steels in the flat or horizontal welding positions is the type E70T-1, which is suited to welding of reasonably clean steel using single-pass or multi-pass welds. Type E70T-2 has added deoxidizers and is suited to surfaces with mill scale or other contamination. This type is used when no more than two layers of weld are to be applied. Type E70T-5 is used for single-pass or multi-pass welds where superior impact properties or improved crack resistance are required. The E70T-X electrodes typically range in size from 0.045 to  $\frac{3}{32}$  in. (1.2 to 2.4 mm) in diameter. Type E71T-1 all-position electrodes are available in diameters of 0.035 in. (1 mm) to 0.062 in. (1.6 mm). With the FCAW process, multi-pass welds are defined as a condition where three or more weld passes are placed on top of each other.

**Settings for Gas-Shielded, All-Position, FCAW Electrodes.**—The optimum setting range (volts and amps) for vertical up welding with all-position FCAW electrodes is rather narrow. The welder usually obtains the greatest degree of weld puddle control at the recommended low to medium current settings. The electrode manufacturers' recommended current range for an E71T-1 electrode of 0.045-in. (1.2-mm) diameter for vertical up welding may be approximately 130 to 250 amps. Using the 0.045-in. (1.2-mm) diameter electrode at 250 amps for a vertical up weld in  $\frac{1}{4}$ -in. (6.4-mm) thick steel, the welder may find that after 3 to 4 inches (75–100 mm) of weld, the weld heat built up in the steel being welded is sufficient to make the weld puddle fluidity increasingly difficult to control. Reducing the current to 160–220 amps will make it possible to maintain control over the weld puddle.

A typical optimum setting for a vertical up weld with an E71T-1, 0.035-in. (1.2-mm) diameter, all-position electrode is as follows. First, set the wire feed rate. If the wire feeder maximum rate is 650 to 750 in./min, the setting mark on the adjustment knob should be set between the one and two o'clock positions on the dial to obtain a feed rate of 450 in./min. If the wire feeder has a digital readout, the rate setting should be the same. At the 450-in./min setting, the welding current with the 0.035-in. all-position electrode should be optimized at between 160 and 170 amps. The welding voltage should be set at 27 to 28 volts with the electrode tip just touching the weld. If there is a gap causing the weld puddle to become too fluid, the voltage should be lowered. If the electrode runs into the weld, causing spatter, the voltage needs to be increased.

With the above conditions, welding steel of  $\frac{1}{8}$  to  $\frac{1}{4}$  in. thickness will deposit 5 to 7 lb/h (2.2 to 3 kg/h). The 0.035-in. electrode is also ideal for welding steel pipe with wall thicknesses of less than  $\frac{1}{2}$  in. (13 mm). The thickness of the pipe after bevelling controls the size

of electrode to be used. The 0.035-in. (6.4-mm) electrode can produce a  $\frac{1}{4}$ -in. (6.4-mm) vertical up fillet weld on such a pipe without weaving.

**Contact Tip Recess.**—The dimension labeled contact tip recess in Fig. 2, and indicated as  $\frac{1}{8}$  in., should be about  $\frac{1}{2}$  in. (13 mm) for a minimum electrode extension of  $\frac{3}{4}$  in. (19 mm), for FCAW welding. This dimension is critical for obtaining high-quality welds with all-position electrodes because they have a fast-freezing slag and operate with low to medium current and voltage. If the recess dimension is less than the optimum, the voltage may be lower than the minimum recommended, and if the settings are less than the minimum, the fast-freezing slag may solidify too rapidly, causing excess porosity or “worm tracks” on the weld surface.

The recommended length of electrode extension for all-position FCAW, E71T-1 electrodes is  $\frac{3}{4}$  to 1 in. (19 to 25 mm). The size of this extension not only affects the minimum required parameters, but a long electrode extension also ensures preheating of the electrode and allows lower current to be used. Preheating the electrode is further beneficial as it reduces moisture on the electrode surface, and in the electrode flux. When a change is made from the GMAW to the FCAW process, welders must be aware of the influence on weld quality of the electrode extension in the FCAW process.

**Porosity and Worm Tracks.**—As mentioned above, porosity and worm tracks typically result from a combination of incorrect electrode extension, incorrect welding settings, humidity, electrode moisture, refill scale, rust, paint, oils, or poor welding technique. Where humidity levels are high, potential for porosity and worm tracks increases. The FCAW process is less sensitive to mill scale than the GMAW spray transfer mode but mill scale will often cause excess weld porosity. The best way to avoid the effects of mill scale, rust, oil, and surface contaminants is to grind the area to be welded.

Another way to reduce porosity is to keep weaving to a minimum. If the correct size flux-cored electrode is used, weaving can be kept to a minimum for most flux-cored applications. The forehand technique produces the best weld bead surface on fillet weld beads up to  $\frac{3}{4}$  in. (19 mm) steel thickness in the flat and horizontal weld positions. On larger single-pass fillet welds, the backhand technique is beneficial because the voltage directed at the weld provides additional weld puddle control to the fluid welds. The backhand technique used for flat and horizontal welds produces a more convex weld bead, reduces potential for porosity, and increases penetration.

If porosity or worm tracks occur, the prime solution is in weld practices that increase heat at the weld, but the following remedies can also be tried. Grind clean the surface to be welded; use recommended electrode extensions; increase current (wire feed rate) decrease voltage; use the backhand welding technique; slow down travel speed, consider use of a different electrode formulation containing increased deoxidizers, avoid weaving; change from argon + CO<sub>2</sub> mixture to straight CO<sub>2</sub>; and provide a protective cover to keep the electrode spool clean and dry.

**Welding with 0.045-in. (1.2-mm) Diameter All-Position Electrodes.**—Fig. 5 shows wire feed settings for welding of steel with 0.045-in. (1.2-mm) diameter, E71T-1 all-position electrodes using a mixture of argon + 15 to 25 per cent CO<sub>2</sub> as the shielding gas, and an electrode extension of  $\frac{3}{4}$  in. (18 mm). Parameters for vertical up welding, shown at the left in Fig. 5, include setting the wire feed rate at the twelve o'clock position, or about 350 in./min, using 200 to 190 amps, and setting the voltage between 24 and 25 volts. Optimum parameters for flat welding, shown at the right in Fig. 5 include setting the wire feed rate at three o'clock position, or 560 in./min (240 mm/s), and 270 amps at 25 to 27 volts.

**Welding with 0.052-in. (1.3-mm) Diameter All-Position Electrodes.**—Settings for vertical up and flat welding with all-position E71T-1 electrodes of 0.052-in. (1.3-mm) diameter are seen at the left in Fig. 6. These electrodes are suited to welding steel having

Fig. 5. Wire Feed and Voltage Settings for FCAW Welding with 0.045-in. (1.2-mm) Diameter E71T-1 Electrodes. Optimum settings are circled.

thicknesses of  $\frac{1}{4}$  in. (6 mm) and thicker. For vertical up welding, the wire feed rate is set between the ten and eleven o'clock positions, or 250 in./min (106 mm/s), with about 200 amps at 25 volts. Flat welding with these electrodes is best done with the wire feed rate set between the two and three o'clock positions, or 490 to 560 in./min (207 to 237 mm/s), giving approximately 300 amps at 28 volts.

Settings for all-position E71T-1 electrodes of 0.062-in. (1.6-mm) diameter, shown at the right in Fig. 6, for vertical up welding are just before the ten o'clock position, or 190 in./min, giving 230 to 240 amps with voltage adjusted to 24–25 volts. For flat welding, the wire feed is set to the twelve o'clock position, giving 340–350 amps with a voltage of 29–30 volts.

**High-Deposition, All-Position Electrodes.**—Vertical up weld deposition rates of 10 to 14 lb/h can be achieved with the E71T-1, 0.062-in. (1.6-mm) and 0.045-in. (1.2-mm) flux-cored electrodes. Settings are shown in Fig. 6 for E71T-1, FCAW electrodes of 0.052- and 0.062-in. (1.4- and 1.6-mm) diameter. These electrodes are suited to applications in which the steel thickness is  $\frac{1}{4}$  in. and thicker, and are the most cost-effective diameter for all-position welds on carbon and stainless steels of  $\frac{1}{4}$  in. (6.35 mm) thickness and thicker. In contrast, vertical up welds, using GMAW or SMAW, may deposit an average of 2 to 4 lb/h (1 to 2 kg/h). Deposition rates are based on welding 60 minutes of each hour. Pulsed GMAW provides deposition rates of 3 to 6 lb/h (1.3-2.7 kg/h). Average rates for vertical up welding with all-position, flux-cored electrodes are shown in Table 8.

Fig. 6. Wire Feed and Voltage Settings for Vertical Up Welding with 0.052- and 0.062-in. Diameter Electrodes

The average deposition rates in Table 9 are to be expected with FCAW electrodes available today. Special electrodes are also available that are specifically designed to provide higher deposition rates. A typical manual welder, welding on steel of  $\frac{1}{4}$  to  $\frac{3}{8}$  in. thickness for 30 minutes of each hour with an all-position flux-cored 0.062-in. (1.6-mm) or 0.045-in. (1.2-mm) diameter electrode would deposit about 4–5 lb/h.

**Table 8. Deposition Rates for Vertical Up Welding with All-Position, Flux-Cored Electrodes (ET71T-1)**

| Electrode Diameter |       | Typical Deposition Rate Range |           | Average Deposition Rate |        |
|--------------------|-------|-------------------------------|-----------|-------------------------|--------|
| in.                | (mm)  | lb/h                          | (kg/h)    | lb/h                    | (kg/h) |
| 0.035              | (1)   | 2.7–6.5                       | (1.2–3)   | 5                       | (2.3)  |
| 0.045              | (1.2) | 5–11                          | (2.3–5)   | 8                       | (3.6)  |
| 0.052              | (1.4) | 4–8                           | (1.8–3.6) | 6.5                     | (3)    |
| 0.062              | (1.6) | 4–11                          | (1.8–5)   | 8.5                     | (4)    |

**Table 9. Average Deposition Rates for Flat and Horizontal Welds**

| Process             | Electrode Size |       | Cost-Effective Current Range (amps) | Optimum Current (amps) | Deposition Rate |        |
|---------------------|----------------|-------|-------------------------------------|------------------------|-----------------|--------|
|                     | in.            | (mm)  |                                     |                        | lb/h            | (kg/h) |
| GMAW spray transfer | 0.035          | (1)   | 250–350                             | 285                    | 9               | (4)    |
|                     | 0.045          | (1.2) | 300–400                             | 385                    | 13              | (5.9)  |
|                     | 0.052          | (1.4) | 350–470                             | 410                    | 11              | (5)    |
|                     | 0.062          | (1.6) | 375–500                             | 450                    | 17              | (7.7)  |
| FCAW                | 0.045          | (1.2) | 225–310                             | 300                    | 14              | (6.4)  |
|                     | 0.052          | (1.4) | 260–350                             | 310                    | 15              | (6.8)  |
|                     | 0.062          | (1.6) | 300–400                             | 340                    | 15              | (6.8)  |
|                     | $\frac{3}{32}$ | (2.4) | 380–560                             | 460                    | 17              | (7.7)  |

The average deposition rates of pulsed GMAW and FCAW for vertical up welds are similar for applications where the steel thickness is  $\frac{1}{8}$  in. (3.2 mm) or less. On steels thicker than  $\frac{1}{8}$  in., where the current may be increased, and larger-diameter all-position FCAW electrodes may be used, deposition rates will be much greater than with pulsed GMAW. Compared with GMAW electrodes for pulsed welding, FCAW all-position electrodes require less costly equipment, less welding skill, and have potential for increased weld fusion with less porosity than with GMAW pulsed techniques.

**Electrode Diameters and Deposition Rates.**—A cost-effective welding shop can achieve deposition rates on flat and horizontal welds of 12 to 15 lb/h (5 to 7 kg/h) with both the GMAW 0.045-in. wire and the 0.062-in. flux-cored wire electrodes, without welder discomfort, and with welds of consistent quality.

The first consideration in selecting the optimum size of gas-shielded FCAW E70T-X electrode for manual flat and horizontal welds on steels thicker than  $\frac{1}{4}$  in. (6.4 mm) is the current requirements needed to achieve deposition rates of 12 to 15 lb/h (5 to 7 kg/h). Large-size electrodes of  $\frac{3}{32}$ -in. (2.4-mm) diameter require 500 amps or more to attain optimum deposition rates. These  $\frac{3}{32}$ -in. diameter electrodes are often used with power sources in the 300–400 amp range, but even when the power source provides 500 to 600 amps, welding is often performed at the low end of the electrode's current requirements. With the large,  $\frac{3}{32}$ -in. diameter electrodes, welder appeal is low, smoke is often excessive, and deposition rates are often only comparable with smaller, easier-to-operate FCAW electrodes.

Typical deposition rates for flat and horizontal welds with various electrode sizes and weld settings are shown in [Table 9](#). In connection with this table, it may be noted that high deposition rates in welding steel plate thicker than  $\frac{1}{4}$  in. require use of currents above the minimum shown for the various sizes of electrodes. The optimum current requirements for the most popular electrode sizes indicate that a 450-amp power source is the most suitable for welding steel of more than  $\frac{1}{4}$  in. thickness. The two most cost-effective and versatile consumables for thin and thick steel sections are the 0.045 in. for GMAW and the 0.062 in. for FCAW electrodes.

The approach to a welding application is critical to achievement of optimum weld quality at minimum cost. In many applications, minimal consideration is given to weld costs. Half of every man-hour of welding in many shops could be saved with selection of the correct electrode diameter used with optimum parameter settings. A practical point that is often overlooked in selection of FCAW electrodes is that the larger the electrode diameter, the more restricted is the application thickness range. Large FCAW electrodes such as the  $\frac{3}{32}$  in. (2.4 mm) are neither suitable nor cost-effective for the common steel thickness range of  $\frac{1}{4}$  to  $\frac{1}{2}$  in. (6.4 to 13 mm). Smaller FCAW electrodes such as the  $\frac{1}{16}$ -in. (1.6-mm) diameter, are suitable for both thin and thick applications. A  $\frac{1}{16}$ -in. diameter FCAW electrode used in the 300- to 350-amp range provides excellent deposition rates with superior welder appeal and negligible smoke.

Large-diameter  $\frac{3}{32}$ -in. (2.4-mm) electrodes are popular for manual applications. However, from a practical point of view, this electrode size is often better suited to mechanized high-current welding in which the high currents required for optimum deposition rates may be safely used without health risks. Use of an electrode at 60 to 80 per cent of its welding current capability indicates that the correct diameter electrode has been selected for the application. When an electrode is used at its maximum-current capability, it shows that the next size larger electrode should be preferred, and when the low end of the current capability is in use, the electrode selected is typically too large.

**The 0.062-in. (1.6-mm) Diameter, E70T-X Electrode.**—The 0.062-in. (1.6-mm) diameter FCAW electrode is the most practical size of its type and will provide excellent deposition rate potential with a practical current range and the broadest application range. Settings for the common  $\frac{1}{16}$ -in. diameter E70T-1 electrode are shown in [Fig. 7](#). With the GMAW process, a  $\frac{3}{8}$ - to  $\frac{1}{16}$ -in. (9.6- to 11-mm) minimum-weave fillet weld is typically the maximum size that can be made in a single pass. The 0.062-in. ( $\frac{1}{16}$ -in., 1.6-mm) FCAW electrode can easily produce a  $\frac{3}{4}$ -in. (19-mm), nonweave, single-pass fillet weld. This size of electrode is also a practical choice for welding steel of  $\frac{1}{4}$  in. (6.4 mm) or greater thickness. From a cost perspective, FCAW consumable electrodes should be used whenever the GMAW process is not suitable.

The average deposition efficiency of a flux-cored electrode is 85 per cent, which means that for every 100 lb or kg of electrode material used, 85 lb or kg ends up as weld material. In contrast, the average deposition efficiency of a GMAW electrode used with argon mixtures and correct equipment settings should be a minimum of 99 per cent.

**Shielding Gases and FCAW Electrodes.**—The E70T-X flux-cored electrodes that are recommended for flat and horizontal welds use  $\text{CO}_2$  gas shielding. Because of new OSHA welding smoke restrictions, manufacturers of FCAW electrodes now provide E70T-X consumable electrodes that can be used with less reactive argon +  $\text{CO}_2$  mixtures to reduce smoke levels. The fast-freezing slag, all-position, E71T-1 flux-cored electrodes can use either  $\text{CO}_2$  or argon + 15 to 25 per cent  $\text{CO}_2$  mixtures for welding carbon, low-alloy, or stainless steels. The argon +  $\text{CO}_2$  mixture is often selected because it provides the highest energy from a reactive gas mixture with a compatible voltage range.

Fig. 7. Settings for  $\frac{1}{16}$ -in. (1.6-mm) FCAW, E70T-X Electrodes.

Instead of  $\text{CO}_2$ , welders often prefer the arc characteristics, lower smoke levels, and lower voltage requirements of the argon +  $\text{CO}_2$  mixtures for all-position welding. However, if lower reactive argon mixtures such as argon + oxygen, or argon with less than 13 per cent  $\text{CO}_2$ , are used, the weld voltage requirements and the arc plasma energy are reduced, adding to the possibility of changing the mechanical properties significantly, increasing the porosity, and raising the potential for forming worm tracks.

### Shielded Metal Arc Welding

With the shielded metal arc welding (SMAW) process, commonly known as stick welding, it is most important to select an electrode that is suited to the application. For welding austenitic stainless or high-alloy steels, the electrode is first selected to match the mechanical and chemical requirements of the metal to be welded. Secondary requirements such as the welding position, penetration potential, deposition capabilities, and ease of slag removal are then considered. Many electrodes for SMAW welding of low- to medium-carbon steels have unique characteristics making them the most suitable and cost-effective for a specific welding application.

In interpreting the ANSI/AWS Standard specification code for SMAW electrodes shown in Table 10, for example, E60XX, the E stands for a low-carbon steel, metal arc welding electrode. The next two digits, such as 60 or 70, indicate the approximate tensile strength of the weld deposit in thousands of psi.

Of the last two digits, the first indicates the usability as follows: 1 = usable in all welding positions; 2 = usable for flat or horizontal positions; and 3 = usable in flat position only.

The final digit, combined with the above, indicates the type of flux coating, as shown in Table 10.

British Standard BS 639:1986 defines requirements for covered carbon- and carbon-manganese-steel electrodes for manual metal arc welding, depositing weld metal having a tensile strength of not more than  $650 \text{ N/mm}^2$ . Appendix A of this standard lists minimum mandatory and optional characteristics of these electrodes. The extensive classifications provide for electrodes to be rated for strength, toughness, and covering (STC), with codes such as E 51 5 4 BB [160 3 0 H]. In this series, E indicates that the electrode is covered and is for manual metal arc welding. The next two digits (51) indicate the strength (tensile, yield, and elongation) properties. The next digits (5 and 4) give the temperatures at which minimum average impact strengths of 28J (at  $-40^\circ\text{C}$ ) and 47J (at  $-30^\circ\text{C}$ ), using Charpy V-notch test specimens, are required. The next group is for the covering and the BB stands for basic, high efficiency. Other letters are B for basic; C for cellulosic; R for rutile, RR for rutile, heavy coated; and S for other.

**Table 10. Significance of Digits in ANSI/AWS A5.18-1979 Standard**

| Third and Fourth Digits | Flux Type and Characteristics, SMAW Electrodes  |
|-------------------------|---|
| 10                      | High-cellulose coating bonded with sodium silicate. Deep penetration, energetic spray-type arc. All-positional, DCEP <sup>a</sup> only                              |
| 11                      | Similar to 10 but bonded with potassium silicate to permit use with AC or DCEP  |
| 12                      | High-rutile coating, bonded with sodium silicate. Quiet arc, medium penetration, all-positional, AC or DCEN   |
| 13                      | Similar to 12 but bonded with sodium silicate and with easily ionized materials added. Gives steady arc on low voltage. All-positional, AC or DCEN                  |
| 14                      | Similar to 12 with addition of medium amount of iron powder. All-positional, AC or DC   |
| 15                      | Lime-fluoride coating (basic low-hydrogen) bonded with sodium silicate. All-positional. For welding high-tensile steels. DCEP only                                  |
| 16                      | Similar to 15 but bonded with potassium silicate. AC or DCEP  |
| 18                      | Similar to 15 but with addition of iron powder. All-positional, AC or DC  |
| 20                      | High iron-oxide coating bonded with sodium silicate. Flat or HV positions. Good X-ray quality. AC or DC   |
| 24                      | Heavy coating containing high percentage of iron powder for fast deposition rates. Flat and horizontal positions only. AC or DC                                     |
| 27                      | Very heavy coating with ingredients similar to 20 and high percentage of iron powder. Flat or horizontal positions. High X-ray quality. AC or DC                    |
| 28                      | Similar to 18 but heavier coating and suited for use in flat and HV positions only. AC or DC  |
| 30                      | High-iron-oxide-type coating but produces less fluid slag than 20. For use in flat position only (primarily narrow-groove butt welds). Good X-ray quality. AC or DC |

<sup>a</sup> DC = direct current, AC = alternating current, EP = electrode positive, EN = electrode negative.

The letters in brackets are optional, and the first group indicates the efficiency, which is the ratio of the mass of weld metal to the mass of nominal diameter core wire consumed with the largest diameter electrode, rounded up to the nearest multiple of 10. The next digit (3) is the maker's advice for the position(s) to be used. Codes for this category include 1, all positions; 2, all positions except vertical down; 3, flat, and for fillet welds, horizontal/vertical; 4, flat; 5, flat, vertical/down; and for fillet welds, horizontal/vertical; and 9, other. The digit at (0), which may have numbers from 0 to 9, shows the polarity, and the minimum open-circuit voltage to be used for that electrode. A 0 here indicates that the electrode is not suited for use with AC. The (H) is included only for hydrogen-controlled electrodes that will deposit not more than 15 ml of diffusible hydrogen for each 100 g of deposited weld metal. The corresponding ISO Standard for BS 639 is ISO 2560. Low-alloy steel electrodes and chromium and chromium nickel steel electrodes are covered in BS 2493 and BS 2926.

The most common electrodes used for the SMAW process are the AWS types E60XX and E70XX. SMAW welding electrode Standards are issued by the American Welding Society (AWS), the British Standards Institute (BS), Canada (CSA), Germany (DIN), and Japan (JIS) and are shown in [Table 11](#).

**AWS E60XX Electrodes.**—Characteristics of the E60XX electrodes influence the weld position capability, ease of slag removal, penetration potential, weld travel speed capability, and weld deposition rates. These electrodes are designed for welding low-carbon steels and they provide welds with typical tensile strength in the range of 58,000 to 65,000 lb/in<sup>2</sup>,

depending on the specific electrode utilized, the base metal condition and chemistry, and the amount of weld dilution. In selecting an electrode for SMAW welding, knowing that the mechanical and chemical requirements have been matched, it is necessary to choose electrodes with characteristics that influence the features required, as shown in Table 11.

**Table 11. Characteristics of SMAW Welding Electrodes Made to Standards of Various Countries**

| Standard  | Description  |
|---|--|
| AWS E6010<br>CSA E41010<br>BS E4343C10<br>DIN E4343C4<br>JIS        | Designed for welding pipe and general structures. Excellent for all-position and vertical down welding. Slag is light and easy to remove. Deep, penetrating arc. Low deposition rates. Polarity DC + (electrode positive).   |
| AWS E6011<br>CSA E41011<br>BS E4343C13<br>DIN E4343C4<br>JIS D4311  | Similar to E6010 but modified to allow use of AC. Excellent for welding sheet metal corner joints vertical down. Polarity AC or DC + (electrode positive).   |
| AWS 6012<br>CSA E41012<br>BS E4332R12<br>DIN E4332R(C)<br>JIS D4313 | Designed for welding sheet metal and light structural steels. Medium penetration suitable for gaps or where minimum weld dilution is needed. Ideal for flat, horizontal, or vertical down welding. Will weld faster than the E6010-11 electrode. Polarity AC or DC—(electrode negative). |
| AWS E6013<br>CSA E41013<br>BS E4332R21<br>DIN E4332R3<br>JIS D4313  | Excellent AC or DC—performance. All-position. Shallow penetration. Good choice for low open-circuit welding machines. AC or DC both excellent on thin structural applications. Polarity AC or DC (DC both polarities).   |
| AWS 6027<br>CSA 41027<br>BSE4343A13035<br>DIN 4343AR11<br>JIS D4327 | Iron powder is added to the flux to provide higher deposition rates. Ideal for multipass groove and fillet welding in flat and horizontal positions. Polarity AC or DC (both polarities).  |

Table 12 shows approximate current requirements for AWS E60XX electrodes for welding sheet metal carbon steels. The current ranges specified vary slightly with different electrode manufacturers. For welding sheet metal start at the low end of the given current requirements with electrodes of  $\frac{3}{16}$ -in (5-mm) diameter or smaller. For metals thicker than 10 gage (0.134 in.), start in the center of the current range, then adjust to suit. A high DC current may result in arc blow, and improved results may then be obtained with AC.

**Table 12. Diameters of AWS E6010/E6011 SMAW Electrodes for Welding Low-Carbon Steel Sheet Metal**

| SWG of Sheet Metal to be Welded | Electrode Diameter |       | Current Starting Level (amps) |
|---------------------------------|--------------------|-------|-------------------------------|
|                                 | in.                | (mm)  |                               |
| 18                              | $\frac{3}{32}$     | (2.5) | 45–60                         |
| 16–14                           | $\frac{1}{8}$      | (3.2) | 80–110                        |
| 12                              | $\frac{5}{32}$     | (4)   | 125–135                       |
| 10                              | $\frac{3}{16}$     | (5)   | 135–150                       |

For welding thicker materials, a good starting setting is in the middle of the current range shown in Table 12. In welding material less than  $\frac{1}{4}$ -in. (6.4-mm) thick, vertically, with an E6010 electrode, try a  $\frac{1}{8}$ -in. (3.2-mm) electrode at 90 to 100 amps. For welding thicknesses between  $\frac{3}{16}$  and  $\frac{5}{16}$  in. (5 and 8 mm) with the E6010 electrode, vertically, try the  $\frac{5}{16}$ -in. (8-mm) diameter electrode at 100 to 125 amps. For thicknesses of  $\frac{3}{8}$  to 1 in. (9.5 to 25 mm), try a  $\frac{3}{16}$ -in. (5-mm) diameter electrode at 155 to 165 amps.

Recommended current ranges, shown in Table 13 for the various sizes of AWS E60XX electrodes most commonly used for welding carbon steel, will give optimum results with SMAW electrodes. An ideal starting point for the current setting for any SMAW electrode diameter is in the middle of the range. The current ranges shown are average values taken from literature of electrode manufacturers in three different countries.

**Table 13. Current Ranges for AWS E60XX SMAW Electrodes**

| Electrode Diameter |       | E6010/E6011 | E6012   | E6013   | E6027   |
|--------------------|-------|-------------|---------|---------|---------|
| in.                | (mm)  | (amps)      | (amps)  | (amps)  | (amps)  |
| $\frac{1}{16}$     | (1.6) | ...         | 25–50   | 20–40   | ...     |
| $\frac{3}{32}$     | (2.5) | 40–75       | 40–100  | 50–100  | ...     |
| $\frac{1}{8}$      | (3.2) | 75–130      | 85–140  | 75–135  | 120–180 |
| $\frac{5}{32}$     | (4)   | 90–170      | 115–185 | 110–185 | 155–245 |
| $\frac{3}{16}$     | (5)   | 135–220     | 145–240 | 150–235 | 200–300 |
| $\frac{1}{4}$      | (6.4) | 205–325     | 250–390 | 240–340 | 300–410 |
| $\frac{5}{16}$     | (8)   | 260–420     | 290–480 | 310–425 | 370–480 |

**AWS E70XX Electrodes.**—Information on the most commonly used AWS E70XX electrodes is given in Table 15. For critical welding applications, low-hydrogen electrodes are typically used. It is most important that manufacturers' instructions regarding storage requirements for keeping low-hydrogen electrodes free from moisture are followed. Current ranges for welding low-carbon steel sheet metal with E70XX electrodes of diameters from  $\frac{3}{32}$  to  $\frac{3}{16}$  in. (2.5 to 5 mm) are shown in Table 14. The optimum starting point is in the middle of the current range indicated.

**Table 14. Current Ranges for SMAW E70XX Welding Electrodes**

| Electrode Diameter |       | E7014   | E7018   | E7024   |
|--------------------|-------|---------|---------|---------|
| in.                | (mm)  | (amps)  | (amps)  | (amps)  |
| $\frac{3}{32}$     | (2.5) | 75–120  | 70–105  | 85–135  |
| $\frac{1}{8}$      | (3.2) | 110–155 | 110–160 | 130–180 |
| $\frac{5}{32}$     | (4)   | 145–210 | 150–215 | 175–240 |
| $\frac{3}{16}$     | (5)   | 190–280 | 180–275 | 230–315 |
| $\frac{7}{32}$     | (5.5) | 255–335 | 255–350 | 280–370 |
| $\frac{1}{4}$      | (6.4) | 330–415 | 295–360 | 325–450 |
| $\frac{5}{16}$     | (8)   | 380–490 | 370–480 | 390–530 |

In using AWS E7018 electrodes for vertical up welding of plate thicknesses of  $\frac{3}{16}$  to  $\frac{5}{16}$  in. (5 to 8 mm), try a  $\frac{1}{8}$ -in. (3.2-mm) diameter electrode. For vertical up welding of thicknesses greater than  $\frac{5}{16}$  in. (8 mm), try a  $\frac{5}{32}$ -in. (4-mm) electrode. With AWS E7018 electrodes, to make horizontal fillet welds in plate thicknesses of 10 swg (0.135 in., 3.4 mm), try a  $\frac{3}{16}$ -in. (5-mm) electrode, for  $\frac{1}{4}$ -in. (6.4-mm) plate, try the  $\frac{7}{32}$ -in. (5.5-mm) electrode, and for steel plate thicker than  $\frac{1}{4}$  in., try the  $\frac{1}{4}$ -in. (6.4-mm) diameter electrode.

**Table 15. Characteristics of AWS Electrodes for SMAW Welding**

| Standard   | Description   |
|--|---|
| AWS E7014<br>CSA E48014<br>BS E5121RR11011<br>DIN E5121RR8<br>JIS D4313      | An iron-powder, all-position electrode for shallow penetration. Excellent for vertical down and applications with poor fit. Similar to AWS E6012-E6013 with added iron powder. For welding mild and low-alloy steels. Polarity AC or DC, + or -.                              |
| AWS E7018<br>CSA E48018<br>BS E5154B11026(H)<br>DIN E5154B(R)10<br>JIS D5016 | An iron-powder, low-hydrogen, all-position electrode. Excellent for rigid, highly stressed structures of low- to medium-carbon steel. Can also be used for welding mild and high-strength steels, high-carbon steels, and alloy steels. Polarity AC or DC + reverse polarity. |
| AWS 7024<br>CSA E48024<br>BS E5122RR13034<br>DIN E5122RR11<br>JIS D4324      | An iron-powder electrode with low hydrogen, usable in all positions. Excellent for high-amperage, large, fillet welds in flat and horizontal positions. Polarity AC or DC, + or -.  |
| AWS E7028<br>CSA E48028<br>BS E514B12036(H)<br>DIN E5143B(R)12<br>JIS D5026  | An iron-powder, low-hydrogen electrode suitable for horizontal fillets and grooved flat position welding. Higher deposition rates. More cost-effective than the AWS E7018 electrode. Polarity AC or DC + reverse polarity.  |

The E7024 electrode is suggested for horizontal fillet welds. For 10-gage (0.135-in, 3.4-mm) material, try the  $\frac{1}{8}$ -in. (3.2-mm) diameter electrode; for above 10-gage to  $\frac{3}{16}$ -in. (5-mm) material, try the  $\frac{5}{32}$ -in. (4-mm) diameter electrode. For plate of  $\frac{3}{16}$ - to  $\frac{1}{4}$ -in. thickness, try the  $\frac{3}{16}$ -in. size, and for plate thicker than  $\frac{1}{4}$  in., try the  $\frac{1}{4}$ -in. (6.4-mm) electrode.

### Gas Tungsten Arc Welding

Often called TIG (for tungsten inert gas) welding, gas tungsten arc welding (GTAW) uses a nonconsumable tungsten electrode with a gas shield, and was, until the development of plasma arc welding (PAW), the most versatile of all common manual welding processes. Plasma arc welding is a modified GTAW process. In contrast to GTAW, plasma arc welding has less sensitivity to arc length variations, superior low-current arc stability, greater potential tungsten life, and the capability for single-pass, full-penetration welds on thick sections.

In examining a potential welding application, the three primary considerations are: achieving a quality weld, ease of welding, and cost. Selecting the optimum weld process becomes more complex as sophisticated electronic technology is applied to conventional welding equipment and consumable electrodes. Rapid advances in gas metal arc and PAW welding power source technology, and the development of many new flux-cored electrodes, have made selection of the optimum welding process or weld consumable more difficult. When several manual welding processes are available, the logical approach in considering GTAW for production welding is to first examine whether the job can be welded by gas metal arc or flux-cored methods.

**GTAW Welding Current.**—A major benefit offered by GTAW, compared with GMAW, FCAW, or SMAW, is the highly concentrated, spatter-free, inert heat from the tungsten arc, which is beneficial for many applications. The GTAW process can use any of three types of welding current, including: direct-current straight polarity, electrode negative (DC-), direct-current reverse polarity, electrode positive (DC+), alternating current with high frequency for arc stabilization (ACHF). Each of the different current types provides benefits that can be used for a specific application.

**GTAW Direct-Current Straight Polarity (DC-):** The most common GTAW current is straight polarity, where the electrode is connected to the negative terminal on the power source and the ground is connected to the positive terminal. Gas tungsten arc welding is used with inert gases such as argon, and argon + helium to weld most metals. During a DC- straight-polarity weld, electrons flow from the negative tungsten electrode tip and pass through the electric field in the arc plasma to the positive workpiece, as shown in Fig. 8.

Plasma is a high-temperature, ionized, gaseous column that is formed when electrons in the arc collide with the shielding gas molecules. The gas atoms lose one or more electrons, leaving them positively charged. The electrons and the resulting plasma are concentrated at the electrode tip, where they cause the plasma pressure to be at its greatest. The electron density thins out as the electrons travel from the straight-polarity, negatively charged, tungsten electrode across the open arc. As the electrons traverse the arc to the work, the resulting arc column width increases slightly, controlled in part by the electromagnetic forces generated by the current. With the increase in the arc column width, the density and pressure of the plasma decrease. The electrons collide with the work, liberating much heat. The downward pressure of the plasma is exerted against the surface of the weld pool. The gas ions in the plasma are positively charged and greater in mass than the electrons.

In DC-, straight-polarity welding, the positive gas ions are drawn to the negative electrode. The electron flow to the weld ensures that most of the arc heat is generated at the positive work side of the arc. This current setup provides maximum penetration potential, as indicated in Fig. 8. With DC-, straight polarity, the tungsten electrode can carry a higher current and operate at lower temperatures than with the other current arrangements.

**Direct-Current Reverse Polarity (DC+):** With direct-current positive polarity (DC+), the tungsten electrode is connected to the power-source positive terminal so that the electrons flow from the negative work to the positive electrode. As illustrated in Fig. 9, the electrons impinging on the electrode tip reverse the direction of the heat concentration that occurs with straight polarity, as described above. Approximately two-thirds of the heat generated with DC+ reverse polarity is at the electrode tip, and the electrode becomes very hot, even with low current levels. DC+ reverse polarity requires large-diameter electrodes.

Fig. 8. Straight Polarity (DC-) Provides Highest Electrode Current Capacity and Deepest Penetration Potential.

In the current range of 100 to 150 amps, DC+ reverse polarity requires a  $\frac{1}{4}$ -in. (6.4-mm) diameter electrode. This larger electrode produces a weld puddle almost twice as wide as that produced by a 120-amp,  $\frac{1}{16}$ -in. (1.6-mm) diameter, DC- straight polarity electrode. Most of the heat is generated at the electrode tip with DC+ reverse polarity, so penetration is much less than with DC- straight polarity. With DC+ reverse polarity, the positive gas ions in the arc plasma are drawn to the negative workpiece where they bombard and break up the surface oxides that form on metals such as aluminum and magnesium. However, the best welding method for aluminum and magnesium is to use alternating current (AC), which combines the benefits of DC- straight and DC+ reverse polarity.

**Alternating Current (AC):** The surface oxides formed on metals such as aluminum and magnesium disturb the arc and reduce the weld quality. Welding of these metals requires DC+ reverse or AC polarity to break up the surface oxides. An alternating current (AC) cycle consists of one-half cycle of straight polarity and one-half cycle of reverse polarity. With alternating current, the cleaning action benefits of the reverse-polarity arc can be combined with the electrode current-carrying capacity of the straight-polarity arc. In welding aluminum and magnesium, the half cycles of AC polarity may become unbalanced. During the AC cycle, the reverse electrode-positive portion of the cycle is restricted by the oxides on the surfaces of these materials. The surface oxides are poor conductors and make it difficult for the electrons generated by the reverse-polarity part of the cycle to flow from the work to the electrode tip, but they do not upset the straight polarity in which the electrons flow from the electrode to the work.

Fig. 9. Direct-Current (DC+) Reverse Polarity Provides a Shallow, Wide, Weld Pool.

**DC Component:** The part of the reverse-polarity cycle of alternating current (AC) that is upset by the poor conductivity of the oxides is changed into direct-current, straight polarity (DC-) and is directed back to the power source where it may cause overheating. The feedback is referred to as the DC component and its characteristics are important in deciding which process to use because, if an AC power source designed for shielded metal arc welding is to be used to weld aluminum by the GTAW process, the power source must be derated to protect the equipment. The power-source manufacturer will provide information on the level of derating required.

Power sources are available for GTAW that provide a balanced AC wave, and manufacturers will provide information about the benefits of balanced wave versus unbalanced wave, GTAW power sources, and equipment to protect against the DC component.

**High Frequency and AC:** To maintain the stability of the alternating-current (AC) arc when the positive cycle of the arc is upset by the aluminum oxide, and to avoid contamination of the tungsten electrode, high-frequency current is used to assist in arc ignition during each AC cycle. In direct-current, straight-polarity (DC-) welding of carbon and stainless steels, the high-frequency current is typically selected by the HF arc start-only switch. During AC welding of steels without oxide problems, the HF switch may be left on the arc start-only setting. When AC is used on aluminum, magnesium, or other metals with poor electron-conductive oxides, the HF switch should be moved to the continuous setting.

High-frequency current is also beneficial in that it promotes gas ionization. The more positively charged molecules produced, the more cleaning action takes place in the direct-current, reverse-polarity (DCRP) cycle.

**Selecting the Tungsten Electrode Type.**—Use of the correct tungsten electrode composition is vital to producing good-quality GTAW welds. Tungsten has the highest melting temperature of all metals. Pure tungsten provides a low-current capacity and requires addi-

tion of such alloying elements as thorium or zirconium to increase the current-carrying capability. The electrode diameter and the electrode tip configuration also require consideration as both have a great influence on the performance and application potential of GTAW welding.

Table 17 shows typical compositions of commonly used GTAW tungsten electrode materials from the American Welding Society AWS A5.12 Standard. New electrode compositions have been designed that utilize other alloys and rare-earth metals. These electrodes are designed for longer lives in both GTAW and plasma welding.

*Pure Tungsten:* Pure tungsten electrode material provides good arc stability with alternating current (AC). Tungsten has low current capacity and low resistance to electrode contamination. Pure tungsten is good for low-amperage welding of aluminum and magnesium alloys. On medium- to high-current ferrous applications, there is a potential for tungsten inclusions in the weld.

With DC, the current capacity of pure tungsten is lower than with the alloyed tungsten electrodes. During AC welding, a molten ball shape forms at the pure tungsten electrode tip, and this formation is desirable for welding aluminum.

**Table 16. Selection of Gas Tungsten Arc Welding (GTAW) Electrodes**

| Base Metal                                      | Electrode                  | Current | Recommendations                                       |
|---|----------------------------|---------|---|
| Carbon, low-alloy, stainless, and nickel steels | Thoriated                  | DCEN    | Use EWZr electrodes with AC on thin materials         |
| Aluminum  | Zirconium or pure tungsten | AC      | Use EWZr on critical applications                     |
| Aluminum  | Thoriated zirconium        | DCEP    | Use EWZr or EWP electrodes with DCEP on thin sections |
| Copper and copper alloys                        | Thoriated                  | DCEN    | Use EWZr or EWP with AC on thin sections              |
| Magnesium                                       | Zirconium                  | AC      | Use DCEP with same electrode on thin sections         |
| Titanium  | Thoriated                  | DCEN    | ...   |

**Table 17. Common Tungsten Electrode Compositions**

| Classification | Color  | Tungsten (%) | Thorium Oxide (%) | Zirconium Oxide (%) |
|----------------|--------|--------------|-------------------|---------------------|
| EWP            | Green  | 99.50        | ...               | ...                 |
| EWTh-1         | Yellow | 98.50        | 0.8-1.2           | ...                 |
| EWTh-2         | Red    | 97.50        | 1.7-2.2           | ...                 |
| EWTh-3         | Blue   | 98.95        | 0.35-0.55         | ...                 |
| EWZr           | Brown  | 99.20        | ...               | 0.15-0.4            |

In the classification column, E = electrode; W = tungsten; P = pure; Th = thoriated (thorium oxide); Zr = zirconiated (zirconium oxide). The colors are codes used by manufacturers to identify the material. Tungsten percentages are minimum requirements. The EWTh-3 is also called striped tungsten because it is made with a strip of thoriated material along the length. This electrode needs to be preheated by striking an arc to melt the tip, providing for the thorium and the tungsten to combine before welding is started.

The electrode recommendations in Table 16 are a guide to attaining good-quality GTAW welds from the venous types of polarities available.

**Electrode and Current Selection.**—Tables 18 and 19 show approximate current recommendations for common electrode types and diameters. The GTAW electrode size should be selected so that its midrange current provides the energy required for the intended application. If the electrode is too thin, excess current may be required, causing the electrode to wear too quickly or melt and contaminate the weld. If the electrodes used are found to be constantly at the top end of the current range, a change should be made to the next larger size. Tables 20 and 21 show recommended sizes of electrodes and filler metal rods or wires for welding various thicknesses of carbon, low-alloy, and stainless steels and aluminum.

**Table 18. Recommended Current Ranges for Thoriated GTAW Electrodes**

| Electrode          |          | Current Range (amps) |
|--------------------|----------|----------------------|
| $\frac{1}{16}$ in. | (1.6 mm) | 60–150               |
| $\frac{3}{32}$ in. | (2.4 mm) | 150–250              |
| $\frac{1}{8}$ in.  | (3.2 mm) | 250–400              |
| $\frac{5}{32}$ in. | (4 mm)   | 400–500              |

The electrode selected must suit the application and the current capacity of the power source.

**Table 19. Current Ranges for EWP and EWZr GTAW Electrodes**

| Electrode      |       | Ampere Range<br>AC Balanced |         | Ampere Range<br>AC Unbalanced |         |
|----------------|-------|-----------------------------|---------|-------------------------------|---------|
|                |       | EWP                         | EWZr    | EWP                           | EWZr    |
| in.            | (mm)  |                             |         |                               |         |
| $\frac{1}{16}$ | (1.6) | 30–80                       | 60–120  | 50–100                        | 70–150  |
| $\frac{3}{32}$ | (2.4) | 60–130                      | 100–180 | 100–160                       | 140–235 |
| $\frac{1}{8}$  | (3.2) | 100–180                     | 160–250 | 150–210                       | 225–325 |
| $\frac{5}{32}$ | (4)   | 160–240                     | 200–320 | 200–275                       | 300–400 |

**Table 20. Electrode and Current Recommendations for Carbon, Low-Alloy, and Stainless Steels**

| Material Thickness |       | Electrode Diameter |       | Filler Rod Diameter |       | Current Range (amps) |      |
|--------------------|-------|--------------------|-------|---------------------|-------|----------------------|------|
| in.                | (mm)  | in.                | (mm)  | in.                 | (mm)  | DCEN                 | EWTh |
| $\frac{1}{16}$     | (1.6) | $\frac{1}{16}$     | (1.6) | $\frac{1}{16}$      | (1.6) | 60–100               |      |
| $\frac{1}{8}$      | (3.2) | $\frac{3}{32}$     | (2.4) | $\frac{3}{32}$      | (2.4) | 150–170              |      |
| $\frac{3}{16}$     | (4.8) | $\frac{3}{32}$     | (2.4) | $\frac{1}{8}$       | (3.2) | 180–220              |      |
| $\frac{1}{4}$      | (6.4) | $\frac{1}{8}$      | (3.2) | $\frac{5}{32}$      | (7.2) | 260–300              |      |

Note: The shielding gas is argon at 15 to 20 cu ft/h (CFH). For stainless steel, reduce the current by approximately 10 per cent.

**Table 21. Recommendations for GTAW Welding of Aluminum with EWP Electrodes Using AC and High-Frequency Current**

| Material Thickness |       | Electrode Diameter |       | Filler Rod Diameter |       | AC Current Range |
|--------------------|-------|--------------------|-------|---------------------|-------|------------------|
| in.                | (mm)  | in.                | (mm)  | in.                 | (mm)  | (amps)           |
| $\frac{1}{16}$     | (1.6) | $\frac{1}{16}$     | (1.6) | $\frac{1}{16}$      | (1.6) | 40–70            |
| $\frac{1}{8}$      | (3.2) | $\frac{3}{32}$     | (2.4) | $\frac{3}{32}$      | (2.4) | 70–125           |
| $\frac{3}{16}$     | (4.8) | $\frac{1}{8}$      | (3.2) | $\frac{1}{8}$       | (3.2) | 110–170          |
| $\frac{1}{4}$      | (6.4) | $\frac{5}{32}$     | (4)   | $\frac{3}{16}$      | (4.8) | 170–220          |

**Thoriated Electrodes:** In contrast with the pure EWP electrodes, thoriated electrodes have a higher melting temperature and up to about 50 per cent more current-carrying capacity, with superior arc starting and arc stability. These electrodes are typically the first choice for critical DC welding applications, but do not have the potential to maintain a rounded ball shape at the tip. The best welding mode for these electrodes is with the tip ground to a tapered or fine point.

**Zirconiated Electrodes:** Tungsten electrodes with zirconium are practical for critical applications and have less sensitivity to contamination and superior current capacity than pure tungsten electrodes.

**Protecting and Prolonging Electrode Life:** To improve tungsten electrode life, the tip should be tapered in accordance with the manufacturer's recommendations. There must also be preflow, postflow shielding gas coverage to protect the electrode before and after

the weld. When possible, high frequency should be used to avoid scratch starts, which contaminate the electrode. The shortest possible electrode extension should be employed, to avoid the possibility of the electrode touching the filler or weld metal. The grinding wheel used to sharpen the tungsten must not be contaminated from grinding other metals or with dirt.

**Filler Metals.**—Specifications covering composition and mechanical properties for GTAW filler metal are published by the American Welding Society under the following classifications: A5.7, copper and copper alloys; A5.9, chromium and chromium nickel; A5.10, aluminum; A5.14, nickel; A5.16, titanium; A5.18, carbon steels; A5.19, magnesium; and A5.28, low-alloy steels.

Filler metals must be kept dry and clean if they are to be used satisfactorily.

**Shielding Gases.**—Inert gases such as argon, and argon + helium mixtures are most commonly used for GTAW. Helium provides greater thermal conductivity and additional arc voltage potential than argon, and is normally added to argon when more weld energy is required for improved penetration and increased mechanized welding travel speeds. Argon gas mixtures containing 30 to 75 per cent helium provide benefits for manual welding of aluminum over  $\frac{3}{8}$  in. (9.6 mm) thick; mechanized welding of aluminum where high speeds are required; mechanized welding of carbon and stainless steels where good penetration is needed; mechanized welding of stainless steel where good penetration and faster speeds are required; and for copper of  $\frac{1}{4}$  in. (6.4 mm) thickness and thicker.

Shielding gas purity for GTAW welding is important. Welding-grade argon is supplied at a purity of at least 99.996 per cent and helium is produced to a minimum purity of 99.995 per cent. However, shielding gases may be contaminated due to poor cylinder filling practices. If impure gas is suspected, the following test is suggested. With the HF and power on, create an arc without welding and hold the arc for about 30 seconds. Examine the electrode tip for signs of unusual coloration, oxidation, or contamination, which result from impurities in the shielding gas.

### Plasma Arc Welding (PAW)

When an electric current passes between two electrodes through certain gases, the energy of the gas molecules is increased so that they accelerate and collide with each other more often. With increases in energy, the binding forces between the nuclei and the electrons are exceeded, and electrons are released from the nuclei. The gas now consists of neutral molecules, positively charged atoms, and negatively charged electrons. The plasma gas is said to be ionized, so that it is capable of conducting electric current. Plasma forms in all welding arcs but in plasma arc welding it is generated by a series of events that begins with inert gas passing through the welding torch nozzle. High-frequency current is then generated between the tungsten electrode (cathode) and the torch nozzle (anode), forming a low-current pilot arc. The ionized path of this nontransferred arc is then transferred from the tungsten electrode to the work, and a preset plasma current is generated.

The above sequence of events provides the ionized path for the plasma current between the electrode and the work so that arcing between the electrode and the nozzle ceases. (Nontransferred arcs may be used for metal spraying or nonmetallic welds.) Forcing the ionized gas through the small orifice in the nozzle increases both the level of ionization and the arc velocity, and arc temperatures between 30,000 and 50,000°F (16,650 and 27,770°C) are generated.

**Gases for Plasma Arc Welding.**—Argon is the preferred gas for plasma arc welding (PAW) as it is easily ionized and the plasma column formed by argon can be sustained by a low voltage. The low thermal conductivity of argon produces a plasma column with a narrow, concentrated hot core surrounded by a cooler outer zone. Argon plasmas are suited to welding steel up to  $\frac{1}{8}$  in. (3.2 mm). For thicker materials, requiring a hotter arc and using

higher current melt-in technique, a mixture of argon 25 + helium 75 per cent may be used. Additions of helium and hydrogen to the gas mixture improve heat transfer, reduce porosity, and increase weld travel speed. For welding materials thinner than  $\frac{1}{8}$  in. thick by the plasma gas keyhole method (full penetration welds), gases may contain up to 15 per cent hydrogen with the remainder argon. Good results are obtained with argon + 5 per cent hydrogen in welding stainless and nickel steels over  $\frac{1}{8}$  in. thick.

**Shielding Gases.**—A shielding gas is needed to protect the narrow plasma arc column and the weld pool, and generally is provided by mixtures of argon, argon + hydrogen, argon + helium, or argon +  $O_2$  +  $CO_2$ , depending on compatibility with the material being welded. Shielding gas flow rates vary from 5 to 35 cu ft/h (2.4 to 17 l/min). However, if argon is used for both plasma and shielding, the plasma gas will become less concentrated. The normally tight plasma arc column will expand in contact with the colder shielding gas, reducing ionization and thus concentration and intensity of the plasma column. With no shielding gas, the tight column is unaffected by the surrounding oxygen and nitrogen of the atmosphere, which are not easily ionized.

*Hydrogen* is added to the shielding gas when welding low-alloy steels of less than  $\frac{1}{16}$  in. (1.6 mm) thickness, or stainless and nickel steels, with many benefits. The hydrogen molecules dissociate in contact with the arc at temperatures of about 7,000°F (3,870°C) and the energy thus created is released when the hydrogen molecules recombine on contact with the work surface. The diatomic molecular action creates a barrier around the plasma, maintaining column stiffness. Hydrogen in the shielding gas combines with oxygen in the weld zone, releasing it into the atmosphere and keeping the weld clean. Hydrogen reduces the surface tension of the weld pool, increasing fluidity, and the added energy increases penetration.

*Helium* mixed with the argon shielding gas is beneficial for all metals as it increases the ionization potential, allowing use of higher voltages that give increased welding temperatures. Flow rates are in the range of 15 to 50 cu ft/h (7 to 24 l/min). Arc-starting efficiency is reduced with pure helium, but adding 25 per cent of argon helps both arc starting and stability. Helium additions of 25 to 75 per cent are made to obtain increased thermal benefits.

Argon +  $CO_2$  shielding gas mixtures are beneficial in fusion welding of carbon steels. A mixture of argon with 20 to 30 per cent  $CO_2$  improves weld fluidity. Shielding gas mixtures of argon +  $CO_2$  with an argon + 5 per cent hydrogen plasma should be considered for welding carbon steel of  $\frac{1}{16}$  to  $\frac{1}{4}$  in. thickness. Steels with higher amounts of carbon have higher heat conductivity and need application of more heat than is needed with stainless steels. Manufacturers usually make recommendations on types of gas mixtures to use with their equipment.

**PAW Welding Equipment.**—The PAW process uses electrode negative (DCEN) polarity in a current range from 25 to 400 amps, and equipment is offered by many manufacturers. Solid-state inverter units are available with nonmechanical contactors. Most PAW units contain a high-frequency generator, a small DC power supply, controls for welding and shielding gas mixtures, and a torch coolant control. A weld sequencer is recommended, especially for keyhole mode welding, but it is also useful in automated fusion welding. The sequencer provides control of up-slope and down-slope conditions for gas mixtures and current, so that it is possible to make welds without run-on and run-off tabs, as is necessary with circumferential welds.

Generally, plasma arc torches are liquid-cooled using deionized water in the coolant lines to the torch to avoid effects of electrolysis. Electrodes are usually tungsten with 2 per cent thorium. If the welding shop already has a constant-current power supply and a coolant recirculator, plasma arc welding may be used by addition of a pilot arc welding console and a torch.

**Applications.**—Fusion welding is the main use for plasma arc welding. The process is used for high-volume, repetitive, high-duty cycle, manual and automated operations on lap, flange, butt, and corner fusion welds, in all positions. Joint design for materials less than 0.01 in. (0.254 mm) thick may require a flange type joint for rigidity and to allow use of extra, weld metal reinforcement. Filler metal may be added during fusion welding, and automated hot or cold wire feeders can be used. Fusion welding uses a soft, less-restricted arc with low gas flows, and the current level may vary from approximately 25 to 200 amps. The soft arc is obtained by setting the end of the tungsten electrode level with the face of the torch nozzle, in which position lower currents and gas flows are required. With these conditions, the weld bead is slightly wider than a bead produced with a recessed electrode.

*Low-Current Plasma Fusion Welding:* With the reduced consumption of gas and electric current, the low-current plasma fusion welding method is ideal for welding metals down to 0.001 in. (0.025 mm) in thickness, as the low-current plasma pilot arc allows arcs to be started consistently with currents of less than 1 amp. With currents below 1 amp, the pilot arc is usually left in the continuous mode to maintain the arc. In the conditions described, arc stability is improved and the process is much less sensitive to variations in the distance of the torch from the workpiece. Given this height tolerance, setting up is simplified, and with the smaller torches required, it is often easier to see the weld pool than with the GTAW process. Some plasma welding units incorporate gas flow meters that are designed for low flow rates, and currents in the range of 0.1 to 15 amps can be selected.

Low-current plasma arc welding is more economical than other gas tungsten arc welding methods, especially with solid-state inverter systems and smaller torches. The process is useful for sealing type welds where joint access is good, and for welding components of office furniture, household items, electronic and aerospace parts, metallic screening, and thin-wall tubing.

*Keyhole mode welding* describes a method whereby abutting edges of two plates are melted simultaneously, forming a vapor capillary (or keyhole) and the resulting molten-walled hole moves along the joint line. This method requires the end of the tungsten electrode to be positioned well back inside the torch nozzle to produce a high-velocity, restricted arc column with sufficient energy to pierce the workpiece. This mode is also used for the plasma cutting process, but the major difference is that welding uses very low plasma flow rates of the order of 1 to 3 cu ft/h (0.5 to 1.4 l/min) for work thicknesses of  $\frac{1}{16}$  to  $\frac{3}{32}$  in. (1.6 to 4 mm). These low rates avoid unwanted displacement of the weld metal. After the arc pierces the workpiece, the torch moves along the weld line and the thin layer of molten metal is supported by surface tension as it flows to the rear of the line of movement, where it solidifies and forms the weld.

As it passes through the keyhole, the high-velocity plasma gas column flushes the molten weld pool and carries away trapped gases and contaminants that otherwise would be trapped in the weld. Plasma arc keyhole welding is affected less by surface and internal defects in the work material than is the GTAW process. Most metals that can be welded by the gas tungsten arc method can be plasma arc welded with the conventional DC electrode, negative keyhole method, except aluminum, which requires a variable polarity keyhole method.

Plasma keyhole welding is usually automated because it requires consistent travel speed and torch height above the work. A typical operation is welding steel with square abutting edges (no bevels) in thicknesses of 0.09 to 0.375 in. (2.3 to 9 mm), where 100 per cent penetration in a single pass is required. Producing square-groove butt welds in materials thicker than  $\frac{1}{2}$  in. by the plasma arc keyhole process requires some edge preparation and several filler passes. The finished weld is uniformly narrow and the even distribution of heat means that distortion is minimized.

**Welding Aluminum.**—The variable polarity plasma arc (VPPA) process was developed for welding metals that form an oxide skin, such as aluminum. Electrode negative

(straight) polarity is necessary for the plasma arc to provide sufficient heat to the workpiece and minimize heat buildup in the tungsten electrode. With electrode negative polarity, electrons move rapidly from the negative cathode tungsten electrode to the positive anode workpiece, generating most of the heat in the workpiece. Because of the oxide skin on aluminum, however, straight polarity produces an erratic arc, poor weld fluidity, and an irregularly shaped weld bead. The oxide skin must be broken up if the metal flow is to be controlled, and this breakup is effected by a power supply that constantly switches from negative to positive polarity.

A typical cycle uses a 20-ms pulse of electrode negative polarity and a 3-ms pulse of electrode positive polarity. The pulses are generated as square waves and the positive (cleaning) pulse is set at 30 to 80 amps higher than the negative pulse for greater oxide-breaking action. The tenacious oxide skin is thus broken constantly and the rapid cycle changes result in optimum cathode cleaning with minimum deterioration of the tungsten electrode and consistent arc stability. Varying polarity has advantages in both gas metal arc and plasma arc welding, but with the keyhole process it allows single-pass, square-groove, full-penetration welds in materials up to  $\frac{1}{2}$  in. (12.7 mm) thick.

The VPPA process ensures extremely low levels of porosity in weld areas in aluminum. VPPA welding is often used in the vertical up position for aluminum because it provides superior control of root reinforcement, which tends to be excessive when welding is done in the flat position. Pulsing in the VPPA process when welding aluminum of  $\frac{1}{8}$  to  $\frac{1}{4}$  in. thickness in the flat position gives satisfactory root profiles. Pulsing gives improved arc control in keyhole welds in both ferrous and nonferrous metals and is beneficial with melt-in fusion welding of thin materials as it provides better control of heat input to the workpiece.

### Plasma Arc Surface Coating

*Plasma Arc Surfacing* uses an arc struck between the electrode and the workpiece, or transferred arc, to apply coatings of other metals or alloys to the workpiece surface. This high-temperature process produces homogeneous welds in which the ionized plasma gas stream melts both the work surface and a stream of powdered alloy or filler wire fed into the arc. Dilution of the base metal can be held below 5 per cent if required. With arc temperatures between 25,000 and 50,000°F (14,000 and 28,000°C), deposition occurs rapidly, and a rate of 15 lb/h (6.8 kg/h) of powdered alloy is not unusual. Deposition from wire can be performed at rates up to 28 lb/h (12.7 kg/h), much higher than with oxygen/fuel or gas metal/arc methods.

In the nontransferred arc process used for coating of surfaces, the arc is struck between the electrode and the torch nozzle, so that it does not attach to the work surface. This process is sometimes called metal spraying, and is used for building up surfaces for hard facing, and for application of anticorrosion and barrier layers. Argon is frequently used as the plasma gas. As the coating material in the form of powder or wire enters the plasma, it is melted thoroughly by the plasma column and is propelled toward the work at high velocity to form a mechanical bond with the work surface. Some 500 different powder combinations are available for this process, so that a variety of requirements can be fulfilled, and deposition rates up to 100 lb/h (45 kg/h) can be achieved.

The plasma arc process allows parts to be modified or recovered if worn, and surfaces with unique properties can be provided on new or existing components. Low levels of porosity in the deposited metal can be achieved. Metal spraying can be performed manually or automatically, and its use depends primarily on whether a mechanical bond is acceptable. Other factors include the volume of parts to be treated, the time needed for the process and for subsequent finishing, the quality requirements for the finished parts, rejection rates, and costs of consumable materials and energy.

Some systems are available that can use either metal powder or wire as the spray material, and can be operated at higher voltage settings that result in longer plasma arc lengths at temperatures over 10,000°F (5,537°C). With these systems, the plasma velocity is increased to about 12,000 ft/s (3,658 m/s), giving an extremely dense coating with less than 1 per cent porosity. Current ranges of 30 to 500 amps are available, and nitrogen is frequently used as the plasma gas, coupled with CO<sub>2</sub>, nitrogen, or compressed air as the shielding gas. Gas flow rates are between 50 and 350 cu ft/h (24 and 165 l/min). Large or small surface areas can be coated at low cost, with minimum heat input, if other aspects of the process are compatible with the product being made.

### Plasma Arc Cutting of Metals

**Plasma Arc Cutting.**—Higher current and gas flow rates than for plasma arc welding are used for the plasma arc cutting (PAC) process, which operates on DC straight polarity, and uses a transferred arc to melt through the material to be cut. The nozzle is positioned close to the work surface and the velocity of the plasma jet is greatly increased by a restricting nozzle orifice so that it blows away the metal as it is melted to make the cut. The higher energy level makes the process much faster than cutting with an oxygen/fuel torch on cutting steel of less than ½ in. thick, but the process produces kerfs with some variation in the width and in the bevel angle, affecting the precision of the part. Some of the molten metal may recast itself on the edges of the cut and may be difficult to remove.

Factors that affect plasma cutting include the type and pressure of the gas, its flow pattern, the current, the size and shape of the nozzle orifice, and its closeness to the work surface. To reduce noise and fumes, mechanized plasma arc cutting is often performed with the workpiece submerged in water. Oxidation of cut surfaces is almost nonexistent with the underwater method.

**Precision Plasma Arc Cutting.**—A later development of the above process uses a magnetic field in the cutter head to stabilize the plasma arc by means of Lorentz forces that cause it to spin faster and tighter on the electrode tip. The magnetic field also confines the spinning plasma so that a narrower kerf is produced without adverse effect on cutting speed. Results from this process are somewhat comparable with those from laser cutting and, with numerical control of machine movements, it is used for production of small batches of blanks for stamping and similar applications. With galvanized and aluminized steel, edges are clean and free from burrs, but some slag may cling to edges of mild-steel parts.

### Cutting Metals with an Oxidizing Flame

The oxyhydrogen and oxyacetylene flames are especially adapted to cutting metals. When iron or steel is heated to a high temperature, it has a great affinity for oxygen and readily combines with it to form various oxides, and causing the metal to be disintegrated and burned with great rapidity. The metal-cutting or burning torch operates on this principle. A torch tip is designed to preheat the metal, which is then burned or oxidized by a jet of pure oxygen. The kerf or path left by the flame is suggestive of a saw cut when the cutting torch has been properly adjusted and used. The traversing motion of the torch along the work may be controlled either by hand or mechanically.

**Arc Cutting.**—According to the *Procedure Handbook of Arc-Welding Design & Practice*, published by The Lincoln Electric Co., a steel may be cut easily, and with great accuracy by means of the oxyacetylene torch. All metals, however, do not cut as easily as steel. Cast iron, stainless steels, manganese steels, and nonferrous materials are not as readily cut and shaped with the oxyacetylene cutting process because of their reluctance to oxidize. For these materials, arc cutting is often used to good advantage.

The cutting of steel is a chemical action. The oxygen combines readily with the iron to form iron oxide. In cast iron, this action is hindered by the presence of carbon in graphite

form. Thus, cast iron cannot be cut as readily as steel; higher temperatures are necessary and cutting is slower. In steel, the action starts at bright red heat, whereas in cast iron, the temperature must be nearer to the melting point to obtain a sufficient reaction.

**The Cutting Torch.**—The ordinary cutting torch consists of a heating jet using oxygen and acetylene, oxygen and hydrogen, or, in fact, any other gas that, when combined with oxygen, will produce sufficient heat. By the use of this heating jet, the metal is first brought to a sufficiently high temperature, and an auxiliary jet of pure oxygen is then turned onto the red-hot metal, and the action just referred to takes place. Some cutting torches have a number of preheating flame ports surrounding the central oxygen port, so that a preheating flame will precede the oxygen regardless of the direction in which the torch is moved. This arrangement has been used to advantage in mechanically guided torches. The rate of cutting varies with the thickness of the steel, the size of the tip, and the oxygen pressure.

**Adjustment and Use of Cutting Torch.**—When using the cutting torch for the cutting of steel plate, the preheating flame first comes into contact with the edge of the plate and quickly raises it to a white-hot temperature. The oxygen valve is then opened, and as the pure oxygen comes into contact with the heated metal, the latter is burned or oxidized.

**Metals That Can Be Cut.**—Metals such as wrought iron and steels of comparatively low-carbon content can be cut readily with the cutting torch. High-carbon steels may be cut successfully if preheated to a temperature that depends somewhat on the carbon content. The higher the carbon content, the greater the degree of preheating required. A black heat is sufficient for ordinary tool steel, but a low red heat may be required for some alloy tool steels. Brass and bronze plates have been cut by interposing them between steel plates.

**Cutting Stainless Steel.**—Stainless steel can be cut readily by the flux-injection method. The elements that give stainless steels their desirable properties produce oxides that reduce the flame cutting operation to a slow melting-away process when the conventional oxy-acetylene cutting equipment is used. By injecting a suitable flux directly into the stream of cutting oxygen before it enters the torch, the obstructing oxides can be removed. Portable flux feeding units are designed to inject a predetermined amount of the flux powder. The rate of flux flow is accurately regulated by a vibrator type of dispenser with rheostat control. The flux-injection method is applicable either to machine cutting or to a hand-controlled torch. The operating procedure and speed of cutting are practically the same as in cutting mild steel.

**Cutting Cast Iron.**—The cutting of cast iron with the oxyacetylene torch is practicable, although it cannot be cut as readily as steel. The ease of cutting seems to depend largely on the physical character of the cast iron, very soft cast iron being more difficult to cut than harder varieties. The cost is much higher than that for cutting the same thickness of steel, because of the larger preheating flame necessary and the larger oxygen consumption. In spite of this extra cost, however, this method is often economical. The slag from a cast-iron cut contains considerable melted cast iron, whereas in steel, the slag is practically free from particles of the metal, indicating that cast-iron cutting is partly a melting operation. Increased speed and decreased cost often can be obtained by feeding a steel rod, about  $\frac{1}{4}$  inch in diameter, into the top of the cut, beneath the torch tip. This rod furnishes a large amount of slag that flows over the cut and increases the temperature of the cast iron. Special tips are used because of the larger amounts of heat and oxygen required.

**Mechanically Guided Torches.**—Cutting torches used for cutting openings in plates or blocks or for cutting parts to some definite outline are often guided mechanically or by numerical control. Torches guided by pantograph mechanisms are especially adapted for tracing the outline to be cut from a pattern or drawing. Other designs are preferable for straight-line cutting and one type is designed for circular cutting.

**Cutting Steel Castings.**—When cutting steel castings, care should be taken to prevent burning pockets in the metal when the flame strikes a blowhole. If a blowhole is pene-

trated, the molten oxide will splash into the cavity and the flame will be diverted. The presence of the blowhole is generally indicated by excessive sparks. The operator should immediately move the torch back along the cut and direct it at an angle so as to strike the metal beneath the blowhole and burn it away if possible beyond the cavity. Cutting in the normal position then may be resumed.

**Thickness of Metal That Can Be Cut.**—The maximum thickness of metal that can be cut by these high-temperature flames depends largely upon the gases used and the pressure of the oxygen, which may be as high as 150 lb/in.<sup>2</sup> The thicker the metal, the higher the pressure required. When using an oxyacetylene flame, it might be practicable to cut iron or steel up to 12 or 14 inches in thickness, whereas an oxyhydrogen flame has been used to cut steel plates 24 inches thick. The oxyhydrogen flame will cut thicker material principally because it is longer than the oxyacetylene flame and can penetrate to the full depth of the cut, thus keeping all the oxide in a molten condition so that it can be easily blown out by the oxygen cutting jet. A mechanically guided torch will cut thick material more satisfactorily than a hand-guided torch, because the flame is directed straight into the cut and does not wobble, as it tends to do when the torch is held by hand. With any flame, the cut is less accurate and the kerf wider, as the thickness of the metal increases. When cutting light material, the kerf might be  $\frac{1}{16}$  inch wide, whereas for heavy stock, it might be  $\frac{1}{4}$  or  $\frac{3}{8}$  inch wide.

### Hard Facing

Hard facing is a method of adding a coating, edge, or point, of a metal or alloy capable of resisting abrasion, corrosion, heat, or impact, to a metal component. The process can be applied equally well to new parts or old worn parts. The most common welding methods used to apply hard-facing materials include the oxyacetylene gas, shielded-metal arc, submerged arc, plasma arc, and inert-gas-shielded arc (consuming and nonconsuming electrode). Such coatings can also be applied by a spraying process, using equipment designed to handle the coating material in the form of a wire or a powder.

**Hard-Facing Materials.**—The first thing to be considered in the selection of a hard-facing material is the type of service the part in question is to undergo. Other considerations include machinability, cost of hard-facing material, porosity of the deposit, appearance in use, and ease of application. Only generalized information can be given here to guide the selection of a material as the choice is dependent upon experience with a particular type of service. Generally, the greater the hardness of the facing material, the greater is its resistance to abrasion and shock or impact wear. Many hardenable materials may be used for hard facing such as carbon steels, low-alloy steels, medium-alloy steels, and medium-high alloys but none of these is outstanding. Some of the materials that might be considered to be preferable are high-speed steel, austenitic manganese steel, austenitic high-chromium iron, cobalt-chromium alloy, copper-base alloy, and nickel-chromium-boron alloy.

**High-Speed Steels.**—These steels are available in the form of welding rods (RFe5) and electrodes (EFe5) for hard facing where hardness is required at service temperatures up to 1100 degrees F and where wear resistance and toughness are also required. Typical surfacing operations are done on cutting tools, shear blades, reamers, forming dies, shearing dies, guides, ingot tongs, and broaches using these metals.

**Hardness:** These steels have a hardness of 55 to 60 on the Rockwell C scale in the as-welded condition and a hardness of 30 Rockwell C in the annealed condition. At a temperature of 1100 degrees F, the as-deposited hardness of 60 Rockwell C falls off very slowly to 47 Rockwell C. At about 1200 degrees F, the maximum Rockwell C hardness is 30.

**Resistance Properties:** As deposited, the alloys can withstand only medium impact, but when tempered, the impact resistance is increased appreciably. Deposits of these alloys will oxidize readily because of their high molybdenum content but can withstand atmospheric corrosion. They do not withstand liquid corrosives.

*Other Properties or Characteristics:* The metals are well suited for metal-to-metal wear especially at elevated temperatures. They retain their hardness at elevated temperatures and can take a high polish. For machining, these alloys must first be annealed. Full hardness may be regained by a subsequent heat treatment of the metal.

**Austenitic Manganese Steels.**—These metals are available in the form of electrodes (EFeMn) for hard facing when dealing with metal-to-metal wear and impact. Uses include facing rock-crushing equipment and railway frogs and crossings.

*Hardness:* Hardness of the as-deposited metals are 170 to 230 Bhn, but they can be work-hardened to 450 to 550 Bhn very readily. For all practical purposes, these metals have no hot hardness as they become brittle when reheated above 500 to 600 degrees F.

*Resistance Properties:* These metals have high impact resistance. Their corrosion and oxidation resistance are similar to those of ordinary carbon steels. Their resistance to abrasion is only mediocre compared with hard abrasives like quartz.

*Other Properties or Characteristics:* The yield strength of the deposited metal in compression is low, but any compressive deformation rapidly raises it until plastic flow ceases. This property is an asset in impact wear situations. Machining is difficult with ordinary tools and equipment; finished surfaces are usually ground.

**Austenitic High-Chromium Irons.**—These metals are available in rod (RFeCr-A) and electrode (EFeCr-A) form and are used for facing agricultural machinery parts, coke chutes, steel mill guides, sand-blasting equipment, and brick-making machinery.

*Hardness:* The as-welded deposit ranges in hardness from 51 to 62 Rockwell C. Under impact, the deposit work hardens somewhat, but the resulting deformation also leads to cracking and impact service is therefore avoided. Hot hardness decreases slowly at temperatures up to 800 and 900 degrees F. At 900 degrees F, the instantaneous hardness is 43 Rockwell C. In 3 minutes under load, the hardness drops to 37 Rockwell C. At 1200 degrees F, the instantaneous hardness is 5 Rockwell C. The decrease in hardness during hot testing is practically recovered on cooling to ambient temperatures.

*Resistance Properties:* Deposits will withstand only light impact without cracking. Dynamic compression stresses above 60,000 pounds per square inch should be avoided. These metals exhibit good oxidation resistance up to 1800 degrees F and can be considered for hot wear applications where hot plasticity is not objectionable. They are not very resistant to corrosion from liquids and will rust in moist air, but are more stable than ordinary iron and steel. Resistance to low-stress scratching is outstanding and is related to the amount of hard carbides present. However, under high-stress grinding abrasion, performance is only mediocre and they are not deemed suitable for such service.

*Other Properties or Characteristics:* The deposited metals have a yield strength (0.1 per cent offset) of between 80,000 and 140,000 pounds per square inch in compression and an ultimate strength of from 150,000 to 280,000 pounds per square inch. Their tensile strength is low and therefore tension uses are avoided in design. These deposits are considered to be commercially unmachinable and are also very difficult to grind. When ground, a grinding wheel of aluminum oxide abrasive with a 24-grit size and a hard (Q) and medium-spaced resinoid bond is recommended for off-hand high-speed work and a slightly softer (P) vitrified bond for off-hand low-speed work.

**Cobalt-Base Alloys.**—These metals are available in both rod (RCoCr) and electrode (ECoCr) form and are frequently used to surface the contact surfaces of exhaust valves in aircraft, truck, and bus engines. Other uses include parts such as valve trim in steam engines, and on pump shafts, where conditions of corrosion and erosion are encountered. Several metals with a greater carbon content are available (CoCr-B, CoCr-C) and are used in applications requiring greater hardness and abrasion resistance but where impact resistance is not mandatory or expected to be a factor.

**Hardness:** Hardness ranges on the Rockwell C scale for gas-welded deposits are as follows: CoCr-A, 38 to 47; CoCr-B, 45 to 49; and CoCr-C, 48 to 58. For arc-welded deposits, hardness ranges (Rockwell C) as follows: CoCr-A, 23 to 47; CoCr-B, 34 to 47; and CoCr-C, 43 to 58. The values for arc-weld deposits depend for the most part on the base metal dilution. The greater the dilution, the lower the hardness. Many surfacing alloys are softened permanently by heating to elevated temperatures, however, these metals are exceptional. They do exhibit lower hardness values when hot but return to their approximate original hardness values upon cooling. Elevated-temperature strength and hardness are outstanding properties of this group. Their use at 1200 degrees F and above is considered advantageous but between 1000 and 1200 degrees F, their advantages are not definitely established, and at temperatures below 1000 degrees F, other surfacing metals may prove better.

**Resistance Properties:** In the temperature range from 1000 to 1200 degrees F, weld deposits of these metals have a great resistance to creep. Tough martensitic steel deposits are considered superior to cobalt-base deposits in both flow resistance and toughness. The chromium in the deposited metal promotes the formation of a thin, tightly adherent scale that provides a scaling resistance to combustion products of internal combustion engines, including deposits from leaded fuels. These metals are corrosion-resistant in such media as air, food, and certain acids. It is advisable to conduct field tests to determine specific corrosion resistance for the application being considered.

**Other Properties or Characteristics:** Deposits are able to take a high polish and have a low coefficient of friction and therefore are well suited for metal-to-metal wear resistance. Machining of these deposits is difficult; the difficulty increases in proportion to the increase in carbon content. CoCr-A alloys are preferably machined with sintered carbide tools. CoCr-C deposits are finished by grinding.

**Copper-Base Alloys.**—These metals are available in rod (RCuA1-A2, RCuA1-B, RCuA1-C, RCuA1-D, RCuA1-E, RCuSi-A, RCuSn, RCuSn-D, RCuSn-E, and RCuZn-E) and electrode (ECuA1-A2, ECuA1-B, ECuA1-C, ECuA1-D, ECuA1-E, ECuSi, ECuSn-A, ECuSn-C, ECuSn-E, and ECuZn-E) forms and are used in depositing overlays and inlays for bearing, corrosion-resistant, and wear-resistant surfaces. The CuA1-A2 rods and electrodes are used for surfacing bearing surfaces between the hardness ranges of 130 to 190 Bhn as well as for corrosion-resistant surfaces. The CuA1-B and CuA1-C rods and electrodes are used for surfacing bearing surfaces of hardness ranges 140 to 290 Bhn. The CuA1-D and CuA1-E rods and electrodes are used on bearing and wear-resistant surfaces requiring the higher hardnesses of 230 to 390 Bhn such as are found on gears, cams, wear plates, and dies. The copper-tin (CuSn) metals are used where a lower hardness is required for surfacing, for corrosion-resistant surfaces, and sometimes for wear-resistant applications.

**Hardness:** Hardness of a deposit depends upon the welding process employed and the manner of depositing the metal. Deposits made by the inert-gas metal-arc process (both consumable and nonconsumable electrode) will be higher in hardness than deposits made with the gas, metal-arc, and carbon-arc processes because lower losses of aluminum, tin, silicon, and zinc are achieved due to the better shielding from oxidation. Copper-base alloys are not recommended for use at elevated temperatures because their hardness and mechanical properties decrease consistently as the temperature goes above 400 degrees F.

**Resistance Properties:** The highest impact resistance of the copper-base alloy metals is exhibited by CuA1-A2 deposits. As the aluminum content increases, the impact resistance decreases markedly. CuSi weld deposits have good impact properties. CuSn metals as deposited have low impact resistance and CuZn-E deposits have a very low impact resistance. Deposits of the CuA1 filler metals form a protective oxide coating upon exposure to the atmosphere. Oxidation resistance of CuSi deposits is fair and that of CuSn deposits are comparable to pure copper. With the exception of the CuSn-E and CuZn-E alloys, these

metals are widely used to resist many acids, mild alkalies, and salt water. Copper-base alloy deposits are not recommended for use where severe abrasion is encountered in service. CuAl filler metals are used to overlay surfaces subjected to excessive wear from metal-to-metal contact such as gears, cams, sheaves, wear plates, and dies.

*Other Properties or Characteristics:* All copper-base alloy metals are used for overlays and inlays for bearing surfaces with the exception of the CuSi metals. Metals selected for bearing surfaces should have a Brinell hardness of 50 to 75 units below that of the mating metal surface. Slight porosity is generally acceptable in bearing service as a porous deposit is able to retain oil for lubricating purposes. CuAl deposits in compression have elastic limits ranging from 25,000 TO 65,000 lb/in.<sup>2</sup> and ultimate strengths of 120,000 to 171,000 lb/in.<sup>2</sup> The elastic limit and ultimate strength of CuSi deposits in compression are 22,000 lb/in.<sup>2</sup> and 60,000 lb/in.<sup>2</sup>, respectively. CuZn-E deposits in compression have an elastic limit of only about 5000 lb/in.<sup>2</sup> and an ultimate strength of 20,000 lb/in.<sup>2</sup> All copper-base alloy deposits can be machined.

**Nickel-Chromium-Boron Alloys.**—These metals are available in both rod (RNiCr) and electrode (ENiCr) form and their deposits have good metal-to-metal wear resistance, good low-stress, scratch-abrasion resistance, corrosion resistance, and retention of hardness at elevated temperatures. These properties make the alloys suitable for use on seal rings, cement pump screws, valves, screw conveyors, and cams. Three different formulations of these metals are recognized (NiCr-A, NiCr-B, and NiCr-C).

*Hardness:* Hardness of the deposited NiCr-A from rods range from 35 to 40 Rockwell C; of NiCr-B rods, 45 to 50 Rockwell C; of NiCr-C rods, 56 to 62 Rockwell C. Hardness of the deposited NiCr-A from electrodes ranges from 24 to 35 Rockwell C; of NiCr-B from electrodes, 30 to 45 Rockwell C; and of NiCr-C electrodes, 35 to 56. The lower hardness values and greater ranges of hardness values of the electrode deposits are attributed to the dilution of deposit and base metals. Hot Rockwell C hardness values of NiCr-A electrode deposits range from 30 to 19 in the temperature range from 600 to 1000 degrees F from instantaneous loading to a 3-minute loading interval. NiCr-A rod deposits range from 34 to 24 in the same temperature range and under the same load conditions. Hot Rockwell C hardness values of NiCr-B electrode deposits range from 41 to 26 in the temperature range from 600 to 1000 degrees F from instantaneous loading to a 3-minute loading interval. NiCr-B rod deposits range from 46 to 37 in the same temperature range and under the same load conditions. Hot Rockwell C hardness values of NiCr-C electrode deposits range from 49 to 31 in the temperature range from 600 to 1000 degrees F from instantaneous loading to a 3-minute loading interval. NiCr-C rod deposits range from 55 to 40 in the same temperature range and under the same load conditions.

*Resistance Properties:* Deposits of these metal alloys will withstand light impact fairly well. When plastic deformation occurs, cracks are more likely to appear in the NiCr-C deposit than in the NiCr-A and NiCr-B deposits. NiCr deposits are oxidation-resistant up to 1800 degrees F. Their use above 1750 degrees F is not recommended because fusion may begin near this temperature. NiCr deposits are completely resistant to atmospheric, steam, salt water, and salt spray corrosion and to the milder acids and many common corrosive chemicals. It is advisable to conduct field tests when a corrosion application is contemplated. These metals are not recommended for high-stress grinding abrasion. NiCr deposits have good metal-to-metal wear resistance, take a high polish under wearing conditions, and are particularly resistant to galling. These properties are especially evident in the NiCr-C alloy.

*Other Properties or Characteristics:* In compression, these alloys have an elastic limit of 42,000 lb/in.<sup>2</sup> Their yield strength in compression is 92,000 lb/in.<sup>2</sup> (0.01 per cent offset), 150,000 lb/in.<sup>2</sup> (0.10 per cent offset), and 210,000 lb/in.<sup>2</sup> (0.20 per cent offset). Deposits of NiCr filler metals may be machined with tungsten carbide tools using slow speeds, light

feeds, and heavy tool shanks. They are also finished by grinding using a soft-to-medium vitrified silicon carbide wheel.

**Chromium Plating.**—Chromium plating is an electrolytic process of depositing chromium on metals either as a protection against corrosion or to increase the surface-wearing qualities. The value of chromium-plating plug and ring gages has probably been more thoroughly demonstrated than any other single application of this treatment. Chromium-plated gages not only wear longer, but when worn, the chromium may be removed and the gage replated and reground to size.

In general, chromium-plated tools have operated well, giving greatly improved performance on nearly all classes of materials such as brass, bronze, copper, nickel, aluminum, cast iron, steel, plastics, asbestos compositions, and similar materials. Increased cutting life has been obtained with chromium-plated drills, taps, reamers, files, broaches, tool tips, saws, thread chasers, and the like. Dies for stamping, drawing, hot forging, die casting, and for molding plastics materials have shown greatly increased life after being plated with hard chromium.

Special care is essential in grinding and lapping tools preparatory to plating the cutting edges, because the chromium deposit is influenced materially by the grain structure and hardness of the base metal. The thickness of the plating may vary from 0.0001 to 0.001 or 0.002 inch, the thicker platings being used to build up undersize tools such as taps and reamers. A common procedure in the hard chromium plating of tools, as well as for parts to be salvaged by depositing chromium to increase diameters, is as follows:

- 1) Degrease with solvent; 2) Mount the tools on racks; 3) Clean in an anodic alkali bath held at a temperature of 82 degrees C for from 3 to 5 minutes; 4) Rinse in boiling water; 5) Immerse in a 20 per cent hydrochloric acid solution for 2 to 3 seconds; 6) Rinse in cold water; 7) Rinse in hot water; 8) Etch in a reverse-current chromic acid bath for 2 to 5 minutes; 9) Place work immediately in the chromium plating bath; and 10) Remove hydrogen embrittlement, if necessary, by immersing the plated tools for 2 hours in an oil bath maintained at 177 degrees C.

Chromium has a very low coefficient of friction. The static coefficient of friction for steel on chromium-plated steel is 0.17, and the sliding coefficient of friction is 0.16. This value may be compared with the static coefficient of friction for steel on steel of 0.30 and a sliding coefficient of friction of 0.20. The static coefficient of friction for steel on babbitt is 0.25, and the sliding coefficient of friction 0.20, whereas for chromium-plated steel on babbitt, the static coefficient of friction is 0.15, and the sliding coefficient of friction is 0.13. These figures apply to highly polished bearing surfaces. Articles that are to be chromium plated in order to resist frictional wear should be highly polished before plating so that full advantage can be taken of the low coefficient of friction that is characteristic of chromium. Chromium resists attack by almost all organic and inorganic compounds, except muriatic and sulfuric acids. The melting point of chromium is 2930 degrees F, and it remains bright up to 1200 degrees F. Above 1200 degrees F, a light adherent oxide forms and does not readily become detached. For this reason, chromium has been used successfully for protecting articles that must resist high temperatures, even above 2000 degrees F.

### **Electron-Beam (EB) Welding**

Heat for melting of metals in electron-beam welding is obtained by generating electrons, concentrating them into a beam, and accelerating them to between 30 and 70 per cent of the speed of light, using voltages between 25 and 200 kV. The apparatus used is called an electron-beam gun, and it is provided with electrical coils to focus and deflect the beam as needed for the welding operation. Energy input depends on the number of electrons impinging on the work in unit time, their velocity, the degree of concentration of the beam, and the traveling speed of the workpiece being welded. Some  $6.3 \times 10^{15}$  electrons/s are generated in a 1-mA current stream. With beam diameters of 0.01 to 0.03 in. (0.25 to 0.76

mm), beam power can reach 100 kW and power density can be as high as  $10^7$  W/in<sup>2</sup> ( $1.55 \times 10^4$  W/mm<sup>2</sup>), higher than most arc welding levels.

At these power densities, an electron beam can penetrate steel up to 4 in thick and form a vapor capillary or keyhole, as described earlier. Although patterns can be traced by deflecting the beam, the method used in welding is to move the electron gun or the workpiece. A numerical control, or computer numerical control, program is used because of the accuracy required to position the narrow beam in relation to the weld line.

Equipment is available for electron-beam welding under atmospheric pressure or at various degrees of vacuum. The process is most efficient (produces the narrowest width and deepest penetration welds) at high levels of vacuum, of the order of  $10^{-6}$  to  $10^{-3}$  torr or lower (standard atmospheric pressure is about 760 torr, or 760 mm of mercury), so that a vacuum chamber large enough to enclose the work is needed. Operation in a vacuum minimizes contamination of the molten weld material by oxygen and nitrogen. Gases produced during welding are also extracted rapidly by the vacuum pump so that welding of reactive metals is eased. However, the pumping time and the size of many workpieces restrict the use of high-vacuum enclosures.

At atmospheric pressures, scattering of the beam electrons by gas molecules is increased in relation to the number of stray molecules and the distance traveled, so that penetration depth is less and the beam spread is greater. In the atmosphere, the gun-to-work distance must be less than about 1.5 in. (38 mm). Electron-beam welding at atmospheric pressure requires beam-accelerating voltages above 150 kV, but lower values can be used with a protective gas. Helium is preferred because it is lighter than air and permits greater penetration. Argon, which is heavier than air and allows less penetration, can also be used to prevent contamination.

Required safety precautions, such as radiation shields to guard workers against the effects of X-rays when the electron beam strikes the work, are essential when electron-beam welding is done at atmospheric pressure. Such barriers are usually built into enclosures that are designed specifically for electron-beam welding in a partial vacuum. Adequate ventilation is also required to remove ozone and other gases generated when the process is used in the atmosphere.

Carbon, low-alloy, and stainless steels; high-temperature and refractory alloys; copper and aluminum alloys can be electron-beam welded, and single-pass, reasonably square, butt welds can be made in materials up to 1 in. (25.4 mm) thick at good speeds with nonvacuum equipment rated at 60 kW. Edges of thick material to be electron-beam welded require precision machining to provide good joint alignment and minimize the joint gap. Dissimilar metals usually may be welded without problems.

Because of the heat-sink effect, electron-beam welds solidify and cool very rapidly, causing cracking in certain materials such as low-ferrite stainless steel. Although capital costs for electron-beam welding are generally higher than for other methods, welding of large numbers of parts and the high welding travel rates make the process competitive.

### Pipe Welding

**Pipe Welding.**—Welding of (usually steel) pipe is commonly performed manually, with the pipe joint stationary, or held in a fixture whereby rotation can be used to keep the weld location in a fixed, downhand, position. Alternatively, pipe may need to be welded on site, without rotation, and the welder then has to exert considerable skill to produce a satisfactory, pressure-tight joint. Before welding stationary pipe, a welder must be proficient in welding in the four basic positions: 1G flat, 2G horizontal, 3G vertical and 4G overhead, depicted at the top in [Figs. 1a, 1b, 1c, and 1d](#).

## Positioning of Joint Components in Pipe Welding

Fig. 1a. Flat Position 1G

Fig. 1b. Horizontal Position 2G

Fig. 1c. Vertical Position 3G

Fig. 1d. Overhead Position 4G

Fig. 1e. Horizontal position 2G  
Pipe Axis VerticalFig. 1f. Position 5G  
Pipe Fixed, Axis HorizontalFig. 1g. Position 6G  
Pipe Fixed, Axis Inclined

At the bottom are shown pipe joints in three positions, the first of which, Fig. 1e, corresponds to the 2G horizontal (non-rotational) position in the upper row. The remaining two are respectively 5G, Fig. 1f, that represents pipe with the weld in a fixed vertical (non-rotational) position; and 6G, Fig. 1g, that typifies pipe to be welded at an angle and not rotated during welding.

For satisfactory pipe welding, consideration must be given to the chemical composition and thickness of the metal to be welded; selection of a suitable electrode material composition and size; determination of the current, voltage and wire feed rate to be used; preparation of the joint or edges of the pipes; and ways of holding the pipes in the positions needed while welding is carried out. High-quality tack welds, each about 1.5 inches (38 mm) long, and projecting about  $\frac{1}{16}$  inch (1.6 mm) beyond the inner wall of the pipe, are usually made to hold the parts of the assembly in position during welding.

SMAW (stick) welding was used almost exclusively for pipe welding until the advent of MIG welding with its potential for much greater rates of deposition. It cannot be emphasized too strongly that practices suitable for SMAW cannot be transferred to MIG welding, for which greater expertise is required if satisfactory welds are to be produced. MIG short-circuit, globular, and spray transfer, and pulsed MIG, with flux or metal-cored consumables (electrodes) can now all be used for pipe welding. Use of all-position, flux-cored, MIG consumables in particular, can reduce skill requirements, improve weld quality, and hold down costs in pipe welding.

Among the important items involved in the change to the MIG process is the automatic wire feeder. With today's wire feeding equipment, an increase of one increment on the dial, say from the 9 to the 10 o'clock position, can increase the wire feed rate by 70 in/min. As an example, such an increase could raise the weld current from 110 to 145 amps and the weld voltage from 16 to 17, resulting in an increase of 40 per cent in the energy supplied to the weld. Another vital parameter is the amount that the wire sticks out from the contact tip. In low-parameter, short-circuit welding, a small change in the wire stick-out can alter the energy supplied to the weld by 20 to 30 per cent.

*Root passes:* Whatever welding process is selected, the most important step in pipe welding, as in other types of welding, is the root pass, which helps to determine the degree of penetration of the weld metal, and affects the amount of lack of fusion in the finished weld. During the root pass, the action of the arc in the weld area should reshape the gap between

the adjacent sides of the joint into a pear-shaped opening, often called a "keyhole." As the work proceeds, this keyhole opening is continuously being filled, on the trailing side of the weld, by the metal being deposited from the electrode. The keyhole travels along with the weld so that the root pass produces a weld that penetrates slightly through the inner wall of the pipe.

MIG short-circuit root welding of carbon steel pipe requires a gap of  $\frac{5}{32} \pm \frac{1}{32}$  ( $4 \pm 0.8$  mm), between the ends of the pipe, and the width of the root faces (at the base of the bevels) should be  $\frac{1}{16}$  to  $\frac{3}{32}$  inch (1.6 to 2.4 mm). The recommended bevel angle for MIG pipe welding is 40E (80E included angle) and the maximum root gap is  $\frac{3}{16}$  inch (4.8 mm). The root pass in 1G welds should be made in the vertical-down direction with the electrode held between the 2 and 3 o'clock positions. When an 0.035-inch (0.9-mm) diameter E70S-3 MIG wire is used with the above root dimensions, weaving is not needed for the root pass except when welding over tack welds.

*Fill passes:* In welding carbon steel pipe in the 1G position with an 0.035-inch diameter electrode wire, MIG short circuit fill passes should use a minimum of 135 amps and be done in the vertical-up position. Fill passes should deposit a maximum thickness of no more than  $\frac{1}{8}$  inch (3.2 mm). Inclusion of CO<sub>2</sub> gas in the mixture will improve weld fusion. With flux-cored electrodes, the minimum amount of wire stick out is  $\frac{3}{4}$  inch (19 mm). Weld fusion can be improved in welding pipe of 0.4 inch (10 mm) wall thickness and thicker by preheating the work to a temperature between 400 and 500°F.

*Horizontal Pipe Welding:* In 1G welds (see Fig. 1a), the pipe should be rotated in the direction that moves the solidifying area away from the wire tip, to minimize penetration and resulting breakthrough. Welding of pipe in the 2G, horizontal position is made more difficult by the tendency for the molten metal to drip from the weld pool. Such dripping may cause an excessively large keyhole to form during the root-welding pass, and in subsequent passes electrode metal may be lost. Metal may also be lost from the edge of the upper pipe, causing an undercut at that side of the weld.

*Vertical-down welding:* With the pipe axis horizontal (as in the 5G position in Fig. 1f), vertical-down welding is usually started at the top or 12 o'clock location, and proceeds until the 6 o'clock location is reached. Welding then starts again at the 12 o'clock location and continues in the opposite direction until the 6 o'clock location is reached. Vertical-down welding is mainly used for thin-walled, low-carbon steel pipe of  $\frac{1}{8}$  to  $\frac{5}{16}$  inch (3.2 to 7.9 mm) wall thickness, which has low heat-retaining capacity so that the weld metal cools slowly, producing a soft and ductile structure. The slow rate of cooling also permits faster weld deposition, and, when several beads are deposited, causes an annealing effect that may refine the entire weld structure.

*Vertical-up welding:* In the 5G position, vertical-up welding normally begins at the 6 o'clock location and continues up to the 12 o'clock location, the weld then being completed by starting at the 6 o'clock location on the other side of the pipe and traversing up to the 12 o'clock location again. Vertical-up welding is more suited to pipe with thick walls and to alloy steels. However, the greater heat sink effect of the heavy-walled pipe may result in a faster cooling rate and embrittlement of the material, especially in alloy steels. The cooling rate can be reduced by slowing the rate of traverse and depositing a heavier bead of metal, both facilitated by welding in the vertical-up direction.

Using a thicker electrode and higher current for thicker-walled pipe to reduce the number of beads required may result in dripping from the molten puddle of metal. Defects such as pin holes, lack of fusion, and cold lap, may then appear in the weld. Vertical-up welding of pipe in the 5G, fixed, horizontal position, Fig. 1f, used for thick-walled pipe, is probably the most difficult for a welder, but once mastered will form the basis for other methods of pipe welding. Starting at the 6 o'clock location, the arc for the root pass is struck overhead, with the electrode at an angle of 5 to 10° from the vertical, on the joint, not on the tack weld.

A long arc should be maintained for a short-period while weaving the electrode to pre-heat the area ahead of the weld. Only small amounts of filler metal will be transferred while this long arc is maintained in the overhead position. The electrode tip is then advanced to establish the correct arc length and held in position long enough for the keyhole to form before starting to lay down the root bead, moving up toward the 12 o'clock location.

*Thin-wall pipe:* The optimum globular/spray parameters for welding rotated, (1G position) thin-wall pipe of less than 12 inch diameter are 0.035-inch electrode wire fed at 380 to 420 in/min with a protective gas mixture of argon 80 to 85, CO<sub>2</sub> 15 to 20 per cent, and current of 190 to 210 amps. These conditions will provide deposition rates of about 6 lb/hr (3 kg/hr).

**Use of Flux-cored Electrodes.**—Small diameter, flux cored electrodes developed in the eighties are still a rarity in many pipe welding shops, but flux cored welding can produce consistent, high-quality, low-cost welds on carbon steel or stainless pipe. Flux cored E71T-1, 0.035-inch (1 mm) diameter wire provides a continuous, medium energy, open arc, with a practical current range of 135 to 165 amps for welding pipe. This current range is similar to the optimum MIG short-circuit current range, and is 25 to 30 percent less current than the minimum open arc spray transfer current for an 0.035-inch diameter MIG wire.

In contrast to MIG short circuit welding, FCAW works with an open arc and no short circuits. The FCAW arc energy is continuous, and, in contrast to short-circuit transfer, provides increased weld fusion potential. The weld metal from the flux-cored tubular wire is transferred from the periphery and the center of the wire, resulting in broad coverage of the weld. The plasma in the flux cored arc is wider than MIG plasma, and the flux-cored arc is less focused and easier to control than the MIG spray arc.

Open arc, gas shielded, flux-cored welding can produce spray type transfer at lower currents than open arc MIG spray transfer. With FCAW, the current density is high because the electrode wire cross-sectional area is less than that of the same size MIG solid wire due to the central core of flux. This higher density provides for improved weld penetration potential. The FCAW process produces slag, which serves as a mold to hold the fluid molten metal in place, an ideal arrangement for vertical-up and overhead welds.

All position, flux-cored wires require less operator skill for vertical-up and overhead welds than MIG, SMAW, and TIG processes. Fill passes can also be completed in 30 to 50 percent less time with all-position, flux-cored wires than with MIG short circuit and SMAW wires.

For good quality FCAW, welders need to know the best root and bevel dimensions, and the importance of maintaining those dimensions for continuous weld fusion; the preferred direction of pipe rotation; the diameter of flux cored electrode best suited for welding thin wall pipe; the optimum parameter range for that electrode on 1G and 5G welds; the preferred amount of wire stick out (typically 0.7 inch or 18 mm); and how to fine tune the voltage. When flux-cored welding is to be used for the fill passes, MIG short circuit welding is recommended for the root welds to reduce the possibility of slag from the flux being trapped in the weld. Higher weld deposit rates are provided with flux-cored, vertical-up welding, and there is the temptation to weld faster with a process that's easy to use. Conservative wire feed settings are recommended unless the high deposition rates are shown to provide consistent weld fusion. Wire feed settings should allow the welder time to control and direct the weave into the critical groove locations.

**Complete Weld Fusion.**—It is essential that new weld metal deposits be completely fused with the pipe components, and with metal laid down in successive passes. Factors that can prevent complete fusing are too numerous to list here. Some basic rules that, if followed, will improve weld fusion and quality in MIG welding in the 1G and 5G positions are:

- 1) The maximum gap at the root should be  $\frac{3}{16}$  inch (5 mm)
- 2) The root land should be  $\frac{1}{16}$  to  $\frac{3}{32}$  inch (1.6 to 2.4 mm) wide

- 3) A bevel angle of 80° inclusive should be used for MIG and flux-cored welding of pipe to provide width for weaving and improve fusion.
- 4) An 0.035-in MIG electrode should have a minimum short circuit current of 135 amps for fill passes
- 5) Tack and root welds should be made in the vertical-down position.
- 6) Tack welds should be about 1.5 in (38 mm) long by  $\frac{1}{16}$  to  $\frac{3}{32}$  inch (1.6 to 2.4 mm) thick.
- 7) Short circuit fill passes should be made in the vertical-up position.
- 8) With flux-cored electrodes, a minimum of 0.7 inch (18 mm) wire stick out from the contact tip must be maintained.
- 9) Current and voltage must be related to the pipe wall thickness
- 10) Argon+25 per cent CO<sub>2</sub> is recommended for short circuit welding of pipe roots.
- 11) Use of undiluted CO<sub>2</sub> gas will improve MIG weld fusion in fill passes because of the "digging" action of the arc, and the increased weld energy
- 12) With pipe wall thicknesses of 0.4 in (10 mm) or greater, preheating to between 400 and 500° F (205 and 260°C), will help make fusion complete

**Other Methods.**—Pulsed MIG is a viable alternative to flux-cored for all-position welds on 5G pipe, but requires more costly equipment. The pulsed MIG process however, has few advantages over conventional MIG and flux-cored when the latter are used correctly. Pulsed MIG may have some advantage on mechanized 5G welds, and on welding of stainless steel, pipe in the 5G position.

Metal-cored electrode wire also has few advantages for pipe welds because they work best with low-energy gas welds, which cancels out the increased current density claimed for them.

On most manual pipe welds, the welder needs time to control and direct the weave to ensure even heating and avoid lack of fusion. Satisfactory welds are often performed at travel speeds of 4 to 12 in/min giving deposit rates of 3 to 5 lb/hr.

### Pipe Welding Procedure

Because of the variety of parameter combinations that can be used in pipe welding, it is suggested that charts be prepared and displayed in welding booths to remind welders of the basic settings to be used. Examples of such charts for tack, root, fill and cover passes, are included in what follows:

**FCAW 5G (Non-rotated) MIG Welding of Thick-Walled, Carbon-steel Pipes, Procedure for Root Welding.**—This procedure can be applied to most pipe sizes, and should be given special consideration for 5G (non-rotated) welds on carbon steel pipe with  $\frac{3}{8}$  inch (10 mm) wall thickness and thicker.

#### Pipe and Weld Data

Pipe bevel included angle = 80°

Root face land =  $\frac{3}{32} \pm \frac{1}{32}$  inch (2.4 ± 0.8 mm)

Root gap between faces =  $\frac{5}{32} \pm \frac{1}{32}$  inch (4 ± 0.8 mm)

Electrode for root weld = 0.035-inch (0.9 mm) diameter, E70S-3 flux-cored.

Gas = argon with 15–25% CO<sub>2</sub>

Gas flow rates = 30 to 40 cubic ft/hr

Set wire feeder to 210–280 in/min (10 to 11 o'clock position on many feeders) for current of 140–170 amps, 17–18 volts.

**Wire extension:** For MIG root weld, set contact tip to stick outside the nozzle,  $\frac{1}{16}$  to  $\frac{1}{8}$  inch (1.6 to 3 mm). Maintain  $\frac{3}{8}$  to  $\frac{5}{8}$  inch (10 to 16 mm) maximum wire stick out from contact tip.

*Tack Welding Procedures for FCAW 5G Pipe Welds:* Make tack welds 1.5 to 2 inches (38 to 50 mm) long. After welding, grind full length of tack to thickness of approximately  $\frac{1}{16}$  inch (1.6 mm). Feather tack ends back  $\frac{3}{8}$  to  $\frac{1}{2}$  inches (9.5 to 13 mm).

On pipes of less than 6 inches (15 cm) outside diameter, use three tack welds, equally spaced, starting at 12 o'clock.

On pipes over 6 inches outside diameter use 4 tack welds. Locate tack welds at 12, 3, 6, and 9 o'clock.

*Root Welding Procedures for FCAW 5G Pipe Welds:* Root weld MIG vertical-down. Weld sequence: 12 to 3, 9 to 6, 3 to 6, and 12 to 9 o'clock positions.

Start and finish MIG root welds at tack centers. Use slight weave oscillation over tacks. No weave necessary if  $\frac{1}{8}$ - to  $\frac{5}{32}$ -inch root gap is maintained. Weaving may be required if root gap is less than  $\frac{1}{8}$  inch (3 mm). Weaving is also beneficial for root welds between 7 and 6 o'clock, and between 5 and 6 o'clock. After each root pass, blend the starts and stops back to the original tack thickness.

To complete the root, ensure that the weld stops and starts on the last tack, and that the root weld center is ground flat or slightly concave. Remove any slag islands.

**FCAW 5G (Non-rotated) MIG Welding of Thick-Walled, Carbon-steel Pipes, Procedure for Fill and Cover Welds.**—This procedure can be applied to most common pipe sizes, and should be given special consideration for 5G (non-rotated) welds on carbon steel pipe with  $\frac{3}{8}$  inch (10 mm) wall thickness and thicker.

#### *Pipe and Weld Data*

*Electrode for fill and cover passes* = 0.035 inch (0.9 mm) diameter, 71T-1 flux-cored

*Gas* = argon with 15–25% CO<sub>2</sub>

*Gas flow rates* = 30 to 40 cubic ft/hr

Set an initial wire feed rate of 350 to 450 in/min (12 to 1 o'clock position on typical wire feed unit), 135–165 amps, 25–28 volts. Alternatively, use a wire feed setting of 350 in/min (12 o'clock on wire feed unit), which should result in about 135–145 amps, 25–26 volts. If the weld pool and weld heat build up permit, increase the wire feed rate to 380 in/min (between the 12 and 1 o'clock positions), 150 amps, 27 volts. Try also a wire feed setting of 420 in/min (1 o'clock on the wire feeder), 165 amps, 28 volts. Determine the low and maximum wire feed rates to be used by examination of the weld fusion obtained in sectioned test samples.

*Wire extension:* Adjust contact tip so it is recessed  $\frac{1}{2}$  inch within the nozzle to provide a total wire stick out from the contact tip of 0.7 to 1 inch (18 to 25 mm).

*Fill and Cover Pass Procedures for FCAW 5G Pipe Welds:* Weld vertical-up. If the pipe diameter allows the fill pass to be made in two passes, start at the 7 o'clock position and weld to the 1 o'clock position. This approach is preferable to starting and finishing on the root tacks. Starting at the 7 o'clock position will ensure that optimum weld energy is achieved as the first pass welds over the initial 6 o'clock root tack location. Use the grinder to feather the first 1 inch (25 mm) of the weld start and stop of the first pass, before applying the second vertical-up weld pass. Use a slight weave action for the fill pass.

Remove all flux-cored slag between weld passes. Make sure no fill pass is greater in depth than  $\frac{1}{8}$  inch (3 mm). Use a straight weave across the root face. At the bevel edge use a slight upward motion with the gun. The motion should be no greater than the wire diameter. Then use a slight back step for added bevel fusion and to avoid undercuts.

Leave  $\frac{1}{32}$  to  $\frac{1}{16}$  inch (0.8 to 1.6 mm) of the groove depth to provide for the optimum cover pass profile. The bevel edge will act as a guide for the cover pass weld. If more weld fusion is required for pipe thicker than  $\frac{3}{8}$  inch (10 mm), after the root weld is complete, preheat the

pipe to between 400 and 600°F (200–300°C) before welding. Preheating is typically not necessary for a cover pass.

For pipe diameters on which the welder needs more than two passes for the vertical-up welds, the recommended sequence for vertical-up welding is:

- 1) First pass, weld from the 7 to the 4 o'clock position. Start with a slight forehand nozzle angle. At the 4 o'clock position, the gun should be at the same angle as the pipe.
- 2) Second pass, weld from the 10 to the 1 o'clock position, then grind all stops and start again at the 1-inch (25 mm) position.
- 3) Third pass, weld from the 4 to the 1 o'clock position.
- 4) Fourth pass, weld from the 7 to the 10 o'clock position.

**FCAW 5G (Non-rotated) Welding of Thin-Walled Carbon Steel Pipes, Procedure for Root, Fill and Cover Pass Welding.**—This procedure can be applied to most common pipe sizes, and should be given special consideration for 5G (non-rotated) welding of carbon steel pipe with wall thicknesses up to  $\frac{3}{8}$  inch (10 mm).

*Pipe and Weld Data*

*Electrode for root weld* = 0.035 inch diameter, E70S-6 flux cored.

*Gas* = argon with 15–25% CO<sub>2</sub>

*Gas flow rates* = 30 to 40 cubic ft/hr

*Root Welding Procedure for 5G Welds:* Use root welding data from *Root Welding Procedures for FCAW 5G Pipe Welds*, above.

*Fill and Cover Pass Procedures for 5G Welds:* Use MIG short-circuit, vertical-up for fill and cover passes. Electrode wire and gas, same as for root weld.

Weld vertical-up. If the vertical-up fill pass can be made in two passes, weld from the 7 to the 1 o'clock position, to avoid starting and finishing on the root tacks. Starting just past 6 o'clock ensures that optimum weld energy is achieved as the first pass welds over the initial 6 o'clock root tack location. Feather 1 inch (25 mm) of the weld start and stop on the first pass with the grinder before applying the second vertical-up weld pass. Use a slight weave action.

Use MIG short-circuit wire feed, 200–230 in/min 125–135 amps, 19–22 volts. Start at optimum 210 in/min (10 o'clock on the wire feeder) for 130 amps, 21–22 volts. Fine tune voltage by listening to arc sound to obtain a consistent rapid crackle sound.

Electrode sticks out  $\frac{1}{2}$  to  $\frac{5}{8}$  inch, contact tip flush with nozzle end.

Remove MIG surface slag islands between weld passes. No fill pass should be thicker than  $\frac{1}{8}$  inch (3 mm). Use straight weave across the root face. At the bevel, use a slight upward motion with the gun. The motion should be no greater than the wire diameter. Then use a slight back step for added bevel fusion and to avoid possibility of undercut.

For the cover pass, leave  $\frac{1}{32}$  to  $\frac{1}{16}$  inch of the groove depth for the optimum cover pass profile. The bevel edge will act as a guide for the cover pass weld.

If more weld fusion is required after the root is complete and between fill passes, pre-heat pipe to 200 to 400°F.

For pipe diameters on which more than two passes are required for the circumference the weld sequence is:

- 1) First pass, weld from the 7 to the 4 o'clock position. Start with a slight forehand nozzle angle. At the 4 o'clock position the gun should point straight at the joint;
- 2) Second pass, weld from the 10 to the 1 o'clock position, then grind all stops and starts for at least 1 inch (25 mm);
- 3) Third pass, weld from the 4 to the 1 o'clock position; and
- 4) Fourth pass, weld from the 7 to the 10 o'clock position.

## Weld and Welding Symbols

**American National Standard Weld and Welding Symbols.**—Graphical symbols for welding provide a means of conveying complete welding information from the designer to the welder by means of drawings. The symbols and their method of use (examples of which are given in the table following this section) are part of the American National Standard ANSI/AWS A2.4-79 sponsored by the American Welding Society.

In the Standard a distinction is made between the terms *weld symbol* and *welding symbol*. Weld symbols, shown in the table *Basic Weld Symbols*, are ideographs used to indicate the type of weld desired, whereas welding symbol denotes a symbol made up of as many as eight elements conveying explicit welding instructions.

The eight elements which may appear in a welding symbol are: reference line; arrow; basic weld symbols; dimensions and other data; supplementary symbols; finish symbols; tail and specification; and process or other reference.

The standard location of elements of a welding symbol are shown in Fig. 1.

Fig. 1. Standard Location of Elements of a Welding Symbol

**Reference Line:** This is the basis of the welding symbol. All other elements are oriented with respect to this line. The arrow is affixed to one end and a tail, when necessary, is affixed to the other.

**Arrow:** This connects the reference line to one side of the joint in the case of groove, fillet, flange, and flash or upset welding symbols. This side of the joint is known as the *arrow side* of the joint. The opposite side is known as the *other side* of the joint. In the case of plug, slot, projection, and seam welding symbols, the arrow connects the reference line to the outer surface of one of the members of the joint at the center line of the weld. In this case the member to which the arrow points is the *arrow side* member; the other member is the *other side* member. In the case of bevel and J-groove weld symbols, a two-directional arrow pointing toward a member indicates that the member is to be chamfered.

**Basic Weld Symbols:** These designate the type of welding to be performed. The basic symbols which are shown in the table *Basic Weld Symbols* are placed approximately in the

center of the reference line, either above or below it or on both sides of it as shown in Fig. 1. Welds on the arrow side of the joint are shown by placing the weld symbols on the side of the reference line towards the reader (lower side). Welds on the other side of the joint are shown by placing the weld symbols on the side of the reference line away from the reader (upper side).

**Supplementary Symbols:** These convey additional information relative to the extent of the welding, where the welding is to be performed, and the contour of the weld bead. The “weld-all-around” and “field” symbols are placed at the end of the reference line at the base of the arrow as shown in Fig. 1 and the table *Supplementary Weld Symbols*.

**Dimensions:** These include the size, length, spacing, etc., of the weld or welds. The size of the weld is given to the left of the basic weld symbol and the length to the right. If the length is followed by a dash and another number, this number indicates the center-to-center spacing of intermittent welds. Other pertinent information such as groove angles, included angle of countersink for plug welds and the designation of the number of spot or projection welds are also located above or below the weld symbol. The number designating the number of spot or projection welds is always enclosed in parentheses.

**Contour and Finish Symbols:** The contour symbol is placed above or below the weld symbol. The finish symbol always appears above or below the contour symbol (see Fig. 1).

The following finish symbols indicate the method, not the degrees of finish: C—chipping; G—grinding; M—machining; R—rolling; and H—hammering.

For indication of surface finish refer to the section *SURFACE TEXTURE* starting on page 724.

**Tail:** The tail which appears on the end of the reference line opposite to the arrow end is used when a specification, process, or other reference is made in the welding symbol. When no specification, process, or other reference is used with a welding symbol, the tail may be omitted.

**Table 1. Basic Weld Symbols**

| Groove Weld Symbols |                    |                    |       |                 |           |         |             |
|---------------------|--------------------|--------------------|-------|-----------------|-----------|---------|-------------|
| Square              | Scarf <sup>a</sup> | V                  | Bevel | U               | J         | Flare V | Flare bevel |
|                     |                    |                    |       |                 |           |         |             |
| Other Weld Symbols  |                    |                    |       |                 |           |         |             |
| Fillet              | Plug or slot       | Spot or projection | Seam  | Back or backing | Surfacing | Flange  |             |
|                     |                    |                    |       |                 |           | Edge    | Corner      |
|                     |                    |                    |       |                 |           |         |             |

<sup>a</sup>This scarf symbol used for brazing only (see page 1388).

For examples of basic weld symbol applications see starting on page 1436.

Table 2. Supplementary Weld Symbols

| Weld all around | Field weld | Melt-thru | Backing or spacer material | Countour |        |         |
|-----------------|------------|-----------|----------------------------|----------|--------|---------|
|                 |            |           |                            | Flush    | Convex | Concave |
|                 |            |           |                            |          |        |         |

**Melt-Thru Symbol:** The melt-thru symbol is used only where 100 per cent joint or member penetration plus reinforcement are required.

**Specification, Process, or Other Designation:** These are placed in the tail of the welding symbol and are in accordance with the American National Standard. They do not have to be used if a note is placed on the drawing indicating that the welding is to be done to some specification or that instructions are given elsewhere as to the welding procedure to be used.

**Letter Designations:** American National Standard letter designations for welding and allied processes are shown in the table on page 1435.

**Further Information:** For complete information concerning welding specification by the use of standard symbols, reference should be made to American National Standard ANSI/AWS A2.4-79, which may be obtained from either the American National Standards Institute or the American Welding Society listed below.

**Welding Codes, Rules, Regulations, and Specifications.**—Codes recommending procedures for obtaining specified results in the welding of various structures have been established by societies, institutes, bureaus, and associations, as well as state and federal departments.

The latest codes, rules, etc., may be obtained from these agencies, whose names and addresses are listed as follows: PV = Pressure Vessels; P = Piping; T = Tanks; SB = Structural and Bridges; S = Ships; AC = Aircraft Construction; and EWM = Electrical Welding Machinery.

## Application of American National Standard Welding Symbols

| Desired Weld  | Symbol  | Symbol Meaning  |
|---|---|---|
|    |    | Symbol indicates fillet weld on <i>arrow side</i> of the joint.   |
|    |    | Symbol indicates square-groove weld on <i>other side</i> of the joint.  |
|    |    | Symbol indicates bevel-groove weld on both sides of joint. Breaks in arrow indicate bevels on upper member of joint. Breaks in arrows are used on symbols designating bevel and J-groove welds.   |
|   |   | Symbol indicates plug weld on <i>arrow side</i> of joint.   |
|  |  | Symbol indicates resistance-seam weld. Weld symbol appears on both sides of reference line pointing up the fact that <i>arrow</i> and <i>other side</i> of joint references have no significance. |
|   |  | Symbol indicates electron beam seam weld on <i>other side</i> of joint.   |

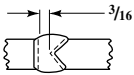

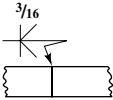

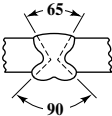

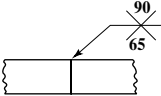

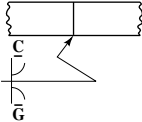

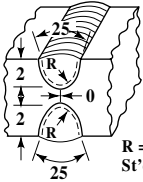

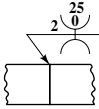

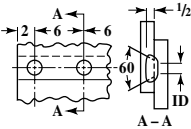

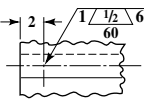

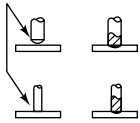

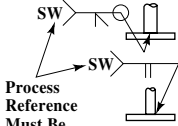

## Application of American National Standard Welding Symbols (Continued)

| Desired Weld   | Symbol  | Symbol Meaning   |
|--|---|--|
| <p>Groove Weld Made Before Welding Other Side</p>  <p>Back Weld</p> |                                        | <p>Symbol indicates single-pass back weld.</p>   |
|    |                                        | <p>Symbol indicates a built-up surface <math>\frac{1}{8}</math> inch thick.</p>  |
|   |                                        | <p>Symbol indicates a bead-type back weld on the <i>other side</i> of joint, and a J-groove grooved horizontal member (shown by break in arrow) and fillet weld on <i>arrow side</i> of the joint.</p> |
|   |                                       | <p>Symbol indicates two fillet welds, both with <math>\frac{1}{2}</math>-inch leg dimensions.</p>  |
|   |                                      | <p>Symbol indicates a <math>\frac{1}{2}</math>-inch fillet weld on <i>arrow side</i> of the joint and a <math>\frac{1}{4}</math>-inch fillet weld on <i>far side</i> of the joint.</p>                 |
|   |  <p>Orientation Shown on Drawing</p> | <p>Symbol indicates a fillet weld on <i>arrow side</i> of joint with <math>\frac{1}{4}</math>- and <math>\frac{1}{2}</math>-inch legs. Orientation of legs must be shown on drawing.</p>               |

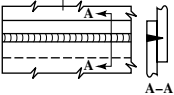

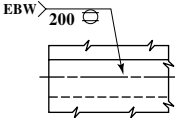

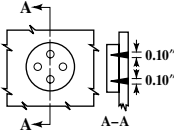

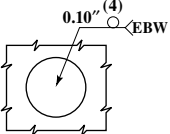

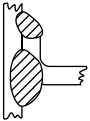

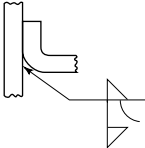

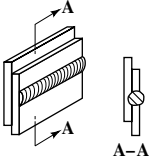

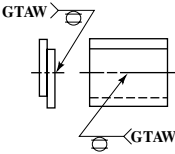

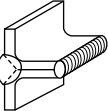

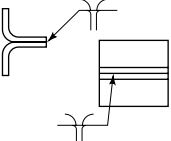

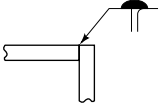

Application of American National Standard Welding Symbols (Continued)

| Desired Weld  | Symbol  | Symbol Meaning   |
|---|---|--|
|    |    | <p>Symbol indicates a 24-inch long fillet weld on the <i>arrow side</i> of the joint.</p>  |

### Nondestructive Testing

Nondestructive testing (NDT) is aimed at examination of a component or assembly, usually for surface or internal cracks or other nonhomogeneities, to determine the structure, or to measure thickness, by some means that will not impair its use for the intended purpose. Traditional methods include use of radiography, ultrasonic vibration, dye penetrants, magnetic particles, acoustic emission, leakage, and eddy currents. These methods are simple to use but some thought needs to be given to their application and to interpretation of the results. Space limitations preclude a full discussion of NDT here, but the nature of the welding process makes these methods particularly useful, so some information on use of NDT for testing welds is given below.

**Nondestructive Testing Symbol Application.**—The application of nondestructive testing symbols is also covered in American National Standard ANSI/AWS A2.4-79.

*Basic Testing Symbols:* These are shown in the following table.

**ANSI Basic Symbols for Nondestructive Testing ANSI/AWS A2.4-79**

| Symbol | Type of Test         | Symbol | Type of Test |
|--------|----------------------|--------|--------------|
| AET    | Acoustic Emission    | PT     | Penetrant    |
| ET     | Eddy Current         | PRT    | Proof        |
| LT     | Leak                 | RT     | Radiographic |
| MT     | Magnetic Particle    | UT     | Ultrasonic   |
| NRT    | Neutron Radiographic | VT     | Visual       |

*Testing Symbol Elements:* The testing symbol consists of the following elements: Reference Line, Arrow, Basic Testing Symbol, Test-all-around Symbol, (N) Number of Tests, Test in Field, Tail, and Specification or other reference.

The standard location of the testing symbol elements are shown in the following figure.

Locations of Testing Symbol Elements

The arrow connects the reference line to the part to be tested. The side of the part to which the arrow points is considered to be the *arrow side*. The side opposite the arrow side is considered to be the *other side*.

*Location of Testing Symbol:* Tests to be made on the arrow side of the part are indicated by the basic testing symbol on the side of the reference line toward the reader.

Tests to be made on the other side of the part are indicated by the basic testing symbol on the side of the reference line away from the reader.

To specify where only a certain length of a section is to be considered, the actual length or percentage of length to be tested is shown to the right of the basic test symbol. To specify the number of tests to be taken on a joint or part, the number of tests is shown in parentheses.

Tests to be made on both sides of the part are indicated by test symbols on both sides of the reference line. Where nondestructive symbols have no arrow or other significance, the testing symbols are centered in the reference line.

*Combination of Symbols:* Nondestructive basic testing symbols may be combined and nondestructive and welding symbols may be combined.

*Direction of Radiation:* When specified, the direction of radiation may be shown in conjunction with the radiographic or neutron radiographic basic testing symbols by means of a radiation symbol located on the drawing at the desired angle.

*Tests Made All Around the Joint:* To specify tests to be made all around a joint a circular test-all-around symbol is used.

*Areas of Revolution:* For nondestructive testing of areas of revolution, the area is indicated by the test-all-around symbol and appropriate dimensions.

*Plane Areas:* The area to be examined is enclosed by straight broken lines having a small circle around the angle apex at each change in direction.

## LASERS

### Introduction

Lasers are used for cutting, welding, drilling, surface treatment, and marking. The word laser stands for Light Amplification by Stimulated Emission of Radiation, and a laser is a unit that produces optical-frequency radiation in intense, controllable quantities of energy. When directed against the surface of a material, this quantity of energy is high enough to cause a localized effect. Heating by a laser is controlled to produce only the desired result in a specific area, ensuring low part distortion.

The four basic components of a laser, shown in Fig. 1, are an amplifying medium, a means to excite this medium, mirrors arranged to form an optical resonator, and an output transmission device to cause beam energy to exit from the laser. The laser output wavelength is controlled by the type of amplifying medium used. The most efficient industrial lasers use optical excitation or electrical discharge to stimulate the medium and start the lasing action.

Solid-state lasers, in which the medium is a solid crystal of an optically pure material such as glass or yttrium aluminum garnet (YAG) doped with neodymium (Nd), are excited by a burst of light from a flashlamp(s) arranged in a reflective cavity that acts to concentrate the excitation energy into the crystal. Neodymium lasers emit radiation at  $1.06\ \mu\text{m}$  ( $1\ \mu\text{m} = 0.00004\ \text{in.}$ ), in the near infrared portion of the spectrum.

The carbon dioxide ( $\text{CO}_2$ ) laser uses a gaseous mixture of helium, nitrogen, and carbon dioxide. The gas molecules are energized by an electric discharge between strategically placed cathodes and anodes. The light produced by  $\text{CO}_2$  lasers has a wavelength of approximately  $10.6\ \mu\text{m}$ .

**Laser Light.**—The characteristics of light emitted from a laser are determined by the medium and the design of the optical resonator. Photons traveling parallel to the optical axis are amplified and the design provides for a certain portion of this light energy to be transmitted from the resonator. This amplifier/resonator action determines the wavelength and spatial distribution of the laser light.

The transmitted laser light beam is monochromatic (one color) and coherent (parallel rays), with low divergence and high brightness, characteristics that distinguish coherent laser light from ordinary incoherent light and set the laser apart as a beam source with high energy density. A typical industrial laser operating in a very narrow wavelength band determined by the laser medium is called monochromatic because it emits light in a specific segment of the optical spectrum. The wavelength is important for beam focusing and material absorption effects.

Coherent laser light can be 100,000 times higher in energy density than equivalent-power incoherent light. The most important aspect of coherent light for industrial laser applications is directionality, which reduces dispersion of energy as the beam is directed over comparatively long distances to the workpiece.

**Laser Beams.**—The slight tendency of a laser beam to expand in diameter as it moves away from its source is called beam divergence, and is important in determining the size of the spot where it is focused on the work surface. The beam-divergence angle for high-power lasers used in processing industrial materials is larger than the diffraction-limited value because the divergence angle tends to increase with increasing laser output power. The amount of divergence thus is a major factor in concentration of energy in the work.

The power emitted per unit area per unit solid angle is called brightness. Because the laser can produce very high levels of power in very narrowly collimated beams, it is a source of high brightness energy. This brightness factor is a major characteristic of solid-state lasers. Other important beam characteristics in industrial lasers include spatial mode and depth of focus. Ideally, the output beam of the laser selected should have a mode structure, divergence, and wavelength sufficient to process the application in optimum time and

with a minimum of heat input. A beam-quality factor,  $M^2$ , is commonly used to define the productive performance of a laser. This factor is a measure of the ratio between the spot diameter of a given laser to that of a theoretically perfect beam. Beam quality is expressed as “times diffraction” and is always greater than 1. For CO<sub>2</sub> lasers at the 1-kW level,  $M^2 = 1.5$ , and for YAG lasers at 500 W,  $M^2 = 12.0$  is typical.

The mode of a laser beam is described by the power distribution profile over its cross-section. Called transverse modes, these profiles are represented by the term TEM<sub>*m*,*n*</sub>, where TEM stands for transverse electromagnetic, and *m* and *n* are small integers indicating that power distribution is bell-shaped (Gaussian) TEM<sub>00</sub>, or donut-shaped TEM<sub>01</sub>\*.

Fig. 1. Basic Components of a Laser

Fig. 2. Spatial Intensity Distribution in Laser Beams

Fig. 2 shows various transverse electromagnetic modes commonly used in materials processing applications. For such applications, it is helpful to determine the peak and total power generated by the laser. Diffraction in Gaussian beams is inherently limited and other modes of operation may have larger beam-divergence angles, causing less power to be delivered to the workpiece. The selection process for industrial applications should consider only those lasers that produce the lowest-order mode beam, in a Gaussian-shaped energy profile (see Fig. 2), with a narrow beam divergence. Solid-state lasers do not meet all these criteria, and with high-power CO<sub>2</sub> lasers, it is sometimes necessary to compromise because of reduced output power, large physical size, and complexity of the laser design.

Although a laser with a TEM<sub>00</sub> output beam is preferred for optimum performance, the application may not always require such a beam. For example, many CO<sub>2</sub> laser cutting operations are performed with a TEM<sub>01</sub>\* beam and welding is often done with a mixture of each of these modes. Lasers can be operated in three temporal modes, continuous wave (CW), pulsed, and superpulsed (called Q-switched for YAG lasers), depending on the materials being processed.

The smallest focused spot diameter that will provide the highest energy intensity can be produced by a TEM<sub>00</sub> laser. The fundamental mode output of CO<sub>2</sub> lasers is limited to 2500 watts. Complex spatial patterns are often caused by inhomogeneities in solid-state laser crystals and are controlled by insertion of apertures that greatly reduce output power. However, standard lasers suit the needs of most industrial users as beam divergence is only one factor in laser design.

**Beam Focusing.**—The diameter of a focused laser beam spot can be estimated by multiplying the published beam divergence value by the focal length of the lensor by the relationship of the wavelength to the unfocused beam diameter. Thus, the beam from a CO<sub>2</sub>

laser operating at a 10.6- $\mu\text{m}$  wavelength, using the same focal length lens, will produce a focused spot ten times larger than the beam from a Nd:YAG laser operating at a 1.06- $\mu\text{m}$  wavelength.

$$\text{Spot Diameter, } d = f\theta = 4\lambda F/\pi D$$

$$\text{Power Density, } H = 4P/d^2$$

$$\text{Depth of Focus, } Z = \pm d^2/4\lambda$$

Fig. 3. Focus Characteristics of a Laser Beam.

Fig. 4. Typical Laser Systems.

Effects of various beam spot sizes and depths of focus are shown in Fig. 3. High-power density is required for most focused beam applications such as cutting, welding, drilling, and scribing, so these applications generally require a tightly focused beam. The peak power density of a Gaussian beam is found by dividing the power at the workpiece by the area of the focused spot. Power density varies with the square of the area, so that a change in the focused spot size can influence power density by a factor of 4 and careful attention must be given to maintaining beam focus.

Another factor of concern in laser processing is depth of focus, defined as the range of depth over which the focused spot varies by  $\pm 5$  per cent. This relationship is extremely important in cutting sheet metal, where it is affected by variations in surface flatness. Cutting heads that adapt automatically to maintain constant surface-to-nozzle spacing are used to reduce this effect.

**Types of Industrial Lasers.**—Specific types of lasers are suited to specific applications, and Fig. 1 lists the most common lasers used in processing typical industrial materials. Solid-state lasers are typically used for drilling, cutting, spot and seam welding, and marking on thin sheet metal. CO<sub>2</sub> lasers are used to weld, cut, surface treat, and mark both metals and nonmetals. For example, CO<sub>2</sub> lasers are suited to ceramic scribing and Nd:YAG lasers for drilling turbine blades. Factors that affect suitability include wavelength, power density, and spot size. Some applications can use more than one laser type. Cutting sheet metal, an established kilowatt-level CO<sub>2</sub> laser application, can also be done with kilowatt-level Nd:YAG lasers. For some on-line applications that require multiaxis beam motion, the Nd:YAG laser may have advantages in close coupling the laser beam to the workpiece through fiber optics.

Table 1. Common Industrial Laser Applications

| Type            | Wavelength ( $\mu\text{m}$ ) | Operating Mode | Power Range (watts) | Applications  |
|-----------------|------------------------------|----------------|---------------------|---------------|
| Nd:YAG          | 1.06                         | Pulsed         | 10–2,000            | A, B, D, E, F |
| Nd: YAG         | 1.06                         | Continuous     | 500–3,000           | A, B, C       |
| Nd: YAG         | 1.06                         | Q-switched     | 5–150               | D, E, F       |
| CO <sub>2</sub> | 10.6                         | Pulsed         | 5–3,000             | A, B, D, E    |
| CO <sub>2</sub> | 10.6                         | Superpulsed    | 1,000–5,000         | A             |
| CO <sub>2</sub> | 10.6                         | Continuous     | 100–25,000          | A, B, C       |

Applications: A = cutting, B = welding, C = surface treatment, D = drilling, E = marking, F = micro-machining.

**Industrial Laser Systems.**—The laser should be located as close as possible to the workpiece to minimize beam-handling problems. Ability to locate the beam source away from

its power supply and ancillary equipment, and to arrange the beam source at an angle to the workpiece allows the laser to be used in many automatic and numerically controlled set ups. Fig. 4 shows typical laser system arrangements.

Lasers require power supplies and controllers for lasers are usually housed in industrial grade enclosures suited to factory floor conditions. Because the laser is a relatively inefficient converter of electrical energy to electromagnetic energy (light), the waste heat from the beam source must be removed by heat exchangers located away from the processing area. Flowing gas CO<sub>2</sub> lasers require a source of laser gas, used to make up any volume lost in the normal recycling process. Gas can be supplied from closely linked tanks or piped from remote bulk storage.

Delivery of a high-quality beam from the laser to the workpiece often requires sub-systems that change the beam path by optical means or cause the beam to be directed along two or more axes. Five-axis beam motion systems, for example, using multiple optical elements to move the beam in X, Y, Z, and rotation/tilt, are available.

Solid-state laser beams can be transmitted through flexible optical fibers. If there is no beam motion, the workpiece must be moved. The motion systems used can be as simple as an XY or rotary table, or as complex as a multistation, dual-feed table. Hybrid systems offer a combination of beam and workpiece motion and are frequently used in multi-axis cutting applications. All motions are controlled by an auxiliary unit such as a CNC, NC, paper tape, or programmable controller. Newer types of controllers interface with the beam source to control the entire process. Gas jet nozzles, wire feed, or seam tracking equipment are often used, and processing may be monitored and controlled by signals from height sensors, ionized by-product (plasma) detectors, and other systems.

**Safety.**—Safety for lasers is covered in ANSI Z136.1-2000: Safe Use Of Lasers. Most industrial lasers require substantial electrical input at high-voltage and -amperage conditions. Design of the beam source and the associated power supply should be to accepted industry electrical standards. Protective shielding is advised where an operator could interact, physically, with the laser beam, and would be similar to safety shields provided on other industrial equipment.

Radiation from a laser is intense light concentrated in tight bundles of energy. The high energy density and selective absorption characteristics of the laser beam have the potential to cause serious damage to the eye. For this reason, direct viewing of the beam from the laser should be restricted. Safety eyewear is commercially available to provide protection for each type of laser used. Certain lasers, such as the 1.06- $\mu\text{m}$  solid-state units, should be arranged in a system such that workers are shielded from direct and indirect radiation. Other types of lasers, such as the 10.6- $\mu\text{m}$  CO<sub>2</sub> laser, when operated without shielding, should meet industry standards for maximum permissible exposure levels. Much information is published on laser radiation safety, so that the subject is highly documented. Laser suppliers are very familiar with local regulations and are a good source for prepurchase information. Certain materials, notably many plastics compositions, when vaporized, will produce potentially harmful fumes. Precautionary measures such as workstation exhaust systems typically handle this problem.

**Laser Beam/Material Interaction.**—Industrial lasers fall into categories of effectiveness because the absorption of laser light by industrial materials depends on the specific wavelength. However, at room temperature, CO<sub>2</sub> laser light at 10.6  $\mu\text{m}$  wavelength is fully absorbed by most organic and inorganic nonmetals.

Both CO<sub>2</sub> and YAG can be used in metalworking applications, although YAG laser light at 1.06  $\mu\text{m}$  is absorbed to a higher degree in metals. Compensation for the lower absorption of CO<sub>2</sub> light by metals is afforded by high-energy-density beams, which create small amounts of surface temperature change that tend to increase the beam-coupling coefficient.

At  $\text{CO}_2$  power densities in excess of  $10^6 \text{ W/cm}^2$ , effective absorptivity in metals approaches that of nonmetals. Above certain temperatures, metals will absorb more infrared energy. In steel at  $400^\circ\text{C}$ , for instance, the absorption rate is increased by 50 per cent. In broad-area beam processing, where the energy density ( $10^4 \text{ W/cm}^2$ ) is low, some form of surface coating may be required to couple the beam energy into a metal surface.

Fig. 5. Laser Energy Absorption Intensity vs. Temperature

Fig. 6. Factors in Laser Cutting.

**Thermal Properties of Workpieces.**—When a laser beam is coupled to a workpiece, initial conversion of energy to work, in the form of heat, is confined to a very thin layer (100-200 Ångstroms) of surface material. The absorbed energy converted to heat will change the physical state of the workpiece, and depending on the energy intensity of the beam, a material will heat, melt, or vaporize. Fig. 5 shows percentage of energy absorption versus temperature for various phase changes in materials.

Heating, melting, and vaporization of a material by laser radiation depends on the thermal conductivity and specific heat of the material. The heating rate is inversely proportional to the specific heat per unit volume, so that the important factor for heat flow is the thermal diffusivity of the work material. This value determines how rapidly a material will accept and conduct thermal energy, and a high thermal diffusivity will allow a greater depth of fusion penetration with less risk of thermal cracking.

Heat produced by a laser in surface layers is rapidly quenched into the material and the complementary cooling rate is also rapid. In some metals, the rate is  $10^6 \text{ C}^\circ/\text{s}$ . This rapid cooling results in minimum residual heat effects, due to the slower thermal diffusivity of heat spreading from the processed area. However, rapid cooling may produce undesired effects in some metals. Cooling that is too rapid prevents chemical mixing and may result in brittle welds.

Thermosetting plastics are specifically sensitive to reheating, which may produce a gummy appearance or a charred, ashlike residue. Generally, the sensitivity of a material to heat from a laser is as apparent as with any other localized heating process. Any literature describing the behavior of materials when exposed to heat will apply to laser processing.

### Cutting Metal with Lasers

The energy in a laser beam is absorbed by the surface of the impinged material, and the energy is converted into work in the form of heat, which raises the temperature to the melting or vaporization point. A jet of gas is arranged to expel excess molten metal and vapor from the molten area. Moving the resulting molten-walled hole along a path with continuous or rapidly pulsed beam power produces a cut. The width of this cut (kerf), the quality of

the cut edges, and the appearance of the underside of the cut (where the dross collects) are determined by choice of laser, beam quality, delivered power, and type of motion employed (beam, workpiece, or combination). Fig. 6 identifies the factors involved in producing a high-quality cut.

Power versus penetration and cutting rate are essentially straight-line functions for most ferrous metals cut with lasers. A simple relationship states that process depth is proportional to power and inversely proportional to speed. Thus, for example, doubling power will double penetration depth. The maximum possible thickness that can be cut is, therefore, a function of power, cutting rate, and compromise on cut quality. Currently, 25 mm (1 in.) is considered the maximum thickness of steel alloys that can be cut. The most economically efficient range of thicknesses is up to 12.5 mm (0.49 in.).

Metals reflect laser light at increasing percentages with increasing wavelength. The high-energy densities generated by high-power CO<sub>2</sub> lasers overcome these reflectivity effects. Shorter-wavelength lasers such as Nd:YAG do not suffer these problems because more of their beam energy is absorbed.

**Beam Assistance Techniques.**—In cutting ferrous alloys, a jet of oxygen concentric with the laser beam is directed against the heated surface of the metal. The heat of the molten puddle of steel produced by the laser power causes the oxygen to combine with the metal, so that the jet burns through the entire thickness of the steel. This melt ablation process also uses the gas pressure to eject the molten metal from the cut kerf. Control of the gas pressure, shape of the gas stream, and positioning of the gas nozzle orifice above the metal surface are critical factors. A typical gas jet nozzle is shown in Fig. 7. Cutting highly alloyed steels, such as stainless steel, is done with pulsed CO<sub>2</sub> laser beams. High-pressure gas jets with the nozzle on the surface of the metal and nonoxidizing gas assistance can be used to minimize or eliminate clinging dross.

Fig. 7. Laser Gas Cutting Nozzle for Steel.

The narrow kerf produced by the laser allows cut patterns to be nested as close as one beam diameter apart, and sharply contoured and profiled cuts can be made, even in narrow angle locations. For this type of work and for other reasons, confining the kerf width to a dimension equal to, or slightly greater than, the diameter of the laser beam is important. Kerf width is a function of beam quality, focus, focus position, gas pressure, gas nozzle to surface spacing, and processing rate. Table 2 shows typical kerf widths.

**Cut Edge Roughness.**—Cutting with a continuous-wave (CW) output CO<sub>2</sub> laser can produce surface roughness values of 8–15 μm (315–590 μin) in 1.6-mm (0.063-in) cold-rolled steel and 30–35 μm (1180–1380 μin) in mild steel. Surface roughness of 30–50 μm (1180–1970 μin) in thin-gage stainless steel sheets is routine when using oxygen to assist cutting. Table 3 lists some surface roughness values.

**Table 2. Typical Kerf Widths in CO<sub>2</sub> Laser Cutting**

| Material     | Thickness |       | Kerf              |       |
|--------------|-----------|-------|-------------------|-------|
|              | mm        | in.   | mm                | in.   |
| Carbon Steel | 1.5       | 0.06  | 0.05              | 0.002 |
|              | 2.25      | 0.09  | 0.12              | 0.005 |
|              | 3.12      | 0.12  | 0.2               | 0.008 |
|              | 6.25      | 0.25  | 0.3               | 0.012 |
| Aluminum     | 2.25      | 0.09  | 0.25              | 0.01  |
| Plastics     | <4.0      | <0.16 | 2 × beam diameter |       |

**Table 3. Surface Roughness Values for Laser Cutting with Oxygen**

| Material          | Thickness |      | Surface Finish |      |
|-------------------|-----------|------|----------------|------|
|                   | mm        | in.  | μm             | μin  |
| Stainless Steel   | 1         | 0.04 | 30             | 1200 |
|                   | 2         | 0.08 | 35             | 1400 |
|                   | 3         | 0.12 | 50             | 2000 |
| Cold-Rolled Steel | 1         | 0.04 | 8              | 320  |
|                   | 2         | 0.08 | 10             | 400  |
|                   | 3         | 0.12 | 15             | 600  |
| Mild Steel        | 1         | 0.04 | 30             | 1200 |
|                   | 2         | 0.08 | 30             | 1200 |
|                   | 3         | 0.12 | 35             | 1400 |

**Heat-Affected Zones.**—Control of beam focus, focus position, assist gas conditions, and processing rates produces differences in hardness that are barely discernible in steels up to 2 mm (0.078 in.) thick. Small increases in hardness to a depth of 0.1–0.2 mm (0.004–0.008 in.) are common. Cutting with a pulsed CO<sub>2</sub> laser reduces these values to less than 0.1 mm (0.004 in.), making this mode of operation beneficial for some end-use applications. [Table 4](#) shows typical values for the heat-affected zone in mild steels.

**Table 4. Heat-Affected Zone in Mild Steels**

| Material Thickness |       | CW HAZ |       | Pulsed HAZ |       |
|--------------------|-------|--------|-------|------------|-------|
| mm                 | in.   | mm     | in.   | mm         | in.   |

| 1                  | 0.039 | 0.75   | 0.030 | 0.07       | 0.003 |

Rates for laser cutting of metals are typically reported as data developed under ideal conditions, that is, in a controlled development laboratory environment using technician-operated equipment. Rates achieved on the shop floor using semiskilled system operators to produce complicated shapes may vary dramatically from published data. Speed versus thickness for cutting steel is shown in [Fig. 8](#) for 1000- and 1500-W power levels, and cutting performance for several other metals of various thicknesses is shown in [Table 5](#). Cutting rate data for pulsed and CW Nd:YAG lasers for steel also are shown in [Fig. 8](#), and for Nd:YAG cutting of other metals in [Table 5](#).

**Table 5. CO<sub>2</sub> and Nd: YAG Cutting Speeds for Nonferrous Metals**

| Material    | CO <sub>2</sub> (1500 watts) |      |       |        | Nd: YAG   |       |       |        |                |
|-------------|------------------------------|------|-------|--------|-----------|-------|-------|--------|----------------|

Fig. 8. Typical Cutting Rates for CO<sub>2</sub> and YAG Lasers.

**Cutting of Nonmetals.**—Laser cutting of nonmetals has three requirements: a focused beam of energy at a wavelength that will be absorbed easily by the material so that melting or vaporization can occur; a concentric jet of gas, usually compressed air, to remove the by-products from the cut area; and a means to generate cuts in straight or curved outlines. Residual thermal effects resulting from the process present a greater problem than in cutting of metals and limit applications of lasers in nonmetal processing.

When subjected to a laser beam, paper, wood, and other cellular materials undergo vaporization caused by combustion. The cutting speed depends on laser power, material thickness, and water and air content of the material. Thermoplastic polymer materials are cut by melting and gas jet expulsion of the melted material from the cut area. The cutting speed is governed by laser power, material thickness, and pressure of gas used to eject the displaced material.

Polymers that may be cut by combustion or chemical degradation include the thermosetting plastics, for example, epoxies and phenolics. Cutting speed is determined by the laser

power and is higher for thermosets than for other polymers due to the phase change to vapor.

Composite materials are generally easy to cut, but the resulting cut may not be of the highest quality, depending on the heat sensitivity of the composite materials. High-pressure cutting processes such as fluid jets have proven to be more effective than lasers for cutting many composite materials.

Nonmetal cutting processes require moderate amounts of power, so the only limitation on cut thickness is the quality of the cut. In practice, the majority of cutting applications are to materials less than 12 mm thick. Cutting rates for some commonly used nonmetals are shown in Table 6. Nonmetal cutting applications require a gas jet to remove molten, vaporized, or chemically degraded matter from the cut area.

Compressed air is used for many plastics cutting applications because it is widely available and cheap to produce, so it is a small cost factor in nonmetal cutting. A narrow kerf is a feature of nonmetal cutting, and it is especially important in the cutting of compactly nested parts such as those produced in cutting of fabrics. Nonmetals react in a variety of ways to laser-generated heat, so that it is difficult to generalize on edge roughness, but thermally sensitive materials will usually show edge effects.

**Table 6. CO<sub>2</sub> Laser Cutting Rates for Nonmetals**

| Material      | Thickness |      | Speed |        | Power | Material   | Thickness |       | Speed |        | Power |
|---------------|-----------|------|-------|--------|-------|------------|-----------|-------|-------|--------|-------|
|               | mm        | in   | m/min | ft/min | watts |            | mm        | in    | m/min | ft/min | watts |

### Welding with Lasers

**Laser Welding Theory.**—Conversion of absorbed laser energy into heat causes metals to undergo a phase change from solid to liquid and, as energy is removed, back to solid. This fusion welding process is used to produce selective area spot welds or linear continuous seam welds. The two types of laser welding processes, conduction and deep penetration, or keyhole, are shown in Fig. 9.

*Conduction welding:* relies on the thermal diffusivity characteristics of the metal to conduct heat into the joint area. By concentrating heat into the focused beam diameter and programming this heat input for short time periods, more heat is conducted into the joint than is radiated outward from the joint. Conduction welds are generally used for spot welding and partial penetration seam welding.

*Deep penetration keyhole welding:* is produced by beam energy converted to heat that causes a hole to be produced through the thickness of the metal. Vapor pressure of evaporated metal holds a layer of molten metal in place against the hole wall.

Movement of the hole, by beam or workpiece motion, causes the molten metal to flow around the hole and solidify behind the beam interaction point. The resolidified metal has a different structure than the base metal. Maximum practical penetration limits are approximately 25 mm (2 in.) with today's available laser power technology.

If the physical change from solid to liquid to solid does not produce a ductile fusion zone, and if the brittleness of the resolidified metal cannot be reduced easily by postweld annealing, then the laser welding process, as with other fusion welding processes, may not be viable. If the metal-to-metal combination does not produce an effective weld, other

considerations such as filler metal additions to modify fusion zone chemistry should be considered.

Fig. 9. Types of Laser Welds.

**Welded Joint Design.**—For optimum results, the edges of parts to be laser beam welded should be in close contact. When a part is being designed and there is a choice of welding process, designers should design joints and joint tolerances to the optimum for laser welding. Fig. 10 shows suitable joint designs for the laser fusion welding process. Joint tolerances are one of the more important parameters influencing part weldability, and for corner, tee, and lap joints, gaps should be not more than 25 per cent of the thickness of the thinnest section. For butt and edge joints, the percentage is reduced to 10. Addition of filler metal to compensate for large joint gaps is becoming popular.

Fig. 10. Examples of Laser Weld Joint Designs.

**Welding Rates.**—The information presented in Fig. 11 for welding with  $\text{CO}_2$  and Nd:YAG lasers should be considered as typical for the specific lasers shown and is for use in optimum conditions. These data are provided only as guidelines.

**Processing Gas.**—The proper choice of processing gas is important for both conduction and keyhole welding. Gases that ionize easily should not be used to shield the beam/material interaction point. Energy intensities of  $10^6 \text{ W/cm}^2$  or higher can occur in the zone where incident and reflected laser light overlap and gases can vaporize, producing a plasma that attenuates further beam transmission.

One of the most important advantages of laser welding is the low total heat input characteristic of the focused high-energy density beam. Heat concentration resulting from the beam energy conversion at the workpiece surface causes most conduction to be perpendicular to the direction of motion. With the beam (or workpiece) moving faster than the speed of thermal conduction, there is significant heat flow only in the perpendicular direction. Thus, material solid to solid, or solid to liquid, changes tend to occur only in the narrow

path of heat conduction, and the amount of heat necessary to penetrate a given material thickness is reduced to only that needed to fuse the joint. With limited excess heat through the low total heat mechanism, parts can be produced by laser welding with minimum thermal distortion.

Helium is the ideal gas for laser welding, but other gases such as CO<sub>2</sub> and argon have been used. Neither CO<sub>2</sub> nor argon produces a clean, perfectly smooth weld, but weld integrity seems sufficient to suggest them as alternatives. The cost of welding assistance gas can be greater than for laser gases in CO<sub>2</sub> laser welding and may be a significant factor in manufacturing cost per welded part.

Fig. 11. Rates for CO<sub>2</sub> and Nd:YAG Laser Welding.

### Drilling with Lasers

**Laser Drilling Theory.**—Laser drilling is performed by direct, percussive, and trepanning methods that produce holes of increasing quality respectively, using increasingly more sophisticated equipment. The drilling process occurs when the localized heating of the material by a focused laser beam raises the surface temperature above the melting temperature for metal or, for nonmetals, above the vaporization temperature.

**Direct Drilling.**—The single-pulse, single-hole process is called direct drilling. The process hole size is determined by the thermal characteristics of the material, the beam spot size, the power density, the beam quality, and the focus location. Of these parameters, beam quality, in terms of beam divergence, is an important criterion because of its effect on the hole size. Single-pulse drilled holes are usually limited to a depth of 1.5 mm (0.06 in.) in metals and up to 8 mm (0.315 in.) in nonmetals. Maximum hole diameter for pulsed solid-state laser metal drilling is in the 0.5- to 0.75-mm (0.02- to 0.03-in.) range, and CO<sub>2</sub> direct drilling can produce holes up to 1.0 mm (0.04 in.) in diameter. The aspect ratio (depth to midhole diameter) is typically under 10:1 in metals and for many nonmetals it can be 15:1. Hole taper is usually present in direct drilling of metals. The amount of taper (entrance hole to exit hole diameter change) can be as much as 25 per cent in many metals. Direct drilling produces a recast layer with a depth of about 0.1 mm (0.004 in.). Diameter tolerances are  $\pm 10$  per cent for the entrance hole, depending on beam quality and assist gas pressure.

**Percussive Drilling.**—Firing a rapid sequence of pulses produces a hole of higher quality than direct drilling in metal thicknesses up to 25 mm (1 in.). This process is known as percussive drilling. Multiple pulses may be necessary, depending on the metal thickness. Typical results using percussion drilled holes are: maximum depth achievable, 25 mm (1 in.); maximum hole diameter, 1.5 mm (0.06 in.); aspect ratio, 50:1; recast layer, 0.5 mm (0.02 in.); taper under 10 per cent; and hole diameter tolerance  $\pm 5$  per cent.

**Trepanning.**—To improve hole quality, some companies use the trepanning method to cut a hole. In this process, a focused beam is moved around the circumference of the hole to be drilled by a rotating mirror assembly. The closeness of spacing of the beam pulses that need to be overlapped to produce the hole depends on the quality requirements. Typical results are: maximum hole depth, 10 mm (0.39 in.); maximum hole diameter, 2.5 mm (0.1 in.); and recast layer thickness, 25  $\mu\text{m}$  (985  $\mu\text{in}$ ).

**Drilling Rates.**—Laser drilling is a fast process but is very dependent on the above-mentioned process factors. It is difficult to generalize on laser drilling rates because of the large number of combinations of material, hole diameter, depth, number of holes per part, and part throughput. With Nd:YAG lasers, direct drilling rates of 1 ms are typical.

### Heat Treatment with Lasers

The defocused beam from a CO<sub>2</sub> laser impinging on a metal surface at room temperature will have 90 per cent or more of its power reflected. In steels, the value is about 93 per cent. Compared with focused beam processing, which uses power densities greater than 10<sup>5</sup> W/cm<sup>2</sup>, the power density of laser beams designed for heat treatment, at less than 10<sup>4</sup> W/cm<sup>2</sup>, is insufficient to overcome reflectivity effects. Therefore, the metal surface needs to be prepared by one of several processes that will enhance absorption characteristics. Surface roughening can be used to produce tiny craters that can trap portions of the beam long enough to raise the surface temperature to a point where more beam energy is absorbed. Coating the metal surface is a common expedient. Black enamel paint is easy to apply and the laser beam causes the enamel to vaporize, leaving a clean surface.

The absorbed laser beam energy, converted to heat, raises the temperature of the metal in the beam pattern for as long as the beam remains in one place. The length of the dwell time is used to control the depth of the heat treatment and is an extremely effective means for control of case depth in hardening.

**Materials Applicability.**—Hardenable ferrous metals, such as medium- and high-carbon steels, tool steels, low-alloy steels and cast irons, and steels with fine-carbide dispersion, are good candidates for laser heat treating. Marginally hardenable metals include annealed carbon steels, spheroidized carbon steels, mild-carbon steels (0.2 per cent C), and ferritic nodular cast irons. Low-carbon steels (<0.1 per cent C), austenitic stainless steels, and non-ferrous alloys and metals are not hardenable.

The effect of the metal microstructure on depth of hardening is an important factor. Cast iron, with a graphite and tempered martensite structure, presents a low carbon-diffusion distance that favors deep-hardened cases. The same is true for steel with a tempered martensite or bainite structure. On the other hand, cast iron with a graphite/ferrite structure and spheroidized iron (Fe<sub>3</sub>C plus ferrite) structures have large carbon-diffusion patterns and therefore produce very shallow or no case depths.

**Hardening Rates.**—Laser hardening is typically slower than conventional techniques such as induction heating. However, by limiting the area to be hardened, the laser can prove to be cost-effective through the elimination of residual heat effects that cause part distortion. A typical hardening rate is 130 cm<sup>2</sup>/min. (20 in<sup>2</sup>/min.) for a 1-mm (0.039-in) case depth in 4140 steel.

### Cladding with Lasers

In laser cladding, for applying a coating of a hard metal to a softer alloy, for instance, a shaped or defocused laser beam is used to heat either preplaced or gravity-fed powdered alloys. The cladding alloy melts and flows across the surface of the substrate, rapidly solidifying when laser power is removed. Control of laser power, beam or part travel speed, clad thickness, substrate thickness, powder feed rate, and shielding gas are process variables that are determined for each part.

Many of the alloys currently used in plasma arc or metal inert gas cladding techniques can be used with the laser cladding process. Among these materials, Stellites, Colmonoys, and other alloys containing carbides are included, plus Inconel, Triballoy, Fe-Cr-C-X alloys, and tungsten and titanium carbides.

Controlled minimal dilution may be the key technical advantage of the laser cladding process. Dilution is defined as the total volume of the surface layer contributed by melting of the substrate, and it increases with increasing power, but decreases with either increasing travel speed or increasing beam width transverse to the direction of travel. Tests comparing laser dilution to other cladding techniques show the laser at <2 per cent compared to 5–15 per cent for plasma arc and 20–25 per cent for stick electrode processes.

The laser cladding process results in a dense, homogenous, nonporous clad layer that is metallurgically bonded to the substrate. These qualities are in contrast to the mechanically bonded, more porous layer produced by other methods.

### Marking with Lasers

Laser marking technology can be divided into two groups; those that produce a repetitive mark are listed as mask marking, and those that involve rapid changes of mark characteristics are classified as scanned beam marking. The amount of data that can be marked in a unit of time (writing speed) depends on laser energy density, galvanometer speed, computer control, and the dimensions of the mark. Heat-type marks have been made at rates up to 2500 mm/s (100 in/s) and engraved marks at rates of 500–800 mm/s (20–30 in/s). Writing fields are of various sizes, but a typical field measures 100 × 100 mm (4 × 4 in.).

**Mask Marking.**—In mask marking, the beam from a CO<sub>2</sub> laser is projected through a reflective mask that passes beam energy only through uncoated areas. The beam energy is reimaged by a wide field lens onto the material's surface where the absorbed heat changes the molecular structure of the material to produce a visible mark. Examples are clouding PVC or acrylics, effecting a change in a colored surface (usually by adjusting proportions of pigment dyes), or by ablating a surface layer to expose a sublayer of a different color.

CO<sub>2</sub> lasers can be pulsed at high rates and have produced legible marks at line speeds of 20,000 marks/h. These lasers produce energy densities in the 1–20 J/cm<sup>2</sup> range, which corresponds to millions of watts/cm<sup>2</sup> of power density and allows marking to be performed in areas covering 0.06 to 6 cm<sup>2</sup>. The minimum width of an individual line is 0.1 mm (0.004 in.). Mask marking is done by allowing the beam from a laser to be projected through a mask containing the mark to be made. Reimaging the beam by optics onto the workpiece causes a visible change in the material, resulting in a permanent mark. Mask marking is used for materials that are compatible with the wavelength of the laser used.

**Scanned-Beam Marking.**—Focusing a pulsed laser beam to a small diameter concentrates the power and produces high-energy density that will cause a material to change its visual character. Identified by several names (spot, stroke, pattern generation, or engraving), this application is best known as scanned beam.

In the scanned-beam method, the beam from a pulsed YAG or CO<sub>2</sub> laser is directed onto the surface of a part by a controlled mirror oscillation that changes the beam path in a pre-programmed manner. The programming provides virtually unlimited choice of patterns to be traced on the part. The pulsed laser output can be sequenced with beam manipulation to produce a continuous line or a series of discrete spots that visually suggest a pattern (dot matrix).

The energy density in the focused beam is sufficient to produce a physical or chemical change in most materials. For certain highly reflective metals, such as aluminum, better results are obtained by pretreating the surface (anodizing). Not all scanned beam applications result in removal of base metal. Some remove only a coating or produce a discoloration, caused by heating, that serves as a mark.

## FINISHING OPERATIONS

## Power Brush Finishing

Power brush finishing is a production method of metal finishing that employs wire, elastomer bonded wire, or non-metallic (cord, natural fiber or synthetic) brushing wheels in automatic machines, semi-automatic machines and portable air tools to smooth or roughen surfaces, remove surface oxidation and weld scale or remove burrs.

**Description of Brushes.**—Brushes work in the following ways: the wire points of a brush can be considered to act as individual culling tools so that the brush, in effect, is a multiple-tipped cutting tool. The fill material, as it is rotated, contacts the surface of the work and imparts an impact action which produces a coldworking effect. The type of finish produced depends upon the wheel material, wheel speed, and how the wheel is applied.

Brushes differ in the following ways 1) fill material (wire—carbon steel, stainless steel; synthetic; Tampico; and cord); 2) length of fill material (or trim); and 3) the density of the fill material.

To aid in wheel selection and use, the accompanying table made up from information supplied by *The Osborn Manufacturing Company* lists the characteristics and mayor uses of brushing wheels.

**Use of Brushes.**—The brushes should be located so as to bring the full face of the brush in contact with the work. Full face contact is necessary to avoid grooving the brush. Operations that are set up with the brush face not in full contact with the work require some provision for dressing the brush face. When the tips of a brush, used with full face contact, become dull during use with subsequent loss of working clearance, reconditioning and resharping is necessary. This is accomplished simply and efficiently by alternately reversing the direction of rotation during use.

**Deburring and Producing a Radius on the Tooth Profile of Gears.**—The brush employed for deburring and producing a radius on the tooth profile of gears is a short trim, dense, wire-fill radial brush. The brush should be set up so as to brush across the edge as shown in Fig. 1A. Line contact brushing, as shown in Fig. 1B should be avoided because the Crisis face will wear non-uniformly; and the wire points, being flexible, tend to flare to the side, thus minimizing the effectiveness of the brushing operation. When brushing gears, the brushes are spaced and contact the tooth profile on the center line of the gear as shown in Fig. 2. This facilitates using brush reversal to maintain the wire brushing points at their maximum cutting efficiency.

The setup for brushing spline bores differs from brushing gears in that the brushes are located off-center, as illustrated in Fig. 3. When helical gears are brushed, it is sometimes necessary to favor the acute side of the gear tooth to develop a generous radius prior to shaving. This can be accomplished by locating the brushes as shown in Fig. 4. Elastomer bonded wire-filled brushes are used for deburring fine pitch gears. These brushes remove the burrs without leaving any secondary roll. The use of bonded brushes is necessary when the gears are not shaved after hobbing or gear shaping.

### Adjustments for Eliminating Undesirable Conditions in Power Brush Finishing

| Undesirable Condition                          | Possible Adjustments for Eliminating Condition  |
|--|---|
| Brush works too slowly                         | (1) Decrease trim length and increase fill density.<br>(2) Increase filament diameter.<br>(3) Increase surface speed by increasing R.P.M. or outside diameter.  |
| Brush works too fast                           | (1) Reduce filament diameter.<br>(2) Reduce surface speed by reducing R.P.M. or outside diameter.<br>(3) Reduce fill density.<br>(4) Increase trim length.  |
| Action of brush peens burr to adjacent surface | (1) Decrease trim length and increase fill density.<br>(2) If wire brush tests indicate metal too ductile (burr is peened rather than removed), change to nonmetallic brush such as a treated Tampico brush used with a burring compound. |
| Finer or smoother finish required              | (1) Decrease trim length and increase fill density.<br>(2) Decrease filament diameter.<br>(3) Try treated Tampico or cord brushes with suitable compounds at recommended speeds.<br>(4) Use auxiliary buffing compound with brush.        |
| Finish too smooth and lustrous                 | (1) Increase trim length.<br>(2) Reduce brush fill density.<br>(3) Reduce surface speed.<br>(4) Increase filament diameter.   |
| Brushing action not sufficiently uniform       | (1) Devise hand-held or mechanical fixture or machine which will avoid irregular off-hand manipulation.<br>(2) Increase trim length and decrease fill density.  |

### Polishing and Buffing

The terms "polishing" and "buffing" are sometimes applied to similar classes of work in different plants, but according to approved usage of the terms, there is the following distinction: Polishing is any operation performed with wheels having abrasive glued to the working surfaces, whereas buffing is done with wheels having the abrasive applied loosely instead of imbedding it into glue; moreover, buffing is not so harsh an operation as ordinary polishing, and it is commonly utilized to obtain very fine surfaces having a "grainless finish."

**Polishing Wheels.**—The principal materials from which polishing wheels are made are wood, leather, canvas, cotton cloth, plastics, felt, paper, sheepskin, impregnated rubber, canvas composition, and wool. Leather and canvas are the materials most commonly used in polishing wheel construction. Wooden wheels covered with material to which emery or some other abrasive is glued are employed extensively for polishing flat surfaces, espe-

**Characteristics and Applications of Brushes Used in Power Finishing**

| Brush Type   | Description  | Operating Speed Range, sfpm                              | Uses   | Remarks  |
|--|--|--|--|--|
| Radial, short trim dense wire fill   | Develops very little impact action but maximum cutting action.   | 6500   | Removal of burrs from gear teeth and sprockets. Produces blends and radii at juncture of intersecting surfaces.  | Brush should be set up so as to brush across any edge. Reversal of rotation needed to maintain maximum cutting efficiency of brush points.   |
| Radial, medium to long trim twisted knot wire fill                           | Normally used singly and on portable tools. Brush is versatile and provides high impact action.  | 7500–9500 for high speeds. 1200 for slow speeds.         | For cleaning welds in the automotive and pipeline industries. Also for cleaning surfaces prior to painting, stripping rubber flash from molded products and cleaning mesh-wire conveyor belts.                               | Surface speed plays an important role since at low speeds the brush is very flexible and at high speeds it is extremely hard and fast cutting.   |
| Radial, medium to long trim crimped wire fill                                | With the 4- to 8-inch diameter brush, part is hand held. With the 10- to 15-inch diameter brush, part is held by machine.                        | 4500–6000  | Serves as utility tool on bench grinder for removing feather grinding burrs, machining burrs, and for cleaning and producing a satin or matte finish.  | Good for hand held parts as brush is soft enough to conform to irregular surfaces and hard-to-reach areas. Smaller diameter brushes are not recommended for high-production operations.                      |
| Radial, sectional, non-metallic fill (treated and untreated Tampico or cord) | Provides means for improving finish or improving surface for plating. Works best with grease base deburring or buffing compound.                 | 5500–6500<br>7500 for polishing                          | For producing radii and improving surface finish. Removes the sharp peaks that fixed abrasives leave on a surface so that surface will accept a uniform plating. Polishing marks and draw marks can be successfully blended. | Brush is selective to an edge which means that it removes metal from an edge but not from adjoining surfaces. It will produce a very uniform radius without peening or rolling any secondary metal.          |
| Radial, wide-face, nonmetallic fill (natural fibers or synthetics)           | Can be used with flow-through mounting which facilitates feeding of cold water and hot alkaline solutions through brush face to prevent buildup. | 750–1200 for cleaning steel. 600 when used with slurries | For cleaning steel. Used in electrolytic tinplate lines, continuous galvanizing and annealing lines, and cold reduction lines. Used to produce dull or matte-type finishes on stainless steel and synthetics.                | Speeds above 3600 sfpm will not appreciably improve operation as brush wear will be excessive. Avoid excessive pressures. Ammeters should be installed in drive-motor circuit to indicate brushing pressure. |

### Characteristics and Applications of Brushes Used in Power Finishing (Continued)

| Brush Type  | Description  | Operating Speed Range, sfpm  | Uses  | Remarks   |
|---|--|--|---|---|
| Radial, wide face, metallic fill                                      | This brush is made to customer's specifications. It is dynamically balanced at the speed at which it will operate.                               | 2000–4000  | Removes buildup of aluminum oxide from work rolls in aluminum mill. Removes lime or magnesium coatings from certain types of steel. Burnishes hot-dipped galvanized steel to produce a minimum spangled surface.  | Each brush should have its own drive. An ammeter should be present in drive-motor circuit to measure brushing pressure. If strip is being brushed, a steel backup roll should be opposite the brush roll. |
| Radial, wide face, strip (interrupted brush face)                     | Performs cleaning operations that would cause a solid face brush to become loaded and unusable.  | When cleaning conveyor belts, brush speed is 2 to 3 times that of conveyor belt.         | Need for cleaning rubber and fabric conveyor belts of carry-back material which would normally foul snubber pulley and return idlers.   | Designed for medium- to light-duty work. Brush face does not load.  |
| Radial, Cup, Flared End, and Straight End, wire fill elastomer bonded | Extremely fast cutting with maximum operator safety. No loss of wire through fatigue. Always has uniform face.                                   | 3600–9000  | For removing oxide weld scale, burrs, and insulation from wire.   | Periodic reversing of brush direction will result in a brush life ten times greater than non-bonded wheels. Fast cutting action necessitates precise holding of part with respect to brush.               |
| Cup, twisted knot wire fill   | Fast cutting wheel used on portable tools to clean welds, scale, rust, and other oxides.   | 8000–10,000<br>4500–6500 for deburring and producing a radius around periphery of holes. | Used in shipyards and in structural steel industry. For cleaning outside diameter of pipe and removing burrs and producing radii on heat exchanger tube sheets and laminations for stator cores.                  | Fast acting brush cleans large areas economically. Setup time is short.   |
| Radial, wire or treated Tampico or cord                               | For use with standard centerless grinders. Brush will not remove metal from a cylindrical surface. Parts must be ground to size before brushing. | ...  | For removing feather grinding burrs and improving surface finish. Parts of 24 microinches can be finished down to 15 to 10 microinches. Parts of 10 to 12 microinches can be finished down to 7 to 4 microinches. | Follows centerless grinding principles, except that accuracy in pressure and adjustment is not critical. A machine no longer acceptable for grinding can be used for brushing.                            |

cially when good edges must be maintained. Cloth wheels are made in various ways; wheels having disks that are cemented together are very hard and used for rough, coarse work, whereas those having sewn disks are made of varying densities by sewing together a larger or smaller number of disks into sections and gluing them.

Wheels in which the disks are held together by thread or metal stitches and which are not stiffened by the use of glue usually require metal side plates to support the canvas disks. Muslin wheels are made from sewed or stapled buffs glued together, but the outer edges of a wheel frequently are left open or free from glue to provide an open face of any desired depth. Wool felt wheels are flexible and resilient, and the density may be varied by sewing two or more disks together and then cementing to form a wheel. Solid felt wheels are quite popular for fine finishing but have little value as general utility wheels. Paper wheels are made from strawboard paper disks and are cemented together under pressure to form a very hard wheel for rough work. Softer wheels are similarly made from felt paper. The "compress" canvas wheel has a cushion of polishing material formed by pieces of leather, canvas, or felt, that are held in a crosswise radial position by two side plates attached to the wheel hub. This cushion of polishing material may be varied in density to suit the requirements; it may be readily shaped to conform to the curvature of the work and this shape can be maintained. Sheepskin polishing wheels and paper wheels are little used.

**Polishing Operations and Abrasives.**—Polishing operations on such parts as chisels, hammers, screwdrivers, wrenches, and similar parts that are given a fine finish but are not plated, usually require four operations, which are "roughing," "dry fining," "greasing," and "coloring." The roughing is frequently regarded as a solid grinding wheel job. Sometimes there are two steps to the greasing operation—rough and fine greasing. For some hardware, such as the cheaper screwdrivers, wrenches, etc., the operations of roughing and dry fining are considered sufficient. For knife blades and cutlery, the roughing operation is performed with solid grinding wheels and the polishing is known as fine or blue glazing, but these terms are never used when referring to the polishing of hardware parts, plumbers' supplies, etc. A term used in finishing German silver, white metal, and similar materials is "sand-buffing," which, in distinction from the ordinary buffing operation that is used only to produce a very high finish, actually removes considerable metal, as in rough polishing or flexible grinding. For sand-buffing, pumice and other abrasive powders are loosely applied.

Aluminum oxide abrasives are widely used for polishing high-tensile-strength metals such as carbon and alloy steels, tough iron, and nonferrous alloys. Silicon carbide abrasives are recommended for hard, brittle substances such as grey iron, cemented carbide tools, and materials of low tensile strength such as brass, aluminum, and copper.

**Buffing Wheels.**—Buffing wheels are manufactured from disks (either whole or pieced) of bleached or unbleached cotton or woolen cloth, and they are used as the agent for carrying abrasive powders, such as tripoli, crocus, rouge, lime, etc., which are mixed with waxes or greases as a bond. There are two main classes of buffs, one of which is known as the "pieced-sewed" buffs, and is made from various weaves and weights of cloth. The other is the "full-disk" buffs, which are made from specially woven material. Bleached cloth is harder and stiffer than unbleached cloth, and is used for the faster cutting buffs. Coarsely woven unbleached cloth is recommended for highly colored work on soft metals, and the finer woven unbleached cloths are better adapted for harder metals. When working at the usual speed, a stiff buff is not suitable for "cutting down" soft metal or for light plated ware, but is used on harder metals and for heavy nickel-plated articles.

**Speed of Polishing Wheels.**—The proper speed for polishing is governed to some extent by the nature of the work, but for ordinary operations, the polishing wheel should have a peripheral speed of about 7500 ft/min. If run at a lower speed, the work tends to tear the polishing material from the wheel too readily, and the work is not as good in quality. Muslin, felt, or leather polishing wheels having wood or iron centers should be run at peripheral speeds varying from 300 to 7000 ft/min. It is rarely necessary to exceed 6000 ft/min, and

for most purposes, 4000 ft/min is sufficient. If the wheels are kept in good condition, in perfect balance, and are suitably mounted on substantial buffing lathes, they can be used safely at speeds within the limits given. However, manufacturers' recommendations concerning wheel speeds should be followed, where they apply.

**Grain Numbers of Emery.**—The numbers commonly used in designating the different grains of emery, corundum, and other abrasives are 10, 12, 14, 16, 18, 20, 24, 30, 36, 40, 46, 54, 60, 70, 80, 90, 100, 120, 150, 180, and 200, ranging from coarse to fine, respectively. These numbers represent the number of meshes per linear inch in the grading sieve. An abrasive finer than No. 200 is known as "flour" and the degree of fineness is designated by the letters CF, F, FF, FFF, FFFF, and PCF or SF, ranging from coarse to fine. The methods of grading flour-emery adopted by different manufacturers do not exactly agree, the letters differing somewhat for the finer grades. Again, manufacturers' recommendations should be followed.

**Grades of Emery Cloth.**—The coarseness of emery cloth is indicated by letters and numbers corresponding to the grain number of the loose emery used in the manufacture of the cloth. The letters and numbers for grits ranging from fine to coarse are as follows: FF, F, 120, 100, 90, 80, 70, 60, 54, 46, and 40. For large work roughly filed, use coarse cloth such as numbers 46 or 54, and then finer grades to obtain the required polish. If the work has been carefully filed, a good polish can be obtained with numbers 60 and 90 cloth, and a brilliant polish can be achieved by finishing with number 120 and flour-emery.

**Mixture for Cementing Emery Cloth to a Lapping Wheel.**—Many proprietary adhesives are available for application of emery cloth to the periphery of a buffing or lapping wheel, and generally are supplied with application instructions. In the absence of such instructions, clean the wheel thoroughly before applying the adhesive, and then rub the emery cloth down so as to exclude all air from between the surface of the wheel and the cloth.

### Etching and Etching Fluids

**Etching Fluids for Different Metals.**—A common method of etching names or simple designs upon steel is to apply a thin, even coating of beeswax or some similar substance which will resist acid; then mark the required lines or letters in the wax with a sharp-pointed scriber, thus exposing the steel (where the wax has been removed by the scriber point) to the action of an acid, which is finally applied. To apply a very thin coating of beeswax, place the latter in a silk cloth, warm the piece to be etched, and tub the pad over it. Regular coach varnish is also used instead of wax, as a "resist."

An etching fluid ordinarily used for carbon steel consists of nitric acid, 1 part; water, 4 parts. It may be necessary to vary the amount of water, as the exact proportion depends upon the carbon content and whether the steel is hard or soft. For hard steel, use nitric acid, 2 parts; acetic acid, 1 part. For high-speed steel, nickel or brass, use nitro-hydrochloric acid (nitric, 1 part; hydrochloric, 4 parts). For high-speed steel it is sometimes better to add a little more nitric acid. For etching bronze, use nitric acid, 100 parts; muriatic acid, 5 parts. For brass, nitric acid, 16 parts; water, 160 parts, dissolve 6 parts potassium chlorate in 100 parts of water; then mix the two solutions and apply.

A fluid which may be used either for producing a frosted effect or for deep etching (depending upon the time it is allowed to act) is composed of 1 ounce sulphate of copper (blue vitriol);  $\frac{1}{4}$  ounce alum;  $\frac{1}{2}$  teaspoonful of salt; 1 gill of vinegar, and 20 drops of nitric acid. For aluminum, use a solution composed of alcohol, 4 ounces; acetic acid, 6 ounces; antimony chloride, 4 ounces; water, 40 ounces.

Various acid-resisting materials are used for covering the surfaces of steel rules etc., prior to marking off the lines on a graduating machine. When the graduation lines are fine and very closely spaced, as on machinists' scales which are divided into hundredths or sixty-fourths, it is very important to use a thin resist that will cling to the metal and prevent

any under-cutting of the acid: the resist should also enable fine lines to be drawn without tearing or crumbling as the tool passes through it. One resist that has been extensively used is composed of about 50 per cent of asphaltum, 25 per cent of beeswax, and, in addition, a small percentage of Burgundy pitch, black pitch, and turpentine. A thin covering of this resisting material is applied to the clean polished surface to be graduated and, after it is dry, the work is ready for the graduating machine. For some classes of work, paraffin is used for protecting the surface surrounding the graduation lines which are to be etched. The method of application consists in melting the paraffin and raising its temperature high enough so that it will flow freely; then the work is held at a slight angle and the paraffin is poured on its upper surface. The melted paraffin forms a thin protective coating.

### **Conversion Coatings and the Coloring of Metals**

**Conversion Coatings.**—Conversion coatings are thin, adherent chemical compounds that are produced on metallic surfaces by chemical or electrochemical treatment. These coatings are insoluble, passive, and protective, and are divided into two basic systems: oxides or mixtures of oxides with other compounds, usually chromates or phosphates. Conversion coatings are used for corrosion protection, as an adherent paint base; and for decorative purposes because of their inherent color and because they can absorb dyes and colored sealants.

Conversion coatings are produced in three or four steps. First there is a pretreatment, which often involves mechanical surface preparation followed by decreasing and/or chemical or electrochemical cleaning or etching. Then thermal, chemical, or electrochemical surface conversion processes take place in acid or alkaline solutions applied by immersion spraying, or brushing. A post treatment follows, which includes rinsing and drying, and may also include sealing or dyeing. If coloring is the main purpose of the coating, then oiling, waxing, or lacquering may be required.

**Passivation of Copper.**—The blue-green patina that forms on copper alloys during atmospheric exposure is a passivated film; i.e., it prevents corrosion. This patina may be produced artificially or its growth may be accelerated by a solution of ammonium sulfate, 6 pounds; copper sulfate, 3 ounces; ammonia (technical grade, 0.90 specific gravity), 1.34 fluid ounces; and water, 6.5 gallons. This solution is applied as a fine spray to a chemically cleaned surface and is allowed to dry between each of five or six applications. In about 6 hours a patina somewhat bluer than natural begins to develop and continues after exposure to weathering.

Small copper parts can be coated with a passivated film by immersion in or brushing with a solution consisting of the following weight proportions: copper, 30; nitric acid, concentrated, 60; acetic acid (6%), 600; ammonium chloride, 11; and ammonium hydroxide (technical grade, 0.90 specific gravity), 20. To prepare the solution, the copper is dissolved in the nitric acid before the remaining chemicals are added, and the solution is allowed to stand for several days before use. A coating of linseed oil is applied to the treated parts.

**Coloring of Copper Alloys.**—Metals are colored to enhance their appearance, to produce an undercoat for an organic finish, or to reduce light reflection. Copper alloys can be treated to produce a variety of colors, with the final color depending on the base metal composition, the coloring solution's composition, the immersion time, and the operator's skill. Cleaning is an important part of the pretreatment; nitric and sulfuric acid solutions are used to remove oxides and to activate the surface.

The following solutions are used to color alloys that contain 85 per cent or more of copper. A dark red color is produced by immersing the parts in molten potassium nitrate, at 1200–1300°F, for up to 20 seconds, followed by a hot water quench. The parts must then be lacquered. A steel black color can be obtained by immersing the parts in a 180°F solution of arsenious oxide (white arsenic), 4 ounces; hydrochloric acid (1.16 specific gravity), 8 fluid ounces; and water, 1 gallon. The parts are immersed until a uniform color is

obtained; they are scratch brushed while wet, and then dried and lacquered. A light brown color is obtained using a room-temperature solution of barium sulfate, 0.5 ounce; ammonium carbonate, 0.25 ounce; and water, 1 gallon.

The following solutions are used to color alloys that contain less than 85 per cent copper. To color brass black, parts are placed in an oblique tumbling barrel made of stainless steel and covered with 3 to 5 gallons of water. Three ounces of copper sulfate and 6 ounces of sodium thiosulfate are dissolved in warm water and added to the barrel's contents. After tumbling for 15 to 30 minutes to obtain the finish, the solution is drained from the barrel, and the parts are washed thoroughly in clean water, dried in sawdust or air-blasted and, if necessary, lacquered. To produce a blue-black color, the parts are immersed in a 130–175°F solution of copper carbonate 1 pound; ammonium hydroxide (0.89 specific gravity), 1 quart; and water, 3 quarts. Excess copper carbonate should be present. The proper color is obtained in 1 minute. To color brass a hardware green, immerse the parts in a 160°F solution of ferric nitrate, 1 ounce; sodium thiosulfate, 6 ounces; and water, 1 gallon. To color brass a light brown, immerse the parts in a 195–212°F solution of potassium chlorate, 5.5 ounces; nickel sulfate, 2.75 ounces; copper sulfate, 24 ounces; and water, 1 gallon.

*Post treatment:* The treated parts should be scratch brushed to remove any excess or loose deposits. A contrast of colors may be obtained by brushing with a slurry of fine pumice, hand nabbing with an abrasive paste, mass finishing, or buffing to remove the color from the highlights. In order to prolong the life of parts used for outdoor decorative purposes, a clear lacquer should be applied. Parts intended for indoor purposes are often used without additional protection.

**Coloring of Iron and Steel.**—Thin black oxide coatings are applied to steel by immersing the parts to be coated in a boiling solution of sodium hydroxide and mixtures of nitrates nitrites. These coatings serve as paint bases and, in some cases, as final finishes. When the coatings are impregnated with oil or wax, they furnish fairly good corrosion resistance. These finishes are relatively inexpensive compared to other coatings.

*Phosphate Coatings:* Phosphate coatings are applied to iron and steel parts by reacting them with a dilute solution of phosphoric acid and other chemicals. The surface of the metal is converted into an integral, mildly protective layer of insoluble crystalline phosphate. Small items are coated in tumbling barrels; large items are spray coated on conveyors.

The three types of phosphate coatings in general use are zinc, iron, and manganese. Zinc phosphate coatings vary from light to dark gray. The color depends on the carbon content and pretreatment of the steel's surface, as well as the composition of the solution. Zinc phosphate coatings are generally used as a base for paint or oil, as an aid in cold working, for increased wear resistance, or for rustproofing. Iron phosphate coatings were the first type to be used; they produce dark gray coatings and their chief application is as a paint base. Manganese phosphate coatings are usually dark gray; however, since they are used almost exclusively as an oil base, for break in and to prevent galling, they become black in appearance.

In general, stainless steels and certain alloy steels cannot be phosphated. Most cast irons and alloy steels accept coating with various degrees of difficulty depending on alloy content.

**Anodizing Aluminum Alloys.**—In the anodizing process, the aluminum object to be treated is immersed as the anode in an acid electrolyte, and a direct current is applied. Oxidation of the surface occurs, producing a greatly thickened, hard, porous film of aluminum oxide. The object is then immersed in boiling water to seal the porosity and render the film impermeable. Before sealing, the film can be colored by impregnation with dyes or pigments. Special electrolytes may also be used to produce colored anodic films directly in the anodizing bath. The anodic coatings are used primarily for corrosion protection and abrasion resistance, and as a paint base.

The three principal types of anodizing processes are: chromic, in which the active agent is chromic acid; sulfuric, in which the active agent is sulfuric acid, and hard anodizing, in which sulfuric acid is used by itself or with additives in a low-temperature electrolyte bath. Most of the anodic coatings range in thickness from 0.2 to 0.7 mil. The hard anodizing process can produce coatings up to 2 mils. The chromic acid coating is less brittle than the sulfuric, and, since the chromic electrolyte does not attack aluminum, it does not present a corrosion problem when it is trapped in crevices. The chromic coating is less resistant to abrasion than the sulfuric, but it cannot be used with alloys containing more than 5 per cent copper due to corrosion of the base metal.

*Chemical Conversion Coatings for Aluminum:* Chemical conversion coatings for aluminum alloys are adherent surface layers of low volatility oxide, phosphate, or chromate compounds produced by the reaction of the metal surface with suitable reagents. The conversion coatings are much thinner and softer than anodic coatings but they are less expensive and serve as an excellent paint base.

**Magnesium Alloys.**—Chemical treatment of magnesium alloys is used to provide a paint base and to improve corrosion resistance. The popular conversion “dip” coatings are chrome pickle and dichromate treatments, and they are very thin. Anodic coatings are thicker and harder, and, after sealing, give the same protection against corrosion, although painting is still desirable.

**Titanium Alloys.**—Chemical conversion coatings are used on titanium alloys to improve lubricity by acting as a base for the retention of lubricants. The coatings are applied by immersion, spraying, or brushing. A popular coating bath is an aqueous solution of phosphates, fluorides, and hydrofluoric acid. The coating is composed primarily of titanium and potassium fluorides and phosphates.

### Plating

**Surface Coatings.**—The following is a list of military plating and coating specifications.

*Anodize (Chromic and Sulfuric), MIL-A-8625F:* Conventional Types I, IB, and II anodic coatings are intended to improve surface corrosion protection under severe conditions or as a base for paint systems. Coatings can be colored with a large variety of dyes and pigments. Class 1 is non-dyed; Class 2 dyed. Color is to be specified on the contract. Prior to dyeing or sealing, coatings shall meet the weight requirements.

Type I and IB coatings should be used on fatigue critical components (due to thinness of coating). Type I unless otherwise specified shall not be applied to aluminum alloys with over 5% copper or 7% silicon or total alloying constituents over 7.5%. Type IC is a mineral or mixed mineral/organic acid that anodizes. It provides a non-chromate alternative for Type I and IB coatings where corrosion resistance, paint adhesion, and fatigue resistance are required. Type IIB is a thin sulfuric anodizing coating for use as non-chromate alternatives for Type I and IB coatings where corrosion resistance, paint adhesion, and fatigue resistance are required. Be sure to specify the class of anodic coating and any special sealing requirements.

Types I, IB, IC, and IIB shall have a thickness between 0.00002 and 0.0007 in. Type II shall have a thickness between 0.0007 and 0.0010 in.

*Black Chrome, MIL-C-14538C:* A hard, non-reflective, abrasion, heat and corrosion resistant coating approximately 0.0002 in. thick. Provides limited corrosion protection, but added protection can be obtained by specifying underplate such as nickel. Color is a dull dark gray, approaching black and may be waxed or oiled to darken.

Black chromium has poor throwing power, and conforming anodes are necessary for intricate shapes. Apply coating after heat treating and all mechanical operations are performed. Steel parts with hardness in excess of 40 Rc shall be stress relieved prior to plating by baking one hour or more (300 to 500°F) and baked after plating (375°F ± 25°F) for 3 hours.

*Black Oxide Coating, MIL-C-13924C:* A uniform, mostly decorative black coating for ferrous metals used to decrease light reflection. Only very limited corrosion protection under mild corrosion conditions. Black oxide coatings should normally be given a supplementary treatment.

Used for moving parts that cannot tolerate the dimensional change of a more corrosion resistant finish. Use alkaline oxidizing for wrought iron, cast and malleable irons, plain carbon, low alloy steel and corrosion resistant steel alloys. Alkaline-chromite oxidizing may be used on certain corrosion resistant steel alloys tempered at less than 900°F Salt oxidizing is suitable for corrosion resistant steel alloys that are tempered at 900°F or higher.

*Cadmium, QQ-P-416F:* Cadmium plating is required to be smooth, adherent, uniform in appearance, free from blisters, pits, nodules, burning, and other defects when examined visually without magnification. Unless otherwise specified in the engineering drawing or procurement documentation, the use of brightening agents in the plating solution to modify luster is prohibited on components with a specified heat treatment of 180 ksi minimum tensile strength (or 40 Rc) and higher. Either a bright (not caused by brightening agents) or dull luster shall be acceptable. Baking on Types II and III shall be done prior to application of supplementary coatings. For Classes 1, 2, and 3 the minimum thicknesses shall be 0.0005, 0.0003, and 0.0002 in. respectively.

Type I is to be used as plated. Types II and III require supplementary chromate and phosphate treatment respectively. Chromate treatment required for type II may be colored iridescent bronze to brown including olive drab, yellow and forest green. Type II is recommended for corrosion resistance. Type III is used as a paint base and is excellent for plating stainless steels that are to be used in conjunction with aluminum to prevent galvanic corrosion. For Types II and III the minimum cadmium thickness requirement shall be met after the supplementary treatment.

*Chemical Films, MIL-C-5541E:* The materials that qualify produce coatings that range in color from clear to iridescent yellow or brown. Inspection difficulties may arise with clear coatings because of their invisibility.

Class 1A chemical conversion coatings are intended to provide corrosion prevention when left unpainted as well as to improve adhesion of paint finish systems on aluminum and aluminum alloys. May be used on tanks, tubings, and component structures where paint finishes are not required for the exterior surfaces but are required for the interior surfaces.

Class 3 chemical conversion coatings are intended for use as a corrosive film for electrical and electronic applications where lower resistant contacts are required. The primary difference between Class 1A and Class 3 coating is thickness.

*Chemical Finish: Black, MIL-F-495E:* A uniform black corrosion retardant for copper. Coating has no abrasion resistance. Used to blacken color and reduce gloss on copper-alloy surfaces other than food service and water supply items. Also used as a base for subsequent coatings such as lacquer, varnish, oil, and wax.

*Chrome, QQ-C-320B:* Has excellent hardness, wear resistance, and erosion resistance. In addition chrome has a low coefficient of friction, is resistant to heat, and can be rendered porous for lubrication purposes.

Types I and II have bright and satin appearances respectively.

Class 1 is used as plating for corrosion protection and Class 2, for engineering plating. Class 1 and 2 both shall have a minimum thickness of 0.00001 in. on all visible surfaces. If thickness is not specified use 0.002 in.

Class 2a will be plated to specified dimensions or processed to specified dimensions after plating. Class 2b will be used on parts below 40 Rc and subject to static loads or designed for limited life under dynamic loads. Class 2c will be used on parts below 40 Rc and designed for unlimited life under dynamic loads. Class 2d parts have hardness of 40 Rc or above, which are subject to static loads or designed for unlimited life under dynamic loads.

Class 2e parts have hardness of 40 Rc or above, which are designed for unlimited life under dynamic loads.

All coated steel parts having a hardness of Rc 36 and higher shall be baked at a minimum of 375°F ± 25°F per the following conditions. With a tensile strength of 160-180 (ksi), the time at temperature will be 3 hr.; at 181-220 ksi, the time will be 8 hr.; and at 221 ksi and above, the time will be 12 hr.

*Copper, MIL-C-14550B:* Has good corrosion resistance when used as an undercoat. A number of copper processes are available, each designed for a specific purpose such as, to improve brightness (to eliminate the need for buffing), high speed (for electro-forming), and fine grain (to prevent case-hardening).

All steel parts having a hardness of Rc 35 and higher shall be baked at 375°F ± 25°F for 24 hours, within four hours after plating to provide hydrogen embrittlement relief. Plated springs and other parts subject to flexure shall not be flexed prior to baking operations.

Class 0 will have a thickness 0.001 - 0.005 in. and is used for heat treatment stop-off; Class 1 is 0.001 in. and is used to provide carburizing shield, also for plated through printed circuit boards. Class 2 is 0.0005 in. thick and is used as an undercoat for nickel and other platings. Class 3 is 0.0002 in. thick and is used to prevent basis metal migration into tin (prevents poisoning solderability). Class 4 is 0.0001 in. thick.

*Tin Lead, MIL-P-81728A:* It has excellent solderability. Either a matte or bright luster is acceptable. For electronics components, use only parts with a matte or flow brightened finish.

For brightened electronic components, the maximum thickness will be 0.0003 in. Tin 50 to 70% by weight and with a lead remainder, 0.0003-0.0005 in.

*Magnesium Process, MIL-M-3171C:* Process #1-A chrome pickle treatment for magnesium. Color varies from matte gray to yellow-red. Has only fair corrosion resistance (< 24 hours, 20% salt spray resistance).

#7-A dichromate treatment for magnesium. Color varies from light brown to gray depending on alloy. Only fair corrosion resistance (< 24 hours, 20% salt spray resistance).

#9-A galvanic anodize treatment for magnesium. Produces a dark brown to black coating. Designed to give a protective film on alloys which do not react to Dow No. 7 treatment. Only fair corrosion resistance (< 24 hours, 20% salt spray resistance).

| Type/Class | Thickness (in.)   | Comments   |
|------------|---|--|
| Type I     | Removes metal. (approx. 0.0006 for wrought, less for die castings.) No dimensional change | Used for protecting magnesium during shipment, storage and machining. Can be used as a paint base. NOTE: Must remove Type I coating before applying Type III and Type IV treatments.   |
| Type III   | ...   | Note: precleaning and pickling may result in dimensional changes due to metal loss.  |
| Type IV    | No dimensional change   | Can be used as a paint base, and is applicable to all magnesium alloys. Used where optical properties (black) are required on close tolerance parts. NOTE: Precleaning and pickling may result in dimensional changes due to metal loss. |

*Magnesium Anodic Treatment, MIL-M-45202C:* The HAE anodic finish is probably the hardest coating currently available for magnesium. It exhibits stability at high temperatures and has good dielectric strength. It serves as an excellent paint base. It requires resin seal or paint for maximum corrosion protection.

| Type/Class             | Typical Thickness | Comments  |
|------------------------|-------------------|---|
| Type I, Light coating. |                   |   |
| Class A                | 0.2 mil           | Tan coating (HAE)   |
| Grade 1                | ...               | Without post treatment (dyed)   |
| Grade 2                | ...               | With bifluoride-dichromate post treatment   |
| Class C                | 0.3 mil           | Light green coating (Dow #17)   |
| Type II, Heavy coating |                   |   |
| Class A                | 1.5 mil           | Hard brown coating (HAE)  |
| Grade 1                | ...               | Without post treatment  |
| Grade 3                | ...               | With bifluoride-dichromate post treatment   |
| Grade 4                | ...               | With bifluoride-dichromate post treatment including moist heat aging                        |
| Grade 5                | ...               | With double application of bifluoride-dichromate post treatment including moist heat aging. |
| Class D                | 1.2 mil           | Dark green coating (Dow #17)  |

Coatings range from thin clear to light gray-green, to thick dark-green coatings. The clear coatings are used as a base for subsequent clear lacquers or paints to produce a final appearance similar to clear anodizing on aluminum. The light gray-green coatings are used in most applications which are to be painted. The thick, dark-green coating offers the best combination of abrasion resistance, protective value and paint base characteristics.

*Electroless Nickel, AMS 2404C, AMS 2405B, AMS 2433B:* Is typically used as a coating to provide a hard-ductile, wear-resistant, and corrosion-resistant surface for operation in service up to 1000°F, to provide uniform build-up on complex shapes.

AMS 2404C, is deposited directly on the basis metal without a flash coating of other metal, unless otherwise specified. AMS 2405B, is deposited directly on the basis metal except where parts fabricated from corrosion resistant steels or alloys where a "strike" coating of nickel or other suitable metal is required, unless otherwise specified. AMS 2433B, is a type of electroless nickel typically used to enhance the solderability of surfaces, but usage is not limited to such applications. Generally, the plate shall be placed directly on the basis metal. However, aluminum alloys shall be zinc immersion coated per ASTM B253 followed by copper flash; corrosion resistant steels and nickel and cobalt alloys or other basis metals may use a nickel or copper flash undercoat when the purchaser permits.

**Electroless Nickel Preparation:** Parts having a hardness higher than Rc 40 and have been machined or ground after heat treatment shall be suitably stress-relieved before cleaning and plating.

After treatment, parts having a hardness of Rc 33 and over shall be heated to 375°F ± 15°F for three hours. If such treatment is injurious to the parts, bake at 275°F ± 15°F for four hours.

Electroless Nickel, Low-Phosphorous

*Note:* If permitted by drawing, the maximum hardness and wear resistance are obtained by heating parts for 30-60 minutes, preferably in an inert atmosphere, at 750°F ± 15°F except aluminum parts shall be baked at 450°F ± 15°F for four hours. If such heating is not specified, bake at 375°F ± 15°F for three hours. If this treatment is injurious to parts or assemblies, bake at 275°F for five hours.

**Plating:** nickel-thallium-boron (Electroless Deposition) and nickel-boron (Electroless Deposition)

**Preparation:** All fabrication-type operations shall be completed.

Post-treatment: Cold worked or heat treated parts and aluminum alloys and other parts requiring special thermal treatment shall be post treated as agreed upon by purchaser and vendor. Other plated parts within four hours after plating shall be heat treated for  $90 \pm 10$  minutes at  $675^\circ\text{F} \pm 15^\circ\text{F}$ .

*Electropolishing, (No MIL-SPEC No.):* This process electrolytically removes or diminishes scratches, burrs, and unwanted sharp edges from most metals. Finishes from satin to mirror-bright are produced by controlling time, temperature, or both.

Typically the thickness loss is 0.0002 in. This process is not recommended for close tolerance surfaces.

*Gold, MIL-G-45204C:* Has a yellow to orange color depending on the proprietary process used. Will range from matte to bright finish depending on basis metal. It has good corrosive resistance and a high tarnish resistance. It provides a low contact resistance, is a good conductor of electricity, and has excellent solderability. If the hardness grade for the gold coating is not specified, Type I shall be furnished at a hardness of Grade A, and Type II furnished at a hardness of Grade C.

For soldering, a thin pure soft gold coating is preferred. A minimum and maximum thickness 0.00005 and 0.00010 in., respectively, shall be plated.

Unless otherwise specified, gold over silver underplate combinations shall be excluded from electronics hardware. Silver or copper plus silver may not be used as an underplate unless required by the item specification. When gold is applied to brass bronze or beryllium copper, or a copper plate or strike, an antidiffusion underplate such as nickel shall be applied.

Type I is 99.7% gold minimum (Grades A, B, or C); Type II is 99.0% (Grades B, C, or D); and Type III is 99.9% (Grade A only).

Grade A is 90 Knoop maximum; Grade B is 91-129 Knoop; Grade C is 130-200 Knoop; and Grade D is 201 Knoop and over.

Class 00 has a thickness of 0.00002 in. minimum; Class 0, 0.00003 in.; Class 1, 0.00005 in.; Class 2, 0.0001 in.; Class 3, 0.0002 in.; Class 4, 0.0003 in.; Class 5, 0.0005 in.; and Class 6, 0.0015 in.

*Hard Anodize, MIL-A-8625F:* The color will vary from light tan to black depending on alloy and thickness. Can be dyed in darker colors depending on the thickness. Coating penetrates base metal as much as builds up on the surface. The term thickness includes both the buildup and penetration. It provides a very hard ceramic type coating. Abrasion resistance will vary with alloy and thickness of coating. Has good dielectric properties.

Do not seal coatings where the main function is to obtain maximum abrasion or wear resistance. When used for exterior applications requiring corrosion resistance but permitting reduced abrasion, the coating shall be sealed (boiling deionized water or hot 5% sodium dichromate solution, or other suitable chemical solutions).

Type III will have a thickness specified on the contract or applicable drawing. If not specified use a nominal thickness of 0.002 in. Hard coatings may vary in thickness from 0.0005 - 0.0045 in.

Class 1 shall be not dyed or pigmented. Class 2 shall be dyed and the color specified on the contract. The process can be controlled to very close thickness tolerances. Where maximum serviceability or special properties are required, consult metal finisher for best alloy choice. Thick coatings (those over 0.004 in.) will tend to break down sharp edges. Can be used as an electrical insulation coating. "Flash" hard anodize may be used instead of conventional anodize for corrosion resistance and may be more economical in conjunction with other hard anodized areas.

*Lubrication, Solid Film MIL-L-46010D:* The Military Plating Specification establishes the requirements for three types of heat cured solid film lubricants that are intended to

reduce wear and prevent galling, corrosion, and seizure of metals. For use on aluminum, copper, steel, stainless steel, titanium, and chromium, and nickel bearing surfaces.

Types I, II, and III have a thicknesses of 0.008 - 0.013 mm. No single reading less than 0.005 mm or greater than 0.018 mm.

Type I has a curing temperature of  $150 \pm 15^\circ\text{C}$  and an endurance life of 250 minutes; Type II,  $204 \pm 15^\circ\text{C}$  and 450 minutes; and Type III is a low volatile organic compound (VOC) content lubricant with cure cycles of  $150 \pm 15^\circ\text{C}$  for two hours, or  $204 \pm 15^\circ\text{C}$  for one hour with an endurance life of 450 minutes. Color 1 has a natural product color and Color 2 has a black color.

*Nickel, QQ-N-290A:* There is a nickel finish for almost any need. Nickel can be deposited soft, hard-dull, or bright, depending on process used and conditions employed in plating. Thus, hardness can range from 150-500 Vickers. Nickel can be similar to stainless steel in color, or can be a dull gray (almost white) color. Corrosion resistance is a function of thickness. Nickel has a low coefficient of thermal expansion.

All steel parts having a tensile strength of 220,000 or greater shall not be a nickel plate without specific approval of procuring agency.

Class 1 is used for corrosion protection. Plating shall be applied over an underplating of copper or yellow brass on zinc and zinc based alloys. In no case, shall the copper underplate be substituted for any part of the specified nickel thickness. Class 2 is used in engineering applications.

Grade A has a thickness of 0.0016 in.; Grade B, 0.0012 in.; Grade C, 0.001 in.; Grade D, 0.0008 in.; Grade E, 0.0006 in.; Grade F, 0.0004 in.; and Grade G, 0.002 in.

*Palladium, MIL-P-45209B:* A gray, dense deposit good for undercoats. Has good wear characteristics, corrosion resistance, catalytic properties, and good conductivity.

The thickness shall be 0.00005 in. unless otherwise specified.

Steel springs and other steel parts subject to flexure or repeated impact and of hardness greater than Rc 40 shall be heated to  $375^\circ\text{F} \pm 25^\circ\text{F}$  for three hours after plating.

*Passivate, QQ-P-35C:* Intended to improve the corrosion resistance of parts made from austenitic, ferritic, and martensitic corrosion-resistant steels of the 200, 300, and 400 series and precipitation hardened corrosion resistant steels. 440C grades may be exempt from passivation treatments of the procuring activity.

Type II is a medium temperature nitric acid solution with sodium dichromate additive. Type VI, a low temperature nitric acid solution; Type VII, a medium temperature nitric acid solution; and Type VIII, a medium temperature high concentration nitric acid solution.

*Phosphate Coating: Light, TT-C-490D:* This specification covers cleaning methods and pretreatment processes.

| Methods /Types   | Typical Thickness (in.) | Comments   |
|------------------|-------------------------|--|
| Cleaning Methods |                         |  |
|                  | –                       | Light coating for use as a paint base.                       |
| Method I         | ...                     | Mechanical or abrasive cleaning (for ferrous surfaces only). |
| Method II        | ...                     | Used for solvent cleaning.                                   |
| Method III       | ...                     | Used for hot alkalines (for ferrous surfaces only).          |
| Method IV        | ...                     | Emulsion.  |
| Method V         | ...                     | Used for alkaline derusting (for ferrous surfaces only).     |
| Method VI        | ...                     | Phosphoric acid.   |

| Pretreatment Coatings |                 |   |
|-----------------------|-----------------|---|
| Type I                | ...             | Zinc phosphate. Class 1-spray application: Class 2A and 2B-Immersion or Dip application |
| Type II               | ...             | Aqueous Iron Phosphate  |
| Type III              | 0.0003 – 0.0005 | Is an organic pretreatment coating  |
| Type IV               | ...             | Non-aqueous iron phosphate  |
| Type V                | ...             | Zinc phosphate  |

Type I is intended as a general all-purpose pretreatment prior to painting. Type II and IV are intended primarily for use where metal parts are to be formed after painting. Type III is intended for use where size and shape preclude using Type I, II, or IV and where items containing mixed metal components are assembled prior to treatment.

*Phosphate Coating: Heavy, DOD-P-16232-F:* The primary differences are that Type M is used as a heavy manganese phosphate coating for corrosion and wear resistance and Type Z is used as a Zinc phosphate coating.

Type M has a thickness from 0.0002-0.0004 in. and Type Z, 0.0002-0.0006 in. Class 1, for both types has a supplementary preservative treatment or coating as specified; Class 2, has a supplementary treatment with lubricating oil; and Class 3, no supplementary treatment is required. For Type M, Class 4 is chemically converted (may be dyed to color as specified) with no supplementary coating or supplementary coating as specified. For Type Z, Class 4 is the same as Class 3.

This coating is for medium and low alloy steels. The coatings range from gray to black in color. The "heavy" phosphate coatings covered by this specification are intended as a base for holding/retaining supplemental coatings which provide the major portion of the corrosion resistance. "Light" phosphate coatings used for a paint base are covered by other specifications. Heavy zinc phosphate coatings may be used when paint and supplemental oil coatings are required on various parts or assemblies.

*Rhodium, MIL-R-46085B:* Rhodium is metallic and similar to stainless steel in color, has excellent corrosion and abrasion resistance, is almost as hard as chromium, and has a high reflectivity. Thicker coatings of Rhodium are very brittle.

| Class/Types | Thickness (in.) | Comments  |
|-------------|-----------------|---|
| Type I      | –               | Over nickel, silver, gold, or platinum.   |
| Type II     | –               | Over other metals, requires nickel undercoat.   |
| Class 1     | 0.000002        | Used on silver for tarnish resistance.  |
| Class 2     | 0.00001         |   |
| Class 3     | 0.00002         | Applications range from electronic to nose cones -wherever wear, corrosion resist solderability and reflectivity are important. |
| Class 4     | 0.00010         |   |
| Class 5     | 0.00025         |   |

Parts having a hardness of Rc 33 or above shall be baked at 375°F for three hours prior to cleaning. Parts having hardness of 40 Rc and above shall be baked within four hours after plating at 375°F for three hours.

*Silver, QQ-S-365D:* Silver has an increasing use in both decorative and engineering fields, including electrical and electronic fields.

Silver is white matte to very bright in appearance. Has good corrosion resistance, depending on base metal and will tarnish easily. Its hardness varies from about 90-135 Brinell depending on process and plating conditions. Solderability is excellent, but decreases with age. Silver is the best conductor of electricity. Has excellent lubricity and

smear characteristics for antigalling uses on static seals, bushing, etc. Stress relief steel parts at a minimum  $375^{\circ}\text{F} \pm 25^{\circ}\text{F}$  or more prior to cleaning and plating if they contain or are suspected of having damaging residual tensile stresses.

All types and grades will have a minimum thickness of 0.0005 in. unless otherwise specified. Type I is matte, Type II is semi-bright, and Type III is bright. Grade A has a chromate post-treatment to improve tarnish resistance. In contrast Grade B has no supplementary treatment.

*Tin, MIL-T-10727C:* There are two different types of coating methods used, electrodeposited (based on Use ASTM B545 standard specification for electrodeposited coatings of tin) and hot dipped.

Thickness as specified on drawing (thickness is not part of the specification) is 0.0001-0.0025 in., flash for soldering; 0.0002-0.0004 in., to prevent galling and seizing; 0.0003 in. minimum, where corrosion resistance is important; and 0.0002-0.0006 to prevent formation of case during nitriding.

Color is a gray-white color in plated condition. Tin is soft, but very ductile. It has good corrosion resistance, and has excellent solderability. Tin is not good for low temperature applications.

If a bright finish is desired to be used in lieu of fused tin, specify Bright Tin plate. Thickness can exceed that of fused tin and deposit shows excellent corrosion resistance and solderability.

*Vacuum Cadmium, MIL-C-8837B:* Is used primarily to provide corrosion resistance to ferrous parts free from hydrogen contamination and possible embrittlement. Recommended on steels with a strength of  $2.2 \times 10^5$  psi or above.

Coating is applied after all machining, brazing, welding, and forming has been completed. Prior to coating, all steel parts shall be stress relieved by baking at  $375^{\circ}\text{F} \pm 25$  for three hours if suspected of having residual tensile stresses. Immediately prior to coating, lightly dry abrasive blast areas are to be coated.

Type I shall be as plated; and Types II and III require supplementary chromate and phosphate treatments respectively.

Classes 1, 2, and 3 have thicknesses of 0.0005, 0.0003, and 0.0002 in. respectively.

Cadmium coating shall not be used, if in service, temperature reaches  $450^{\circ}\text{F}$ .

A salt spray test is required for type II and is 96 hours.

*Zinc, ASTM-B633:* This specification covers requirements for electrodeposited zinc coatings applied to iron or steel articles to protect them from corrosion. It does not cover zinc-coated wire or sheets.

Type I will be as plated; Type II will have colored chromate conversion coatings; Type III will have colorless chromate conversion coatings; and Type IV will have phosphate conversion coatings.

High strength steels (tensile strength over 1700 MPa) shall not be electroplated.

Stress relief: All parts with ultimate tensile strength 1000 MPa and above at minimum  $190^{\circ}\text{C}$  for three hours or more before cleaning and plating.

Hydrogen embrittlement relief: All electroplated parts 1200 MPa or higher shall be baked at  $190^{\circ}\text{C}$  for three hours or more within four hours after electroplating.

| Corrosion Resistance Requirements |                 |
|-----------------------------------|-----------------|
| Types                             | Test Period Hr. |
| II                                | 96              |
| III                               | 12              |

**Flame Spraying Process**

In this process, the forerunner of which was called the metal spraying process, metals, alloys, ceramics, and cermets are deposited on metallic or other surfaces. The object may be to build up worn or undersize parts, provide wear-resisting or corrosion-resisting surfaces, correct defective castings, etc.

Different types of equipment are available that provide the means of depositing the coatings on the surfaces. In one, wire is fed automatically through the nozzle of the spray gun; then a combustible gas, oxygen and compressed air serve to melt and blow the atomized metal against the surface to be coated. The gas usually used is acetylene but other gases may be used. Any desired thickness of metal may be deposited and the metals include steels, ranging from low to high carbon content, various brass and bronze compositions, babbitt metal, tin, zinc, lead, nickel, copper, and aluminum. The movement of the spray gun, in covering a given surface, is controlled either mechanically or by hand. In enlarging worn or undersize shafts, spindles, etc., it is common practice to clamp the gun in a lathe toolholder and use the feed mechanism to traverse the gun at a uniform rate while the metal is being deposited upon the rotating workpiece. The spraying operation may be followed by machining or grinding to obtain a more precise dimension.

Some typical production applications using the wire process are the coating of automotive exhaust valves, refinishing of transfer ink rollers for the printing industry and the rebuilding of worn truck clutch plates. Other production applications include the metallizing of glass meter box windows, the spraying of aluminum onto cloth gauze to produce electrolytic condenser plates, and the spraying of zinc or copper for coating ceramic insulators.

With another type of equipment, metal, refractory, and ceramic powder are used instead of wire. Ordinarily this equipment employs the use of two gases, oxygen and a fuel gas. The fuel gas is usually acetylene but in some instances hydrogen may be used. When hand-held, a small reservoir supplies the powder to the equipment but a larger reservoir is used for lathe-mounted equipment or for large-scale production work. The four basic types of coating powders used with this equipment are ceramics, oxidation-resistant metals and alloys, self-bonding alloys, and alloys for fused coatings. These powders are used to produce wear-resistant, corrosion-resistant, heat-resistant, and electrically conductive coatings.

Still other equipment employs the use of plasma flame with which vapors of materials are raised to a higher energy level than the ordinary gaseous state. Its use raises the temperature ceiling and provides a controlled atmosphere by permitting employment of an inert or chemically inactive gas so that chemical action, such as oxidation, during the heating and application of the spray material can be controlled. The temperatures that can be obtained with commercially available plasma equipment often exceed 30,000 degrees F but for most plasma flame spray processes the temperature range of from 12,000 to 20,000 degrees F is optimum. Plasma flame spray materials include alumina, zirconia, tungsten, molybdenum, tantalum, copper, aluminum, carbides, and nickel-base alloys.

Regardless of the equipment used, what is important is the proper preparation of the surface that will receive the sprayed coating. Preparation activities include the degreasing or solvent cleaning of the surface, undercutting of the surface to provide room for the proper coating thickness, abrasive or grit blasting the substrate to provide a roughened surface, grooving (in the case of flat surfaces) or rough threading (in the case of cylindrical work) the surface to be coated, preheating the base metal. Methods of obtaining a bond between the sprayed material and the substrate are: heating the base, roughening the base, or spraying a "self-bonding" material onto a smooth surface; however, heating alone is seldom used in machine element work as the elevated temperatures required to obtain the proper bond causes problems of warpage and surface corrosion.

All dimensions in inches. The edge of flat and oval head screws may be flat or rounded. Wood screws are also available with Types I, IA, and II recessed heads. Consult the standard for recessed head dimensions. \*The length of the thread,  $L_T$ , on wood screws having cut threads shall be equivalent to approximately two-thirds of the nominal length of the screw. For rolled threads,  $L_T$  shall be at least four times the basic screw diameter or two-thirds of the nominal screw length, whichever is greater. Screws of nominal lengths that are too short to accommodate the minimum thread length shall have threads extending as close to the underside of the head as practicable.

Pilot Hole Drill Sizes for Wood Screws

## RIVETS AND RIVETED JOINTS

### Riveted Joint Design

**Classes and Types of Riveted Joints.**—Riveted joints may be classified by application as: 1) pressure vessel; 2) structural; and 3) machine member.

For information and data concerning joints for pressure vessels such as boilers, reference should be made to standard sources such as the ASME Boiler Code. The following sections will cover only structural and machine-member riveted joints.

Basically there are two kinds of riveted joints, the *lap-joint* and the *butt-joint*. In the ordinary *lap-joint*, the plates overlap each other and are held together by one or more rows of rivets. In the *butt-joint*, the plates being joined are in the same plane and are joined by means of a cover plate or butt strap, which is riveted to both plates by one or more rows of rivets. The term *single riveting* means one row of rivets in a lap-joint or one row on each side of a butt-joint; *double riveting* means two rows of rivets in a lap-joint or two rows on each side of the joint in butt riveting. Joints are also triple and quadruple riveted. Lap-joints may also be made with inside or outside cover plates. Types of lap and butt joints are illustrated in the tables on starting at page 1482.

**General Design Considerations for Riveted Joints.**—Factors to be considered in the design or specification of a riveted joint are: type of joint; spacing of rivets; type and size of rivet; type and size of hole; and rivet material.

*Spacing of Rivets:* The spacing between rivet centers is called *pitch* and between row center lines, *back pitch* or *transverse pitch*. The distance between centers of rivets nearest each other in adjacent rows is called *diagonal pitch*. The distance from the edge of the plate to the center line of the nearest row of rivets is called *margin*.

Examination of a riveted joint made up of several rows of rivets will reveal that after progressing along the joint a given distance, the rivet pattern or arrangement is repeated. (For a butt joint, the length of a *repeating section* is usually equal to the *long pitch* or pitch of the rivets in the outer row, that is the row farthest from the edge of the joint.) For structural and machine-member joints, the proper pitch may be determined by making the tensile strength of the plate over the length of the repeating section, that is the distance between rivets in the outer row, equal to the total shear strength of the rivets in the repeating section. Minimum pitch and diagonal pitch are also governed by the clearance required for the hold-on (Dolly bar) and rivet set. Dimensions for different sizes of hold-ons and rivet sets are given in the table on page 1487.

When fastening thin plate, it is particularly important to maintain accurate spacing to avoid buckling.

*Size and Type of Rivets:* The rivet diameter  $d$  commonly falls between  $d = 1.2\sqrt{t}$  and  $d = 1.4\sqrt{t}$ , where  $t$  is the thickness of the plate. Dimensions for various types of American Standard large ( $\frac{1}{2}$ -inch diameter and up) rivets and small solid rivets are shown in tables that follow. It may be noted that countersunk heads are not as strong as other types.

*Size and Type of Hole:* Rivet holes may be punched, punched and reamed, or drilled. Rivet holes are usually made  $\frac{1}{16}$  inch larger in diameter than the nominal diameter of the rivet although in some classes of work in which the rivet is driven cold, as in automatic machine riveting, the holes are reamed to provide minimum clearance so that the rivet fills the hole completely.

When holes are punched in heavy steel plate, there may be considerable loss of strength unless the holes are reamed to remove the inferior metal immediately surrounding them. This results in the diameter of the punched hole being increased by from  $\frac{1}{16}$  to  $\frac{1}{8}$  inch. Annealing after punching tends to restore the strength of the plate in the vicinity of the holes.

**Rivet Material:** Rivets for structural and machine-member purposes are usually made of wrought iron or soft steel, but for aircraft and other applications where light weight or resistance to corrosion is important, copper, aluminum alloy, Monel, Inconel, etc., may be used as rivet material.

**Simplified Design Assumptions:** In the design of riveted joints, a simplified treatment is frequently used in which the following assumptions are made:

- 1) The load is carried equally by the rivets.
- 2) No combined stresses act on a rivet to cause failure.
- 3) The shearing stress in a rivet is uniform across the cross-section under question.
- 4) The load that would cause failure in single shear would have to be doubled to cause failure in double shear.
- 5) The bearing stress of rivet and plate is distributed equally over the projected area of the rivet.
- 6) The tensile stress is uniform in the section of metal between the rivets.

**Failure of Riveted Joints.**—Rivets may fail by:

- 1) Shearing through one cross-section (single shear)
- 2) Shearing through two cross-sections (double shear)
- 3) Crushing

Plates may fail by:

- 4) Shearing along two parallel lines extending from opposite sides of the rivet hole to the edge of the plate
- 5) Tearing along a single line from middle of rivet hole to edge of plate
- 6) Crushing
- 7) Tearing between adjacent rivets (tensile failure) in the same row or in adjacent rows

Types 4 and 5 failures are caused by rivets being placed too close to the edge of the plate. These types of failure are avoided by placing the center of the rivet at a minimum of one and one-half times the rivet diameter away from the edge.

Types of Rivet and Plate Failure

Failure due to tearing on a diagonal between rivets in adjacent rows when the pitch is four times the rivet diameter or less is avoided by making the transverse pitch one and three-quarters times the rivet diameter.

**Theoretical versus Actual Riveted Joint Failure:** If it is assumed that the rivets are placed the suggested distance from the edge of the plate and each row the suggested distance from another row, then the failure of a joint is most likely to occur as a result of shear failure of the rivets, bearing failure (crushing) of the plate or rivets, or tensile failure of the plate, alone or in combination depending on the makeup of the joints.

Joint failure in actuality is more complex than this. Rivets do not undergo pure shear especially in lap-joints where rivets are subjected to single shear. The rivet, in this instance, would be subject to a combination of tensile and shearing stresses and it would fail because

of combined stresses, not a single stress. Furthermore, the shearing stress is usually considered to be distributed evenly over the cross-section, which is also not the case.

Rivets that are usually driven hot contract on cooling. This contraction in the length of the rivet draws the plates together and sets up a stress in the rivet estimated to be equal in magnitude to the yield point of the rivet steel. The contraction in the diameter of the rivet results in a little clearance between the rivet and the hole in the plate. The tightness in the plates caused by the contraction in length of the rivet gives rise to a condition in which quite a sizeable frictional force would have to be overcome before the plates would slip over one another and subject the rivets to a shearing force. It is European practice to design joints for resistance to this slipping. It has been found, however, that the strength-basis designs obtained in American and English practice are not very different from European designs.

**Allowable Stresses.**—The design stresses for riveted joints are usually set by codes, practices, or specifications. The American Institute of Steel Construction issues specifications for the design, fabrication, and erection of structural steel for buildings in which the allowable stress permitted in tension for structural steel and rivets is specified at 20,000 pounds per square inch, the allowable bearing stress for rivets is 40,000 psi in double shear and 32,000 psi in single shear, and the allowable shearing stress for rivets is 15,000 psi. The American Society of Mechanical Engineers in its Boiler Code lists the following ultimate stresses: tensile, 55,000 psi; shearing, 44,000 psi; compressive or bearing, 95,000 psi. The design stresses usually are one-fifth of these, that is tensile, 11,000 psi; shearing, 8800 psi; compressive or bearing, 19,000 psi. In machine design work, values close to these or somewhat lower are commonly used.

**Analysis of Joint Strength.**—The following examples and strength analyses of riveted joints are based on the six previously outlined *Simplified Design Assumptions*.

*Example 1:* Consider a 12-inch section of single-riveted lap-joint made up with plates of  $\frac{1}{4}$ -inch thickness and six rivets,  $\frac{5}{8}$  inch in diameter. Assume that rivet holes are  $\frac{1}{16}$  inch larger in diameter than the rivets. In this joint, the entire load is transmitted from one plate to the other by means of the rivets. Each plate and the six rivets carry the entire load. The safe tensile load  $L$  and the efficiency  $\eta$  may be determined in the following way: Design stresses of 8500 psi for shear, 20,000 psi for bearing, and 10,000 psi for tension are arbitrarily assigned and it is assumed that the rivets will not tear or shear through the plate to the edge of the joint.

a) The safe tensile load  $L$  based on single shear of the rivets is equal to the number of rivets  $n$  times the cross-sectional area of one rivet  $A_r$  times the allowable shearing stress  $S_s$  or

$$L = n \times A_r \times S_s = 6 \times \frac{\pi}{4} (0.625)^2 \times 8500 = 15,647 \text{ pounds}$$

b) The safe tensile load  $L$  based on bearing stress is equal to the number of rivets  $n$  times the projected bearing area of the rivet  $A_b$  (diameter times thickness of plate) times the allowable bearing stress  $S_c$  or  $L = n \times A_b \times S_c = 6 \times (0.625 \times 0.25) \times 20,000 = 18,750$  pounds.

c) The safe load  $L$  based on the tensile stress is equal to the net cross-sectional area of the plate between rivet holes  $A_p$  times the allowable tensile stress  $S_t$  or

$$L = A_p \times S_t = 0.25[12 - 6(0.625 + 0.0625)] \times 10,000 = 19,688 \text{ pounds.}$$

The safe tensile load for the joint would be the least of the three loads just computed or 15,647 pounds and the efficiency  $\eta$  would be equal to this load divided by the tensile strength of the section of plate under consideration, if it were unperforated or

$$\eta = \frac{15,647}{12 \times 0.25 \times 10,000} \times 100 = 52.2 \text{ per cent}$$

*Example 2:* Under consideration is a 12-inch section of double-riveted butt-joint with main plates  $\frac{1}{2}$  inch thick and two cover plates each  $\frac{5}{16}$  inch thick. There are 3 rivets in the inner row and 2 on the outer and their diameters are  $\frac{7}{8}$  inch. Assume that the diameter of the

rivet holes is  $\frac{1}{16}$  inch larger than that of the rivets. The rivets are so placed that the main plates will not tear diagonally from one rivet row to the others nor will they tear or fail in shear out to their edges. The safe tensile load  $L$  and the efficiency  $\eta$  may be determined in the following way: Design stresses for 8500 psi for shear, 20,000 psi for bearing, and 10,000 psi for tension are arbitrarily assigned.

a) The safe tensile load  $L$  based on double shearing of the rivets is equal to the number of rivets  $n$  times the number of shearing planes per rivet times the cross-sectional area of one rivet  $A_r$  times the allowable shearing stress  $S_s$  or

$$L = n \times 2 \times A_r \times S_s = 5 \times 2 \times \frac{\pi}{4}(0.875)^2 \times 8500 = 51,112 \text{ pounds}$$

b) The safe tensile load  $L$  based on bearing stress is equal to the number of rivets  $n$  times the projected bearing area of the rivet  $A_b$  (diameter times thickness of plate) times the allowable bearing stress  $S_c$  or  $L = n \times A_b \times S_c = 5 \times (0.875 \times 0.5) \times 20,000 = 43,750$  pounds.

(Cover plates are not considered since their combined thickness is  $\frac{1}{4}$  inch greater than the main plate thickness.)

c) The safe tensile load  $L$  based on the tensile stress is equal to the net cross-sectional area of the plate between the two rivets in the outer row  $A_p$  times the allowable tensile stress  $S_t$  or  $L = A_p \times S_t = 0.5[12 - 2(0.875 + 0.0625)] \times 10,000 = 50,625$  pounds.

In completing the analysis, the sum of the load that would cause tearing between rivets in the three-hole section plus the load carried by the two rivets in the two-hole section is also investigated. The sum is necessary because if the joint is to fail, it must fail at both sections simultaneously. The least safe load that can be carried by the two rivets of the two-hole section is based on the bearing stress (see the foregoing calculations).

1) The safe tensile load  $L$  based on the bearing strength of two rivets of the two-hole section is  $L = n \times A_b \times S_c = 2 \times (0.875 \times 0.5) \times 20,000 = 17,500$  pounds.

2) The safe tensile load  $L$  based on the tensile strength of the main plate between holes in the three-hole section is  $L \times A_p \times S_t = 0.5[12 - 3(0.875 + 0.0625)] \times 10,000 = 45,938$  pounds.

The total safe tensile load based on this combination is  $17,500 + 45,938 = 63,438$  pounds, which is greater than any of the other results obtained.

The safe tensile load for the joint would be the least of the loads just computed or 43,750 pounds and the efficiency  $\eta$  would be equal to this load divided by the tensile strength of the section of plate under consideration, if it were unperforated or

$$\eta = \frac{43,750}{0.5 \times 12 \times 10,000} \times 100 = 72.9 \text{ per cent}$$

**Formulas for Riveted Joint Design.**—A riveted joint may fail by shearing through the rivets (single or double shear), crushing the rivets, tearing the plate between the rivets, crushing the plate or by a combination of two or more of the foregoing causes. Rivets placed too close to the edge of the plate may tear or shear the plate out to the edge but this type of failure is avoided by placing the center of the rivet 1.5 times the rivet diameter away from the edge.

The efficiency of a riveted joint is equal to the strength of the joint divided by the strength of the unriveted plate, expressed as a percentage.

In the following formulas, let

$d$  = diameter of holes     $t$  = thickness of plate     $t_c$  = thickness of cover plates

$p$  = pitch of inner row of rivets     $P$  = pitch of outer row of rivets

$S_s$  = shear stress for rivets     $S_t$  = tensile stress for plates

$S_c$  = compressive or bearing stress for rivets or plates

In the joint examples that follow, dimensions are usually specified in inches and stresses in pounds per square inch. See page 1480 for a discussion of allowable stresses that may be used in calculating the strengths given by the formulas. The design stresses are usually set by codes, practices, or specifications.

*Single-Riveted Lap-Joint*

- (1) Resistance to shearing one rivet =  $\frac{\pi d^2}{4} S_s$
- (2) Resistance to tearing plate between rivets =  $(p - D)tS_t$
- (3) Resistance to crushing rivet or plate =  $dtS_c$

*Double-Riveted Lap-Joint*

- (1) Resistance to shearing two rivets =  $\frac{2\pi d^2}{4} S_s$
- (2) Resistance to tearing between two rivets =  $(p - D)tS_t$
- (3) Resistance to crushing in front of two rivets =  $2dtS_c$

*Single-Riveted Lap-Joint with Inside Cover Plate*

- (1) Resistance to tearing between outer row of rivets =  $(P - D)tS_t$
- (2) Resistance to tearing between inner row of rivets, and shearing outer row of rivets =  $(P - 2D)tS_t + \frac{\pi d^2}{4} S_s$
- (3) Resistance to shearing three rivets =  $\frac{3\pi d^2}{4} S_s$
- (4) Resistance to crushing in front of three rivets =  $3tS_c$
- (5) Resistance to tearing at inner row of rivets, and crushing in front of one rivet in outer row =  $(P - 2D)tS_t + tS_c$

*Double-Riveted Lap-Joint with Inside Cover Plate*

- (1) Resistance to tearing at outer row of rivets =  $(P - D)tS_t$
- (2) Resistance to shearing four rivets =  $\frac{4\pi d^2}{4} S_s$
- (3) Resistance to tearing at inner row and shearing outer row of rivets =  $(P - 1\frac{1}{2}D)tS_t + \frac{\pi d^2}{4} S_s$
- (4) Resistance to crushing in front of four rivets =  $4tS_c$
- (5) Resistance to tearing at inner row of rivets, and crushing in front of one rivet =  $(P - 1\frac{1}{2}D)tS_t + tS_c$

*Double-Riveted Butt-Joint*

- (1) Resistance to tearing at outer row of rivets =  $(P - D)tS_t$
- (2) Resistance to shearing two rivets in double shear and one in single shear =  $\frac{5\pi d^2}{4} S_s$
- (3) Resistance to tearing at inner row of rivets and shearing one rivet of the outer row =  $(P - 2D)tS_t + \frac{\pi d^2}{4} S_s$
- (4) Resistance to crushing in front of three rivets =  $3tdS_c$
- (5) Resistance to tearing at inner row of rivets, and crushing in front of one rivet in outer row =  $(P - 2D)tS_t + tdS_c$

*Triple-Riveted Butt-Joint*

- (1) Resistance to tearing at outer row of rivets =  $(P - D)tS_t$
- (2) Resistance to shearing four rivets in double shear and one in single shear =  $\frac{9\pi d^2}{4} S_s$
- (3) Resistance to tearing at middle row of rivets and shearing one rivet =  $(P - 2D)tS_t + \frac{\pi d^2}{4} S_s$
- (4) Resistance to crushing in front of four rivets and shearing one rivet =  $4dtS_c + \frac{\pi d^2}{4} S_s$
- (5) Resistance to crushing in front of five rivets =  $4dtS_c + dt_c S_c$

**American National Standard Rivets**

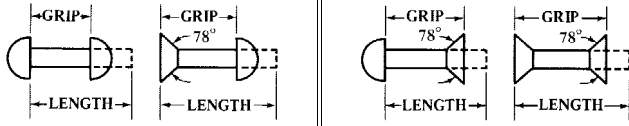

Standards for rivets published by the American National Standards Institute and the British Standards Institution are as follows:

**American National Standard Large Rivets.**—The types of rivets covered by this standard (ANSI B18.1.2-1972 (R1995)) are shown on pages 1485, 1486, and 1487. It may be noted, however, that when specified, the swell neck included in this standard is applicable to all standard large rivets except the flat countersunk head and oval countersunk head types. Also shown are the hold-on (dolly bar) and rivet set impression dimensions (see page 1487). All standard large rivets have fillets under the head not exceeding an 0.062-inch radius. The length tolerances for these rivets are given as follows: through 6 inches in length,  $\frac{1}{2}$ - and  $\frac{5}{8}$ -inch diameters,  $\pm 0.03$  inch;  $\frac{3}{4}$ - and  $\frac{7}{8}$ -inch diameters,  $\pm 0.06$ -inch; and 1-through  $1\frac{3}{4}$ -inch diameters,  $\pm 0.09$  inch. For rivets over 6 inches in length,  $\frac{1}{2}$ - and  $\frac{5}{8}$ -inch diameters,  $\pm 0.06$  inch;  $\frac{3}{4}$ - and  $\frac{7}{8}$ -inch diameters,  $\pm 0.12$  inch; and 1- through  $1\frac{3}{4}$ -inch diameters,  $\pm 0.19$  inch. Steel and wrought iron rivet materials appear in ASTM Specifications A31, A131, A152, and A502.

**American National Standard Small Solid Rivets.**—The types of rivets covered by this standard (ANSI/ASME B18.1.1-1972 (R1995)) are shown on pages 1488 through 1490. In addition, the standard gives the dimensions of 60-degree flat countersunk head rivets used to assemble ledger plates and guards for mower cutter bars, but these are not shown. As the heads of standard rivets are not machined or trimmed, the circumference may be somewhat irregular and edges may be rounded or flat. Rivets other than countersunk types are furnished with a definite fillet under the head, whose radius should not exceed 10 per cent of the maximum shank diameter or 0.03 inch, whichever is the smaller. With regard to head dimensions, tolerances shown in the dimensional tables are applicable to rivets pro-

**Rivet Lengths for Forming Round and Countersunk Heads<sup>a</sup>**

<sup>a</sup> All dimensions are given in inches. Basic dimension as manufactured. For tolerances see table footnote on page 1483. The following formulas give basic dimensions for manufactured shapes: *Flat Countersunk Head*,  $A = 1.810D$ ;  $H = 1.192(\text{Max } A - D)/2$ ; included angle  $Q$  of head = 78 degrees. *Oval Countersunk Head*,  $A = 1.810D$ ;  $H = 1.192(\text{Max } A - D)/2$ ; included angle of head = 78 degrees. Length  $L$  is measured parallel to the rivet axis, from the extreme end to the intersection of the head top surface with the head diameter for countersunk head-type rivets.

<sup>b</sup> Sharp edged head.

<sup>c</sup> Rounded or flat edged irregularly shaped head (heads are not machined or trimmed).

duced by the normal cold heading process. Unless otherwise specified, rivets should have plain sheared ends that should be at right angles within 2 degrees to the axis of the rivet and be reasonably flat. When so specified by the user, rivets may have the standard header points shown on page 1485. Rivets may be made of ASTM Specification A31, Grade A steel; or may adhere to SAE Recommended Practice, Mechanical and Chemical Requirements for Nonthreaded Fasteners—SAE J430, Grade 0. When specified, rivets may be made of other materials.

ANSI/ASME B18.1.3M-1983 (R1995), Metric Small Solid Rivets, provides data for small, solid rivets with flat, round, and flat countersunk heads in metric dimensions. The main series of rivets has body diameters, in millimeters, of 1.6, 2, 2.5, 3, 4, 5, 6, 8, 10, and 12. A secondary series (nonpreferred) consists of sizes, 1, 1.2, 1.4, 3.5, 7, 9, and 11 millimeters.

### British Standard Rivets

**British Standard Rivets for General Engineering.**—Dimensions in metric units of rivets for general engineering purposes are given in this British Standard, BS 4620:1970, which is based on ISO Recommendation ISO/R 1051. The snap head rivet dimensions of 14 millimeters and above are taken from the German Standard DIN 124, Round Head Rivets for Steel Structures. The shapes of heads have been restricted to those in common use in

**Table 1b. American National Standard Large Rivets—ANSI B18.1.2-1972 (R1995)**

| $1\frac{5}{8}$       | 2.844             | 2.969               | 1.422             | 1.344               | 2.600                           | 2.734               | 1.138               | 1.062                 |  |
| $1\frac{3}{4}$       | 3.062             | 3.203               | 1.531             | 1.453               | 2.800                           | 2.938               | 1.225               | 1.141                 |  |

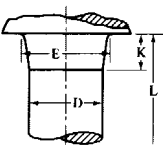

<sup>a</sup>Tolerance for diameter of body is plus and minus from nominal and for  $\frac{1}{2}$ -in. size equals  $+0.020, -0.022$ ; for sizes  $\frac{5}{8}$  to 1-in., incl., equals  $+0.030, -0.025$ ; for sizes  $1\frac{1}{8}$  and  $1\frac{1}{4}$ -in. equals  $+0.035, -0.027$ ; for sizes  $1\frac{3}{8}$  and  $1\frac{1}{2}$ -in. equals  $+0.040, -0.030$ ; for sizes  $1\frac{5}{8}$  and  $1\frac{3}{4}$ -in. equals  $+0.040, -0.037$ .

<sup>b</sup>Note 1. Basic dimensions of head as manufactured. All dimensions are given in inches. The following formulas give the basic dimensions for manufactured shapes: *Button Head*,  $A = 1.750D$ ;  $H = 0.750D$ ;  $G = 0.885D$ . *High Button Head*,  $A = 1.500D + 0.031$ ;  $H = 0.750D + 0.125$ ;  $F = 0.750D + 0.281$ ;  $G = 0.750D - 0.281$ . *Cone Head*,  $A = 1.750D$ ;  $B = 0.938D$ ;  $H = 0.875D$ . *Pan Head*,  $A = 1.600D$ ;  $B = 1.000D$ ;  $H = 0.700D$ . Length  $L$  is measured parallel to the rivet axis, from the extreme end to the bearing surface plane for flat bearing surface head type rivets, or to the intersection of the head top surface with the head diameter for countersunk head-type rivets.

<sup>c</sup>Note 2. Dimensions of manufactured head after driving and also of driven head.

<sup>d</sup>Note 3. Slight flat permissible within the specified head-height tolerance.

<sup>a</sup> The swell neck is applicable to all standard forms of large rivets except the flat countersunk and oval countersunk head types.

<sup>b</sup> All dimensions are given in inches. The following formulas give basic dimensions for manufactured shapes: *Swell Neck*,  $E = D + 0.063$ ;  $K = 0.500D$ . Length *L* is measured parallel to the rivet axis, from the extreme end to the bearing surface plane for flat bearing surface head-type rivets. Basic dimension as manufactured. For tolerances see table footnote on page 1483.

<sup>a</sup> All dimensions are given in inches.

the United Kingdom. Table 3b shows the rivet dimensions. Table 3a shows a tentative range of preferred nominal lengths as given in an appendix to the Standard. It is stated that these lengths will be reviewed in the light of usage. The rivets are made by cold or hot forging methods from mild steel, copper, brass, pure aluminum, aluminum alloys, or other suitable metal. It is stated that the radius under the head of a rivet shall run smoothly into the face of the head and shank without step or discontinuity.

<sup>a</sup> All dimensions in inches except where otherwise noted. Size numbers in pounds refer to the approximate weight of 1000 rivets.

<sup>b</sup> When specified American National Standard Small Solid Rivets may be obtained with points. Point dimensions for belt and coopers rivets are given in the accompanying tables. Formulas for calculating point dimensions of other rivets are given alongside the right diagram in Table 2a.

**Table 2b. American National Standard Small Solid Rivets**

<sup>a</sup> All dimensions in inches. Length tolerance on belt rivets is plus 0.031 inch, minus 0 inch.

<sup>b</sup> Size number refers to the Stub's iron wire gage number of the stock used in the shank of the rivet.

<sup>c</sup> Note: American National Standard Small Solid Rivets may be obtained with or without points. Point proportions are given in the diagram in Table 2a.

Table 2c. American National Standard Small Solid Rivets ANSI/ASME B18.1.1-1972 (R1995) and Appendix

<sup>a</sup> All dimensions in inches. Length tolerance of all rivets is plus or minus 0.016 inch. Approximate proportions of rivets: flat head,  $A = 2.00 \times D$ ,  $H = 0.33 D$ ; flat countersunk head,  $A = 1.850 \times D$ ,  $H = 0.425 \times D$ ; button head,  $A = 1.750 \times D$ ,  $H = 0.750 \times D$ ,  $R = 0.885 \times D$ ; pan head,  $A = 1.720 \times D$ ,  $H = 0.570 \times D$ ,  $R_1 = 0.314 \times D$ ,  $R_2 = 0.850 \times D$ ,  $R_3 = 3.430 \times D$ . Note: ANSI Small Solid Rivets may be obtained with or without points. Point proportions are given in the diagram in Table 2a.

<sup>b</sup> Given for reference purposes only. Variations in this dimension are controlled by the head and shank diameters and the included angle of the head.

<sup>c</sup> Tabulated maximum values calculated on basic diameter of rivet and  $92^\circ$  included angle extended to a sharp edge.

<sup>d</sup> Minimum of rounded or flat-edged irregular-shaped head. Rivet heads are not machined or trimmed and the circumference may be irregular and edges rounded or flat.

In this Standard, **Tables 3a** and **3b**, the following definitions apply: 1) *Nominal diameter*: The diameter of the shank; 2) *Nominal length of rivets other than countersunk or raised countersunk rivets*: The length from the underside of the head to the end of the shank; 3) *Nominal length of countersunk and raised countersunk rivets*: The distance from the periphery of the head to the end of the rivet measured parallel to the axis of the rivet; and 4) *Manufactured head*: The head on the rivet as received from the manufacturer.

**Table 3a. Tentative Range of Lengths for Rivets** Appendix to BS 4620:1970 (1998)

All dimensions are in millimeters.

Note: Sizes and lengths shown in parenthesis are nonpreferred and should be avoided if possible.

**British Standard Small Rivets for General Purposes.**—Dimensions of small rivets for general purposes are given in British Standard 641:1951 and are shown in **Table 4** on page 1493. In addition, the standard lists the standard lengths of these rivets, gives the dimensions of washers to be used with countersunk head rivets (140°), indicates that the rivets may be made from mild steel, copper, brass, and a range of aluminum alloys and pure aluminum specified in B.S. 1473, and gives the dimensions of Coopers' flat head rivets ½ inch in diameter and below, in an appendix. In all types of rivets, except those with countersunk heads, there is a small radius or chamfer at the junction of the head and the shank.

**British Standard Dimensions of Rivets (½ to 1¾ inch diameter).**—The dimensions of rivets covered in BS 275:1927 (obsolescent) are given on page 1494 and do not apply to boiler rivets. With regard to this standard the terms "nominal diameter" and "standard diameter" are synonymous. The term "tolerance" refers to the variation from the nominal diameter of the rivet and not to the difference between the diameter under the head and the diameter near the point.

| $\frac{13}{4}$                                   | $\frac{13}{4}$              | $\frac{125}{32}$ | $\frac{147}{64}$           | $\frac{13}{4}$   | $\frac{147}{64}$           |

<sup>a</sup> All dimensions that are tabulated are given in inches. This standard does not apply to Boiler Rivets

<sup>b</sup> Tolerances of the rivet diameter are as follows: at position X, plus  $\frac{1}{32}$  inch, minus zero; at position Y, plus zero, minus  $\frac{1}{64}$  inch; at position Z, minus  $\frac{1}{64}$  inch but in no case shall the difference between the diameters at positions X and Y exceed  $\frac{1}{32}$  inch, nor shall the diameter of the shank between positions X and Y be less than the minimum diameter specified at position Y.

<sup>c</sup> The location of positions Y and Z are as follows: Position Y is located  $\frac{1}{2}D$  from the end of the rivet for rivet lengths 5 diameters long and under. For longer rivets, position Y is located  $4\frac{1}{2}D$  from the head of the rivet. Position Z (found only on rivets longer than  $5D$ ) is located  $\frac{1}{2}D$  from the end of the rivet.

<sup>d</sup> At the recommendation of the British Standards Institution, these sizes are to be dispensed with wherever possible.

## TORQUE AND TENSION IN FASTENERS

**Tightening Bolts:** Bolts are often tightened by applying torque to the head or nut, which causes the bolt to stretch. The stretching results in bolt tension or preload, which is the force that holds a joint together. Torque is relatively easy to measure with a torque wrench, so it is the most frequently used indicator of bolt tension. Unfortunately, a torque wrench does not measure bolt tension accurately, mainly because it does not take friction into account. The friction depends on bolt, nut, and washer material, surface smoothness, machining accuracy, degree of lubrication, and the number of times a bolt has been installed. Fastener manufacturers often provide information for determining torque requirements for tightening various bolts, accounting for friction and other effects. If this information is not available, the methods described in what follows give general guidelines for determining how much tension should be present in a bolt, and how much torque may need to be applied to arrive at that tension.

High preload tension helps keep bolts tight, increases joint strength, creates friction between parts to resist shear, and improves the fatigue resistance of bolted connections. The recommended preload  $F_i$ , which can be used for either static (stationary) or fatigue (alternating) applications, can be determined from:  $F_i = 0.75 \times A_t \times S_p$  for reusable connections, and  $F_i = 0.9 \times A_t \times S_p$  for permanent connections. In these formulas,  $F_i$  is the bolt preload,  $A_t$  is the tensile stress area of the bolt, and  $S_p$  is the proof strength of the bolt. Determine  $A_t$  from screw-thread tables or by means of formulas in this section. Proof strength  $S_p$  of commonly used ASTM and SAE steel fasteners is given in this section and in the section on metric screws and bolts for those fasteners. For other materials, an approximate value of proof strength can be obtained from:  $S_p = 0.85 \times S_y$ , where  $S_y$  is the yield strength of the material. Soft materials should not be used for threaded fasteners.

Once the required preload has been determined, one of the best ways to be sure that a bolt is properly tensioned is to measure its tension directly with a strain gage. Next best is to measure the change in length (elongation) of the bolt during tightening, using a micrometer or dial indicator. Each of the following two formulas calculates the required change in length of a bolt needed to make the bolt tension equal to the recommended preload. The change in length  $\delta$  of the bolt is given by:

$$\delta = F_i \times \frac{A_d \times l_t + A_t \times l_d}{A_d \times A_t \times E} \quad (1) \quad \text{or} \quad \delta = \frac{F_i \times l}{A \times E} \quad (2)$$

In Equation (1),  $F_i$  is the bolt preload;  $A_d$  is the major-diameter area of the bolt;  $A_t$  is the tensile-stress area of the bolt;  $E$  is the bolt modulus of elasticity;  $l_t$  is the length of the threaded portion of the fastener within the grip; and  $l_d$  is the length of the unthreaded portion of the grip. Here, the grip is defined as the total thickness of the clamped material. Equation (2) is a simplified formula for use when the area of the fastener is constant, and gives approximately the same results as Equation (1). In Equation (2),  $l$  is the bolt length;  $A$  is the bolt area; and  $\delta$ ,  $F_i$ , and  $E$  are as described before.

If measuring bolt elongation is not possible, the torque necessary to tighten the bolt must be estimated. If the recommended preload is known, use the following general relation for the torque:  $T = K \times F_i \times d$ , where  $T$  is the wrench torque,  $K$  is a constant that depends on the bolt material and size,  $F_i$  is the preload, and  $d$  is the nominal bolt diameter. A value of  $K = 0.2$  may be used in this equation for mild-steel bolts in the size range of  $\frac{1}{4}$  to 1 inch. For other steel bolts, use the following values of  $K$ : nonplated black finish, 0.3; zinc-plated, 0.2; lubricated, 0.18; cadmium-plated, 0.16. Check with bolt manufacturers and suppliers for values of  $K$  to use with bolts of other sizes and materials.

The proper torque to use for tightening bolts in sizes up to about  $\frac{1}{2}$  inch may also be determined by trial. Test a bolt by measuring the amount of torque required to fracture it (use bolt, nut, and washers equivalent to those chosen for the real application). Then, use a tightening torque of about 50 to 60 per cent of the fracture torque determined by the test. The tension in a bolt tightened using this procedure will be about 60 to 70 per cent of the elastic limit (yield strength) of the bolt material.

The table that follows can be used to get a rough idea of the torque necessary to properly tension a bolt by using the bolt diameter  $d$  and the coefficients  $b$  and  $m$  from the table; the approximate tightening torque  $T$  in ft-lb for the listed fasteners is obtained by solving the equation  $T = 10^{b+m \log d}$ . This equation is approximate, for use with unlubricated fasteners as supplied by the mill. See the notes at the end of the table for more details on using the equation.

**Wrench Torque  $T = 10^{b+m \log d}$  for Steel Bolts, Studs, and Cap Screws (see notes)**

| Fastener Grade(s)                     | Bolt Diameter $d$ (in.)         | $m$   | $b$   |
|---------------------------------------|---------------------------------|-------|-------|
| SAE 2, ASTM A307                      | $\frac{1}{4}$ to 3              | 2.940 | 2.533 |
| SAE 3                                 | $\frac{1}{4}$ to 3              | 3.060 | 2.775 |
| ASTM A-449, A-354-BB, SAE 5           | $\frac{1}{4}$ to 3              | 2.965 | 2.759 |
| ASTM A-325 <sup>a</sup>               | $\frac{1}{2}$ to $1\frac{1}{2}$ | 2.922 | 2.893 |
| ASTM A-354-BC                         | $\frac{1}{4}$ to $\frac{5}{8}$  | 3.046 | 2.837 |
| SAE 6, SAE 7                          | $\frac{1}{4}$ to 3              | 3.095 | 2.948 |
| SAE 8                                 | $\frac{1}{4}$ to 3              | 3.095 | 2.983 |
| ASTM A-354-BD, ASTM A490 <sup>a</sup> | $\frac{3}{8}$ to $1\frac{3}{4}$ | 3.092 | 3.057 |
| Socket Head Cap Screws                | $\frac{1}{4}$ to 3              | 3.096 | 3.014 |

<sup>a</sup> Values for permanent fastenings on steel structures.

Usage: Values calculated using the preceding equation are for standard, unplated industrial fasteners as received from the manufacturer; for cadmium-plated cap screws, multiply the torque by 0.9; for cadmium-plated nuts and bolts, multiply the torque by 0.8; for fasteners used with special lubricants, multiply the torque by 0.9; for studs, use cap screw values for equivalent grade.

**Preload for Bolts in Loaded Joints.**—The following recommendations are based on MIL-HDBK-60, a subsection of FED-STD-H28, Screw Thread Standards for Federal Service. Generally, bolt preload in joints should be high enough to maintain joint members in contact and in compression. Loss of compression in a joint may result in leakage of pressurized fluids past compression gaskets, loosening of fasteners under conditions of cyclic loading, and reduction of fastener fatigue life.

The relationship between fastener fatigue life and fastener preload is illustrated by Fig. 1. An axially loaded bolted joint in which there is no bolt preload is represented by line OAB, that is, the bolt load is equal to the joint load. When joint load varies between  $P_a$  and  $P_b$ , the bolt load varies accordingly between  $P_{Ba}$  and  $P_{Bb}$ . However, if preload  $P_{B1}$  is applied to the bolt, the joint is compressed and bolt load changes more slowly than the joint load (indicated by line  $P_{B1}A$ , whose slope is less than line OAB) because some of the load is absorbed as a reduction of compression in the joint. Thus, the axial load applied to the joint varies between  $P_{Ba'}$  and  $P_{Bb'}$ , as joint load varies between  $P_a$  and  $P_b$ . This condition results in a considerable reduction in cyclic bolt-load variation and thereby increases the fatigue life of the fastener.

**Preload for Bolts In Shear.**—In shear-loaded joints, with members that slide, the joint members transmit shear loads to the fasteners in the joint and the preload must be sufficient to hold the joint members in contact. In joints that do not slide (i.e., there is no relative motion between joint members), shear loads are transmitted within the joint by frictional forces that mainly result from the preload. Therefore, preload must be great enough for the resulting friction forces to be greater than the applied shear force. With high applied shear loads, the shear stress induced in the fastener during application of the preload must also be

considered in the bolted-joint design. Joints with combined axial and shear loads must be analyzed to ensure that the bolts will not fail in either tension or shear.

Fig. 1. Bolt Load in a Joint with Applied Axial Load

**General Application of Preload.**—Preload values should be based on joint requirements, as outlined before. Fastener applications are generally designed for maximum utilization of the fastener material; that is to say, the fastener size is the minimum required to perform its function and a maximum safe preload is generally applied to it. However, if a low-strength fastener is replaced by one of higher strength, for the sake of convenience or standardization, the preload in the replacement should not be increased beyond that required in the original fastener.

To utilize the maximum amount of bolt strength, bolts are sometimes tightened to or beyond the yield point of the material. This practice is generally limited to ductile materials, where there is considerable difference between the yield strength and the ultimate (breaking) strength, because low-ductility materials are more likely to fail due to unexpected overloads when preloaded to yield. Joints designed for primarily static load conditions that use ductile bolts, with a yield strain that is relatively far from the strain at fracture, are often preloaded above the yield point of the bolt material. Methods for tightening up to and beyond the yield point include tightening by feel without special tools, and the use of electronic equipment designed to compare the applied torque with the angular rotation of the fastener and detect changes that occur in the elastic properties of fasteners at yield.

Bolt loads are maintained below the yield point in joints subjected to cyclic loading and in joints using bolts of high-strength material where the yield strain is close to the strain at fracture. For these conditions, the maximum preloads generally fall within the following ranges: 50 to 80 per cent of the minimum tensile ultimate strength; 75 to 90 per cent of the minimum tensile yield strength or proof load; or 100 per cent of the observed proportional limit or onset of yield.

Bolt heads, driving recesses (in socket screws, for example), and the juncture of head and shank must be sufficiently strong to withstand the preload and any additional stress encountered during tightening. There must also be sufficient thread to prevent stripping (generally, at least three fully engaged threads). Materials susceptible to stress-corrosion cracking may require further preload limitations.

**Preload Adjustments.**—Preloads may be applied directly by axial loading or indirectly by turning of the nut or bolt. When preload is applied by turning of nuts or bolts, a torsion load component is added to the desired axial bolt load. This combined loading increases the tensile stress on the bolt. It is frequently assumed that the additional torsion load component dissipates quickly after the driving force is removed and, therefore, can be largely ignored. This assumption may be reasonable for fasteners loaded near to or beyond yield strength, but for critical applications where bolt tension must be maintained below yield, it is important to adjust the axial tension requirements to include the effects of the preload torsion. For this adjustment, the combined tensile stress (*von Mises* stress)  $F_{tc}$  in psi (MPa) can be calculated from the following:

$$F_{tc} = \sqrt{F_t^2 + 3F_s^2} \quad (3)$$

where  $F_t$  is the axial applied tensile stress in psi (MPa), and  $F_s$  is the shear stress in psi (MPa) caused by the torsion load application.

Some of the torsion load on a bolt, acquired when applying a preload, may be released by springback when the wrenching torque is removed. The amount of relaxation depends on the friction under the bolt head or nut. With controlled back turning of the nut, the torsional load may be reduced or eliminated without loss of axial load, reducing bolt stress and lowering creep and fatigue potential. However, calculation and control of the back-turn angle is difficult, so this method has limited application and cannot be used for short bolts because of the small angles involved.

For relatively soft work-hardenable materials, tightening bolts in a joint slightly beyond yield will work-harden the bolt to some degree. Back turning of the bolt to the desired tension will reduce embedment and metal flow and improve resistance to preload loss.

The following formula for use with single-start Unified inch screw threads calculates the combined tensile stress,  $F_{tc}$ :

$$F_{tc} = F_t \sqrt{1 + 3 \left( \frac{1.96 + 2.31\mu}{1 - 0.325P/d_2} - 1.96 \right)^2} \quad (4)$$

Single-start UNJ screw threads in accordance with MIL-S-8879 have a thread stress diameter equal to the bolt pitch diameter. For these threads,  $F_{tc}$  can be calculated from:

$$F_{tc} = F_t \sqrt{1 + 3 \left( \frac{0.637P}{d_2} + 2.31\mu \right)^2} \quad (5)$$

where  $\mu$  is the coefficient of friction between threads,  $P$  is the thread pitch ( $P = 1/n$ , and  $n$  is the number of threads per inch), and  $d_2$  is the bolt-thread pitch diameter in inches. Both Equations (2) and (3) are derived from Equation (1); thus, the quantity within the radical ( $\sqrt{\quad}$ ) represents the proportion of increase in axial bolt tension resulting from preload torsion. In these equations, tensile stress due to torsion load application becomes most significant when the thread friction,  $\mu$ , is high.

**Coefficients of Friction for Bolts and Nuts.**—Table 1 gives examples of coefficients of friction that are frequently used in determining torque requirements. Dry threads, indicated by the words "None added" in the Lubricant column, are assumed to have some residual machine oil lubrication. Table 1 values are not valid for threads that have been cleaned to remove all traces of lubrication because the coefficient of friction of these threads may be very much higher unless a plating or other film is acting as a lubricant.

**Table 1. Coefficients of Friction of Bolts and Nuts**

| Bolt/Nut Materials  | Lubricant                     | Coefficient of Friction, $\mu \pm 20\%$ |
|---|-------------------------------|---|
| Steel <sup>a</sup>  | Graphite in petrolatum or oil | 0.07                                    |
|   | Molybdenum disulfide grease   | 0.11                                    |
|   | Machine oil                   | 0.15                                    |
| Steel, <sup>a</sup> cadmium-plated                                      | None added                    | 0.12                                    |
| Steel, <sup>a</sup> zinc-plated   | None added                    | 0.17                                    |
| Steel <sup>a</sup> /bronze  | None added                    | 0.15                                    |
| Corrosion-resistant steel or nickel-base alloys/silver-plated materials | None added                    | 0.14                                    |
| Titanium/steel <sup>a</sup>   | Graphite in petrolatum        | 0.08                                    |
| Titanium  | Molybdenum disulfide grease   | 0.10                                    |

<sup>a</sup>"Steel" includes carbon and low-alloy steels but not corrosion-resistant steels.

Where two materials are separated by a slash (/), either may be the bolt material; the other is the nut material.

**Preload Relaxation.**—Local yielding, due to excess bearing stress under nuts and bolt heads (caused by high local spots, rough surface finish, and lack of perfect squareness of bolt and nut bearing surfaces), may result in preload relaxation after preloads are first applied to a bolt. Bolt tension also may be unevenly distributed over the threads in a joint, so thread deformation may occur, causing the load to be redistributed more evenly over the threaded length. Preload relaxation occurs over a period of minutes to hours after the application of the preload, so retightening after several minutes to several days may be required. As a general rule, an allowance for loss of preload of about 10 per cent may be made when designing a joint.

Increasing the resilience of a joint will make it more resistant to local yielding, that is, there will be less loss of preload due to yielding. When practical, a joint-length to bolt-diameter ratio of 4 or more is recommended (e.g., a ¼-inch bolt and a 1-inch or greater joint length). Through bolts, far-side tapped holes, spacers, and washers can be used in the joint design to improve the joint-length to bolt-diameter ratio.

Over an extended period of time, preload may be reduced or completely lost due to vibration; temperature cycling, including changes in ambient temperature; creep; joint load; and other factors. An increase in the initial bolt preload or the use of thread-locking methods that prevent relative motion of the joint may reduce the problem of preload relaxation due to vibration and temperature cycling. Creep is generally a high-temperature effect, although some loss of bolt tension can be expected even at normal temperatures. Harder materials and creep-resistant materials should be considered if creep is a problem or high-temperature service of the joint is expected.

The mechanical properties of fastener materials vary significantly with temperature, and allowance must be made for these changes when ambient temperatures range beyond 30 to 200°F. Mechanical properties that may change include tensile strength, yield strength, and modulus of elasticity. Where bolts and flange materials are generically dissimilar, such as carbon steel and corrosion-resistant steel or steel and brass, differences in thermal expansion that might cause preload to increase or decrease must be taken into consideration.

**Methods of Applying and Measuring Preload.**—Depending on the tightening method, the accuracy of preload application may vary up to 25 per cent or more. Care must be taken to maintain the calibration of torque and load indicators. Allowance should be made for uncertainties in bolt load to prevent overstressing the bolts or failing to obtain sufficient preload. The method of tensioning should be based on the required accuracy and relative costs.

The most common methods of bolt tension control are indirect because it is usually difficult or impractical to measure the tension produced in each fastener during assembly. Table 2 lists the most frequently used methods of applying bolt preload and the approximate accuracy of each method. For many applications, fastener tension can be satisfactorily controlled within certain limits by applying a known torque to the fastener. Laboratory tests have shown that whereas a satisfactory torque tension relationship can be established for a given set of conditions, a change of any of the variables, such as fastener material, surface finish, and the presence or absence of lubrication, may severely alter the relationship. Because most of the applied torque is absorbed in intermediate friction, a change in the surface roughness of the bearing surfaces or a change in the lubrication will drastically affect the friction and thus the torque tension relationship. Regardless of the method or accuracy of applying the preload, tension will decrease in time if the bolt, nut, or washer seating faces deform under load, if the bolt stretches or creeps under tensile load, or if cyclic loading causes relative motion between joint members.

**Table 2. Accuracy of Bolt Preload Application Methods**

| Method                    | Accuracy | Method                     | Accuracy |
|---------------------------|----------|----------------------------|----------|
| By feel                   | ±35%     | Computer-controlled wrench |          |
| Torque wrench             | ±25%     | below yield (turn-of-nut)  | ±15%     |
| Turn-of-nut               | ±15%     | yield-point sensing        | ±8%      |
| Preload indicating washer | ±10%     | Bolt elongation            | ±3–5%    |
| Strain gages              | ±1%      | Ultrasonic sensing         | ±1%      |

Tightening methods using power drivers are similar in accuracy to equivalent manual methods.

**Elongation Measurement.**— Bolt elongation is directly proportional to axial stress when the applied stress is within the elastic range of the material. If both ends of a bolt are accessible, a micrometer measurement of bolt length made before and after the application of tension will ensure the required axial stress is applied. The elongation  $\delta$  in inches (mm) can be determined from the formula  $\delta = F_t \times L_B \div E$ , given the required axial stress  $F_t$  in psi (MPa), the bolt modulus of elasticity  $E$  in psi (MPa), and the effective bolt length  $L_B$  in inches (mm).  $L_B$ , as indicated in Fig. 2, includes the contribution of bolt area and ends (head and nut) and is calculated from:

$$L_B = \left(\frac{d_{ts}}{d}\right)^2 \times \left(L_S + \frac{H_B}{2}\right) + L_J - L_S + \frac{H_N}{2} \quad (6)$$

where  $d_{ts}$  is the thread stress diameter,  $d$  is the bolt diameter,  $L_S$  is the unthreaded length of the bolt shank,  $L_J$  is the overall joint length,  $H_B$  is the height of the bolt head, and  $H_N$  is the height of the nut.

Fig. 2. Effective Length Applicable in Elongation Formulas

The micrometer method is most easily and accurately applied to bolts that are essentially uniform throughout the bolt length, that is, threaded along the entire length or that have only a few threads in the bolt grip area. If the bolt geometry is complex, such as tapered or stepped, the elongation is equal to the sum of the elongations of each section with allowances made for transitional stresses in bolt head height and nut engagement length.

The direct method of measuring elongation is practical only if both ends of a bolt are accessible. Otherwise, if the diameter of the bolt or stud is sufficiently large, an axial hole can be drilled, as shown in Fig. 3, and a micrometer depth gage or other means used to determine the change in length of the hole as the fastener is tightened. A similar method uses a special indicating bolt that has a blind axial hole containing a pin fixed at the bottom. The pin is usually made flush with the bolt head surface before load application. As the bolt is loaded, the elongation causes the end of the pin to move below the reference surface. The displacement of the pin can be converted directly into unit stress by means of a calibrated gage. In some bolts of this type, the pin is set a distance above the bolt so that the pin is flush with the bolt head when the required axial load is reached.

Fig. 3. Hole Drilled to Measure Elongation When One End of Stud or Bolt Is Not Accessible

The *ultrasonic method* of measuring elongation uses a sound pulse, generated at one end of a bolt, that travels the length of a bolt, bounces off the far end, and returns to the sound generator in a measured period of time. The time required for the sound pulse to return depends on the length of the bolt and the speed of sound in the bolt material. The speed of sound in the bolt depends on the material, the temperature, and the stress level. The ultrasonic measurement system can compute the stress, load, or elongation of the bolt at any time by comparing the pulse travel time in the loaded and unstressed conditions. In a similar method, measuring round-trip transit times of longitudinal and shear wave sonic pulses allows calculation of tensile stress in a bolt without consideration of bolt length. This method permits checking bolt tension at any time and does not require a record of the ultrasonic characteristics of each bolt at zero load.

To ensure consistent results, the ultrasonic method requires that both ends of the bolt be finished square to the bolt axis. The accuracy of ultrasonic measurement compares favorably with strain gage methods, but is limited by sonic velocity variations between bolts of the same material and by corrections that must be made for unstressed portions of the bolt heads and threads.

The *turn-of-nut method* applies preload by turning a nut through an angle that corresponds to a given elongation. The elongation of the bolt is related to the angle turned by the formula:  $\delta_B = \theta \times l \div 360$ , where  $\delta_B$  is the elongation in inches (mm),  $\theta$  is the turn angle of the nut in degrees, and  $l$  is the lead of the thread helix in inches (mm). Substituting  $F_t \times L_B \div E$  for elongation  $\delta_B$  in this equation gives the turn-of-nut angle required to attain preload  $F_t$ :

$$\theta = 360 \frac{F_t L_B}{E l} \quad (7)$$

where  $L_B$  is given by Equation (6), and  $E$  is the modulus of elasticity.

Accuracy of the turn-of-nut method is affected by elastic deformation of the threads, by roughness of the bearing surfaces, and by the difficulty of determining the starting point for measuring the angle. The starting point is usually found by tightening the nut enough to seat the contact surfaces firmly, and then loosening it just enough to release any tension and twisting in the bolt. The nut-turn angle will be different for each bolt size, length, mate-

rial, and thread lead. The preceding method of calculating the nut-turn angle also requires elongation of the bolt without a corresponding compression of the joint material. The turn-of-nut method, as just outlined, is not valid for joints with compressible gaskets or other soft material, or if there is a significant deformation of the nut and joint material relative to that of the bolt. The nut-turn angle would then have to be determined empirically using a simulated joint and a tension-measuring device.

The Japanese Industrial Standards (JIS) Handbook, *Fasteners and Screw Threads*, indicates that the turn-of-nut tightening method is applicable in both elastic and plastic region tightening. Refer to JIS B 1083 for more detail on this subject.

*Heating* causes a bolt to expand at a rate proportional to its coefficient of expansion. When a hot bolt and nut are fastened in a joint and cooled, the bolt shrinks and tension is developed. The temperature necessary to develop an axial stress,  $F_p$ , (when the stress is below the elastic limit) can be found as follows:

$$T = \frac{F_t}{Ee} + T_o \quad (8)$$

In this equation,  $T$  is the temperature in degrees Fahrenheit needed to develop the axial tensile stress  $F_t$  in psi,  $E$  is the bolt material modulus of elasticity in psi,  $e$  is the coefficient of linear expansion in in./in.-°F, and  $T_o$  is the temperature in degrees Fahrenheit to which the bolt will be cooled.  $T - T_o$  is, therefore, the temperature change of the bolt. In finite-element simulations, heating and cooling are frequently used to preload mesh elements in tension or compression. Equation (8) can be used to determine required temperature changes in such problems.

*Example:* A tensile stress of 40,000 psi is required for a steel bolt in a joint operating at 70°F. If  $E$  is  $30 \times 10^6$  psi and  $e$  is  $6.2 \times 10^{-6}$  in./in.-°F, determine the temperature of the bolt needed to develop the required stress on cooling.

$$T = \frac{40,000}{(30 \times 10^6)(6.2 \times 10^{-6})} + 70 = 285^\circ\text{F}$$

In practice, the bolt is heated slightly above the required temperature (to allow for some cooling while the nut is screwed down) and the nut is tightened snugly. Tension develops as the bolt cools. In another method, the nut is tightened snugly on the bolt, and the bolt is heated in place. When the bolt has elongated sufficiently, as indicated by inserting a thickness gage between the nut and the bearing surface of the joint, the nut is tightened. The bolt develops the required tension as it cools; however, preload may be lost if the joint temperature increases appreciably while the bolt is being heated.

**Calculating Thread Tensile-Stress Area.**—The tensile-stress area for Unified threads is based on a diameter equivalent to the mean of the pitch and minor diameters. The pitch and the minor diameters for Unified screw threads can be found from the major (nominal) diameter,  $d$ , and the screw pitch,  $P = 1/n$ , where  $n$  is the number of threads per inch, by use of the following formulas: the pitch diameter  $d_p = d - 0.649519 \times P$ ; the minor diameter  $d_m = d - 1.299038 \times P$ . The tensile stress area,  $A_s$ , for Unified threads can then be found as follows:

$$A_s = \frac{\pi}{4} \left( \frac{d_m + d_p}{2} \right)^2 \quad (9)$$

UNJ threads in accordance with MIL-S-8879 have a tensile thread area that is usually considered to be at the basic bolt pitch diameter, so for these threads,  $A_s = \pi d_p^2/4$ . The tensile stress area for Unified screw threads is smaller than this area, so the required tightening torque for UNJ threaded bolts is greater than for an equally stressed Unified threaded bolt

in an equivalent joint. To convert tightening torque for a Unified fastener to the equivalent torque required with a UNJ fastener, use the following relationship:

$$\text{UNJ}_{\text{torque}} = \left( \frac{d \times n - 0.6495}{d \times n - 0.9743} \right)^2 \times \text{Unified}_{\text{torque}} \quad (10)$$

where  $d$  is the basic thread major diameter, and  $n$  is the number of threads per inch.

The tensile stress area for metric threads is based on a diameter equivalent to the mean of the pitch diameter and a diameter obtained by subtracting  $\frac{1}{6}$  the height of the fundamental thread triangle from the external-thread minor diameter. The Japanese Industrial Standard JIS B 1082 (see also ISO 898/1) defines the stress area of metric screw threads as follows:

$$A_s = \frac{\pi}{4} \left( \frac{d_2 + d_3}{2} \right)^2 \quad (11)$$

In Equation (11),  $A_s$  is the stress area of the metric screw thread in  $\text{mm}^2$ ;  $d_2$  is the pitch diameter of the external thread in mm, given by  $d_2 = d - 0.649515 \times P$ ; and  $d_3$  is defined by  $d_3 = d_1 - H/6$ . Here,  $d$  is the nominal bolt diameter;  $P$  is the thread pitch;  $d_1 = d - 1.082532 \times P$  is the minor diameter of the external thread in mm; and  $H = 0.866025 \times P$  is the height of the fundamental thread triangle. Substituting the formulas for  $d_2$  and  $d_3$  into Equation (11) results in  $A_s = 0.7854(d - 0.9382P)^2$ .

The stress area,  $A_s$ , of Unified threads in  $\text{mm}^2$  is given in JIS B 1082 as:

$$A_s = 0.7854 \left( d - \frac{0.9743}{n} \times 25.4 \right)^2 \quad (12)$$

**Relation between Torque and Clamping Force.**—The Japanese Industrial Standard JIS B 1803 defines fastener tightening torque  $T_f$  as the sum of the bearing surface torque  $T_w$  and the shank (threaded) portion torque  $T_s$ . The relationship between the applied tightening torque and bolt preload  $F_{ft}$  is as follows:  $T_f = T_s + T_w = K \times F_f \times d$ . In the preceding,  $d$  is the nominal diameter of the screw thread, and  $K$  is the torque coefficient defined as follows:

$$K = \frac{1}{2d} \left( \frac{P}{\pi} + \mu_s d_2 \sec \alpha' + \mu_w D_w \right) \quad (13)$$

where  $P$  is the screw thread pitch;  $\mu_s$  is the coefficient of friction between threads;  $d_2$  is the pitch diameter of the thread;  $\mu_w$  is the coefficient of friction between bearing surfaces;  $D_w$  is the equivalent diameter of the friction torque bearing surfaces; and  $\alpha'$  is the flank angle at the ridge perpendicular section of the thread ridge, defined by  $\tan \alpha' = \tan \alpha \cos \beta$ , where  $\alpha$  is the thread half angle ( $30^\circ$ , for example), and  $\beta$  is the thread helix, or lead, angle.  $\beta$  can be found from  $\tan \beta = l \div 2\pi r$ , where  $l$  is the thread lead, and  $r$  is the thread radius (i.e., one-half the nominal diameter  $d$ ). When the bearing surface contact area is circular,  $D_w$  can be obtained as follows:

$$D_w = \frac{2}{3} \times \frac{D_o^3 - D_i^3}{D_o^2 - D_i^2} \quad (14)$$

where  $D_o$  and  $D_i$  are the outside and inside diameters, respectively, of the bearing surface contact area.

The torques attributable to the threaded portion of a fastener,  $T_s$ , and bearing surfaces of a joint,  $T_w$ , are as follows:

$$T_s = \frac{F_f}{2} \left( \frac{P}{\pi} + \mu_s d_2 \sec \alpha' \right) \quad (15)$$

$$T_w = \frac{F_f}{2} \mu_w D_w \quad (16)$$

where  $F_{fy}$ ,  $P$ ,  $\mu$ ,  $d_2$ ,  $\alpha'$ ,  $\mu_w$ , and  $D_w$  are as previously defined.

Tables 3 and 4 give values of torque coefficient  $K$  for coarse- and fine-pitch metric screw threads corresponding to various values of  $\mu_s$  and  $\mu_w$ . When a fastener material yields according to the shearing-strain energy theory, the torque corresponding to the yield clamping force (see Fig. 4) is  $T_{fy} = K \times F_{fy} \times d$ , where the yield clamping force  $F_{fy}$  is given by:

$$F_{fy} = \frac{\sigma_y A_s}{\sqrt{1 + 3 \left[ \frac{2}{d_A} \left( \frac{P}{\pi} + \mu_s d_2 \sec \alpha' \right) \right]^2}} \quad (17)$$

**Table 3. Torque Coefficients  $K$  for Metric Hexagon Head Bolt and Nut Coarse Screw Threads**

| Between Threads, $\mu_s$ | Coefficient of Friction<br>Between Bearing Surfaces, $\mu_w$ |       |       |       |       |       |       |       |       |       |

Values in the table are average values of torque coefficient calculated using: Equations (13) and (14) for  $K$  and  $D_w$ ; diameters  $d$  of 4, 5, 6, 8, 10, 12, 16, 20, 24, 30, and 36 mm; and selected corresponding pitches  $P$  and pitch diameters  $d_2$  according to JIS B 0205 (ISO 724) thread standard. Dimension  $D_i$  was obtained for a Class 2 fit without chamfer from JIS B 1001, Diameters of Clearance Holes and Counterbores for Bolts and Screws (equivalent to ISO 273-1979). The value of  $D_o$  was obtained by multiplying the reference dimension from JIS B 1002, width across the flats of the hexagon head, by 0.95.

Values in the table are average values of torque coefficient calculated using Equations (13) and (14) for  $K$  and  $D_w$ ; diameters  $d$  of 8, 10, 12, 16, 20, 24, 30, and 36 mm; and selected respective pitches  $P$  and pitch diameters  $d_2$  according to JIS B 0207 thread standard (ISO 724). Dimension  $D_i$  was obtained for a Class 1 fit without chamfer from JIS B 1001, Diameters of Clearance Holes and Counterbores for Bolts and Screws (equivalent to ISO 273-1979). The value of  $D_o$  was obtained by multiplying the reference dimension from JIS B 1002 (small type series), width across the flats of the hexagon head, by 0.95.

In Equation (17),  $\sigma_y$  is the yield point or proof stress of the bolt,  $A_s$  is the stress area of the thread, and  $d_A = (4A_s/\pi)^{1/2}$  is the diameter of a circle having an area equal to the stress area of the thread. The other variables have been identified previously.

*Example:* Find the torque required to tighten a 10-mm coarse-threaded ( $P = 1.5$ ) grade 8.8 bolt to yield assuming that both the thread- and bearing-friction coefficients are 0.12.

*Solution:* From Equation (17), calculate  $F_{fy}$  and then solve  $T_{fy} = KF_{fy}d$  to obtain the torque required to stress the bolt to the yield point.

$$\sigma_y = 800 \text{ N/mm}^2 \text{ (MPa) (minimum, based on 8.8 grade rating)}$$

$$A_s = 0.7854(10 - 0.9382 \times 1.5)^2 = 57.99 \text{ mm}^2$$

$$d_A = (4A_s/\pi)^{1/2} = 8.6 \text{ mm}$$

$$d_2 = 9.026 \text{ mm (see JIS B 0205 or ISO 724)}$$

Find  $\alpha'$  from  $\tan \alpha' = \tan \alpha \cos \beta$  using:

$$\alpha = 30^\circ; \tan \beta = l \div 2\pi r; l = P = 1.5; \text{ and } r = d \div 2 = 5 \text{ mm}$$

$$\tan \beta = 1.5 \div 10\pi = 0.048, \text{ therefore } \beta = 2.73^\circ$$

$$\tan \alpha' = \tan \alpha \cos \beta = \tan 30^\circ \times \cos 2.73^\circ = 0.577, \text{ and } \alpha' = 29.97^\circ$$

Solving Equation (17) gives the yield clamping force as follows:

$$F_{fy} = \frac{800 \times 58.0}{\sqrt{1 + 3 \left[ \frac{2}{8.6} \left( \frac{1.5}{\pi} + 0.12 \times 9.026 \times \sec 29.97^\circ \right) \right]^2}} = 38,075 \text{ N}$$

$K$  can be determined from Tables 3 (coarse thread) and Tables 4 (fine thread) or from Equations (13) and (14). From Table 3, for  $\mu_s$  and  $\mu_w$  equal to 0.12,  $K = 0.164$ . The yield-point tightening torque can then be found from  $T_{fy} = K \times F_{fy} \times d = 0.164 \times 38,075 \times 10 = 62.4 \times 10^3 \text{ N}\cdot\text{mm} = 62.4 \text{ N}\cdot\text{m}$ .

**Obtaining Torque and Friction Coefficients.**—Given suitable test equipment, the torque coefficient  $K$  and friction coefficients between threads  $\mu_s$  or between bearing surfaces  $\mu_w$  can be determined experimentally as follows: Measure the value of the axial tight-

ening tension and the corresponding tightening torque at an arbitrary point in the 50 to 80 per cent range of the bolt yield point or proof stress (for steel bolts, use the minimum value of the yield point or proof stress multiplied by the stress area of the bolt). Repeat this test several times and average the results. The tightening torque may be considered as the sum of the torque on the threads plus the torque on the bolt head- or nut-to-joint bearing surface. The torque coefficient can be found from  $K = T_f \div F_f \times d$ , where  $F_f$  is the measured axial tension, and  $T_f$  is the measured tightening torque.

To measure the coefficient of friction between threads or bearing surfaces, obtain the total tightening torque and that portion of the torque due to the thread or bearing surface friction. If only tightening torque and the torque on the bearing surfaces can be measured, then the difference between these two measurements can be taken as the thread-tightening torque. Likewise, if only the tightening torque and threaded-portion torque are known, the torque due to bearing can be taken as the difference between the known torques. The coefficients of friction between threads and bearing surfaces, respectively, can be obtained from the following:

$$\mu_s = \frac{2T_s \cos \alpha'}{d_2 F_f} - \cos \alpha' \tan \beta \quad (18) \quad \mu_w = \frac{2T_w}{D_w F_f} \quad (19)$$

As before,  $T_s$  is the torque attributable to the threaded portion of the screw,  $T_w$  is the torque due to bearing,  $D_w$  is the equivalent diameter of friction torque on bearing surfaces according to Equation (14), and  $F_f$  is the measured axial tension.

**Torque-Tension Relationships.**—Torque is usually applied to develop an axial load in a bolt. To achieve the desired axial load in a bolt, the torque must overcome friction in the threads and friction under the nut or bolt head. In Fig. 5, the axial load  $P_B$  is a component of the normal force developed between threads. The normal-force component perpendicular to the thread helix is  $P_{N\beta}$  and the other component of this force is the torque load  $P_B \tan \beta$  that is applied in tightening the fastener. Assuming the turning force is applied at the pitch diameter of the thread, the torque  $T_1$  needed to develop the axial load is  $T_1 = P_B \times \tan \beta \times d_2/2$ . Substituting  $\tan \beta = l \div \pi d_2$  into the previous expression gives  $T_1 = P_B \times l \div 2\pi$ .

Fig. 5. Free Body Diagram of Thread Helix Forces

Fig. 6. Thread Friction Force

In Fig. 6, the normal-force component perpendicular to the thread flanks is  $P_{N\alpha}$ . With a coefficient of friction  $\mu_1$  between the threads, the friction load is equal to  $\mu_1 P_{N\alpha}$ , or  $\mu_1 P_B \div \cos \alpha$ . Assuming the force is applied at the pitch diameter of the thread, the torque  $T_2$  to overcome thread friction is given by:

$$T_2 = \frac{d_2 \mu_1 P_B}{2 \cos \alpha} \quad (20)$$

With the coefficient of friction  $\mu_2$  between a nut or bolt-head pressure face and a component face, as in Fig. 7, the friction load is equal to  $\mu_2 P_B$ . Assuming the force is applied midway between the nominal (bolt) diameter  $d$  and the pressure-face diameter  $b$ , the torque  $T_3$  to overcome the nut or bolt underhead friction is:

$$T_3 = \frac{d+b}{4} \mu_2 P_B \quad (21)$$

The total torque,  $T$ , required to develop axial bolt load,  $P_B$ , is equal to the sum of the torques  $T_1$ ,  $T_2$ , and  $T_3$  as follows:

$$T = P_B \left( \frac{l}{2\pi} + \frac{d_2 \mu_1}{2 \cos \alpha} + \frac{(d+b)\mu_2}{4} \right) \quad (22)$$

For a fastener system with  $60^\circ$  threads,  $\alpha = 30^\circ$  and  $d_2$  is approximately  $0.92d$ . If no loose washer is used under the rotated nut or bolt head,  $b$  is approximately  $1.5d$  and Equation (22) reduces to:

$$T = P_B [0.159 \times l + d(0.531 \mu_1 + 0.625 \mu_2)] \quad (23)$$

In addition to the conditions of Equation (23), if the thread and bearing friction coefficients,  $\mu_1$  and  $\mu_2$ , are equal (which is not necessarily so), then  $\mu_1 = \mu_2 = \mu$ , and the previous equation reduces to:

$$T = P_B (0.159l + 1.156\mu d) \quad (24)$$

*Example:* Estimate the torque required to tighten a UNC  $\frac{1}{2}$ -13 grade 8 steel bolt to a pre-load equivalent to 55 per cent of the minimum tensile bolt strength. Assume that the bolt is unplated and both the thread and bearing friction coefficients equal 0.15.

*Solution:* The minimum tensile strength for SAE grade 8 bolt material is 150,000 psi (from page 1508). To use Equation (24), find the stress area of the bolt using Equation (9) with  $P = 1/13$ ,  $d_m = d - 1.2990P$ , and  $d_p = d - 0.6495P$ , and then calculate the necessary preload,  $P_B$ , and the applied torque,  $T$ .

$$A_s = \frac{\pi}{4} \left( \frac{0.4500 + 0.4001}{2} \right)^2 = 0.1419 \text{ in.}^2$$

$$P_B = \sigma_{\text{allow}} \times A_s = 0.55 \times 150,000 \times 0.1419 = 11,707 \text{ lb}_f$$

$$T = 11,707 \left( \frac{0.159}{13} + 1.156 \times 0.15 \times 0.500 \right) = 1158 \text{ lb-in.} = 96.5 \text{ lb-ft}$$

Fig. 7. Nut or Bolt Head Friction Force

**Grade Marks and Material Properties for Bolts and Screws.**—Bolts, screws, and other fasteners are marked on the head with a symbol that identifies the grade of the fastener. The grade specification establishes the minimum mechanical properties that the fastener must meet. Additionally, industrial fasteners must be stamped with a registered head mark that identifies the manufacturer. The grade identification table identifies the grade markings and gives mechanical properties for some commonly used ASTM and SAE steel fasteners. Metric fasteners are identified by property grade marks, which are specified in ISO and SAE standards. These marks are discussed with metric fasteners.

**Grade Identification Marks and Mechanical Properties of Bolts and Screws**

| Identifier | Grade               | Size (in.) | Min. Strength (10 <sup>3</sup> psi) |         |       | Material & Treatment |
|------------|---------------------|------------|-------------------------------------|---------|-------|----------------------|
|            |                     |            | Proof                               | Tensile | Yield |                      |
| A          | SAE Grade 1         | ¼ to 1½    | 33                                  | 60      | 36    | 1                    |
|            | ASTM A307           | ¼ to 1½    | 33                                  | 60      | 36    | 3                    |
|            | SAE Grade 2         | ¼ to ¾     | 55                                  | 74      | 57    | 1                    |
|            |                     | ¾ to 1½    | 33                                  | 60      | 36    |                      |
|            | SAE Grade 4         | ¼ to 1½    | 65                                  | 115     | 100   | 2, a                 |
| B          | SAE Grade 5         | ¼ to 1     | 85                                  | 120     | 92    | 2, b                 |
|            | ASTM A449           | 1⅛ to 1½   | 74                                  | 105     | 81    |                      |
|            | ASTM A449           | 1¾ to 3    | 55                                  | 90      | 58    |                      |
| C          | SAE Grade 5.2       | ¼ to 1     | 85                                  | 120     | 92    | 4, b                 |
| D          | ASTM A325, Type 1   | ½ to 1     | 85                                  | 120     | 92    | 2, b                 |
|            |                     | 1⅛ to 1½   | 74                                  | 105     | 81    |                      |
| E          | ASTM A325, Type 2   | ½ to 1     | 85                                  | 120     | 92    | 4, b                 |
|            |                     | 1⅛ to 1½   | 74                                  | 105     | 81    |                      |
| F          | ASTM A325, Type 3   | ½ to 1     | 85                                  | 120     | 92    | 5, b                 |
|            |                     | 1⅛ to 1½   | 74                                  | 105     | 81    |                      |
| G          | ASTM A354, Grade BC | ¼ to 2½    | 105                                 | 125     | 109   | 5, b                 |
|            |                     | 2¾ to 4    | 95                                  | 115     | 99    |                      |
| H          | SAE Grade 7         | ¼ to 1½    | 105                                 | 133     | 115   | 7, b                 |
| I          | SAE Grade 8         | ¼ to 1½    | 120                                 | 150     | 130   | 7, b                 |
|            | ASTM A354, Grade BD | ¼ to 1½    | 120                                 | 150     | 130   | 6, b                 |
| J          | SAE Grade 8.2       | ¼ to 1     | 120                                 | 150     | 130   | 4, b                 |
| K          | ASTM A490, Type 1   | ½ to 1½    | 120                                 | 150     | 130   | 6, b                 |
| L          | ASTM A490, Type 3   |            |                                     |         |       | 5, b                 |

Material Steel: 1—low or medium carbon; 2—medium carbon; 3—low carbon; 4—low-carbon martensite; 5—weathering steel; 6—alloy steel; 7— medium-carbon alloy. Treatment: a—cold drawn; b—quench and temper.

**Detecting Counterfeit Fasteners.**—Fasteners that have markings identifying them as belonging to a specific grade or property class are counterfeit if they do not meet the standards established for that class. Counterfeit fasteners may break unexpectedly at smaller loads than expected. Generally, these fasteners are made from the wrong material or they are not properly strengthened during manufacture. Either way, counterfeit fasteners can lead to dangerous failures in assemblies. The law now requires testing of fasteners used in some critical applications. Detection of counterfeit fasteners is difficult because the counterfeits look genuine. The only sure way to determine if a fastener meets its specification is to test it. However, reputable distributors will assist in verifying the authenticity of the fasteners they sell. For important applications, fasteners can be checked to determine whether they perform according to the standard. Typical laboratory checks used to detect fakes include testing hardness, elongation, and ultimate loading, and a variety of chemical tests.

**Mechanical Properties and Grade Markings of Nuts.**—Three grades of hex and square nuts designated Grades 2, 5, and 8 are specified by the SAE J995 standard covering nuts in the  $\frac{1}{4}$ - to  $1\frac{1}{2}$ -inch diameter range. Grades 2, 5, and 8 nuts roughly correspond to the SAE specified bolts of the same grade. Additional specifications are given for miscellaneous nuts such as hex jam nuts, hex slotted nuts, heavy hex nuts, etc. Generally speaking, use nuts of a grade equal to or greater than the grade of the bolt being used. Grade 2 nuts are not required to be marked, however, all Grades 5 and 8 nuts in the  $\frac{1}{4}$ - to  $1\frac{1}{2}$ -inch range must be marked in one of three ways: Grade 5 nuts may be marked with a dot on the face of the nut and a radial or circumferential mark at  $120^\circ$  counterclockwise from the dot; or a dot at one corner of the nut and a radial line at  $120^\circ$  clockwise from the nut, or one notch at each of the six corners of the nut. Grade 8 nuts may be identified by a dot on the face of the nut with a radial or circumferential mark at  $60^\circ$  counterclockwise from the dot; or a dot at one corner of the nut and a radial line at  $60^\circ$  clockwise from the nut, or two notches at each of the six corners of the nut.

**Working Strength of Bolts.**—When the nut on a bolt is tightened, an initial tensile load is placed on the bolt that must be taken into account in determining its safe working strength or external load-carrying capacity. The total load on the bolt theoretically varies from a maximum equal to the sum of the initial and external loads (when the bolt is absolutely rigid and the parts held together are elastic) to a minimum equal to either the initial or external loads, whichever is the greater (where the bolt is elastic and the parts held together are absolutely rigid). No material is absolutely rigid, so in practice the total load values fall somewhere between these maximum and minimum limits, depending upon the relative elasticity of the bolt and joint members.

Some experiments made at Cornell University to determine the initial stress due to tightening nuts on bolts sufficiently to make a packed joint steam-tight showed that experienced mechanics tighten nuts with a pull roughly proportional to the bolt diameter. It was also found that the stress due to nut tightening was often sufficient to break a  $\frac{1}{2}$ -inch (12.7-mm) bolt, but not larger sizes, assuming that the nut is tightened by an experienced mechanic. It may be concluded, therefore, that bolts smaller than  $\frac{5}{8}$  inch (15.9 mm) should not be used for holding cylinder heads or other parts requiring a tight joint. As a result of these tests, the following empirical formula was established for the working strength of bolts used for packed joints or joints where the elasticity of a gasket is greater than the elasticity of the studs or bolts.

$$W = S_t(0.55d^2 - 0.25d)$$

In this formula,  $W$  = working strength of bolt or permissible load, in pounds, after allowance is made for initial load due to tightening;  $S_t$  = allowable working stress in tension, pounds per square inch; and  $d$  = nominal outside diameter of stud or bolt, inches. A somewhat more convenient formula, and one that gives approximately the same results, is

$$W = S_t(A - 0.25d)$$

In this formula,  $W$ ,  $S_t$ , and  $d$  are as previously given, and  $A$  = area at the root of the thread, square inches.

*Example:* What is the working strength of a 1-inch bolt that is screwed tightly in a packed joint when the allowable working stress is 10,000 psi?

$$W = 10,000(0.55 \times 1 - 0.25 \times 1) = 3000 \text{ pounds approx.}$$

**Formulas for Stress Areas and Lengths of Engagement of Screw Threads.**—The critical areas of stress of mating screw threads are: 1) The effective cross-sectional area, or tensile-stress area, of the external thread; 2) the shear area of the external thread, which depends principally on the minor diameter of the tapped hole; and 3) the shear area of the internal thread, which depends principally on the major diameter of the external thread. The relation of these three stress areas to each other is an important factor in determining how a threaded connection will fail, whether by breakage in the threaded section of the screw (or bolt) or by stripping of either the external or internal thread.

If failure of a threaded assembly should occur, it is preferable for the screw to break rather than have either the external or internal thread strip. In other words, the length of engagement of mating threads should be sufficient to carry the full load necessary to break the screw without the threads stripping.

If mating internal and external threads are manufactured of materials having equal tensile strengths, then to prevent stripping of the external thread, the length of engagement should be not less than that given by [Formula \(1\)](#):

$$L_e = \frac{2 \times A_t}{3.1416 K_n \max[\frac{1}{2} + 0.57735n(E_s \min - K_n \max)]} \quad (1)$$

In this formula, the factor of 2 means that it is assumed that the area of the screw in shear must be twice the tensile-stress area to attain the full strength of the screw (this value is slightly larger than required and thus provides a small factor of safety against stripping);  $L_e$  = length of engagement, in inches;  $n$  = number of threads per inch;  $K_n \max$  = maximum minor diameter of internal thread;  $E_s \min$  = minimum pitch diameter of external thread for the class of thread specified; and  $A_t$  = tensile-stress area of screw thread given by [Formula \(2a\)](#) or [\(2b\)](#) or the thread tables for Unified threads, [Tables 4a](#) through [5h](#) starting on page [1763](#), which are based on [Formula \(2a\)](#).

For steels of up to 100,000 psi ultimate tensile strength,

$$A_t = 0.7854 \left( D - \frac{0.9743}{n} \right)^2 \quad (2a)$$

For steels of over 100,000 psi ultimate tensile strength,

$$A_t = 3.1416 \left( \frac{E_s \min}{2} - \frac{0.16238}{n} \right)^2 \quad (2b)$$

In these formulas,  $D$  = basic major diameter of the thread and the other symbols have the same meanings as before.

*Stripping of Internal Thread:* If the internal thread is made of material of lower strength than the external thread, stripping of the internal thread may take place before the screw breaks. To determine whether this condition exists, it is necessary to calculate the factor  $J$  for the relative strength of the external and internal threads given by [Formula \(3\)](#):

$$J = \frac{A_s \times \text{tensile strength of external thread material}}{A_n \times \text{tensile strength of internal thread material}} \quad (3)$$

If  $J$  is less than or equal to 1, the length of engagement determined by [Formula \(1\)](#) is adequate to prevent stripping of the internal thread; if  $J$  is greater than 1, the required length of engagement  $Q$  to prevent stripping of the internal thread is obtained by multiplying the length of engagement  $L_e$ , [Formula \(1\)](#), by  $J$ :

$$Q = JL_e \quad (4)$$

In [Formula \(3\)](#),  $A_s$  and  $A_n$  are the shear areas of the external and internal threads, respectively, given by [Formulas \(5\)](#) and [\(6\)](#):

$$A_s = 3.1416nL_eK_n \max \left[ \frac{1}{2n} + 0.57735(E_s \text{ min} - K_n \text{ max}) \right] \quad (5)$$

$$A_n = 3.1416nL_eD_s \text{ min} \left[ \frac{1}{2n} + 0.57735(D_s \text{ min} - E_n \text{ max}) \right] \quad (6)$$

In these formulas,  $n$  = threads per inch;  $L_e$  = length of engagement from [Formula \(1\)](#);  $K_n \text{ max}$  = maximum minor diameter of internal thread;  $E_s \text{ min}$  = minimum pitch diameter of the external thread for the class of thread specified;  $D_s \text{ min}$  = minimum major diameter of the external thread; and  $E_n \text{ max}$  = maximum pitch diameter of internal thread.

**Load to Break Threaded Portion of Screws and Bolts.**—The direct tensile load  $P$  to break the threaded portion of a screw or bolt (assuming that no shearing or torsional stresses are acting) can be determined from the following formula:

$$P = SA_t$$

where  $P$  = load in pounds to break screw;  $S$  = ultimate tensile strength of material of screw or bolt in pounds per square inch; and  $A_t$  = tensile-stress area in square inches from [Formula \(2a\)](#), [\(2b\)](#), or from the screw thread tables.

**Lock Wire Procedure Detail.**—Wire ties are frequently used as a locking device for bolted connections to prevent loosening due to vibration and loading conditions, or tampering. The use of safety wire ties is illustrated in [Figs. 1](#) and [2](#) below. The illustrations assume the use of right-hand threaded fasteners and the following additional rules apply:

1) No more than three (3) bolts may be tied together; 2) Bolt heads may be tied as shown only when the female thread receiver is captive; 3) Pre-drilled nuts may be tied in a fashion similar to that illustrated with the following conditions. a) Nuts must be heat-treated; and b) Nuts are factory drilled for use with lock wire.

4) Lock wire must fill a minimum of 75% of the drilled hole provided for the use of lock wire; and 5) Lock wire must be aircraft quality stainless steel of 0.508 mm (0.020 inch) diameter, 0.8128 mm (0.032 inch) diameter, or 1.067 mm (0.042 inch) diameter. Diameter of lock wire is determined by the thread size of the fastener to be safe-tied. a) Thread sizes of 6 mm (0.25 inch) and smaller use 0.508mm (0.020 inch) wire; b) Thread sizes of 6 mm (0.25 inch) to 12 mm (0.5 inch) use 0.8128 mm (0.032 inch) wire; c) Thread sizes > 12 mm (0.5 inch) use 1.067 mm (0.042 inch) wire; and d) The larger wire may be used in smaller bolts in cases of convenience, but smaller wire must not be used in larger fastener sizes.

## INCH THREADED FASTENERS

Dimensions of bolts, screws, nuts, and washers used in machine construction are given here. For data on thread forms, see the section *SCREW THREAD SYSTEMS* starting on page 1725.

**American Square and Hexagon Bolts, Screws, and Nuts.**—The 1941 American Standard ASA B18.2 covered head dimensions only. In 1952 and 1955 the Standard was revised to cover the entire product. Some bolt and nut classifications were simplified by elimination or consolidation in agreements reached with the British and Canadians. In 1965 ASA B18.2 was redesignated into two standards: B18.2.1 covering square and hexagon bolts and screws including hexagon cap screws and lag screws and B18.2.2 covering square and hexagon nuts. In B18.2.1-1965, hexagon head cap screws and finished hexagon bolts were consolidated into a single product heavy semifinished hexagon bolts and heavy finished hexagon bolts were consolidated into a single product; regular semifinished hexagon bolts were eliminated; a new tolerance pattern for all bolts and screws and a positive identification procedure for determining whether an externally threaded product should be designated as a bolt or screw were established. Also included in this standard are heavy hexagon bolts and heavy hexagon structural bolts. In B18.2.2-1965, regular semifinished nuts were discontinued; regular hexagon and heavy hexagon nuts in sizes  $\frac{1}{4}$  through 1 inch, finished hexagon nuts in sizes larger than  $1\frac{1}{2}$  inches, washer-faced semifinished style of finished nuts in sizes  $\frac{5}{8}$ -inch and smaller and heavy series nuts in sizes  $\frac{7}{16}$ -inch and smaller were eliminated.

Further revisions and refinements include the addition of askew head bolts and hex head lag screws and the specifying of countersunk diameters for the various hex nuts. Heavy hex structural bolts and heavy hex nuts were moved to a new structural applications standard. Additionally, B18.2.1 has been revised to allow easier conformance to Public Law 101-592. All these changes are reflected in ANSI/ASME B18.2.1-1996, and ANSI/ASME B18.2.2-1987 (R1999).

**Unified Square and Hexagon Bolts, Screws, and Nuts.**—Items that are recognized in the Standard as “unified” dimensionally with British and Canadian standards are shown in bold-face in certain tables.

The other items in the same tables are based on formulas accepted and published by the British for sizes outside the ranges listed in their standards which, as a matter of information, are BS 1768:1963 (obsolescent) for Precision (Normal Series) Unified Hexagon Bolts, Screws, Nuts (UNC and UNF Threads) and B.S. 1769 and amendments for Black (Heavy Series) Unified Hexagon Bolts, etc. Tolerances applied to comparable dimensions of American and British Unified bolts and nuts may differ because of rounding off practices and other factors.

**Differentiation between Bolt and Screw.**—A bolt is an externally threaded fastener designed for insertion through holes in assembled parts, and is normally intended to be tightened or released by torquing a nut.

A screw is an externally threaded fastener capable of being inserted into holes in assembled parts, of mating with a preformed internal thread or forming its own thread and of being tightened or released by torquing the head.

An externally threaded fastener which is prevented from being turned during assembly, and which can be tightened or released only by torquing a nut is a *bolt*. (Example: round head bolts, track bolts, plow bolts.)

An externally threaded fastener that has a thread form which prohibits assembly with a nut having a straight thread of multiple pitch length is a *screw*. (Example: wood screws, tapping screws.)

An externally threaded fastener that must be assembled with a nut to perform its intended service is a *bolt*. (Example: heavy hex structural bolt.)

An externally threaded fastener that must be torqued by its head into a tapped or other preformed hole to perform its intended service is a *screw*. (Example: square head set screw.)

Fig. 5. Hex Nuts, Heavy Hex Nuts (Table 7)

Fig. 6. Hex Jam Nuts, Heavy Hex Jam Nuts (Table 7)

**Square and Hex Bolts, Screws, and Nuts.**—The dimensions for square and hex bolts and screws given in the following tables have been taken from American National Standard ANSI/ASME B18.2.1-1996 and for nuts from American National Standard ANSI/ASME B18.2.2-1987 (R1999) Reference should be made to these Standards for information or data not found in the following text and tables:

*Designation:* Bolts and screws should be designated by the following data in the sequence shown: nominal size (fractional and decimal equivalent); threads per inch (omit for lag screws); product length for bolts and screws (fractional or two-place decimal equivalent); product name; material, including specification, where necessary; and protective finish, if required. Examples: (1)  $\frac{3}{8}$ -16  $\times$   $1\frac{1}{2}$  Square Bolt, Steel, Zinc Plated; (2)  $\frac{1}{2}$ -13  $\times$  3

Hex Cap Screw, SAE Grade 8 Steel; and (3) .75 × 5.00 Hex Lag Screw, Steel. (4) 1/2-13 Square Nut, Steel, Zinc Plated; (5) 3/4-16 Heavy Hex Nut, SAE J995 Grade 5 Steel; and (6) 1000-8 Hex Thick Slotted Nut, ASTM F594 (Alloy Group 1) Corrosion-Resistant Steel.

<sup>a</sup> Heavy hex structural bolts have been removed from the latest version, ANSI/ASME B18.2.1-1996. The table has been included for reference.

All dimensions are in inches. **Bold type shows bolts unified dimensionally with British and Canadian Standards.** Threads, when rolled, shall be Unified Coarse, Fine, or 8-thread series (UNRC, UNRF, or 8 UNR Series), Class 2A. Threads produced by other methods may be Unified Coarse, Fine, or 8-thread series (UNC, UNF, or 8 UN Series), Class 2A.

**Table 3. American National Standard and Unified Standard Hex and Heavy Hex Bolts ANSI/ASME B18.2.1-1996**

<sup>a</sup> *Nominal Size*: Where specifying nominal size in decimals, zeros preceding the decimal point and in the fourth decimal place are omitted.

<sup>b</sup> Thread lengths, *L<sub>T</sub>*, shown are for bolt lengths 6 inches and shorter. For longer bolt lengths add 0.250 inch to thread lengths shown.

All dimensions are in inches.

**Bold type shows bolts unified dimensionally with British and Canadian Standards.**

*Threads*: Threads, when rolled, are Unified Coarse, Fine, or 8-thread series (UNRC, UNRF, or 8 UNR Series), Class 2A. Threads produced by other methods may be Unified Coarse, Fine or 8-thread series (UNC, UNF, or 8 UN Series), Class 2A.

*Body Diameter*: Bolts may be obtained in "reduced diameter body." Where "reduced diameter body" is specified, the body diameter may be reduced to approximately the pitch diameter of the thread. A shoulder of full body diameter under the head may be supplied at the option of the manufacturer.

*Material*: Unless otherwise specified, chemical and mechanical properties of steel bolts conform to ASTM A307, Grade A. Other materials are as agreed upon by manufacturer and purchaser.

<sup>a</sup> *Nominal Size*: Where specifying nominal size in decimals, zeros preceding the decimal and in the fourth decimal place are omitted.

<sup>b</sup> Thread lengths, *L<sub>T</sub>*, shown are for bolt lengths 6 inches and shorter. For longer bolt lengths add 0.250 inch to thread lengths shown.

<sup>c</sup> Thread lengths, *L<sub>T</sub>*, shown are for bolt lengths over 6 inches.

All dimensions are in inches.

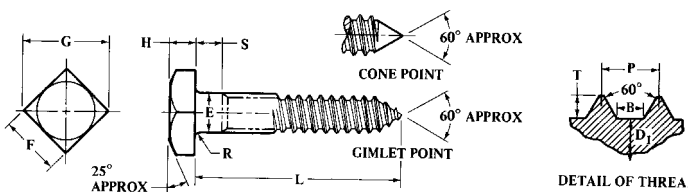

**Unification: Bold type indicates product features unified dimensionally with British and Canadian Standards.** Unification of fine thread products is limited to sizes 1 inch and smaller.

**Bearing Surface:** Bearing surface is flat and washer faced. Diameter of bearing surface is equal to the maximum width across flats within a tolerance of minus 10 per cent.

**Threads Series:** Threads, when rolled, are Unified Coarse, Fine, or 8-thread series (UNRC, UNRF, or 8 UNR Series), Class 2A. Threads produced by other methods shall preferably be UNRC, UNRF or 8 UNR but, at manufacturer's option, may be Unified Coarse, Fine or 8-thread series (UNC, UNF, or 8 UN Series), Class 2A.

**Material:** Chemical and mechanical properties of steel screws normally conform to Grades 2, 5, or 8 of SAE J429, ASTM A449 or ASTM A354 Grade BD. Where specified, screws may also be made from brass, bronze, corrosion-resisting steel, aluminum alloy or other materials.

All dimensions are in inches. Threads are Unified Standard Class 2B, UNC or UNF Series.

**American National Standard Round Head and Round Head Square Neck Bolts**  
ANSI/ASME B18.5-1990

All dimensions are in inches unless otherwise specified.

Threads are Unified Standard, Class 2A, UNC Series, in accordance with ANSI B1.1. For threads with additive finish, the maximum diameters of Class 2A shall apply before plating or coating, whereas the basic diameters (Class 2A maximum diameters plus the allowance) shall apply to a bolt after plating or coating.

Bolts are designated in the sequence shown: nominal size (number, fraction or decimal equivalent); threads per inch; nominal length (fraction or decimal equivalent); product name; material; and protective finish, if required.

i.e.: ½-13 × 3 Round Head Square Neck Bolt, Steel .375-16 × 2.50 Step Bolt, Steel, Zinc Plated

**American National Standard T-Head Bolts ANSI/ASME B18.5-1990**

<sup>a</sup> Where specifying nominal size in decimals, zeros preceding the decimal point and in the fourth decimal place are omitted. For information as to threads and method of bolt designation, see footnotes to preceding table.

All dimensions are given in inches.

For threads with additive finish, the maximum diameters of Class 2A apply before plating or coating, whereas the basic diameters (Class 2A maximum diameters plus the allowance) apply to a bolt after plating or coating.

Bolts are designated in the sequence shown: nominal size (number, fraction or decimal equivalent); threads per inch; nominal length (fraction or decimal equivalent); product name; material; and protective finish, if required. For example,

1/2-13 x 3 Round Head Short Square Neck Bolt, Steel

.375-16 x 2.50 Round Head Short Square Neck Bolt, Steel, Zinc Plated

**American National Standard Round Head Fin Neck Bolts ANSI/ASME B18.5-1990**

| Nominal Size | Body Dia., E |       | Head Dia., A |       | Head Height, H |       | Fin Thick., M |       | Dist. Across Fins, O |       | Fin Depth, P |       |
|--------------|--------------|-------|--------------|-------|----------------|-------|---------------|-------|----------------------|-------|--------------|-------|

<sup>a</sup> Where specifying nominal size in decimals, zeros preceding decimal and in the fourth decimal place shall be omitted.

<sup>b</sup> Tolerance on the No. 10 through  $\frac{1}{2}$  in. sizes for nominal lengths  $\frac{3}{8}$  in. and shorter shall be +0.031 and -0.000.

<sup>c</sup> The minimum radius is one half of the value shown.

All dimensions are given in inches unless otherwise specified.  
For information as to threads and method of designating bolts, see following table.

\*These sizes pertain to 114 degree countersunk square neck bolts only. Dimensions given in last seven columns to the right are for these bolts only.

All dimensions are in inches unless otherwise specified.

Threads are Unified Standard, Class 2A, UNC Series, in accordance with ANSI B1.1. For threads with additive finish, the maximum diameters of Class 2A shall apply before plating or coating, whereas the basic diameters (Class 2A maximum diameters plus the allowance) shall apply to a bolt after plating or coating.

Bolts are designated in the sequence shown: nominal size (number, fraction or decimal equivalent); threads per inch; nominal length (fraction or decimal equivalent); product name; material; and protective finish, if required. For example

1/2-13 x 3 Round Head Square Neck Bolt, Steel .375-16 x 2.50 Step Bolt, Steel, Zinc Plated

<sup>a</sup> Where specifying size in decimals, zeros preceding decimal and in fourth decimal place are omitted.

<sup>b</sup> Flat on minimum diameter head calculated on minimum sharp and absolute minimum head diameters and 82° head angle.

<sup>c</sup> Maximum head height calculated on maximum sharp head diameter, basic bolt diameter, and 78° head angle.

<sup>d</sup> Minimum head height calculated on minimum sharp head diameter, basic bolt diameter, and 82° head angle.

All dimensions are given in inches.

For thread information and method of bolt designation see footnotes to previous table.

Heads are unslotted unless otherwise specified. For slot dimensions see Table 1 in Slotted Head Cap Screw section.

<sup>a</sup> Wrenches are marked with the "Nominal Size of Wrench," which is equal to the basic or maximum width across flats of the corresponding nut. Minimum wrench opening is (1.005W + 0.001). Tolerance on wrench opening is (0.005W + 0.004) from minimum, where W equals nominal size of wrench.

<sup>b</sup> Openings for 5/32 to 3/8 widths from old ASA B18.2-1960 and italic values are from former ANSI B18.2.2-1972.

All dimensions given in inches.

**Wrench Clearance Dimensions.**—Wrench clearances are given in Tables 1 and 2. They are based on a wrench opening corresponding to the dimensions across the flats of the fastener. The listed values were obtained from a composite study of the alloy steel wrenches that are commercially available and military specifications. They are suitable for general use as minimum requirements.

<sup>a</sup> Nominal washer sizes are intended for use with comparable nominal screw or bolt sizes.

<sup>b</sup> The 0.734-inch, 1.156-inch, and 1.469-inch outside diameters avoid washers which could be used in coin operated devices.

All dimensions are in inches.

Preferred sizes are for the most part from series previously designated "Standard Plate" and "SAE." Where common sizes existed in the two series, the SAE size is designated "N" (narrow) and the Standard Plate "W" (wide). These sizes as well as all other sizes of Type A Plain Washers are to be ordered by ID, OD, and thickness dimensions.

Additional selected sizes of Type A Plain Washers are shown in [Table 1b](#).

**Table 1b. American National Standard Type A Plain Washers — Additional Selected Sizes ANSI/ASME B18.22.1-1965 (R1998)**

| Inside Diameter |           |       | Outside Diameter   |           |       | Thickness |       |       |

<sup>a</sup> The 0.734-inch and 1.469-inch outside diameters avoid washers which could be used in coin operated devices.

All dimensions are in inches.

The above sizes are to be ordered by ID, OD, and thickness dimensions.

Preferred Sizes of Type A Plain Washers are shown in [Table 1a](#).

**ANSI Standard Plain Washers.**—The Type A plain washers were originally developed in a light, medium, heavy and extra heavy series. These series have been discontinued and the washers are now designated by their nominal dimensions.

The Type B plain washers are available in a narrow, regular and wide series with proportions designed to distribute the load over larger areas of lower strength materials.

Plain washers are made of ferrous or non-ferrous metal, plastic or other material as specified. The tolerances indicated in the tables are intended for metal washers only.

**Table 2. American National Standard Type B Plain Washers —**

| Nominal Washer Size <sup>a</sup> |       | Series <sup>b</sup> | Inside Diameter |           |       | Outside Diameter   |           |       | Thickness |       |       |

<sup>a</sup> Nominal washer sizes are intended for use with comparable nominal screw or bolt sizes.

<sup>b</sup> N indicates Narrow; R, Regular; and W, Wide Series.

<sup>c</sup> The 0.734-inch and 1.469-inch outside diameter avoids washers which could be used in coin operated devices.

All dimensions are in inches.

Inside and outside diameters shall be concentric within at least the inside diameter tolerance.

Washers shall be flat within 0.005-inch for basic outside diameters up through 0.875-inch and within 0.010 inch for larger outside diameters.

For 2 1/4-, 2 1/2-, 2 3/4-, and 3-inch sizes see ANSI/ASME B18.22.1-1965 (R1998).

**American National Standard Helical Spring and Tooth Lock Washers ANSI/ASME B18.21.1-1994.**— This standard covers helical spring lock washers of carbon steel; boron steel; corrosion resistant steel, Types 302 and 305; aluminum-zinc alloy; phosphor-bronze; silicon-bronze; and K-Monel; in various series. Tooth lock washers of carbon steel having internal teeth, external teeth, and both internal and external teeth, of two constructions, designated as Type A and Type B. Washers intended for general industrial application are also covered. American National Standard Lock Washers (Metric Series) ANSI/ASME B18.21.2M-1994 covers metric sizes for helical spring and tooth lock washers.

*Helical spring lock washers:* These washers are used to provide: 1) good bolt tension per unit of applied torque for tight assemblies; 2) hardened bearing surfaces to create uniform torque control; 3) uniform load distribution through controlled radii—section—cut-off; and 4) protection against looseness resulting from vibration and corrosion.

Nominal washer sizes are intended for use with comparable nominal screw or bolt sizes. These washers are designated by the following data in the sequence shown: Product name; nominal size (number, fraction or decimal equivalent); series; material; and protective finish, if required. For example: Helical Spring Lock Washer, 0.375 Extra Duty, Steel, Phosphate Coated.

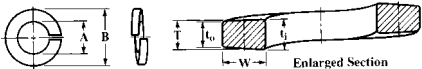

Helical spring lock washers are available in four series: Regular, heavy, extra duty and hi-collar as given in [Tables 2 and 1](#). Helical spring lock washers made of materials other than carbon steel are available in the regular series as given in [Table 2](#).

<sup>a</sup>T = mean section thickness = (t<sub>1</sub> + t<sub>2</sub>) ÷ 2.

WASHERS

All dimensions are given in inches.\*See ANSI/ASME B18.21.1-1994 standard for sizes over 1½ to 3, inclusive, for regular and heavy helical spring lock washers and over 1½ to 2, inclusive, for extra-duty helical spring lock washers.

When carbon steel helical spring lock washers are to be hot-dipped galvanized for use with hot-dipped galvanized bolts or screws, they are to be coated to limits onto inch in excess of those specified in Tables 2 and 1 for minimum inside diameter and maximum outside diameter. Galvanizing washers under ¼ inch nominal size are not recommended.

*Tooth lock washers:* These washers serve to lock fasteners, such as bolts and nuts, to the component parts of an assembly, or increase the friction between the fasteners and the assembly. They are designated in a manner similar to helical spring lock washers, and are available in carbon steel. Dimensions are given in Tables 3 and 4.

**Table 3. American National Standard Internal-External Tooth Lock Washers**  
ANSI/ASME B18.21.1-1994

All dimensions are given in inches except whole numbers under "Size"

| Size   | A               |      | B                |       |           |      | Size | A               |       | B                |       |           |      |

<sup>a</sup> Starting with #4, approx. O.D.'s are: 0.213, 0.289, 0.322, 0.354, 0.421, 0.454, 0.505, 0.599, 0.765, 0.867, and 0.976.

All dimensions are given in inches.

**METRIC THREADED FASTENERS**

A number of American National Standards covering metric bolts, screws, nuts, and washers have been established in cooperation with the Department of Defense in such a way that they could be used by the Government for procurement purposes. Extensive information concerning these metric fasteners is given in the following text and tables, but for additional manufacturing and acceptance specifications reference should be made to the respective Standards which may be obtained by nongovernmental agencies from the American National Standards Institute, 25 West 43rd Street, New York, N.Y. 10036. These Standards are:

|  |          |
|--|----------|

| ANSI B18.2.4.6M-1979 (R1990) Metric Heavy Hex Nuts             | Table 31 |
| ANSI B18.22M-1981 (R1990) Metric Plain Washers                 | Table 32 |

Manufacturers should be consulted concerning which items and sizes are in stock production.

**Comparison with ISO Standards.**—American National Standards for metric bolts, screws and nuts have been coordinated to the extent possible with the comparable ISO Standards or proposed Standards. The dimensional differences between the ANSI and the comparable ISO Standards or proposed Standards are few, relatively minor, and none will affect the functional interchangeability of bolts, screws, and nuts manufactured to the requirements of either.

Where no comparable ISO Standard had been developed, as was the case when the ANSI Standards for Metric Heavy Hex Screws, Metric Heavy Hex Bolts, and Metric Hex Lag Screws were adopted, nominal diameters, thread pitches, body diameters, widths across flats, head heights, thread lengths, thread dimensions, and nominal lengths are in accord with ISO Standards for related hex head screws and bolts. At the time of ANSI adoption (1982) there was no ISO Standard for round head square neck bolts.

The following functional characteristics of hex head screws and bolts are in agreement between the respective ANSI Standard and the comparable ISO Standard or proposed Standard: diameters and thread pitches, body diameters, widths across flats (see exception below), bearing surface diameters (except for metric hex bolts), flange diameters (for metric hex flange screws), head heights, thread lengths, thread dimensions, and nominal lengths.

**Table 1. American National Standard Metric Hex Cap Screws**  
ANSI/ASME B18.2.3.1M-1979 (R1995)

\* This size with width across flats of 15 mm is not standard. Unless specifically ordered, M10 hex cap screws with 16 mm width across flats will be furnished.

All dimensions are in millimeters.

Basic thread lengths,  $B$ , are the same as given in Table 12.

Transition thread length,  $X$ , includes the length of incomplete threads and tolerances on grip gaging length and body length. It is intended for calculation purposes.

For additional manufacturing and acceptance specifications, reference should be made to the ANSI/ASME B18.2.3.1M-1979 (R1995).

<sup>a</sup>This size with width across flats of 15 mm is not standard. Unless specifically ordered, M10 formed hex screws with 16 mm width across flats will be furnished.

All dimensions are in millimeters.

†Basic thread lengths,  $B$ , are the same as given in Table 12.

‡Transition thread length,  $X$ , includes the length of incomplete threads and tolerances on the grip gaging length and body length. It is intended for calculation purposes.

For additional manufacturing and acceptance specifications, reference should be made to the Standard.

Socket head cap screws ANSI B18.3.1M-1986 are functionally interchangeable with screws which conform to ISO R861-1968 or ISO 4762-1977. However, the thread lengths specified in the ANSI Standard are equal to or longer than required by either ISO Standard. Consequently the grip lengths also vary on screws where the North American thread length practice differs. Minor variations in head diameter, head height, key engagement and wall thickness are due to diverse tolerancing practice and will be found documented in the ANSI Standard.

One exception with respect to width across flats for metric hex cap screws, formed hex screws, and hex bolts is the M10 size. These are currently being produced in the United States with a width across flats of 15 mm. This size, however, is not an ISO Standard. Unless these M10 screws and bolts with 15 mm width across flats are specifically ordered, the M10 size with 16 mm across flats will be furnished.

| M24 × 3                                    | 24.00                | 23.67 | 41.00                   | 40.00 | 47.34                     | 45.20 | 15.44            | 14.56 | 10.5                    | 0.8                        | 0.4 | 38.0                    |
| M30 × 3.5                                  | 30.00                | 29.67 | 50.00                   | 49.00 | 57.74                     | 55.37 | 19.48            | 17.92 | 13.1                    | 0.8                        | 0.4 | 46.6                    |
| M36 × 4                                    | 36.00                | 35.61 | 60.00                   | 58.80 | 69.28                     | 66.44 | 23.38            | 21.72 | 15.8                    | 0.8                        | 0.4 | 55.9                    |

All dimensions are in millimeters.

Basic thread lengths,  $B$ , are the same as given in Table 12.

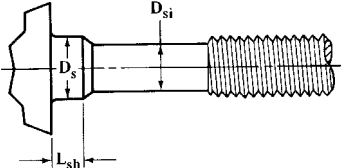

Transition thread length,  $X$ , includes the length of incomplete threads and tolerances on grip gaging length and body length. It is intended for calculation purposes.

For additional manufacturing and acceptance specifications, reference should be made to the Standard.

ANSI letter symbols designating dimensional characteristics are in accord with those used in ISO Standards except capitals have been used for data processing convenience instead of the lower case letters used in the ISO Standards.

**Metric Screw and Bolt Diameters.**—Metric screws and bolts are furnished with full diameter body within the limits shown in the respective dimensional tables, or are threaded to the head (see *Metric Screw and Bolt Thread Lengths* on page 1551) unless the purchaser specifies "reduced body diameter." Metric formed hex screws (Table 4), hex flange screws (Table 4), hex bolts (Table 4), heavy hex bolts (Table 4), hex lag screws (Table 5), heavy hex flange screws (Table 6), and round head square neck bolts (Table 8) may be obtained with reduced diameter body, if so specified; however, formed hex screws, hex flange screws, heavy hex flange screws, hex bolts, or heavy hex bolts with nominal lengths shorter than  $4D$ , where  $D$  is the nominal diameter, are not recommended. Metric formed hex screws, hex flange screws, heavy hex flange screws, and hex lag screws with reduced body diameter will be furnished with a shoulder under the head. For metric hex bolts and heavy hex bolts this is optional with the manufacturer.

For bolts and lag screws there may be a reasonable swell, fin, or die seam on the body adjacent to the head not exceeding the nominal bolt diameter by: 0.50 mm for M5, 0.65 mm for M6, 0.75 mm for M8 through M14, 1.25 mm for M16, 1.50 mm for M20 through M30, 2.30 mm for M36 through M48, 3.00 mm for M56 through M72, and 4.80 mm for M80 through M100.

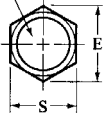

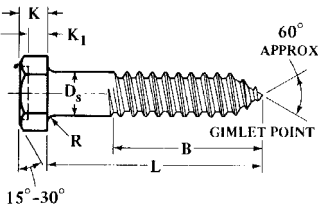

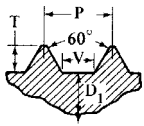

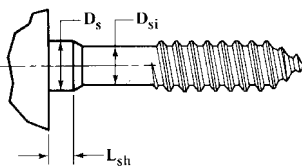

**Table 4. American National Standard Metric Hex Screws and Bolts — Reduced Body Diameters**

| Nominal Dia., $D$ , and Thread Pitch                   | Shoulder Diameter, <sup>a</sup> $D_s$ |       | Body Diameter, $D_{si}$ |       | Shoulder Length, <sup>a</sup> $L_{sh}$ |     | Nominal Dia., $D$ , and Thread Pitch | Shoulder Diameter, <sup>a</sup> $D_s$ |       | Body Diameter, $D_{si}$ |       | Shoulder Length, <sup>a</sup> $L_{sh}$ |      |

<sup>a</sup> Shoulder is mandatory for formed hex screws, hex flange screws, and heavy hex flange screws. Shoulder is optional for hex bolts and heavy hex bolts.

All dimensions are in millimeters.

All dimensions are in millimeters. Basic thread lengths,  $B$ , are as given in Table 12. Transition thread length,  $x$ , includes the length of incomplete threads and tolerances on grip gaging length and body length. It is intended for calculation purposes. For additional manufacturing and acceptance specifications, reference should be made to ANSI/ASME B18.2.3.9M-1984 standard.

All dimensions are in millimeters.

† $L_g$  is the grip gaging length which controls the length of thread *B*.

‡ $B$  is the basic thread length and is a reference dimension (see Table 13).

For additional manufacturing and acceptance specifications, see ANSI/ASME B18.5.2.2M-1982, R1993.

<sup>a</sup> Basic thread length, *B*, is a reference dimension.

<sup>b</sup> Transition thread length, *X*, includes the length of incomplete threads and tolerances on grip gaging length and body length. It is intended for calculation purposes.

All dimensions are in millimeters.

For additional manufacturing and acceptance specifications, reference should be made to the ANSI B18.2.3.7M-1979 (R1995) standard.

<sup>a</sup> Basic thread length,  $B$ , is a reference dimension.

<sup>b</sup> This size with width across flats of 15 mm is not standard. Unless specifically ordered, M10 hex bolts with 16 mm width across flats will be furnished.

All dimensions are in millimeters.

For additional manufacturing and acceptance specifications, reference should be made to the ANSI B18.2.3.5M-1979 (R1995) standard.

**Materials and Mechanical Properties.**—Unless otherwise specified, steel metric screws and bolts, with the exception of heavy hex structural bolts, hex lag screws, and socket head cap screws, conform to the requirements specified in SAE J1199 or ASTM F568. Steel heavy hex structural bolts conform to ASTM A325M or ASTM A490M. Alloy steel socket head cap screws conform to ASTM A574M, property class 12.9, where the numeral 12 represents approximately one-hundredth of the minimum tensile strength in megapascals and the decimal .9 approximates the ratio of the minimum yield stress to the minimum tensile stress. This is in accord with ISO designation practice. Screws and bolts

of other materials, and all materials for hex lag bolts, have properties as agreed upon by the purchaser and the manufacturer.

Except for socket head cap screws, metric screws and bolts are furnished with a natural (as processed) finish, unplated or uncoated unless otherwise specified.

Alloy steel socket head cap screws are furnished with an oiled black oxide coating (thermal or chemical) unless a protective plating or coating is specified by the purchaser.

**Metric Screw and Bolt Identification Symbols.**—Screws and bolts are identified on the top of the head by property class symbols and manufacturer's identification symbol.

**Metric Screw and Bolt Designation.**—Metric screws and bolts with the exception of socket head cap screws are designated by the following data, preferably in the sequence shown: product name, nominal diameter and thread pitch (except for hex lag screws), nominal length, steel property class or material identification, and protective coating, if required.

*Example:* Hex cap screw, M10 × 1.5 × 50, class 9.8, zinc plated

Heavy hex structural bolt, M24 × 3 × 80, ASTM A490M

Hex lag screw, 6 × 35, silicon bronze.

Socket head cap screws (metric series) are designated by the following data in the order shown: ANSI Standard number, nominal size, thread pitch, nominal screw length, name of product (may be abbreviated SHCS), material and property class (alloy steel screws are supplied to property class 12.9 as specified in ASTM A574M: corrosion-resistant steel screws are specified to the property class and material requirements in ASTM F837M), and protective finish, if required.

*Example:* B18.3.1M—6 × 1 × 20 Hexagon Socket Head Cap Screw, Alloy Steel

B18.3.1M—10 × 1.5 × 40 SHCS, Alloy Steel Zinc Plated.

**Metric Screw and Bolt Thread Lengths.**—The length of thread on metric screws and bolts (except for metric lag screws) is controlled by the grip gaging length,  $L_g$  max. This is the distance measured parallel to the axis of the screw or bolt, from under the head bearing surface to the face of a noncounterbored or noncountersunk standard GO thread ring gage assembled by hand as far as the thread will permit. The maximum grip gaging length, as calculated and rounded to one decimal place, is equal to the nominal screw length,  $L$ , minus the basic thread length,  $B$ , or in the case of socket head cap screws, minus the minimum thread length  $L_T$ .  $B$  and  $L_T$  are reference dimensions intended for calculation purposes only and will be found in Tables 12 and 14, respectively.

**Table 13. Basic Thread Lengths for Metric Round Head Square Neck Bolts**  
ANSI/ASME B18.5.2.2M-1982, R1993

| Nom. Bolt Dia., $D$ and Thread Pitch | Bolt Length, $L$         |                 |       | Nom. Bolt Dia., $D$ and Thread Pitch | Bolt Length, $L$         |                 |       |
|--------------------------------------|--------------------------|-----------------|-------|--------------------------------------|--------------------------|-----------------|-------|
|                                      | ≤ 125                    | > 125 and ≤ 200 | > 200 |                                      | ≤ 125                    | > 125 and ≤ 200 | > 200 |
|                                      | Basic Thread Length, $B$ |                 |       |                                      | Basic Thread length, $B$ |                 |       |

All dimensions are in millimeters

Basic thread length  $B$  is a reference dimension intended for calculation purposes only.

**Table 14. Socket Head Cap Screws (Metric Series)—Length of Complete Thread**  
*ANSI/ASME B18.3.1M-1986*

| Nominal Size | Length of Complete Thread, $L_T$ | Nominal Size | Length of Complete Thread, $L_T$ | Nominal Size | Length of Complete Thread, $L_T$ |
|--------------|----------------------------------|--------------|----------------------------------|--------------|----------------------------------|
| M1.6         | 15.2                             | M6           | 24.0                             | M20          | 52.0                             |
| M2           | 16.0                             | M8           | 28.0                             | M24          | 60.0                             |
| M2.5         | 17.0                             | M10          | 32.0                             | M30          | 72.0                             |
| M3           | 18.0                             | M12          | 36.0                             | M36          | 84.0                             |
| M4           | 20.0                             | M14          | 40.0                             | M42          | 96.0                             |
| M5           | 22.0                             | M16          | 44.0                             | M48          | 108.0                            |

Grip length,  $L_G$  equals screw length,  $L$ , minus  $L_T$ . Total length of thread  $L_{TT}$  equals  $L_T$  plus 5 times the pitch of the coarse thread for the respective screw size. Body length  $L_B$  equals  $L$  minus  $L_{TT}$ .

The minimum thread length for hex lag screws is equal to one-half the nominal screw length plus 12 mm, or 150 mm, whichever is shorter. Screws too short for this formula to apply are threaded as close to the head as practicable.

**Metric Screw and Bolt Diameter-Length Combinations.**—For a given diameter, the recommended range of lengths of metric cap screws, formed hex screws, heavy hex screws, hex flange screws, and heavy hex flange screws can be found in Table 16, for heavy hex structural bolts in Table 17, for hex lag screws in Table 15, for round head square neck bolts in Table 18, and for socket head cap screws in Table 19. No recommendations for diameter-length combinations are given in the Standards for hex bolts and heavy hex bolts.

Hex bolts in sizes M5 through M24 and heavy hex bolts in sizes M12 through M24 are standard only in lengths longer than 150 mm or  $10D$ , whichever is shorter. When shorter lengths of these sizes are ordered, hex cap screws are normally supplied in place of hex bolts and heavy hex screws in place of heavy hex bolts. Hex bolts in sizes M30 and larger and heavy hex bolts in sizes M30 and M36 are standard in all lengths; however, at manufacturer's option, hex cap screws may be substituted for hex bolts and heavy hex screws for heavy hex bolts for any diameter-length combination.

**Table 15. Recommended Diameter-Length Combinations for Metric Hex Lag Screws**  
*ANSI B18.2.3.8M-1981 (R1999)*

| Nominal Length, $L$ | Nominal Screw Diameter |     |     |     |     |     |     |     | Nominal Length, $L$ | Nominal Screw Diameter |     |     |     |    |
|---------------------|------------------------|-----|-----|-----|-----|-----|-----|-----|---------------------|------------------------|-----|-----|-----|----|

All dimensions are in millimeters.

Recommended diameter-length combinations are indicated by the symbol  $d$ .

**Table 16. Rec'd Diameter-Length Combinations for Metric Hex Cap Screws, Formed Hex and Heavy Hex Screws, Hex Flange and Heavy Hex Flange Screws**

<sup>a</sup> Lengths in parentheses are not recommended. Recommended lengths of formed hex screws, hex flange screws, and heavy hex flange screws do not extend above 150 mm. Recommended lengths of heavy hex screws do not extend below 20 mm. Standard sizes for government use. Recommended diameter-length combinations are indicated by the symbol *d*. Screws with lengths above heavy cross lines are threaded full length.

<sup>b</sup> Does not apply to hex flange screws and heavy hex flange screws.

All dimensions are in millimeters.

For available diameters of each type of screw, see respective dimensional table.

**Table 17. Recommended Diameter-Length Combinations for Metric Heavy Hex Structural Bolts**

| Nominal Length, <i>L</i> | Nominal Diameter and Thread Pitch |           |           |         |         |           |         |
|--------------------------|-----------------------------------|-----------|-----------|---------|---------|-----------|---------|

<sup>a</sup> Bolts with lengths above the heavy cross lines are threaded full length. Lengths in ( ) are not recommended.

All dimensions are in millimeters. Recommended diameter-length combinations are indicated by the symbol *a*. Standard sizes for government use.

**Table 19. Diameter-Length Combinations for Socket Head Cap Screws (Metric Series)**

All dimensions are in millimeters. Screws with lengths above heavy cross lines are threaded full length. Diameter-length combinations are indicated by the symbol *a*. Standard sizes for government use. In addition to the lengths shown, the following lengths are standard: 3, 4, 5, 6, 8, 10, 12, and 16 mm. No diameter-length combinations are given in the Standard for these lengths. Screws larger than M24 with lengths equal to or shorter than  $L_{TT}$  (see Table 14 footnote) are threaded full length.

**Metric Screw and Bolt Thread Series.**—Unless otherwise specified, metric screws and bolts, except for hex lag screws, are furnished with metric coarse threads conforming to the dimensions for general purpose threads given in ANSI B1.13M (see *American National Standard Metric Screw Threads M Profile* on page 1783). Except for socket head cap screws, the tolerance class is 6g, which applies to plain finish (unplated or uncoated) screws or bolts and to plated or coated screws or bolts before plating or coating. For screws with additive finish, the 6g diameters may be exceeded by the amount of the allowance, i.e. the basic diameters apply to the screws or bolts after plating or coating. For socket head cap screws, the tolerance class is 4g6g, but for plated screws, the allowance g may be consumed by the thickness of plating so that the maximum limit of size after plating is tolerance class 4h6h. Thread limits are in accordance with ANSI B1.13M. Metric hex lag screws have a special thread which is covered in Table 5.

**Metric Screw and Bolt Clearance Holes.**—Clearance holes for screws and bolts with the exception of hex lag screws, socket head cap screws, and round head square neck bolts are given in Table 20. Clearance holes for round head square neck bolts are given in Table 8 and drill and counterbore sizes for socket head cap screws are given in Table 21.

**Table 20. Recommended Clearance Holes for Metric Hex Screws and Bolts**

| Nominal Dia., $D$ and Thread Pitch | Clearance Hole Dia., Basic, $D_h$ |                   |       | Nominal Dia., $D$ and Thread Pitch | Clearance Hole Dia., Basic, $D_h$ |                   |       |

<sup>a</sup> Applies only to heavy hex structural bolts.

All dimensions are in millimeters.

Does not apply to hex lag screws, hex socket head cap screws, or round head square neck bolts.

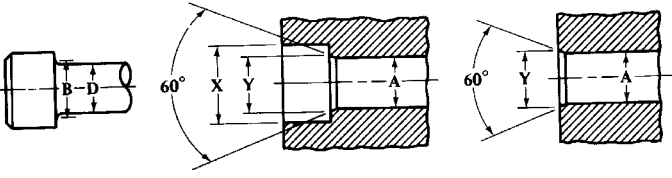

**Normal Clearance:** This is preferred for general purpose applications and should be specified unless special design considerations dictate the need for either a close or loose clearance hole.

**Close Clearance:** This should be specified only where conditions such as critical alignment of assembled parts, wall thickness or other limitations necessitate use of a minimum hole. When close clearance holes are specified, special provision (e.g. countersinking) must be made at the screw or bolt entry side to permit proper seating of the screw or bolt head.

**Loose Clearance:** This should be specified only for applications where maximum adjustment capability between components being assembled is necessary.

**Recommended Tolerances:** The clearance hole diameters given in this table are minimum size. Recommended tolerances are: for screw or bolt diameter M5, +0.2 mm; for M6 through M16, +0.3 mm; for M20 through M42, +0.4 mm; for M48 through M72, +0.5 mm; and for M80 through M100, +0.6 mm.

Table 21. Drill and Counterbore Sizes for Metric Socket Head Cap Screws

| M48                                  | 49.00                  | 50.00                   | 75.00                   | 52.6                                 |

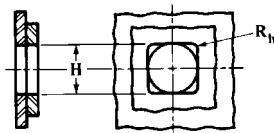

<sup>a</sup> *Countersink*: It is considered good practice to countersink or break the edges of holes which are smaller than  $B$  Max. (see Table 24) in parts having a hardness which approaches, equals, or exceeds the screw hardness. If such holes are not countersunk, the heads of screws may not seat properly or the sharp edges on holes may deform the fillets on screws, thereby making them susceptible to fatigue in applications involving dynamic loading. The countersink or corner relief, however, should not be larger than is necessary to ensure that the fillet on the screw is cleared. Normally, the diameter of countersink does not have to exceed  $B$  Max. Countersinks or corner reliefs in excess of this diameter reduce the effective bearing area and introduce the possibility of embedment where the parts to be fastened are softer than the screws or of brinelling or flaring the heads of the screws where the parts to be fastened are harder than the screws.

<sup>b</sup> *Close Fit*: The close fit is normally limited to holes for those lengths of screws which are threaded to the head in assemblies where only one screw is to be used or where two or more screws are to be used and the mating holes are to be produced either at assembly or by matched and coordinated tooling.

<sup>c</sup> *Normal Fit*: The normal fit is intended for screws of relatively long length or for assemblies involving two or more screws where the mating holes are to be produced by conventional tolerancing methods. It provides for the maximum allowable eccentricity of the longest standard screws and for certain variations in the parts to be fastened, such as: deviations in hole straightness, angularity between the axis of the tapped hole and that of the hole for shank, differences in center distances of the mating holes, etc.

All dimensions are in millimeters.

<sup>a</sup> *Close Clearance:* Close clearance should be specified only for square holes in very thin and/or soft material, or for slots, or where conditions such as critical alignment of assembled parts, wall thickness, or other limitations necessitate use of a minimal hole. Allowable swell or fins on the bolt body and/or fins on the corners of the square neck may interfere with close clearance round or square holes.

<sup>b</sup> *Normal Clearance:* Normal clearance hole sizes are preferred for general purpose applications and should be specified unless special design considerations dictate the need for either a close or loose clearance hole.

<sup>c</sup> *Loose Clearance:* Loose clearance hole sizes should be specified only for applications where maximum adjustment capability between components being assembled is necessary. Loose clearance square hole or slots may not prevent bolt turning during wrenching.

All dimensions are in millimeters.

All dimensions are in millimeters.

Drilled head metric hexagon socket head cap screws normally are not available in screw sizes smaller than M3 nor larger than M36. The M3 and M4 nominal screw sizes have two drilled holes spaced 180 degrees apart. Nominal screw sizes M5 and larger have six drilled holes spaced 60 degrees apart unless the purchaser specifies two drilled holes. The positioning of holes on opposite sides of the socket should be such that the hole alignment check plug will pass completely through the head without any deflection. When so specified by the purchaser, the edges of holes on the outside surface of the head will be chamfered 45 degrees to a depth of 0.30 to 0.50 mm.

<sup>a</sup> See also Table 25.

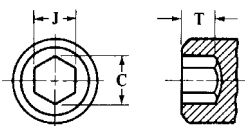

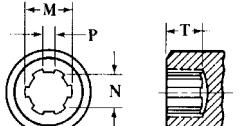

<sup>b</sup> The M14 × 2 size is not recommended for use in new designs.

All dimensions are in millimeters

$L_G$  is grip length and  $L_B$  is body length (see Table 14). For length of complete thread, see Table 14.

For additional manufacturing and acceptance specifications, see ANSI/ASME B18.3.1M-1986.

| 2.819  | 2.9210                         | 2.8702                           | 2.4892  | 2.4384                         | 0.6350                           | 0.5842 |
| 3.378  | 3.4798                         | 3.4290                           | 2.9972  | 2.9464                         | 0.7620                           | 0.7112 |
| 4.648  | 4.7752                         | 4.7244                           | 4.1402  | 4.0894                         | 0.9906                           | 0.9398 |
| 5.486  | 5.6134                         | 5.5626                           | 4.8260  | 4.7752                         | 1.2700                           | 1.2192 |
| 7.391  | 7.5692                         | 7.5184                           | 6.4516  | 6.4008                         | 1.7272                           | 2.6764 |

<sup>a</sup> The tabulated dimensions represent direct metric conversions of the equivalent inch size spline sockets shown in American National Standard Socket Cap, Shoulder and Set Screws — Inch Series ANSI B18.3. Therefore, the spline keys and bits shown therein are applicable for wrenching the corresponding size metric spline sockets.

**Metric Nuts**

The American National Standards covering metric nuts have been established in cooperation with the Department of Defense in such a way that they could be used by the Government for procurement purposes. Extensive information concerning these nuts is given in the following text and tables, but for more complete manufacturing and acceptance specifications, reference should be made to the respective Standards, which may be obtained by

non-governmental agencies from the American National Standards Institute, 25 West 43rd Street, New York, N. Y. 10036. Manufacturers should be consulted concerning items and sizes which are in stock production.

**Comparison with ISO Standards.**—American National Standards for metric nuts have been coordinated to the extent possible with comparable ISO Standards or proposed Standards, thus: ANSI B18.2.4.1M Metric Hex Nuts, Style 1 with ISO 4032; B18.2.4.2M Metric Hex Nuts, Style 2 with ISO 4033; B18.2.4.4M Metric Hex Flange Nuts with ISO 4161; B18.2.4.5M Metric Hex Jam Nuts with ISO 4035; and B18.2.4.3M Metric Slotted Hex Nuts, B18.2.4.6M Metric Heavy Hex Nuts in sizes M12 through M36, and B18.16.3M Prevailing-Torque Type Steel Metric Hex Nuts and Hex Flange Nuts with comparable draft ISO Standards. The dimensional differences between each ANSI Standard and the comparable ISO Standard or draft Standard are very few, relatively minor, and none will affect the interchangeability of nuts manufactured to the requirements of either.

At its meeting in Varna, May 1977, ISO/TC2 studied several technical reports analyzing design considerations influencing determination of the best series of widths across flats for hex bolts, screws, and nuts. A primary technical objective was to achieve a logical ratio between under head (nut) bearing surface area (which determines the magnitude of compressive stress on the bolted members) and the tensile stress area of the screw thread (which governs the clamping force that can be developed by tightening the fastener). The series of widths across flats in the ANSI Standards agree with those which were selected by ISO/TC2 to be ISO Standards.

One exception for width across flats of metric hex nuts, styles 1 and 2, metric slotted hex nuts, metric hex jam nuts, and prevailing-torque metric hex nuts is the M10 size. These nuts in M10 size are currently being produced in the United States with a width across flats of 15 mm. This width, however, is not an ISO Standard. Unless these M10 nuts with width across flats of 15 mm are specifically ordered, the M10 size with 16 mm width across flats will be furnished.

In ANSI Standards for metric nuts, letter symbols designating dimensional characteristics are in accord with those used in ISO Standards, except capitals have been used for data processing convenience instead of lower case letters used in ISO Standards.

**Metric Nut Tops and Bearing Surfaces.**—Metric hex nuts, styles 1 and 2, slotted hex nuts, and hex jam nuts are double chamfered in sizes M16 and smaller and in sizes M20 and larger may either be double chamfered or have a washer-faced bearing surface and a chamfered top at the option of the manufacturer. Metric heavy hex nuts are optional either way in all sizes. Metric hex flange nuts have a flange bearing surface and a chamfered top and prevailing-torque type metric hex nuts have a chamfered bearing surface. Prevailing-torque type metric hex flange nuts have a flange bearing surface. All types of metric nuts have the tapped hole countersunk on the bearing face and metric slotted hex nuts, hex flange nuts, and prevailing-torque type hex nuts and hex flange nuts may be countersunk on the top face.

**Materials and Mechanical Properties.**—Nonheat-treated carbon steel metric hex nuts, style 1 and slotted hex nuts conform to material and property class requirements specified for property class 5 nuts; hex nuts, style 2 and hex flange nuts to property class 9 nuts; hex jam nuts to property class 04 nuts, and nonheat-treated carbon and alloy steel heavy hex nuts to property classes 5, 9, 8S, or 8S3 nuts; all as covered in ASTM A563M. Carbon steel metric hex nuts, style 1 and slotted hex nuts that have specified heat treatment conform to material and property class requirements specified for property class 10 nuts; hex nuts, style 2 to property class 12 nuts; hex jam nuts to property class 05 nuts; hex flange nuts to property classes 10 and 12 nuts; and carbon or alloy steel heavy hex nuts to property classes 10S, 10S3, or 12 nuts, all as covered in ASTM A563M. Carbon steel prevailing-torque type hex nuts and hex flange nuts conform to mechanical and property class requirements as given in ANSI B18.16.1M.

**Table 26. American National Standard Metric Hex Nuts, Styles 1 and 2**  
*ANSI/ASME B18.2.4.1M and B18.2.4.2M-1979 (R1995)*

| Nominal Nut Dia. and Thread Pitch | Width Across Flats, <i>S</i> |       | Width Across Corners, <i>E</i> |       | Thickness, <i>M</i> |       | Bearing Face Dia., <i>D<sub>w</sub></i> | Washer Face Thickness, <i>C</i> |     |

\*This size with width across flats of 15 mm is not standard. Unless specifically ordered, M10 slotted hex nuts with 16 mm width across flats will be furnished.

All dimensions are in millimeters.

Metric nuts of other materials, such as stainless steel, brass, bronze, and aluminum alloys, have properties as agreed upon by the manufacturer and purchaser. Properties of nuts of several grades of non-ferrous materials are covered in ASTM F467M.

Unless otherwise specified, metric nuts are furnished with a natural (unprocessed) finish, unplated or uncoated.

**Metric Nut Thread Series.**—Metric nuts have metric coarse threads with class 6H tolerances in accordance with ANSI B1.13M (see *Metric Screw and Bolt Diameter-Length Combinations* Metric Screw Threads in index). For prevailing-torque type metric nuts this condition applies before introduction of the prevailing torque feature. Nuts intended for use with externally threaded fasteners which are plated or coated with a plating or coating thickness (e.g., hot dip galvanized) requiring overtapping of the nut thread to permit assembly, have over-tapped threads in conformance with requirements specified in ASTM A563M.

All dimensions are in millimeters.

**Types of Metric Prevailing-Torque Type Nuts.**—There are three basic designs for prevailing-torque type nuts:

- 1) All-metal, one-piece construction nuts which derive their prevailing-torque characteristics from controlled distortion of the nut thread and/or body.
- 2) Metal nuts which derive their prevailing-torque characteristics from addition or fusion of a nonmetallic insert, plug, or patch in their threads.
- 3) Top insert, two-piece construction nuts which derive their prevailing-torque characteristics from an insert, usually a full ring of non-metallic material, located and retained in the nut at its top surface.

The first two designs are designated in [Tables 29](#) and [30](#) as “all-metal” type and the third design as “top-insert” type.

<sup>a</sup> Also includes metal nuts with non-metallic inserts, plugs, or patches in their threads.

<sup>b</sup> This size with width across flats of 15 mm is not standard. Unless specifically ordered, M10 slotted hex nuts with 16 mm width across flats will be furnished.

All dimensions are in millimeters.

<sup>a</sup> Also includes metal nuts with nonmetallic inserts, plugs, or patches in their threads.

All dimensions are in millimeters.

**Metric Nut Identification Symbols.**—Carbon steel hex nuts, styles 1 and 2, hex flange nuts, and carbon and alloy steel heavy hex nuts are marked to identify the property class and manufacturer in accordance with requirements specified in ASTM A563M. The aforementioned nuts when made of other materials, as well as slotted hex nuts and hex jam nuts, are marked to identify the property class and manufacturer as agreed upon by manufacturer and purchaser. Carbon steel prevailing-torque type hex nuts and hex flange nuts are marked to identify property class and manufacturer as specified in ANSI B18.16.1M. Prevailing-torque type nuts of other materials are identified as agreed upon by the manufacturer and purchaser.

**Metric Nut Designation.**—Metric nuts are designated by the following data, preferably in the sequence shown: product name, nominal diameter and thread pitch, steel property class or material identification, and protective coating, if required. (Note: It is common practice in ISO Standards to omit thread pitch from the product designation when the nut threads are the metric coarse thread series, e.g., M10 stands for M10 × 1.5).

*Example:* Hex nut, style 1, M10 × 1.5, ASTM A563M class 10, zinc plated  
 Heavy hex nut, M20 × 2.5, silicon bronze, ASTM F467, grade 651  
 Slotted hex nut, M20, ASTM A563M class 10.

<sup>a</sup> This size with width across flats of 15 mm is not standard. Unless specifically ordered, M10 hex jam nuts with 16 mm width across flats will be furnished.

All dimensions are in millimeters.

**Metric Washers**

**Metric Plain Washers.**—American National Standard ANSI B18.22M-1981 (R1990) covers general specifications and dimensions for flat, round-hole washers, both soft (as fabricated) and hardened, intended for use in general-purpose applications. Dimensions are given in the following table. Manufacturers should be consulted for current information on stock sizes.

**Comparison with ISO Standards.**—The washers covered by this ANSI Standard are nominally similar to those covered in various ISO documents. Outside diameters were selected, where possible, from ISO/TC2/WG6/N47 “General Plan for Plain Washers for Metric Bolts, Screws, and Nuts.” The thicknesses given in the ANSI Standard are similar to the nominal ISO thicknesses, however the tolerances differ. Inside diameters also differ.

ISO metric washers are currently covered in ISO 887, “Plain Washers for Metric Bolts, Screws, and Nuts – General Plan.”

**Types of Metric Plain Washers.**—Soft (as fabricated) washers are generally available in nominal sizes 1.6 mm through 36 mm in a variety of materials. They are normally used in low-strength applications to distribute bearing load, to provide a uniform bearing surface, and to prevent marring of the work surface.

Hardened steel washers are normally available in sizes 6 mm through 36 mm in the narrow and regular series. They are intended primarily for use in high-strength joints to minimize embedment, to provide a uniform bearing surface, and to bridge large clearance holes and slots.

**Metric Plain Washer Materials and Finish.**—Soft (as fabricated) washers are made of nonhardened steel unless otherwise specified by the purchaser. Hardened washers are made of through-hardened steel tempered to a hardness of 38 to 45 Rockwell C.

Unless otherwise specified, washers are furnished with a natural (as fabricated) finish, unplated or uncoated with a light film of oil or rust inhibitor.

**Metric Plain Washer Designation.**—When specifying metric plain washers, the designation should include the following data in the sequence shown: description, nominal size, series, material type, and finish, if required.

*Example:* Plain washer, 6 mm, narrow, soft, steel, zinc plated  
Plain washer, 10 mm, regular, hardened steel.

**Table 32. American National Standard Metric Plain Washers**  
ANSI B18.22M-1981, R1990

| Nominal Washer Size <sup>a</sup> | Washer Series | Inside Diameter, A |       | Outside Diameter, B |                    | Thickness, C |      |
|----------------------------------|---------------|--------------------|-------|---------------------|--------------------|--------------|------|
|                                  |               | Max                | Min   | Max                 | Min                | Max          | Min  |
| 1.6                              | Narrow        | 2.09               | 1.95  | 4.00                | 3.70               | 0.70         | 0.50 |

|                                  | Wide          | 38.92              | 38.30 | 110.00              | 108.60             | 8.50         | 7.00 |

<sup>a</sup> Nominal washer sizes are intended for use with comparable screw and bolt sizes.

<sup>b</sup> The 18.80/18.37 and 25.40/24.48 mm outside diameters avoid washers which could be used in coin-operated devices.

All dimensions are in millimeters.

## BRITISH FASTENERS

**British Standard Square and Hexagon Bolts, Screws and Nuts.**—Important dimensions of precision hexagon bolts, screws and nuts (BSW and BSF threads) as covered by British Standard 1083:1965 are given in [Tables 1](#) and [2](#). The use of fasteners in this standard will decrease as fasteners having Unified inch and ISO metric threads come into increasing use.

Dimensions of Unified precision hexagon bolts, screws and nuts (UNC and UNF threads) are given in BS 1768:1963 (obsolescent); of Unified black hexagon bolts, screws and nuts (UNC and UNF threads) in BS 1769:1951 (obsolescent); and of Unified black square and hexagon bolts, screws and nuts (UNC and UNF threads) in BS 2708:1956 (withdrawn). Unified nominal and basic dimensions in these British Standards are the same as the comparable dimensions in the American Standards, but the tolerances applied to these basic dimensions may differ because of rounding-off practices and other factors. For Unified dimensions of square and hexagon bolts and nuts as given in ANSI/ASME B18.2.1-1996 and ANSI/ASME B18.2.2-1987 (R1999) see [Tables 1](#) through [4](#) starting on page [1514](#), and [7](#) to [10](#) starting on page [1519](#).

ISO metric precision hexagon bolts, screws and nuts are specified in the British Standard BS 3692:1967 (obsolescent) (see *British Standard ISO Metric Precision Hexagon Bolts, Screws and Nuts* starting on page [1578](#)), and ISO metric black hexagon bolts, screws and nuts are covered by British Standard BS 4190:1967 (obsolescent).

See the section *MACHINE SCREWS AND NUTS* starting on page [1587](#) for information on British Standard metric, Unified, Whitworth, and BSF machine screws and nuts.

**British Standard Screwed Studs.**—General purpose screwed studs are covered in British Standard 2693: Part 1:1956. The aim in this standard is to provide for a stud having tolerances which would not render it expensive to manufacture and which could be used in association with standard tapped holes for most purposes. Provision has been made for the use of both Unified Fine threads, Unified Coarse threads, British Standard Fine threads, and British Standard Whitworth threads as shown in the table on page [1573](#).

*Designations:* The *metal end* of the stud is the end which is screwed into the component. The *nut end* is the end of the screw of the stud which is not screwed into the component. The *plain portion* of the stud is the unthreaded length.

*Recommended Fitting Practices for Metal End of Stud:* It is recommended that holes tapped to Class 3B limits (see [Table 3](#) starting on page [1736](#)) in accordance with B.S. 1580 “Unified Screw Threads” or to Close Class limits in accordance with B.S. 84 “Screw Threads of Whitworth Form” as appropriate, be used in association with the metal end of the stud specified in this standard. Where fits are not critical, however, holes may be tapped to Class 2B limits (see table on page [1736](#)) in accordance with B.S. 1580 or Normal Class limits in accordance with B.S. 84.

It is recommended that the B.A. stud specified in this standard be associated with holes tapped to the limits specified for nuts in B.S. 93, 1919 edition. Where fits for these studs are not critical, holes may be tapped to limits specified for nuts in the current edition of B.S. 93.

In general, it will be found that the amount of oversize specified for the studs will produce a satisfactory fit in conjunction with the standard tapping as above. Even when interference is not present, locking will take place on the thread runout which has been carefully controlled for this purpose. Where it is considered essential to assure a true interference fit, higher grade studs should be used. It is recommended that standard studs be used even under special conditions where selective assembly may be necessary.

British Standard Whitworth (BSW) and Fine (BSF) Precision Hexagon Bolts, Screws, and Nuts

For dimensions, see [Tables 1 and 2](#).

**Table 1. British Standard Whitworth (BSW) and Fine (BSF) Precision Hexagon Slotted and Castle Nuts BS 1083:1965 (obsolescent)**

| Nominal Size<br><i>D</i>    | Number of Threads per Inch |      | Bolts, Screws, and Nuts  |                            |      |                                     |                               | Bolts and Screws |   |        |           |       | Nuts      |       |       |       |       |

<sup>a</sup>When bolts from  $\frac{1}{4}$  to 1 inch are hot forged, the tolerance on the width across flats shall be two and a half times the tolerance shown in the table and shall be unilaterally minus from maximum size. For dimensional notation, see diagram on page 1571.

<sup>b</sup>Noted standard with BSW thread.

All dimensions in inches except where otherwise noted.

<sup>a</sup> Not standard with BSW thread. For widths across flats, widths across corners, and diameter of washer face see [Table 1](#). For dimensional notation, see diagram on page [1571](#).

All dimensions in inches except where otherwise noted.

<sup>a</sup> Sizes shown in parentheses are non-preferred.<sup>b</sup> A true radius is not essential provided that the curve is smooth and lies wholly within the maximum radius, determined from the maximum transitional diameter, and the minimum radius specified.All dimensions are in millimeters. For illustration of bolts and screws see [Table 3](#).

<sup>a</sup> Sizes shown in parentheses are non-preferred.

All dimensions are in millimeters. For illustration of hexagon slotted nuts and castle nuts see [Table 3](#).

After several years of use of BS 2693:Part 1:1956 (obsolescent), it was recognized that it would not meet the requirements of all stud users. The thread tolerances specified could result in clearance of interference fits because locking depended on the run-out threads. Thus, some users felt that true interference fits were essential for their needs. As a result, the British Standards Committee has incorporated the Class 5 interference fit threads specified in American Standard ASA B1.12 into the BS 2693:Part 2:1964, "Recommendations for High Grade Studs."

**British Standard ISO Metric Precision Hexagon Bolts, Screws and Nuts.**—This British Standard BS 3692:1967 (obsolescent) gives the general dimensions and tolerances of precision hexagon bolts, screws and nuts with ISO metric threads in diameters from 1.6 to 68 mm. It is based on the following ISO recommendations and draft recommendations: R 272, R 288, DR 911, DR 947, DR 950, DR 952 and DR 987. Mechanical properties are given only with respect to carbon or alloy steel bolts, screws and nuts, which are not to be used for special applications such as those requiring weldability, corrosion resistance or ability to withstand temperatures above 300°C or below -50°C. The dimensional requirements of this standard also apply to non-ferrous and stainless steel bolts, screws and nuts.

*Finish:* Finishes may be dull black which results from the heat-treating operation or may be bright finish, the result of bright drawing. Other finishes are possible by mutual agreement between purchaser and producer. It is recommended that reference be made to BS 3382 "Electroplated Coatings on Threaded Components" in this respect.

*General Dimensions:* The bolts, screws and nuts conform to the general dimensions given in Tables 3, 4, 5 and 6.

*Nominal Lengths of Bolts and Screws:* The nominal length of a bolt or screw is the distance from the underside of the head to the extreme end of the shank including any chamfer or radius. Standard nominal lengths and tolerances thereon are given in Table 7.

**Table 7. British Standard ISO Metric Bolt and Screw Nominal Lengths**  
*BS 3692:1967 (obsolescent)*

<sup>a</sup> Nominal lengths shown in parentheses are non-preferred.

All dimensions are in millimeters.

*Bolt and Screw Ends:* The ends of bolts and screws may be finished with either a 45-degree chamfer to a depth slightly exceeding the depth of thread or a radius approximately

equal to  $1\frac{1}{4}$  times the nominal diameter of the shank. With rolled threads, the lead formed at the end of the bolt by the thread rolling operation may be regarded as providing the necessary chamfer to the end; the end being reasonably square with the center line of the shank.

*Screw Thread Form:* The form of thread and diameters and associated pitches of standard ISO metric bolts, screws, and nuts are in accordance with BS 3643:Part 1:1981 (1998), "Principles and Basic Data" The screw threads are made to the tolerances for the medium class of fit (6H/6g) as specified in BS 3643:Part 2:1981 (1998), "Specification for Selected Limits of Size."

*Length of Thread on Bolts:* The length of thread on bolts is the distance from the end of the bolt (including any chamfer or radius) to the leading face of a screw ring gage which has been screwed as far as possible onto the bolt by hand. Standard thread lengths of bolts are  $2d + 6$  mm for a nominal length of bolt up to and including 125 mm,  $2d + 12$  mm for a nominal bolt length over 125 mm up to and including 200 mm, and  $2d + 25$  mm for a nominal bolt length over 200 mm. Bolts that are too short for minimum thread lengths are threaded as screws and designated as screws. The tolerance on bolt thread lengths are plus two pitches for all diameters.

*Length of Thread on Screws:* Screws are threaded to permit a screw ring gage being screwed by hand to within a distance from the underside of the head not exceeding two and a half times the pitch for diameters up to and including 52 mm and three and a half times the pitch for diameters over 52 mm.

*Angularity and Eccentricity of Bolts, Screws and Nuts:* The axis of the thread of the nut is square to the face of the nut subject to the "squareness tolerance" given in Table 5.

In gaging, the nut is screwed by hand onto a gage, having a truncated taper thread, until the thread of the nut is tight on the thread of the gage. A sleeve sliding on a parallel extension of the gage, which has a face of diameter equal to the minimum distance across the flats of the nut and exactly at 90 degrees to the axis of the gage, is brought into contact with the leading face of the nut. With the sleeve in this position, it should not be possible for a feeler gage of thickness equal to the "squareness tolerance" to enter anywhere between the leading nut face and sleeve face.

The hexagon flats of bolts, screws and nuts are square to the bearing face, and the angularity of the head is within the limits of 90 degrees, plus or minus 1 degree. The eccentricity of the hexagon flats of nuts relative to the thread diameter should not exceed the values given in Table 5 and the eccentricity of the head relative to the width across flats and eccentricity between the shank and thread of bolts and screws should not exceed the values given in Table 4.

*Chamfering, Washer Facing and Countersinking:* Bolt and screw heads have a chamfer of approximately 30 degrees on their upper faces and, at the option of the manufacturer, a washer face or full bearing face on the underside. Nuts are countersunk at an included angle of 120 degrees plus or minus 10 degrees at both ends of the thread. The diameter of the countersink should not exceed the nominal major diameter of the thread plus 0.13 mm up to and including 12 mm diameter, and plus 0.25 mm above 12 mm diameter. This stipulation does not apply to slotted, castle or thin nuts.

*Strength Grade Designation System for Steel Bolts and Screws:* This Standard includes a strength grade designation system consisting of two figures. The first figure is one tenth of the minimum tensile strength in  $\text{kgf/mm}^2$ , and the second figure is one tenth of the ratio between the minimum yield stress (or stress at permanent set limit,  $R_{0.2}$ ) and the minimum tensile strength, expressed as a percentage. For example with the strength designation grade 8.8, the first figure 8 represents  $\frac{1}{10}$  the minimum tensile strength of 80  $\text{kgf/mm}^2$  and the second figure 8 represents  $\frac{1}{10}$  the ratio

$$\frac{\text{stress at permanent set limit } R_{0.2}\%}{\text{minimum tensile strength}} = \frac{1}{10} \times \frac{64}{80} \times \frac{100}{1}$$

the numerical values of stress and strength being obtained from the accompanying table.

### Strength Grade Designations of Steel Bolts and Screws

| Strength Grade Designation                        | 4.6 | 4.8 | 5.6 | 5.8 | 6.6 | 6.8 | 8.8 | 10.9 | 12.9 | 14.9 |
|---|-----|-----|-----|-----|-----|-----|-----|------|------|------|
| Tensile Strength ( $R_m$ ), Min.                  | 40  | 40  | 50  | 50  | 60  | 60  | 80  | 100  | 120  | 140  |
| Yield Stress ( $R_e$ ), Min.                      | 24  | 32  | 30  | 40  | 36  | 48  | ... | ...  | ...  | ...  |
| Stress at Permanent Set Limit ( $R_{0.2}$ ), Min. | ... | ... | ... | ... | ... | ... | 64  | 90   | 108  | 126  |

All stress and strength values are in kgf/mm<sup>2</sup> units.

**Strength Grade Designation System for Steel Nuts:** The strength grade designation system for steel nuts is a number which is one-tenth of the specified proof load stress in kgf/mm<sup>2</sup>. The proof load stress corresponds to the minimum tensile strength of the highest grade of bolt or screw with which the nut can be used.

### Strength Grade Designations of Steel Nuts

| Strength Grade Designation               | 4  | 5  | 6  | 8  | 12  | 14  |
|--|----|----|----|----|-----|-----|
| Proof Load Stress (kgf/mm <sup>2</sup> ) | 40 | 50 | 60 | 80 | 120 | 140 |

### Recommended Bolt and Nut Combinations

| Grade of Bolt            | 4.6 | 4.8 | 5.6 | 5.8 | 6.6 | 6.8 | 8.8 | 10.9 | 12.9 | 14.9 |
|--------------------------|-----|-----|-----|-----|-----|-----|-----|------|------|------|
| Recommended Grade of Nut | 4   | 4   | 5   | 5   | 6   | 6   | 8   | 12   | 12   | 14   |

*Note:* Nuts of a higher strength grade may be substituted for nuts of a lower strength grade.

**Marking:** The marking and identification requirements of this Standard are only mandatory for steel bolts, screws and nuts of 6 mm diameter and larger; manufactured to strength grade designations 8.8 (for bolts or screws) and 8 (for nuts) or higher. Bolts and screws are identified as ISO metric by either of the symbols "ISO M" or "M", embossed or indented on top of the head. Nuts may be indented or embossed by alternative methods depending on their method of manufacture.

**Designation:** Bolts 10 mm diameter, 50 mm long manufactured from steel of strength grade 8.8, would be designated:

"Bolts M10 × 50 to BS 3692 — 8.8."

Brass screws 8 mm diameter, 20 mm long would be designated:

"Brass screws M8 × 20 to BS 3692."

Nuts 12 mm diameter, manufactured from steel of strength grade 6, cadmium plated could be designated:

"Nuts M12 to BS 3692 — 6, plated to BS 3382: Part 1."

**Miscellaneous Information:** The Standard also gives mechanical properties of steel bolts, screws and nuts [i.e., tensile strengths; hardnesses (Brinell, Rockwell, Vickers); stresses (yield, proof load); etc.], material and manufacture of steel bolts, screws and nuts; and information on inspection and testing. Appendices to the Standard give information on gaging; chemical composition; testing of mechanical properties; examples of marking of bolts, screws and nuts; and a table of preferred standard sizes of bolts and screws, to name some.

<sup>a</sup> The standard also gives preferred and standard lengths of studs: Preferred lengths of studs: 7/8, 1, 1 1/8, 1 1/4, 1 3/8, 1 1/2, 1 3/4, 2, 2 1/4, 2 1/2, 2 3/4, 3, 3 1/4, 3 1/2 and for lengths above 3 1/2 the preferred increment is 1/2. Standard lengths of studs: 7/8, 1, 1 1/8, 1 1/4, 1 3/8, 1 1/2, 1 5/8, 1 3/4, 1 7/8, 2, 2 1/8, 2 1/4, 2 3/8, 2 1/2, 2 5/8, 2 3/4, 2 7/8, 3, 3 1/8, 3 1/4, 3 3/8, 3 1/2 and for lengths above 3 1/2 the standard increment is 1/4.

All dimensions are in inches except where otherwise noted.  
See page 1877 for interference-fit threads.

All dimensions are given in millimeters. Sizes shown in parentheses are non-preferred, and are not usually stock sizes. The free height of double coil washers before compression is normally approximately five times the thickness but, if required, washers with other free heights may be obtained by arrangement with manufacturer.

All dimensions are in millimeters. Sizes shown in parentheses are nonpreferred and are not usually stock sizes.

**British Standard for Metric Series Metal Washers.**—BS 4320:1968 (1998) specifies bright and black metal washers for general engineering purposes.

**Bright Metal Washers:** These washers are made from either CS4 cold-rolled strip steel BS 1449:Part 3B or from CZ 108 brass strip B.S. 2870: 1980, both in the hard condition. However, by mutual agreement between purchaser and supplier, washers may be made available with the material in any other condition, or they may be made from another material, or may be coated with a protective or decorative finish to some appropriate British Standard. Washers are reasonably flat and free from burrs and are normally supplied unchamfered. They may, however, have a 30-degree chamfer on one edge of the external diameter. These washers are made available in two size categories, normal and large diameter, and in two thicknesses, normal (Form A or C) and light (Form B or D). The thickness of a light-range washer is from  $\frac{1}{2}$  to  $\frac{2}{3}$  the thickness of a normal range washer.

**Black Metal Washers:** These washers are made from mild steel, and can be supplied in three size categories designated normal, large, and extra large diameters. The normal-diameter series is intended for bolts ranging from M5 to M68 (Form E washers), the large-diameter series for bolts ranging from M8 to M39 (Form F washers), and the extra large series for bolts from M5 to M39 (Form G washers). A protective finish can be specified by the purchaser in accordance with any appropriate British Standard.

*Washer Designations:* The Standard specifies the details that should be given when ordering or placing an inquiry for washers. These details are the general description, namely, bright or black washers; the nominal size of the bolt or screw involved, for example, M5; the designated form, for example, Form A or Form E; the dimensions of any chamfer required on bright washers; the number of the Standard BS 4320:1968 (1998), and coating information if required, with the number of the appropriate British Standard and the coating thickness needed. As an example, in the use of this information, the designation for a chamfered, normal-diameter series washer of normal-range thickness to suit a 12-mm diameter bolt would be: Bright washers M12 (Form A) chamfered to B.S. 4320.

### British Standard Bright Metal Washers — Metric Series BS 4320:1968 (1998)

All dimensions are in millimeters.

Nominal bolt or screw sizes shown in parentheses are nonpreferred.

MACHINE SCREWS AND NUTS

**American National Standard Machine Screws and Machine Screw Nuts.**—This Standard ANSI B18.6.3 covers both slotted and recessed head machine screws. Dimensions of various types of slotted machine screws, machine screw nuts, and header points are given in Tables 1 through 12. The Standard also covers flat trim head, oval trim head and drilled fillister head machine screws and gives cross recess dimensions and gaging dimensions for all types of machine screw heads. Information on metric machine screws B18.6.7M is given beginning on page 1596.

**Threads:** Except for sizes 0000, 000, and 00, machine screw threads may be either Unified Coarse (UNC) and Fine thread (UNF) Class 2A (see *American Standard for Unified Screw Threads* starting on page 1732) or UNRC and UNRF Series, at option of manufacturer. Thread dimensions for sizes 0000, 000, and 00 are given in Table 7 on page 1592.

Threads for hexagon machine screw nuts may be either UNC or UNF, Class 2B, and for square machine screw nuts are UNC Class 2B.

**Length of thread:** Machine screws of sizes No. 5 and smaller with nominal lengths equal to 3 diameters and shorter have full form threads extending to within 1 pitch (thread) of the bearing surface of the head, or closer, if practicable. Nominal lengths greater than 3 diameters, up to and including 1 1/8 inch, have full form threads extending to within two pitches (threads) of the bearing surface of the head, or closer, if practicable. Unless otherwise specified, screws of longer nominal length have a minimum length of full form thread of 1.00 inch. Machine screws of sizes No. 6 and larger with nominal length equal to 3 diameters and shorter have full form threads extending to within 1 pitch (thread) of the bearing surface of the head, or closer, if practicable. Nominal lengths greater than 3 diameters, up to and including 2 inches, have full form threads extending to within 2 pitches (threads) of the bearing surface of the head, or closer, if practicable. Screws of longer nominal length, unless otherwise specified, have a minimum length of full form thread of 1.50 inches.

| 3/8       | 0.3750     | 5/8     | 0.625  | 0.607  | 0.884  | 0.833  | 0.722               | 0.692               | 0.257  | 0.239  |

All dimensions in inches. Hexagon machine screw nuts have tops flat and chamfered. Diameter of top circle should be the maximum width across flats within a tolerance of minus 15 per cent. Bottoms are flat but may be chamfered if so specified. Square machine screw nuts have tops and bottoms flat without chamfer.

*Diameter of body:* The diameter of machine screw bodies is not less than Class 2A thread minimum pitch diameter nor greater than the basic major diameter of the thread. Cross-recessed trim head machine screws not threaded to the head have an 0.062 in. minimum length shoulder under the head with diameter limits as specified in the dimensional tables in the standard.

*Designation:* Machine screws are designated by the following data in the sequence shown: Nominal size (number, fraction, or decimal equivalent); threads per inch; nominal length (fraction or decimal equivalent); product name, including head type and driving provision; header point, if desired; material; and protective finish, if required. For example:

$\frac{1}{4}$  - 20 x  $1\frac{1}{4}$  Slotted Pan Head Machine Screw, Steel, Zinc Plated

6 - 32 x  $\frac{3}{4}$  Type IA Cross Recessed Fillister Head Machine Screw, Brass

Machine screw nuts are designated by the following data in the sequence shown: Nominal size (number, fraction, or decimal equivalent); threads per inch; product name; material; and protective finish, if required. For example:

10 - 24 Hexagon Machine Screw Nut, Steel, Zinc Plated

0.138 - 32 Square Machine Screw Nut, Brass

<sup>a</sup> Where specifying nominal size in decimals, zeros preceding decimal and in the fourth decimal place are omitted.

<sup>b</sup> There is no allowance provided on the external threads.

<sup>c</sup> The minor diameter limits for internal threads are not specified, they being determined by the amount of thread engagement necessary to satisfy the strength requirements and tapping performance in the intended application.

All dimensions are in inches.

All dimensions are in inches.

<sup>1</sup>Where specifying nominal size in decimals, zeros preceding decimal points and in the fourth decimal place are omitted.

<sup>2</sup>Drilled hole shall be approximately perpendicular to the axis of slot and may be permitted to break through bottom of the slot. Edges of the hole shall be free from burrs.

<sup>3</sup>A slight rounding of the edges at periphery of head is permissible provided the diameter of the bearing circle is equal to no less than 90 per cent of the specified minimum head diameter.

<sup>a</sup> When specifying nominal size in decimals, zeros preceding decimal point and in the fourth decimal place are omitted.

All dimensions are in inches.

Not recommended, use Pan Head machine screws.

**ANSI Cross References for Machine Screws and Metric Machine Screw**

**Machine Screw Cross Recesses.**—Four cross recesses, Types I, IA, II, and III, may be used in lieu of slots in machine screw heads. Dimensions for recess diameter *M*, width *N*, and depth *T* (not shown above) together with recess penetration gaging depths are given in American National Standard ANSI B18.6.3-1972 (R1991) for machine screws, and in ANSI/ASME B18.6.7M-1985 for metric machine screws.

**American National Standard Metric Machine Screws.**—This Standard B18.6.7M covers metric flat and oval countersunk and slotted and recessed pan head machine screws and metric hex head and hex flange head machine screws. Dimensions are given in [Tables 1 through 4](#) and 6.

<sup>a</sup>The length tolerances for metric machine screws are: up to 3 mm, incl., ± 0.2 mm; over 3 to 10 mm, incl., ± 0.3 mm; over 10 to 16 mm, incl., ± 0.4 mm; over 16 to 50 mm, incl., ± 0.5 mm; over 50 mm, ± 1.0 mm.

<sup>b</sup>Unthreaded lengths  $L_U$  and  $L_{US}$  represent the distance, measured parallel to the axis of screw, from the underside of the head to the face of a nonchamfered or noncounterbored standard GO thread ring gage assembled by hand as far as the thread will permit.

<sup>c</sup>Refer to the illustrations for respective screw head styles.

<sup>d</sup>The  $L_{US}$  values apply only to heat treated recessed flat countersunk head screws.

<sup>e</sup>The  $L_U$  values apply to all screws except heat treated recessed flat countersunk head screws.

All dimensions in millimeters.

<sup>a</sup> All recessed head heat-treated steel screws of property class 9.8 or higher strength have the Style B head form. Recessed head screws other than those specifically designated to be Style B have the Style A head form. The underhead shoulder on the Style B head form is mandatory and all other head dimensions are common to both the Style A and Style B head forms.

<sup>b</sup> This size is not specified for Type III square recessed flat countersunk heads; Type II cross recess is not specified for any size.

All dimensions in millimeters.

For dimension *B*, see [Table 1](#).

For dimension *L*, see [Table 7](#).

| M6 × 1                              | 4.25           | 3.85 | 40                   |
| M8 × 1.25                           | 5.82           | 5.30 | 40                   |
| M10 × 1.5                           | 7.36           | 6.71 | 40                   |
| M12 × 1.75                          | 8.90           | 8.11 | 45                   |

<sup>a</sup> Header points apply to these nominal lengths or shorter. The pointing of longer lengths may require machining to the dimensions specified.

All dimensions in millimeters.

The edge of the point may be rounded and the end of point need not be flat nor perpendicular to the axis of screw shank.

**Threads:** Threads for metric machine screws are coarse M profile threads, as given in ANSI B1.13M (see page 1783), unless otherwise specified.

**Length of Thread:** The lengths of threads on metric machine screws are given in Table 1 for the applicable screw type, size, and length.

**Diameter of Body:** The body diameters of metric machine screws are within the limits specified in the dimensional tables (Tables 3 through 4 and 6).

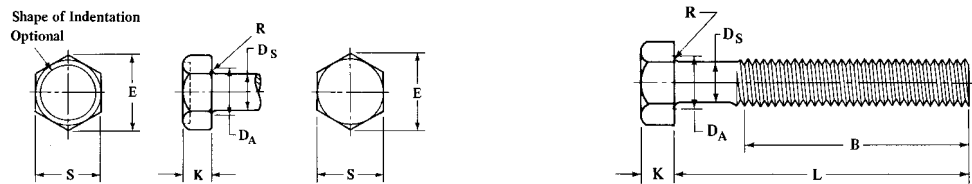

**Designation:** Metric machine screws are designated by the following data in the sequence shown: Nominal size and thread pitch; nominal length; product name, including head type and driving provision; header point if desired; material (including property class, if steel); and protective finish, if required. For example:

M8 × 1.25 × 30 Slotted Pan Head Machine Screw, Class 4.8 Steel, Zinc Plated

M3.5 × 0.6 × 20 Type IA Cross Recessed Oval Countersunk Head Machine Screw, Header Point, Brass

It is common ISO practice to omit the thread pitch from the product size designation when screw threads are the metric coarse thread series, e.g., M10 stands for M10 × 1.5.

Table 6. American National Standard Hex and Hex Flange Head Metric Machine Screws ANSI/ASME B18.6.7M-1985

| Hex Head   |                |       |                           |       |                                |                |     |                   |        |

<sup>a</sup> Dimensions across flats and across corners of the head are measured at the point of maximum metal. Taper of sides of head (angle between one side and the axis) shall not exceed 2° or 0.10 mm, whichever is greater, the specified width across flats being the large dimension.

<sup>b</sup> The M10 size screws having heads with 15 mm width across flats are not ISO Standard. Unless M10 size screws with 15 mm width across flats are specifically ordered, M10 size screws with 16 mm width across flats shall be furnished.

<sup>a</sup>Dimensions across flats and across corners of the head are measured at the point of maximum metal. Taper of sides of head (angle between one side and the axis) shall not exceed 2° or 0.10 mm, whichever is greater, the specified width across flats being the large dimension.

<sup>b</sup>The contour of the edge at periphery of flange is optional provided the minimum flange thickness is maintained at the minimum flange diameter. The top surface of flange may be straight or slightly rounded (convex) upward.

All dimensions in millimeters.

A slight rounding of all edges of the hexagon surfaces of indented hex heads is permissible provided the diameter of the bearing circle is not less than the equivalent of 90 per cent of the specified minimum width across flats dimension.

Heads may be indented, trimmed, or fully upset at the option of the manufacturer.

For dimension  $B$ , see Table 1.

For dimension  $L$ , see Table 7.

| 90                   |                    |      |    |      |    |    |    |    | A   | H   |

All dimensions in millimeters.

<sup>1</sup>The nominal screw lengths included between the heavy lines are recommended for the respective screw sizes and screw head styles as designated by the symbols.

A — Signifies screws of all head styles covered in this standard.

P — Signifies pan head screws.

H — Signifies hex and hex flange head screws.

**Table 8. Clearance Holes for Metric Machine Screws  
ANSI/ASME B18.6.7M-1985 Appendix**

| Nominal Screw Size | Basic Clearance Hole Diameter <sup>a</sup> |   |                              |
|--------------------|--|---|------------------------------|
|                    | Close Clearance <sup>b</sup>               | Normal Clearance (Preferred) <sup>b</sup> | Loose Clearance <sup>b</sup> |
| M2                 | 2.20                                       | 2.40                                      | 2.60                         |
| M2.5               | 2.70                                       | 2.90                                      | 3.10                         |
| M3                 | 3.20                                       | 3.40                                      | 3.60                         |
| M3.5               | 3.70                                       | 3.90                                      | 4.20                         |
| M4                 | 4.30                                       | 4.50                                      | 4.80                         |
| M5                 | 5.30                                       | 5.50                                      | 5.80                         |
| M6                 | 6.40                                       | 6.60                                      | 7.00                         |
| M8                 | 8.40                                       | 9.00                                      | 10.00                        |
| M10                | 10.50                                      | 11.00                                     | 12.00                        |
| M12                | 13.00                                      | 13.50                                     | 14.50                        |

<sup>a</sup>The values given in this table are minimum limits. The recommended plus tolerances are as follows: for clearance hole diameters over 1.70 to and including 5.80 mm, plus 0.12, 0.20, and 0.30 mm for close, normal, and loose clearances, respectively; for clearance hole diameters over 5.80 to 14.50 mm, plus 0.18, 0.30, and 0.45 mm for close, normal, and loose clearances, respectively.

<sup>b</sup>Normal clearance hole sizes are preferred. Close clearance hole sizes are for situations such as critical alignment of assembled components, wall thickness, or other limitations which necessitate the use of a minimal hole. Countersinking or counterboring at the fastener entry side may be necessary for the proper seating of the head. Loose clearance hole sizes are for applications where maximum adjustment capability between the components being assembled is necessary.

All dimensions in millimeters.

**British Machine Screws.**—Many of these classifications of fasteners are covered in British Standards B.S. 57:1951, “B.A. Screws, Bolts and Nuts”; BS 450:1958 (obsolescent), “Machine Screws and Machine Screw Nuts (BSW and BSF Threads)”; B.S. 1981:1953, “Unified Machine Screws and Machine Screw Nuts”; BS 2827:1957 (obsolescent):1957, “Machine Screw Nuts, Pressed Type (B.A. and Whitworth Form Threads)”; B.S. 3155:1960, “American Machine Screws and Nuts in Sizes Below  $\frac{1}{4}$  inch Diameter”; and BS 4183:1967 (obsolescent), “Machine Screws and Machine Screw Nuts, Metric Series.” At a conference organized by the British Standards Institution in 1965 at which the major sectors of British industry were represented, a policy statement was approved that urged British firms to regard the traditional screw thread systems—Whitworth, B.A. and BSF—as obsolescent, and to make the internationally-agreed ISO metric thread their first choice (with ISO Unified thread as second choice) for all future designs. It is recognized that some sections of British industry already using ISO inch (Unified) screw threads may find it necessary, for various reasons, to continue with their use for some time: Whitworth and B.A. threads should, however, be superseded by ISO metric threads in preference to an intermediate change to ISO inch threads. Fasteners covered by B.S. 57, B.S. 450 and BS 2827:1957 (obsolescent) eventually would be superseded and replaced by fasteners specified by B.S. 4183.

**British Standard Whitworth (BSW) and Fine (BSF) Machine Screws.**—British Standard BS 450:1958 (obsolescent) covers machine screws and nuts with British Standard Whitworth and British Standard Fine threads. All the various heads in common use in both slotted and recessed forms are covered. Head shapes are shown on page 1614 and dimensions on page 1617. It is intended that this standard will eventually be superseded by B.S. 4183, “Machine Screws and Machine Screw Nuts, Metric Series.”

**British Standard Machine Screws and Machine Screw Nuts, Metric Series.**—British Standard BS 4183:1967 (obsolescent) gives dimensions and tolerances for: countersunk head, raised countersunk head, and cheese head slotted head screws in a diameter range from M1 (1 mm) to M20 (20 mm); pan head slotted head screws in a diameter range from M2.5 (2.5 mm) to M10 (10 mm); countersunk head and raised countersunk head recessed head screws in a diameter range from M2.5 (2.5 mm) to M12 (12 mm); pan head recessed head screws in a diameter range from M2.5 (2.5 mm) to M10 (10 mm); and square and hexagon machine screw nuts in a diameter range from M1.6 (1.6 mm) to M10 (10 mm). Mechanical properties are also specified for steel, brass and aluminum alloy machine screws and machine screw nuts in this standard.

*Material:* The materials from which the screws and nuts are manufactured have a tensile strength not less than the following: steel, 40 kgf/mm<sup>2</sup> (392 N/mm<sup>2</sup>); brass, 32 kgf/mm<sup>2</sup> (314 N/mm<sup>2</sup>); and aluminum alloy, 32 kgf/mm<sup>2</sup> (314 N/mm<sup>2</sup>). The unit, kgf/mm<sup>2</sup> is in accordance with ISO DR 911 and the unit in parentheses has the relationship, 1 kgf = 9.80665 Newtons. These minimum strengths are applicable to the finished products. Steel machine screws conform to the requirements for strength grade designation 4.8. The strength grade designation system for machine screws consists of two figures, the first is  $\frac{1}{10}$  of the minimum tensile strength in kgf/mm<sup>2</sup>, the second is  $\frac{1}{10}$  of the ratio between the yield stress and the minimum tensile strength expressed as a percentage:  $\frac{1}{10}$  minimum tensile strength of 40 kgf/mm<sup>2</sup> gives the symbol “4”;  $\frac{1}{10}$  ratio  $\frac{\text{yield stress}}{\text{minimum tensile strength}} \% = \frac{1}{10} \times \frac{32}{40} \times 100/1 = “8”$ ; giving the strength grade designation “4.8.” Multiplication of these two figures gives the minimum yield stress in kgf/mm<sup>2</sup>.

*Coating of Screws and Nuts:* It is recommended that the coating comply with the appropriate part of BS 3382. “Electroplated Coatings on Threaded Components.”

**Screw Threads:** Screw threads are ISO metric coarse pitch series threads in accordance with B.S. 3643. "ISO Metric Screw Threads," Part 1, "Thread Data and Standard Thread Series." The external threads used for screws conform to tolerance Class 6g limits (medium fit) as given in B.S. 3643, "ISO Metric Screw Threads," Part 2, "Limits and Tolerances for Coarse Pitch Series Threads." The internal threads used for nuts conform to tolerance Class 6H limits (medium fit) as given in B.S. 3643: Part 2.

**Nominal Lengths of Screws:** For countersunk head screws the nominal length is the distance from the upper surface of the head to the extreme end of the shank, including any chamfer, radius, or cone point. For raised countersunk head screws the nominal length is the distance from the upper surface of the head (excluding the raised portion) to the extreme end of the shank, including any chamfer, radius, or cone point. For pan and cheese head screws the nominal length is the distance from the underside of the head to the extreme end of the shank, including any chamfer, radius, or cone point. Standard nominal lengths and tolerances are given in [Table 5](#).

**Lengths of Thread on Screws:** The length of thread is the distance from the end of the screw (including any chamfer, radius, or cone point) to the leading face of a nut without countersink which has been screwed as far as possible onto the screw by hand. The minimum thread length is shown in the following table:

|                            |        |      |        |      |     |        |       |     |        |     |
|----------------------------|--------|------|--------|------|-----|--------|-------|-----|--------|-----|
| Nominal Thread Dia., $d^a$ | M1     | M1.2 | (M1.4) | M1.6 | M2  | (M2.2) | M2.5  | M3  | (M3.5) | M4  |
| Thread Length $b$ (Min.)   | b      | b    | b      | 15   | 16  | 17     | 18    | 19  | 20     | 22  |
| Nominal Thread Dia., $d^a$ | (M4.5) | M5   | M6     | M8   | M10 | M12    | (M14) | M16 | (M18)  | M20 |
| Thread Length $b$ (Min.)   | 24     | 25   | 28     | 34   | 40  | 46     | 52    | 58  | 64     | 70  |

<sup>a</sup> Items shown in parentheses are non-preferred.

<sup>b</sup> Threaded up to the head.

All dimensions are in millimeters.

Screws of nominal thread diameter M1, M1.2 and M1.4 and screws of larger diameters that are too short for the above thread lengths are threaded as far as possible up to the head.

In these screws the length of unthreaded shank under the head does not exceed  $1\frac{1}{2}$  pitches for lengths up to twice the diameter and 2 pitches for longer lengths, and is defined as the distance from the leading face of a nut that has been screwed as far as possible onto the screw by hand to: 1) the junction of the basic major diameter and the countersunk portion of the head on countersunk and raised countersunk heads; and 2) the underside of the head on other types of heads.

**Diameter of Unthreaded Shank on Screws:** The diameter of the unthreaded portion of the shank on screws is not greater than the basic major diameter of the screw thread and not less than the minimum effective diameter of the screw thread. The diameter of the unthreaded portion of shank is closely associated with the method of manufacture; it will generally be nearer the major diameter of the thread for turned screws and nearer the effective diameter for those produced by cold heading.

**Radius Under the Head of Screws:** The radius under the head of pan and cheese head screws runs smoothly into the face of the head and shank without any step or discontinuity. A true radius is not essential providing that the curve is smooth and lies wholly within the maximum radius. Any radius under the head of countersunk head screws runs smoothly into the conical bearing surface of the head and the shank without any step or discontinuity. The radius values given in [Tables 1](#) and [2](#) are regarded as the maximum where the shank diameter is equal to the major diameter of the thread and minimum where the shank diameter is approximately equal to the effective diameter of the thread.

<sup>a</sup>Nominal sizes shown in parentheses are non-preferred.<sup>b</sup>See *Radius Under the Head of Screws* description in text.<sup>c</sup>See *Dimensions of 90-Degree Countersunk Head Screws* description in text.<sup>d</sup>See text following table in *Lengths of Thread on Screws* description in text.<sup>e</sup>Threaded up to head.

All dimensions are given in millimeters. For dimensional notation, see diagram on page 1610. Recessed head screws are also standard and are available. For dimensions see British Standard.

<sup>a</sup>Nominal sizes shown in parentheses are non-preferred.<sup>b</sup>See *Radius Under the Head of Screws* description in text.<sup>c</sup>See text following table in *Lengths of Thread on Screws* description in text.<sup>d</sup>Threaded up to head.

All dimensions are given in millimeters. For dimensional notation see diagram on page 1610. Recessed head screws are also standard and available. For dimensions see British Standard.

*Ends of Screws:* When screws are made with rolled threads, the "lead" formed by the thread rolling operation is normally regarded as providing the necessary chamfer and no other machining is necessary. The ends of screws with cut threads are normally finished with a chamfer conforming to the dimension in Fig. 1a through Fig. 1d. At the option of the manufacturer, the ends of screws smaller than M6 (6-mm diameter) may be finished with a radius approximately equal to  $1\frac{1}{4}$  times the nominal diameter of the shank. When cone point ends are required, they should have the dimensions given in Fig. 1a through Fig. 1d.

Fig. 1c. Cut Thread Radiused End (Permissible on Sizes Below M6 Dia.)

Fig. 1d. Cone Pointed End (Permissible on Cut or Rolled Thread Screws, but Regarded as "Special")

*Dimensions of 90-Degree Countersunk Head Screws:* One of the appendices to this British Standard states that countersunk head screws should fit into the countersunk hole with as great a degree of flushness as possible. To achieve this condition, it is necessary for the dimensions of both the head of the screw and the countersunk hole to be controlled within prescribed limits. The maximum or design size of the head is controlled by a theoretical diameter to a sharp corner and the minimum head angle of 90 degrees. The minimum head size is controlled by a minimum head diameter, the maximum head angle of 92 degrees and a flushness tolerance (see Fig. 2). The edge of the head may be flat or rounded, as shown in Fig. 3.

<sup>a</sup>Nominal sizes shown in parentheses are non-preferred.<sup>b</sup>Threaded up to head.<sup>c</sup>See text following table in *Lengths of Thread on Screws* description in text.

All dimensions are given in millimeters. For dimensional notation, see diagram on page 1610.

**General Dimensions:** The general dimensions and tolerances for screws and nuts are given in the accompanying tables. Although slotted screw dimensions are given, recessed head screws are also standard and available. Dimensions of recessed head screws are given in BS 4183:1967 (obsolescent).

**Table 5. British Standard Machine Screws and Nuts — Metric Series BS 4183:1967 (obsolescent)**

<sup>a</sup>Nominal sizes and lengths shown in parentheses are non-preferred.

All dimensions are given in millimeters. For dimensional notation, see diagram on page 1610.

**British Unified Machine Screws and Nuts.**—British Standard B.S. 1981:1953 covers certain types of machine screws and machine screw nuts for which agreement has been reached with the United States and Canada as to general dimensions for interchangeability. These types are: countersunk, raised-countersunk, pan, and raised-cheese head screws with slotted or recessed heads; small hexagon head screws; and precision and pressed nuts. All have Unified threads. Head shapes are shown on page 1614 and dimensions are given on page 1616.

*Identification:* As revised by Amendment No. 1 in February 1955, this standard now requires that the above-mentioned screws and nuts that conform to this standard should have a distinguishing feature applied to identify them as Unified. All *recessed head screws* are to be identified as Unified by a groove in the form of four arcs of a circle in the upper surface of the head. All *hexagon head screws* are to be identified as Unified by: 1) a circular recess in the upper surface of the head; 2) a continuous line of circles indented on one or more of the flats of the hexagon and parallel to the screw axis; and 3) at least two contiguous circles indented on the upper surface of the head. All *machine screw nuts* of the pressed type shall be identified as Unified by means of the application of a groove indented in one face of the nut approximately midway between the major diameter of the thread and flats of the square or hexagon. *Slotted head screws* shall be identified as Unified either by a circular recess or by a circular platform or raised portion on the upper surface of the head. *Machine screw nuts* of the *precision type* shall be identified as Unified by either a groove indented on one face of the front approximately midway between the major diameter of the thread and the flats of the hexagon or a continuous line of circles indented on one or more of the flats of the hexagon and parallel to the nut axis.

Hexagon machine screw nut (Unified)

\*Countersinks to suit the screws should have a maximum angle of 80° (Unified) or 90° (BSF and BSW) with a negative tolerance.

†Unified countersunk and raised countersunk head screws 2 inches long and under are threaded right up to the head. Other Unified, BSW and BSF machine screws 2 inches long and under have an unthread shank equal to twice the pitch. All Unified, BSW and BSF machine screws longer than 2 inches have a minimum thread length of 1¼ inches.

<sup>a</sup> All dimensions, except *J*, given for the 1/8-inch through 5/8-inch sizes also apply to all the 90° Raised Countersunk Head Screw dimensions given in the Standard.

<sup>b</sup> These screws are also available with recessed heads; dimensions of recess are not given here but may be found in the Standard.

<sup>c</sup> Non-preferred size; avoid use whenever possible.

<sup>d</sup> By arrangement may also be 0.309.

<sup>e</sup> By arrangement may also be 0.468.

All dimensions in inches.

See diagram on page 1614 for a pictorial representation of screws and letter dimensions.

CAP AND SET SCREWS

**Slotted Head Cap Screws.**— American National Standard ANSI/ASME B18.6.2-1998 is intended to cover the complete general and dimensional data for the various styles of slotted head cap screws as well as square head and slotted headless set screws (see page 1625). Reference should be made to this Standard for information or data not found in the following text or tables.

*Length of Thread:* The length of complete (full form) thread on cap screws is equal to twice the basic screw diameter plus 0.250 in. with a plus tolerance of 0.188 in. or an amount equal to 2½ times the pitch of the thread, whichever is greater. Cap screws of lengths too short to accommodate the minimum thread length have full form threads extending to within a distance equal to 2½ pitches (threads) of the head.

*Designation:* Slotted head cap screws are designated by the following data in the sequence shown: Nominal size (fraction or decimal equivalent); threads per inch; screw length (fraction or decimal equivalent); product name; material; and protective finish, if required. Examples: ½-13 × 3 Slotted Round Head Cap Screw, SAE Grade 2 Steel, Zinc Plated. .750-16 × 2.25 Slotted Flat Countersunk Head Cap Screw, Corrosion Resistant Steel.

<sup>a</sup> Key engagement depths are minimum. Spline socket sizes are nominal.

All dimensions in inches. The body length  $L_B$  of the screw is the length of the unthreaded cylindrical portion of the shank. The length of thread,  $L_T$ , is the distance from the extreme point to the last complete (full form) thread. Standard length increments for screw diameters up to 1 inch are 1/16 inch for lengths 1/8 through 1/4 inch, 1/8 inch for lengths 1/4 through 1 inch, 1/4 inch for lengths 1 through 3 1/2 inches, 1/2 inch for lengths 3 1/2 through 7 inches, 1 inch for lengths 7 through 10 inches and for diameters over 1 inch are 1/2 inch for lengths 1 through 7 inches, 1 inch for lengths 7 through 10 inches, and 2 inches for lengths over 10 inches.

Heads may be plain or knurled, and chamfered to an angle  $E$  of 30 to 45 degrees with the surface of the flat. The thread conforms to the Unified Standard with radius root, Class 3A UNRC and UNRF for screw sizes No. 0 through 1 inch inclusive, Class 2A UNRC and UNRF for over 1 inch through 1 1/2 inches inclusive, and Class 2A UNRC for larger sizes. Socket dimensions are given in Table 11. For details not shown, including materials, see ANSI/ASME B18.3-1998.

Table 5. Drill and Counterbore Sizes For Socket Head Cap Screws (1960 Series)

| Nominal Size or Basic Screw Diameter | Nominal Drill Size        |                  |                           |                  | Counterbore Diameter | Countersink Diameter <sup>a</sup> |       |
|--------------------------------------|---------------------------|------------------|---------------------------|------------------|----------------------|-----------------------------------|-------|
|                                      | Close Fit <sup>b</sup>    |                  | Normal Fit <sup>c</sup>   |                  |                      |                                   |       |
|                                      | Number or Fractional Size | Decimal Size     | Number or Fractional Size | Decimal Size     |                      |                                   |       |

<sup>a</sup> **Countersink:** It is considered good practice to countersink or break the edges of holes which are smaller than  $(D \text{ Max} + 2F \text{ Max})$  in parts having a hardness which approaches, equals or exceeds the screw hardness. If such holes are not countersunk, the heads of screws may not seat properly or the sharp edges on holes may deform the fillets on screws thereby making them susceptible to fatigue in applications involving dynamic loading. The countersink or corner relief, however, should not be larger than is necessary to insure that the fillet on the screw is cleared.

<sup>b</sup> **Close Fit:** The close fit is normally limited to holes for those lengths of screws which are threaded to the head in assemblies where only one screw is to be used or where two or more screws are to be used and the mating holes are to be produced either at assembly or by matched and coordinated tooling.

<sup>c</sup> **Normal Fit:** The normal fit is intended for screws of relatively long length or for assemblies involving two or more screws where the mating holes are to be produced by conventional tolerancing methods. It provides for the maximum allowable eccentricity of the longest standard screws and for certain variations in the parts to be fastened, such as: deviations in hole straightness, angularity between the axis of the tapped hole and that of the hole for the shank, differences in center distances of the mating holes, etc.

All dimensions in inches.

All dimensions in inches.

The body of the screw is the unthreaded cylindrical portion of the shank where not threaded to the head; the shank being the portion of the screw from the point of juncture of the conical bearing surface and the body to the flat of the point. The length of thread  $L_T$  is the distance measured from the extreme point to the last complete (full form) thread.

Standard length increments of No. 0 through 1-inch sizes are as follows: 1/16 inch for nominal screw lengths of 1/8 through 1/4 inch; 1/8 inch for lengths of 1/4 through 1 inch; 1/4 inch for lengths of 1 inch through 3 1/2 inches; 1/2 inch for lengths of 3 1/2 through 7 inches; and 1 inch for lengths of 7 through 10 inches, incl. For screw sizes over 1 inch, length increments are: 1/2 inch for nominal screw lengths of 1 inch through 7 inches; 1 inch for lengths of 7 through 10 inches; and 2 inches for lengths over 10 inches.

Threads shall be Unified external threads with radius root; Class 3A UNRC and UNRF series for sizes No. 0 through 1 inch and Class 2A UNRC and UNRF series for sizes over 1 inch to 1 1/2 inches, incl.

For manufacturing details not shown, including materials, see American National Standard ANSI/ASME B18.3-1998 Socket dimensions are given in [Table 11](#).

<sup>a</sup> Socket dimensions are given in Table 11.

All dimensions in inches.

These cap screws have been designed and recommended for light fastening applications. They are not suggested for use in critical high-strength applications where socket head cap screws should normally be used.

Standard length increments for socket button head cap screws are as follows: ⅛ inch for nominal screw lengths of ⅛ through ¼ inch, ⅜ inch for nominal screw lengths of ¼ through 1 inch, and ¼ inch for nominal screw lengths of 1 inch through 2 inches. Tolerances on lengths are -0.03 inch for lengths up to 1 inch inclusive. For lengths from 1 through 2 inches, inclusive, length tolerances are -0.04 inch.

The thread conforms to the Unified standard, Class 3A, with radius root, UNRC and UNRF.

To prevent interference, American National Standard ANSI/ASME B18.3.4M-1986 gives metric dimensional and general requirements for a lower head profile hexagon socket button head cap screw. Because of its design, wrenchability and other design factors are reduced; therefore, B18.3.4M should be reviewed carefully. Available only in metric sizes and with metric threads.

For manufacturing details, including materials, not shown, see American National Standard ANSI/ASME B18.3-1998

All dimensions are in inches. The shoulder is the enlarged, unthreaded portion of the screw. Standard length increments for shoulder screws are: 1/8 inch for nominal screw lengths of 1/4 through 3/4 inch; 1/4 inch for lengths above 3/4 through 5 inches; and 1/2 inch for lengths over 5 inches. The thread conforms to the Unified Standard Class 3A, UNC. Hexagon socket sizes for the respective shoulder screw sizes are the same as for set screws of the same nominal size (see Table 7) except for shoulder screw size 1 inch, socket size is 1/2 inch, for screw size 1 1/2 inches, socket size is 7/8 inch, and for screw size 2 inches, socket size is 1 1/4 inches. For details not shown, including materials, see ANSI/ASME B18.3-1998.

<sup>a</sup> When specifying a nominal size in decimals a zero preceding the decimal point or any zero in the fourth decimal place is omitted.

All dimensions are in inches.

**Crown Radius, *I*:** The crown radius has the same value as the basic screw diameter to three decimal places.

**Oval Point Radius, *R*:** Values of the oval point radius according to nominal screw size are: For a screw size of 0, a radius of .045; 1, .055; 2, .064; 3, .074; 4, .084; 5, .094; 6, .104; 8, .123; 10, .142; 12, .162; ¼, .188; ⅜, .234; ½, .281; ⅝, .328; ¾, .375; ⅞, .422; 1, .469; and for ¼, .562.

**Cone Point Angle, *Y*:** The cone point angle is 90° ± 2° for the following nominal lengths, or longer, shown according to screw size: For nominal size 0, a length of ⅜; 1, ⅜; 2, ⅞; 3, 1; 4, ⅝; 5, ⅝; 6, ⅝; 8, 1; 10, 1; 12, 1; ¼, 1; ⅜, 1; ½, 1; ⅝, 1; ¾, 1; 1, 1; 1 ¼, 1; 1 ½, 1; 1 ¾, 1; 2, 1; 2 ¼, 1; 2 ½, 1; 2 ¾, 1; 3, 1; 3 ¼, 1; and for ¼, ⅞. For shorter screws, the cone point angle is 118° ± 2°.

**Point Angle *X*:** The point angle is 45°, +5°, -0°, for screws of nominal lengths, or longer, as given just above for cone point angle, and 30°, min. for shorter screws.

**Threads:** are Unified Standard Class 2A; UNC and UNF Series or UNRC and UNRF Series.

All dimensions are in inches.

\* Socket depths, T, for various screw types are given in the standard but are not shown here.

Where sockets are chamfered, the depth of chamfer shall not exceed 10 per cent of the nominal socket size for sizes up to and including  $\frac{1}{16}$  inch for hexagon sockets and 0.060 for spline sockets, and 7.5 per cent for larger sizes.

All dimensions are in inches.

\*Threads: Threads are Unified Standard Class 2A; UNC, UNF and 8 UN Series or UNRC, UNRF and 8 UNR Series.

**Length of Thread:** Square head set screws have complete (full form) threads extending over that portion of the screw length which is not affected by the point. For the respective constructions, threads extend into the neck relief, to the conical underside of head, or to within one thread (as measured with a thread ring gage) from the flat underside of the head. Threads through angular or crowned portions of points have fully formed roots with partial crests.

\*When specifying a nominal size in decimals, the zero preceding the decimal point is omitted as is any zero in the fourth decimal place.

**Designation:** Square head set screws are designated by the following data in the sequence shown: Nominal size (number, fraction or decimal equivalent); threads per inch; screw length (fraction or decimal equivalent); product name; point style; material; and protective finish, if required. Examples:  $\frac{1}{4}$  - 20  $\times$   $\frac{3}{4}$  Square Head Set Screw, Flat Point, Steel, Cadmium Plated. .500 - 13  $\times$  1.25 Square Head Set Screw, Cone Point, Corrosion Resistant Steel.

**Cone Point Angle, *Y*:** For the following nominal lengths, or longer, shown according to nominal size, the cone point angle is  $90^\circ \pm 2^\circ$ : For size No. 10,  $\frac{1}{4}$ ,  $\frac{1}{4}$ ,  $\frac{5}{16}$ ,  $\frac{5}{16}$ ,  $\frac{3}{8}$ ,  $\frac{3}{8}$ ,  $\frac{7}{16}$ ,  $\frac{7}{16}$ ,  $\frac{1}{2}$ ,  $\frac{1}{2}$ ,  $\frac{9}{16}$ ,  $\frac{9}{16}$ ,  $\frac{5}{8}$ ,  $\frac{5}{8}$ ,  $\frac{3}{4}$ ,  $\frac{3}{4}$ ,  $\frac{7}{8}$ ,  $\frac{7}{8}$ ; 1; 1,  $1\frac{1}{8}$ ,  $1\frac{1}{8}$ ,  $1\frac{1}{4}$ ,  $1\frac{1}{4}$ ,  $1\frac{1}{2}$ ,  $1\frac{3}{8}$ ,  $1\frac{5}{8}$ ; and for  $1\frac{1}{2}$ ,  $1\frac{3}{4}$ . For shorter screws the cone point angle is  $118^\circ \pm 2^\circ$ .

**Point Types:** Unless otherwise specified, square head set screws are supplied with cup points. Cup points as furnished by some manufacturers may be externally or internally knurled. Where so specified by the purchaser, screws have cone, dog, half-dog, flat or oval points as given on the following page.

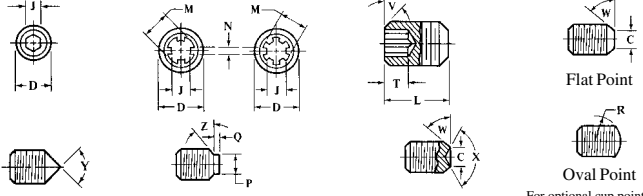

**Point Angle, *X*:** The point angle is  $45^\circ$ ,  $+5^\circ$ ,  $-0^\circ$  for screws of the nominal lengths, or longer, given just above for cone point angle, and  $30^\circ$  min. for shorter lengths.

**Table 14. Applicability of Hexagon and Spline Keys and Bits**

| Nominal Key or Bit Size      | Cap Screws 1960 Series          | Flat Countersunk Head Cap Screws | Button Head Cap Screws | Shoulder Screws | Set Screws                      |
|------------------------------|---------------------------------|----------------------------------|------------------------|-----------------|---------------------------------|

| 2                                    | 2.0000      | 1         | ...                          | 1.244 | 1.193          | 1.500      | 1.510             | 1.500                     | ...          | 2.25                  |

For optional cup points and their dimensions see Table 10.

<sup>a</sup> Reference should be made to the Standard for shortest optimum nominal lengths to which the minimum key engagement depths  $T_H$  and  $T_S$  apply.

<sup>b</sup> Cone point angle  $Y$  is 90 degrees plus or minus 2 degrees for these nominal lengths or longer and 118 degrees plus or minus 2 degrees for shorter nominal lengths.

All dimensions are in inches. The thread conforms to the Unified Standard, Class 3A, UNC and UNF series. The socket depth  $T$  is included in the Standard and some are shown here. The nominal length  $L$  of all socket type set screws is the total or overall length. For nominal screw lengths of 1/16 through 3/16 inch (0 through 3 sizes incl.) the standard length increment is 0.06 inch; for lengths 1/8 through 1 inch the increment is 1/8 inch; for lengths 1 through 2 inches the increment is 1/4 inch; for lengths 2 through 6 inches the increment is 1/2 inch; for lengths 6 inches and longer the increment is 1 inch. Socket dimensions are given in Table 11.

Length Tolerance: The allowable tolerance on length  $L$  for all set screws of the socket type is  $\pm 0.01$  inch for set screws up to 5/8 inch long;  $\pm 0.02$  inch for screws over 5/8 to 2 inches long;  $\pm 0.03$  inch for screws over 2 to 6 inches long and  $\pm 0.06$  inch for screws over 6 inches long. Socket dimensions are given in Table 11.

For manufacturing details, including materials, not shown, see American National Standard ANSI/ASME B18.3-1998.

**British Standard Hexagon Socket Screws — Metric Series.**—The first five parts of British Standard BS 4168: 1981 provide specifications for hexagon socket head cap screws and hexagon socket set screws.

*Hexagon Socket Head Cap Screws:* The dimensional data in [Table 1](#) are based upon BS 4168: Part 1: 1981. These screws are available in stainless steel and alloy steel, the latter having class 12.9 properties as specified in BS 6104:Part 1. When ordering these screws, the designation “Hexagon socket head cap screw BS 4168 M5 × 20-12.9” would mean, as an example, a cap screw having a thread size of  $d = M5$ , nominal length  $l = 20$  mm, and property class 12.9. Alloy steel cap screws are furnished with a black oxide finish (thermal or chemical); stainless steel cap screws with a plain finish. Combinations of thread size, nominal length, and length of thread are shown in [Table 2](#); the screw threads in these combinations are in the ISO metric coarse pitch series specified in BS 3643 with tolerances in the 5g6g class. (See Metric Screw Threads in Index.)

*Hexagon Socket Set Screws:* Part 2 of B.S. 4168:1981 specifies requirements for hexagon socket set screws with flat point having ISO metric threads, and diameters from 1.6 mm up to and including 24 mm. The dimensions of these set screws along with those of cone-point, dog-point, and cup-point set screws in accord, respectively, with Parts 3, 4, and 5 of the Standard are given in [Table 3](#) and the accompanying illustration. All of these set screws are available in either steel processed to mechanical properties class 45H B.S. 6104:Part 3; or stainless steel processed to mechanical properties described in B.S. 6105. Steel set screws are furnished with black oxide (thermal or chemical) finish; stainless steel set screws are furnished plain. The tolerances applied to the threads of these set screws are for ISO product grade A, based on ISO 4759/1-1978 “Tolerances for fasteners — Part 1: Bolts, screws, and nuts with thread diameters greater than or equal to 1.6 mm and less than or equal to 150 mm and product grades A, B, and C.”

Hexagon socket set screws are designated by the type, the thread size, nominal length, and property class. As an example, for a flat-point set screw of thread size  $d = M6$ , nominal length  $l = 12$  mm, and property class 45H:

Hexagon socket set screw flat point BS 4168 M6 × 12-45H

*British Standard Hexagon Socket Countersunk and Button Head Screws — Metric Series:* British Standard BS 4168:1967 provides a metric series of hexagon socket countersunk and button head screws. The dimensions of these screws are given in [Table 4](#). The revision of this Standard will constitute Parts 6 and 8 of BS 4168.

*British Standards for Mechanical Properties of Fasteners:* B.S. 6104: Part 1:1981 specifies mechanical properties for bolts, screws, and studs with nominal diameters up to and including 39 mm of any triangular ISO thread and made of carbon or alloy steel. It does not apply to set screws and similar threaded fasteners. Part 2 of this Standard specifies the mechanical properties of set screws and similar fasteners, not under tensile stress, in the range from M1.6 up to and including M39 and made of carbon or alloy steel.

B.S. 6105:1981 provides specifications for bolts, screws, studs, and nuts made from austenitic, ferritic, and martensitic grades of corrosion-resistant steels. This Standard applies only to fastener components after completion of manufacture with nominal diameters from M1.6 up to and including M39. These Standards are not described further here. Copies may be obtained from the British Standards Institution, 2 Park Street, London W1A 2BS and also from the American National Standards Institute, 25 West 43rd Street, New York, N.Y. 10036.

<sup>a</sup>The size shown in ( ) is non-preferred.

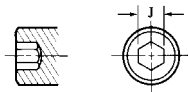

<sup>b</sup>See Table 2 for min/max.

<sup>c</sup>For plain heads.

<sup>d</sup>For knurled heads.

All dimensions are given in millimeters.

| ...   | ...                                 | ...  | 19                  | 19.275                              | 19.065 |

All dimensions are in millimeters.

The popular lengths are those between the stepped solid lines. Lengths above the shaded areas are threaded to the head within 3 pitch lengths ( $3P$ ). Lengths within and below the shaded areas have values of  $L_g$  and  $L_s$  (see Table 1) given by the formulas:  $L_g \text{ max} = L \text{ nom} - b \text{ ref}$ , and  $L_s \text{ min} = L_g \text{ max} - 5P$ .

<sup>a</sup>The smaller of the two *t* min. values applies to certain short-length set screws. These short-length screws are those whose length is approximately equal to the diameter of the screw. The larger *t* min. values apply to longer-length screws.

<sup>b</sup>A dog point set screw having a nominal length equal to or less than the length shown in the (\*) column of the table is supplied with length *z* shown in the short dog column. For set screws of lengths greater than shown in the (\*) column, *z* for long dogs applies.

All dimensions are in millimeters. For dimensional notation, see diagram, page 1637.

All dimensions are given in millimeters.

## British Standard Hexagon Socket Set Screws — Metric Series

BS 4168: Parts 2, 3, 4, and 5: 1994

\*The 120° angle is mandatory for short-length screws shown in the Standard. Short-length screws are those whose length is, approximately, equal to the diameter of the screw.

\*\*The 45° angle applies only to that portion of the point below the root diameter,  $d_f$ , of the thread.

\*\*\*The cone angle applies only to the portion of the point below the root diameter,  $d_f$ , of the thread and shall be 120° for certain short lengths listed in the Standard. All other lengths have a 90° cone angle.

†The popular length ranges of these set screws are listed in Table 3. These lengths have been selected from the following nominal lengths: 2, 2.5, 3, 4, 6, 8, 10, 12, 16, 20, 25, 30, 35, 40, 45, 50, 55, and 60 millimeters.

**Holding Power of Set-screws.**— While the amount of power a set-screw of given size will transmit without slipping (when used for holding a pulley, gear, or other part from turning relative to a shaft) varies somewhat according to the physical properties of both set-screw and shaft and other variable factors, experiments have shown that the safe holding force in pounds for different diameters of set-screws should be approximately as follows: For  $\frac{1}{4}$ -inch diameter set-screws the safe holding force is 100 pounds, for  $\frac{3}{8}$ -inch

diameter set-screws the safe holding force is 250 pounds, for 1/2-inch diameter set-screws the safe holding force is 500 pounds, for 3/4-inch diameter set-screws the safe holding force is 1300 pounds, and for 1-inch diameter set-screws the safe holding force is 2500 pounds.

The power or torque that can be safely transmitted by a set-screw may be determined from the formulas,  $P = (DNd^{2.3}) \div 50$ ; or  $T = 1250Dd^{2.3}$  in which  $P$  is the horsepower transmitted;  $T$  is the torque in inch-pounds transmitted;  $D$  is the shaft diameter in inches;  $N$  is the speed of the shaft in revolutions per minute; and  $d$  is the diameter of the set-screw in inches.

*Example:* How many 1/2-inch diameter set-screws would be required to transmit 3 horsepower at a shaft speed of 1000 rpm if the shaft diameter is 1 inch?

Using the first formula given above, the power transmitted by a single 1/2-inch diameter set-screw is determined:  $P = [1 \times 1000 \times (1/2)^{2.3}] \div 50 = 4.1$  hp. Therefore a single 1/2-inch diameter set-screw is sufficient.

*Example:* In the previous example, how many 3/8-inch diameter set-screws would be required?  $P = [1 \times 1000 \times (3/8)^{2.3}] \div 50 = 2.1$  hp. Therefore two 3/8-inch diameter set-screws are required.

**Table 5. British Standard Whitworth (BSW) and British Standard Fine (BSF) Bright Square Head Set-Screws (With Flat Chamfered Ends)**

| Nominal Size and Max. Dia., Inches | Number of Threads per Inch |     | No. 1 Standard       |                 | No. 2 Standard       |                 | No. 3 Standard       |                 |

\* Depth of Head B, D and F same as for Width Across Flats, No. 1 Standard. Dimensions A, B, C, D, E, and F are in inches.

## SELF-THREADING SCREWS

**ANSI Standard Sheet Metal, Self-Tapping, and Metallic Drive Screws.**—Table 1 shows the various types of “self-tapping” screw threads covered by the ANSI B18.6.4-1981 (R1991) standard. (Metric thread forming and thread cutting tapping screws are discussed beginning on page 1654). ANSI designations are also shown. Types A, AB, B, BP and C when turned into a hole of proper size form a thread by a displacing action. Types D, F, G, T, BF and BT when turned into a hole of proper size form a thread by a cutting action. Type U when driven into a hole of proper size forms a series of multiple threads by a displacing action. These screws have the following descriptions and applications:

*Type A:* Spaced-thread screw with gimlet point primarily for use in light sheet metal, resin-impregnated plywood, and asbestos compositions. This type is no longer recommended. Use Type AB in new designs and whenever possible substitute for Type A in existing designs.

*Type AB:* Spaced-thread screw with same pitches as Type B but with gimlet point, primarily for similar uses as for Type A.

*Type B:* Spaced-thread screw with a blunt point with pitches generally somewhat finer than Type A. Used for thin metal, non-ferrous castings, plastics, resin-impregnated plywood, and asbestos compositions.

*Type BP:* Spaced-thread screw, the same as Type B but having a conical point extending beyond incomplete entering threads. Used for piercing fabrics or in assemblies where holes are misaligned.

*Type C:* Screws having machine screw diameter-pitch combinations with threads approximately Unified Form and with blunt tapered points. Used where a machine screw thread is preferable to the spaced-thread types of thread forming screws. Also useful when chips from machine screw thread-cutting screws are objectionable. In view of the declining use of Type C screws, which in general require high driving torques, in favor of more efficient designs of thread tapping screws, they are not recommended for new designs.

*Types D, F, G, and T:* Thread-cutting screws with threads approximating machine screw threads, with blunt point, and with tapered entering threads having one or more cutting edges and chip cavities. The tapered threads of the Type F may be complete or incomplete at the producer's option; all other types have incomplete tapered threads. These screws can be used in materials such as aluminum, zinc, and lead die-castings; steel sheets and shapes; cast iron; brass; and plastics.

*Types BF and BT:* Thread-cutting screws with spaced threads as in Type B, with blunt points, and one or more cutting grooves. Used in plastics, asbestos, and other similar compositions.

*Type U:* Multiple-threaded drive screw with large helix angle, having a pilot point, for use in metal and plastics. This screw is forced into the work by pressure and is intended for making permanent fastenings.

*ANSI Standard Head Types for Tapping and Metallic Drive Screws:* Many of the head types used with “self-tapping” screw threads are similar to the head types of American National Standard machine screws shown in the section with that heading.

*Round Head:* The round head has a semi-elliptical top surface and a flat bearing surface. Because of the superior slot driving characteristics of pan head screws over round head screws, and the overlap in dimensions of cross recessed pan heads and round heads, it is recommended that pan head screws be used in new designs and wherever possible substituted in existing designs.

*Undercut Flat and Oval Countersunk Heads:* For short lengths, 82-degree and oval countersunk head tapping screws have heads undercut to 70 per cent of normal side height to afford greater length of thread on the screws.

*Flat Countersunk Head:* The flat countersunk head has a flat top surface and a conical bearing surface with a head angle for one design of approximately 82 degrees and for another design of approximately 100 degrees. Because of its limited usage and in the interest of curtailing product varieties, the 100-degree flat countersunk head is considered non-preferred.

*Oval Countersunk Head:* The oval countersunk head has a rounded top surface and a conical bearing surface with a head angle of approximately 82 degrees.

*Flat and Oval Countersunk Trim Heads:* Flat and oval countersunk trim heads are similar to the 82-degree flat and oval countersunk heads except that the size of head for a given size screw is one (large trim head) or two (small trim head) sizes smaller than the regular flat and oval countersunk head size. Oval countersunk trim heads have a definite radius where the curved top surface meets the conical bearing surface. Trim heads are furnished only in cross recessed types.

*Pan Head:* The slotted pan head has a flat top surface rounded into cylindrical sides and a flat bearing surface. The recessed pan head has a rounded top and a flat bearing surface. This head type is now preferred to the round head.

*Fillister Head:* The fillister head has a rounded top surface, cylindrical sides, and a flat bearing surface.

*Hex Head:* The hex head has a flat or indented top surface, six flat sides, and a flat bearing surface. Because the slotted hex head requires a secondary operation in manufacture which often results in burrs at the extremity of the slot that interfere with socket wrench engagement and the wrenching capability of the hex far exceeds that of the slot, it is not recommended for new designs.

*Hex Washer Head:* The hex washer head has an indented top surface and six flat sides formed integrally with a flat washer that projects beyond the sides and provides a flat bearing surface. Because the slotted hex washer head requires a secondary operation in manufacture which often results in burrs at the extremity of the slot that often interferes with socket wrench engagement and because the wrenching capability of the hex far exceeds that of the slot in the indented head, it is not recommended for new designs.

*Truss Head:* The truss head has a low rounded top surface with a flat bearing surface, the diameter of which for a given screw size is larger than the diameter of the corresponding round head. In the interest of product simplification and recognizing that the truss head is an inherently weak design, it is not recommended for new designs.

**Method of Designation.**—Tapping screws are designated by the following data in the sequence shown: Nominal size (number, fraction or decimal equivalent); threads per inch; nominal length (fraction or decimal equivalent); point type; product name, including head type and driving provision; material; and protective finish, if required.

Examples:

$\frac{1}{4}$ -14  $\times$  1 $\frac{1}{2}$  Type AB Slotted Pan Head Tapping Screw, Steel, Nickel Plated

6-32  $\times$   $\frac{3}{4}$  Type T, Type 1A Cross Recessed Pan Head Tapping Screw, Corrosion Resistant Steel

0.375-16  $\times$  1.50 Type D, Washer Head Tapping Screw, Steel

*Metallic Drive Screws:* Type U metallic drive screws are designated by the following data in the sequence shown: Nominal size (number, fraction, or decimal equivalent); nominal length (fraction or decimal equivalent); product name, including head type; material; and protective finish, if required. Examples:

10  $\times$   $\frac{5}{16}$  Round Head Metallic Drive Screw, Steel

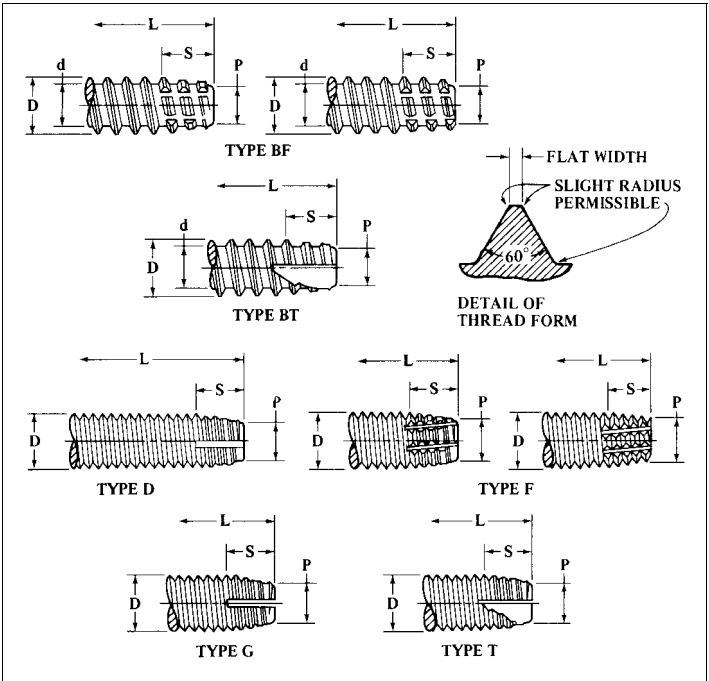

0.312  $\times$  0.50 Round Head Metallic Drive Screw, Steel, Zinc Plated

**Table 1. ANSI Standard Threads and Points for Thread Forming Self-Tapping Screws ANSI B18.6.4-1981 (R1991)**

See Tables 3, 5, and 6 for thread data.

**Table 2. ANSI Standard Threads and Points for Thread Cutting Self-Tapping Screws ANSI B18.6.4-1981 (R1991)**

See Tables 5 and 7 for thread data.

**Cross Recesses.**—Type I cross recess has a large center opening, tapered wings, and blunt bottom, with all edges relieved or rounded. Type IA cross recess has a large center opening, wide straight wings, and blunt bottom, with all edges relieved or rounded. Type II consists of two intersecting slots with parallel sides converging to a slightly truncated apex at the bottom of the recess. Type III has a square center opening, slightly tapered side walls, and a conical bottom, with top edges relieved or rounded.

**Table 3. ANSI Standard Cross Recesses for Self-Tapping Screws ANSI B18.6.4-1981 (R1991) and Metric Thread Forming and Thread Cutting Tapping Screws ANSI/ASME B18.6.5M-1986**

**Table 4. ANSI Standard Thread and Point Dimensions for Types AB, A and U Thread Forming Tapping Screws ANSI B18.6.4-1981 (R1991)**

| Type AB (Formerly BA)                  |                  |                |              |                |              |                                 |                 |  |  |

All dimensions are in inches. See Table 1 for thread diagrams.

Sizes shown in bold face type are preferred. Type A screws are no longer recommended.

**Table 5. ANSI Standard Thread and Point Dimensions for B and BP Thread Forming and BF and BT Thread Cutting Tapping Screws ANSI B18.6.4-1981 (R1991)**

<sup>a</sup> Where specifying nominal size in decimals, zeros preceding decimal and in the fourth decimal place shall be omitted.

<sup>b</sup> The width of flat at crest of thread shall not exceed 0.004 inch for sizes up to No. 8, inclusive, and 0.006 inch for larger sizes.

<sup>c</sup> Point diameters specified apply to screw threads before roll threading.

<sup>d</sup> Points of screws are tapered and fluted or slotted. The flute on Type BT screws has an included angle of 90 to 95 degrees and the thread cutting edge is located above the axis of the screw. Flutes and slots extend through first full form thread beyond taper except for Type BF screw on which tapered threads may be complete at manufacturer's option and flutes may be one pitch short of first full form thread.

<sup>a</sup> Where specifying nominal size in decimals, zeros preceding decimal and in the fourth decimal place shall be omitted.

<sup>b</sup> The tabulated values apply to screw blanks before roll threading.

<sup>c</sup> Screws of these nominal lengths and shorter shall have point taper length specified above for short screws. Longer lengths shall have point taper length specified for long screws.

All dimensions are in inches. See [Table 1](#) for thread diagrams. Type C is not recommended for new designs.

Tapered threads shall have unfinished crests.

**Table 7. ANSI Standard Thread and Point Dimensions for Types D, F, G, and T  
Thread Cutting Tapping Screws ANSI B18.6.4-1981 (R1991)**

| Nominal Size <sup>a</sup> or Basic Screw Diameter | Threads per inch | D              |        | P                           |       | S                               |               |                 |       | L  |                 |   |                 |                 |                |

<sup>a</sup> Where specifying nominal size in decimals, zeros preceding decimal and in the fourth decimal place shall be omitted.

<sup>b</sup> The tabulated values apply to screw blanks before roll threading.

<sup>c</sup> Screws of these nominal lengths and shorter shall have point taper length specified above for short screws. Longer lengths shall have point taper length specified for long screws.

All dimensions are in inches. See Table 2 for thread diagrams.

Type "Type D" otherwise designated "Type 1."

Type "Type T" otherwise designated "Type 23."

**Table 8. Approximate Hole Sizes for Type A Steel Thread Forming Screws**

| In Steel, Stainless Steel, Monel Metal, Brass, and Aluminum Sheet Metal |                 |                     |                          |            |            |                 |                     |                          |            |            |  |
|---|-----------------|---------------------|--------------------------|------------|------------|-----------------|---------------------|--------------------------|------------|------------|--|
| Screw Size  | Metal Thickness | Hole Size           |                          |            | Screw Size | Metal Thickness | Hole Size           |                          |            | Drill Size |  |
|   |                 | Pierced or Extruded | Drilled or Clean Punched | Drill Size |            |                 | Pierced or Extruded | Drilled or Clean Punched | Drill Size |            |  |

All dimensions are in inches except drill sizes. It may be necessary to vary the hole size to suit a particular application.

Type C is not recommended for new designs.

<sup>a</sup>Data below apply to Types B and BP only.

All dimensions are in inches except whole number screw and drill sizes.

Since conditions differ widely, it may be necessary to vary the hole size to suit a particular application.

**Table 12a. Approximate Drilled or Clean-Punched Hole Sizes for Types AB, B, and BP Steel Thread Forming Screws**

<sup>a</sup>For Types B and BP only; for Type AB see concluded Table 12b following.

Since conditions differ widely, it may be necessary to vary the hole size to suit a particular application. Hole sizes for metal thicknesses above 0.075 inch are for Types B and BP only.

SELF-THREADING SCREWS

**Table 12b. Supplementary Data for Types AB Thread Forming Screws in Steel, Stainless Steel, Monel Metal, and Brass Sheet Metal**

| Screw Size  | Metal Thickness | Hole Size | Drill Size | Screw Size | Metal Thickness | Hole Size | Drill Size | Screw Size | Metal Thickness | Hole Size | Drill Size |

All dimensions are in inches except numbered drill and screw sizes. It may be necessary to vary the hole size to suit a particular application.

**Table 14. Approximate Hole Sizes for Types D, F, G, and T Steel Thread Cutting Screws in Cast Metals and Plastics**

| Screw Size | Thick-ness | Cast Iron |            | Zinc and Aluminum <sup>a</sup> |            | Screw Size | Thick-ness | Cast Iron |            | Zinc and Aluminum <sup>a</sup> |            |
|------------|------------|-----------|------------|--------------------------------|------------|------------|------------|-----------|------------|--------------------------------|------------|

Torsional strength data are in pound-inches.

**Self-tapping Thread Inserts.**—Self-tapping screw thread inserts are essentially hard bushings with internal and external threads. The internal threads conform to Unified and American standard classes 2B and 3B, depending on the type of insert used. The external thread has cutting edges on the end that provide the self-tapping feature. These inserts may be used in magnesium, aluminum, cast iron, zinc, plastics, and other materials. Self-tapping inserts are made of case-hardened carbon steel, stainless steel, and brass, the brass type being designed specifically for installation in wood.

**Screw Thread Inserts.**—Screw thread inserts are helically formed coils of diamond-shaped stainless steel or phosphor bronze wire that screw into a threaded hole to form a mating internal thread for a screw or stud. These inserts provide a convenient means of repairing stripped-out threads and are also used to provide stronger threads in soft materials such as aluminum, zinc die castings, wood, magnesium, etc. than can be obtained by direct tapping of the base metal involved.

According to the Heli-Coil Corp., conventional design practice in specifying boss diameters or edge distances can usually be applied since the major diameter of a hole tapped to receive a thread insert is not much larger than the major diameter of thread the insert provides.

Screw thread inserts are available in thread sizes from 4–40 to  $1\frac{1}{2}$ –6 inch National and Unified Coarse Thread Series and in 6–40 to  $1\frac{1}{2}$ –12 sizes in the fine-thread series. When used in conjunction with appropriate taps and gages, screw thread inserts will meet requirements of 2, 2B, 3, and 3B thread classes.

**ANSI Standard Metric Thread Forming and Thread Cutting Tapping Screws.**—

Table 1 shows the various types of metric thread forming and thread cutting screw threads covered by the standard ANSI/ASME B18.6.5M-1986. The designations of the American National Standards Institute are shown.

**Table 1. ANSI Standard Threads and Points for Metric Thread Forming and Thread Cutting Tapping Screws ANSI/ASME B18.6.5M-1986**

See Tables 3 and 4 for thread data.

**Thread Forming Tapping Screws:** These types are generally for application in materials where large internal stresses are permissible or desirable, to increase resistance to loosening. These screws have the following descriptions and applications:

*Type AB:* Spaced thread screw with gimlet point primarily intended for use in thin metal, resin impregnated plywood, and asbestos compositions.

*Type B:* Spaced thread screw with a blunt point that has tapered entering threads with unfinished crests and same pitches as Type AB. Used for thin metal, nonferrous castings, resin impregnated plywood, certain resilient plastics, and asbestos compositions.

*Thread Cutting Tapping Screws:* These screws are generally for application in materials where disruptive internal stresses are undesirable or where excessive driving torques are encountered with thread forming tapping screws. These screws have the following descriptions and applications:

*Types BF and BT:* Spaced threads with blunt point and tapered entering threads having unfinished crests, as on Type B, with one or more cutting edges or chip cavities, intended for use in plastics, asbestos compositions, and other similar materials.

*Types D, F, and T:* Tapping screws with threads of machine screw diameter-pitch combinations (metric coarse thread series) approximating a 60 degree basic thread form (not necessarily conforming to any standard thread profile) with a blunt point and tapered entering threads with unfinished crests and having one or more cutting edges and chip cavities, intended for use in materials such as aluminum, zinc, and lead die castings; steel sheets and shapes; cast iron; brass; and plastics.

**ANSI Standard Head Types for Metric Thread Forming and Cutting Tapping Screws.**—The head types covered by ANSI/ASME B18.6.5M-1986 include those commonly applicable to metric tapping screws and are described as follows:

*Flat Countersunk Head:* The flat countersunk head has a flat top surface and a conical bearing surface with a head angle of 90 to 92 degrees.

*Oval Countersunk Head:* The oval countersunk head has a rounded top surface and a conical bearing surface with a head angle of 90 to 92 degrees.

*Pan Head:* The slotted pan head has a flat top surface rounding into cylindrical sides and a flat bearing surface. The recessed pan head has a rounded top surface blending into cylindrical sides and a flat bearing surface.

*Hex Head:* The hex head has a flat or indented top surface, six flat sides, and a flat bearing surface.

*Hex Flange Head:* The hex flange head has a flat or indented top surface and six flat sides formed integrally with a frustroconical or slightly rounded (convex) flange that projects beyond the sides and provides a flat bearing surface.

**Method of Designation.**—Metric tapping screws are designated with the following data, preferably in the sequence shown: Nominal size; thread pitch; nominal length; thread and point type; product name, including head style and driving provision; material; and protective finish, if required.

*Examples:*

6.3 × 1.8 × 30 Type AB, Slotted Pan Head Tapping Screw, Steel, Zinc Plated

6 × 1 × 20 Type T, Type 1A Cross Recessed Pan Head Tapping Screw, Corrosion Resistant Steel

4.2 × 1.4 × 13 Type BF, Type 1 Cross Recessed Oval Countersunk Head Tapping Screw, Steel, Chromium Plated

10 × 1.5 × 40 Type D, Hex Flange Head Tapping Screw, Steel

**Table 2. Recommended Nominal Screw Lengths for Metric Tapping Screws  
ANSI/ASME B18.6.5M-1986**

| Nominal Screw Length | Nominal Screw Size for Types AB, B, BF, and BT |     |     |     |     |     |     |     |    |     |

| 9.5 × 2.1  | 9.525                | 2.12               | 9.65                  | 9.43             | 7.85                  | 7.59 | 7.44                        | 7.24 | 4.2                                    | 3.2 | 8.0                         | 19   | 24               | 14     | 19     |

<sup>a</sup> The body diameter (unthreaded portion) is not less than the minimum minor diameter nor greater than the maximum major diameter of the thread.

<sup>b</sup> The tabulated values shall apply to screw blanks prior to roll threading.

<sup>c</sup> The tabulated maximum limits are equal to approximately two times the thread pitch.

<sup>d</sup> Lengths shown are theoretical minimums and are intended to assist the user in the selection of appropriate short screw lengths. Refer to Table 2 for recommended diameter-length combinations.

<sup>e</sup> Basic screw diameter and basic thread pitch shall be used for calculation purposes wherever these factors appear in formulations for dimensions.

<sup>f</sup> The minimum effective grip length on Type AB tapping screws shall be determined by subtracting the point length factor from the minimum screw length.

All dimensions are in millimeters. See Table 1 for thread diagrams.

<sup>7</sup> Pan, hex, and hex flange heads.

<sup>8</sup> Flat and oval countersunk heads.

<sup>a</sup> The tabulated values apply to screw blanks prior to roll threading.

<sup>b</sup> The tabulated maximum limits are equal to approximately two times the thread pitch.

<sup>c</sup> Lengths shown are theoretical minimums and are intended to assist in the selection of appropriate short screw lengths. See Table 2 for recommended length-diameter combinations. For Types D, F, and T, shorter screws are available with the point length reduced to the limits tabulated for short screws.

<sup>d</sup> Basic screw diameter and basic thread pitch are used for calculation purposes whenever these factors appear in formulations for dimensions.

| Types D, F, T                       |                       |      |                             |      |                |                    |                  |     |                              |   |                               |                           |

<sup>a</sup> Minimum limits for body diameter (unthreaded portion) are tabulated for convenient reference. For Types BF and BT, the body diameter is not less than the minimum minor diameter nor greater than the maximum major diameter of the thread.

<sup>b</sup> Long screws are screws of nominal lengths equal to or longer than those listed under L.

All dimensions are in millimeters. See Table 1 for thread diagrams.

**Material and Heat Treatment.**—Tapping screws are normally fabricated from carbon steel and are suitably processed to meet the performance and test requirements outlined in the standard, B18.6.5M. Tapping screws may also be made from corrosion resistant steel, Monel, brass, and aluminum alloys. The materials, properties, and performance characteristics applicable to such screws should be mutually agreed upon between the manufacturer and the purchaser.

| 9.5 × 2.1                           | 10.00                                      | 10.50                                     | 11.50                        | 10 × 1.5                            | 10.50                                      | 11.00                                     | 12.00                        |

<sup>a</sup> The values given in this table are minimum limits. The recommended plus tolerances are as follows: for clearance hole diameters over 1.70 to and including 5.80 mm, plus 0.12, 0.20, and 0.30 mm for close, normal, and loose clearances, respectively; over 5.80 to and including 14.50 mm, plus 0.18, 0.30, and 0.45 mm for close, normal, and loose clearances, respectively.

<sup>b</sup> Normal clearance hole sizes are preferred. Close clearance hole sizes are for situations such as critical alignment of assembled components, wall thickness, or other limitations that necessitate the use of a minimal hole. Countersinking or counterboring at the fastener entry side may be necessary for the proper seating of the head. Loose clearance hole sizes are for applications where maximum adjustment capability between the components being assembled is necessary.

All dimensions are in millimeters.

**Approximate Installation Hole Sizes for Metric Tapping Screws.**—The approximate hole sizes given in Tables 7 through 9 provide general guidance in selecting holes for installing the respective types of metric thread forming and thread cutting tapping screws in various commonly used materials. Types AB, B, BF, and BT metric tapping screws are covered in these tables; hole sizes for Types D, F, and T metric thread cutting tapping screws are still under development.

**Table 6. Approximate Pierced or Extruded Hole Sizes for Steel Types AB and B Metric Thread Forming Tapping Screws**

| Nominal Screw Size and Thread Pitch                     | Metal Thickness | Hole Size | Nominal Screw Size and Thread Pitch | Metal Thickness | Hole Size | Nominal Screw Size and Thread Pitch | Metal Thickness | Hole Size |
|---|-----------------|-----------|-------------------------------------|-----------------|-----------|-------------------------------------|-----------------|-----------|
| In Steel, Stainless Steel, Monel, and Brass Sheet Metal |                 |           |                                     |                 |           |                                     |                 |           |
| 2.9 × 1   | 0.38            | 2.18      | 4.2 × 1.4                           | 0.46            | 3.45      | 5.5 × 1.8                           | 0.61            | 4.70      |

<sup>a</sup> Customary drill size references have been retained where the metric hole diameters are direct conversions of their decimal inch equivalents.

All dimensions are in millimeters except drill sizes.

**Table 8. Approximate Hole Sizes for Steel Type AB Metric Thread Forming Tapping Screws in Plywoods and Asbestos**

| Nominal Screw Size and Thread Pitch | Hole Size | Drill Size <sup>a</sup> | Min Mat'l Thickness | Penetration in Blind Holes |       | Hole Size                | Drill Size <sup>a</sup> | Min Mat'l Thickness | Penetration in Blind Holes |       |  |
|-------------------------------------|-----------|-------------------------|---------------------|----------------------------|-------|--------------------------|-------------------------|---------------------|----------------------------|-------|--|

<sup>a</sup> Customary drill size references have been retained where the metric hole sizes are direct conversions of their decimal inch equivalents.

All dimensions are in millimeters except drill sizes.

The finish (plating or coating) on metric tapping screws and the material composition and hardness of the mating component are factors that affect assembly torques in individual applications. Although the recommended installation hole sizes given in Tables 7 through 9 were based on the use of plain unfinished carbon steel metric tapping screws, experience has shown that the specified holes are also suitable for screws having most types of commercial finishes. However, owing to various finishes providing different degrees of lubricity, some adjustment of installation torques may be necessary to suit individual applications. Also, where exceptionally heavy finishes are involved or screws are to be assembled into materials of higher hardness, some deviation from the specified hole sizes may be required to provide optimum assembly. The necessity and extent of such deviations can best be determined by experiment in the particular assembly environment.

<sup>a</sup> Width of tongue (tenon) to be used with the above T-Slots will be found in the complete standard, B5.1M.

<sup>b</sup> Throat dimensions are basic. When slots are intended to be used for holding only, tolerances can be  $0.0 + 0.010$  inch or H12 Metric (ISO/R286); when intended for location, tolerance can be  $0.0 + 0.001$  inch or H8 Metric (see page 670).

<sup>c</sup> Corners of T-Slots may be square or may be rounded or broken to the indicated maximum dimensions at the manufacturer's option.

For the dimensions of tongue seats, inserted tongues, and solid tongues refer to the complete standard, B5.1M.

<sup>a</sup>T-slot dimensions to fit the above nuts will be found in Table 1.

<sup>b</sup>For tolerances of inch threads see page 1736.

<sup>c</sup>No tolerances are given for "Total Thickness" or "Nut Length" as they need not be held to close limits.

<sup>d</sup>Metric tapped thread grade and tolerance position is 5H (see page 1790).

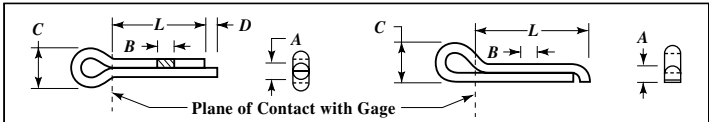

## PINS AND STUDS

**Dowel-Pins.**—Dowel-pins are used either to retain parts in a fixed position or to preserve alignment. Under normal conditions a properly fitted dowel-pin is subjected solely to shearing strain, and this strain occurs only at the junction of the surfaces of the two parts which are being held by the dowel-pin. It is seldom necessary to use more than two dowel-pins for holding two pieces together and frequently one is sufficient. For parts that have to be taken apart frequently, and where driving out of the dowel-pins would tend to wear the holes, and also for very accurately constructed tools and gages that have to be taken apart, or that require to be kept in absolute alignment, the taper dowel-pin is preferable. The taper dowel-pin is most commonly used for average machine work, but the straight type is given the preference on tool and gage work, except where extreme accuracy is required, or where the tool or gage is to be subjected to rough handling.

The size of the dowel-pin is governed by its application. For locating nests, gage plates, etc., pins from  $\frac{1}{8}$  to  $\frac{3}{16}$  inch in diameter are satisfactory. For locating dies, the diameter of the dowel-pin should never be less than  $\frac{1}{4}$  inch; the general rule is to use dowel-pins of the same size as the screws used in fastening the work. The length of the dowel-pin should be about one and one-half to two times its diameter in each plate or part to be doweled.

When hardened cylindrical dowel-pins are inserted in soft parts, ream the hole about 0.001 inch smaller than the dowel-pin. If the doweled parts are hardened, grind (or lap) the hole 0.0002 to 0.0003 inch under size. The hole should be ground or lapped straight, that is, without taper or "bell-mouth."

## American National Standard Cotter Pins ANSI B18.8.1-1972 (R1994)

The technical drawings show two types of cotter pins: a standard cotter pin on the left and a clevis pin on the right. Both drawings include side and end views. Dimensions are labeled as follows: C is the head diameter, L is the prong length, B is the wire width, D is the hole diameter, and A is the hole diameter for the clevis pin. A dashed line indicates the 'Plane of Contact with Gage'.

<sup>a</sup> Tolerance is  $-0.05$  inch.<sup>b</sup> Tolerance is  $-0.02$  inch.<sup>c</sup> Tolerance is  $\pm 0.01$  inch.<sup>d</sup> Tolerance is  $-0.015$  inch.<sup>e</sup> Tolerance is  $-0.01$  inch.<sup>f</sup> Lengths tabulated are intended for use with standard clevises, without spacers. When other lengths are required, it is recommended that they be limited wherever possible to nominal lengths in 0.06-inch increments.<sup>g</sup> Tolerance is  $-0.020$  inch.

All dimensions are in inches.

**British Standard for Metric Series Dowel Pins.**—Steel parallel dowel pins specified in British Standard 1804:Part 2:1968 are divided into three grades which provide different degrees of pin accuracy.

*Grade 1* is a precision ground pin made from En 32A or En 32B low carbon steel (BS 970) or from high carbon steel to BS 1407 or BS 1423. Pins below 4 mm diameter are unhardened. Those of 4 mm diameter and above are hardened to a minimum of 750 HV 30 in accordance with BS 427, but if they are made from steels to BS 1407 or BS 1423 then the hardness shall be within the range 600 to 700 HV 30, in accordance with BS 427. The values of other hardness scales may be used in accordance with BS 860.

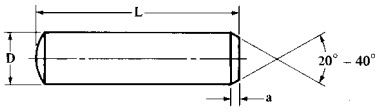

*Grade 2* is a ground pin made from any of the steels used for Grade 1. The pins are normally supplied unhardened, unless a different condition is agreed on between the purchaser and supplier.

*Grade 3* pins are made from En 1A free cutting steel (BS 970) and are supplied with a machined, bright rolled or drawn finish. They are normally supplied unhardened unless a different condition is agreed on between the purchaser and supplier.

Pins of any grade may be made from different steels in accordance with BS 970, by mutual agreement between the purchaser and manufacturer. If steels other than those in the

standard range are used, the hardness of the pins shall also be decided on by mutual agreement between purchaser and supplier. As shown in the illustration at the head of the accompanying table, one end of each pin is chamfered to provide a lead. The other end may be similarly chamfered, or domed.

<sup>a</sup> The limits of tolerance for grades 1 and 2 dowel pins have been chosen to provide satisfactory assembly when used in standard reamed holes (H7 and H8 tolerance zones). If the assembly is not satisfactory, refer to B.S. 1916: Part 1, Limits and Fits for Engineering, and select a different class of fit.

<sup>b</sup> This tolerance is larger than that given in BS 1916, and has been included because the use of a closer tolerance would involve precision grinding by the manufacturer, which is uneconomic for a grade 2 dowel pin.

The tolerance limits on the overall length of all grades of dowel pin up to and including 50 mm long are +0.5, -0.0 mm, and for pins over 50 mm long are +0.8, -0.0 mm. The Standard specifies that the roughness of the cylindrical surface of grades 1 and 2 dowel pins, when assessed in accordance with BS 1134, shall not be greater than 0.4 μm CLA (16 CLA).

<sup>a</sup> Where specifying nominal size as basic diameter, zeros preceding decimal and in the fourth decimal place are omitted.

<sup>b</sup> Lengths increase in  $\frac{1}{16}$ -inch steps up to  $\frac{3}{8}$  inch, in  $\frac{1}{8}$ -inch steps from  $\frac{3}{8}$  inch to 1 inch, in  $\frac{1}{4}$ -inch steps from 1 inch to 2 $\frac{1}{2}$  inches, and in  $\frac{1}{2}$ -inch steps above 2 $\frac{1}{2}$  inches. Tolerance on length is  $\pm 0.010$  inch.

<sup>c</sup> These hole sizes have been commonly used for press fitting Standard Series machine dowel pins into materials such as mild steels and cast iron. In soft materials such as aluminum or zinc die castings, hole size limits are usually decreased by 0.0005 inch to increase the press fit.

<sup>d</sup> Nonpreferred sizes, not recommended for use in new designs.

All dimensions are in inches.

If a dowel pin is driven into a blind hole where no provision is made for releasing air, the worker assembling the pin may be endangered, and damage may be caused to the associated component, or stresses may be set up. The appendix of the Standard describes one method of overcoming this problem by providing a small flat surface along the length of a pin to permit the release of air.

For purposes of marking, the Standard states that each package or lot of dowel pins shall bear the manufacturer's name or trademark, the BS number, and the grade of pin.

**American National Standard Hardened Ground Machine Dowel Pins.**—Hardened ground machine dowel pins are furnished in two diameter series: Standard Series having basic diameters 0.0002 inch over the nominal diameter, intended for initial installations; and Oversize Series having basic diameters 0.001 inch over the nominal diameter, intended for replacement use.

*Preferred Lengths and Sizes:* The preferred lengths and sizes in which these pins are normally available are given in [Table 1](#). Other sizes and lengths are produced as required by the purchaser.

*Effective Length:* The effective length,  $L_e$ , must not be less than 75 per cent of the overall length of the pin.

*Shear Strength:* Single shear strength values are listed in [Table 1](#). Prior versions of ANSI/ASME B18.8.2-1995 had listed double shear load minimum values and had specified a minimum single shear strength of 130,000 psi. See ANSI/ASME B18.8.2-1995, Appendix B for a description of the double shear test.

*Designation:* These pins are designated by the following data in the sequence shown: Product name (noun first), including pin series, nominal pin diameter (fraction or decimal equivalent), length (fraction or decimal equivalent), material, and protective finish, if required.

*Examples:* Pins, Hardened Ground Machine Dowel — Standard Series,  $\frac{3}{8} \times 1\frac{1}{2}$ , Steel, Phosphate Coated.

Pins, Hardened Ground Machine Dowel — Oversize Series,  $0.625 \times 2.500$ , Steel

*Installation Precaution:* Pins should not be installed by striking or hammering and when installing with a press, a shield should be used and safety glasses worn.

**American National Standard Hardened Ground Production Dowel Pins.**—Hardened ground production dowel pins have basic diameters that are 0.0002 inch over the nominal pin diameter.

*Preferred Lengths and Sizes:* The preferred lengths and sizes in which these pins are available are given in [Table 2](#). Other sizes and lengths are produced as required by the purchaser.

*Shear Strength:* Single shear strength values are listed in [Table 2](#). Prior versions of ANSI/ASME B18.8.2-1995 had listed double shear load minimum values and had specified a minimum single shear strength of 102,000 psi. See ANSI/ASME B18.8.2-1995, Appendix B for a description of the double shear test.

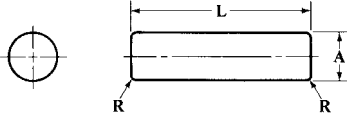

*Ductility:* These standard pins are sufficiently ductile to withstand being pressed into holes 0.0005 inch smaller than the nominal pin diameter in hardened steel without cracking or shattering.

*Designation:* These pins are designated by the following data in the sequence shown: Product name (noun first), nominal pin diameter (fraction or decimal equivalent), length (fraction or decimal equivalent), material, and protective finish, if required.

*Examples:* Pins, Hardened Ground Production Dowel,  $\frac{1}{8} \times \frac{3}{4}$ , Steel, Phosphate Coated

Pins, Hardened Ground Production Dowel,  $0.375 \times 1.500$ , Steel

<sup>a</sup> Where specifying nominal pin size in decimals, zeros preceding decimal and in the fourth decimal place are omitted.

<sup>b</sup> Lengths increase in 1/16-inch steps up to 1 inch, in 1/8-inch steps from 1 inch to 2 inches and then are 2/4, 2 1/2, and 3 inches.

<sup>c</sup> These hole sizes have been commonly used for press fitting production dowel pins into materials such as mild steels and cast iron. In soft materials such as aluminum or zinc die castings, hole size limits are usually decreased by 0.0005 inch to increase the press fit.

All dimensions are in inches.

**American National Standard Unhardened Ground Dowel Pins.**—Unhardened ground dowel pins are normally produced by grinding the outside diameter of commercial wire or rod material to size. Consequently, the maximum diameters of the pins, as specified in Table 3, are below the minimum commercial stock sizes by graduated amounts from 0.0005 inch on the 1/16-inch nominal pin size to 0.0028 inch on the 1-inch nominal pin size.

*Preferred Lengths and Sizes:* The preferred lengths and sizes in which unhardened ground pins are normally available are given in Table 3. Other sizes and lengths are produced as required by the purchaser.

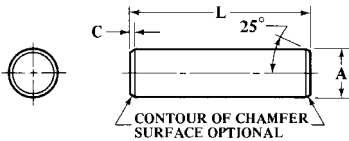

*Shear Strength:* These pins must have a single shear strength of 64,000 psi minimum for pins made from steel and 40,000 psi minimum for pins made from brass and must be capable of withstanding the minimum double shear loads given in Table 3 when tested in accordance with the procedure outlined in ANSI/ASME B18.8.2-1995, Appendix B.

*Designation:* These pins are designated by the following data in the order shown: Product name (noun first), nominal pin diameter (fraction or decimal equivalent), length (fraction or decimal equivalent), material, and protective finish, if required.

*Examples:* Pins, Unhardened Ground Dowel, 1/8 x 3/4, Steel

Pins, Unhardened Ground Dowel, 0.250 x 2.500, Steel, Zinc Plated

| 7/8   | 0.8750             | 0.8705 | 0.8700               | 0.070 | 0.050   | 7/8, 1, 1 1/4, 1 1/2, 1 3/4, 2, 2 1/2-4      | 0.8692 | 0.8677                        | 76,090 | 47,550 |
| 1   | 1.0000             | 0.9952 | 0.9947               | 0.070 | 0.050   | 1, 1 1/4, 1 1/2, 1 3/4, 2, 2 1/2-4           | 0.9938 | 0.9923                        | 99,460 | 62,160 |

<sup>a</sup> Where specifying pin size in decimals, zeros preceding decimal and in the fourth decimal place are omitted.

<sup>b</sup> Lengths increase in 1/16-inch increments from 1/4 to 1 inch, in 1/8-inch increments from 1 inch to 2 inches, and in 1/4-inch increments from 2 to 2 1/2 inches, and in 1/2-inch increments from 2 1/2 to 4 inches.

<sup>c</sup> These hole sizes have been found to be satisfactory for press fitting pins into mild steel and cast and malleable irons. In soft materials such as aluminum alloys or zinc die castings, hole size limits are usually decreased by 0.0005 inch to increase the press fit.

<sup>d</sup> Nonpreferred size, not recommended for use in new designs.

All dimensions are in inches.

**American National Standard Straight Pins.**—The diameter of both chamfered and square end straight pins is that of the commercial wire or rod from which the pins are made. The tolerances shown in Table 4 are applicable to carbon steel and some deviations in the diameter limits may be necessary for pins made from other materials.

**Table 4. American National Standard Chamfered and Square End Straight Pins**  
ANSI/ASME B18.8.2-1995

| CHAMFERED STRAIGHT PIN                          |                 |        |                   |       | SQUARE END STRAIGHT PIN                         |                 |       |                   |        |       |       |

<sup>a</sup> Where specifying nominal size in decimals, zeros preceding decimal point are omitted.

<sup>b</sup> Where specifying nominal size in decimals, zeros preceding decimal point are omitted.

All dimensions are in inches.

**Length Increments:** Lengths are as specified by the purchaser; however, it is recommended that nominal pin lengths be limited to increments of not less than 0.062 inch.

**Material:** Straight pins are normally made from cold drawn steel wire or rod having a maximum carbon content of 0.28 per cent. Where required, pins may also be made from corrosion resistant steel, brass, or other metals.

**Designation:** Straight pins are designated by the following data, in the sequence shown: Product name (noun first), nominal size (fraction or decimal equivalent), material, and protective finish, if required.

**Examples:** Pin, Chamfered Straight,  $\frac{1}{8} \times 1.500$ , Steel

Pin, Square End Straight,  $0.250 \times 2.250$ , Steel, Zinc Plated

**American National Standard Taper Pins.**—Taper pins have a uniform taper over the pin length with both ends crowned. Most sizes are supplied in commercial and precision classes, the latter having generally tighter tolerances and being more closely controlled in manufacture.

**Diameters:** The major diameter of both commercial and precision classes of pins is the diameter of the large end and is the basis for pin size. The diameter at the small end is computed by multiplying the nominal length of the pin by the factor 0.02083 and subtracting the result from the basic pin diameter. See also [Table 5](#).

**Taper:** The taper on commercial class pins is  $0.250 \pm 0.006$  inch per foot and on the precision class pins is  $0.250 \pm 0.004$  inch per foot of length.

**Materials:** Unless otherwise specified, taper pins are made from SAE 1211 steel or cold drawn SAE 1212 or 1213 steel or equivalents, and no mechanical property requirements apply.

**Hole Sizes:** Under most circumstances, holes for taper pins require taper reaming. Sizes and lengths of taper pins for which standard reamers are available are given in [Table 6](#). Drilling specifications for taper pins are given below.

*Designation:* Taper pins are designated by the following data in the sequence shown: Product name (noun first), class, size number (or decimal equivalent), length (fraction or three-place decimal equivalent), material, and protective finish, if required.

*Examples:* Pin, Taper (Commercial Class) No. 0  $\times \frac{3}{4}$ , Steel

Pin, Taper (Precision Class) 0.219  $\times$  1.750, Steel, Zinc Plated

**Table 5. Nominal Diameter at Small Ends of Standard Taper Pins**

| Pin Length in inches | Pin Number and Small End Diameter for Given Length |       |       |       |       |       |       |       |       |       |       |

**Drilling Specifications for Taper Pins.**—When helically fluted taper pin reamers are used, the diameter of the through hole drilled prior to reaming is equal to the diameter at the small end of the taper pin. (See Table 5.) However, when straight fluted taper reamers are to be used, it may be necessary, for long pins, to step drill the hole before reaming, the number and sizes of the drills to be used depending on the depth of the hole (pin length).

To determine the number and sizes of step drills required: Find the length of pin to be used at the top of the chart on page 1676 and follow this length down to the intersection with that heavy line which represents the size of taper pin (see taper pin numbers at the right-hand end of each heavy line). If the length of pin falls between the first and second dots, counting from the left, only one drill is required. Its size is indicated by following the nearest horizontal line from the point of intersection (of the pin length) on the heavy line over to the drill diameter values at the left. If the intersection of pin length comes between the second and third dots, then two drills are required. The size of the smaller drill then corresponds to the intersection of the pin length and the heavy line and the larger is the corresponding drill diameter for the intersection of one-half this length with the heavy line. Should the pin length fall between the third and fourth dots, three drills are required. The smallest drill will have a diameter corresponding to the intersection of the total pin length with the heavy line, the next in size will have a diameter corresponding to the intersection of two-thirds of this length with the heavy line and the largest will have a diameter corresponding to the intersection of one-third of this length with the heavy line. Where the intersection falls between two drill sizes, use the smaller.

TAPER-PIN REAMER DRILLS

Chart to Facilitate Selection of Number and Sizes of Drills for Step-Drilling Prior to Taper Reaming

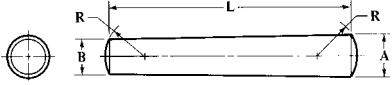

Examples: For a No. 10 taper pin 6-inches long, three drills would be used, of the sizes and for the depths shown in the accompanying diagram.

For a No. 10 taper pin 3-inches long, two drills would be used because the 3-inch length falls between the second and third dots. The first or through drill will be 0.6406 inch and the second drill, 0.6719 inch for a depth of 1½ inches.

<sup>a</sup> When specifying nominal pin size in decimals, zeros preceding the decimal and in the fourth decimal place are omitted.

<sup>b</sup> Lengths increase in ⅛-inch steps up to 1 inch and in ¼-inch steps above 1 inch.

<sup>c</sup> Standard reamers are available for pin lengths in this column.

All dimensions are in inches.

For nominal diameters, B, see Table 5.

**American National Standard Grooved Pins.**—These pins have three equally spaced longitudinal grooves and an expanded diameter over the crests of the ridges formed by the material displaced when the grooves are produced. The grooves are aligned with the axes of the pins. There are seven types of grooved pins as shown in the illustration on page 1679.

*Standard Sizes and Lengths:* The standard sizes and lengths in which grooved pins are normally available are given in Table 7.

*Materials:* Grooved pins are normally made from cold drawn low carbon steel wire or rod. Where additional performance is required, carbon steel pins may be supplied surface hardened and heat treated to a hardness consistent with the performance requirements. Pins may also be made from alloy steel, corrosion resistant steel, brass, Monel and other non-ferrous metals having chemical properties as agreed upon between manufacturer and purchaser.

*Performance Requirements:* Grooved pins are required to withstand the minimum double shear loads given in [Table 7](#) for the respective materials shown, when tested in accordance with the Double Shear Testing of Pins as set forth in ANSI/ASME B18.8.2-1995, Appendix B.

*Hole Sizes:* To obtain maximum product retention under average conditions, it is recommended that holes for the installation of grooved pins be held as close as possible to the limits shown in [Table 7](#). The minimum limits correspond to the drill size, which is the same as the basic pin diameter. The maximum limits are generally suitable for length-diameter ratios of not less than 4 to 1 nor greater than 10 to 1. For smaller length-to-diameter ratios, the hole should be held closer to the minimum limits where retention is critical. Conversely for larger ratios where retention requirements are less important, it may be desirable to increase the hole diameters beyond the maximum limits shown.

*Designation:* Grooved pins are designated by the following data in the sequence shown: Product name (noun first) including type designation, nominal size (number, fraction or decimal equivalent), length (fraction or decimal equivalent), material, including specification or heat treatment where necessary, protective finish, if required.

*Examples:* Pin, Type A Grooved,  $\frac{3}{32} \times \frac{3}{4}$ , Steel, Zinc Plated

Pin, Type F Grooved, 0.250  $\times$  1.500, Corrosion Resistant Steel

**American National Standard Grooved T-Head Cotter Pins and Round Head Grooved Drive Studs.**—The cotter pins have a T-head and the studs a round head. Both pins and studs have three equally spaced longitudinal grooves and an expanded diameter over the crests of the raised ridges formed by the material displaced when the grooves are formed.

*Standard Sizes and Lengths:* The standard sizes and range of standard lengths are given in [Tables 8](#) and [9](#).

*Material:* Unless otherwise specified these pins are made from low carbon steel. Where so indicated by the purchaser they may be made from corrosion resistant steel, brass or other non-ferrous alloys.

*Hole Sizes:* To obtain optimum product retention under average conditions, it is recommended that holes for the installation of grooved T-head cotter pins and grooved drive studs be held as close as possible to the limits tabulated. The minimum limits given correspond to the drill size, which is equivalent to the basic shank diameter. The maximum limits shown are generally suitable for length-diameter ratios of not less than 4 to 1 and not greater than 10 to 1. For smaller length-to-diameter ratios, the holes should be held closer to minimum limits where retention is critical. Conversely, for larger length-to-diameter ratios or where retention requirements are not essential, it may be desirable to increase the hole diameter beyond the maximum limits shown.

*Designation:* Grooved T-head cotter pins and round head grooved drive studs are designated by the following data, in the order shown: Product name (noun first), nominal size (number, fraction or decimal equivalent), length (fraction or decimal equivalent), material including specification or heat treatment where necessary, and protective finish, if required.

*Examples:* Pin, Grooved T-Head Cotter,  $\frac{1}{4} \times 1\frac{1}{4}$ , Steel, Zinc Plated

Drive Stud, Round Head Grooved, No. 10  $\times$   $\frac{1}{2}$ , Corrosion Resistant Steel

Types of American National Standard Grooved Pins, ANSI/ASME B18.8.2-1995 (For notes see bottom of Table 7.)

<sup>a</sup> For expanded diameters, B, see ANSI/ASME B18.8.2-1995.

<sup>b</sup> Pins in 1/32- and 3/64-inch sizes of any length and all sizes of 1/4-inch nominal length or shorter are not crowned or chamfered.

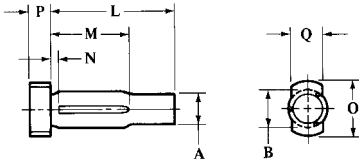

<sup>c</sup> Standard lengths increase in 1/8-inch steps from 1/8 to 1 inch, and in 1/4-inch steps above 1 inch. Standard lengths for the 1/32-, 3/64-, 1/16-, and 5/64-inch sizes and the 1/4-inch length for the 3/32-, 7/64-, and 1/8-inch sizes do not apply to Type G grooved pins.

<sup>d</sup> Non-stock items, not recommended for new designs.

<sup>a</sup> When specifying nominal size in decimals, zeros preceding decimal point and in the fourth decimal place are omitted.

<sup>b</sup> Lengths increase in  $\frac{1}{8}$ -inch steps from  $\frac{3}{4}$  to 1 $\frac{1}{4}$  inch and in  $\frac{1}{4}$ -inch steps above 1 $\frac{1}{4}$  inches. For groove length, *M*, dimensions see ANSI/ASME B18.8.2-1995.

All dimensions are in inches.

For expanded diameter, *B*, dimensions, see ANSI/ASME B18.8.2-1995.

<sup>a</sup> Where specifying nominal size in decimals, zeros preceding decimal point and in the fourth decimal place are omitted.

<sup>b</sup> Lengths increase in  $\frac{1}{16}$ -inch steps from  $\frac{1}{8}$  to  $\frac{3}{8}$  inch and in  $\frac{1}{8}$ -inch steps above  $\frac{3}{8}$  inch.

All dimensions are in inches.

For pilot length, *M*, and expanded diameter, *B*, dimensions see ANSI/ASME B18.8.2-1995.

<sup>a</sup> Where specifying nominal size in decimals, zeros preceding decimal point are omitted.

<sup>b</sup> Length increments are  $\frac{1}{16}$  inch from  $\frac{1}{8}$  to 1 inch;  $\frac{1}{8}$  from 1 inch to 2 inches; and  $\frac{1}{4}$  inch from 2 inches to 6 inches.

All dimensions are in inches.

**American National Standard Spring Pins.**—These pins are made in two types: one type has a slot throughout its length; the other is shaped into a coil.

**Preferred Lengths and Sizes:** The preferred lengths and sizes in which these pins are normally available are given in Tables 10 and 11.

**Materials:** Spring pins are normally made from SAE 1070-1095 carbon steel, SAE 6150H alloy steel, SAE types 51410 through 51420, 30302 and 30304 corrosion resistant steels, and beryllium copper alloy, heat treated or cold worked to attain the hardness and performance characteristics set forth in ANSI/ASME B18.8.2-1995.

**Designation:** Spring pins are designated by the following data in the sequence shown:

**Examples:** Pin, Coiled Spring,  $\frac{1}{4} \times 1\frac{1}{4}$ , Standard Duty, Steel, Zinc Plated

Pin, Slotted Spring,  $\frac{1}{2} \times 3$ , Steel, Phosphate Coated

<sup>a</sup> Sizes  $\frac{1}{32}$  inch through 0.052 inch are not available in SAE 1070-1095 carbon steel.

<sup>b</sup> Sizes  $\frac{3}{8}$  inch and larger are produced from SAE 6150H alloy steel, not SAE 1070-1095 carbon steel. Practical lengths, L, for sizes  $\frac{1}{32}$  through 0.052 inch are  $\frac{1}{8}$  through  $\frac{3}{8}$  inch and for the  $\frac{1}{16}$  inch size,  $\frac{1}{4}$  through  $1\frac{1}{4}$  inches. For lengths of other sizes see Table 10.

All dimensions are in inches.

## RETAINING RINGS

**Retaining Rings.**—The purpose of a retaining ring is to act as an artificial shoulder that will retain an object in a housing (internal ring), as shown in Fig. 1, or on a shaft (external ring). Two types of retaining ring are common, the stamped ring and the spiral-wound ring. The stamped type of retaining ring, or snap ring, is stamped from tempered sheet metal and has a nonuniform cross-section. The typical spiral-wound retaining ring has a uniform cross-section and is made up of two or more turns of coiled, spring-tempered steel, although one-turn spiral-wound rings are common. Spiral-wound retaining rings provide a continuous gapless shoulder to a housing or shaft. Most stamped rings can only be installed at or near the end of a shaft or housing. The spiral-wound design generally requires installation from the end of a shaft or housing. Both types, stamped and spiral, are usually installed into grooves on the shaft or housing.

Fig. 1. Typical Retaining Ring Installation Showing Maximum Total Radius or Chamfer (Courtesy Spirolox Retaining Rings)

In the section that follows, Tables 1 through 6 give dimensions and data on general-purpose tapered and reduced cross-section metric retaining rings (stamped type) covered by ANSI B27.7-1977, R1993. Tables 1 and 4 cover Type 3AM1 tapered external retaining rings, Tables 2 and 5 cover Type 3BM1 tapered internal rings, and Tables 3 and 6 cover Type 3CM1 reduced cross-section external rings. Tables 7 through 10 cover inch sizes of internal and external spiral retaining rings corresponding to MIL-R-27426 Types A (external) and B (internal), Class 1 (medium duty) and Class 2 (heavy duty). Tables 11 through 17 cover stamped retaining rings in inch sizes.

All dimensions are in millimeters. Sizes -4, -5, and -6 are available in beryllium copper only.

These rings are designated by series symbol and shaft diameter, thus: for a 4 mm diameter shaft, 3AM1-4; for a 20 mm diameter shaft, 3AM1-20; etc.

**Ring Free Diameter Tolerances:** For ring sizes -4 through -6, +0.05, -0.10 mm; for sizes -7 through -12, +0.05, -0.15 mm; for sizes -13 through -26, +0.15, -0.25 mm; for sizes -27 through -38, +0.25, -0.40 mm; for sizes -40 through -50, +0.35, -0.50 mm; for sizes -52 through -62, +0.35, -0.65 mm; and for sizes -65 through -100, +0.50, -0.75 mm.

**Groove Diameter Tolerances:** For ring sizes -4 through -6, -0.08 mm; for sizes -7 through -10, -0.10 mm; for sizes -11 through -15, -0.12 mm; for sizes -16 through -26, -0.15 mm; for sizes -27 through -36, -0.20 mm; for sizes -38 through -55, -0.30 mm; and for sizes -57 through -100, -0.40 mm.

**Groove Diameter F.I.M. (full indicator movement)** or maximum allowable deviation of concentricity between groove and shaft: For ring sizes -4 through -6, 0.03 mm; for ring sizes -7 through -12, 0.05 mm; for sizes -13 through -28, 0.10 mm; for sizes -30 through -55, 0.15 mm; and for sizes -57 through -100, 0.20 mm.

**Groove Width Tolerances:** For ring size -4, +0.05 mm; for sizes -5 and -6, +0.10 mm, for sizes -7 through -38, +0.15 mm; and for sizes -40 through -100, +0.20 mm.

**Groove Maximum Bottom Radii, R:** For ring sizes -4 through -6, none; for sizes -7 through -18, 0.1 mm; for sizes -19 through -30, 0.2 mm; for sizes -32 through -50, 0.3 mm; and for sizes -52 through -100, 0.4 mm. For manufacturing details not shown, including materials, see ANSI B27.7-1977, R1993.

**Table 2. American National Standard Metric Tapered Retaining Rings — Basic Internal Series — 3BM1 ANSI B27.7-1977, R1993**

| Shaft Dia. | Ring      |           |       | Groove |       |             |           | Shaft Dia. | Ring      |       |       | Groove |             |  |  |
|------------|-----------|-----------|-------|--------|-------|-------------|-----------|------------|-----------|-------|-------|--------|-------------|--|--|
|            | Free Dia. | Thickness | Dia.  | Width  | Depth | Edge Margin | Free Dia. |            | Thickness | Dia.  | Width | Depth  | Edge Margin |  |  |
| S          | D         | t         | G     | W      | d ref | Z min       | S         | D          | t         | G     | W     | d ref  | Z min       |  |  |

All dimensions are in millimeters.

These rings are designated by series symbol and shaft diameter, thus: for a 9 mm diameter shaft, 3BM1-9; for a 22 mm diameter shaft, 3BM1-22; etc.

**Ring Free Diameter Tolerances:** For ring sizes -8 through -20, +0.25, -0.13 mm; for sizes -21 through -26, +0.40, -0.25 mm; for sizes -27 through -38, +0.65, -0.50 mm; for sizes -40 through -50, +0.90, -0.65 mm; for sizes -52 through -75, +1.00, -0.75 mm; for sizes -78 through -92, +1.40,

-1.40 mm; for sizes -95 through -155, +1.65, -1.65 mm; for sizes -160 through -180, +2.05, -2.05 mm; and for sizes -185 through -250, +2.30, -2.30 mm.

**Groove Diameter Tolerances:** For ring sizes -8 and -9, +0.06 mm; for sizes -10 through -18, +0.10 mm; for sizes -19 through -28, +0.15 mm; for sizes -30 through -50, +0.20 mm; for sizes -52 through -98, +0.30; for sizes -100 through -160, +0.40 mm; and for sizes -165 through -250, +0.50 mm.

**Groove Diameter F.I.M. (full indicator movement)** or maximum allowable deviation of concentricity between groove and shaft: For ring sizes -8 through -10, 0.03 mm; for sizes -11 through -15, 0.05 mm; for sizes -16 through -25, 0.10 mm; for sizes -26 through -45, 0.15 mm; for sizes -46 through -80, 0.20 mm; for sizes -82 through -150, 0.25 mm; and for sizes -155 through -250, 0.30 mm.

**Groove Width Tolerances:** For ring size -8, +0.10 mm; for sizes -9 through -38, +0.15 mm; for sizes -40 through -130, +0.20 mm; and for sizes -135 through -250, +0.25 mm.

**Groove Maximum Bottom Radii:** For ring sizes -8 through -17, 0.1 mm; for sizes -18 through -30, 0.2 mm; for sizes -32 through -55, 0.3 mm; and for sizes -56 through -250, 0.4 mm.

For manufacturing details not shown, including materials, see ANSI B27.7-1977, R1993.

All dimensions are in millimeters. Size -1 is available in beryllium copper only.

These rings are designated by series symbol and shaft diameter, thus: for a 2 mm diameter shaft, 3CM1-2; for a 13 mm shaft, 3CM1-13; etc.

**Ring Free Diameter Tolerances:** For ring sizes -1 through -7, +0.03, -0.08 mm; for sizes -8 through -13, +0.05, -0.10 mm; and for sizes -15 through -25, +0.10, -0.15 mm.

**Groove Diameter Tolerances:** For ring sizes -1 and -2, -0.05 mm; for sizes -3 through -6, -0.08; for sizes -7 through -11, -0.10 mm; for sizes -12 through -18, -0.15 mm; and for sizes -20 through -25, -0.20 mm.

**Groove Diameter F.I.M. (Full Indicator Movement)** or maximum allowable deviation of concentricity between groove and shaft: For ring sizes -1 through -3, 0.04 mm; for -4 through -6, 0.05 mm; for -7 through -10, 0.08 mm; for -11 through -25, 0.10 mm.

**Groove Width Tolerances:** For ring sizes -1 and -2, +0.05 mm; for size -3, +0.10 mm; and for sizes -4 through -25, +0.15 mm.

**Groove Maximum Bottom Radii:** For ring sizes -1 and -2, 0.05 mm; for -3 through -7, 0.15 mm; for -8 through -13, 0.25 mm; and for -15 through -25, 0.4 mm.

For manufacturing details not shown, including materials, see ANSI B27.7-1977, R1993.

**Table 4. American National Standard Metric Basic External Series 3AM1 Retaining Rings, Checking and Performance Data ANSI B27.7-1977, R1993**

| Ring Series and Size No. | Clearance Dia.  |                | Gaging Diameter <sup>a</sup> | Allowable Thrust Loads Sharp Corner Abutment |         | Maximum Allowable Corner Radii and Chamfers |          | Allowable Assembly Speed <sup>b</sup> |

<sup>a</sup> For checking when ring is seated in groove.

<sup>b</sup> These values have been calculated for steel rings.

<sup>c</sup> These values apply to rings made from SAE 1060–1090 steels and PH 15-7 Mo stainless steel used on shafts hardened to  $R_c$  50 minimum, with the exception of sizes -4, -5, and -6 which are supplied in beryllium copper only. Values for other sizes made from beryllium copper can be calculated by multiplying the listed values by 0.75. The values listed include a safety factor of 4.

<sup>d</sup> These values are for all standard rings used on low carbon steel shafts. They include a safety factor of 2.

Maximum allowable assembly loads with  $R$  max or  $Ch$  max are: For rings sizes -4, 0.2 kN; for sizes -5 and -6, 0.5 kN; for sizes -7 through -12, 2.1 kN; for sizes -13 through -17, 4.0 kN; for sizes -18 through -26, 6.0 kN; for sizes -27 through -38, 8.6 kN; for sizes -40 through -50, 13.2 kN; for sizes -52 through -68, 22.0 kN; for sizes -70 through -85, 32 kN; and for sizes -88 through -100, 47 kN.

<sup>a</sup> For checking when ring is seated in groove.

<sup>b</sup> These values apply to rings made from SAE 1060-1090 steels and PH 15-7 Mo stainless steel used in bores hardened to  $R_c$  50 minimum. Values for rings made from beryllium copper can be calculated by multiplying the listed values by 0.75. The values listed include a safety factor of 4.

<sup>c</sup> These values are for standard rings used in low carbon steel bores. They include a safety factor of 2. Maximum allowable assembly loads for  $R$  max or  $Ch$  max are: For ring size -8, 0.8 kN; for sizes -9 through -12, 2.0 kN; for sizes -13 through -21, 4.0 kN; for sizes -22 through -26, 7.4 kN; for sizes -27 through -38, 10.8 kN; for sizes -40 through -50, 17.4 kN; for sizes -52 through -63, 27.4 kN; for size -65, 42.0 kN; for sizes -68 through -72, 39 kN; for sizes -75 through -130, 54 kN; for sizes -135 through -155, 67 kN; for sizes -160 through -180, 102 kN; and for sizes -185 through -250, 151 kN.

<sup>a</sup>These values have been calculated for steel rings.

<sup>b</sup>These values apply to rings made from SAE 1060-1090 steels and PH 15-7 Mo stainless steel used on shafts hardened to  $R_c$  50 minimum, with the exception of size -1 which is supplied in beryllium copper only. Values for other sizes made from beryllium copper can be calculated by multiplying the listed values by 0.75. The values listed include a safety factor of 4.

<sup>c</sup>These values apply to all standard rings used on low carbon steel shafts. They include a safety factor of 2.

Maximum allowable assembly loads with  $R$  max or  $Ch$  max are as follows:

| Ring Size No. | Maximum Allowable Load, kN | Ring Size No. | Maximum Allowable Load, kN | Ring Size No. | Maximum Allowable Load, kN |
|---------------|----------------------------|---------------|----------------------------|---------------|----------------------------|
| -1            | 0.06                       | -8            | 1.4                        | -16           | 6.6                        |

Source: Spirolox Retaining Rings, RR Series. All dimensions are in inches. Depth of groove  $d = (C - A)/2$ . Standard material: carbon spring steel (SAE 1070-1090).

**Ring Thickness, F:** For shaft sizes 0.500 through 0.718, 0.025; for sizes 0.750 through 0.938, 0.031; for sizes 0.968 through 1.156, 0.037; for sizes 1.188 through 1.500, 0.043; for sizes 1.562 through 2.952, 0.049; for sizes 3.000 through 4.562, 0.061; for sizes 4.625 through 6.000, 0.072; for sizes 6.125 through 11.000, 0.086.

**Ring Free Diameter Tolerances:** For housing sizes 0.500 through 1.031, +0.013, -0.000; for sizes 1.062 through 1.500, +0.015, -0.000; for sizes 1.562 through 2.047, +0.020, -0.000; for sizes 2.062 through 3.000, +0.025, -0.000; for sizes 3.062 through 4.063, +0.030, -0.000; for sizes 4.125 through 5.125, +0.035, -0.000; for sizes 5.250 through 6.125, +0.045, -0.000; for sizes 6.250 through 7.125, +0.055, -0.000; for sizes 7.250 through 11.000, +0.065, -0.000.

**Ring Thickness Tolerances:** Thickness indicated is for unplated rings; add 0.002 to upper thickness tolerance for plated rings. For housing sizes 0.500 through 1.500,  $\pm 0.002$ ; for sizes 1.562 through 4.562,  $\pm 0.003$ ; for sizes 4.625 through 11.000,  $\pm 0.004$ .

**Groove Diameter Tolerances:** For housing sizes 0.500 through 0.750,  $\pm 0.002$ ; for sizes 0.777 through 1.031,  $\pm 0.003$ ; for sizes 1.062 through 1.500,  $\pm 0.004$ ; for sizes 1.562 through 2.047,  $\pm 0.005$ ; for sizes 2.062 through 5.125,  $\pm 0.006$ ; for sizes 5.250 through 6.000,  $\pm 0.007$ ; for sizes 6.125 through 11.000,  $\pm 0.008$ .

**Groove Width Tolerances:** For housing sizes 0.500 through 1.156, +0.003, -0.000; for sizes 1.188 through 2.952, +0.004, -0.000; for sizes 3.000 through 6.000, +0.005, -0.000; for sizes 6.125 through 11.000, +0.006, -0.000.

**Table 8. Medium Duty External Spiral Retaining Rings MIL-R-27426**

| Shaft Dia. A | Ring   |        | Groove |         | Static Thrust Load (lb) |        | Shaft Dia. A | Ring   |        | Groove |         | Static Thrust Load (lb) |        |

Source: Spirolox Retaining Rings, RS Series. All dimensions are in inches. Depth of groove  $d = (A - C)/2$ . Standard material: carbon spring steel (SAE 1070–1090).

**Ring Thickness, F:** For shaft sizes 0.500 through 0.718, 0.025; for sizes 0.750 through 0.937, 0.031; for sizes 0.968 through 1.156, 0.037; for sizes 1.188 through 1.500, 0.043; for sizes 1.562 through 2.952, 0.049; for sizes 3.000 through 4.500, 0.061; for sizes 4.562 through 6.000, 0.072; for sizes 6.125 through 11.000, 0.086.

**Ring Free Diameter Tolerances:** For shaft sizes 0.500 through 1.031, +0.000, +0.000, -0.013; for sizes 1.062 through 1.500, +0.000, -0.015; for sizes 1.562 through 2.125, +0.000, -0.020; for sizes 2.156 through 2.688, +0.000, -0.025; for sizes 2.750 through 3.437, +0.000, -0.030; for sizes 3.500 through 5.125, +0.000, -0.040; for sizes 5.250 through 6.125, +0.000, -0.050; for sizes 6.250 through 7.375, +0.000, -0.060; for sizes 7.500 through 11.000, +0.000, -0.070.

**Ring Thickness Tolerances:** Thickness indicated is for unplated rings; add 0.002 to upper tolerance for plated rings. For shaft sizes 0.500 through 1.500,  $\pm 0.002$ ; for sizes 1.562 through 4.500,  $\pm 0.003$ ; for sizes 4.562 through 11.000,  $\pm 0.004$ .

**Groove Diameter Tolerances:** For shaft sizes 0.500 through 0.562,  $\pm 0.002$ ; for sizes 0.594 through 1.031,  $\pm 0.003$ ; for sizes 1.062 through 1.500,  $\pm 0.004$ ; for sizes 1.562 through 2.000,  $\pm 0.005$ ; for sizes 2.062 through 5.125,  $\pm 0.006$ ; for sizes 5.250 through 6.000,  $\pm 0.007$ ; for sizes 6.125 through 11.000,  $\pm 0.008$ .

**Groove Width Tolerances:** For shaft sizes 0.500 through 1.156, +0.003, -0.000; for sizes 1.188 through 2.952, +0.004, -0.000; for sizes 3.000 through 6.000, +0.005, -0.000; for sizes 6.125 through 11.000, +0.006, -0.000.

**Table 9. Heavy Duty Internal Spiral Retaining Rings MIL-R-27426**

| Bore Dia. A | Ring   |        | Groove |         | Static Thrust Load (lb) |        | Bore Dia. A | Ring   |        | Groove |         | Static Thrust Load (lb) |        |

Source: Spirolox Retaining Rings, RRN Series. All dimensions are in inches. Depth of groove  $d = (C - A)/2$ . Thickness indicated is for unplated rings; add 0.002 to upper thickness tolerance for plated rings. Standard material: carbon spring steel (SAE 1070-1090).

**Ring Thickness, F:** For housing sizes 0.500 through 0.750, 0.035; for sizes 0.777 through 1.023, 0.042; for sizes 1.062 through 1.500, 0.050; for sizes 1.562 through 2.000, 0.062; for sizes 2.062 through 2.531, 0.078; for sizes 2.562 through 3.000, 0.093; for sizes 3.062 through 5.000, 0.111; for sizes 5.250 through 7.000, 0.156; for sizes 7.250 through 15.000, 0.187.

**Ring Free Diameter Tolerances:** For housing sizes 0.500 through 1.500, +0.013, -0.000; for sizes 1.562 through 2.000, +0.020, -0.000; for sizes 2.062 through 2.531, +0.025, -0.000; for sizes 2.562 through 3.000, +0.030, -0.000; for sizes 3.062 through 5.000, +0.035, -0.000; for sizes 5.250 through 6.000, +0.050, -0.000; for sizes 6.250 through 7.000, +0.055, -0.000; for sizes 7.250 through 10.500, +0.070, -0.000; for sizes 10.750 through 12.750, +0.120, -0.000; for sizes 13.000 through 15.000, +0.140, -0.000.

**Ring Thickness Tolerances:** For housing sizes 0.500 through 1.500,  $\pm 0.002$ ; for sizes 1.562 through 5.000,  $\pm 0.003$ ; for sizes 5.250 through 6.000,  $\pm 0.004$ ; for sizes 6.250 through 15.000,  $\pm 0.005$ .

**Groove Diameter Tolerances:** For housing sizes 0.500 through 0.750,  $\pm 0.002$ ; for sizes 0.777 through 1.023,  $\pm 0.003$ ; for sizes 1.062 through 1.500,  $\pm 0.004$ ; for sizes 1.562 through 2.000,  $\pm 0.005$ ; for sizes 2.062 through 5.000,  $\pm 0.006$ ; for sizes 5.250 through 6.000,  $\pm 0.007$ ; for sizes 6.250 through 10.500,  $\pm 0.008$ ; for sizes 10.750 through 12.500,  $\pm 0.010$ ; for sizes 12.750 through 15.000,  $\pm 0.012$ .

**Groove Width Tolerances:** For housing sizes 0.500 through 1.023, +0.003, -0.000; for sizes 1.062 through 2.000, +0.004, -0.000; for sizes 2.062 through 5.000, +0.005, -0.000; for sizes 5.250 through 6.000, +0.006, -0.000; for sizes 6.250 through 7.000, +0.008, -0.000; for sizes 7.250 through 15.000, +0.008, -0.000.

*Source:* Spirolox Retaining Rings, RSN Series. All dimensions are in inches. Depth of groove  $d = (A - C)/2$ . Thickness indicated is for unplated rings; add 0.002 to upper tolerance for plated rings. Standard material: carbon spring steel (SAE 1070-1090).

*Ring Thickness, F:* For shaft size 0.469, 0.025; for sizes 0.500 through 0.669, 0.035; for sizes 0.688 through 1.023, 0.042; for sizes 1.062 through 1.500, 0.050; for sizes 1.562 through 2.000, 0.062; for sizes 2.062 through 2.687, 0.078; for sizes 2.750 through 3.437, 0.093; for sizes 3.500 through 5.000, 0.111; for sizes 5.250 through 6.000, 0.127; for sizes 6.250 through 7.250, 0.156; for sizes 7.500 through 15.000, 0.187.

*Ring Free Diameter Tolerances:* For shaft sizes 0.469 through 1.500, +0.000, -0.013; for sizes 1.562 through 2.000, +0.000, -0.020; for sizes 2.062 through 2.687, +0.000, -0.025; for sizes 2.750 through 3.437, +0.000, -0.030; for sizes 3.500 through 5.000, +0.000, -0.035; for sizes 5.250 through 6.000, +0.000, -0.050; for sizes 6.250 through 7.000, +0.000, -0.060; for sizes 7.250 through 10.000, +0.000, -0.070; for sizes 10.250 through 12.500, +0.000, -0.090; for sizes 12.750 through 15.000, +0.000, -0.110.

*Ring Thickness Tolerances:* For shaft sizes 0.469 through 1.500,  $\pm 0.002$ ; for sizes 1.562 through 5.000,  $\pm 0.003$ ; for sizes 5.250 through 6.000,  $\pm 0.004$ ; for sizes 6.250 through 15.000,  $\pm 0.005$ .

*Groove Diameter Tolerances:* For shaft sizes 0.469 through 0.562,  $\pm 0.002$ ; for sizes 0.594 through 1.023,  $\pm 0.003$ ; for sizes 1.062 through 1.500,  $\pm 0.004$ ; for sizes 1.562 through 2.000,  $\pm 0.005$ ; for sizes 2.062 through 5.000,  $\pm 0.006$ ; for sizes 5.250 through 6.000,  $\pm 0.007$ ; for sizes 6.250 through 10.000,  $\pm 0.008$ ; for sizes 10.250 through 12.500,  $\pm 0.010$ ; for sizes 12.750 through 15.000,  $\pm 0.012$ .

*Groove Width Tolerances:* For shaft sizes 0.469 through 1.023, +0.003, -0.000; for sizes 1.062 through 2.000, +0.004, -0.000; for sizes 2.062 through 5.000, +0.005, -0.000; for sizes 5.250 through 6.000, +0.006, -0.000; for sizes 6.250 through 7.250, +0.008, -0.000; for sizes 7.500 through 15.000, +0.008, -0.000.

*Thrust Load Capacity:* The most important criterion in determining which ring is best suited for a specific application is thrust load capacity. The strength of the retaining ring and groove must both be considered when analyzing the thrust load capacity of an application to determine whether the groove or the retaining ring is likely to fail first. When a retaining ring application fails, the fault will usually be with the groove, unless the groove material is of very high strength.

*Ring Material:* The standard materials for spiral-wound retaining rings are SAE 1070 to 1090 carbon spring steels and 18-8 type 302 stainless steels. The 1070 to 1090 carbon spring steels provide high-strength retaining rings at low cost. Type 302 stainless steel withstands ordinary rusting. Other materials are used for specialized applications, such as the type 316 stainless frequently used in the food industry. For high-temperature use, superalloy A286 rings can be used at up to 900°F and Inconel X-750 at up to 1200°F. Other materials, such as 316 stainless steel, 17-7PH and Inconel stainless steels are sometimes used for special-purpose and custom-made rings. Standard ring are typically supplied uncoated, however, special finishes such as cadmium, phosphate, zinc, or black oxide coatings for carbon spring steel rings and passivation of stainless steel rings are available.

**Table 11. Important Dimensions of Inch Series External Retaining Rings**  
MS 16624

Lugs: D = 0.125 to 0.236      Lugs: D = 4.25 to 8.00

Source: Industrial Retaining Rings, 3100 Series. All dimensions are in inches. Depth of groove  $d = (D - G)/2$ . Thickness indicated is for unplated rings; for most plated rings, the maximum ring thickness will not exceed the minimum groove width (W) minus 0.0002 inch. Standard material: carbon spring steel (SAE 1060-1090).

**Ring Free Diameter Tolerances:** For shaft sizes 0.125 through 0.250, +0.002, -0.004; for sizes 0.276 through 0.500, +0.002, -0.005; for sizes 0.551 through 1.023, +0.005, -0.010; for sizes 1.062 through 1.500, +0.010, -0.015; for sizes 1.562 through 2.000, +0.013, -0.020; for sizes 2.062 through 2.500, +0.015, -0.025; for sizes 2.559 through 5.000, +0.020, -0.030; for sizes 5.250 through 6.000, +0.020, -0.040; for sizes 6.250 through 6.750, +0.020, -0.050; for sizes 7.000 and 7.500, +0.050, -0.130.

**Ring Thickness Tolerances:** For shaft sizes 0.125 and 0.156, ±0.001; for sizes 0.188 through 1.500, ±0.002; for sizes 1.562 through 5.000, ±0.003; for sizes 5.250 through 6.000, ±0.004; for sizes 6.250 through 7.500, ±0.005.

**Groove Diameter Tolerances:** For shaft sizes 0.125 through 0.250, ±0.0015; for sizes 0.276 through 0.562, ±0.002; for sizes 0.594 through 1.023, ±0.003; for sizes 1.062 through 1.500, ±0.004; for sizes 1.562 through 2.000, ±0.005; for sizes 2.062 through 5.000, ±0.006; for sizes 5.250 through 6.000, ±0.007; for sizes 6.250 through 7.500, ±0.008.

**Groove Width Tolerances:** For shaft sizes 0.125 through 0.236, +0.002, -0.000; for sizes 0.250 through 1.023, +0.003, -0.000; for sizes 1.062 through 2.000, +0.004, -0.000; for sizes 2.062 through 5.000, +0.005, -0.000; for sizes 5.250 through 6.000, +0.006, -0.000; for sizes 6.250 through 7.500, +0.008, -0.000.

**Table 12. Important Dimensions of Inch Series Internal Retaining Rings**

| Housing Dia. D | Ring   |          | Groove |         |          | Housing Dia. D | Ring   |          | Groove |         |          |

<sup>a</sup> *Thrust Load Safety Factors:* Ring, 4; groove, 2. Groove wall thrust loads are for grooves machined in cold-rolled steel with a tensile yield strength of 45,000 psi; for other shaft materials, the thrust load varies proportionally with the yield strength.

*Source:* Industrial Retaining Rings, 2000 Series. All dimensions are in inches. Depth of groove  $d = (D - G)/2$ . Standard material: carbon spring steel (SAE 1060-1090). Thickness indicated is for unplated rings; for most plated rings with shaft sizes less than 1.000 inch, the maximum thickness will not exceed the minimum groove width (W) minus 0.0002 inch; for larger rings, the ring thickness may increase by 0.002 inch.

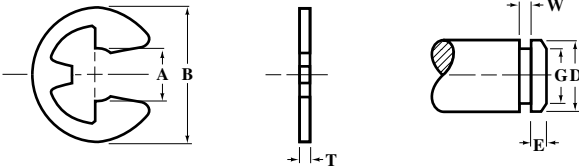

*Groove Maximum Bottom Radii:* For shaft diameters less than 0.500 inch, 0.005 inch; for shaft sizes 0.500 through 1.000 inch, 0.010 inch; all larger sizes, 0.015 inch.

*Ring Free Diameter Tolerances:* For shaft sizes 0.125 through 0.188, +0.002, -0.004; for sizes 0.219 through 0.437, +0.003, -0.005; for sizes 0.500 through 0.625,  $\pm 0.006$ ; for sizes 0.687 through 1.000,  $\pm 0.007$ ; for sizes 1.125 through 1.500,  $\pm 0.008$ ; for sizes 1.750 and 2.000,  $\pm 0.010$ .

*Ring Thickness Tolerances:* For shaft sizes 0.125 through 1.500,  $\pm 0.002$ ; for sizes 1.750 and 2.000,  $\pm 0.003$ .

*Groove Diameter Tolerances:* For shaft sizes 0.125 through 0.188,  $\pm 0.0015$ ; for sizes 0.219 through 0.437,  $\pm 0.002$ ; for sizes 0.500 through 1.000,  $\pm 0.003$ ; for sizes 1.125 through 1.500,  $\pm 0.004$ ; for sizes 1.750 and 2.000,  $\pm 0.005$ .

*Groove Width Tolerances:* For shaft sizes 0.125 through 0.188, +0.002, -0.000; for sizes 0.219 through 1.000, +0.003, -0.000; for sizes 1.125 through 2.000, +0.004, -0.000.

<sup>a</sup> Thrust Load Safety Factors: Ring 3; groove, 2.

*Source:* Industrial Retaining Rings, 1000 Series. All dimensions are in inches. Depth of groove  $d = (D - G)/2$ . Standard material: carbon spring steel (SAE 1060–1090). Thickness indicated is for unplated rings; for most plated rings with shaft sizes less than 0.625, the maximum ring thickness will not exceed the minimum groove width (W) minus 0.0002 inch; for larger rings, the thickness may increase by 0.002 inch.

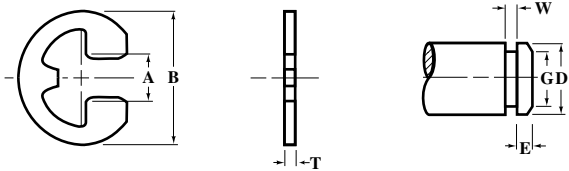

*Groove Maximum Bottom Radii:* For shaft sizes 0.040 and 0.062, 0.003 inch; for sizes 0.094 through 0.250, 0.005 inch; for sizes 0.312 through 0.437, 0.010 inch; for sizes 0.500 through 1.375, 0.015 inch.

*Ring Free Diameter Tolerances:* For shaft sizes 0.040 through 0.250, +0.001, -0.003; for sizes 0.312 through 0.500, +0.002, -0.004; for sizes 0.625 through 1.000, +0.003, -0.005; for sizes 1.188 and 1.375, +0.006, -0.010.

*Ring Thickness Tolerances:* For shaft sizes 0.040 and 0.062<sup>a</sup>, ±0.001; for sizes 0.062<sup>b</sup> through 1.000, ±0.002; for sizes 1.188 and 1.375, ±0.003.

*Groove Diameter Tolerances:* For shaft sizes 0.040 through 0.218, +0.002, -0.000; for sizes 0.250 through 1.000, +0.003, -0.000; for sizes 1.188 and 1.375, +0.005, -0.000.

*Groove Width Tolerances:* For shaft sizes 0.040 through 0.140<sup>c</sup>, +0.002, -0.000; for sizes 0.140<sup>d</sup> through 1.000, +0.003, -0.000; for sizes 1.188 and 1.375, +0.004, -0.000.

\*Thrust Load Safety Factors: Ring, 3; groove, 2.

Source: Industrial Retaining Rings, 1200 Series. All dimensions are in inches. Depth of groove  $d = (D - G)/2$ . Standard material: carbon spring steel (SAE 1060-1090). Thickness indicated is for unplated rings; for most plated rings the maximum thickness will not exceed the minimum groove width (W) minus 0.0002 inch.

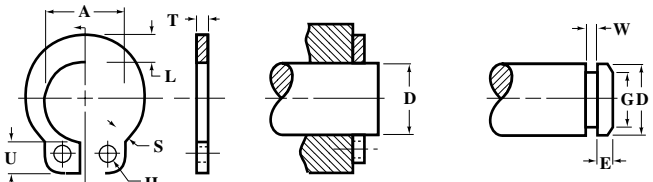

**Groove Maximum Bottom Radii:** For shaft sizes 0.250 and smaller, 0.005 inch; for sizes 0.312 through 0.438, 0.010 inch; for sizes 0.500 and 0.562, 0.015 inch. **Ring Free Diameter Tolerances:** For shaft sizes 0.094 through 0.156, +0.001, -0.003; for sizes 0.188 through 0.312,  $\pm 0.003$ ; for sizes 0.375 through 0.562,  $\pm 0.004$ . **Ring Thickness Tolerances:** For all shaft sizes,  $\pm 0.002$ . **Groove Diameter Tolerances:** For shaft sizes 0.094 through 0.188, +0.002, -0.000; for sizes 0.219 and 0.250,  $\pm 0.002$ ; for sizes 0.312 through 0.562,  $\pm 0.003$ . **Groove Width Tolerances:** For shaft sizes 0.094 and 0.125, +0.002, -0.000; for sizes 0.156 through 0.562, +0.003, -0.000.

The thrust load capacities shown in the tables of this section include safety factors. Usually, a safety factor of 2 is used for groove thrust load calculations when the load is applied through a retained part and groove with both having sharp corners and where the minimum side clearance exists between the retained part and the shaft or bore. Groove thrust load values in the tables of this section are based on these conditions. A safety factor of 3 is usual for calculations of thrust load capacity based on ring shear.

Ideally, the corner of a retained part in contact with a retaining ring should have square corners and contact the ring as closely as possible to the shaft or housing. The tabulated thrust capacities assume that minimum clearances exist between the retained part and shaft or housing, that the groove and retained part have square corners, and that contact between the retained part and the ring occurs close to the shaft or housing. If these conditions apply, the tabulated thrust loads apply. If the application does not meet the previous conditions but the side clearances, radii, and chamfers are less than the maximum total radius or chamfer of Fig. 1, then the thrust load capacity must be reduced by dividing the tabulated value by 2. The maximum total radius is given by  $0.5(b - d)$  and the maximum total chamfer by  $0.375(b - d)$ , where  $b$  is the radial wall thickness, and  $d$  is the groove depth. The recommended maximum total radius or chamfer specifications are intended to be used as guidelines by the designer, and to ensure the ring application will withstand published and calculated values of static thrust loads.

In analyzing the retaining ring loading conditions, a static, uniformly applied load is usually assumed. Dynamic and eccentric loads, however, are frequently encountered. Eccentric loading occurs when the load is concentrated on a small portion of the ring, such as may be caused by incorrectly machined surfaces, cocking of the retained part, and axial misalignment of parts. Conditions leading to eccentric loading on the ring should be avoided. In addition to the factors that affect the static thrust capacity, applications in which shock or impact loading occurs must be evaluated very carefully and tested in service to assess the effect of the mass and velocity of the retained part striking the ring. Vibration caused by impact loading can also cause the ring to fail if the resonant frequency of the system (retaining ring application) coincides with the resonant frequency of the retaining ring.

**Table 16. Dimensions of Inch Series Self-Locking External Retaining Rings**

| Shaft Diameter |        | Ring        |             | Optical Groove  |         |          | <sup>a</sup> Static Thrust Load (lb) |        |

Source: Industrial Retaining Rings, 6000 Series (internal) and 6100 Series (external). All dimensions are in inches, thrust loads are in pounds. Thickness indicated is for unplated rings. Standard material: carbon spring steel (SAE 1060-1090).

**Internal Rings:** Thrust loads are for rings made of standard material inserted into cold-rolled, low-carbon housing. **Ring Thickness Tolerances:** For housing sizes 0.311 through 0.627,  $\pm 0.001$ ; for sizes 0.748 through 1.502,  $\pm 0.002$ . **Ring Diameter Tolerances:** For housing sizes 0.311 through 0.439,  $\pm 0.005$ ; for sizes 0.498 through 1.502,  $\pm 0.010$ .

**External Rings:** Thrust loads are for rings made of standard material installed onto cold-rolled, low-carbon shafts. **Ring Thickness Tolerances:** For shaft sizes 0.093 through 0.220,  $\pm 0.001$ ; for size 0.239,  $\pm 0.002$ ; for sizes 0.249 through 0.376,  $\pm 0.001$ ; for sizes 0.437 through 1.002,  $\pm 0.002$ . **Ring Diameter Tolerances:** For shaft sizes 0.093 through 0.502,  $\pm 0.005$ ; for sizes 0.560 through 1.002,  $\pm 0.010$ .

**Centrifugal Capacity:** Proper functioning of a retaining ring depends on the ring remaining seated on the groove bottom. External rings "cling" to the groove bottom because the ring ID is slightly smaller than the diameter at the bottom of the groove. Ring speed should be kept below the allowable steady-state speed of the ring, or self-locking rings specially designed for high-speed applications should be used, otherwise an external ring can lose its grip on the groove. Applications of large retaining rings that tend to spin in their grooves when subjected to sudden acceleration or deceleration of the retained part can benefit from a ring with more "cling" (i.e., a smaller interior diameter) as long as the stress of installation is within permissible limits. Special rings are also available that lock into a hole in the bottom of the groove, thereby preventing rotation. The following equation can be used to determine the allowable steady-state speed  $N$  of an external spiral retaining ring:

$$N = \sqrt{\frac{0.466C_1E^3 \times 10^{12}}{R_n^3(1+C_1)(R_o^3-R_i^3)}} \quad (1)$$

where the speed  $N$  is in revolutions per minute,  $C_1$  is the minimum ring cling to groove bottom,  $E$  is the ring radial wall,  $R_n$  is the free neutral ring radius,  $R_o$  is the free outside ring radius, and  $R_i$  is the free inside ring radius, all in inches. For external spiral rings, the minimum ring cling is given by:  $C_1 = (C - G)/G$ , where  $C$  is the mean groove diameter in inches, and  $G$  is the maximum ring free ID in inches.

Fig. 2. Localized Groove Yielding under Load. (a) Groove Profile before Loading; (b) Localized Yielding of Retained Part and Groove under Load; (c) Groove Profile after Loading beyond Thrust Capacity (Courtesy Spirolox Retaining Rings)

**Rotation between Parts:** The use of spiral-wound rings to retain a rotating part should be limited to applications with rotation in only one direction. The ring should be matched so that the rotation tends to wind the spring into the groove. External rings should be wound in the direction of rotation of the retained part but internal rings should be wound against the direction of rotation of the rotating part. Failure to observe these precautions will cause the ring to wind out of the groove. Spiral-wound rings can be obtained with either right-hand (normal rotation) or left-hand (reverse rotation) wound configurations. Stamped retaining rings do not have these limitations, and may be used for applications that require rotation of the retained part, regardless of the direction of rotation.

**Retaining Ring Failure.**—Failure of a retaining ring application can result from failure of the ring itself, failure of the groove, or both. If a ring fails, the cause is likely to be from shearing of the ring. Shear failure occurs when a ring is installed in a groove and loaded by a retained part with both the groove and the retained part having a compressive yield strength greater than 45,000 psi; or when the load is applied through a retained part and groove, both having sharp corners and line-to-line contact; or when the ring is too thin in section compared with its diameter. To examine the possibility of ring shear, the allowable thrust  $P_s$ , based on the shear strength of the ring material, is given by

$$P_s = \frac{\pi D t S_s}{K} \quad (2)$$

where  $P_s$  is in lb<sub>f</sub>,  $D$  is the shaft or housing diameter in inches,  $t$  is the ring thickness in inches,  $S_s$  is the shear strength of the ring material in lb/in.<sup>2</sup>, and  $K$  is the factor of safety.

**Groove Failure:** The most common type of groove failure is yielding of the groove material that occurs when the thrust load, applied through the retaining ring against the corner of the groove, exceeds the compressive yield strength of the groove. This yielding of the groove results from a low compressive yield strength of the groove material, and allows the ring to tilt and come out of the groove, as illustrated in Fig. 2(b).

When dishing of a ring occurs as a result of yielding in the groove material, a bending moment across the cross-section of the ring generates a tensile stress that is highest at the

interior diameter of the ring. If the maximum stress is greater than the yield strength of the ring material, the ring ID will grow and the ring will become permanently dished in shape. To determine the thrust load capacity of a ring based on groove deformation, the allowable angle of ring deflection must be calculated, then the thrust load based on groove yield can be determined. However, for spiral-wound rings, the thrust load  $P_G$  that initiates the onset of groove deformation can be estimated from the following:

$$P_G = \frac{\pi D d S_y}{K} \quad (3)$$

where  $P_G$  is given in lb<sub>f</sub>,  $D$  is the shaft or housing diameter in inches,  $d$  is the groove depth in inches,  $S_y$  is the yield strength of the groove material, and  $K$  is the safety factor. For stamped rings, estimate  $P_G$  by multiplying Equation (3) by the fraction of the groove circumference that contacts the ring.

The thrust load capacity of a particular retaining ring application can be increased by changing the workpiece material that houses the groove. Increasing the yield strength of the groove material increases the thrust load capacity of the retaining ring application. However, increasing the strength of the groove material may cause the failure mechanism to shift from groove deformation to ring shear. Therefore, use the lower of the values obtained from Equations (2) and (3) for the allowable thrust load.

*Groove Design and Machining:* In most applications, grooves are located near the end of a shaft or housing bore to facilitate installation and removal of the rings. The groove is normally located a distance at least two to three times the groove depth from the end of the shaft or bore. If the groove is too close to the end of the shaft or bore, the groove may shear or yield. The following equation can be used to determine the minimum safe distance  $Y$  of a groove from the end of a shaft or housing:

$$Y = \frac{K P_t}{\pi D S_c} \quad (4)$$

where  $K$  is the factor of safety,  $P_t$  is the thrust load on the groove in pounds,  $S_c$  is the shear strength of the groove material in psi, and  $D$  is the shaft or housing diameter in inches.

A properly designed and machined groove is just as important in a retaining ring application as the ring itself. The walls of grooves should be perpendicular to the shaft or bore diameter; the grooves should have square corners on the top edges, and radii at the bottom, within the tolerances specified by the manufacturers, as shown in Fig. 1 (page 1684). Test data indicate that the ultimate thrust capacity for both static and dynamic loading conditions is greatly affected if these groove requirements are not met. For spiral-wound rings, the maximum bottom groove radius is 0.005 inch for rings up to 1.000 inch free diameter and 0.010 inch for larger rings, internal or external. For stamped rings, the maximum bottom groove radius varies with ring size and style.

WING NUTS, WING SCREWS, AND THUMB SCREWS

**Wing Nuts.**—A wing nut is a nut having wings designed for manual turning without driver or wrench. As covered by ANSI B18.17-1968 (R1983) wing nuts are classified first, by type on the basis of the method of manufacture; and second, by style on the basis of design characteristics. They consist of:

*Type A:* Type A wing nuts are cold forged or cold formed solid nuts having wings of moderate height. In some sizes they are produced in regular, light, and heavy series to best suit the requirements of specific applications. Dimensions are given in Table 1.

**Table 1. American National Standard Type A Wing Nuts**  
ANSI B18.17-1968, R1983

| Nominal Size or Basic Major Diameter of Thread <sup>a</sup> | Thds. per Inch | Series <sup>b</sup> | Nut Blank Size (Ref) | A           |             | B           |             | C           |             | D             |             | E           |             | G           |             |

<sup>a</sup> Where specifying nominal size in decimals, zeros in the fourth decimal place are omitted.

<sup>b</sup> Lgt. = Light; Hvy. = Heavy; Reg. = Regular. Sizes shown in bold face are preferred.

All dimensions in inches.

Type B: Type B wing nuts are hot forged solid nuts available in two wing styles: Style 1, having wings of moderate height; and Style 2, having high wings. Dimensions are given in Table 2.

**Table 2. American National Standard Type B Wing Nuts**  
ANSI B18.17-1968, R1983

<sup>a</sup> Where specifying nominal size in decimals, zeros in the fourth decimal place are omitted.

All dimensions in inches. Sizes shown in **bold face** are preferred.

**Type C:** Type C wing nuts are die cast solid nuts and are available in three wing styles: Style 1, having wings of moderate height; Style 2, having low wings; and Style 3, having high wings. In some sizes, the Style 1 nuts are produced in regular, light, and heavy series to best suit the requirements of specific applications. Dimensions are given in [Table 3](#).

<sup>a</sup> Where specifying nominal size in decimals, zeros in the fourth decimal place are omitted.

<sup>b</sup> Lgt. = Light; Hvy. = Heavy; Reg. = Regular.

All dimensions in inches.

**Type D:** Type D wing nuts are stamped sheet metal nuts and are available in three styles: Style 1, having wings of moderate height; Style 2, having low wings; and Style 3, having wings of moderate height and a larger bearing surface. In some sizes, Styles 2 and 3 are produced in regular, light, and heavy series to best suit the requirements of specific applications. Dimensions are given in Table 4.

**Specification of Wing Nuts.**—When specifying wing nuts, the following data should be included in the designation and should appear in the following sequence: nominal size (number, fraction or decimal equivalent), threads per inch, type, style and/or series, material, and finish.

*Examples:* 10—32 Type A Wing Nut, Regular Series, Steel, Zinc Plated.

0.250—20 Type C Wing Nut, Style 1, Zinc Alloy, Plain.

**Threads for Wing Nuts.**—Threads are in conformance with the ANSI Standard Unified Thread, Class 2B for all types of wing nuts except type D which have a modified Class 2B thread. Because of the method of manufacture, the minor diameter of the thread in type D

## 1716 WING NUTS, WING SCREWS AND THUMB SCREWS

nuts may be somewhat larger than the Unified Thread Class 2B maximum but shall in no case exceed the minimum pitch diameter.

**Materials and Finish for Wing Nuts.**—Types A, B, and D wing nuts are normally supplied as specified by the user in carbon steel, brass or corrosion resistant steel of good quality and adaptable to the manufacturing process. Type C wing nuts are made from die cast zinc alloy. Unless otherwise specified, wing nuts are supplied with a plain (unplated or uncoated) finish.

**Wing Screws.**—A wing screw is a screw having a wing-shaped head designed for manual turning without a driver or wrench. As covered by ANSI B18.17-1968 (R1983) wing screws are classified first, by type on the basis of the method of manufacture, and second, by style on the basis of design characteristics. They consist of the following:

*Type A:* Type A wing screws are of two-piece construction having cold formed or cold forged wing portions of moderate height. In some sizes they are produced in regular, light, and heavy series to best suit the requirements of specific applications. Dimensions are given in [Table 5](#).

*Type B:* Type B wing screws are of hot forged one-piece construction available in two wing styles: Style 1, having wings of moderate height; and Style 2, having high wings. Dimensions are given in [Table 5](#).

*Type C:* Type C wing screws are available in two styles: Style 1, of a one-piece die cast construction having wings of moderate height; and Style 2, of a two-piece construction having a die cast wing portion of moderate height. Dimensions are given in [Table 6](#).

*Type D:* Type D wing screws are of two-piece welded construction having stamped sheet metal wing portions of moderate height. Dimensions are given in [Table 6](#).

*Materials for Wing Screws and Thumb Screws:* Type A wing screws are normally supplied in carbon steel with the shank portion case hardened. When so specified, they also may be made from corrosion resistant steel, brass or other materials as agreed upon by the manufacturer and user.

Type B wing screws are normally made from carbon steel but also may be made from corrosion resistant steel, brass or other materials.

Type C, Style 1, wing screws are supplied only in die cast zinc alloy. Type C, Style 2, wing screws have the wing portion made from die cast zinc alloy with the shank portion normally made from carbon steel. Where so specified, the shank portion may be made from corrosion resistant steel, brass or other materials as agreed upon by the manufacturer and user.

Type D wing screws are normally supplied in carbon steel but also may be made from corrosion resistant steel, brass or other materials.

Thumb screws of all types are normally made from a good commercial quality of carbon steel having a maximum ultimate tensile strength of 48,000 psi. Where so specified, carbon steel thumb screws are case hardened. They are also made from corrosion resistant steel, brass, and other materials as agreed upon by the manufacturer and user.

Unless otherwise specified, wing screws and thumb screws are supplied with a plain (unplated or uncoated) finish.

**Thumb Screws.**—A thumb screw is a screw having a flattened head designed for manual turning without a driver or wrench. As covered by ANSI B18.17-1968 (R1983) thumb screws are classified by type on the basis of design characteristics. They consist of the following:

*Type A:* Type A thumb screws are forged one-piece screws having a shoulder under the head and are available in two series: regular and heavy. Dimensions are given in [Table 7](#).

*Type B:* Type B thumb screws are forged one-piece screws without a shoulder and are available in two series: regular and heavy. Dimensions are given in [Table 7](#).

All dimensions in inches. Sizes shown in bold face are preferred.

<sup>1</sup>Plain point, unless alternate point from styles shown in Table 8 is specified by user.

<sup>a</sup> Where specifying nominal size in decimals, zeros in the fourth decimal place are omitted.

<sup>b</sup> Hvy. = Heavy; Lgt. = Light; Reg. = Regular.

**Table 6. American National Standard Types C and D Wing Screws**

All dimensions in inches.

<sup>a</sup> Plain point, unless alternate point from styles shown in Table 8 is specified by user.

<sup>a</sup> Where specifying nominal size in decimals, zeros in the fourth decimal place are omitted.

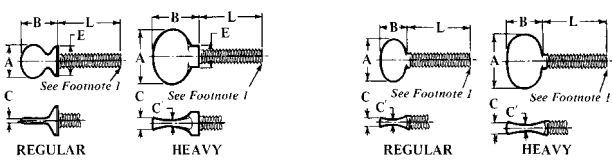

**Wing Screw and Thumb Screw Designation.**—When specifying wing and thumb screws, the following data should be included in the designation and should appear in the following sequence: nominal size (number, fraction or decimal equivalent), threads per inch, length (fractions or decimal equivalents), type, style and/or series, point (if other than plain point), materials, and finish.

Examples: 10—32 × 1¼, Thumb Screw, Type A, Regular, Steel, Zinc Plated.

0.375—16 × 2.00, Wing Screw, Type B, Style 2, Steel, Cadmium Plated.

0.250—20 × 1.50, Wing Screw, Type C, Style 2, Zinc Alloy Wings, Steel Shank, Brass Plated.

**Table 7. American National Standard Types A and B Thumb Screws**

<sup>a</sup> Where specifying nominal size in decimals, zeroes in fourth decimal place are omitted. All dimensions in inches.

<sup>1</sup> Plain point, unless alternate point from styles shown in Table 8 is specified by user.

**Lengths of Wing and Thumb Screws.**—The length of wing or thumb screws is measured parallel to the axis of the screw from the intersection of the head or shoulder with the shank to the extreme point of the screw. Standard length increments are as follows: For

1720 WING NUTS, WING SCREWS AND THUMB SCREWS

sizes No. 4 through 1/4 inch and for nominal lengths of 0.25 to 0.75 inch, 0.12-inch increments; from 0.75- to 1.50-inch lengths, 0.25-inch increments; and for 1.50- to 3.00-inch lengths, 0.50-inch increments. For sizes 5/16 through 1/2 inch and for 0.50- to 1.50-inch lengths, 0.25-inch increments; for 1.50- to 3.00-inch lengths, 0.50-inch increments; and for 3.00- to 4.00-inch lengths, 1.00-inch increments.

**Threads for Wing Screws and Thumb Screws.**—Threads for all types of wing screws and thumb screws are in conformance with ANSI Standard Unified Thread, Class 2A. For threads with an additive finish the Class 2A maximum diameters apply to an unplated screw or to a screw before plating, whereas the basic diameters (Class 2A maximum diameters plus the allowance) apply to a screw after plating. All types of wing and thumb screws should have complete (full form) threads extending as close to the head or shoulder as practicable.

**Points for Wing and Thumb Screws.**—Wing and thumb screws are normally supplied with plain points (sheared ends). Where so specified, these screws may be obtained with cone, cup, dog, flat or oval points as shown in Table 8.

**Table 8. American National Standard Alternate Points for Wing and Thumb Screws**  
ANSI B18.17-1968, R1983

| Nominal Size or Basic Screw Diameter <sup>a</sup> | O                           |       | P                      |       | Q     |       | R                 |       |
|---|-----------------------------|-------|------------------------|-------|-------|-------|-------------------|-------|

| 5/8 (0.6250)                                      | 0.371                       | 0.347 | 0.469                  | 0.456 | 0.321 | 0.305 | 0.500             | 0.469 |

<sup>a</sup> Where specifying nominal size in decimals, zeros in the fourth decimal place are omitted.

<sup>b</sup> The axis of dog points shall not be eccentric with the axis of the screw by more than 3 per cent of the basic screw diameter or 0.005 in., whichever is the smaller.

All dimensions in inches.

<sup>1</sup> The external point angles specified shall apply to those portions of the angles which lie below the thread root diameter, it being recognized the angle within the thread profile may be varied due to the manufacturing processes.

## SCREW THREAD SYSTEMS

## Screw Thread Forms

Of the various screw thread forms which have been developed, the most used are those having symmetrical sides inclined at equal angles with a vertical center line through the thread apex. Present-day examples of such threads would include the Unified, the Whitworth and the Acme forms. One of the early forms was the Sharp V which is now used only occasionally. Symmetrical threads are relatively easy to manufacture and inspect and hence are widely used on mass-produced general-purpose threaded fasteners of all types. In addition to general-purpose fastener applications, certain threads are used to repeatedly move or translate machine parts against heavy loads. For these so-called translation threads a stronger form is required. The most widely used translation thread forms are the square, the Acme, and the buttress. Of these, the square thread is the most efficient, but it is also the most difficult to cut owing to its parallel sides and it cannot be adjusted to compensate for wear. Although less efficient, the Acme form of thread has none of the disadvantages of the square form and has the advantage of being somewhat stronger. The buttress form is used for translation of loads in one direction only because of its non-symmetrical form and combines the high efficiency and strength of the square thread with the ease of cutting and adjustment of the Acme thread.

**V-Thread, Sharp V-thread.**—The sides of the thread form an angle of 60 degrees with each other. The top and bottom or root of this thread form are theoretically sharp, but in actual practice the thread is made with a slight flat, owing to the difficulty of producing a perfectly sharp edge and because of the tendency of such an edge to wear away or become battered. This flat is usually equal to about one twenty-fifth of the pitch, although there is no generally recognized standard.

Owing to the difficulties connected with the V-thread, the tap manufacturers agreed in 1909 to discontinue the making of sharp V-thread taps, except when ordered. One advantage of the V-thread is that the same cutting tool may be used for all pitches, whereas, with the American Standard form, the width of the point or the flat varies according to the pitch.

The V-thread is regarded as a good form where a steam-tight joint is necessary, and many of the taps used on locomotive work have this form of thread. Some modified V-threads, for locomotive boiler taps particularly, have a depth of  $0.8 \times$  pitch.

The American Standard screw thread is used largely in preference to the sharp V-thread because it has several advantages; see *American Standard for Unified Screw Threads*. If  $p$  = pitch of thread, and  $d$  depth of thread, then

$$d = p \times \cos 30 \text{ deg.} = 0.866 \times p = \frac{0.866}{\text{No. of threads per inch}}$$

**United States Standard Screw Thread.**—William Sellers of Philadelphia, in a paper read before the Franklin Institute in 1864, originally proposed the screw thread system that later became known as the U. S. Standard system for screw threads. A report was made to the United States Navy in May, 1868, in which the Sellers system was recommended as a standard for the Navy Department, which accounts for the name of U. S. Standard. The American Standard Screw Thread system is a further development of the United States Standard. The thread form which is known as the American (National) form is the same as the United States Standard form. See *American Standard for Unified Screw Threads*.

**American National and Unified Screw Thread Forms.**—The American National form (formerly known as the United States Standard) was used for many years for most screws, bolts, and miscellaneous threaded products produced in the United States. The American

National Standard for Unified Screw Threads now in use includes certain modifications of the former standard as is explained below and on page 1732. The basic profile is shown in Fig. 1 and is identical for both UN and UNR screw threads. In this figure  $H$  is the height of a sharp V-thread,  $P$  is the pitch,  $D$  and  $d$  are the basic major diameters,  $D_2$  and  $d_2$  are the basic pitch diameters, and  $D_1$  and  $d_1$  are the basic minor diameters. Capital letters are used to designate the internal thread dimensions ( $D$ ,  $D_2$ ,  $D_1$ ), and lowercase letters to designate the external thread dimensions ( $d$ ,  $d_2$ ,  $d_1$ ). Definitions of *Basic Size* and *Basic Profile of Thread* are given on page 1727.

Fig. 1. Basic Profile of UN and UNF Screw Threads

In the past, other symbols were used for some of the thread dimensions illustrated above. These symbols were changed to conform with current practice in nomenclature as defined in ANSI/ASME B1.7M, "Nomenclature, Definitions, and Letter Symbols for Screw Threads." The symbols used above are also in accordance with terminology and symbols used for threads of the ISO metric thread system.

**International Metric Thread System.**—The *Système Internationale* (S.I.) Thread was adopted at the International Congress for the standardization of screw threads held in Zurich in 1898. The thread form is similar to the American standard (formerly U.S. Standard), excepting the depth which is greater. There is a clearance between the root and mating crest fixed at a maximum of  $\frac{1}{16}$  the height of the fundamental triangle or  $0.054 \times$  pitch. A rounded root profile is recommended. The angle in the plane of the axis is 60 degrees and the crest has a flat like the American standard equal to  $0.125 \times$  pitch. This system formed the basis of the normal metric series (ISO threads) of many European countries, Japan, and many other countries, including metric thread standards of the United States.

Depth  $d = 0.7035 P$  max.;  $0.6855 P$  min.

Flat  $f = 0.125 P$

Radius  $r = 0.0633 P$  max.;  $0.054 P$  min.

Tap drill dia = major dia. – pitch

**International Metric Fine Thread:** The International Metric Fine Thread form of thread is the same as the International system but the pitch for a given diameter is smaller.

**German Metric Thread Form:** The German metric thread form is like the International Standard but the thread depth =  $0.6945 P$ . The root radius is the same as the maximum for the International Standard or  $0.0633 P$ .

**ISO Metric Thread System.**—ISO refers to the International Organization for Standardization, a worldwide federation of national standards bodies (for example, the American National Standards Institute is the ISO national body representing the United States) that develops standards on a very wide variety of subjects.

The basic profile of ISO metric threads is specified in ISO 68 and shown in Fig. 2. The basic profile of this thread is very similar to that of the Unified thread, and as previously discussed,  $H$  is the height of a sharp V-thread,  $P$  is the pitch,  $D$  and  $d$  are the basic major diameters,  $D_2$  and  $d_2$  are the basic pitch diameters, and  $D_1$  and  $d_1$  are the basic minor diameters. Here also, capital letters designate the internal thread dimensions ( $D$ ,  $D_2$ ,  $D_1$ ), and lowercase letters designate the external thread dimensions ( $d$ ,  $d_2$ ,  $d_1$ ). This metric thread is discussed in detail in the section *METRIC SCREW THREADS* starting on page 1783.

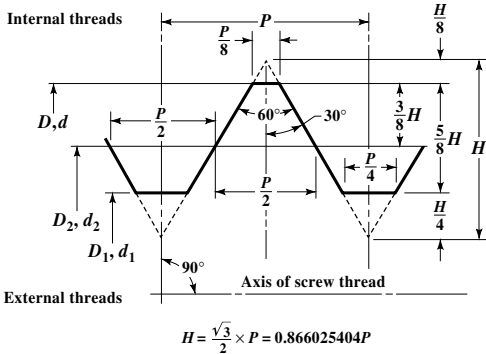

Fig. 2. ISO 68 Basic Profile

### Definitions of Screw Threads

The following definitions are based on American National Standard ANSI/ASME B1.7M-1984 (R2001) "Nomenclature, Definitions, and Letter Symbols for Screw Threads," and refer to both straight and taper threads.

**Actual Size:** An actual size is a measured size.

**Allowance:** An allowance is the prescribed difference between the design (maximum material) size and the basic size. It is numerically equal to the absolute value of the ISO term *fundamental deviation*.

**Axis of Thread:** Thread axis is coincident with the axis of its pitch cylinder or cone.

**Basic Profile of Thread:** The basic profile of a thread is the cyclical outline, in an axial plane, of the permanently established boundary between the provinces of the external and internal threads. All deviations are with respect to this boundary.

**Basic Size:** The basic size is that size from which the limits of size are derived by the application of allowances and tolerances.

**Bilateral Tolerance:** This is a tolerance in which variation is permitted in both directions from the specified dimension.

**Black Crest Thread:** This is a thread whose crest displays an unfinished cast, rolled, or forged surface.

**Blunt Start Thread:** "Blunt start" designates the removal of the incomplete thread at the starting end of the thread. This is a feature of threaded parts that are repeatedly assembled

by hand, such as hose couplings and thread plug gages, to prevent cutting of hands and crossing of threads. It was formerly known as a Higbee cut.

*Chamfer:* This is a conical surface at the starting end of a thread.

*Class of Thread:* The class of a thread is an alphanumeric designation to indicate the standard grade of tolerance and allowance specified for a thread.

*Clearance Fit:* This is a fit having limits of size so prescribed that a clearance always results when mating parts are assembled at their maximum material condition.

*Complete Thread:* The complete thread is that thread whose profile lies within the size limits. (See also *Effective Thread* and *Length of Complete Thread*.) *Note:* Formerly in pipe thread terminology this was referred to as "the perfect thread" but that term is no longer considered desirable.

*Crest:* This is that surface of a thread which joins the flanks of the thread and is farthest from the cylinder or cone from which the thread projects.

*Crest Truncation:* This is the radial distance between the sharp crest (crest apex) and the cylinder or cone that would bound the crest.

*Depth of Thread Engagement:* The depth (or height) of thread engagement between two coaxially assembled mating threads is the radial distance by which their thread forms overlap each other.

*Design Size:* This is the basic size with allowance applied, from which the limits of size are derived by the application of a tolerance. If there is no allowance, the design size is the same as the basic size.

*Deviation:* Deviation is a variation from an established dimension, position, standard, or value. In ISO usage, it is the algebraic difference between a size (actual, maximum, or minimum) and the corresponding basic size. The term deviation does not necessarily indicate an error. (See also *Error*.)

*Deviation, Fundamental (ISO term):* For standard threads, the fundamental deviation is the upper or lower deviation closer to the basic size. It is the upper deviation  $es$  for an external thread and the lower deviation  $EI$  for an internal thread. (See also *Allowance* and *Tolerance Position*.)

*Deviation, Lower (ISO term):* The algebraic difference between the minimum limit of size and the basic size. It is designated  $EI$  for internal and  $ei$  for external thread diameters.

*Deviation, Upper (ISO term):* The algebraic difference between the maximum limit of size and the basic size. It is designated  $ES$  for internal and  $es$  for external thread diameters.

*Dimension:* A numerical value expressed in appropriate units of measure and indicated on drawings along with lines, symbols, and notes to define the geometrical characteristic of an object.

*Effective Size:* See *Pitch Diameter*, *Functional Diameter*.

*Effective Thread:* The effective (or useful) thread includes the complete thread, and those portions of the incomplete thread which are fully formed at the root but not at the crest (in taper pipe threads it includes the so-called black crest threads); thus excluding the vanish thread.

*Error:* The algebraic difference between an observed or measured value beyond tolerance limits, and the specified value.

*External Thread:* A thread on a cylindrical or conical external surface.

*Fit:* Fit is the relationship resulting from the designed difference, before assembly, between the sizes of two mating parts which are to be assembled.

*Flank:* The flank of a thread is either surface connecting the crest with the root. The flank surface intersection with an axial plane is theoretically a straight line.

*Flank Angle:* The flank angles are the angles between the individual flanks and the perpendicular to the axis of the thread, measured in an axial plane. A flank angle of a symmetrical thread is commonly termed the half-angle of thread.

*Flank Diametral Displacement:* In a boundary profile defined system, flank diametral displacement is twice the radial distance between the straight thread flank segments of the

maximum and minimum boundary profiles. The value of flank diametral displacement is equal to pitch diameter tolerance in a pitch line reference thread system.

*Height of Thread:* The height (or depth) of thread is the distance, measured radially, between the major and minor cylinders or cones, respectively.

*Helix Angle:* On a straight thread, the helix angle is the angle made by the helix of the thread and its relation to the thread axis. On a taper thread, the helix angle at a given axial position is the angle made by the conical spiral of the thread with the axis of the thread. The helix angle is the complement of the lead angle. (See also page 1966 for diagram.)

*Higbee Cut:* See *Blunt Start Thread*.

*Imperfect Thread:* See *Incomplete Thread*.

*Included Angle:* This is the angle between the flanks of the thread measured in an axial plane.

*Incomplete Thread:* A threaded profile having either crests or roots or both, not fully formed, resulting from their intersection with the cylindrical or end surface of the work or the vanish cone. It may occur at either end of the thread.

*Interference Fit:* A fit having limits of size so prescribed that an interference always results when mating parts are assembled.

*Internal Thread:* A thread on a cylindrical or conical internal surface.

*Lead:* Lead is the axial distance between two consecutive points of intersection of a helix by a line parallel to the axis of the cylinder on which it lies, i.e., the axial movement of a threaded part rotated one turn in its mating thread.

*Lead Angle:* On a straight thread, the lead angle is the angle made by the helix of the thread at the pitch line with a plane perpendicular to the axis. On a taper thread, the lead angle at a given axial position is the angle made by the conical spiral of the thread with the perpendicular to the axis at the pitch line.

*Lead Thread:* That portion of the incomplete thread that is fully formed at the root but not fully formed at the crest that occurs at the entering end of either an external or internal thread.

*Left-hand Thread:* A thread is a left-hand thread if, when viewed axially, it winds in a counterclockwise and receding direction. Left-hand threads are designated LH.

*Length of Complete Thread:* The axial length of a thread section having full form at both crest and root but also including a maximum of two pitches at the start of the thread which may have a chamfer or incomplete crests.

*Length of Thread Engagement:* The length of thread engagement of two mating threads is the axial distance over which the two threads, each having full form at both crest and root, are designed to contact. (See also *Length of Complete Thread*.)

*Limits of Size:* The applicable maximum and minimum sizes.

*Major Clearance:* The radial distance between the root of the internal thread and the crest of the external thread of the coaxially assembled designed forms of mating threads.

*Major Cone:* The imaginary cone that would bound the crests of an external taper thread or the roots of an internal taper thread.

*Major Cylinder:* The imaginary cylinder that would bound the crests of an external straight thread or the roots of an internal straight thread.

*Major Diameter:* On a straight thread the major diameter is that of the major cylinder. On a taper thread the major diameter at a given position on the thread axis is that of the major cone at that position. (See also *Major Cylinder* and *Major Cone*.)

*Maximum Material Condition: (MMC):* The condition where a feature of size contains the maximum amount of material within the stated limits of size. For example, minimum internal thread size or maximum external thread size.

*Minimum Material Condition: (Least Material Condition (LMC)):* The condition where a feature of size contains the least amount of material within the stated limits of size. For example, maximum internal thread size or minimum external thread size.

*Minor Clearance:* The radial distance between the crest of the internal thread and the root of the external thread of the coaxially assembled design forms of mating threads.

*Minor Cone:* The imaginary cone that would bound the roots of an external taper thread or the crests of an internal taper thread.

*Minor Cylinder:* The imaginary cylinder that would bound the roots of an external straight thread or the crests of an internal straight thread.

*Minor Diameter:* On a straight thread the minor diameter is that of the minor cylinder. On a taper thread the minor diameter at a given position on the thread axis is that of the minor cone at that position. (See also *Minor Cylinder* and *Minor Cone*.)

*Multiple-Start Thread:* A thread in which the lead is an integral multiple, other than one, of the pitch.

*Nominal Size:* Designation used for general identification.

*Parallel Thread:* See *Screw Thread*.

*Partial Thread:* See *Vanish Thread*.

*Pitch:* The pitch of a thread having uniform spacing is the distance measured parallel with its axis between corresponding points on adjacent thread forms in the same axial plane and on the same side of the axis. Pitch is equal to the lead divided by the number of thread starts.

*Pitch Cone:* The pitch cone is an imaginary cone of such apex angle and location of its vertex and axis that its surface would pass through a taper thread in such a manner as to make the widths of the thread ridge and the thread groove equal. It is, therefore, located equidistantly between the sharp major and minor cones of a given thread form. On a theoretically perfect taper thread, these widths are equal to one-half the basic pitch. (See also *Axis of Thread* and *Pitch Diameter*.)

*Pitch Cylinder:* The pitch cylinder is an imaginary cylinder of such diameter and location of its axis that its surface would pass through a straight thread in such a manner as to make the widths of the thread ridge and groove equal. It is, therefore, located equidistantly between the sharp major and minor cylinders of a given thread form. On a theoretically perfect thread these widths are equal to one-half the basic pitch. (See also *Axis of Thread* and *Pitch Diameter*.)

*Pitch Diameter:* On a straight thread the pitch diameter is the diameter of the pitch cylinder. On a taper thread the pitch diameter at a given position on the thread axis is the diameter of the pitch cone at that position. *Note:* When the crest of a thread is truncated beyond the pitch line, the pitch diameter and pitch cylinder or pitch cone would be based on a theoretical extension of the thread flanks.

*Pitch Diameter, Functional Diameter:* The functional diameter is the pitch diameter of an enveloping thread with perfect pitch, lead, and flank angles and having a specified length of engagement. It includes the cumulative effect of variations in lead (pitch), flank angle, taper, straightness, and roundness. Variations at the thread crest and root are excluded. Other, nonpreferred terms are *virtual diameter*, *effective size*, *virtual effective diameter*, and *thread assembly diameter*.

*Pitch Line:* The generator of the cylinder or cone specified in *Pitch Cylinder* and *Pitch Cone*.

*Right-hand Thread:* A thread is a right-hand thread if, when viewed axially, it winds in a clockwise and receding direction. A thread is considered to be right-hand unless specifically indicated otherwise.

*Root:* That surface of the thread which joins the flanks of adjacent thread forms and is immediately adjacent to the cylinder or cone from which the thread projects.

*Root Truncation:* The radial distance between the sharp root (root apex) and the cylinder or cone that would bound the root. See also *Sharp Root (Root Apex)*.

*Runout:* As applied to screw threads, unless otherwise specified, runout refers to circular runout of major and minor cylinders with respect to the pitch cylinder. Circular runout, in accordance with ANSI Y14.5M, controls cumulative variations of circularity and coaxiality. Runout includes variations due to eccentricity and out-of-roundness. The amount of runout is usually expressed in terms of full indicator movement (FIM).

*Screw Thread:* A screw thread is a continuous and projecting helical ridge usually of uniform section on a cylindrical or conical surface.

*Sharp Crest (Crest Apex):* The apex formed by the intersection of the flanks of a thread when extended, if necessary, beyond the crest.

*Sharp Root (Root Apex):* The apex formed by the intersection of the adjacent flanks of adjacent threads when extended, if necessary, beyond the root.

*Standoff:* The axial distance between specified reference points on external and internal taper thread members or gages, when assembled with a specified torque or under other specified conditions.

*Straight Thread:* A straight thread is a screw thread projecting from a cylindrical surface.

*Taper Thread:* A taper thread is a screw thread projecting from a conical surface.

*Tensile Stress Area:* The tensile stress area is an arbitrarily selected area for computing the tensile strength of an externally threaded fastener so that the fastener strength is consistent with the basic material strength of the fastener. It is typically defined as a function of pitch diameter and/or minor diameter to calculate a circular cross section of the fastener correcting for the notch and helix effects of the threads.

*Thread:* A thread is a portion of a screw thread encompassed by one pitch. On a single-start thread it is equal to one turn. (See also *Threads per Inch* and *Turns per Inch*.)

*Thread Angle:* See *Included Angle*.

*Thread Runout:* See *Vanish Thread*.

*Thread Series:* Thread Series are groups of diameter/pitch combinations distinguished from each other by the number of threads per inch applied to specific diameters.

*Thread Shear Area:* The thread shear area is the total ridge cross-sectional area intersected by a specified cylinder with diameter and length equal to the mating thread engagement. Usually the cylinder diameter for external thread shearing is the minor diameter of the internal thread and for internal thread shearing it is the major diameter of the external thread.

*Threads per Inch:* The number of threads per inch is the reciprocal of the axial pitch in inches.

*Tolerance:* The total amount by which a specific dimension is permitted to vary. The tolerance is the difference between the maximum and minimum limits.

*Tolerance Class: (metric):* The tolerance class (metric) is the combination of a tolerance position with a tolerance grade. It specifies the allowance (fundamental deviation), pitch diameter tolerance (flank diametral displacement), and the crest diameter tolerance.

*Tolerance Grade: (metric):* The tolerance grade (metric) is a numerical symbol that designates the tolerances of crest diameters and pitch diameters applied to the design profiles.

*Tolerance Limit:* The variation, positive or negative, by which a size is permitted to depart from the design size.

*Tolerance Position: (metric):* The tolerance position (metric) is a letter symbol that designates the position of the tolerance zone in relation to the basic size. This position provides the allowance (fundamental deviation).

*Total Thread:* Includes the complete and all the incomplete thread, thus including the vanish thread and the lead thread.

*Transition Fit:* A fit having limits of size so prescribed that either a clearance or an interference may result when mating parts are assembled.

*Turns per Inch:* The number of turns per inch is the reciprocal of the lead in inches.

*Unilateral Tolerance:* A tolerance in which variation is permitted in one direction from the specified dimension.

*Vanish Thread: (Partial Thread, Washout Thread, or Thread Runout):* That portion of the incomplete thread which is not fully formed at the root or at crest and root. It is produced by the chamfer at the starting end of the thread forming tool.

*Virtual Diameter:* See *Pitch Diameter, Functional Diameter*.

*Washout Thread:* See *Vanish Thread*.

## UNIFIED SCREW THREADS

## American Standard for Unified Screw Threads

American Standard B1.1-1949 was the first American standard to cover those Unified Thread Series agreed upon by the United Kingdom, Canada, and the United States to obtain screw thread interchangeability among these three nations. These Unified threads are now the basic American standard for fastening types of screw threads. In relation to previous American practice, Unified threads have substantially the same thread form and are mechanically interchangeable with the former American National threads of the same diameter and pitch.

The principal differences between the two systems lie in: 1) application of allowances; 2) variation of tolerances with size; 3) difference in amount of pitch diameter tolerance on external and internal threads; and 4) differences in thread designation.

In the Unified system an allowance is provided on both the Classes 1A and 2A external threads whereas in the American National system only the Class I external thread has an allowance. Also, in the Unified system, the pitch diameter tolerance of an internal thread is 30 per cent greater than that of the external thread, whereas they are equal in the American National system.

**Revised Standard.**—The revised screw thread standard ANSI/ASME B1.1-1989 (R2001) is much the same as that of ANSI B1.1-1982. The latest symbols in accordance with ANSI/ASME B1.7M-1984 (R2001) Nomenclature, are used. Acceptability criteria are described in ANSI/ASME B1.3M-1992 (R2001), Screw Thread Gaging Systems for Dimensional Acceptability, Inch or Metric Screw Threads (UN, UNR, UNJ, M, and MJ).

Where the letters U, A or B do not appear in the thread designations, the threads conform to the outdated American National screw threads.

**Advantages of Unified Threads.**—The Unified standard is designed to correct certain production difficulties resulting from the former standard. Often, under the old system, the tolerances of the product were practically absorbed by the combined tool and gage tolerances, leaving little for a working tolerance in manufacture. Somewhat greater tolerances are now provided for nut threads. As contrasted with the old “classes of fit” 1, 2, and 3, for each of which the pitch diameter tolerance on the external and internal threads were equal, the Classes 1B, 2B, and 3B (internal) threads in the new standard have, respectively, a 30 per cent larger pitch diameter tolerance than the 1A, 2A, and 3A (external) threads. Relatively more tolerance is provided for fine threads than for coarse threads of the same pitch. Where previous tolerances were more liberal than required, they were reduced.

**Thread Form.**—The Design Profiles for Unified screw threads, shown on page 1733, define the maximum material condition for external and internal threads with no allowance and are derived from the Basic Profile, shown on page 1726.

*UN External Screw Threads:* A flat root contour is specified, but it is necessary to provide for some threading tool crest wear, hence a rounded root contour cleared beyond the 0.25P flat width of the Basic Profile is optional.

*UNR External Screw Threads:* To reduce the rate of threading tool crest wear and to improve fatigue strength of a flat root thread, the Design Profile of the UNR thread has a smooth, continuous, non-reversing contour with a radius of curvature not less than 0.108P at any point and blends tangentially into the flanks and any straight segment. At the maximum material condition, the point of tangency is specified to be at a distance not less than 0.625H (where H is the height of a sharp V-thread) below the basic major diameter.

*UN and UNR External Screw Threads:* The Design Profiles of both UN and UNR external screw threads have flat crests. However, in practice, product threads are produced with partially or completely rounded crests. A rounded crest tangent at 0.125P flat is shown as an option on page 1733.

**UN Internal Screw Thread:** In practice it is necessary to provide for some threading tool crest wear, therefore the root of the Design Profile is rounded and cleared beyond the  $0.125P$  flat width of the Basic Profile. There is no internal UNR screw thread.

**American National Standard Unified Internal and External Screw Thread Design Profiles (Maximum Material Condition).—**

**Thread Series.**—Thread series are groups of diameter-pitch combinations distinguished from each other by the numbers of threads per inch applied to a specific diameter. The various diameter-pitch combinations of eleven standard series are shown in Table 2. The limits of size of threads in the eleven standard series together with certain selected combinations of diameter and pitch, as well as the symbols for designating the various threads, are given in Table 3. (Text continues on page 1763)

<sup>a</sup> Sizes shown in parentheses are secondary sizes. Primary sizes of 4 1/4, 4 1/2, 4 3/4, 5, 5 1/4, 5 1/2, 5 3/4 and 6 inches also are in the 4, 6, 8, 12, and 16 thread series; secondary sizes of 4 1/8, 4 3/8, 4 7/8, 5 1/8, 5 3/8, 5 7/8, and 5 7/16 also are in the 4, 6, 8, 12, and 16 thread series.

<sup>b</sup> For diameters over 1 1/2 inches, use 12-thread series.

<sup>c</sup> For diameters over 1 11/16 inches, use 16-thread series.

For UNR thread form substitute UNR for UN for external threads only.

Table 3. Standard Series and Selected Combinations — Unified Screw Threads

| Nominal Size,<br>Threads per Inch,<br>and Series<br>Designation <sup>a</sup> | External <sup>b</sup> |                |                  |        |                  |                  |        |   | Internal <sup>b</sup> |                |        |                |        |                   |
