All dimensions are in inches except where otherwise stated.  
 Chamfer Designation: P — Plug, B — Bottoming. These taps are high-speed steel.  
 Style 1 taps, sizes M1.6 through M5, have external center on thread and shank ends (may be removed on thread end of bottoming taps).  
 Style 2 taps, sizes M6, M7, M8, and M10, have external center on thread end (may be removed on bottoming taps) and external partial cone center on shank end with length of cone approximately  $\frac{1}{4}$  of diameter of shank.  
 Style 3 taps, sizes larger than M10 have external center on thread and shank ends.  
 For standard thread limits see [Tables 4a](#) and [4b](#).  
 For eccentricity tolerances of tap elements see [Table 22](#).

All dimensions are in inches except where otherwise stated.

Chamfer Designation: P — Plug. These taps are high-speed steel.

Style 1 taps, sizes M1.6 through M5, have external center on thread and shank ends.

Style 2 taps, sizes M6, M8 and M10, have external center on thread end and external partial cone center on shank end with length of cone approximately  $\frac{1}{4}$  of diameter of shank.

Style 3 taps, sizes larger than M10 have external center on thread and shank ends.

For standards thread limits see [Table 4a](#) and [4b](#).

For eccentricity tolerances of tap elements see [Table 22](#).

All dimensions are given in inches. These taps have an internal center in the thread end. *Taper Pipe Threads:* The 1/8-inch pipe tap is furnished with large size shank unless the small shank is specified. These taps have 2 to 3 1/2 threads chamfer. The first few threads on interrupted thread pipe taps are left full. The following styles and sizes are standard: 1/16 to 2 inches regular ground thread, NPT, NPTF, and ANPT; 1/8 to 2 inches interrupted ground thread, NPT, NPTF and ANPT; 1/8 to 3 inches carbon steel regular cut thread, NPT; 1/8 to 2 inches high-speed steel, regular cut thread, NPT; 1/8 to 1 1/4 inches high-speed steel interrupted cut thread, NPT. For standard thread limits see [Tables 6a](#) and [6b](#). *Straight Pipe Threads:* The 1/8-inch pipe tap is furnished with large size shank unless the small size is specified. These taps are standard with plug chamfer only. The following styles and sizes are standard: ground threads — 1/8 to 1 inch, NPSC and NPSM; 1/8 to 3/4 inch, NPSF; cut threads — 1/8 to 1 inch, NPSC and NPSM. For standard thread limits see [Tables 7a](#), [7b](#), and [7c](#). For eccentricity tolerances see [Table 22](#).

<sup>a</sup> Cut thread taps in all fractional sizes and in numbered sizes 3 to 12 NC and NF may be used under normal conditions and in average materials to produce tapped holes in this classification.

<sup>b</sup> Standard G H4 taps are also suitable for this class of thread.

All dimensions are given in inches.

The above recommended taps normally produce the class of thread indicated in average materials when used with reasonable care. However, if the tap specified does not give a satisfactory gage fit in the work, a choice of some other limit tap will be necessary.

**Standard System of Tap Marking.**—Ground thread taps, inch screw threads, are marked with the nominal size, number of threads per inch, the proper symbol to identify the thread form, “HS” for high-speed steel, “G” for ground thread, and designators for tap pitch diameter and special features, such as left-hand and multi-start threads.

Cut thread taps, inch screw threads, are marked with the nominal size, number of threads per inch, and the proper symbol to identify the thread form. High-speed steel taps are marked “HS,” but carbon steel taps need not be marked.

Ground thread taps made with metric screw threads, M profile, are marked with “M,” followed by the nominal size and pitch in millimeters, separated by “x.” Marking also includes “HS” for high-speed steel, “G” for ground thread, designators for tap pitch diameter and special features, such as left-hand and multi-start threads.

Thread symbol designators are listed in the accompanying table. Tap pitch diameter designators, systems of limits, special features, and examples for ground threads are given in the following section.

**Standard System Tap Thread Limits and Identification for Unified Inch Screw Threads, Ground Thread.**—*H or L Limits:* For Unified inch screw threads, when the maximum tap pitch diameter is over basic pitch diameter by an even multiple of 0.0005 in. or the minimum tap pitch diameter limit is under basic pitch diameter by an even multiple of 0.0005 in., the taps are marked “H” or “L,” respectively, followed by a limit number, determined as follows:

H limit number = Amount maximum tap PD limit is over basic PD divided by 0.0005

L limit number = Amount minimum tap PD limit is under basic PD divided by 0.0005

**Table 20. Thread Series Designations**

| Standard Tap Marking             | Product Thread Designation | Third Series  |

| NEF                              | UNREF                      | Extra-fine pitch series, with rounded root of radius not less than 0.108 <i>P</i> (ext. thd. only)                                  |
| NS                               | UNS                        | Special diameter pitch, or length of engagement   |

The PD limits for various H limit numbers are given in [Table 2](#). The PD limits for L limit numbers are determined as follows. The minimum tap PD equals the basic PD minus the number of half-thousandths (0.0005 in.) represented by the limit number. The maximum tap PD equals the minimum PD plus the PD tolerance given in [Table 21](#).

**Table 21. PD Tolerance for Unified Inch Screw Threads  
Ground Thread ASME B94.9-1999**

| Threads per Inch | To 1 in., incl. | Over 1 in. to 1½ in., incl. | Over 1½ to 2½ in., incl. | Over 2½ in. |
|------------------|-----------------|-----------------------------|--------------------------|-------------|
| 80-28            | 0.0005          | 0.0010                      | 0.0010                   | 0.0015      |
| 24-18            | 0.0005          | 0.0010                      | 0.0015                   | 0.0015      |
| 16-18            | 0.0005          | 0.0010                      | 0.0015                   | 0.0020      |
| 7-6              | 0.0010          | 0.0010                      | 0.0020                   | 0.0025      |
| 5½-4             | 0.0010          | 0.0015                      | 0.0020                   | 0.0025      |

*Example:*  $\frac{3}{8}$ -16 NC HS H1

Max. tap PD = 0.3349

Min. tap PD = 0.3344

*Example:*  $\frac{3}{8}$ -16 NC HS G L2

Min. tap PD = Basic PD - 0.0010 in. = 0.3344 - 0.0010 = 0.3334

Max. tap PD = Min. Tap PD + 0.0005 = 0.3334 + 0.0005 = 0.3339

*Overize or Undersize:* When the maximum tap PD over basic PD or the minimum tap PD under basic PD is not an even multiple of 0.0005, the tap PD is usually designated as an amount overize or undersize. The amount overize is added to the basic PD to establish the *minimum* tap PD. The amount undersize is subtracted from the basic PD to establish the *minimum* tap PD. The PD tolerance in [Table 21](#) is added to the minimum tap PD to establish the maximum tap PD for both.

*Example:*  $\frac{7}{16}$ -14 NC plus 0.0017 HS G

Min. tap PD = Basic PD + 0.0017 in.

Max. tap PD = Min. tap PD + 0.0005 in.

Whenever possible for overize or other special tap PD requirements, the maximum and minimum tap PD requirements should be specified.

*Special Tap Pitch Diameter:* Taps not made to H or L limit numbers, to [Table 22](#), or to the formula for overize or undersize taps, may be marked with the letter "S" enclosed by a circle or by some other special identifier. *Example:*  $\frac{1}{2}$ -16 NC HS G.

**Table 22. ANSI Standard Runout and Location Tolerance of Tap Elements  
ASME B94.9-1999**

| Element                                  | Range Sizes are Inclusive |          |                                  | Cut Thread   |                  | Ground Thread |                  | Location, inch |

|  | $\frac{1}{32}$ -4"        | M14-M100 | $\frac{1}{4}$ -4"                | 0.0030       | 0.0060           | 0.0015        | 0.0030           | ...            |

<sup>a</sup> tiv = total indicator variation. This data no longer included in Standard, but for reference figures are given for both eccentricity and total indicator variation to avoid misunderstanding.

<sup>b</sup> Chamfer should preferably be inspected by light projection to avoid errors due to indicator contact points dropping into the thread groove.

All dimensions are given in inches.

*Left-Hand Taps:* Taps with left-hand threads are marked "LEFT HAND" or "LH."

*Example:*  $\frac{3}{8}$ -16 NC LH HS G H3.

*Multiple-Start Threads:* Taps with multiple-start threads are marked with the lead designated as a fraction, also "Double," "Triple," etc. The Unified Screw Thread form symbol is always designated as "NS" for multiple-start threads. *Example:*  $\frac{3}{8}$ -16 NS Double  $\frac{1}{8}$  Lead HS G H5.

**Standard System of Ground Thread Tap Limits and Identification for Metric Screw Threads, M Profile.**—All calculations for metric taps use millimeter values. When U.S. customary values are needed, they are translated from the three-place millimeter tap diameters only after the calculations are completed.

**Table 23. PD Tolerance for Metric Screw Threads  
M Profile—Ground Threads ASME B94.9-1999**

| Pitch, $P$ (mm) | M1.6 to M6.3,<br>inclusive. | Over M6.3 to M25,<br>inclusive | Over M25 to M90,<br>inclusive | Over M90 |

*D or DU Limits:* When the maximum tap pitch diameter is over basic pitch diameter by an even multiple of 0.013 mm (0.000512 in. reference), or the minimum tap pitch diameter limit is under basic pitch diameter by an even multiple of 0.013 mm, the taps are marked with the letters "D" or "DU," respectively, followed by a limit number. The limit number is determined as follows:

D limit number = Amount maximum tap PD limit is over basic PD divided by 0.013

DU limit number = Amount minimum tap PD limit is under basic PD divided by 0.013

The PD limits for various D limit numbers are given in [Table 4b](#). The PD limits for DU limit numbers are determined as follows. The minimum tap PD equals the basic PD minus the number of millimeters represented by the limit number (multiples of 0.013 mm). The maximum tap PD equals the minimum tap PD plus the PD tolerance given in [Table 23](#).

*Example:* M1.6 × 0.35 HS G D3

Max. tap PD = 1.412

Min. tap PD = 1.397

M6 × 1 HS G DU4

Min. tap PD = Basic PD - 0.052 mm = 5.350 - 0.052 = 5.298

Max. tap PD = Min. tap PD + 0.025 mm = 5.323

Metric oversize or undersize taps, taps with special pitch diameters, and left-hand taps follow the marking system given for inch taps.

*Examples:* M12 × 1.75 + 0.044 HS G

M10 × 1.5 HS G

M10 × 1.5 LH HS G D6

*Multiple-Start Threads:* Metric taps with multiple-start threads are marked with the lead designated in millimeters preceded by the letter "L," the pitch in millimeters preceded by the letter "P," and the words "(2 starts)," "(3 starts)," etc.

*Examples:* M16 × L4-P2 (2 starts) HS G D8

M14 × L6-P2 (3 starts) HS G D7

### Acme and Square-Threaded Taps

These taps are usually made in sets, three taps in a set being the most common. For very fine pitches, two taps in a set will be found sufficient, whereas as many as five taps in a set are used for coarse pitches. The table on the next page gives dimensions for proportioning both Acme and square-threaded taps when made in sets. In cutting the threads of square-threaded taps, one leading tap maker uses the following rules: The width of the groove between two threads is made equal to one-half the pitch of the thread, less 0.004 inch, making the width of the thread itself equal to one-half of the pitch, plus 0.004 inch. The depth of the thread is made equal to 0.45 times the pitch, plus 0.0025 inch. This latter rule produces a thread that for all the ordinarily used pitches for square-threaded taps has a depth less than the generally accepted standard depth, this latter depth being equal to one-half the pitch. The object of this shallow thread is to ensure that if the hole to be threaded by the tap is not bored out so as to provide clearance at the bottom of the thread, the tap will cut its own clearance. The hole should, however, always be drilled out large enough so that the cutting of the clearance is not required of the tap.

The table, *Dimensions of Acme Threads Taps in Sets of Three Taps*, may also be used for the length dimensions for Acme taps. The dimensions in this table apply to single-threaded taps. For multiple-threaded taps or taps with very coarse pitch, relative to the diameter, the length of the chamfered part of the thread may be increased. Square-threaded taps are made to the same table as Acme taps, with the exception of the figures in column *K*, which for square-threaded taps should be equal to the nominal diameter of the tap, no oversize allowance being customary in these taps. The first tap in a set of Acme taps (not square-threaded taps) should be turned to a taper at the bottom of the thread for a distance of about one-quarter of the length of the threaded part. The taper should be so selected that the root diameter is about  $\frac{1}{32}$  inch smaller at the point than the proper root diameter of the tap. The first tap should preferably be provided with a short pilot at the point. For very coarse pitches, the first tap may be provided with spiral flutes at right angles to the angle of the thread. Acme and square-threaded taps should be relieved or backed off on the top of the thread of the chamfered portion on all the taps in the set. When the taps are used as machine taps, rather than as hand taps, they should be relieved in the angle of the thread, as well as on the top,

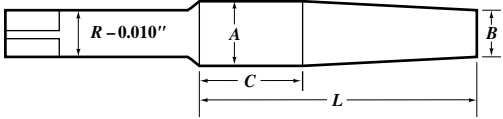

**Table 24. Dimensions of Acme Threads Taps in Sets of Three Taps**

The diagram illustrates the dimensions of three different Acme thread taps in a set. The 1st Tap in Set has dimensions A, B, C, D, and E. The 2nd Tap in Set has dimensions F and G. The Finishing Tap has dimensions H, I, and K. All three taps have a root diameter of -0.010 inches.

| Nominal Dia. | A      | B       | C       | D       | E       | F      | G       | H      | I      | K     |
|--------------|--------|---------|---------|---------|---------|--------|---------|--------|--------|-------|
| 1/2          | 4 1/4  | 1 7/8   | 2 3/8   | 1/2     | 1 7/8   | 5/8    | 1 3/4   | 7/8    | 1 1/2  | 0.520 |
| 9/16         | 4 7/8  | 2 1/8   | 2 3/4   | 9/16    | 2 3/16  | 3/4    | 2       | 1      | 1 3/4  | 0.582 |
| 5/8          | 5 1/2  | 2 3/8   | 3 3/8   | 5/8     | 2 1/2   | 7/8    | 2 1/4   | 1 1/8  | 2      | 0.645 |
| 11/16        | 6      | 2 1/2   | 3 1/2   | 3 13/16 | 2 13/16 | 15/16  | 2 1/16  | 1 1/4  | 2 1/4  | 0.707 |
| 3/4          | 6 1/2  | 2 11/16 | 3 13/16 | 1 1/16  | 3 3/8   | 1      | 2 13/16 | 1 3/8  | 2 7/16 | 0.770 |
| 13/16        | 6 7/8  | 2 13/16 | 4 1/16  | 3/4     | 3 5/16  | 1 1/16 | 3       | 1 7/16 | 2 5/8  | 0.832 |
| 7/8          | 7 1/4  | 3       | 4 1/4   | 3/4     | 3 1/2   | 1 1/8  | 3 3/8   | 1 1/2  | 2 3/4  | 0.895 |
| 15/16        | 7 7/16 | 3 1/8   | 4 7/16  | 13/16   | 3 3/8   | 1 3/16 | 3 1/4   | 1 9/16 | 2 7/8  | 0.957 |
| 1            | 7 7/8  | 3 1/4   | 4 5/8   | 13/16   | 3 13/16 | 1 1/4  | 3 3/8   | 1 5/8  | 3      | 1.020 |
| 1 1/8        | 8 1/2  | 3 9/16  | 4 15/16 | 7/8     | 4 1/16  | 1 5/16 | 3 5/8   | 1 3/4  | 3 3/16 | 1.145 |
| 1 1/4        | 9      | 3 3/4   | 5 1/4   | 15/16   | 4 5/16  | 1 3/8  | 3 7/8   | 1 7/8  | 3 3/8  | 1.270 |
| 1 3/8        | 9 1/2  | 4       | 5 1/2   | 1       | 4 1/2   | 1 7/16 | 4 1/16  | 2      | 3 1/2  | 1.395 |
| 1 1/2        | 10     | 4 1/4   | 5 3/4   | 1       | 4 3/4   | 1 1/2  | 4 1/4   | 2 1/8  | 3 5/8  | 1.520 |
| 1 5/8        | 10 1/2 | 4 1/2   | 6       | 1       | 5       | 1 1/2  | 4 1/2   | 2 1/8  | 3 7/8  | 1.645 |
| 1 3/4        | 11     | 4 3/4   | 6 1/4   | 1 1/16  | 5 3/16  | 1 9/16 | 4 11/16 | 2 1/4  | 4      | 1.770 |
| 1 7/8        | 11 3/8 | 4 7/8   | 6 1/2   | 1 1/16  | 5 7/16  | 1 9/16 | 4 15/16 | 2 1/4  | 4 1/4  | 1.895 |
| 2            | 11 3/4 | 5       | 6 3/4   | 1 1/8   | 5 5/8   | 1 5/8  | 5 1/8   | 2 3/8  | 4 3/8  | 2.020 |
| 2 1/4        | 12 1/2 | 5 1/4   | 7 1/4   | 1 1/8   | 6 3/8   | 1 3/16 | 5 1/2   | 2 1/2  | 4 3/4  | 2.270 |
| 2 1/2        | 13 1/4 | 5 1/2   | 7 3/4   | 1 3/4   | 6 9/16  | 1 7/8  | 5 7/8   | 2 5/8  | 5 1/8  | 2.520 |
| 2 3/4        | 14     | 5 3/4   | 8 1/4   | 1 1/4   | 7       | 2      | 6 1/4   | 2 3/4  | 5 1/2  | 2.770 |
| 3            | 15     | 6 1/4   | 8 3/4   | 1 1/4   | 7 1/2   | 2      | 6 3/4   | 3      | 5 3/4  | 3.020 |

for the whole length of the chamfered portion. Acme taps should also always be relieved on the front side of the thread to within 1/32 inch of the cutting edge.

*Adjustable Taps:* Many adjustable taps are now used, especially for accurate work. Some taps of this class are made of a solid piece of tool steel that is split and provided with means of expanding sufficiently to compensate for wear. Most of the larger adjustable taps have inserted blades or chasers that are held rigidly, but are capable of radial adjustment. The use of taps of this general class enables standard sizes to be maintained readily.

**Table 25. Proportions of Acme and Square-Threaded Taps Made in Sets**

$R =$  root diameter of thread.  $D =$  full diameter of tap.  
 $T =$  double depth of full thread.

| Kind of Tap      | No. of Taps in Set   | Order of Tap in Set | A            | B                    | C                                |
|------------------|----------------------|---------------------|--------------|----------------------|----------------------------------|
| Acme Thread Taps | 2                    | 1st                 | $R + 0.65T$  | $R + 0.010$          | $\frac{1}{8}L$ to $\frac{1}{6}L$ |
|                  |                      | 2d                  | $D$          | A on 1st tap - 0.005 | $\frac{1}{4}L$ to $\frac{1}{3}L$ |
|                  | 3                    | 1st                 | $R + 0.45T$  | $R + 0.010$          | $\frac{1}{8}L$ to $\frac{1}{6}L$ |
|                  |                      | 2d                  | $R + 0.80T$  | A on 1st tap - 0.005 | $\frac{1}{6}L$ to $\frac{1}{4}L$ |

**Drill Hole Sizes for Acme Threads.**—Many tap and die manufacturers and vendors make available to their customers computer programs designed to calculate drill hole sizes for all the Acme threads in their ranges from the basic dimensions. The large variety and combination of dimensions for such tools prevent inclusion of a complete set of tables of tap drills for Acme taps in this Handbook. The following formulas (dimensions in inches) for calculating drill hole sizes for Acme threads are derived from the American National Standard, ANSI/ASME B1.5-1997, Acme Screw Threads.

To select a tap drill size for an Acme thread, first calculate the maximum and minimum internal product minor diameters for the thread to be produced. (Dimensions for general purpose, centralizing, and stub Acme screw threads are given in the Threads and Threading section, starting on page 1825.) Then select a drill that will yield a finished hole somewhere between the established maximum and minimum product minor diameters. Consider staying close to the maximum product limit in selecting the hole size, to reduce the amount of material to be removed when cutting the thread. If there is no standard drill size that matches the hole diameter selected, it may be necessary to drill and ream, or bore the hole to size, to achieve the required hole diameter.

*Diameters of General-Purpose Acme Screw Threads of Classes 2G, 3G, and 4G* may be calculated from:

minimum diameter = basic major diameter – pitch

maximum diameter = minimum minor diameter +  $0.05 \times$  pitch

pitch =  $1/\text{number of threads per inch}$

*Example:*  $\frac{1}{2}$ -10 Acme 2G, pitch =  $1/10 = 0.1$

minimum diameter =  $0.5 - 0.1 = 0.4$

maximum diameter =  $0.4 + (0.05 \times 0.1) = 0.405$

drill selected = letter X or  $0.3970 + 0.0046$  (probable oversize) = 0.4016

*Diameters of Acme Centralizing Screw Threads of Classes 2C, 3C, and 4C* may be calculated from:

minimum diameter = basic major diameter –  $0.9 \times$  pitch

maximum diameter = minimum minor diameter +  $0.05 \times$  pitch

pitch =  $1/\text{number of threads per inch}$

*Example:*  $\frac{1}{2}$ -10 Acme 2C, pitch =  $1/10 = 0.1$

minimum diameter =  $0.5 - (0.9 \times 0.1) = 0.41$

maximum diameter =  $0.41 + (0.05 \times 0.1) = 0.415$

drill selected =  $\frac{13}{32}$  or  $0.4062 + 0.0046$  (probable oversize) = 0.4108.

*Diameters for Acme Centralizing Screw Threads of Classes 5C and 6C:* These classes are not recommended for new designs, but may be calculated from:

minimum diameter = [basic major diameter –  $(0.025 \sqrt{\text{basic major diameter}})$ ] –  $0.9 \times$  pitch

maximum diameter = minimum minor diameter +  $0.05 \times$  pitch

pitch =  $1/\text{number of threads per inch}$

*Example:*  $\frac{1}{2}$ -10 Acme 5C, pitch =  $1/10 = 0.1$

minimum diameter =  $[0.5 - (0.025 \sqrt{0.5})] - (0.9 \times 0.1) = 0.3923$

maximum diameter =  $0.3923 + (0.05 \times 0.1) = 0.3973$

drill selected =  $\frac{25}{64}$  or  $0.3906 + 0.0046$  (probable oversize) = 0.3952

**British Standard Screwing Taps for ISO Metric Threads.**—BS 949: Part 1:1976 provides dimensions and tolerances for screwing taps for ISO metric coarse-pitch series threads in accordance with BS 3643: Part 2; and for metric fine-pitch series threads in accordance with BS 3643: Part 3.

Table 26 provides dimensional data for the cutting portion of cut-thread taps for coarse-series threads of ISO metric sizes. The sizes shown were selected from the first-choice combinations of diameter and pitch listed in BS 3643:Part 1:1981 (1998). Table 13 provides similar data for ground-thread taps for both coarse- and fine-pitch series threads of ISO metric sizes.

**Table 26. British Standard Screwing Taps for ISO Metric Threads  
Dimensional Limits for the Threaded Portion of Cut Taps—  
Coarse Pitch Series BS 949: Part 1:1976**

| Designation | Pitch | Major Diameter       |        | Pitch Diameter |        |      | Tolerance on Thread Angle, Degrees |
|-------------|-------|----------------------|--------|----------------|--------|------|------------------------------------|
|             |       | Minimum <sup>a</sup> | Basic  | Max.           | Min.   | Min. |                                    |
| M1          | 0.25  | 1.030                | 0.838  | 0.875          | 0.848  | 4.0  |                                    |

<sup>a</sup> The maximum tap major diameter,  $d_{\max}$ , is not specified and is left to the manufacturer's discretion.

All dimension are in millimeters. The thread sizes in the table have been selected from the preferred series shown in BS 3643:Part 1:1981 (1998). For other sizes, and for second and third choice combinations of diameters and pitches, see the Standard.

**Tolerance Classes of Taps:** Three tolerance classes (class 1, class 2, and class 3) are used for the designation of taps used for the production of nuts of the following classes:

nut classes 4H, 5H, 6H, 7H, and 8H, all having zero minimum clearance;

nut classes 4G, 5G, and 6G, all having positive minimum clearance.

The tolerances for the three classes of taps are stated in terms of a tolerance unit  $t$ , the value of which is equal to the pitch diameter tolerance,  $T_{D_2}$ , grade 5, of the nut. Thus,  $t = T_{D_2}$ , grade 5, of the nut. Taps of the different classes vary in the limits of size of the tap pitch diameter. The tolerance on the tap pitch diameter,  $T_{d_2}$ , is the same for all three classes of taps (20 percent of  $t$ ), but the position of the tolerance zone with respect to the basic pitch diameter depends upon the lower deviation value  $Em$  which is: for tap class 1,  $Em = +0.1t$ ; for tap class 2,  $Em = +0.3t$ ; and for tap class 3,  $Em = +0.5t$ .

The disposition of the tolerances described is shown in the accompanying illustration of nut class tolerances compared against tap class tolerances. The distance  $EI$  shown in this illustration is the minimum clearance, which is zero for  $H$  classes and positive for  $G$  classes of nuts.

**Choice of Tap Tolerance Class:** Unless otherwise specified, class 1 taps are used for nuts of classes 4H and 5H; class 2 taps for nuts of classes 6H, 4G, and 5G; and class 3 taps for nuts of classes 7H, 8H, and 6G. This relationship of tap and nut classes is a general one, since the accuracy of tapping varies with a number of factors such as the material being tapped, the condition of the machine tool used, the tapping attachment used, the tapping speed, and the lubricant.

**Tap Major Diameter:** Except when a screwed connection has to be tight against gaseous or liquid pressure, it is undesirable for the mating threads to bear on the roots and crests. By avoiding contact in these regions of the threads, the opposite flanks of the two threads are allowed to make proper load bearing contact when the connection is tightened. In general, the desired clearance between crests and roots of mating threads is obtained by increasing the major and minor diameters of the internal thread. Such an increase in the minor diameter is already provided on threads such as the ISO metric thread, in which there is a basic clearance between the crests of minimum size nuts and the roots of maximum size bolts. For this reason, and the fact that taps are susceptible to wear on the crests of their threads, a minimum size is specified for the major diameter of new taps which provides a reasonable margin for the wear of their crests and at the same time provides the desired clearance at the major diameter of the hole. These minimum major diameters for taps are shown in [Tables 26 and 13](#). The maximum tap major diameter is not specified and is left to the manufacturer to take advantage of this concession to produce taps with as liberal a margin possible for wear on the major diameter.

**Tapping Square Threads.**—If it is necessary to tap square threads, this should be done by using a set of taps that will form the thread by a progressive cutting action, the taps varying in size in order to distribute the work, especially for threads of comparatively coarse pitch. From three to five taps may be required in a set, depending upon the pitch. Each tap should have a pilot to steady it. The pilot of the first tap has a smooth cylindrical end from 0.003 to 0.005 inch smaller than the hole, and the pilots of following taps should have teeth.

## STANDARD TAPERS

## Standard Tapers

Certain types of small tools and machine parts, such as twist drills, end mills, arbors, lathe centers, etc., are provided with taper shanks which fit into spindles or sockets of corresponding taper, thus providing not only accurate alignment between the tool or other part and its supporting member, but also more or less frictional resistance for driving the tool. There are several standards for "self-holding" tapers, but the American National, Morse, and the Brown & Sharpe are the standards most widely used by American manufacturers.

The name *self-holding* has been applied to the smaller tapers—like the Morse and the Brown & Sharpe—because, where the angle of the taper is only 2 or 3 degrees, the shank of a tool is so firmly seated in its socket that there is considerable frictional resistance to any force tending to turn or rotate the tool relative to the socket. The term "self-holding" is used to distinguish relatively small tapers from the larger or *self-releasing* type. A milling machine spindle having a taper of  $3\frac{1}{2}$  inches per foot is an example of a self-releasing taper. The included angle in this case is over 16 degrees and the tool or arbor requires a positive locking device to prevent slipping, but the shank may be released or removed more readily than one having a smaller taper of the self-holding type.

**Morse Taper.**—Dimensions relating to Morse standard taper shanks and sockets may be found in an accompanying table. The taper for different numbers of Morse tapers is slightly different, but it is approximately  $\frac{5}{8}$  inch per foot in most cases. The table gives the actual tapers, accurate to five decimal places. Morse taper shanks are used on a variety of tools, and exclusively on the shanks of twist drills. Dimensions for *Morse Stub Taper Shanks* are given in [Table 1a](#), and for *Morse Standard Taper Shanks* in [Table 1b](#).

**Brown & Sharpe Taper.**—This standard taper is used for taper shanks on tools such as end mills and reamers, the taper being approximately  $\frac{1}{2}$  inch per foot for all sizes except for taper No. 10, where the taper is 0.5161 inch per foot. Brown & Sharpe taper sockets are used for many arbors, collets, and machine tool spindles, especially milling machines and grinding machines. In many cases there are a number of different lengths of sockets corresponding to the same number of taper; all these tapers, however, are of the same diameter at the small end.

**Jarno Taper.**—The Jarno taper was originally proposed by Oscar J. Beale of the Brown & Sharpe Mfg. Co. This taper is based on such simple formulas that practically no calculations are required when the number of taper is known. The taper per foot of all Jarno taper sizes is 0.600 inch on the diameter. The diameter at the large end is as many eighths, the diameter at the small end is as many tenths, and the length as many half inches as are indicated by the number of the taper. For example, a No. 7 Jarno taper is  $\frac{7}{8}$  inch in diameter at the large end;  $\frac{7}{10}$ , or 0.700 inch at the small end; and  $\frac{7}{2}$ , or  $3\frac{1}{2}$  inches long; hence, diameter at large end = No. of taper  $\div$  8; diameter at small end = No. of taper  $\div$  10; length of taper = No. of taper  $\div$  2. The Jarno taper is used on various machine tools, especially profiling machines and die-sinking machines. It has also been used for the headstock and tailstock spindles of some lathes.

*American National Standard Machine Tapers:* This standard includes a self-holding series ([Tables 2, 3, 4, 5](#) and [7a](#)) and a steep taper series, [Table 6](#). The self-holding taper series consists of 22 sizes which are listed in [Table 7a](#). The reference gage for the self-holding tapers is a plug gage. [Table 7b](#) gives the dimensions and tolerances for both plug and ring gages applying to this series. [Tables 2](#) through [5](#) inclusive give the dimensions for self-holding taper shanks and sockets which are classified as to (1) means of transmitting torque from spindle to the tool shank, and (2) means of retaining the shank in the socket. The steep machine tapers consist of a preferred series (bold-face type, [Table 6](#)) and an intermediate series (light-face type). A self-holding taper is defined as "a taper with an

angle small enough to hold a shank in place ordinarily by friction without holding means. (Sometimes referred to as slow taper.)" A steep taper is defined as "a taper having an angle sufficiently large to insure the easy or self-releasing feature." The term "gage line" indicates the basic diameter at or near the large end of the taper.

<sup>a</sup>These are basic dimensions.

<sup>b</sup>These dimensions are calculated for reference only.

All dimensions in inches.

Radius *J* is  $\frac{3}{64}$ ,  $\frac{1}{16}$ ,  $\frac{5}{64}$ ,  $\frac{3}{32}$ , and  $\frac{1}{8}$  inch respectively for Nos. 1, 2, 3, 4, and 5 tapers.

All dimensions are in inches. (1) See [Table 7b](#) for plug and ring gage dimensions.

**Tolerances:** For shank diameter A at gage line, + 0.002 – 0.000; for hole diameter A, + 0.000 – 0.002. For tang thickness E up to No. 5 inclusive, + 0.000 – 0.006; No. 6, + 0.000 – 0.008. For width N of tang slot up to No. 5 inclusive, + 0.006; – 0.000; No. 6, + 0.008 – 0.000. For centrality of tang E with center line of taper, 0.0025 (0.005 total indicator variation). These centrality tolerances also apply to the tang slot N. On rate of taper, all sizes 0.002 per foot. This tolerance may be applied on *shanks* only in the direction which *increases* the rate of taper and on *sockets* only in the direction which *decreases* the rate of taper. Tolerances for two-decimal dimensions are plus or minus 0.010, unless otherwise specified.

All dimensions are in inches. (1) See [Table 7b](#) for plug and ring gage dimensions.

**Tolerances:** For shank diameter A at gage line, +0.002, -0; for hole diameter A, +0, -0.002. For tang thickness E up to No. 5 inclusive, +0, -0.006; larger than No. 5, +0, -0.008. For width of slots N and N' up to No. 5 inclusive, +0.006, -0; larger than No. 5, +0.008, -0. For centrality of tang E with center line of taper 0.0025 (0.005 total indicator variation). These centrality tolerances also apply to slots N and N'. On rate of taper, see footnote in [Table 2](#). Tolerances for two-decimal dimensions are ±0.010 unless otherwise specified.

<sup>a</sup> Thread is UNF-2B for hole; UNF-2A for screw. (1) See Table 7b for plug and ring gage dimensions.

All dimensions are in inches. AE is 0.005 greater than one-half of A.

Width of drive key R'' is 0.001 less than width R'' of keyway.

**Tolerances:** For diameter A of hole at gage line, +0, -0.002; for diameter A of shank at gage line, +0.002, -0; for width of slots N and N', +0.008, -0; for width of drive keyway R' in socket, +0, -0.001; for width of drive keyway R in shank, 0.010, -0; for centrality of slots N and N' with center line of spindle, 0.007; for centrality of keyway with spindle center line: for R, 0.004 and for R', 0.002 T.I.V. On rate of taper, see footnote in Table 2. Two-decimal dimensions, ±0.010 unless otherwise specified.

**Table 5. American National Standard Nose Key Drive with Drawbolt, Self-Holding Tapers ANSI/ASME B5.10-1994 (R2002)**

All dimensions in inches.

Exposed length  $C$  is 0.003 minimum and 0.035 maximum for all sizes.

Drive Key  $D'$  screw sizes are  $\frac{3}{8}$ -24 UNF-2A up to taper No. 400 inclusive and  $\frac{1}{2}$ -20 UNF-2A for larger tapers.

**Tolerances:** For diameter  $A$  of hole at gage line, +0.000, -0.002 for all sizes; for diameter  $A$  of shank at gage line, +0.002, -0.000; for all sizes; for width of drive keyway  $R'$  in socket, +0.000, -0.001; for width of drive keyway  $R$  in shank, +0.010, -0.000; for centrality of drive keyway  $R'$ , with center line of shank, 0.004 total indicator variation, and for drive keyway  $R'$ , with center line of spindle, 0.002. On rate of taper, see footnote in Table 2. Tolerances for two-decimal dimensions are ±0.010 unless otherwise specified.

<sup>a</sup>This taper corresponds to an included angle of 16°, 35', 39.4".

<sup>b</sup>The basic diameter at gage line is at large end of taper.

All dimensions given in inches.

The tapers numbered 10, 20, 30, 40, 50, and 60 that are printed in heavy-faced type are designated as the "Preferred Series." The tapers numbered 5, 15, 25, 35, 45, and 55 that are printed in light-faced type are designated as the "Intermediate Series."

<sup>a</sup> The taper per foot and diameter A at gage line are basic dimensions. Dimensions in Column A' are calculated for reference only.

<sup>b</sup> Tolerances for diameter A are plus for plug gages and minus for ring gages.

All dimensions are in inches.

The amount of taper deviation for Class X, Class Y, and Class Z gages are the same, respectively, as the amounts shown for tolerances on diameter A. Taper deviation is the permissible allowance from true taper at any point of diameter in the length of the gage. On taper *plug* gages, this deviation may be applied only in the direction which *decreases* the rate of taper. On taper *ring* gages, this deviation may be applied only in the direction which *increases* the rate of taper. Tolerances on two-decimal dimensions are  $\pm 0.010$ .

**British Standard Tapers.**—British Standard 1660: 1972, "Machine Tapers, Reduction Sleeves, and Extension Sockets," contains dimensions for self-holding and self-releasing tapers, reduction sleeves, extension sockets, and turret sockets for tools having Morse and metric 5 per cent taper shanks. Adapters for use with  $\frac{7}{24}$  tapers and dimensions for spindle noses and tool shanks with self-release tapers and cotter slots are included in this Standard.

Table 8. Dimensions of Morse Taper Sleeves

The diagram shows a Morse Taper Sleeve with various dimensions labeled. A is the number of Morse Taper Outside, and B is the number of Morse Taper Inside. Dimensions C, D, E, F, G, H, I, K, L, and M are indicated with arrows and lines. C is the total length, D is the outer diameter at the large end, E is the diameter at the small end, F is the diameter of the hole at the small end, G is the diameter of the hole at the large end, H is the length of the hole, I is the taper diameter, K is the length of the sleeve, L is the length of the hole, and M is the diameter of the hole at the large end.

| A | B | C                               | D     | E     | F     | G     | H     | I     | K       | L      | M     |

Table 9. Morse Taper Sockets — Hole and Shank Sizes

The diagram shows a Morse Taper Socket with a hole and a shank. The hole is shown with a dashed line, and the shank is shown with a solid line. The hole and shank are both tapered.

<sup>a</sup> Special lengths of keyway are used instead of standard lengths in some places. Standard lengths need not be used when keyway is for driving only and not for admitting key to force out tool.

<sup>b</sup> "B & S Standard" Plug Depths are not used in all cases.

<sup>c</sup> Adopted by American Standards Association.

Table 11. Jarno Taper Shanks

$$D = \frac{\text{no. of taper}}{8} \quad C = \frac{\text{no. of taper}}{10} \quad B = \frac{\text{no. of taper}}{2}$$

| Number of Taper | Length A          | Length B        | Diameter C | Diameter D | Taper per foot |

**Tapers for Machine Tool Spindles.**—Most lathe spindles have Morse tapers, most milling machine spindles have American Standard tapers, almost all smaller milling machine spindles have R8 tapers, and large vertical milling machine spindles have American Standard tapers. The spindles of drilling machines and the taper shanks of twist drills are made to fit the Morse taper. For lathes, the Morse taper is generally used, but lathes may have the Jarno, Brown & Sharpe, or a special taper. Of 33 lathe manufacturers, 20 use the Morse taper; 5, the Jarno; 3 use special tapers of their own; 2 use modified Morse (longer than the standard but the same taper); 2 use Reed (which is a short Jarno); 1 uses the Brown & Sharpe standard. For grinding machine centers, Jarno, Morse, and Brown & Sharpe tapers are used. Of ten grinding machine manufacturers, 3 use Brown & Sharpe; 3 use Morse; and 4 use Jarno. The Brown & Sharpe taper is used extensively for milling machine and dividing head spindles. The standard milling machine spindle adopted in 1927 by the milling machine manufacturers of the National Machine Tool Builders' Association (now The Association for Manufacturing Technology [AMT]), has a taper of 3 $\frac{1}{2}$  inches per foot. This comparatively steep taper was adopted to ensure easy release of arbors.

**Table 12. American National Standard Plug and Ring Gages for Steep Machine Tapers ANSI/ASME B5.10-1994 (R2002)**

| No. of Taper | Taper per Foot <sup>a</sup> (Basic) | Diameter at Gage Line <sup>a</sup> A | Tolerances for Diameter A <sup>b</sup> |              |              | Diameter at Small End <sup>a</sup> A' | Length Gage Line to Small End L | Overall Length of Gage Body B | Dia. of Opening C |

<sup>a</sup>The taper per foot and diameter A at gage line are basic dimensions. Dimensions in Column A' are calculated for reference only.

<sup>b</sup>Tolerances for diameter A are plus for plug gages and minus for ring gages.

All dimensions are in inches.

The amounts of taper deviation for Class X, Class Y, and Class Z gages are the same, respectively, as the amounts shown for tolerances on diameter A. Taper deviation is the permissible allowance from true taper at any point of diameter in the length of the gage. On taper *plug* gages, this deviation may be applied only in the direction which *decreases* the rate of taper. On taper *ring* gages, this deviation may be applied only in the direction which *increases* the rate of taper. Tolerances on two-decimal dimensions are  $\pm 0.010$ .

**Table 13. Jacobs Tapers and Threads for Drill Chucks and Spindles**

American Standard Thread Form

| Taper Series       | A      | B       | C       | Taper per Ft. | Taper Series | A      | B      | C      | Taper per Ft. |

<sup>a</sup>Except for 1-8, 1-10, 1 1/2-8 all threads are now manufactured to the American National Standard Unified Screw Thread System, Internal Class 2B, External Class 2A. Effective date 1976.

<sup>b</sup>Tolerances for dimension *H* are as follows: 0.030 inch for thread sizes 5/16-24 to 3/4-16, inclusive and 0.125 inch for thread sizes 1-8 to 1 1/2-8, inclusive.

<sup>c</sup>Length for Jacobs 0B5/16 chuck is 0.375 inch, length for 1B5/16 chuck is 0.437 inch.

<sup>d</sup>Length for Jacobs No. 1BS chuck is 0.437 inch.

*Usual Chuck Capacities for Different Taper Series Numbers:* No. 0 taper, drill diameters, 0-5/32 inch; No. 1, 0-1/4 inch; No. 2, 0-1/2 inch; No. 2 "Short," 0-5/16 inch; No. 3, 0-1/2, 1/8-5/8, 3/16-3/4, or 1/4-13/16 inch; No. 4, 1/8-3/4 inch; No. 5, 3/8-1; No. 6, 0-1/2 inch; No. 33, 0-1/2 inch.

*Usual Chuck Capacities for Different Thread Sizes:* Size 5/16-24, drill diameters 0-1/4 inch; size 3/8-24, drill diameters 0-3/8, 1/16-3/8, or 5/64-1/2 inch; size 1/2-20, drill diameters 0-1/2, 1/16-3/8, or 5/64-1/2 inch; size 5/8-11, drill diameters 0-1/2 inch; size 5/8-16, drill diameters 0-1/2, 1/8-5/8, or 3/16-3/4 inch; size 45/64-16, drill diameters 0-1/2 inch; size 3/4-16, drill diameters 0-1/2 or 3/16-3/4.

All dimensions are given in inches.

**Tolerances:**

Two-digit decimal dimensions  $\pm 0.010$  unless otherwise specified.

*A*—Taper: Tolerance on rate of taper to be 0.001 inch per foot applied only in direction which decreases rate of taper.

*F'*—Centrality of keyway with axis of taper 0.002 total at maximum material condition. (0.002 Total indicator variation)

*F*—Centrality of solid key with axis of taper 0.002 total at maximum material condition. (0.002 Total indicator variation)

*Note 1*: Holes spaced as shown and located within 0.006 inch diameter of true position.

*Note 2*: Holes spaced as shown and located within 0.010 inch diameter of true position.

*Note 3*: Maximum turnout on test plug:

0.0004 at 1 inch projection from gage line.

0.0010 at 12 inch projection from gage line.

*Note 4*: Squareness of mounting face measured near mounting bolt hole circle.

All dimensions are given in inches.

*Tolerances:* Two digit decimal dimensions  $\pm 0.010$  inch unless otherwise specified.

*M*—Permissible for Class 2B “NoGo” gage to enter five threads before interference.

*N*—Taper tolerance on rate of taper to be 0.001 inch per foot applied only in direction which increases rate of taper.

*Y*—Centrality of drive slot with axis of taper shank 0.004 inch at maximum material condition. (0.004 inch total indicator variation)

All dimensions are given in inches.

**Tolerances:** Two-digit decimal dimensions ± 0.010 unless otherwise specified.

A—Tolerance on rate of taper to be 0.001 inch per foot applied only in direction which decreases rate of taper.

F—Centrality of solid key with axis of taper 0.002 inch total at maximum material condition. (0.002 inch Total indicator variation)

F<sub>1</sub>—Centrality of keyseat with axis of taper 0.002 inch total at maximum material condition. (0.002 inch Total indicator variation)

**Note 1:** Maximum runout on test plug: 0.0004 at 1 inch projection from gage line. 0.0010 at 12 inch projection from gage line.

**Note 2:** Squareness of mounting face measured near mounting bolt hole circle.

**Note 3:** Holes located as shown and within 0.010 inch diameter of true position.

## ARBORS, CHUCKS, AND SPINDLES

## Portable Tool Spindles

**Circular Saw Arbors.**—ANSI Standard B107.4-1982 “Driving and Spindle Ends for Portable Hand, Air, and Air Electric Tools” calls for a round arbor of  $\frac{5}{8}$ -inch diameter for nominal saw blade diameters of 6 to 8.5 inches, inclusive, and a  $\frac{3}{4}$ -inch diameter round arbor for saw blade diameters of 9 to 12 inches, inclusive.

**Spindles for Geared Chucks.**—Recommended threaded and tapered spindles for portable tool geared chucks of various sizes are as given in the following table:

Recommended Spindle Sizes

| Chuck Sizes,<br>Inch                    | Recommended Spindles                   |                    |
|---|--|--------------------|
|   | Threaded                               | Taper <sup>a</sup> |
| $\frac{3}{16}$ and $\frac{1}{4}$ Light  | $\frac{3}{8}$ -24                      | 1                  |
| $\frac{1}{4}$ and $\frac{5}{16}$ Medium | $\frac{3}{8}$ -24 or $\frac{1}{2}$ -20 | 2 Short            |
| $\frac{3}{8}$ Light                     | $\frac{3}{8}$ -24 or $\frac{1}{2}$ -20 | 2                  |
| $\frac{3}{8}$ Medium                    | $\frac{1}{2}$ -20 or $\frac{5}{8}$ -16 | 2                  |
| $\frac{1}{2}$ Light                     | $\frac{1}{2}$ -20 or $\frac{5}{8}$ -16 | 33                 |
| $\frac{1}{2}$ Medium                    | $\frac{5}{8}$ -16 or $\frac{3}{4}$ -16 | 6                  |
| $\frac{5}{8}$ and $\frac{3}{4}$ Medium  | $\frac{5}{8}$ -16 or $\frac{3}{4}$ -16 | 3                  |

<sup>a</sup>Jacobs number.

**Vertical and Angle Portable Tool Grinder Spindles.**—The  $\frac{5}{8}$ -11 spindle with a length of  $1\frac{1}{8}$  inches shown on page 950 is designed to permit the use of a jam nut with threaded cup wheels. When a revolving guard is used, the length of the spindle is measured from the wheel bearing surface of the guard. For unthreaded wheels with a  $\frac{7}{8}$ -inch hole, a safety sleeve nut is recommended. The unthreaded wheel with  $\frac{5}{8}$ -inch hole is not recommended because a jam nut alone may not resist the inertia effect when motor power is cut off.

**Straight Grinding Wheel Spindles for Portable Tools.**—Portable grinders with pneumatic or induction electric motors should be designed for the use of organic bond wheels rated 9500 feet per minute. Light-duty electric grinders may be designed for vitrified wheels rated 6500 feet per minute. Recommended maximum sizes of wheels of both types are as given in the following table:

Recommended Maximum Grinding Wheel Sizes for Portable Tools

| Spindle<br>Size                    | Maximum Wheel Dimensions |                       |                      |                       |
|------------------------------------|--------------------------|-----------------------|----------------------|-----------------------|
|                                    | 9500 fpm                 |                       | 6500 fpm             |                       |
|                                    | Diameter<br><i>D</i>     | Thickness<br><i>T</i> | Diameter<br><i>D</i> | Thickness<br><i>T</i> |
| $\frac{3}{8}$ -24 × $1\frac{1}{8}$ | $2\frac{1}{2}$           | $\frac{1}{2}$         | 4                    | $\frac{1}{2}$         |
| $\frac{1}{2}$ -13 × $1\frac{3}{4}$ | 4                        | $\frac{3}{4}$         | 5                    | $\frac{3}{4}$         |
| $\frac{5}{8}$ -11 × $2\frac{1}{8}$ | 8                        | 1                     | 8                    | 1                     |
| $\frac{5}{8}$ -11 × $3\frac{1}{8}$ | 6                        | 2                     | ...                  | ...                   |
| $\frac{5}{8}$ -11 × $3\frac{3}{8}$ | 8                        | $1\frac{1}{2}$        | ...                  | ...                   |
| $\frac{3}{4}$ -10 × $3\frac{1}{4}$ | 8                        | 2                     | ...                  | ...                   |

Minimum *T* with the first three spindles is about  $\frac{1}{8}$  inch to accommodate cutting off wheels. Flanges are assumed to be according to ANSI B7.1 and threads to ANSI B1.1.

All dimensions in inches.

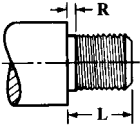

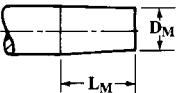

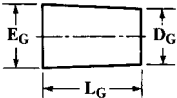

Incorporating fillet radius ( $R_M$ ) at shoulder of male tang precludes use of minimum diameter cross-hole in socket ( $E_F$ ), unless female drive end is chamfered (shown as optional).

If female drive end is not chamfered, socket cross-hole diameter ( $E_F$ ) is increased to compensate for fillet radius  $R_M$ , max.

Minimum clearance across flats male to female is 0.001 inch through 3/4-inch size; 0.002 inch in 1- and 1 1/2-inch sizes. For impact wrenches  $A_M$  should be held as close to maximum as practical.

$C_F$ , min. for both designs A and B should be equal to  $C_M$ , max.

All dimensions in inches. Tolerances on *B* is plus or minus 0.005 inch.

**Mounted Wheels and Mounted Points**

These wheels and points are used in hard-to-get-at places and are available with a vitrified bond. The wheels are available with aluminum oxide or silicon carbide abrasive grains. The aluminum oxide wheels are used to grind tough and tempered die steels and the silicon carbide wheels, cast iron, chilled iron, bronze, and other non-ferrous metals.

The illustrations on pages 952 and 953 give the standard shapes of mounted wheels and points as published by the Grinding Wheel Institute. A note about the maximum operating speed for these wheels is given at the bottom of the first page of illustrations. Metric sizes are given on page 954.

Fig. 1a. Standard Shapes and Sizes of Mounted Wheels and Points ANSI B74.2-1982

See Table 1 for inch sizes of Group W shapes, and for metric sizes for all shapes

The maximum speeds of mounted vitrified wheels and points of average grade range from about 38,000 to 152,000 rpm for diameters of 1 inch down to 1/4 inch. However, the safe operating speed usually is limited by the critical speed (speed at which vibration or whip tends to become excessive) which varies according to wheel or point dimensions, spindle diameter, and overhang.

Fig. 1b. Standard Shapes and Sizes of Mounted Wheels and Points ANSI B74.2-1982

## BROACHES AND BROACHING

### The Broaching Process

The broaching process may be applied in machining holes or other internal surfaces and also to many flat or other external surfaces. Internal broaching is applied in forming either symmetrical or irregular holes, grooves, or slots in machine parts, especially when the size or shape of the opening, or its length in proportion to diameter or width, make other machining processes impracticable. Broaching originally was utilized for such work as cutting keyways, machining round holes into square, hexagonal, or other shapes, forming splined holes, and for a large variety of other internal operations. The development of broaching machines and broaches finally resulted in extensive application of the process to external, flat, and other surfaces. Most external or surface broaching is done on machines of vertical design, but horizontal machines are also used for some classes of work. The broaching process is very rapid, accurate, and it leaves a finish of good quality. It is employed extensively in automotive and other plants where duplicate parts must be produced in large quantities and for dimensions within small tolerances.

**Types of Broaches.**—A number of typical broaches and the operations for which they are intended are shown by the diagrams, Fig. 1. Broach *A* produces a round-cornered, square hole. Prior to broaching square holes, it is usually the practice to drill a round hole having a diameter  $d$  somewhat larger than the width of the square. Hence, the sides are not completely finished, but this unfinished part is not objectionable in most cases. In fact, this clearance space is an advantage during the broaching operation in that it serves as a channel for the broaching lubricant; moreover, the broach has less metal to remove. Broach *B* is for finishing round holes. Broaching is superior to reaming for some classes of work, because the broach will hold its size for a much longer period, thus insuring greater accuracy. Broaches *C* and *D* are for cutting single and double keyways, respectively. Broach *C* is of rectangular section and, when in use, slides through a guiding bushing which is inserted in the hole. Broach *E* is for forming four integral splines in a hub. The broach at *F* is for producing hexagonal holes. Rectangular holes are finished by broach *G*. The teeth on the sides of this broach are inclined in opposite directions, which has the following advantages: The broach is stronger than it would be if the teeth were opposite and parallel to each other; thin work cannot drop between the inclined teeth, as it tends to do when the teeth are at right angles, because at least two teeth are always cutting; the inclination in opposite directions neutralizes the lateral thrust. The teeth on the edges are staggered, the teeth on one side being midway between the teeth on the other edge, as shown by the dotted line. A double cut broach is shown at *H*. This type is for finishing, simultaneously, both sides  $f$  of a slot, and for similar work. Broach *I* is the style used for forming the teeth in internal gears. It is practically a series of gear-shaped cutters, the outside diameters of which gradually increase toward the finishing end of the broach. Broach *J* is for round holes but differs from style *B* in that it has a continuous helical cutting edge. Some prefer this form because it gives a shearing cut. Broach *K* is for cutting a series of helical grooves in a hub or bushing. In helical broaching, either the work or the broach is rotated to form the helical grooves as the broach is pulled through.

In addition to the typical broaches shown in Fig. 1, many special designs are now in use for performing more complex operations. Two surfaces on opposite sides of a casting or forging are sometimes machined simultaneously by twin broaches and, in other cases, three or four broaches are drawn through a part at the same time, for finishing as many duplicate holes or surfaces. Notable developments have been made in the design of broaches for external or "surface" broaching.

**Burnishing Broach:** This is a broach having teeth or projections which are rounded on the top instead of being provided with a cutting edge, as in the ordinary type of broach. The teeth are highly polished, the tool being used for broaching bearings and for operations on

## BROACHING

Fig. 1. Types of Broaches

other classes of work where the metal is relatively soft. The tool compresses the metal, thus making the surface hard and smooth. The amount of metal that can be displaced by a smooth-toothed burnishing broach is about the same as that removed by reaming. Such broaches are primarily intended for use on babbitt, white metal, and brass, but may also be satisfactorily used for producing a glazed surface on cast iron. This type of broach is also used when it is only required to accurately size a hole.

**Pitch of Broach Teeth.**—The pitch of broach teeth depends upon the depth of cut or chip thickness, length of cut, the cutting force required and power of the broaching machine. In the pitch formulas which follow

$L$  = length, in inches, of layer to be removed by broaching

$d$  = depth of cut per tooth as shown by Table 1 (For internal broaches,  $d$  = depth of cut as measured on one side of broach or one-half difference in diameters of successive teeth in case of a round broach)

$F$  = a factor. (For brittle types of material,  $F = 3$  or  $4$  for roughing teeth, and  $6$  for finishing teeth. For ductile types of material,  $F = 4$  to  $7$  for roughing teeth and  $8$  for finishing teeth.)

$b$  = width of inches, of layer to be removed by broaching

$P$  = pressure required in tons per square inch, of an area equal to depth of cut times width of cut, in inches (Table 2)

$T$  = usable capacity, in tons, of broaching machine = 70% of maximum tonnage

**Table 1. Designing Data for Surface Broaches**

| Material to be Broached        | Depth of Cut per Tooth, Inch |           | Face Angle or Rake, Degrees | Clearance Angle, Degrees |           |

<sup>a</sup> The lower depth-of-cut values for roughing are recommended when work is not very rigid, the tolerance is small, a good finish is required, or length of cut is comparatively short.

<sup>b</sup> In broaching these materials, smooth surfaces for tooth and chip spaces are especially recommended.

**Table 2. Broaching Pressure *P* for Use in Pitch Formula (2)**

| Material to be Broached   | Depth <i>d</i> of Cut per Tooth, Inch     |       |       |       |       | Pressure <i>P</i> , Side-cutting Broaches |
|---------------------------|---|-------|-------|-------|-------|---|
|                           | 0.024                                     | 0.010 | 0.004 | 0.002 | 0.001 |   |
|                           | Pressure <i>P</i> in Tons per Square Inch |       |       |       |       |   |
| Steel, High Ten. Strength | ...                                       | ...   | ...   | 250   | 312   | 200-.004"cut                              |

| Magnesium Alloy           | 35  | 35    | ...   | ...   | ...   | .....                                     |

The minimum pitch shown by Formula (1) is based upon the receiving capacity of the chip space. The minimum, however, should not be less than 0.2 inch unless a smaller pitch is required for exceptionally short cuts to provide at least two teeth in contact simultaneously, with the part being broached. A reduction below 0.2 inch is seldom required in surface broaching but it may be necessary in connection with internal broaching.

$$\text{Minimum pitch} = 3\sqrt{LdF} \tag{1}$$

Whether the minimum pitch may be used or not depends upon the power of the available machine. The factor *F* in the formula provides for the increase in volume as the material is broached into chips. If a broach has adjustable inserts for the finishing teeth, the pitch of the finishing teeth may be smaller than the pitch of the roughing teeth because of the smaller depth *d* of the cut. The higher value of *F* for finishing teeth prevents the pitch from becoming too small, so that the spirally curled chips will not be crowded into too small a space.

The pitch of the roughing and finishing teeth should be equal for broaches without separate inserts (notwithstanding the different values of  $d$  and  $F$ ) so that some of the finishing teeth may be ground into roughing teeth after wear makes this necessary.

$$\text{Allowable pitch} = \frac{dLbP}{T} \quad (2)$$

If the pitch obtained by [Formula \(2\)](#) is larger than the minimum obtained by [Formula \(1\)](#), this larger value should be used because it is based upon the usable power of the machine. As the notation indicates, 70 per cent of the maximum tonnage  $T$  is taken as the usable capacity. The 30 per cent reduction is to provide a margin for the increase in broaching load resulting from the gradual dulling of the cutting edges. The procedure in calculating both minimum and allowable pitches will be illustrated by an example.

*Example:* Determine pitch of broach for cast iron when  $L = 9$  inches;  $d = 0.004$ ; and  $F = 4$ .

$$\text{Minimum pitch} = 3\sqrt{9 \times 0.004 \times 4} = 1.14$$

Next, apply [Formula \(2\)](#). Assume that  $b = 3$  and  $T = 10$ ; for cast iron and depth  $d$  of 0.004,  $P = 115$  ([Table 2](#)). Then,

$$\text{Allowable pitch} = \frac{0.004 \times 9 \times 3 \times 115}{10} = 1.24$$

This pitch is safely above the minimum. If in this case the usable tonnage of an available machine were, say, 8 tons instead of 10 tons, the pitch as shown by [Formula \(2\)](#) might be increased to about 1.5 inches, thus reducing the number of teeth cutting simultaneously and, consequently, the load on the machine; or the cut per tooth might be reduced instead of increasing the pitch, especially if only a few teeth are in cutting contact, as might be the case with a short length of cut. If the usable tonnage in the preceding example were, say, 15, then a pitch of 0.84 would be obtained by [Formula \(2\)](#); hence the pitch in this case should not be less than the minimum of approximately 1.14 inches.

**Depth of Cut per Tooth.**—The term “depth of cut” as applied to surface or external broaches means the difference in the heights of successive teeth. This term, as applied to internal broaches for round, hexagonal or other holes, may indicate the total increase in the diameter of successive teeth; however, to avoid confusion, the term as here used means in all cases and regardless of the type of broach, the depth of cut as measured on one side.

In broaching free cutting steel, the Broaching Tool Institute recommends 0.003 to 0.006 inch depth of cut for surface broaching; 0.002 to 0.003 inch for multispline broaching; and 0.0007 to 0.0015 inch for round hole broaching. The accompanying table contains data from a German source and applies specifically to surface broaches. All data relating to depth of cut are intended as a general guide only. While depth of cut is based primarily upon the machinability of the material, some reduction from the depth thus established may be required particularly when the work supporting fixture in surface broaching is not sufficiently rigid to resist the thrust from the broaching operation. In some cases, the pitch and cutting length may be increased to reduce the thrust force. Another possible remedy in surface broaching certain classes of work is to use a side-cutting broach instead of the ordinary depth cutting type. A broach designed for side cutting takes relatively deep narrow cuts which extend nearly to the full depth required. The side cutting section is followed by teeth arranged for depth cutting to obtain the required size and surface finish on the work. In general, small tolerances in surface broaching require a reduced cut per tooth to minimize work deflection resulting from the pressure of the cut. See [Cutting Speed for Broaching](#) starting on page [1074](#) for broaching speeds.

Terms Commonly Used in Broach Design

**Face Angle or Rake.**—The face angle (see diagram) of broach teeth affects the chip flow and varies considerably for different materials. While there are some variations in practice, even for the same material, the angles given in the accompanying table are believed to represent commonly used values. Some broach designers increase the rake angle for finishing teeth in order to improve the finish on the work.

**Clearance Angle.**—The clearance angle (see illustration) for roughing steel varies from 1.5 to 3 degrees and for finishing steel from 0.5 to 1 degree. Some recommend the same clearance angles for cast iron and others, larger clearance angles varying from 2 to 4 or 5 degrees. Additional data will be found in [Table 1](#).

**Land Width.**—The width of the land usually is about  $0.25 \times$  pitch. It varies, however, from about one-fourth to one-third of the pitch. The land width is selected so as to obtain the proper balance between tooth strength and chip space.

**Depth of Broach Teeth.**—The tooth depth as established experimentally and on the basis of experience, usually varies from about 0.37 to 0.40 of the pitch. This depth is measured radially from the cutting edge to the bottom of the tooth fillet.

**Radius of Tooth Fillet.**—The “gullet” or bottom of the chip space between the teeth should have a rounded fillet to strengthen the broach, facilitate curling of the chips, and safeguard against cracking in connection with the hardening operation. One rule is to make the radius equal to one-fourth the pitch. Another is to make it equal 0.4 to 0.6 the tooth depth. A third method preferred by some broach designers is to make the radius equal one-third of the sum obtained by adding together the land width, one-half the tooth depth, and one-fourth of the pitch.

**Total Length of Broach.**—After the depth of cut per tooth has been determined, the total amount of material to be removed by a broach is divided by this decimal to ascertain the number of cutting teeth required. This number of teeth multiplied by the pitch gives the length of the active portion of the broach. By adding to this dimension the distance over three or four straight teeth, the length of a pilot to be provided at the finishing end of the broach, and the length of a shank which must project through the work and the faceplate of the machine to the draw-head, the overall length of the broach is found. This calculated length is often greater than the stroke of the machine, or greater than is practical for a broach of the diameter required. In such cases, a set of broaches must be used.

**Chip Breakers.**—The teeth of broaches frequently have rounded chip-breaking grooves located at intervals along the cutting edges. These grooves break up wide curling chips and prevent them from clogging the chip spaces, thus reducing the cutting pressure and strain on the broach. These chip-breaking grooves are on the roughing teeth only. They are staggered and applied to both round and flat or surface broaches. The grooves are formed by a round edged grinding wheel and usually vary in width from about  $\frac{1}{32}$  to  $\frac{3}{32}$  inch depending upon the size of broach. The more ductile the material, the wider the chip breaker grooves should be and the smaller the distance between them. Narrow slotting broaches may have the right- and left-hand corners of alternate teeth beveled to obtain chip-breaking action.

**Shear Angle.**—The teeth of surface broaches ordinarily are inclined so they are not at right angles to the broaching movement. The object of this inclination is to obtain a shearing cut which results in smoother cutting action and an improvement in surface finish. The shearing cut also tends to eliminate troublesome vibration. Shear angles for surface broaches are not suitable for broaching slots or any profiles that resist the outward movement of the chips. When the teeth are inclined, the fixture should be designed to resist the resulting thrusts unless it is practicable to incline the teeth of right- and left-hand sections in opposite directions to neutralize the thrust. The shear angle usually varies from 10 to 25 degrees.

**Types of Broaching Machines.**—Broaching machines may be divided into horizontal and vertical designs, and they may be classified further according to the method of operation, as, for example, whether a broach in a vertical machine is pulled up or pulled down in forcing it through the work. Horizontal machines usually pull the broach through the work in internal broaching but short rigid broaches may be pushed through. External surface broaching is also done on some machines of horizontal design, but usually vertical machines are employed for flat or other external broaching. Although parts usually are broached by traversing the broach itself, some machines are designed to hold the broach or broaches stationary during the actual broaching operation. This principle has been applied both to internal and surface broaching.

*Vertical Duplex Type:* The vertical duplex type of surface broaching machine has two slides or rams which move in opposite directions and operate alternately. While the broach connected to one slide is moving downward on the cutting stroke, the other broach and slide is returning to the starting position, and this returning time is utilized for reloading the fixture on that side; consequently, the broaching operation is practically continuous. Each ram or slide may be equipped to perform a separate operation on the same part when two operations are required.

*Pull-up Type:* Vertical hydraulically operated machines which pull the broach or broaches up through the work are used for internal broaching of holes of various shapes, for broaching bushings, splined holes, small internal gears, etc. A typical machine of this kind is so designed that all broach handling is done automatically.

*Pull-down Type:* The various movements in the operating cycle of a hydraulic pull-down type of machine equipped with an automatic broach-handling slide, are the reverse of the pull-up type. The broaches for a pull-down type of machine have shanks on each end, there being an upper one for the broach-handling slide and a lower one for pulling through the work.

*Hydraulic Operation:* Modern broaching machines, as a general rule, are operated hydraulically rather than by mechanical means. Hydraulic operation is efficient, flexible in the matter of speed adjustments, low in maintenance cost, and the "smooth" action required for fine precision finishing may be obtained. The hydraulic pressures required, which frequently are 800 to 1000 pounds per square inch, are obtained from a motor-driven pump forming part of the machine. The cutting speeds of broaching machines frequently are between 20 and 30 feet per minute, and the return speeds often are double the cutting speed, or higher, to reduce the idle period.

**Ball-Broaching.**—Ball-broaching is a method of securing bushings, gears, or other components without the need for keys, pins, or splines. A series of axial grooves, separated by ridges, is formed in the bore of the workpiece by cold plastic deformation of the metal when a tool, having a row of three rotating balls around its periphery, is pressed through the parts. When the bushing is pressed into a broached bore, the ridges displace the softer material of the bushing into the grooves—thus securing the assembly. The balls can be made of high-carbon chromium steel or carbide, depending on the hardness of the component.

**Broaching Difficulties.**—The accompanying table has been compiled from information supplied by the National Broach and Machine Co. and presents some of the common broaching difficulties, their causes and means of correction.

### Causes of Broaching Difficulties

| Broaching Difficulty                                   | Possible Causes   |
|--|---|
| Stuck broach   | <p>Insufficient machine capacity; dulled teeth; clogged chip gullets; failure of power during cutting stroke.</p> <p>To remove a stuck broach, workpiece and broach are removed from the machine as a unit; never try to back out broach by reversing machine. If broach does not loosen by tapping workpiece lightly and trying to slide it off its starting end, mount workpiece and broach in a lathe and turn down workpiece to the tool surface. Workpiece may be sawed longitudinally into several sections in order to free the broach.</p> <p>Check broach design, perhaps tooth relief (back off) angle is too small or depth of cut per tooth is too great.</p> |
| Galling and pickup                                     | <p>Lack of homogeneity of material being broached—uneven hardness, porosity; improper or insufficient coolant; poor broach design, mutilated broach; dull broach; improperly sharpened broach; improperly designed or outworn fixtures.</p> <p>Good broach design will do away with possible chip build-up on tooth faces and excessive heating. Grinding of teeth should be accurate so that the correct gullet contour is maintained. Contour should be fair and smooth.</p>  |
| Broach breakage  | <p>Overloading; broach dullness; improper sharpening; interrupted cutting stroke; backing up broach with workpiece in fixture; allowing broach to pass entirely through guide hole; ill fitting and/or sharp edged key; crooked holes; untrue locating surface; excessive hardness of workpiece; insufficient clearance angle; sharp corners on pull end of broach.</p> <p>When grinding bevels on pull end of broach use wheel that is not too pointed.</p>  |
| Chatter  | <p>Too few teeth in cutting contact simultaneously; excessive hardness of material being broached; loose or poorly constructed tooling; surging of ram due to load variations.</p> <p>Chatter can be alleviated by changing the broaching speed, by using shear cutting teeth instead of right angle teeth, and by changing the coolant and the face and relief angles of the teeth.</p>  |
| Drifting or misalignment of tool during cutting stroke | <p>Lack of proper alignment when broach is sharpened in grinding machine, which may be caused by dirt in the female center of the broach; inadequate support of broach during the cutting stroke, on a horizontal machine especially; body diameter too small; cutting resistance variable around I.D. of hole due to lack of symmetry of surfaces to be cut; variations in hardness around I.D. of hole; too few teeth in cutting contact.</p>   |
| Streaks in broached surface                            | <p>Lands too wide; presence of forging, casting or annealing scale; metal pickup; presence of grinding burrs and grinding and cleaning abrasives.</p>   |
| Rings in the broached hole                             | <p>Due to surging resulting from uniform pitch of teeth; presence of sharpening burrs on broach; tooth clearance angle too large; locating face not smooth or square; broach not supported for all cutting teeth passing through the work. The use of differential tooth spacing or shear cutting teeth helps in preventing surging. Sharpening burrs on a broach may be removed with a wood block.</p>   |

## FILES AND BURS

### Files

**Definitions of File Terms.**—The following file terms apply to hand files but not to rotary files and burs.

*Axis:* Imaginary line extending the entire length of a file equidistant from faces and edges.

*Back:* The convex side of a file having the same or similar cross-section as a half-round file.

*Bastard Cut:* A grade of file coarseness between coarse and second cut of American pattern files and rasps.

*Blank:* A file in any process of manufacture before being cut.

*Blunt:* A file whose cross-sectional dimensions from point to tang remain unchanged.

*Coarse Cut:* The coarsest of all American pattern file and rasp cuts.

*Coarseness:* Term describing the relative number of teeth per unit length, the coarsest having the least number of file teeth per unit length; the smoothest, the most. American pattern files and rasps have four degrees of coarseness: coarse, bastard, second and smooth. Swiss pattern files usually have seven degrees of coarseness: 00, 0, 1, 2, 3, 4, 6 (from coarsest to smoothest). Curved tooth files have three degrees of coarseness: standard, fine and smooth.

*Curved Cut:* File teeth which are made in curved contour across the file blank.

*Cut:* Term used to describe file teeth with respect to their coarseness or their character (single, double, rasp, curved, special).

*Double Cut:* A file tooth arrangement formed by two series of cuts, namely the overcut followed, at an angle, by the upcut.

*Edge:* Surface joining faces of a file. May have teeth or be smooth.

*Face:* Widest cutting surface or surfaces that are used for filing.

*Heel or Shoulder:* That portion of a file that abuts the tang.

*Hopped:* A term used among file makers to represent a very wide skip or spacing between file teeth.

*Length:* The distance from the heel to the point.

*Overcut:* The first series of teeth put on a double-cut file.

*Point:* The front end of a file; the end opposite the tang.

*Rasp Cut:* A file tooth arrangement of round-topped teeth, usually not connected, that are formed individually by means of a narrow, punch-like tool.

*Re-cut:* A worn-out file which has been re-cut and re-hardened after annealing and grinding off the old teeth.

*Safe Edge:* An edge of a file that is made smooth or uncut, so that it will not injure that portion or surface of the workplace with which it may come in contact during filing.

*Second Cut:* A grade of file coarseness between bastard and smooth of American pattern files and rasps.

*Set:* To blunt the sharp edges or corners of file blanks before and after the overcut is made, in order to prevent weakness and breakage of the teeth along such edges or corners when the file is put to use.

*Shoulder or Heel:* See *Heel or Shoulder*.

*Single Cut:* A file tooth arrangement where the file teeth are composed of single unbroken rows of parallel teeth formed by a single series of cuts.

*Smooth Cut:* An American pattern file and rasp cut that is smoother than second cut.

*Tang:* The narrowed portion of a file which engages the handle.

*Upcut:* The series of teeth superimposed on the overcut, and at an angle to it, on a double-cut file.

**File Characteristics.**—Files are classified according to their shape or cross-section and according to the pitch or spacing of their teeth and the nature of the cut.

*Cross-section and Outline:* The cross-section may be quadrangular, circular, triangular, or some special shape. The outline or contour may be tapered or blunt. In the former, the point is more or less reduced in width and thickness by a gradually narrowing section that extends for one-half to two-thirds of the length. In the latter the cross-section remains uniform from tang to point.

*Cut:* The character of the teeth is designated as single, double, rasp or curved. The *single cut file* (or *float* as the coarser cuts are sometimes called) has a single series of parallel teeth extending across the face of the file at an angle of from 45 to 85 degrees with the axis of the file. This angle depends upon the form of the file and the nature of the work for which it is intended. The single cut file is customarily used with a light pressure to produce a smooth finish. The *double cut file* has a multiplicity of small pointed teeth inclining toward the point of the file arranged in two series of diagonal rows that cross each other. For general work, the angle of the first series of rows is from 40 to 45 degrees and of the second from 70 to 80 degrees. For *double cut finishing files* the first series has an angle of about 30 degrees and the second, from 80 to 87 degrees. The second, or upcut, is almost always deeper than the first or overcut. Double cut files are usually employed, under heavier pressure, for fast metal removal and where a rougher finish is permissible. The *rasp* is formed by raising a series of individual rounded teeth from the surface of the file blank with a sharp narrow, punch-like cutting tool and is used with a relatively heavy pressure on soft substances for fast removal of material. The curved tooth file has teeth that are in the form of parallel arcs extending across the face of the file, the middle portion of each arc being closest to the point of the file. The teeth are usually single cut and are relatively coarse. They may be formed by steel displacement but are more commonly formed by milling.

With reference to coarseness of cut the terms *coarse*, *bastard*, *second* and *smooth cuts* are used, the coarse or bastard files being used on the heavier classes of work and the second or smooth cut files for the finishing or more exacting work. These degrees of coarseness are only comparable when files of the same length are compared, as the number or teeth per inch of length decreases as the length of the file increases. The number of teeth per inch varies considerably for different sizes and shapes and for files of different makes. The coarseness range for the curved tooth files is given as standard, fine and smooth. In the case of Swiss pattern files, a series of numbers is used to designate coarseness instead of names; Nos. 00, 0, 1, 2, 3, 4 and 6 being the most common with No. 00 the coarsest and No. 6 the finest.

**Classes of Files.**—There are five main classes of files: mill or saw files; machinists' files; curved tooth files; Swiss pattern files; and rasps. The first two classes are commonly referred to as American pattern files.

*Mill or Saw Files:* These are used for sharpening mill or circular saws, large crosscut saws; for lathe work; for draw filing; for filing brass and bronze; and for smooth filing generally. The number identifying the following files refers to the illustration in [Fig. 1](#)

- 1) *Cantsaw files* have an obtuse isosceles triangular section, a blunt outline, are single cut and are used for sharpening saws having "M"-shaped teeth and teeth of less than 60-degree angle; 2) *Crosscut files* have a narrow triangular section with short side rounded, a blunt outline, are single cut and are used to sharpen crosscut saws. The rounded portion is used to deepen the gullets of saw teeth and the sides are used to sharpen the teeth themselves. ;
- 3) *Double ender files* have a triangular section, are tapered from the middle to both ends, are tangless are single cut and are used reversibly for sharpening saws; 4) The *mill file* itself, is usually single cut, tapered in width, and often has two square cutting edges in addition to the cutting sides. Either or both edges may be rounded, however, for filing the gul-

lets of saw teeth. The *blunt mill file* has a uniform rectangular cross-section from tip to tang; 5) The *triangular saw files or taper saw files* have an equilateral triangular section, are tapered, are single cut and are used for filing saws with 60-degree angle teeth. They come in taper, slim taper, extra slim taper and double extra slim taper thicknesses *Blunt triangular* and *blunt hand saw files* are without taper; and 6) *Web saw files* have a diamond-shaped section, a blunt outline, are single cut and are used for sharpening pulpwood or web saws. .

*Machinists' Files:* These files are used throughout industry where metal must be removed rapidly and finish is of secondary importance. Except for certain exceptions in the round and half-round shapes, all are double cut. 7) *Flat files* have a rectangular section, are tapered in width and thickness, are cut on both sides and edges and are used for general utility work; 8) *Halfround files* have a circular segmental section, are tapered in width and thickness, have their flat side double cut, their rounded side mostly double but sometimes single cut, and are used to file rounded holes, concave corners, etc. in general filing work; 9) *Hand files* are similar to flat files but taper in thickness only. One edge is uncut or "safe."; and 10) *Knife files* have a "knife-blade" section, are tapered in width only, are double cut, and are used by tool and die makers on work having acute angles.

*Machinist's general purpose files* have a rectangular section, are tapered and have single cut teeth divided by angular serrations which produce short cutting edges. These edges help stock removal but still leave a smooth finish and are suitable for use on various materials including aluminum, bronze, cast iron, malleable iron, mild steels and annealed tool steels.

11) *Pillar files* are similar to hand files but are thicker and not as wide; 12) *Round files* have a circular section, are tapered, single cut, and are generally used to file circular openings or curved surfaces; 13) *Square files* have a square section, are tapered, and are used for filing slots, keyways and for general surface filing where a heavier section is preferred; 14) *Three square files* have an equilateral triangular section and are tapered on all sides. They are double cut and have sharp corners as contrasted with taper triangular files which are single cut and have somewhat rounded corners. They are used for filing accurate internal angles, for clearing out square corners, and for filing taps and cutters; and 15) *Warding files* have a rectangular section, and taper in width to a narrow point. They are used for general narrow space filing. .

*Wood files* are made in the same sections as flat and half round files but with coarser teeth especially suited for working on wood.

Fig. 1. Styles of Mill or Saw Files

*Curved Tooth Files:* Regular curved tooth files are made in both rigid and flexible forms. The rigid type has either a tang for a conventional handle or is made plain with a hole at each end for mounting in a special holder. The flexible type is furnished for use in special holders only. The curved tooth files come in standard fine and smooth cuts and in parallel

flat, square, pillar, pillar narrow, half round and shell types. A special curved tooth file is available with teeth divided by long angular serrations. The teeth are cut in an "off center" arc. When moved across the work toward one edge of the file a fast cutting action is provided; when moved toward the other edge, a smoothing action; thus the file is made to serve a dual purpose.

*Swiss Pattern Files:* These are used by tool and die makers, model makers and delicate instrument parts finishers. They are made to closer tolerances than the conventional American pattern files although with similar cross-sections. The points of the Swiss pattern files are smaller, the tapers are longer and they are available in much finer cuts. They are primarily finishing tools for removing burrs left from previous finishing operations truing up narrow grooves, notches and keyways, cleaning out corners and smoothing small parts. For very fine work, *round and square handled needle files*, available in numerous cross-sectional shapes in overall lengths from 4 to 7  $\frac{3}{4}$  inches, are used. Die sinkers use *die sinkers files* and *die sinkers rifflers*. The files, also made in many different cross-sectional shapes, are 3  $\frac{1}{2}$  inches in length and are available in the cut Nos. 0, 1, 2, and 4. The rifflers are from 5  $\frac{1}{2}$  to 6  $\frac{3}{4}$  inches long, have cutting surfaces on either end, and come in numerous cross-sectional shapes in cut Nos. 0, 2, 3, 4 and 6. These rifflers are used by die makers for getting into corners, crevices, holes and contours of intricate dies and molds. Used in the same fashion as die sinkers rifflers, *silversmiths rifflers*, that have a much heavier cross-section, are available in lengths from 6  $\frac{7}{8}$  to 8 inches and in cuts Nos. 0, 1, 2, and 3. *Blunt machine files* in Cut Nos. 00, 0, and 2 for use in ordinary and bench filing machines are available in many different cross-sectional shapes, in lengths from 3 to 8 inches.

*Rasps:* Rasps are employed for work on relatively soft substances such as wood, leather, and lead where fast removal or material is required. They come in rectangular and half round cross-sections, the latter with and without a sharp edge.

*Special Purpose Files:* Falling under one of the preceding five classes of files, but modified to meet the requirements of some particular function, are a number of special purpose files. The *long angle lathe file* is used for filing work that is rotating in a lathe. The long tooth angle provides a clean shear, eliminates drag or tear and is self-clearing. This file has safe or uncut edges to protect shoulders of the work which are not to be filed. The *foundry file* has especially sturdy teeth with heavy set edges for the snagging of castings—the removing of fins, sprues, and other projections. The *die casting file* has extra strong teeth on corners and edges as well as sides for working on die castings of magnesium, zinc, or aluminum alloys. A special file for stainless steel is designed to stand up under the abrasive action of stainless steel alloys. *Aluminum rasps and files* are designed to eliminate clogging. A special tooth construction is used in one type of aluminum tile which breaks up the filings, allows the file to clear itself and overcomes chatter. A *brass file* is designed so that with a little pressure the sharp, high-cut teeth bite deep while with less pressure, their short uncut angle produces a smoothing effect. The *lead float* has coarse, single cut teeth at almost right angles to the file axis. These shear away the metal under ordinary pressure and produce a smoothing effect under light pressure. The *shear tooth file* has a coarse single cut with a long angle for soft metals or alloys, plastics, hard rubber and wood. *Chain saw files* are designed to sharpen all types of chain saw teeth. These files come in round, rectangular, square and diamond-shaped sections. The round and square sectioned files have either double or single cut teeth, the rectangular files have single cut teeth and the diamond-shaped files have double cut teeth.

**Effectiveness of Rotary Files and Burs.**—There is very little difference in the efficiency of rotary files or burs when used in electric tools and when used in air tools, provided the speeds have been reasonably well selected. Flexible-shaft and other machines used as a source of power for these tools have a limited number of speeds which govern the revolutions per minute at which the tools can be operated.

The carbide bur may be used on hard or soft materials with equally good results. The principle difference in construction of the carbide bur is that its teeth or flutes are provided with a negative rather than a radial rake. Carbide burs are relatively brittle, and must be treated more carefully than ordinary burs. They should be kept cutting freely, in order to prevent too much pressure, which might result in crumbling of the cutting epics.

At the same speeds, both high-speed steel and carbide burs remove approximately the same amount of metal. However, when carbide burs are used at their most efficient speeds, the rate of stock removal may be as much as four times that of ordinary burs. In certain cases, speeds much higher than those shown in the table can be used. It has been demonstrated that a carbide bur will last up to 100 times as long as a high-speed steel bur of corresponding size and shape.

### Approximate Speeds of Rotary Files and Burs

| Tool<br>Diam.,<br>Inches | Medium Cut, High-Speed Steel Bur or File |           |        |          |           | Carbide Bur   |             |
|--------------------------|--|-----------|--------|----------|-----------|---------------|-------------|
|                          | Mild Steel                               | Cast Iron | Bronze | Aluminum | Magnesium | Medium<br>Cut | Fine<br>Cut |
|                          | Speed, Revolutions per Minute            |           |        |          |           | Any Material  |             |
| 1/8                      | 4600                                     | 7000      | 15,000 | 20,000   | 30,000    | 45,000        | 30,000      |
| 1/4                      | 3450                                     | 5250      | 11,250 | 15,000   | 22,500    | 30,000        | 20,000      |
| 3/8                      | 2750                                     | 4200      | 9000   | 12,000   | 18,000    | 24,000        | 16,000      |
| 1/2                      | 2300                                     | 3500      | 7500   | 10,000   | 15,000    | 20,000        | 13,350      |
| 5/8                      | 2000                                     | 3100      | 6650   | 8900     | 13,350    | 18,000        | 12,000      |
| 3/4                      | 1900                                     | 2900      | 6200   | 8300     | 12,400    | 16,000        | 10,650      |
| 7/8                      | 1700                                     | 2600      | 5600   | 7500     | 11,250    | 14,500        | 9650        |
| 1                        | 1600                                     | 2400      | 5150   | 6850     | 10,300    | 13,000        | 8650        |
| 1 1/8                    | 1500                                     | 2300      | 4850   | 6500     | 9750      | ...           | ...         |

As recommended by the Nicholson File Company.

**Steel Wool.**—Steel wool is made by shaving thin layers of steel from wire. The wire is pulled, by special machinery built for the purpose, past cutting tools or through cutting dies which shave off chips from the outside. Steel wool consists of long, relatively strong, and resilient steel shavings having sharp edges. This characteristic renders it an excellent abrasive. The fact that the cutting characteristics of steel wool vary with the size of the fiber, which is readily controlled in manufacture, has adapted it to many applications.

Metals other than steel have been made into wool by the same processes as steel, and when so manufactured have the same general characteristics. Thus wool has been made from copper, lead, aluminum, bronze, brass, monel metal, and nickel. The wire from which steel wool is made may be produced by either the Bessemer, or the basic or acid open-hearth processes. It should contain from 0.10 to 0.20 per cent carbon; from 0.50 to 1.00 per cent manganese; from 0.020 to 0.090 per cent sulphur; from 0.050 to 0.120 per cent phosphorus; and from 0.001 to 0.010 per cent silicon. When drawn on a standard tensile-strength testing machine, a sample of the steel should show an ultimate strength of not less than 120,000 pounds per square inch.

### Steel Wool Grades

| Description | Grade | Fiber Thickness |            | Description   | Grade | Fiber Thickness |            |
|-------------|-------|-----------------|------------|---------------|-------|-----------------|------------|
|             |       | Inch            | Millimeter |               |       | Inch            | Millimeter |
| Super Fine  | 0000  | 0.001           | 0.025      | Medium        | 1     | 0.0025          | 0.06       |
| Extra Fine  | 000   | 0.0015          | 0.035      | Medium Coarse | 2     | 0.003           | 0.075      |
| Very Fine   | 00    | 0.0018          | 0.04       | Coarse        | 3     | 0.0035          | 0.09       |
| Fine        | 0     | 0.002           | 0.05       | Extra Coarse  | 4     | 0.004           | 0.10       |

## TOOL WEAR AND SHARPENING

Metal cutting tools wear constantly when they are being used. A normal amount of wear should not be a cause for concern until the size of the worn region has reached the point where the tool should be replaced. Normal wear cannot be avoided and should be differentiated from abnormal tool breakage or excessively fast wear. Tool breakage and an excessive rate of wear indicate that the tool is not operating correctly and steps should be taken to correct this situation.

There are several basic mechanisms that cause tool wear. It is generally understood that tools wear as a result of abrasion which is caused by hard particles of work material plowing over the surface of the tool. Wear is also caused by diffusion or alloying between the work material and the tool material. In regions where the conditions of contact are favorable, the work material reacts with the tool material causing an attrition of the tool material. The rate of this attrition is dependent upon the temperature in the region of contact and the reactivity of the tool and the work materials with each other. Diffusion or alloying also occurs where particles of the work material are welded to the surface of the tool. These welded deposits are often quite visible in the form of a built-up edge, as particles or a layer of work material inside a crater or as small mounds attached to the face of the tool. The diffusion or alloying occurring between these deposits and the tool weakens the tool material below the weld. Frequently these deposits are again rejoined to the chip by welding or they are simply broken away by the force of collision with the passing chip. When this happens, a small amount of the tool material may remain attached to the deposit and be plucked from the surface of the tool, to be carried away with the chip. This mechanism can cause chips to be broken from the cutting edge and the formation of small craters on the tool face called pull-outs. It can also contribute to the enlargement of the larger crater that sometimes forms behind the cutting edge. Among the other mechanisms that can cause tool wear are severe thermal gradients and thermal shocks, which cause cracks to form near the cutting edge, ultimately leading to tool failure. This condition can be caused by improper tool grinding procedures, heavy interrupted cuts, or by the improper application of cutting fluids when machining at high cutting speeds. Chemical reactions between the active constituents in some cutting fluids sometimes accelerate the rate of tool wear. Oxidation of the heated metal near the cutting edge also contributes to tool wear, particularly when fast cutting speeds and high cutting temperatures are encountered. Breakage of the cutting edge caused by overloading, heavy shock loads, or improper tool design is not normal wear and should be corrected.

The wear mechanisms described bring about visible manifestations of wear on the tool which should be understood so that the proper corrective measures can be taken, when required. These visible signs of wear are described in the following paragraphs and the corrective measures that might be required are given in the accompanying Tool Trouble-Shooting Check List. The best procedure when trouble shooting is to try to correct only one condition at a time. When a correction has been made it should be checked. After one condition has been corrected, work can then start to correct the next condition.

*Flank Wear:* Tool wear occurring on the flank of the tool below the cutting edge is called flank wear. Flank wear always takes place and cannot be avoided. It should not give rise to concern unless the rate of flank wear is too fast or the flank wear land becomes too large in size. The size of the flank wear can be measured as the distance between the top of the cutting edge and the bottom of the flank wear land. In practice, a visual estimate is usually made instead of a precise measurement, although in many instances flank wear is ignored and the tool wear is "measured" by the loss of size on the part. The best measure of tool wear, however, is flank wear. When it becomes too large, the rubbing action of the wear land against the workpiece increases and the cutting edge must be replaced. Because conditions vary, it is not possible to give an exact amount of flank wear at which the tool should be replaced. Although there are many exceptions, as a rough estimate, high-speed steel

tools should be replaced when the width of the flank wear land reaches 0.005 to 0.010 inch for finish turning and 0.030 to 0.060 inch for rough turning; and for cemented carbides 0.005 to 0.010 inch for finish turning and 0.020 to 0.040 inch for rough turning.

Under ideal conditions which, surprisingly, occur quite frequently, the width of the flank wear land will be very uniform along its entire length. When the depth of cut is uneven, such as when turning out-of-round stock, the bottom edge of the wear land may become somewhat slanted, the wear land being wider toward the nose. A jagged-appearing wear land usually is evidence of chipping at the cutting edge. Sometimes, only one or two sharp depressions of the lower edge of the wear land will appear, to indicate that the cutting edge has chipped above these depressions. A deep notch will sometimes occur at the "depth of cut line," or that part of the cutting opposite the original surface of the work. This can be caused by a hard surface scale on the work, by a work-hardened surface layer on the work, or when machining high-temperature alloys. Often the size of the wear land is enlarged at the nose of the tool. This can be a sign of crater breakthrough near the nose or of chipping in this region. Under certain conditions, when machining with carbides, it can be an indication of deformation of the cutting edge in the region of the nose.

When a sharp tool is first used, the initial amount of flank wear is quite large in relation to the subsequent total amount. Under normal operating conditions, the width of the flank wear land will increase at a uniform rate until it reaches a critical size after which the cutting edge breaks down completely. This is called catastrophic failure and the cutting edge should be replaced before this occurs. When cutting at slow speeds with high-speed steel tools, there may be long periods when no increase in the flank wear can be observed. For a given work material and tool material, the rate of flank wear is primarily dependent on the cutting speed and then the feed rate.

*Cratering:* A deep crater will sometimes form on the face of the tool which is easily recognizable. The crater forms at a short distance behind the side cutting edge leaving a small shelf between the cutting edge and the edge of the crater. This shelf is sometimes covered with the built-up edge and at other times it is uncovered. Often the bottom of the crater is obscured with work material that is welded to the tool in this region. Under normal operating conditions, the crater will gradually enlarge until it breaks through a part of the cutting edge. Usually this occurs on the end cutting edge just behind the nose. When this takes place, the flank wear at the nose increases rapidly and complete tool failure follows shortly. Sometimes cratering cannot be avoided and a slow increase in the size of the crater is considered normal. However, if the rate of crater growth is rapid, leading to a short tool life, corrective measures must be taken.

*Cutting Edge Chipping:* Small chips are sometimes broken from the cutting edge which accelerates tool wear but does not necessarily cause immediate tool failure. Chipping can be recognized by the appearance of the cutting edge and the flank wear land. A sharp depression in the lower edge of the wear land is a sign of chipping and if this edge of the wear land has a jagged appearance it indicates that a large amount of chipping has taken place. Often the vacancy or cleft in the cutting edge that results from chipping is filled up with work material that is tightly welded in place. This occurs very rapidly when chipping is caused by a built-up edge on the face of the tool. In this manner the damage to the cutting edge is healed; however, the width of the wear land below the chip is usually increased and the tool life is shortened.

*Deformation:* Deformation occurs on carbide cutting tools when taking a very heavy cut using a slow cutting speed and a high feed rate. A large section of the cutting edge then becomes very hot and the heavy cutting pressure compresses the nose of the cutting edge, thereby lowering the face of the tool in the area of the nose. This reduces the relief under the nose, increases the width of the wear land in this region, and shortens the tool life.

*Surface Finish:* The finish on the machined surface does not necessarily indicate poor cutting tool performance unless there is a rapid deterioration. A good surface finish is,

however, sometimes a requirement. The principal cause of a poor surface finish is the built-up edge which forms along the edge of the cutting tool. The elimination of the built-up edge will always result in an improvement of the surface finish. The most effective way to eliminate the built-up edge is to increase the cutting speed. When the cutting speed is increased beyond a certain critical cutting speed, there will be a rather sudden and large improvement in the surface finish. Cemented carbide tools can operate successfully at higher cutting speeds, where the built-up edge does not occur and where a good surface finish is obtained. Whenever possible, cemented carbide tools should be operated at cutting speeds where a good surface finish will result. There are times when such speeds are not possible. Also, high-speed tools cannot be operated at the speed where the built-up edge does not form. In these conditions the most effective method of obtaining a good surface finish is to employ a cutting fluid that has active sulphur or chlorine additives.

Cutting tool materials that do not alloy readily with the work material are also effective in obtaining an improved surface finish. Straight titanium carbide and diamond are the two principal tool materials that fall into this category.

The presence of feed marks can mar an otherwise good surface finish and attention must be paid to the feed rate and the nose radius of the tool if a good surface finish is desired. Changes in the tool geometry can also be helpful. A small "flat," or secondary cutting edge, ground on the end cutting edge behind the nose will sometimes provide the desired surface finish. When the tool is in operation, the flank wear should not be allowed to become too large, particularly in the region of the nose where the finished surface is produced.

**Sharpening Twist Drills.**—Twist drills are cutting tools designed to perform concurrently several functions, such as penetrating directly into solid material, ejecting the removed chips outside the cutting area, maintaining the essentially straight direction of the advance movement and controlling the size of the drilled hole. The geometry needed for these multiple functions is incorporated into the design of the twist drill in such a manner that it can be retained even after repeated sharpening operations. Twist drills are resharpened many times during their service life, with the practically complete restitution of their original operational characteristics. However, in order to assure all the benefits which the design of the twist drill is capable of providing, the surfaces generated in the sharpening process must agree with the original form of the tool's operating surfaces, unless a change of shape is required for use on a different work material.

The principal elements of the tool geometry which are essential for the adequate cutting performance of twist drills are shown in Fig. 1. The generally used values for these dimensions are the following:

*Point angle:* Commonly  $118^\circ$ , except for high strength steels,  $118^\circ$  to  $135^\circ$ ; aluminum alloys,  $90^\circ$  to  $140^\circ$ ; and magnesium alloys,  $70^\circ$  to  $118^\circ$ .

*Helix angle:* Commonly  $24^\circ$  to  $32^\circ$ , except for magnesium and copper alloys,  $10^\circ$  to  $30^\circ$ .

*Lip relief angle:* Commonly  $10^\circ$  to  $15^\circ$ , except for high strength or tough steels,  $7^\circ$  to  $12^\circ$ .

The lower values of these angle ranges are used for drills of larger diameter, the higher values for the smaller diameters. For drills of diameters less than  $\frac{1}{4}$  inch, the lip relief angles are increased beyond the listed maximum values up to  $24^\circ$ . For soft and free machining materials,  $12^\circ$  to  $18^\circ$  except for diameters less than  $\frac{1}{4}$  inch,  $20^\circ$  to  $26^\circ$ .

**Relief Grinding of the Tool Flanks.**—In sharpening twist drills the tool flanks containing the two cutting edges are ground. Each flank consists of a curved surface which provides the relief needed for the easy penetration and free cutting of the tool edges. In grinding the flanks, Fig. 2, the drill is swung around the axis *A* of an imaginary cone while resting in a support which holds the drill at one-half the point angle *B* with respect to the face of the grinding wheel. Feed *f* for stock removal is in the direction of the drill axis. The relief angle is usually measured at the periphery of the twist drill and is also specified by that value. It is not a constant but should increase toward the center of the drill.

The relief grinding of the flank surfaces will generate the chisel angle on the web of the twist drill. The value of that angle, typically  $55^\circ$ , which can be measured, for example, with the protractor of an optical projector, is indicative of the correctness of the relief grinding.

Fig. 1. The principal elements of tool geometry on twist drills.

Fig. 2. In grinding the face of the twist drill the tool is swung around the axis *A* of an imaginary cone, while resting in a support tilted by half of the point angle  $\beta$  with respect to the face of the grinding wheel. Feed *f* for stock removal is in the direction of the drill axis.

Fig. 3. The chisel edge *C* after thinning the web by grinding off area *T*.

Fig. 4. Split point or "crankshaft" type web thinning.

**Drill Point Thinning.**—The chisel edge is the least efficient operating surface element of the twist drill because it does not cut, but actually squeezes or extrudes the work material. To improve the inefficient cutting conditions caused by the chisel edge, the point width is often reduced in a drill-point thinning operation, resulting in a condition such as that shown in Fig. 3. Point thinning is particularly desirable on larger size drills and also on those which become shorter in usage, because the thickness of the web increases toward the shaft of the twist drill, thereby adding to the length of the chisel edge. The extent of point thinning is limited by the minimum strength of the web needed to avoid splitting of the drill point under the influence of cutting forces.

Both sharpening operations—the relieved face grinding and the point thinning—should be carried out in special drill grinding machines or with twist drill grinding fixtures mounted on general-purpose tool grinding machines, designed to assure the essential accu-

racy of the required tool geometry. Off-hand grinding may be used for the important web thinning when a special machine is not available; however, such operation requires skill and experience.

Improperly sharpened twist drills, e.g. those with unequal edge length or asymmetrical point angle, will tend to produce holes with poor diameter and directional control.

For deep holes and also drilling into stainless steel, titanium alloys, high temperature alloys, nickel alloys, very high strength materials and in some cases tool steels, split point grinding, resulting in a "crankshaft" type drill point, is recommended. In this type of pointing, see Fig. 4, the chisel edge is entirely eliminated, extending the positive rake cutting edges to the center of the drill, thereby greatly reducing the required thrust in drilling. Points on modified-point drills must be restored after sharpening to maintain their increased drilling efficiency.

**Sharpening Carbide Tools.**—Cemented carbide indexable inserts are usually not resharpened but sometimes they require a special grind in order to form a contour on the cutting edge to suit a special purpose. Brazed type carbide cutting tools are resharpened after the cutting edge has become worn. On brazed carbide tools the cutting-edge wear should not be allowed to become excessive before the tool is re-sharpened. One method of determining when brazed carbide tools need resharpening is by periodic inspection of the flank wear and the condition of the face. Another method is to determine the amount of production which is normally obtained before excessive wear has taken place, or to determine the equivalent period of time. One disadvantage of this method is that slight variations in the work material will often cause the wear rate not to be uniform and the number of parts machined before regrinding will not be the same each time. Usually, sharpening should not require the removal of more than 0.005 to 0.010 inch of carbide.

*General Procedure in Carbide Tool Grinding:* The general procedure depends upon the kind of grinding operation required. If the operation is to resharpen a dull tool, a diamond wheel of 100 to 120 grain size is recommended although a finer wheel—up to 150 grain size—is sometimes used to obtain a better finish. If the tool is new or is a "standard" design and changes in shape are necessary, a 100-grit diamond wheel is recommended for roughing and a finer grit diamond wheel can be used for finishing. Some shops prefer to rough grind the carbide with a vitrified silicon carbide wheel, the finish grinding being done with a diamond wheel. A final operation commonly designated as lapping may or may not be employed for obtaining an extra-fine finish.

*Wheel Speeds:* The speed of silicon carbide wheels usually is about 5000 feet per minute. The speeds of diamond wheels generally range from 5000 to 6000 feet per minute; yet lower speeds (550 to 3000 fpm) can be effective.

*Offhand Grinding:* In grinding single-point tools (excepting chip breakers) the common practice is to hold the tool by hand, press it against the wheel face and traverse it continuously across the wheel face while the tool is supported on the machine rest or table which is adjusted to the required angle. This is known as "offhand grinding" to distinguish it from the machine grinding of cutters as in regular cutter grinding practice. The selection of wheels adapted to carbide tool grinding is very important.

**Silicon Carbide Wheels.**—The green colored silicon carbide wheels generally are preferred to the dark gray or gray-black variety, although the latter are sometimes used.

*Grain or Grit Sizes:* For roughing, a grain size of 60 is very generally used. For finish grinding with silicon carbide wheels, a finer grain size of 100 or 120 is common. A silicon carbide wheel such as C60-I-7V may be used for grinding both the steel shank and carbide tip. However, for under-cutting steel shanks up to the carbide tip, it may be advantageous to use an aluminum oxide wheel suitable for grinding softer, carbon steel.

*Grade:* According to the standard system of marking, different grades from soft to hard are indicated by letters from A to Z. For carbide tool grinding fairly soft grades such as G, H, I, and J are used. The usual grades for roughing are I or J and for finishing H, I, and J. The

grade should be such that a sharp free-cutting wheel will be maintained without excessive grinding pressure. Harder grades than those indicated tend to overheat and crack the carbide.

*Structure:* The common structure numbers for carbide tool grinding are 7 and 8. The larger cup-wheels (10 to 14 inches) may be of the porous type and be designated as 12P. The standard structure numbers range from 1 to 15 with progressively higher numbers indicating less density and more open wheel structure.

**Diamond Wheels.**—Wheels with diamond-impregnated grinding faces are fast and cool cutting and have a very low rate of wear. They are used extensively both for resharpening and for finish grinding of carbide tools when preliminary roughing is required. Diamond wheels are also adapted for sharpening multi-tooth cutters such as milling cutters, reamers, etc., which are ground in a cutter grinding machine.

*Resinoid bonded* wheels are commonly used for grinding chip breakers, milling cutters, reamers or other multi-tooth cutters. They are also applicable to precision grinding of carbide dies, gages, and various external, internal and surface grinding operations. Fast, cool cutting action is characteristic of these wheels.

*Metal bonded* wheels are often used for offhand grinding of single-point tools especially when durability or long life and resistance to grooving of the cutting face, are considered more important than the rate of cutting. *Vitrified bonded* wheels are used both for roughing of chipped or very dull tools and for ordinary resharpening and finishing. They provide rigidity for precision grinding, a porous structure for fast cool cutting, sharp cutting action and durability.

**Diamond Wheel Grit Sizes.**—For roughing with diamond wheels a grit size of 100 is the most common both for offhand and machine grinding.

Grit sizes of 120 and 150 are frequently used in offhand grinding of single point tools 1) for resharpening; 2) for a combination roughing and finishing wheel; and 3) for chip-breaker grinding.

Grit sizes of 220 or 240 are used for ordinary finish grinding all types of tools (offhand and machine) and also for cylindrical, internal and surface finish grinding. Grits of 320 and 400 are used for "lapping" to obtain very fine finishes, and for hand hones. A grit of 500 is for lapping to a mirror finish on such work as carbide gages and boring or other tools for exceptionally fine finishes.

**Diamond Wheel Grades.**—Diamond wheels are made in several different grades to better adapt them to different classes of work. The grades vary for different types and shapes of wheels. Standard Norton grades are H, J, and L, for resinoid bonded wheels, grade N for metal bonded wheels and grades J, L, N, and P, for vitrified wheels. Harder and softer grades than standard may at times be used to advantage.

**Diamond Concentration.**—The relative amount (by carat weight) of diamond in the diamond section of the wheel is known as the "diamond concentration." Concentrations of 100 (high), 50 (medium) and 25 (low) ordinarily are supplied. A concentration of 50 represents one-half the diamond content of 100 (if the depth of the diamond is the same in each case) and 25 equals one-fourth the content of 100 or one-half the content of 50 concentration.

*100 Concentration:* Generally interpreted to mean 72 carats of diamond/in.<sup>3</sup> of abrasive section. (A 75 concentration indicates 54 carats/in.<sup>3</sup>.) Recommended (especially in grit sizes up to about 220) for general machine grinding of carbides, and for grinding cutters and chip breakers. Vitrified and metal bonded wheels usually have 100 concentration.

*50 Concentration:* In the finer grit sizes of 220, 240, 320, 400, and 500, a 50 concentration is recommended for offhand grinding with resinoid bonded cup-wheels.

**25 Concentration:** A low concentration of 25 is recommended for offhand grinding with resinoid bonded cup-wheels with grit sizes of 100, 120 and 150.

**Depth of Diamond Section:** The radial depth of the diamond section usually varies from  $\frac{1}{16}$  to  $\frac{1}{4}$  inch. The depth varies somewhat according to the wheel size and type of bond.

**Dry Versus Wet Grinding of Carbide Tools.**—In using silicon carbide wheels, grinding should be done either absolutely dry or with enough coolant to flood the wheel and tool. Satisfactory results may be obtained either by the wet or dry method. However, dry grinding is the most prevalent usually because, in wet grinding, operators tend to use an inadequate supply of coolant to obtain better visibility of the grinding operation and avoid getting wet; hence checking or cracking in many cases is more likely to occur in wet grinding than in dry grinding.

**Wet Grinding with Silicon Carbide Wheels:** One advantage commonly cited in connection with wet grinding is that an ample supply of coolant permits using wheels about one grade harder than in dry grinding thus increasing the wheel life. Plenty of coolant also prevents thermal stresses and the resulting cracks, and there is less tendency for the wheel to load. A dust exhaust system also is unnecessary.

**Wet Grinding with Diamond Wheels:** In grinding with diamond wheels the general practice is to use a coolant to keep the wheel face clean and promote free cutting. The amount of coolant may vary from a small stream to a coating applied to the wheel face by a felt pad.

**Coolants for Carbide Tool Grinding.**—In grinding either with silicon carbide or diamond wheels a coolant that is used extensively consists of water plus a small amount either of soluble oil, sal soda, or soda ash to prevent corrosion. One prominent manufacturer recommends for silicon carbide wheels about 1 ounce of soda ash per gallon of water and for diamond wheels kerosene. The use of kerosene is quite general for diamond wheels and usually it is applied to the wheel face by a felt pad. Another coolant recommended for diamond wheels consists of 80 per cent water and 20 per cent soluble oil.

**Peripheral Versus Flat Side Grinding.**—In grinding single point carbide tools with silicon carbide wheels, the roughing preparatory to finishing with diamond wheels may be done either by using the flat face of a cup-shaped wheel (side grinding) or the periphery of a “straight” or disk-shaped wheel. Even where side grinding is preferred, the periphery of a straight wheel may be used for heavy roughing as in grinding back chipped or broken tools (see left-hand diagram). Reasons for preferring peripheral grinding include faster cutting with less danger of localized heating and checking especially in grinding broad surfaces. The advantages usually claimed for side grinding are that proper rake or relief angles are easier to obtain and the relief or land is ground flat. The diamond wheels used for tool sharpening are designed for side grinding. (See right-hand diagram.)

**Lapping Carbide Tools.**—Carbide tools may be finished by lapping, especially if an exceptionally fine finish is required on the work as, for example, tools used for precision boring or turning non-ferrous metals. If the finishing is done by using a diamond wheel of very fine grit (such as 240, 320, or 400), the operation is often called “lapping.” A second lapping method is by means of a power-driven lapping disk charged with diamond dust, Norbide powder, or silicon carbide finishing compound. A third method is by using a hand lap or hone usually of 320 or 400 grit. In many plants the finishes obtained with carbide tools meet requirements without a special lapping operation. In all cases any feather edge which may be left on tools should be removed and it is good practice to bevel the edges of roughing tools at 45 degrees to leave a chamfer 0.005 to 0.010 inch wide. This is done by hand honing and the object is to prevent crumbling or flaking off at the edges when hard scale or heavy chip pressure is encountered.

*Hand Honing:* The cutting edge of carbide tools, and tools made from other tool materials, is sometimes hand honed before it is used in order to strengthen the cutting edge. When interrupted cuts or heavy roughing cuts are to be taken, or when the grade of carbide is slightly too hard, hand honing is beneficial because it will prevent chipping, or even possibly, breakage of the cutting edge. Whenever chipping is encountered, hand honing the cutting edge before use will be helpful. It is important, however, to hone the edge lightly and only when necessary. Heavy honing will always cause a reduction in tool life. Normally, removing 0.002 to 0.004 inch from the cutting edge is sufficient. When indexable inserts are used, the use of pre-honed inserts is preferred to hand honing although sometimes an additional amount of honing is required. Hand honing of carbide tools in between cuts is sometimes done to defer grinding or to increase the life of a cutting edge on an indexable insert. If correctly done, so as not to change the relief angle, this procedure is sometimes helpful. If improperly done, it can result in a reduction in tool life.

**Chip Breaker Grinding.**—For this operation a straight diamond wheel is used on a universal tool and cutter grinder, a small surface grinder, or a special chipbreaker grinder. A resinoid bonded wheel of the grade J or N commonly is used and the tool is held rigidly in an adjustable holder or vise. The width of the diamond wheel usually varies from  $\frac{1}{8}$  to  $\frac{1}{4}$  inch. A vitrified bond may be used for wheels as thick as  $\frac{1}{4}$  inch, and a resinoid bond for relatively narrow wheels.

**Summary of Miscellaneous Points.**—In grinding a single-point carbide tool, traverse it across the wheel face continuously to avoid localized heating. This traverse movement should be quite rapid in using silicon carbide wheels and comparatively slow with diamond wheels. A hand traversing and feeding movement, whenever practicable, is generally recommended because of greater sensitivity. In grinding, maintain a constant, moderate pressure. Manipulating the tool so as to keep the contact area with the wheel as small as possible will reduce heating and increase the rate of stock removal. Never cool a hot tool by dipping it in a liquid, as this may crack the tip. Wheel rotation should preferably be *against* the cutting edge or from the front face toward the back. If the grinder is driven by a reversing motor, opposite sides of a cup wheel can be used for grinding right- and left-hand tools and with rotation against the cutting edge. If it is necessary to grind the top face of a single-point tool, this should precede the grinding of the side and front relief, and top-face grinding should be minimized to maintain the tip thickness. In machine grinding with a diamond wheel, limit the feed per traverse to 0.001 inch for 100 to 120 grit; 0.0005 inch for 150 to 240 grit; and 0.0002 inch for 320 grit and finer.

## JIGS AND FIXTURES

## Jig Bushings

**Material for Jig Bushings.**—Bushings are generally made of a good grade of tool steel to ensure hardening at a fairly low temperature and to lessen the danger of fire cracking. They can also be made from machine steel, which will answer all practical purposes, provided the bushings are properly casehardened to a depth of about  $\frac{1}{16}$  inch. Sometimes, bushings for guiding tools may be made of cast iron, but only when the cutting tool is of such a design that no cutting edges come within the bushing itself. For example, bushings used simply to support the smooth surface of a boring-bar or the shank of a reamer might, in some instances, be made of cast iron, but hardened steel bushings should always be used for guiding drills, reamers, taps, etc., when the cutting edges come in direct contact with the guiding surfaces. If the outside diameter of the bushing is very large, as compared with the diameter of the cutting tool, the cost of the bushing can sometimes be reduced by using an outer cast-iron body and inserting a hardened tool steel bushing.

When tool steel bushings are made and hardened, it is recommended that A-2 steel be used. The furnace should be set to 1750°F and the bushing placed in the furnace and held there approximately 20 minutes after the furnace reaches temperature. Remove the bushing and cool in still air. After the part cools to 100–150°F, immediately place in a tempering furnace that has been heated to 300°F. Remove the bushing after one hour and cool in still air. If an atmospherically controlled furnace is unavailable, the part should be wrapped in stainless foil to prevent scaling and oxidation at the 1750°F temperature.

**American National Standard Jig Bushings.**—Specifications for the following types of jig bushings are given in American National Standard B94.33-1974 (R1986). Head Type Press Fit Wearing Bushings, Type H (Fig. 1 and Tables 1 and 3); Headless Type Press Fit Wearing Bushings, Type P (Fig. 2 and Tables 1 and 3); Slip Type Renewable Wearing Bushings, Type S (Fig. 3 and Tables 4 and 5); Fixed Type Renewable Wearing Bushings, Type F (Fig. 4 and Tables 5 and 6); Headless Type Liner Bushings, Type L (Fig. 5 and Table 7); and Head Type Liner Bushings, Type HL (Fig. 6 and Table 8). Specifications for locking mechanisms are also given in Table 9.

All dimensions are in inches. See [Table 3](#) for additional specifications.

**Table 3. Specifications for Head Type H and Headless Type P Press Fit Wearing Bushings ANSI B94.33-1974 (R1986)**

All dimensions given in inches. Tolerance on dimensions where not otherwise specified shall be  $\pm 0.010$  inch.  
 Size and type of chamfer on lead end to be manufacturer's option.  
 The length, *C*, is the overall length for the headless type and length underhead for the head type.  
 The head design shall be in accordance with the manufacturer's practice.  
 Diameter *A* must be concentric to diameter *B* within 0.0005 T.I.V. on finish ground bushings.  
 The body diameter, *B*, for unfinished bushings is larger than the nominal diameter in order to provide grinding stock for fitting to jig plate holes. The grinding allowance is:  
     0.005 to 0.010 in. for sizes 0.156, 0.203 and 0.250 in.  
     0.010 to 0.015 in. for sizes 0.312 and 0.406 in.  
     0.015 to 0.020 in. for sizes 0.500 in. and up.  
 Hole sizes are in accordance with American National Standard Twist Drill Sizes.  
 The maximum and minimum values of the hole size, *A*, shall be as follows:

| Nominal Size of Hole              | Maximum              | Minimum              |
|-----------------------------------|----------------------|----------------------|
| Above 0.0135 to 0.2500 in., incl. | Nominal + 0.0004 in. | Nominal + 0.0001 in. |
| Above 0.2500 to 0.7500 in., incl. | Nominal + 0.0005 in. | Nominal + 0.0001 in. |
| Above 0.7500 to 1.5000 in., incl. | Nominal + 0.0006 in. | Nominal + 0.0002 in. |
| Above 1.5000 in.                  | Nominal + 0.0007 in. | Nominal + 0.0003 in. |

Bushings in the size range from 0.0135 through 0.3125 will be counterbored to provide for lubrication and chip clearance.  
 Bushings without counterbore are optional and will be furnished upon request.  
 The size of the counterbore shall be inside diameter of the bushing + 0.031 inch.  
 The included angle at the bottom of the counterbore shall be 118 deg.  $\pm$  2 deg.  
 The depth of the counterbore shall be in accordance with the table below to provide adequate drill bearing.

| Body Length | Drill Bushing Hole Size           |       |                  |       |                  |       |                  |       |                  |       |                  |       |       |
|-------------|-----------------------------------|-------|------------------|-------|------------------|-------|------------------|-------|------------------|-------|------------------|-------|-------|

All dimensions are in inches. See also Table 5 for additional specifications.

**Table 5. Specifications for Slip Type S and Fixed Type F Renewable Wearing Bushings ANSI B94.33-1974 (R1986)**

|   |                         |       |                      |       |                  |       |                      |       |                  |       |                  |       |
|---|-------------------------|-------|----------------------|-------|------------------|-------|----------------------|-------|------------------|-------|------------------|-------|
| Tolerance on dimensions where not otherwise specified shall be plus or minus 0.010 inch.  |                         |       |                      |       |                  |       |                      |       |                  |       |                  |       |
| Hole sizes are in accordance with the American Standard Twist Drill Sizes.  |                         |       |                      |       |                  |       |                      |       |                  |       |                  |       |
| The maximum and minimum values of hole size, A, shall be as follows:  |                         |       |                      |       |                  |       |                      |       |                  |       |                  |       |
| Nominal Size of Hole  |                         |       | Maximum              |       |                  |       | Minimum              |       |                  |       |                  |       |
| Above 0.0135 to 0.2500 in. incl.  |                         |       | Nominal + 0.0004 in. |       |                  |       | Nominal + 0.0001 in. |       |                  |       |                  |       |
| Above 0.2500 to 0.7500 in. incl.  |                         |       | Nominal + 0.0005 in. |       |                  |       | Nominal + 0.0001 in. |       |                  |       |                  |       |
| Above 0.7500 to 1.5000 in. incl.  |                         |       | Nominal + 0.0006 in. |       |                  |       | Nominal + 0.0002 in. |       |                  |       |                  |       |
| Above 1.5000  |                         |       | Nominal + 0.0007 in. |       |                  |       | Nominal + 0.0003 in. |       |                  |       |                  |       |
| The head design shall be in accordance with the manufacturer's practice.  |                         |       |                      |       |                  |       |                      |       |                  |       |                  |       |
| Head of slip type is usually knurled.   |                         |       |                      |       |                  |       |                      |       |                  |       |                  |       |
| When renewable wearing bushings are used with liner bushings of the head type, the length under the head will still be equal to the thickness of the jig plate, because the head of the liner bushing will be countersunk into the jig plate. |                         |       |                      |       |                  |       |                      |       |                  |       |                  |       |
| Diameter A must be concentric to diameter B within 0.0005 T.I.R. on finish ground bushings.   |                         |       |                      |       |                  |       |                      |       |                  |       |                  |       |
| Size and type of chamfer on lead end to be manufacturer's option.   |                         |       |                      |       |                  |       |                      |       |                  |       |                  |       |
| Bushings in the size range from 0.0135 through 0.3125 will be counterbored to provide for lubrication and chip clearance.   |                         |       |                      |       |                  |       |                      |       |                  |       |                  |       |
| Bushings without counterbore are optional and will be furnished upon request.   |                         |       |                      |       |                  |       |                      |       |                  |       |                  |       |
| The size of the counterbore shall be inside diameter of the bushings plus 0.031 inch.   |                         |       |                      |       |                  |       |                      |       |                  |       |                  |       |
| The included angle at the bottom of the counterbore shall be 118 deg., plus or minus 2 deg.   |                         |       |                      |       |                  |       |                      |       |                  |       |                  |       |
| The depth of the counterbore shall be in accordance with the table below to provide adequate drill bearing.   |                         |       |                      |       |                  |       |                      |       |                  |       |                  |       |
| Body Length   | Drill Bearing Hole Size |       |                      |       |                  |       |                      |       |                  |       |                  |       |

All dimensions are in inches.

Tolerances on dimensions where otherwise not specified are  $\pm 0.010$  in.

The body diameter, *B*, for unfinished bushings is 0.015 to 0.020 in. larger than the nominal diameter in order to provide grinding stock for fitting to jig plate holes.

Diameter *A* must be concentric to diameter *B* within 0.0005 T.I.R. on finish ground bushings.

| 1.750   | 2.312                                     | 0.625            | 0.375 | 0.188                             | 1.000 | 30°         | 1.391              | 0.200-0.194                                | 0.187-0.177                        | 2.375   | 3                       |
| 2.250   | 2.812                                     | 0.625            | 0.375 | 0.188                             | 1.250 | 25°         | 1.641              | 0.200-0.194                                | 0.187-0.177                        | 2.875   | 3                       |

All dimensions are in inches.

**Jig Bushing Definitions.**— *Renewable Bushings:* Renewable wearing bushings to guide the tool are for use in liners which in turn are installed in the jig. They are used where the bushing will wear out or become obsolete before the jig or where several bushings are to be interchangeable in one hole. Renewable wearing bushings are divided into two classes, "Fixed" and "Slip." Fixed renewable bushings are installed in the liner with the intention of leaving them in place until worn out. Slip renewable bushings are interchangeable in a given size of liner and, to facilitate removal, they are usually made with a knurled head. They are most frequently used where two or more operations requiring different inside diameters are performed in a single jig, such as where drilling is followed by reaming, tapping, spot facing, counterboring, or some other secondary operation.

*Press Fit Bushings:* Press fit wearing bushings to guide the tool are for installation directly in the jig without the use of a liner and are employed principally where the bushings are used for short production runs and will not require replacement. They are intended also for short center distances.

*Liner Bushings:* Liner bushings are provided with and without heads and are permanently installed in a jig to receive the renewable wearing bushings. They are sometimes called master bushings.

**Jig Plate Thickness.**— The standard length of the press fit portion of jig bushings as established are based on standardized uniform jig plate thicknesses of  $\frac{3}{16}$ ,  $\frac{3}{8}$ ,  $\frac{1}{2}$ ,  $\frac{3}{4}$ , 1,  $1\frac{1}{8}$ ,  $1\frac{3}{4}$ ,  $2\frac{1}{8}$ ,  $2\frac{1}{2}$ , and 3 inches.

**Jig Bushing Designation System.**— *Inside Diameter:* The inside diameter of the hole is specified by a decimal dimension.

*Type Bushing:* The type of bushing is specified by a letter: S for Slip Renewable, F for Fixed Renewable, L for Headless Liner, HL for Head Liner, P for Headless Press Fit, and H for Head Press Fit.

*Body Diameter:* The body diameter is specified in multiples of 0.0156 inch. For example, a 0.500-inch body diameter =  $0.500/0.0156 = 32$ .

*Body Length:* The effective or body length is specified in multiples of 0.0625 inch. For example, a 0.500-inch length =  $0.500/0.0625 = 8$ .

*Unfinished Bushings:* All bushings with grinding stock on the body diameter are designated by the letter U following the number.

*Example:* A slip renewable bushing having a hole diameter of 0.5000 inch, a body diameter of 0.750 inch, and a body length of 1.000 inch would be designated as .5000-S-48-16.

## Jig Boring

**Definition of Jig and Fixture.**— The distinction between a jig and fixture is not easy to define, but, as a general rule, it is as follows: A jig either holds or is held on the work, and, at the same time, contains guides for the various cutting tools, whereas a fixture holds the work while the cutting tools are in operation, but does not contain any special arrangements for guiding the tools. A fixture, therefore, must be securely held or fixed to the machine on which the operation is performed—hence the name. A fixture is sometimes provided with a number of gages and stops, but not with bushings or other devices for guiding and supporting the cutting tools.

**Jig Borers.**— Jig borers are used for precision hole-location work. For this reason, the coordinate measuring systems on these machines are designed to provide longitudinal and transverse movements that are accurate to 0.0001 in. One widely used method of obtaining this accuracy utilizes ultraprecision lead screws. Another measuring system employs precision end measuring rods and a micrometer head that are placed in a trough which is parallel to the table movement. However, the purpose of all coordinate measuring systems used is the same: to provide a method of aligning the spindle at the precise location where a hole is to be produced. Since the work table of a jig borer moves in two directions, the

coordinate system of dimensioning is used, where dimensions are given from two perpendicular reference axes, usually the sides of the workpiece, frequently its upper left-hand corner. See Fig. 1C.

**Jig-Boring Practice.**—The four basic steps to follow to locate and machine a hole on a jig borer are:

*Align and Clamp the Workpiece:* The first consideration in placing the workpiece on the jig-borer table should be the relation of the coordinate measuring system of the jig borer to the coordinate dimensions on the drawing. Therefore, the coordinate measuring system is designed so that the readings of the coordinate measurements are direct when the table is moved toward the left and when it is moved toward the column of the jig borer. The result would be the same if the spindle were moved toward the right and away from the column, with the workpiece situated in such a position that one reference axis is located at the left and the other axis at the back, toward the column.

If the holes to be bored are to pass through the bottom of the workpiece, then the workpiece must be placed on precision parallel bars. In order to prevent the force exerted by the clamps from bending the workpiece the parallel bars are placed directly under the clamps, which hold the workpiece on the table. The reference axes of the workpiece must also be aligned with respect to the transverse and longitudinal table movements before it is firmly clamped. This alignment can be done with a dial-test indicator held in the spindle of the jig borer and bearing against the longitudinal reference edge. As the table is traversed in the longitudinal direction, the workpiece is adjusted until the dial-test indicator readings are the same for all positions.

*Locate the Two Reference Axes of the Workpiece with Respect to the Spindle:* The jig-borer table is now moved to position the workpiece in a precise and known location from where it can be moved again to the location of the holes to be machined. Since all the holes are dimensioned from the two reference axes, the most convenient position to start from is where the axis of the jig-borer spindle and the intersection of the two workpiece reference axes are aligned. This is called the starting position, which is similar to a zero reference position. When so positioned, the longitudinal and transverse measuring systems of the jig borer are set to read zero. Occasionally, the reference axes are located outside the body of the workpiece: a convenient edge or hole on the workpiece is picked up as the starting position, and the dimensions from this point to the reference axes are set on the positioning measuring system.

*Locate the Hole:* Precise coordinate table movements are used to position the workpiece so that the spindle axis is located exactly where the hole is to be machined. When the measuring system has been set to zero at the starting position, the coordinate readings at the hole location will be the same as the coordinate dimensions of the hole center.

The movements to each hole must be made in one direction for both the transverse and longitudinal directions, to eliminate the effect of any backlash in the lead screw. The usual table movements are toward the left and toward the column.

The most convenient sequence on machines using micrometer dials as position indicators (machines with lead screws) is to machine the hole closest to the starting position first and then the next closest, and so on. On jig borers using end measuring rods, the opposite sequence is followed: The farthest hole is machined first and then the next farthest, and so on, since it is easier to remove end rods and replace them with shorter rods.

*Drill and Bore Hole to Size:* The sequence of operations used to produce a hole on a jig borer is as follows: 1) a short, stiff drill, such as a center drill, that will not deflect when cutting should be used to spot a hole when the work and the axis of the machine tool spindle are located at the exact position where the hole is wanted; 2) the initial hole is made by a twist drill; and 3) a single-point boring tool that is set to rotate about the axis of the machine tool spindle is then used to generate a cut surface that is concentric to the axis of rotation.

Heat will be generated by the drilling operation, so it is good practice to drill all the holes first, and then allow the workpiece to cool before the holes are bored to size.

**Transfer of Tolerances.**—All of the dimensions that must be accurately held on precision machines and engine parts are usually given a tolerance. And when such dimensions are changed from the conventional to the coordinate system of dimensioning, the tolerances must also be included. Because of their importance, the transfer of the tolerances must be done with great care, keeping in mind that the sum of the tolerances of any pair of dimensions in the coordinate system must not be larger than the tolerance of the dimension that they replaced in the conventional system. An example is given in Fig. 1.

The first step in the procedure is to change the tolerances given in Fig. 1A to equal, bilateral tolerances given in Fig. 1B. For example, the dimension  $2.125^{+0.003}_{-0.001}$  has a total tolerance of 0.004. The equal, bilateral tolerance would be plus or minus one-half of this value, or  $\pm 0.002$ . Then to keep the limiting dimensions the same, the basic dimension must be changed to 2.126, in order to give the required values of 2.128 and 2.124. When changing to equal, bilateral tolerances, if the upper tolerance is decreased (as in this example), the basic dimension must be increased by a like amount. The upper tolerance was decreased by  $0.003 - 0.002 = 0.001$ ; therefore, the basic dimension was increased by 0.001 to 2.126. Conversely, if the upper tolerance is increased, the basic dimension is decreased.

The next step is to transfer the revised basic dimension to the coordinate dimensioning system. To transfer the 2.126 dimension, the distance of the applicable holes from the left reference axis must be determined. The first holes to the right are 0.8750 from the reference axis. The second hole is 2.126 to the right of the first holes. Therefore, the second hole is  $0.8750 + 2.126 = 3.0010$  to the right of the reference axis. This value is then the coordinate dimension for the second hole, while the 0.8750 value is the coordinate dimension of the first two, vertically aligned holes. This procedure is followed for all the holes to find their distances from the two reference axes. These values are given in Fig. 1C.

The final step is to transfer the tolerances. The 2.126 value in Fig. 1B has been replaced by the 0.8750 and 3.0010 values in Fig. 1C. The 2.126 value has an available tolerance of  $\pm 0.002$ . Dividing this amount equally between the two replacement values gives  $0.8750 \pm 0.001$  and  $3.0010 \pm 0.001$ . The sum of these tolerances is .002, and as required, does not exceed the tolerance that was replaced. Next transfer the tolerance of the 0.502 dimension. Divide the available tolerance,  $\pm 0.002$ , equally between the two replacement values to yield  $3.0010 \pm 0.001$  and  $3.5030 \pm 0.001$ . The sum of these two tolerances equals the replaced tolerance, as required. However, the 1.125 value of the last hole to the right (coordinate dimension 4.6280 in.) has a tolerance of only  $\pm 0.001$ . Therefore, the sum of the tolerances on the 3.5030 and 4.6280 values cannot be larger than 0.001. Dividing this tolerance equally would give  $3.5030 \pm .0005$  and  $4.6280 \pm 0.0005$ . This new, smaller tolerance replaces the  $\pm 0.001$  tolerance on the 3.5030 value in order to satisfy all tolerance sum requirements. This example shows how the tolerance of a coordinate value is affected by more than one other dimensional requirement.

The following discussion will summarize the various tolerances listed in Fig. 1C. For the  $0.8750 \pm 0.0010$  dimension, the  $\pm 0.0010$  tolerance together with the  $\pm 0.0010$  tolerance on the 3.0010 dimension is required to maintain the  $\pm 0.002$  tolerance of the 2.126 dimension. The  $\pm .0005$  tolerances on the 3.5030 and 4.2680 dimensions are required to maintain the  $\pm 0.001$  tolerance of the 1.125 dimension, at the same time as the sum of the  $\pm .0005$  tolerance on the 3.5030 dimension and the  $\pm 0.001$  tolerance on the 3.0010 dimension does not exceed the  $\pm 0.002$  tolerance on the replaced 0.503 dimension. The  $\pm 0.0005$  tolerances on the 1.0000 and 2.0000 values maintain the  $\pm 0.001$  tolerance on the 1.0000 value given at the right in Fig. 1A. The  $\pm 0.0045$  tolerance on the 3.0000 dimension together with the  $\pm 0.0005$  tolerance on the 1.0000 value maintains the  $\pm .005$  tolerance on the 2.0000 dimension of Fig. 1A. It should be noted that the  $2.000 \pm .005$  dimension in Fig. 1A was replaced by the 1.0000 and 3.0000 dimensions in Fig. 1C. Each of these values could have had a tol-

JIG BORING

Fig. 1. (A) Conventional Dimensions, Mixed Tolerances; (B) Conventional Dimensions, All Equal, Bilateral Tolerances; and (C) Coordinate Dimensions

erance of  $\pm 0.0025$ , except that the tolerance on the 1.0000 dimension on the left in Fig. 1A is also bound by the  $\pm 0.001$  tolerance on the 1.0000 dimension on the right, thus the  $\pm 0.0005$  tolerance value is used. This procedure requires the tolerance on the 3.0000 value to be increased to  $\pm 0.0045$ .

### Determining Hole Coordinates

On the following pages are given tables of the lengths of chords for spacing off the circumferences of circles. The object of these tables is to make possible the division of the periphery into a number of equal parts without trials with the dividers. The first table, Table 10, is calculated for circles having a diameter equal to 1. For circles of other diameters, the length of chord given in the table should be multiplied by the diameter of the circle. Table 10 may be used by toolmakers when setting "buttons" in circular formation. Assume that it is required to divide the periphery of a circle of 20 inches diameter into thirty-two equal parts. From the table the length of the chord is found to be 0.098017 inch, if the diameter of the circle were 1 inch. With a diameter of 20 inches the length of the chord for one division would be  $20 \times 0.098017 = 1.9603$  inches. Another example in metric units: For a 100 millimeter diameter requiring 5 equal divisions, the length of the chord for one division would be  $100 \times 0.587785 = 58.7785$  millimeters.

Tables 11a and 11b starting on page 991 are additional tables for the spacing off of circles; the tables, in this case, being worked out for diameters from  $\frac{1}{16}$  inch to 14 inches. As an example, assume that it is required to divide a circle having a diameter of  $6\frac{1}{2}$  inches into seven equal parts. Find first, in the column headed "6" and in line with 7 divisions, the length of the chord for a 6-inch circle, which is 2.603 inches. Then find the length of the chord for a  $\frac{1}{2}$ -inch diameter circle, 7 divisions, which is 0.217. The sum of these two values,  $2.603 + 0.217 = 2.820$  inches, is the length of the chord required for spacing off the circumference of a  $6\frac{1}{2}$ -inch circle into seven equal divisions.

As another example, assume that it is required to divide a circle having a diameter of  $9\frac{23}{32}$  inches into 15 equal divisions. First find the length of the chord for a 9-inch circle, which is 1.871 inch. The length of the chord for a  $\frac{23}{32}$ -inch circle can easily be estimated from the table by taking the value that is exactly between those given for  $\frac{11}{16}$  and  $\frac{3}{4}$  inch. The value for  $\frac{11}{16}$  inch is 0.143, and for  $\frac{3}{4}$  inch, 0.156. For  $\frac{23}{32}$  the value would be 0.150. Then,  $1.871 + 0.150 = 2.021$  inches.

**Hole Coordinate Dimension Factors for Jig Boring.**—Tables of hole coordinate dimension factors for use in jig boring are given in Tables 12 through 15 starting on page 993. The coordinate axes shown in the figure accompanying each table are used to reference the tool path; the values listed in each table are for the end points of the tool path. In this machine coordinate system, a positive *Y* value indicates that the effective motion of the tool with reference to the work is toward the front of the jig borer (the actual motion of the jig borer table is toward the column). Similarly, a positive *X* value indicates that the effective motion of the tool with respect to the work is toward the right (the actual motion of the jig borer table is toward the left). When entering data into most computer-controlled jig borers, current practice is to use the more familiar Cartesian coordinate axis system in which the positive *Y* direction is "up" (i.e., pointing toward the column of the jig borer). The computer will automatically change the signs of the entered *Y* values to the signs that they would have in the machine coordinate system. Therefore, before applying the coordinate dimension factors given in the tables, it is important to determine the coordinate system to be used. If a Cartesian coordinate system is to be used for the tool path, then the sign of the *Y* values in the tables must be changed, from positive to negative and from negative to positive. For example, when programming for a three-hole type A circle using Cartesian coordinates, the *Y* values from Table 14 would be  $y_1 = +0.50000$ ,  $y_2 = -0.25000$ , and  $y_3 = -0.25000$ .

**Table 10. Lengths of Chords for Spacing Off the Circumferences of Circles with a Diameter Equal to 1 (English or metric units)**

| No. of Spaces | Length of Chord | No. of Spaces | Length of Chord | No. of Spaces | Length of Chord | No. of Spaces | Length of Chord |
|---------------|-----------------|---------------|-----------------|---------------|-----------------|---------------|-----------------|

For circles of other diameters, multiply length given in table by diameter of circle.

*Example:* In a drill jig, 8 holes, each  $\frac{1}{2}$  inch diameter, were spaced evenly on a 6-inch diameter circle. To test the accuracy of the jig, plugs were placed in adjacent holes, and the distance over the plugs was measured with a micrometer. What should be the micrometer reading?

*Solution:* The micrometer reading equals the diameter of one plug plus 6 times the chordal distance between adjacent hole centers given in the table above. Thus, the reading should be  $\frac{1}{2} + (6 \times 0.382683) = 2.796098$  inches.

Table 11a. Table for Spacing Off the Circumferences of Circles

| No. of Divisions | Degrees in Arc     | Diameter of Circle to be Spaced Off |               |                |               |                |               |                |               |                |               |                 |               |                 |               |                 |
|------------------|--------------------|-------------------------------------|---------------|----------------|---------------|----------------|---------------|----------------|---------------|----------------|---------------|-----------------|---------------|-----------------|---------------|-----------------|
|                  |                    | $\frac{1}{16}$                      | $\frac{1}{8}$ | $\frac{3}{16}$ | $\frac{1}{4}$ | $\frac{5}{16}$ | $\frac{3}{8}$ | $\frac{7}{16}$ | $\frac{1}{2}$ | $\frac{9}{16}$ | $\frac{5}{8}$ | $\frac{11}{16}$ | $\frac{3}{4}$ | $\frac{13}{16}$ | $\frac{7}{8}$ | $\frac{15}{16}$ |

The diagram shows a type "A" circle for a 5-hole circle. Coordinates  $x$ ,  $y$  are given in the table for hole circles of from 3 to 28 holes. Dimensions are for holes numbered in a counterclockwise direction (as shown). Dimensions given are based upon a hole circle of unit diameter. For a hole circle of, say, 3-inch or 3-centimeter diameter, multiply table values by 3.

The diagram shows a type "A" circle for a 5-hole circle. Coordinates x, y are given in the table for hole circles of from 3 to 28 holes. Dimensions are for holes numbered in a counterclockwise direction (as shown). Dimensions given are based upon a hole circle of unit diameter. For a hole circle of, say, 3-inch or 3-centimeter diameter, multiply table values by 3.

The diagram shows a type "A" circle for a 5-hole circle. Coordinates  $x$ ,  $y$  are given in the table for hole circles of from 3 to 28 holes. Dimensions are for holes numbered in a counterclockwise direction (as shown). Dimensions given are based upon a hole circle of unit diameter. For a hole circle of, say, 3-inch or 3-centimeter diameter, multiply table values by 3.

**Table 13. Hole Coordinate Dimension Factors for Jig Boring — Type "B" Hole Circles (English or Metric Units)**

| 3 Holes  |         | 4 Holes  |         | 5 Holes  |         | 6 Holes  |         | 7 Holes  |         | 8 Holes  |         | 9 Holes  |         |

The diagram shows a type "B" circle for a 5-hole circle. Coordinates  $x$ ,  $y$  are given in the table for hole circles of from 3 to 28 holes. Dimensions are for holes numbered in a counterclockwise direction (as shown). Dimensions given are based upon a hole circle of unit diameter. For a hole circle of, say, 3-inch or 3-centimeter diameter, multiply table values by 3.

**Table 13. (Continued) Hole Coordinate Dimension Factors for Jig Boring — Type "B" Hole Circles (English or Metric Units)**

The diagram shows a type "B" circle for a 5-hole circle. Coordinates x, y are given in the table for hole circles of from 3 to 28 holes. Dimensions are for holes numbered in a counterclockwise direction (as shown). Dimensions given are based upon a hole circle of unit diameter. For a hole circle of, say, 3-inch or 3-centimeter diameter, multiply table values by 3.

The diagram shows a type "B" circle for a 5-hole circle. Coordinates  $x$ ,  $y$  are given in the table for hole circles of from 3 to 28 holes. Dimensions are for holes numbered in a counterclockwise direction (as shown). Dimensions given are based upon a hole circle of unit diameter. For a hole circle of, say, 3-inch or 3-centimeter diameter, multiply table values by 3.

**Table 14. Hole Coordinate Dimension Factors for Jig Boring — Type "A" Hole Circles, Central Coordinates (English or Metric Units)**

| 3 Holes   |          | 4 Holes  |          | 5 Holes  |          | 6 Holes  |          | 7 Holes  |          | 8 Holes  |          | 9 Holes  |          |
|---|----------|----------|----------|----------|----------|----------|----------|----------|----------|----------|----------|----------|----------|
| <p>The diagram shows a type "A" circle for a 5-hole circle. Coordinates <math>x</math>, <math>y</math> are given in the table for hole circles of from 3 to 28 holes. Dimensions are for holes numbered in a counterclockwise direction (as shown). Dimensions given are based upon a hole circle of unit diameter. For a hole circle of, say, 3-inch or 3-centimeter diameter, multiply table values by 3.</p> |          |          |          |          |          |          |          |          |          |          |          |          |          |

**Table 14. (Continued) Hole Coordinate Dimension Factors for Jig Boring — Type "A" Hole Circles, Central Coordinates (English or Metric Units)**

The diagram shows a type "A" circle for a 5-hole circle. Coordinates  $x$ ,  $y$  are given in the table for hole circles of from 3 to 28 holes. Dimensions are for holes numbered in a counterclockwise direction (as shown). Dimensions given are based upon a hole circle of unit diameter. For a hole circle of, say, 3-inch or 3-centimeter diameter, multiply table values by 3.

The diagram shows a type "A" circle for a 5-hole circle. Coordinates  $x$ ,  $y$  are given in the table for hole circles of from 3 to 28 holes. Dimensions are for holes numbered in a counterclockwise direction (as shown). Dimensions given are based upon a hole circle of unit diameter. For a hole circle of, say, 3-inch or 3-centimeter diameter, multiply table values by 3.

**Table 15. Hole Coordinate Dimension Factors for Jig Boring — Type "B" Hole Circles Central Coordinates (English or Metric units)**

| 3 Holes  |          | 4 Holes  |          | 5 Holes  |          | 6 Holes  |          | 7 Holes  |          | 8 Holes  |          | 9 Holes  |          |

The diagram shows a type "B" circle for a 5-hole circle. Coordinates x, y are given in the table for hole circles of from 3 to 28 holes. Dimensions are for holes numbered in a counterclockwise direction (as shown). Dimensions given are based upon a hole circle of unit diameter. For a hole circle of, say, 3-inch or 3-centimeter diameter, multiply table values by 3.

**Table 15. (Continued) Hole Coordinate Dimension Factors for Jig Boring — Type "B" Hole Circles Central Coordinates (English or Metric units)**

The diagram shows a type "B" circle for a 5-hole circle. Coordinates x, y are given in the table for hole circles of from 3 to 28 holes. Dimensions are for holes numbered in a counterclockwise direction (as shown). Dimensions given are based upon a hole circle of unit diameter. For a hole circle of, say, 3-inch or 3-centimeter diameter, multiply table values by 3.

The diagram shows a type "B" circle for a 5-hole circle. Coordinates x, y are given in the table for hole circles of from 3 to 28 holes. Dimensions are for holes numbered in a counterclockwise direction (as shown). Dimensions given are based upon a hole circle of unit diameter. For a hole circle of, say, 3-inch or 3-centimeter diameter, multiply table values by 3.

## CUTTING SPEEDS AND FEEDS

### Introduction to Speeds and Feeds

**Work Materials.**—The large number of work materials that are commonly machined vary greatly in their basic structure and the ease with which they can be machined. Yet it is possible to group together certain materials having similar machining characteristics, for the purpose of recommending the cutting speed at which they can be cut. Most materials that are machined are metals and it has been found that the most important single factor influencing the ease with which a metal can be cut is its microstructure, followed by any cold work that may have been done to the metal, which increases its hardness. Metals that have a similar, but not necessarily the same microstructure, will tend to have similar machining characteristics. Thus, the grouping of the metals in the accompanying tables has been done on the basis of their microstructure.

With the exception of a few soft and gummy metals, experience has shown that harder metals are more difficult to cut than softer metals. Furthermore, any given metal is more difficult to cut when it is in a harder form than when it is softer. It is more difficult to penetrate the harder metal and more power is required to cut it. These factors in turn will generate a higher cutting temperature at any given cutting speed, thereby making it necessary to use a slower speed, for the cutting temperature must always be kept within the limits that can be sustained by the cutting tool without failure. Hardness, then, is an important property that must be considered when machining a given metal. Hardness alone, however, cannot be used as a measure of cutting speed. For example, if pieces of AISI 11L17 and AISI 1117 steel both have a hardness of 150 Bhn, their recommended cutting speeds for high-speed steel tools will be 140 fpm and 130 fpm, respectively. In some metals, two entirely different microstructures can produce the same hardness. As an example, a fine pearlite microstructure and a tempered martensite microstructure can result in the same hardness in a steel. These microstructures will not machine alike. For practical purposes, however, information on hardness is usually easier to obtain than information on microstructure; thus, hardness alone is usually used to differentiate between different cutting speeds for machining a metal. In some situations, the hardness of a metal to be machined is not known. When the hardness is not known, the material condition can be used as a guide.

The surface of ferrous metal castings has a scale that is more difficult to machine than the metal below. Some scale is more difficult to machine than others, depending on the foundry sand used, the casting process, the method of cleaning the casting, and the type of metal cast. Special electrochemical treatments sometimes can be used that almost entirely eliminate the effect of the scale on machining, although castings so treated are not frequently encountered. Usually, when casting scale is encountered, the cutting speed is reduced approximately 5 or 10 per cent. Difficult-to-machine surface scale can also be encountered when machining hot-rolled or forged steel bars.

Metallurgical differences that affect machining characteristics are often found within a single piece of metal. The occurrence of hard spots in castings is an example. Different microstructures and hardness levels may occur within a casting as a result of variations in the cooling rate in different parts of the casting. Such variations are less severe in castings that have been heat treated. Steel bar stock is usually harder toward the outside than toward the center of the bar. Sometimes there are slight metallurgical differences along the length of a bar that can affect its cutting characteristics.

**Cutting Tool Materials.**—The recommended cutting feeds and speeds in the accompanying tables are given for high-speed steel, coated and uncoated carbides, ceramics, cermets, and polycrystalline diamonds. More data are available for HSS and carbides because these materials are the most commonly used. Other materials that are used to make cutting tools are cemented oxides or ceramics, cermets, cast nonferrous alloys (Stellite), single-crystal diamonds, polycrystalline diamonds, and cubic boron nitride.

*Carbon Tool Steel:* It is used primarily to make the less expensive drills, taps, and reamers. It is seldom used to make single-point cutting tools. Hardening in carbon steels is very shallow, although some have a small amount of vanadium and chromium added to improve their hardening quality. The cutting speed to use for plain carbon tool steel should be approximately one-half of the recommended speed for high-speed steel.

*High-Speed Steel:* This designates a number of steels having several properties that enhance their value as cutting tool material. They can be hardened to a high initial or room-temperature hardness ranging from 63 Rc to 65 Rc for ordinary high-speed steels and up to 70 Rc for the so-called superhigh-speed steels. They can retain sufficient hardness at temperatures up to 1,000 to 1,100°F to enable them to cut at cutting speeds that will generate these tool temperatures, and they will return to their original hardness when cooled to room temperature. They harden very deeply, enabling high-speed steels to be ground to the tool shape from solid stock and to be reground many times without sacrificing hardness at the cutting edge. High-speed steels can be made soft by annealing so that they can be machined into complex cutting tools such as drills, reamers, and milling cutters and then hardened.

The principal alloying elements of high-speed steels are tungsten (W), molybdenum (Mo), chromium (Cr), vanadium (V), together with carbon (C). There are a number of grades of high-speed steel that are divided into two types: tungsten high-speed steels and molybdenum high-speed steels. Tungsten high-speed steels are designated by the prefix T before the number that designates the grade. Molybdenum high-speed steels are designated by the prefix letter M. There is little performance difference between comparable grades of tungsten or molybdenum high-speed steel.

The addition of 5 to 12 per cent cobalt to high-speed steel increases its hardness at the temperatures encountered in cutting, thereby improving its wear resistance and cutting efficiency. Cobalt slightly increases the brittleness of high-speed steel, making it susceptible to chipping at the cutting edge. For this reason, cobalt high-speed steels are primarily made into single-point cutting tools that are used to take heavy roughing cuts in abrasive materials and through rough abrasive surface scales.

The M40 series and T15 are a group of high-hardness or so-called super high-speed steels that can be hardened to 70 Rc; however, they tend to be brittle and difficult to grind. For cutting applications, they are usually heat treated to 67–68 Rc to reduce their brittleness and tendency to chip. The M40 series is appreciably easier to grind than T15. They are recommended for machining tough die steels and other difficult-to-cut materials; they are not recommended for applications where conventional high-speed steels perform well. High-speed steels made by the powder-metallurgy process are tougher and have an improved grindability when compared with similar grades made by the customary process. Tools made of these steels can be hardened about 1 Rc higher than comparable high-speed steels made by the customary process without a sacrifice in toughness. They are particularly useful in applications involving intermittent cutting and where tool life is limited by chipping. All these steels augment rather than replace the conventional high-speed steels.

*Cemented Carbides:* They are also called sintered carbides or simply carbides. They are harder than high-speed steels and have excellent wear resistance. Information on cemented carbides and other hard metal tools is included in the section *CEMENTED CARBIDES* starting on page 773.

Cemented carbides retain a very high degree of hardness at temperatures up to 1400°F and even higher; therefore, very fast cutting speeds can be used. When used at fast cutting speeds, they produce good surface finishes on the workpiece. Carbides are more brittle than high-speed steel and, therefore, must be used with more care.

Hundreds of grades of carbides are available and attempts to classify these grades by area of application have not been entirely successful.

There are four distinct types of carbides: 1) straight tungsten carbides; 2) crater-resistant carbides; 3) titanium carbides; and 4) coated carbides.

*Straight Tungsten Carbide:* This is the most abrasion-resistant cemented carbide and is used to machine gray cast iron, most nonferrous metals, and nonmetallic materials, where abrasion resistance is the primary criterion. Straight tungsten carbide will rapidly form a crater on the tool face when used to machine steel, which reduces the life of the tool. Titanium carbide is added to tungsten carbide in order to counteract the rapid formation of the crater. In addition, tantalum carbide is usually added to prevent the cutting edge from deforming when subjected to the intense heat and pressure generated in taking heavy cuts.

*Crater-Resistant Carbides:* These carbides, containing titanium and tantalum carbides in addition to tungsten carbide, are used to cut steels, alloy cast irons, and other materials that have a strong tendency to form a crater.

*Titanium Carbides:* These carbides are made entirely from titanium carbide and small amounts of nickel and molybdenum. They have an excellent resistance to cratering and to heat. Their high hot hardness enables them to operate at higher cutting speeds, but they are more brittle and less resistant to mechanical and thermal shock. Therefore, they are not recommended for taking heavy or interrupted cuts. Titanium carbides are less abrasion-resistant and not recommended for cutting through scale or oxide films on steel. Although the resistance to cratering of titanium carbides is excellent, failure caused by crater formation can sometimes occur because the chip tends to curl very close to the cutting edge, thereby forming a small crater in this region that may break through.

*Coated Carbides:* These are available only as indexable inserts because the coating would be removed by grinding. The principal coating materials are titanium carbide (TiC), titanium nitride (TiN), and aluminum oxide ( $Al_2O_3$ ). A very thin layer (approximately 0.0002 in.) of coating material is deposited over a cemented carbide insert; the material below the coating is called the substrate. The overall performance of the coated carbide is limited by the substrate, which provides the required toughness and resistance to deformation and thermal shock. With an equal tool life, coated carbides can operate at higher cutting speeds than uncoated carbides. The increase may be 20 to 30 per cent and sometimes up to 50 per cent faster. Titanium carbide and titanium nitride coated carbides usually operate in the medium (200–800 fpm) cutting speed range, and aluminum oxide coated carbides are used in the higher (800–1600 fpm) cutting speed range.

*Carbide Grade Selection:* The selection of the best grade of carbide for a particular application is very important. An improper grade of carbide will result in a poor performance—it may even cause the cutting edge to fail before any significant amount of cutting has been done. Because of the many grades and the many variables that are involved, the carbide producers should be consulted to obtain recommendations for the application of their grades of carbide. A few general guidelines can be given that are useful to form an orientation. Metal cutting carbides usually range in hardness from about 89.5 Ra (Rockwell A Scale) to 93.0 Ra with the exception of titanium carbide, which has a hardness range of 90.5 Ra to 93.5 Ra. Generally, the harder carbides are more wear-resistant and more brittle, whereas the softer carbides are less wear-resistant but tougher. A choice of hardness must be made to suit the given application. The very hard carbides are generally used for taking light finishing cuts. For other applications, select the carbide that has the highest hardness with sufficient strength to prevent chipping or breaking. Straight tungsten carbide grades should always be used unless cratering is encountered. Straight tungsten carbides are used to machine gray cast iron, ferritic malleable iron, austenitic stainless steel, high-temperature alloys, copper, brass, bronze, aluminum alloys, zinc alloy die castings, and plastics. Crater-resistant carbides should be used to machine plain carbon steel, alloy steel, tool steel, pearlitic malleable iron, nodular iron, other highly alloyed cast irons, ferritic stainless steel, martensitic stainless steel, and certain high-temperature alloys. Titanium carbides are recommended for taking high-speed finishing and semifinishing cuts on steel, especially the low-carbon, low-alloy steels, which are less abrasive and have a strong tendency to form a crater. They are also used to take light cuts on alloy cast iron and on

some high-nickel alloys. Nonferrous materials, such as some aluminum alloys and brass, that are essentially nonabrasive may also be machined with titanium carbides. Abrasive materials and others that should not be machined with titanium carbides include gray cast iron, titanium alloys, cobalt- and nickel-base superalloys, stainless steel, bronze, many aluminum alloys, fiberglass, plastics, and graphite. The feed used should not exceed about 0.020 inch per revolution.

Coated carbides can be used to take cuts ranging from light finishing to heavy roughing on most materials that can be cut with these carbides. The coated carbides are recommended for machining all free-machining steels, all plain carbon and alloy steels, tool steels, martensitic and ferritic stainless steels, precipitation-hardening stainless steels, alloy cast iron, pearlitic and martensitic malleable iron, and nodular iron. They are also recommended for taking light finishing and roughing cuts on austenitic stainless steels. Coated carbides should not be used to machine nickel- and cobalt-base superalloys, titanium and titanium alloys, brass, bronze, aluminum alloys, pure metals, refractory metals, and nonmetals such as fiberglass, graphite, and plastics.

*Ceramic Cutting Tool Materials:* These are made from finely powdered aluminum oxide particles sintered into a hard dense structure without a binder material. Aluminum oxide is also combined with titanium carbide to form a composite, which is called a cermet. These materials have a very high hot hardness enabling very high cutting speeds to be used. For example, ceramic cutting tools have been used to cut AISI 1040 steel at a cutting speed of 18,000 fpm with a satisfactory tool life. However, much lower cutting speeds, in the range of 1000 to 4000 fpm and lower, are more common because of limitations placed by the machine tool, cutters, and chucks. Although most applications of ceramic and cermet cutting tool materials are for turning, they have also been used successfully for milling. Ceramics and cermets are relatively brittle and a special cutting edge preparation is required to prevent chipping or edge breakage. This preparation consists of honing or grinding a narrow flat land, 0.002 to 0.006 inch wide, on the cutting edge that is made about 30 degrees with respect to the tool face. For some heavy-duty applications, a wider land is used. The setup should be as rigid as possible and the feed rate should not normally exceed 0.020 inch, although 0.030 inch has been used successfully. Ceramics and cermets are recommended for roughing and finishing operations on all cast irons, plain carbon and alloy steels, and stainless steels. Materials up to a hardness of 60 Rockwell C Scale can be cut with ceramic and cermet cutting tools. These tools should not be used to machine aluminum and aluminum alloys, magnesium alloys, titanium, and titanium alloys.

*Cast Nonferrous Alloy:* Cutting tools of this alloy are made from tungsten, tantalum, chromium, and cobalt plus carbon. Other alloying elements are also used to produce materials with high temperature and wear resistance. These alloys cannot be softened by heat treatment and must be cast and ground to shape. The room-temperature hardness of cast nonferrous alloys is lower than for high-speed steel, but the hardness and wear resistance is retained to a higher temperature. The alloys are generally marketed under trade names such as Stellite, Crobalt, and Tantung. The initial cutting speed for cast nonferrous tools can be 20 to 50 per cent greater than the recommended cutting speed for high-speed steel as given in the accompanying tables.

*Diamond Cutting Tools:* These are available in three forms: single-crystal natural diamonds shaped to a cutting edge and mounted on a tool holder on a boring bar; polycrystalline diamond indexable inserts made from synthetic or natural diamond powders that have been compacted and sintered into a solid mass, and chemically vapor-deposited diamond. Single-crystal and polycrystalline diamond cutting tools are very wear-resistant, and are recommended for machining abrasive materials that cause other cutting tool materials to wear rapidly. Typical of the abrasive materials machined with single-crystal and polycrystalline diamond tools and cutting speeds used are the following: fiberglass, 300 to 1000 fpm; fused silica, 900 to 950 fpm; reinforced melamine plastics, 350 to 1000 fpm; reinforced phenolic plastics, 350 to 1000 fpm; thermosetting plastics, 300 to 2000 fpm; Teflon,

600 fpm; nylon, 200 to 300 fpm; mica, 300 to 1000 fpm; graphite, 200 to 2000 fpm; babbitt bearing metal, 700 fpm; and aluminum-silicon alloys, 1000 to 2000 fpm. Another important application of diamond cutting tools is to produce fine surface finishes on soft nonferrous metals that are difficult to finish by other methods. Surface finishes of 1 to 2 microinches can be readily obtained with single-crystal diamond tools, and finishes down to 10 microinches can be obtained with polycrystalline diamond tools. In addition to babbitt and the aluminum-silicon alloys, other metals finished with diamond tools include: soft aluminum, 1000 to 2000 fpm; all wrought and cast aluminum alloys, 600 to 1500 fpm; copper, 1000 fpm; brass, 500 to 1000 fpm; bronze, 300 to 600 fpm; oilite bearing metal, 500 fpm; silver, gold, and platinum, 300 to 2500 fpm; and zinc, 1000 fpm. Ferrous alloys, such as cast iron and steel, should not be machined with diamond cutting tools because the high cutting temperatures generated will cause the diamond to transform into carbon.

*Chemically Vapor-Deposited (CVD) Diamond:* This is a new tool material offering performance characteristics well suited to highly abrasive or corrosive materials, and hard-to-machine composites. CVD diamond is available in two forms: thick-film tools, which are fabricated by brazing CVD diamond tips, approximately 0.020 inch (0.5 mm) thick, to carbide substrates; and thin-film tools, having a pure diamond coating over the rake and flank surfaces of a ceramic or carbide substrate.

CVD is pure diamond, made at low temperatures and pressures, with no metallic binder phase. This diamond purity gives CVD diamond tools extreme hardness, high abrasion resistance, low friction, high thermal conductivity, and chemical inertness. CVD tools are generally used as direct replacements for PCD (polycrystalline diamond) tools, primarily in finishing, semifinishing, and continuous turning applications of extremely wear-intensive materials. The small grain size of CVD diamond (ranging from less than 1  $\mu\text{m}$  to 50  $\mu\text{m}$ ) yields superior surface finishes compared with PCD, and the higher thermal conductivity and better thermal and chemical stability of pure diamond allow CVD tools to operate at faster speeds without generating harmful levels of heat. The extreme hardness of CVD tools may also result in significantly longer tool life.

CVD diamond cutting tools are recommended for the following materials: aluminum and other ductile; nonferrous alloys such as copper, brass, and bronze; and highly abrasive composite materials such as graphite, carbon-carbon, carbon-filled phenolic, fiberglass, and honeycomb materials.

*Cubic Boron Nitride (CBN):* Next to diamond, CBN is the hardest known material. It will retain its hardness at a temperature of 1800°F and higher, making it an ideal cutting tool material for machining very hard and tough materials at cutting speeds beyond those possible with other cutting tool materials. Indexable inserts and cutting tool blanks made from this material consist of a layer, approximately 0.020 inch thick, of polycrystalline cubic boron nitride firmly bonded to the top of a cemented carbide substrate. Cubic boron nitride is recommended for rough and finish turning hardened plain carbon and alloy steels, hardened tool steels, hard cast irons, all hardness grades of gray cast iron, and superalloys. As a class, the superalloys are not as hard as hardened steel; however, their combination of high strength and tendency to deform plastically under the pressure of the cut, or gumminess, places them in the class of hard-to-machine materials. Conventional materials that can be readily machined with other cutting tool materials should not be machined with cubic boron nitride. Round indexable CBN inserts are recommended when taking severe cuts in order to provide maximum strength to the insert. When using square or triangular inserts, a large lead angle should be used, normally 15°, and whenever possible, 45°. A negative rake angle should always be used, which for most applications is negative 5°. The relief angle should be 5° to 9°. Although cubic boron nitride cutting tools can be used without a coolant, flooding the tool with a water-soluble type coolant is recommended.

**Cutting Speed, Feed, Depth of Cut, Tool Wear, and Tool Life.**—The cutting conditions that determine the rate of metal removal are the cutting speed, the feed rate, and the depth of cut. These cutting conditions and the nature of the material to be cut determine the

power required to take the cut. The cutting conditions must be adjusted to stay within the power available on the machine tool to be used. Power requirements are discussed in Estimating Machining Power later in this section.

The cutting conditions must also be considered in relation to the tool life. Tool life is defined as the cutting time to reach a predetermined amount of wear, usually flank wear. Tool life is determined by assessing the time—the tool life—at which a given predetermined flank wear is reached (0.01, 0.015, 0.025, 0.03 inch, for example). This amount of wear is called the tool wear criterion, and its size depends on the tool grade used. Usually, a tougher grade can be used with a bigger flank wear, but for finishing operations, where close tolerances are required, the wear criterion is relatively small. Other wear criteria are a predetermined value of the machined surface roughness and the depth of the crater that develops on the rake face of the tool.

The ANSI standard, Specification For Tool Life Testing With Single-Point Tools (ANSI B94.55M-1985), defines the end of tool life as a given amount of wear on the flank of a tool. This standard is followed when making scientific machinability tests with single-point cutting tools in order to achieve uniformity in testing procedures so that results from different machinability laboratories can be readily compared. It is not practicable or necessary to follow this standard in the shop; however, it should be understood that the cutting conditions and tool life are related.

Tool life is influenced most by cutting speed, then by the feed rate, and least by the depth of cut. When the depth of cut is increased to about 10 times greater than the feed, a further increase in the depth of cut will have no significant effect on the tool life. This characteristic of the cutting tool performance is very important in determining the operating or cutting conditions for machining metals. Conversely, if the cutting speed or the feed is decreased, the increase in the tool life will be proportionately greater than the decrease in the cutting speed or the feed.

Tool life is reduced when either feed or cutting speed is increased. For example, the cutting speed and the feed may be increased if a shorter tool life is accepted; furthermore, the reduction in the tool life will be proportionately greater than the increase in the cutting speed or the feed. However, it is less well understood that a higher feed rate (feed/rev  $\times$  speed) may result in a longer tool life if a higher feed/rev is used in combination with a lower cutting speed. This principle is well illustrated in the speed tables of this section, where two sets of feed and speed data are given (labeled *optimum* and *average*) that result in the same tool life. The *optimum* set results in a greater feed rate (i.e., increased productivity) although the feed/rev is higher and cutting speed lower than the *average* set. Complete instructions for using the speed tables and for estimating tool life are given in *How to Use the Feeds and Speeds Tables* starting on page 1022.

**Selecting Cutting Conditions.**—The first step in establishing the cutting conditions is to select the depth of cut. The depth of cut will be limited by the amount of metal that is to be machined from the workpiece, by the power available on the machine tool, by the rigidity of the workpiece and the cutting tool, and by the rigidity of the setup. The depth of cut has the least effect upon the tool life, so the heaviest possible depth of cut should always be used.

The second step is to select the feed (feed/rev for turning, drilling, and reaming, or feed/tooth for milling). The available power must be sufficient to make the required depth of cut at the selected feed. The maximum feed possible that will produce an acceptable surface finish should be selected.

The third step is to select the cutting speed. Although the accompanying tables provide recommended cutting speeds and feeds for many materials, experience in machining a certain material may form the best basis for adjusting the given cutting speeds to a particular job. However, in general, the depth of cut should be selected first, followed by the feed, and last the cutting speed.

**Table 16. Tool Troubleshooting Check List**

| Problem                                  | Tool Material   | Remedy   |
|--|-----------------|--|
| Excessive flank wear—Tool life too short | Carbide         | <ol style="list-style-type: none"> <li>1. Change to harder, more wear-resistant grade</li> <li>2. Reduce the cutting speed</li> <li>3. Reduce the cutting speed and increase the feed to maintain production</li> <li>4. Reduce the feed</li> <li>5. For work-hardenable materials—increase the feed</li> <li>6. Increase the lead angle</li> <li>7. Increase the relief angles</li> </ol>                                       |

**Cutting Speed Formulas**

Most machining operations are conducted on machine tools having a rotating spindle. Cutting speeds are usually given in feet or meters per minute and these speeds must be converted to spindle speeds, in revolutions per minute, to operate the machine. Conversion is accomplished by use of the following formulas:

$$\begin{array}{ll} \text{For U.S. units:} & \text{For metric units:} \\ N = \frac{12V}{\pi D} = 3.82 \frac{V}{D} \text{ rpm} & N = \frac{1000V}{\pi D} = 318.3 \frac{V}{D} \text{ rpm} \end{array}$$

where  $N$  is the spindle speed in revolutions per minute (rpm);  $V$  is the cutting speed in feet per minute (fpm) for U.S. units and meters per minute (m/min) for metric units. In turning,  $D$  is the diameter of the workpiece; in milling, drilling, reaming, and other operations that use a rotating tool,  $D$  is the cutter diameter in inches for U.S. units and in millimeters for metric units.  $\pi = 3.1416$ .

*Example:* The cutting speed for turning a 4-inch (101.6-mm) diameter bar has been found to be 575 fpm (175.3 m/min). Using both the inch and metric formulas, calculate the lathe spindle speed.

$$N = \frac{12V}{\pi D} = \frac{12 \times 575}{3.1416 \times 4} = 549 \text{ rpm} \quad N = \frac{1000V}{\pi D} = \frac{1000 \times 175.3}{3.1416 \times 101.6} = 549 \text{ rpm}$$

When the cutting tool or workpiece diameter and the spindle speed in rpm are known, it is often necessary to calculate the cutting speed in feet or meters per minute. In this event, the following formulas are used.

$$\begin{array}{ll} \text{For U.S. units:} & \text{For metric units:} \\ V = \frac{\pi DN}{12} \text{ fpm} & V = \frac{\pi DN}{1000} \text{ m/min} \end{array}$$

As in the previous formulas,  $N$  is the rpm and  $D$  is the diameter in inches for the U.S. unit formula and in millimeters for the metric formula.

*Example:* Calculate the cutting speed in feet per minute and in meters per minute if the spindle speed of a  $\frac{3}{4}$ -inch (19.05-mm) drill is 400 rpm.

$$\begin{array}{l} V = \frac{\pi DN}{12} = \frac{\pi \times 0.75 \times 400}{12} = 78.5 \text{ fpm} \\ V = \frac{\pi DN}{1000} = \frac{\pi \times 19.05 \times 400}{1000} = 24.9 \text{ m/min} \end{array}$$

## Cutting Speeds and Equivalent RPM for Drills of Number and Letter Sizes

| Size No. | Cutting Speed, Feet per Minute          |      |      |      |      |      |      |      |      |      |       |
|----------|---|------|------|------|------|------|------|------|------|------|-------|

## SPEED AND FEED TABLES

### How to Use the Feeds and Speeds Tables

**Introduction to the Feed and Speed Tables.**—The principal tables of feed and speed values are listed in the table below. In this section, [Tables 1](#) through [9](#) give data for turning, [Tables 10](#) through [15e](#) give data for milling, and [Tables 17](#) through [23](#) give data for reaming, drilling, threading.

The materials in these tables are categorized by description, and Brinell hardness number (Bhn) range or material condition. So far as possible, work materials are grouped by similar machining characteristics. The types of cutting tools (HSS end mill, for example) are identified in one or more rows across the tops of the tables. Other important details concerning the use of the tables are contained in the footnotes to [Tables 1](#), [10](#) and [17](#). Information concerning specific cutting tool grades is given in notes at the end of each table.

Each of the cutting speed tables in this section contains two distinct types of cutting speed data. The speed columns at the left of each table contain traditional Handbook cutting speeds for use with high-speed steel (HSS) tools. For many years, this extensive collection of cutting data has been used successfully as starting speed values for turning, milling, drilling, and reaming operations. Instructions and adjustment factors for use with these speeds are given in Table 5c (feed and depth-of-cut factors) for turning, and in Table 15a (feed, depth of cut, and cutter diameter) for milling. Feeds for drilling and reaming are discussed in Using the Feed and Speed Tables for Drilling, Reaming, and Threading. With traditional speeds and feeds, tool life may vary greatly from material to material, making it very difficult to plan efficient cutting operations, in particular for setting up unattended jobs on CNC equipment where the tool life must exceed cutting time, or at least be predictable so that tool changes can be scheduled. This limitation is reduced by using the combined feed/speed data contained in the remaining columns of the speed tables.

The combined feed/speed portion of the speed tables gives two sets of feed and speed data for each material represented. These feed/speed pairs are the *optimum* and *average* data (identified by *Opt.* and *Avg.*); the *optimum* set is always on the left side of the column and the *average* set is on the right. The *optimum* feed/speed data are approximate values of feed and speed that achieve minimum-cost machining by combining a high productivity rate with low tooling cost at a fixed tool life. The *average* feed/speed data are expected to achieve approximately the same tool life and tooling costs, but productivity is usually lower, so machining costs are higher. The data in this portion of the tables are given in the form of two numbers, of which the first is the feed in thousandths of an inch per revolution (or per tooth, for milling) and the second is the cutting speed in feet per minute. For example, the feed/speed set 15/215 represents a feed of 0.015 in./rev at a speed of 215 fpm. Blank cells in the data tables indicate that feed/speed data for these materials were not available at the time of publication.

Generally, the feed given in the *optimum* set should be interpreted as the maximum safe feed for the given work material and cutting tool grade, and the use of a greater feed may result in premature tool wear or tool failure before the end of the expected tool life. The primary exception to this rule occurs in milling, where the feed may be greater than the *optimum* feed if the radial depth of cut is less than the value established in the table footnote; this topic is covered later in the milling examples. Thus, except for milling, the speed and tool life adjustment tables, to be discussed later, do not permit feeds that are greater than the *optimum* feed. On the other hand, the speed and tool life adjustment factors often result in cutting speeds that are well outside the given *optimum* to *average* speed range.

The combined feed/speed data in this section were contributed by Dr. Colding of Colding International Corp., Ann Arbor, MI. The speed, feed, and tool life calculations were made by means of a special computer program and a large database of cutting speed and tool life testing data. The COMP computer program uses tool life equations that are extensions of the F. W. Taylor tool life equation, first proposed in the early 1900s. The Colding tool life equations use a concept called equivalent chip thickness (*ECT*), which simplifies cutting speed and tool life predictions, and the calculation of cutting forces, torque, and power requirements. *ECT* is a basic metal cutting parameter that combines the four basic turning variables (depth of cut, lead angle, nose radius, and feed per revolution) into one basic parameter. For other metal cutting operations (milling, drilling, and grinding, for example), *ECT* also includes additional variables such as the number of teeth, width of cut, and cutter diameter. The *ECT* concept was first presented in 1931 by Prof. R. Woxen, who showed that equivalent chip thickness is a basic metal cutting parameter for high-speed cutting tools. Dr. Colding later extended the theory to include other tool materials and metal cutting operations, including grinding.

The equivalent chip thickness is defined by  $ECT = A/CEL$ , where *A* is the cross-sectional area of the cut (approximately equal to the feed times the depth of cut), and *CEL* is the cutting edge length or tool contact rubbing length. *ECT* and several other terms related to tool

geometry are illustrated in Figs. 1 and 2. Many combinations of feed, lead angle, nose radius and cutter diameter, axial and radial depth of cut, and numbers of teeth can give the same value of *ECT*. However, for a constant cutting speed, no matter how the depth of cut, feed, or lead angle, etc., are varied, if a constant value of *ECT* is maintained, the tool life will also remain constant. A constant value of *ECT* means that a constant cutting speed gives a constant tool life and an increase in speed results in a reduced tool life. Likewise, if *ECT* were increased and cutting speed were held constant, as illustrated in the generalized cutting speed vs. *ECT* graph that follows, tool life would be reduced.

- $a$  = depth of cut
- $A = A'$  = chip cross-sectional area
- $CEL = CELe$  = engaged cutting edge length
- $ECT$  = equivalent chip thickness =  $A'/CEL$
- $f$  = feed/rev
- $r$  = nose radius
- $LA$  = lead angle (U.S.)
- $LA(ISO) = 90 - LA$

Fig. 1. Cutting Geometry, Equivalent Chip Thickness, and Cutting Edge Length

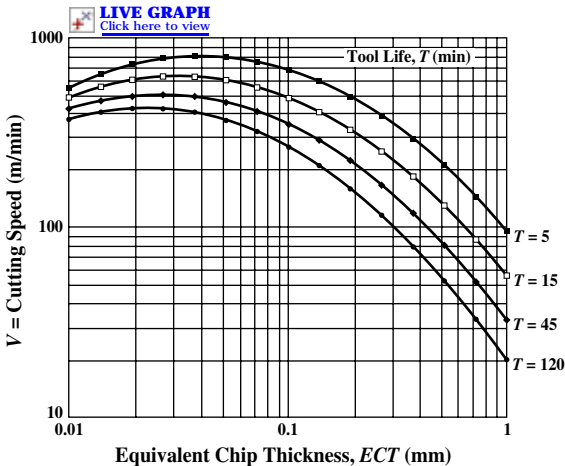

Fig. 2. Cutting Geometry for Turning

In the tables, the *optimum* feed/speed data have been calculated by COMP to achieve a fixed tool life based on the maximum *ECT* that will result in successful cutting, without premature tool wear or early tool failure. The same tool life is used to calculate the *average* feed/speed data, but these values are based on one-half of the maximum *ECT*. Because the data are not linear except over a small range of values, both *optimum* and *average* sets are required to adjust speeds for feed, lead angle, depth of cut, and other factors.

Tool life is the most important factor in a machining system, so feeds and speeds cannot be selected as simple numbers, but must be considered with respect to the many parameters that influence tool life. The accuracy of the combined feed/speed data presented is believed to be very high. However, machining is a variable and complicated process and use of the feed and speed tables requires the user to follow the instructions carefully to achieve good predictability. The results achieved, therefore, may vary due to material condition, tool material, machine setup, and other factors, and cannot be guaranteed.

The feed values given in the tables are valid for the standard tool geometries and fixed depths of cut that are identified in the table footnotes. If the cutting parameters and tool geometry established in the table footnotes are maintained, turning operations using either the *optimum* or *average* feed/speed data (Tables 1 through 9) should achieve a constant tool life of approximately 15 minutes; tool life for milling, drilling, reaming, and threading data (Tables 10 through 14 and Tables 17 through 22) should be approximately 45 minutes. The reason for the different economic tool lives is the higher tooling cost associated with milling-drilling operations than for turning. If the cutting parameters or tool geometry are different from those established in the table footnotes, the same tool life (15 or 45 minutes) still may be maintained by applying the appropriate speed adjustment factors, or tool life may be increased or decreased using tool life adjustment factors. The use of the speed and tool life adjustment factors is described in the examples that follow.

Both the *optimum* and *average* feed/speed data given are reasonable values for effective cutting. However, the *optimum* set with its higher feed and lower speed (always the left entry in each table cell) will usually achieve greater productivity. In Table 1, for example, the two entries for turning 1212 free-machining plain carbon steel with uncoated carbide are 17/805 and 8/1075. These values indicate that a feed of 0.017 in./rev and a speed of 805 ft/min, or a feed of 0.008 in./rev and a speed of 1075 ft/min can be used for this material. The tool life, in each case, will be approximately 15 minutes. If one of these feed and speed pairs is assigned an arbitrary cutting time of 1 minute, then the relative cutting time of the second pair to the first is equal to the ratio of their respective feed  $\times$  speed products. Here, the same amount of material that can be cut in 1 minute, at the higher feed and lower speed (17/805), will require 1.6 minutes at the lower feed and higher speed (8/1075) because  $17 \times 805 / (8 \times 1075) = 1.6$  minutes.

Cutting Speed versus Equivalent Chip Thickness with Tool Life as a Parameter

**Speed and Feed Tables for Turning.**—Speeds for HSS (high-speed steel) tools are based on a feed of 0.012 inch/rev and a depth of cut of 0.125 inch; use [Table 5c](#) to adjust the given speeds for other feeds and depths of cut. The combined feed/speed data in the remaining columns are based on a depth of cut of 0.1 inch, lead angle of 15 degrees, and nose radius of  $\frac{3}{64}$  inch. Use [Table 5a](#) to adjust given speeds for other feeds, depths of cut, and lead angles; use [Table 5b](#) to adjust given speeds for increased tool life up to 180 minutes. Examples are given in the text.

*Examples Using the Feed and Speed Tables for Turning:* The examples that follow give instructions for determining cutting speeds for turning. In general, the same methods are also used to find cutting speeds for milling, drilling, reaming, and threading, so reading through these examples may bring some additional insight to those other metalworking processes as well. The first step in determining cutting speeds is to locate the work material in the left column of the appropriate table for turning, milling, or drilling, reaming, and threading.

*Example 1, Turning:* Find the cutting speed for turning SAE 1074 plain carbon steel of 225 to 275 Brinell hardness, using an uncoated carbide insert, a feed of 0.015 in./rev, and a depth of cut of 0.1 inch.

In [Table 1](#), feed and speed data for two types of uncoated carbide tools are given, one for hard tool grades, the other for tough tool grades. In general, use the speed data from the tool category that most closely matches the tool to be used because there are often significant differences in the speeds and feeds for different tool grades. From the uncoated carbide hard grade values, the *optimum* and *average* feed/speed data given in [Table 1](#) are 17/615 and 8/815, or 0.017 in./rev at 615 ft/min and 0.008 in./rev at 815 ft/min. Because the selected feed (0.015 in./rev) is different from either of the feeds given in the table, the cutting speed must be adjusted to match the feed. The other cutting parameters to be used must also be compared with the general tool and cutting parameters given in the speed tables to determine if adjustments need to be made for these parameters as well. The general tool and cutting parameters for turning, given in the footnote to [Table 1](#), are depth of cut = 0.1 inch, lead angle =  $15^\circ$ , and tool nose radius =  $\frac{3}{64}$  inch.

[Table 5a](#) is used to adjust the cutting speeds for turning (from [Tables 1](#) through [9](#)) for changes in feed, depth of cut, and lead angle. The new cutting speed  $V$  is found from  $V = V_{opt} \times F_f \times F_d$ , where  $V_{opt}$  is the *optimum* speed from the table (always the lower of the two speeds given), and  $F_f$  and  $F_d$  are the adjustment factors from [Table 5a](#) for feed and depth of cut, respectively.

To determine the two factors  $F_f$  and  $F_d$ , calculate the ratio of the selected feed to the *optimum* feed,  $0.015/0.017 = 0.9$ , and the ratio of the two given speeds  $V_{avg}$  and  $V_{opt}$ ,  $815/615 = 1.35$  (approximately). The feed factor  $F_f = 1.07$  is found in [Table 5a](#) at the intersection of the feed ratio row and the speed ratio column. The depth-of-cut factor  $F_d = 1.0$  is found in the same row as the feed factor in the column for depth of cut = 0.1 inch and lead angle =  $15^\circ$ , or for a tool with a  $45^\circ$  lead angle,  $F_d = 1.18$ . The final cutting speed for a  $15^\circ$  lead angle is  $V = V_{opt} \times F_f \times F_d = 615 \times 1.07 \times 1.0 = 658$  fpm. Notice that increasing the lead angle tends to permit higher cutting speeds; such an increase is also the general effect of increasing the tool nose radius, although nose radius correction factors are not included in this table. Increasing lead angle also increases the radial pressure exerted by the cutting tool on the workpiece, which may cause unfavorable results on long, slender workpieces.

*Example 2, Turning:* For the same material and feed as the previous example, what is the cutting speed for a 0.4-inch depth of cut and a  $45^\circ$  lead angle?

As before, the feed is 0.015 in./rev, so  $F_f$  is 1.07, but  $F_d = 1.03$  for depth of cut equal to 0.4 inch and a  $45^\circ$  lead angle. Therefore,  $V = 615 \times 1.07 \times 1.03 = 676$  fpm. Increasing the lead angle from  $15^\circ$  to  $45^\circ$  permits a much greater (four times) depth of cut, at the same feed and nearly constant speed. Tool life remains constant at 15 minutes. (*Continued on page 1036*)

Speeds for HSS (high-speed steel) tools are based on a feed of 0.012 inch/rev and a depth of cut of 0.125 inch; use Table 5c to adjust the given speeds for other feeds and depths of cut. The combined feed/speed data in the remaining columns are based on a depth of cut of 0.1 inch, lead angle of 15 degrees, and nose radius of  $\frac{3}{64}$  inch. Use Table 5a to adjust given speeds for other feeds, depths of cut, and lead angles; use Table 5b to adjust given speeds for increased tool life up to 180 minutes. Examples are given in the text.

The combined feed/speed data in this table are based on tool grades (identified in Table 16) as follows: uncoated carbides, hard = 17, tough = 19, † = 15; coated carbides, hard = 11, tough = 14; ceramics, hard = 2, tough = 3, ‡ = 4; cermet = 7.

Table 2. Cutting Feeds and Speeds for Turning Tool Steels

Speeds for HSS (high-speed steel) tools are based on a feed of 0.012 inch/rev and a depth of cut of 0.125 inch; use Table 5c to adjust the given speeds for other feeds and depths of cut. The combined feed/speed data in the remaining columns are based on a depth of cut of 0.1 inch, lead angle of 15 degrees, and nose radius of  $\frac{3}{64}$  inch. Use Table 5a to adjust given speeds for other feeds, depths of cut, and lead angles; use Table 5b to adjust given speeds for increased tool life up to 180 minutes. Examples are given in the text. The combined feed/speed data in this table are based on tool grades (identified in Table 16) as follows: uncoated carbides, hard = 17, tough = 19, † = 15; coated carbides, hard = 11, tough = 14; ceramics, hard = 2, tough = 3, ‡ = 4; cermet = 7.

Table 3. Cutting Feeds and Speeds for Turning Stainless Steels

| Material  | Brinell Hardness   | Tool Material |  |           |           |           |                |           |          |           |           |            |          |
|---|--------------------|---------------|--|-----------|-----------|-----------|----------------|-----------|----------|-----------|-----------|------------|----------|

Speeds for HSS (high-speed steel) tools are based on a feed of 0.012 inch/rev and a depth of cut of 0.125 inch; use [Table 5c](#) to adjust the given speeds for other feeds and depths of cut. The combined feed/speed data in the remaining columns are based on a depth of cut of 0.1 inch, lead angle of 15 degrees, and nose radius of  $\frac{3}{64}$  inch. Use [Table 5a](#) to adjust the given speeds for other feeds, depths of cut, and lead angles; use [Table 5b](#) to adjust given speeds for increased tool life up to 180 minutes. Examples are given in the text.

The combined feed/speed data in this table are based on tool grades (identified in [Table 16](#)) as follows: uncoated carbides, tough = 15; Coated carbides, hard = 11, tough = 14; ceramics, hard = 2, tough = 3; cermet = 7; CBN = 1.

Table 4b. Cutting Feeds and Speeds for Turning Ferrous Cast Metals

| Material   | Brinell Hardness | Tool Material                                |                  |      |       |      |                |      |       |      |         |      |       |      |         |     |

Use with Tables 1 through 9. Not for HSS tools. Tables 1 through 9 data, except for HSS tools, are based on depth of cut = 0.1 inch, lead angle = 15 degrees, and tool life = 15 minutes. For other depths of cut, lead angles, or feeds, use the two feed/speed pairs from the tables and calculate the ratio of desired (new) feed to optimum feed (largest of the two feeds given in the tables), and the ratio of the two cutting speeds ( $V_{avg}/V_{opt}$ ). Use the value of these ratios to find the feed factor  $F_f$  at the intersection of the feed ratio row and the speed ratio column in the left half of the table. The depth-of-cut factor  $F_d$  is found in the same row as the feed factor in the right half of the table under the column corresponding to the depth of cut and lead angle. The adjusted cutting speed can be calculated from  $V = V_{opt} \times F_f \times F_d$ , where  $V_{opt}$  is the smaller (optimum) of the two speeds from the speed table (from the left side of the column containing the two feed/speed pairs). See the text for examples.

**Table 5b. Tool Life Factors for Turning with Carbides, Ceramics, Cermet, CBN, and Polycrystalline Diamond**

| Tool Life, $T$<br>(minutes) | Turning with Carbides:<br>Workpiece < 300 Bhn |       |       | Turning with Carbides: Workpiece > 300 Bhn;<br>Turning with Ceramics: Any Hardness |       |       | Turning with Mixed Ceramics:<br>Any Workpiece Hardness |       |       |
|-----------------------------|---|-------|-------|--|-------|-------|--|-------|-------|
|                             | $f_s$   | $f_m$ | $f_l$ | $f_s$  | $f_m$ | $f_l$ | $f_s$  | $f_m$ | $f_l$ |
| 15                          | 1.0   | 1.0   | 1.0   | 1.0  | 1.0   | 1.0   | 1.0  | 1.0   | 1.0   |
| 45                          | 0.86  | 0.81  | 0.76  | 0.80   | 0.75  | 0.70  | 0.89   | 0.87  | 0.84  |
| 90                          | 0.78  | 0.71  | 0.64  | 0.70   | 0.63  | 0.56  | 0.82   | 0.79  | 0.75  |
| 180                         | 0.71  | 0.63  | 0.54  | 0.61   | 0.53  | 0.45  | 0.76   | 0.72  | 0.67  |

Except for HSS speed tools, feeds and speeds given in Tables 1 through 9 are based on 15-minute tool life. To adjust speeds for another tool life, multiply the cutting speed for 15-minute tool life  $V_{15}$  by the tool life factor from this table according to the following rules: for small feeds where feed  $\leq \frac{1}{2}f_{opt}$ , the cutting speed for desired tool life is  $V_T = f_s \times V_{15}$ ; for medium feeds where  $\frac{1}{2}f_{opt} < \text{feed} < \frac{3}{4}f_{opt}$ ,  $V_T = f_m \times V_{15}$ ; and for larger feeds where  $\frac{3}{4}f_{opt} \leq \text{feed} \leq f_{opt}$ ,  $V_T = f_l \times V_{15}$ . Here,  $f_{opt}$  is the largest (optimum) feed of the two feed/speed values given in the speed tables.

For use with HSS tool data only from Tables 1 through 9. Adjusted cutting speed  $V = V_{HSS} \times F_f \times F_d$ , where  $V_{HSS}$  is the tabular speed for turning with high-speed tools.

**Example 3, Turning:** Determine the cutting speed for turning 1055 steel of 175 to 225 Brinell hardness using a hard ceramic insert, a  $15^\circ$  lead angle, a 0.04-inch depth of cut and 0.0075 in./rev feed.

The two feed/speed combinations given in Table 5a for 1055 steel are 15/1610 and 8/2780, corresponding to 0.015 in./rev at 1610 fpm and 0.008 in./rev at 2780 fpm, respectively. In Table 5a, the feed factor  $F_f = 1.75$  is found at the intersection of the row corresponding to  $feed/f_{opt} = 7.5/15 = 0.5$  and the column corresponding to  $V_{avg}/V_{opt} = 2780/1610 = 1.75$  (approximately). The depth-of-cut factor  $F_d = 1.23$  is found in the same row, under the column heading for a depth of cut = 0.04 inch and lead angle =  $15^\circ$ . The adjusted cutting speed is  $V = 1610 \times 1.75 \times 1.23 = 3466$  fpm.

**Example 4, Turning:** The cutting speed for 1055 steel calculated in Example 3 represents the speed required to obtain a 15-minute tool life. Estimate the cutting speed needed to obtain a tool life of 45, 90, and 180 minutes using the results of Example 3.

To estimate the cutting speed corresponding to another tool life, multiply the cutting speed for 15-minute tool life  $V_{15}$  by the adjustment factor from the Table 5b, Tool Life Factors for Turning. This table gives three factors for adjusting tool life based on the feed used,  $f_s$  for feeds less than or equal to  $\frac{1}{2}f_{opt}$ ,  $\frac{3}{4}f_m$  for midrange feeds between  $\frac{1}{2}$  and  $\frac{3}{4}f_{opt}$  and  $f_l$  for large feeds greater than or equal to  $\frac{3}{4}f_{opt}$  and less than  $f_{opt}$ . In Example 3,  $f_{opt}$  is 0.015 in./rev and the selected feed is 0.0075 in./rev =  $\frac{1}{2}f_{opt}$ . The new cutting speeds for the various tool lives are obtained by multiplying the cutting speed for 15-minute tool life  $V_{15}$  by the factor

for small feeds  $f_s$  from the column for turning with ceramics in Table 5b. These calculations, using the cutting speed obtained in Example 3, follow.

| Tool Life | Cutting Speed                             |
|-----------|---|
| 15 min    | $V_{15} = 3466$ fpm                       |
| 45 min    | $V_{45} = V_{15} \times 0.80 = 2773$ fpm  |
| 90 min    | $V_{90} = V_{15} \times 0.70 = 2426$ fpm  |
| 180 min   | $V_{180} = V_{15} \times 0.61 = 2114$ fpm |

Depth of cut, feed, and lead angle remain the same as in Example 3. Notice, increasing the tool life from 15 to 180 minutes, a factor of 12, reduces the cutting speed by only about one-third of the  $V_{15}$  speed.

**Table 6. Cutting Feeds and Speeds for Turning Copper Alloys**

The speed recommendations for turning with HSS (high-speed steel) tools may be used as starting speeds for milling titanium alloys, using Table 15a to estimate the feed required. Speeds for HSS (high-speed steel) tools are based on a feed of 0.012 inch/rev and a depth of cut of 0.125 inch; use Table 5c to adjust the given speeds for other feeds and depths of cut. The combined feed/speed data in the remaining columns are based on a depth of cut of 0.1 inch, lead angle of 15 degrees, and nose radius of 3/64 inch. Use Table 5a to adjust given speeds for other feeds, depths of cut, and lead angles; use Table 5b to adjust given speeds for increased tool life up to 180 minutes. Examples are given in the text. The combined feed/speed data in this table are based on tool grades (identified in Table 16) as follows: uncoated carbide, 15.

**Table 8. Cutting Feeds and Speeds for Turning Light Metals**

| Material Description  | Material Condition | Tool Material |  |            |                         |                         |           |

<sup>a</sup>The feeds and speeds for turning Al alloys 308.0 and 319.0 with (polycrystalline) diamond tooling represent an expected tool life  $T = 960$  minutes = 16 hours; corresponding feeds and speeds for 15-minute tool life are 11/28600 and 6/37500.

Abbreviations for material condition: A, annealed; AC, as cast; CD, cold drawn; and ST and A, solution treated and aged, respectively. Speeds for HSS (high-speed steel) tools are based on a feed of 0.012 inch/rev and a depth of cut of 0.125 inch; use Table 5c to adjust the HSS speeds for other feeds and depths of cut. The combined feed/speed data are based on a depth of cut of 0.1 inch, lead angle of 15 degrees, and nose radius of  $\frac{3}{64}$  inch. Use Table 5a to adjust given speeds for other feeds, depths of cut, and lead angles; use Table 5b to adjust given speeds for increased tool life up to 180 minutes. The data are based on tool grades (identified in Table 16) as follows: uncoated carbide, 15; diamond, 9.

**Table 9. Cutting Feeds and Speeds for Turning Superalloys**

The speed recommendations for rough turning may be used as starting values for milling and drilling with HSS tools. The combined feed/speed data in this table are based on tool grades (identified in Table 16) as follows: uncoated carbide = 15; ceramic, hard = 4, tough = 3; CBN = 1.

Speeds for HSS (high-speed steel) tools are based on a feed of 0.012 inch/rev and a depth of cut of 0.125 inch; use [Table 5c](#) to adjust the given speeds for other feeds and depths of cut. The combined feed/speed data in the remaining columns are based on a depth of cut of 0.1 inch, lead angle of 15 degrees, and nose radius of  $\frac{3}{64}$  inch. Use [Table 5a](#) to adjust given speeds for other feeds, depths of cut, and lead angles; use [Table 5b](#) to adjust given speeds for increased tool life up to 180 minutes. Examples are given in the text.

**Speed and Feed Tables for Milling.**—[Tables 10](#) through [14](#) give feeds and speeds for milling. The data in the first speed column can be used with high-speed steel tools using the feeds given in [Table 15a](#); these are the same speeds contained in previous editions of the Handbook. The remaining data in [Tables 10](#) through [14](#) are combined feeds and speeds for end, face, and slit, slot, and side milling that use the speed adjustment factors given in [Tables 15b, 15c, and 15d](#). Tool life for the combined feed/speed data can also be adjusted using the factors in [Table 15e](#). [Table 16](#) lists cutting tool grades and vendor equivalents.

*End Milling:* Table data for end milling are based on a 3-tooth, 20-degree helix angle tool with a diameter of 1.0 inch, an axial depth of cut of 0.2 inch, and a radial depth of cut of 1 inch (full slot). Use [Table 15b](#) to adjust speeds for other feeds and axial depths of cut, and [Table 15c](#) to adjust speeds if the radial depth of cut is less than the tool diameter. Speeds are valid for all tool diameters.

*Face Milling:* Table data for face milling are based on a 10-tooth, 8-inch diameter face mill, operating with a 15-degree lead angle,  $\frac{3}{64}$ -inch nose radius, axial depth of cut = 0.1 inch, and radial depth (width) of cut = 6 inches (i.e., width of cut to cutter diameter ratio =  $\frac{3}{4}$ ). These speeds are valid if the cutter axis is above or close to the center line of the workpiece (eccentricity is small). Under these conditions, use [Table 15d](#) to adjust speeds for other feeds and axial and radial depths of cut. For larger eccentricity (i.e., when the cutter axis to workpiece center line offset is one half the cutter diameter or more), use the end and side milling adjustment factors ([Tables 15b and 15c](#)) instead of the face milling factors.

*Slit and Slot Milling:* Table data for slit milling are based on an 8-tooth, 10-degree helix angle tool with a cutter width of 0.4 inch, diameter  $D$  of 4.0 inch, and a depth of cut of 0.6 inch. Speeds are valid for all tool diameters and widths. See the examples in the text for adjustments to the given speeds for other feeds and depths of cut.

Tool life for all tabulated values is approximately 45 minutes; use [Table 15e](#) to adjust tool life from 15 to 180 minutes.

*Using the Feed and Speed Tables for Milling:* The basic feed for milling cutters is the feed per tooth ( $f$ ), which is expressed in inches per tooth. There are many factors to consider in selecting the feed per tooth and no formula is available to resolve these factors. Among the factors to consider are the cutting tool material; the work material and its hardness; the width and the depth of the cut to be taken; the type of milling cutter to be used and its size; the surface finish to be produced; the power available on the milling machine; and the rigidity of the milling machine, the workpiece, the workpiece setup, the milling cutter, and the cutter mounting.

The cardinal principle is to always use the maximum feed that conditions will permit. Avoid, if possible, using a feed that is less than 0.001 inch per tooth because such low feeds reduce the tool life of the cutter. When milling hard materials with small-diameter end mills, such small feeds may be necessary, but otherwise use as much feed as possible. Harder materials in general will require lower feeds than softer materials. The width and the depth of cut also affect the feeds. Wider and deeper cuts must be fed somewhat more slowly than narrow and shallow cuts. A slower feed rate will result in a better surface finish; however, always use the heaviest feed that will produce the surface finish desired. Fine chips produced by fine feeds are dangerous when milling magnesium because spontaneous combustion can occur. Thus, when milling magnesium, a fast feed that will produce a relatively thick chip should be used. Cutting stainless steel produces a work-hardened layer on the surface that has been cut. Thus, when milling this material, the feed should be large enough to allow each cutting edge on the cutter to penetrate below the work-hardened

layer produced by the previous cutting edge. The heavy feeds recommended for face milling cutters are to be used primarily with larger cutters on milling machines having an adequate amount of power. For smaller face milling cutters, start with smaller feeds and increase as indicated by the performance of the cutter and the machine.

When planning a milling operation that requires a high cutting speed and a fast feed, always check to determine if the power required to take the cut is within the capacity of the milling machine. Excessive power requirements are often encountered when milling with cemented carbide cutters. The large metal removal rates that can be attained require a high horsepower output. An example of this type of calculation is given in the section on Machining Power that follows this section. If the size of the cut must be reduced in order to stay within the power capacity of the machine, start by reducing the cutting speed rather than the feed in inches per tooth.

The formula for calculating the table feed rate, when the feed in inches per tooth is known, is as follows:

$$f_m = f_t n_t N$$

where  $f_m$  = milling machine table feed rate in inches per minute (ipm)

$f_t$  = feed in inch per tooth (ipt)

$n_t$  = number of teeth in the milling cutter

$N$  = spindle speed of the milling machine in revolutions per minute (rpm)

*Example:* Calculate the feed rate for milling a piece of AISI 1040 steel having a hardness of 180 Bhn. The cutter is a 3-inch diameter high-speed steel plain or slab milling cutter with 8 teeth. The width of the cut is 2 inches, the depth of cut is 0.062 inch, and the cutting speed from Table 11 is 85 fpm. From Table 15a, the feed rate selected is 0.008 inch per tooth.

$$N = \frac{12V}{\pi D} = \frac{12 \times 85}{3.14 \times 3} = 108 \text{ rpm}$$

$$\begin{aligned} f_m &= f_t n_t N = 0.008 \times 8 \times 108 \\ &= 7 \text{ ipm (approximately)} \end{aligned}$$

*Example 1, Face Milling:* Determine the cutting speed and machine operating speed for face milling an aluminum die casting (alloy 413) using a 4-inch polycrystalline diamond cutter, a 3-inch width of cut, a 0.10-inch depth of cut, and a feed of 0.006 inch/tooth.

Table 10 gives the feeds and speeds for milling aluminum alloys. The feed/speed pairs for face milling die cast alloy 413 with polycrystalline diamond (PCD) are 8/2320 (0.008 in./tooth feed at 2320 fpm) and 4/4755 (0.004 in./tooth feed at 4755 fpm). These speeds are based on an axial depth of cut of 0.10 inch, an 8-inch cutter diameter  $D$ , a 6-inch radial depth (width) of cut  $ar$ , with the cutter approximately centered above the workpiece, i.e., eccentricity is low, as shown in Fig. 3. If the preceding conditions apply, the given feeds and speeds can be used without adjustment for a 45-minute tool life. The given speeds are valid for all cutter diameters if a radial depth of cut to cutter diameter ratio ( $ar/D$ ) of  $\frac{3}{4}$  is maintained (i.e.,  $\frac{9}{8} = \frac{3}{4}$ ). However, if a different feed or axial depth of cut is required, or if the  $ar/D$  ratio is not equal to  $\frac{3}{4}$ , the cutting speed must be adjusted for the conditions. The adjusted cutting speed  $V$  is calculated from  $V = V_{opt} \times F_f \times F_d \times F_{ar}$ , where  $V_{opt}$  is the lower of the two speeds given in the speed table, and  $F_f$ ,  $F_d$ , and  $F_{ar}$  are adjustment factors for feed, axial depth of cut, and radial depth of cut, respectively, obtained from Table 15d (face milling); except, when cutting near the end or edge of the workpiece as in Fig. 4, Table 15c (side milling) is used to obtain  $F_f$ .

Fig. 3.

Fig. 4.

In this example, the cutting conditions match the standard conditions specified in the speed table for radial depth of cut to cutter diameter (3 in./4 in.), and depth of cut (0.01 in), but the desired feed of 0.006 in./tooth does not match either of the feeds given in the speed table (0.004 or 0.008). Therefore, the cutting speed must be adjusted for this feed. As with turning, the feed factor  $F_f$  is determined by calculating the ratio of the desired feed  $f$  to maximum feed  $f_{opt}$  from the speed table, and from the ratio  $V_{avg}/V_{opt}$  of the two speeds given in the speed table. The feed factor is found at the intersection of the feed ratio row and the speed ratio column in Table 15d. The speed is then obtained using the following equation:

$$\frac{\text{Chosen feed}}{\text{Optimum feed}} = \frac{f}{f_{opt}} = \frac{0.006}{0.008} = 0.75 \quad \frac{\text{Average speed}}{\text{Optimum speed}} = \frac{V_{avg}}{V_{opt}} = \frac{4755}{2320} \approx 2.0$$

$$F_f = (1.25 + 1.43)/2 = 1.34$$

$$F_d = 1.0$$

$$F_{ar} = 1.0$$

$$V = 2320 \times 1.34 \times 1.0 \times 1.0 = 3109 \text{ fpm, and } 3.82 \times 3109/4 = 2970 \text{ rpm}$$

**Example 2, End Milling:** What cutting speed should be used for cutting a full slot (i.e., a slot cut from the solid, in one pass, that is the same width as the cutter) in 5140 steel with hardness of 300 Bhn using a 1-inch diameter coated carbide (insert)  $0^\circ$  lead angle end mill, a feed of 0.003 in./tooth, and a 0.2-inch axial depth of cut?

The feed and speed data for end milling 5140 steel, Brinell hardness = 275–325, with a coated carbide tool are given in Table 11 as 15/80 and 8/240 for optimum and average sets, respectively. The speed adjustment factors for feed and depth of cut for full slot (end milling) are obtained from Table 15b. The calculations are the same as in the previous examples:  $ff_{opt} = 3/15 = 0.2$  and  $V_{avg}/V_{opt} = 240/80 = 3.0$ , therefore,  $F_f = 6.86$  and  $F_d = 1.0$ . The cutting speed for a 45-minute tool life is  $V = 80 \times 6.86 \times 1.0 = 548.8$ , approximately 550 ft/min.

**Example 3, End Milling:** What cutting speed should be used in Example 2 if the radial depth of cut  $ar$  is 0.02 inch and axial depth of cut is 1 inch?

In end milling, when the radial depth of cut is less than the cutter diameter (as in Fig. 4), first obtain the feed factor  $F_f$  from Table 15c, then the axial depth of cut and lead angle factor  $F_d$  from Table 15b. The radial depth of cut to cutter diameter ratio  $ar/D$  is used in Table 15c to determine the maximum and minimum feeds that guard against tool failure at high feeds and against premature tool wear caused by the tool rubbing against the work at very low feeds. The feed used should be selected so that it falls within the minimum to maximum feed range, and then the feed factor  $F_f$  can be determined from the feed factors at minimum and maximum feeds,  $F_{f1}$  and  $F_{f2}$  as explained below.

The maximum feed  $f_{max}$  is found in Table 15c by multiplying the optimum feed from the speed table by the maximum feed factor that corresponds to the  $ar/D$  ratio, which in this instance is  $0.02/1 = 0.02$ ; the minimum feed  $f_{min}$  is found by multiplying the optimum feed by the minimum feed factor. Thus,  $f_{max} = 4.5 \times 0.015 = 0.0675$  in./tooth and  $f_{min} = 3.1 \times 0.015 = 0.0465$  in./tooth. If a feed between these maximum and minimum values is selected, 0.050 in./tooth for example, then for  $ar/D = 0.02$  and  $V_{avg}/V_{opt} = 3.0$ , the feed factors at maximum and minimum feeds are  $F_{f1} = 7.90$  and  $F_{f2} = 7.01$ , respectively, and by interpolation,  $F_f = 7.01 + (0.050 - 0.0465)(0.0675 - 0.0465) \times (7.90 - 7.01) = 7.16$ , approximately 7.2.

The depth of cut factor  $F_d$  is obtained from Table 15b, using  $f_{max}$  from Table 15c instead of the optimum feed  $f_{opt}$  for calculating the feed ratio (chosen feed/optimum feed). In this example, the feed ratio = chosen feed/ $f_{max} = 0.050/0.0675 = 0.74$ , so the feed factor is  $F_d = 0.93$  for a depth of cut = 1.0 inch and  $0^\circ$  lead angle. Therefore, the final cutting speed is  $80 \times 7.2 \times 0.93 = 587$  ft/min. Notice that  $f_{max}$  obtained from Table 15c was used instead of the optimum feed from the speed table, in determining the feed ratio needed to find  $F_d$ .

**Slit Milling.**—The tabular data for slit milling is based on an 8-tooth, 10-degree helix angle cutter with a width of 0.4 inch, a diameter  $D$  of 4.0 inch, and a depth of cut of 0.6 inch. The given feeds and speeds are valid for any diameters and tool widths, as long as sufficient machine power is available. Adjustments to cutting speeds for other feeds and depths of cut are made using Table 15c or 15d, depending on the orientation of the cutter to the work, as illustrated in Case 1 and Case 2 of Fig. 5. The situation illustrated in Case 1 is approximately equivalent to that illustrated in Fig. 3, and Case 2 is approximately equivalent to that shown in Fig. 4.

*Case 1:* If the cutter is fed directly into the workpiece, i.e., the feed is perpendicular to the surface of the workpiece, as in cutting off, then Table 15d (face milling) is used to adjust speeds for other feeds. The depth of cut portion of Table 15d is not used in this case ( $F_d = 1.0$ ), so the adjusted cutting speed  $V = V_{opt} \times F_f \times F_{ar}$ . In determining the factor  $F_{ar}$  from Table 15d, the radial depth of cut  $ar$  is the length of cut created by the portion of the cutter engaged in the work.

*Case 2:* If the cutter feed is parallel to the surface of the workpiece, as in slotting or side milling, then Table 15c (side milling) is used to adjust the given speeds for other feeds. In Table 15c, the cutting depth (slot depth, for example) is the radial depth of cut  $ar$  that is used to determine maximum and minimum allowable feed/tooth and the feed factor  $F_f$ . These minimum and maximum feeds are determined in the manner described previously, however, the axial depth of cut factor  $F_d$  is not required. The adjusted cutting speed, valid for cutters of any thickness (width), is given by  $V = V_{opt} \times F_f$ .

Fig. 5. Determination of Radial Depth of Cut in Slit Milling

**Table 10. Cutting Feeds and Speeds for Milling Aluminum Alloys**

| Material  | Material Condition* | End Milling                                    |           |                                   |           | Face Milling                      |           |                         |           | Slit Milling |            |                                   |           |            |

Abbreviations designate: A, annealed; AC, as cast; CD, cold drawn; and ST and A, solution treated and aged, respectively.

**End Milling:** Table data for end milling are based on a 3-tooth, 20-degree helix angle tool with a diameter of 1.0 inch, an axial depth of cut of 0.2 inch, and a radial depth of cut of 1 inch (full slot). Use [Table 15b](#) to adjust speeds for other feeds and axial depths of cut, and [Table 15c](#) to adjust speeds if the radial depth of cut is less than the tool diameter. Speeds are valid for all tool diameters.

**Face Milling:** Table data for face milling are based on a 10-tooth, 8-inch diameter face mill, operating with a 15-degree lead angle,  $\frac{3}{4}$ -inch nose radius, axial depth of cut = 0.1 inch, and radial depth (width) of cut = 6 inches (i.e., width of cut to cutter diameter ratio =  $\frac{3}{4}$ ). These speeds are valid if the cutter axis is above or close to the center line of the workpiece (eccentricity is small). Under these conditions, use [Table 15d](#) to adjust speeds for other feeds and axial and radial depths of cut. For larger eccentricity (i.e., when the cutter axis to workpiece center line offset is one half the cutter diameter or more), use the end and side milling adjustment factors ([Tables 15b](#) and [15c](#)) instead of the face milling factors.

**Slit and Slot Milling:** Table data for slit milling are based on an 8-tooth, 10-degree helix angle tool with a cutter width of 0.4 inch, diameter  $D$  of 4.0 inch, and a depth of cut of 0.6 inch. Speeds are valid for all tool diameters and widths. See the examples in the text for adjustments to the given speeds for other feeds and depths of cut.

Tool life for all tabulated values is approximately 45 minutes; use [Table 15e](#) to adjust tool life from 15 to 180 minutes. The combined feed/speed data in this table are based on tool grades (identified in [Table 16](#)) as follows: uncoated carbide = 15; diamond = 9.

For HSS (high-speed steel) tools in the first speed column only, use [Table 15a](#) for recommended feed in inches per tooth and depth of cut.

**End Milling:** Table data for end milling are based on a 3-tooth, 20-degree helix angle tool with a diameter of 1.0 inch, an axial depth of cut of 0.2 inch, and a radial depth of cut of 1 inch (full slot). Use [Table 15b](#) to adjust speeds for other feeds and axial depths of cut, and [Table 15c](#) to adjust speeds if the radial depth of cut is less than the tool diameter. Speeds are valid for all tool diameters.

**Face Milling:** Table data for face milling are based on a 10-tooth, 8-inch diameter face mill, operating with a 15-degree lead angle,  $\frac{3}{64}$ -inch nose radius, axial depth of cut = 0.1 inch, and radial depth (width) of cut = 6 inches (i.e., width of cut to cutter diameter ratio =  $\frac{3}{4}$ ). These speeds are valid if the cutter axis is above or close to the center line of the workpiece (eccentricity is small). Under these conditions, use [Table 15d](#) to adjust speeds for other feeds and axial and radial depths of cut. For larger eccentricity (i.e., when the cutter axis to workpiece center line offset is one half the cutter diameter or more), use the end and side milling adjustment factors ([Tables 15b](#) and [15c](#)) instead of the face milling factors.

**Slit and Slot Milling:** Table data for slit milling are based on an 8-tooth, 10-degree helix angle tool with a cutter width of 0.4 inch, diameter  $D$  of 4.0 inches, and a depth of cut of 0.6 inch. Speeds are valid for all tool diameters and widths. See the examples in the text for adjustments to the given speeds for other feeds and depths of cut.

Tool life for all tabulated values is approximately 45 minutes; use [Table 15e](#) to adjust tool life from 15 to 180 minutes. The combined feed/speed data in this table are based on tool grades (identified in [Table 16](#)) as follows: end and slit milling uncoated carbide = 20 except † = 15; face milling uncoated carbide = 19; end, face, and slit milling coated carbide = 10.

Table 12. Cutting Feeds and Speeds for Milling Tool Steels

| Material   | Brinell Hardness                 | HSS         | End Milling                                    |         |                  |          | Face Milling   |          |                  |           | Slit Milling |          |                  |           |                |           |           |

|  | 225-275                          | 30          |  |         |                  |          |                |          |                  |           |              |          |                  |           |                |           |           |

For HSS (high-speed steel) tools in the first speed column only, use [Table 15a](#) for recommended feed in inches per tooth and depth of cut.

**End Milling:** Table data for end milling are based on a 3-tooth, 20-degree helix angle tool with a diameter of 1.0 inch, an axial depth of cut of 0.2 inch, and a radial depth of cut of 1 inch (full slot). Use [Table 15b](#) to adjust speeds for other feeds and axial depths of cut, and [Table 15c](#) to adjust speeds if the radial depth of cut is less than the tool diameter. Speeds are valid for all tool diameters.

**Face Milling:** Table data for face milling are based on a 10-tooth, 8-inch diameter face mill, operating with a 15-degree lead angle,  $\frac{3}{64}$ -inch nose radius, axial depth of cut = 0.1 inch, and radial depth (width) of cut = 6 inches (i.e., width of cut to cutter diameter ratio =  $\frac{3}{4}$ ). These speeds are valid if the cutter axis is above or close to the center line of the workpiece (eccentricity is small). Under these conditions, use [Table 15d](#) to adjust speeds for other feeds and axial and radial depths of cut. For larger eccentricity (i.e., when the cutter axis to workpiece center line offset is one half the cutter diameter or more), use the end and side milling adjustment factors ([Tables 15b](#) and [15c](#)) instead of the face milling factors.

**Slit and Slot Milling:** Table data for slit milling are based on an 8-tooth, 10-degree helix angle tool with a cutter width of 0.4 inch, diameter  $D$  of 4.0 inches, and a depth of cut of 0.6 inch. Speeds are valid for all tool diameters and widths. See the examples in the text for adjustments to the given speeds for other feeds and depths of cut.

Tool life for all tabulated values is approximately 45 minutes; use [Table 15e](#) to adjust tool life from 15 to 180 minutes. The combined feed/speed data in this table are based on tool grades (identified in [Table 16](#)) as follows: uncoated carbide = 20,  $\ddagger$  = 15; coated carbide = 10; CBN = 1.

**Table 13. Cutting Feeds and Speeds for Milling Stainless Steels**

| Material   | Brinell Hardness                  | HSS     | End Milling |      |                  |      |                |      | Face Milling   |      | Slit Milling     |      |                |      |

For HSS (high-speed steel) tools in the first speed column only, use [Table 15a](#) for recommended feed in inches per tooth and depth of cut.

**End Milling:** Table data for end milling are based on a 3-tooth, 20-degree helix angle tool with a diameter of 1.0 inch, an axial depth of cut of 0.2 inch, and a radial depth of cut of 1 inch (full slot). Use [Table 15b](#) to adjust speeds for other feeds and axial depths of cut, and [Table 15c](#) to adjust speeds if the radial depth of cut is less than the tool diameter. Speeds are valid for all tool diameters.

**Face Milling:** Table data for face milling are based on a 10-tooth, 8-inch diameter face mill, operating with a 15-degree lead angle,  $\frac{3}{4}$ -inch nose radius, axial depth of cut = 0.1 inch, and radial depth (width) of cut = 6 inches (i.e., width of cut to cutter diameter ratio =  $\frac{3}{4}$ ). These speeds are valid if the cutter axis is above or close to the center line of the workpiece (eccentricity is small). Under these conditions, use [Table 15d](#) to adjust speeds for other feeds and axial and radial depths of cut. For larger eccentricity (i.e., when the cutter axis to workpiece center line offset is one half the cutter diameter or more), use the end and side milling adjustment factors ([Tables 15b](#) and [15c](#)) instead of the face milling factors.

**Slit and Slot Milling:** Table data for slit milling are based on an 8-tooth, 10-degree helix angle tool with a cutter width of 0.4 inch, diameter  $D$  of 4.0 inch, and a depth of cut of 0.6 inch. Speeds are valid for all tool diameters and widths. See the examples in the text for adjustments to the given speeds for other feeds and depths of cut.

Tool life for all tabulated values is approximately 45 minutes; use [Table 15e](#) to adjust tool life from 15 to 180 minutes. The combined feed/speed data in this table are based on tool grades (identified in [Table 16](#)) as follows: uncoated carbide = 20; coated carbide = 10.

Table 14. Cutting Feeds and Speeds for Milling Ferrous Cast Metals

For HSS (high-speed steel) tools in the first speed column only, use Table 15a for recommended feed in inches per tooth and depth of cut.

**End Milling:** Table data for end milling are based on a 3-tooth, 20-degree helix angle tool with a diameter of 1.0 inch, an axial depth of cut of 0.2 inch, and a radial depth of cut of 1 inch (full slot). Use Table 15b to adjust speeds for other feeds and axial depths of cut, and Table 15c to adjust speeds if the radial depth of cut is less than the tool diameter. Speeds are valid for all tool diameters.

**Face Milling:** Table data for face milling are based on a 10-tooth, 8-inch diameter face mill, operating with a 15-degree lead angle,  $\frac{3}{4}$ -inch nose radius, axial depth of cut = 0.1 inch, and radial depth (width) of cut = 6 inches (i.e., width of cut to cutter diameter ratio =  $\frac{3}{4}$ ). These speeds are valid if the cutter axis is above or close to the center line of the workpiece (eccentricity is small). Under these conditions, use Table 15d to adjust speeds for other feeds and axial and radial depths of cut. For larger eccentricity (i.e., when the cutter axis to workpiece center line offset is one half the cutter diameter or more), use the end and side milling adjustment factors (Tables 15b and 15c) instead of the face milling factors.

**Slit and Slot Milling:** Table data for slit milling are based on an 8-tooth, 10-degree helix angle tool with a cutter width of 0.4 inch, diameter  $D$  of 4.0 inches, and a depth of cut of 0.6 inch. Speeds are valid for all tool diameters and widths. See the examples in the text for adjustments to the given speeds for other feeds and depths of cut.

Tool life for all tabulated values is approximately 45 minutes; use Table 15e to adjust tool life from 15 to 180 minutes. The combined feed/speed data in this table are based on tool grades (identified in Table 16) as follows: uncoated carbide = 15 except † = 20; end and slit milling coated carbide = 10; face milling coated carbide = 11 except ‡ = 10. ceramic = 6; CBN = 1.

For HSS (high-speed steel) tool speeds in the first speed column of [Tables 10 through 14](#), use [Table 15a](#) to determine appropriate feeds and depths of cut.

Cutting feeds and speeds for end milling given in [Tables 11 through 14](#) (except those for high-speed steel in the first speed column) are based on milling a 0.20-inch deep full slot (i.e., radial depth of cut = end mill diameter) with a 1-inch diameter, 20-degree helix angle, 0-degree lead angle end mill. For other depths of cut (axial), lead angles, or feed, use the two feed/speed pairs from the tables and calculate the ratio of desired (new) feed to optimum feed (largest of the two feeds are given in the tables), and the ratio of the two cutting speeds ( $V_{avg}/V_{opt}$ ). Find the feed factor  $F_f$  at the intersection of the feed ratio row and the speed ratio column in the left half of the Table. The depth of cut factor  $F_d$  is found in the same row as the feed factor, in the right half of the table under the column corresponding to the depth of cut and lead angle. The adjusted cutting speed can be calculated from  $V = V_{opt} \times F_f \times F_d$ , where  $V_{opt}$  is the smaller (optimum) of the two speeds from the speed table (from the left side of the column containing the two feed/speed pairs). See the text for examples.

If the radial depth of cut is less than the cutter diameter (i.e., for cutting less than a full slot), the feed factor  $F_f$  in the previous equation and the maximum feed  $f_{max}$  must be obtained from [Table 15c](#). The axial depth of cut factor  $F_d$  can then be obtained from this table using  $f_{max}$  in place of the optimum feed in the feed ratio. Also see the footnote to [Table 15c](#).

Table 15c. End, Slit, and Side Milling Speed Adjustment Factors for Radial Depth of Cut

| Ratio of Radial Depth of Cut to Diameter | Cutting Speed, $V = V_{opt} \times F_f \times F_d$ |   |      |      |      |      |       |                           |   |      |      |      |      |       |

This table is for side milling, end milling when the radial depth of cut (width of cut) is less than the tool diameter (i.e., less than full slot milling), and slit milling when the feed is parallel to the work surface (slotting). The radial depth of cut to diameter ratio is used to determine the recommended maximum and minimum values of feed/tooth, which are found by multiplying the feed/tooth factor from the appropriate column above (maximum or minimum) by  $f_{opt}$  from the speed tables. For example, given two feed/speed pairs  $\frac{7}{15}$  and  $\frac{4}{45}$  for end milling cast, medium-carbon, alloy steel, and a radial depth of cut to diameter ratio  $ar/D$  of 0.10 (a 0.05-inch width of cut for a  $\frac{1}{2}$ -inch diameter end mill, for example), the maximum feed  $f_{max} = 2.05 \times 0.007 = 0.014$  in./tooth and the minimum feed  $f_{min} = 1.44 \times 0.007 = 0.010$  in./tooth. The feed selected should fall in the range between  $f_{min}$  and  $f_{max}$ . The feed factor  $F_f$  is determined by interpolating between the feed factors  $F_{f1}$  and  $F_{f2}$  corresponding to the maximum and minimum feed per tooth, at the appropriate  $ar/D$  and speed ratio. In the example given,  $ar/D = 0.10$  and  $V_{avg}/V_{opt} = 45/15 = 3$ , so the feed factor  $F_{f1}$  at the maximum feed per tooth is 6.77, and the feed factor  $F_{f2}$  at the minimum feed per tooth is 7.76. If a working feed of 0.012 in./tooth is chosen, the feed factor  $F_f$  is half way between 6.77 and 7.76 or by formula,  $F_f = F_{f1} + (\text{feed} - f_{min})/(f_{max} - f_{min}) \times (f_{f2} - f_{f1}) = 6.77 + (0.012 - 0.010)/(0.014 - 0.010) \times (7.76 - 6.77) = 7.27$ . The cutting speed is  $V = V_{opt} \times F_f \times F_d$ , where  $F_d$  is the depth of cut and lead angle factor from Table 15b that corresponds to the feed ratio (chosen feed)/ $f_{max}$ , not the ratio (chosen feed)/optimum feed. For a feed ratio =  $0.012/0.014 = 0.86$  (chosen feed/ $f_{max}$ ), depth of cut = 0.2 inch and lead angle =  $45^\circ$ , the depth of cut factor  $F_d$  in Table 15b is between 0.72 and 0.74. Therefore, the final cutting speed for this example is  $V = V_{opt} \times F_f \times F_d = 15 \times 7.27 \times 0.73 = 80$  ft/min.

**Slit and Side Milling:** This table only applies when feed is parallel to the work surface, as in slotting. If feed is perpendicular to the work surface, as in cutting off, obtain the required speed-correction factor from Table 15d (face milling). The minimum and maximum feeds/tooth for slit and side milling are determined in the manner described above, however, the axial depth of cut factor  $F_d$  is not required. The adjusted cutting speed, valid for cutters of any thickness (width), is given by  $V = V_{opt} \times F_f$ . Examples are given in the text.

**Table 15d. Face Milling Speed Adjustment Factors for Feed, Depth of Cut, and Lead Angle**

For HSS (high-speed steel) tool speeds in the first speed column, use Table 15a to determine appropriate feeds and depths of cut.

Tabular feeds and speeds data for face milling in Tables 11 through 14 are based on a 10-tooth, 8-inch diameter face mill, operating with a 15-degree lead angle,  $\frac{3}{64}$ -inch cutter insert nose radius, axial depth of cut = 0.1 inch, and radial depth (width) of cut = 6 inches (i.e., width of cut to cutter diameter ratio =  $\frac{3}{8}$ ). For other depths of cut (radial or axial), lead angles, or feed, calculate the ratio of desired (new) feed to optimum feed (largest of the two feeds given in the speed table), and the ratio of the two cutting speeds ( $V_{avg}/V_{opt}$ ). Use these ratios to find the feed factor  $F_f$  at the intersection of the feed ratio row and the speed ratio column in the left third of the table. The depth of cut factor  $F_d$  is found in the same row as the feed factor, in the center third of the table, in the column corresponding to the depth of cut and lead angle. The radial depth of cut factor  $F_{ar}$  is found in the same row as the feed factor, in the right third of the table, in the column corresponding to the radial depth of cut to cutter diameter ratio  $ar/D$ . The adjusted cutting speed can be calculated from  $V = V_{opt} \times F_f \times F_d \times F_{ar}$ , where  $V_{opt}$  is the smaller (optimum) of the two speeds from the speed table (from the left side of the column containing the two feed/speed pairs).

The cutting speeds as calculated above are valid if the cutter axis is centered above or close to the center line of the workpiece (eccentricity is small). For larger eccentricity (i.e., the cutter axis is offset from the center line of the workpiece by about one-half the cutter diameter or more), use the adjustment factors from Tables 15b and 15c (end and side milling) instead of the factors from this table. Use Table 15e to adjust end and face milling speeds for increased tool life up to 180 minutes.

**Slit and Slot Milling:** Tabular speeds are valid for all tool diameters and widths. Adjustments to the given speeds for other feeds and depths of cut depend on the circumstances of the cut. *Case 1:* If the cutter is fed directly into the workpiece, i.e., the feed is perpendicular to the surface of the workpiece, as in cutting off, then this table (face milling) is used to adjust speeds for other feeds. The depth of cut factor is not used for slit milling ( $F_d = 1.0$ ), so the adjusted cutting speed  $V = V_{opt} \times F_f \times F_{ar}$ . For determining the factor  $F_{ar}$ , the radial depth of cut  $ar$  is the length of cut created by the portion of the cutter engaged in the work. *Case 2:* If the cutter is fed parallel to the surface of the workpiece, as in slotting, then Tables 15b and 15c are used to adjust the given speeds for other feeds. See Fig. 5.

**Table 15e. Tool Life Adjustment Factors for Face Milling, End Milling, Drilling, and Reaming**

| Tool Life, $T$<br>(minutes) | Face Milling with Carbides and Mixed Ceramics |       |       | End Milling with Carbides and HSS |       |       | Twist Drilling and Reaming with HSS |       |       |
|-----------------------------|---|-------|-------|-----------------------------------|-------|-------|-------------------------------------|-------|-------|
|                             | $f_s$   | $f_m$ | $f_l$ | $f_s$                             | $f_m$ | $f_l$ | $f_s$                               | $f_m$ | $f_l$ |
| 15                          | 1.69  | 1.78  | 1.87  | 1.10                              | 1.23  | 1.35  | 1.11                                | 1.21  | 1.30  |
| 45                          | 1.00  | 1.00  | 1.00  | 1.00                              | 1.00  | 1.00  | 1.00                                | 1.00  | 1.00  |
| 90                          | 0.72  | 0.70  | 0.67  | 0.94                              | 0.89  | 0.83  | 0.93                                | 0.89  | 0.85  |
| 180                         | 0.51  | 0.48  | 0.45  | 0.69                              | 0.69  | 0.69  | 0.87                                | 0.80  | 0.72  |

The feeds and speeds given in Tables 11 through 14 and Tables 17 through 23 (except for HSS speeds in the first speed column) are based on a 45-minute tool life. To adjust the given speeds to obtain another tool life, multiply the adjusted cutting speed for the 45-minute tool life  $V_{45}$  by the tool life factor from this table according to the following rules: for small feeds, where feed  $\leq \frac{1}{2}f_{opt}$ , the cutting speed for the desired tool life  $T$  is  $V_T = f_s \times V_{15}$ ; for medium feeds, where  $\frac{1}{2}f_{opt} < \text{feed} < \frac{3}{4}f_{opt}$ ,  $V_T = f_m \times V_{15}$ ; and for larger feeds, where  $\frac{3}{4}f_{opt} \leq \text{feed} \leq f_{opt}$ ,  $V_T = f_l \times V_{15}$ . Here,  $f_{opt}$  is the largest (optimum) feed of the two feed/speed values given in the speed tables or the maximum feed  $f_{max}$  obtained from Table 15c, if that table was used in calculating speed adjustment factors.

**Table 16. Cutting Tool Grade Descriptions and Common Vendor Equivalents**

| Grade Description   | Tool Identification Code | Approximate Vendor Equivalents |            |       |          |
|---------------------|--------------------------|--------------------------------|------------|-------|----------|

See Table 2 on page 779 and the section *Cemented Carbides and Other Hard Materials* for more detailed information on cutting tool grades.

The identification codes in column two correspond to the grade numbers given in the footnotes to Tables 1 to 4b, 6 to 14, and 17 to 23.

**Using the Feed and Speed Tables for Drilling, Reaming, and Threading.**—The first two speed columns in [Tables 17](#) through [23](#) give traditional Handbook speeds for drilling and reaming. The following material can be used for selecting feeds for use with the traditional speeds.

The remaining columns in [Tables 17](#) through [23](#) contain combined feed/speed data for drilling, reaming, and threading, organized in the same manner as in the turning and milling tables. Operating at the given feeds and speeds is expected to result in a tool life of approximately 45 minutes, except for indexable insert drills, which have an expected tool life of approximately 15 minutes per edge. Examples of using this data follow.

Adjustments to HSS drilling speeds for feed and diameter are made using [Table 22](#); [Table 5a](#) is used for adjustments to indexable insert drilling speeds, where one-half the drill diameter  $D$  is used for the depth of cut. Tool life for HSS drills, reamers, and thread chasers and taps may be adjusted using [Table 15e](#) and for indexable insert drills using [Table 5b](#).

The feed for drilling is governed primarily by the size of the drill and by the material to be drilled. Other factors that also affect selection of the feed are the workpiece configuration, the rigidity of the machine tool and the workpiece setup, and the length of the chisel edge. A chisel edge that is too long will result in a very significant increase in the thrust force, which may cause large deflections to occur on the machine tool and drill breakage.

For ordinary twist drills, the feed rate used is 0.001 to 0.003 in./rev for drills smaller than  $\frac{1}{8}$  in, 0.002 to 0.006 in./rev for  $\frac{1}{8}$ - to  $\frac{1}{4}$ -in drills; 0.004 to 0.010 in./rev for  $\frac{1}{4}$ - to  $\frac{1}{2}$ -in drills; 0.007 to 0.015 in./rev for  $\frac{1}{2}$ - to 1-in drills; and, 0.010 to 0.025 in./rev for drills larger than 1 inch.

The lower values in the feed ranges should be used for hard materials such as tool steels, superalloys, and work-hardening stainless steels; the higher values in the feed ranges should be used to drill soft materials such as aluminum and brass.

*Example 1, Drilling:* Determine the cutting speed and feed for use with HSS drills in drilling 1120 steel.

[Table 15a](#) gives two sets of feed and speed parameters for drilling 1120 steel with HSS drills. These sets are 16/50 and 8/95, i.e., 0.016 in./rev feed at 50 ft/min and 0.008 in./rev at 95 fpm, respectively. These feed/speed sets are based on a 0.6-inch diameter drill. Tool life for either of the given feed/speed settings is expected to be approximately 45 minutes.

For different feeds or drill diameters, the cutting speeds must be adjusted and can be determined from  $V = V_{opt} \times F_f \times F_d$ , where  $V_{opt}$  is the minimum speed for this material given in the speed table (50 fpm in this example) and  $F_f$  and  $F_d$  are the adjustment factors for feed and diameter, respectively, found in [Table 22](#).

Table 17. Feeds and Speeds for Drilling, Reaming, and Threading Plain Carbon and Alloy Steels

| Material   | Brinell Hardness | Drilling    | Reaming | Drilling                                     |          |                                 |          | Reaming  |           | Threading |           |           |

The two leftmost speed columns in this table contain traditional Handbook speeds for drilling and reaming with HSS steel tools. The section Feed Rates for Drilling and Reaming contains useful information concerning feeds to use in conjunction with these speeds.

**HSS Drilling and Reaming:** The combined feed/speed data for drilling are based on a 0.60-inch diameter HSS drill with standard drill point geometry (2-flute with  $118^\circ$  tip angle). Speed adjustment factors in Table 22 are used to adjust drilling speeds for other feeds and drill diameters. Examples of using this data are given in the text. The given feeds and speeds for reaming are based on an 8-tooth,  $\frac{25}{32}$ -inch diameter,  $30^\circ$  lead angle reamer, and a 0.008-inch radial depth of cut. For other feeds, the correct speed can be obtained by interpolation using the given speeds if the desired feed lies in the recommended range (between the given values of *optimum* and *average* feed). If a feed lower than the given *average* value is chosen, the speed should be maintained at the corresponding *average* speed (i.e., the highest of the two speed values given). The cutting speeds for reaming do not require adjustment for tool diameters for standard ratios of radial depth of cut to reamer diameter (i.e.,  $f_d = 1.00$ ). Speed adjustment factors to modify tool life are found in Table 15c.

**Indexable Insert Drilling:** The feed/speed data for indexable insert drilling are based on a tool with two cutting edges, an insert nose radius of  $\frac{3}{64}$  inch, a 10-degree lead angle, and diameter  $D = 1$  inch. Adjustments to cutting speed for feed and depth of cut are made using Table 5a Adjustment Factors) using a depth of cut of  $D/2$ , or one-half the drill diameter. Expected tool life at the given feeds and speeds is approximately 15 minutes for short hole drilling (i.e., where maximum hole depth is about  $2D$  or less). Speed adjustment factors to increase tool life are found in Table 5b.

**Tapping and Threading:** The data in this column are intended for use with thread chasers and for tapping. The feed used for tapping and threading must be equal to the lead (feed = lead = pitch) of the thread being cut. The two feed/speed pairs given for each material, therefore, are representative speeds for two thread pitches, 12 and 50 threads per inch ( $1/0.083 = 12$ , and  $1/0.020 = 50$ ). Tool life is expected to be approximately 45 minutes at the given feeds and speeds. When cutting fewer than 12 threads per inch (pitch  $\geq 0.08$  inch), use the lower (*optimum*) speed; for cutting more than 50 threads per inch (pitch  $\leq 0.02$  inch), use the larger (*average*) speed; and, in the intermediate range between 12 and 50 threads per inch, interpolate between the given *average* and *optimum* speeds.

The combined feed/speed data in this table are based on tool grades (identified in Table 16) as follows: coated carbide = 10.

**Example 2, Drilling:** If the 1120 steel of Example 1 is to be drilled with a 0.60-inch drill at a feed of 0.012 in./rev, what is the cutting speed in ft/min? Also, what spindle rpm of the drilling machine is required to obtain this cutting speed?

To find the feed factor  $F_d$  in Table 22, calculate the ratio of the desired feed to the *optimum* feed and the ratio of the two cutting speeds given in the speed tables. The desired feed is 0.012 in./rev and the *optimum* feed, as explained above is 0.016 in./rev, therefore,  $\text{feed}/f_{opt} = 0.012/0.016 = 0.75$  and  $V_{avg}/V_{opt} = 95/50 = 1.9$ , approximately 2.

The feed factor  $F_f$  is found at the intersection of the feed ratio row and the speed ratio column.  $F_f = 1.40$  corresponds to about halfway between 1.31 and 1.50, which are the feed factors that correspond to  $V_{avg}/V_{opt} = 2.0$  and  $\text{feed}/f_{opt}$  ratios of 0.7 and 0.8, respectively.  $F_d$ , the diameter factor, is found on the same row as the feed factor (halfway between the 0.7 and 0.8 rows, for this example) under the column for drill diameter = 0.60 inch. Because the speed table values are based on a 0.60-inch drill diameter,  $F_d = 1.0$  for this example, and the cutting speed is  $V = V_{opt} \times F_f \times F_d = 50 \times 1.4 \times 1.0 = 70$  ft/min. The spindle speed in rpm is  $N = 12 \times V/(\pi \times D) = 12 \times 70/(3.14 \times 0.6) = 445$  rpm.

**Example 3, Drilling:** Using the same material and feed as in the previous example, what cutting speeds are required for 0.079-inch and 4-inch diameter drills? What machine rpm is required for each?

Because the feed is the same as in the previous example, the feed factor is  $F_f = 1.40$  and does not need to be recalculated. The diameter factors are found in Table 22 on the same row as the feed factor for the previous example (about halfway between the diameter factors corresponding to  $\text{feed}/f_{opt}$  values of 0.7 and 0.8) in the column corresponding to drill diameters 0.079 and 4.0 inches, respectively. Results of the calculations are summarized below.

| <i>Drill diameter = 0.079 inch</i>              | <i>Drill diameter = 4.0 inches</i>          |
|---|---|
| $F_f = 1.40$                                    | $F_f = 1.40$                                |
| $F_d = (0.34 + 0.38)/2 = 0.36$                  | $F_d = (1.95 + 1.73)/2 = 1.85$              |
| $V = 50 \times 1.4 \times 0.36 = 25.2$ fpm      | $V = 50 \times 1.4 \times 1.85 = 129.5$ fpm |
| $12 \times 25.2/(3.14 \times 0.079) = 1219$ rpm | $12 \times 129.5/(3.14 \times 4) = 124$ rpm |

*Drilling Difficulties:* A drill split at the web is evidence of too much feed or insufficient lip clearance at the center due to improper grinding. Rapid wearing away of the extreme outer corners of the cutting edges indicates that the speed is too high. A drill chipping or breaking out at the cutting edges indicates that either the feed is too heavy or the drill has been ground with too much lip clearance. Nothing will "check" a high-speed steel drill quicker than to turn a stream of cold water on it after it has been heated while in use. It is equally bad to plunge it in cold water after the point has been heated in grinding. The small checks or cracks resulting from this practice will eventually chip out and cause rapid wear or breakage. Insufficient speed in drilling small holes with hand feed greatly increases the risk of breakage, especially at the moment the drill is breaking through the farther side of the work, due to the operator's inability to gage the feed when the drill is running too slowly.

Small drills have heavier webs and smaller flutes in proportion to their size than do larger drills, so breakage due to clogging of chips in the flutes is more likely to occur. When drilling holes deeper than three times the diameter of the drill, it is advisable to withdraw the drill (peck feed) at intervals to remove the chips and permit coolant to reach the tip of the drill.

*Drilling Holes in Glass:* The simplest method of drilling holes in glass is to use a standard, tungsten-carbide-tipped masonry drill of the appropriate diameter, in a gun-drill. The edges of the carbide in contact with the glass should be sharp. Kerosene or other liquid may be used as a lubricant, and a light force is maintained on the drill until just before the point breaks through. The hole should then be started from the other side if possible, or a very light force applied for the remainder of the operation, to prevent excessive breaking of material from the sides of the hole. As the hard particles of glass are abraded, they accumulate and act to abrade the hole, so it may be advisable to use a slightly smaller drill than the required diameter of the finished hole.

Alternatively, for holes of medium and large size, use brass or copper tubing, having an outside diameter equal to the size of hole required. Revolve the tube at a peripheral speed of about 100 feet per minute, and use carborundum (80 to 100 grit) and light machine oil between the end of the pipe and the glass. Insert the abrasive under the drill with a thin piece of soft wood, to avoid scratching the glass. The glass should be supported by a felt or rubber cushion, not much larger than the hole to be drilled. If practicable, it is advisable to drill about halfway through, then turn the glass over, and drill down to meet the first cut. Any fin that may be left in the hole can be removed with a round second-cut file wetted with turpentine.

Smaller-diameter holes may also be drilled with triangular-shaped cemented carbide drills that can be purchased in standard sizes. The end of the drill is shaped into a long tapering triangular point. The other end of the cemented carbide bit is brazed onto a steel shank. A glass drill can be made to the same shape from hardened drill rod or an old three-cornered file. The location at which the hole is to be drilled is marked on the workpiece. A dam of putty or glazing compound is built up on the work surface to contain the cutting fluid, which can be either kerosene or turpentine mixed with camphor. Chipping on the back edge of the hole can be prevented by placing a scrap plate of glass behind the area to be drilled and drilling into the backup glass. This procedure also provides additional support to the workpiece and is essential for drilling very thin plates. The hole is usually drilled with an electric hand drill. When the hole is being produced, the drill should be given a small circular motion using the point as a fulcrum, thereby providing a clearance for the drill in the hole.

Very small round or intricately shaped holes and narrow slots can be cut in glass by the ultrasonic machining process or by the abrasive jet cutting process.

Table 18. Feeds and Speeds for Drilling, Reaming, and Threading Tool Steels

Abbreviations designate: A, annealed; AC, as cast; CD, cold drawn; and ST and A, solution treated and aged, respectively. See the footnote to Table 17 for instructions concerning the use of this table. The combined feed/speed data in this table are based on tool grades (identified in Table 16) as follows; uncoated carbide = 15.

This table is specifically for use with the combined feed/speed data for HSS twist drills in [Tables 17 through 23](#); use [Tables 5a and 5b](#) to adjust speed and tool life for indexable insert drilling with carbides. The combined feed/speed data for HSS twist drilling are based on a 0.60-inch diameter HSS drill with standard drill point geometry (2-flute with 118° tip angle). To adjust the given speeds for different feeds and drill diameters, use the two feed/speed pairs from the tables and calculate the ratio of desired (new) feed to optimum feed (largest of the two feeds from the speed table), and the ratio of the two cutting speeds  $V_{avg}/V_{opt}$ . Use the values of these ratios to find the feed factor  $F_f$  at the intersection of the feed ratio row and the speed ratio column in the left half of the table. The diameter factor  $F_d$  is found in the same row as the feed factor, in the right half of the table, under the column corresponding to the drill diameter. For diameters not given, interpolate between the nearest available sizes. The adjusted cutting speed can be calculated from  $V = V_{opt} \times F_f \times F_d$ , where  $V_{opt}$  is the smaller (optimum) of the two speeds from the speed table (from the left side of the column containing the two feed/speed pairs). Tool life using the selected feed and the adjusted speed should be approximately 45 minutes. Speed adjustment factors to modify tool life are found in [Table 15c](#).

**Table 23. Feeds and Speeds for Drilling and Reaming Copper Alloys**

| Group 1  |                    |             |         |  |      |                                   |      |         |      |     |

Abbreviations designate: A, annealed; CD, cold drawn. The two leftmost speed columns in this table contain traditional Handbook speeds for HSS steel tools. The text contains information concerning feeds to use in conjunction with these speeds.

**HSS Drilling and Reaming:** The combined feed/speed data for drilling and Table 22 are used to adjust drilling speeds for other feeds and drill diameters. Examples are given in the text. The given feeds and speeds for reaming are based on an 8-tooth,  $\frac{25}{32}$ -inch diameter, 30° lead angle reamer, and a 0.008-inch radial depth of cut. For other feeds, the correct speed can be obtained by interpolation using the given speeds if the desired feed lies in the recommended range (between the given values of optimum and average feed). The cutting speeds for reaming do not require adjustment for tool diameter as long as the radial depth of cut does not become too large. Speed adjustment factors to modify tool life are found in Table 15e.

**Indexable Insert Drilling:** The feed/speed data for indexable insert drilling are based on a tool with two cutting edges, an insert nose radius of  $\frac{3}{64}$  inch, a 10-degree lead angle, and diameter *D* of 1 inch. Adjustments for feed and depth of cut are made using Table 5a (Turning Speed Adjustment Factors) using a depth of cut of *D*/2, or one-half the drill diameter. Expected tool life at the given feeds and speeds is 15 minutes for short hole drilling (i.e., where hole depth is about 2*D* or less). Speed adjustment factors to increase tool life are found in Table 5b. The combined feed/speed data in this table are based on tool grades (identified in Table 16) as follows: uncoated carbide = 15.

**Using the Feed and Speed Tables for Tapping and Threading.**—The feed used in tapping and threading is always equal to the pitch of the screw thread being formed. The

threading data contained in the tables for drilling, reaming, and threading (Tables 17 through 23) are primarily for tapping and thread chasing, and do not apply to thread cutting with single-point tools.

The threading data in Tables 17 through 23 give two sets of feed (pitch) and speed values, for 12 and 50 threads/inch, but these values can be used to obtain the cutting speed for any other thread pitches. If the desired pitch falls between the values given in the tables, i.e., between 0.020 inch (50 tpi) and 0.083 inch (12 tpi), the required cutting speed is obtained by interpolation between the given speeds. If the pitch is less than 0.020 inch (more than 50 tpi), use the *average* speed, i.e., the largest of the two given speeds. For pitches greater than 0.083 inch (fewer than 12 tpi), the *optimum* speed should be used. Tool life using the given feed/speed data is intended to be approximately 45 minutes, and should be about the same for threads between 12 and 50 threads per inch.

*Example:* Determine the cutting speed required for tapping 303 stainless steel with a  $\frac{1}{2}$ -20 coated HSS tap.

The two feed/speed pairs for 303 stainless steel, in Table 19, are 83/35 (0.083 in./rev at 35 fpm) and 20/45 (0.020 in./rev at 45 fpm). The pitch of a  $\frac{1}{2}$ -20 thread is  $1/20 = 0.05$  inch, so the required feed is 0.05 in./rev. Because 0.05 is between the two given feeds (Table 19), the cutting speed can be obtained by interpolation between the two given speeds as follows:

$$V = 35 + \frac{0.05 - 0.02}{0.083 - 0.02}(45 - 35) = 40 \text{ fpm}$$

The cutting speed for coarse-pitch taps must be lower than for fine-pitch taps with the same diameter. Usually, the difference in pitch becomes more pronounced as the diameter of the tap becomes larger and slight differences in the pitch of smaller-diameter taps have little significant effect on the cutting speed. Unlike all other cutting tools, the feed per revolution of a tap cannot be independently adjusted—it is always equal to the lead of the thread and is always greater for coarse pitches than for fine pitches. Furthermore, the thread form of a coarse-pitch thread is larger than that of a fine-pitch thread; therefore, it is necessary to remove more metal when cutting a coarse-pitch thread.

Taps with a long chamfer, such as starting or taper taps, can cut faster in a short hole than short chamfer taps, such as plug taps. In deep holes, however, short chamfer or plug taps can run faster than long chamfer taps. Bottoming taps must be run more slowly than either starting or plug taps. The chamfer helps to start the tap in the hole. It also functions to involve more threads, or thread form cutting edges, on the tap in cutting the thread in the hole, thus reducing the cutting load on any one set of thread form cutting edges. In so doing, more chips and thinner chips are produced that are difficult to remove from deeper holes. Shortening the chamfer length causes fewer thread form cutting edges to cut, thereby producing fewer and thicker chips that can easily be disposed of. Only one or two sets of thread form cutting edges are cut on bottoming taps, causing these cutting edges to assume a heavy cutting load and produce very thick chips.

Spiral-pointed taps can operate at a faster cutting speed than taps with normal flutes. These taps are made with supplementary angular flutes on the end that push the chips ahead of the tap and prevent the tapped hole from becoming clogged with chips. They are used primarily to tap open or through holes although some are made with shorter supplementary flutes for tapping blind holes.

The tapping speed must be reduced as the percentage of full thread to be cut is increased. Experiments have shown that the torque required to cut a 100 per cent thread form is more than twice that required to cut a 50 per cent thread form. An increase in the percentage of full thread will also produce a greater volume of chips.

The tapping speed must be lowered as the length of the hole to be tapped is increased. More friction must be overcome in turning the tap and more chips accumulate in the hole.

It will be more difficult to apply the cutting fluid at the cutting edges and to lubricate the tap to reduce friction. This problem becomes greater when the hole is being tapped in a horizontal position.

Cutting fluids have a very great effect on the cutting speed for tapping. Although other operating conditions when tapping frequently cannot be changed, a free selection of the cutting fluid usually can be made. When planning the tapping operation, the selection of a cutting fluid warrants a very careful consideration and perhaps an investigation.

Taper threaded taps, such as pipe taps, must be operated at a slower speed than straight thread taps with a comparable diameter. All the thread form cutting edges of a taper threaded tap that are engaged in the work cut and produce a chip, but only those cutting edges along the chamfer length cut on straight thread taps. Pipe taps often are required to cut the tapered thread from a straight hole, adding to the cutting burden.

The machine tool used for the tapping operation must be considered in selecting the tapping speed. Tapping machines and other machines that are able to feed the tap at a rate of advance equal to the lead of the tap, and that have provisions for quickly reversing the spindle, can be operated at high cutting speeds. On machines where the feed of the tap is controlled manually—such as on drill presses and turret lathes—the tapping speed must be reduced to allow the operator to maintain safe control of the operation.

There are other special considerations in selecting the tapping speed. Very accurate threads are usually tapped more slowly than threads with a commercial grade of accuracy. Thread forms that require deep threads for which a large amount of metal must be removed, producing a large volume of chips, require special techniques and slower cutting speeds. Acme, buttress, and square threads, therefore, are generally cut at lower speeds.

**Cutting Speed for Broaching.**—Broaching offers many advantages in manufacturing metal parts, including high production rates, excellent surface finishes, and close dimensional tolerances. These advantages are not derived from the use of high cutting speeds; they are derived from the large number of cutting teeth that can be applied consecutively in a given period of time, from their configuration and precise dimensions, and from the width or diameter of the surface that can be machined in a single stroke. Most broaching cutters are expensive in their initial cost and are expensive to sharpen. For these reasons, a long tool life is desirable, and to obtain a long tool life, relatively slow cutting speeds are used. In many instances, slower cutting speeds are used because of the limitations of the machine in accelerating and stopping heavy broaching cutters. At other times, the available power on the machine places a limit on the cutting speed that can be used; i.e., the cubic inches of metal removed per minute must be within the power capacity of the machine.

The cutting speeds for high-speed steel broaches range from 3 to 50 feet per minute, although faster speeds have been used. In general, the harder and more difficult to machine materials are cut at a slower cutting speed and those that are easier to machine are cut at a faster speed. Some typical recommendations for high-speed steel broaches are: AISI 1040, 10 to 30 fpm; AISI 1060, 10 to 25 fpm; AISI 4140, 10 to 25 fpm; AISI 41L40, 20 to 30 fpm; 201 austenitic stainless steel, 10 to 20 fpm; Class 20 gray cast iron, 20 to 30 fpm; Class 40 gray cast iron, 15 to 25 fpm; aluminum and magnesium alloys, 30 to 50 fpm; copper alloys, 20 to 30 fpm; commercially pure titanium, 20 to 25 fpm; alpha and beta titanium alloys, 5 fpm; and the superalloys, 3 to 10 fpm. Surface broaching operations on gray iron castings have been conducted at a cutting speed of 150 fpm, using indexable insert cemented carbide broaching cutters. In selecting the speed for broaching, the cardinal principle of the performance of all metal cutting tools should be kept in mind; i.e., increasing the cutting speed may result in a proportionately larger reduction in tool life, and reducing the cutting speed may result in a proportionately larger increase in the tool life. When broaching most materials, a suitable cutting fluid should be used to obtain a good surface finish and a better tool life. Gray cast iron can be broached without using a cutting fluid although some shops prefer to use a soluble oil.

## Spade Drills

Spade drills are used to produce holes ranging in size from about 1 inch to 6 inches diameter, and even larger. Very deep holes can be drilled and blades are available for core drilling, counterboring, and for bottoming to a flat or contoured shape. There are two principal parts to a spade drill, the blade and the holder. The holder has a slot into which the blade fits; a wide slot at the back of the blade engages with a tongue in the holder slot to locate the blade accurately. A retaining screw holds the two parts together. The blade is usually made from high-speed steel, although cast nonferrous metal and cemented carbide-tipped blades are also available. Spade drill holders are classified by a letter symbol designating the range of blade sizes that can be held and by their length. Standard stub, short, long, and extra long holders are available; for very deep holes, special holders having wear strips to support and guide the drill are often used. Long, extra long, and many short length holders have coolant holes to direct cutting fluid, under pressure, to the cutting edges. In addition to its function in cooling and lubricating the tool, the cutting fluid also flushes the chips out of the hole. The shank of the holder may be straight or tapered; special automotive shanks are also used. A holder and different shank designs are shown in Fig. 1; Figs. 2a through Fig. 2f show some typical blades.

Fig. 1. Spade Drill Blade Holder

**Spade Drill Geometry.**—Metal separation from the work is accomplished in a like manner by both twist drills and spade drills, and the same mechanisms are involved for each. The two cutting lips separate the metal by a shearing action that is identical to that of chip formation by a single-point cutting tool. At the chisel edge, a much more complex condition exists. Here the metal is extruded sideways and at the same time is sheared by the rotation of the blunt wedge-formed chisel edge. This combination accounts for the very high thrust force required to penetrate the work. The chisel edge of a twist drill is slightly rounded, but on spade drills, it is a straight edge. Thus, it is likely that it is more difficult for the extruded metal to escape from the region of the chisel edge with spade drills. However, the chisel edge is shorter in length than on twist drills and the thrust for spade drilling is less.

## Typical Spade Drill Blades

Fig. 2a. Standard blade

Fig. 2b. Standard blade with corner chamfer

Fig. 2c. Core drilling blade

Fig. 2d. Center cutting facing or bottoming blade

Fig. 2e. Standard blade with split point or crankshaft point

Fig. 2f. Center cutting radius blade

Basic spade drill geometry is shown in Fig. 3. Normally, the point angle of a standard tool is 130 degrees and the lip clearance angle is 18 degrees, resulting in a chisel edge angle of 108 degrees. The web thickness is usually about  $\frac{1}{4}$  to  $\frac{5}{16}$  as thick as the blade thickness. Usually, the cutting edge angle is selected to provide this web thickness and to provide the necessary strength along the entire length of the cutting lip. A further reduction of the chisel edge length is sometimes desirable to reduce the thrust force in drilling. This reduction can be accomplished by grinding a secondary rake surface at the center or by grinding a split point, or crankshaft point, on the point of the drill.

The larger point angle of a standard spade drill—130 degrees as compared with 118 degrees on a twist drill—causes the chips to flow more toward the periphery of the drill, thereby allowing the chips to enter the flutes of the holder more readily. The rake angle facilitates the formation of the chip along the cutting lips. For drilling materials of average hardness, the rake angle should be 10 to 12 degrees; for hard or tough steels, it should be 5 to 7 degrees; and for soft and ductile materials, it can be increased to 15 to 20 degrees. The rake surface may be flat or rounded, and the latter design is called radial rake. Radial rake is usually ground so that the rake angle is maximum at the periphery and decreases uniformly toward the center to provide greater cutting edge strength at the center. A flat rake surface is recommended for drilling hard and tough materials in order to reduce the tendency to chipping and to reduce heat damage.

A most important feature of the cutting edge is the chip splitters, which are also called chip breaker grooves. Functionally, these grooves are chip dividers; instead of forming a single wide chip along the entire length of the cutting edge, these grooves cause formation of several chips that can be readily disposed of through the flutes of the holder. Chip splitters must be carefully ground to prevent the chips from packing in the grooves, which greatly reduces their effectiveness. Splitters should be ground perpendicular to the cutting lip and parallel to the surface formed by the clearance angle. The grooves on the two cut-

ting lips must not overlap when measured radially along the cutting lip. Fig. 4 and the accompanying table show the groove form and dimensions.

Fig. 3. Spade Drill Blade

On spade drills, the front lip clearance angle provides the relief. It may be ground on a drill grinding machine but usually it is ground flat. The normal front lip clearance angle is 8 degrees; in some instances, a secondary relief angle of about 14 degrees is ground below the primary clearance. The wedge angle on the blade is optional. It is generally ground on thicker blades having a larger diameter to prevent heel dragging below the cutting lip and to reduce the chisel edge length. The outside-diameter land is circular, serving to support and guide the blade in the hole. Usually it is ground to have a back taper of 0.001 to 0.002 inch per inch per side. The width of the land is approximately 20 to 25 per cent of the blade thickness. Normally, the outside-diameter clearance angle behind the land is 7 to 10 degrees. On many spade drill blades, the outside-diameter clearance surface is stepped about 0.030 inch below the land.

Fig. 4. Spade Drill Chip Splitter Dimensions

**Spade Drilling.**—Spade drills are used on drilling machines and other machine tools where the cutting tool rotates; they are also used on turning machines where the work

rotates and the tool is stationary. Although there are some slight operational differences, the methods of using spade drills are basically the same. An adequate supply of cutting fluid must be used, which serves to cool and lubricate the cutting edges; to cool the chips, thus making them brittle and more easily broken; and to flush chips out of the hole. Flood cooling from outside the hole can be used for drilling relatively shallow holes, of about one to two and one-half times the diameter in depth. For deeper holes, the cutting fluid should be injected through the holes in the drill. When drilling very deep holes, it is often helpful to blow compressed air through the drill in addition to the cutting fluid to facilitate ejection of the chips. Air at full shop pressure is throttled down to a pressure that provides the most efficient ejection. The cutting fluids used are light and medium cutting oils, water-soluble oils, and synthetics, and the type selected depends on the work material.

Starting a spade drill in the workpiece needs special attention. The straight chisel edge on the spade drill has a tendency to wander as it starts to enter the work, especially if the feed is too light. This wander can result in a mispositioned hole and possible breakage of the drill point. The best method of starting the hole is to use a stub or short-length spade drill holder and a blade of full size that should penetrate at least  $\frac{1}{8}$  inch at full diameter. The holder is then changed for a longer one as required to complete the hole to depth. Difficulties can be encountered if spotting with a center drill or starting drill is employed because the angles on these drills do not match the 130-degree point angle of the spade drill. Longer spade drills can be started without this starting procedure if the drill is guided by a jig bushing and if the holder is provided with wear strips.

Chip formation warrants the most careful attention as success in spade drilling is dependent on producing short, well-broken chips that can be easily ejected from the hole. Straight, stringy chips or chips that are wound like a clock spring cannot be ejected properly; they tend to pack around the blade, which may result in blade failure. The chip splitters must be functioning to produce a series of narrow chips along each cutting edge. Each chip must be broken, and for drilling ductile materials they should be formed into a "C" or "figure 9" shape. Such chips will readily enter the flutes on the holder and flow out of the hole.

Proper chip formation is dependent on the work material, the spade drill geometry, and the cutting conditions. Brittle materials such as gray cast iron seldom pose a problem because they produce a discontinuous chip, but austenitic stainless steels and very soft and ductile materials require much attention to obtain satisfactory chip control. Thinning the web or grinding a split point on the blade will sometimes be helpful in obtaining better chip control, as these modifications allow use of a heavier feed. Reducing the rake angle to obtain a tighter curl on the chip and grinding a corner chamfer on the tool will sometimes help to produce more manageable chips.

In most instances, it is not necessary to experiment with the spade drill blade geometry to obtain satisfactory chip control. Control usually can be accomplished by adjusting the cutting conditions; i.e., the cutting speed and the feed rate.

Normally, the cutting speed for spade drilling should be 10 to 15 per cent lower than that for an equivalent twist drill, although the same speed can be used if a lower tool life is acceptable. The recommended cutting speeds for twist drills on [Tables 17 through 23](#), starting on page [1061](#), can be used as a starting point; however, they should be decreased by the percentage just given. It is essential to use a heavy feed rate when spade drilling to produce a thick chip, and to force the chisel edge into the work. In ductile materials, a light feed will produce a thin chip that is very difficult to break. The thick chip on the other hand, which often contains many rupture planes, will curl and break readily. [Table 1](#) gives suggested feed rates for different spade drill sizes and materials. These rates should be used as a starting point and some adjustments may be necessary as experience is gained.

Table 1. Feed Rates for Spade Drilling

| Material                       | Hardness,<br>Bhn | Feed—Inches per Revolution  |       |       |       |       |       |

**Power Consumption and Thrust for Spade Drilling.**—In each individual setup, there are factors and conditions influencing power consumption that cannot be accounted for in a simple equation; however, those given below will enable the user to estimate power consumption and thrust accurately enough for most practical purposes. They are based on experimentally derived values of unit horsepower, as given in Table 2. As a word of caution, these values are for sharp tools. In spade drilling, it is reasonable to estimate that a dull tool will increase the power consumption and the thrust by 25 to 50 per cent. The unit horsepower values in the table are for the power consumed at the cutting edge, to which must be added the power required to drive the machine tool itself, in order to obtain the horsepower required by the machine tool motor. An allowance for power to drive the machine is provided by dividing the horsepower at the cutter by a mechanical efficiency factor,  $e_m$ . This factor can be estimated to be 0.90 for a direct spindle drive with a belt, 0.75 for a back gear drive, and 0.70 to 0.80 for geared head drives. Thus, for spade drilling the formulas are

$$hp_c = uhp \left( \frac{\pi D^2}{4} \right) f N$$

$$B_s = 148,500 \text{ uhp} f D$$

$$hp_m = \frac{hp_c}{e_m}$$

$$f = \frac{f_m}{N}$$

where  $hp_c$  = horsepower at the cutter     $hp_m$  = horsepower at the motor

$B_s$  = thrust for spade drilling in pounds

$uhp$  = unit horsepower

$D$  = drill diameter in inches

$f$  = feed in inches per revolution

$f_m$  = feed in inches per minute

$N$  = spindle speed in revolutions per minute

$e_m$  = mechanical efficiency factor

**Table 2. Unit Horsepower for Spade Drilling**

| Material                     | Hardness    | uhp  | Material         | Hardness    | uhp  |
|------------------------------|-------------|------|------------------|-------------|------|
| Plain Carbon and Alloy Steel | 85–200 Bhn  | 0.79 | Titanium Alloys  | 250–375 Bhn | 0.72 |
|                              | 200–275     | 0.94 | High-Temp Alloys | 200–360 Bhn | 1.44 |
|                              | 275–375     | 1.00 | Aluminum Alloys  | ...         | 0.22 |
|                              | 375–425     | 1.15 | Magnesium Alloys | ...         | 0.16 |
|                              | 45–52 Rc    | 1.44 | Copper Alloys    | 20–80 Rb    | 0.43 |
| Cast Irons                   | 110–200 Bhn | 0.5  |                  | 80–100 Rb   | 0.72 |
|                              | 200–300     | 1.08 |                  |             |      |
| Stainless Steels             | 135–275 Bhn | 0.94 |                  |             |      |
|                              | 30–45 Rc    | 1.08 |                  |             |      |

*Example:* Estimate the horsepower and thrust required to drive a 2-inch diameter spade drill in AISI 1045 steel that is quenched and tempered to a hardness of 275 Bhn. From Table 17 on page 1061, the cutting speed,  $V$ , for drilling this material with a twist drill is 50 feet per minute. This value is reduced by 10 per cent for spade drilling and the speed selected is thus  $0.9 \times 50 = 45$  feet per minute. The feed rate (from Table 1, page 1079) is 0.015 in/rev. and the unit horsepower from Table 2 above is 0.94. The machine efficiency factor is estimated to be 0.80 and it will be assumed that a 50 per cent increase in the unit horsepower must be allowed for dull tools.

Step 1. Calculate the spindle speed from the following formula:

$$N = \frac{12V}{\pi D}$$

where:  $N$  = spindle speed in revolutions per minute

$V$  = cutting speed in feet per minute

$D$  = drill diameter in inches

$$\text{Thus, } N = \frac{12 \times 45}{\pi \times 2} = 86 \text{ revolutions per minute}$$

Step 2. Calculate the horsepower at the cutter:

$$\text{hp}_c = \text{uhp} \left( \frac{\pi D^2}{4} \right) f N = 0.94 \left( \frac{\pi \times 2^2}{4} \right) 0.015 \times 86 = 3.8$$

Step 3. Calculate the horsepower at the motor and provide for a 50 per cent power increase for the dull tool:

$$\text{hp}_m = \frac{\text{hp}_c}{e_m} = \frac{3.8}{0.80} = 4.75 \text{ horsepower}$$

$$\text{hp}_m \text{ (with dull tool)} = 1.5 \times 4.75 = 7.125 \text{ horsepower}$$

Step 4. Estimate the spade drill thrust:

$$B_s = 148,500 \times \text{uhp} \times f D = 148,500 \times 0.94 \times 0.015 \times 2 = 4188 \text{ lb (for sharp tool)}$$

$$B_s = 1.5 \times 4188 = 6282 \text{ lb (for dull tool)}$$

**Trepanning.**—Cutting a groove in the form of a circle or boring or cutting a hole by removing the center or core in one piece is called trepanning. Shallow trepanning, also called face grooving, can be performed on a lathe using a single-point tool that is similar to a grooving tool but has a curved blade. Generally, the minimum outside diameter that can be cut by this method is about 3 inches and the maximum groove depth is about 2 inches. Trepanning is probably the most economical method of producing deep holes that are 2 inches, and larger, in diameter. Fast production rates can be achieved. The tool consists of a hollow bar, or stem, and a hollow cylindrical head to which a carbide or high-speed steel, single-point cutting tool is attached. Usually, only one cutting tool is used although for some applications a multiple cutter head must be used; e.g., heads used to start the hole have multiple tools. In operation, the cutting tool produces a circular groove and a residue core that enters the hollow stem after passing through the head. On outside-diameter exhaust trepanning tools, the cutting fluid is applied through the stem and the chips are flushed around the outside of the tool; inside-diameter exhaust tools flush the chips out through the stem with the cutting fluid applied from the outside. For starting the cut, a tool that cuts a starting groove in the work must be used, or the trepanning tool must be guided by a bushing. For holes less than about five diameters deep, a machine that rotates the trepanning tool can be used. Often, an ordinary drill press is satisfactory; deeper holes should be machined on a lathe with the work rotating. A hole diameter tolerance of  $\pm 0.010$  inch can be obtained easily by trepanning and a tolerance of  $\pm 0.001$  inch has sometimes been held. Hole runout can be held to  $\pm 0.003$  inch per foot and, at times, to  $\pm 0.001$  inch per foot. On heat-treated metal, a surface finish of 125 to 150  $\mu\text{m}$  AA can be obtained and on annealed metals 100 to 250  $\mu\text{m}$  AA is common.

## ESTIMATING SPEEDS AND MACHINING POWER

**Estimating Planer Cutting Speeds.**—Whereas most planers of modern design have a means of indicating the speed at which the table is traveling, or cutting, many older planers do not. Thus, the following formulas are useful for planers that do not have a means of indicating the table or cutting speed. It is not practicable to provide a formula for calculating the exact cutting speed at which a planer is operating because the time to stop and start the table when reversing varies greatly. The formulas below will, however, provide a reasonable estimate.

$$V_c \cong S_c L$$

$$S_c \cong \frac{V_c}{L}$$

where  $V_c$  = cutting speed; fpm or m/min

$S_c$  = number of cutting strokes per minute of planer table

$L$  = length of table cutting stroke; ft or m

**Cutting Speed for Planing and Shaping.**—The traditional HSS cutting tool speeds in [Tables 1](#) through [4b](#) and [Tables 6](#) through [9](#) can be used for planing and shaping. The feed and depth of cut factors in [Tables 5c](#) should also be used, as explained previously. Very often, other factors relating to the machine or the setup will require a reduction in the cutting speed used on a specific job.

**Cutting Time for Turning, Boring, and Facing.**—The time required to turn a length of metal can be determined by the following formula in which  $T$  = time in minutes,  $L$  = length of cut in inches,  $f$  = feed in inches per revolution, and  $N$  = lathe spindle speed in revolutions per minute.

$$T = \frac{L}{fN}$$

When making job estimates, the time required to load and to unload the workpiece on the machine, and the machine handling time, must be added to the cutting time for each length cut to obtain the floor-to-floor time.

**Planing Time.**—The approximate time required to plane a surface can be determined from the following formula in which  $T$  = time in minutes,  $L$  = length of stroke in feet,  $V_c$  = cutting speed in feet per minute,  $V_r$  = return speed in feet per minute;  $W$  = width of surface to be planed in inches,  $F$  = feed in inches, and 0.025 = approximate reversal time factor per stroke in minutes for most planers:

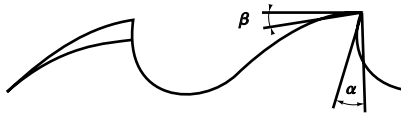

$$T = \frac{W}{F} \left[ L \times \left( \frac{1}{V_c} + \frac{1}{V_r} \right) + 0.025 \right]$$

**Speeds for Metal-Cutting Saws.**—The following speeds and feeds for solid-tooth, high-speed-steel, circular, metal-cutting saws are recommended by Saws International, Inc. (sfpm = surface feet per minute =  $3.142 \times$  blade diameter in inches  $\times$  rpm of saw shaft  $\div 12$ ).

**Speeds for Turning Unusual Materials.**—*Slate*, on account of its peculiarly stratified formation, is rather difficult to turn, but if handled carefully, can be machined in an ordinary lathe. The cutting speed should be about the same as for cast iron. A sheet of fiber or pressed paper should be interposed between the chuck or steadyrest jaws and the slate, to protect the latter. Slate rolls must not be centered and run on the tailstock. A satisfactory method of supporting a slate roll having journals at the ends is to bore a piece of lignum vitae to receive the turned end of the roll, and center it for the tailstock spindle.

*Rubber* can be turned at a peripheral speed of 200 feet per minute, although it is much easier to grind it with an abrasive wheel that is porous and soft. For cutting a rubber roll in

## Speeds, Feeds, and Tooth Angles for Sawing Various Materials

$\alpha$  = Cutting angle  
 $\beta$  = Relief angle

| Materials                        | Front Rake Angle $\alpha$ (deg) | Back Rake Angle $\beta$ (deg) | Stock Diameters (inches)      |                                |                                  |                                  |
|----------------------------------|---------------------------------|-------------------------------|-------------------------------|--------------------------------|----------------------------------|----------------------------------|

two, the ordinary parting tool should not be used, but a tool shaped like a knife; such a tool severs the rubber without removing any material.

*Gutta percha* can be turned as easily as wood, but the tools must be sharp and a good soap-and-water lubricant used.

*Copper* can be turned easily at 200 feet per minute.

*Limestone* such as is used in the construction of pillars for balconies, etc., can be turned at 150 feet per minute, and the formation of ornamental contours is quite easy. *Marble* is a treacherous material to turn. It should be cut with a tool such as would be used for brass, but

at a speed suitable for cast iron. It must be handled very carefully to prevent flaws in the surface.

The foregoing speeds are for high-speed steel tools. Tools tipped with tungsten carbide are adapted for cutting various non-metallic products which cannot be machined readily with steel tools, such as slate, marble, synthetic plastic materials, etc. In drilling slate and marble, use flat drills; and for plastic materials, tungsten-carbide-tipped twist drills. Cutting speeds ranging from 75 to 150 feet per minute have been used for drilling slate (without coolant) and a feed of 0.025 inch per revolution for drills  $\frac{3}{4}$  and 1 inch in diameter.

**Estimating Machining Power.**—Knowledge of the power required to perform machining operations is useful when planning new machining operations, for optimizing existing machining operations, and to develop specifications for new machine tools that are to be acquired. The available power on any machine tool places a limit on the size of the cut that it can take. When much metal must be removed from the workpiece it is advisable to estimate the cutting conditions that will utilize the maximum power on the machine. Many machining operations require only light cuts to be taken for which the machine obviously has ample power; in this event, estimating the power required is a wasteful effort. Conditions in different shops may vary and machine tools are not all designed alike, so some variations between the estimated results and those obtained on the job are to be expected. However, by using the methods provided in this section a reasonable estimate of the power required can be made, which will suffice in most practical situations.

The measure of power in customary inch units is the horsepower; in SI metric units it is the kilowatt, which is used for both mechanical and electrical power. The power required to cut a material depends upon the rate at which the material is being cut and upon an experimentally determined power constant,  $K_p$ , which is also called the unit horsepower, unit power, or specific power consumption. The power constant is equal to the horsepower required to cut a material at a rate of one cubic inch per minute; in SI metric units the power constant is equal to the power in kilowatts required to cut a material at a rate of one cubic centimeter per second, or 1000 cubic millimeters per second ( $1 \text{ cm}^3 = 1000 \text{ mm}^3$ ). Different values of the power constant are required for inch and for metric units, which are related as follows: to obtain the SI metric power constant, multiply the inch power constant by 2.73; to obtain the inch power constant, divide the SI metric power constant by 2.73. Values of the power constant in [Tables 3a](#), and [3b](#) can be used for all machining operations except drilling and grinding. Values given are for sharp tools.

**Table 3a. Power Constants,  $K_p$ , Using Sharp Cutting Tools**

The value of the power constant is essentially unaffected by the cutting speed, the depth of cut, and the cutting tool material. Factors that do affect the value of the power constant, and thereby the power required to cut a material, include the hardness and microstructure of the work material, the feed rate, the rake angle of the cutting tool, and whether the cutting edge of the tool is sharp or dull. Values are given in the power constant tables for different material hardness levels, whenever this information is available. Feed factors for the power constant are given in [Table 4](#). All metal cutting tools wear but a worn cutting edge requires more power to cut than a sharp cutting edge.

Factors to provide for tool wear are given in [Table 5](#). In this table, the extra-heavy-duty category for milling and turning occurs only on operations where the tool is allowed to wear more than a normal amount before it is replaced, such as roll turning. The effect of the rake angle usually can be disregarded. The rake angle for which most of the data in the power constant tables are given is positive 14 degrees. Only when the deviation from this angle is large is it necessary to make an adjustment. Using a rake angle that is more positive reduces the power required approximately 1 per cent per degree; using a rake angle that is more negative increases the power required; again approximately 1 per cent per degree.

Many indexable insert cutting tools are formed with an integral chip breaker or other cutting edge modifications, which have the effect of reducing the power required to cut a material. The extent of this effect cannot be predicted without a test of each design. Cutting fluids will also usually reduce the power required, when operating in the lower range of cutting speeds. Again, the extent of this effect cannot be predicted because each cutting fluid exhibits its own characteristics.

The machine tool transmits the power from the driving motor to the workpiece, where it is used to cut the material. The effectiveness of this transmission is measured by the machine tool efficiency factor,  $E$ . Average values of this factor are given in Table 6. Formulas for calculating the metal removal rate,  $Q$ , for different machining operations are given in Table 7. These formulas are used together with others given below. The following formulas can be used with either customary inch or with SI metric units.

$$P_c = K_p C Q W \quad (1)$$

$$P_m = \frac{P_c}{E} = \frac{K_p C Q W}{E} \quad (2)$$

where  $P_c$  = power at the cutting tool; hp, or kW

<sup>a</sup>Turning, in/rev; milling, in/tooth; planing and shaping, in/stroke; broaching, in/tooth.

<sup>b</sup>Turning, mm/rev; milling, mm/tooth; planing and shaping, mm/stroke; broaching, mm/tooth.

**Table 5. Tool Wear Factors,  $W$** 

| Type of Operation                           |  | $W$       |
|---|--|-----------|
| For all operations with sharp cutting tools |  | 1.00      |
| Turning:                                    | Finish turning (light cuts)  | 1.10      |
|   | Normal rough and semifinish turning                                    | 1.30      |
|   | Extra-heavy-duty rough turning   | 1.60–2.00 |
| Milling:                                    | Slab milling   | 1.10      |
|   | End milling  | 1.10      |
|   | Light and medium face milling  | 1.10–1.25 |
|   | Extra-heavy-duty face milling  | 1.30–1.60 |
| Drilling:                                   | Normal drilling  | 1.30      |
|   | Drilling hard-to-machine materials and drilling with a very dull drill | 1.50      |
| Broaching:                                  | Normal broaching   | 1.05–1.10 |
|   | Heavy-duty surface broaching   | 1.20–1.30 |
| Planing and Shaping                         | Use values given for turning   |           |

$P_m$  = power at the motor; hp, or kW

$K_p$  = power constant (see Tables 3a and 3b)

$Q$  = metal removal rate; in<sup>3</sup>/min or cm<sup>3</sup>/s (see Table 7)

$C$  = feed factor for power constant (see Table 4)

$W$  = tool wear factor (see Table 5)

$E$  = machine tool efficiency factor (see Table 6)

$V$  = cutting speed, fpm, or m/min

$N$  = cutting speed, rpm

$f$  = feed rate for turning; in/rev or mm/rev

- $f$  = feed rate for planing and shaping; in/stroke, or mm/stroke  
 $f_t$  = feed per tooth; in/tooth, or mm/tooth  
 $f_m$  = feed rate; in/min or mm/min  
 $d_t$  = maximum depth of cut per tooth; inch, or mm  
 $d$  = depth of cut; inch, or mm  
 $n_t$  = number of teeth on milling cutter  
 $n_c$  = number of teeth engaged in work  
 $w$  = width of cut; inch, or mm

**Table 6. Machine Tool Efficiency Factors,  $E$** 

| Type of Drive     | $E$  | Type of Drive       | $E$       |
|-------------------|------|---------------------|-----------|
| Direct Belt Drive | 0.90 | Geared Head Drive   | 0.70–0.80 |
| Back Gear Drive   | 0.75 | Oil-Hydraulic Drive | 0.60–0.90 |

**Table 7. Formulas for Calculating the Metal Removal Rate,  $Q$** 

| Operation   | Metal Removal Rate                                  |  |
|---|---|--|
|   | For Inch Units Only<br>$Q = \text{in}^3/\text{min}$ | For SI Metric Units Only<br>$Q = \text{cm}^3/\text{s}$ |
| Single-Point Tools<br>(Turning, Planing, and Shaping) | $12Vfd$   | $\frac{V}{60}fd$                                       |
| Milling   | $f_m wd$  | $\frac{f_m wd}{60,000}$                                |
| Surface Broaching                                     | $12Vwn_c d_t$                                       | $\frac{V}{60}un_c d_t$                                 |

*Example:* A 180–200 Bhn AISI 4130 shaft is to be turned on a geared head lathe using a cutting speed of 350 fpm (107 m/min), a feed rate of 0.016 in/rev (0.40 mm/rev), and a depth of cut of 0.100 inch (2.54 mm). Estimate the power at the cutting tool and at the motor, using both the inch and metric data.

Inch units:

$$K_p = 0.62 \text{ (from Table 3b)}$$

$$C = 0.94 \text{ (from Table 4)}$$

$$W = 1.30 \text{ (from Table 5)}$$

$$E = 0.80 \text{ (from Table 6)}$$

$$Q = 12 Vfd = 12 \times 350 \times 0.016 \times 0.100 \text{ (from Table 7)}$$

$$Q = 6.72 \text{ in}^3/\text{min}$$

$$P_c = K_p C Q W = 0.62 \times 0.94 \times 6.72 \times 1.30 = 5.1 \text{ hp}$$

$$P_m = \frac{P_c}{E} = \frac{5}{0.80} = 6.4 \text{ hp}$$

SI metric units:

$$K_p = 1.69 \text{ (from Table 3b)}$$

$$C = 0.94 \text{ (from Table 4)}$$

$$W = 1.30 \text{ (from Table 5)}$$

$$E = 0.80 \text{ (from Table 6)}$$

$$Q = \frac{V}{60}fd = \frac{107}{60} \times 0.40 \times 2.54 = 1.81 \text{ cm}^3/\text{s} \text{ (from Table 7)}$$

$$P_c = K_p C Q W = 1.69 \times 0.94 \times 1.81 \times 1.30 = 3.74 \text{ kW}$$

$$P_m = \frac{P_c}{E} = \frac{3.74}{0.80} = 4.677 \text{ kW}$$

Whenever possible the maximum power available on a machine tool should be used when heavy cuts must be taken.

The cutting conditions for utilizing the maximum power should be selected in the following order: 1) select the maximum depth of cut that can be used; 2) select the maximum feed rate that can be used; and 3) estimate the cutting speed that will utilize the maximum power available on the machine. This sequence is based on obtaining the longest tool life of the cutting tool and at the same time obtaining as much production as possible from the machine.

*The life of a cutting tool is most affected by the cutting speed, then by the feed rate, and least of all by the depth of cut.* The maximum metal removal rate that a given machine is capable of machining from a given material is used as the basis for estimating the cutting speed that will utilize all the power available on the machine.

*Example:* A 0.125 inch deep cut is to be taken on a 200–210 Bhn AISI 1050 steel part using a 10 hp geared head lathe. The feed rate selected for this job is 018 in./rev. Estimate the cutting speed that will utilize the maximum power available on the lathe.

$$K_p = 0.85 \text{ (From Table 3b)}$$

$$C = 0.92 \text{ (From Table 4)}$$

$$W = 1.30 \text{ (From Table 5)}$$

$$E = 0.80 \text{ (From Table 6)}$$

$$Q_{max} = \frac{P_m E}{K_p C W} = \frac{10 \times 0.80}{0.85 \times 0.92 \times 1.30} \quad \left( P_m = \frac{K_p C Q W}{E} \right)$$

$$= 7.87 \text{ in}^3/\text{min}$$

$$V = \frac{Q_{max}}{12fd} = \frac{7.87}{12 \times 0.018 \times 0.125} \quad (Q = 12Vfd)$$

$$= 291 \text{ fpm}$$

*Example:* A 160–180 Bhn gray iron casting that is 6 inches wide is to have  $\frac{1}{8}$  inch stock removed on a 10 hp milling machine, using an 8 inch diameter, 10 tooth, indexable insert cemented carbide face milling cutter. The feed rate selected for this cutter is 0.012 in/tooth, and all the stock (0.125 inch) will be removed in one cut. Estimate the cutting speed that will utilize the maximum power available on the machine.

$$K_p = 0.52 \text{ (From Table 3a)}$$

$$C = 1.00 \text{ (From Table 4)}$$

$$W = 1.20 \text{ (From Table 5)}$$

$$E = 0.80 \text{ (From Table 6)}$$

$$Q_{max} = \frac{P_m E}{K_p C W} = \frac{10 \times 0.80}{0.52 \times 1.00 \times 1.20} = 12.82 \text{ in}^3/\text{min} \quad \left( P_m = \frac{K_p C Q W}{E} \right)$$

$$f_m = \frac{Q_{max}}{w d} = \frac{12.82}{6 \times 0.125} = 17.1 \text{ in/min} \quad (Q = f_m w d)$$

$$N = \frac{f_{max}}{f_t n_t} = \frac{17}{0.012 \times 10} = 142.4 \text{ rpm} \quad (f_m = f_t n_t N)$$

$$V = \frac{\pi D N}{12} = \frac{\pi \times 8 \times 142}{12} = 298.3 \text{ fpm} \quad \left( N = \frac{12 V}{\pi D} \right)$$

**Estimating Drilling Thrust, Torque, and Power.**—Although the lips of a drill cut metal and produce a chip in the same manner as the cutting edges of other metal cutting tools, the chisel edge removes the metal by means of a very complex combination of extrusion and cutting. For this reason a separate method must be used to estimate the power required for drilling. Also, it is often desirable to know the magnitude of the thrust and the torque required to drill a hole. The formulas and tabular data provided in this section are based on information supplied by the National Twist Drill Division of Regal-Beloit Corp. The values in Tables 8 through 11 are for sharp drills, and tool wear factors are given in Table 5. For most ordinary drilling operations 1.30 can be used as the tool wear factor. When drilling most difficult-to-machine materials and when the drill is allowed to become very dull, 1.50 should be used as the value of this factor. It is usually more convenient to measure the web thickness at the drill point than the length of the chisel edge; for this reason, the approximate  $w/d$  ratio corresponding to each  $c/d$  ratio for a correctly ground drill is provided in Table 9. For most standard twist drills the  $c/d$  ratio is 0.18, unless the drill has been ground short or the web has been thinned. The  $c/d$  ratio of split point drills is 0.03. The formulas given below can be used for spade drills, as well as for twist drills. Separate formulas are required for use with customary inch units and for SI metric units.

**Table 8. Work Material Factor,  $K_d$ , for Drilling with a Sharp Drill**

| Work Material                                      | Material Constant, $K_d$   |
|--|--|
| AISI 1117 (Resulfurized free machining mild steel) | 12,000   |
| Steel, 200 Bhn                                     | 24,000   |
| Steel, 300 Bhn                                     | 31,000   |
| Steel, 400 Bhn                                     | 34,000   |
| Cast Iron, 150 Bhn                                 | 14,000   |
| Most Aluminum Alloys                               | 7,000  |
| Most Magnesium Alloys                              | 4,000  |
| Most Brasses                                       | 14,000   |
| Leaded Brass                                       | 7,000  |
| Austenitic Stainless Steel (Type 316)              | 24,000 <sup>a</sup> for Torque<br>35,000 <sup>a</sup> for Thrust |
| Titanium Alloy Ti6Al4V 40R <sub>c</sub>            | 18,000 <sup>a</sup> for Torque<br>29,000 <sup>a</sup> for Thrust |
| René 41 40R <sub>c</sub>                           | 40,000 <sup>ab</sup> min.  |
| Hastelloy-C  | 30,000 <sup>a</sup> for Torque<br>37,000 <sup>a</sup> for Thrust |

<sup>a</sup> Values based upon a limited number of tests.

<sup>b</sup> Will increase with rapid wear.

| 0.10       | 0.085                 | 1.020                        | 1.235                        | 0.010                        | 0.30       | 0.260                 | 1.235                        | 1.500                        | 0.090                        |
| 0.13       | 0.110                 | 1.040                        | 1.270                        | 0.017                        | 0.35       | 0.300                 | 1.310                        | 1.575                        | 0.120                        |
| 0.15       | 0.130                 | 1.080                        | 1.310                        | 0.022                        | 0.40       | 0.350                 | 1.395                        | 1.620                        | 0.160                        |

For drills of standard design, use  $c/d = 0.18$ ; for split point drills, use  $c/d = 0.03$

$c/d$  = Length of Chisel Edge  $\div$  Drill Diameter.

$w/d$  = Web Thickness at Drill Point  $\div$  Drill Diameter.

For inch units only:

$$T = 2K_d F_f F_T B W + K_d D^2 J W \quad (1)$$

$$M = K_d F_f F_M A W \quad (2)$$

$$P_c = MN / 63.025 \quad (3)$$

For SI metric units only:

$$T = 0.05 K_d F_f F_T B W + 0.007 K_d D^2 J W \quad (4)$$

$$M = \frac{K_d F_f F_M A W}{40,000} = 0.000025 K_d F_f F_M A W \quad (5)$$

$$P_c = MN / 9550 \quad (6)$$

Use with either inch or metric units:

$$P_m = \frac{P_c}{E} \quad (7)$$

where  $P_c$  = Power at the cutter; hp, or kW     $P_m$  = Power at the motor; hp, or kW

$M$  = Torque; in. lb, or N.m

$T$  = Thrust; lb, or N

$K_d$  = Work material factor (See Table 8)

$F_f$  = Feed factor (See Table 10)

$F_T$  = Thrust factor for drill diameter (See Table 11)

$F_M$  = Torque factor for drill diameter (See Table 11)

$A$  = Chisel edge factor for torque (See Table 9)

$B$  = Chisel edge factor for thrust (See Table 9)

$J$  = Chisel edge factor for thrust (See Table 9)

$W$  = Tool wear factor (See Table 5)

$N$  = Spindle speed; rpm

$E$  = Machine tool efficiency factor (See Table 6)

$D$  = Drill diameter; in., or mm

$c$  = Chisel edge length; in., or mm (See Table 9)

$w$  = Web thickness at drill point; in., or mm (See Table 9)

*Example:* A standard  $\frac{7}{8}$  inch drill is to drill steel parts having a hardness of 200 Bhn on a drilling machine having an efficiency of 0.80. The spindle speed to be used is 350 rpm and the feed rate will be 0.008 in./rev. Calculate the thrust, torque, and power required to drill these holes:

$$K_d = 24,000 \text{ (From Table 8)} \quad F_f = 0.021 \text{ (From Table 10)}$$

$$F_T = 0.899 \text{ (From Table 11)} \quad F_M = 0.786 \text{ (From Table 11)}$$

$$A = 1.085 \text{ (From Table 9)} \quad B = 1.355 \text{ (From Table 9)} \quad J = 0.030 \text{ (From Table 9)}$$

**Table 10. Feed Factors  $F_f$  for Drilling**

| Inch Units    |        |               |       | SI Metric Units |       |              |       |
|---------------|--------|---------------|-------|-----------------|-------|--------------|-------|
| Feed, in./rev | $F_f$  | Feed, in./rev | $F_f$ | Feed, mm/rev    | $F_f$ | Feed, mm/rev | $F_f$ |
| 0.0005        | 0.0023 | 0.012         | 0.029 | 0.01            | 0.025 | 0.30         | 0.382 |

$W = 1.30$  (From Table 5)

$$T = 2K_d F_f F_T B W + K_d d^2 J W$$

$$= 2 \times 24,000 \times 0.21 \times 0.899 \times 1.355 \times 1.30 + 24,000 \times 0.875^2 \times 0.030 \times 1.30$$

$$= 2313 \text{ lb}$$

$$M = K_d F_f F_M A W$$

$$= 24,000 \times 0.021 \times 0.786 \times 1.085 \times 1.30 = 559 \text{ in. lb}$$

$$P_c = \frac{MN}{63,025} = \frac{559 \times 350}{63,025} = 3.1 \text{ hp} \quad P_m = \frac{P_c}{E} = \frac{3.1}{0.80} = 3.9 \text{ hp}$$

Twist drills are generally the most highly stressed of all metal cutting tools. They must not only resist the cutting forces on the lips, but also the drill torque resulting from these forces and the very large thrust force required to push the drill through the hole. Therefore, often when drilling smaller holes, the twist drill places a limit on the power used and for very large holes, the machine may limit the power.

## MACHINING ECONOMETRICS

## Tool Wear And Tool Life Relationships

**Tool wear.**—Tool-life is defined as the cutting time to reach a predetermined wear, called the tool wear criterion. The size of tool wear criterion depends on the grade used, usually a tougher grade can be used at bigger flank wear. For finishing operations, where close tolerances are required, the wear criterion is relatively small. Other alternative wear criteria are a predetermined value of the surface roughness, or a given depth of the crater which develops on the rake face of the tool. The most appropriate wear criteria depends on cutting geometry, grade, and materials.

Tool-life is determined by assessing the time — the tool-life — at which a given predetermined flank wear is reached, 0.25, 0.4, 0.6, 0.8 mm etc. Fig. 1 depicts how flank wear varies with cutting time (approximately straight lines in a semi-logarithmic graph) for three combinations of cutting speeds and feeds. Alternatively, these curves may represent how variations of machinability impact on tool-life, when cutting speed and feed are constant. All tool wear curves will sooner or later bend upwards abruptly and the cutting edge will break, i.e., catastrophic failure as indicated by the white arrows in Fig. 1.

Fig. 1. Flank Wear as a Function of Cutting Time

The maximum deviation from the average tool-life 60 minutes in Fig. 1 is assumed to range between 40 and 95 minutes, i.e.  $-33\%$  and  $+58\%$  variation. The positive deviation from the average (longer than expected tool-life) is not important, but the negative one (shorter life) is, as the edge may break before the scheduled tool change after 60 minutes, when the flank wear is 0.6 mm.

It is therefore important to set the wear criterion at a safe level such that tool failures due to “normal” wear become negligible. This is the way machinability variations are mastered.

**Equivalent Chip Thickness (*ECT*).**—*ECT* combines the four basic turning variables, depth of cut, lead angle, nose radius and feed per revolution into one basic parameter. For all other metal cutting operations such as drilling, milling and grinding, additional variables such as number of teeth, width of cut, and cutter diameter are included in the parameter *ECT*. In turning, milling, and drilling, according to the *ECT* principle, when the product of feed times depth of cut is constant the tool-life is constant no matter how the depth of cut or feed is selected, provided that the cutting speed and cutting edge length are maintained constant. By replacing the geometric parameters with *ECT*, the number of tool-life tests to evaluate cutting parameters can be reduced considerably, by a factor of 4 in turning, and in milling by a factor of 7 because radial depth of cut, cutter diameter and number of teeth are additional parameters.

The introduction of the *ECT* concept constitutes a major simplification when predicting tool-life and calculating cutting forces, torque, and power. *ECT* was first presented in 1931 by Professor R. Woxen, who both theoretically and experimentally proved that *ECT* is a basic metal cutting parameter for high-speed cutting tools. Dr. Colding later proved that the concept also holds for carbide tools, and extended the calculation of *ECT* to be valid for cutting conditions when the depth of cut is smaller than the tool nose radius, or for round inserts. Colding later extended the concept to all other metal cutting operations, including the grinding process.

The definition of *ECT* is:

$$ECT = \frac{Area}{CEL} \text{ (mm or inch)}$$

where  $A$  = cross sectional area of cut (approximately = feed  $\times$  depth of cut), (mm<sup>2</sup> or inch<sup>2</sup>)

$CEL$  = cutting edge length (tool contact rubbing length), (mm or inch), see Fig. 9.

An exact value of  $A$  is obtained by the product of *ECT* and  $CEL$ . In turning, milling, and drilling, *ECT* varies between 0.05 and 1 mm, and is always less than the feed/rev or feed/tooth; its value is usually about 0.7 to 0.9 times the feed.

*Example 1:* For a feed of 0.8 mm/rev, depth of cut  $a = 3$  mm, and a cutting edge length  $CEL = 4$  mm<sup>2</sup>, the value of *ECT* is approximately  $ECT = 0.8 \times 3 \div 4 = 0.6$  mm.

The product of *ECT*,  $CEL$ , and cutting speed  $V$  (m/min or ft/min) is equal to the metal removal rate, *MRR*, which is measured in terms of the volume of chips removed per minute:

$$\begin{aligned} MRR &= 1000V \times Area = 1000V \times ECT \times CEL \text{ mm}^3/\text{min} \\ &= V \times Area \text{ cm}^3/\text{min or inch}^3/\text{min} \end{aligned}$$

The specific metal removal rate *SMRR* is the metal removal rate per mm cutting edge length  $CEL$ , thus:

$$\begin{aligned} SMMR &= 1000V \times ECT \text{ mm}^3/\text{min}/\text{mm} \\ &= V \times ECT \text{ cm}^3/\text{min}/\text{mm or inch}^3/\text{min}/\text{inch} \end{aligned}$$

*Example 2:* Using above data and a cutting speed of  $V = 250$  m/min specific metal removal rate becomes  $SMRR = 0.6 \times 250 = 150$  (cm<sup>3</sup>/min/mm).

*ECT in Grinding:* In grinding *ECT* is defined as in the other metal cutting processes, and is approximately equal to  $ECT = V_w \times ar \div V$ , where  $V_w$  is the work speed,  $ar$  is the depth of cut, and  $A = V_w \times ar$ . Wheel life is constant no matter how depth  $ar$ , or work speed  $V_w$ , is selected at  $V = \text{constant}$  (usually the influence of grinding contact width can be neglected). This translates into the same wheel life as long as the specific metal removal rate is constant, thus:

$$SMMR = 1000V_w \times ar \text{ mm}^3/\text{min}/\text{mm}$$

In grinding, *ECT* is much smaller than in the other cutting processes, ranging from about 0.0001 to 0.001 mm (0.000004 to 0.00004 inch). The grinding process is described in a separate chapter *GRINDING FEEDS AND SPEEDS* starting on page 1158.

**Tool-life Relationships.**—Plotting the cutting times to reach predetermined values of wear typically results in curves similar to those shown in Fig. 2 (cutting time versus cutting speed at constant feed per tooth) and Fig. 3 (cutting time versus feed per tooth at constant cutting speed). These tests were run in 1993 with mixed ceramics turn-milling hard steel, 82 R<sub>C</sub>, at the Technische Hochschule Darmstadt.

Fig. 2. Influence of feed per tooth on cutting time Fig. 3. Influence of cutting speed on tool-life

Tool-life has a maximum value at a particular setting of feed and speed. Economic and productive cutting speeds always occur on the right side of the curves in Figs. 2 and 4, which are called Taylor curves, represented by the so called Taylor's equation.

The variation of tool-life with feed and speed constitute complicated relationships, illustrated in Figs. 6a, 6b, and 6c.

**Taylor's Equation.**—Taylor's equation is the most commonly used relationship between tool-life  $T$ , and cutting speed  $V$ . It constitutes a straight line in a log-log plot, one line for each feed, nose radius, lead angle, or depth of cut, mathematically represented by:

$$V \times T^n = C \tag{1a}$$

where  $n$  = is the slope of the line

$C$  = is a constant equal to the cutting speed for  $T = 1$  minute

By transforming the equation to logarithmic axes, the Taylor lines become straight lines with slope =  $n$ . The constant  $C$  is the cutting speed on the horizontal ( $V$ ) axis at tool-life  $T = 1$  minute, expressed as follows

$$\ln V + n \times \ln T = \ln C \tag{1b}$$

For different values of feed or  $ECT$ , log-log plots of Equation (1a) form approximately straight lines in which the slope decreases slightly with a larger value of feed or  $ECT$ . In practice, the Taylor lines are usually drawn parallel to each other, i.e., the slope  $n$  is assumed to be constant.

Fig. 4 illustrates the Taylor equation, tool-life  $T$  versus cutting speed  $V$ , plotted in log-log coordinates, for four values of  $ECT = 0.1, 0.25, 0.5$  and  $0.7$  mm.

In Fig. 4, starting from the right, each  $T-V$  line forms a generally straight line that bends off and reaches its maximum tool-life, then drops off with decreasing speed (see also Figs. 2 and 3). When operating at short tool-lives, approximately when  $T$  is less than 5 minutes, each line bends a little so that the cutting speed for 1 minute life becomes less than the value calculated by constant  $C$ .

The Taylor equation is a very good approximation of the right hand side of the real tool-life curve (slightly bent). The portion of the curve to the left of the maximum tool-life gives shorter and shorter tool-lives when decreasing the cutting speed starting from the point of maximum tool-life. Operating at the maximum point of maximum tool-life, or to the left of it, causes poor surface finish, high cutting forces, and sometimes vibrations.

Fig. 4. Definition of slope  $n$  and constant  $C$  in Taylor's equation

**Evaluation of Slope  $n$ , and Constant  $C$ .**—When evaluating the value of the Taylor slope based on wear tests, care must be taken in selecting the tool-life range over which the slope is measured, as the lines are slightly curved.

The slope  $n$  can be found in three ways:

- Calculate  $n$  from the formula  $n = (\ln C - \ln V)/\ln T$ , reading the values of  $C$  and  $V$  for any value of  $T$  in the graph.
- Alternatively, using two points on the line,  $(V_1, T_1)$  and  $(V_2, T_2)$ , calculate  $n$  using the relationship  $V_1 \times T_1^n = V_2 \times T_2^n$ . Then, solving for  $n$ ,

$$n = \frac{\ln(V_1/V_2)}{\ln(T_2/T_1)}$$

- Graphically,  $n$  may be determined from the graph by measuring the distances “ $a$ ” and “ $b$ ” using a mm scale, and  $n$  is the ratio of  $a$  and  $b$ , thus,  $n = a/b$

*Example:* Using Fig. 4, and a given value of  $ECT=0.7$  mm, calculate the slope and constant of the Taylor line.

On the Taylor line for  $ECT=0.7$ , locate points corresponding to tool-lives  $T_1 = 15$  minutes and  $T_2 = 60$  minutes. Read off the associated cutting speeds as, approximately,  $V_1 = 110$  m/min and  $V_2 = 65$  m/min.

The slope  $n$  is then found to be  $n = \ln(110/65)/\ln(60/15) = 0.38$

The constant  $C$  can be then determined using the Taylor equation and either point  $(T_1, V_1)$  or point  $(T_2, V_2)$ , with equivalent results, as follows:

$$C = V \times T^n = 110 \times 15^{0.38} = 65 \times 60^{0.38} = 308 \text{ m/min (1027 fpm)}$$

**The Generalized Taylor Equation.**—The above calculated slope and constant  $C$  define tool-life at one particular value of feed  $f$ , depth of cut  $a$ , lead angle  $LA$ , nose radius  $r$ , and other relevant factors.

The generalized Taylor equation includes these parameters and is written

$$T^n = A \times f^m \times a^p \times LA^q \times r^s \quad (2)$$

where  $A$  = area; and,  $n, m, p, q,$  and  $s$  = constants.

There are two problems with the generalized equation: 1) a great number of tests have to be run in order to establish the constants  $n, m, p, q, s,$  etc.; and 2) the accuracy is not very good because Equation (2) yields straight lines when plotted versus  $f, a, LA,$  and  $r,$  when in reality, they are parabolic curves..

The Generalized Taylor Equation using Equivalent Chip Thickness (ECT): Due to the compression of the aforementioned geometrical variables ( $f, a, LA, r, \text{etc.}$ ) into ECT, Equation (2) can now be rewritten:

$$V \times T^n = A \times ECT^m \tag{3}$$

Experimental data confirms that the Equation (3) holds, approximately, within the range of the test data, but as soon as the equation is extended beyond the test results, the error can become very great because the  $V$ -ECT curves are represented as straight lines by Equation (3) and the real curves have a parabolic shape.

**The Colding Tool-life Relationship.**—This relationship contains 5 constants  $H, K, L, M,$  and  $N_0$ , which attain different values depending on tool grade, work material, and the type of operation, such as longitudinal turning versus grooving, face milling versus end milling, etc.

This tool-life relationship is proven to describe, with reasonable accuracy, how tool-life varies with ECT and cutting speed for any metal cutting and grinding operation. It is expressed mathematically as follows either as a generalized Taylor equation (4a), or, in logarithmic coordinates (4b):

$$V \times T^{(N_0 - L \times \ln ECT)} \times ECT^{\left(-\frac{H}{2M} + \frac{\ln ECT}{4M}\right)} = e^{\left(K - \frac{H}{4M}\right)} \tag{4a}$$

$$y = K - \frac{x - H}{4M} - z(N_0 - L_x) \tag{4b}$$

where  $x = \ln ECT$   $y = \ln V$   $z = \ln T$

$M$  = the vertical distance between the maximum point of cutting speed ( $ECT_H, V_H$ ) for  $T = 1$  minute and the speed  $V_G$ , at point ( $ECT_G, V_G$ ), as shown in Fig. 5.

$2M$  = the horizontal distance between point ( $ECT_H, V_G$ ) and point ( $V_G, ECT_G$ )

$H$  and  $K$  = the logarithms of the coordinates of the maximum speed point ( $ECT_H, V_H$ ) at tool-life  $T = 1$  minute, thus  $H = \ln(ECT_H)$  and  $K = \ln(V_H)$

$N_0$  and  $L$  = the variation of the Taylor slope  $n$  with ECT:  $n = N_0 - L \times \ln(ECT)$

Fig. 5. Definitions of the constants  $H, K, L, M,$  and  $N_0$  for tool-life equation in the  $V$ -ECT plane with tool-life constant

The constants  $L$  and  $N_0$  are determined from the slopes  $n_1$  and  $n_2$  of two Taylor lines at  $ECT_1$  and  $ECT_2$ , and the constant  $M$  from 3  $V$ -ECT values at any constant tool-life. Constants  $H$  and  $K$  are then solved using the tool-life equation with the above-calculated values of  $L, N_0$  and  $M$ .

**The G- and H-curves.**—The *G*-curve defines the longest possible tool-life for any given metal removal rate, *MRR*, or specific metal removal rate, *SMRR*. It also defines the point where the total machining cost is minimum, after the economic tool-life  $T_E$ , or optimal tool-life  $T_O$ , has been calculated, see *Optimization Models, Economic Tool-life when Feed is Constant* starting on page 1110.

The tool-life relationship is depicted in the 3 planes:  $T-V$ , where *ECT* is the plotted parameter (the Taylor plane);  $T-ECT$ , where *V* is plotted; and,  $V-ECT$ , where *T* is a parameter. The latter plane is the most useful because the optimal cutting conditions are more readily understood when viewing in the  $V-ECT$  plane. Figs. 6a, 6b, and 6c show how the tool-life curves look in these 3 planes in log-log coordinates.

Fig. 6a. Tool-life vs. cutting speed  $T-V$ ,  $ECT$  plotted

Fig. 6a shows the Taylor lines, and Fig. 6b illustrates how tool-life varies with  $ECT$  at different values of cutting speed, and shows the *H*-curve. Fig. 6c illustrates how cutting speed varies with  $ECT$  at different values of tool-life. The *H*- and *G*-curves are also drawn in Fig. 6c.

Fig. 6b. Tool-life vs.  $ECT$ ,  $T-ECT$ , cutting speed plotted

A simple and practical method to ascertain that machining is not done to the left of the *H*-curve is to examine the chips. When  $ECT$  is too small, about 0.03-0.05 mm, the chips tend to become irregular and show up more or less as dust.

Fig. 6c. Cutting speed vs.  $ECT$ ,  $V-ECT$ , tool-life plotted

**The  $V-ECT-T$  Graph and the Tool-life Envelope.**— The tool-life envelope, in Fig. 7, is an area laid over the  $V-ECT-T$  graph, bounded by the points A, B, C, D, and E, within which successful cutting can be realized. The H- and G-curves represent two borders, lines AE and BC. The border curve, line AB, shows a lower limit of tool-life,  $T_{MIN} = 5$  minutes, and border curve, line DE, represents a maximum tool-life,  $T_{MAX} = 300$  minutes.

$T_{MIN}$  is usually 5 minutes due to the fact that tool-life versus cutting speed does not follow a straight line for short tool-lives; it decreases sharply towards one minute tool-life.  $T_{MAX}$  varies with tool grade, material, speed and  $ECT$  from 300 minutes for some carbide tools to 10000 minutes for diamond tools or diamond grinding wheels, although systematic studies of maximum tool-lives have not been conducted.

Sometimes the metal cutting system cannot utilize the maximum values of the  $V-ECT-T$  envelope, that is, cutting at optimum  $V-ECT$  values along the G-curve, due to machine power or fixture constraints, or vibrations. Maximum  $ECT$  values,  $ECT_{MAX}$ , are related to the strength of the tool material and the tool geometry, and depend on the tool grade and material selection, and require a relatively large nose radius.

Fig. 7. Cutting speed vs.  $ECT$ ,  $V-ECT$ , tool-life plotted

Minimum  $ECT$  values,  $ECT_{MIN}$ , are defined by the conditions at which surface finish suddenly deteriorates and the cutting edge begins rubbing rather than cutting. These conditions begin left of the H-curve, and are often accompanied by vibrations and built-up edges on the tool. If feed or  $ECT$  is reduced still further, excessive tool wear with sparks and tool breakage, or melting of the edge occurs. For this reason, values of  $ECT$  lower than approx-

imately 0.03 mm should not be allowed. In Fig. 7, the  $ECT_{MIN}$  boundary is indicated by contour line  $A'E'$ .

In milling the minimum feed/tooth depends on the ratio  $ar/D$ , of radial depth of cut  $ar$ , and cutter diameter  $D$ . For small  $ar/D$  ratios, the chip thickness becomes so small that it is necessary to compensate by increasing the feed/tooth. See *High-speed Machining Econometrics* starting on page 1122 for more on this topic.

Fig. 7 demonstrates, in principle, minimum cost conditions for roughing at point  $O_R$ , and for finishing at point  $O_F$ , where surface finish or tolerances have set a limit. Maintaining the speed at  $O_R$ , 125 m/min, and decreasing feed reaches a maximum tool-life = 300 minutes at  $ECT = 0.2$ , and a further decrease of feed will result in shorter lives.

Similarly, starting at point X ( $V = 150$ ,  $ECT = 0.5$ ,  $T = 15$ ) and reducing feed, the  $H$ -curve will be reached at point E ( $ECT = 0.075$ ,  $T = 300$ ). Continuing to the left, tool-life will decrease and serious troubles occur at point E' ( $ECT = 0.03$ ).

Starting at point  $O_F$  ( $V = 300$ ,  $ECT = 0.2$ ,  $T = 15$ ) and reducing feed the  $H$ -curve will be reached at point E ( $ECT = 0.08$ ,  $T = 15$ ). Continuing to the left, life will decrease and serious troubles occur at  $ECT = 0.03$ .

Starting at point X ( $V = 400$ ,  $ECT = 0.2$ ,  $T = 5$ ) and reducing feed the  $H$ -curve will be reached at point E ( $ECT = 0.09$ ,  $T = 7$ ). Continuing to the left, life will decrease and serious troubles occur at point A' ( $ECT = 0.03$ ), where  $T = 1$  minute.

**Cutting Forces and Chip Flow Angle.**—There are three cutting forces, illustrated in Fig. 8, that are associated with the cutting edge with its nose radius  $r$ , depth of cut  $a$ , lead angle  $LA$ , and feed per revolution  $f$ , or in milling feed per tooth  $f_z$ . There is one drawing for roughing and one for finishing operations.

Fig. 8. Definitions of equivalent chip thickness,  $ECT$ , and chip flow angle,  $CFA$ .

The cutting force  $F_C$ , or tangential force, is perpendicular to the paper plane. The other two forces are the feed or axial force  $F_A$ , and the radial force  $F_R$  directed towards the work piece. The resultant of  $F_A$  and  $F_R$  is called  $F_H$ . When finishing,  $F_R$  is bigger than  $F_A$ , while in roughing  $F_A$  is usually bigger than  $F_R$ . The direction of  $F_H$ , measured by the chip flow angle  $CFA$ , is perpendicular to the rectangle formed by the cutting edge length  $CEL$  and  $ECT$  (the product of  $ECT$  and  $CEL$  constitutes the cross sectional area of cut,  $A$ ). The important task of determining the direction of  $F_H$ , and calculation of  $F_A$  and  $F_R$ , are shown in the formulas given in the Fig. 8.

The method for calculating the magnitudes of  $F_H$ ,  $F_A$ , and  $F_R$  is described in the following. The first thing is to determine the value of the cutting force  $F_C$ . Approximate formulas

to calculate the tangential cutting force, torque and required machining power are found in the section *ESTIMATING SPEEDS AND MACHINING POWER* starting on page 1082.

*Specific Cutting Force,  $K_c$* : The specific cutting force, or the specific energy to cut,  $K_c$ , is defined as the ratio between the cutting force  $F_C$  and the chip cross sectional area,  $A$ , thus,  $K_c = F_C \div A$  N/mm<sup>2</sup>.

The value of  $K_c$  decreases when  $ECT$  increases, and when the cutting speed  $V$  increases. Usually,  $K_c$  is written in terms of its value at  $ECT = 1$ , called  $K_{c1}$ , and neglecting the effect of cutting speed, thus  $K_c = K_{c1} \times ECT^B$ , where  $B$  = slope in log-log coordinates

Fig. 9.  $K_c$  vs.  $ECT$ , cutting speed plotted

A more accurate relationship is illustrated in Fig. 9, where  $K_c$  is plotted versus  $ECT$  at 3 different cutting speeds. In Fig. 9, the two dashed lines represent the aforementioned equation, which each have different slopes,  $B$ . For the middle value of cutting speed,  $K_c$  varies with  $ECT$  from about 1900 to 1300 N/mm<sup>2</sup> when  $ECT$  increases from 0.1 to 0.7 mm. Generally the speed effect on the magnitude of  $K_c$  is approximately 5 to 15 percent when using economic speeds.

Fig. 10.  $F_H/F_C$  vs.  $ECT$ , cutting speed plotted

*Determination of Axial,  $F_A$ , and Radial,  $F_R$ , Forces*: This is done by first determining the resultant force  $F_H$  and then calculating  $F_A$  and  $F_R$  using the Fig. 8 formulas.  $F_H$  is derived

from the ratio  $F_H/F_C$ , which varies with  $ECT$  and speed in a fashion similar to  $Kc$ . Fig. 10 shows how this relationship may vary.

As seen in Fig. 10,  $F_H/F_C$  is in the range 0.3 to 0.6 when  $ECT$  varies from 0.1 to 1 mm, and speed varies from 200 to 250 m/min using modern insert designs and grades. Hence, using reasonable large feeds  $F_H/F_C$  is around 0.3–0.4 and when finishing about 0.5–0.6.

*Example:* Determine  $F_A$  and  $F_R$ , based on the chip flow angle and the cutting force  $F_C$ , in turning.

Using a value of  $Kc = 1500 \text{ N/mm}^2$  for roughing, when  $ECT = 0.4$ , and the cutting edge length  $CEL = 5 \text{ mm}$ , first calculate the area  $A = 0.4 \times 5 = 2 \text{ mm}^2$ . Then, determine the cutting force  $F_C = 2 \times 1500 = 3000 \text{ Newton}$ , and an approximate value of  $F_H = 0.5 \times 3000 = 1500 \text{ Newton}$ .

Using a value of  $Kc = 1700 \text{ N/mm}^2$  for finishing, when  $ECT = 0.2$ , and the cutting edge length  $CEL = 2 \text{ mm}$ , calculate the area  $A = 0.2 \times 2 = 0.4 \text{ mm}^2$ . The cutting force  $F_C = 0.4 \times 1700 = 680 \text{ Newton}$  and an approximate value of  $F_H = 0.35 \times 680 = 238 \text{ Newton}$ .

Fig. 8 can be used to estimate  $CFA$  for rough and finish turning. When the lead angle  $LA$  is 15 degrees and the nose radius is relatively large, an estimated value of the chip flow angle becomes about 30 degrees when roughing, and about 60 degrees in finishing. Using the formulas for  $F_A$  and  $F_R$  relative to  $F_H$  gives:

#### Roughing:

$$F_A = F_H \times \cos(CFA) = 1500 \times \cos 30 = 1299 \text{ Newton}$$

$$F_R = F_H \times \sin(CFA) = 1500 \times \sin 30 = 750 \text{ Newton}$$

#### Finishing:

$$F_A = F_H \times \cos(CFA) = 238 \times \cos 60 = 119 \text{ Newton}$$

$$F_R = F_H \times \sin(CFA) = 238 \times \sin 60 = 206 \text{ Newton}$$

The force ratio  $F_H/F_C$  also varies with the tool rake angle and increases with negative rakes. In grinding,  $F_H$  is much larger than the grinding cutting force  $F_C$ ; generally  $F_H/F_C$  is approximately 2 to 4, because grinding grits have negative rakes of the order  $-35$  to  $-45$  degrees.

**Forces and Tool-life.**—Forces and tool life are closely linked. The ratio  $F_H/F_C$  is of particular interest because of the unique relationship of  $F_H/F_C$  with tool-life.

Fig. 11a.  $F_H/F_C$  vs.  $ECT$

The results of extensive tests at Ford Motor Company are shown in Figs. 11a and 11b, where  $F_H/F_C$  and tool-life  $T$  are plotted versus  $ECT$  at different values of cutting speed  $V$ .

For any constant speed, tool-life has a maximum at approximately the same values of  $ECT$  as has the function  $F_H/F_C$ . [LIVE GRAPH](#)  
[Click here to view](#)

Fig. 11b. Tool-life vs.  $ECT$

*The Force Relationship:* Similar tests performed elsewhere confirm that the  $F_H/F_C$  function can be determined using the 5 tool-life constants ( $H, K, M, L, N_0$ ) introduced previously, and a new constant ( $L_F/L$ ).

$$\ln\left(\frac{1}{a} \cdot \frac{F_H}{F_C}\right) = \frac{K - y - \frac{(x - H)^2}{4M}}{\frac{L_F}{L}(N_0 - Lx)} \tag{5}$$

The constant  $a$  depends on the rake angle; in turning  $a$  is approximately 0.25 to 0.5 and  $L_F/L$  is 10 to 20.  $F_C$  attains its maximum values versus  $ECT$  along the  $H$ -curve, when the tool-life equation has maxima, and the relationships in the three force ratio planes look very similar to the tool-life functions shown in the tool-life planes in Figs. 6a, 6b, and 6c.

Fig. 12. Tool-life vs.  $F_H/F_C$

Tool-life varies with  $F_H/F_C$  with a simple formula according to Equation (5) as follows:

$$T = \left( \frac{F_H}{aF_C} \right)^{\frac{L_F}{L}}$$

where  $L$  is the constant in the tool-life equation, Equation (4a) or (4b), and  $L_F$  is the corresponding constant in the force ratio equation, Equation (5). In Fig. 12 this function is plotted for  $a = 0.5$  and for  $L_F/L = 5, 10, \text{ and } 20$ .

Accurate calculations of aforementioned relationships require elaborate laboratory tests, or better, the design of a special test and follow-up program for parts running in the ordinary production. A software machining program, such as Colding International Corp. *COMP* program can be used to generate the values of all 3 forces, torque and power requirements both for sharp and worn tools

**Surface Finish  $R_a$  and Tool-life.**—It is well known that the surface finish in turning decreases with a bigger tool nose radius and increases with feed; usually it is assumed that  $R_a$  increases with the square of the feed per revolution, and decreases inversely with increasing size of the nose radius. This formula, derived from simple geometry, gives rise to great errors. In reality, the relationship is more complicated because the tool geometry must taken into account, and the work material and the cutting conditions also have a significant influence.

Fig. 13.  $R_a$  vs.  $ECT$ , nose radius  $r$  constant

Fig. 13 shows surface finish  $R_a$  versus  $ECT$  at various cutting speeds for turning cast iron with carbide tools and a nose radius  $r = 1.2$  mm. Increasing the cutting speed leads to a smaller  $R_a$  value.

Fig. 14 shows how the finish improves when the tool nose radius,  $r$ , increases at a constant cutting speed (168 m/min) in cutting nodular cast iron.

In Fig. 15,  $R_a$  is plotted versus  $ECT$  with cutting speed  $V$  for turning a 4310 steel with carbide tools, for a nose radius  $r = 1.2$  mm, illustrating that increasing the speed also leads to a smaller  $R_a$  value for steel machining.

A simple rule of thumb for the effect of increasing nose radius  $r$  on decreasing surface finish  $R_a$ , regardless of the ranges of  $ECT$  or speeds used, albeit within common practical values, is as follows. In finishing,

$$\frac{R_{a1}}{R_{a2}} = \left( \frac{r_2}{r_1} \right)^{0.5} \quad (6)$$

Fig. 14.  $R_a$  vs.  $ECT$   
cutting speed constant, nose radius  $r$  varies

Fig. 15.  $R_a$  vs.  $ECT$ ,  
cutting speed and nose radius  $r$  constant

In roughing, multiply the finishing values found using Equation (6) by 1.5, thus,  $R_{a(Rough)} = 1.5 \times R_{a(Finish)}$  for each  $ECT$  and speed.

*Example 1:* Find the decrease in surface roughness resulting from a tool nose radius change from  $r = 0.8$  mm to  $r = 1.6$  mm in finishing. Also, find the comparable effect in roughing.

For finishing, using  $r_2 = 1.6$  and  $r_1 = 0.8$ ,  $R_{a1}/R_{a2} = (1.6/0.8)^{0.5} = 1.414$ , thus, the surface roughness using the larger tool radius is  $R_{a2} = R_{a1} \div 1.414 = 0.7R_{a1}$

In roughing, at the same  $ECT$  and speed,  $R_a = 1.5 \times R_{a2} = 1.5 \times 0.7R_{a1} = 1.05R_{a1}$

*Example 2:* Find the decrease in surface roughness resulting from a tool nose radius change from  $r = 0.8$  mm to  $r = 1.2$  mm

For finishing, using  $r_2 = 1.2$  and  $r_1 = 0.8$ ,  $R_{a1}/R_{a2} = (1.2/0.8)^{0.5} = 1.224$ , thus, the surface roughness using the larger tool radius is  $R_{a2} = R_{a1} \div 1.224 = 0.82R_{a1}$

In roughing, at the same  $ECT$  and speed,  $R_a = 1.5 \times R_{a2} = 1.5 \times 0.82R_{a1} = 1.23R_{a1}$

It is interesting to note that, at a given  $ECT$ , the  $R_a$  curves have a minimum, see Figs. 13 and 15, while tool-life shows a maximum, see Figs. 6b and 6c. As illustrated in Fig. 16,  $R_a$  increases with tool-life  $T$  when  $ECT$  is constant, in principle in the same way as does the force ratio.

Fig. 16.  $R_a$  vs.  $T$ , holding  $ECT$  constant

*The Surface Finish Relationship:*  $R_a$  is determined using the same type of mathematical relationship as for tool-life and force calculations:

$$y = K_{Ra} - \frac{x - H_{Ra}}{4M_{Ra}} - (N_{ORa} - L_{Ra}) \ln(R_a)$$

where  $K_{Ra}$ ,  $H_{Ra}$ ,  $M_{Ra}$ ,  $N_{ORa}$ , and  $L_{Ra}$  are the 5 surface finish constants.

**Shape of Tool-life Relationships for Turning, Milling, Drilling and Grinding Operations—Overview.**—A summary of the general shapes of tool-life curves ( $V$ - $ECT$ - $T$  graphs) for the most common machining processes, including grinding, is shown in double logarithmic coordinates in Fig. 17a through Fig. 17h.

**Calculation Of Optimized Values Of Tool-life, Feed And Cutting Speed**

**Minimum Cost.**—Global optimum is defined as the absolute minimum cost considering all alternative speeds, feeds and tool-lives, and refers to the determination of optimum tool-life  $T_O$ , feed  $f_O$ , and cutting speed  $V_O$ , for either minimum cost or maximum production rate. When using the tool-life equation,  $T = f(V, ECT)$ , determine the corresponding feed, for given values of depth of cut and operation geometry, from optimum equivalent chip thickness,  $ECT_O$ . Mathematically the task is to determine minimum cost, employing the cost function  $C_{TOT} = \text{cost of machining time} + \text{tool changing cost} + \text{tooling cost}$ . Minimum cost optima occur along the so-called *G*-curve, identified in Fig. 6c.

Another important factor when optimizing cutting conditions involves choosing the proper cost values for cost per edge  $C_E$ , replacement time per edge  $T_{RPL}$ , and not least, the hourly rate  $H_R$  that should be applied.  $H_R$  is defined as the portion of the hourly shop rate that is applied to the operations and machines in question. If optimizing all operations in the portion of the shop for which  $H_R$  is calculated, use the full rate; if only one machine is involved, apply a lower rate, as only a portion of the general overhead rate should be used, otherwise the optimum, and anticipated savings, are erroneous.

**Production Rate.**—The production rate is defined as the cutting time or the metal removal rate, corrected for the time required for tool changes, but neglecting the cost of tools.

The result of optimizing production rate is a shorter tool-life, higher cutting speed, and a higher feed compared to minimum cost optimization, and the tooling cost is considerably higher. Production rates optima also occur along the *G*-curve.

**The Cost Function.**—There are a number of ways the total machining cost  $C_{TOT}$  can be plotted, for example, versus feed, *ECT*, tool-life, cutting speed or other parameter. In Fig. 18a, cost for a face milling operation is plotted versus cutting time, holding feed constant, and using a range of tool-lives, *T*, varying from 1 to 240 minutes.

Fig. 18a. Variation of tooling cost  $C_{TOOL}$  and total cost  $C_C$  with cutting time  $t_c$ , including minimum cost cutting time

The tabulated values show the corresponding cutting speeds determined from the tool-life equation, and the influence of tooling on total cost. Tooling cost,  $C_{TOOL}$  = sum of tool cost + cost of replacing worn tools, decreases the longer the cutting time, while the total cost,  $C_{TOT}$ , has a minimum at around 10 seconds of cutting time. The dashed line in the graph represents the cost of machining time: the product of hourly rate  $H_R$ , and the cutting time  $t_c$  divided by 60. The slope of the line defines the value of  $H_R$ .

Fig. 18b. Total cost vs. cutting time for simultaneously cutting with 1, 2, and 4 tools

The cutting time for minimum cost varies with the ratio of tooling cost and  $H_R$ . Minimum cost moves towards a longer cutting time (longer tool-life) when either the price of the tooling increases, or when several tools cut simultaneously on the same part. In Fig. 18b, this is exemplified by running 2 and 4 cutters simultaneously on the same work piece, at the same feed and depth of cut, and with a similar tool as in Fig. 18a. As the tooling cost goes up 2 and 4 times, respectively, and  $H_R$  is the same, the total costs curves move up, but also moves to the right, as do the points of minimum cost and optimal cutting times. This means that going somewhat slower, with more simultaneously cutting tools, is advantageous.

**Global Optimum.**—Usually, global optimum occurs for large values of feed, heavy roughing, and in many cases the cutting edge will break trying to apply the large feeds required. Therefore, true optima cannot generally be achieved when roughing, in particular when using coated and wear resistant grades; instead, use the maximum values of feed,  $ECT_{max}$ , along the tool-life envelope, see Fig. 7.

As will be shown in the following, the first step is to determine the optimal tool-life  $T_O$ , and then determine the optimum values of feeds and speeds.

| Optimum Tool-life $T_O = 22$ minutes     |              |              |               |               |
|--|--------------|--------------|---------------|---------------|
| $f_z$                                    | $V_{22}$     | $t_c$ , sec. | $C_{TOOL}$    | $C_{TOT}$     |
| 0.03                                     | 416          | 28.067       | 0.1067        | 0.4965        |
| 0.08                                     | 397          | 11.017       | 0.0419        | 0.1949        |
| 0.10                                     | 374          | 9.357        | 0.0356        | 0.1655        |
| 0.17                                     | 301          | 6.831        | 0.0260        | 0.1208        |

| 13.467                                   | 0.005        | 0.192        | 240           | 260           |

Fig. 19. Variation of tooling and total cost with cutting time, comparing global optimum with minimum cost at  $f_z = 0.1$  mm

The example in Fig. 19 assumes that  $T_O = 22$  minutes and the feed and speed optima were calculated as  $f_o = 0.6$  mm/tooth,  $V_o = 119$  m/min, and cutting time  $t_{cO} = 4.9$  secs.

The point of maximum production rate corresponds to  $f_o = 0.7$  mm/tooth,  $V_o = 163$  m/min, at tool-life  $T_O = 5$  minutes, and cutting time  $t_{cO} = 3.6$  secs. The tooling cost is approximately 3 times higher than at minimum cost (0.059 versus 0.0186), while the piece cost is only slightly higher: \$0.109 versus \$0.087.

When comparing the global optimum cost with the minimum at feed = 0.1 mm/tooth the graph shows it to be less than half (0.087 versus 0.164), but also the tooling cost is about 1/3 lower (0.0186 versus 0.027). The reason why tooling cost is lower depends on the tooling cost term  $t_c \times C_{E/T}$  (see *Calculation of Cost of Cutting and Grinding Operations* on page

1115). In this example, cutting times  $t_c = 4.9$  and  $9.81$  seconds, at  $T = 22$  and  $30$  minutes respectively, and the ratios are proportional to  $4.9/22 = 0.222$  and  $9.81/30 = 0.327$  respectively.

The portions of the total cost curve for shorter cutting times than at minimum corresponds to using feeds and speeds right of the  $G$ -curve, and those on the other side are left of this curve.

**Optimization Models, Economic Tool-life when Feed is Constant.**—Usually, optimization is performed versus the parameters tool-life and cutting speed, keeping feed at a constant value. The cost of cutting as function of cutting time is a straight line with the slope  $= H_R =$  hourly rate. This cost is independent of the values of tool change and tooling. Adding the cost of tool change and tooling, gives the variation of total cutting cost which shows a minimum with cutting time that corresponds to an economic tool-life,  $T_E$ . Economic tool-life represents a local optima (minimum cost) at a given constant value of feed, feed/tooth, or  $ECT$ .

Using the Taylor Equation:  $V \times T = C$  and differentiating  $C_{TOT}$  with respect to  $T$  yields:

**Economic tool-life:**

$$T_E = T_V \times (1/n - 1), \text{ minutes}$$

**Economic cutting speed:**

$$V_E = C/T_E^n, \text{ m/min, or sfm}$$

In these equations,  $n$  and  $C$  are constants in the Taylor equation for the given value of feed. Values of Taylor slopes,  $n$ , are estimated using the speed and feed Tables 1 through 23 starting on page 1027 and handbook Table 5b on page 1035 for turning, and Table 15e on page 1059 for milling and drilling; and  $T_V$  is the equivalent tooling-cost time.  $T_V = T_{RPL} + 60 \times C_E \div H_R$ , minutes, where  $T_{RPL}$  = time for replacing a worn insert, or a set of inserts in a milling cutter or inserted drill, or a twist drill, reamer, thread chaser, or tap.  $T_V$  is described in detail, later;  $C_E$  = cost per edge, or set of edges, or cost per regrind including amortized price of tool;

and  $H_R$  = hourly shop rate, or that rate that is impacted by the changes of cutting conditions.

In two dimensions, Fig. 20a shows how economic tool-life varies with feed per tooth. In this figure, the equivalent tooling-cost time  $T_V$  is constant, however the Taylor constant  $n$  varies with the feed per tooth.

Fig. 20a. Economic tool-life,  $T_E$  vs. feed per tooth,  $f_z$

Economic tool-life increases with greater values of  $T_V$ , either when  $T_{RPL}$  is longer, or when cost per edge  $C_E$  is larger for constant  $H_R$ , or when  $H_R$  is smaller and  $T_{RPL}$  and  $C_E$  are unchanged. For example, when using an expensive machine (which makes  $H_R$  bigger) the value of  $T_V$  gets smaller, as does the economic tool-life,  $T_E = T_V \times (1/n - 1)$ . Reducing  $T_E$  results in an increase in the economic cutting speed,  $V_E$ . This means raising the cutting speed, and illustrates the importance, in an expensive system, of utilizing the equipment better by using more aggressive machining data.

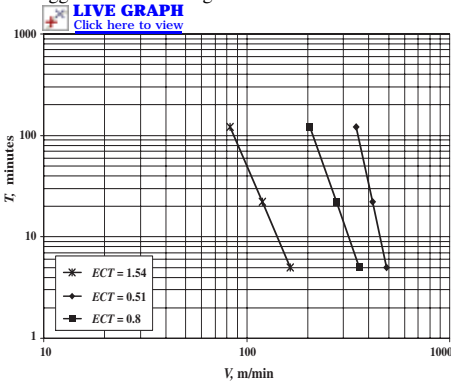

Fig. 20b. Tool-life vs. cutting speed, constant  $ECT$

As shown in Fig. 20a for a face milling operation, economic tool-life  $T_E$  varies considerably with feed/tooth  $f_z$ , in spite of the fact that the Taylor lines have only slightly different slopes ( $ECT = 0.51, 0.6, 1.54$ ), as shown in Fig. 20b. The calculation is based on the following cost data:  $T_V = 6$ , hourly shop rate  $H_R = \$60/\text{hour}$ , cutter diameter  $D = 125$  mm with number of teeth  $z = 10$ , and radial depth of cut  $ar = 40$  mm.

The conclusion relating to the determination of economic tool-life is that both hourly rate  $H_R$  and slope  $n$  must be evaluated with reasonable accuracy in order to arrive at good values. However, the method shown will aid in setting the trend for general machining economics evaluations.

**Global Optimum, Graphical Method.**—There are several ways to demonstrate in graphs how cost varies with the production parameters including optimal conditions. In all cases, tool-life is a crucial parameter.

Cutting time  $t_c$  is inversely proportional to the specific metal removal rate,  $SMRR = V \times ECT$ , thus,  $1/t_c = V \times ECT$ . Taking the log of both sides,

$$\ln V = -\ln ECT - \ln t_c + C \quad (7)$$

where  $C$  is a constant.

Equation (7) is a straight line with slope  $(-1)$  in the  $V-ECT$  graph when plotted in a log-log graph. This means that a constant cutting time is a straight 45-degree line in the  $V-ECT$  graph, when plotted in log-log coordinates with the same scale on both axis (a square graph).

The points at which the constant cutting time lines (at 45 degrees slope) are tangent to the tool-life curves define the  $G$ -curve, along which global optimum cutting occurs.

*Note:* If the ratio  $a/CEL$  is not constant when  $ECT$  varies, the constant cutting time lines are not straight, but the cutting time deviation is quite small in most cases.

In the  $V$ - $ECT$  graph, Fig. 21, 45-degree lines have been drawn tangent to each tool-life curve:  $T=1, 5, 15, 30, 60$  and 300 minutes. The tangential points define the  $G$ -curve, and the 45-degree lines represent different constant cutting times: 1, 2, 3, 10 minutes, etc. Following one of these lines and noting the intersection points with the tool-life curves  $T=1, 5, \text{etc.}$ , many different speed and feed combinations can be found that will give the same cutting time. As tool-life gets longer (tooling cost is reduced),  $ECT$  (feed) increases but the cutting speed has to be reduced.

Fig. 21. Constant cutting time in the  $V$ - $ECT$  plane, tool-life constant

**Global Optimum, Mathematical Method.**—Global optimization is the search for extremum of  $C_{TOT}$  for the three parameters:  $T$ ,  $ECT$ , and  $V$ . The results, in terms of the tool-life equation constants, are:

**Optimum tool-life:**

$$T_O = T_V \times \left( \frac{1}{n_O} - 1 \right)$$

$$n_O = 2M \times (L \times \ln T_O)^2 + 1 - N_0 + L \times (2M + H)$$

where  $n_O$  = slope at optimum  $ECT$ .

The same approach is used when searching for maximum production rate, but without the term containing tooling cost.

**Optimum cutting speed:**

$$V_O = e^{-M + K + (H \times L - N_0) \times \ln T_O + M \times L^2 \times (\ln T_O)^2}$$

**Optimum  $ECT$ :**

$$ECT_O = e^{H + 2M \times (L \times \ln(T_O) + 1)}$$

Global optimum is not reached when face milling for very large feeds, and  $C_{TOT}$  decreases continually with increasing feed/tooth, but can be reached for a cutter with many teeth, say 20 to 30. In end milling, global optimum can often be achieved for big feeds and for 3 to 8 teeth.

### Determination Of Machine Settings And Calculation Of Costs

Based on the rules and knowledge presented in Chapters 1 and 2, this chapter demonstrates, with examples, how machining times and costs are calculated.

Additional formulas are given, and the speed and feed tables given in *SPEED AND FEED TABLES* starting on page 1022 should be used. Finally the selection of feeds, speeds and tool-lives for optimized conditions are described with examples related to turning, end milling, and face milling.

There are an infinite number of machine settings available in the machine tool power train producing widely different results. In practice only a limited number of available settings are utilized. Often, feed is generally selected independently of the material being cut, however, the influence of material is critical in the choice of cutting speed. The tool-life is normally not known or directly determined, but the number of pieces produced before the change of worn tools is better known, and tool-life can be calculated using the formula for piece cutting time  $t_c$  given in this chapter.

It is well known that increasing feeds or speeds reduces the number of pieces cut between tool changes, but not how big are the changes in the basic parameter tool-life. Therefore, there is a tendency to select "safe" data in order to get a long tool-life. Another common practice is to search for a tool grade yielding a longer life using the current speeds and feeds, or a 10–20% increase in cutting speed while maintaining the current tool-life. The reason for this old-fashioned approach is the lack of knowledge about the opportunities the metal cutting process offers for increased productivity.

For example, when somebody wants to calculate the cutting time, he/she can select a value of the feed rate (product of feed and rpm), and easily find the cutting time by dividing cutting distance by the feed rate. The number of pieces obtained out of a tool is a guess-work, however. This problem is very common and usually the engineers find desired tool-lives after a number of trial and error runs using a variety of feeds and speeds. If the user is not well familiar with the material cut, the tool-life obtained could be any number of seconds or minutes, or the cutting edge might break.

There are an infinite number of feeds and speeds, giving the same feed rate, producing equal cutting time. The same cutting time per piece  $t_c$  is obtained independent of the selection of feed/rev  $f$  and cutting speed  $V$ , (or rpm), as long as the feed rate  $F_R$  remains the same:  $F_R = f_1 \times \text{rpm}_1 = f_2 \times \text{rpm}_2 = f_3 \times \text{rpm}_3 \dots$ , etc. However, the number of parts before tool change  $N_{ch}$  will vary considerably including the tooling cost  $c_{tool}$  and the total cutting cost  $c_{tot}$ .

The dilemma confronting the machining-tool engineer or the process planner is how to set feeds and speeds for either desired cycle time, or number of parts between tool changes, while balancing the process versus other operations or balancing the total times in one cell with another. These problems are addressed in this section.

#### Nomenclature

$f$  = feed/rev or tooth, mm     $f_E$  = economic feed     $f_O$  = optimum feed  
 $T$  = tool-life, minutes     $T_E$  = economic tool-life     $T_O$  = optimum tool-life  
 $V$  = cutting speed, m/min     $V_E$  = economic cutting speed     $V_O$  = optimum cutting speed, m/min

Similarly, economic and optimum values of:

$c_{tool}$  = piece cost of tooling, \$     $C_{TOOL}$  = cost of tooling per batch, \$  
 $c_{tot}$  = piece total cost of cutting, \$     $C_{TOT}$  = total cost of cutting per batch, \$  
 $F_R$  = feed rate measured in the feeding direction, mm/rev  
 $N$  = batch size  
 $N_{ch}$  = number of parts before tool change  
 $t_c$  = piece cutting time, minutes     $T_C$  = cutting time per batch, minutes  
 $t_{cyc}$  = piece cycle time, minutes     $T_{CYC}$  = cycle time before tool change, minutes

$t_i$  = idle time (tool "air" motions during cycle), minutes

$z$  = cutter number of teeth

The following variables are used for calculating the per batch cost of cutting:

$C_C$  = cost of cutting time per batch, \$

$C_{CH}$  = cost of tool changes per batch, \$

$C_E$  = cost per edge, for replacing or regrinding, \$

$H_R$  = hourly rate, \$

$T_V$  = equivalent tooling-cost time, minutes

$T_{RPL}$  = time for replacing worn edge(s), or tool for regrinding, minutes

*Note:* In the list above, when two variables use the same name, one in capital letters and one lower case,  $T_C$  and  $t_c$  for example, the variable name in capital letters refers to batch processing and lowercase letters to per piece processing, such as  $T_C = N_{ch} \times t_c$ ,  $C_{TOT} = N_{ch} \times c_{tot}$ , etc.

### Formulas Valid For All Operation Types Including Grinding

#### Calculation of Cutting Time and Feed Rate

##### Feed Rate:

$F_R = f \times \text{rpm}$  (mm/min), where  $f$  is the feed in mm/rev along the feeding direction,

rpm is defined in terms of work piece or cutter diameter  $D$  in mm, and cutting speed  $V$  in m/min, as follows:

$$\text{rpm} = \frac{1000V}{\pi D} = \frac{318V}{D}$$

##### Cutting time per piece:

*Note:* Constant cutting time is a straight 45-degree line in the  $V$ - $ECT$  graph, along which tool-life varies considerably, as is shown in Chapter 2.

$$t_c = \frac{Dist}{F_R} = \frac{Dist}{f \times \text{rpm}} = \frac{Dist \times \pi D}{1000V \times f}$$

where the units of distance cut  $Dist$ , diameter  $D$ , and feed  $f$  are mm, and  $V$  is in m/min.

In terms of  $ECT$ , cutting time per piece,  $t_c$ , is as follows:

$$t_c = \frac{Dist \times \pi D}{1000V} \times \frac{a}{CEL \times ECT}$$

where  $a$  = depth of cut, because feed  $\times$  cross sectional chip area =  $f \times a = CEL \times ECT$ .

*Example 3, Cutting Time:* Given  $Dist = 105$  mm,  $D = 100$  mm,  $f = 0.3$  mm,  $V = 300$  m/min, rpm = 700,  $F_R = 210$  mm/min, find the cutting time.

Cutting time =  $t_c = 105 \times 3.1416 \times 100 \div (1000 \times 300 \times 0.3) = 0.366$  minutes = 22 seconds

#### Scheduling of Tool Changes

##### Number of parts before tool change:

$$N_{ch} = T \div t_c$$

##### Cycle time before tool change:

$T_{CYC} = N_{ch} \times (t_c + t_i)$ , where  $t_{CYC} = t_c + t_i$ , where  $t_c$  = cutting time per piece,  $t_i$  = idle time per piece

##### Tool-life:

$$T = N_{ch} \times t_c$$

*Example 4:* Given tool-life  $T = 90$  minutes, cutting time  $t_c = 3$  minutes, and idle time  $t_i = 3$  minutes, find the number of parts produced before a tool change is required and the time until a tool change is required.

Number of parts before tool change =  $N_{ch} = 90/3 = 30$  parts.

Cycle time before tool change =  $T_{CYC} = 30 \times (3 + 3) = 180$  minutes

*Example 5:* Given cutting time,  $t_c = 1$  minute, idle time  $t_i = 1$  minute,  $N_{ch} = 100$  parts, calculate the tool-life  $T$  required to complete the job without a tool change, and the cycle time before a tool change is required.

Tool-life =  $T = N_{ch} \times t_c = 100 \times 1 = 100$  minutes.

Cycle time before tool change =  $T_{CYC} = 100 \times (1 + 1) = 200$  minutes.

**Calculation of Cost of Cutting and Grinding Operations.**—When machining data varies, the cost of cutting, tool changing, and tooling will change, but the costs of idle and slack time are considered constant.

**Cost of Cutting per Batch:**

$$C_C = H_R \times T_C / 60$$

$T_C$  = cutting time per batch = (number of parts)  $\times t_c$ , minutes, or when determining time for tool change  $T_{Cch} = N_{ch} \times t_c$  minutes = cutting time before tool change.

$t_c$  = Cutting time/part, minutes

$H_R$  = Hourly Rate

**Cost of Tool Changes per Batch:**

$$C_{CH} = \frac{H_R}{60} \times T_C \times \frac{T_{RPL}}{T} \quad \frac{\$}{min} \cdot min = \$$$

where  $T$  = tool-life, minutes, and  $T_{RPL}$  = time for replacing a worn edge(s), or tool for regrinding, minutes

**Cost of Tooling per Batch:**

Including cutting tools and holders, but without tool changing costs,

$$C_{TOOL} = \frac{H_R}{60} \times T_C \times \frac{60C_E}{T} \quad \frac{\$}{min} \cdot min \cdot \frac{min}{hr} \cdot \frac{\$}{min} = \$$$

**Cost of Tooling + Tool Changes per Batch:**

Including cutting tools, holders, and tool changing costs,

$$(C_{TOOL} + C_{CH}) = \frac{H_R}{60} \times T_C \times \frac{T_{RPL} + \frac{60C_E}{H_R}}{T}$$

**Total Cost of Cutting per Batch:**

$$C_{TOT} = \frac{H_R}{60} \times T_C \left( 1 + \frac{T_{RPL} + \frac{60C_E}{H_R}}{T} \right)$$

**Equivalent Tooling-cost Time,  $T_V$ :**

The two previous expressions can be simplified by using  $T_V = T_{RPL} + \frac{60C_E}{H_R}$

thus:

$$(C_{TOOL} + C_{CH}) = \frac{H_R}{60} \times T_C \times \frac{T_V}{T}$$

$$C_{TOT} = \frac{H_R}{60} \times T_C \left( 1 + \frac{T_V}{T} \right)$$

$C_E$  = cost per edge(s) is determined using two alternate formulas, depending on whether tools are reground or inserts are replaced:

#### Cost per Edge, Tools for Regrinding

$$C_E = \frac{\text{cost of tool} + (\text{number of regrinds} \times \text{cost/regrind})}{1 + \text{number of regrinds}}$$

#### Cost per Edge, Tools with Inserts:

$$C_E = \frac{\text{cost of insert(s)}}{\text{number of edges per insert}} + \frac{\text{cost of cutter body}}{\text{cutter body life in number of edges}}$$

*Note:* In practice allow for insert failures by multiplying the insert cost by 4/3, that is, assuming only 3 out of 4 edges can be effectively used.

*Example 6, Cost per Edge—Tools for Regrinding:* Use the data in the table below to calculate the cost per edge(s)  $C_E$ , and the equivalent tooling-cost time  $T_V$ , for a drill.

| Time for cutter replacement $T_{RPL}$ , minute | Cutter Price, \$ | Cost per regrind, \$ | Number of regrinds | Hourly shop rate, \$ | Batch size | Taylor slope, $n$ | Economic cutting time, $t_{cE}$ minute |
|--|------------------|----------------------|--------------------|----------------------|------------|-------------------|--|
| 1  | 40               | 6                    | 5                  | 50                   | 1000       | 0.25              | 1.5                                    |

Using the cost per edge formula for reground tools,  $C_E = (40 + 5 \times 6) \div (1 + 5) = \$6.80$

When the hourly rate is \$50/hr,  $T_V = T_{RPL} + \frac{60C_E}{H_R} = 1 + \frac{60(6.8)}{50} = 9.16$  minutes

Calculate economic tool-life using  $T_E = T_V \times \left( \frac{1}{n} - 1 \right)$  thus,  $T_E = 9.17 \times (1/0.25 - 1) = 9.16 \times 3 = 27.48$  minutes.

Having determined, elsewhere, the economic cutting time per piece to be  $t_{cE} = 1.5$  minutes, for a batch size = 1000 calculate:

Cost of Tooling + Tool Change per Batch:

$$(C_{TOOL} + C_{CH}) = \frac{H_R}{60} \times T_C \times \frac{T_V}{T} = \frac{50}{60} \times 1000 \times 1.5 \times \frac{9.16}{27.48} = \$ 417$$

Total Cost of Cutting per Batch:

$$C_{TOT} = \frac{H_R}{60} \times T_C \left( 1 + \frac{T_V}{T} \right) = \frac{50}{60} \times 1000 \times 1.5 \times \left( 1 + \frac{9.16}{27.48} \right) = \$ 1617$$

*Example 7, Cost per Edge—Tools with Inserts:* Use data from the table below to calculate the cost of tooling and tool changes, and the total cost of cutting.

For face milling, multiply insert price by safety factor 4/3 then calculate the cost per edge:  $C_E = 10 \times (5/3) \times (4/3) + 750/500 = 23.72$  per set of edges

When the hourly rate is \$50, equivalent tooling-cost time is  $T_V = 2 + 23.72 \times 60/50 = 30.466$  minutes (first line in table below). The economic tool-life for Taylor slope  $n = 0.333$  would be  $T_E = 30.466 \times (1/0.333 - 1) = 30.466 \times 2 = 61$  minutes.

When the hourly rate is \$25, equivalent tooling-cost time is  $T_V = 2 + 23.72 \times 60/25 = 58.928$  minutes (second line in table below). The economic tool-life for Taylor slope  $n = 0.333$  would be  $T_E = 58.928 \times (1/0.333 - 1) = 58.928 \times 2 = 118$  minutes.

| Time for replacement of inserts<br>$T_{RPL}$ , minutes | Number of inserts | Price per insert | Edges per insert | Cutter Price | Edges per cutter | Cost per set of edges, $C_E$ | Hourly shop rate | $T_V$ minutes |
|--|-------------------|------------------|------------------|--------------|------------------|------------------------------|------------------|---------------|
| Face mill  |                   |                  |                  |              |                  |                              |                  |               |
| 2  | 10                | 5                | 3                | 750          | 500              | 23.72                        | 50               | 30.466        |
| 2  | 10                | 5                | 3                | 750          | 500              | 23.72                        | 25               | 58.928        |
| End mill   |                   |                  |                  |              |                  |                              |                  |               |
| 1  | 3                 | 6                | 2                | 75           | 200              | 4.375                        | 50               | 6.25          |
| Turning  |                   |                  |                  |              |                  |                              |                  |               |
| 1  | 1                 | 5                | 3                | 50           | 100              | 2.72                         | 30               | 6.44          |

With above data for the face mill, and after having determined the economic cutting time as  $t_{cE} = 1.5$  minutes, calculate for a batch size = 1000 and \$50 per hour rate:

Cost of Tooling + Tool Change per Batch:

$$(C_{TOOL} + C_{CH}) = \frac{H_R}{60} \times T_C \times \frac{T_V}{T} = \frac{50}{60} \times 1000 \times 1.5 \times \frac{30.466}{61} = \$ 624$$

Total Cost of Cutting per Batch:

$$C_{TOT} = \frac{H_R}{60} \times T_C \left(1 + \frac{T_V}{T}\right) = \frac{50}{60} \times 1000 \times 1.5 \times \left(1 + \frac{30.466}{61}\right) = \$ 1874$$

Similarly, at the \$25/hour shop rate,  $(C_{TOOL} + C_{CH})$  and  $C_{TOT}$  are \$312 and \$937, respectively.

*Example 8, Turning:* Production parts were run in the shop at feed/rev = 0.25 mm. One series was run with speed  $V_1 = 200$  m/min and tool-life was  $T_1 = 45$  minutes. Another was run with speed  $V_2 = 263$  m/min and tool-life was  $T_2 = 15$  minutes. Given idle time  $t_i = 1$  minute, cutting distance  $Dist = 1000$  mm, work diameter  $D = 50$  mm.

First, calculate Taylor slope,  $n$ , using Taylor's equation  $V_1 \times T_1^n = V_2 \times T_2^n$ , as follows:

$$n = \ln \frac{V_1}{V_2} \div \ln \frac{T_2}{T_1} = \ln \frac{200}{263} \div \ln \frac{15}{45} = 0.25$$

Economic tool-life  $T_E$  is next calculated using the equivalent tooling-cost time  $T_V$ , as described previously. Assuming a calculated value of  $T_V = 4$  minutes, then  $T_E$  can be calculated from

$$T_E = T_V \times \left(\frac{1}{n} - 1\right) = 4 \times \left(\frac{1}{0.25} - 1\right) = 12 \text{ minutes}$$

Economic cutting speed,  $V_E$  can be found using Taylor's equation again, this time using the economic tool-life, as follows,

$$V_{E1} \times (T_E)^n = V_2 \times (T_2)^n$$

$$V_{E1} = V_2 \times \left(\frac{T_2}{T_E}\right)^n = 263 \times \left(\frac{15}{12}\right)^{0.25} = 278 \text{ m/min}$$

Using the process data, the remaining economic parameters can be calculated as follows:

Economic spindle rpm,  $rpm_E = (1000V_E)/(\pi D) = (1000 \times 278)/(3.1416 \times 50) = 1770$  rpm

Economic feed rate,  $F_{RE} = f \times rpm_E = 0.25 \times 1770 = 443$  mm/min

Economic cutting time,  $t_{cE} = Dist / F_{RE} = 1000 / 443 = 2.259$  minutes

Economic number of parts before tool change,  $N_{chE} = T_E \div t_{cE} = 12 \div 2.259 = 5.31$  parts

Economic cycle time before tool change,  $T_{CYCE} = N_{chE} \times (t_c + t_i) = 5.31 \times (2.259 + 1) = 17.3$  minutes.

### Variation Of Tooling And Total Cost With The Selection Of Feeds And Speeds

It is a well-known fact that tool-life is reduced when either feed or cutting speed is increased. When a higher feed/rev is selected, the cutting speed must be decreased in order to maintain tool-life. However, a higher feed rate (feed rate = feed/rev  $\times$  rpm, mm/min) can result in a longer tool-life if proper cutting data are applied. Optimized cutting data require accurate machinability databases and a computer program to analyze the options. Reasonably accurate optimized results can be obtained by selecting a large feed/rev or tooth, and then calculating the economic tool-life  $T_E$ . Because the cost versus feed or  $ECT$  curve is shallow around the true minimum point, i.e., the global optimum, the error in applying a large feed is small compared with the exact solution.

Once a feed has been determined, the economic cutting speed  $V_E$  can be found by calculating the Taylor slope, and the time/cost calculations can be completed using the formulas described in last section.

The remainder of this section contains examples useful for demonstrating the required procedures. Global optimum may or may not be reached, and tooling cost may or may not be reduced, compared to currently used data. However, the following examples prove that significant time and cost reductions are achievable in today's industry.

*Note:* Starting values of reasonable feeds in mm/rev can be found in the Handbook speed and feed tables, see *Principal Speed and Feed Tables* on page 1022, by using the  $f_{avg}$  values converted to mm as follows: feed (mm/rev) = feed (inch/rev)  $\times$  25.4 (mm/inch), thus 0.001 inch/rev = 0.001  $\times$  25.4 = 0.0254 mm/rev. When using speed and feed [Tables 1](#) through [23](#), where feed values are given in thousandths of inch per revolution, simply multiply the given feed by 25.4/1000 = 0.0254, thus feed (mm/rev) = feed (0.001 inch/rev)  $\times$  0.0254 (mm/0.001inch).

*Example 9, Converting Handbook Feed Values From Inches to Millimeters:* Handbook tables give feed values  $f_{opt}$  and  $f_{avg}$  for 4140 steel as 17 and 8  $\times$  (0.001 inch/rev) = 0.017 and 0.009 inch/rev, respectively. Convert the given feeds to mm/rev.

$$\text{feed} = 0.017 \times 25.4 = 17 \times 0.0254 = 0.4318 \text{ mm/rev}$$

$$\text{feed} = 0.008 \times 25.4 = 8 \times 0.0254 = 0.2032 \text{ mm/rev}$$

*Example 10, Using Handbook Tables to Find the Taylor Slope and Constant:* Calculate the Taylor slope and constant, using cutting speed data for 4140 steel in [Table 1](#) starting on page [1027](#), and for ASTM Class 20 grey cast iron using data from [Table 4a](#) on page [1033](#), as follows:

For the 175–250 Brinell hardness range, and the hard tool grade,

$$n = \frac{\ln(V_1/V_2)}{\ln(T_2/T_1)} = \frac{\ln(525/705)}{\ln(15/45)} = 0.27 \quad C = V_1 \times (T_1)^n = 1458$$

For the 175–250 Brinell hardness range, and the tough tool grade,

$$n = \frac{\ln(V_1/V_2)}{\ln(T_2/T_1)} = \frac{\ln(235/320)}{\ln(15/45)} = 0.28 \quad C = V_1 \times (T_1)^n = 685$$

For the 300–425 Brinell hardness range, and the hard tool grade,

$$n = \frac{\ln(V_1/V_2)}{\ln(T_2/T_1)} = \frac{\ln(330/440)}{\ln(15/45)} = 0.26 \quad C = V_1 \times (T_1)^n = 894$$

For the 300–425 Brinell hardness range, and the tough tool grade,

$$n = \frac{\ln(V_1/V_2)}{\ln(T_2/T_1)} = \frac{\ln(125/175)}{\ln(15/45)} = 0.31 \quad C = V_1 \times (T_1)^n = 401$$

For ASTM Class 20 grey cast iron, using hard ceramic,

$$n = \frac{\ln(V_1/V_2)}{\ln(T_2/T_1)} = \frac{\ln(1490/2220)}{\ln(15/45)} = 0.36 \quad C = V_1 \times (T_1)^n = 5932$$

**Selection of Optimized Data.**—Fig. 22 illustrates cutting time, cycle time, number of parts before a tool change, tooling cost, and total cost, each plotted versus feed for a constant tool-life. Approximate minimum cost conditions can be determined using the formulas previously given in this section.

First, select a large feed/rev or tooth, and then calculate economic tool-life  $T_E$ , and the economic cutting speed  $V_E$ , and do all calculations using the time/cost formulas as described previously.

Fig. 22. Cutting time, cycle time, number of parts before tool change, tooling cost, and total cost vs. feed for tool-life = 15 minutes, idle time = 10 s, and batch size = 1000 parts

**Example 11, Step by Step Procedure: Turning – Facing out:** 1) Select a big feed/rev, in this case  $f = 0.9$  mm/rev (0.035 inch/rev). A Taylor slope  $n$  is first determined using the Handbook tables and the method described in Example 10. In this example, use  $n = 0.35$  and  $C = 280$ .

2) Calculate  $T_V$  from the tooling cost parameters:

If cost of insert = \$7.50; edges per insert = 2; cost of tool holder = \$100; life of holder = 100 insert sets; and for tools with inserts, allowance for insert failures = cost per insert by 4/3, assuming only 3 out of 4 edges can be effectively used.

Then, cost per edge =  $C_E$  is calculated as follows:

$$C_E = \frac{\text{cost of insert(s)}}{\text{number of edges per insert}} + \frac{\text{cost of cutter body}}{\text{cutter body life in number of edges}}$$

$$= \frac{7.50 \times 4/3}{2} + \frac{100}{100} = \$6.00$$

The time for replacing a worn edge of the facing insert =  $T_{RPL} = 2.24$  minutes. Assuming an hourly rate  $H_R = \$50/\text{hour}$ , calculate the equivalent tooling-cost time  $T_V$

$$T_V = T_{RPL} + 60 \times C_E/H_R = 2.24 + 60 \times 6/50 = 9.44 \text{ minutes}$$

3) Determine economic tool-life  $T_E$

$$T_E = T_V \times (1/n - 1) = 9.44 \times (1/0.35 - 1) = 17.5 \text{ minutes}$$

4) Determine economic cutting speed using the Handbook tables using the method shown in Example 10,

$$V_E = C/T_E^n \text{ m/min} = 280 / 17.5^{0.35} = 103 \text{ m/min}$$

5) Determine cost of tooling per batch (cutting tools, holders and tool changing) then total cost of cutting per batch:

$$C_{TOOL} = H_R \times T_C \times (C_E/T)/60$$

$$(C_{TOOL} + C_{CH}) = H_R \times T_C \times ((T_{RPL} + C_E/T)/60)$$

$$C_{TOT} = H_R \times T_C (1 + (T_{RPL} + C_E)/T)$$

*Example 12, Face Milling – Minimum Cost*: This example demonstrates how a modern firm, using the formulas previously described, can determine optimal data. It is here applied to a face mill with 10 teeth, milling a 1045 type steel, and the radial depth versus the cutter diameter is 0.8. The  $V-ECT-T$  curves for tool-lives 5, 22, and 120 minutes for this operation are shown in Fig. 23a. [LIVE GRAPH](#)  
[Click here to view](#)

Fig. 23a. Cutting speed vs. ECT, tool-life constant

The global cost minimum occurs along the  $G$ -curve, see Fig. 6c and Fig. 23a, where the 45-degree lines defines this curve. Optimum  $ECT$  is in the range 1.5 to 2 mm.

For face and end milling operations,  $ECT = z \times f_z \times ar/D \times aa/CEL \div \pi$ . The ratio  $aa/CEL = 0.95$  for lead angle  $LA = 0$ , and for  $ar/D = 0.8$  and 10 teeth, using the formula to calculate the feed/tooth range gives for  $ECT = 1.5$ ,  $f_z = 0.62$  mm and for  $ECT = 2$ ,  $f_z = 0.83$  mm.

Fig. 23b. Cutting time per part vs. feed per tooth

Using computer simulation, the minimum cost occurs approximately where Fig. 23a indicates it should be. Total cost has a global minimum at  $f_z$  around 0.6 to 0.7 mm and a speed of around 110 m/min.  $ECT$  is about 1.9 mm and the optimal cutter life is  $T_O = 22$  minutes. Because it may be impossible to reach the optimum feed value due to tool breakage,

the maximum practical feed  $f_{max}$  is used as the optimal value. The difference in costs between a global optimum and a practical minimum cost condition is negligible, as shown in Figs. 23c and 23e. A summary of the results are shown in Figs. 23a through 23e, and Table 1.

Fig. 23c. Total cost vs. feed/tooth

When plotting cutting time/part,  $t_c$ , versus feed/tooth,  $f_z$ , at  $T = 5, 22, 120$  in Figs. 23b, tool-life  $T = 5$  minutes yields the shortest cutting time, but total cost is the highest; the minimum occurs for  $f_z$  about 0.75 mm, see Figs. 23c. The minimum for  $T = 120$  minutes is about 0.6 mm and for  $T_O = 22$  minutes around 0.7 mm.

Fig. 23d. Tooling cost versus feed/tooth

Fig. 23d shows that tooling cost drop off quickly when increasing feed from 0.1 to 0.3 to 0.4 mm, and then diminishes slowly and is almost constant up to 0.7 to 0.8 mm/tooth. It is generally very high at the short tool-life 5 minutes, while tooling cost of optimal tool-life 22 minutes is about 3 times higher than when going slow at  $T=120$  minutes.

## MACHINING ECONOMETRICS

Fig. 23e. Total cost vs. cutting speed at 3 constant tool-lives, feed varies

The total cost curves in Fig. 23e. were obtained by varying feed and cutting speed in order to maintain constant tool-lives at 5, 22 and 120 minutes. Cost is plotted as a function of speed  $V$  instead of feed/tooth. Approximate optimum speeds are  $V = 150$  m/min at  $T = 5$  minutes,  $V = 180$  m/min at  $T = 120$  minutes, and the global optimum speed is  $V_0 = 110$  m/min for  $T_0 = 22$  minutes.

Table 1 displays the exact numerical values of cutting speed, tooling cost and total cost for the selected tool-lives of 5, 22, and 120 minutes, obtained from the software program.

**Table 1. Face Milling, Total and Tooling Cost versus  $ECT$ , Feed/tooth  $f_z$ , and Cutting Speed  $V$ , at Tool-lives 5, 22, and 120 minutes**

| $f_z$ | $ECT$ | $T = 5$ minutes |           |            | $T = 22$ minutes |           |            | $T = 120$ minutes |           |            |
|-------|-------|-----------------|-----------|------------|------------------|-----------|------------|-------------------|-----------|------------|

### High-speed Machining Econometrics

**High-speed Machining – No Mystery.**—This section describes the theory and gives the basic formulas for any milling operation and high-speed milling in particular, followed by several examples on high-speed milling econometrics. These rules constitute the basis on which selection of milling feed factors is done. Selection of cutting speeds for general milling is done using the Handbook Table 10 through 14, starting on page 1044.

High-speed machining is no mystery to those having a good knowledge of metal cutting. Machining materials with very good machinability, such as low-alloyed aluminum, have for ages been performed at cutting speeds well below the speed values at which these materials should be cut. Operating at these low speeds often results in built-up edges and poor surface finish, because the operating conditions selected are on the wrong side of the Taylor curve, i.e. to the left of the  $H$ -curve representing maximum tool-life values (see Fig. 4 on page 1096).

In the 1950's it was discovered that cutting speed could be raised by a factor of 5 to 10 when hobbing steel with HSS cutters. This is another example of being on the wrong side of the Taylor curve.

One of the first reports on high-speed end milling using high-speed steel (HSS) and carbide cutters for milling 6061-T651 and A356-T6 aluminum was reported in a study funded by Defense Advanced Research Project Agency (DARPA). Cutting speeds of up to 4400 m/min (14140 fpm) were used. Maximum tool-lives of 20 through 40 minutes were obtained when the feed/tooth was 0.2 through 0.25 mm (0.008 to 0.01 inch), or measured in terms of *ECT* around 0.07 to 0.09 mm. Lower or higher feed/tooth resulted in shorter cutter lives. The same types of previously described curves, namely *T-ECT* curves with maximum tool-life along the *H*-curve, were produced.

When examining the influence of *ECT*, or feed/rev, or feed/tooth, it is found that too small values cause chipping, vibrations, and poor surface finish. This is caused by inadequate (too small) chip thickness, and as a result the material is not cut but plowed away or scratched, due to the fact that operating conditions are on the wrong (left) side of the tool-life versus *ECT* curve (*T-ECT* with constant speed plotted).

There is a great difference in the thickness of chips produced by a tooth traveling through the cutting arc in the milling process, depending on how the center of the cutter is placed in relation to the workpiece centerline, in the feed direction. Although end and face milling cut in the same way, from a geometry and kinematics standpoint they are in practice distinguished by the cutter center placement away from, or close to, the work centerline, respectively, because of the effect of cutter placement on chip thickness. This is the criteria used to distinguishing between the end and face milling processes in the following.

*Depth of Cut/Cutter Diameter, ar/D* is the ratio of the radial depth of cut *ar* and the cutter diameter *D*. In face milling when the cutter axis points approximately to the middle of the work piece axis, eccentricity is close to zero, as illustrated in Figs. 3 and 4, page 1042, and Fig. 5 on page 1043. In end milling, *ar/D* = 1 for full slot milling.

*Mean Chip Thickness, hm* is a key parameter that is used to calculate forces and power requirements in high-speed milling. If the mean chip thickness *hm* is too small, which may occur when feed/tooth is too small (this holds for all milling operations), or when *ar/D* decreases (this holds for ball nose as well as for straight end mills), then cutting occurs on the left (wrong side) of the tool-life versus *ECT* curve, as illustrated in Figs. 6b and 6c.

In order to maintain a given chip thickness in end milling, the feed/tooth has to be increased, up to 10 times for very small *ar/D* values in an extreme case with no run out and otherwise perfect conditions. A 10 times increase in feed/tooth results in 10 times bigger feed rates ( $F_R$ ) compared to data for full slot milling (valid for *ar/D* = 1), yet maintain a given chip thickness. The cutter life at any given cutting speed will not be the same, however.

Increasing the number of teeth from say 2 to 6 increases equivalent chip thickness *ECT* by a factor of 3 while the mean chip thickness *hm* remains the same, but does not increase the feed rate to 30 ( $3 \times 10$ ) times bigger, because the cutting speed must be reduced. However, when the *ar/D* ratio matches the number of teeth, such that one tooth enters when the second tooth leaves the cutting arc, then  $ECT = hm$ . Hence, *ECT* is proportional to the number of teeth. Under ideal conditions, an increase in number of teeth *z* from 2 to 6 increases the feed rate by, say, 20 times, maintaining tool-life at a reduced speed. In practice about 5 times greater feed rates can be expected for small *ar/D* ratios (0.01 to 0.02), and up to 10 times with 3 times as many teeth. So, high-speed end milling is no mystery.

**Chip Geometry in End and Face Milling.**—Fig. 24 illustrates how the chip forming process develops differently in face and end milling, and how mean chip thickness *hm* varies with the angle of engagement *AE*, which depends on the *ar/D* ratio. The pertinent chip geometry formulas are given in the text that follows.

Fig. 24.

Comparison of face milling and end milling geometry

High-speed end milling refers to values of  $ar/D$  that are less than 0.5, in particular to  $ar/D$  ratios which are considerably smaller. When  $ar/D = 0.5$  ( $AE = 90$  degrees) and diminishing in end milling, the chip thickness gets so small that poor cutting action develops, including plowing or scratching. This situation is remedied by increasing the feed/tooth, as shown in Table 2a as an increasing  $f_z/f_{z0}$  ratio with decreasing  $ar/D$ . For end milling, the  $f_z/f_{z0}$  feed ratio is 1.0 for  $ar/D = 1$  and also for  $ar/D = 0.5$ . In order to maintain the same  $hm$  as at  $ar/D = 1$ , the feed/tooth should be increased, by a factor of 6.38 when  $ar/D$  is 0.01 and by more than 10 when  $ar/D$  is less than 0.01. Hence high-speed end milling could be said to begin when  $ar/D$  is less than 0.5

In end milling, the ratio  $f_z/f_{z0} = 1$  is set at  $ar/D = 1.0$  (full slot), a common value in vendor catalogs and handbooks, for  $hm = 0.108$  mm.

The face milling chip making process is exactly the same as end milling when face milling the side of a work piece and  $ar/D = 0.5$  or less. However, when face milling close to and along the work centerline (eccentricity is close to zero) chip making is quite different, as shown in Fig. 24. When  $ar/D = 0.74$  ( $AE = 95$  degrees) in face milling, the  $f_z/f_{z0}$  ratio = 1 and increases up to 1.4 when the work width is equal to the cutter diameter ( $ar/D = 1$ ). The face milling  $f_z/f_{z0}$  ratio continues to diminish when the  $ar/D$  ratio decreases below  $ar/D = 0.74$ , but very insignificantly, only about 11 percent when  $ar/D = 0.01$ .

In face milling  $f_z/f_{z0} = 1$  is set at  $ar/D = 0.74$ , a common value recommended in vendor catalogs and handbooks, for  $hm = 0.151$  mm.

Fig. 25 shows the variation of the feed/tooth-ratio in a graph for end and face milling.

Fig. 25. Feed/tooth versus  $ar/D$  for face and end milling

**Table 2a. Variation of Chip Thickness and  $f_z/f_{z0}$  with  $ar/D$**

| $ar/D$ | Face Milling   |         |       |          |              | End Milling (straight)   |         |       |          |              |

| 0.0625 | 7.167  | 0.999   | 0.170 | 0.159    | 0.891        | 28.955   | 0.247   | 0.042 | 0.161    | 2.574        |
| 0.0300 | 3.438  | 1.000   | 0.170 | 0.076    | 0.890        | 19.948   | 0.172   | 0.029 | 0.111    | 3.694        |
| 0.0100 | 1.146  | 1.000   | 0.170 | 0.025    | 0.890        | 11.478   | 0.100   | 0.017 | 0.064    | 6.377        |
| 0.0010 | 0.115  | 1.000   | 0.000 | 0.000    | 0.890        | 3.624  | 0.000   | 0.000 | 0.000    | 20.135       |

In Table 2a, a standard value  $f_{z0} = 0.17$  mm/tooth (commonly recommended average feed) was used, but the  $f_z/f_{z0}$  values are independent of the value of feed/tooth, and the previously mentioned relationships are valid whether  $f_{z0} = 0.17$  or any other value.

In both end and face milling,  $hm = 0.108$  mm for  $f_{z0} = 0.17$  mm when  $ar/D = 1$ . When the  $f_z/f_{z0}$  ratio = 1,  $hm = 0.15$  for face milling, and 0.108 in end milling both at  $ar/D = 1$  and 0.5. The tabulated data hold for perfect milling conditions, such as, zero run-out and accurate sharpening of all teeth and edges.

**Mean Chip Thickness  $hm$  and Equivalent Chip Thickness  $ECT$ .**—The basic formula for equivalent chip thickness  $ECT$  for any milling process is:

$ECT = f_z \times z/\pi \times (ar/D) \times aa/CEL$ , where  $f_z$  = feed/tooth,  $z$  = number of teeth,  $D$  = cutter diameter,  $ar$  = radial depth of cut,  $aa$  = axial depth of cut, and  $CEL$  = cutting edge length. As a function of mean chip thickness  $hm$ :

$ECT = hm \times (z/2) \times (AE/180)$ , where  $AE$  = angle of engagement.

Both terms are exactly equal when one tooth engages as soon as the preceding tooth leaves the cutting section. Mathematically,  $hm = ECT$  when  $z = 360/AE$ ; thus:

for face milling,  $AE = \arccos(1 - 2 \times (ar/D)^2)$

for end milling,  $AE = \arccos(1 - 2 \times (ar/D))$

*Calculation of Equivalent Chip Thickness (ECT) versus Feed/tooth and Number of teeth.*: Table 2b is a continuation of Table 2a, showing the values of  $ECT$  for face and end milling for decreasing values  $ar/D$ , and the resulting  $ECT$  when multiplied by the  $f_z/f_{z0}$  ratio  $f_{z0} = 0.17$  (based on  $hm = 0.108$ ).

Small  $ar/D$  ratios produce too small mean chip thickness for cutting chips. In practice, minimum values of  $hm$  are approximately 0.02 through 0.04 mm for both end and face milling.

**Formulas.**— Equivalent chip thickness can be calculated for other values of  $f_z$  and  $z$  by means of the following formulas:

Face milling:  $ECT_F = ECT_{0F} \times (z/8) \times (f_z/0.17) \times (aa/CEL)$

or, if  $ECT_F$  is known calculate  $f_z$  using:

$f_z = 0.17 \times (ECT_F/ECT_{0F}) \times (8/z) \times (CEL/aa)$

**Table 2b. Variation of  $ECT$ , Chip Thickness and  $f_z/f_{z0}$  with  $ar/D$** 

| $ar/D$ | Face Milling |              |       |  | End Milling (straight) |              |       |  |
|--------|--------------|--------------|-------|--|------------------------|--------------|-------|--|

| 0.0300 | 0.170        | 0.890        | 0.012 | 0.011                                    | 0.029                  | 3.694        | 0.003 | 0.011                                    |
| 0.0100 | 0.170        | 0.890        | 0.004 | 0.004                                    | 0.017                  | 6.377        | 0.001 | 0.007                                    |
| 0.0010 | 0.170        | 0.890        | 0.002 | 0.002                                    | 0.005                  | 20.135       | 0.001 | 0.005                                    |

In face milling, the approximate values of  $aa/CEL = 0.95$  for lead angle  $LA = 0^\circ$  ( $90^\circ$  in the metric system); for other values of  $LA$ ,  $aa/CEL = 0.95 \times \sin(LA)$ , and  $0.95 \times \cos(LA)$  in the metric system.

*Example, Face Milling:* For a cutter with  $D = 250$  mm and  $ar = 125$  mm, calculate  $ECT_F$  for  $f_z = 0.1$ ,  $z = 12$ , and  $LA = 30$  degrees. First calculate  $ar/D = 0.5$ , and then use [Table 2b](#) and find  $ECT_{0F} = 0.2$ .

Calculate  $ECT_F$  with above formula:

$$ECT_F = 0.2 \times (12/8) \times (0.1/0.17) \times 0.95 \times \sin 30 = 0.084 \text{ mm.}$$

*End milling:*  $ECT_E = ECT_{0E} \times (z/2) \times (f_z/0.17) \times (aa/CEL)$ ,

or if  $ECT_E$  is known calculate  $f_z$  from:

$$f_z = 0.17 \times (ECT_E/ECT_{0E}) \times (2/z) \times (CEL/aa)$$

The approximate values of  $aa/CEL = 0.95$  for lead angle  $LA = 0^\circ$  ( $90^\circ$  in the metric system).

*Example, High-speed End Milling:* For a cutter with  $D = 25$  mm and  $ar = 3.125$  mm, calculate  $ECT_E$  for  $f_z = 0.1$  and  $z = 6$ . First calculate  $ar/D = 0.125$ , and then use [Table 2b](#) and find  $ECT_{0E} = 0.0249$ .

Calculate  $ECT_E$  with above formula:

$$ECT_E = 0.0249 \times (6/2) \times (0.1/0.17) \times 0.95 \times 1 = 0.042 \text{ mm.}$$

*Example, High-speed End Milling:* For a cutter with  $D = 25$  mm and  $ar = 0.75$  mm, calculate  $ECT_E$  for  $f_z = 0.17$  and  $z = 2$  and  $6$ . First calculate  $ar/D = 0.03$ , and then use [Table 2b](#) and find  $f_z/f_{z0} = 3.694$

Then,  $f_z = 3.694 \times 0.17 = 0.58$  mm/tooth and  $ECT_E = 0.0119 \times 0.95 = 0.0113$  mm and  $0.0357 \times 0.95 = 0.0339$  mm for 2 and 6 teeth respectively. These cutters are marked HS2 and HS6 in [Figs. 26a, 26d, and 26e](#).

*Example, High-speed End Milling:* For a cutter with  $D = 25$  mm and  $ar = 0.25$  mm, calculate  $ECT_E$  for  $f_z = 0.17$  and  $z = 2$  and  $6$ . First calculate  $ar/D = 0.01$ , and then use [Table 2b](#) and find  $ECT_{0E} = 0.0069$  and  $0.0207$  for 2 and 6 teeth respectively. When obtaining such small values of  $ECT$ , there is a great danger to be far on the left side of the  $H$ -curve, at least when there are only 2 teeth. Doubling the feed would be the solution if cutter design and material permit.

*Example, Full Slot Milling:* For a cutter with  $D = 25$  mm and  $ar = 25$  mm, calculate  $ECT_E$  for  $f_z = 0.17$  and  $z = 2$  and  $6$ . First calculate  $ar/D = 1$ , and then use [Table 2b](#) and find  $ECT_E =$

$0.108 \times 0.95 = 0.103$  and  $3 \times 0.108 \times 0.95 = 0.308$  for 2 and 6 teeth, respectively. These cutters are marked SL2 and SL6 in Figs. 26a, 26d, and 26e.

**Physics behind  $hm$  and  $ECT$ , Forces and Tool-life ( $T$ ).**—The  $ECT$  concept for all metal cutting and grinding operations says that the more energy put into the process, by increasing feed/rev, feed/tooth, or cutting speed, the life of the edge decreases. When increasing the number of teeth (keeping everything else constant) the work and the process are subjected to a higher energy input resulting in a higher rate of tool wear.

In high-speed milling when the angle of engagement  $AE$  is small the contact time is shorter compared to slot milling ( $ar/D = 1$ ) but the chip becomes shorter as well. Maintaining the same chip thickness as in slot milling has the effect that the energy consumption to remove the chip will be different. Hence, maintaining a constant chip thickness is a good measure when calculating cutting forces (keeping speed constant), but not when determining tool wear. Depending on cutting conditions the wear rate can either increase or decrease, this depends on whether cutting occurs on the left or right side of the  $H$ -curve.

Fig. 26a shows an example of end milling of steel with coated carbide inserts, where cutting speed  $V$  is plotted versus  $ECT$  at 5, 15, 45 and 180 minutes tool-lives. Notice that the  $ECT$  values are independent of  $ar/D$  or number of teeth or feed/tooth, or whether  $f_z$  or  $f_{z0}$  is used, as long as the corresponding  $f_z/f_{z0}$ -ratio is applied to determine  $ECT_E$ . The result is one single curve per tool-life. Had cutting speed been plotted versus  $f_{z0}$ ,  $ar/D$ , or  $z$  values (number of teeth), several curves would be required at each constant tool-life, one for each of these parameters. This illustrates the advantage of using the basic parameter  $ECT$  rather than  $f_z$ , or  $hm$ , or  $ar/D$  on the horizontal axis.

Fig. 26a. Cutting speed vs.  $ECT$ , tool-life plotted, for end milling

*Example:* The points (HS2, HS6) and (SL2, SL6) on the 45-minute curve in Fig. 26a relate to the previous high-speed and full slot milling examples for 2 and 6 teeth, respectively.

Running a slot at  $f_{z0} = 0.17$  mm/tooth ( $hm = 0.108$ ,  $ECT_E = 0.103$  mm) with 2 teeth and for a tool-life 45 minutes, the cutting speed should be selected at  $V = 340$  m/min at point SL2 and for six teeth ( $hm = 0.108$  mm,  $ECT_E = 0.308$ ) at  $V = 240$  m/min at point SL6.

When high-speed milling for  $ar/D = 0.03$  at  $f_z = 3.394 \times 0.17 = 0.58$  mm/tooth = 0.58 mm/tooth,  $ECT$  is reduced to 0.011 mm ( $hm = 0.108$ ) the cutting speed is 290 m/min to maintain  $T = 45$  minutes, point HS2. This point is far to the left of the  $H$ -curve in Fig. 26b, but if the number of teeth is increased to 6 ( $ECT_E = 3 \times 0.103 = 0.3090$ ), the cutting speed is 360 m/min at  $T = 45$  minutes and is close to the  $H$ -curve, point HS6. Slotting data using 6 teeth are on the right of this curve at point SL6, approaching the  $G$ -curve, but at a lower slotting speed of 240 m/min.

Depending on the starting  $f_z$  value and on the combination of cutter grade - work material, the location of the  $H$ -curve plays an important role when selecting high-speed end milling data.

**Feed Rate and Tool-life in High-speed Milling, Effect of ECT and Number of Teeth.**—Calculation of feed rate is done using the formulas in previously given:

Feed Rate:

$$F_R = z \times f_z \times \text{rpm}, \text{ where } z \times f_z = f \text{ (feed/rev of cutter). Feed is measured along the feeding direction.}$$

$$\text{rpm} = 1000 \times V/3.1416/D, \text{ where } D \text{ is diameter of cutter.}$$

Fig. 26b. High speed feed rate and cutting speed versus  $ar/D$  at  $T = 5, 15, 45,$  and  $180$  minutes

Fig. 26c. High speed feed rate and cutting speed versus  $ECT, ar/D$  plotted at  $T = 5, 15, 45,$  and  $180$  minutes

Fig. 26b shows the variation of feed rate  $F_R$  plotted versus  $ar/D$  for tool-lives 5, 15, 45 and 180 minutes with a 25 mm diameter cutter and 2 teeth. Fig. 26c shows the variation of feed rate  $F_R$  when plotted versus  $ECT$ . In both graphs the corresponding cutting speeds are also plotted. The values for  $ar/D = 0.03$  in Fig. 26b correspond to  $ECT = 0.011$  in Fig. 26c.

Feed rates have minimum around values of  $ar/D = 0.8$  and  $ECT = 0.75$  and not along the  $H$ -curve. This is due to the fact that the  $f_z/f_{z=0}$  ratio to maintain a mean chip thickness = 0.108 mm changes  $F_R$  in a different proportion than the cutting speed.

Fig. 26d. Feed rate versus  $ECT$  comparison of slot milling ( $ar/D = 1$ ) and high-speed milling (at  $ar/D = 0.03$ ) for 2, 4, and 6 teeth at  $T = 45$  minutes

A comparison of feed rates for full slot ( $ar/D = 1$ ) and high-speed end milling ( $ar/D = 0.03$  and  $f_z = 3.69 \times f_{z0} = 0.628$  mm) for tool-life 45 minutes is shown in Fig. 26d. The points SL2, SL4, SL6 and HS2, HS4, HS6, refer to 2, 4, and 6 teeth (2 to 6 teeth are commonly used in practice). Feed rate is also plotted versus number of teeth  $z$  in Fig. 26e, for up to 16 teeth, still at  $f_z = 0.628$  mm.

Comparing the effect of using 2 versus 6 teeth in high-speed milling shows that feed rates increase from 5250 mm/min (413 ipm) up to 18000 mm/min (1417 ipm) at 45 minutes tool-life. The effect of using 2 versus 6 teeth in full slot milling is that feed rate increases from 1480 mm/min (58 ipm) up to 3230 mm/min (127 ipm) at tool-life 45 minutes. If 16 teeth could be used at  $ar/D = 0.03$ , the feed rate increases to  $F_R = 44700$  mm/min (1760 ipm), and for full slot milling  $F_R = 5350$  mm/min (210 ipm).

Fig. 26e. Feed rate versus number of teeth comparison of slot milling ( $ar/D = 1$ ) and high-speed milling at ( $ar/D = 0.03$ ) for 2, 4, and 6 teeth at  $T = 45$  minutes

Comparing the feed rates that can be obtained in steel cutting with the one achieved in the earlier referred DARPA investigation, using HSS and carbide cutters milling 6061-T651 and A356-T6 aluminum, it is obvious that aluminium end milling can be run at 3 to 6 times higher feed rates. This requires 3 to 6 times higher spindle speeds (cutter diameter 25 mm, radial depth of cut  $ar = 12.5$  mm, 2 teeth). Had these tests been run with 6 teeth, the feed rates would increase up to 150000-300000 mm/min, when feed/tooth =  $3.4 \times 0.25 = 0.8$  mm/tooth at  $ar/D = 0.03$ .

**Process Econometrics Comparison of High-speed and Slot End Milling.**—When making a process econometrics comparison of high-speed milling and slot end milling use the formulas for total cost  $c_{tot}$  (*Determination Of Machine Settings And Calculation Of Costs* starting on page 1113). Total cost is the sum of the cost of cutting, tool changing, and tooling:

$$c_{tot} = H_R \times (Dist/F_R) \times (1 + T_V/T)/60$$

where  $T_V = T_{RPL} + 60 \times C_E/H_R =$  equivalent tooling-cost time, minutes

$T_{RPL}$  = replacement time for a set of edges or tool for regrinding

$C_E$  = cost per edge(s)

$H_R$  = hourly rate, \$

Fig. 27. compares total cost  $c_{tot}$ , using the end milling cutters of the previous examples, for full slot milling with high-speed milling at  $ar/D=0.03$ , and versus  $ECT$  at  $T=45$  minutes.

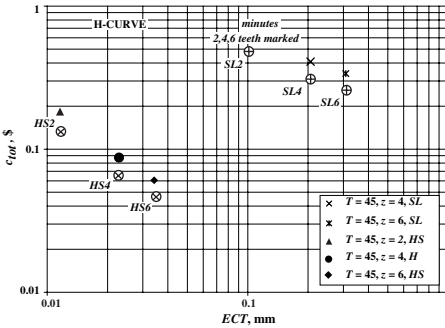

Fig. 27. Cost comparison of slot milling ( $ar/D = 1$ ) and high-speed milling at  $ar/D = 0.03$  for 2, 4, and 6 teeth at  $T = 45$  minutes

The feed/tooth for slot milling is  $f_{z0} = 0.17$  and for high-speed milling at  $ar/D = 0.03$  the feed is  $f_z = 3.69 \times f_{z0} = 0.628$  mm.

The calculations for total cost are done according to above formula using tooling cost at  $T_V = 6, 10,$  and  $14$  minutes, for  $z = 2, 4,$  and  $6$  teeth respectively. The distance cut is  $Dist = 1000$  mm. Full slot milling costs are,

at feed rate  $F_R = 3230$  and  $z = 6$

$$c_{tot} = 50 \times (1000/3230) \times (1 + 14/45)/60 = \$0.338 \text{ per part}$$

at feed rate  $F_R = 1480$  and  $z = 2$

$$c_{tot} = 50 \times (1000/1480) \times (1 + 6/45)/60 = \$0.638 \text{ per part}$$

High-speed milling costs,

at  $F_R = 18000, z = 6$

$$c_{tot} = 50 \times (1000/18000) \times (1 + 14/45)/60 = \$0.0606 \text{ per part}$$

at  $F_R = 5250, z = 2$

$$c_{tot} = 50 \times (1000/5250) \times (1 + 6/45)/60 = \$0.180 \text{ per part}$$

The cost reduction using high-speed milling compared to slotting is enormous. For high-speed milling with 2 teeth, the cost for high-speed milling with 2 teeth is 61 percent ( $0.208/0.338$ ) of full slot milling with 6 teeth ( $z = 6$ ). The cost for high-speed milling with 6 teeth is 19 percent ( $0.0638/0.338$ ) of full slot for  $z = 6$ .

Aluminium end milling can be run at 3 to 6 times lower costs than when cutting steel. Costs of idle (non-machining) and slack time (waste) are not considered in the example. These data hold for perfect milling conditions such as zero run-out and accurate sharpening of all teeth and edges.

## SCREW MACHINE FEEDS AND SPEEDS

**Feeds and Speeds for Automatic Screw Machine Tools.**—Approximate feeds and speeds for standard screw machine tools are given in the accompanying table.

**Knurling in Automatic Screw Machines.**—When knurling is done from the cross slide, it is good practice to feed the knurl gradually to the center of the work, starting to feed when the knurl touches the work and then passing off the center of the work with a quick rise of the cam. The knurl should also dwell for a certain number of revolutions, depending on the pitch of the knurl and the kind of material being knurled. See also *KNURLS AND KNURLING* starting on page 1240.

When two knurls are employed for spiral and diamond knurling from the turret, the knurls can be operated at a higher rate of feed for producing a spiral than they can for producing a diamond pattern. The reason for this is that in the first case the knurls work in the same groove, whereas in the latter case they work independently of each other.

**Revolutions Required for Top Knurling.**—The depth of the teeth and the feed per revolution govern the number of revolutions required for top knurling from the cross slide. If  $R$  is the radius of the stock,  $d$  is the depth of the teeth,  $c$  is the distance the knurl travels from the point of contact to the center of the work at the feed required for knurling, and  $r$  is the radius of the knurl; then

$$c = \sqrt{(R+r)^2 - (R+r-d)^2}$$

For example, if the stock radius  $R$  is  $\frac{5}{32}$  inch, depth of teeth  $d$  is 0.0156 inch, and radius of knurl  $r$  is 0.3125 inch, then

$$\begin{aligned} c &= \sqrt{(0.1562 + 0.3125)^2 - (0.1562 + 0.3125 - 0.0156)^2} \\ &= 0.120 \text{ inch} = \text{cam rise required} \end{aligned}$$

Assume that it is required to find the number of revolutions to knurl a piece of brass  $\frac{5}{16}$  inch in diameter using a 32 pitch knurl. The included angle of the teeth for brass is 90 degrees, the circular pitch is 0.03125 inch, and the calculated tooth depth is 0.0156 inch. The distance  $c$  (as determined in the previous example) is 0.120 inch. Referring to the accompanying table of feeds and speeds, the feed for top knurling brass is 0.005 inch per revolution. The number of revolutions required for knurling is, therefore,  $0.120 \div 0.005 = 24$  revolutions. If conditions permit, the higher feed of 0.008 inch per revolution given in the table may be used, and 15 revolutions are then required for knurling.

**Cams for Threading.**—The table *Spindle Revolutions and Cam Rise for Threading* on page 1134 gives the revolutions required for threading various lengths and pitches and the corresponding rise for the cam lobe. To illustrate the use of this table, suppose a set of cams is required for threading a screw to the length of  $\frac{3}{8}$  inch in a Brown & Sharpe machine. Assume that the spindle speed is 2400 revolutions per minute; the number of revolutions to complete one piece, 400; time required to make one piece, 10 seconds; pitch of the thread,  $\frac{1}{32}$  inch or 32 threads per inch. By referring to the table, under 32 threads per inch, and opposite  $\frac{3}{8}$  inch (length of threaded part), the number of revolutions required is found to be 15 and the rise required for the cam, 0.413 inch.

Approximate Cutting Speeds and Feeds for Standard Automatic Screw Machine Tools—Brown and Sharpe

| Tool  | Cut                             |                                | Material to be Machined     |                             |                              |                          |                             |                              |                 |

Threading cams are often cut on a circular milling attachment. When this method is employed, the number of minutes the attachment should be revolved for each 0.001 inch rise, is first determined. As 15 spindle revolutions are required for threading and 400 for completing one piece, that part of the cam surface required for the actual threading operation equals  $15 \div 400 = 0.0375$ , which is equivalent to 810 minutes of the circumference. The total rise, through an arc of 810 minutes is 0.413 inch, so the number of minutes for each 0.001 inch rise equals  $810 \div 413 = 1.96$  or, approximately, two minutes. If the attachment is graduated to read to five minutes, the cam will be fed laterally 0.0025 inch each time it is turned through five minutes of arc.

**Practical Points on Cam and Tool Design.**—The following general rules are given to aid in designing cams and special tools for automatic screw machines, and apply particularly to Brown and Sharpe machines:

- 1) Use the highest speeds recommended for the material used that the various tools will stand.
- 2) Use the arrangement of circular tools best suited for the class of work.
- 3) Decide on the quickest and best method of arranging the operations before designing the cams.
- 4) Do not use turret tools for forming when the cross-slide tools can be used to better advantage.
- 5) Make the shoulder on the circular cutoff tool large enough so that the clamping screw will grip firmly.
- 6) Do not use too narrow a cutoff blade.
- 7) Allow 0.005 to 0.010 inch for the circular tools to approach the work and 0.003 to 0.005 inch for the cutoff tool to pass the center.
- 8) When cutting off work, the feed of the cutoff tool should be decreased near the end of the cut where the piece breaks off.
- 9) When a thread is cut up to a shoulder, the piece should be grooved or necked to make allowance for the lead on the die. An extra projection on the forming tool and an extra amount of rise on the cam will be needed.
- 10) Allow sufficient clearance for tools to pass one another.
- 11) Always make a diagram of the cross-slide tools in position on the work when difficult operations are to be performed; do the same for the tools held in the turret.
- 12) Do not drill a hole the depth of which is more than 3 times the diameter of the drill, but rather use two or more drills as required. If there are not enough turret positions for the extra drills needed, make provision for withdrawing the drill clear of the hole and then advancing it into the hole again.
- 13) Do not run drills at low speeds. Feeds and speeds recommended in the table starting on page 1132 should be followed as far as is practicable.
- 14) When the turret tools operate farther in than the face of the chuck, see that they will clear the chuck when the turret is revolved.
- 15) See that the bodies of all turret tools will clear the side of the chute when the turret is revolved.
- 16) Use a balance turning tool or a hollow mill for roughing cuts.
- 17) The rise on the thread lobe should be reduced so that the spindle will reverse when the tap or die holder is drawn out.
- 18) When bringing another tool into position after a threading operation, allow clearance before revolving the turret.
- 19) Make provision to revolve the turret rapidly, especially when pieces are being made in from three to five seconds and when only a few tools are used in the turret. It is sometimes desirable to use two sets of tools.
- 20) When using a belt-shifting attachment for threading, clearance should be allowed, as it requires extra time to shift the belt.

21) When laying out a set of cams for operating on a piece that requires to be slotted, cross-drilled or burred, allowance should be made on the lead cam so that the transferring arm can descend and ascend to and from the work without coming in contact with any of the turret tools.

22) Always provide a vacant hole in the turret when it is necessary to use the transferring arm.

23) When designing special tools allow as much clearance as possible. Do not make them so that they will just clear each other, as a slight inaccuracy in the dimensions will often cause trouble.

24) When designing special tools having intricate movements, avoid springs as much as possible, and use positive actions.

**Stock for Screw Machine Products.**—The amount of stock required for the production of 1000 pieces on the automatic screw machine can be obtained directly from the table *Stock Required for Screw Machine Products*. To use this table, add to the length of the work the width of the cut-off tool blade; then the number of feet of material required for 1000 pieces can be found opposite the figure thus obtained, in the column headed "Feet per 1000 Parts." Screw machine stock usually comes in bars 10 feet long, and in compiling this table an allowance was made for chucking on each bar.

The table can be extended by using the following formula, in which

$F$  = number of feet required for 1000 pieces

$L$  = length of piece in inches

$W$  = width of cut-off tool blade in inches

$$F = (L + W) \times 84$$

The amount to add to the length of the work, or the width of the cut-off tool, is given in the following, which is standard in a number of machine shops:

| Diameter of Stock, Inches | Width of Cut-off Tool Blade, Inches |
|---------------------------|-------------------------------------|
| 0.000–0.250               | 0.045                               |
| 0.251–0.375               | 0.062                               |
| 0.376–0.625               | 0.093                               |
| 0.626–1.000               | 0.125                               |
| 1.001–1.500               | 0.156                               |

It is sometimes convenient to know the weight of a certain number of pieces, when estimating the price. The weight of round bar stock can be found by means of the following formulas, in which

$W$  = weight in pounds

$D$  = diameter of stock in inches

$F$  = length in feet

For brass stock:  $W = D^2 \times 2.86 \times F$

For steel stock:  $W = D^2 \times 2.675 \times F$

For iron stock:  $W = D^2 \times 2.65 \times F$

**Stock Required for Screw Machine Products**

The table gives the amount of stock, in feet, required for 1000 pieces, when the length of the finished part plus the thickness of the cut-off tool blade is known. Allowance has been made for chucking. To illustrate, if length of cut-off tool and work equals 0.140 inch, 11.8 feet of stock is required for the production of 1000 parts.

| Length of Piece and Cut-Off Tool | Feet per 1000 Parts | Length of Piece and Cut-Off Tool | Feet per 1000 Parts | Length of Piece and Cut-Off Tool | Feet per 1000 Parts | Length of Piece and Cut-Off Tool | Feet per 1000 Parts |

**Band Saw Blade Selection.**—The primary factors to consider in choosing a saw blade are: the pitch, or the number of teeth per inch of blade; the tooth form; and the blade type (material and construction). Tooth pitch selection depends on the size and shape of the work, whereas tooth form and blade type depend on material properties of the workpiece and on economic considerations of the job.

*Courtesy of American Saw and Manufacturing Company*

The tooth selection chart above is a guide to help determine the best blade pitch for a particular job. The tooth specifications in the chart are standard variable-pitch blade sizes as specified by the Hack and Band Saw Association. The variable-pitch blades listed are designated by two numbers that refer to the approximate maximum and minimum tooth pitch. A 4/6 blade, for example, has a maximum tooth spacing of approximately  $\frac{1}{4}$  inch and a minimum tooth spacing of about  $\frac{1}{6}$  inch. Blades are available, from most manufacturers, in sizes within about  $\pm 10$  per cent of the sizes listed.

To use the chart, locate the length of cut in inches on the outside circle of the table (for millimeters use the inside circle) and then find the tooth specification that aligns with the length, on the ring corresponding to the material shape. The length of cut is the distance that any tooth of the blade is in contact with the work as it passes once through the cut. For cutting solid round stock, use the diameter as the length of cut and select a blade from the ring with the solid circle. When cutting angles, channels, I-beams, tubular pieces, pipe, and hollow or irregular shapes, the length of cut is found by dividing the cross-sectional area of the cut by the distance the blade needs to travel to finish the cut. Locate the length of cut on the outer ring (inner ring for mm) and select a blade from the ring marked with the angle, I-beam, and pipe sections.

*Example:* A 4-inch pipe with a 3-inch inside diameter is to be cut. Select a variable pitch blade for cutting this material.

The area of the pipe is  $\pi/4 \times (4^2 - 3^2) = 5.5 \text{ in.}^2$ . The blade has to travel 4 inches to cut through the pipe, so the average length of cut is  $5.5/4 = 1.4$  inches. On the tooth selection wheel, estimate the location of 1.4 inches on the outer ring, and read the tooth specification from the ring marked with the pipe, angle, and I-beam symbols. The chart indicates that a 4/6 variable-pitch blade is the preferred blade for this cut.

**Tooth Forms.**—Band saw teeth are characterized by a tooth form that includes the shape, spacing (pitch), rake angle, and gullet capacity of the tooth. Tooth form affects the cutting efficiency, noise level, blade life, chip-carrying capacity, and the surface finish quality of the cut. The rake angle, which is the angle between the face of the tooth and a line perpendicular to the direction of blade travel, influences the cutting speed. In general, positive rake angles cut faster. The *standard tooth* form has conventional shape teeth, evenly spaced with deep gullets and a  $0^\circ$  rake angle. Standard tooth blades are used for general-purpose cutting on a wide variety of materials. The *skip tooth* form has shallow, widely spaced teeth arranged in narrow bands and a  $0^\circ$  rake angle. Skip tooth blades are used for cutting soft metals, wood, plastics, and composite materials. The *hook tooth* form is similar to the skip tooth, but has a positive rake angle and is used for faster cutting of large sections of soft metal, wood, and plastics, as well as for cutting some metals, such as cast iron, that form a discontinuous chip. The *variable-tooth* (variable-pitch) form has a conventional tooth shape, but the tips of the teeth are spaced a variable distance (pitch) apart. The variable pitch reduces vibration of the blade and gives smoother cutting, better surface finish, and longer blade life. The *variable positive tooth* form is a variable-pitch tooth with a positive rake angle that causes the blade to penetrate the work faster. The variable positive tooth blade increases production and gives the longest blade life.

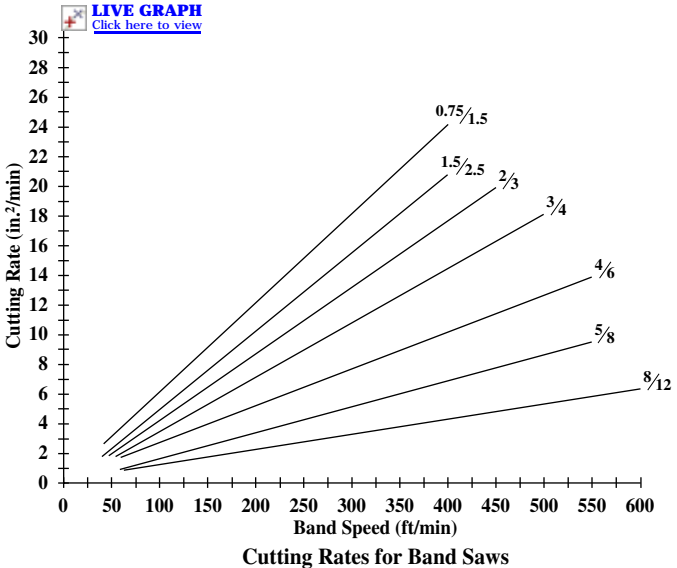

*Set* is the angle that the teeth are offset from the straight line of a blade. The set affects the blade efficiency (i.e., cutting rate), chip-carrying ability, and quality of the surface finish. *Alternate set* blades have adjacent teeth set alternately one to each side. Alternate set blades, which cut faster but with a poorer finish than other blades, are especially useful for rapid rough cutting. A *raker set* is similar to the alternate set, but every few teeth, one of the teeth is set to the center, not to the side (typically every third tooth, but sometimes every fifth or seventh tooth). The raker set pattern cuts rapidly and produces a good surface finish. The *vari-raker set*, or variable raker, is a variable-tooth blade with a raker set. The vari-raker is quieter and produces a better surface finish than a raker set standard tooth blade. *Wavy set* teeth are set in groups, alternately to one side, then to the other. Both wavy set and vari-raker set blades are used for cutting tubing and other interrupted cuts, but the blade efficiency and surface finish produced are better with a vari-raker set blade.

**Types of Blades.**—The most important band saw blade types are carbon steel, bimetal, carbide tooth, and grit blades made with embedded carbide or diamond. *Carbon steel blades* have the lowest initial cost, but they may wear out faster. Carbon steel blades are used for cutting a wide variety of materials, including mild steels, aluminum, brass, bronze, cast iron, copper, lead, and zinc, as well as some abrasive materials such as cork, fiberglass, graphite, and plastics. *Bimetal blades* are made with a high-speed steel cutting edge that is welded to a spring steel blade back. Bimetal blades are stronger and last longer, and they tend to produce straighter cuts because the blade can be tensioned higher than carbon steel blades. Because bimetal blades last longer, the cost per cut is frequently lower than when using carbon steel blades. Bimetal blades are used for cutting all ferrous and nonferrous metals, a wide range of shapes of easy to moderately machinable material, and solids and heavy wall tubing with moderate to difficult machinability. *Tungsten carbide blades* are similar to bimetal blades but have tungsten carbide teeth welded to the blade back. The welded teeth of carbide blades have greater wear and high-temperature resistance than either carbon steel or bimetal blades and produce less tooth vibration, while giving smoother, straighter, faster, and quieter cuts requiring less feed force. Carbide blades are used on tough alloys such as cobalt, nickel- and titanium-based alloys, and for nonferrous materials such as aluminum castings, fiberglass, and graphite. The *carbide grit blade*

has tungsten carbide grit metallurgically bonded to either a gulletted (serrated) or toothless steel band. The blades are made in several styles and grit sizes. Both carbide grit and diamond grit blades are used to cut materials that conventional (carbon and bimetal) blades are unable to cut such as: fiberglass, reinforced plastics, composite materials, carbon and graphite, aramid fibers, plastics, cast iron, stellites, high-hardness tool steels, and superalloys.

**Band Saw Speed and Feed Rate.**—The band speed necessary to cut a particular material is measured in feet per minute (fpm) or in meters per minute (m/min), and depends on material characteristics and size of the workpiece. Typical speeds for a bimetal blade cutting 4-inch material with coolant are given in the speed selection table that follows. For other size materials or when cutting without coolant, adjust speeds according to the instructions at the bottom of the table.

The feed or cutting rate, usually measured in square inches or square meters per minute, indicates how fast material is being removed and depends on the speed and pitch of the blade, not on the workpiece material. The graph above, based on material provided by American Saw and Mfg., gives approximate cutting rates (in.<sup>2</sup>/min) for various variable-pitch blades and cutting speeds. Use the value from the graph as an initial starting value and then adjust the feed based on the performance of the saw. The size and character of the chips being produced are the best indicators of the correct feed force. Chips that are curly, silvery, and warm indicate the best feed rate and band speed. If the chips appear burned and heavy, the feed is too great, so reduce the feed rate, the band speed, or both. If the chips are thin or powdery, the feed rate is too low, so increase the feed rate or reduce the band speed. The actual cutting rate achieved during a cut is equal to the area of the cut divided by the time required to finish the cut. The time required to make a cut is equal to the area of the cut divided by the cutting rate in square inches per minute.

The speed figures given are for 4-in. material (length of cut) using a 3/4 variable-tooth bimetal blade and cutting fluid. For cutting dry, reduce speed 30–50%; for carbon steel band saw blades, reduce speed 50%. For other cutting lengths: increase speed 15% for 1/4-in. material (10/14 blade); increase speed 12% for 3/4-in. material (6/10 blade); increase speed 10% for 1 1/4-in. material (4/6 blade); decrease speed 12% for 8-in. material (2/3 blade).

Table data are based on material provided by LENOX Blades, American Saw & Manufacturing Co.

*Example:* Find the band speed, the cutting rate, and the cutting time if the 4-inch pipe of the previous example is made of 304 stainless steel.

The preceding blade speed table gives the band speed for 4-inch 304 stainless steel as 120 fpm (feet per minute). The average length of cut for this pipe (see the previous example) is 1.4 inches, so increase the band saw speed by about 10 per cent (see footnote on ) to 130 fpm to account for the size of the piece. On the cutting rate graph above, locate the point on the 4/6 blade line that corresponds to the band speed of 130 fpm and then read the cutting rate from the left axis of the graph. The cutting rate for this example is approximately 4 in. <sup>2</sup>/min. The cutting time is equal to the area of the cut divided by the cutting rate, so cutting time = 5.5/4 = 1.375 minutes.

**Band Saw Blade Break-In.**—A new band saw blade must be broken in gradually before it is allowed to operate at its full recommended feed rate. Break-in relieves the blade of residual stresses caused by the manufacturing process so that the blade retains its cutting ability longer. Break-in requires starting the cut at the material cutting speed with a low feed rate and then gradually increasing the feed rate over time until enough material has been cut. A blade should be broken in with the material to be cut.

To break in a new blade, first set the band saw speed at the recommended cutting speed for the material and start the first cut at the feed indicated on the starting feed rate graph below. After the saw has penetrated the work to a distance equal to the width of the blade, increase the feed slowly. When the blade is about halfway through the cut, increase the feed again slightly and finish the cut without increasing the feed again. Start the next and each successive cut with the same feed rate that ended the previous cut, and increase the feed rate slightly again before the blade reaches the center of the cut. Repeat this procedure until the area cut by the new blade is equal to the total area required as indicated on the graph below. At the end of the break-in period, the blade should be cutting at the recommended feed rate, otherwise adjusted to that rate.

### Cutting Fluids for Machining

The goal in all conventional metal-removal operations is to raise productivity and reduce costs by machining at the highest practical speed consistent with long tool life, fewest rejects, and minimum downtime, and with the production of surfaces of satisfactory accuracy and finish. Many machining operations can be performed "dry," but the proper application of a cutting fluid generally makes possible: higher cutting speeds, higher feed rates, greater depths of cut, lengthened tool life, decreased surface roughness, increased dimensional accuracy, and reduced power consumption. Selecting the proper cutting fluid for a specific machining situation requires knowledge of fluid functions, properties, and limitations. Cutting fluid selection deserves as much attention as the choice of machine tool, tooling, speeds, and feeds.

To understand the action of a cutting fluid it is important to realize that almost all the energy expended in cutting metal is transformed into heat, primarily by the deformation of the metal into the chip and, to a lesser degree, by the friction of the chip sliding against the tool face. With these factors in mind it becomes clear that the primary functions of any cut-

ting fluid are: cooling of the tool, workpiece, and chip; reducing friction at the sliding contacts; and reducing or preventing welding or adhesion at the contact surfaces, which forms the "built-up edge" on the tool. Two other functions of cutting fluids are flushing away chips from the cutting zone and protecting the workpiece and tool from corrosion.

The relative importance of the functions is dependent on the material being machined, the cutting tool and conditions, and the finish and accuracy required on the part. For example, cutting fluids with greater lubricity are generally used in low-speed machining and on most difficult-to-cut materials. Cutting fluids with greater cooling ability are generally used in high-speed machining on easier-to-cut materials.

**Types of Cutting and Grinding Fluids.**—In recent years a wide range of cutting fluids has been developed to satisfy the requirements of new materials of construction and new tool materials and coatings.

There are four basic types of cutting fluids; each has distinctive features, as well as advantages and limitations. Selection of the right fluid is made more complex because the dividing line between types is not always clear. Most machine shops try to use as few different fluids as possible and prefer fluids that have long life, do not require constant changing or modifying, have reasonably pleasant odors, do not smoke or fog in use, and, most important, are neither toxic nor cause irritation to the skin. Other issues in selection are the cost and ease of disposal.

The major divisions and subdivisions used in classifying cutting fluids are:

*Cutting Oils*, including straight and compounded mineral oils plus additives.

*Water-Miscible Fluids*, including emulsifiable oils; chemical or synthetic fluids; and semichemical fluids.

*Gases*.

*Paste and Solid Lubricants*.

Since the cutting oils and water-miscible types are the most commonly used cutting fluids in machine shops, discussion will be limited primarily to these types. It should be noted, however, that compressed air and inert gases, such as carbon dioxide, nitrogen, and Freon, are sometimes used in machining. Paste, waxes, soaps, graphite, and molybdenum disulfide may also be used, either applied directly to the workpiece or as an impregnant in the tool, such as in a grinding wheel.

**Cutting Oils.**—Cutting oils are generally compounds of mineral oil with the addition of animal, vegetable, or marine oils to improve the wetting and lubricating properties. Sulfur, chlorine, and phosphorous compounds, sometimes called extreme pressure (EP) additives, provide for even greater lubricity. In general, these cutting oils do not cool as well as water-miscible fluids.

**Water-Miscible Fluids.**—*Emulsions or soluble oils* are a suspension of oil droplets in water. These suspensions are made by blending the oil with emulsifying agents (soap and soaplike materials) and other materials. These fluids combine the lubricating and rust-prevention properties of oil with water's excellent cooling properties. Their properties are affected by the emulsion concentration, with "lean" concentrations providing better cooling but poorer lubrication, and with "rich" concentrations having the opposite effect. Additions of sulfur, chlorine, and phosphorus, as with cutting oils, yield "extreme pressure" (EP) grades.

*Chemical fluids* are true solutions composed of organic and inorganic materials dissolved in water. Inactive types are usually clear fluids combining high rust inhibition, high cooling, and low lubricity characteristics with high surface tension. Surface-active types include wetting agents and possess moderate rust inhibition, high cooling, and moderate lubricating properties with low surface tension. They may also contain chlorine and/or sulfur compounds for extreme pressure properties.

*Semichemical fluids* are combinations of chemical fluids and emulsions. These fluids have a lower oil content but a higher emulsifier and surface-active-agent content than

emulsions, producing oil droplets of much smaller diameter. They possess low surface tension, moderate lubricity and cooling properties, and very good rust inhibition. Sulfur, chlorine, and phosphorus also are sometimes added.

**Selection of Cutting Fluids for Different Materials and Operations.**—The choice of a cutting fluid depends on many complex interactions including the machinability of the metal; the severity of the operation; the cutting tool material; metallurgical, chemical, and human compatibility; fluid properties, reliability, and stability; and finally cost. Other factors affect results. Some shops standardize on a few cutting fluids which have to serve all purposes. In other shops, one cutting fluid must be used for all the operations performed on a machine. Sometimes, a very severe operating condition may be alleviated by applying the “right” cutting fluid manually while the machine supplies the cutting fluid for other operations through its coolant system. Several voluminous textbooks are available with specific recommendations for the use of particular cutting fluids for almost every combination of machining operation and workpiece and tool material. In general, when experience is lacking, it is wise to consult the material supplier and/or any of the many suppliers of different cutting fluids for advice and recommendations. Another excellent source is the Machinability Data Center, one of the many information centers supported by the U.S. Department of Defense. While the following recommendations represent good practice, they are to serve as a guide only, and it is not intended to say that other cutting fluids will not, in certain specific cases, also be effective.

**Steels:** Caution should be used when using a cutting fluid on steel that is being turned at a high cutting speed with cemented carbide cutting tools. See *Application of Cutting Fluids to Carbides* later. Frequently this operation is performed dry. If a cutting fluid is used, it should be a soluble oil mixed to a consistency of about 1 part oil to 20 to 30 parts water. A sulfurized mineral oil is recommended for reaming with carbide tipped reamers although a heavy-duty soluble oil has also been used successfully.

The cutting fluid recommended for machining steel with high speed cutting tools depends largely on the severity of the operation. For ordinary turning, boring, drilling, and milling on medium and low strength steels, use a soluble oil having a consistency of 1 part oil to 10 to 20 parts water. For tool steels and tough alloy steels, a heavy-duty soluble oil having a consistency of 1 part oil to 10 parts water is recommended for turning and milling. For drilling and reaming these materials, a light sulfurized mineral-fatty oil is used. For tough operations such as tapping, threading, and broaching, a sulfochlorinated mineral-fatty oil is recommended for tool steels and high-strength steels, and a heavy sulfurized mineral-fatty oil or a sulfochlorinated mineral oil can be used for medium- and low-strength steels. Straight sulfurized mineral oils are often recommended for machining tough, stringy low carbon steels to reduce tearing and produce smooth surface finishes.

**Stainless Steel:** For ordinary turning and milling a heavy-duty soluble oil mixed to a consistency of 1 part oil to 5 parts water is recommended. Broaching, threading, drilling, and reaming produce best results using a sulfochlorinated mineral-fatty oil.

**Copper Alloys:** Most brasses, bronzes, and copper are stained when exposed to cutting oils containing active sulfur and chlorine; thus, sulfurized and sulfochlorinated oils should not be used. For most operations a straight soluble oil, mixed to 1 part oil and 20 to 25 parts water is satisfactory. For very severe operations and for automatic screw machine work a mineral-fatty oil is used. A typical mineral-fatty oil might contain 5 to 10 per cent lard oil with the remainder mineral oil.

**Monel Metal:** When turning this material, an emulsion gives a slightly longer tool life than a sulfurized mineral oil, but the latter aids in chip breakage, which is frequently desirable.

**Aluminum Alloys:** Aluminum and aluminum alloys are frequently machined dry. When a cutting fluid is used it should be selected for its ability to act as a coolant. Soluble oils mixed to a consistency of 1 part oil to 20 to 30 parts water can be used. Mineral oil-base

cutting fluids, when used to machine aluminum alloys, are frequently cut back to increase their viscosity so as to obtain good cooling characteristics and to make them flow easily to cover the tool and the work. For example, a mineral-fatty oil or a mineral plus a sulfurized fatty oil can be cut back by the addition of as much as 50 per cent kerosene.

*Cast Iron:* Ordinarily, cast iron is machined dry. Some increase in tool life can be obtained or a faster cutting speed can be used with a chemical cutting fluid or a soluble oil mixed to consistency of 1 part oil and 20 to 40 parts water. A soluble oil is sometimes used to reduce the amount of dust around the machine.

*Magnesium:* Magnesium may be machined dry, or with an air blast for cooling. A light mineral oil of low acid content may be used on difficult cuts. Coolants containing water should not be used on magnesium because of the danger of releasing hydrogen caused by reaction of the chips with water. Proprietary water-soluble oil emulsions containing inhibitors that reduce the rate of hydrogen generation are available.

*Grinding:* Soluble oil emulsions or emulsions made from paste compounds are used extensively in precision grinding operations. For cylindrical grinding, 1 part oil to 40 to 50 parts water is used. Solution type fluids and translucent grinding emulsions are particularly suited for many fine-finish grinding applications. Mineral oil-base grinding fluids are recommended for many applications where a fine surface finish is required on the ground surface. Mineral oils are used with vitrified wheels but are not recommended for wheels with rubber or shellac bonds. Under certain conditions the oil vapor mist caused by the action of the grinding wheel can be ignited by the grinding sparks and explode. To quench the grinding spark a secondary coolant line to direct a flow of grinding oil below the grinding wheel is recommended.

*Broaching:* For steel, a heavy mineral oil such as sulfurized oil of 300 to 500 Saybolt viscosity at 100 degrees F can be used to provide both adequate lubricating effect and a dampening of the shock loads. Soluble oil emulsions may be used for the lighter broaching operations.

**Cutting Fluids for Turning, Milling, Drilling and Tapping.**—The following table, *Cutting Fluids Recommended for Machining Operations*, gives specific cutting oil recommendations for common machining operations.

*Soluble Oils:* Types of oils paste compounds that form emulsions when mixed with water: Soluble oils are used extensively in machining both ferrous and non-ferrous metals when the cooling quality is paramount and the chip-bearing pressure is not excessive. Care should be taken in selecting the proper soluble oil for precision grinding operations. Grinding coolants should be free from fatty materials that tend to load the wheel, thus affecting the finish on the machined part. Soluble coolants should contain rust preventive constituents to prevent corrosion.

*Base Oils:* Various types of highly sulfurized and chlorinated oils containing inorganic, animal, or fatty materials. This "base stock" usually is "cut back" or blended with a lighter oil, unless the chip-bearing pressures are high, as when cutting alloy steel. Base oils usually have a viscosity range of from 300 to 900 seconds at 100 degrees F.

*Mineral Oils:* This group includes all types of oils extracted from petroleum such as paraffin oil, mineral seal oil, and kerosene. Mineral oils are often blended with base stocks, but they are generally used in the original form for light machining operations on both free-machining steels and non-ferrous metals. The coolants in this class should be of a type that has a relatively high flash point. Care should be taken to see that they are nontoxic, so that they will not be injurious to the operator. The heavier mineral oils (paraffin oils) usually have a viscosity of about 100 seconds at 100 degrees F. Mineral seal oil and kerosene have a viscosity of 35 to 60 seconds at 100 degrees F.

## Cutting Fluids Recommended for Machining Operations

| Material to be Cut                     | Turning  | Milling  |

| Magnesium <sup>d</sup>                 | 60-second Mineral Oil  | 20 Per Cent Lard Oil with 80 Per<br>Cent Mineral Oil   |

<sup>a</sup> In machining aluminum, several varieties of coolants may be used. For rough machining, where the stock removal is sufficient to produce heat, water soluble mixtures can be used with good results to dissipate the heat. Other oils that may be recommended are straight mineral seal oil; a 50–50 mixture of mineral seal oil and kerosene; a mixture of 10 per cent lard oil with 90 per cent kerosene; and a 100-second mineral oil cut back with mineral seal oil or kerosene.

<sup>b</sup> The sulfur-base oil referred to contains 4½ per cent sulfur compound. Base oils are usually dark in color. As a rule, they contain sulfur compounds resulting from a thermal or catalytic refinery process. When so processed, they are more suitable for industrial coolants than when they have had such compounds as flowers of sulfur added by hand. The adding of sulfur compounds by hand to the coolant reservoir is of temporary value only, and the non-uniformity of the solution may affect the machining operation.

<sup>c</sup> A soluble oil or low-viscosity mineral oil may be used in machining cast iron to prevent excessive metal dust.

<sup>d</sup>When a cutting fluid is needed for machining magnesium, low or nonacid mineral seal or lard oils are recommended. Coolants containing water should not be used because of the fire danger when magnesium chips react with water, forming hydrogen gas.

<sup>e</sup>Sulfurized oils ordinarily are not recommended for tapping aluminum; however, for some tapping operations they have proved very satisfactory, although the work should be rinsed in a solvent right after machining to prevent discoloration.

**Application of Cutting Fluids to Carbides.**—Turning, boring, and similar operations on lathes using carbides are performed dry or with the help of soluble oil or chemical cutting fluids. The effectiveness of cutting fluids in improving tool life or by permitting higher cutting speeds to be used, is less with carbides than with high-speed steel tools. Furthermore, the effectiveness of the cutting fluid is reduced as the cutting speed is increased. Cemented carbides are very sensitive to sudden changes in temperature and to temperature gradients within the carbide. Thermal shocks to the carbide will cause thermal cracks to form near the cutting edge, which are a prelude to tool failure. An unsteady or interrupted flow of the coolant reaching the cutting edge will generally cause these thermal cracks. The flow of the chip over the face of the tool can cause an interruption to the flow of the coolant reaching the cutting edge even though a steady stream of coolant is directed at the tool. When a cutting fluid is used and frequent tool breakage is encountered, it is often best to cut dry. When a cutting fluid must be used to keep the workpiece cool for size control or to allow it to be handled by the operator, special precautions must be used. Sometimes applying the coolant from the front and the side of the tool simultaneously is helpful. On lathes equipped with overhead shields, it is very effective to apply the coolant from below the tool into the space between the shoulder of the work and the tool flank, in addition to applying the coolant from the top. Another method is not to direct the coolant stream at the cutting tool at all but to direct it at the workpiece above or behind the cutting tool.

The danger of thermal cracking is great when milling with carbide cutters. The nature of the milling operation itself tends to promote thermal cracking because the cutting edge is constantly heated to a high temperature and rapidly cooled as it enters and leaves the workpiece. For this reason, carbide milling operations should be performed dry.

Lower cutting-edge temperatures diminish the danger of thermal cracking. The cutting-edge temperatures usually encountered when reaming with solid carbide or carbide-tipped reamers are generally such that thermal cracking is not apt to occur except when reaming certain difficult-to-machine metals. Therefore, cutting fluids are very effective when used on carbide reamers. Practically every kind of cutting fluid has been used, depending on the job material encountered. For difficult surface-finish problems in holes, heavy duty soluble oils, sulfurized mineral-fatty oils, and sulfochlorinated mineral-fatty oils have been used successfully. On some work, the grade and the hardness of the carbide also have an effect on the surface finish of the hole.

Cutting fluids should be applied where the cutting action is taking place and at the highest possible velocity without causing splashing. As a general rule, it is preferable to supply from 3 to 5 gallons per minute for each single-point tool on a machine such as a turret lathe or automatic. The temperature of the cutting fluid should be kept below 110 degrees F. If the volume of fluid used is not sufficient to maintain the proper temperature, means of cooling the fluid should be provided.

**Cutting Fluids for Machining Magnesium.**—In machining magnesium, it is the general but not invariable practice in the United States to use a cutting fluid. In other places, magnesium usually is machined dry except where heat generated by high cutting speeds would not be dissipated rapidly enough without a cutting fluid. This condition may exist when, for example, small tools without much heat-conducting capacity are employed on automatics.

The cutting fluid for magnesium should be an anhydrous oil having, at most, a very low acid content. Various mineral-oil cutting fluids are used for magnesium.

**Occupational Exposure To Metal working Fluids**

The term *metalworking fluids* (MWFs) describes coolants and lubricants used during the fabrication of products from metals and metal substitutes. These fluids are used to prolong the life of machine tools, carry away debris, and protect or treat the surfaces of the material being processed. MWFs reduce friction between the cutting tool and work surfaces, reduce wear and galling, protect surface characteristics, reduce surface adhesion or welding, carry away generated heat, and flush away swarf, chips, fines, and residues. Table 1 describes the four different classes of metal working fluids:

**Table 1. Classes of Metalworking Fluids (MWFs)**

| MWF  | Description   | Dilution factor                            |
|--|---|--|
| <b>Straight oil</b><br>(neat oil or cutting oil) | Highly refined petroleum oils (lubricant-base oils) or other animal, marine, vegetable, or synthetic oils used singly or in combination with or without additives. These are lubricants, or function to improve the finish on the metal cut, and prevent corrosion.   | none                                       |
| <b>Soluble oil</b><br>(emulsifiable oil)         | Combinations of 30% to 85% highly refined, high-viscosity lubricant-base oils and emulsifiers that may include other performance additives. Soluble oils are diluted with water before use at ratios of parts water.  | 1 part concentrate to 5 to 40 parts water  |
| <b>Semisynthetic</b>                             | Contain smaller amounts of severely refined lubricant-base oil (5 to 30% in the concentrate), a higher proportion of emulsifiers that may include other performance additives, and 30 to 50% water.   | 1 part concentrate to 10 to 40 parts water |
| <b>Synthetic<sup>a</sup></b>                     | Contain no petroleum oils and may be water soluble or water dispersible. The simplest synthetics are made with organic and inorganic salts dissolved in water. Offer good rust protection and heat removal but usually have poor lubricating ability. May be formulated with other performance additives. Stable, can be made bioresistant. | 1 part concentrate to 10 to 40 parts water |

<sup>a</sup> Over the last several decades major changes in the U.S. machine tool industry have increased the consumption of MWFs. Specifically, the use of synthetic MWFs increased as tool and cutting speeds increased.

**Occupational Exposures to Metal Working Fluids (MWFs).—**Workers can be exposed to MWFs by inhalation of aerosols (mists) or by skin contact resulting in an increased risk of respiratory (lung) and skin disease. Health effects vary based on the type of MWF, route of exposure, concentration, and length of exposure.

Skin contact usually occurs when the worker dips his/her hands into the fluid, floods the machine tool, or handling parts, tools, equipment or workpieces coated with the fluid, without the use of personal protective equipment such as gloves and apron. Skin contact can also result from fluid splashing onto worker from the machine if guarding is absent or inadequate.

Inhalation exposures result from breathing MWF mist or aerosol. The amount of mist generated (and the severity of the exposure) depends on a variety of factors: the type of MWF and its application process; the MWF temperature; the specific machining or grinding operation; the presence of splash guarding; and the effectiveness of the ventilation system. In general, the exposure will be higher if the worker is in close proximity to the machine, the operation involves high tool speeds and deep cuts, the machine is not enclosed, or if ventilation equipment was improperly selected or poorly maintained. In addition, high-pressure and/or excessive fluid application, contamination of the fluid with tramp oils, and improper fluid selection and maintenance will tend to result in higher exposure.

Each MWF class consists of a wide variety of chemicals used in different combinations and the risk these chemicals pose to workers may vary because of different manufacturing processes, various degrees of refining, recycling, improperly reclaimed chemicals, different degrees of chemical purity, and potential chemical reactions between components.

Exposure to hazardous contaminants in MWFs may present health risks to workers. Contamination may occur from: process chemicals and ancillary lubricants inadvertently introduced; contaminants, metals, and alloys from parts being machined; water and cleaning agents used for routine housekeeping; and, contaminants from other environmental sources at the worksite. In addition, bacterial and fungal contaminants may metabolize and degrade the MWFs to hazardous end-products as well as produce endotoxins.

The improper use of biocides to manage microbial growth may result in potential health risks. Attempts to manage microbial growth solely with biocides may result in the emergence of biocide-resistant strains from complex interactions that may occur among different member species or groups within the population. For example, the growth of one species, or the elimination of one group of organisms may permit the overgrowth of another. Studies also suggest that exposure to certain biocides can cause either allergic or contact dermatitis.

**Fluid Selection, Use, and Application.**—The MWFs selected should be as nonirritating and nonsensitizing as possible while remaining consistent with operational requirements. Petroleum-containing MWFs should be evaluated for potential carcinogenicity using ASTM Standard E1687-98, “Determining Carcinogenic Potential of Virgin Base Oils in Metalworking Fluids”. If soluble oil or synthetic MWFs are used, ASTM Standard E1497-94, “Safe Use of Water-Miscible Metalworking Fluids” should be consulted for safe use guidelines, including those for product selection, storage, dispensing, and maintenance. To minimize the potential for nitrosamine formation, nitrate-containing materials should not be added to MWFs containing ethanolamines.

Many factors influence the generation of MWF mists, which can be minimized through the proper design and operation of the MWF delivery system. ANSI Technical Report B11 TR2-1997, “Mist Control Considerations for the Design, Installation and Use of Machine Tools Using Metalworking Fluids” provides directives for minimizing mist and vapor generation. These include minimizing fluid delivery pressure, matching the fluid to the application, using MWF formulations with low oil concentrations, avoiding contamination with tramp oils, minimizing the MWF flow rate, covering fluid reservoirs and return systems where possible, and maintaining control of the MWF chemistry. Also, proper application of MWFs can minimize splashing and mist generation. Proper application includes: applying MWFs at the lowest possible pressure and flow volume consistent with provisions for adequate part cooling, chip removal, and lubrication; applying MWFs at the tool/workpiece interface to minimize contact with other rotating equipment; ceasing fluid delivery when not performing machining; not allowing MWFs to flow over the unprotected hands of workers loading or unloading parts; and using mist collectors engineered for the operation and specific machine enclosures.

Properly maintained filtration and delivery systems provide cleaner MWFs, reduce mist, and minimize splashing and emissions. Proper maintenance of the filtration and delivery systems includes: the selection of appropriate filters; ancillary equipment such as chip handling operations, dissolved air-flotation devices, belt-skimmers, chillers or plate and frame heat exchangers, and decantation tanks; guard coolant return trenches to prevent dumping of floor wash water and other waste fluids; covering sumps or coolant tanks to prevent contamination with waste or garbage (e.g., cigarette butts, food, etc.); and, keeping the machine(s) clean of debris. Parts washing before machining can be an important part of maintaining cleaner MWFs.

Since all additives will be depleted with time, the MWF and additives concentrations should be monitored frequently so that components and additives can be made up as needed. The MWF should be maintained within the pH and concentration ranges recom-

mended by the formulator or supplier. MWF temperature should be maintained at the lowest practical level to slow the growth of microorganisms, reduce water losses and changes in viscosity, and—in the case of straight oils—reduce fire hazards.

**Fluid Maintenance.**—Drums, tanks, or other containers of MWF concentrates should be stored appropriately to protect them from outdoor weather conditions and exposure to low or high temperatures. Extreme temperature changes may destabilize the fluid concentrates, especially in the case of concentrates mixed with water, and cause water to seep into unopened drums encouraging bacterial growth. MWFs should be maintained at as low a temperature as is practical. Low temperatures slow the growth of microorganisms, reduce water losses and change in viscosity, and in the case of straight oils, reduce the fire hazard risks.

To maintain proper MWF concentrations, neither water nor concentrate should be used to top off the system. The MWF mixture should be prepared by first adding the concentrate to the clean water (in a clean container) and then adding the emulsion to that mixture in the coolant tank. MWFs should be mixed just before use; large amounts should not be stored, as they may deteriorate before use.

*Personal Protective Clothing:* Personal protective clothing and equipment should always be worn when removing MWF concentrates from the original container, mixing and diluting concentrate, preparing additives (including biocides), and adding MWF emulsions, biocides, or other potentially hazardous ingredients to the coolant reservoir. Personal protective clothing includes eye protection or face shields, gloves, and aprons which do not react with but shed MWF ingredients and additives.

*System Service:* Coolant systems should be regularly serviced, and the machines should be rigorously maintained to prevent contamination of the fluids by tramp oils (e.g., hydraulic oils, gear box oils, and machine lubricants leaking from the machines or total loss slide-way lubrication). Tramp oils can destabilize emulsions, cause pumping problems, and clog filters. Tramp oils can also float to the top of MWFs, effectively sealing the fluids from the air, allowing metabolic products such as volatile fatty acids, mercaptols, scatols, ammonia, and hydrogen sulfide are produced by the anaerobic and facultative anaerobic species growing within the biofilm to accumulate in the reduced state.

When replacing the fluids, thoroughly clean all parts of the system to inhibit the growth of microorganisms growing on surfaces. Some bacteria secrete layers of slime that may grow in stringy configurations that resemble fungal growth. Many bacteria secrete polymers of polysaccharide and/or protein, forming a glycocalyx which cements cells together much as mortar holds bricks. Fungi may grow as masses of hyphae forming mycelial mats. The attached community of microorganisms is called a biofilm and may be very difficult to remove by ordinary cleaning procedures.

*Biocide Treatment:* Biocides are used to maintain the functionality and efficacy of MWFs by preventing microbial overgrowth. These compounds are often added to the stock fluids as they are formulated, but over time the biocides are consumed by chemical and biological demands. Biocides with a wide spectrum of biocidal activity should be used to suppress the growth of the widely diverse contaminant population. Only the concentration of biocide needed to meet fluid specifications should be used since overdosing could lead to skin or respiratory irritation in workers, and under-dosing could lead to an inadequate level of microbial control.

*Ventilation Systems:* The ventilation system should be designed and operated to prevent the accumulation or recirculation of airborne contaminants in the workplace. The ventilation system should include a positive means of bringing in at least an equal volume of air from the outside, conditioning it, and evenly distributing it throughout the exhausted area.

Exhaust ventilation systems function through suction openings placed near a source of contamination. The suction opening or exhaust hood creates an air motion sufficient to overcome room air currents and any airflow generated by the process. This airflow cap-

tures the contaminants and conveys them to a point where they can either be discharged or removed from the airstream. Exhaust hoods are classified by their position relative to the process as canopy, side draft, down draft or enclosure. ANSI Technical Report B11 TR 2-1997 contains guidelines for exhaust ventilation of machining and grinding operations. Enclosures are the only type of exhaust hood recommended by the ANSI committee. They consist of physical barriers between the process and the worker's environment. Enclosures can be further classified by the extent of the enclosure: close capture (enclosure of the point of operation, total enclosure (enclosure of the entire machine), or tunnel enclosure (continuous enclosure over several machines).

If no fresh make up air is introduced into the plant, air will enter the building through open doors and windows, potentially causing cross-contamination of all process areas. Ideally, all air exhausted from the building should be replaced by tempered air from an uncontaminated location. By providing a slight excess of make up air in relatively clean areas and a slight deficit of make up air in dirty areas, cross-contamination can be reduced. In addition, this air can be channeled directly to operator work areas, providing the cleanest possible work environment. Ideally, this fresh air should be supplied in the form of a low-velocity air shower (<100 ft/min to prevent interference with the exhaust hoods) directly above the worker.

*Protective Clothing and Equipment:* Engineering controls are used to reduce worker exposure to MWFs. But in the event of airborne exposures that exceed the NIOSH REL or dermal contact with the MWFs, the added protection of chemical protective clothing (CPC) and respirators should be provided. Maintenance staff may also need CPC because their work requires contact with MWFs during certain operations. All workers should be trained in the proper use and care of CPC. After any item of CPC has been in routine use, it should be examined to ensure that its effectiveness has not been compromised.

Selection of the appropriate respirator depends on the operation, chemical components, and airborne concentrations in the worker's breathing zone. Table 2. lists the NIOSH- recommended respiratory protection for workers exposed to MWF aerosol.

**Table 2. Respiratory Protection for Workers Exposed to MWF Aerosols\***

| Concentration of MWF aerosol (mg/m <sup>3</sup> ) | Minimum respiratory protection <sup>a</sup>   |
|---|---|
| #0.5 mg/m <sup>3</sup> (1 × REL) <sup>b</sup>     | No respiratory protection required for healthy workers <sup>c</sup>   |
| #5.0 mg/m <sup>3</sup> (10 × REL)                 | Any air-purifying, half-mask respirator including a disposable respirator <sup>d,e</sup> equipped with any P- or R-series particulate filter (P95, P99, P100, R95, R99, or R100) number |
| #12.5 mg/m <sup>3</sup> (25 × REL)                | Any powered, air-purifying respirator equipped with a hood or helmet and a HEPA filter <sup>f</sup>   |

<sup>a</sup> Respirators with higher assigned protection factors (APFs) may be substituted for those with lower APFs [NIOSH 1987a].

<sup>b</sup> APF times the NIOSH REL for total particulate mass. The APF [NIOSH 1987b] is the minimum anticipated level of protection provided by each type of respirator.

<sup>c</sup> See text for recommendations regarding workers with asthma and for other workers affected by MWF aerosols.

<sup>d</sup> A respirator that should be discarded after the end of the manufacturer's recommended period of use or after a noticeable increase in breathing resistance or when physical damage, hygiene considerations, or other warning indicators render the respirator unsuitable for further use.

<sup>e</sup> An APF of 10 is assigned to disposable particulate respirators if they have been properly fitted.

<sup>f</sup> High-efficiency particulate air filter. When organic vapors are a potential hazard during metalworking operations, a combination particulate and organic vapor filter is necessary.

\* Only NIOSH/MSHA-approved or NIOSH-approved (effective date July 10, 1995) respiratory equipment should be used.

**MACHINING NONFERROUS METALS  
AND NON-METALLIC MATERIALS****Nonferrous Metals**

**Machining Aluminum.**—Some of the alloys of aluminum have been machined successfully without any lubricant or cutting compound, but some form of lubricant is desirable to obtain the best results. For many purposes, a soluble cutting oil is good.

Tools for aluminum and aluminum alloys should have larger relief and rake angles than tools for cutting steel. For high-speed steel turning tools the following angles are recommended: relief angles, 14 to 16 degrees; back rake angle, 5 to 20 degrees; side rake angle, 15 to 35 degrees. For very soft alloys even larger side rake angles are sometimes used. High silicon aluminum alloys and some others have a very abrasive effect on the cutting tool. While these alloys can be cut successfully with high-speed-steel tools, cemented carbides are recommended because of their superior abrasion resistance. The tool angles recommended for cemented carbide turning tools are: relief angles, 12 to 14 degrees; back rake angle, 0 to 15 degrees; side rake angle, 8 to 30 degrees.

Cut-off tools and necking tools for machining aluminum and its alloys should have from 12 to 20 degrees back rake angle and the end relief angle should be from 8 to 12 degrees. Excellent threads can be cut with single-point tools in even the softest aluminum. Experience seems to vary somewhat regarding the rake angle for single-point thread cutting tools. Some prefer to use a rather large back and side rake angle although this requires a modification in the included angle of the tool to produce the correct thread contour. When both rake angles are zero, the included angle of the tool is ground equal to the included angle of the thread. Excellent threads have been cut in aluminum with zero rake angle thread-cutting tools using large relief angles, which are 16 to 18 degrees opposite the front side of the thread and 12 to 14 degrees opposite the back side of the thread. In either case, the cutting edges should be ground and honed to a keen edge. It is sometimes advisable to give the face of the tool a few strokes with a hone between cuts when chasing the thread to remove any built-up edge on the cutting edge.

Fine surface finishes are often difficult to obtain on aluminum and aluminum alloys, particularly the softer metals. When a fine finish is required, the cutting tool should be honed to a keen edge and the surfaces of the face and the flank will also benefit by being honed smooth. Tool wear is inevitable, but it should not be allowed to progress too far before the tool is changed or sharpened. A sulphurized mineral oil or a heavy-duty soluble oil will sometimes be helpful in obtaining a satisfactory surface finish. For best results, however, a diamond cutting tool is recommended. Excellent surface finishes can be obtained on even the softest aluminum and aluminum alloys with these tools.

Although ordinary milling cutters can be used successfully in shops where aluminum parts are only machined occasionally, the best results are obtained with coarse-tooth, large helix-angle cutters having large rake and clearance angles. Clearance angles up to 10 to 12 degrees are recommended. When slab milling and end milling a profile, using the peripheral teeth on the end mill, climb milling (also called down milling) will generally produce a better finish on the machined surface than conventional (or up) milling. Face milling cutters should have a large axial rake angle. Standard twist drills can be used without difficulty in drilling aluminum and aluminum alloys although high helix-angle drills are preferred. The wide flutes and high helix-angle in these drills helps to clear the chips. Sometimes split-point drills are preferred. Carbide tipped twist drills can be used for drilling aluminum and its alloys and may afford advantages in some production applications. Ordinary hand and machine taps can be used to tap aluminum and its alloys although spiral-fluted ground thread taps give superior results. Experience has shown that such taps should have a right-hand ground flute when intended to cut right-hand threads and the helix angle should be similar to that used in an ordinary twist drill.

**Machining Magnesium.**—Magnesium alloys are readily machined and with relatively low power consumption per cubic inch of metal removed. The usual practice is to employ high cutting speeds with relatively coarse feeds and deep cuts. Exceptionally fine finishes can be obtained so that grinding to improve the finish usually is unnecessary. The horsepower normally required in machining magnesium varies from 0.15 to 0.30 per cubic inch per minute. While this value is low, especially in comparison with power required for cast iron and steel, the total amount of power for machining magnesium usually is high because of the exceptionally rapid rate at which metal is removed.

Carbide tools are recommended for maximum efficiency, although high-speed steel frequently is employed. Tools should be designed so as to dispose of chips readily or without excessive friction, by employing polished chip-bearing surfaces, ample chip spaces, large clearances, and small contact areas. *Keen-edged tools should always be used.*

*Feeds and Speeds for Magnesium:* Speeds ordinarily range up to 5000 feet per minute for rough- and finish-turning, up to 3000 feet per minute for rough-milling, and up to 9000 feet per minute for finish-milling. For rough-turning, the following combinations of speed in feet per minute, feed per revolution, and depth of cut are recommended: Speed 300 to 600 feet per minute — feed 0.030 to 0.100 inch, depth of cut 0.5 inch; speed 600 to 1000 — feed 0.020 to 0.080, depth of cut 0.4; speed 1000 to 1500 — feed 0.010 to 0.060, depth of cut 0.3; speed 1500 to 2000 — feed 0.010 to 0.040, depth of cut 0.2; speed 2000 to 5000 — feed 0.010 to 0.030, depth of cut 0.15.

*Lathe Tool Angles for Magnesium:* The true or actual rake angle resulting from back and side rakes usually varies from 10 to 15 degrees. Back rake varies from 10 to 20, and side rake from 0 to 10 degrees. Reduced back rake may be employed to obtain better chip breakage. The back rake may also be reduced to from 2 to 8 degrees on form tools or other broad tools to prevent chatter.

*Parting Tools:* For parting tools, the back rake varies from 15 to 20 degrees, the front end relief 8 to 10 degrees, the side relief measured perpendicular to the top face 8 degrees, the side relief measured in the plane of the top face from 3 to 5 degrees.

*Milling Magnesium:* In general, the coarse-tooth type of cutter is recommended. The number of teeth or cutting blades may be one-third to one-half the number normally used; however, the two-blade fly-cutter has proved to be very satisfactory. As a rule, the land relief or primary peripheral clearance is 10 degrees followed by secondary clearance of 20 degrees. The lands should be narrow, the width being about  $\frac{3}{64}$  to  $\frac{1}{16}$  inch. The rake, which is positive, is about 15 degrees.

For rough-milling and speeds in feet per minute up to 900 — feed, inch per tooth, 0.005 to 0.025, depth of cut up to 0.5; for speeds 900 to 1500 — feed 0.005 to 0.020, depth of cut up to 0.375; for speeds 1500 to 3000 — feed 0.005 to 0.010, depth of cut up to 0.2.

*Drilling Magnesium:* If the depth of a hole is less than five times the drill diameter, an ordinary twist drill with highly polished flutes may be used. The included angle of the point may vary from 70 degrees to the usual angle of 118 degrees. The relief angle is about 12 degrees. The drill should be kept sharp and the outer corners rounded to produce a smooth finish and prevent burr formation. For deep hole drilling, use a drill having a helix angle of 40 to 45 degrees with large polished flutes of uniform cross-section throughout the drill length to facilitate the flow of chips. A pyramid-shaped “spur” or “pilot point” at the tip of the drill will reduce the “spiraling or run-off.”

Drilling speeds vary from 300 to 2000 feet per minute with feeds per revolution ranging from 0.015 to 0.050 inch.

*Reaming Magnesium:* Reamers up to 1 inch in diameter should have four flutes; larger sizes, six flutes. These flutes may be either parallel with the axis or have a negative helix angle of 10 degrees. The positive rake angle varies from 5 to 8 degrees, the relief angle from 4 to 7 degrees, and the clearance angle from 15 to 20 degrees.

*Tapping Magnesium:* Standard taps may be used unless Class 3B tolerances are required, in which case the tap should be designed for use in magnesium. A high-speed steel concentric type with a ground thread is recommended. The concentric form, which eliminates the radial thread relief, prevents jamming of chips while the tap is being backed out of the hole. The positive rake angle at the front may vary from 10 to 25 degrees and the "heel rake angle" at the back of the tooth from 3 to 5 degrees. The chamfer extends over two to three threads. For holes up to  $\frac{1}{4}$  inch in diameter, two-fluted taps are recommended; for sizes from  $\frac{1}{2}$  to  $\frac{3}{4}$  inch, three flutes; and for larger holes, four flutes. Tapping speeds ordinarily range from 75 to 200 feet per minute, and mineral oil cutting fluid should be used.

*Threading Dies for Magnesium:* Threading dies for use on magnesium should have about the same cutting angles as taps. Narrow lands should be used to provide ample chip space. Either solid or self-opening dies may be used. The latter type is recommended when maximum smoothness is required. Threads may be cut at speeds up to 1000 feet per minute.

*Grinding Magnesium:* As a general rule, magnesium is ground dry. The highly inflammable dust should be formed into a sludge by means of a spray of water or low-viscosity mineral oil. Accumulations of dust or sludge should be avoided. For surface grinding, when a fine finish is desirable, a low-viscosity mineral oil may be used.

**Machining Zinc Alloy Die-Castings.**—Machining of zinc alloy die-castings is mostly done without a lubricant. For particular work, especially deep drilling and tapping, a lubricant such as lard oil and kerosene (about half and half) or a 50-50 mixture of kerosene and machine oil may be used to advantage. A mixture of turpentine and kerosene has been found effective on certain difficult jobs.

*Reaming:* In reaming, tools with six straight flutes are commonly used, although tools with eight flutes irregularly spaced have been found to yield better results by one manufacturer. Many standard reamers have a land that is too wide for best results. A land about 0.015 inch wide is recommended but this may often be ground down to around 0.007 or even 0.005 inch to obtain freer cutting, less tendency to loading, and reduced heating.

*Turning:* Tools of high-speed steel are commonly employed although the application of Stellite and carbide tools, even on short runs, is feasible. For steel or Stellite, a positive top rake of from 0 to 20 degrees and an end clearance of about 15 degrees are commonly recommended. Where side cutting is involved, a side clearance of about 4 degrees minimum is recommended. With carbide tools, the end clearance should not exceed 6 to 8 degrees and the top rake should be from 5 to 10 degrees positive. For boring, facing, and other lathe operations, rake and clearance angles are about the same as for tools used in turning.

**Machining Monel and Nickel Alloys.**—These alloys are machined with high-speed steel and with cemented carbide cutting tools. High-speed steel lathe tools usually have a back rake of 6 to 8 degrees, a side rake of 10 to 15 degrees, and relief angles of 8 to 12 degrees. Broad-nose finishing tools have a back rake of 20 to 25 degrees and an end relief angle of 12 to 15 degrees. In most instances, standard commercial cemented-carbide tool holders and tool shanks can be used which provide an acceptable tool geometry. Honing the cutting edge lightly will help if chipping is encountered.

The most satisfactory tool materials for machining Monel and the softer nickel alloys, such as Nickel 200 and Nickel 230, are M2 and T5 for high-speed steel and crater resistant grades of cemented carbides. For the harder nickel alloys such as K Monel, Permanickel, Duranickel, and Nitinol alloys, the recommended tool materials are T15, M41, M42, M43, and for high-speed steel, M42. For carbides, a grade of crater resistant carbide is recommended when the hardness is less than 300 Bhn, and when the hardness is more than 300 Bhn, a grade of straight tungsten carbide will often work best, although some crater resistant grades will also work well.

A sulfurized oil or a water-soluble oil is recommended for rough and finish turning. A sulfurized oil is also recommended for milling, threading, tapping, reaming, and broaching. Recommended cutting speeds for Monel and the softer nickel alloys are 70 to 100 fpm for high-speed steel tools and 200 to 300 fpm for cemented carbide tools. For the harder nickel alloys, the recommended speed for high-speed steel is 40 to 70 fpm for a hardness up to 300 Bhn and for a higher hardness, 10 to 20 fpm; for cemented carbides, 175 to 225 fpm when the hardness is less than 300 Bhn and for a higher hardness, 30 to 70 fpm.

Nickel alloys have a high tendency to work harden. To minimize work hardening caused by machining, the cutting tools should be provided with adequate relief angles and positive rake angles. Furthermore, the cutting edges should be kept sharp and replaced when dull to prevent burnishing of the work surface. The depth of cut and feed should be sufficiently large to ensure that the tool penetrates the work without rubbing.

**Machining Copper Alloys.**—Copper alloys can be machined by tooling and methods similar to those used for steel, but at higher surface speeds. Machinability of copper alloys is discussed in [Table 2](#) on page 556 and [Table 3](#) on page 560. Machinability is based on a rating of 100 per cent for the free-cutting alloy C35000, which machines with small, easily broken chips. As with steels, copper alloys containing lead have the best machining properties, with alloys containing tin, and lead, having machinability ratings of 80 and 70 per cent. Tellurium and sulphur are added to copper alloys to increase machinability with minimum effect on conductivity. Lead additions are made to facilitate machining, as their effect is to produce easily broken chips.

Copper alloys containing silicon, aluminum, manganese and nickel become progressively more difficult to machine, and produce long, stringy chips, the latter alloys having only 20 per cent of the machinability of the free-cutting alloys. Although copper is frequently machined dry, a cooling compound is recommended. Other lubricants that have been used include tallow for drilling, gasoline for turning, and beeswax for threading.

### Machining Non-metals

**Machining Hard Rubber.**—Tools suitable for steel may be used for hard rubber, with no top or side rake angles and 10 to 20 degree clearance angles, of high speed steel or tungsten carbide. Without coolant, surface speeds of about 200 ft/min. are recommended for turning, boring and facing, and may be increased to 300 surface ft/min. with coolant.

*Drilling of hard rubber* requires high speed steel drills of 35 to 40 degree helix angle to obtain maximum cutting speeds and drill life. Feed rates for drilling range up to 0.015 in/rev. Deep-fluted taps are best for threading hard rubber, and should be 0.002 to 0.005 in. oversize if close tolerances are to be held. Machine oil is used for a lubricant. Hard rubber may be sawn with band saws having 5 to 10 teeth per inch, running at about 3000 ft/min. or cut with abrasive wheels. Use of coolant in grinding rubber gives a smoother finish.

*Piercing and blanking* of sheet rubber is best performed with the rubber or dies heated. Straightening of the often-distorted blanks may be carried out by dropping them into a pan of hot water.

**Formica Machining.**—Blanks can be cut from sheets of "Formica" either by a band saw or by trepanning tools in a boring mill or a drill press. To saw blanks, first describe a circle as a guide line, then use a 21-gage 3½-point saw running at a speed of 5000 feet per minute. The saw should be sharp, with a ¼-inch set on both sides. In drilling, use an ordinary high-speed drill whose point is ground to an included angle of 55 to 60 degrees. Another method is to grind the drill point slightly off center. The feed must be rapid and caution used to prevent the drill from lagging in its work, and the speed must be 1200 revolutions per minute. For all machining operations on "Formica" gear material, provision must be made in grinding for the tools to clear themselves. For reaming, the entry of the reamer and the reaming process must be rapid. There must not be a lag between the end of the reaming operation and the withdrawal of the reamer. In turning the outside diameter and the sides of blanks,

## MACHINING MICARTA

1157

the tools must be sharp and have 3 to 5 degrees more rake than is common practice for metal. A cutting speed of 750 feet per minute, which is equal to 720 revolutions per minute on a 4-inch diameter blank, is recommended. The depth of the cut can be  $\frac{1}{16}$  to  $\frac{1}{8}$  inch, but the feed should be 0.010 inch, regardless of the depth of the cut. Teeth may be cut on a hobbing machine, shaper, or milling machine. The speed of the cutter should be 150 feet per minute, and the feed from 0.023 to 0.040 inch per revolution. It is advisable to back up the blank to prevent fraying or breaking out of the material as the cutter comes through. The backing plates can be economically made from hard wood.

**Micarta Machining.**—In cutting blanks from sheets of “micarta” a band saw running at a speed of 350 revolutions per minute has been found suitable. The saw should be of the bevel-tooth type, seven teeth to the inch. For large quantities a trepanning tool should be used. In trepanning blanks, the tool should be fed so as to cut part way through all of the “layouts”; then the micarta plate should be turned over, and the cutting completed from the reverse side.

Turning tools should be of high-speed steel cutting at speeds similar to those used for bronze or cast iron. If two cuts are taken, about 0.010 inch of stock should be left for the finishing cut.

Drilling at right angles to the layers is done with a standard drill, which should be backed off sufficiently to provide plenty of clearance. When drilling parallel to layers, a “flat” or “bottom” drill should be used. In rough-drilling, the hole should preferably be drilled partly through the material from each side to prevent possible splitting as the tool protrudes. If this is impracticable, the hole can be drilled all the way through the material, provided the material is “backed up” with wood, stiff cardboard, or any other material that is sufficiently rigid to support the under surface at the point where the drill comes through.

The methods described for drilling apply as well to tapping, except that when the tapping is done parallel to the layers, it is advisable to clamp the material to equalize the stress on the layers and prevent possible splitting.

In milling, a standard tool may be used at a speed and feed corresponding to that used in working bronze or soft steel. The cutting angle of the cutter will give better results if ground with a slight rake.

While there is a wide range of practice as to feeds and speeds in cutting gears on hobbing machines, a hob speed of not less than 140 revolutions per minute, has given satisfaction. In machining gear teeth on a gear shaper, a speed of about 100 to 130 strokes per minute with a fairly fine feed has given good results. Backing-up plates should be used in machining micarta gears.

**Ultrasonic Machining.**—This method of cutting and engraving hard materials such as glass, precious stones, and carbides uses a transducer (vibratory unit) to obtain the necessary mechanical vibrations needed. The transducer converts the input energy, in this case electrical, into another form of energy, in this case mechanical.

A tool of the required size and shape is made of brass or other soft material and is attached to the transducer. The tool is lowered until it just barely touches the work, and current is applied. At the same time, a slurry of water and fine abrasive, usually boron carbide, is pumped over the work. The tool does not actually touch the work, but the vibrations literally hammer the particles of abrasive into the surface and chip off tiny fragments. Some wear does take place in the tool, but it is very slight and, as it is equally distributed, it does not change the shape. The method is quite commonly applied to cutting designs in the stones of signet rings, but it is also applied to cutting intricately shaped holes in carbide or hardened steel.

## GRINDING FEEDS AND SPEEDS

Grinding data are scarcely available in handbooks, which usually recommend a small range of depths and work speeds at constant wheel speed, including small variations in wheel and work material composition. Wheel life or grinding stiffness are seldom considered.

Grinding parameter recommendations typically range as follows:

- Wheel speeds are usually recommended in the 1200 to 1800 m/min (4000 to 6000 fpm) range, or in rare cases up to 3600 m/min (12000 fpm)
- Work speeds are in the range 20 to 40 m/min (70 to 140 fpm); and, depths of cut of 0.01 to 0.025 mm (0.0004 to 0.001 inch) for roughing, and around 0.005 mm (.0002 in.) for finish grinding.
- Grit sizes for roughing are around 46 to 60 for easy-to-grind materials, and for difficult-to-grind materials higher such as 80 grit. In finishing, a smaller grit size (higher grit number) is recommended. Internal grinding grit sizes for small holes are approximately 100 to 320.
- Specific metal removal rate,  $SMRR$ , represents the rate of material removal per unit of wheel contact width and are commonly recommended from 200 to 500 mm<sup>3</sup>/mm width/min (0.3 to 0.75 in<sup>3</sup>/inch width/min).
- Grinding stiffness is a major variable in determining wheel-life and spark-out time. A typical value of system stiffness in outside-diameter grinding, for 10:1 length/diameter ratio, is approximately  $K_{ST} = 30\text{--}50 \text{ N}/\mu\text{m}$ . System stiffness  $K_{ST}$  is calculated from the stiffness of the part,  $K_w$  and the machine and fixtures,  $K_m$ . Machine values can be obtained from manufacturers, or can be measured using simple equipment along with the part stiffness.
- Generally a lower wheel hardness (soft wheel) is recommended when the system stiffness is poor or when a better finish is desired.

### Basic Rules

The wheel speed  $V$  and *equivalent chip thickness*  $ECT = SMRR \div V \div 1000$  are the primary parameters that determine wheel-life, forces and surface finish in grinding. The following general rules and recommendations, using  $ECT$ , are based on extensive laboratory and industry tests both in Europe and USA. The relationships and shapes of curves pertaining to grinding tool-life, grinding time, and cost are similar to those of any metal cutting operation such as turning, milling and drilling.

In turning and milling, the  $ECT$  theory says that if the product of feed times depth of cut is constant, the tool-life is constant no matter how the depth of cut or feed is varied, provided that the cutting speed and cutting edge length are maintained constant.

In grinding, wheel-life  $T$  remains constant for constant cutting speed  $V$ , regardless of how depth of cut  $a_r$  or work speed  $V_w$  are selected as long as the specific metal removal rate  $SMRR = V_w \times a_r$  is held constant (neglecting the influence of grinding contact width).

$ECT$  is much smaller in grinding than in milling, ranging from about 0.0001 to 0.001 mm (0.000004 to 0.00004 inch). See the section *MACHINING ECONOMETRICS* starting on page 1093 for a detailed explanation of the role of  $ECT$  in conventional machining.

**Wheel life  $T$  and Grinding Ratio.**—A commonly used measure of relative wheel-life in grinding is the *grinding ratio* that is used to compare grindability when varying grinding wheel composition and work material properties under otherwise constant cutting conditions.

The *grinding ratio* is defined as the slope of the wear curve versus metal removal rate:  $\text{grinding ratio} = MRR \div W^*$ , where  $MRR$  is the metal removal rate, and  $W^*$  is the volume wheel wear at which the wheel has to be dressed. The grinding ratio is not a measure of wheel-life, but a relationship between *grinding ratio* and wheel-life  $T$  can be obtained from

the formula  $\text{grinding ratio} = SMRR \times T \div W^*$ , where  $SMRR$  (specific metal removal rate) is determined from  $MRR = SMRR \times T$  or from  $ECT = SMRR \div V \div 1000$ .

Thus,  $\text{grinding ratio} = 1000 \times ECT \times V \times T \div W^*$ , and  $T = \text{grinding ratio} \times W^* \div (1000 \times ECT \times V)$ , provided that the wheel wear criterion  $W^*$  is valid for all data combinations.

*Example 1:* If  $W^*$  in one test is found to be  $500 \text{ mm}^3$  for  $ECT = 0.00033 \text{ mm}$  and  $V = 3600 \text{ m/min}$ , and  $\text{grinding ratio} = 10$ , then wheel-life will vary with measured grinding ratios, wheel speed, and  $ECT$  as follows:  $T = 500 \times \text{grinding ratio} \div (V \times ECT) = 4.2$  minutes.

In the remainder of this section the  $\text{grinding ratio}$  will not be used, and wheel-life is expressed in terms of  $ECT$  or  $SMRR$  and wheel speed  $V$ .

**ECT in Grinding.**—In turning and milling,  $ECT$  is defined as the volume of chips removed per unit cutting edge length per revolution of the work or cutter. In milling specifically,  $ECT$  is defined as the ratio of (number of teeth  $z \times$  feed per tooth  $f_z \times$  radial depth of cut  $a_r \times$  and axial depth of cut  $a_a$ ) and (cutting edge length  $CEL$  divided by  $\pi D$ ), where  $D$  is the cutter diameter, thus,

$$ECT = \frac{\pi D z f_z a_r a_a}{CEL}$$

In grinding, the same definition of  $ECT$  applies if we replace the number of teeth with the average number of grits along the wheel periphery, and replace the feed per tooth by the average feed per grit. This definition is not very practical, however, and  $ECT$  is better defined by the ratio of the specific metal removal rate  $SMRR$ , and the wheel speed  $V$ . Thus,  $ECT = 1000 \times SMRR \div V$ . Keeping  $ECT$  constant when varying  $SMRR$  requires that the wheel speed must be changed proportionally.

In milling and turning  $ECT$  can also be redefined in terms of  $SMRR$  divided by the work and the cutter speeds, respectively, because  $SMRR$  is proportional to the feed rate  $F_R$ .

**Work Speed and Depth of Cut Selection:** Work speed  $V_w$  is determined by dividing  $SMRR$  by the depth of cut  $a_r$ , or by using the graph in Fig. 1.

Fig. 1. Work speed  $V_w$  vs. depth of cut  $a_r$ .

Referring to Fig. 1, for depths of cuts of 0.01 and 0.0025 mm, a specific metal removal rate  $SMRR = 1000 \text{ mm}^3/\text{mm width/min}$  is achieved at work speeds of 100 and 400 m/min, respectively, and for  $SMRR = 100 \text{ mm}^3/\text{mm width/min}$  at work speeds of 10 and 40 m/min, respectively.

Unfortunately, the common use of low values of work speed (20 to 40 m/min) in finishing cause thermal surface damage, disastrous in critical parts such as aircraft components. As the grains slide across the work they generate surface heat and fatigue-type loading may cause residual tensile stresses and severe surface cracks. Proper finish grinding conditions

are obtained by increasing the work speed 5 to 10 times higher than the above recommendations indicate. These higher work speeds will create compressive stresses that are not detrimental to the surface. The by-product of higher work speeds is much higher *SMRR* values and thereby much shorter grinding times. Compressive stresses are also obtained by reducing the depth of cut  $a_r$ .

**Wheel Life Relationships and Optimum Grinding Data.**—Figs. 2a, 2b, and 2c show, in three planes, the 3-dimensional variation of wheel-life  $T$  with wheel speed  $V$  and  $ECT$  when grinding a hardened tool steel. Fig. 2a depicts wheel-life versus wheel speed (the  $T$ - $V$  plane) with constant  $ECT$  appearing as approximately straight lines when plotted in log-log coordinates.

In grinding, the wheel-life variation follows curves similar to those obtained for conventional metal cutting processes, including a bend-off of the Taylor lines ( $T$ - $V$  graph) towards shorter life and lower cutting speeds when a certain maximum life is achieved for each value of  $ECT$ . In the two other planes ( $T$ - $ECT$ , and  $V$ - $ECT$ ) we usually find smooth curves in which the maximum values of wheel-life are defined by points along a curve called the  $H$ -curve.

Fig. 2a. Taylor lines:  $T$  vs.  $V$ ,  $ECT$  plotted for grinding M4 tool steel, hardness Rc 64

**Example 2:** The variation of  $SMRR = V \times ECT \times 1000$  and wheel-life at various wheel speeds can be obtained from Fig. 2a. Using sample values of  $ECT = 33 \times 10^{-5}$  mm and  $V = 1300$  and  $1900$  m/min,  $SMRR = 1300 \times 33 \times 10^{-5} \times 1000 = 429$ , and  $1900 \times 33 \times 10^{-5} \times 1000 = 627$  mm<sup>3</sup>/mm width/min, respectively; the corresponding wheel lives are read off as approximately 70 and 30 minutes, respectively.

Fig. 2b.  $T$  vs.  $ECT$ ,  $V$  plotted

Fig. 2b depicts wheel-life  $T$  versus  $ECT$  with constant wheel speed  $V$  shown as curves plotted in log-log coordinates, similar to those for the other cutting operations.

*Example 3:* Fig. 2b shows that maximum values of wheel-life occur along the *H*-curve. For the 3 speeds 1800, 2700, and 3600 m/min, maximum wheel lives are approximately 70, 14 and 4 minutes, respectively, at *ECT* around  $17 \times 10^{-5}$  through  $20 \times 10^{-5}$  mm along the *H*-curve. Left and right of the *H*-curve wheel-life is shorter.

Fig. 2c depicts wheel speed *V* versus *ECT* with wheel-life *T* parameter shown as curves in log-log coordinates, similar to those for the other cutting operations, with the characteristic *H*- and *G*-curves.

Fig. 2c. *V* vs. *ECT*, *T* plotted

*Optimum grinding data for roughing* occur along the *G*-curve, which is determined from the *V-ECT* graph by drawing 45-degree lines tangent to the *T*-curves, as shown in Fig. 2c, and drawing a line (the *G*-curve) through the points of tangency on the respective *T*-curves, thus the location and direction of the *G*-curve is determined. Globally optimum data correspond to the *T*-curve for which wheel-life is calculated using the corresponding equivalent tooling-cost time,  $T_v$ , calculated from  $T_v = T_{RPL} + 60 \times C_E \div H_R$ , minutes, where  $T_{RPL}$  is the time required to replace wheel,  $C_E$  = cost per wheel dressing = wheel cost + cost per dressing, and  $H_R$  is the hourly rate.

*Minimum cost conditions* occur along the *G*-curve; if optimum life  $T_O$  was determined at either 10 or 30 minutes then  $V_O = 1500$  and 1100 m/min, respectively, and *ECT* is around  $65 - 70 \times 10^{-5}$  mm in both cases. The corresponding optimum values of *SMRR* are  $1000 \times 1500 \times 67 \times 10^{-5} = 1000$  and  $1000 \times 1100 \times 67 \times 10^{-5} = 740$  mm<sup>3</sup>/min/mm wheel contact width (1.5 to 1.1 in<sup>3</sup>/in/min).

Using Fig. 1 we find optimum work speeds for depths of cut  $a_r = 0.01$  and 0.005 mm to be  $V_w = 100$  and 75 m/min, and 200 and 150 m/min (330 and 250 fpm, and 660 and 500 fpm) respectively for 10- and 30-minute wheel-life.

These high work speeds are possible using proper dressing conditions, high system stiffness, good grinding fluid quality and wheel composition.

Fig. 3 shows the variation of specific metal removal rate with wheel speed for several materials and a range of *ECT*s at 10- and 30-minutes wheel-life. *ECT* decreases when moving to the left and down along each curve. The two curves for unhardened 1020 steel have the largest values of *SMRR*, and represent the most productive grinding conditions, while the heat resistant alloy Inconel yields the least productive grinding conditions. Each

branch attains a maximum  $SMRR$  along the  $G$ -curve (compare with the same curve in the  $V$ - $ECT$  graph, Fig. 2c) and a maximum speed region along the  $H$ -curve. When the  $SMRR$ -values are lower than the  $H$ -curve the  $ECT$  values for each branch decrease towards the bottom of the graph, then the speed for constant wheel-life must be reduced due to the fact that the  $ECT$  values are to the left of their respective  $H$ -curves in  $V$ - $ECT$  graphs.

Fig. 3. Specific metal removal rate vs. cutting speed at  $T=10$  and 30 minutes wheel life

In the figure, IncX is Inconel; M4, and T-15 are tool steels; and 1020 Unh is unhardened 1020 steel.

**Surface Finish,  $R_a$ .**—The finish is improved by decreasing the value of  $ECT$  as shown in Fig. 4, where  $R_a$  is plotted versus  $ECT$  at 3 different wheel lives 1, 10 and 30 minutes at constant wheel speed. Because  $ECT$  is proportional to the depth of cut, a smaller depth of cut is favorable for reducing surface roughness when the work speed is constant.

Fig. 4. Surface finish,  $R_a$  vs.  $ECT$ , wheel-life  $T$  plotted

In Fig. 5,  $R_a$  is plotted versus wheel-life at 5 different  $ECT$ 's. Both Figs. 4 and 5 illustrate that a shorter life improves the surface finish, which means that either an increased wheel speed (wheel-life decreases) at constant  $ECT$ , or a smaller  $ECT$  at constant speed (wheel-life increases), will result in an improved finish. For a required surface finish,  $ECT$  and wheel-life have to be selected appropriately in order to also achieve an optimum grinding time or cost. In cylindrical grinding a reduction of side feed  $f_s$  improves  $R_a$  as well.

In terms of specific metal removal rate, reducing  $SMRR$  will improve the surface finish  $R_a$ .

Fig. 5. Surface roughness,  $R_a$  vs. wheel life  $T$ ,  $ECT$  plotted

*Example 4, Specific Metal Removal Rates and Work Speeds in Rough and Finish Grinding:* The tabulated values in the following table indicate that a decreasing  $ECT$  combined with a higher wheel speed for 10 minutes wheel-life will decrease the metal removal rate and thereby increasing the grinding time. This change is accompanied by a better finish in both roughing and finishing operations. Note the high work speeds when finishing.

| $ECT$ mm | Tool Life $T = 10$ minutes    |  | Roughing Depth<br>$a_r = 0.025$ mm | Finishing Depth<br>$a_f = 0.0025$ mm |
|----------|-------------------------------|--|------------------------------------|--------------------------------------|
|          | Wheel speed<br>$V_{10}$ m/min | Removal Rate<br>$SMRR_{10}$ mm <sup>3</sup> /mm/ min | Work speed $V_w$ m/min             |                                      |
| 0.00050  | 1970                          | 985  | 39                                 | 390                                  |
| 0.00033  | 2580                          | 850  | 34                                 | 340                                  |
| 0.00017  | 2910                          | 500  | 20                                 | 200                                  |

The grit size, however, is a major parameter. Fig. 6, shows that a high wheel speed, combined with a small grit size, say 320 Mesh, can achieve  $R_A$  values as small as 0.03 microns.

Fig. 6. Wheel speed vs. wheel mesh,  $R_a$  plotted

**Spark-out Time.**— Fig. 7 shows how spark-out time varies with system stiffness. As with surface finish, when wheel-life is short (high wear rate) the spark-out time decreases.

*Equivalent Diameter (Work Conformity) Factor:* The difference in curvature of the work and wheel in the contact region, determined by the equivalent diameter or work conformity formula, is an important factor for calculating spark-out time and forces, but has a

## GRINDING FEEDS AND SPEEDS

Fig. 7. Sparkout time vs. system stiffness, wheel-life  $T$  plotted

negligible influence on wheel-life. Therefore, an equivalent diameter,  $D_e = D/(1 \pm (D/D_w))$ , with the minus sign for internal grinding and the plus sign for external grinding operations, is used to consider the effect of conformity when using internal and external grinding with varying work and wheel diameters.  $D_e$  is equal to the wheel diameter in surface grinding (work flat); in internal grinding, the wheel conforms closely to the work and  $D_e$  is therefore larger than in external grinding.

**Grinding Cutting Forces, Torque and Power.**—Formulas to calculate the tangential cutting force, torque and required machining power are found in *Estimating Machining Power* on page 1084, but the values of  $K_c$ , specific cutting force or specific energy, are approximately 30 to 40 times higher in grinding than in turning, milling and drilling. This is primarily due to the fact that the  $ECT$  values in grinding are 1000 to 10000 times smaller, and also due to the negative rake angles of the grit. Average grinding rake angles are around  $-35$  to  $-45$  degrees.  $K_c$  for grinding unhardened steel is around 50000 to 70000  $N/mm^2$  and up to 150000 to 200000  $N/mm^2$  for hardened steels and heat resistant alloys. The grinding cutting forces are relatively small because the chip area is very small.

Fig. 8. Specific grinding force  $K_c$  vs.  $ECT$ ;  $V$  plotted

As in the other metal cutting operations, the forces vary with  $ECT$  and to a smaller extent with the wheel speed  $V$ . An example is shown in Fig. 8, where  $K_c$ , specific cutting force, is plotted versus  $ECT$  at wheel speeds between 1000 and 6000 m/min. The material is medium unhardened carbon steel ground by an aluminum oxide wheel. The impact of wheel speed is relatively small (2 to 5% lower with increasing speed).

*Example 5:* Find the cutting force when  $ECT = 0.00017$  mm, the cutting edge length (width of cut)  $CEL$  is 10 mm, and  $K_c = 150000$  N/mm<sup>2</sup>.

The chip area is  $ECT \times CEL = 0.0017$  mm<sup>2</sup>. For  $K_c = 150000$ , the cutting force is  $0.0017 \times 150000 = 255$  Newton.

Another difference compared to turning is the influence of the negative rake angles, illustrated by the ratio of  $F_H/F_C$ , where  $F_H$  is the normal force and  $F_C$  the tangential grinding force acting in the wheel speed direction.  $F_H$  is much larger than the grinding cutting force, generally  $F_H/F_C$  ratio is approximately 2 to 4. An example is shown in Fig. 9, where  $F_H/F_C$  is plotted versus  $ECT$  at wheel speeds between 1000 and 6000 m/min, under the same conditions as in Fig. 8.

Fig. 9.  $F_H/F_C$  vs.  $ECT$ ; cutting speed plotted

In both Fig. 8 and Fig. 9, it is apparent that both  $K_c$  and  $F_H/F_C$  attain maximum values for given small values of  $ECT$ , in this case approximately  $ECT = 0.00005$  mm. This fact illustrates that forces and wheel-life are closely linked; for example, wheel speed has a maximum for constant wheel-life at approximately the same values of  $ECT$  shown in the two graphs (compare with the trends illustrated in Figs. 2a, 2b, 2c, and 3). As a matter of fact, force relationships obey the same type of relationships as those of wheel-life. Colding's force relationship uses the same 5 constants as the tool life equation, but requires values for the specific cutting force at  $ECT = 0.001$  and an additional constant, obtained by a special data base generator. This requires more elaborate laboratory tests, or better, the design of a special test and follow-up program for parts running in the ordinary production.

### Grinding Data Selection Including Wheel Life

The first estimate of machine settings is based on dividing work materials into 10 groups, based on grindability, as given in Table 1. Compositions of these work materials are found in the Handbook in the section *STANDARD STEELS* starting on page 438.

Grinding wheel nomenclature is described in *American National Standard Grinding Wheel Markings* starting on page 1179. The wheel compositions are selected according to the grade recommendations in the section *The Selection of Grinding Wheels* starting on page 1180. Grinding fluid recommendations are given in *Cutting Fluids for Machining* starting on page 1143.

*Note:* Maximum wheel speeds should always be checked using the safety standards in the section *Safe Operating Speeds* starting on page 1209, because the recommendations will sometimes lead to speeds above safety levels.

The material in this section is based on the use of a typical standard wheel composition such as 51-A-46-L-5-V-23, with wheel grade (wheel hardness) = L or above, and mesh (grit size) = 46 or above.

**Table 1. Grindability Groups**

| Group                         | Examples                               |
|-------------------------------|--|
| Group 1 Unhardened Steels     |  |
| Group 2 Stainless Steels      | SAE 30201–30347, 51409–51501           |
| Group 3 Cast Iron             |  |
| Group 4 Tool Steels           | M1, M8, T1, H, O, L, F, 52100          |
| Group 5 Tool Steels           | M2, T2, T5, T6, D2, H41, H42, H43, M50 |
| Group 6 Tool Steels           | M3, M4, T3, D7                         |
| Group 7 Tool Steels           | T15, M15                               |
| Group 8 Heat Resistant Steels | Inconel, Rene etc.                     |
| Group 9 Carbide Materials     | P30 Diamond Wheel                      |
| Group 10 Ceramic Materials    |  |

For each grindability group there is one table and 2 graphs (one with Taylor lines and the other with  $SMRR$  versus wheel speed  $V$ ) that are used to get a first estimate of standardized machine settings, assuming a good system stiffness ( $K_{ST} > 30 \text{ N}/\mu\text{m}$ ). These data are then calibrated with the users own data in order to refine the estimate and optimize the grinding process, as discussed in *User Calibration of Recommendations*. The recommendations are valid for all grinding processes such as plunge grinding, cylindrical, and surface grinding with periphery or side of wheel, as well as for creep feed grinding.

The grinding data machinability system is based on the basic parameters equivalent chip thickness  $ECT$ , and wheel speed  $V$ , and is used to determine specific metal removal rates  $SMRR$  and wheel-life  $T$ , including the work speed  $V_w$  after the grinding depths for roughing and finishing are specified.

For each material group, the grinding data machinability system consists of  $T$ - $V$  Taylor lines in log-log coordinates for 3 wheel speeds at wheel lives of 1, 10 and 100 minutes wheel-life with 4 different values of equivalent chip thickness  $ECT$ . The wheel speeds are designated  $V_1$ ,  $V_{10}$ , and  $V_{100}$  respectively. In each table the corresponding specific metal removal rates  $SMRR$  are also tabulated and designated as  $SMRR_1$ ,  $SMRR_{10}$  and  $SMRR_{100}$  respectively. The user can select any value of  $ECT$  and interpolate between the Taylor lines. These curves look the same in grinding as in the other metal cutting processes and the slope is set at  $n = 0.26$ , so each Taylor line is formulated by  $V \times T^{0.26} = C$ , where  $C$  is a constant tabulated at four  $ECT$  values,  $ECT = 17, 33, 50$  and  $75 \times 10^{-5} \text{ mm}$ , for each material group. Hence, for each value of  $ECT$ ,  $V_1 \times 1^{0.26} = V_{10} \times 10^{0.26} = V_{100} \times 100^{0.26} = C$ .

**Side Feed, Roughing and Finishing.**—In cylindrical grinding, the side feed,  $f_s = C \times \text{Width}$ , does not impact on the values in the tables, but on the feed rate  $F_R$ , where the fraction of the wheel width  $C$  is usually selected for roughing and in finishing operations, as shown in the following table.

| Work Material    | Roughing, C | Finishing, C |
|------------------|-------------|--------------|
| Unhardened Steel | 2/3–3/4     | 1/3–3/8      |
| Stainless Steel  | 1/2         | 1/4          |
| Cast Iron        | 3/4         | 3/8          |
| Hardened Steel   | 1/2         | 1/4          |

**Finishing:** The depth of cut in rough grinding is determined by the allowance and usually set at  $a_r = 0.01$  to  $0.025 \text{ mm}$ . The depth of cut for finishing is usually set at  $a_f = 0.0025 \text{ mm}$  and accompanied by higher wheel speeds in order to improve surface finish. However, the most important criterion for critical parts is to increase the work speed in order to avoid thermal damage and surface cracks. In cylindrical grinding, a reduction of side feed  $f_s$

improves  $R_a$  as well. Small grit sizes are very important when very small finishes are required. See Figs. 4, 5, and 6 for reference.

#### Terms and Definitions

$a_a$  = depth of cut

$a_r$  = radial depth of cut, mm

$C$  = fraction of grinding wheel width

$CEL$  = cutting edge length, mm

$C_U$  = Taylor constant

$D$  = wheel diameter, mm

$DIST$  = grinding distance, mm

$d_w$  = work diameter, mm

$ECT$  = equivalent chip thickness =  $f(a_r, V, V_w, f_s)$ , mm

$$= 1 \div (V \div V_w \div a_r + 1 \div f_s) = \frac{V_w f_s (a_r + 1)}{V}$$

= approximately  $V_w \times a_r \div V = SMRR \div V \div 1000$

=  $z \times f_z \times a_r \times a_a \div CEL \div (\pi D)$  mm

$F_R$  = feed rate, mm/min

=  $f_s \times RPM_w$  for cylindrical grinding

=  $f_i \times RPM_w$  for plunge (in-feed) grinding

$f_i$  = in-feed in plunge grinding, mm/rev of work

$f_s$  = side feed or engaged wheel width in cylindrical grinding =  $C \times Width = a_a$  approximately equal to the cutting edge length  $CEL$

*Grinding ratio* =  $MRR \div W^* = SMRR \times T \div W^* = 1000 \times ECT \times V \times T \div W^*$

$MRR$  = metal removal rate =  $SMRR \times T = 1000 \times f_s \times a_r \times V_w$  mm<sup>3</sup>/min

$SMRR$  = specific metal removal rate obtained by dividing  $MRR$  by the engaged wheel width ( $C \times Width$ ) =  $1000 \times a_r \times V_w$  mm<sup>3</sup>/mm width/min

*Note:* 100 mm<sup>3</sup>/mm/min = 0.155 in<sup>3</sup>/in/min, and 1 in<sup>3</sup>/in/min = 645.16 mm<sup>3</sup>/mm/min

$T, T_U$  = wheel-life = *Grinding ratio*  $\times W \div (1000 \times ECT \times V)$  minutes

$t_c$  = grinding time per pass =  $DIST \div F_R$  min

=  $DIST \div F_R + t_{sp}$  (min) when spark-out time is included

= # Strokes  $\times (DIST \div F_R + t_{sp})$  (min) when spark-out time and strokes are included

$t_{sp}$  = spark-out time, minutes

$V, V_U$  = wheel speed, m/min

$V_w, V_{wU}$  = work speed =  $SMRR \div 1000 \div a_r$  m/min

$W^*$  = volume wheel wear, mm<sup>3</sup>

$Width$  = wheel width (mm)

$RPM$  = wheel speed =  $1000 \times V \div D \div \pi$  rpm

$RPM_w$  = work speed =  $1000 \times V_w \div D_w \div \pi$  rpm

**Relative Grindability.**—An overview of grindability of the data base, which must be based on a constant wheel wear rate, or wheel-life, is demonstrated using 10 minutes wheel-life shown in Table 2.

**Table 2. Grindability Overview**

| Material Group                    | $ECT \times 10^{-5}$ | $V_{10}$         | $SMRR_{10}$       | $V_w$                           |                                   |
|-----------------------------------|----------------------|------------------|-------------------|---------------------------------|-----------------------------------|
|                                   |                      |                  |                   | Roughing Depth<br>$a_r = 0.025$ | Finishing Depth<br>$a_r = 0.0025$ |
| 1 Unhardened                      | 33                   | 3827             | 1263              | 50                              | 500                               |
| 2 Stainless                       | 33                   | 1080             | 360               | 15                              | 150                               |
| 3 Cast Iron                       | 33                   | 4000             | 1320              | 53                              | 530                               |
| 4 Tool Steel                      | 33                   | 3190             | 1050              | 42                              | 420                               |
| 5 Tool Steel                      | 33                   | 2870             | 950               | 38                              | 380                               |
| 6 Tool Steel                      | 33                   | 2580             | 850               | 35                              | 350                               |
| 7 Tool Steel                      | 33                   | 1080             | 360               | 15                              | 150                               |
| 8 Heat resistant                  | 33                   | 1045             | 345               | 14                              | 140                               |
| 9 Carbide with<br>Diamond Wheel   | 5                    | $V_{600} = 1200$ | $SMRR_{600} = 50$ | 2                               | 20                                |
| 10 Ceramics with<br>Diamond Wheel | 5                    | $V_{600} = 411$  | $SMRR_{600} = 21$ | 0.84                            | 84                                |

**Procedure to Determine Data.**—The following wheel-life recommendations are designed for 4 values of  $ECT = 0.00017, 0.00033, 0.00050$  and  $0.00075$  mm (shown as 17, 33, 50 and 75 in the tables). Lower values of  $ECT$  than  $0.00010$  mm ( $0.000004$  in.) are not recommended as these may lie to the left of the  $H$ -curve.

The user selects any one of the  $ECT$  values, or interpolates between these, and selects the wheel speed for 10 or 100 minutes life, denoted by  $V_{10}$  and  $V_{100}$ , respectively. For other desired wheel lives the wheel speed can be calculated from the tabulated Taylor constants  $C$  and  $n = 0.26$  as follows:

$$(V \times T_{(desired)})^{0.26} = C, \text{ the value of which is tabulated for each } ECT \text{ value. } C \text{ is the value of cutting speed } V \text{ at } T = 1 \text{ minute, hence is the same as for the speed } V_I \\ (V_I \times 1^{0.26} = C)$$

$$V_{10}$$

$$C \div 10^{0.26} = C \div 1.82$$

$$V_{100}$$

$$C \div 100^{0.26} = C \div 3.31.$$

**Example 6:** A tool steel in material group 6 with  $ECT = 0.00033$ , has constant  $C = 4690$ ,  $V_{10} = 2578$  m/min, and  $V_{100} = 1417$  m/min. From this information, find the wheel speed for desired wheel-life of  $T = 15$  minutes and  $T = 45$  minutes

For  $T = 15$  minutes we get  $V_{15} = 4690 \div 15^{0.26} = 2319$  m/min (7730 fpm) and for  $T = 45$  minutes  $V_{45} = 4690 \div 45^{0.26} = 1743$  m/min (5810 fpm).

### The Tables are arranged in 3 sections:

1. Speeds  $V_{10}$  and  $V_I = \text{Constant CST (standard)}$  for 4  $ECT$  values  $0.00017, 0.00033, 0.00050$  and  $0.00075$  mm. Values  $C_U$  and  $V_{10U}$  refer to user calibration of the standard values in each material group, explained in the following.

2. Speeds  $V_{100}$  (first row of 3),  $V_{10}$  and  $V_I$  (last in row) corresponding to wheel lives 100, 10 and 1 minutes, for 4  $ECT$  values  $0.00017, 0.00033, 0.00050$  and  $0.00075$  mm.

3. Specific metal removal rates  $SMRR_{100}$ ,  $SMRR_{10}$  and  $SMRR_I$  corresponding to wheel lives 100, 10 and 1 minutes, for the 4  $ECT$  values  $0.00017, 0.00033, 0.00050$ , and  $0.00075$  mm

The 2 Graphs show: wheel life versus wheel speed in double logarithmic coordinates (Taylor lines); and, *SMRR* versus wheel speed in double logarithmic coordinates for 4 *ECT* values: 0.00017, 0.00033, 0.00050 and 0.00075 mm.

**User Calibration of Recommendations**

It is recommended to copy or redraw the standard graph for any of the material groups before applying the data calibration method described below. The method is based on the user's own experience and data. The procedure is described in the following and illustrated in Table 11 and Fig. 12.

Only one shop data set is needed to adjust all four Taylor lines as shown below. The required shop data is the user's wheel-life  $T_U$  obtained at the user's wheel speed  $V_U$ , the user's work speed  $V_{wU}$ , and depth of cut  $a_r$ .

1) First the user finds out which wheel-life  $T_U$  was obtained in the shop, and the corresponding wheel speed  $V_U$ , depth of cut  $a_r$  and work speed  $V_{wU}$ .

2) Second, calculate:

a)  $ECT = V_{wU} \times ar \div V_U$

b) the user Taylor constant  $C_U = V_U \times T_U^{0.26}$

$V_{10U} = C_U \div 10^{0.26}$

$V_{100U} = C_U \div 100^{0.26}$

3) Thirdly, the user Taylor line is drawn in the pertinent graph. If the user wheel-life  $T_U$  is longer than that in the standard graph the speed values will be higher, or if the user wheel-life is shorter the speeds  $C_U, V_{10U}, V_{100U}$  will be lower than the standard values  $C, V_{10}$  and  $V_{100}$ .

The results are a series of lines moved to the right or to the left of the standard Taylor lines for  $ECT = 17, 33, 50$  and  $75 \times 10^{-5}$  mm. Each standard table contains the values  $C = V_U, V_{10}, V_{100}$  and empty spaces for filling out the calculated user values:  $C_U = V_U \times T_U^{0.26}, V_{10U} = C_U \div 10^{0.26}$  and  $V_{100U} = C_U \div 100^{0.26}$ .

*Example 7:* Assume the following test results on a Group 6 material: user speed is  $V_U = 1800$  m/min, wheel-life  $T_U = 7$  minutes, and  $ECT = 0.00017$  mm. The Group 6 data is repeated below for convenience.

*Calculation Procedure*

- 1) Calculate  $V_{IU}$ ,  $V_{10U}$ ,  $V_{100U}$  and  $SMRR_{IU}$ ,  $SMRR_{10U}$ ,  $SMRR_{100U}$  for  $ECT = 0.00017$  mm
- a)  $V_{IU} =$  the user Taylor constant  $C_U = V_U \times T_U^{0.26} = 1800 \times 7^{0.26} = 2985$  m/min, and  
 $SMRR_{IU} = 1000 \times 2985 \times 0.00017 = 507$  mm<sup>3</sup>/mm width/min
- $V_{10U} = C_U \div 10^{0.26} = 2985 \div 10^{0.26} = 1640$  m/min, and  $SMRR_{10U} = 1000 \times 1640 \times 0.00017 = 279$  mm<sup>3</sup>/mm width/min
- $V_{100U} = C_U \div 100^{0.26} = 2985 \div 100^{0.26} = 900$  m/min, and  $SMRR_{100U} = 1000 \times 900 \times 0.00017 = 153$  mm<sup>3</sup>/mm width/min
- 2) For  $ECT = 0.00017$  mm, calculate the ratio of user Taylor constant to standard Taylor constant from the tables  $= C_U \div C_{ST} = C_U \div V_I = 2985 \div 5290 = 0.564$  (see Table 6 for the value of  $C_{ST} = V_I$  at  $ECT = 0.00017$  mm).
- 3) For  $ECT = 0.00033$ ,  $0.00050$ , and  $0.00075$  mm calculate the user Taylor constants from  $C_U = C_{ST} \times$  (the ratio calculated in step 2)  $= V_I \times 0.564 = V_{IU}$ . Then, calculate  $V_{10U}$  and  $V_{100U}$  and  $SMRR_{IU}$ ,  $SMRR_{10U}$ ,  $SMRR_{100U}$  using the method in items 1b) and 1c) above.
- a) For  $ECT = 0.00033$  mm
- $V_{IU} = C_U = 4690 \times 0.564 = 2645$  m/min
- $V_{10U} = C_U \div 10^{0.26} = 2645 \div 10^{0.26} = 1455$  m/min
- $V_{100U} = C_U \div 100^{0.26} = 2645 \div 100^{0.26} = 800$  m/min
- $SMRR_{IU}$ ,  $SMRR_{10U}$ , and  $SMRR_{100U} = 876, 480,$  and  $264$  mm<sup>3</sup>/mm width/min
- b) For  $ECT = 0.00050$  mm
- $V_{IU} = C_U = 3590 \times 0.564 = 2025$  m/min
- $V_{10U} = C_U \div 10^{0.26} = 2025 \div 10^{0.26} = 1110$  m/min
- $V_{100U} = C_U \div 100^{0.26} = 2025 \div 100^{0.26} = 610$  m/min
- $SMRR_{IU}$ ,  $SMRR_{10U}$ , and  $SMRR_{100U} = 1013, 555,$  and  $305$  mm<sup>3</sup>/mm width/min
- c) For  $ECT = 0.00075$  mm
- $V_{IU} = C_U = 2395 \times 0.564 = 1350$  m/min
- $V_{10U} = C_U \div 10^{0.26} = 1350 \div 10^{0.26} = 740$  m/min
- $V_{100U} = C_U \div 100^{0.26} = 1350 \div 100^{0.26} = 405$  m/min
- $SMRR_{IU}$ ,  $SMRR_{10U}$ , and  $SMRR_{100U} = 1013, 555,$  and  $305$  mm<sup>3</sup>/mm width/min

Thus, the wheel speed for any desired wheel-life at a given  $ECT$  can be calculated from  $V = C_U \div T^{0.26}$ . For example, at  $ECT = 0.00050$  mm and desired tool-life  $T = 9$ ,  $V_9 = 2025 \div 9^{0.26} = 1144$  m/min. The corresponding specific metal removal rate is  $SMRR = 1000 \times 1144 \times 0.0005 = 572$  mm<sup>3</sup>/mm width/min (0.886 in<sup>3</sup>/inch width/min).

## GRINDING FEEDS AND SPEEDS

Fig. 12. Calibration of user grinding data to standard Taylor Lines  
User Input:  $V_U = 1800$  m/min,  $T_U = 7$  minutes,  $ECT = 0.00017$  mm

**Optimization.**— As shown, a global optimum occurs along the  $G$ -curve, in selected cases for values of  $ECT$  around 0.00075, i.e. at high metal removal rates as in other machining operations. It is recommended to use the simple formula for economic life:  $T_E = 3 \times T_V$  minutes.  $T_V = T_{RPL} + 60 \times C_E \div H_R$ , minutes, where  $T_{RPL}$  is the time required to replace wheel,  $C_E = \text{cost per wheel dressing} = \text{wheel cost} + \text{cost per dressing}$ , and  $H_R$  is the hourly rate.

In grinding, values of  $T_V$  range between 2 and 5 minutes in conventional grinders, which means that the economic wheel lives range between 6 and 15 minutes indicating higher metal removal rates than are commonly used. When wheels are sharpened automatically after each stroke as in internal grinding, or when grits are continually replaced as in abrasive grinding (machining),  $T_V$  may be less than one minute. This translates into wheel lives around one minute in order to achieve minimum cost grinding.

*Grinding Cost, Optimization and Process Planning:* More accurate results are obtained when the firm collects and systemizes the information on wheel lives, wheel and work speeds, and depths of cut from production runs. A computer program can be used to plan the grinding process and apply the rules and formulas presented in this chapter. A complete grinding process planning program, such as that developed by Colding International Corporation, can be used to optimize machine settings for various feed-speed preferences corresponding wheel-life requirements, minimum cost or maximum production rate grinding, required surface finish and sparkout time; machine and fixture requirements based on the grinding forces, torque and power for sharp and worn grinding wheels; and, detailed time and cost analysis per part and per batch including wheel dressing and wheel changing schedules.

Table 12 summarizes the time and cost savings per batch as it relates to tool life. The sensitivity of how grinding parameters are selected is obvious. Minimum cost conditions yield a 51% reduction of time and 44% reduction of cost, while maximum production rate reduces total time by 65% but, at the expense of heavy wheel consumption (continuous dressing), cost by only 18%.

Table 12. Wheel Life vs. Cost

| Preferences         | Time per Batch, minutes | Cost per Batch, \$ |            | Reduction from Long Life, % |      |
|---------------------|-------------------------|--------------------|------------|-----------------------------|------|
|                     |                         | Tooling            | Total Cost | Time                        | Cost |
| Long Life           | 2995                    | 39                 | 2412       | —                           | —    |
| Economic Life       | 2433                    | 252                | 2211       | 19                          | 8    |
| Minimum Cost        | 1465                    | 199                | 1344       | 51                          | 44   |
| Max Production Rate | 1041                    | 1244               | 1980       | 65                          | 18   |

## GRINDING AND OTHER ABRASIVE PROCESSES

Processes and equipment discussed under this heading use abrasive grains for shaping workpieces by means of machining or related methods. Abrasive grains are hard crystals either found in nature or manufactured. The most commonly used materials are aluminum oxide, silicon carbide, cubic boron nitride and diamond. Other materials such as garnet, zirconia, glass and even walnut shells are used for some applications. Abrasive products are used in three basic forms by industry:

a) *Bonded* to form a solid shaped tool such as disks (the basic shape of grinding wheels), cylinders, rings, cups, segments, or sticks to name a few.

b) *Coated* on backings made of paper or cloth, in the form of sheets, strips, or belts.

c) *Loose*, held in some liquid or solid carrier (for lapping, polishing, tumbling), or propelled by centrifugal force, air, or water pressure against the work surface (blast cleaning).

The applications for abrasive processes are multiple and varied. They include:

a) *Cleaning* of surfaces, also the coarse removal of excess material—such as rough off-hand grinding in foundries to remove gates and risers.

b) *Shaping*, such as in form grinding and tool sharpening.

c) *Sizing*, a general objective, but of primary importance in precision grinding.

d) *Surface finish improvement*, either primarily as in lapping, honing, and polishing or as a secondary objective in other types of abrasive processes.

e) *Separating*, as in cut-off or slicing operations.

The main field of application of abrasive processes is in metalworking, because of the capacity of abrasive grains to penetrate into even the hardest metals and alloys. However, the great hardness of the abrasive grains also makes the process preferred for working other hard materials, such as stones, glass, and certain types of plastics. Abrasive processes are also chosen for working relatively soft materials, such as wood, rubber, etc., for such reasons as high stock removal rates, long-lasting cutting ability, good form control, and fine finish of the worked surface.

### Grinding Wheels

**Abrasive Materials.**—In earlier times, only natural abrasives were available. From about the beginning of this century, however, manufactured abrasives, primarily silicon carbide and aluminum oxide, have replaced the natural materials; even natural diamonds have been almost completely supplanted by synthetics. Superior and controllable properties, and dependable uniformity characterize the manufactured abrasives.

Both silicon carbide and aluminum oxide abrasives are very hard and brittle. This brittleness, called friability, is controllable for different applications. Friable abrasives break easily, thus forming sharp edges. This decreases the force needed to penetrate into the work material and the heat generated during cutting. Friable abrasives are most commonly used for precision and finish grinding. Tough abrasives resist fracture and last longer. They are used for rough grinding, snagging, and off-hand grinding.

As a general rule, although subject to variation:

1) Aluminum oxide abrasives are used for grinding plain and alloyed steel in a soft or hardened condition.

2) Silicon carbide abrasives are selected for cast iron, nonferrous metals, and nonmetallic materials.

3) Diamond is the best type of abrasive for grinding cemented carbides. It is also used for grinding glass, ceramics, and hardened tool steel.

4) Cubic Boron Nitride (CBN) is known by several trade names including Borazon (General Electric Co.), ABN (De Beers), Sho-bon (Showa-Denko), and Elbor (USSR). CBN is a synthetic superabrasive used for grinding hardened steels and wear-resistant superalloys. (See *Cubic Boron Nitride (CBN)* starting on page 1013.) CBN grinding wheels have long lives and can maintain close tolerances with superior surface finishes.

**Bond Properties and Grinding Wheel Grades.**—The four main types of bonds used for grinding wheels are the vitrified, resinoid, rubber, and metal.

*Vitrified bonds* are used for more than half of all grinding wheels made, and are preferred because of their strength and other desirable qualities. Being inert, glass-like materials, vitrified bonds are not affected by water or by the chemical composition of different grinding fluids. Vitrified bonds also withstand the high temperatures generated during normal grinding operations. The structure of vitrified wheels can be controlled over a wide range of strength and porosity. Vitrified wheels, however, are more sensitive to impact than those made with organic bonds.

*Resinoid bonds* are selected for wheels subjected to impact, or sudden loads, or very high operating speeds. They are preferred for snagging, portable grinder uses, or roughing operations. The higher flexibility of this type of bond—essentially a filled thermosetting plastic—helps it withstand rough treatment.

*Rubber bonds* are even more flexible than the resinoid type, and for that reason are used for producing a high finish and for resisting sudden rises in load. Rubber bonded wheels are commonly used for wet cut-off wheels because of the nearly burr-free cuts they produce, and for centerless grinder regulating wheels to provide a stronger grip and more reliable workpiece control.

*Metal bonds* are used in CBN and diamond wheels. In metal bonds produced by electrodeposition, a single layer of superabrasive material (diamond or CBN) is bonded to a metal core by a matrix of metal, usually nickel. The process is so controlled that about 30–40 per cent of each abrasive particle projects above the deposited surface, giving the wheel a very aggressive and free-cutting action. With proper use, such wheels have remarkably long lives. When dulled, or worn down, the abrasive can be stripped off and the wheel renewed by a further deposit process. These wheels are also used in electrical discharge grinding and electrochemical grinding where an electrically conductive wheel is needed.

In addition to the basic properties of the various bond materials, each can also be applied in different proportions, thereby controlling the grade of the grinding wheel.

*Grinding wheel grades* commonly associated with hardness, express the amount of bond material in a grinding wheel, and hence the strength by which the bond retains the individual grains.

During grinding, the forces generated when cutting the work material tend to dislodge the abrasive grains. As the grains get dull and if they don't fracture to resharpen themselves, the cutting forces will eventually tear the grains from their supporting bond. For a "soft" wheel the cutting forces will dislodge the abrasive grains before they have an opportunity to fracture. When a "hard" wheel is used, the situation is reversed. Because of the extra bond in the wheel the grains are so firmly held that they never break loose and the wheel becomes glazed. During most grinding operations it is desirable to have an intermediate wheel where there is a continual slow wearing process composed of both grain fracture and dislodgement.

The grades of the grinding wheels are designated by capital letters used in alphabetical order to express increasing "hardness" from A to Z.

**Grinding Wheel Structure.**—The individual grains, which are encased and held together by the bond material, do not fill the entire volume of the grinding wheel; the intermediate open space is needed for several functional purposes such as heat dissipation, coolant application, and particularly, for the temporary storage of chips. It follows that the

spacing of the grains must be greater for coarse grains which cut thicker chips and for large contact areas within which the chips have to be retained on the surface of the wheel before being disposed of. On the other hand, a wide spacing reduces the number of grains that contact the work surface within a given advance distance, thereby producing a coarser finish.

In general, denser structures are specified for grinding hard materials, for high-speed grinding operations, when the contact area is narrow, and for producing fine finishes and/or accurate forms. Wheels with open structure are used for tough materials, high stock removal rates, and extended contact areas, such as grinding with the face of the wheel. There are, however, several exceptions to these basic rules, an important one being the grinding of parts made by powder metallurgy, such as cemented carbides; although they represent one of the hardest industrial materials, grinding carbides requires wheels with an open structure.

Most kinds of general grinding operations, when carried out with the periphery of the wheel, call for medium spacing of the grains. The structure of the grinding wheels is expressed by numerals from 1 to 16, ranging from dense to open. Sometimes, "induced porosity" is used with open structure wheels. This term means that the grinding wheel manufacturer has placed filler material (which later burns out when the wheel is fired to vitrify the bond) in the grinding wheel mix. These fillers create large "pores" between grain clusters without changing the total volume of the "pores" in the grinding wheel. Thus, an A46-H12V wheel and an A46H12VP wheel will contain the same amounts of bond, abrasive, and air space. In the former, a large number of relatively small pores will be distributed throughout the wheel. The latter will have a smaller number of larger pores.

**American National Standard Grinding Wheel Markings.**—ANSI Standard B74.13-1990 "Markings for Identifying Grinding Wheels and Other Bonded Abrasives," applies to grinding wheels and other bonded abrasives, segments, bricks, sticks, hones, rubs, and other shapes that are for removing material, or producing a desired surface or dimension. It does not apply to specialties such as sharpening stones and provides only a standard system of markings. Wheels having the same standard markings but made by different wheel manufacturers may not—and probably will not—produce exactly the same grinding action. This desirable result cannot be obtained because of the impossibility of closely correlating any measurable physical properties of bonded abrasive products in terms of their grinding action.

Symbols for designating diamond and cubic boron wheel compositions are given on page 1204.

**Sequence of Markings.**—The accompanying illustration taken from ANSI B74.13-1990 shows the makeup of a typical wheel or bonded abrasive marking.

| Prefix | 1<br>Abrasive<br>Type | 2<br>Grain<br>Size | 3<br>Grade | 4<br>Structure | 5<br>Bond<br>Type | 6<br>Manufacturer's<br>Record |
|--------|-----------------------|--------------------|------------|----------------|-------------------|-------------------------------|
| 51     | A                     | 36                 | L          | 5              | V                 | 23                            |

The meaning of each letter and number in this or other markings is indicated by the following complete list.

1) *Abrasive Letters:* The letter (A) is used for aluminum oxide, (C) for silicon carbide, and (Z) for aluminum zirconium. The manufacturer may designate some particular type in any one of these broad classes, by using his own symbol as a prefix (example, 51).

2) *Grain Size:* The grain sizes commonly used and varying from coarse to very fine are indicated by the following numbers: 8, 10, 12, 14, 16, 20, 24, 30, 36, 46, 54, 60, 70, 80, 90, 100, 120, 150, 180, and 220. The following additional sizes are used occasionally: 240, 280, 320, 400, 500, and 600. The wheel manufacturer may add to the regular grain number an additional symbol to indicate a special grain combination.

3) *Grade*: Grades are indicated by letters of the alphabet from A to Z in all bonds or processes. Wheel grades from A to Z range from soft to hard.

4) *Structure*: The use of a structure symbol is optional. The structure is indicated by Nos. 1 to 16 (or higher, if necessary) with progressively higher numbers indicating a progressively wider grain spacing (more open structure).

5) *Bond or Process*: Bonds are indicated by the following letters: V, vitrified; S, silicate; E, shellac or elastic; R, rubber; RF, rubber reinforced; B, resinoid (synthetic resins); BF, resinoid reinforced; O, oxychloride.

6) *Manufacturer's Record*: The sixth position may be used for manufacturer's private factory records; this is optional.

**American National Standard Shapes and Sizes of Grinding Wheels.**—The ANSI Standard B74.2-1982 which includes shapes and sizes of grinding wheels, gives a wide variety of grinding wheel shape and size combinations. These are suitable for the majority of applications. Although grinding wheels can be manufactured to shapes and dimensions different from those listed, it is advisable, for reasons of cost and inventory control, to avoid using special shapes and sizes, unless technically warranted.

Standard shapes and size ranges as given in this Standard together with typical applications are shown in [Table 1a](#) for inch dimensions and in [Table 1b](#) for metric dimensions.

The operating surface of the grinding wheel is often referred to as the wheel face. In the majority of cases it is the periphery of the grinding wheel which, when not specified otherwise, has a straight profile. However, other face shapes can also be supplied by the grinding wheel manufacturers, and also reproduced during usage by appropriate truing. ANSI B74.2-1982 standard offers 13 different shapes for grinding wheel faces, which are shown in [Table 2](#).

**The Selection of Grinding Wheels.**—In selecting a grinding wheel, the determining factors are the composition of the work material, the type of grinding machine, the size range of the wheels used, and the expected grinding results, in this approximate order.

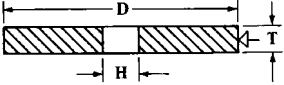

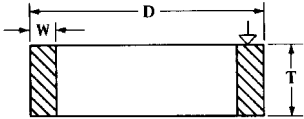

The Norton Company has developed, as the result of extensive test series, a method of grinding wheel recommendation that is more flexible and also better adapted to taking into consideration pertinent factors of the job, than are listings based solely on workpiece categories. This approach is the basis for [Tables 3](#) through [6](#), inclusive. Tool steels and constructional steels are considered in the detailed recommendations presented in these tables.

[Table 3](#) assigns most of the standardized tool steels to five different grindability groups. The AISI-SAE tool steel designations are used.

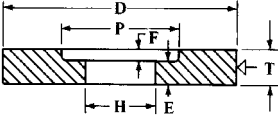

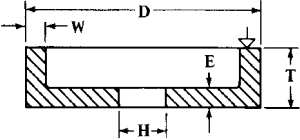

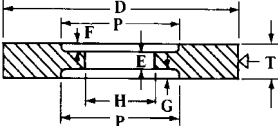

After having defined the grindability group of the tool steel to be ground, the operation to be carried out is found in the first column of [Table 4](#). The second column in this table distinguishes between different grinding wheel size ranges, because wheel size is a factor in determining the contact area between wheel and work, thus affecting the apparent hardness of the grinding wheel. Distinction is also made between wet and dry grinding.

Finally, the last two columns define the essential characteristics of the recommended types of grinding wheels under the headings of first and second choice, respectively. Where letters are used *preceding* A, the standard designation for aluminum oxide, they indicate a degree of friability different from the regular, thus: SF = semi friable (Norton equivalent 16A) and F = friable (Norton equivalent 33A and 38A). The suffix P, where applied, expresses a degree of porosity that is more open than the regular.

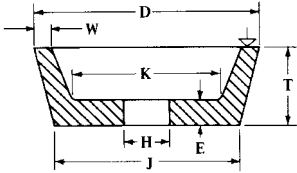

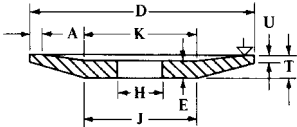

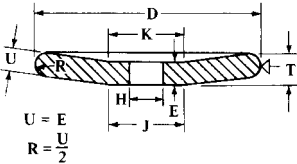

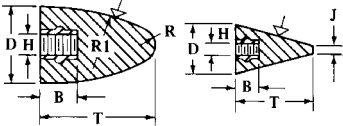

**Table 1a. Standard Shapes and Inch Size Ranges of Grinding Wheels**  
ANSI B74.2-1982

| Applications   | Size Ranges of Principal Dimensions, Inches |                                 |                                  |
|--|---|---------------------------------|----------------------------------|
|  | $D = \text{Dia.}$                           | $T = \text{Thick.}$             | $H = \text{Hole}$                |
|  <p><b>Type 1. Straight Wheel</b> For peripheral grinding.</p>  |   |                                 |                                  |
| CUTTING OFF (Organic bonds only)   | 1 to 48                                     | $\frac{1}{64}$ to $\frac{3}{8}$ | $\frac{1}{16}$ to 6              |
| CYLINDRICAL GRINDING<br>Between centers  | 12 to 48                                    | $\frac{1}{2}$ to 6              | 5 to 20                          |
| CYLINDRICAL GRINDING<br>Centerless grinding wheels   | 14 to 30                                    | 1 to 20                         | 5 or 12                          |
| CYLINDRICAL GRINDING<br>Centerless regulating wheels   | 8 to 14                                     | 1 to 12                         | 3 to 6                           |

| SURFACE GRINDING<br>Vertical spindle machines  | 8 to 20                                     | 4 or 5                          | 1 to 4                           |

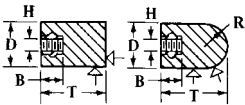

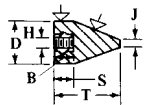

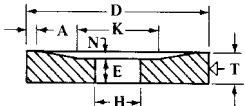

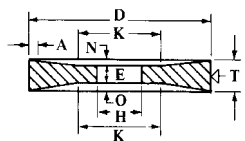

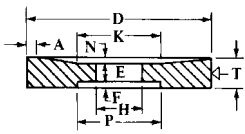

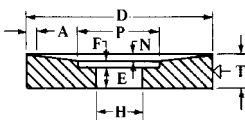

**Table 1a. (Continued) Standard Shapes and Inch Size Ranges of Grinding Wheels**  
ANSI B74.2-1982

| Applications   | Size Ranges of Principal Dimensions, Inches |            |          |
|--|---|------------|----------|
|  | D = Dia.                                    | T = Thick. | H = Hole |
|  <p><b>Type 5. Wheel</b>, recessed one side For peripheral grinding. Allows wider faced wheels than the available mounting thickness, also grinding clearance for the nut and flange.</p>   |   |            |          |
| CYLINDRICAL GRINDING<br>Between centers  | 12 to 36                                    | 1½ to 4    | 5 or 12  |
| CYLINDRICAL GRINDING<br>Centerless regulating wheel  | 8 to 14                                     | 3 to 6     | 3 or 5   |
| INTERNAL GRINDING  | ⅜ to 4                                      | ⅜ to 2     | ⅛ to ⅞   |
| SURFACE GRINDING<br>Horizontal spindle machines  | 7 to 24                                     | ¾ to 6     | 1¼ to 12 |
|  <p><b>Type 6. Straight-Cup Wheel</b> Side grinding wheel, in whose dimensioning the wall thickness (W) takes precedence over the diameter of the recess. Hole is ⅝-11UNC-2B threaded for the snagging wheels and ½ or ¼" for the tool grinding wheels.</p> |   |            |          |
|  |   |            | W = Wall |
| SNAGGING<br>Portable machines, organic bond only.  | 4 to 6                                      | 2          | ¾ to 1½  |
| TOOL GRINDING<br>Broaches, cutters, mills, reamers, taps, etc.   | 2 to 6                                      | 1¼ to 2    | ⅝ or ⅜   |
|  <p><b>Type 7. Wheel</b>, recessed two sides Peripheral grinding. Recesses allow grinding clearance for both flanges and also narrower mounting thickness than overall thickness.</p>   |   |            |          |
| CYLINDRICAL GRINDING<br>Between centers  | 12 to 36                                    | 1½ to 4    | 5 or 12  |
| CYLINDRICAL GRINDING<br>Centerless regulating wheel  | 8 to 14                                     | 4 to 20    | 3 to 6   |
| SURFACE GRINDING<br>Horizontal spindle machines  | 12 to 24                                    | 2 to 6     | 5 to 12  |

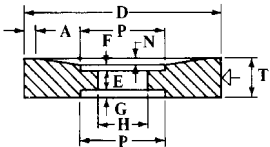

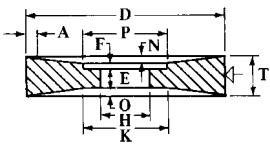

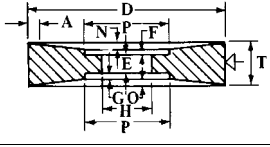

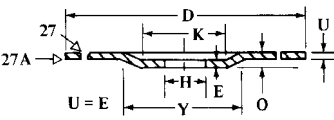

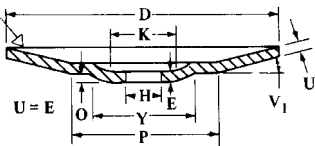

**Table 1a. (Continued) Standard Shapes and Inch Size Ranges of Grinding Wheels**  
ANSI B74.2-1982

| Applications   | Size Ranges of Principal Dimensions, Inches |   |  |
|--|---|---|--|
|  | D = Dia.                                    | T = Thick.  | H = Hole   |
|  <p><b>Type 11. Flaring-Cup Wheel</b> Side grinding wheel with wall tapered outward from the back; wall generally thicker in the back.</p>  |   |   |  |
| <p>SNAGGING<br/>Portable machines, organic bonds only, threaded hole</p> <p>TOOL GRINDING<br/>Broaches, cutters, mills, reamers, taps, etc.</p>  | 4 to 6                                      | 2   | $\frac{5}{8}$ -11 UNC-2B                                 |
|  <p><b>Type 12. Dish Wheel</b> Grinding on the side or on the U-face of the wheel, the U-face being always present in this type.</p>  |   |   |  |
| <p>TOOL GRINDING<br/>Broaches, cutters, mills, reamers, taps, etc.</p>   | 3 to 8                                      | $\frac{1}{2}$ or $\frac{3}{4}$  | $\frac{1}{2}$ to 1 $\frac{1}{4}$                         |

| SNAGGING<br>Portable machines   | 80 to 230   | $U = E = 3.2$ to 10 | 9.53 or 22.23            |

<sup>a</sup> See Table 1a for diagrams and descriptions of each wheel type.  
All dimensions in millimeters.

Table 2. Standard Shapes of Grinding Wheel Faces ANSI B74.2-1982

Recommendations, similar in principle, yet somewhat less discriminating have been developed by the Norton Company for *constructional steels*. These materials can be ground either in their original state (soft) or in their after-hardened state (directly or following carburization). Constructional steels must be distinguished from structural steels which are used primarily by the building industry in mill shapes, without or with a minimum of machining.

Constructional steels are either plain carbon or alloy type steels assigned in the AISI-SAE specifications to different groups, according to the predominant types of alloying elements. In the following recommendations no distinction is made because of different compositions since that factor generally, has a minor effect on grinding wheel choice in constructional steels. However, separate recommendations are made for soft (Table 5) and

hardened (Table 6) constructional steels. For the relatively rare instance where the use of a single type of wheel for both soft and hardened steel materials is considered more important than the selection of the best suited types for each condition of the work materials, Table 5 lists "All Around" wheels in its last column.

For applications where cool cutting properties of the wheel are particularly important, Table 6 lists, as a second alternative, porous-type wheels. The sequence of choices as presented in these tables does not necessarily represent a second, or third best; it can also apply to conditions where the first choice did not provide optimum results and by varying slightly the composition of the grinding wheel, as indicated in the subsequent choices, the performance experience of the first choice might be improved.

**Table 3. Classification of Tool Steels by their Relative Grindability**

| Relative Grindability Group  | AISI-SAE Designation of Tool Steels   |
|--|---|
| <p><i>GROUP 1—Any area of work surface</i></p> <p>High grindability tool and die steels<br/>(Grindability index greater than 12)</p>                                       | <p>W1, W2, W5<br/>S1, S2, S4, S5, S6, S7<br/>O1, O2, O6, O7<br/>H10, H11, H12, H13, H14<br/>L2, L6</p>  |
| <p><i>GROUP 2—Small area of work surface<br/>(as found in tools)</i></p> <p>Medium grindability tool and die steels<br/>(Grindability index 3 to 12)</p>                   | <p>H19, H20, H21, H22, H23, H24, H26<br/>P6, P20, P21<br/>T1, T7, T8<br/>M1, M2, M8, M10, M33, M50<br/>D1, D2, D3, D4, D5, D6<br/>A2, A4, A6, A8, A9, A10</p> |
| <p><i>GROUP 3—Small area of work surface<br/>(as found in tools)</i></p> <p>Low grindability tool and die steels<br/>(Grindability index between 1.0 and 3)</p>            | <p>T4, T5, T6, T8<br/>M3, M6, M7, M34, M36, M41, M42, M46,<br/>M48, M52, M62<br/>D2, D5<br/>A11</p>   |
| <p><i>GROUP 4—Large area of work surface<br/>(as found in dies)</i></p> <p>Medium and low grindability tool and die steels<br/>(Grindability index between 1.0 and 12)</p> | <p>All steels found in Groups 2 and 3</p>   |
| <p><i>GROUP 5—Any area of work surface</i></p> <p>Very low grindability tool and die steels<br/>(Grindability index less than 1.0)</p>                                     | <p>D3, D4, D7<br/>M4<br/>A7<br/>T15</p>   |

| Centerless                            | ...                           | Wet SFA80-M6V                | ...                            |
| Internal                              | Under ½                       | Wet SFA80-N6V                | ...                            |
|                                       | ½ to 1                        | Wet SFA60-M5V                | ...                            |
|                                       | Over 1 to 3                   | Wet SFA54-L5V                | ...                            |
|                                       | Over 3                        | Wet SFA46-K5V                | ...                            |
|                                       | Under ½                       | Dry FA80-L6V                 | ...                            |
|                                       | ½ to 1                        | Dry FA70-K8V                 | ...                            |
|                                       | Over 1 to 3                   | Dry FA60-J8V                 | FA60-H12VP                     |
|                                       | Over 3                        | Dry FA46-J8V                 | FA54-H12VP                     |

**Cubic Boron Nitride (CBN) Grinding Wheels.**—Although CBN is not quite as hard, strong, and wear-resistant as a diamond, it is far harder, stronger, and more resistant to wear than aluminum oxide and silicon carbide. As with diamond, CBN materials are available in different types for grinding workpieces of 50 Rc and above, and for superalloys of 35 Rc and harder. Microcrystalline CBN grinding wheels are suitable for grinding mild steels, medium-hard alloy steels, stainless steels, cast irons, and forged steels. Wheels with larger mesh size grains (up to 20/30), now available, provide for higher rates of metal removal.

Special types of CBN are produced for resin, vitrified, and electrodeposited bonds. Wheel standards and nomenclature generally conform to those used for diamond wheels (page 1201), except that the letter **B** instead of **D** is used to denote the type of abrasive. Grinding machines for CBN wheels are generally designed to take full advantage of the ability of CBN to operate at high surface speeds of 9,000–25,000 sfm. CBN is very responsive to changes in grinding conditions, and an increase in wheel speed from 5,000 to 10,000 sfm can increase wheel life by a factor of 6 or more. A change from a water-based coolant to a coolant such as a sulfochlorinated or sulfurized straight grinding oil can increase wheel life by a factor of 10 or more.

Machines designed specifically for use with CBN grinding wheels generally use either electrodeposited wheels or have special truing systems for other CBN bond wheels, and are totally enclosed so they can use oil as a coolant. Numerical control systems are used, often running fully automatically, including loading and unloading. Machines designed for CBN grinding with electrodeposited wheels are extensively used for form and gear grinding, special systems being used to ensure rapid mounting to exact concentricity and truth in running, no truing or dressing being required. CBN wheels can produce workpieces having excellent accuracy and finish, with no truing or dressing for the life of the wheel, even over many hours or days of production grinding of hardened steel components.

Resin-, metal-, and vitrified-bond wheels are used extensively in production grinding, in standard and special machines. Resin-bonded wheels are used widely for dry tool and cutter resharpening on conventional hand-operated tool and cutter grinders. A typical wheel for such work would be designated 11V9 cup type, 100/120 mesh, 75 concentration, with a  $\frac{1}{16}$  or  $\frac{1}{8}$  in. rim section. Special shapes of resin-bonded wheels are used on dedicated machines for cutting tool manufacture. These types of wheels are usually self-dressing, and allow full machine control of the operation without the need for an operator to see, hear, or feel the action.

Metal-bonded CBN wheels are usually somewhat cheaper than those using other types of bond because only a thin layer of abrasive is present. Metal bonding is also used in manufacture of CBN honing stones. Vitrified-bond CBN wheels are a recent innovation, and high-performance bonds are still being developed. These wheels are used for grinding cams, internal diameters, and bearing components, and can be easily redressed.

An important aspect of grinding with CBN and diamond wheels is reduced heating of the workpiece, thought to result from their superior thermal conductivity compared with aluminum oxide, for instance. CBN and diamond grains also are harder, which means that they stay sharp longer than aluminum oxide grains. The superior ability to absorb heat from the workpiece during the grinding process reduces formation of untempered martensite in the ground surface, caused by overheating followed by rapid quenching. At the same time, a higher compressive residual stress is induced in the surface, giving increased fatigue resistance, compared with the tensile stresses found in surfaces ground with aluminum oxide abrasives. Increased fatigue resistance is of particular importance for gear grinding, especially in the root area.

**Variations from General Grinding Wheel Recommendations.**—Recommendations for the selection of grinding wheels are usually based on average values with regard to both operational conditions and process objectives. With variations from such average values,

the composition of the grinding wheels must be adjusted to obtain optimum results. Although it is impossible to list and to appraise all possible variations and to define their effects on the selection of the best suited grinding wheels, some guidance is obtained from experience. The following tabulation indicates the general directions in which the characteristics of the initially selected grinding wheel may have to be altered in order to approach optimum performance. Variations in a sense opposite to those shown will call for wheel characteristic changes in reverse.

| Conditions or Objectives                  | Direction of Change   |
|---|---|
| To increase cutting rate                  | Coarser grain, softer bond, higher porosity   |
| To retain wheel size and/or form          | Finer grain, harder bond  |
| For small or narrow work surface          | Finer grain, harder bond  |
| For larger wheel diameter                 | Coarser grain   |
| To improve finish on work                 | Finer grain, harder bond, or resilient bond   |
| For increased work speed or feed rate     | Harder bond   |
| For increased wheel speed                 | Generally, softer bond, except for high-speed grinding, which requires a harder bond for added wheel strength |
| For interrupted or coarse work surface    | Harder bond   |
| For thin walled parts                     | Softer bond   |
| To reduce load on the machine drive motor | Softer bond   |

**Dressing and Truing Grinding Wheels.**—The perfect grinding wheel operating under ideal conditions will be self sharpening, i.e., as the abrasive grains become dull, they will tend to fracture and be dislodged from the wheel by the grinding forces, thereby exposing new, sharp abrasive grains. Although in precision machine grinding this ideal sometimes may be partially attained, it is almost never attained completely. Usually, the grinding wheel must be dressed and trued after mounting on the precision grinding machine spindle and periodically thereafter.

Dressing may be defined as any operation performed on the face of a grinding wheel that improves its cutting action. Truing is a dressing operation but is more precise, i.e., the face of the wheel may be made parallel to the spindle or made into a radius or special shape. Regularly applied truing is also needed for accurate size control of the work, particularly in automatic grinding. The tools and processes generally used in grinding wheel dressing and truing are listed and described in [Table 1](#).

**Table 1. Tools and Methods for Grinding Wheel Dressing and Truing**

| Designation            | Description   | Application   |
|------------------------|---|---|
| Rotating Hand Dressers | Freely rotating discs, either star-shaped with protruding points or discs with corrugated or twisted perimeter, supported in a fork-type handle, the lugs of which can lean on the tool rest of the grinding machine. | Preferred for bench- or floor-type grinding machines; also for use on heavy portable grinders (snagging grinders) where free-cutting properties of the grinding wheel are primarily sought and the accuracy of the trued profile is not critical. |
| Abrasive Sticks        | Made of silicon carbide grains with a hard bond. Applied directly or supported in a handle. Less frequently abrasive sticks are also made of boron carbide.   | Usually hand held and use limited to smaller-size wheels. Because it also shears the grains of the grinding wheel, or preshaping, prior to final dressing with, e.g., a diamond.  |

**Table 1. (Continued) Tools and Methods for Grinding Wheel Dressing and Truing**

| Designation                              | Description   | Application  |
|--|---|--|
| Abrasive Wheels (Rolls)                  | Silicon carbide grains in a hard vitrified bond are cemented on ball-bearing mounted spindles. Use either as hand tools with handles or rigidly held in a supporting member of the grinding machine. Generally freely rotating; also available with adjustable brake for diamond wheel dressing.                | Preferred for large grinding wheels as a diamond saver, but also for improved control of the dressed surface characteristics. By skewing the abrasive dresser wheel by a few degrees out of parallel with the grinding wheel axis, the basic crushing action is supplemented with wiping and shearing, thus producing the desired degree of wheel surface smoothness.                              |
| Single-Point Diamonds                    | A diamond stone of selected size is mounted in a steel nib of cylindrical shape with or without head, dimensioned to fit the truing spindle of specific grinding machines. Proper orientation and retainment of the diamond point in the setting is an important requirement.                                   | The most widely used tool for dressing and truing grinding wheels in precision grinding. Permits precisely controlled dressing action by regulating infeed and cross feed rate of the truing spindle when the latter is guided by cams or templates for accurate form truing.  |
| Single-Point Form Truing Diamonds        | Selected diamonds having symmetrically located natural edges with precisely lapped diamond points, controlled cone angles and vertex radius, and the axis coinciding with that of the nib.  | Used for truing operations requiring very accurately controlled, and often steeply inclined wheel profiles, such as are needed for thread and gear grinding, where one or more diamond points participate in generating the resulting wheel periphery form. Dependent on specially designed and made truing diamonds and nibs.   |
| Cluster-Type Diamond Dresser             | Several, usually seven, smaller diamond stones are mounted in spaced relationship across the working surface of the nib. In some tools, more than a single layer of such clusters is set at parallel levels in the matrix, the deeper positioned layer becoming active after the preceding layer has worn away. | Intended for straight-face dressing and permits the utilization of smaller, less expensive diamond stones. In use, the holder is canted at a 3° to 10° angle, bringing two to five points into contact with the wheel. The multiple-point contact permits faster cross feed rates during truing than may be used with single-point diamonds for generating a specific degree of wheel-face finish. |
| Impregnated Matrix-Type Diamond Dressers | The operating surface consists of a layer of small, randomly distributed, yet rather uniformly spaced diamonds that are retained in a bond holding the points in an essentially common plane. Supplied either with straight or canted shaft, the latter being used to cancel the tilt of angular truing posts.  | For the truing of wheel surfaces consisting of a single or several flat elements. The nib face should be held tangent to the grinding wheel periphery or parallel with a flat working surface. Offers economic advantages where technically applicable because of using less expensive diamond splinters presented in a manner permitting efficient utilization.                                   |
| Form-Generating Truing Devices           | Swiveling diamond holder post with adjustable pivot location, arm length, and swivel arc, mounted on angularly adjustable cross slides with controlled traverse movement, permits the generation of various straight and circular profile elements, kept in specific mutual locations.                          | Such devices are made in various degrees of complexity for the positionally controlled interrelation of several different profile elements. Limited to regular straight and circular sections, yet offers great flexibility of setup, very accurate adjustment, and unique versatility for handling a large variety of frequently changing profiles.   |

**Table 1. (Continued) Tools and Methods for Grinding Wheel Dressing and Truing**

| Designation                                      | Description   | Application   |
|--|---|---|
| Contour-Duplicating Truing Devices               | The form of a master, called cam or template, shaped to match the profile to be produced on the wheel, or its magnified version, is translated into the path of the diamond point by means of mechanical linkage, a fluid actuator, or a pantograph device.   | Preferred single-point truing method for profiles to be produced in quantities warranting the making of special profile bars or templates. Used also in small- and medium-volume production when the complexity of the profile to be produced excludes alternate methods of form generation.  |
| Grinding Wheel Contouring by Crush Truing        | A hardened steel or carbide roll, which is free to rotate and has the desired form of the workpiece, is fed gradually into the grinding wheel, which runs at slow speed. The roll will, by crushing action, produce its reverse form in the wheel. Crushing produces a free-cutting wheel face with sharp grains. | Requires grinding machines designed for crush truing, having stiff spindle bearings, rigid construction, slow wheel speed for truing, etc. Due to the cost of crush rolls and equipment, the process is used for repetitive work only. It is one of the most efficient methods for precisely duplicating complex wheel profiles that are capable of grinding in the 8-microinch AA range. Applicable for both surface and cylindrical grinding. |
| Rotating Diamond Roll-Type Grinding Wheel Truing | Special rolls made to agree with specific profile specifications have their periphery coated with a large number of uniformly distributed diamonds, held in a matrix into which the individual stones are set by hand (for larger diamonds) or bonded by a plating process (for smaller elements).                | The diamond rolls must be rotated by an air, hydraulic, or electric motor at about one-fourth of the grinding wheel surface speed and in opposite direction to the wheel rotation. Whereas the initial costs are substantially higher than for single-point diamond truing the savings in truing time warrants the method's application in large-volume production of profile-ground components.  |
| Diamond Dressing Blocks                          | Made as flat blocks for straight wheel surfaces, are also available for radius dressing and profile truing. The working surface consists of a layer of electroplated diamond grains, uniformly distributed and capable of truing even closely toleranced profiles.  | For straight wheels, dressing blocks can reduce dressing time and offer easy installation on surface grinders, where the blocks mount on the magnetic plate. Recommended for small- and medium-volume production for truing intricate profiles on regular surface grinders, because the higher pressure developed in crush dressing is avoided.   |

**Guidelines for Truing and Dressing with Single-Point Diamonds.**—The diamond nib should be canted at an angle of 10 to 15 degrees in the direction of the wheel rotation and also, if possible, by the same amount in the direction of the cross feed traverse during the truing (see diagram). The dragging effect resulting from this “angling,” combined with the occasional rotation of the diamond nib in its holder, will prolong the diamond life by limiting the extent of wear facets and will also tend to produce a pyramid shape of the diamond tip. The diamond may also be set to contact the wheel at about  $\frac{1}{8}$  to  $\frac{1}{4}$  inch below its centerline.

*Depth of Cut:* This amount should not exceed 0.001 inch per pass for general work, and will have to be reduced to 0.0002 to 0.0004 inch per pass for wheels with fine grains used for precise finishing work.

*Diamond crossfeed rate:* This value may be varied to some extent depending on the required wheel surface: faster crossfeed for free cutting, and slower crossfeed for produc-

ing fine finishes. Such variations, however, must always stay within the limits set by the grain size of the wheel. Thus, the advance rate of the truing diamond per wheel revolution should not exceed the diameter of a grain or be less than half of that rate. Consequently, the diamond crossfeed must be slower for a large wheel than for a smaller wheel having the same grain size number.

Typical crossfeed values for frequently used grain sizes are given in Table 2.

**Table 2. Typical Diamond Truing and Crossfeeds**

|                               |             |             |              |             |
|-------------------------------|-------------|-------------|--------------|-------------|
| Grain Size                    | 30          | 36          | 46           | 50          |
| Crossfeed per Wheel Rev., in. | 0.014–0.024 | 0.012–0.019 | 0.008–0.014  | 0.007–0.012 |
| Grain Size                    | 60          | 80          | 120          | ...         |
| Crossfeed per Wheel Rev., in. | 0.006–0.010 | 0.004–0.007 | 0.0025–0.004 | ...         |

These values can be easily converted into the more conveniently used inch-per-minute units, simply by multiplying them by the rpm of the grinding wheel.

*Example:* For a 20-inch diameter wheel, Grain No. 46, running at 1200 rpm: Crossfeed rate for roughing-cut truing—approximately 17 ipm, for finishing-cut truing—approximately 10 ipm

*Coolant* should be applied before the diamond comes into contact with the wheel and must be continued in generous supply while truing.

*The speed of the grinding wheel* should be at the regular grinding rate, or not much lower. For that reason, the feed wheels of centerless grinding machines usually have an additional speed rate higher than functionally needed, that speed being provided for wheel truing only.

*The initial approach of the diamond* to the wheel surface must be carried out carefully to prevent sudden contact with the diamond, resulting in penetration in excess of the selected depth of cut. It should be noted that the highest point of a worn wheel is often in its center portion and not at the edge from which the crossfeed of the diamond starts.

*The general conditions* of the truing device are important for best truing results and for assuring extended diamond life. A rigid truing spindle, well-seated diamond nib, and firmly set diamond point are mandatory. Sensitive infeed and smooth traverse movement at uniform speed also must be maintained.

*Resetting of the diamond point:* Never let the diamond point wear to a degree where the grinding wheel is in contact with the steel nib. Such contact can damage the setting of the diamond point and result in its loss. Expert resetting of a worn diamond can repeatedly add to its useful life, even when applied to lighter work because of reduced size.

**Size Selection Guide for Single-Point Truing Diamonds.**—There are no rigid rules for determining the proper size of the diamond for any particular truing application because of the very large number of factors affecting that choice. Several of these factors are related to the condition, particularly the rigidity, of the grinding machine and truing device, as well as to such characteristics of the diamond itself as purity, crystalline structure, etc. Although these factors are difficult to evaluate in a generally applicable manner, the expected effects of several other conditions can be appraised and should be considered in the selection of the proper diamond size.

The recommended sizes in [Table 3](#) must be considered as informative only and as representing minimum values for generally favorable conditions. Factors calling for larger diamond sizes than listed are the following:

Silicon carbide wheels ([Table 3](#) refers to aluminum oxide wheels)

Dry truing

Grain sizes coarser than No. 46

Bonds harder than M

Wheel speed substantially higher than 6500 sfm.

It is advisable to consider any single or pair of these factors as justifying the selection of one size larger diamond. As an example: for truing an SiC wheel, with grain size No. 36 and hardness P, select a diamond that is two sizes larger than that shown in [Table 3](#) for the wheel size in use.

**Table 3. Recommended Minimum Sizes for Single-Point Truing Diamonds**

| Diamond Size<br>in Carats <sup>a</sup> | Index Number<br>(Wheel Dia. × Width<br>in Inches) | Examples of Max. Grinding Wheel<br>Dimensions |       |
|--|---|---|-------|
|  |   | Diameter                                      | Width |
| 0.25                                   | 3   | 4   | 0.75  |
| 0.35                                   | 6   | 6   | 1     |
| 0.50                                   | 10  | 8   | 1.25  |
| 0.60                                   | 15  | 10  | 1.50  |
| 0.75                                   | 21  | 12  | 1.75  |
| 1.00                                   | 30  | 12  | 2.50  |
| 1.25                                   | 48  | 14  | 3.50  |
| 1.50                                   | 65  | 16  | 4.00  |
| 1.75                                   | 80  | 20  | 4.00  |
| 2.00                                   | 100   | 20  | 5.00  |
| 2.50                                   | 150   | 24  | 6.00  |
| 3.00                                   | 200   | 24  | 8.00  |
| 3.50                                   | 260   | 30  | 8.00  |
| 4.00                                   | 350   | 36  | 10.00 |

<sup>a</sup> One carat equals 0.2 gram.

Single-point diamonds are available as loose stones, but are preferably procured from specialized manufacturers supplying the diamonds set into steel nibs. Expert setting, comprising both the optimum orientation of the stone and its firm retainment, is mandatory for assuring adequate diamond life and satisfactory truing. Because the holding devices for truing diamonds are not yet standardized, the required nib dimensions vary depending on the make and type of different grinding machines. Some nibs are made with angular heads, usually hexagonal, to permit occasional rotation of the nib either manually, with a wrench, or automatically.

### Diamond Wheels

**Diamond Wheels.**—A diamond wheel is a special type of grinding wheel in which the abrasive elements are diamond grains held in a bond and applied to form a layer on the operating face of a non-abrasive core. Diamond wheels are used for grinding very hard or highly abrasive materials. Primary applications are the grinding of cemented carbides, such as the sharpening of carbide cutting tools; the grinding of glass, ceramics, asbestos, and cement products; and the cutting and slicing of germanium and silicon.

**Shapes of Diamond Wheels.**—The industry-wide accepted Standard (ANSI B74.3-1974) specifies ten basic diamond wheel core shapes which are shown in Table 1 with the applicable designation symbols. The applied diamond abrasive layer may have different cross-sectional shapes. Those standardized are shown in Table 2. The third aspect which is standardized is the location of the diamond section on the wheel as shown by the diagrams in Table 3. Finally, modifications of the general core shape together with pertinent designation letters are given in Table 4.

The characteristics of the wheel shape listed in these four tables make up the components of the standard designation symbol for diamond wheel shapes. An example of that symbol with arbitrarily selected components is shown in Fig. 1.

Fig. 1. A Typical Diamond Wheel Shape Designation Symbol

An explanation of these components is as follows:

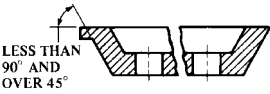

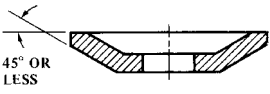

**Basic Core Shape:** This portion of the symbol indicates the basic shape of the core on which the diamond abrasive section is mounted. The shape is actually designated by a number. The various core shapes and their designations are given in Table 1.

**Diamond Cross-Section Shape:** This, the second component, consisting of one or two letters, denotes the cross-sectional shape of the diamond abrasive section. The various shapes and their corresponding letter designations are given in Table 2.

**Diamond Section Location:** The third component of the symbol consists of a number which gives the location of the diamond section, i.e., periphery, side, corner, etc. An explanation of these numbers is shown in Table 3.

**Modification:** The fourth component of the symbol is a letter designating some modification, such as drilled and counterbored holes for mounting or special relieving of diamond section or core. This modification position of the symbol is used only when required. The modifications and their designations are given in Table 4.

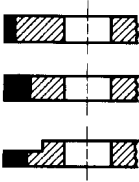

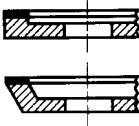

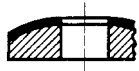

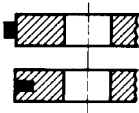

**Table 1. Diamond Wheel Core Shapes and Designations** *ANSI B74.3-1974*

|   |   |   |    |

**Table 3. Designations for Location of Diamond Section on Diamond Wheel** *ANSI B74.3-1974*

| Designation No. and Location | Description   | Illustration  |
|------------------------------|---|---|
| 1 — Periphery                | The diamond section shall be placed on the periphery of the core and shall extend the full thickness of the wheel. The axial length of this section may be greater than, equal to, or less than the depth of diamond, measured radially. A hub or hubs shall not be considered as part of the wheel thickness for this definition.                |    |
| 2 — Side                     | The diamond section shall be placed on the side of the wheel and the length of the diamond section shall extend from the periphery toward the center. It may or may not include the entire side and shall be greater than the diamond depth measured axially. It shall be on that side of the wheel which is commonly used for grinding purposes. |    |
| 3 — Both Sides               | The diamond sections shall be placed on both sides of the wheel and shall extend from the periphery toward the center. They may or may not include the entire sides, and the radial length of the diamond section shall exceed the axial diamond depth.   |    |
| 4 — Inside Bevel or Arc      | This designation shall apply to the general wheel types 2, 6, 11, 12, and 15 and shall locate the diamond section on the side wall. This wall shall have an angle or arc extending from a higher point at the wheel periphery to a lower point toward the wheel center.   |   |
| 5 — Outside Bevel or Arc     | This designation shall apply to the general wheel types, 2, 6, 11, and 15 and shall locate the diamond section on the side wall. This wall shall have an angle or arc extending from a lower point at the wheel periphery to a higher point toward the wheel center.  |  |
| 6 — Part of Periphery        | The diamond section shall be placed on the periphery of the core but shall not extend the full thickness of the wheel and shall not reach to either side.   |  |
| 7 — Part of Side             | The diamond section shall be placed on the side of the core and shall not extend to the wheel periphery. It may or may not extend to the center.  |  |

**Table 3. (Continued) Designations for Location of Diamond Section on Diamond Wheel ANSI B74.3-1974**

| Designation No. and Location | Description  | Illustration  |
|------------------------------|--|---|
| 8 — Throughout               | Designates wheels of solid diamond abrasive section without cores.   |  |
| 9 — Corner                   | Designates a location which would commonly be considered to be on the periphery except that the diamond section shall be on the corner but shall not extend to the other corner. |  |
| 10 — Annular                 | Designates a location of the diamond abrasive section on the inner annular surface of the wheel.   |  |

**Composition of Diamond and Cubic Boron Nitride Wheels.**—According to American National Standard ANSI B74.13-1990, a series of symbols is used to designate the composition of these wheels. An example is shown below.

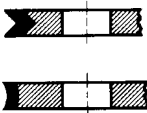

| Prefix   | Abrasive | Grain Size | Grade    | Concentration | Bond Type | Bond Modification | Depth of Abrasive | Manufacturer's Identification Symbol |
|----------|----------|------------|----------|---------------|-----------|-------------------|-------------------|--------------------------------------|
| <b>M</b> | <b>D</b> | <b>120</b> | <b>R</b> | <b>100</b>    | <b>B</b>  | <b>56</b>         | $\frac{1}{8}$     | <b>*</b>                             |

Fig. 2. Designation Symbols for Composition of Diamond and Cubic Boron Nitride Wheels

The meaning of each symbol is indicated by the following list:

- 1) *Prefix*: The prefix is a manufacturer's symbol indicating the exact kind of abrasive. Its use is optional.
- 2) *Abrasive Type*: The letter (B) is used for cubic boron nitride and (D) for diamond.
- 3) *Grain Size*: The grain sizes commonly used and varying from coarse to very fine are indicated by the following numbers: 8, 10, 12, 14, 16, 20, 24, 30, 36, 46, 54, 60, 70, 80, 90, 100, 120, 150, 180, and 220. The following additional sizes are used occasionally: 240, 280, 320, 400, 500, and 600. The wheel manufacturer may add to the regular grain number an additional symbol to indicate a special grain combination.
- 4) *Grade*: Grades are indicated by letters of the alphabet from A to Z in all bonds or processes. Wheel grades from A to Z range from soft to hard.
- 5) *Concentration*: The concentration symbol is a manufacturer's designation. It may be a number or a symbol.
- 6) *Bond*: Bonds are indicated by the following letters: B, resinoid; V, vitrified; M, metal.
- 7) *Bond Modification*: Within each bond type a manufacturer may have modifications to tailor the bond to a specific application. These modifications may be identified by either letters or numbers.
- 8) *Abrasive Depth*: Abrasive section depth, in inches or millimeters (inches illustrated), is indicated by a number or letter which is the amount of total dimensional wear a user may expect from the abrasive portion of the product. Most diamond and CBN wheels are made with a depth of coating on the order of  $\frac{1}{16}$  in.,  $\frac{1}{8}$  in., or more as specified. In some cases the diamond is applied in thinner layers, as thin as one thickness of diamond grains. The L is included in the marking system to identify a layered type product.
- 9) *Manufacturer's Identification Symbol*: The use of this symbol is optional.

**Table 4. Designation Letters for Modifications of Diamond Wheels**  
ANSI B74.3-1974

| Designation Letter <sup>a</sup> | Description   | Illustration  |
|---------------------------------|---|---|
| B — Drilled and Counterbored    | Holes drilled and counterbored in core.   |    |
| C — Drilled and Countersunk     | Holes drilled and countersunk in core.  |    |
| H — Plain Hole                  | Straight hole drilled in core.  |    |
| M — Holes Plain and Threaded    | Mixed holes, some plain, some threaded, are in core.  |    |
| P — Relieved One Side           | Core relieved on one side of wheel. Thickness of core is less than wheel thickness.   |    |
| R — Relieved Two Sides          | Core relieved on both sides of wheel. Thickness of core is less than wheel thickness.   |    |
| S — Segmented-Diamond Section   | Wheel has segmental diamond section mounted on core. (Clearance between segments has no bearing on definition.)   |   |
| SS — Segmental and Slotted      | Wheel has separated segments mounted on a slotted core.   |  |
| T — Threaded Holes              | Threaded holes are in core.   |  |
| Q — Diamond Inserted            | Three surfaces of the diamond section are partially or completely enclosed by the core.   |  |
| V — Diamond Inverted            | Any diamond cross section, which is mounted on the core so that the interior point of any angle, or the concave side of any arc, is exposed shall be considered inverted.<br><i>Exception:</i> Diamond cross section AH shall be placed on the core with the concave side of the arc exposed. |  |

<sup>a</sup> Y — Diamond Inserted and Inverted. See definitions for Q and V.

**The Selection of Diamond Wheels.**—Two general aspects must be defined: (a) The shape of the wheel, also referred to as the basic wheel type and (b) The specification of the abrasive portion.

**Table 5. General Diamond Wheel Recommendations for Wheel Type and Abrasive Specification**

| Typical Applications or Operation   | Basic Wheel Type | Abrasive Specification  |
|---|------------------|---|
| Single Point Tools (offhand grinding)   | D6A2C            | <i>Rough:</i> MD100-N100-B $\frac{1}{8}$<br><i>Finish:</i> MD220-P75-B $\frac{1}{8}$  |
| Single Point Tools (machine ground)   | D6A2H            | <i>Rough:</i> MD180-J100-B $\frac{1}{8}$<br><i>Finish:</i> MD320-L75-B $\frac{1}{8}$  |
| Chip Breakers   | D1A1             | MD150-R100-B $\frac{1}{8}$  |
| Multitooth Tools and Cutters (face mills, end mills, reamers, broaches, etc.) | D11V9            | <i>Rough:</i> MD100-R100-B $\frac{1}{8}$<br><i>Combination:</i> MD150-R100-B $\frac{1}{8}$<br><i>Finish:</i> MD220-R100-B $\frac{1}{8}$ |
| Sharpening and Backing off  |                  |   |
| Fluting   |                  | D12A2   |
| Saw Sharpening  | D12A2            | MD180-R100-B $\frac{1}{8}$  |
| Surface Grinding (horizontal spindle)   | D1A1             | <i>Rough:</i> MD120-N100-B $\frac{1}{8}$<br><i>Finish:</i> MD240-P100-B $\frac{1}{8}$   |
| Surface Grinding (vertical spindle)   | D2A2T            | MD80-R75-B $\frac{1}{8}$  |
| Cylindrical or Centertype Grinding  | D1A1             | MD120-P100-B $\frac{1}{8}$  |
| Internal Grinding   | D1A1             | MD150-N100-B $\frac{1}{8}$  |
| Slotting and Cutoff   | D1A1R            | MD150-R100-B $\frac{1}{4}$  |
| Lapping   | Disc             | MD400-L50-B $\frac{1}{16}$  |
| Hand Honing   | DH1, DH2         | <i>Rough:</i> MD220-B $\frac{1}{16}$<br><i>Finish:</i> MD320-B $\frac{1}{6}$  |

General recommendations for the dry grinding, with resin bond diamond wheels, of most grades of cemented carbides of average surface to ordinary finishes at normal rates of metal removal with average size wheels, as published by Cincinnati Milacron, are listed in [Table 5](#).

A further set of variables are *the dimensions of the wheel*, which must be adapted to the available grinding machine and, in some cases, to the configuration of the work.

The general abrasive specifications in [Table 5](#) may be modified to suit operating conditions by the following suggestions:

Use softer wheel grades for harder grades of carbides, for grinding larger areas or larger or wider wheel faces.

Use harder wheel grades for softer grades of carbides, for grinding smaller areas, for using smaller and narrower face wheels and for light cuts.

Use fine grit sizes for harder grades of carbides and to obtain better finishes.

Use coarser grit sizes for softer grades of carbides and for roughing cuts.

Use higher diamond concentration for harder grades of carbides, for larger diameter or wider face wheels, for heavier cuts, and for obtaining better finish.

**Guidelines for the Handling and Operation of Diamond Wheels.**—Grinding machines used for grinding with diamond wheels should be of the precision type, in good service condition, with true running spindles and smooth slide movements.

*Mounting of Diamond Wheels:* Wheel mounts should be used which permit the precise centering of the wheel, resulting in a runout of less than 0.001 inch axially and 0.0005 inch radially. These conditions should be checked with a 0.0001-inch type dial indicator. Once mounted and centered, the diamond wheel should be retained on its mount and stored in that condition when temporarily removed from the machine.

*Truing and Dressing:* Resinoid bonded diamond wheels seldom require dressing, but when necessary a soft silicon carbide stick may be hand-held against the wheel. Peripheral and cup type wheels may be sharpened by grinding the cutting face with a 60 to 80 grit silicon carbide wheel. This can be done with the diamond wheel mounted on the spindle of the machine, and with the silicon carbide wheel driven at a relatively slow speed by a specially designed table-mounted grinder or by a small table-mounted tool post grinder. The diamond wheel can be mounted on a special arbor and ground on a lathe with a tool post grinder; peripheral wheels can be ground on a cylindrical grinder or with a special brake-controlled truing device with the wheel mounted on the machine on which it is used. Cup and face type wheels are often lapped on a cast iron or glass plate using a 100 grit silicon carbide abrasive. Care must be used to lap the face parallel to the back, otherwise they must be ground to restore parallelism. Peripheral diamond wheels can be trued and dressed by grinding a silicon carbide block or a special diamond impregnated bronze block in a manner similar to surface grinding. Conventional diamonds must not be used for truing and dressing diamond wheels.

**Speeds and Feeds in Diamond Grinding.**—General recommendations are as follows:

*Wheel Speeds:* The generally recommended wheel speeds for diamond grinding are in the range of 5000 to 6000 surface feet per minute, with this upper limit as a maximum to avoid harmful "overspeeding." Exceptions from that general rule are diamond wheels with coarse grains and high concentration (100 per cent) where the wheel wear in dry surface grinding can be reduced by lowering the speed to 2500–3000 sfpm. However, this lower speed range can cause rapid wheel breakdown in finer grit wheels or in those with reduced diamond concentration.

*Work Speeds:* In diamond grinding, work rotation and table traverse are usually established by experience, adjusting these values to the selected infeed so as to avoid excessive wheel wear.

*Infeed per Pass:* Often referred to as downfeed and usually a function of the grit size of the wheel. The following are general values which may be increased for raising the productivity, or lowered to improve finish or to reduce wheel wear.

| Wheel Grit Size Range | Infeed per Pass |
|-----------------------|-----------------|
| 100 to 120            | 0.001 inch      |
| 150 to 220            | 0.0005 inch     |
| 250 and finer         | 0.00025 inch    |

### Grinding Wheel Safety

**Safety in Operating Grinding Wheels.**—Grinding wheels, although capable of exceptional cutting performance due to hardness and wear resistance, are prone to damage caused by improper handling and operation. Vitrified wheels, comprising the major part of grinding wheels used in industry, are held together by an inorganic bond which is actually

a type of pottery product and therefore brittle and breakable. Although most of the organic bond types are somewhat more resistant to shocks, it must be realized that all grinding wheels are conglomerates of individual grains joined by a bond material whose strength is limited by the need of releasing the dull, abrasive grains during use.

It must also be understood that during the grinding process very substantial forces act on the grinding wheel, including the centrifugal force due to rotation, the grinding forces resulting from the resistance of the work material, and shocks caused by sudden contact with the work. To be able to resist these forces, the grinding wheel must have a substantial minimum strength throughout that is well beyond that needed to hold the wheel together under static conditions.

Finally, a damaged grinding wheel can disintegrate during grinding, liberating dormant forces which normally are constrained by the resistance of the bond, thus presenting great hazards to both operator and equipment.

To avoid breakage of the operating wheel and, should such a mishap occur, to prevent damage or injury, specific precautions must be applied. These safeguards have been formulated into rules and regulations and are set forth in the American National Standard ANSI B7.1-1988, entitled the American National Standard Safety Requirements for the Use, Care, and Protection of Abrasive Wheels.

**Handling, Storage and Inspection.**—Grinding wheels should be hand carried, or transported, with proper support, by truck or conveyor. A grinding wheel must not be rolled around on its periphery.

The storage area, positioned not far from the location of the grinding machines, should be free from excessive temperature variations and humidity. Specially built racks are recommended on which the smaller or thin wheels are stacked lying on their sides and the larger wheels in an upright position on two-point cradle supports consisting of appropriately spaced wooden bars. Partitions should separate either the individual wheels, or a small group of identical wheels. Good accessibility to the stored wheels reduces the need of undesirable handling.

Inspection will primarily be directed at detecting visible damage, mostly originating from handling and shipping. Cracks which are not obvious can usually be detected by “ring testing,” which consists of suspending the wheel from its hole and tapping it with a non-metallic implement. Heavy wheels may be allowed to rest vertically on a clean, hard floor while performing this test. A clear metallic tone, a “ring”, should be heard; a dead sound being indicative of a possible crack or cracks in the wheel.

**Machine Conditions.**—The general design of the grinding machines must ensure safe operation under normal conditions. The bearings and grinding wheel spindle must be dimensioned to withstand the expected forces and ample driving power should be provided to ensure maintenance of the rated spindle speed. For the protection of the operator, stationary machines used for dry grinding should have a provision made for connection to an exhaust system and when used for off-hand grinding, a work support must be available.

Wheel guards are particularly important protection elements and their material specifications, wall thicknesses and construction principles should agree with the Standard's specifications. The exposure of the wheel should be just enough to avoid interference with the grinding operation. The need for access of the work to the grinding wheel will define the boundary of guard opening, particularly in the direction of the operator.

**Grinding Wheel Mounting.**—The mass and speed of the operating grinding wheel makes it particularly sensitive to imbalance. Vibrations that result from such conditions are harmful to the machine, particularly the spindle bearings, and they also affect the ground surface, i.e., wheel imbalance causes chatter marks and interferes with size control. Grinding wheels are shipped from the manufacturer's plant in a balanced condition, but retaining the balanced state after mounting the wheel is quite uncertain. Balancing of the mounted wheel is thus required, and is particularly important for medium and large size

wheels, as well as for producing accurate and smooth surfaces. The most common way of balancing mounted wheels is by using balancing flanges with adjustable weights. The wheel and balancing flanges are mounted on a short balancing arbor, the two concentric and round stub ends of which are supported in a balancing stand.

Such stands are of two types: 1) the parallel straight-edged, which must be set up precisely level; and 2) the disk type having two pairs of ball bearing mounted overlapping disks, which form a V for containing the arbor ends without hindering the free rotation of the wheel mounted on that arbor.

The wheel will then rotate only when it is out of balance and its heavy spot is not in the lowest position. Rotating the wheel by hand to different positions will move the heavy spot, should such exist, from the bottom to a higher location where it can reveal its presence by causing the wheel to turn. Having detected the presence and location of the heavy spot, its effect can be cancelled by displacing the weights in the circular groove of the flange until a balanced condition is accomplished.

Flanges are commonly used means for holding grinding wheels on the machine spindle. For that purpose, the wheel can either be mounted directly through its hole or by means of a sleeve which slips over a tapered section of the machine spindle. Either way, the flanges must be of equal diameter, usually not less than one-third of the new wheel's diameter. The purpose is to securely hold the wheel between the flanges without interfering with the grinding operation even when the wheel becomes worn down to the point where it is ready to be discarded. Blotters or flange facings of compressible material should cover the entire contact area of the flanges.

One of the flanges is usually fixed while the other is loose and can be removed and adjusted along the machine spindle. The movable flange is held against the mounted grinding wheel by means of a nut engaging a threaded section of the machine spindle. The sense of that thread should be such that the nut will tend to tighten as the spindle revolves. In other words, to remove the nut, it must be turned in the direction that the spindle revolves when the wheel is in operation.

**Safe Operating Speeds.**—Safe grinding processes are predicated on the proper use of the previously discussed equipment and procedures, and are greatly dependent on the application of adequate operating speeds.

The Standard establishes maximum speeds at which grinding wheels can be operated, assigning the various types of wheels to several classification groups. Different values are listed according to bond type and to wheel strength, distinguishing between low, medium and high strength wheels.

For the purpose of general information, the accompanying table shows an abbreviated version of the Standard's specification. However, for the governing limits, the authoritative source is the manufacturer's tag on the wheel which, particularly for wheels of lower strength, might specify speeds below those of the table.

All grinding wheels of 6 inches or greater diameter must be test run in the wheel manufacturer's plant at a speed that for all wheels having operating speeds in excess of 5000 sfpm is 1.5 times the maximum speed marked on the tag of the wheel.

The table shows the permissible wheel speeds in surface feet per minute (sfpm) units, whereas the tags on the grinding wheels state, for the convenience of the user, the maximum operating speed in revolutions per minute (rpm). The sfpm unit has the advantage of remaining valid for worn wheels whose rotational speed may be increased to the applicable sfpm value. The conversion from either one to the other of these two kinds of units is a matter of simple calculation using the formulas:

$$\text{sfpm} = \text{rpm} \times \frac{D}{12} \times \pi \quad \text{or} \quad \text{rpm} = \frac{\text{sfpm} \times 12}{D \times \pi}$$

where  $D$  = maximum diameter of the grinding wheel, in inches. **Table 2**, showing the conversion values from surface speed into rotational speed, can be used for the direct reading of the rpm values corresponding to several different wheel diameters and surface speeds.

**Special Speeds:** Continuing progress in grinding methods has led to the recognition of certain advantages that can result from operating grinding wheels above, sometimes even higher than twice, the speeds considered earlier as the safe limits of grinding wheel operations. Advantages from the application of high speed grinding are limited to specific processes, but the Standard admits, and offers code regulations for the use of wheels at special high speeds. These regulations define the structural requirements of the grinding machine and the responsibilities of the grinding wheel manufacturers, as well as of the users. High speed grinding should not be applied unless the machines, particularly guards, spindle assemblies, and drive motors, are suitable for such methods. Also, appropriate grinding wheels expressly made for special high speeds must be used and, of course, the maximum operating speeds indicated on the wheel's tag must never be exceeded.

**Portable Grinders.**—The above discussed rules and regulations, devised primarily for stationary grinding machines apply also to portable grinders. In addition, the details of various other regulations, specially applicable to different types of portable grinders are discussed in the Standard, which should be consulted, particularly for safe applications of portable grinding machines.

**Table 1. Maximum Peripheral Speeds for Grinding Wheels  
Based on ANSI B7.1–1988**

| Classification No. | Types of Wheels <sup>a</sup>  | Maximum Operating Speeds, sfpm,<br>Depending on Strength of Bond |                              |
|--------------------|---|--|------------------------------|
|                    |   | Inorganic Bonds  | Organic Bonds                |
| 1                  | Straight wheels — Type 1, except classifications 6, 7, 9, 10, 11, and 12 below<br>Taper Side Wheels — Type 4 <sup>b</sup><br>Types 5, 7, 20, 21, 22, 23, 24, 25, 26<br>Dish wheels — Type 12<br>Saucer wheels — Type 13<br>Cones and plugs — Types 16, 17, 18, 19 | 5,500 to 6,500   | 6,500 to 9,500               |
| 2                  | Cylinder wheels — Type 2<br>Segments  | 5,000 to 6,000   | 5,000 to 7,000               |
| 3                  | Cup shape tool grinding wheels — Types 6 and 11 (for fixed base machines)   | 4,500 to 6,000   | 6,000 to 8,500               |
| 4                  | Cup shape snagging wheels — Types 6 and 11 (for portable machines)  | 4,500 to 6,500   | 6,000 to 9,500               |
| 5                  | Abrasive disks  | 5,500 to 6,500   | 5,500 to 8,500               |
| 6                  | Reinforced wheels — except cutting-off wheels (depending on diameter and thickness)   | ...  | 9,500 to 16,000              |
| 7                  | Type 1 wheels for bench and pedestal grinders, Types 1 and 5 also in certain sizes for surface grinders   | 5,500 to 7,550   | 6,500 to 9,500               |
| 8                  | Diamond and cubic boron nitride wheels<br>Metal bond<br>Steel centered cutting off  | to 6,500<br>to 12,000<br>to 16,000                               | to 9,500<br>...<br>to 16,000 |
| 9                  | Cutting-off wheels — Larger than 16-inch diameter (incl. reinforced organic)  | ...  | 9,500 to 14,200              |
| 10                 | Cutting-off wheels — 16-inch diameter and smaller (incl. reinforced organic)  | ...  | 9,500 to 16,000              |
| 11                 | Thread and flute grinding wheels  | 8,000 to 12,000  | 8,000 to 12,000              |
| 12                 | Crankshaft and camshaft grinding wheels   | 5,500 to 8,500   | 6,500 to 9,500               |

<sup>a</sup> See **Tables 1a** and **1b** starting on page 1181.

<sup>b</sup> Non-standard shape. For snagging wheels, 16 inches and larger — Type 1, internal wheels — Types 1 and 5, and mounted wheels, see ANSI B7.1–1988. Under no conditions should a wheel be operated faster than the maximum operating speed established by the manufacturer.

Values in this table are for general information only.

**Table 2. Revolutions per Minute for Various Grinding Speeds and Wheel Diameters (Based on ANSI B7.1-1988)**

| Wheel Diameter, Inch | Peripheral (Surface) Speed, Feet per Minute |        |        |        |        |        |        |        |        |        |        |        |        |        |        | Wheel Diameter, Inch |        |
|----------------------|---|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|----------------------|--------|

### Cylindrical Grinding

Cylindrical grinding designates a general category of various grinding methods that have the common characteristic of rotating the workpiece around a fixed axis while grinding outside surface sections in controlled relation to that axis of rotation.

The form of the part or section being ground in this process is frequently cylindrical, hence the designation of the general category. However, the shape of the part may be tapered or of curvilinear profile; the position of the ground surface may also be perpendicular to the axis; and it is possible to grind concurrently several surface sections, adjacent or separated, of equal or different diameters, located in parallel or mutually inclined planes, etc., as long as the condition of a common axis of rotation is satisfied.

*Size Range of Workpieces and Machines:* Cylindrical grinding is applied in the manufacture of miniature parts, such as instrument components and, at the opposite extreme, for grinding rolling mill rolls weighing several tons. Accordingly, there are cylindrical grinding machines of many different types, each adapted to a specific work-size range. Machine capacities are usually expressed by such factors as maximum work diameter, work length and weight, complemented, of course, by many other significant data.

**Plain, Universal, and Limited-Purpose Cylindrical Grinding Machines.**—The plain cylindrical grinding machine is considered the basic type of this general category, and is used for grinding parts with cylindrical or slightly tapered form.

The universal cylindrical grinder can be used, in addition to grinding the basic cylindrical forms, for the grinding of parts with steep tapers, of surfaces normal to the part axis, including the entire face of the workpiece, and for internal grinding independently or in conjunction with the grinding of the part's outer surfaces. Such variety of part configurations requiring grinding is typical of work in the tool room, which constitutes the major area of application for universal cylindrical grinding machines.

Limited-purpose cylindrical grinders are needed for special work configurations and for high-volume production, where productivity is more important than flexibility of adaptation. Examples of limited-purpose cylindrical grinding machines are crankshaft and camshaft grinders, polygonal grinding machines, roll grinders, etc.

**Traverse or Plunge Grinding.**—In traverse grinding, the machine table carrying the work performs a reciprocating movement of specific travel length for transporting the rotating workpiece along the face of the grinding wheel. At each or at alternate stroke ends, the wheel slide advances for the gradual feeding of the wheel into the work. The length of the surface that can be ground by this method is generally limited only by the stroke length of the machine table. In large roll grinders, the relative movement between work and wheel is accomplished by the traverse of the wheel slide along a stationary machine table.

In plunge grinding, the machine table, after having been set, is locked and, while the part is rotating, the wheel slide continually advances at a preset rate, until the finish size of the part is reached. The width of the grinding wheel is a limiting factor of the section length that can be ground in this process. Plunge grinding is required for profiled surfaces and for the simultaneous grinding of multiple surfaces of different diameters or located in different planes.

When the configuration of the part does not make use of either method mandatory, the choice may be made on the basis of the following general considerations: traverse grinding usually produces a better finish, and the productivity of plunge grinding is generally higher.

**Work Holding on Cylindrical Grinding Machines.**—The manner in which the work is located and held in the machine during the grinding process determines the configuration of the part that can be adapted for cylindrical grinding and affects the resulting accuracy of the ground surface. The method of work holding also affects the attainable production rate, because the mounting and dismounting of the part can represent a substantial portion of the total operating time.

Whatever method is used for holding the part on cylindrical types of grinding machines, two basic conditions must be satisfied: 1) the part should be located with respect to its correct axis of rotation; and 2) the work drive must cause the part to rotate, at a specific speed, around the established axis.

The lengthwise location of the part, although controlled, is not too critical in traverse grinding; however, in plunge grinding, particularly when shoulder sections are also involved, it must be assured with great accuracy.

Table 1 presents a listing, with brief discussions, of work-holding methods and devices that are most frequently used in cylindrical grinding.

**Table 1. Work-Holding Methods and Devices for Cylindrical Grinding**

| Designation                                     | Description  | Discussion   |
|---|--|--|
| Centers, nonrotating ("dead"), with drive plate | Headstock with nonrotating spindle holds the center. Around the spindle, an independently supported sleeve carries the drive plate for rotating the work. Tailstock for opposite center. | The simplest method of holding the work between two opposite centers is also the potentially most accurate, as long as correctly prepared and located center holes are used in the work.                           |
| Centers, driving type                           | Work held between two centers obtains its rotation from the concurrently applied drive by the live headstock spindle and live tailstock spindle.   | Eliminates the drawback of the common center-type grinding with driver plate, which requires a dog attached to the workpiece. Driven spindles permit the grinding of the work up to both ends.                     |
| Chuck, geared, or cam-actuated                  | Two, three, or four jaws moved radially through mechanical elements, hand-, or power-operated, exert concentrically acting clamping force on the workpiece.                              | Adaptable to workpieces of different configurations and within a generally wide capacity of the chuck. Flexible in uses that, however, do not include high-precision work.   |
| Chuck, diaphragm                                | Force applied by hand or power of a flexible diaphragm causes the attached jaws to deflect temporarily for accepting the work, which is held when force is released.                     | Rapid action and flexible adaptation to different work configurations by means of special jaws offer varied uses for the grinding of disk-shaped and similar parts.  |
| Collets   | Holding devices with externally or internally acting clamping force, easily adaptable to power actuation, assuring high centering accuracy.  | Limited to parts with previously machined or ground holding surfaces, because of the small range of clamping movement of the collet jaws.  |
| Face plate                                      | Has four independently actuated jaws, any or several of which may be used, or entirely removed, using the base plate for supporting special clamps.                                      | Used for holding bulky parts, or those of awkward shape, which are ground in small quantities not warranting special fixtures.   |
| Magnetic plate                                  | Flat plates, with pole distribution adapted to the work, are mounted on the spindle like chucks and may be used for work with the locating face normal to the axis.                      | Applicable for light cuts such as are frequent in tool making, where the rapid clamping action and easy access to both the O.D. and the exposed face are sometimes of advantage.                                   |
| Steady rests                                    | Two basic types are used: (a) the two-jaw type supporting the work from the back (back rest), leaving access by the wheel; (b) the three-jaw type (center rest).                         | A complementary work-holding device, used in conjunction with primary work holders, to provide additional support, particularly to long and/or slender parts.  |
| Special fixtures                                | Single-purpose devices, designed for a particular workpiece, primarily for providing special locating elements.  | Typical workpieces requiring special fixturing are, as examples, crankshafts where the holding is combined with balancing functions; or internal gears located on the pitch circle of the teeth for O.D. grinding. |

**Selection of Grinding Wheels for Cylindrical Grinding.**—For cylindrical grinding, as for grinding in general, the primary factor to be considered in wheel selection is the work material. Other factors are the amount of excess stock and its rate of removal (speeds and feeds), the desired accuracy and surface finish, the ratio of wheel and work diameter, wet or dry grinding, etc. In view of these many variables, it is not practical to set up a complete

list of grinding wheel recommendations with general validity. Instead, examples of recommendations embracing a wide range of typical applications and assuming common practices are presented in Table 2. This is intended as a guide for the starting selection of grinding-wheel specifications which, in case of a not entirely satisfactory performance, can be refined subsequently. The content of the table is a version of the grinding-wheel recommendations for cylindrical grinding by the Norton Company using, however, non-proprietary designations for the abrasive types and bonds.

**Table 2. Wheel Recommendations for Cylindrical Grinding**

| Material                   | Wheel Marking | Material                 | Wheel Marking |
|----------------------------|---------------|--------------------------|---------------|
| Aluminum                   | SFA46-18V     | Forgings                 | A46-M5V       |
| Armatures (laminated)      | SFA100-18V    | Gages (plug)             | SFA80-K8V     |
| Axles (auto & railway)     | A54-M5V       | General-purpose grinding | SFA54-L5V     |
| Brass                      | C36-KV        | Glass                    | BFA220-011V   |
| Bronze                     |               | Gun barrels              |               |
| Soft                       | C36-KV        | Spotting and O.D.        | BFA60-M5V     |
| Hard                       | A46-M5V       | Nitralloy                |               |
| Bushings (hardened steel)  | BFA60-L5V     | Before nitriding         | A60-K5V       |
| Bushings (cast iron)       | C36-JV        | After nitriding          |               |
| Cam lobes (cast alloy)     |               | Commercial finish        | SFA60-18V     |
| Roughing                   | BFA54-N5V     | High finish              | C100-1V       |
| Finishing                  | A70-P6B       | Reflective finish        | C500-19E      |
| Cam lobes (hardened steel) |               | Pistons (aluminum)       | SFA46-18V     |
| Roughing                   | BFA54-L5V     | (cast iron)              | C36-KV        |
| Finishing                  | BFA80-T8B     | Plastics                 | C46-JV        |
| Cast iron                  | C36-JV        | Rubber                   |               |
| Chromium plating           |               | Soft                     | SFA20-K5B     |
| Commercial finish          | SFA60-J8V     | Hard                     | C36-KB        |
| High finish                | A150-K5E      | Spline shafts            | SFA60-N5V     |
| Reflective finish          | C500-19E      | Sprayed metal            | C60-JV        |
| Commutators (copper)       | C60-M4E       | Steel                    |               |
| Crankshafts (airplane)     |               | Soft                     |               |
| Pins                       | BFA46-K5V     | 1 in. dia. and smaller   | SFA60-M5V     |
| Bearings                   | A46-L5V       | over 1 in. dia.          | SFA46-L5V     |
| Crankshafts (automotive    |               | Hardened                 |               |
| pins and bearings)         |               | 1 in. dia. and smaller   | SFA80-L8V     |
| Finishing                  | A54-N5V       | over 1 in. dia.          | SFA60-K5V     |
| Roughing & finishing       | A54-O5V       | 300 series stainless     | SFA46-K8V     |
| Regrinding                 | A54-M5V       | Stellite                 | BFA46-M5V     |
| Regrinding, sprayed        |               | Titanium                 | C60-JV        |
| metal                      | C60-JV        | Valve stems (automotive) | BFA54-N5V     |
| Drills                     | BFA54-N5V     | Valve tappets            | BFA54-M5V     |

Note: Prefixes to the standard designation "A" of aluminum oxide indicate modified abrasives as follows: BFA = Blended friable (a blend of regular and friable), SFA = Semifriable.

**Operational Data for Cylindrical Grinding.**—In cylindrical grinding, similarly to other metalcutting processes, the applied speed and feed rates must be adjusted to the operational conditions as well as to the objectives of the process. Grinding differs, however, from other types of metalcutting methods in regard to the cutting speed of the tool which, in grinding, is generally not a variable; it should be maintained at, or close to the optimum rate, commonly 6500 feet per minute peripheral speed.

In establishing the proper process values for grinding, of prime consideration are the work material, its condition (hardened or soft), and the type of operation (roughing or finishing). Other influencing factors are the characteristics of the grinding machine (stability, power), the specifications of the grinding wheel, the material allowance, the rigidity and

balance of the workpiece, as well as several grinding process conditions, such as wet or dry grinding, the manner of wheel truing, etc.

Variables of the cylindrical grinding process, often referred to as *grinding data*, comprise the speed of work rotation (measured as the surface speed of the work); the infeed (in inches per pass for traverse grinding, or in inches per minute for plunge grinding); and, in the case of traverse grinding, the speed of the reciprocating table movement (expressed either in feet per minute, or as a fraction of the wheel width for each revolution of the work).

For the purpose of starting values in setting up a cylindrical grinding process, a brief listing of basic data for common cylindrical grinding conditions and involving frequently used materials, is presented in [Table 3](#).

**Table 3. Basic Process Data for Cylindrical Grinding**

| Traverse Grinding  |                                |                         |                   |               |  |               |
|--------------------|--------------------------------|-------------------------|-------------------|---------------|--|---------------|
| Work Material      | Material Condition             | Work Surface Speed, fpm | Infeed, Inch/Pass |               | Traverse for Each Work Revolution, In Fractions of the Wheel Width |               |
|                    |                                |                         | Roughing          | Finishing     | Roughing   | Finishing     |
| Plain Carbon Steel | Annealed                       | 100                     | 0.002             | 0.0005        | $\frac{1}{2}$  | $\frac{1}{6}$ |
|                    | Hardened                       | 70                      | 0.002             | 0.0003–0.0005 | $\frac{1}{4}$  | $\frac{1}{8}$ |
| Alloy Steel        | Annealed                       | 100                     | 0.002             | 0.0005        | $\frac{1}{2}$  | $\frac{1}{6}$ |
|                    | Hardened                       | 70                      | 0.002             | 0.0002–0.0005 | $\frac{1}{4}$  | $\frac{1}{8}$ |
| Tool Steel         | Annealed                       | 60                      | 0.002             | 0.0005 max.   | $\frac{1}{2}$  | $\frac{1}{6}$ |
|                    | Hardened                       | 50                      | 0.002             | 0.0001–0.0005 | $\frac{1}{4}$  | $\frac{1}{8}$ |
| Copper Alloys      | Annealed or Cold Drawn         | 100                     | 0.002             | 0.0005 max.   | $\frac{1}{3}$  | $\frac{1}{6}$ |
| Aluminum Alloys    | Cold Drawn or Solution Treated | 150                     | 0.002             | 0.0005 max.   | $\frac{1}{3}$  | $\frac{1}{6}$ |

| Plunge Grinding                |   |           |
|--------------------------------|---|-----------|
| Work Material                  | Infeed per Revolution of the Work, Inch |           |
|                                | Roughing                                | Finishing |
| Steel, soft                    | 0.0005                                  | 0.0002    |
| Plain carbon steel, hardened   | 0.0002                                  | 0.000050  |
| Alloy and tool steel, hardened | 0.0001                                  | 0.000025  |

These data, which are, in general, considered conservative, are based on average operating conditions and may be modified subsequently by: a) reducing the values in case of unsatisfactory quality of the grinding or the occurrence of failures; and b) increasing the rates for raising the productivity of the process, particularly for rigid workpieces, substantial stock allowance, etc.

**High-Speed Cylindrical Grinding.**—The maximum peripheral speed of the wheels in regular cylindrical grinding is generally 6500 feet per minute; the commonly used grinding wheels and machines are designed to operate efficiently at this speed. Recently, efforts were made to raise the productivity of different grinding methods, including cylindrical grinding, by increasing the peripheral speed of the grinding wheel to a substantially higher than traditional level, such as 12,000 feet per minute or more. Such methods are designated by the distinguishing term of high-speed grinding.

For high-speed grinding, special grinding machines have been built with high dynamic stiffness and static rigidity, equipped with powerful drive motors, extra-strong spindles and bearings, reinforced wheel guards, etc., and using grinding wheels expressly made and tested for operating at high peripheral speeds. The higher stock-removal rate accomplished by high-speed grinding represents an advantage when the work configuration and material permit, and the removable stock allowance warrants its application.

**CAUTION:** High-speed grinding must *not* be applied on standard types of equipment, such as general types of grinding machines and regular grinding wheels. Operating grinding wheels, even temporarily, at higher than approved speed constitutes a grave safety hazard.

**Areas and Degrees of Automation in Cylindrical Grinding.**—Power drive for the work rotation and for the reciprocating table traverse are fundamental machine movements that, once set for a certain rate, will function without requiring additional attention. Loading and removing the work, starting and stopping the main movements, and applying infeed by hand wheel are carried out by the operator on cylindrical grinding machines in their basic degree of mechanization. Such equipment is still frequently used in tool room and jobbing-type work.

More advanced levels of automation have been developed for cylindrical grinders and are being applied in different degrees, particularly in the following principal respects:

a) *Infeed*, in which different rates are provided for rapid approach, roughing and finishing, followed by a spark-out period, with presetting of the advance rates, the cutoff points, and the duration of time-related functions.

b) *Automatic cycling* actuated by a single lever to start work rotation, table reciprocation, grinding-fluid supply, and infeed, followed at the end of the operation by wheel slide retraction, the successive stopping of the table movement, the work rotation, and the fluid supply.

c) *Table traverse dwells* (tarry) in the extreme positions of the travel, over preset periods, to assure uniform exposure to the wheel contact of the entire work section.

d) *Mechanized work loading*, clamping, and, after termination of the operation, unloading, combined with appropriate work-feeding devices such as indexing-type drums.

e) *Size control* by in-process or post-process measurements. Signals originated by the gage will control the advance movement or cause automatic compensation of size variations by adjusting the cutoff points of the infeed.

f) *Automatic wheel dressing* at preset frequency, combined with appropriate compensation in the infeed movement.

g) *Numerical control* obviates the time-consuming setups for repetitive work performed on small- or medium-size lots. As an application example: shafts with several sections of different lengths and diameters can be ground automatically in a single operation, grinding the sections in consecutive order to close dimensional limits, controlled by an in-process gage, which is also automatically set by means of the program.

The choice of the grinding machine functions to be automated and the extent of automation will generally be guided by economic considerations, after a thorough review of the available standard and optional equipment. Numerical control of partial or complete cycles is being applied to modern cylindrical and other grinding machines.

**Cylindrical Grinding Troubles and Their Correction.**—Troubles that may be encountered in cylindrical grinding may be classified as work defects (chatter, checking, burning, scratching, and inaccuracies), improperly operating machines (jumpy infeed or traverse), and wheel defects (too hard or soft action, loading, glazing, and breakage). The Landis Tool Company has listed some of these troubles, their causes, and corrections as follows:

*Chatter:* Sources of chatter include: 1) faulty coolant; 2) wheel out of balance; 3) wheel out of round; 4) wheel too hard; 5) improper dressing; 6) faulty work support or rotation; 7) improper operation; 8) faulty traverse; 9) work vibration; 10) outside vibration transmitted to machine; 11) interference; 12) wheel base; and 13) headstock.

Suggested procedures for correction of these troubles are:

1) *Faulty coolant:* Clean tanks and lines. Replace dirty or heavy coolant with correct mixture.

2) *Wheel out of balance:* Rebalance on mounting before and after dressing. Run wheel without coolant to remove excess water. Store a removed wheel on its side to keep retained

water from causing a false heavy side. Tighten wheel mounting flanges. Make sure wheel center fits spindle.

3) *Wheel out of round*: True before and after balancing. True sides to face.

4) *Wheel too hard*: Use coarser grit, softer grade, more open bond. See *Wheel Defects* on page 1219.

5) *Improper dressing*: Use sharp diamond and hold rigidly close to wheel. It must not overhang excessively. Check diamond in mounting.

6) *Faulty work support or rotation*: Use sufficient number of work rests and adjust them more carefully. Use proper angles in centers of work. Clean dirt from footstock spindle and be sure spindle is tight. Make certain that work centers fit properly in spindles.

7) *Improper operation*: Reduce rate of wheel feed.

8) *Faulty traverse*: See *Uneven Traverse or Infeed of Wheel Head* on page 1219.

9) *Work vibration*: Reduce work speed. Check workpiece for balance.

10) *Outside vibration transmitted to machine*: Check and make sure that machine is level and sitting solidly on foundation. Isolate machine or foundation.

11) *Interference*: Check all guards for clearance.

12) *Wheel base*: Check spindle bearing clearance. Use belts of equal lengths or uniform cross-section on motor drive. Check drive motor for unbalance. Check balance and fit of pulleys. Check wheel feed mechanism to see that all parts are tight.

13) *Headstock*: Put belts of same length and cross-section on motor drive; check for correct work speeds. Check drive motor for unbalance. Make certain that headstock spindle is not loose. Check work center fit in spindle. Check wear of face plate and jackshaft bearings.

*Spirals on Work (traverse lines with same lead on work as rate of traverse)*: Sources of spirals include: 1) machine parts out of line; and 2) truing.

Suggested procedures for correction of these troubles are:

1) *Machine parts out of line*: Check wheel base, headstock, and footstock for proper alignment.

2) *Truing*: Point truing tool down 3 degrees at the workwheel contact line. Round off wheel edges.

*Check Marks on Work*: Sources of check marks include: 1) improper operation; 2) improper heat treatment; 3) improper size control; 4) improper wheel; and 5) improper dressing.

Suggested procedures for correction of these troubles are:

1) *Improper operation*: Make wheel act softer. See *Wheel Defects*. Do not force wheel into work. Use greater volume of coolant and a more even flow. Check the correct positioning of coolant nozzles to direct a copious flow of clean coolant at the proper location.

2) *Improper heat treatment*: Take corrective measures in heat-treating operations.

3) *Improper size control*: Make sure that engineering establishes reasonable size limits. See that they are maintained.

4) *Improper wheel*: Make wheel act softer. Use softer-grade wheel. Review the grain size and type of abrasive. A finer grit or more friable abrasive or both may be called for.

5) *Improper dressing*: Check that the diamond is sharp, of good quality, and well set. Increase speed of the dressing cycle. Make sure diamond is not cracked.

*Burning and Discoloration of Work*: Sources of burning and discoloration are: improper operation and improper wheel.

Suggested procedures for correction of these troubles are:

1) *Improper operation*: Decrease rate of infeed. Don't stop work while in contact with wheel.

2) *Improper wheel*: Use softer wheel or obtain softer effect. See *Wheel Defects*. Use greater volume of coolant.

*Isolated Deep Marks on Work:* Source of trouble is an unsuitable wheel. Use a finer wheel and consider a change in abrasive type.

*Fine Spiral or Thread on Work:* Sources of this trouble are: 1) improper operation; and 2) faulty wheel dressing.

Suggested procedures for corrections of these troubles are:

1) *Improper operation:* Reduce wheel pressure. Use more work rests. Reduce traverse with respect to work rotation. Use different traverse rates to break up pattern when making numerous passes. Prevent edge of wheel from penetrating by dressing wheel face parallel to work.

2) *Faulty wheel dressing:* Use slower or more even dressing traverse. Set dressing tool at least 3 degrees down and 30 degrees to the side from time to time. Tighten holder. Don't take too deep a cut. Round off wheel edges. Start dressing cut from wheel edge.

*Narrow and Deep Regular Marks on Work:* Source of trouble is that the wheel is too coarse. Use finer grain size.

*Wide, Irregular Marks of Varying Depth on Work:* Source of trouble is too soft a wheel. Use a harder grade wheel. See *Wheel Defects*.

*Widely Spaced Spots on Work:* Sources of trouble are oil spots or glazed areas on wheel face. Balance and true wheel. Keep oil from wheel face.

*Irregular "Fish-tail" Marks of Various Lengths and Widths on Work:* Source of trouble is dirty coolant. Clean tank frequently. Use filter for fine finish grinding. Flush wheel guards after dressing or when changing to finer wheel.

*Wavy Traverse Lines on Work:* Source of trouble is wheel edges. Round off. Check for loose thrust on spindle and correct if necessary.

*Irregular Marks on Work:* Cause is loose dirt. Keep machine clean.

*Deep, Irregular Marks on Work:* Source of trouble is loose wheel flanges. Tighten and make sure blotters are used.

*Isolated Deep Marks on Work:* Sources of trouble are: 1) grains pull out; coolant too strong; 2) coarse grains or foreign matter in wheel face; and 3) improper dressing.

Respective suggested procedures for corrections of these troubles are: 1) decrease soda content in coolant mixture; 2) dress wheel; and 3) use sharper dressing tool.

Brush wheel after dressing with stiff bristle brush.

*Grain Marks on Work:* Sources of trouble are: 1) improper finishing cut; 2) grain sizes of roughing and finishing wheels differ too much; 3) dressing too coarse; and 4) wheel too coarse or too soft.

Respective suggested procedures for corrections of these troubles are: start with high work and traverse speeds; finish with high work speed and slow traverse, letting wheel "spark-out" completely; finish out better with roughing wheel or use finer roughing wheel; use shallower and slower cut; and use finer grain size or harder-grade wheel.

*Inaccuracies in Work:* Work out-of-round, out-of-parallel, or tapered.

Sources of trouble are: 1) misalignment of machine parts; 2) work centers; 3) improper operation; 4) coolant; 5) wheel; 6) improper dressing; 7) spindle bearings; and 8) work.

Suggested procedures for corrections of these troubles are:

1) *Misalignment of machine parts:* Check headstock and tailstock for alignment and proper clamping.

2) *Work centers:* Centers in work must be deep enough to clear center point. Keep work centers clean and lubricated. Check play of footstock spindle and see that footstock spindle is clean and tightly seated. Regrind work centers if worn. Work centers must fit taper of work-center holes. Footstock must be checked for proper tension.

3) *Improper operation:* Don't let wheel traverse beyond end of work. Decrease wheel pressure so work won't spring. Use harder wheel or change feeds and speeds to make

wheel act harder. Allow work to “spark-out.” Decrease feed rate. Use proper number of work rests. Allow proper amount of tarry. Workpiece must be balanced if it is an odd shape.

4) *Coolant*: Use greater volume of coolant.

5) *Wheel*: Rebalance wheel on mounting before and after truing.

6) *Improper dressing*: Use same positions and machine conditions for dressing as in grinding.

7) *Spindle bearings*: Check clearance.

8) *Work*: Work must come to machine in reasonably accurate form.

*Inaccurate Work Sizing (when wheel is fed to same position, it grinds one piece to correct size, another oversize, and still another undersize)*: Sources of trouble are: 1) improper work support or rotation; 2) wheel out of balance; 3) loaded wheel; 4) improper infeed; 5) improper traverse; 6) coolant; 7) misalignment; and 8) work.

Suggested procedures for corrections of these troubles are:

1) *Improper work support or rotation*: Keep work centers clean and lubricated. Regrind work-center tips to proper angle. Be sure footstock spindle is tight. Use sufficient work rests, properly spaced.

2) *Wheel out of balance*: Balance wheel on mounting before and after truing.

3) *Loaded wheel*: See *Wheel Defects*.

4) *Improper infeed*: Check forward stops of rapid feed and slow feed. When readjusting position of wheel base by means of the fine feed, move the wheel base back after making the adjustment and then bring it forward again to take up backlash and relieve strain in feed-up parts. Check wheel spindle bearings. Don't let excessive lubrication of wheel base slide cause “floating.” Check and tighten wheel feed mechanism. Check parts for wear. Check pressure in hydraulic system. Set infeed cushion properly. Check to see that pistons are not sticking.

5) *Improper traverse*: Check traverse hydraulic system and the operating pressure. Prevent excessive lubrication of carriage ways with resultant “floating” condition. Check to see if carriage traverse piston rods are binding. Carriage rack and driving gear must not bind. Change length of tarry period.

6) *Coolant*: Use greater volume of clean coolant.

7) *Misalignment*: Check level and alignment of machine.

8) *Work*: Workpieces may vary too much in length, permitting uneven center pressure.

*Uneven Traverse or Infeed of Wheel Head*: Sources of uneven traverse or infeed of wheel head are: carriage and wheel head, hydraulic system, interference, unbalanced conditions, and wheel out of balance. Suggested procedures for correction of these troubles are:

1) *Carriage and wheel head*: Ways may be scored. Be sure to use recommended oil for both lubrication and hydraulic system. Make sure ways are not so smooth that they press out oil film. Check lubrication of ways. Check wheel feed mechanism, traverse gear, and carriage rack clearance. Prevent binding of carriage traverse cylinder rods.

2) *Hydraulic systems*: Remove air and check pressure of hydraulic oil. Check pistons and valves for oil leakage and for gumminess caused by incorrect oil. Check worn valves or pistons that permit leakage.

3) *Interference*: Make sure guard strips do not interfere.

4) *Unbalanced conditions*: Eliminate loose pulleys, unbalanced wheel drive motor, uneven belts, or high spindle keys.

5) *Wheel out of balance*: Balance wheel on mounting before and after truing.

*Wheel Defects*: When *wheel is acting too hard*, such defects as glazing, some loading, lack of cut, chatter, and burning of work result.

Suggested procedures for correction of these faults are: 1) Increase work and traverse speeds as well as rate of in-feed; 2) decrease wheel speed, diameter, or width; 3) dress more sharply; 4) use thinner coolant; 5) don't tarry at end of traverse; 6) select softer wheel grade and coarser grain size; 7) avoid gummy coolant; and 8) on hardened work select finer grit, more fragile abrasive or both to get penetration. Use softer grade.

When *wheel is acting too soft*, such defects as wheel marks, tapered work, short wheel life, and not-holding-cut result.

Suggested procedures for correction of these faults are: 1) Decrease work and traverse speeds as well as rate of in-feed; 2) increase wheel speed, diameter, or width; 3) dress with little in-feed and slow traverse; 4) use heavier coolants; 5) don't let wheel run off work at end of traverse; and 6) select harder wheel or less fragile grain or both.

*Wheel Loading and Glazing:* Sources of the trouble of wheel loading or glazing are: 1) Incorrect wheel; 2) improper dress; 3) faulty operation; 4) faulty coolant; and 5) gummy coolant.

Suggested procedures for correction of these faults are:

- 1) *Incorrect wheel:* Use coarser grain size, more open bond, or softer grade.
- 2) *Improper dressing:* Keep wheel sharp with sharp dresser, clean wheel after dressing, use faster dressing traverse, and deeper dressing cut.
- 3) *Faulty operation:* Control speeds and feeds to soften action of wheel. Use less in-feed to prevent loading; more in-feed to stop glazing.
- 4) *Faulty coolant:* Use more, cleaner and thinner coolant, and less oily coolant.
- 5) *Gummy coolant:* To stop wheel glazing, increase soda content and avoid the use of soluble oils if water is hard. In using soluble oil coolant with hard water a suitable conditioner or "softener" should be added.

*Wheel Breakage:* Suggested procedures for the correction of a radial break with three or more pieces are: 1) Reduce wheel speed to or below rated speed; 2) mount wheel properly, use blotters, tight arbors, even flange pressure and be sure to keep out dirt between flange and wheel; 3) use plenty of coolant to prevent over-heating; 4) use less in-feed; and 5) don't allow wheel to become jammed on work.

A radial break with two pieces may be caused by excessive side strain. To prevent an irregular wheel break, don't let wheel become jammed on work; don't allow striking of wheel; and never use wheels that have been damaged in handling. In general, do not use a wheel that is too tight on the arbor since the wheel is apt to break when started. Prevent excessive hammering action of wheel. Follow rules of the American National Standard Safety Requirements for the Use, Care, and Protection of Abrasive Wheels (ANSI B7.1-1988).

### Centerless Grinding

In centerless grinding the work is supported on a work rest blade and is between the grinding wheel and a regulating wheel. The regulating wheel generally is a rubber bonded abrasive wheel. In the normal grinding position the grinding wheel forces the work downward against the work rest blade and also against the regulating wheel. The latter imparts a uniform rotation to the work giving it its same peripheral speed which is adjustable.

The higher the work center is placed above the line joining the centers of the grinding and regulating wheels the quicker the rounding action. Rounding action is also increased by a high work speed and a slow rate of traverse (if a through-feed operation). It is possible to have a higher work center when using softer wheels, as their use gives decreased contact pressures and the tendency of the workpiece to lift off the work rest blade is lessened.

Long rods or bars are sometimes ground with their centers below the line-of-centers of the wheels to eliminate the whipping and chattering due to slight bends or kinks in the rods or bars, as they are held more firmly down on the blade by the wheels.

There are three general methods of centerless grinding which may be described as through-feed, in-feed, and end-feed methods.

**Through-feed Method of Grinding.**—The through-feed method is applied to straight cylindrical parts. The work is given an axial movement by the regulating wheel and passes between the grinding and regulating wheels from one side to the other. The rate of feed depends upon the diameter and speed of the regulating wheel and its inclination which is adjustable. It may be necessary to pass the work between the wheels more than once, the number of passes depending upon such factors as the amount of stock to be removed, the roundness and straightness of the unground work, and the limits of accuracy required.

The work rest fixture also contains adjustable guides on either side of the wheels that directs the work to and from the wheels in a straight line.

**In-feed Method of Centerless Grinding.**—When parts have shoulders, heads or some part larger than the ground diameter, the in-feed method usually is employed. This method is similar to “plungecut” form grinding on a center type of grinder. The length or sections to be ground in any one operation are limited by the width of the wheel. As there is no axial feeding movement, the regulating wheel is set with its axis approximately parallel to that of the grinding wheel, there being a slight inclination to keep the work tight against the end stop.

**End-feed Method of Grinding.**—The end-feed method is applied only to taper work. The grinding wheel, regulating wheel, and the work rest blade are set in a fixed relation to each other and the work is fed in from the front mechanically or manually to a fixed end stop. Either the grinding or regulating wheel, or both, are dressed to the proper taper.

**Automatic Centerless Grinding.**—The grinding of relatively small parts may be done automatically by equipping the machine with a magazine, gravity chute, or hopper feed, provided the shape of the part will permit using these feed mechanisms.

**Internal Centerless Grinding.**—Internal grinding machines based upon the centerless principle utilize the outside diameter of the work as a guide for grinding the bore which is concentric with the outer surface. In addition to straight and tapered bores, interrupted and “blind” holes can be ground by the centerless method. When two or more grinding operations such as roughing and finishing must be performed on the same part, the work can be reucked in the same location as often as required.

**Centerless Grinding Troubles.**—A number of troubles and some corrective measures compiled by a manufacturer are listed here for the through-feed and in-feed methods of centerless grinding.

*Chattermarks* are caused by having the work center too high above the line joining the centers of the grinding and regulating wheels; using too hard or too fine a grinding wheel; using too steep an angle on the work support blade; using too thin a work support blade; “play” in the set-up due to loosely clamped members; having the grinding wheel fit loosely on the spindle; having vibration either transmitted to the machine or caused by a defective drive in the machine; having the grinding wheel out-of-balance; using too heavy a stock removal; and having the grinding wheel or the regulating wheel spindles not properly adjusted.

*Feed lines or spiral marks* in through-feed grinding are caused by too sharp a corner on the exit side of the grinding wheel which may be alleviated by dressing the grinding wheel to a slight taper about  $\frac{1}{2}$  inch from the edge, dressing the edge to a slight radius, or swiveling the regulating wheel a bit.

*Scored work* is caused by burrs, abrasive grains, or removed material being imbedded in or fused to the work support blade. This condition may be alleviated by using a coolant with increased lubricating properties and if this does not help a softer grade wheel should be used.

*Work not ground round* may be due to the work center not being high enough above the line joining the centers of the grinding and regulating wheels. Placing the work center higher and using a softer grade wheel should help to alleviate this condition.

*Work not ground straight* in through-feed grinding may be due to an incorrect setting of the guides used in introducing and removing the work from the wheels, and the existence of convex or concave faces on the regulating wheel. For example, if the work is tapered on the front end, the work guide on the entering side is deflected toward the regulating wheel. If tapered on the back end, then the work guide on the exit side is deflected toward the regulating wheel. If both ends are tapered, then both work guides are deflected toward the regulating wheel. The same barrel-shaped pieces are also obtained if the face of the regulating wheel is convex at the line of contact with the work. Conversely, the work would be ground with hollow shapes if the work guides were deflected toward the grinding wheel or if the face of the regulating wheel were concave at the line of contact with the work. The use of a warped work rest blade may also result in the work not being ground straight and the blade should be removed and checked with a straight edge.

In in-feed grinding, in order to keep the wheel faces straight which will insure straightness of the cylindrical pieces being ground, the first item to be checked is the straightness and the angle of inclination of the work rest blade. If this is satisfactory then one of three corrective measures may be taken: the first might be to swivel the regulating wheel to compensate for the taper, the second might be to true the grinding wheel to that angle that will give a perfectly straight workpiece, and the third might be to change the inclination of the regulating wheel (this is true only for correcting very slight tapers up to 0.0005 inch).

*Difficulties in sizing* the work in in-feed grinding are generally due to a worn in-feed mechanism and may be overcome by adjusting the in-feed nut.

*Flat spots* on the workpiece in in-feed grinding usually occur when grinding heavy work and generally when the stock removal is light. This condition is due to insufficient driving power between the work and the regulating wheel which may be alleviated by equipping the work rest with a roller that exerts a force against the workpiece; and by feeding the workpiece to the end stop using the upper slide.

### Surface Grinding

The term surface grinding implies, in current technical usage, the grinding of surfaces which are essentially flat. Several methods of surface grinding, however, are adapted and used to produce surfaces characterized by parallel straight line elements in one direction, while normal to that direction the contour of the surface may consist of several straight line sections at different angles to each other (e.g., the guideways of a lathe bed); in other cases the contour may be curved or profiled (e.g., a thread cutting chaser).

**Advantages of Surface Grinding.**—Alternate methods for machining work surfaces similar to those produced by surface grinding are milling and, to a much more limited degree, planing. Surface grinding, however, has several advantages over alternate methods that are carried out with metal-cutting tools. Examples of such potential advantages are as follows:

- 1) Grinding is applicable to very hard and/or abrasive work materials, without significant effect on the efficiency of the stock removal.
- 2) The desired form and dimensional accuracy of the work surface can be obtained to a much higher degree and in a more consistent manner.
- 3) Surface textures of very high finish and—when the appropriate system is utilized—with the required lay, are generally produced.
- 4) Tooling for surface grinding as a rule is substantially less expensive, particularly for producing profiled surfaces, the shapes of which may be dressed into the wheel, often with simple devices, in processes that are much more economical than the making and the maintenance of form cutters.

5) Fixturing for work holding is generally very simple in surface grinding, particularly when magnetic chucks are applicable, although the mechanical holding fixture can also be simpler, because of the smaller clamping force required than in milling or planing.

6) Parallel surfaces on opposite sides of the work are produced accurately, either in consecutive operations using the first ground surface as a dependable reference plane or, simultaneously, in double face grinding, which usually operates without the need for holding the parts by clamping.

7) Surface grinding is well adapted to process automation, particularly for size control, but also for mechanized work handling in the large volume production of a wide range of component parts.

**Principal Systems of Surface Grinding.**—Flat surfaces can be ground with different surface portions of the wheel, by different arrangements of the work and wheel, as well as by different interrelated movements. The various systems of surface grinding, with their respective capabilities, can best be reviewed by considering two major distinguishing characteristics:

1) *The operating surface of the grinding wheel*, which may be the periphery or the face (the side);

2) *The movement of the work during the process*, which may be traverse (generally reciprocating) or rotary (continuous), depending on the design of a particular category of surface grinders.

The accompanying [Table 1](#) and the text that follows provides a concise review of the principal surface grinding systems, defined by the preceding characteristics. It should be noted that many surface grinders are built for specific applications, and do not fit exactly into any one of these major categories.

*Operating Surface, Periphery of Wheel: Movement of Work, Reciprocating:* Work is mounted on the horizontal machine table that is traversed in a reciprocating movement at a speed generally selected from a steplessly variable range. The transverse movement, called cross feed of the table or of the wheel slide, operates at the end of the reciprocating stroke and assures the gradual exposure of the entire work surface, which commonly exceeds the width of the wheel. The depth of the cut is controlled by the downfeed of the wheel, applied in increments at the reversal of the transverse movement.

*Operating Surface, Periphery of Wheel: Movement of Work, Rotary:* Work is mounted, usually on the full-diameter magnetic chuck of the circular machine table that rotates at a preset constant or automatically varying speed, the latter maintaining an approximately equal peripheral speed of the work surface area being ground. The wheelhead, installed on a cross slide, traverses over the table along a radial path, moving in alternating directions, toward and away from the center of the table. Infeed is by vertical movement of the saddle along the guideways of the vertical column, at the end of the radial wheelhead stroke. The saddle contains the guideways along which the wheelhead slide reciprocates.

*Operating Surface, Face of Wheel: Movement of Work, Reciprocating:* Operation is similar to the reciprocating table-type peripheral surface grinder, but grinding is with the face, usually with the rim of a cup-shaped wheel, or a segmental wheel for large machines. Capable of covering a much wider area of the work surface than the peripheral grinder, thus frequently no need for cross feed. Provides efficient stock removal, but is less adaptable than the reciprocating table-type peripheral grinder.

*Operating Surface, Face of Wheel: Movement of Work, Rotary:* The grinding wheel, usually of segmental type, is set in a position to cover either an annular area near the periphery of the table or, more commonly, to reach beyond the table center. A large circular magnetic chuck generally covers the entire table surface and facilitates the mounting of workpieces, even of fixtures, when needed. The uninterrupted passage of the work in contact with the large wheel face permits a very high rate of stock removal and the machine,

Table 1. Principal Systems of Surface Grinding — Diagrams

with single or double wheelhead, can be adapted also to automatic operation with continuous part feed by mechanized work handling.

*Operating Surface, Face of Wheel: Movement of Work, Traverse Along Straight or Arcuate Path:* The grinding wheel, usually of segmental type, is set in a position to cover either an annular area near the periphery of the table or, more commonly, to reach beyond the table center. A large circular magnetic chuck generally covers the entire table surface and facilitates the mounting of workpieces, even of fixtures, when needed. The uninterrupted passage of the work in contact with the large wheel face permits a very high rate of stock removal and the machine, with single or double wheelhead, can be adapted also to automatic operation with continuous part feed by mechanized work handling.

**Selection of Grinding Wheels for Surface Grinding.**—The most practical way to select a grinding wheel for surface grinding is to base the selection on the work material. [Table 2a](#) gives the grinding wheel recommendations for Types 1, 5, and 7 straight wheels used on reciprocating and rotary table surface grinders with horizontal spindles. [Table 2b](#) gives the grinding wheel recommendations for Type 2 cylinder wheels, Type 6 cup wheels, and wheel segments used on vertical spindle surface grinders.

The last letters (two or three) that may follow the bond designation V (vitrified) or B (resinoid) refer to: 1) bond modification, “BE” being especially suitable for surface grinding; 2) special structure, “P” type being distinctively porous; and 3) for segments made of 23A type abrasives, the term 12VSM implies porous structure, and the letter “P” is not needed.

The wheel markings in [Tables 2a](#) and [2b](#) are those used by the Norton Co., complementing the basic standard markings with Norton symbols. The complementary symbols used in these tables, that is, those preceding the letter designating A (aluminum oxide) or C (silicon carbide), indicate the special type of basic abrasive that has the friability best suited for particular work materials. Those preceding A (aluminum oxide) are

57—a versatile abrasive suitable for grinding steel in either a hard or soft state.

38—the most friable abrasive.

32—the abrasive suited for tool steel grinding.

23—an abrasive with intermediate grinding action, and

19—the abrasive produced for less heat-sensitive steels.

Those preceding C (silicon carbide) are

37—a general application abrasive, and

39—an abrasive for grinding hard cemented carbide.

**Table 2a. Grinding Wheel Recommendations for Surface Grinding—  
Using Straight Wheel Types 1, 5, and 7**

| Material  | Horizontal-spindle, reciprocating-table surface grinders |                                    | Horizontal-spindle, rotary-table surface grinders |
|---|--|------------------------------------|---|
|   | Wheels less than 16 inches diameter                      | Wheels 16 inches diameter and over | Wheels of any diameter                            |
| Cast iron   | 37C36-K8V or 23A46-I8VBE                                 | 23A36-I8VBE                        | 37C36-K8V or 23A46-I8VBE                          |
| Nonferrous metal                                  | 37C36-K8V  | 37C36-K8V                          | 37C36-K8V   |

| General-purpose use   | 23A30-H8VBE or<br>23A30-E12VBEP | ...                             | 23A30-H8VSM or<br>23A30-G12VSM  |

**Process Data for Surface Grinding.**—In surface grinding, similarly to other metal-cutting processes, the speed and feed rates that are applied must be adjusted to the operational conditions as well as to the objectives of the process. Grinding differs, however, from other types of metal cutting methods in regard to the cutting speed of the tool; the peripheral speed of the grinding wheel is maintained within a narrow range, generally 5500 to 6500 surface feet per minute. Speed ranges different from the common one are used in particular processes which require special wheels and equipment.

**Table 3. Basic Process Data for Peripheral Surface Grinding on Reciprocating Table Surface Grinders**

| Work<br>Material                 | Hardness     | Material<br>Condition                              | Wheel<br>Speed,<br>fpm | Table<br>Speed,<br>fpm | Downfeed,<br>in. per pass |                 | Crossfeed<br>per pass,<br>fraction of<br>wheel width |

In establishing the proper process values for grinding, of prime consideration are the work material, its condition, and the type of operation (roughing or finishing). [Table 3](#) gives basic process data for peripheral surface grinding on reciprocating table surface

grinders. For different work materials and hardness ranges data are given regarding table speeds, downfeed (infeed) rates and cross feed, the latter as a function of the wheel width.

**Common Faults and Possible Causes in Surface Grinding.**—Approaching the ideal performance with regard to both the quality of the ground surface and the efficiency of surface grinding, requires the monitoring of the process and the correction of conditions adverse to the attainment of that goal.

Defective, or just not entirely satisfactory surface grinding may have any one or more of several causes. Exploring and determining the cause for eliminating its harmful effects is facilitated by knowing the possible sources of the experienced undesirable performance. Table 4, associating the common faults with their possible causes, is intended to aid in determining the actual cause, the correction of which should restore the desired performance level.

While the table lists the more common faults in surface grinding, and points out their frequent causes, other types of improper performance and/or other causes, in addition to those indicated, are not excluded.

**Vitrified Grinding Wheels.**—The term “vitrified” denotes the type of bond used in these grinding wheels. The bond in a grinding wheel is the material which holds the abrasive grains together and supports them while they cut. With a given type of bond, it is the amount of bond that determines the “hardness” or softness” of wheels. The abrasive itself is extremely hard in all wheels, and the terms “hard” and “soft” refer to the *strength of bonding*; the greater the percentage of bond with respect to the abrasive, the heavier the coating of bond around the abrasive grains and the stronger the bond posts, the “harder” the wheel.

Most wheels are made with a vitrified bond composed of clays and feldspar selected for their fusibility. During the “burning” process in grinding wheel manufacture, the clays are fused into a molten glass condition. Upon cooling, a span or post of this glass connects each abrasive grain to its neighbors to make a rigid, strong, grinding wheel. These wheels are porous, free cutting and unaffected by water, acids, oils, heat, or cold. Vitrified wheels are extensively used for cylindrical grinding, surface grinding, internal grinding and cutter grinding.

**Silicate Bonding Process.**—Silicate grinding wheels derive their name from the fact that silicate of soda or water glass is the principal ingredient used in the bond. These wheels are also sometimes referred to as *semi-vitrified* wheels. Ordinarily, they cut smoothly and with comparatively little heat, and for grinding operations requiring the lowest wheel wear, compatible with cool cutting, silicate wheels are often used. Their grade is also dependable and much larger wheels can be made by this bonding process than by the vitrified process. Some of the grinding operations for which silicate wheels have been found to be especially adapted are as follows: for grinding high-speed steel machine shop tools, such as reamers, milling cutters, etc.; for hand-grinding lathe and planer tools; for surface grinding with machines of the vertical ring-wheel type; and for operations requiring dish-shaped wheels and cool cutting. These wheels are unequalled for wet grinding on hardened steel and for wet tool grinding. They are easily recognized by their light gray color.

**Oilstones.**—The natural oilstones commonly used are the *Washita* and *Arkansas*. The Washita is a coarser and more rapidly cutting stone, and is generally considered the most satisfactory for sharpening woodworkers' tools. There are various grades of Washita rock, varying from the perfect crystallized and porous whetstone grit, to vitreous flint and hard sandstone. The best whetstones are porous and uniform in texture and are composed entirely of silica crystals. The poorer grades are less porous, making them vitreous or “glassy.” They may also have hard spots or sand holes, or contain grains of sand among the crystals. For general work, a soft, free-grit, quick-cutting stone is required, although a fine-grit medium-hard stone is sometimes preferable. These are commonly furnished in three grits: fine, medium, and coarse, and in all required shapes.

**Table 4. Common Faults and Possible Causes in Surface Grinding**

| CAUSES                       | FAULTS                            | WORK DIMENSION |                   |                   | METALLURGICAL DEFECTS |                     | SURFACE QUALITY |               |                      |             | WHEEL CONDITION |               |                  | WORK RETAINMENT   |                       |
|------------------------------|-----------------------------------|----------------|-------------------|-------------------|-----------------------|---------------------|-----------------|---------------|----------------------|-------------|-----------------|---------------|------------------|-------------------|-----------------------|

### Offhand Grinding

Offhand grinding consists of holding the wheel to the work or the work to the wheel and grinding to broad tolerances and includes such operations as certain types of tool sharpening, weld grinding, snagging castings and other rough grinding. Types of machines that are used for rough grinding in foundries are floor- and bench-stand machines. Wheels for these machines vary from 6 to 30 inches in diameter. Portable grinding machines (electric, flexible shaft, or air-driven) are used for cleaning and smoothing castings.

Many rough grinding operations on castings can be best done with shaped wheels, such as cup wheels (including plate mounted) or cone wheels, and it is advisable to have a good assortment of such wheels on hand to do the odd jobs the best way.

**Floor- and Bench-Stand Grinding.**—The most common method of rough grinding is on double-end floor and bench stands. In machine shops, welding shops, and automotive repair shops, these grinders are usually provided with a fairly coarse grit wheel on one end for miscellaneous rough grinding and a finer grit wheel on the other end for sharpening tools. The pressure exerted is a very important factor in selecting the proper grinding wheel. If grinding is to be done mostly on hard sharp fins, then durable, coarse and hard wheels are required, but if grinding is mostly on large gate and riser pads, then finer and softer wheels should be used for best cutting action.

**Portable Grinding.**—Portable grinding machines are usually classified as air grinders, flexible shaft grinders, and electric grinders. The electric grinders are of two types; namely, those driven by standard 60 cycle current and so-called high-cycle grinders. Portable grinders are used for grinding down and smoothing weld seams; cleaning metal before welding; grinding out imperfections, fins and parting lines in castings and smoothing castings; grinding punch press dies and patterns to proper size and shape; and grinding manganese steel castings.

Wheels used on portable grinders are of three bond types; namely, resinoid, rubber, and vitrified. By far the largest percentage is resinoid. Rubber bond is used for relatively thin wheels and where a good finish is required. Some of the smaller wheels such as cone and plug wheels are vitrified bonded.

Grit sizes most generally used in wheels from 4 to 8 inches in diameter are 16, 20, and 24. In the still smaller diameters, finer sizes are used, such as 30, 36, and 46.

The particular grit size to use depends chiefly on the kind of grinding to be done. If the work consists of sharp fins and the machine has ample power, a coarse grain size combined with a fairly hard grade should be used. If the job is more in the nature of smoothing or surfacing and a fairly good finish is required, then finer and softer wheels are called for.

**Swing-Frame Grinding.**—This type of grinding is employed where a considerable amount of material is to be removed as on snagging large castings. It may be possible to remove 10 times as much material from steel castings using swing-frame grinders as with portable grinders; and 3 times as much material as with high-speed floor-stand grinders.

The largest field of application for swing-frame machines is on castings which are too heavy to handle on a floor stand; but often it is found that comparatively large gates and risers on smaller castings can be ground more quickly with swing-frame grinders, even if fins and parting lines have to be ground on floor stands as a second operation.

In foundries, the swing-frame machines are usually suspended from a trolley on a jib that can be swung out of the way when placing the work on the floor with the help of an overhead crane. In steel mills when grinding billets, a number of swing-frame machines are usually suspended from trolleys on a line of beams which facilitate their use as required.

The grinding wheels used on swing-frame machines are made with coarser grit sizes and harder grades than wheels used on floor stands for the same work. The reason is that greater grinding pressures can be obtained on the swing-frame machines.

**Abrasive Belt Grinding**

Abrasive belts are used in the metalworking industry for removing stock, light cleaning up of metal surfaces, grinding welds, deburring, breaking and polishing hole edges, and finish grinding of sheet steel. The types of belts that are used may be coated with aluminum oxide (the most common coating) for stock removal and finishing of all alloy steels, high-carbon steel, and tough bronzes; and silicon carbide for use on hard, brittle, and low-tensile strength metals which would include aluminum and cast irons.

**Table 1** is a guide to the selection of the proper abrasive belt, lubricant, and contact wheel. This table is entered on the basis of the material used and type of operation to be done and gives the abrasive belt specifications (type of bonding and abrasive grain size and material), the range of speeds at which the belt may best be operated, the type of lubricant to use, and the type and hardness of the contact wheel to use. **Table 2** serves as a guide in the selection of contact wheels. This table is entered on the basis of the type of contact wheel surface and the contact wheel material. The table gives the hardness and/or density, the type of abrasive belt grinding for which the contact wheel is intended, the character of the wheel action and such comments as the uses, and hints for best use. Both tables are intended only as guides for general shop practice; selections may be altered to suit individual requirements.

There are three types of abrasive belt grinding machines. One type employs a contact wheel behind the belt at the point of contact of the workpiece to the belt and facilitates a high rate of stock removal. Another type uses an accurate parallel ground platen over which the abrasive belt passes and facilitates the finishing of precision parts. A third type which has no platens or contact wheel is used for finishing parts having uneven surfaces or contours. In this type there is no support behind the belt at the point of contact of the belt with the workpiece. Some machines are so constructed that besides grinding against a platen or a contact wheel the workpiece may be moved and ground against an unsupported portion of the belt, thereby in effect making it a dual machine.

Although abrasive belts at the time of their introduction were used dry, since the advent of the improved waterproof abrasive belts, they have been used with coolants, oil-mists, and greases to aid the cutting action. The application of a coolant to the area of contact retards loading, resulting in a cool, free cutting action, a good finish and a long belt life.

**Abrasive Cutting**

Abrasive cut-off wheels are used for cutting steel, brass and aluminum bars and tubes of all shapes and hardnesses, ceramics, plastics, insulating materials, glass and cemented carbides. Originally a tool or stock room procedure, this method has developed into a high-speed production operation. While the abrasive cut-off machine and cut-off wheel can be said to have revolutionized the practice of cutting-off materials, the metal saw continues to be the more economical method for cutting-off large cross-sections of certain materials. However, there are innumerable materials and shapes that can be cut with much greater speed and economy by the abrasive wheel method. On conventional chop-stroke abrasive cutting machines using 16-inch diameter wheels, 2-inch diameter bar stock is the maximum size that can be cut with satisfactory wheel efficiency, but bar stock up to 6 inches in diameter can be cut efficiently on oscillating-stroke machines. Tubing up to 3½ inches in diameter can also be cut efficiently.

Abrasive wheels are commonly available in four types of bonds: Resinoid, rubber, shellac and fiber or fabric reinforced. In general, resinoid bonded cut-off wheels are used for dry cutting where burrs and some burn are not objectionable and rubber bonded wheels are used for wet cutting where cuts are to be smooth, clean and free from burrs. Shellac bonded wheels have a soft, free cutting quality which makes them particularly useful in the tool room where tool steels are to be cut without discoloration. Fiber reinforced bonded wheels are able to withstand severe flexing and side pressures and fabric reinforced bonded

Table 1. Guide to the Selection and Application of Abrasive Belts

| Material                     | Type of Operation | Abrasive Belt <sup>a</sup>  | Grit    | Belt Speed, fpm | Type of Grease Lubricant        | Contact Wheel   |                    |
|------------------------------|-------------------|---|---------|-----------------|---------------------------------|---|--------------------|
|                              |                   |   |         |                 |                                 | Type  | Durometer Hardness |
| Hot and Cold-Rolled Steel    | Roughing          | R/R Al <sub>2</sub> O <sub>3</sub>  | 24-60   | 4000-65000      | Light-body or none              | Cog-tooth, serrated rubber  | 70-90              |
|                              | Polishing         | R/G or R/R Al <sub>2</sub> O <sub>3</sub>   | 80-150  | 4500-7000       | Light-body or none              | Plain or serrated rubber, sectional or finger-type cloth wheel, free belt | 20-60              |
|                              | Fine Polishing    | R/G or electro-coated Al <sub>2</sub> O <sub>3</sub> cloth  | 180-500 | 4500-7000       | Heavy or with abrasive compound | Smooth-faced rubber or cloth  | 20-40              |
| Stainless Steel              | Roughing          | R/R Al <sub>2</sub> O <sub>3</sub>  | 50-80   | 3500-5000       | Light-body or none              | Cog-tooth, serrated rubber  | 70-90              |
|                              | Polishing         | R/G or R/R Al <sub>2</sub> O <sub>3</sub>   | 80-120  | 4000-5500       | Light-body or none              | Plain or serrated rubber, sectional or finger-type cloth wheel, free belt | 30-60              |
|                              | Fine Polishing    | Closed-coat SiC   | 150-280 | 4500-5500       | Heavy or oil mist               | Smooth-faced rubber or cloth  | 20-40              |
| Aluminum, Cast or Fabricated | Roughing          | R/R SiC or Al <sub>2</sub> O <sub>3</sub>   | 24-80   | 5000-6500       | Light                           | Cog-tooth, serrated rubber  | 70-90              |
|                              | Polishing         | R/G SiC or Al <sub>2</sub> O <sub>3</sub>   | 100-180 | 4500-6500       | Light                           | Plain or serrated rubber, sectional or finger-type cloth wheel, free belt | 30-50              |
|                              | Fine Polishing    | Closed-coat SiC or electro-coated Al <sub>2</sub> O <sub>3</sub>  | 220-320 | 4500-6500       | Heavy or with abrasive compound | Plain faced rubber, finger-type cloth or free belt                        | 20-50              |
| Copper Alloys or Brass       | Roughing          | R/R SiC or Al <sub>2</sub> O <sub>3</sub>   | 36-80   | 2200-4500       | Light-body                      | Cog-tooth, serrated rubber  | 70-90              |
|                              | Polishing         | Closed-coat SiC or electro-coated Al <sub>2</sub> O <sub>3</sub> or R/G SiC or Al <sub>2</sub> O <sub>3</sub> | 100-150 | 4000-6500       | Light-body                      | Plain or serrated rubber, sectional or finger-type cloth wheel, free belt | 30-50              |
|                              | Fine Polishing    | Closed-coat SiC or electro-coated Al <sub>2</sub> O <sub>3</sub>  | 180-320 | 4000-6500       | Light or with abrasive compound | Same as for polishing   | 20-30              |
| Non-ferrous Die-castings     | Roughing          | R/R SiC or Al <sub>2</sub> O <sub>3</sub>   | 24-80   | 4500-6500       | Light-body                      | Hard wheel depending on application                                       | 50-70              |
|                              | Polishing         | R/G SiC or Al <sub>2</sub> O <sub>3</sub>   | 100-180 | 4500-6500       | Light-body                      | Plain rubber, cloth or free belt  | 30-50              |
|                              | Fine Polishing    | Electro-coated Al <sub>2</sub> O <sub>3</sub> or closed-coat SiC  | 220-320 | 4500-6500       | Heavy or with abrasive compound | Plain or finger-type cloth wheel, or free belt                            | 20-30              |
| Cast Iron                    | Roughing          | R/R Al <sub>2</sub> O <sub>3</sub>  | 24-60   | 2000-4000       | None                            | Cog-tooth, serrated rubber  | 70-90              |
|                              | Polishing         | R/R Al <sub>2</sub> O <sub>3</sub>  | 80-150  | 4000-5500       | None                            | Serrated rubber   | 30-70              |
|                              | Fine Polishing    | R/R Al <sub>2</sub> O <sub>3</sub>  | 120-240 | 4000-5500       | Light-body                      | Smooth-faced rubber   | 30-40              |
| Titanium                     | Roughing          | R/R SiC or Al <sub>2</sub> O <sub>3</sub>   | 36-50   | 700-1500        | Sulfur-chlorinated              | Small-diameter, cog-tooth serrated rubber                                 | 70-80              |
|                              | Polishing         | R/R SiC   | 60-120  | 1200-2000       | Light-body                      | Standard serrated rubber  | 50                 |
|                              | Fine Polishing    | R/R SiC   | 120-240 | 1200-2000       | Light-body                      | Smooth-faced rubber or cloth  | 20-40              |

<sup>a</sup>R/R indicates that both the making and sizing bond coats are resin. R/G indicates that the making coat is glue and the sizing coat is resin. The abbreviations Al<sub>2</sub>O<sub>3</sub> for aluminum oxide and SiC for silicon carbide are used. Almost all R/R and R/G Al<sub>2</sub>O<sub>3</sub> and SiC belts have a heavy-drill weight cloth backing. Most electro-coated Al<sub>2</sub>O<sub>3</sub> and closed-coat SiC belts have a jeans weight cloth backing.

**Table 2. Guide to the Selection and Application of Contact Wheels**

| Surface             | Material                          | Hardness and Density                             | Purposes               | Wheel Action  | Comments   |
|---------------------|-----------------------------------|--|------------------------|---|--|
| Cog-tooth           | Rubber                            | 70 to 90 durometer                               | Roughing               | Fast cutting, allows long belt life.  | For cutting down projections on castings and weld beads.   |
| Standard serrated   | Rubber                            | 40 to 50 durometer, medium density               | Roughing               | Leaves rough- to medium-ground surface.   | For smoothing projections and face defects.  |
| X-shaped serrations | Rubber                            | 20 to 50 durometer                               | Roughing and polishing | Flexibility of rubber allows entry into contours. Medium polishing, light removal.                      | Same as for standard serrated wheels but preferred for soft non-ferrous metals.                      |
| Plain face          | Rubber                            | 20 to 70 durometer                               | Roughing and polishing | Plain wheel face allows controlled penetration of abrasive grain. Softer wheels give better finishes.   | For large or small flat faces.   |
| Flat flexible       | Compressed canvas                 | About nine densities from very hard to very soft | Roughing and polishing | Hard wheels can remove metal, but not as quickly as cog-tooth rubber wheels. Softer wheels polish well. | Good for medium-range grinding and polishing.  |
| Flat flexible       | Solid sectional canvas            | Soft, medium, and hard                           | Polishing              | Uniform polishing. Avoids abrasive pattern on work. Adjusts to contours. Can be performed for contours. | A low-cost wheel with uniform density at the face. Handles all types of polishing.                   |
| Flat flexible       | Buff sectional canvas             | Soft   | Contour polishing      | For fine polishing and finishing.   | Can be widened or narrowed by adding or removing sections. Low cost.                                 |
| Flat flexible       | Sponge rubber inserts             | 5 to 10 durometer, soft                          | Polishing              | Uniform polishing and finishing. Polishes and blends contours.  | Has replaceable segments. Polishes and blends contours. Segments allow density changes.              |
| Flexible            | Fingers of canvas attached to hub | Soft   | Polishing              | Uniform polishing and finishing.  | For polishing and finishing.   |
| Flat flexible       | Rubber segments                   | Varies in hardness                               | Roughing and polishing | Grinds or polishes depending on density and hardness of inserts.  | For portable machines. Uses replaceable segments that save on wheel costs and allow density changes. |
| Flat flexible       | Inflated rubber                   | Air pressure controls hardness                   | Roughing and polishing | Uniform finishing.  | Adjusts to contours.   |

wheels which are highly resistant to breakage caused by extreme side pressures, are fast cutting and have a low rate of wear.

The types of abrasives available in cut-off wheels are: Aluminum oxide, for cutting steel and most other metals; silicon carbide, for cutting non-metallic materials such as carbon, tile, slate, ceramics, etc.; and diamond, for cutting cemented carbides. The method of denoting abrasive type, grain size, grade, structure and bond type by using a system of markings is the same as for grinding wheels (see page 1179). Maximum wheel speeds given in the American National Standard "Safety Requirements for The Use, Care, and Protection of Abrasive Wheels" (ANSI B7.1-1988) range from 9500 to 14,200 surface feet per minute for organic bonded cut-off wheels larger than 16 inches in diameter and from 9500 to 16,000 surface feet per minute for organic bonded cut-off wheels 16 inches in diameter and smaller. Maximum wheel speeds specified by the manufacturer should never be exceeded even though they may be lower than those given in the B7.1 Standard.

There are four basic types of abrasive cutting machines: Chop-stroke, oscillating stroke, horizontal stroke and work rotating. Each of these four types may be designed for dry cutting or for wet cutting (includes submerged cutting).

The accompanying table based upon information made available by The Carborundum Co. gives some of the probable causes of cutting off difficulties that might be experienced when using abrasive cut-off wheels.

**Probable Causes of Cutting-Off Difficulties**

| Difficulty                      | Probable Cause  |
|---------------------------------|---|
| Angular Cuts and Wheel Breakage | (1) Inadequate clamping which allows movement of work while the wheel is in the cut. The work should be clamped on both sides of the cut.<br>(2) Work vise higher on one side than the other causing wheel to be pinched.<br>(3) Wheel vibration resulting from worn spindle bearings.<br>(4) Too fast feeding into the cut when cutting wet. |
| Burning of Stock                | (1) Insufficient power or drive allowing wheel to stall.<br>(2) Cuts too heavy for grade of wheel being used.<br>(3) Wheel fed through the work too slowly. This causes a heating up of the material being cut. This difficulty encountered chiefly in dry cutting.   |
| Excessive Wheel Wear            | (1) Too rapid cutting when cutting wet.<br>(2) Grade of wheel too hard for work, resulting in excessive heating and burning out of bond.<br>(3) Inadequate coolant supply in wet cutting.<br>(4) Grade of wheel too soft for work.<br>(5) Worn spindle bearings allowing wheel vibration.   |
| Excessive Burring               | (1) Feeding too slowly when cutting dry.<br>(2) Grit size in wheel too coarse.<br>(3) Grade of wheel too hard.<br>(4) Wheel too thick for job.  |

### Honing Process

The hone-abrading process for obtaining cylindrical forms with precise dimensions and surfaces can be applied to internal cylindrical surfaces with a wide range of diameters such as engine cylinders, bearing bores, pin holes, etc. and also to some external cylindrical surfaces.

The process is used to: 1) eliminate inaccuracies resulting from previous operations by generating a true cylindrical form with respect to roundness and straightness within minimum dimensional limits; 2) generate final dimensional size accuracy within low tolerances, as may be required for interchangeability of parts; 3) provide rapid and economical stock removal consistent with accomplishment of the other results; and 4) generate surface finishes of a specified degree of surface smoothness with high surface quality.

**Amount and Rate of Stock Removal.**—Honing may be employed to increase bore diameters by as much as 0.100 inch or as little as 0.001 inch. The amount of stock removed by the honing process is entirely a question of processing economy. If other operations are performed before honing then the bulk of the stock should be taken off by the operation that can do it most economically. In large diameter bores that have been distorted in heat treating, it may be necessary to remove as much as 0.030 to 0.040 inch from the diameter to make the bore round and straight. For out-of-round or tapered bores, a good "rule of thumb" is to leave twice as much stock (on the diameter) for honing as there is error in the bore. Another general rule is: For bores over one inch in diameter, leave 0.001 to 0.0015 inch stock per inch of diameter. For example, 0.002 to 0.003 inch of stock is left in two-inch bores and 0.010 to 0.015 inch in ten-inch bores. Where parts are to be honed for finish only, the amount of metal to be left for removing tool marks may be as little as 0.0002 to 0.015 inch on the diameter.

In general, the honing process can be employed to remove stock from bore diameters at the rate of 0.009 to 0.012 inch per minute on cast-iron parts and from 0.005 to 0.008 inch per minute on steel parts having a hardness of 60 to 65 Rockwell C. These rates are based on parts having a length equal to three or four times the diameter. Stock has been removed

from long parts such as gun barrels, at the rate of 65 cubic inches per hour. Recommended honing speeds for cast iron range from 110 to 200 surface feet per minute of rotation and from 50 to 110 lineal feet per minute of reciprocation. For steel, rotating surface speeds range from 50 to 110 feet per minute and reciprocation speeds from 20 to 90 lineal feet per minute. The exact rotation and reciprocation speeds to be used depend upon the size of the work, the amount and characteristics of the material to be removed and the quality of the finish desired. In general, the harder the material to be honed, the lower the speed. Interrupted bores are usually honed at faster speeds than plain bores.

**Formula for Rotative Speeds.**—Empirical formulas for determining rotative speeds for honing have been developed by the Micromatic Hone Corp. These formulas take into consideration the type of material being honed, its hardness and its surface characteristics; the abrasive area; and the type of surface pattern and degree of surface roughness desired. Because of the wide variations in material characteristics, abrasives available, and types of finishes specified, these formulas should be considered as a guide only in determining which of the available speeds (pulley or gear combinations) should be used for any particular application.

The formula for rotative speed,  $S$ , in surface feet per minute is: 
$$S = \frac{K \times D}{W \times N}$$

The formula for rotative speed in revolutions per minute is: 
$$\text{R.P.M.} = \frac{R}{W \times N}$$

where,  $K$  and  $R$  are factors taken from the table on the following page,  $D$  is the diameter of the bore in inches,  $W$  is the width of the abrasive stone or stock in inches, and  $N$  is the number of stones.

Although the actual speed of the abrasive is the resultant of both the rotative speed and the reciprocation speed, this latter quantity is seldom solved for or used. The reciprocation speed is not determined empirically but by testing under operating conditions. Changing the reciprocation speed affects the dressing action of the abrasive stones, therefore, the reciprocation speed is adjusted to provide for a desired surface finish which is usually a well lubricated bearing surface that will not scuff.

**Table of Factors for Use in Rotative Speed Formulas**

| Character of Surface <sup>a</sup> | Material  | Hardness <sup>b</sup> |     |        |     |      |     |
|-----------------------------------|-----------|-----------------------|-----|--------|-----|------|-----|
|                                   |           | Soft                  |     | Medium |     | Hard |     |
|                                   |           | $K$                   | $R$ | $K$    | $R$ | $K$  | $R$ |
| Base Metal                        | Cast Iron | 110                   | 420 | 80     | 300 | 60   | 230 |
|                                   | Steel     | 80                    | 300 | 60     | 230 | 50   | 190 |
| Dressing Surface                  | Cast Iron | 150                   | 570 | 110    | 420 | 80   | 300 |
|                                   | Steel     | 110                   | 420 | 80     | 300 | 60   | 230 |
| Severe Dressing                   | Cast Iron | 200                   | 760 | 150    | 570 | 110  | 420 |
|                                   | Steel     | 150                   | 570 | 110    | 420 | 80   | 300 |

<sup>a</sup>The character of the surface is classified according to its effect on the abrasive; *Base Metal* being a honed, ground or fine bored section that has little dressing action on the grit; *Dressing Surface* being a rough bored, reamed or broached surface or any surface broken by cross holes or ports; *Severe Dressing* being a surface interrupted by keyways, undercuts or burrs that dress the stones severely. If over half of the stock is to be removed after the surface is cleaned up, the speed should be computed using the *Base Metal* factors for  $K$  and  $R$ .

<sup>b</sup>Hardness designations of soft, medium and hard cover the following ranges on the Rockwell "C" hardness scale, respectively: 15 to 45, 45 to 60 and 60 to 70.

**Possible Adjustments for Eliminating Undesirable Honing Conditions**

| Undesirable Condition     | Adjustment Required to Correct Condition <sup>a</sup> |            |          |           |               |               |        |             |               |
|---------------------------|---|------------|----------|-----------|---------------|---------------|--------|-------------|---------------|
|                           | Abrasive <sup>b</sup>                                 |            |          |           | Other         |               |        |             |               |
|                           | Friability  | Grain Size | Hardness | Structure | Feed Pressure | Reciprocation | R.P.M. | Runout Time | Stroke Length |
| Abrasive Glazing          | +   | --         | --       | +         | ++            | ++            | --     | -           | 0             |
| Abrasive Loading          | 0   | --         | -        | -         | ++            | +             | --     | 0           | 0             |
| Too Rough Surface Finish  | 0   | ++         | ++       | -         | -             | -             | ++     | +           | 0             |
| Too Smooth Surface Finish | 0   | --         | --       | +         | +             | +             | --     | -           | 0             |
| Poor Stone Life           | -   | +          | ++       | -         | -             | -             | +      | 0           | 0             |
| Slow Stock Removal        | +   | --         | -        | +         | ++            | ++            | --     | 0           | 0             |
| Taper — Large at Ends     | 0   | 0          | 0        | 0         | 0             | 0             | 0      | 0           | -             |
| Taper — Small at Ends     | 0   | 0          | 0        | 0         | 0             | 0             | 0      | 0           | +             |

<sup>a</sup> The + and ++ symbols generally indicate that there should be an increase or addition while the - and -- symbols indicate that there should be a reduction or elimination. In each case, the double symbol indicates that the contemplated change would have the greatest effect. The 0 symbol means that a change would have no effect.

<sup>b</sup> For the abrasive adjustments the + and ++ symbols indicate a more friable grain, a finer grain, a harder grade or a more open structure and the - and -- symbols just the reverse.

Compiled by Micromatic Hone Corp.

**Abrasive Stones for Honing.**—Honing stones consist of aluminum oxide, silicon carbide, CBN or diamond abrasive grits, held together in stick form by a vitrified clay, resinoid or metal bond. CBN metal-bond stones are particularly suitable and widely used for honing. The grain and grade of abrasive to be used in any particular honing operation depend upon the quality of finish desired, the amount of stock to be removed, the material being honed and other factors.

The following general rules may be followed in the application of abrasive for honing: 1) Silicon-carbide abrasive is commonly used for honing cast iron, while aluminum-oxide abrasive is generally used on steel; 2) The harder the material being honed, the softer the abrasive stick used; 3) A rapid reciprocating speed will tend to make the abrasive cut fast because the dressing action on the grits will be severe; and 4) To improve the finish, use a finer abrasive grit, incorporate more multi-direction action, allow more "run-out" time after honing to size, or increase the speed of rotation.

Surface roughnesses ranging from less than 1 micro-inch r.m.s. to a relatively coarse roughness can be obtained by judicious choice of abrasive and honing time but the most common range is from 3 to 50 micro-inches r.m.s.

**Adjustments for Eliminating Undesirable Honing Conditions.**—The accompanying table indicates adjustments that may be made to correct certain undesirable conditions encountered in honing. Only one change should be made at a time and its effect noted before making other adjustments.

**Tolerances.**—For bore diameters above 4 inches the tolerance of honed surfaces with respect to roundness and straightness ranges from 0.0005 to 0.001 inch; for bore diameters from 1 to 4 inches, 0.0003 to 0.0005 inch; and for bore diameters below 1 inch, 0.00005 to 0.0003 inch.

**Laps and Lapping**

**Material for Laps.**—Laps are usually made of soft cast iron, copper, brass or lead. In general, the best material for laps to be used on very accurate work is soft, close-grained cast iron. If the grinding, prior to lapping, is of inferior quality, or an excessive allowance has been left for lapping, copper laps may be preferable. They can be charged more easily and cut more rapidly than cast iron, but do not produce as good a finish. Whatever material is

used, the lap should be softer than the work, as, otherwise, the latter will become charged with the abrasive and cut the lap, the order of the operation being reversed. A common and inexpensive form of lap for holes is made of lead which is cast around a tapering steel arbor. The arbor usually has a groove or keyway extending lengthwise, into which the lead flows, thus forming a key that prevents the lap from turning. When the lap has worn slightly smaller than the hole and ceases to cut, the lead is expanded or stretched a little by the driving in of the arbor. When this expanding operation has been repeated two or three times, the lap usually must be trued or replaced with a new one, owing to distortion.

The tendency of lead laps to lose their form is an objectionable feature. They are, however, easily molded, inexpensive, and quickly charged with the cutting abrasive. A more elaborate form for holes is composed of a steel arbor and a split cast-iron or copper shell which is sometimes prevented from turning by a small dowel pin. The lap is split so that it can be expanded to accurately fit the hole being operated upon. For hardened work, some toolmakers prefer copper to either cast iron or lead. For holes varying from  $\frac{1}{4}$  to  $\frac{1}{2}$  inch in diameter, copper or brass is sometimes used; cast iron is used for holes larger than  $\frac{1}{2}$  inch in diameter. The arbors for these laps should have a taper of about  $\frac{1}{4}$  or  $\frac{3}{8}$  inch per foot. The length of the lap should be somewhat greater than the length of the hole, and the thickness of the shell or lap proper should be from  $\frac{1}{8}$  to  $\frac{1}{6}$  its diameter.

External laps are commonly made in the form of a ring, there being an outer ring or holder and an inner shell which forms the lap proper. This inner shell is made of cast iron, copper, brass or lead. Ordinarily the lap is split and screws are provided in the holder for adjustment. The length of an external lap should at least equal the diameter of the work, and might well be longer. Large ring laps usually have a handle for moving them across the work.

**Laps for Flat Surfaces.**—Laps for producing plane surfaces are made of cast iron. In order to secure accurate results, the lapping surface must be a true plane. A flat lap that is used for roughing or "blocking down" will cut better if the surface is scored by narrow grooves. These are usually located about  $\frac{1}{2}$  inch apart and extend both lengthwise and crosswise, thus forming a series of squares similar to those on a checker-board. An abrasive of No. 100 or 120 emery and lard oil can be used for charging the roughing lap. For finer work, a lap having an unscored surface is used, and the lap is charged with a finer abrasive. After a lap is charged, all loose abrasive should be washed off with gasoline, for fine work, and when lapping, the surface should be kept moist, preferably with kerosene. Gasoline will cause the lap to cut a little faster, but it evaporates so rapidly that the lap soon becomes dry and the surface caked and glossy in spots. Loose emery should not be applied while lapping, for if the lap is well charged with abrasive in the beginning, is kept well moistened and not crowded too hard, it will cut for a considerable time. The pressure upon the work should be just enough to insure constant contact. The lap can be made to cut only so fast, and if excessive pressure is applied it will become "stripped" in places. The causes of scratches are: Loose abrasive on the lap; too much pressure on the work, and poorly graded abrasive. To produce a perfectly smooth surface free from scratches, the lap should be charged with a very fine abrasive.

**Grading Abrasives for Lapping.**—For high-grade lapping, abrasives can be evenly graded as follows: A quantity of flour-emery or other abrasive is placed in a heavy cloth bag, which is gently tapped, causing very fine particles to be sifted through. When a sufficient quantity has been obtained in this way, it is placed in a dish of lard or sperm oil. The largest particles will then sink to the bottom and in about one hour the oil should be poured into another dish, care being taken not to disturb the sediment at the bottom. The oil is then allowed to stand for several hours, after which it is poured again, and so on, until the desired grade is obtained.

**Charging Laps.**—To charge a flat cast-iron lap, spread a very thin coating of the prepared abrasive over the surface and press the small cutting particles into the lap with a hard steel block. There should be as little rubbing as possible. When the entire surface is apparently charged, clean and examine for bright spots; if any are visible, continue charging until the entire surface has a uniform gray appearance. When the lap is once charged, it should be used without applying more abrasive until it ceases to cut. If a lap is over-charged and an excessive amount of abrasive is used, there is a rolling action between the work and lap which results in inaccuracy. The surface of a flat lap is usually finished true, prior to charging, by scraping and testing with a standard surface-plate, or by the well-known method of scraping-in three plates together, in order to secure a plane surface. In any case, the bearing marks or spots should be uniform and close together. These spots can be blended by covering the plates evenly with a fine abrasive and rubbing them together. While the plates are being ground in, they should be carefully tested and any high spots which may form should be reduced by rubbing them down with a smaller block.

To charge cylindrical laps for internal work, spread a thin coating of prepared abrasive over the surface of a hard steel block, preferably by rubbing lightly with a cast-iron or copper block; then insert an arbor through the lap and roll the latter over the steel block, pressing it down firmly to embed the abrasive into the surface of the lap. For external cylindrical laps, the inner surface can be charged by rolling-in the abrasive with a hard steel roller that is somewhat smaller in diameter than the lap. The taper cast-iron blocks which are sometimes used for lapping taper holes can also be charged by rolling-in the abrasive, as previously described; there is usually one roughing and one finishing lap, and when charging the former, it may be necessary to vary the charge in accordance with any error which might exist in the taper.

**Rotary Diamond Lap.**—This style of lap is used for accurately finishing very small holes, which, because of their size, cannot be ground. While the operation is referred to as lapping, it is, in reality, a grinding process, the lap being used the same as a grinding wheel. Laps employed for this work are made of mild steel, soft material being desirable because it can be charged readily. Charging is usually done by rolling the lap between two hardened steel plates. The diamond dust and a little oil is placed on the lower plate, and as the lap revolves, the diamond is forced into its surface. After charging, the lap should be washed in benzine. The rolling plates should also be cleaned before charging with dust of a finer grade. It is very important not to force the lap when in use, especially if it is a small size. The lap should just make contact with the high spots and gradually grind them off. If a diamond lap is lubricated with kerosene, it will cut freer and faster. These small laps are run at very high speeds, the rate depending upon the lap diameter. Soft work should never be ground with diamond dust because the dust will leave the lap and charge the work.

When using a diamond lap, it should be remembered that such a lap will not produce sparks like a regular grinding wheel; hence, it is easy to crowd the lap and "strip" some of the diamond dust. To prevent this, a sound intensifier or "harker" should be used. This is placed against some stationary part of the grinder spindle, and indicates when the lap touches the work, the sound produced by the slightest contact being intensified.

**Grading Diamond Dust.**—The grades of diamond dust used for charging laps are designated by numbers, the fineness of the dust increasing as the numbers increase. The diamond, after being crushed to powder in a mortar, is thoroughly mixed with high-grade olive oil. This mixture is allowed to stand five minutes and then the oil is poured into another receptacle. The coarse sediment which is left is removed and labeled No. 0, according to one system. The oil poured from No. 0 is again stirred and allowed to stand ten minutes, after which it is poured into another receptacle and the sediment remaining is labeled No. 1. This operation is repeated until practically all of the dust has been recovered from the oil, the time that the oil is allowed to stand being increased as shown by the following table. This is done in order to obtain the smaller particles that require a longer time for precipitation:

|                              |                                      |
|------------------------------|--------------------------------------|
| To obtain No. 1 — 10 minutes | To obtain No. 4 — 2 hours            |
| To obtain No. 2 — 30 minutes | To obtain No. 5 — 10 hours           |
| To obtain No. 3 — 1 hour     | To obtain No. 6 — until oil is clear |

The No. 0 or coarse diamond which is obtained from the first settling is usually washed in benzine, and re-crushed unless very coarse dust is required. This No. 0 grade is sometimes known as "ungraded" dust. In some places the time for settling, in order to obtain the various numbers, is greater than that given in the table.

**Cutting Properties of Laps and Abrasives.**—In order to determine the cutting properties of abrasives when used with different lapping materials and lubricants, a series of tests was conducted, the results of which were given in a paper by W. A. Knight and A. A. Case, presented before the American Society of Mechanical Engineers. In connection with these tests, a special machine was used, the construction being such that quantitative results could be obtained with various combinations of abrasive, lubricant, and lap material. These tests were confined to surface lapping.

It was not the intention to test a large variety of abrasives, three being selected as representative; namely, Naxos emery, carborundum, and alundum. Abrasive No. 150 was used in each case, and seven different lubricants, five different pressures, and three different lap materials were employed. The lubricants were lard oil, machine oil, kerosene, gasoline, turpentine, alcohol, and soda water.

These tests indicated throughout that there is, for each different combination of lap and lubricant, a definite size of grain that will give the maximum amount of cutting. With all the tests, except when using the two heavier lubricants, some reduction in the size of the grain below that used in the tests (No. 150) seemed necessary before the maximum rate of cutting was reached. This reduction, however, was continuous and soon passed below that which gave the maximum cutting rate.

**Cutting Qualities with Different Laps.**—The surfaces of the steel and cast-iron laps were finished by grinding. The hardness of the different laps, as determined by the scleroscope was, for cast-iron, 28; steel, 18; copper, 5. The total amount ground from the test-pieces with each of the three laps showed that, taking the whole number of tests as a standard, there is scarcely any difference between the steel and cast iron, but that copper has somewhat better cutting qualities, although, when comparing the laps on the basis of the highest and lowest values obtained with each lap, steel and cast iron are as good for all practical purposes as copper, when the proper abrasive and lubricant are used.

**Wear of Laps.**—The wear of laps depends upon the material from which they are made and the abrasive used. The wear on all laps was about twice as fast with carborundum as with emery, while with alundum the wear was about one and one-fourth times that with emery. On an average, the wear of the copper lap was about three times that of the cast-iron lap. This is not absolute wear, but wear in proportion to the amount ground from the test-pieces.

**Lapping Abrasives.**—As to the qualities of the three abrasives tested, it was found that carborundum usually began at a lower rate than the other abrasives, but, when once started, its rate was better maintained. The performance gave a curve that was more nearly a straight line. The charge or residue as the grinding proceeded remained cleaner and sharper and did not tend to become pasty or mucklike, as is so frequently the case with emery. When using a copper lap, carborundum shows but little gain over the cast-iron and steel laps, whereas, with emery and alundum, the gain is considerable.

**Effect of Different Lapping Lubricants.**—The action of the different lubricants, when tested, was found to depend upon the kind of abrasive and the lap material.

*Lard and Machine Oil:* The test showed that lard oil, without exception, gave the higher rate of cutting, and that, in general, the initial rate of cutting is higher with the lighter lubri-

cants, but falls off more rapidly as the test continues. The lowest results were obtained with machine oil, when using an emery-charged, cast-iron lap. When using lard oil and a carborundum-charged steel lap, the highest results were obtained.

*Gasoline and Kerosene:* On the cast-iron lap, gasoline was superior to any of the lubricants tested. Considering all three abrasives, the relative value of gasoline, when applied to the different laps, is as follows: Cast iron, 127; copper, 115; steel, 106. Kerosene, like gasoline, gives the best results on cast iron and the poorest on steel. The values obtained by carborundum were invariably higher than those obtained with emery, except when using gasoline and kerosene on a copper lap.

*Turpentine and Alcohol:* Turpentine was found to do good work with carborundum on any lap. With emery, turpentine did fair work on the copper lap, but, with the emery on cast-iron and steel laps, it was distinctly inferior. Alcohol gives the lowest results with emery on the cast-iron and steel laps.

*Soda Water:* Soda water gives medium results with almost any combination of lap and abrasives, the best work being on the copper lap and the poorest on the steel lap. On the cast-iron lap, soda water is better than machine or lard oil, but not so good as gasoline or kerosene. Soda water when used with alundum on the copper lap, gave the highest results of any of the lubricants used with that particular combination.

**Lapping Pressures.**—Within the limits of the pressures used, that is, up to 25 pounds per square inch, the rate of cutting was found to be practically proportional to the pressure. The higher pressures of 20 and 25 pounds per square inch are not so effective on the copper lap as on the other materials.

**Wet and Dry Lapping.**—With the “wet method” of using a surface lap, there is a surplus of oil and abrasive on the surface of the lap. As the specimen being lapped is moved over it, there is more or less movement or shifting of the abrasive particles. With the “dry method,” the lap is first charged by rubbing or rolling the abrasive into its surface. All surplus oil and abrasive are then washed off, leaving a clean surface, but one that has embedded uniformly over it small particles of the abrasive. It is then like the surface of a very fine oilstone and will cut away hardened steel that is rubbed over it. While this has been termed the dry method, in practice, the lap surface is kept moistened with kerosene or gasoline.

Experiments on dry lapping were carried out on the cast-iron, steel, and copper laps used in the previous tests, and also on one of tin made expressly for the purpose. Carborundum alone was used as the abrasive and a uniform pressure of 15 pounds per square inch was applied to the specimen throughout the tests. In dry lapping, much depends upon the manner of charging the lap. The rate of cutting decreased much more rapidly after the first 100 revolutions than with the wet method. Considering the amounts ground off during the first 100 revolutions, and the best result obtained with each lap taken as the basis of comparison, it was found that with a tin lap, charged by rolling No. 150 carborundum into the surface, the rate of cutting, when dry, approached that obtained with the wet method. With the other lap materials, the rate with the dry method was about one-half that of the wet method.

**Summary of Lapping Tests.**—The initial rate of cutting does not greatly differ for different abrasives. There is no advantage in using an abrasive coarser than No. 150. The rate of cutting is practically proportional to the pressure. The wear of the laps is in the following proportions: cast iron, 1.00; steel, 1.27; copper, 2.62. In general, copper and steel cut faster than cast iron, but, where permanence of form is a consideration, cast iron is the superior metal. Gasoline and kerosene are the best lubricants to use with a cast-iron lap. Machine and lard oil are the best lubricants to use with copper or steel laps. They are, however, least effective on a cast-iron lap. In general, wet lapping is from 1.2 to 6 times as fast as dry lapping, depending upon the material of the lap and the manner of charging.

## KNURLS AND KNURLING

**ANSI Standard Knurls and Knurling.**—The ANSI/ASME Standard B94.6-1984 covers knurling tools with standardized diametral pitches and their dimensional relations with respect to the work in the production of straight, diagonal, and diamond knurling on cylindrical surfaces having teeth of uniform pitch parallel to the cylinder axis or at a helix angle not exceeding 45 degrees with the work axis.

These knurling tools and the recommendations for their use are equally applicable to general purpose and precision knurling. The advantage of this ANSI Standard system is the provision by which good tracking (the ability of teeth to mesh as the tool penetrates the work blank in successive revolutions) is obtained by tools designed on the basis of diametral pitch instead of TPI (teeth per inch) when used with work blank diameters that are multiples of  $\frac{1}{64}$  inch for 64 and 128 diametral pitch or  $\frac{1}{32}$  inch for 96 and 160 diametral pitch. The use of knurls and work blank diameters which will permit good tracking should improve the uniformity and appearance of knurling, eliminate the costly trial and error methods, reduce the failure of knurling tools and production of defective work, and decrease the number of tools required. Preferred sizes for cylindrical knurls are given in Table 1 and detailed specifications appear in Table 2.

**Table 1. ANSI Standard Preferred Sizes for Cylindrical Type Knurls**  
ANSI/ASME B94.6-1984

| Nominal Outside Diameter $D_{nr}$                        | Width of Face $F$ | Diameter of Hole $A$ | Standard Diametral Pitches, $P$               |    |     |     |
|--|-------------------|----------------------|---|----|-----|-----|
|  |                   |                      | 64  | 96 | 128 | 160 |
|  |                   |                      | Number of Teeth, $N_r$ , for Standard Pitches |    |     |     |
| $\frac{1}{2}$  | $\frac{3}{16}$    | $\frac{3}{16}$       | 32  | 48 | 64  | 80  |
| $\frac{5}{8}$  | $\frac{1}{4}$     | $\frac{1}{4}$        | 40  | 60 | 80  | 100 |
| $\frac{3}{4}$  | $\frac{3}{8}$     | $\frac{1}{4}$        | 48  | 72 | 96  | 120 |
| $\frac{7}{8}$  | $\frac{3}{8}$     | $\frac{1}{4}$        | 56  | 84 | 112 | 140 |
| Additional Sizes for Bench and Engine Lathe Tool Holders |                   |                      |   |    |     |     |
| $\frac{5}{8}$  | $\frac{5}{16}$    | $\frac{7}{32}$       | 40  | 60 | 80  | 100 |
| $\frac{3}{4}$  | $\frac{5}{8}$     | $\frac{1}{4}$        | 48  | 72 | 96  | 120 |
| 1  | $\frac{3}{8}$     | $\frac{5}{16}$       | 64  | 96 | 128 | 160 |

The 96 diametral pitch knurl should be given preference in the interest of tool simplification. Dimensions  $D_{nr}$ ,  $F$ , and  $A$  are in inches.

**Table 2. ANSI Standard Specifications for Cylindrical Knurls with Straight or Diagonal Teeth**  
ANSI/ASME B94.6-1984

| Diametral Pitch $P$ | Nominal Diameter, $D_{nr}$                          |               |               |               |        | Tracking Correction Factor $Q$ | Tooth Depth, $h$ ,<br>+ 0.0015,<br>- 0.0000 |          | Radius at Root $R$ |
|---------------------|---|---------------|---------------|---------------|--------|--------------------------------|---|----------|--------------------|
|                     | $\frac{1}{2}$                                       | $\frac{5}{8}$ | $\frac{3}{4}$ | $\frac{7}{8}$ | 1      |                                | Straight                                    | Diagonal |                    |
|                     | Major Diameter of Knurl, $D_{nr} + 0.0000, -0.0015$ |               |               |               |        |                                |   |          |                    |
| 64                  | 0.4932  | 0.6165        | 0.7398        | 0.8631        | 0.9864 | 0.0006676                      | 0.024                                       | 0.021    | 0.0070<br>0.0050   |
| 96                  | 0.4960  | 0.6200        | 0.7440        | 0.8680        | 0.9920 | 0.0002618                      | 0.016                                       | 0.014    | 0.0060<br>0.0040   |
| 128                 | 0.4972  | 0.6215        | 0.7458        | 0.8701        | 0.9944 | 0.0001374                      | 0.012                                       | 0.010    | 0.0045<br>0.0030   |
| 160                 | 0.4976  | 0.6220        | 0.7464        | 0.8708        | 0.9952 | 0.00009425                     | 0.009                                       | 0.008    | 0.0040<br>0.0025   |

All dimensions except diametral pitch are in inches.

Approximate angle of space between sides of adjacent teeth for both straight and diagonal teeth is 80 degrees. The permissible eccentricity of teeth for all knurls is 0.002 inch maximum (total indicator reading).

Number of teeth in a knurl equals diametral pitch multiplied by nominal diameter.

Diagonal teeth have 30-degree helix angle,  $\psi$ .

The term *Diametral Pitch* applies to the quotient obtained by dividing the total number of teeth in the circumference of the work by the basic blank diameter; in the case of the knurling tool it would be the total number of teeth in the circumference divided by the *nominal* diameter. In the Standard the diametral pitch and number of teeth are always measured in a transverse plane which is perpendicular to the axis of rotation for diagonal as well as straight knurls and knurling.

**Cylindrical Knurling Tools.**—The cylindrical type of knurling tool comprises a tool holder and one or more knurls. The knurl has a centrally located mounting hole and is provided with straight or diagonal teeth on its periphery. The knurl is used to reproduce this tooth pattern on the work blank as the knurl and work blank rotate together.

*\*Formulas for Cylindrical Knurls*

$$P = \text{diametral pitch of knurl} = N_t \div D_{nt} \quad (1)$$

$$D_{nt} = \text{nominal diameter of knurl} = N_t \div P \quad (2)$$

$$N_t = \text{no. of teeth on knurl} = P \times D_{nt} \quad (3)$$

$$*P_{nt} = \text{circular pitch on nominal diameter} = \pi \div P \quad (4)$$

$$*P_{ot} = \text{circular pitch on major diameter} = \pi D_{ot} \div N_t \quad (5)$$

$$D_{ot} = \text{major diameter of knurl} = D_{nt} - (N_t Q \div \pi) \quad (6)$$

$$Q = P_{nt} - P_{ot} = \text{tracking correction factor in Formula} \quad (7)$$

*Tracking Correction Factor Q:* Use of the preferred pitches for cylindrical knurls, [Table 2](#), results in good tracking on all fractional work-blank diameters which are multiples of  $\frac{1}{64}$  inch for 64 and 128 diametral pitch, and  $\frac{1}{32}$  inch for 96 and 160 diametral pitch; an indication of good tracking is evenness of marking on the work surface during the first revolution of the work.

The many variables involved in knurling practice require that an empirical correction method be used to determine what actual circular pitch is needed at the major diameter of the knurl to produce good tracking and the required circular pitch on the workpiece. The empirical tracking correction factor,  $Q$ , in [Table 2](#) is used in the calculation of the major diameter of the knurl, Formula (6).

\*Note: For diagonal knurls,  $P_{nt}$  and  $P_{ot}$  are the transverse circular pitches which are measured in the plane perpendicular to the axis of rotation.

**Flat Knurling Tools.**—The flat type of tool is a knurling die, commonly used in reciprocating types of rolling machines. Dies may be made with either single or duplex faces having either straight or diagonal teeth. No preferred sizes are established for flat dies.

*Flat Knurling Die with Straight Teeth:*

$R$  = radius at root

$P$  = diametral pitch =  $N_w \div D_w$  (8)

$D_w$  = work blank (pitch) diameter =  $N_w \div P$  (9)

$N_w$  = number of teeth on work =  $P \times D_w$  (10)

$h$  = tooth depth

$Q$  = tracking correction factor (see Table 2)

$P_l$  = linear pitch on die

= circular pitch on work pitch diameter =  $P - Q$  (11)

**Table 3. ANSI Standard Specifications for Flat Knurling Dies**  
ANSI/ASME B94.6-1984

| Diametral Pitch, $P$ | Linear Pitch, <sup>a</sup> $P_l$ | Tooth Depth, $h$ |          | Radius at Root, $R$ | Diametral Pitch, $P$ | Linear Pitch, <sup>a</sup> $P_l$ | Tooth Depth, $h$ |          | Radius at Root, $R$ |
|----------------------|----------------------------------|------------------|----------|---------------------|----------------------|----------------------------------|------------------|----------|---------------------|
|                      |                                  | Straight         | Diagonal |                     |                      |                                  | Straight         | Diagonal |                     |
| 64                   | 0.0484                           | 0.024            | 0.021    | 0.0070<br>0.0050    | 128                  | 0.0244                           | 0.012            | 0.010    | 0.0045<br>0.0030    |
| 96                   | 0.0325                           | 0.016            | 0.014    | 0.0060<br>0.0040    | 160                  | 0.0195                           | 0.009            | 0.008    | 0.0040<br>0.0025    |

<sup>a</sup>The linear pitches are theoretical. The exact linear pitch produced by a flat knurling die may vary slightly from those shown depending upon the rolling condition and the material being rolled.

All dimensions except diametral pitch are in inches.

**Formulas Applicable to Knurled Work.**—The following formulas are applicable to knurled work with straight, diagonal, and diamond knurling.

*Formulas for Straight or Diagonal Knurling with Straight or Diagonal Tooth Cylindrical Knurling Tools Set with Knurl Axis Parallel with Work Axis:*

$$P = \text{diametral pitch} = N_w \div D_w \quad (12)$$

$$D_w = \text{work blank diameter} = N_w \div P \quad (13)$$

$$N_w = \text{no. of teeth on work} = P \times D_w \quad (14)$$

$$a = \text{"addendum" of tooth on work} = (D_{ow} - D_w) \div 2 \quad (15)$$

$h$  = tooth depth (see Table 2)

$$D_{ow} = \text{knurled diameter (outside diameter after knurling)} = D_w + 2a \quad (16)$$

*Formulas for Diagonal and Diamond Knurling with Straight Tooth Knurling Tools Set at an Angle to the Work Axis:*

If,  $\psi$  = angle between tool axis and work axis

$P$  = diametral pitch on tool

$P_\psi$  = diametral pitch produced on work blank (as measured in the transverse plane) by setting tool axis at an angle  $\psi$  with respect to work blank axis

$D_w$  = diameter of work blank; and

$N_w$  = number of teeth produced on work blank (as measured in the transverse plane)

then,  $P_\psi = P \cos \psi$  (17)

and,  $N = D_w P \cos \psi$  (18)

For example, if 30 degree diagonal knurling were to be produced on 1-inch diameter stock with a 160 pitch straight knurl:

$$N_w = D_w P \cos 30^\circ = 1.000 \times 160 \times 0.86603 = 138.56 \text{ teeth}$$

Good tracking is theoretically possible by changing the helix angle as follows to correspond to a whole number of teeth (138):

$$\cos \psi = N_w \div D_w P = 138 \div (1 \times 160) = 0.8625$$

$$\psi = 30\frac{1}{2} \text{ degrees, approximately}$$

Whenever it is more practical to machine the stock, good tracking can be obtained by reducing the work blank diameter as follows to correspond to a whole number of teeth (138):

$$D_w = \frac{N_w}{P \cos \psi} = \frac{138}{160 \times 0.866} = 0.996 \text{ inch}$$

**Table 4. ANSI Standard Recommended Tolerances on Knurled Diameters**  
ANSI/ASME B94.6-1984

| Tolerance Class | Diametral Pitch                       |                    |                    |                    |  |                      |                     |                      |
|-----------------|---------------------------------------|--------------------|--------------------|--------------------|--|----------------------|---------------------|----------------------|
|                 | 64                                    | 96                 | 128                | 160                | 64   | 96                   | 128                 | 160                  |
|                 | Tolerance on Knurled Outside Diameter |                    |                    |                    | Tolerance on Work-Blank Diameter Before Knurling |                      |                     |                      |

**Recommended Tolerances on Knurled Outside Diameters.**—The recommended applications of the tolerance classes shown in Table 4 are as follows:

*Class I:* Tolerances in this classification may be applied to straight, diagonal and raised diamond knurling where the knurled outside diameter of the work need not be held to close dimensional tolerances. Such applications include knurling for decorative effect, grip on thumb screws, and inserts for moldings and castings.

*Class II:* Tolerances in this classification may be applied to straight knurling only and are recommended for applications requiring closer dimensional control of the knurled outside diameter than provided for by Class I tolerances.

*Class III:* Tolerances in this classification may be applied to straight knurling only and are recommended for applications requiring closest possible dimensional control of the knurled outside diameter. Such applications include knurling for close fits.

*Note:* The width of the knurling should not exceed the diameter of the blank, and knurling wider than the knurling tool cannot be produced unless the knurl starts at the end of the work.

**Marking on Knurls and Dies.**—Each knurl and die should be marked as follows: *a.* when straight to indicate its diametral pitch; *b.* when diagonal, to indicate its diametral pitch, helix angle, and hand of angle.

**Concave Knurls.**—The radius of a concave knurl should not be the same as the radius of the piece to be knurled. If the knurl and the work are of the same radius, the material compressed by the knurl will be forced down on the shoulder *D* and spoil the appearance of the work. A design of concave knurl is shown in the accompanying illustration, and all the important dimensions are designated by letters. To find these dimensions, the pitch of the knurl required must be known, and also, approximately, the throat diameter *B*. This diameter must suit the knurl holder used, and be such that the circumference contains an even number of teeth with the required pitch. When these dimensions have been decided upon, all the other unknown factors can be found by the following formulas: Let *R* = radius of piece to be knurled; *r* = radius of concave part of knurl; *C* = radius of cutter or hob for cutting the teeth in the knurl; *B* = diameter over concave part of knurl (throat diameter); *A* = outside diameter of knurl; *d* = depth of tooth in knurl; *P* = pitch of knurl (number of teeth per inch circumference); *p* = circular pitch of knurl; then  $r = R + \frac{1}{2}d$ ;  $C = r + d$ ;  $A = B + 2r - (3d + 0.010 \text{ inch})$ ; and  $d = 0.5 \times p \times \cot \alpha/2$ , where  $\alpha$  is the included angle of the teeth.

As the depth of the tooth is usually very slight, the throat diameter *B* will be accurate enough for all practical purposes for calculating the pitch, and it is not necessary to take into consideration the pitch circle. For example, assume that the pitch of a knurl is 32, that the throat diameter *B* is 0.5561 inch, that the radius *R* of the piece to be knurled is  $\frac{1}{16}$  inch, and that the angle of the teeth is 90 degrees; find the dimensions of the knurl. Using the notation given:

$$p = \frac{1}{P} = \frac{1}{32} = 0.03125 \text{ inch}$$

$$d = 0.5 \times 0.03125 \times \cot 45^\circ = 0.0156 \text{ inch}$$

$$r = \frac{1}{16} + \frac{0.0156}{2} = 0.0703 \text{ inch}$$

$$C = 0.0703 + 0.0156 = 0.0859 \text{ inch}$$

$$A = 0.5561 + 0.1406 - (0.0468 + 0.010) = 0.6399 \text{ inch}$$

## MACHINE TOOL ACCURACY

**Accuracy, Repeatability, and Resolution:** In machine tools, accuracy is the maximum spread in measurements made of slide movements during successive runs at a number of target points, as discussed below. Repeatability is the spread of the normal curve at the target point that has the largest spread. A rule of thumb says that repeatability is approximately half the accuracy value, or twice as good as the accuracy, but this rule is somewhat nullified due to the introduction of error-compensation features on NC machines. Resolution refers to the smallest units of measurement that the system (controller plus servo) can recognize. Resolution is an electronic/electrical term and the unit is usually smaller than either the accuracy or the repeatability. Low values for resolution are usually, though not necessarily, applied to machines of high accuracy. In addition to high cost, a low-resolution-value design usually has a low maximum feed rate and the use of such designs is usually restricted to applications requiring high accuracy.

**Positioning Accuracy:** The positioning accuracy of a numerically controlled machine tool refers to the ability of an NC machine to place the tip of a tool at a preprogrammed target. Although no metal cutting is involved, this test is very significant for a machine tool and the cost of an NC machine will rise almost geometrically with respect to its positioning accuracy. Care, therefore, should be taken when deciding on the purchase of such a machine, to avoid paying the premium for unneeded accuracy but instead to obtain a machine that will meet the tolerance requirements for the parts to be produced.

Accuracy can be measured in many ways. A tool tip on an NC machine could be moved, for example, to a target point whose  $X$ -coordinate is 10.0000 inches. If the move is along the  $X$ -axis, and the tool tip arrives at a point that measures 10.0001 inches, does this mean that the machine has an accuracy of 0.0001 inch? What if a repetition of this move brought the tool tip to a point measuring 10.0003 inches, and another repetition moved the tool to a point that measured 9.9998 inches? In practice, it is expected that there would be a scattering or distribution of measurements and some kind of averaging is normally used.

Fig. 1. In a Normal Distribution, Plotted Points Cluster Around the Mean.

Although averaging the results of several runs is an improvement over a single run, the main problem with averaging is that it does not consider the extent or width of the spread of readings. For example, if one measurement to the 10.0000-inch target is 9.9000 inches and another is 10.1000 inches, the difference of the two readings is 0.2000 inch, and the accuracy is poor. However, the readings average a perfect 10 inches. Therefore, the average and the spread of several readings must both be considered in determining the accuracy.

Plotting the results of a large number of runs generates a *normal distribution curve*, as shown in Fig. 1. In this example, the readings are plotted along the  $X$ -axis in increments of

0.0001 inch (0.0025 mm). Usually, five to ten such readings are sufficient. The distance of any one reading from the target is called the *positional deviation* of the point. The distance of the mean, or average, for the normal distribution from the target is called the *mean positional deviation*.

The spread for the normal curve is determined by a mathematical formula that calculates the distance from the mean that a certain percentage of the readings fall into. The mathematical formula used calculates one *standard deviation*, which represents approximately 32 per cent of the points that will fall within the normal curve, as shown in Fig. 2. One standard deviation is also called one sigma, or  $1\sigma$ . Plus or minus one sigma ( $\pm 1\sigma$ ) represents 64 per cent of all the points under the normal curve. A wider range on the curve,  $\pm 2\sigma$ , means that 95.44 per cent of the points are within the normal curve, and  $\pm 3\sigma$  means that 99.74 per cent of the points are within the normal curve. If an infinite number of runs were made, almost all the measurements would fall within the  $\pm 3\sigma$  range.

Fig. 2. Percentages of Points Falling in the  $\pm 1\sigma$  (64%),  $\pm 2\sigma$  (95.44%), and  $\pm 3\sigma$  (99.74%) Ranges  
The formula for calculating one standard deviation is

$$1\sigma = \sqrt{\frac{1}{n-1} \sum_{i=1}^n (X_{ij} - \bar{X}_j)^2}$$

where  $n$  = number of runs to the target;  $i$  = identification for any one run;  $X_{ij}$  = positional deviation for any one run (see Fig. 1); and,  $\bar{X}_j$  = mean positional deviation (see Fig. 1).

The bar over the  $\bar{X}$  in the formula indicates that the value is the mean or average for the normal distribution.

*Example:* From Fig. 3, five runs were made at a target point that is 10.0000 inches along the X-axis and the positional deviations for each run were:

$x_{1j} = -0.0002$ ,  $x_{2j} = +0.0002$ ,  $x_{3j} = +0.0005$ ,  $x_{4j} = +0.0007$ , and  $x_{5j} = +0.0008$  inch. The algebraic total of these five runs is +0.0020, and the mean positional deviation =  $\bar{X}_j = 0.0020/5 = 0.0004$ .

The calculations for one standard deviation are:

$$\begin{aligned} 1\sigma &= \sqrt{\frac{1}{n-1} [(X_{1j} - \bar{X}_j)^2 + (X_{2j} - \bar{X}_j)^2 + (X_{3j} - \bar{X}_j)^2 + (X_{4j} - \bar{X}_j)^2 + (X_{5j} - \bar{X}_j)^2]} \\ 1\sigma &= \sqrt{\frac{1}{5-1} [(-0.0002 - 0.0004)^2 + (0.0002 - 0.0004)^2 + \\ &\quad (0.0005 - 0.0004)^2 + (0.0007 - 0.0004)^2 + (0.0008 - 0.0004)^2]} \\ &= \sqrt{\frac{1}{4}(0.0000066)} = \sqrt{0.17 \times 10^{-6}} = 0.0004 \end{aligned}$$

Three sigma variations or  $3\sigma$ , is 3 times sigma, equal to 0.0012 for the example.

If an infinite number of trials were made to the target position of 10.0000 inches for the ongoing example, 99.74 per cent of the points would fall between 9.9992 and 10.0016 inches, giving a spread of  $\pm 3\sigma$ , or 0.0024 inch. This spread alone is not considered as the accuracy but rather the repeatability for the target point 10.0000.

Fig. 3. Readings for Five Runs to Target Points  $P_1, P_2, P_3, P_4,$  and  $P_5$  Result in a Mean Positional Deviation of 0.0004

To calculate the accuracy, it is not sufficient to make a number of runs to one target point along a particular axis, but rather to a number of points along the axis, the number depending on the length of axis travel provided. For example, a travel of about 3 ft requires 5, and a travel of 6 ft requires 10 target points. The standard deviation and spread for the normal curve must be determined at each target point, as shown in Fig. 4. The accuracy for the axis would then be the spread between the normal curve with the most negative position and the normal curve with the most positive position. Technically, the accuracy is a spread rather than a  $\pm$  figure, but it is often referred to as a  $\pm$  figure and it may be assumed that a  $\pm 0.003$ , for expediency, is equal to a spread of 0.006.

The above description for measuring accuracy considers unidirectional approaches to target points. Bidirectional movements (additional movements to the same target point from either direction) will give different results, mostly due to backlash in the lead-screw, though backlash is small with ballnut leadscrews. Measurements made with bidirectional movements will show greater spreads and somewhat less accuracy than will unidirectional movements.

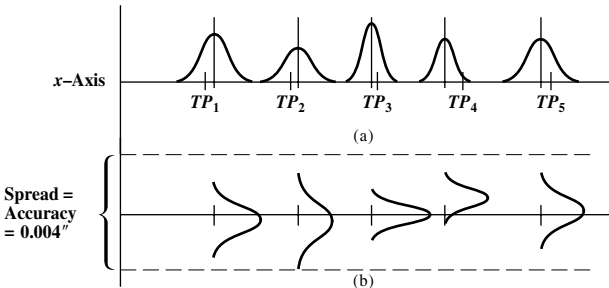

Fig. 4. Two Ways of Plotting Five Target Point Spreads

Rules for determining accuracy were standardized in guidelines last revised by the Association for Manufacturing Technology (AMT) in 1972. Some European machine tool builders use the VDI/DGQ 3441 (German) guidelines, which are similar to those of the

AMT in that normal distributions are used and a number of target points are selected along an axis. Japanese standards JIS B6201, JIS B6336, and JIS B6338 are somewhat simpler and consider only the spread of the readings, so that the final accuracy figure may be almost double that given by the AMT or VDI methods. The International Standards Organization (ISO), in 1988, issued ISO 230-2, which follows the procedures discussed above, but is somewhat less strict than the AMT recommendations. Table 1 lists some types of NC machines and the degree of accuracy that they normally provide.

**Table 1. Degrees of Accuracy Expected with NC Machine Tools**

| Type of NC Machine                                   | Accuracy       |              |
|--|----------------|--------------|
|  | inches         | mm           |
| Large boring machines or boring mills                | 0.0010–0.0020  | 0.025–0.050  |
| Small milling machines                               | 0.0006–0.0010  | 0.015–0.025  |
| Large machining centers                              | 0.0005–0.0008  | 0.012–0.020  |
| Small and medium-sized machining centers             | 0.0003–0.0006  | 0.008–0.015  |
| Lathes, slant bed, small and medium sizes            | 0.0002–0.0005  | 0.006–0.012  |
| Lathes, small precision                              | 0.0002–0.0003  | 0.004–0.008  |
| Horizontal jigmill                                   | 0.0002–0.0004  | 0.004–0.010  |
| Vertical jig boring machines                         | 0.0001–0.0002  | 0.002–0.005  |
| Vertical jig grinding machines                       | 0.0001–0.0002  | 0.002–0.005  |
| Cylindrical grinding machines, small to medium sizes | 0.00004–0.0003 | 0.001–0.007  |
| Diamond turning lathes                               | 0.00002–0.0001 | 0.0005–0.003 |

*Significance of Accuracy:* Numerically controlled machines are generally considered to be more accurate and more consistent in their movements than their conventional counterparts. CNC controllers have improved the accuracy by providing the ability to compensate for mechanical inaccuracies. Thus, compensation for errors in the lead-screw, parallelism and squareness of the machine ways, and for the effects of heating can be made automatically on NC machines. Some machine tool types are expected to be more accurate than others; for instance, grinding machines are more accurate than milling machines, and lathes for diamond turning are more accurate than normal slant-bed lathes.

Accuracy of machine tools depends on temperature, air pressure, local vibrations, and humidity. ISO standard 230-2 requires that, where possible, the ambient temperature for conducting such tests be held between 67.1 and 68.9 degrees F (19.5 and 20.5 degrees C).

*Autocollimation:* Checks on movements of slides and spindles, and alignment and other characteristics of machine tools are performed with great accuracy by means of an autocollimator, which is an optical, noncontact, angle-measuring instrument. Flatness, straightness, perpendicularity, and runout can also be checked by autocollimation. The instrument is designed to project a beam of light from a laser or an incandescent bulb onto an optically flat mirror. When the light beam is reflected back to the instrument, the distance traveled by the beam, also deviations from a straight line, can be detected by the projector and calculated electronically or measured by the scale.

Autocollimators have a small angular measuring range and are usually calibrated in arc-seconds. One arc-second is an angle of 4.85 millionths of an inch (0.00000485 in.) per inch of distance from the vertex, and is often rounded to 5 millionths of an inch per inch. Angles can also be described in terms of radians and 1 arc-second is equal to 4.85 microradians, or 0.0000573 deg.

In practice, the interferometer or autocollimator is fixed to a rigid structure and the optical mirror, which should have a flatness of one-quarter wavelength of the light used (see page 723), is fixed to the workpiece to be measured. The initial reading is taken, and then

the workpiece is moved to another position. Readings of movement can be made to within a few millionths of an inch. Angular displacements, corresponding to successive positions, of about 1 arc-second can be taken from most autocollimators, in azimuth or elevation or a combination of the two. Generally, the line width of the reticle limits the accuracy of reading such instruments.

Laser interferometers are designed to allow autocollimation readings to be taken by a photodetector instead of the eye, and some designs can measure angles to 0.001 arc-second, closer than is required for most machine shop applications. Output from an electronic autocollimator is usually transferred to a computer for recording or analysis if required. The computer calculates, lists, and plots the readings for the target points automatically, under control of the inspection program.

A typical plot from such a setup is seen in Fig. 5, where the central line connects the averages for the normal distributions at each target point. The upper line connects the positive outer limits and the lower line the negative outer limits for the normal distributions. The normal spread, indicating the accuracy of positioning, is 0.00065 inch (0.016 mm), for the Y-axis along which the measurements were taken.

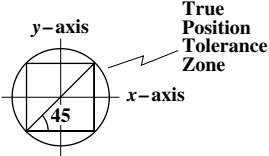

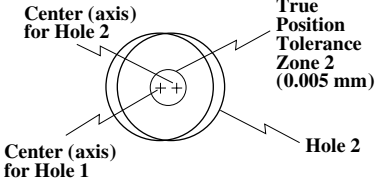

Fig. 5. Laser Interferometer Plots of Movements of Slides on a Large Horizontal Machining Center Showing an Accuracy of 0.00065 inch (0.016 mm) for the y Axis

### Effect of Machine Accuracy on Part Tolerances

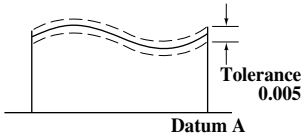

Part tolerances are usually shown on prints, usually in a control block to ANSI Standard 14.5M-1994 (see *Geometric Dimensioning and Tolerancing* starting on page 630.) Table 2 shows some part tolerance symbols that relate to machine tool positioning accuracy. The accuracy of a part is affected by machine and cutting tool dynamics, alignment, fixture accuracy, operator settings, and accuracies of the cutting tools, holders, and collets, but the positioning accuracy of the machine probably has the greatest influence. Spindle rotation accuracy, or runout, also has a large influence on part accuracy.

The ratio of the attainable part accuracy to the no-load positioning accuracy can vary from 1.7:1 to 8.31:1, depending on the type of cutting operation. For instance, making a hole by drilling, followed by a light boring or reaming operation, produces a quite accurate result in about the 1.7:1 range, whereas contour milling on hard material could be at the higher end of the range. A good average for part accuracy versus machine positioning accuracy is 3.3:1, which means that the part accuracy is 3.3 times the positioning accuracy.

**Table 2. Symbols and Feature Control Frames ANSI Y14.5M-1994**

| Symbol  | Characteristic | Meaning of Characteristic   | Relationship to the Machine Tool   |
|---|----------------|---|--|
|  | Position       | <p>The allowable true position tolerance of a feature from a datum (assume feature to be a drilled hole).<br/>Feature control block might appear as:</p> <div style="text-align: center;">  </div> <p>A is the datum, which can be another surface, another hole, or other feature</p> | <p>Assume tolerance is 0.005 mm. Machine positioning accuracy would be at least <math>0.005 \times 0.707 = 0.0035</math> mm even if it is assumed that the hole accuracy is the same as the positioning accuracy. Machine could be milling, drilling, or machining center.</p> <div style="text-align: center;">  </div> |
|   | Position       | <p>Assume feature to be a turned circumference, the axis of which has to be within a tolerance to another feature.<br/>Feature control block would appear as follows if feature A were the axis of hole 1:</p> <div style="text-align: center;">  </div>                               | <div style="text-align: center;">  </div>  |

**Table 2. Symbols and Feature Control Frames ANSI Y14.5M-1994**

| Symbol   | Characteristic       | Meaning of Characteristic  | Relationship to the Machine Tool  |
|--|----------------------|--|---|
|  | Roundness            | <p>The roundness tolerance establishes a band.</p>    | <p>This tolerance would apply to turning and would be the result of radial spindle runout.</p>  |
|  | Diameter             | <p>Usually expressed as a <math>\pm</math> tolerance attached to the dimension.</p>  | <p>Diametral accuracy of the part would depend on the positioning accuracy of the cross-slide of lathe or grinder. Positioning accuracy would be from <math>\frac{1}{2}</math> to <math>\frac{1}{4}</math> of part accuracy, depending chiefly on the rigidity of the tool, depth of cut, and material being cut.</p> |
|  | Profile of a surface | <p>Specifies a uniform boundary, along a true profile.</p>  <p>Feature control block might appear as:</p>  | <p>Affected by positioning accuracy of machine. There would be side and/or end forces on the tool so expect part to machine positioning accuracy to be high, say, 5:1</p>   |

**Table 2. Symbols and Feature Control Frames** ANSI Y14.5M-1994

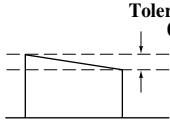

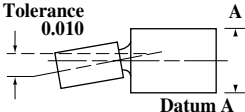

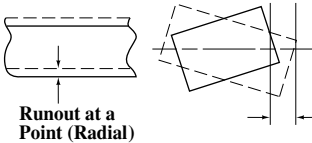

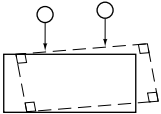

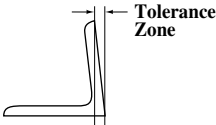

| Symbol   | Characteristic | Meaning of Characteristic  | Relationship to the Machine Tool                                    |
|--|----------------|--|---|
| //   | Parallelism    | <p>A feature (surface) parallel to a datum plane or datum axis.</p>  <p style="text-align: center;"><b>Datum A</b></p> <p>Feature control block might appear as:</p> <div style="text-align: center; border: 1px solid black; padding: 5px; display: inline-block;"> <span style="font-size: 1.2em;">//</span> <span style="font-size: 1.2em;">Ø 0.010</span> <span style="font-size: 1.2em;">A</span> </div>   | Affected by positioning accuracy, machine alignment, and fixturing. |
|  | Concentricity  | <p>Applies to turning. The axis of the feature must lie within the tolerance zone of another axis.</p>  <p style="text-align: center;"><b>Datum A</b></p> <p>Feature control block might appear as follows:</p> <div style="text-align: center; border: 1px solid black; padding: 5px; display: inline-block;"> <span style="font-size: 1.2em;">⊙</span> <span style="font-size: 1.2em;">Ø 0.005</span> <span style="font-size: 1.2em;">A</span> </div> | Affected by positioning accuracy, most likely along Z axis.         |

Table 2. Symbols and Feature Control Frames ANSI Y14.5M-1994

| Symbol   | Characteristic   | Meaning of Characteristic  | Relationship to the Machine Tool  |
|--|------------------|--|---|
|  | Runout           | <p>Applies to the runout (both radial and axial) of a circular feature at any one position around the circumference or flat, perpendicular to the axis.</p>  <p><b>Runout at a Point (Radial)</b>      <b>Runout at a Point (Axial)</b></p> <p>Runout at a Point (Radial)</p> | <p>Radial runout on part is not affected by spindle radial runout unless whole machine is untrue.</p> <p>Axial runout on part is affected by axial runout on machine. Feature would normally be perpendicular to datum.</p> <p>Feature control block might appear as:</p>  |
|  | Total runout     | <p>Similar to runout but applies to total surface and therefore consider both radial and axial runout.</p>    | <p>Would be affected by either radial or axial runout, or both, machine misalignment, or setup.</p>   |
|  | Perpendicularity | <p>A feature is perpendicular to a datum plane or axis.</p>  <p><b>Tolerance Zone</b></p>   | <p>Affected principally by misalignment of machine or fixturing.</p>  |

## NUMERICAL CONTROL

**Introduction.**—The Electronic Industries Association (EIA) defines numerical control as “a system in which actions are controlled by the direct insertion of numerical data at some point.” More specifically, numerical control, or NC as it will be called here, involves machines controlled by electronic systems designed to accept numerical data and other instructions, usually in a coded form. These instructions may come directly from some source such as a punched tape, a floppy disk, directly from a computer, or from an operator.

The key to the success of numerical control lies in its flexibility. To machine a different part, it is only necessary to “play” a different tape. NC machines are more productive than conventional equipment and consequently produce parts at less cost even when the higher investment is considered. NC machines also are more accurate and produce far less scrap than their conventional counterparts. By 1985, over 110,000 NC machine tools were operating in the United States. Over 80 per cent of the dollars being spent on the most common types of machine tools, namely, drilling, milling, boring, and turning machines, are going into NC equipment.

NC is a generic term for the whole field of numerical control and encompasses a complete field of endeavor. Sometimes CNC, which stands for Computer Numerical Control and applies only to the control system, is used erroneously as a replacement term for NC. Albeit a monumental development, use of the term CNC should be confined to installations where the older hardware control systems have been replaced.

Metal cutting is the most popular application, but NC is being applied successfully to other equipment, including punch presses, EDM wire cutting machines, inspection machines, laser and other cutting and torching machines, tube bending machines, and sheet metal cutting and forming machines.

**State of the CNC Technology Today.**—Early numerical control machines were ordinary machines retrofitted with controls and motors to drive tools and tables. The operations performed were the same as the operations were on the machines replaced. Over the years, NC machines began to combine additional operations such as automatically changing tools and workpieces. The structure of the machines has been strengthened to provide more rigid platforms. These changes have resulted in a class of machine that can outperform its predecessors in both speed and accuracy. Typical capabilities of a modern machining center are accuracy better than  $\pm 0.00035$  inch; spindle speeds in the range up to 25,000 rpm or more, and increasing; feed rates up to 400 inches per minute and increasing; tool change times hovering between 2 and 4 seconds and decreasing. Specialized machines have been built that can achieve accuracy better than one millionth (0.000001) of an inch.

Computer numerical control of machines has undergone a great deal of change in the last decade, largely as a result of rapid increases in computer capability. Development of new and improved materials for tooling and bearings, improvements in tool geometry, and the added structural stiffness of the new machines have made it possible to perform cutting operations at speeds and feeds that were formerly impossible to attain.

**Numerical Control vs. Manual Operations.**—The initial cost of a CNC machine is generally much higher than a manual machine of the same nominal capacity, and the higher initial cost leads to a higher overall cost of the machine per hour of its useful life. However, the additional cost of a CNC machine has to be considered against potential savings that the machine may make possible. Some of the individual factors that make NC and CNC machining attractive are considered below.

Labor is usually one of the highest costs in the production of a part, but the labor rate paid to a CNC machine operator may be lower than the rate paid to the operator of conventional machines. This statement is particularly true when there is a shortage of operators with specialized skills necessary for setting up and operating a manual machine. However, it should not be assumed that skilled CNC machine operators are not needed because most CNCs have manual overrides that allow the operator to adjust feeds and speeds and to manually edit or enter programs as necessary. Also, skilled setup personnel and operators are

likely to promote better production rates and higher efficiency in the shop. In addition, the labor rate for setting up and operating a CNC machine can sometimes be divided between two or more machines, further reducing the labor costs and cost per part produced.

The quantity and quality requirements for an order of parts often determines what manufacturing process will be used to produce them. CNC machines are probably most effective when the jobs call for a small to medium number of components that require a wide range of operations to be performed. For example, if a large number of parts are to be machined and the allowable tolerances are large, then manual or automatic fixed-cycle machines may be the most viable process. But, if a large quantity of high quality parts with strict tolerances are required, then a CNC machine will probably be able to produce the parts for the lowest cost per piece because of the speed and accuracy of CNC machines. Moreover, if the production run requires designing and making a lot of specialized form tools, cams, fixtures, or jigs, then the economics of CNC machining improves even more because much of the preproduction work is not required by the nature of the CNC process.

CNC machines can be effective for producing one-of-a-kind jobs if the part is complicated and requires a lot of different operations that, if done manually, would require specialized setups, jigs, fixtures, etc. On the other hand, a single component requiring only one or two setups might be more practical to produce on a manual machine, depending on the tolerances required. When a job calls for a small to medium number of components that require a wide range of operations, CNC is usually preferable. CNC machines are also especially well suited for batch jobs where small numbers of components are produced from an existing part program, as inventory is needed. Once the part program has been tested, a batch of the parts can be run whenever necessary. Design changes can be incorporated by changing the part program as required. The ability to process batches also has an additional benefit of eliminating large inventories of finished components.

CNC machining can help reduce machine idle time. Surveys have indicated that when machining on manual machines, the average time spent on material removal is only about 40 per cent of the time required to complete a part. On particularly complicated pieces, this ratio can drop to as low as 10 per cent or even less. The balance of the time is spent on positioning the tool or work, changing tools, and similar activities. On numerically controlled machines, the metal removal time frequently has been found to be in excess of 70 per cent of the total time spent on the part. CNC nonmachining time is lower because CNC machines perform quicker tool changes and tool or work positioning than manual machines. CNC part programs require a skilled programmer and cost additional preproduction time, but specialized jigs and fixtures that are frequently required with manual machines are not usually required with CNC machines, thereby reducing setup time and cost considerably.

Additional advantages of CNC machining are reduced lead time; improved cutting efficiency and longer tool life, as a result of better control over the feeds and speeds; improved quality and consistently accurate parts, reduced scrap, and less rework; lower inspection costs after the first part is produced and proven correct; reduced handling of parts because more operations can be performed per setup; and faster response to design changes because most part changes can be made by editing the CNC program.

**Numerical Control Standards.**—Standards for NC hardware and software have been developed by many organizations, and copies of the latest standards may be obtained from the following: Electronic Industries Association (EIA), 2001 Pennsylvania Avenue NW, Washington, DC 20006 (EIA and ANSI/EIA); American Society of Mechanical Engineers (ASME), 345 East 47th Street, New York, NY 10017 (ANSI/ASME); American National Standards Institute (ANSI), 25 West 43rd Street, New York, NY 10036 (ANSI, ANSI/EIA, ANSI/ASME, and ISO); National Standards Association, Inc. (NSA), 1200 Quince Orchard Boulevard, Gaithersburg, MD 20878; NMTBA The Association for Manufacturing Technology, 7901 Westpark Drive, McLean, VA 22102. Some of the standards and their contents are listed briefly in the accompanying table.

## Numerical Control Standards

| Standard Title          | Description   |
|-------------------------|---|
| ANSI/CAM-I<br>101-1990  | Dimensional Measuring Interface Specification   |
| ANSI/ASME B5.50         | V-Flange Tool Shanks for Machining Centers with Automatic Tool Changers   |
| ANSI/ASME<br>B5.54-1992 | Methods for Performance Evaluation of Computer Numerically Controlled Machining Centers   |
| ANSI/ASME<br>B89.1.12M  | Methods for Performance Evaluation of Coordinate Measuring Machines   |
| ANSI/EIA 227-A          | 1-inch Perforated Tape  |
| ANSI/EIA 232-D          | Interface Between Data Terminal Equipment and Data Circuit-Terminating Equipment Employing Serial Binary Data Interchange   |
| ANSI/EIA 267-B          | Axis and Motion Nomenclature for Numerically Controlled Machines  |
| ANSI/EIA 274-D          | Interchangeable Variable Block Data Format for Positioning, Contouring and Contouring/Positioning Numerically Controlled Machines   |
| ANSI/EIA 358-B          | Subset of American National Standard Code for Information Interchange for Numerical Machine Control Perforated Tape   |
| ANSI/EIA 408            | Interface Between NC Equipment and Data Terminal Equipment Employing Parallel Binary Data Interchange   |
| ANSI/EIA 423-A          | Electrical Characteristics of Unbalanced Voltage Digital Interface Circuits   |
| ANSI/EIA 431            | Electrical Interface Between Numerical Control and Machine Tools  |
| ANSI/EIA 441            | Operator Interface Function of Numerical Controls   |
| ANSI/EIA 449            | General Purpose 37-position and 9-position Interface for Data Terminal Equipment and Data Circuit-Terminating Equipment Employing Serial Binary Data Interchange  |
| ANSI/EIA 484            | Electrical and Mechanical Interface Characteristics and Line Control Protocol Using Communication Control Characters for Serial Data Link between a Direct Numerical Control System and Numerical Control Equipment Employing Asynchronous Full Duplex Transmission |
| ANSI/EIA 491-A<br>-1990 | Interface between a Numerical Control Unit and Peripheral Equipment Employing Asynchronous Binary Data Interchange over Circuits having EIA-423-A Electrical Characteristics  |
| ANSI/EIA 494            | 32-bit Binary CL Interchange (BCL) Input Format for Numerically Controlled Machines   |
| EIA AB3-D               | Glossary of Terms for Numerically Controlled Machines   |
| EIA Bulletin 12         | Application Notes on Interconnection between Interface Circuits Using RS-449 and RS-232-C   |
| ANSI X 3.94             | Programming Aid for Numerically Controlled Manufacturing  |
| ANSI X 3.37             | Programming Language APT  |
| ANSI X 3.20             | 1-inch Perforated Tape Take-up Reels for Information Interchange  |
| ANSI X 3.82             | One-sided Single Density Unformatted 5.25 inch Flexible Disc Cartridges   |

**Numerical Control Standards (Continued)**

| Standard Title | Description  |
|----------------|--|
| ISO 841        | Numerical Control of Machines—Axis and Motion Nomenclature   |
| ISO 2806       | Numerical Control of Machines—Bilingual Vocabulary   |
| ISO 2972       | Numerical Control of Machines—Symbols  |
| ISO 3592       | Numerical Control of Machines—Numerical Control Processor Output, Logical Structure and Major Words  |
| ISO 4336       | Numerical Control of Machines—Specification of Interface Signals between the Numerical Control Unit and the Electrical Equipment of a Numerically Controlled Machine |
| ISO 4343       | Numerical Control of Machines—NC Processor Output— Minor Elements of 2000-type Records (Post Processor Commands)   |
| ISO TR 6132    | Numerical Control of Machines—Program Format and Definition of Address Words—Part 1: Data Format for Positioning, Line Motion and Contouring Control Systems         |
| ISO 230-1      | Geometric Accuracy of Machines Operating Under No-Load or Finishing Conditions   |
| ISO 230-2      | Determination of Accuracy and Repeatability of Positioning of Numerically Controlled Machine Tools   |
| NAS 911        | Numerically Controlled Skin/Profile Milling Machines   |
| NAS 912        | Numerically Controlled Spar Milling Machines   |
| NAS 913        | Numerically Controlled Profiling and Contouring Milling Machines   |
| NAS 914        | Numerically Controlled Horizontal Boring, Drilling and Milling Machines  |
| NAS 960        | Numerically Controlled Drilling Machines   |
| NAS 963        | Computer Numerically Controlled Vertical and Horizontal Jig Boring Machines  |
| NAS 970        | Basic Tool Holders for Numerically Controlled Machine Tools  |
| NAS 971        | Precision Numerically Controlled Measuring/Inspection Machines   |
| NAS 978        | Numerically Controlled Machining Centers   |
| NAS 990        | Numerically Controlled Composite Filament Tape Laying Machines   |
| NAS 993        | Direct Numerical Control System  |
| NAS 994        | Adaptive Control System for Numerically Controlled Milling Machines  |
| NAS 995        | Specification for Computerized Numerical Control (CNC)   |
| NMTBA          | Common Words as They Relate to Numerical Control Software  |
| NMTBA          | Definition and Evaluation of Accuracy and Repeatability of Numerically Controlled Machine Tools  |
| NMTBA          | Numerical Control Character Code Cross Reference Chart   |
| NMTBA          | Selecting an Appropriate Numerical Control Programming Method  |
| NEMA 1A1       | Industrial Cell Controller Classification Concepts and Selection Guide   |

**Programmable Controller.**—Frequently referred to as a PC or PLC (the latter term meaning Programmable Logic Controller), a programmable controller is an electronic unit or small computer. PLCs are used to control machinery, equipment, and complete processes, and to assist CNC systems in the control of complex NC machine tools and flexible manufacturing modules and cells. In effect, PLCs are the technological replacements for electrical relay systems.

Fig. 1. Programmable Controllers' Four Basic Elements

As shown in Fig. 1, a PLC is composed of four basic elements: the equipment for handling input and output (I/O) signals, the central processing unit (CPU), the power supply, and the memory. Generally, the CPU is a microprocessor and the brain of the PLC. Early PLCs used hardwired special-purpose electronic logic circuits, but most PLCs now being offered are based on microprocessors and have far more logic and control capabilities than was possible with hardwired systems. The CPU scans the status of the input devices continuously, correlates these inputs with the control logic in the memory, and produces the appropriate output responses needed to control the machine or equipment.

Input to a PLC is either discrete or continuous. Discrete inputs may come from push buttons, micro switches, limit switches, photocells, proximity switches or pressure switches, for instance. Continuous inputs may come from sources such as thermocouples, potentiometers, or voltmeters. Outputs from a PLC normally are directed to actuating hardware such as solenoids, solenoid valves, and motor starters. The function of a PLC is to examine the status of an input or set of inputs and, based on this status, actuate or regulate an output or set of outputs.

Digital control logic and sensor input signals are stored in the memory as a series of binary numbers (zeros and ones). Each memory location holds only one "bit" (either 0 or 1) of binary information; however, most of the data in a PLC are used in groups of 8 bits, or bytes. A word is a group of bytes that is operated on at one time by the PLC. The word size in modern PLCs ranges from 8 to 32 bits (1 to 4 bytes), depending on the design of the PLC. In general, the larger the word size that a system is able to operate on (that is, to work on at one time), the faster the system is going to perform. New systems are now beginning to appear that can operate on 64 bits of information at a time.

There are two basic categories of memory: volatile and nonvolatile. Volatile memory loses the stored information when the power is turned off, but nonvolatile memory retains its logic even when power is cut off. A backup battery must be used if the information stored in volatile memory is to be retained. There are six commonly used types of memory. Of these six, random-access memory (RAM) is the most common type because it is the easiest to program and edit. RAM is also the only one of the six common types that is vola-

tile memory. The five nonvolatile memory types are: core memory, read-only memory (ROM), programmable read-only memory (PROM), electronically alterable programmable read-only memory (EAPROM), and electronically erasable programmable read-only memory (EEPROM). EEPROMs are becoming more popular due to their relative ease of programming and their nonvolatile characteristic. ROM is often used as a generic term to refer to the general class of read-only memory types and to indicate that this type of memory is not usually reprogrammed.

More than 90 per cent of the microprocessor PLCs now in the field use RAM memory. RAM is primarily used to store data, which are collected or generated by a process, and to store programs that are likely to change frequently. For example, a part program for machining a workpiece on a CNC machining center is loaded into and stored in RAM. When a different part is to be made, a different program can be loaded in its place. The nonvolatile memory types are usually used to store programs and data that are not expected to be changed. Programs that directly control a specific piece of equipment and contain specific instructions that allow other programs (such as a part program stored in RAM) to access and operate the hardware are usually stored in nonvolatile memory or ROM. The benefit of ROM is that stored programs and data do not have to be reloaded into the memory after the power has been turned off.

PLCs are used primarily with handling systems such as conveyors, automatic retrieval and storage systems, robots, and automatic guided vehicles (AGV), such as are used in flexible manufacturing cells, modules, and systems (see *Flexible Manufacturing Systems (FMS)*, *Flexible Manufacturing Cell*, and *Flexible Manufacturing Module*). PLCs are also to be found in applications as diverse as combustion chamber control, chemical process control, and printed-circuit-board manufacturing.

#### Types of Programmable Controllers

| Type   | No. of I/Os | General Applications  | Math Capability |
|--------|-------------|---|-----------------|
| Mini   | 32          | Replaces relays, timers, and counters.  | Yes             |
| Micro  | 32–64       | Replaces relays, timers, and counters.  | Yes             |
| Small  | 64–128      | Replaces relays, timers, and counters. Used for materials handling, and some process control.   | Yes             |
| Medium | 128–512     | Replaces relays, timers, and counters. Used for materials handling, process control, and data collection.                                   | Yes             |
| Large  | 512+        | Replaces relays, timers, and counters. Master control for other PLCs and cells and for generation of reports. High-level network capability | Yes             |

Types of PLCs may be divided into five groups consisting of micro, mini, small, medium, and large according to the number of I/Os, functional capabilities, and memory capacity. The smaller the number of I/Os and memory capacity, and the fewer the functions, the simpler the PLC. Micro and mini PLCs are usually little more than replacements for relay systems, but larger units may have the functional capabilities of a small computer and be able to handle mathematical functions, generate reports, and maintain high-level communications.

The preceding guidelines have some gray areas because mini, micro, and small PLCs are now available with large memory sizes and functional capacities normally reserved for medium and large PLCs. The accompanying table compares the various types of PLCs and their applications.

Instructions that are input to a PLC are called programs. Four major programming languages are used with PLCs, comprising ladder diagrams, Boolean mnemonics, functional blocks, and English statements. Some PLC systems even support high-level programming languages such as BASIC and PASCAL. Ladder diagrams and Boolean mnemonics are the basic control-level languages. Functional blocks and English statements are considered high-level languages. Ladder diagrams were used with electrical relay systems before these systems were replaced by PLCs and are still the most popular programming method, so they will be discussed further.

Fig. 2. One Rung on a Ladder Diagram

A ladder diagram consists of symbols, or ladder logic elements, that represent relay contacts or switches and other elements in the control system. One of the more basic symbols represents a normally open switch and is described by the symbol  $\text{—}| \text{—}$ . Another symbol is the normally closed switch, described by the symbol  $\text{—}| \text{—} / \text{—}$ . When the normally open switch is activated, it will close, and when the normally closed switch is activated, it will open. Fig. 2 shows one rung (line) on a ladder diagram. Switch 1001 is normally open and switch 1002 is closed. A symbol for a coil (0001) is shown at the right. If switch 1001 is actuated, it will close. If switch 1002 is not activated, it will stay closed. With the two switches closed, current will flow through the line and energize coil 0001. The coil will activate some mechanism such as an electric motor, a robot, or an NC machine tool, for instance.

As an example, Fig. 3 shows a flexible manufacturing module (FMM), consisting of a turning center (NC lathe), an infeed conveyor, an outfeed conveyor, a robot that moves workpieces between the infeed conveyor, the turning center, and the outfeed conveyor, and a PLC. The arrowed lines show the signals going to and coming from the PLC.

Fig. 4 shows a ladder diagram for a PLC that would control the operations of the FMM by:

- 1) Activating the infeed conveyor to move the workpiece to a position where the robot can pick it up
- 2) Activating the robot to pick up the workpiece and load it into the chuck on the NC lathe
- 3) Activating the robot to remove the finished workpiece and place it on the outfeed conveyor
- 4) Activating the outfeed conveyor to move the workpiece to the next operation

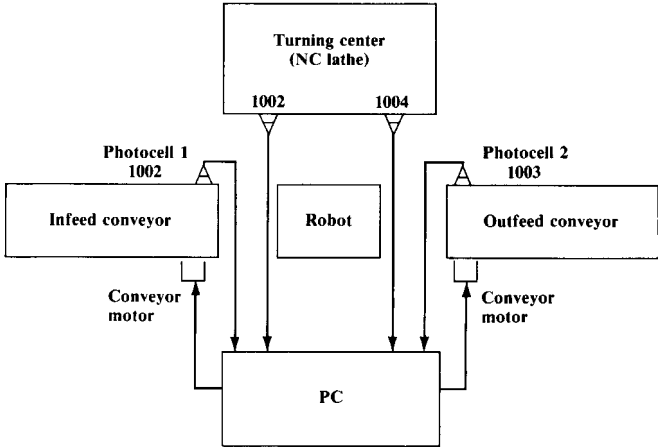

Fig. 3. Layout of a Flexible Manufacturing Module

Fig. 4. Portion of a Typical Ladder Diagram for Control of a Flexible Manufacturing Module Including a Turning Center, Conveyors, a Robot, and a Programmable Controller

In Rung 1 of Fig. 4, a request signal for a workpiece from the NC lathe closes the normally open switch 1001. Switch 1002 will remain closed if photocell 1 is not activated, i.e., if it does not detect a workpiece. The signal therefore closes the circuit, energizes the coil, and starts the conveyor motor to bring the next workpiece into position for the robot to grasp.

In Rung 2, switch 1002 (which has been changed in the program of the PLC from a normally closed to a normally open switch) closes when it is activated as photocell 1 detects the workpiece. The signal thus produced, together with the closing of the now normally open switch 1001, energizes the coil, causing the robot to pick up the workpiece from the infeed conveyor.

In Rung 3, switch 1004 on the lathe closes when processing of the part is completed and it is ready to be removed by the robot. Photocell 2 checks to see if there is a space on the conveyor to accept the completed part. If no part is seen by photocell 2, switch 1003 will remain closed, and with switch 1004 closed, the coil will be energized, activating the robot to transfer the completed part to the outfeed conveyor.

Rung 4 shows activation of the output conveyor when a part is to be transferred. Normally open switch 1004 was closed when processing of the part was completed. Switch 1003 (which also was changed from a normally closed to a normally open switch by the program) closes if photocell 2 detects a workpiece. The circuit is then closed and the coil is energized, starting the conveyor motor to move the workpiece clear to make way for the succeeding workpiece.

**Closed-Loop System.**—Also referred to as a servo or feedback system, a closed-loop system is a control system that issues commands to the drive motors of an NC machine. The system then compares the results of these commands as measured by the movement or location of the machine component, such as the table or spindlehead. The feedback devices normally used for measuring movement or location of the component are called resolvers, encoders, Inductosyns, or optical scales. The resolver, which is a rotary analog mechanism, is the least expensive, and has been the most popular since the first NC machines were developed. Resolvers are normally connected to the lead-screws of NC machines. Linear measurement is derived from monitoring the angle of rotation of the leadscrew and is quite accurate.

Encoders also are normally connected to the leadscrew of the NC machine, and measurements are in digital form. Pulses, or a binary code in digital form, are generated by rotation of the encoder, and represent turns or partial turns of the leadscrew. These pulses are well suited to the digital NC system, and encoders have therefore become very popular with such systems. Encoders generally are somewhat more expensive than resolvers.

The Inductosyn (a trade name of Farrand Controls, Inc.) also produces analog signals, but is attached to the slide or fixed part of a machine to measure the position of the table, spindlehead, or other component. The Inductosyn provides almost twice the measurement accuracy of the resolver, but is considerably more expensive, depending on the length of travel to be measured.

Optical scales generally produce information in digital form and, like the Inductosyn, are attached to the slide or fixed part of the machine. Optical scale measurements are more accurate than either resolvers or encoders and, because of their digital nature, are well suited to the digital computer in a CNC system. Like the Inductosyn, optical scales are more costly than either resolvers or encoders.

**Open-Loop System.**—A control system that issues commands to the drive motors of an NC machine and has no means of assessing the results of these commands is known as an open-loop system. In such a system, no provision is made for feedback of information concerning movement of the slide(s), or rotation of the leadscrew(s). Stepping motors are popular as drives for open-loop systems.

**Adaptive Control.**—Measuring performance of a process and then adjusting the process to obtain optimum performance is called adaptive control. In the machine tool field, adaptive control is a means of adjusting the feed and/or speed of the cutting tool, based on sensor feedback information, to maintain optimum cutting conditions. A typical arrangement is seen in Fig. 5. Adaptive control is used primarily for cutting higher-strength materials

such as titanium, although the concept is applicable to the cutting of any material. The costs of the sensors and software have restricted wider use of the feature.

Fig. 5.

The sensors used for adaptive control are generally mounted on the machine drive shafts, tools, or even built into the drive motor. Typically, sensors are used to provide information such as the temperature at the tip of the cutting tool and the cutting force exerted by the tool. The information measured by the sensors is used by the control system computer to analyze the cutting process and adjust the feeds and speeds of the machine to maximize the material removal rate or to optimize another process variable such as surface finish. For the computer to effectively evaluate the process in real time (i.e., while cutting is in progress), details such as maximum allowable tool temperature, maximum allowable cutting force, and information about the drive system need to be integrated into the computer program monitoring the cutting process.

Adaptive control can be used to detect worn, broken, or dull tooling. Ordinarily, the adaptive control system monitors the cutting process to keep the process variables (cutting speed and feed rate, for example) within the proper range. Because the force required to machine a workpiece is lowest when the tool is new or recently resharpened, a steady increase in cutting force during a machining operation, assuming that the feed remains the same, is an indication that the tool is becoming dull (temperature may increase as well). Upon detecting cutting forces that are greater than a predetermined maximum allowable force, the control system causes the feed rate, the cutting speed, or both to be adjusted to maintain the cutting force within allowable limits. If the cutting force cannot be maintained without causing the speed and/or feed rate to be adjusted outside its allowable limits, the machine will be stopped, indicating that the tool is too dull and must be resharpened or replaced.

On some systems, the process monitoring equipment can interface directly with the machine control system, as discussed above. On other systems, the adaptive control is implemented by a separate monitoring system that is independent of the machine control system. These systems include instrumentation to monitor the operations of the machine tool, but do not have the capability to directly change operating parameters, such as feeds and speeds. In addition, this type of control does not require any modification of the existing part programs for control of the machine.

**Flexible Manufacturing Systems (FMS).**—A flexible manufacturing system (FMS) is a computer-controlled machining arrangement that can perform a variety of continuous metal-cutting operations on a range of components without manual intervention. The objective of such a system is to produce components at the lowest possible cost, especially components of which only small quantities are required. Flexibility, or the ability to switch from manufacture of one type of component to another, or from one type of machining to another, without interrupting production, is the prime requirement of such a system. In general, FMS are used for production of numbers of similar parts between 200 and 2000,

although larger quantities are not uncommon. An FMS involves almost all the departments in a company, including engineering, methods, tooling and part programming, planning and scheduling, purchasing, sales and customer service, accounting, maintenance, and quality control. Initial costs of an FMS are estimated as being borne (percentages in parentheses) by machine tools (46.2), materials handling systems (7.7), tooling and fixtures (5.9), pallets (1.9), computer hardware (3.7), computer software (2.2), wash stations (2.8), automatic storage and retrieval systems (6.8), coolant and chip systems (2.4), spares (2), and others (18.4).

FMS are claimed to bring reductions in direct labor (80–90), production planning and control (65), and inspection (70). Materials handling and shop supervision are reduced, and individual productivity is raised. In the materials field, savings are made in tooling (35), scrap and rework (65), and floor space (50). Inventory is reduced and many other costs are avoided. Intangible savings claimed to result from FMS include reduced tooling changeover time, ability to produce complex parts, to incorporate engineering changes more quickly and efficiently than with other approaches, and to make special designs, so that a company can adapt quickly to changing market conditions. Requirements for spare parts with good fit are easily met, and the lower costs combine with higher quality to improve market share. FMS also are claimed to improve morale among workers, leading to higher productivity, with less paper work and more orderly shop operations. Better control of costs and improved cost data help to produce more accurate forecasts of sales and manpower requirements. Response to surges in demand and more economical materials ordering are other advantages claimed with FMS.

Completion of an FMS project is said to average 57 months, including 20 months from the time of starting investigations to the placing of the purchase order. A further 13 months are needed for delivery and a similar period for installation. Debugging and building of production takes about another 11 months before production is running smoothly. FMS are expensive, requiring large capital outlays and investments in management time, software, engineering, and shop support. Efficient operation of FMS also require constant workflow because gaps in the production cycle are very costly.

**Flexible Manufacturing Cell.**—A flexible manufacturing cell usually consists of two or three NC machines with some form of pallet-changing equipment or an industrial robot. Prismatic-type parts, such as would be processed on a machining center, are usually handled on pallets. Cylindrical parts, such as would be machined on an NC lathe, usually are handled with an overhead type of robot. The cell may be controlled by a computer, but is often run by programmable controllers. The systems can be operated without attendants, but the mixture of parts usually must be less than with a flexible manufacturing system (FMS).

**Flexible Manufacturing Module.**—A flexible manufacturing module is defined as a single machining center (or turning center) with some type of automatic materials handling equipment such as multiple pallets for machining centers, or robots for manipulating cylindrical parts and chucks for turning centers. The entire module is usually controlled by one or more programmable logic controllers.

**Axis Nomenclature.**—To distinguish among the different motions, or axes, of a machine tool, a system of letter addresses has been developed. A letter is assigned, for example, to the table of the machine, another to the saddle, and still another to the spindle head. These letter addresses, or axis designations, are necessary for the electronic control system to assign movement instructions to the proper machine element. The assignment of these letter addresses has been standardized on a worldwide basis and is contained in three standards, all of which are in agreement. These standards are EIA RS-267-B, issued by the Electronics Industries Association; AIA NAS-938, issued by the Aerospace Industries Association; and ISO/R 841, issued by the International Organization for Standardization.

The standards are based on a "right-hand rule," which describes the orientation of the motions as well as whether the motions are positive or negative. If a right hand is laid palm up on the table of a vertical milling machine, as shown in Fig. 1, for example, the thumb will point in the positive  $X$ -direction, the forefinger in the positive  $Y$ -direction, and the erect middle finger in the positive  $Z$ -direction, or up. The direction signs are based on the motion of the cutter relative to the workpiece. The movement of the table shown in Fig. 2 is therefore positive, even though the table is moving to the left, because the motion of the cutter relative to the workpiece is to the right, or in the positive direction. The motions are considered from the part programmer's viewpoint, which assumes that the cutter always moves around the part, regardless of whether the cutter or the part moves. The right-hand rule also holds with a horizontal-spindle machine and a vertical table, or angle plate, as shown in Fig. 3. Here, spindle movement back and away from the angle plate, or workpiece, is a positive  $Z$ -motion, and movement toward the angle plate is a negative  $Z$ -motion.

Rotary motions also are governed by a right-hand rule, but the fingers are joined and the thumb is pointed in the positive direction of the axis. Fig. 4 shows the designations of the rotary motions about the three linear axes,  $X$ ,  $Y$ , and  $Z$ . Rotary motion about the  $X$ -axis is designated as  $A$ ; rotary motion about the  $Y$ -axis is  $B$ ; and rotary motion about the  $Z$ -axis is  $C$ . The fingers point in the positive rotary directions. Movement of the rotary table around the  $Y$ -axis shown in Fig. 4 is a  $B$  motion and is common with horizontal machining centers. Here, the view is from the spindle face looking toward the rotary table. Referring, again, to linear motions, if the spindle is withdrawn axially from the work, the motion is a positive  $Z$ . A move toward the work is a negative  $Z$ .

When a second linear motion is parallel to another linear motion, as with the horizontal boring mill seen in Fig. 5, the horizontal motion of the spindle, or quill, is designated as  $Z$  and a parallel motion of the angle plate is  $W$ . A movement parallel to the  $X$ -axis is  $U$  and a movement parallel to the  $Y$ -axis is  $V$ . Corresponding motions are summarized as follows:

| Linear | Rotary | Linear and Parallel |
|--------|--------|---------------------|
| $X$    | $A$    | $U$                 |
| $Y$    | $B$    | $V$                 |
| $Z$    | $C$    | $W$                 |

Fig. 1.

Fig. 2.

Fig. 3.

Fig. 4.

Axis designations for a lathe are shown in Fig. 6. Movement of the cross-slide away from the workpiece, or the centerline of the spindle, is noted as a plus  $X$ . Movement toward the workpiece is a minus  $X$ . The middle finger points in the positive  $Z$ -direction; therefore, movement away from the headstock is positive and movement toward the headstock is negative. Generally, there is no  $Y$ -movement.

The machine shown in Fig. 6 is of conventional design, but most NC lathes look more like that shown in Fig. 7. The same right-hand rule applies to this four-axis lathe, on which each turret moves along its own two independent axes. Movement of the outside-diameter or upper turret, up and away from the workpiece, or spindle centerline, is a positive  $X$ -motion, and movement toward the workpiece is a negative  $X$ -motion. The same rules apply to the  $U$ -movement of the inside-diameter, or boring, turret. Movement of the lower turret parallel to the  $Z$ -motion of the outside-diameter turret is called the  $W$ -motion. A popular lathe configuration is to have both turrets on one slide, giving a two-axis system rather than the four-axis system shown.  $X$ - and  $Z$ -motions may be addressed for either of the two heads. Upward movement of the boring head therefore is a positive  $X$ -motion.

Fig. 5.

Fig. 6.

On a slant-bed lathe with 2 cross-slides, each tool turret can be operated independently, requiring four addresses,  $X$ ,  $Y$ ,  $U$  and  $W$

Fig. 7.

Axis nomenclature for other machine configurations is shown in Fig. 9. The letters with the prime notation (e.g.,  $X'$ ,  $Y'$ ,  $Z'$ ,  $W'$ ,  $A'$ , and  $B'$ ) mean that the motion shown is positive, because the movement of the cutter with respect to the work is in a positive direction. In these instances, the workpiece is moving rather than the cutter.

**Total Indicator Reading (TIR).**—Total indicator reading is used as a measure of the range of machine tool error. TIR is particularly useful for describing the error in a machine tool spindle, referred to as runout. As shown in Fig. 8, there are two types of runout: axial and radial, which can be measured with a dial indicator. Axial runout refers to the wobble of a spindle and is measured at the spindle face. Radial runout is the range of movement of the spindle centerline and is measured on the side of the spindle or quill.

Fig. 8.

NUMERICAL CONTROL

Fig. 9.

## NUMERICAL CONTROL PROGRAMMING

**Programming.**—A numerical control (NC) program is a list of instructions (commands) that completely describes, in sequence, every operation to be carried out by a machine. When a program is run, each instruction is interpreted by the machine controller, which causes an action such as starting or stopping of a spindle or coolant, changing of spindle speed or rotation, or moving a table or slide a specified direction, distance, or speed. The form that program instructions can take, and how programs are stored and/or loaded into the machine, depends on the individual machine/control system. However, program instructions must be in a form (language) that the machine controller can understand.

A programming language is a system of symbols, codes, and rules that describes the manner in which program instructions can be written. One of the earliest and most widely recognized numerical control programming languages is based on the Standard ANSI/EIA RS-274-D-1980. The standard defines a recommended data format and codes for sending instructions to machine controllers. Although adherence to the standard is not mandatory, most controller manufacturers support it and most NC machine controllers (especially controllers on older NC machines using tape input) can accept data in a format that conforms, at least in part, with the recommended codes described in the RS-274-D standard. Most newer controllers also accept instructions written in proprietary formats offered (specified) by the controller's manufacturer.

One of the primary benefits of a standardized programming format is easy transfer of programs from one machine to another, but even standardized code formats such as RS-274-D are implemented differently on different machines. Consequently, a program written for one machine may not operate correctly on another machine without some modification of the program. On the other hand, proprietary formats are attractive because of features that are not available using the standardized code formats. For example, a proprietary format may make available certain codes that allow a programmer, with only a few lines of code, to program complex motions that would be difficult or even impossible to do in the standard language. The disadvantage of proprietary formats is that transferring programs to another machine may require a great deal of program modification or even complete rewriting. Generally, with programs written in a standardized format, the modifications required to get a program written for one machine to work on another machine are not extensive.

In programming, before describing the movement of any machine part, it is necessary to establish a coordinate system(s) as a reference frame for identifying the type and direction of the motion. A description of accepted terminology used worldwide to indicate the types of motion and the orientation of machine axes is contained in a separate section (Axis Nomenclature). Part geometry is programmed with reference to the same axes as are used to describe motion.

*Manual data input* (MDI) permits the machine operator to insert machining instructions directly into the NC machine control system via push buttons, pressure pads, knobs, or other arrangements. MDI has been available since the earliest NC machines were designed, but the method was less efficient than tape for machining operations and was used primarily for setting up the NC machine. Computer numerical control (CNC) systems, with their canned cycles and other computing capabilities, have now made the MDI concept more feasible and for some work MDI may be more practical than preparing a program. The choice depends very much on the complexity of the machining work to be done and, to a lesser degree, on the skill of the person who prepares the program.

*Conversational part programming* is a form of MDI that requires the operator or programmer to answer a series of questions displayed on the control panel of the CNC. The operator replies to questions that describe the part, material, tool and machine settings, and machining operations by entering numbers that identify the material, blank size and thickness or diameter, tool definitions, and other required data. Depending on capability, some

controls can select the required spindle speed and feed rate automatically by using a materials look-up table; other systems request the appropriate feed and speed data. Tool motions needed to machine a part are described by selecting a linear or circular motion programming mode and entering endpoint and intersection coordinates of lines and radius, diameter, tangent points, and directions of arcs and circles (with some controllers, intersection and tangent points are calculated automatically). Machined elements such as holes, slots, and bolt circles are entered by selecting the appropriate tool and describing its action, or with "canned routines" built into the CNC to perform specific machining operations. On some systems, if a feature is once described, it can be copied and/or moved by: translation (copy and/or move), rotation about a point, mirror image (copy and rotate about an axis), and scaling (copy and change size). On many systems, as each command is entered, a graphic image of the part or operation gives a visual check that the program is producing the intended results. When all the necessary data have been entered, the program is constructed and can be run immediately or saved on tape, floppy disk, or other storage media for later use.

Conversational programming gives complete control of machine operations to the shop personnel, taking advantage of the experience and practical skills of the machine operator/programmer. Control systems that provide conversational programming usually include many built-in routines (fixed or canned cycles) for commonly used machining operations and may also have routines for specialized operations. Built-in routines speed programming because one command may replace many lines of program code that would take considerable time to write. Some built-in cycles allow complex machining operations to be programmed simply by specifying the final component profile and the starting stock size, handling such details as developing tool paths, depth of cut, number of roughing passes, and cutter speed automatically. On turning machines, built-in cycles for reducing diameters, chamfer and radius turning, and cutting threads automatically are common. Although many CNC machines have a conversational programming mode, the programming methods used and the features available are not standardized. Some control systems cannot be programmed from the control panel while another program is running (i.e., while a part is being machined), but those systems that can be thus programmed are more productive because programming does not require the machine to be idle. Conversational programming is especially beneficial in reducing programming time in shops that do most of their part programming from the control panel of the machine.

*Manual part programming* describes the preparation of a part program by manually writing the part program in word addressed format. In the past, this method implied programming without using a computer to determine tool paths, speeds and feeds, or any of the calculations normally required to describe the geometry of a part. Today, however, computers are frequently used for writing and storing the program on disk, as well as for calculations required to program the part. Manual part programming consists of writing codes, in a format appropriate to the machine controller, that instruct the controller to perform a specific action. The most widely accepted form of coding the instructions for numerically controlled machines uses the codes and formats suggested in the ANSI/EIA RS-274-D-1980, standard. This type of programming is sometimes called G-code programming, referring to a commonly used word address used in the RS-274-D standard. Basic details of programming in this format, using the various codes available, are discussed in the next section (G-Code Programming).

*Computer-assisted part programming* (CAPP) uses a computer to help in the preparation of the detailed instructions for operating an NC machine. In the past, defining a curve or complicated surface profile required a series of complex calculations to describe the features in intimate detail. However, with the introduction of the microprocessor as an integral part of the CNC machine, the process of defining many complex shapes has been reduced to the simple task of calling up a canned cycle to calculate the path of the cutter. Most new CNC systems have some graphic programming capability, and many use

graphic images of the part “drawn” on a computer screen. The part programmer moves a cutter about the part to generate the part program or the detailed block format instructions required by the control system. Machining instructions, such as the speed and feed rate, are entered via the keyboard. Using the computer as an assistant is faster and far more accurate than the manual part programming method.

Computer-assisted part programming methods generally can be characterized as either language-based or graphics-based, the distinction between the two methods being primarily in the manner by which the tool paths are developed. Some modern-language-based programming systems, such as Compact II, use interactive alphanumeric input so that programming errors are detected as soon as they are entered. Many of these programming systems are completely integrated with computer graphics and display an image of the part or operation as soon as an instruction is entered. The language-based programming systems are usually based on, or are a variation of, the APT programming language, which is discussed separately within this section (APT Programming).

The choice between computer-assisted part programming and manual part programming depends on the complexity of the part (particularly its geometry) and how many parts need to be programmed. The more complicated the part, the more benefit to be gained by CAPP, and if many parts are to be programmed, even if they are simple ones, the benefits of a computer-aided system are substantial. If the parts are not difficult to program but involve much repetition, computer-assisted part programming may also be preferred. If parts are to be programmed for several different control systems, a high-level part programming language such as APT will make writing the part programs easier. Because almost all machines have some deviations from standard practices, and few control systems use exactly the same programming format, a higher-level language allows the programmer to concentrate primarily on part geometry and machining considerations. The postprocessors (see *Postprocessors* below) for the individual control systems accommodate most of the variations in the programming required. The programmer only needs to write the program; the postprocessor deals with the machine specifics.

*Graphical programming* involves building a two- or three-dimensional model of a part on a computer screen by graphically defining the geometric shapes and surfaces of the part using the facilities of a CAD program. In many cases, depending on features of the CAD software package, the same computer drawing used in the design and drafting stage of a project can also be used to generate the program to produce the part. The graphical entities, such as holes, slots, and surfaces, are linked with additional information required for the specific machining operations needed. Most of the cutter movements (path of the cutter), such as those needed for the generation of pockets and lathe roughing cuts, are handled automatically by the computer. The program may then sort the various machining operations into an efficient sequence so that all operations that can be performed with a particular tool are done together, if possible. The output of graphical part programming is generally an alphanumeric part programming language output file, in a format such as an APT or Compact II file.

The part programming language file can be manually checked, and modified, as necessary before being run, and to help detect errors, many graphics programming systems also include some form of part verification software that simulates machining the part on the computer screen. Nongraphic data, such as feed rates, spindle speeds and coolant on/off, must be typed in by the part programmer or entered from a computer data base at the appropriate points in the program, although some programs prompt for this information when needed. When the part program language file is run or compiled, the result is a center line data (CL data) file describing the part. With most computer-aided part programming output files, the CL data file needs to be processed through a postprocessor (see *Postprocessors* below) to tailor the final code produced to the actual machine being used. Postprocessor output is in a form that can be sent directly to the control system, or can be saved on tape or magnetic media and transferred to the machine tool when necessary. The

graphic image of the part and the alphanumeric output files are saved in separate files so that either can be edited in the future if changes in the part become necessary. Revised files must be run and processed again for the part modifications to be included in the part program. Software for producing part programs is discussed further in the CAD/CAM section.

**Postprocessors.**—A postprocessor is computer software that contains a set of computer instructions designed to tailor the cutter center line location data (CL data), developed by a computerized part programming language, to meet the requirements of a particular machine tool/system combination. Generally, when a machine tool is programmed in a graphical programming environment or any high-level language such as APT, a file is created that describes all movements required of a cutting tool to make the part. The file thus created is run, or compiled, and the result is a list of coordinates (CL data) that describes the successive positions of the cutter relative to the origin of the machine's coordinate system. The output of the program must be customized to fit the input requirements of the machine controller that will receive the instructions. Cutter location data must be converted into a format recognized by the control system, such as G codes and M codes, or into another language or proprietary format recognized by the controller. Generally, some instructions are also added or changed by the programmer at this point.

The lack of standardization among machine tool control systems means that almost all computerized part programming languages require a postprocessor to translate the computer-generated language instructions into a form that the machine controller recognizes. Postprocessors are software and are generally prepared for a fee by the machine tool builder, the control system builder, a third party vendor, or by the user.

### G-Code Programming

Programs written to operate numerical control (NC) machines with control systems that comply with the ANSI/EIA RS-274-D-1980, Standard consist of a series of data blocks, each of which is treated as a unit by the controller and contains enough information for a complete command to be carried out by the machine. Each block is made up of one or more words that indicate to the control system how its corresponding action is to be performed. A word is an ordered set of characters, consisting of a letter plus some numerical digits, that triggers a specific action of a machine tool. The first letter of the word is called the letter address of the word, and is used to identify the word to the control system. For example, X is the letter address of a dimension word that requires a move in the direction of the X-axis, Y is the letter address of another dimension word; and F is the letter address of the feed rate. The assigned letter addresses and their meanings, as listed in ANSI/EIA RS-274-D, are shown in [Table 1](#).

**Format Classification.**—The *format classification sheet* completely describes the format requirements of a control system and gives other important information required to program a particular control including: the type of machine, the format classification shorthand and format detail, a listing of specific letter address codes recognized by the system (for example, G-codes: G01, G02, G17, etc.) and the range of values the available codes may take (S range: 10 to 1800 rpm, for example), an explanation of any codes not specifically assigned by the Standard, and any other unique features of the system.

The *format classification shorthand* is a nine- or ten-digit code that gives the type of system, the number of motion and other words available, the type and format of dimensional data required by the system, the number of motion control channels, and the number of numerically controlled axes of the system. The *format detail* very succinctly summarizes details of the machine and control system. This NC shorthand gives the letter address words and word lengths that can be used to make up a block. The format detail defines the basic features of the control system and the type of machine tool to which it refers. For example, the format detail

**Table 1. Letter Addresses Used in Numerical Control**

| Letter Address | Description   | Refers to                            |
|----------------|---|--------------------------------------|
| A              | Angular dimension about the <i>X</i> -axis. Measured in decimal parts of a degree   | Axis nomenclature                    |
| B              | Angular dimension about the <i>Y</i> -axis. Measured in decimal parts of a degree   | Axis nomenclature                    |
| C              | Angular dimension about the <i>Z</i> -axis. Measured in decimal parts of a degree   | Axis nomenclature                    |
| D              | Angular dimension about a special axis, or third feed function, or tool function for selection of tool compensation               | Axis nomenclature                    |
| E              | Angular dimension about a special axis or second feed function  | Axis nomenclature                    |
| F              | Feed word (code)  | Feed words                           |
| G              | Preparatory word (code)   | Preparatory words                    |
| H              | Unassigned  |                                      |
| I              | Interpolation parameter or thread lead parallel to the <i>X</i> -axis   | Circular interpolation and threading |
| J              | Interpolation parameter or thread lead parallel to the <i>Y</i> -axis   | Circular interpolation and threading |
| K              | Interpolation parameter or thread lead parallel to the <i>Z</i> -axis   | Circular interpolation and threading |
| L              | Unassigned  |                                      |
| M              | Miscellaneous or auxiliary function   | Miscellaneous functions              |
| N              | Sequence number   | Sequence number                      |
| O              | Sequence number for secondary head only   | Sequence number                      |
| P              | Third rapid-traverse dimension or tertiary-motion dimension parallel to <i>X</i>  | Axis nomenclature                    |
| Q              | Second rapid-traverse dimension or tertiary-motion dimension parallel to <i>Y</i>   | Axis nomenclature                    |
| R              | First rapid-traverse dimension or tertiary-motion dimension parallel to <i>Z</i> or radius for constant surface-speed calculation | Axis nomenclature                    |
| S              | Spindle-speed function  | Spindle speed                        |
| T              | Tool function   | Tool function                        |
| U              | Secondary-motion dimension parallel to <i>X</i>   | Axis nomenclature                    |
| V              | Secondary-motion dimension parallel to <i>Y</i>   | Axis nomenclature                    |
| W              | Secondary-motion dimension parallel to <i>Z</i>   | Axis nomenclature                    |
| X              | Primary <i>X</i> -motion dimension  | Axis nomenclature                    |
| Y              | Primary <i>Y</i> -motion dimension  | Axis nomenclature                    |
| Z              | Primary <i>Z</i> -motion dimension  | Axis nomenclature                    |

N4G2X + 24Y + 24Z + 24B24I24J24F31T4M2

specifies that the NC machine is a machining center (has *X*-, *Y*-, and *Z*-axes) and a tool changer with a four-digit tool selection code (T4); the three linear axes are programmed with two digits before the decimal point and four after the decimal point (X + 24Y + 24Z + 24) and can be positive or negative; probably has a horizontal spindle and rotary table (B24

= rotary motion about the Y-axis); has circular interpolation (I24J24); has a feed rate range in which there are three digits before and one after the decimal point (F31); and can handle a four-digit sequence number (N4), two-digit G-words (G2), and two-digit miscellaneous words (M2). The sequence of letter addresses in the format detail is also the sequence in which words with those addresses should appear when used in a block.

The information given in the format shorthand and format detail is especially useful when programs written for one machine are to be used on different machines. Programs that use the variable block data format described in RS-274-D can be used interchangeably on systems that have the same format classification, but for complete program compatibility between machines, other features of the machine and control system must also be compatible, such as the relationships of the axes and the availability of features and control functions.

Control systems differ in the way that the numbers may be written. Most newer CNC machines accept numbers written in a decimal-point format, however, some systems require numbers to be in a fixed-length format that does not use an explicit decimal point. In the latter case, the control system evaluates a number based on the number of digits it has, including zeros. *Zero suppression* in a control system is an arrangement that allows zeros before the first significant figure to be dropped (leading zero suppression) or allows zeros after the last significant figure to be dropped (trailing zero suppression). An X-axis movement of 05.3400, for example, could be expressed as 053400 if represented in the full field format, 53400 (leading zero suppression), or 0534 (trailing zero suppression). With decimal-point programming, the above number is expressed simply as 5.34. To ensure program compatibility between machines, all leading and trailing zeros should be included in numbers unless decimal-point programming is used.

**Sequence Number (N-Word).**—A block normally starts with a sequence number that identifies the block within the part program. Most control systems use a four-digit sequence number allowing step numbers up to N9999. The numbers are usually advanced by fives or tens in order to leave spaces for additional blocks to be inserted later if required. For example, the first block in a program would be N0000, the next block N0005; the next N0010; and so on. The slash character, /, placed in a block, before the sequence number, is called an *optional stop* and causes the block to be skipped over when actuated by the operator. The block that is being worked on by the machine is often displayed on a digital read-out so that the operator may know the precise operation being performed.

**Preparatory Word (G-Word).**—A preparatory word (also referred to as a preparatory function or G-code) consists of the letter address G and usually two digits. The preparatory word is placed at the beginning of a block, normally following the sequence number. Most newer CNC machines allow more than one G-code to be used in a single block, although many of the older systems do not. To ensure compatibility with older machines and with the RS-274-D Standard, only one G-code per block should be used.

The G-word indicates to the control system how to interpret the remainder of the block. For example, G01 refers to linear interpolation and indicates that the words following in the block will move the cutter in a straight line. The G02 code indicates that the words following in the block will move the cutter in a clockwise circular path. A G-word can completely change the normal meaning of other words in a block. For example, X is normally a dimension word that describes a distance or position in the X-direction. However, if a block contains the G04 word, which is the code for a dwell, the X word represents the time, in seconds, that the machine is to dwell.

The majority of G-codes are designated as modal, which means that once used, the code remains in effect for succeeding blocks unless it is specifically changed or canceled. Therefore, it is not necessary to include modal G-codes in succeeding blocks except to change or cancel them. Unless a G-code is modal, it is only effective within its designated block for the operation it defines. [Table 2](#), G-Code Addresses, lists standardized G-code addresses and modality.

Table 2. G-Code Addresses

| Code                            | Description   | Code                     | Description   |
|---------------------------------|---|--------------------------|---|
| G00                             | <sup>abs</sup> Rapid traverse, point to point (M,L)   | G34                      | <sup>abs</sup> Thread cutting, increasing lead (L)  |
| G01                             | <sup>abc</sup> Linear interpolation (M,L)   | G35                      | <sup>abc</sup> Thread cutting, decreasing lead (L)  |
| G02                             | <sup>abc</sup> Circular interpolation—clockwise movement (M,L)  | G36-G39                  | <sup>ab</sup> Permanently unassigned  |
| G03                             | <sup>abc</sup> Circular interpolation—counter-clockwise movement (M,L)  | G36                      | <sup>c</sup> Used for automatic acceleration and deceleration when the blocks are short (M,L)                           |
| G04                             | <sup>ab</sup> Dwell—a programmed time delay (M,L)   | G37, G37.1, G37.2, G37.3 | Used for tool gaging (M,L)  |
| G05                             | <sup>ab</sup> Unassigned  | G37.4                    |   |

| G27-G29                         | Used for automatically moving to and returning from home position (M,L)   | G53                      | <sup>c</sup> Call for motion in the machine coordinate system (M,L)   |
| G30                             | Return to an alternate home position (M,L)  | G54-G59                  | <sup>bc</sup> Datum shifts (M,L)  |
| G31, G31.1, G31.2, G31.3, G31.4 | External skip function, moves an axis on a linear path until an external signal aborts the move (M,L)                 | G54-G59.3                | <sup>c</sup> Allows for presetting of work coordinate systems (M,L)   |
| G33                             | <sup>abc</sup> Thread cutting, constant lead (L)  | G60-G62                  | <sup>abc</sup> Unassigned   |

Table 2. (Continued) G-Code Addresses

| Code    | Description   | Code   | Description  |
|---------|---|--------|--|
| G61     | c Modal equivalent of G09 except that rapid moves are not taken to a complete stop before the next motion block is executed (M,L)     | G80    | abc Cancel fixed cycles  |
| G62     | c Automatic corner override, reduces the feed rate on an inside corner cut (M,L)  | G81    | abc Drill cycle, no dwell and rapid out (M,L)  |
| G63     | a Unassigned  | G82    | abc Drill cycle, dwell and rapid out (M,L)   |
| G63     | bc Tapping mode (M,L)   | G83    | abc Deep hole peck drilling cycle (M,L)  |
| G64–G69 | abc Unassigned  | G84    | abc Right-hand tapping cycle (M,L)   |
| G64     | c Cutting mode, usually set by the system installer (M,L)   | G84.1  | c Left-hand tapping cycle (M,L)  |
| G65     | c Calls for a parametric macro (M,L)  | G85    | abc Boring cycle, no dwell, feed out (M,L)   |
| G66     | c Calls for a parametric macro. Applies to motion blocks only (M,L)   | G86    | abc Boring cycle, spindle stop, rapid out (M,L)  |
| G66.1   | c Same as G66 but applies to all blocks (M,L)   | G87    | abc Boring cycle, manual retraction (M,L)  |
| G67     | c Stop the modal parametric macro (see G65, G66, G66.1) (M,L)   | G88    | abc Boring cycle, spindle stop, manual retraction (M,L)  |
| G68     | c Rotates the coordinate system (i.e., the axes) (M)  | G88.1  | Pocket milling (rectangular and circular), roughing cycle (M)  |
| G69     | c Cancel axes rotation (M)  | G88.2  | Pocket milling (rectangular and circular), finish cycle (M)  |
| G70     | abc Inch programming (M,L)  | G88.3  | Post milling, roughs out material around a specified area (M)  |
| G71     | abc Metric programming (M,L)  | G88.4  | Post milling, finish cuts material around a post (M)   |
| G72     | ac Circular interpolation CW (three-dimensional) (M)  | G88.5  | Hemisphere milling, roughing cycle (M)   |
| G72     | b Unassigned  | G88.6  | Hemisphere milling, finishing cycle (M)  |
| G72     | c Used to perform the finish cut on a turned part along the Z-axis after the roughing cuts initiated under G73, G74, or G75 codes (L) | G89    | abc Boring cycle, dwell and feed out (M,L)   |
| G73     | b Unassigned  | G89.1  | Irregular pocket milling, roughing cycle (M)   |
| G73     | c Deep hole peck drilling cycle (M); OD and ID roughing cycle, running parallel to the Z-axis (L)                                     | G89.2  | Irregular pocket milling, finishing cycle (M)  |
| G74     | ac Cancel multiquadrant circular interpolation (M,L)  | G90    | abc Absolute dimension input (M,L)   |
| G74     | bc Move to home position (M,L)  | G91    | abc Incremental dimension input (M,L)  |
| G74     | c Left-hand tapping cycle (M)   | G92    | abc Preload registers, used to shift the coordinate axes relative to the current tool position (M,L) |
| G74     | Rough facing cycle (L)  | G93    | abc Inverse time feed rate (velocity/distance) (M,L)   |
| G75     | ac Multiquadrant circular interpolation (M,L)   | G94    | c Feed rate in inches or millimeters per minute (ipm or mpm) (M,L)                                   |
| G75     | b Unassigned  | G95    | abc Feed rate given directly in inches or millimeters per revolution (ipr or mpr) (M,L)              |
| G75     | Roughing routine for castings or forgings (L)   | G96    | abc Maintains a constant surface speed, feet (meters) per minute (L)                                 |
| G76–G79 | ab Unassigned   | G97    | abc Spindle speed programmed in rpm (M,L)  |
|         |   | G98–99 | ab Unassigned  |

<sup>a</sup> Adheres to ANSI/EIA RS-274-D;

<sup>b</sup> Adheres to ISO 6983/1,2,3 Standards; where both symbols appear together, the ANSI/EIA and ISO standard codes are comparable;

<sup>c</sup> This code is modal. All codes that are not identified as modal are nonmodal, when used according to the corresponding definition.

<sup>d</sup> Indicates a use of the code that does not conform with the Standard.

Symbols following a description: (M) indicates that the code applies to a mill or machining center; (L) indicates that the code applies to turning machines; (M,L) indicates that the code applies to both milling and turning machines.

Codes that appear more than once in the table are codes that are in common use, but are not defined by the Standard or are used in a manner that is different than that designated by the Standard (e.g., see G61).

Most systems that support the RS-274-D Standard codes do not use all the codes available in the Standard. Unassigned G-words in the Standard are often used by builders of machine tool control systems for a variety of special purposes, sometimes leading to confusion as to the meanings of unassigned codes. Even more confusing, some builders of systems and machine tools use the less popular standardized codes for other than the meaning listed in the Standard. For these reasons, machine code written specifically for one machine/controller will not necessarily work correctly on another machine controller without modification.

*Dimension words* contain numerical data that indicate either a distance or a position. The dimension units are selected by using G70 (inch programming) or G71 (metric programming) code. G71 is canceled by a G70 command, by miscellaneous functions M02 (end of program), or by M30 (end of data). The dimension words immediately follow the G-word in a block and on multiaxis machines should be placed in the following order: X, Y, Z, U, V, W, P, Q, R, A, B, C, D, and E.

*Absolute programming* (G90) is a method of defining the coordinate locations of points to which the cutter (or workpiece) is to move based on the fixed machine zero point. In Fig. 1, the X–Y coordinates of P1 are  $X = 1.0$ ,  $Y = 0.5$  and the coordinates of P2 are  $X = 2.0$ ,  $Y = 1.1$ . To indicate the movement of the cutter from one point to another when using the absolute coordinate system, only the coordinates of the destination point P2 are needed.

*Incremental programming* (G91) is a method of identifying the coordinates of a particular location in terms of the distance of the new location from the current location. In the example shown in Fig. 2, a move from P1 to P2 is written as  $X + 1.0$ ,  $Y + 0.6$ . If there is no movement along the Z-axis, Z is zero and normally is not noted. An X–Y incremental move from P2 to P3 in Fig. 2 is written as  $X + 1.0$ ,  $Y - 0.7$ .

Fig. 1.

Fig. 2.

Most CNC systems offer both absolute and incremental part programming. The choice is handled by G-code G90 for absolute programming and G91 for incremental programming. G90 and G91 are both modal, so they remain in effect until canceled.

The G92 word is used to preload the registers in the control system with desired values. A common example is the loading of the axis-position registers in the control system for a lathe. Fig. 3 shows a typical home position of the tool tip with respect to the zero point on the machine. The tool tip here is registered as being 15.0000 inches in the Z-direction and 4.5000 inches in the X-direction from machine zero. No movement of the tool is required. Although it will vary with different control system manufacturers, the block to accomplish the registration shown in Fig. 3 will be approximately:

N0050 G92 X4.5 Z15.0

**Miscellaneous Functions (M-Words).**—Miscellaneous functions, or M-codes, also referred to as auxiliary functions, constitute on-off type commands. M functions are used to control actions such as starting and stopping of motors, turning coolant on and off, changing tools, and clamping and unclamping parts. M functions are made up of the letter M followed by a two-digit code. Table 3 lists the standardized M-codes, however, the functions available will vary from one control system to another. Most systems provide fewer M functions than the complete list and may use some of the unassigned codes to provide additional functions that are not covered by the Standard. If an M-code is used in a block, it follows the T-word and is normally the last word in the block.

**Table 3. Miscellaneous Function Words from ANSI/EIA RS-274-D**

| Code       | Description  |
|------------|--|
| M00        | Automatically <i>stops</i> the machine. The operator must push a button to continue with the remainder of the program.   |
| M01        | An <i>optional stop</i> acted upon only when the operator has previously signaled for this command by pushing a button. The machine will automatically stop when the control system senses the M01 code. |
| M02        | This <i>end-of-program</i> code stops the machine when all commands in the block are completed. May include rewinding of tape.   |
| M03        | Start <i>spindle rotation</i> in a <i>clockwise</i> direction—looking out from the spindle face.   |
| M04        | Start <i>spindle rotation</i> in a <i>counterclockwise</i> direction—looking out from the spindle face.  |
| M05        | <i>Stop</i> the spindle in a normal and efficient manner.  |
| M06        | Command to <i>change a tool</i> (or tools) manually or automatically. Does not cover tool selection, as is possible with the T-words.  |
| M07 to M08 | M07 (coolant 2) and M08 (coolant 1) are codes to <i>turn on coolant</i> . M07 may control <i>flood</i> coolant and M08 <i>mist</i> coolant.  |
| M09        | Shuts off the coolant.   |
| M10 to M11 | M10 applies to automatic <i>clamping</i> of the machine slides, workpiece, fixture spindle, etc. M11 is an unclamping code.  |
| M12        | An inhibiting code used to synchronize multiple sets of axes, such as a four-axis lathe having two independently operated heads (turrets).   |
| M13        | Starts <i>CCW spindle</i> motion and <i>coolant on</i> in the same command.  |
| M14        | Starts <i>CCW spindle</i> motion and <i>coolant on</i> in the same command.  |
| M15 to M16 | Rapid traverse of feed motion in either the +(M15) or -(M16) direction.  |
| M17 to M18 | Unassigned.  |
| M19        | Oriented spindle stop. Causes the spindle to stop at a predetermined angular position.   |
| M20 to M29 | Permanently unassigned.  |
| M30        | An <i>end-of-tape</i> code similar to M02, but M30 will also rewind the tape; also may switch automatically to a second tape reader.   |
| M31        | A command known as <i>interlock bypass</i> for temporarily circumventing a normally provided interlock.  |

**Table 3. (Continued) Miscellaneous Function Words from ANSI/EIA RS-274-D**

| Code       | Description   |
|------------|---|
| M32 to M35 | Unassigned.   |
| M36 to M39 | Permanently unassigned.   |
| M40 to M46 | Used to signal gear changes if required at the machine; otherwise, unassigned.  |
| M47        | Continues program execution from the start of the program unless inhibited by an interlock signal.                    |
| M48 to M49 | M49 deactivates a manual spindle or feed override and returns the parameter to the programmed value; M48 cancels M49. |
| M50 to M57 | Unassigned.   |
| M58 to M59 | Holds the rpm constant at the value in use when M59 is initiated; M58 cancels M59.                                    |
| M60 to M89 | Unassigned.   |
| M90 to M99 | Reserved for use by the machine user.   |

**Feed Function (F-Word).**—F-word stands for feed-rate word or feed rate. The meaning of the feed word depends on the system of units in use and the feed mode. For example, F15 could indicate a feed rate of 0.15 inch (or millimeter) per revolution or 15 inches (or millimeters) per minute, depending on whether G70 or G71 is used to indicate inch or metric programming and whether G94 or G95 is used to specify feed rate expressed as inches (or mm) per minute or revolution. The G94 word is used to indicate inches/minute (ipm) or millimeters/minute (mmpm) and G95 is used for inches/revolution (ipr) or millimeters/revolution (mmpr). The default system of units is selected by G70 (inch programming) or G71 (metric programming) prior to using the feed function. The feed function is modal, so it stays in effect until it is changed by setting a new feed rate. In a block, the feed function is placed immediately following the dimension word of the axis to which it applies or immediately following the last dimension word to which it applies if it is used for more than one axis.

Fig. 3.

In turning operations, when G95 is used to set a constant feed rate per revolution, the spindle speed is varied to compensate for the changing diameter of the work — the spindle speed increases as the working diameter decreases. To prevent the spindle speed from increasing beyond a maximum value, the S-word, see *Spindle Function (S-Word)*, is used to specify the maximum allowable spindle speed before issuing the G95 command. If the spindle speed is changed after the G95 is used, the feed rate is also changed accordingly. If G94 is used to set a constant feed per unit of time (inches or millimeters per minute), changes in the spindle speed do not affect the feed rate.

Feed rates expressed in inches or millimeters per revolution can be converted to feed rates in inches or millimeters per minute by multiplying the feed rate by the spindle speed in revolutions per minute:  $\text{feed/minute} = \text{feed/revolution} \times \text{spindle speed in rpm}$ . Feed rates for milling cutters are sometimes given in inches or millimeters per tooth. To convert feed

per tooth to feed per revolution, multiply the feed rate per tooth by the number of cutter teeth: feed/revolution = feed/tooth  $\times$  number of teeth.

For certain types of cuts, some systems require an inverse-time *feed command* that is the reciprocal of the time in minutes required to complete the block of instructions. The feed command is indicated by a G93 code followed by an F-word value found by dividing the feed rate, in inches (millimeters) or degrees per minute, by the distance moved in the block: feed command = feed rate/distance = (distance/time)/distance = 1/time.

*Feed-rate override* refers to a control, usually a rotary dial on the control system panel, that allows the programmer or operator to override the programmed feed rate. Feed-rate override does not change the program; permanent changes can only be made by modifying the program. The range of override typically extends from 0 to 150 per cent of the programmed feed rate on CNC machines; older hardwired systems are more restrictive and most cannot be set to exceed 100 per cent of the preset rate.

**Spindle Function (S-Word).**—An S-word specifies the speed of rotation of the spindle. The spindle function is programmed by the address S followed by the number of digits specified in the format detail (usually a four-digit number). Two G-codes control the selection of spindle speed input: G96 selects a constant cutting speed in surface feet per minute (sfm) or meters per minute (mpm) and G97 selects a constant spindle speed in revolutions per minute (rpm).

In turning, a constant spindle speed (G97) is applied for threading cycles and for machining parts in which the diameter remains constant. Feed rate can be programmed with either G94 (inches or millimeters per minute) or G95 (inches or millimeters per revolution) because each will result in a constant cutting speed to feed relationship.

G96 is used to select a constant cutting speed (i.e., a constant surface speed) for facing and other cutting operations in which the diameter of the workpiece changes. The spindle speed is set to an initial value specified by the S-word and then automatically adjusted as the diameter changes so that a constant surface speed is maintained. The control system adjusts spindle speed automatically, as the working diameter of the cutting tool changes, decreasing spindle speed as the working diameter increases or increasing spindle speed as the working diameter decreases. When G96 is used for a constant cutting speed, G95 in a succeeding block maintains a constant feed rate per revolution.

Speeds given in surface feet or meters per minute can be converted to speeds in revolutions per minute (rpm) by the formulas:

$$\text{rpm} = \frac{\text{sfm} \times 12}{\pi \times d} \qquad \text{rpm} = \frac{\text{mpm} \times 1000}{\pi \times d}$$

where  $d$  is the diameter, in inches or millimeters, of the part on a lathe or of the cutter on a milling machine; and  $\pi$  is equal to 3.14159.

**Tool Function (T-Word).**—The T-word calls out the tool that is to be selected on a machining center or lathe having an automatic tool changer or indexing turret. On machines without a tool changer, this word causes the machine to stop and request a tool change. This word also specifies the proper turret face on a lathe. The word usually is accompanied by several numbers, as in T0101, where the first pair of numbers refers to the tool number (and carrier or turret if more than one) and the second pair of numbers refers to the tool offset number. Therefore, T0101 refers to tool 1, offset 1.

Information about the tools and the tool setups is input to the CNC system in the form of a *tool data table*. Details of specific tools are transferred from the table to the part program via the T-word. The tool nose radius of a lathe tool, for example, is recorded in the tool data table so that the necessary tool path calculations can be made by the CNC system. The miscellaneous code M06 can also be used to signal a tool change, either manually or automatically.

Compensation for variations in the tool nose radius, particularly on turning machines, allows the programmer to program the part geometry from the drawing and have the tool follow the correct path in spite of variations in the tool nose shape. Typical of the data required, as shown in Fig. 4, are the nose radius of the cutter, the X and Z distances from the gage point to some fixed reference point on the turret, and the orientation of the cutter (tool tip orientation code), as shown in Fig. 5. Details of nose radius compensation for numerical control is given in a separate section (Indexable Insert Holders for NC).

Fig. 4.

Tool tip orientation codes

Fig. 5.

*Tool offset*, also called cutter offset, is the amount of cutter adjustment in a direction parallel to the axis of a tool. Tool offset allows the programmer to accommodate the varying dimensions of different tooling by assuming (for the sake of the programming) that all the tools are identical. The actual size of the tool is totally ignored by the programmer who programs the movement of the tools to exactly follow the profile of the workpiece shape. Once tool geometry is loaded into the tool data table and the cutter compensation controls of the machine activated, the machine automatically compensates for the size of the tools in the programmed movements of the slide. In gage length programming, the tool length and tool radius or diameter are included in the program calculations. Compensation is then used only to account for minor variations in the setup dimensions and tool size.

Fig. 6.

Customarily, the tool offset is used in the beginning of a program to initialize each individual tool. Tool offset also allows the machinist to correct for conditions, such as tool wear, that would cause the location of the cutting edge to be different from the programmed location. For example, owing to wear, the tool tip in Fig. 6 is positioned a distance of 0.0065 inch from the location required for the work to be done. To compensate for this wear, the operator (or part programmer), by means of the CNC control panel, adjusts the tool tip with reference to the X- and Z-axes, moving the tool closer to the work by

0.0065 inch throughout its traverse. The tool offset number causes the position of the cutter to be displaced by the value assigned to that offset number.

Fig. 7.

Fig. 8.

Changes to the programmed positions of cutting tool tip(s) can be made by *tool length offset* programs included in the control system. A dial or other means is generally provided on milling, drilling, and boring machines, and machining centers, allowing the operator or part programmer to override the programmed axial, or Z-axis, position. This feature is particularly helpful when setting the lengths of tools in their holders or setting a tool in a turret, as shown in Fig. 7, because an exact setting is not necessary. The tool can be set to an approximate length and the discrepancy eliminated by the control system.

The amount of offset may be determined by noting the amount by which the cutter is moved manually to a fixed point on the fixture or on the part, from the programmed Z-axis location. For example, in Fig. 7, the programmed Z-axis motion results in the cutter being moved to position A, whereas the required location for the tool is at B. Rather than resetting the tool or changing the part program, the tool length offset amount of 0.0500 inch is keyed into the control system. The 0.0500-inch amount is measured by moving the cutter tip manually to position B and reading the distance moved on the readout panel. Thereafter, every time that cutter is brought into the machining position, the programmed Z-axis location will be overridden by 0.0500 inch.

Manual adjustment of the cutter center path to correct for any variance between nominal and actual cutter radius is called *cutter compensation*. The net effect is to move the path of the center of the cutter closer to, or away from, the edge of the workpiece, as shown in Fig. 8. The compensation may also be handled via a tool data table.

When cutter compensation is used, it is necessary to include in the program a G41 code if the cutter is to be to the left of the part and a G42 code if to the right of the part, as shown in Fig. 8. A G40 code cancels cutter compensation. Cutter compensation with earlier hardware systems was expensive, very limited, and usually held to  $\pm 0.0999$  inch. The range for cutter compensation with CNC control systems can go as high as  $\pm 999.9999$  inches, although adjustments of this magnitude are unlikely to be required.

Fig. 9.

**Linear Interpolation.**—The ability of the control system to guide the workpiece along a straight-line path at an angle to the slide movements is called linear interpolation. Move-

ments of the slides are controlled through simultaneous monitoring of pulses by the control system. For example, if monitoring of the pulses for the  $X$ -axis of a milling machine is at the same rate as for the  $Y$ -axis, the cutting tool will move at a 45-degree angle relative to the  $X$ -axis. However, if the pulses are monitored at twice the rate for the  $X$ -axis as for the  $Y$ -axis, the angle that the line of travel will make with the  $X$ -axis will be 26.57 degrees (tangent of 26.57 degrees =  $\frac{1}{2}$ ), as shown in Fig. 9. The data required are the distances traveled in the  $X$ - and  $Y$ -directions, and from these data, the control system will generate the straight line automatically. This monitoring concept also holds for linear motions along three axes. The required G-code for linear interpolation blocks is G01. The code is modal, which means that it will hold for succeeding blocks until it is changed.

**Circular Interpolation.**—A simplified means of programming circular arcs in one plane, using one block of data, is called circular interpolation. This procedure eliminates the need to break the arc into straight-line segments. Circular interpolation is usually handled in one plane, or two dimensions, although three-dimensional circular interpolation is described in the Standards. The plane to be used is selected by a G or preparatory code. In Fig. 10, G17 is used if the circle is to be formed in the  $X$ - $Y$  plane,

Fig. 10.

Fig. 11.

G18 if in the  $X$ - $Z$  plane, and G19 if in the  $Y$ - $Z$  plane. Often the control system is preset for the circular interpolation feature to operate in only one plane (e.g., the  $X$ - $Y$  plane for milling machines or machining centers or the  $X$ - $Z$  plane for lathes), and for these machines, the G-codes are not necessary.

A circular arc may be described in several ways. Originally, the RS-274 Standard specified that, with incremental programming, the block should contain:

1) A G-code describing the direction of the arc, G02 for clockwise (CW), and G03 for counterclockwise (CCW).

2) Directions for the component movements around the arc parallel to the axes. In the example shown in Fig. 11, the directions are  $X = +1.1$  inches and  $Y = +1.0$  inch. The signs are determined by the direction in which the arc is being generated. Here, both  $X$  and  $Y$  are positive.

3) The  $I$  dimension, which is parallel to the  $X$ -axis with a value of 1.3 inches, and the  $J$  dimension, which is parallel to the  $Y$ -axis with a value of 0.3 inch. These values, which locate point A with reference to the center of the arc, are called offset dimensions. The block for this work would appear as follows:

```
N0025 G02 X011000 Y010000 I013000 J003000
```

(The sequence number, N0025, is arbitrary.)

The block would also contain the plane selection (i.e., G17, G18, or G19), if this selection is not preset in the system. Most of the newer control systems allow duplicate words in the

same block, but most of the older systems do not. In these older systems, it is necessary to insert the plane selection code in a separate and prior block, for example, N0020 G17.

Another stipulation in the Standard is that the arc is limited to one quadrant. Therefore, four blocks would be required to complete a circle. Four blocks would also be required to complete the arc shown in Fig. 12, which extends into all four quadrants.

When utilizing absolute programming, the coordinates of the end point are described. Again from Fig. 11, the block, expressed in absolute coordinates, appears as:

N0055 G02 X01800 Y019000 I013000 J003000

where the arc is continued from a previous block; the starting point for the arc in this block would be the end point of the previous block.

Fig. 12.

Fig. 13.

The Standard still contains the format discussed, but simpler alternatives have been developed. The latest version of the Standard (RS-274-D) allows *multiple quadrant programming* in one block, by inclusion of a G75 word. In the absolute-dimension mode (G90), the coordinates of the arc center are specified. In the incremental-dimension mode (G91), the signed (plus or minus) incremental distances from the beginning point of the arc to the arc center are given. Most system builders have introduced some variations on this format. One system builder utilizes the center and the end point of the arc when in an absolute mode, and might describe the block for going from A to B in Fig. 13 as:

N0065 G75 G02 X2.5 Y0.7 I2.2 J1.6

The I and the J words are used to describe the coordinates of the arc center. Decimal-point programming is also used here. A block for the same motion when programmed incrementally might appear as:

N0075 G75 G02 X1.1 Y - 1.6 I0.7 J0.7

This approach is more in conformance with the RS-274-D Standard in that the X and Y values describe the displacement between the starting and ending points (points A and B), and the I and J indicate the offsets of the starting point from the center. Another and even more convenient way of formulating a circular motion block is to note the coordinates of the ending point and the radius of the arc. Using absolute programming, the block for the motion in Fig. 13 might appear as:

N0085 G75 G02 X2.5 Y0.7 R10.0

The starting point is derived from the previous motion block. Multi-quadrant circular interpolation is canceled by a G74 code.

**Helical and Parabolic Interpolation.**—Helical interpolation is used primarily for milling large threads and lubrication grooves, as shown in Fig. 14. Generally, helical interpolation involves motion in all three axes (X, Y, Z) and is accomplished by using circular

interpolation (G02 or G03) while changing the third dimension. Parabolic interpolation (G06) is simultaneous and coordinated control of motion—such that the resulting cutter path describes part of a parabola. The RS-274-D Standard provides further details.

**Subroutine.**—A subroutine is a set of instructions or blocks that can be inserted into a program and repeated whenever required. Parametric subroutines permit letters or symbols to be inserted into the program in place of numerical values (see *Parametric Expressions and Macros*). Parametric subroutines can be called during part programming and values assigned to the letters or symbols. This facility is particularly helpful when dealing with families of parts.

A subprogram is similar to a subroutine except that a subprogram is not wholly contained within another program, as is a subroutine. Subprograms are used when it is necessary to perform the same task frequently, in different programs. The advantage of subprograms over subroutines is that subprograms may be called by any other program, whereas the subroutine can only be called by the program that contains the subroutine.

There is no standard subroutine format; however, the example below is typical of a program that might be used for milling the three pockets shown in Fig. 15. In the example, the beginning and end of the subroutine are indicated by the codes M92 and M93, respectively, and M94 is the code that is used to call the subroutine. The codes M92, M93, and M94 are not standardized (M-codes M90 through M99 are reserved for the user) and may be different from control system to control system. The subroutine functions may use different codes or may not be available at all on other systems.

|                      |   |
|----------------------|---|
| N0010 G00 X.6 Y.85   | Cutter is moved at a rapid traverse rate to a position over the corner of the first pocket to be cut. |
| N0020 M92            | Tells the system that the subroutine is to start in the next block.                                   |
| N0030 G01 Z-.25 F2.0 | Cutter is moved axially into the workpiece 0.25 inch at 2.0 ipm.                                      |
| N0040 X.8            | Cutter is moved to the right 0.8 inch.  |
| N0050 Y.2            | Cutter is moved laterally up 0.2 inch.  |
| N0060 X-.8           | Cutter is moved to the left 0.8 inch.   |
| N0070 Y.2            | Cutter is moved laterally up 0.2 inch.  |

Fig. 14.

Fig. 15.

|                     |  |
|---------------------|--|
| N0080 X.8           | Cutter is moved to the right 0.8 inch.   |
| N0090 G00 Z.25 M93  | Cutter is moved axially out of pocket at rapid traverse rate. Last block of subroutine is signaled by word M93.                      |
| N0100 X.75 Y.5      | Cutter is moved to bottom left-hand corner of second pocket at rapid traverse rate.  |
| N0110 M94 N0030     | Word M94 calls for repetition of the subroutine that starts at sequence number N0030 and ends at sequence number N0090.              |
| N0120 G00 X.2 Y-1.3 | After the second pocket is cut by repetition of sequence numbers N0030 through N0090, the cutter is moved to start the third pocket. |
| N0130 M94 N0030     | Repetition of subroutine is called for by word M94 and the third pocket is cut.  |

**Parametric Expressions and Macros.**—Parametric programming is a method whereby a variable or replaceable parameter representing a value is placed in the machining code instead of using the actual value. In this manner, a section of code can be used several or many times with different numerical values, thereby simplifying the programming and reducing the size of the program. For example, if the values of X and Y in lines N0040 to N0080 of the previous example are replaced as follows:

N0040 X#1

N0050 Y#2

N0060 X#3

N0070 Y#4

then the subroutine starting at line N0030 is a parametric subroutine. That is, the numbers following the # signs are the variables or parameters that will be replaced with actual values when the program is run. In this example, the effect of the program changes is to allow the same group of code to be used for milling pockets of different sizes. If on the other hand, lines N0010, N0100, and N0120 of the original example were changed in a similar manner, the effect would be to move the starting location of each of the slots to the location specified by the replaceable parameters.

Before the program is run, the values that are to be assigned to each of the parameters or variables are entered as a list at the start of the part program in this manner:

#1 = .8

#2 = .2

#3 = .8

#4 = .2

All that is required to repeat the same milling process again, but this time creating a different size pocket, is to change the values assigned to each of the parameters #1, #2, #3, and #4 as necessary. Techniques for using parametric programming are not standardized and are not recognized by all control systems. For this reason, consult the programming manual of the particular system for specific details.

As with a parametric subroutine, macro describes a type of program that can be recalled to allow insertion of finite values for letter variables. The difference between a macro and a parametric subroutine is minor. The term macro normally applies to a source program that is used with computer-assisted part programming; the parametric subroutine is a feature of the CNC system and can be input directly into that system.

**Conditional Expressions.**—It is often useful for a program to make a choice between two or more options, depending on whether or not a certain condition exists. A program can contain one or more blocks of code that are not needed every time the program is run, but are needed some of the time. For example, refer to the previous program for milling three slots. An occasion arises that requires that the first and third slots be milled, but not the second one. If the program contained the following block of code, the machine could be easily instructed to skip the milling of the second slot:

```
N0095 IF [#5 EQ 0] GO TO N0120
```

In this block, #5 is the name of a variable; EQ is a conditional expression meaning *equals*; and GO TO is a branch statement meaning resume execution of the program at the following line number. The block causes steps N0100 and N0110 of the program to be skipped if the value of #5 (a dummy variable) is set equal to zero. If the value assigned to #5 is any number other than zero, the expression (#5 EQ 0) is not true and the remaining instructions in block N0095 are not executed. Program execution continues with the next step, N0100, and the second pocket is milled. For the second pocket to be milled, parameter #5 is initialized at the beginning of the program with a statement such as #5 = 1 or #5 = 2. Initializing #5 = 0 guarantees that the pocket is not machined. On control systems that automatically initialize all variables to zero whenever the system is reset or a program is loaded, the second slot will not be machined unless the #5 is assigned a nonzero value each time the program is run.

Other conditional expressions are: NE = not equal to; GT = greater than; LT = less than; GE = greater than or equal to; and LE = less than or equal to. As with parametric expressions, conditional expressions may not be featured on all machines and techniques and implementation will vary. Therefore, consult the control system programming manual for the specific command syntax.

**Fixed (Canned) Cycles.**—Fixed (canned) cycles comprise sets of instructions providing for a preset sequence of events initiated by a single command or a block of data. Fixed cycles generally are offered by the builder of the control system or machine tool as part of the software package that accompanies the CNC system. Limited numbers of canned cycles began to appear on hardware control systems shortly before their demise. The canned cycles offered generally consist of the standard G-codes covering drilling, boring, and tapping operations, plus options that have been developed by the system builder such as thread cutting and turning cycles. (See *Thread Cutting* and *Turning Cycles*.) Some standard canned cycles included in RS-274-D are shown herewith. A block of data that might be used to generate the cycle functions is also shown above each illustration. Although the G-codes for the functions are standardized, the other words in the block and the block format are not, and different control system builders have different arrangements. The blocks shown are reasonable examples of fixed cycles and do not represent those of any particular system builder.

The G81 block for a simple drilling cycle is:

N\_\_\_G81 X\_\_\_Y\_\_\_C\_\_\_D\_\_\_F\_\_\_EOB  
 N\_\_\_X\_\_\_Y\_\_\_EOB

This G81 drilling cycle will move the drill point from position A to position B and then down to C at a rapid traverse rate; the drill point will next be fed from C to D at the programmed feed rate, then returned to C at the rapid traverse rate. If the cycle is to be repeated at a subsequent point, such as point E in the illustration, it is necessary Only to give the required X and Y coordinates. This repetition capability is typical of canned cycles.

The G82 block for a spotfacing or drilling cycle with a dwell is:

N\_\_\_G82 X\_\_\_Y\_\_\_C\_\_\_D\_\_\_T\_\_\_F\_\_\_EOB

This G82 code produces a cycle that is very similar to the cycle of the G81 code except for the dwell period at point D. The dwell period allows the tool to smooth out the bottom of the counterbore or spotface. The time for the dwell, in seconds, is noted as a T-word.

The G83 block for a peck-drilling cycle is:

N\_\_\_G83 X\_\_\_Y\_\_\_C\_\_\_D\_\_\_K\_\_\_F\_\_\_EOB

In the G83 peck-drilling cycle, the drill is moved from point A to point B and then to point C at the rapid traverse rate; the drill is then fed the incremental distance K, followed by

rapid return to C. Down feed again at the rapid traverse rate through the distance K is next, after which the drill is fed another distance K. The drill is then rapid traversed back to C, followed by rapid traverse for a distance of  $K + K$ ; down feed to D follows before the drill is rapid traversed back to C, to end the cycle.

The G84 block for a tapping cycle is:

N \_\_\_\_\_ G84 X \_\_\_\_\_ Y \_\_\_\_\_ C \_\_\_\_\_ D \_\_\_\_\_ F \_\_\_\_\_ EOB

The G84 canned tapping cycle starts with the end of the tap being moved from point A to point B and then to point C at the rapid traverse rate. The tap is then fed to point D, reversed, and moved back to point C.

The G85 block for a boring cycle with tool retraction at the feed rate is:

N \_\_\_\_\_ G85 X \_\_\_\_\_ Y \_\_\_\_\_ C \_\_\_\_\_ D \_\_\_\_\_ F \_\_\_\_\_ EOB

In the G85 boring cycle, the tool is moved from point A to point B and then to point C at the rapid traverse rate. The tool is next fed to point D and then, while still rotating, is moved back to point C at the same feed rate.

The G86 block for a boring cycle with rapid traverse retraction is:

N \_\_\_\_\_ G86 X \_\_\_\_\_ Y \_\_\_\_\_ C \_\_\_\_\_ D \_\_\_\_\_ F \_\_\_\_\_ EOB

The G86 boring cycle is similar to the G85 cycle except that the tool is withdrawn at the rapid traverse rate.

The G87 block for a boring cycle with manual withdrawal of the tool is:

N \_\_\_ G87 X \_\_\_ Y \_\_\_ C \_\_\_ D \_\_\_ F \_\_\_ EOB

In the G87 canned boring cycle, the cutting tool is moved from A to B and then to C at the rapid traverse rate. The tool is then fed to D. The cycle is identical to the other boring cycles except that the tool is withdrawn manually.

The G88 block for a boring cycle with dwell and manual withdrawal is:

N \_\_\_ G88 X \_\_\_ Y \_\_\_ C \_\_\_ D \_\_\_ T \_\_\_ F \_\_\_ EOB

In the G88 dwell cycle, the tool is moved from A to B to C at the rapid traverse rate and then fed at the prescribed feed rate to D. The tool dwells at D, then stops rotating and is withdrawn manually.

The G89 block for a boring cycle with dwell and withdrawal at the feed rate is:

N \_\_\_ G89 X \_\_\_ Y \_\_\_ C \_\_\_ D \_\_\_ T \_\_\_ F \_\_\_ EOB

Fig. 16.

**Turning Cycles.**—Canned turning cycles are available from most system builders and are designed to allow the programmer to describe a complete turning operation in one or a few blocks. There is no standard for this type of operation, so a wide variety of programs have developed. Fig. 16 shows a hypothetical sequence in which the cutter is moved from the start point to depth for the first pass. If incremental programming is in effect, this distance is specified as D1. The depths of the other cuts will also be programmed as D2, D3, and so on. The length of the cut will be set by the W-word, and will remain the same with each pass. The preparatory word that calls for the roughing cycle is G77. The roughing feed rate is 0.03 ipr (inch per revolution), and the finishing feed rate (last pass) is 0.005 ipr. The block appears as follows:

```
N0054 G77 W=3.1 D1=.4 D2=.3 D3=.3 D4=.1 F1=.03 F2=.005
```

**Thread Cutting.**—Most NC lathes can produce a variety of thread types including constant-lead threads, variable-lead threads (increasing), variable-lead threads (decreasing), multiple threads, taper threads, threads running parallel to the spindle axis, threads (spiral groove) perpendicular to the spindle axis, and threads containing a combination of the preceding. Instead of the feed rate, the lead is specified in the threading instruction block, so that the feed rate is made consistent with, and dependent upon, the selected speed (rpm) of the spindle.

The thread lead is generally noted by either an I- or a K-word. The I-word is used if the thread is parallel to the X-axis and the K-word if the thread is parallel to the Z-axis, the latter being by far the most common. The G-word for a constant-lead thread is G33, for an increasing variable-lead thread is G34, and for a decreasing variable-lead thread is G35. Taper threads are obtained by noting the X- and Z-coordinates of the beginning and end points of the thread if the G90 code is in effect (absolute programming), or the incremental movement from the beginning point to the end point of the thread if the G91 code (incremental programming) is in effect.

|                           |   |
|---------------------------|---|
| N0001 G91                 | (Incremental programming)                             |
| N0002 G00 X-.1000         | (Rapid traverse to depth)                             |
| N0003 G33 Z-1.0000 K.0625 | (Produce a thread with a constant lead of 0.625 inch) |
| N0004 G00 X.1000          | (Withdraw at rapid traverse)                          |
| N0005 Z1.0000             | (Move back to start point)                            |

Fig. 17.

Fig. 18.

Multiple threads are specified by a code in the block that spaces the start of the threads equally around the cylinder being threaded. For example, if a triple thread is to be cut, the threads will start 120 degrees apart. Typical single-block thread cutting utilizing a plunge cut is illustrated in Fig. 17 and shows two passes. The passes are identical except for the distance of the plunge cut. Builders of control systems and machine tools use different code-words for threading, but those shown below can be considered typical. For clarity, both zeros and decimal points are shown.

The only changes in the second pass are the depth of the plunge cut and the withdrawal. The blocks will appear as follows:

```
N0006 X - .1050
N0007 G33 Z - 1.0000 K.0625
N0008 G00 X.1050
N0009 Z1.000
```

Compound thread cutting, rather than straight plunge thread cutting, is possible also, and is usually used on harder materials. As illustrated in Fig. 18, the starting point for the thread is moved laterally in the  $-Z$  direction by an amount equal to the depth of the cut times the tangent of an angle that is slightly less than 30 degrees. The program for the second pass of the example shown in Fig. 18 is as follows:

```
N0006 X - .1050 Z - .0028
N0007 G33 Z - 1.0000 K.0625
N0008 G00 X.1050
N0009 Z1.0000
```

Fixed (canned), one-block cycles also have been developed for CNC systems to produce the passes needed to complete a thread. These cycles may be offered by the builder of the control system or machine tool as standard or optional features. Subroutines also can generally be prepared by the user to accomplish the same purpose (see Subroutine). A one-block fixed threading cycle might look something like:

```
N0048 G98 X - .2000 Z - 1.0000 D.0050 F.0010
```

where G98 = preparatory code for the threading cycle

X-.2000 = total distance from the starting point to the bottom of the thread

Z-1.0000 = length of the thread

D.0050 = depths of successive cuts

F.0010 = depth(s) of the finish cut(s)

### APT Programming

**APT.**—APT stands for Automatically Programmed Tool and is one of many computer languages designed for use with NC machine tools. The selection of a computer-assisted part-programming language depends on the type and complexity of the parts being machined more than on any other factor. Although some of the other languages may be easier to use, APT has been chosen to be covered in this book because it is a nonproprietary

language in the public domain, has the broadest range of capability, and is one of the most advanced and universally accepted NC programming languages available. APT (or a variation thereof) is also one of the languages that is output by many computer programs that produce CNC part programs directly from drawings produced with CAD systems.

APT is suitable for use in programming part geometry from simple to exceptionally complex shapes. APT was originally designed and used on mainframe computers, however, it is now available, in many forms, on mini- and microcomputers as well. APT has also been adopted as ANSI Standard X3.37 and by the International Organization for Standardization (ISO) as a standardized language for NC programming. APT is a very dynamic program and is continually being updated. APT is being used as a processor for part-programming graphic systems, some of which have the capability of producing an APT program from a graphic screen display or CAD drawing and of producing a graphic display on the CAD system from an APT program.

APT is a high-level programming language. One difference between APT and the ANSI/EIA RS-274-D (G-codes) programming format discussed in the last section is that APT uses English like words and expressions to describe the motion of the tool or work-piece. APT has the capability of programming the machining of parts in up to five axes, and also allows computations and variables to be included in the programming statements so that a whole family of similar parts can be programmed easily. This section describes the general capabilities of the APT language and includes a ready reference guide to the basic geometry and motion statements of APT, which is suitable for use in programming the machining of the majority of cubic type parts involving two-dimensional movements. Some of the three-dimensional geometry capability of APT and a description of its five-dimensional capability are also included.

As shown above, the APT system can be thought of comprising the input program, the five sections 0 through IV, and the output program. The input program shown on the left progresses through the first four sections and all four are controlled by the fifth, section 0. Section IV, the postprocessor, is the software package that is added to sections II and III to customize the output and produce the necessary program format (including the G-words, M-words, etc.) so that the coded instructions will be recognizable by the control system. The postprocessor is software that is separate from the main body of the APT program, but for purposes of discussion, it may be easier to consider it as a unit within the APT program.

**APT Computational Statements.**—Algebraic and trigonometric functions and computations can be performed with the APT system as follows:

| Arithmetic Form | APT Form | Arithmetic Form | APT Form         | Arithmetic Form | APT Form         |
|-----------------|----------|-----------------|------------------|-----------------|------------------|
| $25 \times 25$  | 25*25    | $25^2$          | 25**2            | $\cos \theta$   | COSF( $\theta$ ) |
| $25 \div 25$    | 25/25    | $25^n$          | 25**n            | $\tan \theta$   | TANF( $\theta$ ) |
| $25 + 25$       | 25 + 25  | $\sqrt{25}$     | SQRTF (25)       | $\arctan .5000$ | ATANF(.5)        |
| $25 - 25$       | 25 - 25  | $\sin \theta$   | SINF( $\theta$ ) |                 |                  |

Computations may be used in the APT system in two ways. One way is to let a factor equal the computation and then substitute the factor in a statement; the other is to put the computation directly into the statement. The following is a series of APT statements illustrating the first approach.

P1 =POINT/0,0,1

T=(25\*2/3 + (3\*\*2 - 1))

P2 =POINT/T,0,0

The second way would be as follows;

P1 =POINT/0,0,1

P2 =POINT/(25\*2/3 + (3\*\*2 - 1)),0,0

*Note:* The parentheses have been used as they would be in an algebraic formula so that the calculations will be carried out in proper sequence. The operations within the inner parentheses would be carried out first. It is important for the total number of left-hand parentheses to equal the total number of right-hand parentheses; otherwise, the program will fail.

**APT Geometry Statements.**—Before movements around the geometry of a part can be described, the geometry must be defined. For example, in the statement GOTO/P1, the computer must know where P1 is located before the statement can be effective. P1 therefore must be described in a geometry statement, prior to its use in the motion statement GOTO/P1. The simplest and most direct geometry statement for a point is

P1 =POINT/X ordinate, Y ordinate, Z ordinate

If the Z ordinate is zero and the point lies on the X–Y plane, the Z location need not be noted. There are other ways of defining the position of a point, such as at the intersection of two lines or where a line is tangent to a circular arc. These alternatives are described below, together with ways to define lines and circles. Referring to the preceding statement, P1 is known as a symbol. Any combination of letters and numbers may be used as a symbol providing the total does not exceed six characters and at least one of them is a letter. MOUSE2 would be an acceptable symbol, as would CAT3 or FRISBE. However, it is sensible to use symbols that help define the geometry. For example, C1 or CIR3 would be good symbols for a circle. A good symbol for a vertical line would be VL5.

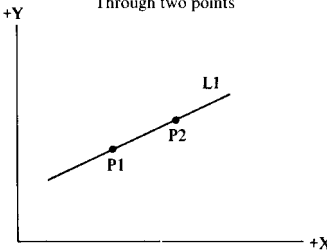

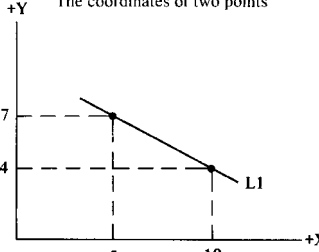

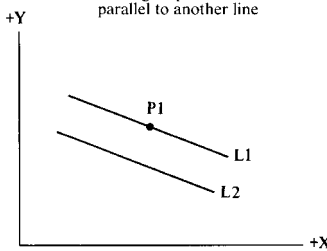

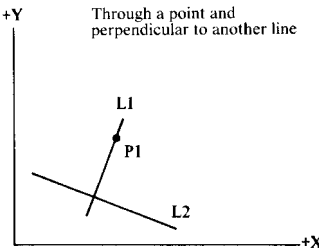

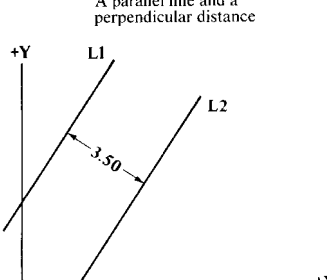

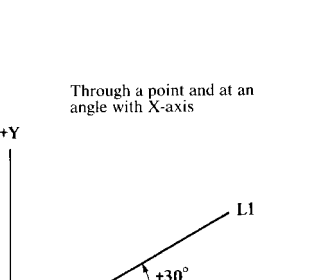

Next, and after the equal sign, the particular geometry is noted. Here, it is a POINT. This word is a vocabulary word and must be spelled exactly as prescribed. Throughout, the designers of APT have tried to use words that are as close to English as possible. A slash follows the vocabulary word and is followed by a specific description of the particular geometry, such as the coordinates of the point P1. A usable statement for P1 might appear as P1 = POINT/1,5,4. The 1 would be the X ordinate; the 5, the Y ordinate; and the 4, the Z ordinate.

Lines as calculated by the computer are infinitely long, and circles consist of 360 degrees. As the cutter is moved about the geometry under control of the motion statements, the lengths of the lines and the amounts of the arcs are “cut” to their proper size. (Some of the geometry statements shown in the accompanying illustrations for defining POINTS, LINES, CIRCLES, TABULATED CYLINDERS, CYLINDERS, CONES, and SPHERES, in the APT language, may not be included in some two-dimensional [ADAPT] systems.)

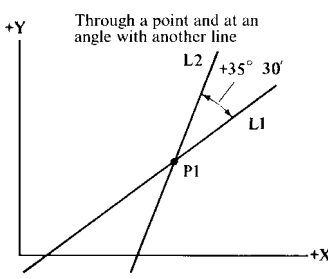

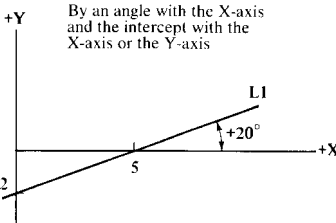

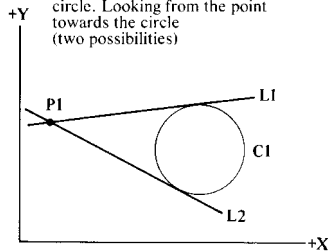

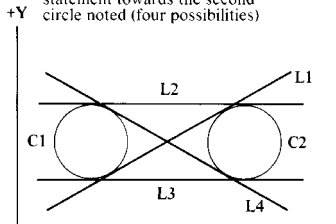

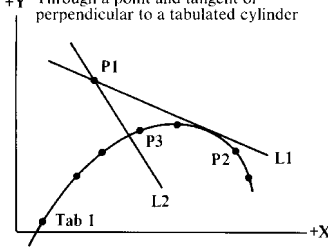

## Points

## Circles

**APT Motion Statements.**—APT is based on the concept that a milling cutter is guided by two surfaces when in a contouring mode. Examples of these surfaces are shown in Fig. 1, and they are called the “part” and the “drive” surfaces. Usually, the part surface guides the bottom of the cutter and the drive surface guides the side of the cutter. These surfaces may or may not be actual surfaces on the part, and although they may be imaginary to the part programmer, they are very real to the computer. The cutter is either stopped or redirected by a third surface called a check surface. If one were to look directly down on these surfaces, they would appear as lines, as shown in Figs. 2a through 2c.

Fig. 1. Contouring Mode Surfaces

When the cutter is moving toward the check surface, it may move to it, onto it, or past it, as illustrated in Fig. 2a. When the cutter meets the check surface, it may go right, denoted by the APT command GORGT, or go left, denoted by the command GOLFT, in Fig. 2b.

Alternatively, the cutter may go forward, instructed by the command GOFWD, as in Fig. 2c. The command GOFWD is used when the cutter is moving either onto or off a tangent circular arc. These code instructions are part of what are called motion commands. Fig. 3 shows a cutter moving along a drive surface, L1, toward a check surface, L2. When it arrives at L2, the cutter will make a right turn and move along L2 and past the new check surface L3. Note that L2 changes from a check surface to a drive surface the moment the cutter begins to move along it. The APT motion statement for this move is:

GORGT/L2,PAST,L3

### Contouring Cutter Movements

Fig. 2a.

Fig. 2b.

Fig. 2c.

Fig. 3. Motion Statements for Movements Around a Workpiece

Still referring to Fig. 3, the cutter moves along L3 until it comes to L4. L3 now becomes the drive surface and L4 the check surface. The APT statement is:

GORGT/L3,TO,L4

The next statement is:

GOLFT/L4,TANTO,C1

Even though the cutter is moving to the right, it makes a left turn if one is looking in the direction of travel of the cutter. In writing the motion statements, the part programmers must imagine they are steering the cutter. The drive surface now becomes L4 and the check surface, C1. The next statement will therefore be:

GOFWD/C1,TANTO,L5

This movement could continue indefinitely, with the cutter being guided by the drive, part, and check surfaces.

**Start-Up Statements:** For the cutter to move along them, it must first be brought into contact with the three guiding surfaces by means of a start-up statement. There are three different start-up statements, depending on how many surfaces are involved.

A three-surface start-up statement is one in which the cutter is moved to the drive, part, and check surfaces, as seen in Fig. 4a. A two-surface start-up is one in which the cutter is

moved to the drive and part surfaces, as in Fig. 4b. A one-surface start-up is one in which the cutter is moved to the drive surface and the X-Y plane, where  $Z = 0$ , as in Fig. 4c. With the two- and one-surface start-up statements, the cutter moves in the most direct path, or perpendicular to the surfaces. Referring to Fig. 4a (three-surface start-up), the move is initiated from a point P1. The two statements that will move the cutter from P1 to the three surfaces are:

FROM/P1  
GO/TO,DS,TO,PS,TO,CS

### Circles

Tangent to a line and a circle, given the radius (eight possibilities)

C1 = CIRCLE/YSMALL, L1, XLARGE, OUT, C12, RADIUS, .5  
 C2 = CIRCLE/YLARGE, L1, XLARGE, OUT, C12, RADIUS, .5  
 C3 = CIRCLE/YLARGE, L1, XLARGE, IN, C12, RADIUS, .5  
 C4 = CIRCLE/YSMALL, L1, XLARGE, IN, C12, RADIUS, .5  
 C5 = CIRCLE/YLARGE, L1, XSMALL, OUT, C12, RADIUS, .5  
 C6 = CIRCLE/XLARGE, L1, XSMALL, OUT, C12, RADIUS, .5  
 C7 = CIRCLE/YSMALL, L1, XSMALL, OUT, C12, RADIUS, .5  
 C8 = CIRCLE/YSMALL, L1, XSMALL, IN, C12, RADIUS, .5

#### Recommendations:

- Note which side of line circle is on (e.g., YSMALL, L1).
- Note whether the circle being defined is inside (IN), or outside (OUT), the known circle.
- Of the two remaining circles, note whether the circle to be defined is XLARGE, XSMALL, or YLARGE or YSMALL, to arrive at the second modifier in the statement.

Tangent to two circles, given the radius (eight possibilities)

C1 = CIRCLE/YSMALL, OUT, C10, OUT, C11, RADIUS, .75  
 C2 = CIRCLE/YSMALL, OUT, C10, IN, C11, RADIUS, .75  
 C3 = CIRCLE/YSMALL, IN, C10, IN, C11, RADIUS, .75  
 C4 = CIRCLE/YSMALL, IN, C10, OUT, C11, RADIUS, .75  
 C5 = CIRCLE/YLARGE, IN, C10, IN, C11, RADIUS, .75  
 C6 = CIRCLE/YLARGE, OUT, C10, IN, C11, RADIUS, .75  
 C7 = CIRCLE/YLARGE, OUT, C10, OUT, C11, RADIUS, .75  
 C8 = CIRCLE/YLARGE, IN, C10, OUT, C11, RADIUS, .75

#### Recommendations

- Apply IN, OUT modifiers.
- Apply XLARGE, etc., modifiers.

DS is used as the symbol for the Drive Surface; PS as the symbol for the Part Surface; and CS as the symbol for the Check Surface. The surfaces must be denoted in this sequence. The drive surface is the surface that the cutter will move along after coming in contact with the three surfaces. The two statements applicable to the two-surface start-up (Fig. 4b) are:

FROM/P1  
GO/TO,DS,TO,PS

The one-surface start-up (Fig. 4c) is:

FROM/P1  
GO/TO,DS

**Planes**

Planes are often used as the part surface, and are defined by three points not lying in a straight line

$PL1 = PLANE/P1, P2, P3$

A plane that is horizontal, or parallel to the X-Y plane, may be defined as:

$PL1 = PLANE/0, 0, 1, 5$  (0, 0, 1 does not change)

Alternatively, PL2 may be defined as a plane parallel to PL1

$PL2 = PLANE/PARLEL, PL1, ZLARGE, 10$

**Cutter Movement Surfaces**

Fig. 4a.

Fig. 4b.

Fig. 4c.

**Tabulated Cylinder**

A tabulated cylinder is the line that is formed when an irregular cylinder intersects a plane. The plane intersected in the figure at the left is the  $X$ - $Y$  plane.

A section of the line can be defined by a series of points on the line, as seen at the right. This line is called a TABCYL. The line must pass through all the points, therefore, it is best not to use too many. The statement to the computer would read:

TAB1 = TABCYL/NOZ, SPLINE, P1, P2, P3, P4, P5, P6

TAB1 = TABCYL/NOZ, SPLINE, X., Y., X2, Y2, X3, Y3, X4, Y4, X5, Y5, X6, Y6  
 (where  $X$  and  $Y$  are the coordinates of the points)

**3-D Geometry**

**Cylinder**

Length of vector = 1

A cylinder is defined by a vector, a point on the centerline, and the radius

CL1 = CYLNDR/P1, V2, 1.5

where V2 is a unit vector in line with the cylinder centerline, and is described by the  $X$ ,  $Y$ , and  $Z$  components. The cylinder centerline lies on the  $X$ - $Y$  plane and is parallel to the  $Y$ -axis. The statement for the vector is therefore:

V2 = VECTOR/ $X$  component,  $Y$  component,  $Z$  component

V2 = VECTOR/0, 1, 0

**Cone**

A cone is defined by its vertex, its axis as a unit vector, and the half angle (refer to cylinder for an example of a vector statement)

CON1 = CONE/P1,V1,45

**Sphere**

A sphere is defined by the center and the radius  
 SP1 = SPHERE/P1, RADIUS, 2.5

or  
 SP1 = SPHERE/5, 5, 3, 2.5 (where 5, 5, and 3 are the  $X$ ,  $Y$ , and  $Z$  coordinates or P1, and 2.5 is the radius)

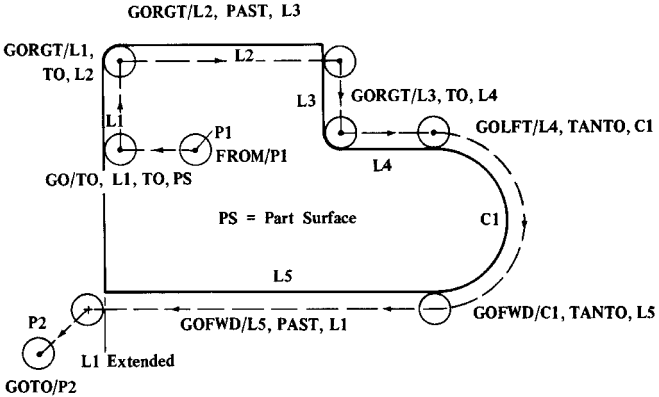

Fig. 5. A Completed Two-Surface Start-Up

Note that, in all three motion statements, the slash mark (/) lies between the GO and the TO. When the cutter is moving to a point rather than to surfaces, such as in a start-up, the statement is GOTO/ rather than GO/TO. A two-surface start-up, Fig. 3, when completed, might appear as shown in Fig. 5, which includes the motion statements needed. The motion statements, as they would appear in a part program, are shown at the left, below:

|                   |         |
|-------------------|---------|
| FROM/P1           | FROM/P1 |
| GO/TO,L1,TO,PS    | GOTO/P2 |
| GORGT/L1,TO,L2    | GOTO/P3 |
| GORGT/L2,PAST,L3  | GOTO/P4 |
| GORGT/L3,TO,L4    | GOTO/P5 |
| GOLFT/L4,TANTO,C1 | GOTO/P6 |
| GOFWD/C1,TANTO,L5 | GOTO/P7 |
| GOFWD/L5,PAST,L1  |         |
| GOTO/P2           |         |

GOTO statements can move the cutter throughout the range of the machine, as shown in Fig. 6. APT statements for such movements are shown at the right in the preceding example. The cutter may also be moved incrementally, as shown in Fig. 7. Here, the cutter is to move 2 inches in the + X direction, 1 inch in the + Y direction, and 1.5 inches in the + Z direction. The incremental move statement (indicated by DLTA) is:

GODLTA/2,1,1.5

The first position after the slash is the X movement; the second the Y movement, and the third, the Z movement.

**Five-Axis Machining:** Machining on five axes is achieved by causing the APT program to generate automatically a unit vector that is normal to the surface being machined, as shown in Fig. 8. The vector would be described by its X, Y, and Z components. These components, along with the X, Y, and Z coordinate positions of the tool tip, are fed into the post-processor, which determines the locations and angles for the machine tool head and/or table.

**APT Postprocessor Statements.**—Statements that refer to the operation of the machine rather than to the geometry of the part or the motion of the cutter about the part are called postprocessor statements. APT postprocessor statements have been standardized internationally. Some common statements and an explanation of their meaning follow:

**MACHIN/**Specifies the postprocessor that is to be used. Every postprocessor has an identity code, and this code must follow the slash mark (/). For example: MACHIN/LATH,82

**FEDRATE/**Denotes the feed rate. If in inches per minute (ipm), only the number

Fig. 6. A Series of GOTO Statements

Fig. 7. Incremental Cutter Movements

Fig. 8. Five-Axis Machining

need be shown. If in inches per revolution (ipr), IPR must be shown, for example: FED-RAT/.005,IPR

**RAPID** Means rapid traverse and applies only to the statement that immediately follows it

**SPINDL/**Refers to spindle speed. If in revolutions per minute (rpm), only the number need be shown. If in surface feet per minute (sfm), the letters SFM need to be shown, for example: SPINDL/ 100SFM

**COOLNT/**Means cutting fluid and can be subdivided into: COOLNT/ON, COOLNT/MIST, COOLNT/FLOOD, COOLNT/OFF

**TURRET/**Used to call for a selected tool or turret position

**CYCLE/**Specifies a cycle operation such as a drilling or boring cycle. An example of a drilling cycle is: CYCLE/DRILL,RAPTO.,45,FEDTO,0,IPR.,.004. The next statement might be GOTO/PI and the drill will then move to P1 and perform the cycle operation. The cycle will repeat until the CYCLE/OFF statement is read

END Stops the machine but does not turn off the control system

Fig. 9. Symbols for Geometrical Elements

**APT Example Program.**—A dimensioned drawing of a part and a drawing with the symbols for the geometry elements are shown in Fig. 9. A complete APT program for this part, starting with the statement PARTNO 47F36542 and ending with FINI, is shown at the left below.

The numbers at the left of the statements are for reference purposes only, and are not part of the program. The cutter is set initially at a point represented by the symbol SP, having coordinates  $X = -0.5$ ,  $Y = -0.5$ ,  $Z = 0.75$ , and moves to L1 (extended) with a one-surface start-up so that the bottom of the cutter rests on the  $X$ - $Y$  plane. The cutter then moves counterclockwise around the part, past L1 (extended), and returns to SP. The coordinates of P1 are  $X = 0$ ,  $Y = 0$ , and  $Z = 1$ .

Referring to the numbers at the left of the program:

- (1) PARTNO must begin every program. Any identification can follow.
- (2) The diameter of the cutter is specified. Here it is 0.25 inch.
- (3) The feed rate is given as 5 inches per minute, which is contained in a postprocessor statement.
- (4)–(10) Geometry statements.
- (11)–(18) Motion statements.
- (19) All APT programs end with FINI.

A computer printout from section II of the APT program is shown at the right, above. This program was run on a desktop personal computer. Lines (1) through (10) repeat the geometry statements from the original program. The motion statements are also repeated, and below each motion statement are shown the  $X$ ,  $Y$ , and  $Z$  coordinates of the end points of the center-line (CL) movements for the cutter. Two lines of data follow those for the circular movements. For example, Line (18), which follows Line (17), GOFWD/C1,TANTO,L2, describes the  $X$  coordinate of the center of the arc, 2.9500, the  $Y$  coordinate of the center of the arc, 0.2500, and the radius of the arc required to be traversed by the cutter.

This radius is that of the arc shown on the part print, plus the radius of the cutter ( $0.2500 + 0.1250 = 0.3750$ ). Line (18) also shows that the cutter is traveling in a counterclockwise (CCLW) motion. A circular motion is described in Lines (22), (23), and (24). Finally, the cutter is directed to return to the starting point, SP, and this command is noted in Line (27). The  $X$ ,  $Y$ , and  $Z$  coordinates of SP are shown in Line (28).

**APT for Turning.**—In its basic form, APT is not a good program for turning. Although APT is probably the most suitable program for three-, four-, and five-axis machining, it is awkward for the simple two-axis geometry required for lathe operations. To overcome this problem, preprocessors have been developed especially for lathe part programming. The statements in the lathe program are automatically converted to basic APT statements in the computer and processed by the regular APT processor. An example of a lathe program, based on the APT processor and made available by the McDonnell Douglas Automation Co., is shown below. The numbers in parentheses are not part of the program, but are used only for reference. Fig. 10 shows the general set-up for the part, and Fig. 11 shows an enlarged view of the part profile with dimensions expressed along what would be the  $X$ - and  $Y$ -axes on the part print.

Line (3) describes the tool. Here, the tool is located on face 1 of the turret and its tip is -1 inch "off" (offset) in the  $X$  direction and -6 inches "off" in the  $Y$  direction, when considering  $X$ - $Y$  rather than  $X$ - $Z$  axes. The cutting tool tip radius is also noted in this statement. Line (4) describes the dimensions of the rough material, or blank. Lines parallel to the  $X$ -axis are noted as FACE lines, and lines parallel to the  $Z$ -axis are noted as TURN lines. The FACE line (LN1) is located 3.5 inches along the  $Z$ -axis and parallel to the  $X$ -axis. The TURN line (LN2) is located 2 inches above the  $Z$ -axis and parallel to it. Note that in Figs. 10 and 11, the  $X$ -axis is shown in a vertical position and the  $Z$ -axis in a horizontal position. Line (5) describes the shape of the finished part. The term FILLET is used in this statement to describe a circle that is tangent to the line described by TURN, 1 and the line that is described by FACE, 1.5. The \$ sign means that the statement is continued on the next line. These geometry elements must be contiguous and must be described in sequence. Line (6) specifies the position of the tool tip at the start of the operation, relative to the point of origin. Line (7) describes the roughing operation and notes that the material to be roughed out lies between BLANK1 and PART1; that the STEP, or depth of roughing cuts, is to be 0.1 inch; that 0.05 inch is to be left for the finish cut; that the speed is to be 300 sfm and the feed rate is to be 0.01 ipr; and that the tool to be used is identified by the symbol T1. Line (8) describes the finish cut, which is to be along the contour described by PART1.

**Indexable Insert Holders for NC.**—Indexable insert holders for numerical control lathes are usually made to more precise standards than ordinary holders. Where applicable, reference should be made to American National Standard B212.3-1986, Precision Holders for Indexable Inserts. This standard covers the dimensional specifications, styles, and designations of precision holders for indexable inserts, which are defined as tool holders that locate the gage insert (a combination of shim and insert thicknesses) from the back or front and end surfaces to a specified dimension with a  $\pm 0.003$  inch ( $\pm 0.08$  mm) tolerance. In NC programming, the programmed path is that followed by the center of the tool tip, which is the center of the point, or nose radius, of the insert. The surfaces produced are the result of the path of the nose and the major cutting edge, so it is necessary to compensate for the nose or point radius and the lead angle when writing the program. Table 1, from B212.3, gives the compensating dimensions for different holder styles. The reference point is determined by the intersection of extensions from the major and minor cutting edges, which would be the location of the point of a sharp pointed tool. The distances from this point to the nose radius are  $L1$  and  $D1$ ;  $L2$  and  $D2$  are the distances from the sharp point to the center of the nose radius. Threading tools have sharp corners and do not require a radius compensation. Other dimensions of importance in programming threading tools are also given in Table 2; the data were developed by Kennametal, Inc.

The  $C$  and  $F$  characters are tool holder dimensions other than the shank size. In all instances, the  $C$  dimension is parallel to the length of the shank and the  $F$  dimension is parallel to the side dimension; actual dimensions must be obtained from the manufacturer. For all  $K$  style holders, the  $C$  dimension is the distance from the end of the shank to the tangent point of the nose radius and the end cutting edge of the insert. For all other holders, the  $C$  dimension is from the end of the shank to a tangent to the nose radius of the insert. The  $F$  dimension on all B, D, E, M, P, and V style holders is measured from the back side of the shank to the tangent point of the nose radius and the side cutting edge of the insert. For all A, F, G, J, K, and L style holders, the  $F$  dimension is the distance from the back side of the shank to the tangent of the nose radius of the insert. In all these designs, the nose radius is the standard radius corresponding to those given in the paragraph *Cutting Point Configuration* on page 758.

**V-Flange Tool Shanks and Retention Knobs.**—Dimensions of ANSI B5.18-1972 (R1998) standard tool shanks and corresponding spindle noses are detailed on pages 940 through 944, and are suitable for spindles used in milling and associated machines. Corresponding equipment for higher-precision numerically controlled machines, using retention knobs instead of drawbars, is usually made to the ANSI/ASME B5.50-1985 standard.

Notes: Dimensions are in inches. Material: low-carbon steel. Heat treatment: carburize and harden to 0.016 to 0.028 in. effective case depth. Hardness of noted surfaces to be Rockwell 56-60; core hardness Rockwell C35-45. Hole *J* shall not be carburized. Surfaces *C* and *R* to be free from tool marks. Deburr all sharp edges. Geometric dimension symbols are to ANSI Y14.5M-1982.

Data for size 60 are not part of Standard.

**CAD/CAM**

**CAD/CAM.**—CAD in engineering means computer-aided design using a computer graphics system to develop mechanical, electrical/electronic, and architectural designs. A second D (CADD) is sometimes added (computer-aided drafting and design) and simply indicates a mechanical drafting or drawing program. CAD technology is the foundation for a wide variety of engineering, design, drafting, analysis, and manufacturing activities. Often a set of drawings initially developed in the design phase of a project is also used for analyzing and optimizing the design, creating mechanical drawings of parts and assemblies and for generating NC/CNC part programs that control machining operations. Formerly, after a component had been designed with CAD, the design was passed to a part programmer who developed a program for machining the components, either manually or directly on the computer (graphic) screen, but the process often required redefining and reentering part geometry. This procedure is often regarded as the CAM part of CAD/CAM, although CAM (for computer-aided manufacturing) has a much broader meaning and involves the computer in many other manufacturing activities such as factory simulation and planning analyses. Improvements in the speed and capability of computers, operating systems, and programs (including, but not limited to CAD) have simplified the process of integrating the manufacturing process and passing drawings (revised, modified, and translated, as necessary) through the design, analysis, simulation, and manufacturing stages.

A CAD drawing is a graphic representation of part geometry data stored in a drawing database file. The drawing database generally contains the complete list of entity (line, arc, etc.) and coordinate information required to build the CAD drawing, and additional information that may be required to define solid surfaces and other model characteristics. The format of data in a drawing file depends on the CAD program used to create the file. Generally, drawings are not directly interchangeable between drawing programs, however, drawings created in one system can usually be translated into an intermediate format or file type, such as DXF, that allows some of the drawing information to be exchanged between different programs. Translation frequently results in some loss of detail or loss of other drawing information because the various drawing programs do not all have the same features. The section Drawing Exchange Standards covers some of the available methods of transferring drawing data between different CAD programs.

Fig. 1. Simple Wireframe Cube with Hidden Lines Automatically Removed

The simplest CAD drawings are two-dimensional and conform to normal engineering drafting practice showing orthographic (front, top, and side views, for example), exploded, isometric, or other views of a component. Depending on the complexity of the part and machining requirements, two-dimensional drawings are often sufficient for use in developing NC/CNC part programs. If a part can be programmed within a two-dimensional

CAD framework, a significant cost saving may be realized because 3-D drawings require considerably more time, drawing skill, and experience to produce than 2-D drawings.

*Wireframes* are the simplest two- and three-dimensional forms of drawing images and are created by defining all edges of a part and, where required, lines defining surfaces. Wireframe drawing elements consist primarily of lines and arcs that can be used in practically any combination. A wireframe drawing of a cube, as in Fig. 1, consists of 12 lines of equal length (some are hidden and thus not shown), each perpendicular to the others. Information about the interior of the cube and the character of the surfaces is not included in the drawing. With such a system, if a 1-inch cube is drawn and a 0.5-inch cylinder is required to intersect the cube's surface at the center of one of its faces, the intersection points cannot be determined because nothing is known about the area between the edges. A wireframe model of this type is ambiguous if the edges overlap or do not meet where they should. Hidden-line removal can be used to indicate the relative elevations of the drawing elements, but normally a drawing cannot be edited when hidden lines have been removed. Hidden lines can be shown dashed or can be omitted from the view.

Two-dimensional drawing elements, such as lines, arcs, and circles, are constructed by directly or indirectly specifying point coordinates, usually  $x$  and  $y$ , that identify the location, size, and orientation of the entities. Three-dimensional drawings are also made up of a collection of lines, arcs, circles, and other drawing elements and are stored in a similar manner. A third point coordinate,  $z$ , indicates the elevation of a point in 3-D drawings. On the drawing screen, working in the  $x$ - $y$  plane, the elevation is commonly thought of as the distance of a point or object into the screen (away from the observer) or out of the viewing screen (toward the observer). Coordinate axes are oriented according to the right-hand rule: If the fingers of the right hand point in the direction from the positive  $x$ -axis to the positive  $y$ -axis, the thumb of the right hand points in the direction of the positive  $z$ -axis.

Assigning a thickness (or extruding) to objects drawn in two dimensions quickly gives some 3-D characteristics to an object and can be used to create simple prismatic 3-D shapes, such as cubes and cylinders. Usually, the greatest difficulty in creating 3-D drawings is in picking and visualizing the three-dimensional points in a two-dimensional workspace (the computer display screen). To assist in the selection of 3-D points, many CAD programs use a split or windowed screen drawing area that can simultaneously show different views of a drawing. Changes made in the current or active window are reflected in each of the other windows. A typical window setup might show three orthogonal (mutually perpendicular) views of the drawing and a perspective or 3-D view. Usually, the views shown can be changed as required to suit the needs of the operator.

If carefully constructed, wireframe images may contain enough information to completely define the external geometry of simple plane figures. Wireframe images are especially useful for visualization of 3-D objects and are effectively used during the design process to check fits, clearances, and dimensional accuracy. Parts designed to be used together can be checked for accuracy of fit by bringing them together in a drawing, superimposing the images, and graphically measuring clearances. If the parts have been designed or drawn incorrectly, the errors will frequently be obvious and appropriate corrections can be made.

A more complicated level of 3-D drawing involves solids, with sections of the part being depicted on the screen as solid geometrical structures called primitives, such as cylinders, spheres, and cubes. Primitives can be assembled on a drawing to show more complex parts. Three distinct forms of image may be generated by 3-D systems, although not all systems make use of all three.

*Surface Images:* A surface image defines not only the edges of the part, but also the "skin" of each face or surface. For the example mentioned previously, the intersection for the 0.5-inch cylinder would be calculated and drawn in position. Surface models are necessary for designing free-form objects such as automotive body panels and plastics injection moldings used in consumer goods. For a surface model, the computer must be provided

with much more information about the part in addition to the  $x$ ,  $y$ ,  $z$  coordinates defining each point, as in a wireframe. This information may include tangent vectors, surface normals, and weighting that determines how much influence one point has on another, twists, and other mathematical data that define abstract curves, for instance. Fig. 2 shows a typical 3-D surface patch.

*Shaded images* may be constructed using simulated light sources, reflections, colors, and textures to make renderings more lifelike. Surface images are sometimes ambiguous, with surfaces that overlap or miss each other entirely. Information about the interior of the part, such as the center of gravity or the volume, also may not be available, depending on the CAD package.

Fig. 2. A 3-D Surface Patch

Fig. 3. Isometric Drawing Showing Orientation of Principle Drawing Axes

*Solid Images:* A solid image is the ultimate electronic representation of a part, containing all the necessary information about edges, surfaces, and the interior. Most solid-imaging programs can calculate volume, center of mass, centroid, and moment of inertia. Several methods are available for building a solid model. One method is to perform Boolean operations on simple shapes such as cylinders, cones, cubes, and blocks. Boolean operations are used to union (join), difference (subtract one from another), and intersect (find the common volume between two objects). Thus, making a hole in a part requires subtracting a cylinder from a rectangular block. This type of program is called constructive solid geometry (CSG).

The boundary representation type of imaging program uses profiles of 2-D shapes that it extrudes, rotates, and otherwise translates in 3-D space to create the required solid. Sometimes combinations of the above two programs are used to attain a blend of flexibility, accuracy, and performance. For more precision, greatly increased time is needed for calculations, so compromises sometimes are needed to maintain reasonable productivity. Solid images may be sliced or sectioned on the screen to provide a view of the interior. This type of image is also useful for checking fit and assembly of one part with another.

Solid images provide complete, unambiguous representation of a part, but the programs require large amounts of computer memory. Each time a Boolean operation is performed, the list of calculations that must be done to define the model becomes longer, so that computation time increases.

**Drawing Projections.**—Several different techniques are used to display objects on paper or a computer screen to give an accurate three-dimensional appearance. Several of these methods are commonly used in CAD drawings.

*Isometric drawings*, as in Fig. 3, can be used to good effect for visualizing a part because they give the impression of a 3-D view and are often much faster to create. Isometric drawings are created in 2-D space, with the  $x$ - and  $y$ -axes being inclined at 30 degrees to the horizontal, as shown in Fig. 3, and the  $z$ -axis as vertical. Holes and cylinders in isometric drawings become elliptical. Because of the orientation of the  $x$ -,  $y$ -, and  $z$ -axes, the true length of lines may not be accurately represented in isometric drawings and dimensions

should not be taken directly from a print. Some CAD programs have a special set of pre-defined drawing axes to facilitate creating isometric drawings.

In *parallel projections*, lines that are parallel in an object, assembly, or part being portrayed remain parallel in the drawing. Parallel projections show 3-D objects in a dimensionally correct manner, so that relative and scaled dimensions may be taken directly from a drawing. However, drawings may not appear as realistic as isometric or perspective drawings.

A characteristic of *perspective drawings* is that parallel lines converge (see Fig. 4) so that objects that are farther away from the observer appear smaller. Perspective drawing techniques are used in some three-dimensional drawings to convey the true look of an object, or group of objects. Because objects in perspective drawings are not drawn to scale, dimensional information cannot be extracted from the drawings of a part. Some 3-D drawing packages have a true perspective drawing capability, and others use a simulation technique to portray a 3-D perspective.

An *axonometric projection* is a 3-D perpendicular projection of an object onto a surface, such that the object is tilted relative to its normal orientation. An axonometric projection of a cube, as in Fig. 1, shows three faces of the cube. CAD systems are adept at using this type of view, making it easy to see an object from any angle.

Fig. 4. Perspective Drawing of Three Equal-Size Cubes and Construction Lines

Fig. 5. A Common Positioning Error

**Drawing Tips and Traps.**—Images sometimes appear correct on the screen but contain errors that show up when the drawing is printed or used to produce NC/CNC part programs. In Fig. 5, the two lines within the smaller circle appear to intersect at a corner, but when the view of the intersection is magnified, as in the larger circle, it is clear that the lines actually do not touch. Although an error of this type may not be easily visible, other parts placed in the drawing relative to this part will be out of position.

A common problem that shows up in plotting, but is difficult to detect on the screen, comes from placing lines in the same spot. When two or more lines occupy exactly the same location on the screen, there is usually no noticeable effect on the display. However, when the drawing is plotted, each line is plotted separately, causing the single line visible to become thicker and darker. Likewise, if a line that appears continuous on the screen is actually made up of several segments, plotting the line will frequently result in a broken, marred, or blotted appearance to the line because the individual segments are plotted separately, and at different times. To avoid these problems and to get cleaner looking plots, replace segmented lines with single lines and avoid constructions that place one line directly on top of another.

Exact decimal values should be used when entering point coordinates from the keyboard, if possible; fractional sizes should be entered as fractions, not truncated decimals. For example,  $\frac{5}{16}$  should be entered as 0.3125 or  $\frac{5}{16}$ , not 0.313. Accumulated rounding errors and surprises later on when parts do not fit are thus reduced. Drawing dimensions, on the

other hand, should not have more significant digits or be more precise than necessary. Unnecessary precision in dimensioning leads to increased difficulty in the production stage because the part has to be made according to the accuracy indicated on the drawing.

*Snap* and *object snap* commands make selecting lines, arcs, circles, or other drawing entities faster, easier, and more accurate when picking and placing objects on the screen. Snap permits only points that are even multiples of the snap increment to be selected by the pointer. A  $\frac{1}{8}$ -inch snap setting, for example, will allow points to be picked at exactly  $\frac{1}{8}$ -inch intervals. Set the *snap increment* to the smallest distance increment (1 in.,  $\frac{1}{4}$  in., 1 ft., etc.) being used in the area of the drawing under construction and reset the snap increment frequently, if necessary. The snap feature can be turned off during a command to override the setting or to select points at a smaller interval than the snap increment allows. Some systems permit setting a different snap value for each coordinate axis.

The *object snap* selection mode is designed to select points on a drawing entity according to predefined characteristics of the entity. For example, if end-point snap is in effect, picking a point anywhere along a line will select the end point of the line nearest the point picked. Object snap modes include point, intersection, midpoint, center and quadrants of circles, tangency point (allows picking a point on an arc or circle that creates a tangent to a line), and perpendicular point (picks a point that makes a perpendicular from the base point to the object selected). When two or more object snap modes are used together, the nearest point that meets the selection criteria will be chosen. Using object snap will greatly reduce the frequency of the type of problem shown in Fig. 5.

*Copy*: Once drawn, avoid redrawing the same object. It is almost always faster to copy and modify a drawing than to draw it again. The basic copy commands are: copy, array, offset, and mirror. Use these, along with move and rotate and the basic editing commands, to modify existing objects. Copy and move should be the most frequently used commands. If possible, create just one instance of a drawing object and then copy and move it to create others.

To create multiple copies of an object, use the *copy, multiple* feature to copy selected objects as many times as required simply by indicating the destination points. The *array* command makes multiple copies of an object according to a regular pattern. The rectangular array produces rows and columns, and the polar array puts the objects into a circular pattern, such as in a bolt circle. *Offset* copies an entity and places the new entity a specified distance from the original and is particularly effective at placing parallel lines and curves, and for creating concentric copies of closed shapes. *Mirror* creates a mirror image copy of an object, and is useful for making right- and left-hand variations of an object as well as for copying objects from one side of an assembly to the other. In some CAD programs, a system variable controls whether text is mirrored along with other objects.

Many manufacturers distribute drawings of their product lines in libraries of CAD drawings, usually as DXF files, that can be incorporated into existing drawings. The suitability of such drawings depends on the CAD program and drawing format being used, the skill of the technician who created the drawings, and the accuracy of the drawings. A typical example, Fig. 6, shows a magnetically coupled actuator drawing distributed by Tol-O-Matic, Inc. Libraries of frequently used drawing symbols and blocks are also available from commercial sources.

*Create Blocks of Frequently Used Objects*: Once created, complete drawings or parts of drawings can be saved and later recalled, as needed, into another drawing. Such objects can be scaled, copied, stretched, mirrored, rotated, or otherwise modified without changing the original. When shapes are initially drawn in unit size (i.e., fitting within a  $1 \times 1$  square) and saved, they can be inserted into any drawing and scaled very easily. One or more individual drawing elements can be saved as a group element, or *block*, that can be manipulated in a drawing as a single element. Block properties vary, depending on the drawing program, but are among the most powerful features of CAD. Typically, blocks are uniquely named

and, as with simple objects, may be saved in a file on the disk. Blocks are ideal for creating libraries of frequently used drawing symbols. Blocks can be copied, moved, scaled very easily, rotated, arrayed, and inserted as many times as is required in a drawing and manipulated as one object. When scaled, each object within the block is also scaled to the same degree.

Fig. 6. Manufacturer's Drawing of a Magnetically Coupled Actuator (Courtesy of Tol-O-Matic, Inc.)

When a family of parts is to be drawn, create and block a single drawing of the part that fits within a unit cube of convenient size, such as  $1 \times 1 \times 1$ . When the block is inserted in a drawing, it is scaled appropriately in the  $x$ -,  $y$ -, and  $z$ -directions. For example,  $\frac{3}{8}$ -inch bolts can be drawn 1 inch long in the  $x$ -direction and  $\frac{3}{8}$ -inch in diameter in the  $y$ - $z$  plane. If a 5-inch bolt is needed, insert the "bolt" block with a scale of 5 in the  $x$ -direction and a scale of 1 in the  $y$ - and  $z$ -directions.

Once blocked, the individual components of a block (lines, arcs, circles, surfaces, and text, for example) cannot be individually changed or edited. To edit a block, a copy (instance) of the block must be *exploded* (unblocked) to divide it into its original components. Once exploded, all the individual elements of the block (except other blocks) can be edited. When the required changes have been made, the block must be redefined (redeclared as a block by giving it a name and identifying its components). If the block is redefined using the same name, any previous references to the block in the drawing will be updated to match the redefined block. For example, an assembly drawing is needed that shows a mechanical frame with 24 similar control panels attached to it. Once one of the panels is drawn and defined as a block (using the name *PANEL*, for instance), the block can be inserted (or copied) into the drawing 24 times. Later, if changes need to be made to the panel design, one instance of the block *PANEL* can be exploded, modified, and redefined with the name *PANEL*. When *PANEL* is redefined, every other copy of the *PANEL* block in the drawing is also redefined, so every copy of *PANEL* in the drawing is updated. On the other hand, if the block was redefined with a different name, say, *PANEL1*, existing copies of *PANEL* remain unchanged. When redefining a block that already exists in the drawing, be sure to use the same insertion point that was used for the original definition of the block; otherwise, the positions of existing blocks with the same name will be changed.

*Use of Text Attributes to Request Drawing Information Automatically:* Text attributes are a useful method for attaching textual information to a particular part or feature of a drawing. An attribute is basically a text variable that has a name and can be assigned a value. Attributes are created by defining attribute characteristics such as a name, location in the drawing, text size and style, and default value. The attribute value is assigned when the attribute is inserted into a drawing as part of a block.

Fig. 7 shows two views of a title block for size A to C drawing sheets. The upper figure includes the title block dimensions (included only for reference) and the names and locations of the attributes (COMPANY, TITLE1, TITLE2, etc.). When a block containing text

attributes is inserted in a drawing, the operator is asked to enter the value of each attribute. To create this title block, first draw the frame of the title block and define the attributes (name, location and default value for: company name and address, drawing titles [2 lines], drawing size, drawing number, revision number, scale, and sheet number). Finally, create and name a block containing the title frame and all the attribute definitions (do not include the dimensions).

Fig. 7. Title Block for A to C Size Drawing Sheets Showing the Placement of Text Attributes. The Lower Figure Shows the Completed Block

When the block is inserted into a drawing, the operator is asked to enter the attribute values (such as company name, drawing title, etc.), which are placed into the title block at the predetermined location. The lower part of Fig. 7 shows a completed title block as it might appear inserted in a drawing. A complete drawing sheet could include several additional blocks, such as a sheet frame, a revision block, a parts list block, and any other supplementary blocks needed. Some of these blocks, such as the sheet frame, title, and parts list blocks, might be combined into a single block that could be inserted into a drawing at one time.

**Define a Default Drawing Configuration:** Drawing features that are commonly used in a particular type of drawing can be set up in a template file so that frequently used settings, such as text and dimension styles, text size, drawing limits, initial view, and other default settings, are automatically set up when a new drawing is started. Different configurations can be defined for each frequently used drawing type, such as assembly, parts, or printed circuit drawings. When creating a new drawing, use one of the template files as a pattern or open a template file and use it to create the new drawing, saving it with a new name.

**Scaling Drawings:** Normally, for fast and accurate drawing, it is easiest to draw most objects full scale, or with a 1:1 scale. This procedure greatly simplifies creation of the initial drawing, and ensures accuracy, because scale factors do not need to be calculated. If it becomes necessary to fit a large drawing onto a small drawing sheet (for example, to fit a 15 × 30 inch assembly onto a 11 × 17 inch, B-sized, drawing sheet), the drawing sheet can be scaled larger to fit the assembly size. Likewise, large drawing sheets can be scaled down to fit small drawings. The technique takes some practice, but it permits the drawing assembly to be treated full scale. If editing is required at a later date (to move something or add a hole in a particular location, for example), changes can be made without rescaling and dimensions can be taken directly from the unscaled drawing on the computer.

**Scaling Text on Drawing Sheets:** It is usually desirable that text, dimensions, and a few other features on drawings stay a consistent size on each sheet, even when the drawing size is very different. The following procedure ensures that text and dimensions (other features

as well, if desired) will be the same size, from drawing to drawing without resorting to scaling the drawing to fit onto the drawing sheet.

Create a drawing sheet having the exact dimensions of the actual sheet to be output (A, B, C, D, or E size, for example). Use text attributes, such as the title block illustrated in Fig. 7, to include any text that needs to be entered each time the drawing sheet is used. Create a block of the drawing sheet, including the text attributes, and save the block to disk. Repeat for each size drawing sheet required.

Establish the nominal text and dimension size requirements for the drawing sheet when it is plotted full size (1:1 scale). This is the size text that will appear on a completed drawing. Use Table 1 as a guide to recommended text sizes of various drawing features.

**Table 1. Standard Sizes of Mechanical Drawing Lettering ANSI Y14.2M-1992**

| Use For  | Inch                      |                  | Metric                    |              |
|--|---------------------------|------------------|---------------------------|--------------|
|  | Min. Letter Heights, (in) | Drawing Size     | Min. Letter Heights, (mm) | Drawing Size |
| Drawing title, drawing size, CAGE Code, drawing number, and revision letter <sup>a</sup> | 0.24                      | D, E, F, H, J, K | 6                         | A0, A1       |
|  | 0.12                      | A, B, C, G       | 3                         | A2, A3, A4   |
| Section and view letters   | 0.24                      | All              | 6                         | All          |
| Zone letters and numerals in borders   | 0.24                      | All              | 6                         | All          |
| Drawing block headings   | 0.10                      | All              | 2.5                       | All          |
| All other characters   | 0.12                      | All              | 3                         | All          |

<sup>a</sup> When used within the title block.

Test the sheet by setting the text size and dimension scale variables to their nominal values (established above) and place some text and dimensions onto the drawing sheet. Plot a copy of the drawing sheet and check that text and dimensions are the expected size.

To use the drawing sheet, open a drawing to be placed on the sheet and insert the sheet block into the drawing. Scale and move the sheet block to locate the sheet relative to the drawing contents. When scaling the sheet, try to use whole-number scale factors (3:1, 4:1, etc.), if possible; this will make setting text size and dimension scale easier later on. Set the text-size variable equal to the nominal text size multiplied by the drawing sheet insertion scale (for example, for 0.24 text height on a drawing sheet scaled 3:1, the text-size variable will be set to  $3 \times 0.24 = 0.72$ ). Likewise, set the dimension-scale variable equal to the nominal dimension size multiplied by the drawing sheet insertion scale.

Once the text size and dimensions scale variables have been set, enter all the text and dimensions into the drawing. If text of another size is needed, multiply the *new* nominal text size by the sheet scale to get the actual size of the text to use in the drawing.

*Use Appropriate Detail:* Excessive detail may reduce the effectiveness of the drawing, increase the drawing time on individual commands and the overall time spent on a drawing, and reduce performance and speed of the CAD program. Whenever possible, symbolic drawing elements should be used to represent more complicated parts of a drawing unless the appearance of that particular component is essential to the drawing.

Drawing everything to scale often serves no purpose but to complicate a drawing and increase drawing time. The importance of detail depends on the purpose of a drawing, but detail in one drawing is unnecessary in another. For example, the slot size of a screw head (length and width) varies with almost every size of screw. If the purpose of a drawing is to show the type and location of the hardware, a symbolic representation of a screw is usually all that is required. The same is generally true of other screw heads, bolt threads, bolt head diameters and width across the flats, wire diameters, and many other hardware features.

**Drawing Exchange Standards.**—The ability to transfer working data between different CAD, CAD/CAM, design analysis, and NC/CNC programs is one of the most important requirements of engineering drawing programs. Once an engineer, designer, draftsman, or machinist enters relevant product data into his or her machine (computer or machine tool), the information defining the characteristics of the product should be available to the others

involved in the project without recreating or reentering it. In view of manufacturing goals of reducing lead time and increasing productivity, concurrent engineering, and improved product performance, interchangeable data are a critical component in a CAD/CAM program. Depending on the requirements of a project, it may be entirely possible to transfer most if not all of the necessary product drawings from one drawing system to another.

*IGES* stands for Initial Graphics Exchange Specification and is a means of exchanging or converting drawings and CAD files for use in a different computer graphics system. The concept is shown diagrammatically in Fig. 8. Normally, a drawing prepared on the computer graphics system supplied by company A would have to be redrawn before it would operate on the computer graphics system supplied by company B. However, with IGES, the drawing can be passed through a software package called a preprocessor that converts it into a standardized IGES format that can be stored on a magnetic disk. A postprocessor at company B is then used to convert the standard IGES format to that required for their graphics system. Both firms would be responsible for purchasing or developing their own preprocessors and postprocessors, to suit their own machines and control systems. Almost all the major graphics systems manufacturing companies today either have or are developing IGES preprocessor and postprocessor programs to convert software from one system to another.

Fig. 8.

*DXF* stands for Drawing Exchange Format and is a pseudo-standard file format used for exchanging drawings and associated information between different CAD and design analysis programs. Nearly all two- and three-dimensional CAD programs support some sort of drawing exchange through the use of DXF files, and most can read and export DXF files. There are, however, differences in the drawing features supported and the manner in which the DXF files are handled by each program. For example, if a 3-D drawing is exported in the DXF format and imported into a 2-D CAD program, some loss of information results because all the 3-D features are not supported by the 2-D program, so that most attempts to make a transfer between such programs fail completely. Most common drawing entities (lines, arcs, etc.) will transfer successfully, although other problems may occur. For example, drawing entities that are treated as a single object in an original drawing (such as blocks, hatch patterns, and symbols) may be divided into hundreds of individual components when converted into a DXF file. Consequently, such a drawing may become much more difficult to edit after it is transferred to another drawing program.

*ASCII* stands for American Standard Code for Information Interchange. ASCII is a code system that describes the manner in which character-based information is stored in a computer system. Files stored in the ASCII format can be transferred easily between computers, even those using different operating systems. Although ASCII is not a drawing file format, many CAD drawing formats (DXF and IGES, for example) are ASCII files. In these files, the drawing information is stored according to a specific format using ASCII characters. ASCII files are often referred to as pure text files because they can be read and edited by simple text editors.

*HPGL*, for Hewlett-Packard Graphics Language, is a format that was first developed for sending vector- (line-) based drawing information to pen plotters. The format is commonly used for sending drawing files to printers and plotters for printing. Because HPGL is a character-based format (ASCII), it can be transferred between computers easily. Normally, devices that recognize the HPGL format can print the files without using the program on which the file (a drawing, for example) was created.

*STL* is a CAD drawing format that is primarily used to send CAD drawings to *rapid automated prototyping* machines. *STL* is a mnemonic abbreviation for stereo-lithography, the technique that is used to create three-dimensional solid models directly from computer-generated drawings and for which the drawing format was originally developed. Most prototyping machines use 3-D CAD drawing files in *STL* format to create a solid model of the part represented by a drawing.

*STEP* stands for Standard for Exchange of Product Model Data and is a series of existing and proposed ISO standards written to allow access to all the data that surround a product. It extends the *IGES* idea of providing a geometric data transfer to include all the other data that would need to be communicated about a product over its lifetime, and facilitates the use and accessibility of the product data. Although *STEP* is a new standard, software tools have been developed for converting data from the *IGES* to *STEP* format and from *STEP* to *IGES*.

**Rapid Automated Prototyping.**—Rapid automated prototyping is a method of quickly creating an accurate three-dimensional physical model directly from a computerized conception of the part. The process is accomplished without machining or the removal of any material, but rather is a method of building up the model in three-dimensional space. The process makes it possible to easily and automatically create shapes that would be difficult or impossible to produce by any other method. Currently, production methods are able to produce models with an accuracy tolerance of  $\pm 0.005$  inch. Models are typically constructed of photoreactive polymer resins, nylon, polycarbonate or other thermoplastics, and investment casting wax. The model size is limited by the capability of the modeling machines to about 1 cubic foot at the present, however, large models can be built in sections and glued or otherwise fastened together.

Much of the work and a large part of the cost associated with creating a physical model by rapid prototyping are in the initial creation of the CAD model. The model needs to be a 3-D design model, built using wireframe, surface, or solid CAD modeling techniques. Many full-featured CAD systems support translation of drawing files into the *STL* format, which is the preferred file format for downloading CAD models to rapid prototyping machines. CAD programs without *STL* file format capability can use the *IGES* or *DXF* file format. This process can be time-consuming and expensive because additional steps may have to be taken by the service bureau to recreate features lost in converting the *IGES* or *DXF* file into *STL* format. If the design file has to be edited by a service bureau to recreate surfaces lost in the translation, unwanted changes to the model may occur, unnoticed. The safest route is to create a CAD model and export it directly into the *STL* format, leaving little chance for unexpected errors. Reverse *STL* generators are also available that will display a file saved in *STL* format or convert it into a form that can be imported into a CAD program.

**DNC.**—*DNC* stands for Direct Numerical Control and refers to a method of controlling numerical control machines from a remote location by means of a link to a computer or computer network. In its simplest form, *DNC* consists of one *NC* or *CNC* machine linked by its serial port to a computer. The computer may be used to develop and store *CNC* part programs and to transfer part programs to the machine as required. *DNC* links are normally two-directional, meaning that the *NC/CNC* can be operated from a computer terminal and the computer can be operated or ordered to supply data to the *NC/CNC* from the machine's control panel.

The number of machines that can be connected to a *DNC* network depends on the network's capability; in theory, any number of machines can be attached, and controlled. The type of network depends on the individual *DNC* system, but most industry standard network protocols are supported, so *DNC* nodes can be connected to existing networks very easily. Individual *NC/CNC* machines on a network can be controlled locally, from a network terminal in another building, or even from a remote location miles away through phone or leased lines.

**Machinery Noise.**—Noise from machinery or mechanical systems can be controlled to some degree in the design or development stage if quantified noise criteria are provided the designer. Manufacturers and consumers may also use the same information in deciding whether the noise generated by a machine will be acceptable for a specific purpose.

Noise criteria for may be classified as follows: 1) relating to the degree of interference with speech communications; 2) relating to physiological damage to humans, especially hearing; and 3) those relating to psychological disturbances in people exposed to noise.

*Sound Level Specifications:* Noise criteria generally are specified in some system of units representing sound levels. One commonly used system specifies sound levels in units called decibels on the "A" scale, written dBA. The dBA scale designates a sound level system weighted to match human hearing responses to various frequencies and loudness. For example, to permit effective speech communication, typical criteria for indoor maximum noise levels are: meeting and conference rooms, 42 dBA; private offices and small meeting rooms, 38 to 47 dBA; supervisors' offices and reception rooms, 38 to 52 dBA; large offices and cafeterias, 42 to 52 dBA; laboratories, drafting rooms, and general office areas, 47 to 56 dBA; maintenance shops, computer rooms, and washrooms, 52 to 61 dBA; control and electrical equipment rooms, 56 to 66 dBA; and manufacturing areas and foremen's offices, 66 dBA. Similarly, there are standards and recommendations for daily permissible times of exposure at various steady sound levels to avoid hearing damage. For a working shift of 8 hours, a steady sound level of 90 dBA is the maximum generally permitted, with marked reduction in allowable exposure times for higher sound levels.\*

**Measuring Machinery Noise.**—The noise level produced by a single machine can be measured by using a standard sound level meter of the handheld type set to the dBA scale. However, when other machines are running at the same time, or when there are other background noises, the noise of the machine cannot be measured directly. In such cases, two measurements, taken as follows, can be used to calculate the noise level of the individual machine. The meter should be held at arm's length and well away from any bystanders to avoid possible significant error up to 5 dBA.

Step 1. At the point of interest, measure the total noise,  $T$ , in decibels; that is, measure the noise of the shop and the machine in question when all machines are running; Step 2. Turn off the machine in question and measure  $B$ , the remaining background noise level; Step 3. Calculate  $M$ , the noise of the machine alone,  $M = 10\log_{10}[10^{(T/10)} - 10^{(B/10)}]$ .

$$M = 10\log\left(10^{\frac{T}{10}} - 10^{\frac{B}{10}}\right)$$

*Example 1:* With a machine running, the sound level meter reads 51 decibels as the total shop noise  $T$ ; and with the machine shut off the meter reads 49 decibels as the remaining background noise  $B$ . What is the noise level  $M$  of the machine alone?

$$M = 10\log\left(10^{\frac{51}{10}} - 10^{\frac{49}{10}}\right) = 46.7 \text{ decibels dBA}$$

*Example 2:* If in [Example 1](#) the remaining background noise level  $B$  was 41 decibels instead of 49, what is the noise level of the machine alone?

$$M = 10\log\left(10^{\frac{51}{10}} - 10^{\frac{41}{10}}\right) = 50.5 \text{ decibels dBA}$$

*Note:* From this example it is evident that when the background noise level  $B$  is approximately 10 or more decibels lower than the total noise level  $T$  measured at the machine in question, then the background noise does not contribute significantly to the sound level at the machine and, for practical purposes,  $M = T$  and no calculation is required.

\* After April 1983, if employee noise exposures equal or exceed an 8-hour, time-weighted average sound level of 85 dB, OSHA requires employers to administer an effective hearing conservation program.

## TABLE OF CONTENTS

### MANUFACTURING PROCESSES

#### PUNCHES, DIES, AND PRESS WORK

- 1329 Punches and Dies
- 1329 Clearance
- 1330 Lubricants for Press Work
- 1330 Annealing Drawn Shells

## PUNCHES, DIES, AND PRESS WORK

**Clearance between Punches and Dies.**—The amount of clearance between a punch and die for blanking and perforating is governed by the thickness and kind of stock to be operated upon. For thin material, the punch should be a close sliding fit to prevent ragged edges, but for heavier stock, there should be some clearance. The clearance between the punch and die in cutting heavy material reduces the pressure required for the punching operation and the danger of breaking the punch.

**Meaning of the Term "Clearance".**—There is a difference of opinion among diemakers as to the method of designating clearance. The prevailing practice of fifteen firms specializing in die work is as follows: Ten of these firms define clearance as the space between the punch and die on *one side*, or one-half the difference between the punch and die sizes. The remaining five firms consider clearance as the total difference between the punch and die sizes; for example, if the die is round, clearance equals die diameter minus punch diameter. The advantage of designating clearance as the space on each side is particularly evident with dies of irregular form or of angular shape. Although the practice of designating clearance as the difference between the punch and die diameters may be satisfactory for round dies, it leads to confusion when the dies are of unsymmetrical forms. The term "clearance" should not be used in specifications without indicating clearly just what it means. According to one die manufacturer, the term "cutting clearance" is used to indicate the space between the punch and die on each side, and the term "die clearance" refers to the angular clearance provided below the cutting edge so that the parts will fall easily through the die. The term "clearance" as here used means the space on one side only; hence, for round dies, clearance equals die radius minus punch radius.

**Clearances Generally Allowed.**—For brass and soft steel, most dies are given a clearance on one side equal to the stock thickness multiplied by 0.05 or 0.06; but one-half of this clearance is preferred for some classes of work, and a clearance equal to the stock thickness multiplied by 0.10 may give the cleanest fracture for certain other operations such as punching holes in ductile steel boiler plate.

**Where Clearance Is Applied.**—Whether clearance is deducted from the diameter of the punch or added to the diameter of the die depends upon the nature of the work. If a blank of given size is required, the die is made to that size and the punch is made smaller. Inversely, when holes of a given size are required, the punch is made to the diameter wanted and the die is made larger. Therefore, for blanking to a given size, the clearance is deducted from the size of the punch, and for perforating, the clearance is added to the size of the die.

**Effect of Clearance on Working Pressure.**—Clearance affects not only the smoothness of the fracture, but also the pressure required for punching or blanking. This pressure is greatest when the punch diameter is small compared to the thickness of the stock. In one test, for example, a punching pressure of about 32,000 pounds was required to punch  $\frac{3}{4}$ -inch holes into  $\frac{5}{16}$ -inch mild steel plate when the clearance was about 10 per cent. With a clearance of about 4.5 per cent, the pressure increased to 33,000 pounds and a clearance of 2.75 per cent resulted in a pressure of 34,500 pounds.

Soft ductile metal requires more clearance than hard metal, although it has been common practice to increase the clearance for harder metals. In punching holes in fairly hard steel, a clean fracture was obtained with a clearance of only 0.03 times stock thickness.

**Angular Clearance for Dies.**—The angular clearance ordinarily used in a blanking die varies from 1 to 2 degrees, although dies intended for producing a comparatively small number of blanks are sometimes given a clearance angle of 4 or 5 degrees to facilitate making the die quickly. When large numbers of blanks are required, a clearance of about 1 degree is used.

There are two methods of giving clearance to dies: In one method, the clearance extends to the top face of the die; and in the other, there is a space about  $\frac{1}{8}$  inch below the cutting edge that is left practically straight, or having a very small amount of clearance.

For very soft metal, such as soft, thin brass, the first method is employed, but for harder material, such as hard brass, steel, etc., it is better to have a very small clearance for a short distance below the cutting edge. When a die is made in this way, thousands of blanks can be cut with little variation in their size, as grinding the die face will not enlarge the hole to any appreciable extent.

**Lubricants for Press Work.**—Blanking dies used for carbon and low-alloy steels are often run with only residual mill lubricant, but will last longer if lightly oiled. Higher alloy and stainless steels require thicker lubricants. Kerosene is usually used with aluminum. Lubricant thickness needs to be about 0.0001 in. and can be obtained with about 1 pint of fluid to cover 500 sq. ft of material. During successive strokes, metal debris adheres to the punch and may accelerate wear, but damage may be reduced by application of the lubricant to the sheet or strip by means of rollers or spray. High-speed blanking may require heavier applications or a continuous airless spraying of oil. For sheet thicker than  $\frac{1}{8}$  in. and for stainless steel, high-pressure lubricants containing sulfurs and chlorines are often used.

Shallow drawing and forming of steel can be done with low-viscosity oils and soap solutions, but deeper draws require light- to medium-viscosity oils containing fats and such active elements as sulfur or phosphorus, and mineral fillers such as chalk or mica. Deep drawing often involves ironing or thinning of the walls by up to 35 per cent, and thick oils containing high proportions of chemically active compounds are used. Additives used in drawing compounds are selected for their ability to maintain a physical barrier between the tool surfaces and the metal being shaped. Dry soaps and polymer films are frequently used for these purposes. Aluminum can be shallow drawn with oils of low to medium viscosity, and for deep drawing, tallow may be added, also wax or soap suspensions for very large reductions.

**Annealing Drawn Shells.**—When drawing steel, iron, brass, or copper, annealing is necessary after two or three draws have been made, because the metal is hardened by the drawing process. For steel and brass, anneal between alternate reductions, at least. Tin plate or stock that cannot be annealed without spoiling the finish must ordinarily be drawn to size in one or two operations. Aluminum can be drawn deeper and with less annealing than the other commercial metals, provided the proper grade is used. If it is necessary to anneal aluminum, it should be heated in a muffle furnace, care being taken to see that the temperature does not exceed 700 degrees F.

**Drawing Brass.**—When drawing brass shells or cup-shaped articles, it is usually possible to make the depth of the first draw equal to the diameter of the shell. By heating brass to a temperature just below what would show a dull red in a dark room, it is possible to draw difficult shapes, otherwise almost impossible, and to produce shapes with square corners.

**Drawing Rectangular Shapes.**—When square or rectangular shapes are to be drawn, the radius of the corners should be as large as possible, because defects usually occur in the corners when drawing. Moreover, the smaller the radius, the less the depth that can be obtained in the first draw.

The maximum depths that can be drawn with corners of a given radii are approximately as follows: With a radius of  $\frac{3}{32}$  to  $\frac{3}{16}$  inch, depth of draw, 1 inch; radius  $\frac{3}{16}$  to  $\frac{3}{8}$  inch, depth  $1\frac{1}{2}$  inches; radius  $\frac{3}{8}$  to  $\frac{1}{2}$  inch, depth 2 inches; and radius  $\frac{1}{2}$  to  $\frac{3}{4}$  inch, depth 3 inches.

These figures are taken from actual practice and can doubtless be exceeded slightly when using metal prepared for the process. If the box needs to be quite deep and the radius is quite small, two or more drawing operations will be necessary.

**Speeds and Pressures for Presses.**—The speeds for presses equipped with cutting dies depend largely upon the kind of material being worked, and its thickness. For punching

and shearing ordinary metals not over  $\frac{1}{4}$  inch thick, the speeds usually range between 50 and 200 strokes per minute, 100 strokes per minute being a fair average. For punching metal over  $\frac{1}{4}$  inch thick, geared presses with speeds ranging from 25 to 75 strokes per minute are commonly employed.

The cutting pressures required depend upon the shearing strength of the material, and the actual area of the surface being severed. For round holes, the pressure required equals the circumference of the hole  $\times$  the thickness of the stock  $\times$  the shearing strength.

To allow for some excess pressure, the tensile strength may be substituted for the shearing strength; the tensile strength for these calculations may be roughly assumed as follows: Mild steel, 60,000; wrought iron, 50,000; bronze, 40,000; copper, 30,000; aluminum, 20,000; zinc, 10,000; and tin and lead, 5,000 pounds per square inch.

**Pressure Required for Punching.**—The formula for the force in tons required to punch a circular hole in sheet steel is  $\pi DST/2000$ , where  $S$  = the shearing strength of the material in lb/in.<sup>2</sup>,  $T$  = thickness of the steel in inches, and 2000 is the number of lb in 1 ton. An approximate formula is  $DT \times 80$ , where  $D$  and  $T$  are the diameter of the hole and the thickness of the steel, respectively, both in inches, and 80 is a factor for steel. The result is the force in tons.

*Example:* Find the pressure required to punch a hole, 2 inches in diameter, through  $\frac{1}{4}$ -in. thick steel. By applying the approximate formula,  $2 \times \frac{1}{4} \times 80 = 40$  tons.

If the hole is not circular, replace the hole diameter with the value of one-third of the perimeter of the hole to be punched.

*Example:* Find the pressure required to punch a 1-inch square hole in  $\frac{1}{4}$ -in. thick steel. The total length of the hole perimeter is 4 in. and one-third of 4 in. is  $1\frac{1}{3}$  in., so the force is  $1\frac{1}{3} \times \frac{1}{4} \times 80 = 26\frac{2}{3}$  tons.

The corresponding factor for punching holes in brass is 65 instead of 80. So, to punch a hole measuring 1 by 2 inches in  $\frac{1}{4}$ -in. thick brass sheet, the factor for hole size is the perimeter length  $6 \div 3 = 2$ , and the formula is  $2 \times \frac{1}{4} \times 65 = 32\frac{1}{2}$  tons.

**Shut Height of Press.**—The term “shut height,” as applied to power presses, indicates the die space when the slide is at the bottom of its stroke and the slide connection has been adjusted upward as far as possible. The “shut height” is the distance from the lower face of the slide, either to the top of the bed or to the top of the bolster plate, there being two methods of determining it; hence, this term should always be accompanied by a definition explaining its meaning. According to one press manufacturer, the safest plan is to define “shut height” as the distance from the top of the bolster to the bottom of the slide, with the stroke down and the adjustment up, because most dies are mounted on bolster plates of standard thickness, and a misunderstanding that results in providing too much die space is less serious than having insufficient die space. It is believed that the expression “shut height” was applied first to dies rather than to presses, the shut height of a die being the distance from the bottom of the lower section to the top of the upper section or punch, excluding the shank, and measured when the punch is in the lowest working position.

**Diameters of Shell Blanks.**—The diameters of blanks for drawing plain cylindrical shells can be obtained from Table 1 on the following pages, which gives a very close approximation for thin stock. The blank diameters given in this table are for sharp-cornered shells and are found by the following formula in which  $D$  = diameter of flat blank;  $d$  = diameter of finished shell; and  $h$  = height of finished shell.

$$D = \sqrt{d^2 + 4dh} \quad (1)$$

*Example:* If the diameter of the finished shell is to be 1.5 inches, and the height, 2 inches, the trial diameter of the blank would be found as follows:

$$D = \sqrt{1.5^2 + 4 \times 1.5 \times 2} = \sqrt{14.25} = 3.78 \text{ inches}$$

For a round-cornered cup, the following formula, in which  $r$  equals the radius of the corner, will give fairly accurate diameters, provided the radius does not exceed, say,  $\frac{1}{4}$  the height of the shell:

$$D = \sqrt{d^2 + 4dh} - r \quad (2)$$

These formulas are based on the assumption that the thickness of the drawn shell is the same as the original thickness of the stock, and that the blank is so proportioned that its area will equal the area of the drawn shell. This method of calculating the blank diameter is quite accurate for thin material, when there is only a slight reduction in the thickness of the metal incident to drawing; but when heavy stock is drawn and the thickness of the finished shell is much less than the original thickness of the stock, the blank diameter obtained from [Formula \(1\)](#) or [\(2\)](#) will be too large, because when the stock is drawn thinner, there is an increase in area. When an appreciable reduction in thickness is to be made, the blank diameter can be obtained by first determining the "mean height" of the drawn shell by the following formula. This formula is only approximately correct, but will give results sufficiently accurate for most work:

$$M = \frac{ht}{T} \quad (3)$$

where  $M$  = approximate mean height of drawn shell;  $h$  = height of drawn shell;  $t$  = thickness of shell; and  $T$  = thickness of metal before drawing.

After determining the mean height, the blank diameter for the required shell diameter is obtained from the table previously referred to, the mean height being used instead of the actual height.

*Example:* Suppose a shell 2 inches in diameter and  $3\frac{3}{4}$  inches high is to be drawn, and that the original thickness of the stock is 0.050 inch, and the thickness of drawn shell, 0.040 inch. To what diameter should the blank be cut? Obtain the mean height from [Formula \(3\)](#):

$$M = \frac{ht}{T} = \frac{3.75 \times 0.040}{0.050} = 3 \text{ inches}$$

According to the table, the blank diameter for a shell 2 inches in diameter and 3 inches high is 5.29 inches. [Formula \(3\)](#) is accurate enough for all practical purposes, unless the reduction in the thickness of the metal is greater than about one-fifth the original thickness. When there is considerable reduction, a blank calculated by this formula produces a shell that is too long. However, the error is in the right direction, as the edges of drawn shells are ordinarily trimmed.

If the shell has a rounded corner, the radius of the corner should be deducted from the figures given in the table. For example, if the shell referred to in the foregoing example had a corner of  $\frac{1}{4}$ -inch radius, the blank diameter would equal  $5.29 - 0.25 = 5.04$  inches.

Another formula that is sometimes used for obtaining blank diameters for shells, when there is a reduction in the thickness of the stock, is as follows:

$$D = \sqrt{a^2 + (a^2 - b^2)\frac{h}{t}} \quad (4)$$

Table 1. Diameters of Blanks for Drawn Cylindrical Shells

| Diam.<br>of<br>Shell | Height of Shell |               |               |      |                |                |                |      |                |                |                |       |                |                |                |       |                |       |                |       |
|----------------------|-----------------|---------------|---------------|------|----------------|----------------|----------------|------|----------------|----------------|----------------|-------|----------------|----------------|----------------|-------|----------------|-------|----------------|-------|
|                      | $\frac{1}{4}$   | $\frac{1}{2}$ | $\frac{3}{4}$ | 1    | $1\frac{1}{4}$ | $1\frac{1}{2}$ | $1\frac{3}{4}$ | 2    | $2\frac{1}{4}$ | $2\frac{1}{2}$ | $2\frac{3}{4}$ | 3     | $3\frac{1}{4}$ | $3\frac{1}{2}$ | $3\frac{3}{4}$ | 4     | $4\frac{1}{2}$ | 5     | $5\frac{1}{2}$ | 6     |
| $\frac{1}{4}$        | 0.56            | 0.75          | 0.90          | 1.03 | 1.14           | 1.25           | 1.35           | 1.44 | 1.52           | 1.60           | 1.68           | 1.75  | 1.82           | 1.89           | 1.95           | 2.01  | 2.14           | 2.25  | 2.36           | 2.46  |
| $\frac{1}{2}$        | 0.87            | 1.12          | 1.32          | 1.50 | 1.66           | 1.80           | 1.94           | 2.06 | 2.18           | 2.29           | 2.40           | 2.50  | 2.60           | 2.69           | 2.78           | 2.87  | 3.04           | 3.21  | 3.36           | 3.50  |

In this formula,  $D$  = blank diameter;  $a$  = outside diameter;  $b$  = inside diameter;  $t$  = thickness of shell at bottom; and  $h$  = depth of shell. This formula is based on the volume of the metal in the drawn shell. It is assumed that the shells are cylindrical, and no allowance is made for a rounded corner at the bottom, or for trimming the shell after drawing. To allow for trimming, add the required amount to depth  $h$ . When a shell is of irregular cross-section, if its weight is known, the blank diameter can be determined by the following formula:

$$D = 1.1284 \sqrt{\frac{W}{wt}} \quad (5)$$

where  $D$  = blank diameter in inches;  $W$  = weight of shell;  $w$  = weight of metal per cubic inch; and  $t$  = thickness of the shell.

In the construction of dies for producing shells, especially of irregular form, a common method to be used is to make the drawing tool first. The actual blank diameter then can be determined by trial. One method is to cut a trial blank as near to size and shape as can be estimated. The outline of this blank is then scribed on a flat sheet, after which the blank is drawn. If the finished shell shows that the blank is not of the right diameter or shape, a new trial blank is cut either larger or smaller than the size indicated by the line previously scribed, this line acting as a guide. If a model shell is available, the blank diameter can also be determined as follows:

First, cut a blank somewhat large, and from the same material used for making the model; then, reduce the size of the blank until its weight equals the weight of the model.

**Depth and Diameter Reductions of Drawn Cylindrical Shells.**—The depth to which metal can be drawn in one operation depends upon the quality and kind of material, its thickness, the slant or angle of the dies, and the amount that the stock is thinned or “ironed” in drawing. A general rule for determining the depth to which cylindrical shells can be drawn in one operation is as follows: The depth or length of the first draw should never be greater than the diameter of the shell. If the shell is to have a flange at the top, it may not be practicable to draw as deeply as is indicated by this rule, unless the metal is extra good, because the stock is subjected to a higher tensile stress, owing to the larger blank needed to form the flange. According to another rule, the depth given the shell on the first draw should equal one-third the diameter of the blank. Ordinarily, it is possible to draw sheet steel of any thickness up to  $\frac{1}{4}$  inch, so that the diameter of the first shell equals about six-tenths of the blank diameter. When drawing plain shells, the amount that the diameter is reduced for each draw must be governed by the quality of the metal and its susceptibility to drawing. The reduction for various thicknesses of metal is about as follows:

|   |                |               |                |               |                |
|---|----------------|---------------|----------------|---------------|----------------|
| Approximate thickness of sheet steel                              | $\frac{1}{16}$ | $\frac{1}{8}$ | $\frac{3}{16}$ | $\frac{1}{4}$ | $\frac{5}{16}$ |
| Possible reduction in diameter for each succeeding step, per cent | 20             | 15            | 12             | 10            | 8              |

For example, if a shell made of  $\frac{1}{16}$ -inch stock is 3 inches in diameter after the first draw, it can be reduced 20 per cent on the next draw, and so on until the required diameter is obtained. These figures are based upon the assumption that the shell is annealed after the first drawing operation, and at least between every two of the following operations. Necking operations—that is, the drawing out of a short portion of the lower part of the cup into a long neck—may be done without such frequent annealings. In double-action presses, where the inside of the cup is supported by a bushing during drawing, the reductions possible may be increased to 30, 24, 18, 15, and 12 per cent, respectively. (The latter figures may also be used for brass in single-action presses.)

When a hole is to be pierced at the bottom of a cup and the remaining metal is to be drawn after the hole has been pierced or punched, always pierce from the opposite direction to

that in which the stock is to be drawn after piercing. It may be necessary to machine the metal around the pierced hole to prevent the starting of cracks or flaws in the subsequent drawing operations.

The foregoing figures represent conservative practice and it is often possible to make greater reductions than are indicated by these figures, especially when using a good drawing metal. Taper shells require smaller reductions than cylindrical shells, because the metal tends to wrinkle if the shell to be drawn is much larger than the punch. The amount that the stock is "ironed" or thinned out while being drawn must also be considered, because a reduction in gage or thickness means greater force will be exerted by the punch against the bottom of the shell; hence the amount that the shell diameter is reduced for each drawing operation must be smaller when much ironing is necessary. The extent to which a shell can be ironed in one drawing operation ranges between 0.002 and 0.004 inch per side, and should not exceed 0.001 inch on the final draw, if a good finish is required.

**Allowances for Bending Sheet Metal.**—In bending steel, brass, bronze, or other metals, the problem is to find the length of straight stock required for each bend; these lengths are added to the lengths of the straight sections to obtain the total length of the material before bending.

If  $L$  = length in inches, of straight stock required before bending;  $T$  = thickness in inches; and  $R$  = inside radius of bend in inches:

For 90° bends in soft brass and soft copper see [Table 2](#) or:

$$L = (0.55 \times T) + (1.57 \times R) \quad (1)$$

For 90° bends in half-hard copper and brass, soft steel, and aluminum see [Table 3](#) or:

$$L = (0.64 \times T) + (1.57 \times R) \quad (2)$$

For 90° bends in bronze, hard copper, cold-rolled steel, and spring steel see [Table 4](#) or:

$$L = (0.71 \times T) + (1.57 \times R) \quad (3)$$

*Angle of Bend Other Than 90 Degrees:* For angles other than 90 degrees, find length  $L$ , using tables or formulas, and multiply  $L$  by angle of bend, in degrees, divided by 90 to find length of stock before bending. In using this rule, note that *angle of bend* is the angle through which the material has actually been bent; hence, it is not always the angle as given on a drawing. To illustrate, in [Fig. 1](#), the angle on the drawing is 60 degrees, but the angle of bend  $A$  is 120 degrees ( $180 - 60 = 120$ ); in [Fig. 2](#), the angle of bend  $A$  is 60 degrees; in [Fig. 3](#), angle  $A$  is  $90 - 30 = 60$  degrees. [Formulas \(1\), \(2\), and \(3\)](#) are based on extensive experiments of the Westinghouse Electric Co. They apply to parts bent with simple tools or on the bench, where limits of  $\pm \frac{1}{64}$  inch are specified. If a part has two or more bends of the same radius, it is, of course, only necessary to obtain the length required for one of the bends and then multiply by the number of bends, to obtain the total allowance for the bent sections.

Fig. 1.

Fig. 2.

Fig. 3.

*Example, Showing Application of Formulas:* Find the length before bending of the part illustrated by [Fig. 4](#). Soft steel is to be used.

For bend at left-hand end (180-degree bend)

$$L = [(0.64 \times 0.125) + (1.57 \times 0.375)] \times \frac{180}{90} = 1.338$$

Table 2. Lengths of Straight Stock Required for 90-Degree Bends in Soft Copper and Soft Brass

For bend at right-hand end (60-degree bend)

$$L = [(0.64 \times 0.125) + (1.57 \times 0.625)] \times \frac{60}{90} = 0.707$$

Total length before bending =  $3.5 + 1.338 + 0.707 = 5.545$  inches

Fig. 4.

Fig. 5.

**Other Bending Allowance Formulas.**—When bending sheet steel or brass, add from  $\frac{1}{3}$  to  $\frac{1}{2}$  of the thickness of the stock, for *each bend*, to the sum of the inside dimensions of the finished piece, to get the length of the straight blank. The harder the material the greater the allowance ( $\frac{1}{3}$  of the thickness is added for soft stock and  $\frac{1}{2}$  of the thickness for hard material). The data given in the table, *Allowances for Bends in Sheet Metal* on page 1340, refer more particularly to the bending of sheet metal for counters, bank fittings and general office fixtures, for which purpose it is not absolutely essential to have the sections of the bends within very close limits. Absolutely accurate data for this work cannot be deduced, as the stock varies considerably as to hardness, etc. The figures given apply to sheet steel, aluminum, brass and bronze. Experience has demonstrated that for the semisquare corners, such as are formed in a V-die, the amount to be deducted from the sum of the outside bend dimensions, as shown in Fig. 5 by the sum of the letters from *a* to *e*, is as follows:  $X = 1.67 BG$ , where  $X$  = the amount to be deducted;  $B$  = the number of bends; and  $G$  = the decimal equivalent of the gage. The values of  $X$  for different gages and numbers of bends are given in the table. Its application may be illustrated by an example: A strip having two bends is to have outside dimensions of 2,  $1\frac{1}{2}$  and 2 inches, and is made of stock 0.125 inch thick. The sum of the outside dimensions is thus  $5\frac{1}{2}$  inches, and from the table the amount to be deducted is found to be 0.416; hence the blank will be  $5.5 - 0.416 = 5.084$  inches long.

The lower part of the table applies to square bends which are either drawn through a block of steel made to the required shape, or else drawn through rollers in a drawbench. The pressure applied not only gives a much sharper corner, but it also elongates the material more than in the V-die process. In this case, the deduction is  $X = 1.33 BG$ .

### Joining and Edging

A duct system is an assembly whose main function is to convey air. Elements of the duct system are sheets, transverse joints, longitudinal seams, and reinforcements. The sheets must be able to withstand deflection caused by both internal pressure and vibration due to turbulent air flow. Transverse joints must be able to withstand 1.5 times the maximum operating pressure without failure. Transverse joint designs should be consistent with the static pressure class, sealing requirements, materials involved, and support interval distances. Notching, bending, folding, and fit up tolerances shall be appropriate for the proper class. Longitudinal seams also must be able to withstand 1.5 times the operating pressure without deformation. Seams shall be formed and assembled with proper dimension and proportion for tight and secure fit up. Seams may be a butt, corner, plug, or spot weld design. Seams shall be selected based on material and pressure. A duct section between adjacent hangers must be able to carry its own weight and to resist external loads for which

## Allowances for Bends in Sheet Metal

| Square Bends                    | Gage | Thickness Inches | Amount to be Deducted from the Sum of the Outside Bend Dimensions, Inches |         |         |         |         |         |         |

it is constructed. The reinforcing members must be able to resist the deflection of the sheet, and its own deflection.

There is a relationship between duct width, reinforcement spacing, reinforcement size, pressure, and sheet thickness. For constant pressure and constant duct size, the thicker sheet allows more distance between reinforcements. The higher the pressure the shorter the spacing between reinforcements. Joints and intermediate reinforcements are labor intensive and may be more costly than the savings gained by a reduction in wall thickness. Thicker duct wall and stronger joints are more cost effective than using more reinforcement.

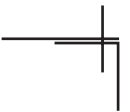

The following material illustrates various joint designs, used both in duct work and other sheet metal assemblies.

## Sheet Metal Joints

## Plain Lap and Flush Lap:

|   |  |
|---|--|
|  <p>Fig. 6. Plain Lap</p> | <p>The <i>plain lap</i> (Fig. 6) and <i>flush lap</i> (Fig. 7) are both used for various materials such as galvanized or black iron, copper, stainless steel, aluminum, or other metals, and may be soldered, and/or riveted, as well as spot, tack, or solid-welded. Lap dimensions vary with the particular application, and since it is the duty of the draftsman to specify straight joints in lengths that use full-sheet sizes, transverse lap dimensions must be known.</p> |
|  <p>Fig. 7. Flush Lap</p> |  |

## Raw and Flange Corner:

|  |   |
|--|---|
|  <p>Fig. 8. Raw and Flange Corner</p> | <p>The <i>raw and flange corner</i> (Fig. 8) is generally spot-welded, but may be riveted or soldered. For heavy gages it is tack-welded or solid-welded.</p> |
|--|---|

*Flange and Flange Corner:*

Fig. 9. Flange and Flange Corner

The *flange and flange corner* (Fig. 9) is a refinement of the raw and flange corner. It is particularly useful for heavy-gage duct sections which require flush outside corners and must be field-erected.

*Standing Seam:*

Fig. 10. Standing Seam

The *standing seam* (Fig. 10) is often used for large plenums, or casings. Before the draftsman is able to lay out a casing drawing, one of the items of information needed is seam allowance measurements, so that panel sizes can be detailed for economical use of standard sheets. Considering velocity levels, standing seams are considered for duct interiors: 1" seam is normally applied for duct widths up to 42", and 1½" for bigger ducts.

*Groove Seam:*

Fig. 11. Groove Seam

The *groove seam* (Fig. 11) is often used for rectangular or round duct straight joints, or to join some sheets for fittings that are too large to be cut out from standard sheets. It is also known as the pipelock, or flat lock seam.

*Corner Standing Seam:*

Fig. 12. Corner Standing Seam

The *corner standing seam* (Fig. 12) has similar usage to the standing seam, and also can be used for straight-duct sections. This type of seams are mostly applied at the ends at 8" intervals.

*Double Seam:*

Fig. 13. Double Corner Seam

The *double corner seam* (Fig. 13) at one time was the most commonly used method for duct fitting fabrication. However, although it is seldom used because of the hand operations required for assembly, the double seam can be used advantageously for duct fittings with compound curves. It is called the slide lock seam. Machines are available to automatically close this seam.

*Slide-Corner:*

Fig. 14. Slide Corner

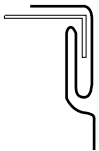

The *slide-corner* (Fig. 14) is a large version of the double seam. It is often used for field assembly of straight joints, such as in an existing ceiling space, or other restricted working area where ducts must be built in place. To assemble the duct segments, opposite ends of each seam are merely "entered" and then pushed into position. Ducts are sent to job sites "knocked-down" for more efficient use of shipping space.

*Button Punch Snap Lock:*

Fig. 15. Button Punch Snap Lock

The *button punch snap lock* (Fig. 15) is a flush-type seam which may be soldered or caulked. This seam can be modified slightly for use as a "snap lock". This types of seam is not applicable for aluminum or other soft metals. This seam may be used up to 4" w.g. by using screws at the ends. The pocket depth should not be smaller than ⅜" for 20, 22 and 26 gage.

*Pittsburg:*

|  |  |
|--|--|
|  <p>Fig. 16. Pittsburgh</p> | <p>The <i>Pittsburg</i> (Fig. 16) is the most commonly used seam for standard gage duct construction. The common pocket depths are <math>\frac{5}{16}</math>" and <math>\frac{5}{8}</math>" depending on the thickness of sheet.</p> |
|--|--|

*Flange:*

|  |  |
|--|--|
|  <p>Fig. 17. Flange</p> | <p>The <i>flange</i> (Fig. 17) is an end edge stiffener. The draftsman must indicate size of the flange, direction of bend, degree of bend (if other than 90°) and when full corners are desired. Full corners are generally advisable for collar connections to concrete or masonry wall openings at louvers.</p> |
|--|--|

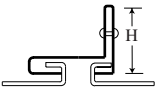

*Hem:*

|   |   |
|---|---|
|  <p>Fig. 18. Hem</p> | <p>The <i>hem edge</i> (Fig. 18) is a flat, finished edge. As with the flange, this must be designated by the draftsman. For example, drawing should show: <math>\frac{3}{4}</math>" hem out.</p> |
|---|---|

*Flat Drive Slip:*

|  |   |
|--|---|
|  <p>Fig. 19. Drive Slip</p> | <p>This is one of the simplest transverse joints. It is applicable where pressure is less than 2" w.g. This is a slide type connection generally used on small ducts in combination of "S" slips. Service above 2" inches w.g. is not applicable.</p> |
|--|---|

*Standing Drive Slip:*

|  |  |
|--|--|
|  <p>Fig. 20. Standing Drive Slip</p> | <p>This is also a slide type connection. It is made by elongating flat drive slip, fasten standing portions 2" from each end. It is applicable for any length in 2" w.g., 36" for 3" inch w.g., and 30" inches at 4" w.g. service.</p> |
|--|--|

*Flat Drive Slip Reinforced:*

|   |  |
|---|--|
|  <p>Fig. 21. Drive Slip Reinforced</p> | <p>This is the reinforcement on flat drive slip by adding a transverse angle section after a fixed interval.</p> |
|---|--|

*Double "S" Slip Reinforced:*

|   |   |
|---|---|
|  <p>Fig. 22. Double "S" Slip</p> | <p>The double "S" slip is applied, to eliminate the problem of notching and bending, especially for large ducts. Apply 24 gage sheet for 30" width or less, 22 gage sheet over 30" width.</p> |
|---|---|

*Flat "S" Slip:*

|  |  |
|--|--|
|  <p>Fig. 23. Plain "S" Slip</p> | <p>Normally the "S" slip is used for small ducts. However, it is also useful if the connection of a large duct is tight to a beam, column or other object, and an "S" slip is substituted for the shop standard slip. Service above 2" inches w.g. is not applicable. Gage shall not be less than 24, and shall not 2 gage less than the duct gage. When it is applied on all four edges, fasten within 2" of the corners and at 12" maximum interval.</p> |
|--|--|

*Hemmed "S" Slip:*

Fig. 24. Hemmed "S" Slip

This is the modified "S" slip, by adding hem and an angle for reinforcing. The hem edge is a flat, and finished edge. Hemmed "S" slip is mostly applied with angle. The drive is generally 16 gage, formed a 1 inch height slip pocket and screws at the end. Notching and bending operations on an "S" slip joints can be cumbersome and costly, especially for large sizes. Tied each section of the duct within 2" from the corner at maximum 6-inch interval.

**Other Types of Duct Connections***Clinch-bar Slip and Flange:*

Fig. 25. Clinch-bar Slip and Flange

The *clinch-bar slip and flange* (Fig. 25), uses the principle of the standing seam, but with a duct lap in the direction of airflow. These slips are generally assembled as a framed unit with full corners either riveted or spot-welded, which adds to the duct cross-section rigidity. Reinforcement may be accomplished by spot welding the flat-bar to the flange of the large end. Accessibility to all four sides of the duct is required because the flange of the slip must be folded over the flange on the large end after the ducts are connected.

*Clinch-bar Slip and Angle :*

Fig. 26. Clinch-bar Slip and Angle

The *clinch bar slip and angle* (Fig. 26), is similar to clinch bar slip (Fig. 25), but it has a riveted or spot-welded angle on the large end. This connection can also have a raw large end which is inserted into the space between the angle and the shop-fabricated slip. Matched angles (minimum of 16 ga) are riveted or spot welded to the smaller sides of the ducts, to pull the connection "home."

**Flanged Duct Connections***Angle Frame, or Ring:*Fig. 27. Raw Ends and Matched  $\angle$ 

Any of the following flanged connections may have gaskets. The draftsman should not allow for gasket thicknesses in calculations for running length dimensions, nor should he indicate angle sizes, bolt centers, etc., as these items are established in job specifications and approved shop standards. Generally, angles are fastened to the duct sections in the shop. If conditions at the job site require consideration for length contingencies, the draftsman should specify "loose angles" such as at a connection to equipment which may be located later. The most common matched angle connection is the *angle frame, or ring* (Fig. 27). The angles are fastened flush to the end of the duct.

*Flanged End and Angle:*Fig. 28. Flanged Ends and Matched  $\angle$ s

The *flanged end and angle* (Fig. 28), is often used for ducts 16 ga or lighter, as the flange provides a metal-to-metal gasket and holds the angle frame or ring on the duct without additional fastening. The draftsman may indicate in a field note that a round-duct fitting is to be "rotated as required". This type of angle-ring-connection is convenient for such a condition.

*Formed Flanges:*

Fig. 29. Formed Flanges

*Double flanges* (Fig. 29), are similar to Fig. 21, except that the connecting flange has a series of matched bolt holes. This connection, caulked airtight, is ideal for single-wall apparatus casings or plenums. The flanges are formed at the ends of the duct, after assembly they will form a T shape. Mating flanges shall be locked together by long clips. In order to form effective seal, gasket is used with suitable density and resiliency. At the corners 16 gage thickness steel corner are used with  $\frac{3}{8}$ " diameter bolts.

*Double Flanges and Cleat:*

*Double Flanges and Cleat* (Fig. 30) is identical to (Fig. 29), but has an air seal cleat. The reinforcements is attached to the duct wall on both sides of the joint.

*Clinch-type Flanged Connections:*

*Clinch-type flanged connections* for round ducts, 16 ga or lighter, are shown in Fig. 31. The angles or rings can be loose, as explained in *Flanged End and Angle*, (Fig. 28). The draftsman should indicate flange sizes, bend direction, and type of assembly. An example such as the flange lap for a field assembly of a 10-gage casing corner would be written:  $1\frac{1}{2}$ " flange out square on side with  $\frac{9}{32}$ "  $\varnothing$  bolt holes 12" CC. At the beginning and ending angles are connected by rivets or welding. The bolt will be  $\frac{3}{16}$ "  $\varnothing$  at 6" maximum spacing 4" w.g..

**Fine Blanking**

The process called fine blanking uses special presses and tooling to produce flat components from sheet metal or plate, with high dimensional accuracy. According to Hydrel A. G., Romanshorn, Switzerland, fine-blanking presses can be powered hydraulically or mechanically, or by a combination of these methods, but they must have three separate and distinct movements. These movements serve to clamp the work material, to perform the blanking operation, and to eject the finished part from the tool. Forces of 1.5–2.5 times those used in conventional stamping are needed for fine blanking, so machines and tools must be designed and constructed accordingly. In mechanical fine-blanking presses the clamping and ejection forces are exerted hydraulically. Such presses generally are of toggle-type design and are limited to total forces of up to about 280 tons. Higher forces generally require all-hydraulic designs. These presses are also suited to embossing, coining, and impact extrusion work.

Cutting elements of tooling for fine blanking generally are made from 12 per cent chromium steel, although high speed steel and tungsten carbide also are used for long runs or improved quality. Cutting clearances between the intermediate punch and die are usually held between 0.0001 and 0.0003 in. The clamping elements are sharp projections of 90-degree V-section that follow the outline of the workpiece and that are incorporated into each tool as part of the stripper plate with thin material and also as part of the die plate when material thicker than 0.15 in. is to be blanked. Pressure applied to the elements containing the V-projections prior to the blanking operation causes the sharp edges to enter the material surface, preventing sideways movement of the blank. The pressure applied as the projections bite into the work surface near the contour edges also squeezes the material, causing it to flow toward the cutting edges, reducing the usual rounding effect at the cut edge. When small details such as gear teeth are to be produced, V-projections are often used on both sides of the work, even with thin materials, to enhance the flow effect. With suitable tooling, workpieces can be produced with edges that are perpendicular to top and bottom surfaces within 0.004 in. on thicknesses of 0.2 in., for instance. V-projection dimensions for various material thicknesses are shown in the table *Dimensions for V-projections Used in Fine-Blanking Tools*.

Fine-blanked edges are free from the fractures that result from conventional tooling, and can have surface finishes down to 80  $\mu\text{in. Ra}$  with suitable tooling. Close tolerances can be

## Dimensions for V-projections Used in Fine-Blanking Tools

V-Projections On Stripper Plate Only

All units are in inches.

held on inner and outer forms, and on hole center distances. Flatness of fine-blanked components is better than that of parts made by conventional methods, but distortion may occur with thin materials due to release of internal stresses. Widths must be slightly greater than are required for conventional press working. Generally, the strip width must be 2-3 times the thickness, plus the width of the part measured transverse to the feed direction. Other factors to be considered are shape, material quality, size and shape of the V-projection in relation to the die outline, and spacing between adjacent blanked parts. Holes and slots can be produced with ratios of width to material thickness down to 0.7, compared with the 1:1 ratio normally specified for conventional tooling. Operations such as countersinking, coining, and bending up to 60 degrees can be incorporated in fine-blanking tooling.

The cutting force in lb exerted in fine blanking is 0.9 times the length of the cut in inches times the material thickness in inches, times the tensile strength in  $\text{lb}_f/\text{in}^2$ . Pressure in lb exerted by the clamping element(s) carrying the V-projections is calculated by multiplying the length of the V-projection, which depends on its shape, in inches by its height ( $h$ ), times the material tensile strength in  $\text{lb}_f/\text{in}^2$ , times an empirical factor  $f$ . Factor  $f$  has been determined to be 2.4-4.4 for a tensile strength of 28,000-113,000  $\text{lb}_f/\text{in}^2$ . The clamping pressure is approximately 30 per cent of the cutting force, calculated as above. Dimensions and positioning of the V-projection(s) are related to the material thickness, quality, and tensile strength. A small V-projection close to the line of cut has about the same effect as a large V-projection spaced away from the cut. However, if the V-projection is too close to the cut, it may move out of the material at the start of the cutting process, reducing its effectiveness.

Positioning the V-projection at a distance from the line of cut increases both material and blanking force requirements. Location of the V-projection relative to the line of cut also affects tool life.

### Steel Rule Dies

Steel rule dies (or knife dies) were patented by Robert Gair in 1879, and, as the name implies, have cutting edges made from steel strips of about the same proportions as the steel strips used in making graduated rules for measuring purposes. According to J. A. Richards, Sr., of the J. A. Richards Co., Kalamazoo, MI, a pioneer in the field, these dies were first used in the printing and shoemaking industries for cutting out shapes in paper, cardboard, leather, rubber, cork, felt, and similar soft materials. Steel rule dies were later adopted for cutting upholstery material for the automotive and other industries, and for cutting out simple to intricate shapes in sheet metal, including copper, brass, and aluminum. A typical steel rule die, partially cut away to show the construction, is shown in Fig. 1, and is designed for cutting a simple circular shape. Such dies generally cost 25 to 35 per cent of the cost of conventional blanking dies, and can be produced in much less time. The die shown also cuts a rectangular opening in the workpiece, and pierces four holes, all in one press stroke.

Fig. 1. Steel Rule Die for Cutting a Circular Shape, Sectioned to Show the Construction

The die blocks that hold the steel strips on edge on the press platen or in the die set may be made from plaster, hot lead or type metal, or epoxy resin, all of which can be poured to shape. However, the material most widely used for light work is  $\frac{3}{4}$ -in. thick, five- or seven-ply maple or birch wood. Narrow slots are cut in this wood with a jig saw to hold the strips vertically. Where greater forces are involved, as with operations on metal sheets, the blocks usually are made from Lignostone densified wood or from metal. In the  $\frac{3}{4}$ -in. thickness mostly used, medium- and high-density grades of Lignostone are available. The  $\frac{3}{4}$ -in. thickness is made from about 35 plies of highly compressed lignite wood, bonded with

phenolformaldehyde resin, which imparts great density and strength. The material is made in thicknesses up to 6 in., and in various widths and lengths.

Steel rule die blocks can carry punches of various shapes to pierce holes in the stock, also projections designed to form strengthening ribs and other shapes in material such as aluminum, at the same time as the die cuts the component to shape. Several dies can be combined or nested, and operated together in a large press, to produce various shapes simultaneously from one sheet of material.

As shown in Fig. 1, the die steel is held in the die block slot on its edge, usually against the flat platen of a die set attached to the moving slide of the press. The sharp, free end of the rule faces toward the workpiece, which is supported by the face of the other die half. This other die half may be flat or may have a punch attached to it, as shown, and it withstands the pressure exerted in the cutting or forming action when the press is operated. The closed height of the die is adjusted to permit the cutting edge to penetrate into the material to the extent needed, or, if there is a punch, to carry the cutting edges just past the punch edges for the cutting operation. After the sharp edge has penetrated it, the material often clings to the sides of the knife. Ejector inserts made from rubber, combinations of cork and rubber, and specially compounded plastics material, or purpose-made ejectors, either spring- or positively actuated, are installed in various positions alongside the steel rules and the punch. These ejectors are compressed as the dies close, and when the dies open, they expand, pushing the material clear of the knives or the punch.

The cutting edges of the steel rules can be of several shapes, as shown in profile in Fig. 2, to suit the material to be cut, or the type of cutting operation. Shape *A* is used for shearing in the punch in making tools for blanking and piercing operations, the sharp edge later being modified to a flat, producing a 90° cutting edge, *B*. The other shapes in Fig. 2 are used for cutting various soft materials that are pressed against a flat surface for cutting. The shape at *C* is used for thin, and the shape at *D* for thicker materials.

Fig. 2. Cutting Edges for Steel Rule Dies

Steel rule die steel is supplied in lengths of 30 and 50 in., or in coils of any length, with the edges ground to the desired shape, and heat treated, ready for use. The rule material width is usually referred to as the height, and material can be obtained in heights of 0.95, 1, 1 $\frac{1}{8}$ , 1 $\frac{1}{4}$ , and 1 $\frac{1}{2}$  in. Rules are available in thicknesses of 0.055, 0.083, 0.11, 0.138, 0.166, and 0.25 in. (4 to 18 points in printers' measure of 72 points = 1 in.). Generally, stock thicknesses of 0.138 or 0.166 in. (10 and 12 points) are preferred, the thinner rules being used mainly for dies requiring intricate outlines. The stock can be obtained in soft or hard temper. The standard edge bevel is 46°, but bevels of 40 to 50° can be used. Thinner rule stock is easiest to form to shape and is often used for short runs of 50 pieces or thereabouts. The thickness and hardness of the material to be blanked also must be considered when choosing rule thickness.

**Making of Steel Rule Dies.**—Die making begins with a drawing of the shape required. Saw cutting lines may be marked directly on the face of the die block in a conventional layout procedure using a height gage, or a paper drawing may be pasted to or drawn on the die

board. Because paper stretches and shrinks, Mylar or other nonshrink plastics sheets may be preferred for the drawing. A hole is drilled off the line to allow a jig saw to be inserted, and jig saw or circular saw cuts are then made under manual control along the drawing lines to produce the slots for the rules. Jig saw blades are available in a range of sizes to suit various thicknesses of rule and for sawing medium-density Lignostone, a speed of 300 strokes/min is recommended, the saw having a stroke of about 2 in. To make sure the rule thickness to be used will be a tight fit in the slot, trials are usually carried out on scrap pieces of die block before cuts are made on a new block.

During slot cutting, the saw blade must always be maintained vertical to the board being cut, and magnifying lenses are often used to keep the blade close to the line. Carbide or carbide-tipped saw blades are recommended for clean cuts as well as for long life. To keep any "islands" (such as the center of a circle) in position, various places in the sawn line are cut to less than full depth for lengths of  $\frac{1}{4}$  to  $\frac{1}{2}$  in., and to heights of  $\frac{3}{8}$  to  $\frac{3}{4}$  in. to bridge the gaps. Slots of suitable proportions must be provided in the steel rules, on the sides away from the cutting edges, to accommodate these die block bridges.

Rules for steel rule dies are bent to shape to fit the contours called for on the drawing by means of small, purpose-built bending machines, fitted with suitable tooling. For bends of small radius, the tooling on these machines is arranged to perform a peening or hammering action to force the steel rule into close contact with the radius-forming component of the machine so that quite small radii, as required for jig saw puzzles, for instance, can be produced with good accuracy. Some forms are best made in two or more pieces, then joined by welding or brazing. The edges to be joined are mitered for a perfect fit, and are clamped securely in place for joining. Electrical resistance or a gas heating torch is used to heat the joint. Wet rags are applied to the steel at each side of the joint to keep the material cool and the hardness at the preset level, as long as possible.

When shapes are to be blanked from sheet metal, the steel rule die is arranged with flat, 90° edges (*B*, in Fig. 2), which cut by pushing the work past a close-fitting counter-punch. This counterpunch, shown in Fig. 1, may be simply a pad of steel or other material, and has an outline corresponding to the shape of the part to be cut. Sometimes the pad may be given a gradual, slight reduction in height to provide a shearing action as the moving tool pushes the work material past the pad edges. As shown in Fig. 1, punches can be incorporated in the die to pierce holes, cut slots, or form ribs and other details during the blanking operation. These punches are preferably made from high-carbon, high-vanadium, alloy steel, heat treated to Rc 61 to 63, with the head end tempered to Rc 45 to 50.

Heat treatment of the high-carbon-steel rules is designed to produce a hardness suited to the application. Rules in dies for cutting cartons and similar purposes, with mostly straight cuts, are hardened to Rc 51 to 58. For dies requiring many intricate bends, lower-carbon material is used, and is hardened to Rc 38 to 45. And for dies to cut very intricate shapes, a steel in dead-soft condition with hardness of about Rb 95 is recommended. After the intricate bends are made, this steel must be carburized before it is hardened and tempered. For this material, heat treatment uses an automatic cycle furnace, and consists of carburizing in a liquid compound heated to 1500°F and quenching in oil, followed by "tough" tempering at 550°F and cooling in the furnace.

After the hardened rule has been reinstalled in the die block, the tool is loaded into the press and the sharp die is used with care to shear the sides of the pad to match the die contours exactly. A close fit, with clearances of about half those used in conventional blanking dies, is thus ensured between the steel rule and the punch. Adjustments to the clearances can be made at this point by grinding the die steel or the punch. After the adjustment work is done, the sharp edges of the rule steel are ground flat to produce a land of about  $\frac{1}{64}$  in. wide (*A* in Fig. 2), for the working edges of the die. Clearances for piercing punches should be similar to those used on conventional piercing dies.

## ELECTRICAL DISCHARGE MACHINING

Generally called EDM, electrical discharge machining uses an electrode to remove metal from a workpiece by generating electric sparks between conducting surfaces. The two main types of EDM are termed sinker or plunge, used for making mold or die cavities, and wire, used to cut shapes such as are needed for stamping dies. For die sinking, the electrode usually is made from copper or graphite and is shaped as a positive replica of the shape to be formed on or in the workpiece. A typical EDM sinker machine, shown diagrammatically in Fig. 1, resembles a vertical milling machine, with the electrode attached to the vertical slide. The slide is moved down and up by an electronic, servo-controlled drive unit that controls the spacing between the electrode and the workpiece on the table. The table can be adjusted in three directions, often under numerical control, to positions that bring a workpiece surface to within 0.0005 to 0.030 in. from the electrode surface, where a spark is generated.

Fig. 1. Sinker or Plunge Type EDM Machines Are Used to Sink Cavities in Molds and Dies

Fig. 2. Wire Type EDM Machines Are Used to Cut Stamping Die Profiles.

Wire EDM, shown diagrammatically in Fig. 2, are numerically controlled and somewhat resemble a bandsaw with the saw blade replaced by a fine brass or copper wire, which forms the electrode. This wire is wound off one reel, passed through tensioning and guide rollers, then through the workpiece and through lower guide rollers before being wound onto another reel for storage and eventual recycling. One set of guide rollers, usually the lower, can be moved on two axes at 90 degrees apart under numerical control to adjust the angle of the wire when profiles of varying angles are to be produced. The table also is movable in two directions under numerical control to adjust the position of the workpiece relative to the wire. Provision must be made for the cut-out part to be supported when it is freed from the workpiece so that it does not pinch and break the wire.

EDM applied to grinding machines is termed EDG. The process uses a graphite wheel as an electrode, and wheels can be up to 12 in. in diameter by 6 in. wide. The wheel periphery is dressed to the profile required on the workpiece and the wheel profile can then be transferred to the workpiece as it is traversed past the wheel, which rotates but does not touch the work. EDG machines are highly specialized and are mainly used for producing complex profiles on polycrystalline diamond cutting tools and for shaping carbide tooling such as form tools, thread chasers, dies, and crushing rolls.

**EDM Terms\***.—*Anode*: The positive terminal of an electrolytic cell or battery. In EDM, incorrectly applied to the tool or electrode.

\* Source: Hansvedt Industries

*Barrel effect:* In wire EDM, a condition where the center of the cut is wider than the entry and exit points of the wire, due to secondary discharges caused by particles being pushed to the center by flushing pressure from above and beneath the workpiece.

*Capacitor:* An electrical component that stores an electric charge. In some EDM power supplies, several capacitors are connected across the machining gap and the current for the spark comes directly from the capacitors when they are discharged.

*Cathode:* The negative terminal in an electrolytic cell or battery. In EDM incorrectly applied to the workpiece.

*Colloidal suspension:* Particles suspended in a liquid that are too fine to settle out. In EDM, the tiny particles produced in the sparking action form a colloidal suspension in the dielectric fluid.

*Craters:* Small cavities left on an EDM surface by the sparking action, also known as pits.

*Dielectric filter:* A filter that removes particles from 5  $\mu\text{m}$  (0.00020 in.) down to as fine as 1  $\mu\text{m}$  (0.00004 in) in size, from dielectric fluid.

*Dielectric fluid:* The non-conductive fluid that circulates between the electrode and the workpiece to provide the dielectric strength across which an arc can occur, to act as a coolant to solidify particles melted by the arc, and to flush away the solidified particles.

*Dielectric strength:* In EDM, the electrical potential (voltage) needed to break down (ionize) the dielectric fluid in the gap between the electrode and the workpiece.

*Discharge channel:* The conductive pathway formed by ionized dielectric and vapor between the electrode and the workpiece.

*Dither:* A slight up and down movement of the machine ram and attached electrode, used to improve cutting stability.

*Duty cycle:* The percentage of a pulse cycle during which the current is turned on (on time), relative to the total duration of the cycle.

*EDG:* Electrical discharge grinding using a machine that resembles a surface grinder but has a wheel made from electrode material. Metal is removed by an EDM process rather than by grinding.

*Electrode growth:* A plating action that occurs at certain low-power settings, whereby workpiece material builds up on the electrode, causing an increase in size.

*Electrode wear:* Amount of material removed from the electrode during the EDM process. This removal can be end wear or corner wear, and is measured linearly or volumetrically but is most often expressed as end wear per cent, measured linearly.

*Electro-forming:* An electro-plating process used to make metal EDM electrodes.

*Energy:* Measured in joules, is the equivalent of volt-coulombs or volt-ampere-seconds.

*Farad:* Unit of electrical capacitance, or the energy-storing capacity of a capacitor.

*Gap:* The closest point between the electrode and the workpiece where an electrical discharge will occur. (See *Overcut*)

*Gap current:* The average amperage flowing across the machining gap.

*Gap voltage:* The voltage across the gap while current is flowing. The voltage across the electrode/workpiece before current flows is called the open gap voltage. Heat-affected zone. The layer below the recast layer, which has been subjected to elevated temperatures that have altered the properties of the workpiece metal.

*Ion:* An atom or group of atoms that has lost or gained one or more electrons and is therefore carrying a positive or negative electrical charge, and is described as being ionized.

*Ionization:* The change in the dielectric fluid that is subjected to a voltage potential whereby it becomes electrically conductive, allowing it to conduct the arc.

*Low-wear:* An EDM process in which the volume of electrode wear is between 2 and 15 per cent of the volume of workpiece wear. Normal negative polarity wear ratios are 15 to 40 per cent.

*Negative electrode:* The electrode voltage potential is negative relative to the workpiece.

*No-wear:* An EDM process in which electrode wear is virtually eliminated and the wear ratio is usually less than 2 per cent by volume.

*Orbit:* A programmable motion between the electrode and the workpiece, produced by a feature built in to the machine, or an accessory, that produces a cavity or hole larger than the electrode. The path can be planetary (circular), vectorial, or polygonal (trace). These motions can often be performed in sequence, and combined with x-axis movement of the electrode.

*Overcut:* The distance between one side of an electrode and the adjacent wall of the workpiece cavity.

*Overcut taper:* The difference between the overcut dimensions at the top (entrance) and at the bottom of the cavity.

*Plasma:* A superheated, highly ionized gas that forms in the discharge channel due to the applied voltage.

*Positive electrode:* The electrode voltage potential is positive with respect to the workpiece. is the opposite of this condition.

*Power parameters:* A set of power supply, servo, electrode material, workpiece material, and flushing settings that are selected to produce a desired metal removal rate and surface finish.

*Quench:* The rapid cooling of the EDM surface by the dielectric fluid, which is partially responsible for metallurgical changes in the recast layer and in the heat-affected zone.

*Recast layer:* A layer created by the solidification of molten metal on the workpiece surface after it has been melted by the EDM process.

*Secondary discharge:* A discharge that occurs as conductive particles are carried out along the side of the electrode by the dielectric fluid.

*Spark in:* A method of locating an electrode with respect to the workpiece, using high frequency, low amperage settings so that there is no cutting action. The electrode is advanced toward the workpiece until contact is indicated and this point is used as the basis for setting up the job.

*Spark out:* A technique used in orbiting, which moves the electrode in the same path until sparking ceases.

*Square wave:* An electrical wave shape generated by a solid state power supply.

*Stroke:* The distance the ram travels under servo control.

*UV axis:* A mechanism that provides for movement of the upper head of a wire EDM machine to allow inclined surfaces to be generated.

*White layer:* The surface layer of an EDM cut that is affected by the heat generated during the process. The characteristics of the layer depend on the material, and may be extremely hard martensite or an annealed layer.

*Wire EDM:* An EDM machine or process in which the electrode is a continuously unspooling, conducting wire that moves in preset patterns in relation to the workpiece.

*Wire guide:* A replaceable precision round diamond insert, sized to match the wire, that guides the wire at the entrance and exit points of a wire cut.

*Wire speed:* The rate at which the wire is fed axially through the workpiece (not the rate at which cutting takes place), adjusted so that clean wire is maintained in the cut but slow enough to minimize waste.

**The EDM Process.**—During the EDM process, energy from the sparks created between the electrode and the workpiece is dissipated by the melting and vaporizing of the workpiece material preferentially, only small amounts of material being lost from the electrode. When current starts to flow between the electrode and the work, the dielectric fluid in the small area in which the gap is smallest, and in which the spark will occur, is transformed into a plasma of hydrogen, carbon, and various oxides. This plasma forms a conducting passageway, consisting of ionized or electrically charged particles, through which the spark can form between the electrode and the workpiece. After current starts to flow, to heat and vaporize a tiny area, the striking voltage is reached, the voltage drops, and the field of ionized particles loses its energy, so that the spark can no longer be sustained. As the voltage then begins to rise again with the increase in resistance, the electrical supply is

cut off by the control, causing the plasma to implode and creating a low-pressure pulse that draws in dielectric fluid to flush away metallic debris and cool the impinging area. Such a cycle typically lasts a few microseconds (millionths of a second, or  $\mu\text{s}$ ), and is repeated continuously in various places on the workpiece as the electrode is moved into the work by the control system.

*Flushing:* An insulating dielectric fluid is made to flow in the space between the workpiece and the electrode to prevent premature spark discharge, cool the workpiece and the electrode, and flush away the debris. For sinker machines, this fluid is paraffin, kerosene, or a silicon-based dielectric fluid, and for wire machines, the dielectric fluid is usually deionized water. The dielectric fluid can be cooled in a heat exchanger to prevent it from rising above about 100°F, at which cooling efficiency may be reduced. The fluid must also be filtered to remove workpiece particles that would prevent efficient flushing of the spark gaps. Care must be taken to avoid the possibility of entrapment of gases generated by sparking. These gases may explode, causing danger to life, breaking a valuable electrode or workpiece, or causing a fire.

Flushing away of particles generated during the process is vital to successful EDM operations. A secondary consideration is the heat transferred to the side walls of a cavity, which may cause the workpiece material to expand and close in around the electrode, leading to formation of dc arcs where conductive particles are trapped. Flushing can be done by forcing the fluid to pass through the spark gap under pressure, by sucking it through the gap, or by directing a side nozzle to move the fluid in the tank surrounding the workpiece. In pressure flushing, fluid is usually pumped through strategically placed holes in the electrode or in the workpiece. Vacuum flushing is used when side walls must be accurately formed and straight, and is seldom needed on numerically controlled machines because the table can be programmed to move the workpiece sideways.

Flushing needs careful consideration because of the forces involved, especially where fluid is pumped or sucked through narrow passageways, and large hydraulic forces can easily be generated. Excessively high pressures can lead to displacement of the electrode, the workpiece, or both, causing inaccuracy in the finished product. Many low-pressure flushing holes are preferable to a few high-pressure holes. Pressure-relief valves in the system are recommended.

*Electronic Controls:* The electrical circuit that produces the sparks between the electrode and the workpiece is controlled electronically, the length of the extremely short on and off periods being matched by the operator or the programmer to the materials of the electrode and the workpiece, the dielectric, the rate of flushing, the speed of metal removal, and the quality of surface finish required. The average current flowing between the electrode and the workpiece is shown on an ammeter on the power source, and is the determining factor in machining time for a specific operation. The average spark gap voltage is shown on a voltmeter.

EDM machines can incorporate provision for orbiting the electrode so that flushing is easier, and cutting is faster and increased on one side. Numerical control can also be used to move the workpiece in relation to the electrode with the same results. Numerical control can also be used for checking dimensions and changing electrodes when necessary. The clearance on all sides between the electrode and the workpiece, after the machining operation, is called the overcut or overburn. The overcut becomes greater with increases in the on time, the spark energy, or the amperage applied, but its size is little affected by voltage changes. Allowances must be made for overcut in the dimensioning of electrodes. Side-wall encroachment and secondary discharge can take up parts of these allowances, and electrodes must always be made smaller to avoid making a cavity or hole too large.

*Polarity:* Polarity can affect processing speed, finish, wear, and stability of the EDM operation. On sinker machines, the electrode is generally, made positive to protect the electrode from excessive wear and preserve its dimensional accuracy. This arrangement

removes metal at a slower rate than electrode negative, which is mostly used for high-speed metal removal with graphite electrodes. Negative polarity is also used for machining carbides, titanium, and refractory alloys using metallic electrodes. Metal removal with graphite electrodes can be as much as 50 per cent faster with electrode negative polarity than with electrode positive, but negative polarity results in much faster electrode wear, so it is generally restricted to electrode shapes that can be redressed easily.

Newer generators can provide less than 1 per cent wear with either copper or graphite electrodes during roughing operations. Roughing is typically done with a positive-polarity electrode using elevated on times. Some electrodes, particularly micrograin graphites, have a high resistance to wear. Fine-grain, high-density graphites provide better wear characteristics than coarser, less dense grades, and copper-tungsten resists wear better than pure copper electrodes.

*Machine Settings:* For vertical machines, a rule of thumb for power selection on graphite and copper electrodes is 50 to 65 amps per square inch of electrode engagement. For example, an electrode that is  $\frac{1}{2}$  in. square might use  $0.5 \times 0.5 \times 50 = 12.5$  amps. Although each square inch of electrode surface may be able to withstand higher currents, lower settings should be used with very large jobs or the workpiece may become overheated and it may be difficult to clean up the recast layer. Lower amperage settings are required for electrodes that are thin or have sharp details. The voltage applied across the arc gap between the electrode and the workpiece is ideally about 35 volts, but should be as small as possible to maintain stability of the process.

*Spark Frequency:* Spark frequency is the number of times per second that the current is switched on and off. Higher frequencies are used for finishing operations and for work on cemented carbide, titanium, and copper alloys. The frequency of sparking affects the surface finish produced, low frequencies being used with large spark gaps for rapid metal removal with a rough finish, and higher frequencies with small gaps for finer finishes. High frequency usually increases, and low frequency reduces electrode wear.

*The Duty Cycle:* Electronic units on modern EDM machines provide extremely close control of each stage in the sparking cycle, down to millionths of a second ( $\mu$ s). A typical EDM cycle might last 100  $\mu$ s. Of this time, the current might be on for 40  $\mu$ s and off for 60  $\mu$ s. The relationship between the lengths of the on and off times is called the duty cycle and it indicates the degree of efficiency of the operation. The duty cycle states the on time as a percentage of the total cycle time and in the previous example it is 40 per cent. Although reducing the off time will increase the duty cycle, factors such as flushing efficiency, electrode and workpiece material, and dielectric condition control the minimum off time. Some EDM units incorporate sensors and fuzzy logic circuits that provide for adaptive control of cutting conditions for unattended operation. Efficiency is also reported as the amount of metal removed, expressed as in.<sup>3</sup>/hr.

In the EDM process, work is done only during the on time, and the longer the on time, the more material is removed in each sparking cycle. Roughing operations use extended on time for high metal-removal rates, resulting in fewer cycles per second, or lower frequency. The resulting craters are broader and deeper so that the surface is rougher and the heat-affected zone (HAZ) on the workpiece is deeper. With positively charged electrodes, the spark moves from the electrode toward the workpiece and the maximum material is removed from the workpiece. However, every spark takes a minute particle from the electrode so that the electrode also is worn away. Finishing electrodes tend to wear much faster than roughing electrodes because more sparks are generated in unit time.

The part of the cycle needed for reionizing the dielectric (the off time) greatly affects the operating speed. Although increasing the off time slows the process, longer off times can increase stability by providing more time for the ejected material to be swept away by the flow of the dielectric fluid, and for deionization of the fluid, so that erratic cycling of the servo-mechanisms that advance and retract the electrode is avoided. In any vertical EDM

operation, if the overcut, wear, and finish are satisfactory, machining speed can best be adjusted by slowly decreasing the off time setting in small increments of 1 to 5  $\mu\text{s}$  until machining becomes erratic, then returning to the previous stable setting. As the off time is decreased, the machining gap or gap voltage will slowly fall and the working current will rise. The gap voltage should not be allowed to drop below 35 to 40 volts.

**Metal Removal Rates (MRR):** Amounts of metal removed in any EDM process depend largely on the length of the on time, the energy/spark, and the number of sparks/second. The following data were provided by Poco Graphite, Inc., in their *EDM Technical Manual*. For a typical roughing operation using electrode positive polarity on high-carbon steel, a 67 per cent duty cycle removed 0.28 in.<sup>3</sup>/hr. For the same material, a 50 per cent duty cycle removed 0.15 in.<sup>3</sup>/hr, and a 33 per cent duty cycle for finishing removed 0.075 in.<sup>3</sup>/hr.

In another example, shown in the top data row in Table 1, a 40 per cent duty cycle with a frequency of 10 kHz and peak current of 50 amps was run for 5 minutes of cutting time. Metal was removed at the rate of 0.8 in.<sup>3</sup>/hr with electrode wear of 2.5 per cent and a surface finish of 400  $\mu\text{in. } R_a$ . When the on and off times in this cycle were halved, as shown in the second data row in Table 1, the duty cycle remained at 40 per cent, but the frequency doubled to 20 kHz. The result was that the peak current remained unaltered, but with only half the on time the MRR was reduced to 0.7 in.<sup>3</sup>/hr, the electrode wear increased to 6.3 per cent, and the surface finish improved to 300  $\mu\text{in. } R_a$ . The third and fourth rows in Table 1 show other variations in the basic cycle and the results.

**Table 1. Effect of Electrical Control Adjustments on EDM Operations**

| On Time ( $\mu\text{s}$ ) | Off Time ( $\mu\text{s}$ ) | Frequency (kHz) | Peak Current (Amps) | Metal Removal Rate (in. <sup>3</sup> /hr) | Electrode Wear (%) | Surface Finish ( $\mu\text{in. } R_a$ ) |
|---------------------------|----------------------------|-----------------|---------------------|---|--------------------|---|
| 40                        | 60                         | 10              | 50                  | 0.08                                      | 2.5                | 400                                     |
| 20                        | 30                         | 20              | 50                  | 0.7                                       | 6.3                | 300                                     |
| 40                        | 10                         | 20              | 50                  | 1.2                                       | 1.4                | 430                                     |
| 40                        | 60                         | 10              | 25                  | 0.28                                      | 2.5                | 350                                     |

**The Recast Layer:** One drawback of the EDM process when used for steel is the recast layer, which is created wherever sparking occurs. The oil used as a dielectric fluid causes the EDM operation to become a random heat-treatment process in which the metal surface is heated to a very high temperature, then quenched in oil. The heat breaks down the oil into hydrocarbons, tars, and resins, and the molten metal draws out the carbon atoms and traps them in the resolidified metal to form the very thin, hard, brittle surface called the recast layer that covers the heat-affected zone (HAZ). This recast layer has a white appearance and consists of particles of material that have been melted by the sparks, enriched with carbon, and drawn back to the surface or retained by surface tension. The recast layer is harder than the parent metal and can be as hard as glass, and must be reduced or removed by vapor blasting with glass beads, polishing, electrochemical or abrasive flow machining, after the shaping process is completed, to avoid cracking or flaking of surface layers that may cause failure of the part in service.

Beneath the thin recast layer, the HAZ, in steel, consists of martensite that usually has been hardened by the heating and cooling sequences coupled with the heat-sink cooling effect of a thick steel workpiece. This martensite is hard and its rates of expansion and contraction are different from those of the parent metal. If the workpiece is subjected to heating and cooling cycles in use, the two layers are constantly stressed and these stresses may cause formation of surface cracks. The HAZ is usually much deeper in a workpiece cut on a sinker than on a wire machine, especially after roughing, because of the increased heating effect caused by the higher amounts of energy applied.

The depth of the HAZ depends on the amperage and the length of the on time, increasing as these values increase, to about 0.012 to 0.015 in. deep. Residual stress in the HAZ can range up to 650 N/mm<sup>2</sup>. The HAZ cannot be removed easily, so it is best avoided by programming the series of cuts taken on the machine so that most of the HAZ produced by one cut is removed by the following cut. If time is available, cut depth can be reduced gradually until the finishing cuts produce an HAZ having a thickness of less than 0.0001 in.

**Workpiece Materials.**—Most homogeneous materials used in metalworking can be shaped by the EDM process. Some data on typical workpiece materials are given in Table 2. Sintered materials present some difficulties caused by the use of a cobalt or other binder used to hold the carbide or other particles in the matrix. The binder usually melts at a lower temperature than the tungsten, molybdenum, titanium, or other carbides, so it is preferentially removed by the sparking sequence and the carbide particles are thus loosened and freed from the matrix. The structures of sintered materials based on tungsten, cobalt, and molybdenum require higher EDM frequencies with very short on times, so that there is less danger of excessive heat buildup, leading to melting. Copper-tungsten electrodes are recommended for EDM of tungsten carbides. When used with high frequencies for powdered metals, graphite electrodes often suffer from excessive wear.

Workpieces of aluminum, brass, and copper should be processed with metallic electrodes of low melting points such as copper or copper-tungsten. Workpieces of carbon and stainless steel that have high melting points should be processed with graphite electrodes. The melting points and specific gravities of the electrode material and of the workpiece should preferably be similar.

**Table 2. Characteristics of Common Workpiece Materials for EDM**

| Material        | Specific Gravity | Melting Point |      | Vaporization Temperature |      | Conductivity (Silver = 100) |
|-----------------|------------------|---------------|------|--------------------------|------|-----------------------------|
|                 |                  | °F            | °C   | °F                       | °C   |                             |
| Aluminum        | 2.70             | 1220          | 660  | 4442                     | 2450 | 63.00                       |

**Electrode Materials.**—Most EDM electrodes are made from graphite, which provides a much superior rate of metal removal than copper because of the ability of graphite to resist thermal damage. Graphite has a density of 1.55 to 1.85 g/cm<sup>3</sup>, lower than most metals. Instead of melting when heated, graphite sublimates, that is, it changes directly from a solid to a gas without passing through the liquid stage. Sublimation of graphite occurs at a temperature of 3350°C (6062°F). EDM graphite is made by sintering a compressed mixture of fine graphite powder (1 to 100 micron particle size) and coal tar pitch in a furnace. The open structure of graphite means that it is eroded more rapidly than metal in the EDM process. The electrode surface is also reproduced on the surface of the workpiece. The sizes of individual surface recesses may be reduced during sparking when the work is moved under numerical control of workpiece table movements.

The fine grain sizes and high densities of graphite materials that are specially made for high-quality EDM finishing provide high wear resistance, better finish, and good reproduction of fine details, but these fine grades cost more than graphite of larger grain sizes and lower densities. Premium grades of graphite cost up to five times as much as the least expensive and about three times as much as copper, but the extra cost often can be justified by savings during machining or shaping of the electrode.

Graphite has a high resistance to heat and wear at lower frequencies, but will wear more rapidly when used with high frequencies or with negative polarity. Infiltrated graphites for EDM electrodes are also available as a mixture of copper particles in a graphite matrix, for applications where good machinability of the electrode is required. This material presents a trade-off between lower arcing and greater wear with a slower metal-removal rate, but costs more than plain graphite.

EDM electrodes are also made from copper, tungsten, silver-tungsten, brass, and zinc, which all have good electrical and thermal conductivity. However, all these metals have melting points below those encountered in the spark gap, so they wear rapidly. Copper with 5 per cent tellurium, added for better machining properties, is the most commonly used metal alloy. Tungsten resists wear better than brass or copper and is more rigid when used for thin electrodes but is expensive and difficult to machine. Metal electrodes, with their more even surfaces and slower wear rates, are often preferred for finishing operations on work that requires a smooth finish. In fine-finishing operations, the arc gap between the surfaces of the electrode and the workpiece is very small and there is a danger of dc arcs being struck, causing pitting of the surface. This pitting is caused when particles dislodged from a graphite electrode during fine-finishing cuts are not flushed from the gap. If struck by a spark, such a particle may provide a path for a continuous discharge of current that will mar the almost completed work surface.

Some combinations of electrode and workpiece material, electrode polarity, and likely amounts of corner wear are listed in Table 3. Corner wear rates indicate the ability of the electrode to maintain its shape and reproduce fine detail. The column headed Capacitance refers to the use of capacitors in the control circuits to increase the impact of the spark without increasing the amperage. Such circuits can accomplish more work in a given time, at the expense of surface-finish quality and increased electrode wear.

**Table 3. Types of Electrodes Used for Various Workpiece Materials**

| Electrode       | Electrode Polarity | Workpiece Material | Corner Wear (%) | Capacitance |
|-----------------|--------------------|--------------------|-----------------|-------------|
| Copper          | +                  | Steel              | 2-10            | No          |
| Copper          | +                  | Inconel            | 2-10            | No          |
| Copper          | +                  | Aluminum           | <3              | No          |
| Copper          | -                  | Titanium           | 20-40           | Yes         |
| Copper          | -                  | Carbide            | 35-60           | Yes         |
| Copper          | -                  | Copper             | 34-45           | Yes         |
| Copper          | -                  | Copper-tungsten    | 40-60           | Yes         |
| Copper-tungsten | +                  | Steel              | 1-10            | No          |
| Copper-tungsten | -                  | Copper             | 20-40           | Yes         |
| Copper-tungsten | -                  | Copper-tungsten    | 30-50           | Yes         |
| Copper-tungsten | -                  | Titanium           | 15-25           | Yes         |
| Copper-tungsten | -                  | Carbide            | 35-50           | Yes         |
| Graphite        | +                  | Steel              | <1              | No          |
| Graphite        | -                  | Steel              | 30-40           | No          |
| Graphite        | +                  | Inconel            | <1              | No          |
| Graphite        | -                  | Inconel            | 30-40           | No          |
| Graphite        | +                  | Aluminum           | <1              | No          |
| Graphite        | -                  | Aluminum           | 10-20           | No          |
| Graphite        | -                  | Titanium           | 40-70           | No          |
| Graphite        | -                  | Copper             | N/A             | Yes         |

*Electrode Wear:* Wear of electrodes can be reduced by leaving the smallest amounts of finishing stock possible on the workpiece and using no-wear or low-wear settings to remove most of the remaining material so that only a thin layer remains for finishing with the redressed electrode. The material left for removal in the finishing step should be only slightly more than the maximum depth of the craters left by the previous cut. Finishing operations should be regarded as only changing the quality of the finish, not removing metal or sizing. Low power with very high frequencies and minimal amounts of offset for each finishing cut are recommended.

On manually adjusted machines, fine finishing is usually carried out by several passes of a full-size finishing electrode. Removal of a few thousandths of an inch from a cavity with such an arrangement requires the leading edge of the electrode to recut the cavity over the entire vertical depth. By the time the electrode has been sunk to full depth, it is so worn that precision is lost. This problem sometimes can be avoided on a manual machine by use of an orbiting attachment that will cause the electrode to traverse the cavity walls, providing improved speed, finish, and flushing, and reducing corner wear on the electrode.

*Selection of Electrode Material:* Factors that affect selection of electrode material include metal-removal rate, wear resistance (including volumetric, corner, end, and side, with corner wear being the greatest concern), desired surface finish, costs of electrode manufacture and material, and characteristics of the material to be machined. A major factor is the ability of the electrode material to resist thermal damage, but the electrode's density, the polarity, and the frequencies used are all important factors in wear rates. Copper melts at about 1085°C (1985°F) and spark-gap temperatures must generally exceed 3800°C (6872°F), so use of copper may be made unacceptable because of its rapid wear rates. Graphites have good resistance to heat and wear at low frequencies, but will wear more with high frequency, negative polarity, or a combination of these.

**Making Electrodes.**—Electrodes made from copper and its alloys can be machined conventionally by lathes, and milling and grinding machines, but copper acquires a burr on run-off edges during turning and milling operations. For grinding copper, the wheel must often be charged with beeswax or similar material to prevent loading of the surface. Flat grinding of copper is done with wheels having open grain structures (46-J, for instance) to contain the wax and to allow room for the soft, gummy, copper chips. For finish grinding, wheels of at least 60 and up to 80 grit should be used for electrodes requiring sharp corners and fine detail. These wheels will cut hot and load up much faster, but are necessary to avoid rapid breakdown of sharp corners.

Factors to be considered in selection of electrode materials are: the electrode material cost/in<sup>3</sup>; the time to manufacture electrodes; difficulty of flushing; the number of electrodes needed to complete the job; speed of the EDM; amount of electrode wear during EDM; and workpiece surface-finish requirements.

Copper electrodes have the advantage over graphite in their ability to be discharge-dressed in the EDM, usually under computer numerical control (CNC). The worn electrode is engaged with a premachined dressing block made from copper-tungsten or carbide. The process renews the original electrode shape, and can provide sharp, burr-free edges. Because of its higher vaporization temperature and wear resistance, discharge dressing of graphite is slow, but graphite has the advantage that it can be machined conventionally with ease.

*Machining Graphite:* Graphites used for EDM are very abrasive, so carbide tools are required for machining them. The graphite does not shear away and flow across the face of the tool as metal does, but fractures or is crushed by the tool pressure and floats away as a fine powder or dust. Graphite particles have sharp edges and, if allowed to mix with the machine lubricant, will form an abrasive slurry that will cause rapid wear of machine guiding surfaces. The dust may also cause respiratory problems and allergic reactions, espe-

cially if the graphite is infiltrated with copper, so an efficient exhaust system is needed for machining.

Compressed air can be used to flush out the graphite dust from blind holes, for instance, but provision must be made for vacuum removal of the dust to avoid hazards to health and problems with wear caused by the hard, sharp-edged particles. Air velocities of at least 500 ft/min are recommended for flushing, and of 2000 ft/min in collector ducts to prevent settling out. Fluids can also be used, but small-pore filters are needed to keep the fluid clean. High-strength graphite can be clamped or chucked tightly but care must be taken to avoid crushing. Collets are preferred for turning because of the uniform pressure they apply to the workpiece. Sharp corners on electrodes made from less dense graphite are liable to chip or break away during machining.

For conventional machining of graphite, tools of high-quality tungsten carbide or polycrystalline diamond are preferred and must be kept sharp. Recommended cutting speeds for high-speed steel tools are 100 to 300, tungsten carbide 500 to 750, and polycrystalline diamond, 500 to 2000 surface ft/min. Tools for turning should have positive rake angles and nose radii of  $\frac{1}{64}$  to  $\frac{1}{32}$  in. Depths of cut of 0.015 to 0.020 in. produce a better finish than light cuts such as 0.005 in. because of the tendency of graphite to chip away rather than flow across the tool face. Low feed rates of 0.005 in./rev for rough- and 0.001 to 0.003 in./rev for finish-turning are preferred. Cutting off is best done with a tool having an angle of  $20^\circ$ .

For bandsawing graphite, standard carbon steel blades can be run at 2100 to 3100 surface ft/min. Use low power feed rates to avoid overloading the teeth and the feed rate should be adjusted until the saw has a very slight speed up at the breakthrough point. Milling operations require rigid machines, short tool extensions, and firm clamping of parts. Milling cutters will chip the exit side of the cut, but chipping can be reduced by use of sharp tools, positive rake angles, and low feed rates to reduce tool pressure. Feed/tooth for two-flute end mills is 0.003 to 0.005 in. for roughing and 0.001 to 0.003 in. for finishing.

Standard high-speed steel drills can be used for drilling holes but will wear rapidly, causing holes that are tapered or undersized, or both. High-spiral, tungsten carbide drills should be used for large numbers of holes over  $\frac{1}{16}$  in. diameter, but diamond-tipped drills will last longer. Pecking cycles should be used to clear dust from the holes. Compressed air can be passed through drills with through coolant holes to clear dust. Feed rates for drilling are 0.0015 to 0.002 in./rev for drills up to  $\frac{1}{32}$ , 0.001 to 0.003 in./rev for  $\frac{1}{32}$ - to  $\frac{1}{8}$ -in. drills, and 0.002 to 0.005 in./rev for larger drills. Standard taps without fluid are best used for through holes, and for blind holes, tapping should be completed as far as possible with a taper tap before the bottoming tap is used.

For surface grinding of graphite, a medium (60) grade, medium-open structure, vitreous-bond, green-grit, silicon-carbide wheel is most commonly used. The wheel speed should be 5300 to 6000 surface ft/min, with traversing feed rates at about 56 ft/min. Roughing cuts are taken at 0.005 to 0.010 in./pass, and finishing cuts at 0.001 to 0.003 in./pass. Surface finishes in the range of 18 to 32  $\mu\text{in}$ .  $R_a$  are normal, and can be improved by longer spark-out times and finer grit wheels, or by lapping. Graphite can be centerless ground using a silicon-carbide, resinoid-bond work wheel and a regulating wheel speed of 195 ft/min.

Wire EDM, orbital abrading, and ultrasonic machining are also used to shape graphite electrodes. Orbital abrading uses a die containing hard particles to remove graphite, and can produce a fine surface finish. In ultrasonic machining, a water-based abrasive slurry is pumped between the die attached to the ultrasonic transducer and the graphite workpiece on the machine table. Ultrasonic machining is rapid and can reproduce small details down to 0.002 in. in size, with surface finishes down to 8  $\mu\text{in}$ .  $R_a$ . If coolants are used, the graphite should be dried for 1 hour at over  $400^\circ\text{F}$  (but not in a microwave oven) to remove liquids before used.

**Wire EDM.**—In the wire EDM process, with deionized water as the dielectric fluid, carbon is extracted from the recast layer, rather than added to it. When copper-base wire is used, copper atoms migrate into the recast layer, softening the surface slightly so that wire-cut surfaces are sometimes softer than the parent metal. On wire EDM machines, very high amperages are used with very short on times, so that the heat-affected zone (HAZ) is quite shallow. With proper adjustment of the on and off times, the depth of the HAZ can be held below 1 micron (0.00004 in.).

The cutting wire is used only once, so that the portion in the cut is always cylindrical and has no spark-eroded sections that might affect the cut accuracy. The power source controls the electrical supply to the wire and to the drive motors on the table to maintain the preset arc gap within 0.1 micron (0.000004 in.) of the programmed position. On wire EDM machines, the water used as a dielectric fluid is deionized by a deionizer included in the cooling system, to improve its properties as an insulator. Chemical balance of the water is also important for good dielectric properties.

*Drilling Holes for Wire EDM:* Before an aperture can be cut in a die plate, a hole must be provided in the workpiece. Such holes are often “drilled” by EDM, and the wire threaded through the workpiece before starting the cut. The “EDM drill” does not need to be rotated, but rotation will help in flushing and reduce electrode wear. The EDM process can drill a hole 0.04 in. in diameter through 4-in. thick steel in about 3 minutes, using an electrode made from brass or copper tubing. Holes of smaller diameter can be drilled, but the practical limit is 0.012 in. because of the overcut, the lack of rigidity of tubing in small sizes, and the excessive wear on such small electrodes. The practical upper size limit on holes is about 0.12 in. because of the comparatively large amounts of material that must be eroded away for larger sizes. However, EDM is commonly used for making large or deep holes in such hard materials as tungsten carbide. For instance, a 0.2-in. hole has been made in carbide 2.9 in. thick in 49 minutes by EDM. Blind holes are difficult to produce with accuracy, and must often be made with cut-and-try methods.

Deionized water is usually used for drilling and is directed through the axial hole in the tubular electrode to flush away the debris created by the sparking sequence. Because of the need to keep the extremely small cutting area clear of metal particles, the dielectric fluid is often not filtered but is replaced continuously by clean fluid that is pumped from a supply tank to a disposal tank on the machine.

*Wire Electrodes:* Wire for EDM generally is made from yellow brass containing copper 63 and zinc 37 per cent, with a tensile strength of 50,000 to 145,000 lb<sub>f</sub>/in.<sup>2</sup>, and may be from 0.002 to 0.012 in. diameter.

In addition to yellow brass, electrode wires are also made from brass alloyed with aluminum or titanium for tensile strengths of 140,000 to 160,000 lb<sub>f</sub>/in.<sup>2</sup>. Wires with homogeneous, uniform electrolytic coatings of alloys such as brass or zinc are also used. Zinc is favored as a coating on brass wires because it gives faster cutting and reduced wire breakage due to its low melting temperature of 419°C, and vaporization temperature of 906°C. The layer of zinc can boil off while the brass core, which melts at 930°C, continues to deliver current.

Some wires for EDM are made from steel for strength, with a coating of brass, copper, or other metal. Most wire machines use wire negative polarity (the wire is negative) because the wire is constantly renewed and is used only once, so wear is not important. Important qualities of wire for EDM include smooth surfaces, free from nicks, scratches and cracks, precise diameters to  $\pm 0.00004$  in. for drawn and  $\pm 0.00006$  in. for plated, high tensile strength, consistently good ductility, uniform spooling, and good protective packaging.

## IRON AND STEEL CASTINGS

### Material Properties

Cast irons and cast steels encompass a large family of ferrous alloys, which, as the name implies, are cast to shape rather than being formed by working in the solid state. In general, cast irons contain more than 2 per cent carbon and from 1 to 3 per cent silicon. Varying the balance between carbon and silicon, alloying with different elements, and changing melting, casting, and heat-treating practices can produce a broad range of properties. In most cases, the carbon exists in two forms: free carbon in the form of graphite and combined carbon in the form of iron carbide (cementite). Mechanical and physical properties depend strongly on the shape and distribution of the free graphite and the type of matrix surrounding the graphite particles.

The four basic types of cast iron are white iron, gray iron, malleable iron, and ductile iron. In addition to these basic types, there are other specific forms of cast iron to which special names have been applied, such as chilled iron, alloy iron, and compacted graphite cast iron.

**Gray Cast Iron.**—Gray cast iron may easily be cast into any desirable form and it may also be machined readily. It usually contains from 1.7 to 4.5 per cent carbon, and from 1 to 3 per cent silicon. The excess carbon is in the form of graphite flakes and these flakes impart to the material the dark-colored fracture which gives it its name. Gray iron castings are widely used for such applications as machine tools, automotive cylinder blocks, cast-iron pipe and fittings and agricultural implements.

The American National Standard Specifications for Gray Iron Castings—ANSI/ASTM A48-76 groups the castings into two categories. Gray iron castings in Classes 20A, 20B, 20C, 25A, 25B, 25C, 30A, 30B, 30C, 35A, 35B, and 35C are characterized by excellent machinability, high damping capacity, low modulus of elasticity, and comparative ease of manufacture. Castings in Classes 40B, 40C, 45B, 45C, 50B, 50C, 60B, and 60C are usually more difficult to machine, have lower damping capacity, a higher modulus of elasticity, and are more difficult to manufacture. The prefix number is indicative of the minimum tensile strength in pounds per square inch, i.e., 20 is 20,000 psi, 25 is 25,000 psi, 30 is 30,000 psi, etc.

High-strength iron castings produced by the Meehanite-controlled process may have various combinations of physical properties to meet different requirements. In addition to a number of general engineering types, there are heat-resisting, wear-resisting and corrosion-resisting Meehanite castings.

**White Cast Iron.**—When nearly all of the carbon in a casting is in the combined or cementite form, it is known as white cast iron. It is so named because it has a silvery-white fracture. White cast iron is very hard and also brittle; its ductility is practically zero. Castings of this material need particular attention with respect to design since sharp corners and thin sections result in material failures at the foundry. These castings are less resistant to impact loading than gray iron castings, but they have a compressive strength that is usually higher than 200,000 pounds per square inch as compared to 65,000 to 160,000 pounds per square inch for gray iron castings. Some white iron castings are used for applications that require maximum wear resistance but most of them are used in the production of malleable iron castings.

**Chilled Cast Iron.**—Many gray iron castings have wear-resisting surfaces of white cast iron. These surfaces are designated by the term "chilled cast iron" since they are produced in molds having metal chills for cooling the molten metal rapidly. This rapid cooling results in the formation of cementite and white cast iron.

**Alloy Cast Iron.**—This term designates castings containing alloying elements such as nickel, chromium, molybdenum, copper, and manganese in sufficient amounts to appreciably change the physical properties. These elements may be added either to increase the strength or to obtain special properties such as higher wear resistance, corrosion resistance,

or heat resistance. Alloy cast irons are used extensively for such parts as automotive cylinders, pistons, piston rings, crankcases, brake drums; for certain machine tool castings, for certain types of dies, for parts of crushing and grinding machinery, and for application where the casting must resist scaling at high temperatures. Machinable alloy cast irons having tensile strengths up to 70,000 pounds per square inch or even higher may be produced.

**Malleable-iron Castings.**—Malleable iron is produced by the annealing or graphitization of white iron castings. The graphitization in this case produces temper carbon which is graphite in the form of compact rounded aggregates. Malleable castings are used for many industrial applications where strength, ductility, machinability, and resistance to shock are important factors. In manufacturing these castings, the usual procedure is to first produce a hard, brittle white iron from a charge of pig iron and scrap. These hard white-iron castings are then placed in stationary batch-type furnaces or car-bottom furnaces and the graphitization (malleablizing) of the castings is accomplished by means of a suitable annealing heat treatment. During this annealing period the temperature is slowly (50 hours) increased to as much as 1650 or 1700 degrees F, after which time it is slowly (60 hours) cooled. The American National Standard Specifications for Malleable Iron Castings—ANSI/ASTM A47-77 specifies the following grades and their properties: No. 32520, having a minimum tensile strength of 50,000 pounds per square inch, a minimum yield strength of 32,500 psi., and a minimum elongation in 2 inches of 10 per cent; and No. 35018, having a minimum tensile strength of 53,000 psi., a minimum yield strength of 35,000 psi., and a minimum elongation in 2 inches of 18 per cent.

**Cupola Malleable Iron:** Another method of producing malleable iron involves initially the use of a cupola or a cupola in conjunction with an air furnace. This type of malleable iron, called cupola malleable iron, exhibits good fluidity and will produce sound castings. It is used in the making of pipe fittings, valves, and similar parts and possesses the useful property of being well suited to galvanizing. The American National Standard Specifications for Cupola Malleable Iron — ANSI/ASTM 197-79 calls for a minimum tensile strength of 40,000 pounds per square inch; a minimum yield strength of 30,000 psi.; and a minimum elongation in 2 inches of 5 per cent.

**Pearlitic Malleable Iron:** This type of malleable iron contains some combined carbon in various forms. It may be produced either by stopping the heat treatment of regular malleable iron during production before the combined carbon contained therein has all been transformed to graphite or by reheating regular malleable iron above the transformation range. Pearlitic malleable irons exhibit a wide range of properties and are used in place of steel castings or forgings or to replace malleable iron when a greater strength or wear resistance is required. Some forms are made rigid to resist deformation while others will undergo considerable deformation before breaking. This material has been used in axle housings, differential housings, camshafts, and crankshafts for automobiles; machine parts; ordnance equipment; and tools. Tension test requirements of pearlitic malleable iron castings called for in ASTM Specification A 220-79 are given in the accompanying table.

#### Tension Test Requirements of Pearlitic Malleable Iron Castings ASTM A220-79

| Casting Grade Numbers          |                              | 40010 | 45008 | 45006 | 50005 | 60004 | 70003 | 80002 | 90001 |
|--------------------------------|------------------------------|-------|-------|-------|-------|-------|-------|-------|-------|
| Min. Tensile Strength          | 1000s<br>Lbs. per<br>Sq. In. | 60    | 65    | 65    | 70    | 80    | 85    | 95    | 105   |
| Min. Yield Strength            |                              | 40    | 45    | 45    | 50    | 60    | 70    | 80    | 90    |
| Min. Elong. in 2 In., Per Cent |                              | 10    | 8     | 6     | 5     | 4     | 3     | 2     | 1     |

**Ductile Cast Iron.**—A distinguishing feature of this widely used type of cast iron, also known as spheroidal graphite iron or nodular iron, is that the graphite is present in ball-like form instead of in flakes as in ordinary gray cast iron. The addition of small amounts of magnesium- or cerium-bearing alloys together with special processing produces this spher-

roidal graphite structure and results in a casting of high strength and appreciable ductility. Its toughness is intermediate between that of cast iron and steel, and its shock resistance is comparable to ordinary grades of mild carbon steel. Melting point and fluidity are similar to those of the high-carbon cast irons. It exhibits good pressure tightness under high stress and can be welded and brazed. It can be softened by annealing or hardened by normalizing and air cooling or oil quenching and drawing.

Five grades of this iron are specified in ASTM A 536-80—Standard Specification for Ductile Iron Castings. The grades and their corresponding matrix microstructures and heat treatments are as follows: Grade 60-40-18, ferritic, may be annealed; Grade 65-45-12, mostly ferritic, as-cast or annealed; Grade 80-55-06, ferritic/pearlitic, as-cast; Grade 100-70-03, mostly pearlitic, may be normalized; Grade 120-90-02, martensitic, oil quenched and tempered. The grade nomenclature identifies the minimum tensile strength, on per cent yield strength, and per cent elongation in 2 inches. Thus, Grade 60-40-18 has a minimum tensile strength of 60,000 psi, a minimum 0.2 per cent yield strength of 40,000 psi, and minimum elongation in 2 inches of 18 per cent. Several other types are commercially available to meet specific needs. The common grades of ductile iron can also be specified by only Brinell hardness, although the appropriate microstructure for the indicated hardness is also a requirement. This method is used in SAE Specification J434C for automotive castings and similar applications. Other specifications not only specify tensile properties, but also have limitations in composition. Austenitic types with high nickel content, high corrosion resistance, and good strength at elevated temperatures, are specified in ASTM A439-80.

Ductile cast iron can be cast in molds containing metal chills if wear-resisting surfaces are desired. Hard carbide areas will form in a manner similar to the forming of areas of chilled cast iron in gray iron castings. Surface hardening by flame or induction methods is also feasible. Ductile cast iron can be machined with the same ease as gray cast iron. It finds use as crankshafts, pistons, and cylinder heads in the automotive industry; forging hammer anvils, cylinders, guides, and control levers in the heavy machinery field; and wrenches, clamp frames, face-plates, chuck bodies, and dies for forming metals in the tool and die field. The production of ductile iron castings involves complex metallurgy, the use of special melting stock, and close process control. The majority of applications of ductile iron have been made to utilize its excellent mechanical properties in combination with the castability, machinability, and corrosion resistance of gray iron.

**Steel Castings.**—Steel castings are especially adapted for machine parts that must withstand shocks or heavy loads. They are stronger than either wrought iron, cast iron, or malleable iron and are very tough. The steel used for making steel castings may be produced either by the open-hearth, electric arc, side-blow converter, or electric induction methods. The raw materials used are steel scrap, pig iron, and iron ore, the materials and their proportions varying according to the process and the type of furnace used. The open-hearth method is used when large tonnages are continually required while a small electric furnace might be used for steels of widely differing analyses, which are required in small lot production. The high frequency induction furnace is used for small quantity production of expensive steels of special composition such as high-alloy steels. Steel castings are used for such parts as hydroelectric turbine wheels, forging presses, gears, railroad car frames, valve bodies, pump casings, mining machinery, marine equipment, engine casings, etc.

Steel castings can generally be made from any of the many types of carbon and alloy steels produced in wrought form and respond similarly to heat treatment; they also do not exhibit directionality effects that are typical of wrought steel. Steel castings are classified into two general groups: carbon steel and alloy steel.

**Carbon Steel Castings.**—Carbon steel castings may be designated as low-carbon, medium-carbon, and high-carbon. Low-carbon steel castings have a carbon content of less than 0.20 per cent (most are produced in the 0.16 to 0.19 per cent range). Other elements present are: manganese, 0.50 to 0.85 per cent; silicon, 0.25 to 0.70 per cent; phosphorus,

0.05 per cent max.; and sulfur, 0.06 per cent max. Their tensile strengths (annealed condition) range from 40,000 to 70,000 pounds per square inch. Medium-carbon steel castings have a carbon content of from 0.20 to 0.50 per cent. Other elements present are: manganese, 0.50 to 1.00 per cent; silicon, 0.20 to 0.80 per cent; phosphorus, 0.05 per cent max.; and sulfur, 0.06 per cent max. Their tensile strengths range from 65,000 to 105,000 pounds per square inch depending, in part, upon heat treatment. High-carbon steel castings have a carbon content of more than 0.50 per cent and also contain: manganese, 0.50 to 1.00 per cent; silicon, 0.20 to 0.70 per cent; and phosphorus and sulfur, 0.05 per cent max. each. Fully annealed high-carbon steel castings exhibit tensile strengths of from 95,000 to 125,000 pounds per square inch. See [Table 1](#) for grades and properties of carbon steel castings.

**Table 1. Mechanical Properties of Steel Castings**

| Tensile Strength, Lbs. per Sq. In.             | Yield Point, Lbs. per Sq. In. | Elongation in 2 In., Per Cent | Brinell Hardness Number | Type of Heat Treatment   | Application Indicating Properties  |

For general information only. Not for use as design or specification limit values. The values listed above have been compiled by the Steel Founders' Society of America as those normally expected in the production of steel castings. The castings are classified according to tensile strength values which are given in the first column. Specifications covering steel castings are prepared by the American Society for Testing and Materials, the Association of American Railroads, the Society of Automotive Engineers, the United States Government (Federal and Military Specifications), etc. These specifications appear in publications issued by these organizations.

<sup>a</sup> Quench and temper heat treatments may also be employed for these classes.

**Alloy Steel Castings.**—Alloy cast steels are those in which special alloying elements such as manganese, chromium, nickel, molybdenum, vanadium have been added in sufficient quantities to obtain or increase certain desirable properties. Alloy cast steels are comprised of two groups—the low-alloy steels with their alloy content totaling less than 8 per cent and the high-alloy steels with their alloy content totaling 8 per cent or more. The addition of these various alloying elements in conjunction with suitable heat-treatments, makes it possible to secure steel castings having a wide range of properties. The three accompanying tables give information on these steels. The lower portion of [Table 1](#) gives the engi-

neering grades of low-alloy cast steels grouped according to tensile strengths and gives properties normally expected in the production of steel castings. Tables 2 and 3 give the standard designations and nominal chemical composition ranges of high-alloy castings which may be classified according to heat or corrosion resistance. The grades given in these tables are recognized in whole or in part by the Alloy Casting Institute (ACI), the American Society for Testing and Materials (ASTM), and the Society of Automotive Engineers (SAE).

ksi = kips per square inch = 1000s of pounds per square inch; MPa = megapascals.

<sup>a</sup> Remainder is iron.

The specifications committee of the Steel Founders Society issues a *Steel Castings Handbook* with supplements. Supplement 1 provides design rules and data based on the fluidity and solidification of steel, mechanical principles involved in production of molds and cores, cleaning of castings, machining, and functionality and weight aspects. Data and examples are included to show how these rules are applied. Supplement 2 summarizes the standard steel castings specification issued by the ASTM SAE, Assoc. of Am. Railroads (AAR), Am. Bur of Shipping (ABS), and Federal authorities, and provides guidance as to their applications. Information is included for carbon and alloy cast steels, high alloy cast steels, and centrifugally cast steel pipe. Details are also given of standard test methods for steel castings, including mechanical, non-destructive (visual, liquid penetrant, magnetic particle, radiographic, and ultrasonic), and testing of qualifications of welding procedures and personnel. Other supplements cover such subjects as tolerances, drafting practices, properties, repair and fabrication welding, of carbon, low alloy and high alloy castings, foundry terms, and hardenability and heat treatment.

*Austenitic Manganese Cast Steel:* Austenitic manganese cast steel is an important high-alloy cast steel which provides a high degree of shock and wear resistance. Its composition normally falls within the following ranges: carbon, 1.00 to 1.40 per cent; manganese, 10.00 to 14.00 per cent; silicon, 0.30 to 1.00 per cent; sulfur, 0.06 per cent max.; phosphorus, 0.10 per cent, max. In the as-cast condition, austenitic manganese steel is quite brittle. In order to strengthen and toughen the steel, it is heated to between 1830 and 1940 degrees F and quenched in cold water. Physical properties of quenched austenitic manganese steel that has been cast to size are as follows: tensile strength, 80,000 to 100,000 pounds per square inch; shear strength (single shear), 84,000 pounds per square inch; elongation in 2 inches, 15 to 35 per cent; reduction in area, 15 to 35 per cent; and Brinell hardness number,

<sup>a</sup> Remainder is iron.

<sup>b</sup> For low ferrite or non-magnetic castings of this grade, the following values shall apply: tensile strength, min, 65 ksi (450 MPa); yield point, min, 28 ksi (195 MPa).

180 to 220. When cold worked, the surface of such a casting increases to a Brinell hardness of from 450 to 550. In many cases the surfaces are cold worked to maximum hardness to assure immediate hardness in use. Heat-treated austenitic manganese steel is machined only with great difficulty since it hardens at and slightly ahead of the point of contact of the cutting tool. Grinding wheels mounted on specially adapted machines are used for boring, planing, keyway cutting, and similar operations on this steel. Where grinding cannot be employed and machining must be resorted to, high-speed tool steel or cemented carbide tools are used with heavy, rigid equipment and slow, steady operation. In any event, this procedure tends to be both tedious and expensive. Austenitic manganese cast steel can be arc-welded with manganese-nickel steel welding rods containing from 3 to 5 per cent nickel, 10 to 15 per cent manganese, and, usually, 0.60 to 0.80 per cent carbon.

### Casting of Metals

Molten metals are shaped by pouring (casting) into a mold of the required form, which they enter under gravity, centrifugal force, or various degrees of pressure. Molds are made of refractory materials like sand, plaster, graphite, or metal. Sand molds are formed around a pattern or replica of the part to be made, usually of wood though plastics or metal may be used when large numbers of molds for similar parts are to be made.

*Green-sand molding* is used for most sand castings, sand mixed with a binder being packed around the pattern by hand, with power tools, or in a vibrating machine which may also exert a compressive force to pack the grains more closely. The term "green-sand" implies that the binder is not cured by heating or chemical reactions. The pattern is made in two "halves," which usually are attached to opposite sides of a flat plate. Shaped bars and other projections are fastened to the plate to form connecting channels and funnels in the sand for entry of the molten metal into the casting cavities. The sand is supported at the plate edges by a box-shaped frame or flask, with locating tabs that align the two mold halves when they are later assembled for the pouring operation.

Hollows and undercut surfaces in the casting are produced by cores, also made from sand, that are placed in position before the mold is closed, and held in place by tenons in grooves (called prints) formed in the sand by pattern projections. An *undercut surface* is one from which the pattern cannot be withdrawn in a straight line, so must be formed by a core in the mold. When the poured metal has solidified, the frame is removed and the sand falls or is cleaned off, leaving the finished casting(s) ready to be cut from the runners.

*Gray iron* is easily cast in complex shapes in green-sand and other molds and can be machined readily. The iron usually contains carbon, 1.7–4.5, and silicon, 1–3 per cent by weight. Excess carbon in the form of graphite flakes produces the gray surface from which the name is derived, when a casting is fractured.

*Shell molding*: invented by a German engineer, Croning, uses a resin binder to lock the grains of sand in a  $\frac{1}{4}$  to  $\frac{3}{8}$ -in.-thick layer of sand/resin mixture, which adheres to a heated pattern plate after the mass of the mixture has been dumped back into the container. The hot resin quickly hardens enough to make the shell thus formed sufficiently rigid to be removed from the pattern, producing a half mold. The other half mold is produced on another plate by the same method. Pattern projections form runner channels, basins, core prints, and locating tenons in each mold half. Cores are inserted to form internal passages and undercuts. The shell assembly is placed in a molding box and supported with some other material such as steel shot or a coarse sand, when the molten metal is to be poured in. Some shell molds are strong enough to be filled without backup, and the two mold halves are merely clamped together for metal to be poured in to make the casting(s).

*V-Process* is a method whereby dry, unbonded sand is held to the shape of a pattern by a vacuum. The pattern is provided with multiple vent passages that terminate in various positions all over its surface, and are connected to a common plenum chamber. A heat-softened, 0.002–0.005-in.-thick plastics film is draped over the pattern and a vacuum of 200–400 mm of mercury is applied to the chamber, sucking out the air beneath the film so that the plastics is drawn into close contact with the pattern. A sand box or flask with walls that also contain hollow chambers and a flat grid that spans the central area is placed on the pattern plate to confine the dry unbonded sand that is allowed to fall through the grid on to the pattern.

After vibration to compact the sand around the pattern, a former is used to shape a sprue cup into the upper surface of the sand, connecting with a riser on the pattern, and the top surface of the sand is covered with a plastics film that extends over the flask sides. The hollow chambers in the flask walls are then connected to the vacuum source. The vacuum is sufficient to hold the sand grains in their packed condition between the plastics films above and beneath, firmly in the shape defined by the pattern, so that the flask and the sand half-mold can be lifted from the pattern plate. Matching half molds made by these procedures are assembled into a complete mold, with cores inserted if needed. With both mold halves still held by vacuum, molten metal is poured through the sprue cup into the mold, the plastics film between the mold surfaces being melted and evaporated by the hot metal. After solidification, the vacuum is released and the sand, together with the casting(s), falls from the mold flasks. The castings emerge cleanly, and the sand needs only to be cooled before reuse.

*Permanent mold, or gravity die, casting* is mainly used for nonferrous metals and alloys. The mold (or die) is usually iron or steel, or graphite, and is cooled by water channels or by air jets on the outer surfaces. Cavity surfaces in metal dies are coated with a thin layer of heat-resistant material. The mold or die design is usually in two halves, although many multiple-part molds are in use, with loose sand or metal cores to form undercut surfaces. The cast metal is simply poured into a funnel formed in the top of the mold, although elaborate tilting mechanisms are often used to control the passage of metal into (and emergence of air from) the remote portions of die cavities.

Because the die temperature varies during the casting cycle, its dimensions vary correspondingly. The die is opened and ejectors push the casting(s) out as soon as its temperature is low enough for sufficient strength to build up. During the period after solidification and before ejection, cooling continues but shrinkage of the casting(s) is restricted by the die. The alloy being cast must be sufficiently ductile to accommodate these restrictions without fracturing. An alloy that tears or splits during cooling in the die is said to be *hot short* and cannot be cast in rigid molds. Dimensions of the casting(s) at shop temperatures will be related to the die temperature and the dimensions at ejection. Rules for casting shrinkage that apply to friable (sand) molds do not hold for rigid molds. Designers of metal molds and dies rely on temperature-based calculations and experience in evolving shrinkage allowances.

*Low-pressure casting* uses mold or die designs similar to those for gravity casting. The container (crucible) for the molten metal has provision for an airtight seal with the mold, and when gas or air pressure (6–10 lb/in.<sup>2</sup>) is applied to the bath surface inside the crucible, the metal is forced up a hollow refractory tube (stalk) projecting from the die underside. This stalk extends below the bath level so that metal entering the die is free from oxides and impurities floating on the surface. The rate of filling is controlled so that air can be expelled from the die by the entering metal. With good design and control, high-quality, nonporous castings are made by both gravity and low-pressure methods, though the extra pressure in low-pressure die casting may increase the density and improve the reproduction of fine detail in the die.

*Squeeze casting* uses a metal die, of which one half is clamped to the bed of a large (usually) hydraulic press and the other to the vertically moving ram of the press. Molten metal is poured into the lower die and the upper die is brought down until the die is closed. The amount of metal in the die is controlled to produce a slight overflow as the die closes to ensure complete filling of the cavity. The heated dies are lubricated with graphite and pressures up to 25 tons per square inch may be applied by the press to squeeze the molten metal into the tiniest recesses in the die. When the press is opened, the solidified casting is pushed out by ejectors.

### Finishing Operations for Castings

**Removal of Gates and Risers from Castings.**—After the molten iron or steel has solidified and cooled, the castings are removed from their molds, either manually or by placing them on vibratory machines and shaking the sand loose from the castings. The gates and risers that are not broken off in the shake-out are removed by impact, sawing, shearing, or burning-off methods. In the impact method, a hammer is used to knock off the gates and risers. Where the possibility exists that the fracture would extend into the casting itself, the gates or risers are first notched to assure fracture in the proper place. Some risers have a necked-down section at which the riser breaks off when struck. Sprue-cutter machines are also used to shear off gates. These machines facilitate the removal of a number of small castings from a central runner. Band saws, power saws, and abrasive cut-off wheel machines are also used to remove gates and risers. The use of band saws permits following the contour of the casting when removing unwanted appendages. Abrasive cut-off wheels are used when the castings are too hard or difficult to saw. Oxyacetylene cutting torches are used to cut off gates and risers and to gouge out or remove surface defects on castings.

These torches are used on steel castings where the gates and risers are of a relatively large size. Surface defects are subsequently repaired by conventional welding methods.

Any unwanted material in the form of fins, gates, and riser pads that come above the casting surface, chaplets, parting-line flash, etc., is removed by chipping with pneumatic hammers, or by grinding with such equipment as floor or bench-stand grinders, portable grinders, and swing-frame grinders.

**Blast Cleaning of Castings.**—Blast cleaning of castings is performed to remove adhering sand, to remove cores, to improve the casting appearance, and to prepare the castings for their final finishing operation, which includes painting, machining, or assembling. Scale produced as a result of heat treating can also be removed. A variety of machines are used to handle all sizes of casting. The methods employed include blasting with sand, metal shot, or grit; and hydraulic cleaning or tumbling. In blasting, sharp sand, shot, or grit is carried by a stream of compressed air or water or by centrifugal force (gained as a result of whirling in a rapidly rotating machine) and directed against the casting surface by means of nozzles. The operation is usually performed in cabinets or enclosed booths. In some setups the castings are placed on a revolving table and the abrasive from the nozzles that are either mechanically or hand-held is directed against all the casting surfaces. Tumbling machines are also employed for cleaning, the castings being placed in large revolving drums together with slugs, balls, pins, metal punchings, or some abrasive, such as sandstone or granite chips, slag, silica, sand, or pumice. Quite frequently, the tumbling and blasting methods are used together, the parts then being tumbled and blasted simultaneously. Castings may also be cleaned by hydroblasting. This method uses a water-tight room in which a mixture of water and sand under high pressure is directed at the castings by means of nozzles. The action of the water and sand mixture cleans the castings very effectively.

**Heat Treatment of Steel Castings.**—Steel castings can be heat treated to bring about diffusion of carbon or alloying elements, softening, hardening, stress-relieving, toughening, improved machinability, increased wear resistance, and removal of hydrogen entrapped at the surface of the casting. Heat treatment of steel castings of a given composition follows closely that of wrought steel of similar composition. For discussion of types of heat treatment refer to the "Heat Treatment of Steel" section of this Handbook.

**Estimating Casting Weight.**—Where no pattern or die has yet been made, as when preparing a quotation for making a casting, the weight of a cast component can be estimated with fair accuracy by calculating the volume of each of the casting features, such as box- or rectangular-section features, cylindrical bosses, housings, ribs, and other parts, and adding them together. Several computer programs, also measuring mechanisms that can be applied to a drawing, are available to assist with these calculations. When the volume of metal has been determined it is necessary only to multiply by the unit weight of the alloy to be used, to arrive at the weight of the finished casting. The cost of the metal in the finished casting can then be estimated by multiplying the weight in lb by the cost/lb of the alloy. Allowances for melting losses, and for the extra metal used in risers and runners, and the cost of melting and machining may also be added to the cost/lb. Estimates of the costs of pattern- or die-making, molding, pouring and finishing of the casting(s), may also be added, to complete the quotation estimate.

#### **Pattern Materials—Shrinkage, Draft, and Finish Allowances**

**Woods for Patterns.**—Woods commonly used for patterns are white pine, mahogany, cherry, maple, birch, white wood, and fir. For most patterns, white pine is considered superior because it is easily worked, readily takes glue and varnish, and is fairly durable. For medium- and small-sized patterns, especially if they are to be used extensively, a harder wood is preferable. Mahogany is often used for patterns of this class, although many prefer cherry. As mahogany has a close grain, it is not as susceptible to atmospheric changes as a wood of coarser grain. Mahogany is superior in this respect to cherry, but is more expen-

sive. In selecting cherry, never use young timber. Maple and birch are employed quite extensively, especially for turned parts, as they take a good finish. White wood is sometimes substituted for pine, but it is inferior to the latter in being more susceptible to atmospheric changes.

**Selection of Wood.**—It is very important to select well-seasoned wood for patterns; that is, it should either be kiln-dried or kept 1 or 2 years before using, the time depending upon the size of the lumber. During the seasoning or drying process, the moisture leaves the wood cells and the wood shrinks, the shrinkage being almost entirely across the grain rather than in a lengthwise direction. Naturally, after this change takes place, the wood is less liable to warp, although it will absorb moisture in damp weather. Patterns also tend to absorb moisture from the damp sand of molds, and to minimize troubles from this source they are covered with varnish. Green or water-soaked lumber should not be put in a drying room, because the ends will dry out faster than the rest of the log, thus causing cracks. In a log, there is what is called “sap wood” and “heart wood.” The outer layers form the sap wood, which is not as firm as the heart wood and is more likely to warp; hence, it should be avoided, if possible.

**Pattern Varnish.**—Patterns intended for repeated use are varnished to protect them against moisture, especially when in the damp molding sand. The varnish used should dry quickly to give a smooth surface that readily draws from the sand. Yellow shellac varnish is generally used. It is made by dissolving gum shellac in grain alcohol. Wood alcohol is sometimes substituted, but is inferior. The color of the varnish is commonly changed for covering core prints, in order that the prints may be readily distinguished from the body of the pattern. Black shellac varnish is generally used. At least three coats of varnish should be applied to patterns, the surfaces being rubbed down with sandpaper after applying the preliminary coats, in order to obtain a smooth surface.

**Shrinkage Allowances.**—The shrinkage allowances ordinarily specified for patterns to compensate for the contraction of castings in cooling are as follows: cast iron,  $\frac{3}{32}$  to  $\frac{1}{8}$  inch per foot; common brass,  $\frac{3}{16}$  inch per foot; yellow brass,  $\frac{7}{32}$  inch per foot; bronze,  $\frac{5}{32}$  inch per foot; aluminum,  $\frac{1}{8}$  to  $\frac{5}{32}$  inch per foot; magnesium,  $\frac{1}{8}$  to  $\frac{1}{64}$  inch per foot; steel,  $\frac{3}{16}$  inch per foot. These shrinkage allowances are approximate values only because the exact allowance depends upon the size and shape of the casting and the resistance of the mold to the normal contraction of the casting during cooling. It is, therefore, possible that more than one shrinkage allowance will be required for different parts of the same pattern. Another factor that affects shrinkage allowance is the molding method, which may vary to such an extent from one foundry to another, that different shrinkage allowances for each would have to be used for the same pattern. For these reasons it is recommended that patterns be made at the foundry where the castings are to be produced to eliminate difficulties due to lack of accurate knowledge of shrinkage requirements.

An example of how casting shape can affect shrinkage allowance is given in the Steel Castings Handbook. In this example a straight round steel bar required a shrinkage allowance of approximately  $\frac{5}{32}$  inch per foot. The same bar but with a large knob on each end required a shrinkage allowance of only  $\frac{3}{16}$  inch per foot. A third steel bar with large flanges at each end required a shrinkage allowance of only  $\frac{3}{64}$  inch per foot. This example would seem to indicate that the best practice in designing castings and making patterns is to obtain shrinkage values from the foundry that is to make the casting because there can be no fixed allowances.

**Metal Patterns.**—Metal patterns are especially adapted to molding machine practice, owing to their durability and superiority in retaining the required shape. The original master pattern is generally made of wood, the casting obtained from the wood pattern being finished to make the metal pattern. The materials commonly used are brass, cast iron, aluminum, and steel. Brass patterns should have a rather large percentage of tin, to improve

the casting surface. Cast iron is generally used for large patterns because it is cheaper than brass and more durable. Cast-iron patterns are largely used on molding machines. Aluminum patterns are light but they require large shrinkage allowances. White metal is sometimes used when it is necessary to avoid shrinkage. The gates for the mold may be cast or made of sheet brass. Some patterns are made of vulcanized rubber, especially for light match-board work.

**Obtaining Weight of Casting from Pattern Weight.**—To obtain the approximate weight of a casting, multiply the weight of the pattern by the factor given in the accompanying table. For example, if the weight of a white-pine pattern is 4 pounds what is the weight of a solid cast-iron casting obtained from that pattern? Casting weight =  $4 \times 16 = 64$  pounds. If the casting is cored, fill the core-boxes with dry sand, and multiply the weight of the sand by one of the following factors: For cast iron, 4; for brass, 4.65; for aluminum, 1.4. Then subtract the product of the sand weight and the factor just given from the weight of the solid casting, to obtain the weight of the cored casting. The weight of wood varies considerably, so the results obtained by the use of the table are only approximate, the factors being based on the average weight of the woods listed. For metal patterns, the results may be more accurate.

**Factors for Obtaining Weight of Casting from Pattern Weight**

| Pattern Material   | Factors   |          |        |       |                                   |
|--------------------|-----------|----------|--------|-------|-----------------------------------|
|                    | Cast Iron | Aluminum | Copper | Zinc  | Brass, 70%<br>Copper,<br>30% Zinc |
| White pine         | 16.00     | 5.70     | 19.60  | 15.00 | 19.00                             |
| Mahogany, Honduras | 12.00     | 4.50     | 14.70  | 11.50 | 14.00                             |
| Cherry             | 10.50     | 3.80     | 13.00  | 10.00 | 12.50                             |
| Cast Iron          | 1.00      | 0.35     | 1.22   | 0.95  | 1.17                              |
| Aluminum           | 2.85      | 1.00     | 3.44   | 2.70  | 3.30                              |

### Die Casting

Die casting is a method of producing finished castings by forcing molten metal into a hard metal die, which is arranged to open after the metal has solidified so that the casting can be removed. The die-casting process makes it possible to secure accuracy and uniformity in castings, and machining costs are either eliminated altogether or are greatly reduced. The greatest advantage of the die-casting process is that parts are accurately and often completely finished when taken from the die. When the dies are properly made, castings may be accurate within 0.001 inch or even less and a limit of 0.002 or 0.003 inch per inch of casting dimension can be maintained on many classes of work.

Die castings are used extensively in the manufacture of such products as cash registers, meters, time-controlling devices, small housings, washing machines, and parts for a great variety of mechanisms. Lugs and gear teeth are cast in place and both external and internal screw threads can be cast. Holes can be formed within about 0.001 inch of size and the most accurate bearings require only a finish-reaming operation. Figures and letters may be cast sunken or in relief on wheels for counting or printing devices, and with ingenious die designs, many shapes that formerly were believed too intricate for die casting are now produced successfully by this process.

Die casting uses hardened steel molds (dies) into which the molten metal is injected at high speed, reaching pressures up to 10 tons/in.<sup>2</sup>, force being applied by a hydraulically actuated plunger moving in a cylindrical pressure chamber connected to the die cavity(s). If the plan area of the casting and its runner system cover 50 in.<sup>2</sup>, the total power applied is 10 tons/in.<sup>2</sup> of pressure on the metal  $\times$  50 in.<sup>2</sup> of projected area, producing a force of 500

tons, and the die-casting machine must hold the die shut against this force. Massive toggle mechanisms stretch the heavy (6-in. diameter) steel tie bars through about 0.045 in. on a typical (500-ton) machine to generate this force. Although the die is hot, metal entering the die cavity is cooled quickly, producing layers of rapidly chilled, dense material about 0.015 in. thick in the metal having direct contact with the die cavity surfaces. Because the high injection forces allow castings to be made with thin walls, these dense layers form a large proportion of the total wall thickness, producing high casting strength. This phenomenon is known as the skin effect, and should be taken into account when considering the tensile strengths and other properties measured in (usually thicker) test bars.

As to the limitations of the die-casting process it may be mentioned that the cost of dies is high, and, therefore, die casting is economical only when large numbers of duplicate parts are required. The stronger and harder metals cannot be die cast, so that the process is not applicable for casting parts that must necessarily be made of iron or steel, although special alloys have been developed for die casting that have considerable tensile and compressive strength.

Many die castings are produced by the hot-chamber method in which the pressure chamber connected to the die cavity is immersed permanently in the molten metal and is automatically refilled through a hole that is uncovered as the (vertical) pressure plunger moves back after filling the die. This method can be used for alloys of low melting point and high fluidity such as zinc, lead, tin, and magnesium. Other alloys requiring higher pressure, such as brass, or that can attack and dissolve the ferrous pressure chamber material, such as aluminum, must use the slower cold-chamber method with a water-cooled (horizontal) pressure chamber outside the molten metal.

**Porosity.**—Molten metal injected into a die cavity displaces most of the air, but some of the air is trapped and is mixed with the metal. The high pressure applied to the metal squeezes the pores containing the air to very small size, but subsequent heating will soften the casting so that air in the surface pores can expand and cause blisters. Die castings are seldom solution heat treated or welded because of this blistering problem. The chilling effect of the comparatively cold die causes the outer layers of a die casting to be dense and relatively free of porosity. Vacuum die casting, in which the cavity atmosphere is evacuated before metal is injected, is sometimes used to reduce porosity. Another method is to displace the air by filling the cavity with oxygen just prior to injection. The oxygen is burned by the hot metal so that porosity does not occur.

When these special methods are not used, machining depths must be limited to 0.020–0.035 inch if pores are not to be exposed, but as-cast accuracy is usually good enough for only light finishing cuts to be needed. Special pore-sealing techniques must be used if pressure tightness is required.

**Designing Die Castings.**—Die castings are best designed with uniform wall thicknesses (to reduce cooling stresses) and cores of simple shapes (to facilitate extraction from the die). Heavy sections should be avoided or cored out to reduce metal concentrations that may attract trapped gases and cause porosity concentrations. Designs should aim at arranging for metal to travel through thick sections to reach thin ones if possible. Because of the high metal injection pressures, conventional sand cores cannot be used, so cored holes and apertures are made by metal cores that form part of the die. Small and slender cores are easily bent or broken, so should be avoided in favor of piercing or drilling operations on the finished castings. Ribbing adds strength to thin sections, and fillets should be used on all inside corners to avoid high stress concentrations in the castings. Sharp outside corners should be avoided. Draft allowances on a die casting are usually from 0.5 to 1.5 degrees per side to permit the castings to be pushed off cores or out of the cavity.

**Alloys Used for Die Casting.**—The alloys used in modern die-casting practice are based on aluminum, zinc, and copper, with small numbers of castings also being made from magnesium-, tin-, and lead-based alloys.

**Aluminum-Base Alloys.**—Aluminum-base die-casting alloys are used more extensively than any other base metal alloy because of their superior strength combined with ease of castability. Linear shrinkage of aluminum alloys on cooling is about  $12.9$  to  $15.5 \times 10^{-6}$  in./in.-°F. Casting temperatures are of the order of 1200 deg. F. Most aluminum die castings are produced in aluminum-silicon-copper alloys such as the Aluminum Association (AA) No. 380 (ASTM SC84A; UNS A038000), containing silicon 7.5 to 9.5 and copper 3 to 4 per cent. Silicon increases fluidity for complete die filling, but reduces machinability, and copper adds hardness but reduces ductility in aluminum alloys. A less-used alloy having slightly greater fluidity is AA No. 384 (ASTM SC114A; UNS A03840) containing silicon 10.5 to 12.0 and copper 3.0 to 4.5 per cent. For marine applications, AA 360 (ASTM 100A; UNS A03600) containing silicon 9 to 10 and copper 0.6 per cent is recommended, the copper content being kept low to reduce susceptibility to corrosion in salt atmospheres. The tensile strengths of AA 380, 384, and 360 alloys are 47,000, 48,000, and 46,000 lb/in.<sup>2</sup>, respectively. Although 380, 384, and 360 are the most widely used die-castable alloys, several other aluminum alloys are used for special applications. For instance, the AA 390 alloy, with its high silicon content (16 to 18 per cent), is used for internal combustion engine cylinder castings, to take advantage of the good wear resistance provided by the hard silicon grains. No. 390 alloy also contains 4 to 5 per cent copper, and has a hardness of 120 Brinell with low ductility, and a tensile strength of 41,000 lb/in.<sup>2</sup>.

**Zinc-Base Alloys.**—In the molten state, zinc is extremely fluid and can therefore be cast into very intricate shapes. The metal also is plentiful and has good mechanical properties. Zinc die castings can be made to closer dimensional limits and with thinner walls than aluminum. Linear shrinkage of these alloys on cooling is about  $9$  to  $13 \times 10^{-6}$  in./in.-°F. The low casting temperatures (750–800 deg. F) and the hot-chamber process allow high production rates with simple automation. Zinc die castings can be produced with extremely smooth surfaces, lending themselves well to plating and other finishing methods. The established zinc alloys numbered 3, 5 and 7 [ASTM B86 (AG40A; UNS Z33520), AG41A (UNS Z35531), and AG40B (UNS Z33522)] each contains 3.5 to 4.3 per cent of aluminum, which adds strength and hardness, plus carefully controlled amounts of other elements. Recent research has brought forward three new alloys of zinc containing 8, 12, and 27 per cent of aluminum, which confer tensile strength of 50,000–62,000 lb/in.<sup>2</sup> and hardness approaching that of cast iron (105–125 Brinell). These alloys can be used for gears and racks, for instance, and as housings for shafts that run directly in reamed or bored holes, with no need for bearing bushes.

**Copper-Base Alloys.**—Brass alloys are used for plumbing, electrical, and marine components where resistance to corrosion must be combined with strength and wear resistance. With the development of the cold-chamber casting process, it became possible to make die castings from several standard alloys of copper and zinc such as yellow brass (ASTM B176-Z30A; UNS C85800) containing copper 58, zinc 40, tin 1, and lead 1 per cent. Tin and lead are included to improve corrosion resistance and machinability, respectively, and this alloy has a tensile strength of 45,000 lb/in.<sup>2</sup>. Silicon brass (ASTM B176-ZS331A; UNS C87800) with copper 65 and zinc 34 per cent also contains 1 per cent silicon, giving it more fluidity for castability and with higher tensile strength (58,000 psi) and better resistance to corrosion. High silicon brass or tombasil (ASTM B176-ZS144A), containing copper 82, zinc 14, and silicon 4 per cent, has a tensile strength of 70,000 lb/in.<sup>2</sup> and good wear resistance, but at the expense of machinability.

**Magnesium-Base Alloys.**—Light weight combined with good mechanical properties and excellent damping characteristics are principal reasons for using magnesium die castings. Magnesium has a low specific heat and does not dissolve iron so it may be die cast by the cold- or hot-chamber methods. For the same reasons, die life is usually much longer than for aluminum. The lower specific heat and more rapid solidification make production about 50 per cent faster than with aluminum. To prevent oxidation, an atmosphere of CO<sub>2</sub>

and air, containing about 0.5 per cent of SF<sub>6</sub> gas, is used to exclude oxygen from the surface of the molten metal. The most widely used alloy is AZ91D (ASTM B94; UNS 11916), a high-purity alloy containing aluminum 9 and zinc 0.7 per cent, and having a yield strength of 23,000 lb/in.<sup>2</sup> (Table 8a on page 587). AZ91D has a corrosion rate similar to that of 380 aluminum (see *Aluminum-Base Alloys* on page 1372).

**Tin-Base Alloys.**—In this group tin is alloyed with copper, antimony, and lead. SAE Alloy No. 10 contains, as the principal ingredients, in percentages, tin, 90; copper, 4 to 5; antimony, 4 to 5; lead, maximum, 0.35. This high-quality babbitt mixture is used for main-shaft and connecting-rod bearings or bronze-backed bearings in the automotive and aircraft industries. SAE No. 110 contains tin, 87.75; antimony, 7.0 to 8.5; copper, maximum, 2.25 to 3.75 per cent and other constituents the same as No. 10. SAE No. 11, which contains a little more copper and antimony and about 4 per cent less tin than No. 10, is also used for bearings or other applications requiring a high-class tin-base alloy. These tin-base compositions are used chiefly for automotive bearings but they are also used for milking machines, soda fountains, syrup pumps, and similar apparatus requiring resistance against the action of acids, alkalies, and moisture.

**Lead-Base Alloys.**—These alloys are employed usually where a cheap noncorrosive metal is needed and strength is relatively unimportant. Such alloys are used for parts of lead-acid batteries, for automobile wheel balancing weights, for parts that must withstand the action of strong mineral acids and for parts of X-ray apparatus. SAE Composition No. 13 contains (in percentages) lead, 86; antimony, 9.25 to 10.75; tin, 4.5 to 5.5 per cent. SAE Specification No. 14 contains less lead and more antimony and copper. The lead content is 76; antimony, 14 to 16; and tin, 9.25 to 10.75 per cent. Alloys Nos. 13 and 14 are inexpensive owing to the high lead content and may be used for bearings that are large and subjected to light service.

**Dies for Die-Casting Machines.**—Dies for die-casting machines are generally made of steel although cast iron and nonmetallic materials of a refractory nature have been used, the latter being intended especially for bronze or brass castings, which, owing to their comparatively high melting temperatures, would damage ordinary steel dies. The steel most generally used is a low-carbon steel. Chromium-vanadium and tungsten steels are used for aluminum, magnesium, and brass alloys, when dies must withstand relatively high temperatures.

Making die-casting dies requires considerable skill and experience. Dies must be so designed that the metal will rapidly flow to all parts of the impression and at the same time allow the air to escape through shallow vent channels, 0.003 to 0.005 inch deep, cut into the parting of the die. To secure solid castings, the gates and vents must be located with reference to the particular shape to be cast. Shrinkage is another important feature, especially on accurate work. The amount usually varies from 0.002 to 0.007 inch per inch, but to determine the exact shrinkage allowance for an alloy containing three or four elements is difficult except by experiment.

**Die-Casting Bearing Metals in Place.**—Practically all the metals that are suitable for bearings can be die cast in place. Automobile connecting rods are an example of work to which this process has been applied successfully. After the bearings are cast in place, they are finished by boring or reaming. The best metals for the bearings, and those that also can be die cast most readily, are the babbitts containing about 85 per cent tin with the remainder copper and antimony. These metals should not contain over 9 per cent copper. The copper constitutes the hardening element in the bearing. A recommended composition for a high-class bearing metal is 85 per cent tin, 10 per cent antimony, and 5 per cent copper. The antimony may vary from 7 to 10 per cent and the copper from 5 to 8 per cent. To reduce costs, some bearing metals use lead instead of tin. One bearing alloy contains from 95 to 98 per cent lead. The die-cast metal becomes harder upon seasoning a few days. In die-casting bearings, the work is located from the bolt holes that are drilled previous to die casting. It is

important that the bolt holes be drilled accurately with relation to the remainder of the machined surfaces.

**Injection Molding of Metal.**—The die casting and injection molding processes have been combined to make possible the injection molding of many metal alloys by mixing powdered metal, of 5 to 10  $\mu\text{m}$  (0.0002 to 0.0004 in.) particle size with thermoplastic binders. These binders are chosen for maximum flow characteristics to ensure that the mixture can penetrate to the most remote parts of the die/mold cavities. Moderate pressures and temperatures are used for the injection molding of these mixtures, and the molded parts harden as they cool so that they can be removed as solids from the mold. Shrinkage allowances for the cavities are greater than are required for the die casting process, because the injection molded parts are subject to a larger shrinkage (10 to 35 per cent) after removal from the die, due to evaporation of the binder and consolidation of the powder.

Binder removal may take several days because of the need to avoid distortion, and when it is almost complete the molded parts are sintered in a controlled atmosphere furnace at high temperatures to remove the remaining binder and consolidate the powdered metal component that remains. Density can thus be increased to about 95 per cent of the density of similar material produced by other processes. Tolerances are similar to those in die casting, and some parts are sized by a coining process for greater accuracy. The main limitation of the process is size, parts being restricted to about a 1.5-in. cube.

### Precision Investment Casting

Investment casting is a highly developed process that is capable of great casting accuracy and can form extremely intricate contours. The process may be utilized when metals are too hard to machine or otherwise fabricate; when it is the only practical method of producing a part; or when it is more economical than any other method of obtaining work of the quality required. Precision investment casting is especially applicable in producing either exterior or interior contours of intricate form with surfaces so located that they could not be machined readily if at all. The process provides efficient, accurate means of producing such parts as turbine blades, airplane, or other parts made from alloys that have high melting points and must withstand exceptionally high temperatures, and many other products. The accuracy and finish of precision investment castings may either eliminate machining entirely or reduce it to a minimum. The quantity that may be produced economically may range from a few to thousands of duplicate parts.

Investment casting uses an expendable pattern, usually of wax or injection-molded plastics. Several wax replicas or patterns are usually joined together or to bars of wax that are shaped to form runner channels in the mold. Wax shapes that will produce pouring funnels also are fastened to the runner bars. The mold is formed by dipping the wax assembly (tree) into a thick slurry containing refractory particles. This process is known as investing. After the coating has dried, the process is repeated until a sufficient thickness of material has been built up to form a one-piece mold shell. Because the mold is in one piece, undercuts, apertures, and hollows can be produced easily. As in shell molding, this invested shell is baked to increase its strength, and the wax or plastics pattern melts and runs out or evaporates (lost-wax casting). Some molds are backed up with solid refractory material that is also dried and baked to increase the strength. Molds for lighter castings are often treated similarly to shell molds described before. Filling of the molds may take place in the atmosphere, in a chamber filled with inert gas or under vacuum, to suit the metal being cast.

**Materials That May Be Cast.**—The precision investment process may be applied to a wide range of both ferrous and nonferrous alloys. In industrial applications, these include alloys of aluminum and bronze, Stellite, Hastelloys, stainless and other alloy steels, and iron castings, especially where thick and thin sections are encountered. In producing investment castings, it is possible to control the process in various ways so as to change the porosity or density of castings, obtain hardness variations in different sections, and vary the corrosion resistance and strength by special alloying.

**General Procedure in Making Investment Castings.**—Precision investment casting is similar in principle to the “lost-wax” process that has long been used in manufacturing jewelry, ornamental pieces, and individual dentures, inlays, and other items required in dentistry, which is not discussed here. When this process is employed, both the pattern and mold used in producing the casting are destroyed after each casting operation, but they may both be replaced readily. The “dispensable patterns” (or cluster of duplicate patterns) is first formed in a permanent mold or die and is then used to form the cavity in the mold or “investment” in which the casting (or castings) is made. The investment or casting mold consists of a refractory material contained within a reinforcing steel flask. The pattern is made of wax, plastics, or a mixture of the two. The material used is evacuated from the investment to form a cavity (without parting lines) for receiving the metal to be cast. Evacuation of the pattern (by the application of sufficient heat to melt and vaporize it) and the use of a master mold or die for reproducing it quickly and accurately in making duplicate castings are distinguishing features of this casting process. Modern applications of the process include many developments such as variations in the preparation of molds, patterns, investments, etc., as well as in the casting procedure. Application of the process requires specialized knowledge and experience.

**Master Mold for Making Dispensable Patterns.**—Duplicate patterns for each casting operation are made by injecting the wax, plastics, or other pattern material into a master mold or die that usually is made either of carbon steel or of a soft metal alloy. Rubber, alloy steels, and other materials may also be used. The mold cavity commonly is designed to form a cluster of patterns for multiple castings. The mold cavity is not, as a rule, an exact duplicate of the part to be cast because it is necessary to allow for shrinkage and perhaps to compensate for distortion that might affect the accuracy of the cast product. In producing master pattern molds there is considerable variation in practice. One general method is to form the cavity by machining; another is by pouring a molten alloy around a master pattern that usually is made of monel metal or of a high-alloy stainless steel. If the cavity is not machined, a master pattern is required. Sometimes, a sample of the product itself may be used as a master pattern, when, for example, a slight reduction in size due to shrinkage is not objectionable. The dispensable pattern material, which may consist of waxes, plastics, or a combination of these materials, is injected into the mold by pressure, by gravity, or by the centrifugal method. The mold is made in sections to permit removal of the dispensable pattern. The mold while in use may be kept at the correct temperature by electrical means, by steam heating, or by a water jacket.

**Shrinkage Allowances for Patterns.**—The shrinkage allowance varies considerably for different materials. In casting accurate parts, experimental preliminary casting operations may be necessary to determine the required shrinkage allowance and possible effects of distortion. Shrinkage allowances, in inches per inch, usually average about 0.022 for steel, 0.012 for gray iron, 0.016 for brass, 0.012 to 0.022 for bronze, 0.014 for aluminum and magnesium alloys. (See also *Shrinkage Allowances* on page 1369.)

**Casting Dimensions and Tolerances.**—Generally, dimensions on investment castings can be held to  $\pm 0.005$  in. and on specified dimensions to as low as  $\pm 0.002$  in. Many factors, such as the grade of refractory used for the initial coating on the pattern, the alloy composition, and the pouring temperature, affect the cast surface finish. Surface discontinuities on the as-cast products therefore can range from 30 to 300 microinches in height.

**Investment Materials.**—For investment casting of materials having low melting points, a mixture of plaster of Paris and powdered silica in water may be used to make the molds, the silica forming the refractory and the plaster acting as the binder. To cast materials having high melting points, the refractory may be changed to sillimanite, an alumina-silicate material having a low coefficient of expansion that is mixed with powdered silica as the binder. Powdered silica is then used as the binder. The interior surfaces of the mold are reproduced on the casting so, when fine finishes are needed, a first coating of fine sillimanite sand and a silicon ester such as ethyl silicate with a small amount of piperidine, is

applied and built up to a thickness of about 0.06 in. This investment is covered with a coarser grade of refractory that acts to improve bonding with the main refractory coatings, before the back up coatings are applied.

With light castings, the invested material may be used as a shell, without further reinforcement. With heavy castings the shell is placed in a larger container which may be of thick waxed paper or card, and further slurry is poured around it to form a thicker mold of whatever proportions are needed to withstand the forces generated during pouring and solidification. After drying in air for several hours, the invested mold is passed through an oven where it is heated to a temperature high enough to cause the wax to run out. When pouring is to take place, the mold is pre-heated to between 700 and 1000°C, to get rid of any remaining wax, to harden the binder and prepare for pouring the molten alloy. Pouring metal into a hot mold helps to ensure complete filling of intricate details in the castings. Pouring may be done under gravity, under a vacuum under pressure, or with a centrifuge. When pressure is used, attention must be paid to mold permeability to ensure gases can escape as the metal enters the cavities.

**Casting Operations.**—The temperature of the flask for casting may range all the way from a chilled condition up to 2000 degrees F or higher, depending upon the metal to be cast, the size and shape of the casting or cluster, and the desired metallurgical conditions. During casting, metals are nearly always subjected to centrifugal force vacuum, or other pressure. The procedure is governed by the kind of alloy, the size of the investment cavity, and its contours or shape.

**Investment Removal.**—When the casting has solidified, the investment material is removed by destroying it. Some investments are soluble in water, but those used for ferrous castings are broken by using pneumatic tools, hammers, or by shot or abrasive blasting and tumbling to remove all particles. Gates, sprues, and runners may be removed from the castings by an abrasive cutting wheel or a band saw according to the shape of the cluster and machinability of the material.

**Accuracy of Investment Castings.**—The accuracy of precision investment castings may, in general, compare favorably with that of many machined parts. The overall tolerance varies with the size of the work, the kind of metal and the skill and experience of the operators. Under normal conditions, tolerances may vary from  $\pm 0.005$  or  $\pm 0.006$  inch per inch, down to  $\pm 0.0015$  to  $\pm 0.002$  inch per inch, and even smaller tolerances are possible on very small dimensions. Where tolerances applying to a lengthwise dimension must be smaller than would be normal for the casting process, the casting gate may be placed at one end to permit controlling the length by a grinding operation when the gate is removed.

**Casting Weights and Sizes.**—Investment castings may vary in weight from a fractional part of an ounce up to 75 pounds or more. Although the range of weights representing the practice of different firms specializing in investment casting may vary from about  $\frac{1}{2}$  pound up to 10 or 20 pounds, a practical limit of 10 or 15 pounds is common. The length of investment castings ordinarily does not exceed 12 or 15 inches, but much longer parts may be cast. It is possible to cast sections having a thickness of only a few thousandths of an inch, but the preferred minimum thickness, as a general rule, is about 0.020 inch for alloys of high castability and 0.040 inch for alloys of low castability.

**Design for Investment Casting.**—As with most casting processes, best results from investment casting are achieved when uniform wall thicknesses between 0.040 and 0.375 in. are used for both cast components and channels forming runners in the mold. Gradual transition from thick to thin sections is also desirable. It is important that molten metal should not have to pass through a thin section to fill a thick part of the casting. Thin edges should be avoided because of the difficulty of producing them in the wax pattern. Fillets should be used in all internal corners to avoid stress concentrations that usually accompany sharp angles. Thermal contraction usually causes distortion of the casting, and should be allowed for if machining is to be minimized. Machining allowances vary from 0.010 in. on

small, to 0.040 in. on large parts. With proper arrangement of castings in the mold, grain size and orientation can be controlled and directional solidification can often be used to advantage to ensure desired physical properties in the finished components.

**Casting Milling Cutters by Investment Method.**—Possible applications of precision investment casting in tool manufacture and in other industrial applications are indicated by its use in producing high-speed steel milling cutters of various forms and sizes. Removal of the risers, sand blasting to improve the appearance, and grinding the cutting edges are the only machining operations required. The bore is used as cast. Numerous tests have shown that the life of these cutters compares favorably with high-speed steel cutters made in the usual way.

### Extrusion of Metals

**The Basic Process.**—Extrusion is a metalworking process used to produce long, straight semifinished products such as bars, tubes, solid and hollow sections, wire and strips by squeezing a solid slug of metal, either cast or wrought, from a closed container through a die. An analogy to the process is the dispensing of toothpaste from a collapsible tube.

During extrusion, compressive and shear, but no tensile, forces are developed in the stock, thus allowing the material to be heavily deformed without fracturing. The extrusion process can be performed at either room or high temperature, depending on the alloy and method. Cross sections of varying complexity can also be produced, depending on the materials and dies used.

In the specially constructed presses used for extrusion, the load is transmitted by a ram through an intermediate dummy block to the stock. The press container is usually fitted with a wear-resistant liner and is constructed to withstand high radial loads. The die stack consists of the die, die holder, and die backer, all of which are supported in the press end housing or platen, which resists the axial loads.

The following are characteristics of different extrusion methods and presses: 1) The movement of the extrusion relative to the ram. In "direct extrusion," the ram is advanced toward the die stack; in "indirect extrusion," the die moves down the container bore; 2) The position of the press axis, which is either horizontal or vertical; 3) The type of drive, which is either hydraulic or mechanical; and 4) The method of load application, which is either conventional or hydrostatic.

In forming a hollow extrusion, such as a tube, a mandrel integral with the ram is pushed through the previously pierced raw billet.

**Cold Extrusion:** Cold extrusion has often been considered a separate process from hot extrusion; however, the only real difference is that cold or only slightly warm billets are used as starting stock. Cold extrusion is not limited to certain materials; the only limiting factor is the stresses in the tooling. In addition to the soft metals such as lead and tin, aluminum alloys, copper, zirconium, titanium, molybdenum, beryllium, vanadium, niobium, and steel can be extruded cold or at low deformation temperatures. Cold extrusion has many advantages, such as no oxidation or gas/metal reactions; high mechanical properties due to cold working if the heat of deformation does not initiate recrystallization; narrow tolerances; good surface finish if optimum lubrication is used; fast extrusion speeds can be used with alloys subject to hot shortness.

Examples of cold extruded parts are collapsible tubes, aluminum cans, fire extinguisher cases, shock absorber cylinders, automotive pistons, and gear blanks.

**Hot Extrusion:** Most hot extrusion is performed in horizontal hydraulic presses rated in size from 250 to 12,000 tons. The extrusions are long pieces of uniform cross sections, but complex cross sections are also produced. Most types of alloys can be hot extruded.

Owing to the temperatures and pressures encountered in hot extrusion, the major problems are the construction and the preservation of the equipment. The following are approximate temperature ranges used to extrude various types of alloys: magnesium, 650–850

degrees F; aluminum, 650–900 degrees F; copper, 1200–2000 degrees F; steel, 2200–2400 degrees F; titanium, 1300–2100 degrees F; nickel 1900–2200 degrees F; refractory alloys, up to 4000 degrees F. In addition, pressures range from as low as 5000 to over 100,000 psi. Therefore, lubrication and protection of the chamber, ram, and die are generally required. The use of oil and graphite mixtures is often sufficient at the lower temperatures; while at higher temperatures, glass powder, which becomes a molten lubricant, is used.

*Extrusion Applications:* The stress conditions in extrusion make it possible to work materials that are brittle and tend to crack when deformed by other primary metalworking processes. The most outstanding feature of the extrusion process, however, is its ability to produce a wide variety of cross-sectional configurations; shapes can be extruded that have complex, nonuniform, and nonsymmetrical sections that would be difficult or impossible to roll or forge. Extrusions in many instances can take the place of bulkier, more costly assemblies made by welding, bolting, or riveting. Many machining operations may also be reduced through the use of extruded sections. However, as extrusion temperatures increase, processing costs also increase, and the range of shapes and section sizes that can be obtained becomes narrower.

While many asymmetrical shapes are produced, symmetry is the most important factor in determining extrudability. Adjacent sections should be as nearly equal as possible to permit uniform metal flow through the die. The length of their protruding legs should not exceed 10 times their thickness.

The size and weight of extruded shapes are limited by the section configuration and properties of the material extruded. The maximum size that can be extruded on a press of a given capacity is determined by the "circumscribing circle," which is defined as the smallest diameter circle that will enclose the shape. This diameter controls the die size, which in turn is limited by the press size. For instance, the larger presses are generally capable of extruding aluminum shapes with a 25-in.-diameter circumscribing circle and steel and titanium shapes with about 22-in.-diameter circle.

The minimum cross-sectional area and minimum thickness that can be extruded on a given size press are dependent on the properties of the material, the extrusion ratio (ratio of the cross-sectional area of the billet to the extruded section), and the complexity of shape. As a rule thicker sections are required with increased section size.

The following table gives the approximate minimum cross section and minimum thickness of some commonly extruded metals.

| Material                | Minimum Cross Section (sq in.) | Minimum Thickness (in.) |
|-------------------------|--------------------------------|-------------------------|
| Carbon and alloy steels | 0.40                           | 0.120                   |
| Stainless steels        | 0.45-0.70                      | 0.120-0.187             |
| Titanium                | 0.50                           | 0.150                   |
| Aluminum                | <0.40                          | 0.040                   |
| Magnesium               | <0.40                          | 0.040                   |

Extruded shapes minimize and sometimes eliminate the need for machining; however, they do not have the dimensional accuracy of machined parts. Smooth surfaces with finishes better than 30  $\mu\text{in. rms}$  are attainable in magnesium and aluminum; an extruded finish of 125  $\mu\text{in. rms}$  is generally obtained with most steels and titanium alloys. Minimum corner and fillet radii of  $\frac{1}{64}$  in. are preferred for aluminum and magnesium alloys; while for steel, minimum corner radii of 0.030 in. and fillet radii of 0.125 in. are typical.

*Extrusion of Tubes:* In tube extrusion, the metal passes through a die, which determines its outer diameter, and around a central mandrel, which determines its inner diameter. Either solid or hollow billets may be used, with the solid billet being used most often. When a solid billet is extruded, the mandrel must pierce the billet by pushing axially through it before the metal can pass through the annular gap between the die and the man-

drel. Special presses are used in tube extrusion to increase the output and improve the quality compared to what is obtained using ordinary extrusion presses. These special hydraulic presses independently control ram and mandrel positioning and movement.

### **Powder Metallurgy**

Powder metallurgy is a process whereby metal parts in large quantities can be made by the compressing and sintering of various powdered metals such as brass, bronze, aluminum, and iron. Compressing of the metal powder into the shape of the part to be made is done by accurately formed dies and punches in special types of hydraulic or mechanical presses. The "green" compressed pieces are then sintered in an atmosphere controlled furnace at high temperatures, causing the metal powder to be bonded together into a solid mass. A subsequent sizing or pressing operation and supplementary heat treatments may also be employed. The physical properties of the final product are usually comparable to those of cast or wrought products of the same composition. Using closely controlled conditions, steel of high hardness and tensile strength has also been made by this process.

Any desired porosity from 5 to 50 per cent can be obtained in the final product. Large quantities of porous bronze and iron bearings, which are impregnated with oil for self-lubrication, have been made by this process. Other porous powder metal products are used for filtering liquids and gases. Where continuous porosity is desired in the final product, the voids between particles are kept connected or open by mixing one per cent of zinc stearate or other finely powdered metallic soap throughout the metal powder before briquetting and then boiling this out in a low temperature baking before the piece is sintered.

The dense type of powdered metal products include refractory metal wire and sheet, cemented carbide tools, and electrical contact materials (products which could not be made as satisfactorily by other processes) and gears or other complex shapes which might also have been made by die casting or the precise machining of wrought or cast metal.

**Advantages of Powder Metallurgy.**—Parts requiring irregular curves, eccentrics, radial projections, or recesses often can be produced only by powder metallurgy. Parts that require irregular holes, keyways, flat sides, splines or square holes that are not easily machined, can usually be made by this process. Tapered holes and counter-bores are easily produced. Axial projections can be formed but the permissible size depends on the extent to which the powder will flow into the die recesses. Projections not more than one-quarter the length of the part are practicable. Slots, grooves, blind holes, and recesses of varied depths are also obtainable.

**Limiting Factors in Powdered Metal Process.**—The number and variety of shapes that may be obtained are limited by lack of plastic flow of powders, i.e., the difficulty with which they can be made to flow around corners. Tolerances in diameter usually cannot be held closer than 0.001 inch and tolerances in length are limited to 0.005 inch. This difference in diameter and length tolerances may be due to the elasticity of the powder and spring of the press.

**Factors Affecting Design of Briquetting Tools.**—High-speed steel is recommended for dies and punches and oil-hardening steel for strippers and knock-outs. One manufacturer specifies dimensional tolerances of 0.0002 inch and super-finished surfaces for these tools. Because of the high pressures employed and the abrasive character of certain refractory materials used in some powdered metal composition, there is frequently a tendency toward severe wear of dies and punches. In such instances, carbide inserts, chrome plating, or highly resistant die steels are employed. With regard to the shape of the die, corner radii, fillets, and bevels should be used to avoid sharp corners. Feather edges, threads, and reentrant angles are usually impracticable. The making of punches and dies is particularly exacting because allowances must be made for changes in dimensions due to growth after pressing and shrinkage or growth during sintering.

## SOLDERING AND BRAZING

Metals may be joined without using fasteners by employing soldering, brazing, and welding. Soldering involves the use of a non-ferrous metal whose melting point is below that of the base metal and in all cases below 800 degrees F. Brazing entails the use of a non-ferrous filler metal with a melting point below that of the base metal but above 800 degrees F. In fusion welding, abutting metal surfaces are made molten, are joined in the molten state, and then allowed to cool. The use of a filler metal and the application of pressure are considered to be optional in the practice of fusion welding.

### Soldering

Soldering employs lead- or tin-base alloys with melting points below 800 degrees F and is commonly referred to as soft soldering. Use of hard solders, silver solders and spelter solders which have silver, copper, or nickel bases and have melting points above 800 degrees F is known as brazing. Soldering is used to provide a convenient joint that does not require any great mechanical strength. It is used in a great many instances in combination with mechanical staking, crimping or folding, the solder being used only to seal against leakage or to assure electrical contact. The accompanying table, page 1381, gives some of the properties and uses of various solders that are generally available.

**Forms Available.**—Soft solders can be obtained in bar, cake, wire, pig, slab ingot, ribbon, segment, powder, and foil-form for various uses to which they are put. In bar form they are commonly used for hand soldering. The pigs, ingots, and slabs are used in operations that employ melting kettles. The ribbon, segment, powder and foil forms are used for special applications and the cake form is used for wiping. Wire forms are either solid or they contain acid or rosin cores for fluxing. These wire forms, both solid and core containing, are used in hand and automatic machine applications. Prealloyed powders, suspended in a fluxing medium, are frequently applied by brush and, upon heating, consistently wet the solderable surfaces to produce a satisfactory joint.

**Fluxes for Soldering.**—The surfaces of the metals being joined in the soldering operation must be clean in order to obtain an efficient joint. Fluxes clean the surfaces of the metal in the joint area by removing the oxide coating present, keep the area clean by preventing formation of oxide films, and lower the surface tension of the solder thereby increasing its wetting properties. Rosin, tallow, and stearin are mild fluxes which prevent oxidation but are not too effective in removing oxides present. Rosin is used for electrical applications since the residue is non-corrosive and non-conductive. Zinc chloride and ammonium chloride (sal ammoniac), used separately or in combination, are common fluxes that remove oxide films readily. The residue from these fluxes may in time cause trouble, due to their corrosive effects, if they are not removed or neutralized. Washing with water containing about 5 ounces of sodium citrate (for non-ferrous soldering) or 1 ounce of trisodium phosphate (for ferrous and non-ferrous soldering) per gallon followed by a clear water rinse or washing with commercial water-soluble detergents are methods of inactivating and removing this residue.

**Methods of Application.**—Solder is applied using a soldering iron, a torch, a solder bath, electric induction or resistance heating, a stream of hot neutral gas or by wiping. Clean surfaces which are hot enough to melt the solder being applied or accept molten solder are necessary to obtain a good clean bond. Parts being soldered should be free of oxides, dirt, oil, and scale. Scraping and the use of abrasives as well as fluxes are resorted to for preparing surfaces for soldering. The procedures followed in soldering aluminum, magnesium and stainless steel differ somewhat from conventional soldering techniques and are indicated in the material which follows

*Soldering Aluminum:* Two properties of aluminum which tend to make it more difficult to solder are its high thermal conductivity and the tenacity of its ever-present oxide film.

## Properties of Soft Solder Alloys Appendix, ASTM:B 32-70

| Nominal Composition <sup>a</sup><br>Per Cent |      |     |     | Specific<br>Gravity <sup>b</sup> | Melting Ranges, <sup>c</sup><br>Degrees Fahrenheit |          | Uses   |

| 1  | 97.5 | ... | 1.5 | 11.28                            | 588  | 588      | For use on copper, brass, and similar metals with torch heating.   |

<sup>a</sup> Abbreviations of alloying elements are as follows: Sn, tin; Pb, lead; Sb, antimony; and Ag, silver.

<sup>b</sup> The specific gravity multiplied by 0.0361 equals the density in pounds per cubic inch.

<sup>c</sup> The alloys are completely solid below the lower point given, designated "solidus," and completely liquid above the higher point given, designated "liquidus." In the range of temperatures between these two points the alloys are partly solid and partly liquid.

<sup>d</sup> For some engineering design purposes, it is well to consider these alloys as having practically no mechanical strength above 360 degrees F.

Aluminum soldering is performed in a temperature range of from 550 to 770 degrees F, compared to 375 to 400 degrees F temperature range for ordinary metals, because of the metal's high thermal conductivity. Two methods can be used, one using flux and one using abrasion. The method employing flux is most widely used and is known as flow soldering. In this method flux dissolves the aluminum oxide and keeps it from re-forming. The flux should be fluid at soldering temperatures so that the solder can displace it in the joint. In the friction method the oxide film is mechanically abraded with a soldering iron, wire brush, or multi-toothed tool while being covered with molten solder. The molten solder keeps the oxygen in the atmosphere from reacting with the newly-exposed aluminum surface; thus wetting of the surface can take place.

The alloys that are used in soldering aluminum generally contain from 50 to 75 per cent tin with the remainder zinc.

The following aluminum alloys are listed in order of ease of soldering: commercial and high-purity aluminum; wrought alloys containing not more than 1 per cent manganese or magnesium; and finally the heat-treatable alloys which are the most difficult.

Cast and forged aluminum parts are not generally soldered.

**Soldering Magnesium:** Magnesium is not ordinarily soldered to itself or other metals. Soldering is generally used for filling small surface defects, voids or dents in castings or sheets where the soldered area is not to be subjected to any load. Two solders can be used: one with a composition of 60 per cent cadmium, 30 per cent zinc, and 10 per cent tin has a melting point of 315 degrees F; the other has a melting point of 500 degrees F and has a nominal composition of 90 per cent cadmium and 10 per cent zinc.

The surfaces to be soldered are cleaned to a bright metallic luster by abrasive methods before soldering. The parts are preheated with a torch to the approximate melting temperature of the solder being used. The solder is applied and the surface under the molten solder is rubbed vigorously with a sharp pointed tool or wire brush. This action results in the wetting of the magnesium surface. To completely wet the surface, the solder is kept molten and the rubbing action continued. The use of flux is not recommended.

**Soldering Stainless Steel:** Stainless steel is somewhat more difficult to solder than other common metals. This is true because of a tightly adhering oxide film on the surface of the metal and because of its low thermal conductivity. The surface of the stainless steel must be thoroughly cleaned. This can be done by abrasion or by clean white pickling with acid. Muriatic (hydrochloric) acid saturated with zinc or combinations of this mixture and 25 per cent additional muriatic acid, or 10 per cent additional acetic acid, or 10 to 20 per cent additional water solution of orthophosphoric acid may all be used as fluxes for soldering stainless steel. Tin-lead solder can be used successfully. Because of the low thermal conductivity of stainless steel, a large soldering iron is needed to bring the surfaces to the proper temperature. The proper temperature is reached when the solder flows freely into the area of the joint. Removal of the corrosive flux is important in order to prevent joint failure. Soap and water or a commercial detergent may be used to remove the flux residue.
