**Circular Thickness of Tooth when Outside Diameter has been Enlarged.**—When the outside diameter of a small pinion is not standard but is enlarged to avoid undercut and to improve tooth action, the teeth are located farther out radially relative to the standard pitch diameter and consequently the circular tooth thickness at the standard pitch diameter is increased. To find this increased arc thickness the following formula is used, where  $t$  = tooth thickness;  $e$  = amount outside diameter is increased over standard;  $\phi$  = pressure angle; and  $p$  = circular pitch at the standard pitch diameter.

$$t = \frac{p}{2} + e \tan \phi$$

*Example:* The outside diameter of a pinion having 10 teeth of 5 diametral pitch and a pressure angle of  $14\frac{1}{2}$  degrees is to be increased by 0.2746 inch. The circular pitch equivalent to 5 diametral pitch is 0.6283 inch. Find the arc tooth thickness at the standard pitch diameter.

$$t = \frac{0.6283}{2} + (0.2746 \times \tan 14\frac{1}{2}^\circ)$$

$$t = 0.3142 + (0.2746 \times 0.25862) = 0.3852 \text{ inch}$$

**Circular Thickness of Tooth when Outside Diameter has been Reduced.**—If the outside diameter of a gear is reduced, as is frequently done to maintain the standard center distance when the outside diameter of the mating pinion is increased, the circular thickness of the gear teeth at the standard pitch diameter will be reduced. This decreased circular thickness can be found by the following formula where  $t$  = circular thickness at the standard pitch diameter;  $e$  = amount outside diameter is reduced under standard;  $\phi$  = pressure angle; and  $p$  = circular pitch.

$$t = \frac{p}{2} - e \tan \phi$$

*Example:* The outside diameter of a gear having a pressure angle of  $14\frac{1}{2}$  degrees is to be reduced by 0.2746 inch or an amount equal to the increase in diameter of its mating pinion. The circular pitch is 0.6283 inch. Determine the circular tooth thickness at the standard pitch diameter.

$$t = \frac{0.6283}{2} - (0.2746 \times \tan 14\frac{1}{2}^\circ)$$

$$t = 0.3142 - (0.2746 \times 0.25862) = 0.2432 \text{ inch}$$

**Chordal Thickness of Tooth when Outside Diameter is Standard.**—To find the chordal or straight line thickness of a gear tooth the following formula can be used where  $t_c$  = chordal thickness;  $D$  = pitch diameter; and  $N$  = number of teeth.

$$t_c = D \sin\left(\frac{90^\circ}{N}\right)$$

*Example:* A pinion has 15 teeth of 3 diametral pitch; the pitch diameter is equal to  $15 \div 3$  or 5 inches. Find the chordal thickness at the standard pitch diameter.

$$t_c = 5 \sin\left(\frac{90^\circ}{15}\right) = 5 \sin 6^\circ = 5 \times 0.10453 = 0.5226 \text{ inch}$$

### Chordal Thicknesses and Chordal Addenda of Milled, Full-depth Gear Teeth and of Gear Milling Cutters

$T$  = chordal thickness of gear tooth and cutter tooth at pitch line;  
 $H$  = chordal addendum for full-depth gear tooth;  
 $A$  = chordal addendum of cutter =  $(2.157 \div \text{diametral pitch}) - H$   
 $= (0.6866 \times \text{circular pitch}) - H$ .

| Diametral Pitch | Dimension | Number of Gear Cutter, and Corresponding Number of Teeth |                   |                   |                   |                   |                   |                   |                   |

**Chordal Thickness of Tooth when Outside Diameter is Special.**—When the outside diameter is larger or smaller than standard the chordal thickness at the standard pitch diameter is found by the following formula where  $t_c$  = chordal thickness at the standard pitch diameter  $D$ ;  $t$  = circular thickness at the standard pitch diameter of the enlarged pinion or reduced gear being measured.

$$t_c = t - \frac{t^3}{6 \times D^2}$$

*Example 1:* The outside diameter of a pinion having 10 teeth of 5 diametral pitch has been enlarged by 0.2746 inch. This enlargement has increased the circular tooth thickness at the standard pitch diameter (as determined by the formula previously given) to 0.3852 inch. Find the equivalent chordal thickness.

$$t_c = 0.3852 - \frac{0.3852^3}{6 \times 2^2} = 0.3852 - 0.0024 = 0.3828 \text{ inch}$$

(The error introduced by rounding the circular thickness to three significant figures before cubing it only affects the fifth decimal place in the result.)

*Example 2:* A gear having 30 teeth is to mesh with the pinion in [Example 1](#) and is reduced so that the circular tooth thickness at the standard pitch diameter is 0.2432 inch. Find the equivalent chordal thickness.

$$t_c = 0.2432 - \frac{0.2432^3}{6 \times 6^2} = 0.2432 - 0.00007 = 0.2431 \text{ inch}$$

**Chordal Addendum.**—In measuring the chordal thickness, the vertical scale of a gear tooth caliper is set to the chordal or “corrected” addendum to locate the caliper jaws at the pitch line (see *Method of setting a gear tooth caliper* on page 2052). The simplified formula which follows may be used in determining the chordal addendum either when the addendum is standard for full-depth or stub teeth or when the addendum is either longer or shorter than standard as in case of an enlarged pinion or a gear which is to mesh with an enlarged pinion and has a reduced addendum to maintain the standard center distance. If  $a_c$  = chordal addendum;  $a$  = addendum; and  $t$  = circular thickness of tooth at pitch diameter  $D$ ; then,

$$a_c = a + \frac{t^2}{4D}$$

*Example 1:* The outside diameter of an 8 diametral pitch 14-tooth pinion with 20-degree full-depth teeth is to be increased by using an enlarged addendum of  $1.234 \div 8 = 0.1542$  inch (see [Table 7](#) on page 2050). The basic tooth thickness of the enlarged pinion is  $1.741 \div 8 = 0.2176$  inch. What is the chordal addendum?

$$\text{Chordal addendum} = 0.1542 + \frac{0.2176^2}{4 \times (14 \div 8)} = 0.1610 \text{ inch}$$

*Example 2:* The outside diameter of a 14½-degree pinion having 12 teeth of 2 diametral pitch is to be enlarged 0.624 inch to avoid undercut (see [Table 8](#) on page 2050), thus increasing the addendum from 0.5000 to 0.8120 inch and the arc thickness at the pitch line from 0.7854 to 0.9467 inch. Then,

$$\text{Chordal addendum of pinion} = 0.8120 + \frac{0.9467^2}{4 \times (12 \div 2)} = 0.8493 \text{ inch}$$

**Table 7. Addendums and Tooth Thicknesses for Coarse-Pitch Long-Addendum Pinions and their Mating Short-Addendum Gears—20- and 25-degree Pressure Angles ANSI B6.1-1968 (R1974)**

| Number of Teeth in Pinion   | Addendum |       | Basic Tooth Thickness |       | Number of Teeth in Gear |
|---|----------|-------|-----------------------|-------|-------------------------|
|   | Pinion   | Gear  | Pinion                | Gear  |                         |
| $N_p$   | $a_p$    | $a_G$ | $t_p$                 | $t_G$ | $N_G$ (min)             |
| 20-Degree Involute Full Depth Tooth Form (Less than 20 Diametral Pitch) |          |       |                       |       |                         |
| 10  | 1.468    | .532  | 1.912                 | 1.230 | 25                      |
| 11  | 1.409    | .591  | 1.868                 | 1.273 | 24                      |
| 12  | 1.351    | .649  | 1.826                 | 1.315 | 23                      |
| 13  | 1.292    | .708  | 1.783                 | 1.358 | 22                      |
| 14  | 1.234    | .766  | 1.741                 | 1.400 | 21                      |
| 15  | 1.175    | .825  | 1.698                 | 1.443 | 20                      |
| 16  | 1.117    | .883  | 1.656                 | 1.486 | 19                      |
| 17  | 1.058    | .942  | 1.613                 | 1.529 | 18                      |
| 25-Degree Involute Full Depth Tooth Form (Less than 20 Diametral Pitch) |          |       |                       |       |                         |
| 10  | 1.184    | .816  | 1.742                 | 1.399 | 15                      |
| 11  | 1.095    | .905  | 1.659                 | 1.482 | 14                      |

All values are for 1 diametral pitch. For any other sizes of teeth all linear dimensions should be divided by the diametral pitch. Basic tooth thicknesses do not include an allowance for backlash.

**Table 8. Enlarged Pinion and Reduced Gear Dimensions to Avoid Interference Coarse Pitch 14½-degree Involute Full Depth Teeth**

| Number of Pinion Teeth | Changes in Pinion and Gear Diameters | Circular Tooth Thickness |             | Min. No. of Teeth in Mating Gear |                          |
|------------------------|--------------------------------------|--------------------------|-------------|----------------------------------|--------------------------|
|                        |                                      | Pinion                   | Mating Gear | To Avoid Undercut                | For Full Involute Action |

| 25                     | 0.4328                               | 1.6827                   | 1.4589      | 39                               | 26                       |
| 26                     | 0.3701                               | 1.6665                   | 1.4751      | 38                               | 26                       |
| 27                     | 0.3074                               | 1.6503                   | 1.4913      | 37                               | 26                       |
| 28                     | 0.2447                               | 1.6341                   | 1.5075      | 36                               | 25                       |
| 29                     | 0.1820                               | 1.6179                   | 1.5237      | 35                               | 25                       |
| 30                     | 0.1193                               | 1.6017                   | 1.5399      | 34                               | 24                       |
| 31                     | 0.0566                               | 1.5854                   | 1.5562      | 33                               | 24                       |

All dimensions are given in inches and are for 1 diametral pitch. For other pitches divide tabular values by desired diametral pitch.

Add to the standard outside diameter of the pinion the amount given in the second column of the table divided by the desired diametral pitch, and (to maintain standard center distance) subtract the same amount from the outside diameter of the mating gear. Long addendum pinions will mesh with standard gears, but the center distance will be greater than standard.

*Example 3:* The outside diameter of the mating gear for the pinion in [Example 3](#) is to be reduced 0.624 inch. The gear has 60 teeth and the addendum is reduced from 0.5000 to 0.1881 inch (to maintain the standard center distance), thus reducing the arc thickness to 0.6240 inch. Then,

$$\text{Chordal addendum of gear} = 0.1881 + \frac{0.6240^2}{4 \times (60 \div 2)} = 0.1913 \text{ inch}$$

When a gear addendum is reduced as much as the mating pinion addendum is enlarged, the minimum number of gear teeth required to prevent undercutting depends upon the enlargement of the mating pinion. To illustrate, if a 14½-degree pinion with 13 teeth is enlarged 1.185 inches, then the reduced mating gear should have a minimum of 51 teeth to avoid undercut (see [Table 8](#) on page 2050).

**Tables for Chordal Thicknesses and Chordal Addenda of Milled, Full-depth Teeth.**—Two convenient tables for checking gears with milled, full-depth teeth are given on pages 2047 and 2048. The first shows chordal thicknesses and chordal addenda for the lowest number of teeth cut by gear cutters Nos. 1 through 8, and for the commonly used diametral pitches. The second gives similar data for commonly used circular pitches. In each case the data shown are accurate for the number of gear teeth indicated, but are approximate for other numbers of teeth within the range of the cutter under which they appear in the table. For the higher diametral pitches and lower circular pitches, the error introduced by using the data for any tooth number within the range of the cutter under which it appears is comparatively small. The chordal thicknesses and chordal addenda for gear cutters Nos. 1 through 8 of the more commonly used diametral and circular pitches can be obtained from the table and formulas on pages 2047 and 2048.

**Caliper Measurement of Gear Tooth.**—In cutting gear teeth, the general practice is to adjust the cutter or hob until it grazes the outside diameter of the blank; the cutter is then sunk to the total depth of the tooth space plus whatever slight additional amount may be required to provide the necessary play or backlash between the teeth. (For recommendations concerning backlash and excess depth of cut required, see *Backlash* starting on page 2067.) If the outside diameter of the gear blank is correct, the tooth thickness should also be correct after the cutter has been sunk to the depth required for a given pitch and backlash. However, it is advisable to check the tooth thickness by measuring it, and the vernier gear-tooth caliper (see following illustration) is commonly used in measuring the thickness.

The vertical scale of this caliper is set so that when it rests upon the top of the tooth as shown, the lower ends of the caliper jaws will be at the height of the pitch circle; the horizontal scale then shows the chordal thickness of the tooth at this point. If the gear is being cut on a milling machine or with the type of gear-cutting machine employing a formed milling cutter, the tooth thickness is checked by first taking a trial cut for a short distance at one side of the blank; then the gear blank is indexed for the next space and another cut is taken far enough to mill the full outline of the tooth. The tooth thickness is then measured.

Before the gear-tooth caliper can be used, it is necessary to determine the correct chordal thickness and also the chordal addendum (or “corrected addendum” as it is sometimes called). The vertical scale is set to the chordal addendum, thus locating the ends of the jaws at the height of the pitch circle. The rules or formulas to use in determining the chordal thickness and chordal addendum will depend upon the outside diameter of the gear; for example, if the outside diameter of a small pinion is enlarged to avoid undercut and improve the tooth action, this must be taken into account in figuring the chordal thickness and chordal addendum as shown by the accompanying rules. The detail of a gear tooth included with the gear-tooth caliper illustration, represents the chordal thickness  $T$ , the addendum  $S$ , and the chordal addendum  $H$ . For the caliper measurements over two or more teeth see *Checking Spur Gear Size by Chordal Measurement Over Two or More Teeth* starting on page 2140.

## SPUR GEARING

Method of setting a gear tooth caliper

**Selection of Involute Gear Milling Cutter for a Given Diametral Pitch and Number of Teeth.**—When gear teeth are cut by using formed milling cutters, the cutter must be selected to suit both the pitch and the number of teeth, because the shapes of the tooth spaces vary according to the number of teeth. For instance, the tooth spaces of a small pinion are not of the same shape as the spaces of a large gear of equal pitch. Theoretically, there should be a different formed cutter for every tooth number, but such refinement is unnecessary in practice. The involute formed cutters commonly used are made in series of eight cutters for each diametral pitch (see *Series of Involute, Finishing Gear Milling Cutters for Each Pitch*). The shape of each cutter in this series is correct for a certain number of teeth only, but it can be used for other numbers within the limits given. For instance, a No. 6 cutter may be used for gears having from 17 to 20 teeth, but the tooth outline is correct only for 17 teeth or the lowest number in the range, which is also true of the other cutters listed. When this cutter is used for a gear having, say, 19 teeth, too much material is removed from the upper surfaces of the teeth, although the gear meets ordinary requirements. When greater accuracy of tooth shape is desired to ensure smoother or quieter operation, an intermediate series of cutters having half-numbers may be used provided the number of gear teeth is between the number listed for the regular cutters (see *Series of Involute, Finishing Gear Milling Cutters for Each Pitch*).

Involute gear milling cutters are designed to cut a composite tooth form, the center portion being a true involute while the top and bottom portions are cycloidal. This composite form is necessary to prevent tooth interference when milled mating gears are meshed with each other. Because of their composite form, milled gears will not mate satisfactorily enough for high grade work with those of generated, full-involute form. Composite form hobs are available, however, which will produce generated gears that mesh with those cut by gear milling cutters.

*Metric Module Gear Cutters:* The accompanying table for selecting the cutter number to be used to cut a given number of teeth may be used also to select metric module gear cutters except that the numbers are designated in reverse order. For example, cutter No. 1, in the metric module system, is used for 12–13 teeth, cutter No. 2 for 14–16 teeth, etc.

**Increasing Pinion Diameter to Avoid Undercut or Interference.**—On coarse-pitch pinions with small numbers of teeth (10 to 17 for 20-degree and 10 and 11 for 25-degree pressure angle involute tooth forms) undercutting of the tooth profile or fillet interference with the tip of the mating gear can be avoided by making certain changes from the standard tooth proportions that are specified in [Table 3](#) on page 2038. These changes consist essen-

**Circular Pitch in Gears—Pitch Diameters, Outside Diameters, and Root Diameters**

For any particular circular pitch and number of teeth, use the table as shown in the example to find the pitch diameter, outside diameter, and root diameter. *Example:* Pitch diameter for 57 teeth of 6-inch circular pitch = 10 × pitch diameter given under factor for 5 teeth plus pitch diameter given under factor for 7 teeth. (10 × 9.5493) + 13.3690 = 108.862 inches.

Outside diameter of gear equals pitch diameter plus outside diameter factor from next-to-last column in table = 108.862 + 3.8197 = 112.682 inches.

Root diameter of gear equals pitch diameter minus root diameter factor from last column in table = 108.862 – 4.4194 = 104.443 inches.

| Circular Pitch<br>in<br>Inches | Factor for Number of Teeth                                 |        |        |        |        |         |         |         |         | Outside Dia.<br>Factor | Root<br>Diameter<br>Factor |
|--------------------------------|--|--------|--------|--------|--------|---------|---------|---------|---------|------------------------|----------------------------|

tially in increasing the addendum and hence the outside diameter of the pinion and decreasing the addendum and hence the outside diameter of the mating gear. These changes in outside diameters of pinion and gear do not change the velocity ratio or the procedures in cutting the teeth on a hobbing machine or generating type of shaper or planer.

Data in Table 7 on page 2050 are taken from ANSI Standard B6.1-1968, reaffirmed 1974, and show for 20-degree and 25-degree full-depth standard tooth forms, respectively, the addendums and tooth thicknesses for long addendum pinions and their mating short

addendum gears when the number of teeth in the pinion is as given. Similar data for former standard 14½-degree full-depth teeth (20 diametral pitch and coarser) are given in [Table 8](#) on page 2050.

*Example:* A 14-tooth, 20-degree pressure angle pinion of 6 diametral pitch is to be enlarged. What will be the outside diameters of the pinion and a 60-tooth mating gear? If the mating gear is to have the minimum number of teeth to avoid undercut, what will be its outside diameter?

$$D_o(\text{ pinion}) = \frac{N_P}{P} + 2a = \frac{14}{6} + 2\left(\frac{1.234}{6}\right) = 2.745 \text{ inches}$$

$$D_o(\text{ gear}) = \frac{N_G}{P} + 2a = \frac{60}{6} + 2\left(\frac{0.766}{6}\right) = 10.255 \text{ inches}$$

For a mating gear with minimum number of teeth to avoid undercut:

$$D_o(\text{ gear}) = \frac{N_G}{P} + 2a = \frac{21}{6} + 2\left(\frac{0.766}{6}\right) = 3.755 \text{ inches}$$

### Series of Involute, Finishing Gear Milling Cutters for Each Pitch

| Number of Cutter | Will cut Gears from | Number of Cutter | Will cut Gears from |
|------------------|---------------------|------------------|---------------------|
| 1                | 135 teeth to a rack | 5                | 21 to 25 teeth      |
| 2                | 55 to 134 teeth     | 6                | 17 to 20 teeth      |
| 3                | 35 to 54 teeth      | 7                | 14 to 16 teeth      |
| 4                | 26 to 34 teeth      | 8                | 12 to 13 teeth      |

The regular cutters listed above are used ordinarily.

The cutters listed below (an intermediate series having half numbers) may be used when greater accuracy of tooth shape is essential in cases where the number of teeth is between the numbers for which the regular cutters are intended.

| Number of Cutter | Will cut Gears from | Number of Cutter | Will cut Gears from |
|------------------|---------------------|------------------|---------------------|
| 1½               | 80 to 134 teeth     | 5½               | 19 to 20 teeth      |
| 2½               | 42 to 54 teeth      | 6½               | 15 to 16 teeth      |
| 3½               | 30 to 34 teeth      | 7½               | 13 teeth            |
| 4½               | 23 to 25 teeth      | ...              | ...                 |

Roughing cutters are made with No. 1 form only. Dimensions of roughing and finishing cutters are given on page 816. Dimensions of cutters for bevel gears are given on page 817.

*Enlarged Fine-Pitch Pinions:* American Standard ANSI B6.7–1977, Information Sheet A provides a different system for 20-degree pressure angle pinion enlargement than is used for coarse-pitch gears. Pinions with 11 through 23 teeth (9 through 14 teeth for 25-degree pressure angle) are enlarged so that a standard tooth thickness rack with addendum  $1.05/P$  will start contact 5° of roll above the base circle radius. The use of  $1.05/P$  for the addendum allows for center distance variation and eccentricity of the mating gear outside diameter; the 5° roll angle avoids the fabrication of the involute in the troublesome area near the base circle.

Pinions with less than 11 teeth (9 teeth for 25-degree pressure angle) are enlarged to the extent that the highest point of undercut coincides with the start of contact with the standard rack described previously. The height of undercut considered is that produced by a sharp-cornered 120 pitch hob. Pinions with less than 13 teeth (11 teeth for 25-degree pressure angle) are truncated to provide a top land of  $0.275/P$ . Data for enlarged pinions may be found in [Tables 9a, 9b, 9c, and 9d](#).

$\Delta$  = increase in standard dedendum to provide increased clearance. See footnote to Table 9d.

<sup>a</sup> If enlarged mating pinions are of unequal size, the center distance is increased by an amount equal to one-half the sum of their increase over standard outside diameters. Data in this column are not given in the standard.

<sup>b</sup> To maintain standard center distance when using an enlarged pinion, the mating gear diameter must be decreased by the amount of the pinion enlargement.

All dimensions are given in inches and are for 1 diametral pitch. For other pitches divide tabulated dimensions by the diametral pitch.

<sup>a</sup>Caution should be exercised in the use of pinions above the horizontal lines. They should be checked for suitability, particularly in the areas of contact ratio (less than 1.2 is not recommended), center distance, clearance, and tooth strength.

<sup>b</sup>The actual dedendum is calculated by dividing the values in this column by the desired diametral pitch and then adding to the result an amount  $\Delta$  found in Table 9a. As an example, a 20-degree pressure angle 7-tooth pinion meshing with a 42-tooth gear would have, for 24 diametral pitch, a dedendum of  $0.4565 \div 24 + 0.0004 = 0.0194$ . The 42-tooth gear would have a dedendum of  $2.0235 \div 24 + 0.004 = 0.0847$  inch.

All dimensions are given in inches.

| 13  | 15.2138                                       | 1.1069                            | 1.67047  | 1.1331  | 1.279   | 1.317  | 0.8931  | 1.47112  | 1.3469   | 16  | 1.347  |
| 14  | 16.0686                                       | 1.0343                            | 1.60281  | 1.2057  | 1.328   | 1.343  | 0.9657  | 1.53878  | 1.2743   | 15  | 1.352  |
| 15  | 17.0000                                       | 1.0000                            | 1.57030  | 1.2400  | 1.358   | 1.358  | 1.0000  | 1.57080  | 1.2400   | 15  | 1.358  |

<sup>a</sup> Caution should be exercised in the use of pinions above the horizontal lines. They should be checked for suitability, particularly in the areas of contact ratio (less than 1.2 is not recommended), center distance, clearance, and tooth strength.

<sup>b</sup> The actual dedendum is calculated by dividing the values in this column by the desired diametral pitch and then adding to the result an amount  $\Delta$  found in Table 9a. As an example, a 20-degree pressure angle 7-tooth pinion meshing with a 42-tooth gear would have, for 24 diametral pitch, a dedendum of  $0.4565 \div 24 + 0.0004 = 0.0194$ . The 42-tooth gear would have a dedendum of  $2.0235 \div 24 + 0.0004 = 0.0847$  inch.

All dimensions are given in inches.

All values are for 1 diametral pitch. For any other sizes of teeth, all linear dimensions should be divided by the diametral pitch.

*Note:* The tables in the ANSI B6.7-1977 standard also specify Form Diameter, Roll Angle to Form Diameter, and Top Land. These are not shown here. The top land is in no case less than  $0.275/P$ . The form diameters and the roll angles to form diameter shown in the Standard are the values which should be met with a standard hob when generating the tooth thicknesses shown in the tables. These form diameters provides more than enough length of involute profile for any mating gear smaller than a rack. However, since these form diameters are based on gear tooth generation using standard hobs, they should impose little or no hardship on manufacture except in cases of the most critical quality levels. In such cases, form diameter specifications and master gear design should be based upon actual mating conditions.

**Minimum Number of Teeth to Avoid Undercutting by Hob.**—The data in the above tables give tooth proportions for low numbers of teeth to avoid interference between the gear tooth tip and the pinion tooth flank. Consideration must also be given to possible undercutting of the pinion tooth flank by the hob used to cut the pinion. The minimum number of teeth  $N_{\min}$  of standard proportion that may be cut without undercut is:

$N_{\min} = 2P \csc^2 \phi [a_H - r_t (1 - \sin \phi)]$  where:  $a_H$  = cutter addendum;  $r_t$  = radius at cutter tip or corners;  $\phi$  = cutter pressure angle; and  $P$  = diametral pitch.

**Gear to Mesh with Enlarged Pinion.**—Data in the fifth column of [Table 8](#) show minimum number of teeth in a mating gear which can be cut with hob or rack type cutter without undercut, when outside diameter of gear has been reduced an amount equal to the pinion enlargement to retain the standard center distance. To calculate  $N$  for the gear, insert addendum  $a$  of enlarged mating pinion in the formula  $N = 2a \times \csc^2 \phi$ .

*Example:* A gear is to mesh with a 24-tooth pinion of 1 diametral pitch which has been enlarged 0.4954 inch, as shown by the table. The pressure angle is  $14\frac{1}{2}$  degrees. Find minimum number of teeth  $N$  for reduced gear.

$$\text{Pinion addendum} = 1 + (0.4954 \div 2) = 1.2477$$

$$\text{Hence, } N = 2 \times 1.2477 \times 15.95 = 39.8 \text{ (use 40)}$$

In the case of fine pitch gears with reduced outside diameters, the recommended minimum numbers of teeth given in [Tables 9b](#), [9c](#), and [9d](#), are somewhat more than the minimum numbers required to prevent undercutting and are based upon studies made by the *American Gear Manufacturers Association*.

**Standard Center-distance System for Enlarged Pinions.**—In this system, sometimes referred to as “long and short addendums,” the center distance is made standard for the numbers of teeth in pinion and gear. The outside diameter of the gear is decreased by the same amount that the outside of the pinion is enlarged.

The advantages of this system are: 1) No change in center distance or ratio is required; 2) The operating pressure angle remains standard; and 3) A slightly greater contact ratio is obtained than when the center distance is increased.

The disadvantages are 1) The gears as well as the pinion must be changed from standard dimensions; 2) Pinions having fewer than the minimum number of teeth to avoid undercut cannot be satisfactorily meshed together; and 3) In most cases where gear trains include idler gears, the standard center-distance system cannot be used.

**Enlarged Center-distance System for Enlarged Pinions.**—If an enlarged pinion is meshed with another enlarged pinion or with a gear of standard outside diameter, the center distance must be increased. For fine-pitch gears, it is usually satisfactory to increase the center distance by an amount equal to one-half of the enlargements (see eighth column of [Table 9b](#)). This is an approximation as theoretically there is a slight increase in backlash.

The advantages of this system are: 1) Only the pinions need be changed from the standard dimensions; 2) Pinions having fewer than 18 teeth may engage other pinions in this range; 3) The pinion tooth, which is the weaker member, is made stronger by the enlargement; and 4) The tooth contact stress, which controls gear durability, is lowered by being moved away from the pinion base circle.

The disadvantages are: 1) Center distances must be enlarged over the standard; 2) The operating pressure angle increases slightly with different combinations of pinions and gears, which is usually not important; and 3) The contact ratio is slightly smaller than that obtained with the standard center-distance system.

This consideration is of minor importance as in the worst case the loss is approximately only 6 per cent.

*Enlarged Pinions Meshing without Backlash:* When two enlarged pinions are to mesh without backlash, their center distance will be greater than the standard and less than that

for the enlarged center-distance system. This center distance may be calculated by the formulas given in the following section.

**Center Distance at Which Modified Mating Spur Gears Will Mesh with No Backlash.**—When the tooth thickness of one or both of a pair of mating spur gears has been increased or decreased from the standard value ( $\pi \div 2P$ ), the center distance at which they will mesh tightly (without backlash) may be calculated from the following formulas:

$$\text{inv } \phi_1 = \text{inv } \phi + \frac{P(t+T) - \pi}{n+N}$$

$$C = \frac{n+N}{2P}$$

$$C_1 = \frac{\cos \phi}{\cos \phi_1} \times C$$

In these formulas,  $P$  = diametral pitch;  $n$  = number of teeth in pinion;  $N$  = number of teeth in gear;  $t$  and  $T$  are the actual tooth thicknesses of the pinion and gear, respectively, on their standard pitch circles;  $\text{inv } \phi$  = involute function of standard pressure angle of gears;  $C$  = standard center distance for the gears;  $C_1$  = center distance at which the gears mesh without backlash; and  $\text{inv } \phi_1$  = involute function of operating pressure angle when gears are meshed tightly at center distance  $C_1$ .

*Example:* Calculate the center distance for no backlash when an enlarged 10-tooth pinion of 100 diametral pitch and 20-degree pressure angle is meshed with a standard 30-tooth gear, the circular tooth thickness of the pinion and gear, respectively, being 0.01873 and 0.015708 inch.

$$\text{inv } \phi_1 = \text{inv } 20^\circ + \frac{100(0.01873 + 0.015708) - \pi}{(10 + 30)}$$

From the table of involute functions,  $\text{inv } 20$ -degrees = 0.014904. Therefore,

$$\text{inv } \phi_1 = 0.014904 + \frac{0.34438 - 0.31416}{4} = 0.022459$$

$$\phi_1 = 22^\circ 49' \text{ from page 99}$$

$$C = \frac{n+N}{2P} = \frac{10+30}{2 \times 100} = 0.2000 \text{ inch}$$

$$C_1 = \frac{\cos 20^\circ}{\cos 22^\circ 49'} \times 0.2000 = \frac{0.93969}{0.92175} \times 0.2000 = 0.2039 \text{ inch}$$

**Contact Diameter.**—For two meshing gears it is important to know the contact diameter of each. A first gear with number of teeth,  $n$ , and outside diameter,  $d_0$ , meshes at a standard center distance with a second gear with number of teeth,  $N$ , and outside diameter,  $D_0$ ; both gears have a diametral pitch,  $P$ , and pressure angle,  $\phi$ ,  $a$ ,  $A$ ,  $b$ , and  $B$  are unnamed angles used only in the calculations. The contact diameter,  $d_c$ , is found by a three-step calculation that can be done by hand using a trigonometric table and a logarithmic table or a desk calculator. Slide rule calculation is not recommended because it is not accurate enough to give good results. The three-step formulas to find the contact diameter,  $d_c$ , of the first gear are:

$$\cos A = \frac{N \cos \phi}{D_0 \times P} \quad (1)$$

$$\tan b = \tan \phi - \frac{N}{n} (\tan A - \tan \phi) \quad (2)$$

## SPUR GEARING

$$d_c = \frac{n \cos \phi}{P \cos b} \quad (3)$$

Similarly the three-step formulas to find the contact diameter,  $D_c$ , of the second gear are:

$$\cos a = \frac{n \cos \phi}{d_o \times P} \quad (4)$$

$$\tan B = \tan \phi - \frac{n}{N}(\tan a - \tan \phi) \quad (5)$$

$$D_c = \frac{N \cos \phi}{P \cos B} \quad (6)$$

**Contact Ratio.**—The contact ratio of a pair of mating spur gears must be well over 1.0 to assure a smooth transfer of load from one pair of teeth to the next pair as the two gears rotate under load. Because of a reduction in contact ratio due to such factors as tooth deflection, tooth spacing errors, tooth tip breakage, and outside diameter and center distance tolerances, the contact ratio of gears for power transmission as a general rule should not be less than about 1.4. A contact ratio of as low as 1.15 may be used in extreme cases, provided the tolerance effects mentioned above are accounted for in the calculation. The formula for determining the contact ratio,  $m_f$ , using the nomenclature in the previous section is:

$$m_f = \frac{N}{6.28318}(\tan A - \tan B) \quad (7a)$$

or

$$m_f = \frac{N}{6.28318}(\tan a - \tan b) \quad (7b)$$

or

$$m_f = \frac{\sqrt{R_0^2 - R_B^2} + \sqrt{r_0^2 - r_B^2} - C \sin \theta}{P \cos \theta} \quad (7c)$$

where  $R_0$  = outside radius of first gear;  $R_B$  = base radius of first gear;  $r_0$  = outside radius of second gear;  $r_B$  = base radius of second gear;  $C$  = center distance;  $I$  = pressure angle; and,  $p$  = circular pitch.

Both formulas [Equations \(7a\)](#) and [Equations \(7b\)](#) should give the same answer. It is good practice to use both formulas as a check on the previous calculations.

**Lowest Point of Single Tooth Contact.**—This diameter on the pinion (sometimes referred to as LPSTQ) is used to find the maximum contact compressive stress (sometimes called the Hertz Stress) of a pair of mating spur gears. The two-step formulas for determining this pinion diameter,  $d_L$ , using the same nomenclature as in the previous sections with  $c$  and  $C$  as unnamed angles used only in the calculations are:

$$\tan c = \tan a - \frac{6.28318}{n} \quad (8)$$

$$d_L = \frac{n \cos \phi}{P \cos c} \quad (9)$$

In some cases it is necessary to have a plot of the compressive stress over the whole cycle of contact; in this case the LPSTC for the gear is required also. The similar two-step formulas for this gear diameter are:

$$\tan C = \tan A - \frac{6.28318}{N} \quad (10)$$

$$D_L = \frac{N \cos \phi}{P \cos C} \quad (11)$$

**Maximum Hob Tip Radius.**—The standard gear tooth proportions given by the formulas in Table 2 on page 2035 provide a specified size for the rack fillet radius in the general form of (a constant)  $\times$  (pitch). For any given standard this constant may vary up to a maximum which it is geometrically impossible to exceed; this maximum constant,  $r_c$  (max), is found by the formula:

$$r_c \text{ (max)} = \frac{0.785398 \cos \phi - b \sin \phi}{1 - \sin \phi} \quad (12)$$

where  $b$  is the similar constant in the specified formula for the gear dedendum. The hob tip radius of any standard hob to finish cut any standard gear may vary from zero up to this limiting value.

**Undercut Limit for Hobbled Involute Gears.**—It is well to avoid designing and specifying gears that will have a hobbled trochoidal fillet that undercuts the involute gear tooth profile. This should be avoided because it may cause the involute profile to be cut away up to a point above the required contact diameter with the mating gear so that involute action is lost and the contact ratio reduced to a level that may be too low for proper conjugate action. An undercut fillet will also weaken the beam strength and thus raise the fillet tensile stress of the gear tooth. To assure that the hobbled gear tooth will not have an undercut fillet, the following formula must be satisfied:

$$\frac{b - r_c}{\sin \phi} + r_c \leq 0.5n \sin \phi \quad (13)$$

where  $b$  is the dedendum constant;  $r_c$  is the hob or rack tip radius constant;  $n$  is the number of teeth in the gear; and  $\phi$  is the gear and hob pressure angle. If the gear is not standard or the hob does not roll at the gear pitch diameter, this formula can not be applied and the determination of the expected existence of undercut becomes a considerably more complicated procedure.

**Highest Point of Single Tooth Contact.**—This diameter is used to place the maximum operating load for the determination of the gear tooth fillet stress. The two-step formulas for determining this diameter,  $d_H$ , of the pinion using the same nomenclature as in the previous sections with  $d$  and  $D$  as unnamed angles used only in the calculations are:

$$\tan d = \tan b + \frac{6.28318}{n} \quad (14)$$

$$d_H = \frac{n \cos \phi}{P \cos d} \quad (15)$$

Similarly for the gear:

$$\tan D = \tan B + \frac{6.28318}{N} \quad (16)$$

$$D_H = \frac{N \cos \phi}{P \cos D} \quad (17)$$

**True Involute Form Diameter.**—The point on the gear tooth at which the fillet and the involute profile are tangent to each other should be determined to assure that it lies at a smaller diameter than the required contact diameter with the mating gear. If the TIF diameter is larger than the contact diameter, then fillet interference will occur with severe damage to the gear tooth profile and rough action of the gear set. This two-step calculation is

made by using the following two formulas with  $e$  and  $E$  as unnamed angles used only in the calculations:

$$\tan e = \tan \phi - \frac{4}{n} \left( \frac{b - r_c}{\sin 2\phi} + \frac{r_c}{2 \cos \phi} \right) \quad (18)$$

$$d_{TIF} = \frac{n \cos \phi}{P \cos e} \quad (19)$$

As in the previous sections,  $\phi$  is the pressure angle of the gear;  $n$  is the number of teeth in the pinion;  $b$  is the dedendum constant,  $r_c$  is the rack or hob tip radius constant,  $P$  is the gear diametral pitch and  $d_{TIF}$  is the true involute form diameter.

Similarly, for the mating gear:

$$\tan E = \tan \phi - \frac{4}{N} \left( \frac{b - r_c}{\sin 2\phi} + \frac{r_c}{2 \cos \phi} \right) \quad (20)$$

$$D_{TIF} = \frac{N \cos \phi}{P \cos E} \quad (21)$$

where  $N$  is number of teeth in this mating gear and  $D_{TIF}$  is the true involute form diameter.

**Profile Checker Settings.**—The actual tooth profile tolerance will need to be determined on high performance gears that operate either at high unit loads or at high pitch-line velocity. This is done on an involute checker, a machine which requires two settings, the gear base radius and the roll angle in degrees to significant points on the involute. From the smallest diameter outward these significant points are: TIF, Contact Diameter, LPSTC, Pitch Diameter, HPSTC, and Outside Diameter.

The base radius is:

$$R_b = \frac{N \cos \phi}{2P} \quad (22)$$

The roll angle, in degrees, at any point is equal to the tangent of the pressure angle at that point multiplied by 57.2958. The following table shows the tangents to be used at each significant diameter.

| Significant Point on Tooth Profile | Pinion      | Gear        | For Computation            |
|------------------------------------|-------------|-------------|----------------------------|
| TIF                                | $\tan e$    | $\tan E$    | (See Formulas (18) & (20)) |
| Contact Dia.                       | $\tan b$    | $\tan B$    | (See Formulas (2) & (5))   |
| LPSTC                              | $\tan c$    | $\tan C$    | (See Formulas (8) & (10))  |
| Pitch Dia.                         | $\tan \phi$ | $\tan \phi$ | ( $\phi$ = Pressure angle) |
| HPSTC                              | $\tan d$    | $\tan D$    | (See Formulas (14) & (16)) |
| Outside Dia.                       | $\tan a$    | $\tan A$    | (See Formulas (4) & (1))   |

*Example:* Find the significant diameters, contact ratio and hob tip radius for a 10-diametral pitch, 23-tooth, 20-degree pressure angle pinion of 2.5-inch outside diameter if it is to mesh with a 31-tooth gear of 3.3-inch outside diameter.

Thus:  $n = 23$   
 $d_O = 2.5$   
 $P = 10$   
 $N = 31$   
 $D_O = 3.3$   
 $\phi = 20^\circ$

1) Pinion contact diameter,  $d_c$ 

$$\cos A = \frac{31 \times 0.93969}{3.3 \times 10} \quad (1)$$

$$= 0.88274 \quad A = 28^\circ 1' 30''$$

$$\tan b = 0.36397 - \frac{31}{23}(0.53227 - 0.36397) \quad (2)$$

$$= 0.13713 \quad b = 7^\circ 48' 26''$$

$$d_c = \frac{23 \times 0.93969}{10 \times 0.99073} \quad (3)$$

$$= 2.1815 \text{ inches}$$

2) Gear contact diameter,  $D_c$ 

$$\cos a = \frac{23 \times 0.93963}{2.5 \times 10} \quad (4)$$

$$= 0.86452 \quad a = 30^\circ 10' 20''$$

$$\tan B = 0.36397 - \frac{23}{31}(0.58136 - 0.36937) \quad (5)$$

$$= 0.20267 \quad B = 11^\circ 27' 26''$$

$$D_c = \frac{31 \times 0.93969}{10 \times 0.98000} \quad (6)$$

$$= 2.9725 \text{ inches}$$

3) Contact ratio,  $m_f$ 

$$m_f = \frac{31}{6.28318}(0.53227 - 0.20267) \quad (7a)$$

$$= 1.626$$

$$m_f = \frac{23}{6.28318}(0.58136 - 0.13713) \quad (7b)$$

$$= 1.626$$

4) Pinion LPSTC,  $d_L$ 

$$\tan c = 0.58136 - \frac{6.28318}{23} \quad (8)$$

$$= 0.30818 \quad c = 17^\circ 7' 41''$$

$$d_L = \frac{23 \times 0.93969}{10 \times 0.95565} \quad (9)$$

$$= 2.2616 \text{ inches}$$

5) Gear LPSTC,  $D_L$ 

$$\tan C = 0.53227 - \frac{6.28318}{31} \quad (10)$$

$$= 0.32959 \quad C = 18^\circ 14' 30''$$

$$D_L = \frac{31 \times 0.93969}{10 \times 0.94974} \quad (11)$$

$$= 3.0672 \text{ inches}$$

6) Maximum permissible hob tip radius,  $r_c$  (max). The dedendum factor is 1.25.

$$r_c \text{ (max)} = \frac{0.785398 \times 0.93969 - 1.25 \times 0.34202}{1 - 0.34202} \quad (12)$$

$$= 0.4719 \text{ inch}$$

7) If the hob tip radius  $r_c$  is 0.30, determine if the pinion involute is undercut.

$$\frac{1.25 - 0.30}{0.34202} + 0.30 \leq 0.5 \times 23 \times 0.34202 \quad (13)$$

$$3.0776 < 3.9332$$

8) therefore there is no involute undercut.

9) Pinion HPSTC,  $D_H$

$$\tan d = 0.13713 + \frac{6.28318}{23} \quad (14)$$

$$= 0.41031 \quad d = 22^\circ 18' 32''$$

$$d_H = \frac{23 \times 0.93969}{10 \times 0.92515} \quad (15)$$

$$= 2.3362 \text{ inches}$$

10) Gear HPSTC,  $D_H$

$$\tan D = 0.20267 + \frac{6.28318}{31} \quad (16)$$

$$= 0.40535 \quad D = 22^\circ 3' 55''$$

$$D_H = \frac{31 \times 0.93969}{10 \times 0.92676} \quad (17)$$

$$= 3.1433 \text{ inches}$$

11) Pinion TIF diameter,  $d_{TIF}$

$$\tan e = 0.36397 - \frac{4}{23} \left( \frac{1.25 - 0.30}{0.64279} + \frac{0.30}{2 \times 0.93969} \right) \quad (18)$$

$$= 0.07917 \quad e = 4^\circ 31' 36''$$

$$d_{TIF} = \frac{23 \times 0.93969}{10 \times 0.99688} \quad (19)$$

$$= 2.1681 \text{ inches}$$

12) Gear TIF diameter,  $D_{TIF}$

$$\tan E = 0.36397 - \frac{4}{31} \left( \frac{1.25 - 0.30}{0.64279} + \frac{0.30}{2 \times 0.93969} \right) \quad (20)$$

$$= 0.15267 \quad E = 8^\circ 40' 50''$$

$$D_{TIF} = \frac{31 \times 0.93969}{10 \times 0.98855} = 2.9468 \text{ inches} \quad (21)$$

**Gear Blanks for Fine-pitch Gears.**—The accuracy to which gears can be produced is considerably affected by the design of the gear blank and the accuracy to which the various surfaces of the blank are machined. The following recommendations should not be regarded as inflexible rules, but rather as minimum average requirements for gear-blank quality compatible with the expected quality class of the finished gear.

*Design of Gear Blanks:* The accuracy to which gears can be produced is affected by the design of the blank, so the following points of design should be noted: 1) Gears designed with a hole should have the hole large enough that the blank can be adequately supported during machining of the teeth and yet not so large as to cause distortion; 2) Face widths should be wide enough, in proportion to outside diameters, to avoid springing and to permit obtaining flatness in important surfaces; 3) Short bore lengths should be avoided wherever possible. It is feasible, however, to machine relatively thin blanks in stacks, provided the surfaces are flat and parallel to each other; 4) Where gear blanks with hubs are to be designed, attention should be given to the wall sections of the hubs. Too thin a section will not permit proper clamping of the blank during machining operations and may also affect proper mounting of the gear; and 5) Where pinions or gears integral with their shafts are to be designed, deflection of the shaft can be minimized by having the shaft length and shaft diameter well proportioned to the gear or pinion diameter. The foregoing general principles may also be useful when applied to blanks for coarser pitch gears.

**Specifying Spur and Helical Gear Data on Drawings.**—The data that may be shown on drawings of spur and helical gears falls into three groups: The first group consists of data basic to the design of the gear; the second group consists of data used in manufacturing and inspection; and the third group consists of engineering reference data. The accompanying table may be used as a checklist for the various data which may be placed on gear drawings and the sequence in which they should appear.

*Explanation of Terms Used in Gear Specifications:* 1) Number of teeth is the number of teeth in 360 deg of gear circumference. In a sector gear, both the actual number of teeth in the sector and the theoretical number of teeth in 360 deg should be given.

2) Diametral pitch is the ratio of the number of teeth in the gear to the number of inches in the standard pitch diameter. It is used in this standard as a nominal specification of tooth size.

a) Normal diametral pitch is the diametral pitch in the normal plane.

b) Transverse diametral pitch is the diametral pitch in the transverse plane.

c) Module is the ratio of the number of teeth in the gear to the number of mm in the standard pitch diameter.

d) Normal module is the module measured in the normal plane.

e) Transverse module is the module measured in the transverse plane.

3) Pressure angle is the angle between the gear tooth profile and a radial line at the pitch point. It is used in this standard to specify the pressure angle of the basic rack used in defining the gear tooth profile.

a) Normal pressure angle is the pressure angle in the normal plane.

b) Transverse pressure angle is the pressure angle in the transverse plane.

4) Helix angle is the angle between the pitch helix and an element of the pitch cylinder, unless otherwise specified.

a) Hand of helix is the direction in which the teeth twist as they recede from an observer along the axis. A right hand helix twists clockwise and a left hand helix twists counterclockwise.

5) Standard pitch diameter is the diameter of the pitch circle. It equals the number of teeth divided by the transverse diametral pitch.

6) Tooth form may be specified as standard addendum, long addendum, short addendum, modified involute or special. If a modified involute or special tooth form is required, a detailed view should be shown on the drawing. If a special tooth form is specified, roll angles must be supplied (see page 2062).

7) Addendum is the radial distance between the standard pitch circle and the outside circle. The actual value depends on the specification of outside diameter.

8) Whole depth is the total radial depth of the tooth space. The actual value is dependent on the specification of outside diameter and root diameter.

9) Maximum calculated circular thickness on the standard pitch circle is the tooth thickness which will provide the desired minimum backlash when the gear is assembled in mesh with its mate on minimum center distance. Control may best be exerted by testing in tight mesh with a master which integrates all errors in the several teeth in mesh through the arc of action as explained on page 2073. This value is independent of the effect of runout.

a) Maximum calculated *normal* circular thickness is the circular tooth thickness in the normal plane which satisfies requirements explained in (9).

10) Gear testing radius is the distance from its axis of rotation to the standard pitch line of a standard master when in intimate contact under recommended pressure on a variable-center-distance running gage. Maximum testing radius should be calculated to provide the maximum circular tooth thickness specified in (9) when checked as explained on page 2073. This value is affected by the runout of the gear. Tolerance on testing radius must be equal to or greater than the total composite error permitted by the quality class specified in (11).

11) Quality class is specified for convenience when talking or writing about the accuracy of the gear.

12) Maximum total composite error, and 13) Maximum tooth-to-tooth composite error. Actual tolerance values (12 and 13) permitted by the quality class (11) are specified in inches to provide machine operator or inspector with tolerances required to inspect the gear.

14) Testing pressure recommendations are given on page 2073. Incorrect testing pressure will result in incorrect measurement of testing radius.

15) Master specifications by tool or code number may be required to call for the use of a special master gear when tooth thickness deviates excessively from standard.

16) Measurement over two 0.xxxx diameter pins may be specified to assist the manufacturing department in determining size at machine for setup only.

17) Outside diameter is usually shown on the drawing of the gear together with other blank dimensions so that it will not be necessary for machine operators to search gear tooth data for this dimension. Since outside diameter is also frequently used in the manufacture and inspection of the teeth, it may be included in the data block with other tooth specifications if preferred. To permit use of topping hobs for cutting gears on which the tooth thickness has been modified from standard, the outside diameter should be related to the specified gear testing radius (10).

18) Maximum root diameter is specified to assure adequate clearance for the outside diameter of the mating gear. This dimension is usually considered acceptable if the gear is checked with a master and meets specifications (10) through (13).

19) Active profile diameter of a gear is the smallest diameter at which the mating gear tooth profile can make contact. Because of difficulties involved in checking, this specification is not recommended for gears finer than 48 pitch.

20) Surface roughness on active profile surfaces may be specified in microinches to be checked by instrument up to about 32 pitch, or by visual comparison in the finer pitch ranges. It is difficult to determine accurately the surface roughness of fine pitch gears. For many commercial applications surface roughness may be considered acceptable on gears which meet the maximum tooth-to-tooth-error specification (13).

21) Mating gear part number may be shown as a convenient reference. If the gear is used in several applications, all mating gears may be listed but usual practice is to record this information in a reference file.

22) Number of teeth in mating gear, and 23) Minimum operating center distance. This information is often specified to eliminate the necessity of getting prints of the mating gear and assemblies for checking the design specifications, interference, backlash, determination of master gear specification, and acceptance or rejection of gears made out of tolerance.

## Data for Spur and Helical Gear Drawings

| Type of Data                 | Min. Spur Gear Data | Min. Helical Gear-Data | Add'l Optional Data | Item Number <sup>a</sup>                                  | Data <sup>a</sup>                                      |
|------------------------------|---------------------|------------------------|---------------------|---|--|
| Basic Specifications         | ●                   | ●                      |                     | 1   | Number of teeth  |

<sup>a</sup> An item-by-item explanation of the terms used in this table is given beginning on page 2065.

### Backlash

In general, backlash in gears is play between mating teeth. For purposes of measurement and calculation, backlash is defined as the amount by which a tooth space exceeds the thickness of an engaging tooth. It does not include the effect of center-distance changes of the mountings and variations in bearings. When not otherwise specified, numerical values of backlash are understood to be given on the pitch circles. The general purpose of backlash is to prevent gears from jamming together and making contact on both sides of their teeth simultaneously. Lack of backlash may cause noise, overloading, overheating of the gears and bearings, and even seizing and failure.

Excessive backlash is objectionable, particularly if the drive is frequently reversing, or if there is an overrunning load as in cam drives. On the other hand, specification of an unnecessarily small amount of backlash allowance will increase the cost of gears, because errors in runout, pitch, profile, and mounting must be held correspondingly smaller. Backlash does not affect involute action and usually is not detrimental to proper gear action.

**Determining Proper Amount of Backlash.**—In specifying proper backlash and tolerances for a pair of gears, the most important factor is probably the maximum permissible amount of runout in both gear and pinion (or worm). Next are the allowable errors in profile, pitch, tooth thickness, and helix angle. Backlash between a pair of gears will vary as successive teeth make contact because of the effect of composite tooth errors, particularly runout, and errors in the gear center distances and bearings.

Other important considerations are speed and space for lubricant film. Slow-moving gears, in general, require the least backlash. Fast-moving fine-pitch gears are usually lubri-

cated with relatively light oil, but if there is insufficient clearance for an oil film, and particularly if oil trapped at the root of the teeth cannot escape, heat and excessive tooth loading will occur.

Heat is a factor because gears may operate warmer, and, therefore, expand more, than the housings. The heat may result from oil churning or from frictional losses between the teeth, at bearings or oil seals, or from external causes. Moreover, for the same temperature rise, the material of the gears—for example, bronze and aluminum—may expand more than the material of the housings, usually steel or cast iron.

The higher the helix angle or spiral angle, the more transverse backlash is required for a given normal backlash. The transverse backlash is equal to the normal backlash divided by the cosine of the helix angle.

In designs employing normal pressure angles higher than 20 degrees, special consideration must be given to backlash, because more backlash is required on the pitch circles to obtain a given amount of backlash in a direction normal to the tooth profiles.

Errors in boring the gear housings, both in center distance and alignment, are of extreme importance in determining allowance to obtain the backlash desired. The same is true in the mounting of the gears, which is affected by the type and adjustment of bearings, and similar factors. Other influences in backlash specification are heat treatment subsequent to cutting the teeth, lapping operations, need for recutting, and reduction of tooth thickness through normal wear.

Minimum backlash is necessary for timing, indexing, gun-sighting, and certain instrument gear trains. If the operating speed is very low and the necessary precautions are taken in the manufacture of such gear trains, the backlash may be held to extremely small limits. However, the specification of "zero backlash," so commonly stipulated for gears of this nature, usually involves special and expensive techniques, and is difficult to obtain.

**Table 1. AGMA Recommended Backlash Range for Coarse-Pitch Spur, Helical, and Herringbone Gearing**

| Center Distance (Inches) | Normal Diametral Pitches                    |           |           |           |           |
|--------------------------|---|-----------|-----------|-----------|-----------|
|                          | 0.5–1.99                                    | 2–3.49    | 3.5–5.99  | 6–9.99    | 10–19.99  |
|                          | Backlash, Normal Plane, Inches <sup>a</sup> |           |           |           |           |
| Up to 5                  | ...   | ...       | ...       | ...       | .005–.015 |

| Over 10 to 20            | ...   | ...       | .020–.030 | .015–.025 | .010–.020 |
| Over 20 to 30            | ...   | .030–.040 | .025–.030 | .020–.030 | ...       |
| Over 30 to 40            | .040–.060                                   | .035–.045 | .030–.040 | .025–.035 | ...       |
| Over 40 to 50            | .050–.070                                   | .040–.055 | .035–.050 | .030–.040 | ...       |
| Over 50 to 80            | .060–.080                                   | .045–.065 | .040–.060 | ...       | ...       |
| Over 80 to 100           | .070–.095                                   | .050–.080 | ...       | ...       | ...       |
| Over 100 to 120          | .080–.110                                   | ...       | ...       | ...       | ...       |

<sup>a</sup> Suggested backlash, on nominal centers, measured after rotating to the point of closest engagement. For helical and herringbone gears, divide above values by the cosine of the helix angle to obtain the transverse backlash.

The above backlash tolerances contain allowance for gear expansion due to differential in the operating temperature of the gearing and their supporting structure. The values may be used where the operating temperatures are up to 70 deg F higher than the ambient temperature.

For most gearing applications the recommended backlash ranges will provide proper running clearance between engaging teeth of mating gears. Deviation below the minimum or above the maximum values shown, which do not affect operational use of the gearing, should not be cause for rejection.

Definite backlash tolerances on coarse-pitch gearing are to be considered binding on the gear manufacturer only when agreed upon in writing.

Some applications may require less backlash than shown in the above table. In such cases the amount and tolerance should be by agreement between manufacturer and purchaser.

**Recommended Backlash:** In the following tables American Gear Manufacturers Association recommendations for backlash ranges for various kinds of gears are given.\* For purposes of measurement and calculation, backlash is defined as the amount by which a tooth space exceeds the thickness of an engaging tooth. When not otherwise specified, numerical values of backlash are understood to be measured at the tightest point of mesh on the pitch circle in a direction normal to the tooth surface when the gears are mounted in their specified position.

**Coarse-Pitch Gears:** Table 1 gives the recommended backlash range for coarse-pitch spur, helical and herringbone gearing. Because backlash for helical and herringbone gears is more conveniently measured in the normal plane, Table 1 has been prepared to show backlash in the normal plane for coarse-pitch helical and herringbone gearing and in the transverse plane for spur gears. To obtain backlash in the transverse plane for helical and herringbone gears, divide the normal plane backlash in Table 1 by the cosine of the helix angle.

**Table 2. AGMA Recommended Backlash Range for Bevel and Hypoid Gears**

| Diametral Pitch | Normal Backlash, Inch        |                             | Diametral Pitch | Normal Backlash, Inch        |                             |

| 2.50 to 3.00    | 0.010–0.013                  | 0.015–0.025                 | 20 to 50        | 0.000–0.002                  | 0.000–0.002                 |
| 3.00 to 3.50    | 0.008–0.011                  | 0.012–0.022                 | 50 to 80        | 0.000–0.001                  | 0.000–0.001                 |
| 3.50 to 4.00    | 0.007–0.009                  | 0.010–0.020                 | 80 and finer    | 0.000–0.0007                 | 0.000–0.0007                |
| 4.00 to 5.00    | 0.006–0.008                  | 0.008–0.016                 | ...             | ...                          | ...                         |

Measured at tightest point of mesh

The backlash tolerances given in this table contain allowances for gear expansion due to a differential in the operating temperature of the gearing and their supporting structure. The values may be used where the operating temperature is up to 70 degrees F. higher than the ambient temperature. These backlash values will provide proper running clearances for most gear applications.

The following important factors must be considered in establishing backlash tolerances:

- a) Center distance tolerance; b) Parallelism of gear axes; c) Side runout or wobble;
- d) Tooth thickness tolerance; e) Pitch line runout tolerance; f) Profile tolerance; g) Pitch tolerance; h) Lead tolerance; i) Types of bearings and subsequent wear; j) Deflection under load; k) Gear tooth wear; l) Pitch line velocity; m) Lubrication requirements; and
- n) Thermal expansion of gears and housing.

A tight mesh may result in objectionable gear sound, increased power losses, overheating, rupture of the lubricant film, overloaded bearings and premature gear failure. However, it is recognized that there are some gearing applications where a tight mesh (zero backlash) may be required.

Specifying unnecessarily close backlash tolerances will increase the cost of the gearing. It is obvious from the above summary that the desired amount of backlash is difficult to evaluate. It is, therefore, recommended that when a designer, user or purchaser includes a reference to backlash in a gearing specification and drawing, consultation be arranged with the manufacturer.

*Bevel and Hypoid Gears:* Table 2 gives similar backlash range values for bevel and hypoid gears. These are values based upon average conditions for general purpose gearing, but may require modification to meet specific needs.

Backlash on bevel and hypoid gears can be controlled to some extent by axial adjustment of the gears during assembly. However, due to the fact that actual adjustment of a bevel or hypoid gear in its mounting will alter the amount of backlash, it is imperative that the amount of backlash cut into the gears during manufacture is not excessive. Bevel and hypoid gears must always be capable of operation without interference when adjusted for zero backlash. This requirement is imposed by the fact that a failure of the axial thrust bearing might permit the gears to operate under this condition. Therefore, bevel and hypoid gears should never be designed to operate with normal backlash in excess of  $0.080/P$  where  $P$  is diametral pitch.

*Fine-Pitch Gears:* Table 3 gives similar backlash range values for fine-pitch spur, helical and herringbone gearing.

**Providing Backlash.**—In order to obtain the amount of backlash desired, it is necessary to decrease tooth thicknesses. However, because of manufacturing and assembling inaccuracies not only in the gears but also in other parts, the allowances made on tooth thickness almost always must exceed the desired amount of backlash. Since the amounts of these allowances depend on the closeness of control exercised on all manufacturing operations, no general recommendations for them can be given.

It is customary to make half the allowance for backlash on the tooth thickness of each gear of a pair, although there are exceptions. For example, on pinions having very low numbers of teeth it is desirable to provide all the allowance on the mating gear, so as not to weaken the pinion teeth. In worm gearing, ordinary practice is to provide all of the allowance on the worm which is usually made of a material stronger than that of the worm gear.

In some instances the backlash allowance is provided in the cutter, and the cutter is then operated at the standard tooth depth. In still other cases, backlash is obtained by setting the distance between two tools for cutting the two sides of the teeth, as in straight bevel gears, or by taking side cuts, or by changing the center distance between the gears in their mountings. In spur and helical gearing, backlash allowance is usually obtained by sinking the cutter deeper into the blank than the standard depth. The accompanying table gives the excess depth of cut for various pressure angles.

**Excess Depth of Cut  $E$  to Provide Backlash Allowance**

| Distribution of Backlash  | Pressure Angle $\phi$ , Degrees |                 |           |           |           |
|---|---------------------------------|-----------------|-----------|-----------|-----------|
|   | $14\frac{1}{2}$                 | $17\frac{1}{2}$ | 20        | 25        | 30        |
| Excess Depth of Cut $E$ to Obtain Circular Backlash $B^a$                             |                                 |                 |           |           |           |
| All on One Gear   | $1.93B$                         | $1.59B$         | $1.37B$   | $1.07B$   | $0.87B$   |
| One-half on Each Gear   | $0.97B$                         | $0.79B$         | $0.69B$   | $0.54B$   | $0.43B$   |
| Excess Depth of Cut $E$ to Obtain Backlash $B_b$ Normal to Tooth Profile <sup>b</sup> |                                 |                 |           |           |           |
| All on One Gear   | $2.00B_b$                       | $1.66B_b$       | $1.46B_b$ | $1.18B_b$ | $1.99B_b$ |
| One-half on Each Gear   | $1.00B_b$                       | $0.83B_b$       | $0.73B_b$ | $0.59B_b$ | $0.50B_b$ |

<sup>a</sup> Circular backlash is the amount by which the width of a tooth space is greater than the thickness of the engaging tooth on the pitch circles. As described in pages 2067 and 2071 this is what is meant by backlash unless otherwise specified.

<sup>b</sup> Backlash measured normal to the tooth profile by inserting a feeler gage between meshing teeth; to convert to circular backlash,  $B = B_b \div \cos \phi$ .

**Control of Backlash Allowances in Production.**—Measurement of the tooth thickness of gears is perhaps the simplest way of controlling backlash allowances in production.

There are several ways in which this may be done including: 1) chordal thickness measurements as described on page 2049; 2) caliper measurements over two or more teeth as described on page 2140; and 3) measurements over wires.

In this last method, first the theoretical measurement over wires when the backlash allowance is zero is determined by the method described on page 2125; then the amount this measurement must be reduced to obtain a desired backlash allowance is taken from the table on page 2139.

It should be understood, as explained in the section *Measurement of Backlash* that merely making tooth thickness allowances will not guarantee the amount of backlash in the ready-to-run assembly of two or more gears. Manufacturing limitations will introduce such gear errors as runout, pitch error, profile error, and lead error, and gear-housing errors in both center distance and alignment. All of these make the backlash of the assembled gears different from that indicated by tooth thickness measurements on the individual gears.

**Measurement of Backlash.**—Backlash is commonly measured by holding one gear of a pair stationary and rocking the other back and forth. The movement is registered by a dial indicator having its pointer or finger in a plane of rotation at or near the pitch diameter and in a direction parallel to a tangent to the pitch circle of the moving gear. If the direction of measurement is normal to the teeth, or other than as specified above, it is recommended that readings be converted to the plane of rotation and in a tangent direction at or near the pitch diameter, for purposes of standardization and comparison.

In spur gears, parallel helical gears, and bevel gears, it is immaterial whether the pinion or gear is held stationary for the test. In crossed helical and hypoid gears, readings may vary according to which member is stationary; hence, it is customary to hold the pinion stationary and measure on the gear.

In some instances, backlash is measured by thickness gages or feelers. A similar method utilizes a soft lead wire inserted between the teeth as they pass through mesh. In both methods, it is likewise recommended that readings be converted to the plane of rotation and in a tangent direction at or near the pitch diameter, taking into account the normal pressure angle, and the helix angle or spiral angle of the teeth.

Sometimes backlash in parallel helical or herringbone gears is checked by holding the gear stationary, and moving the pinion axially back and forth, readings being taken on the face or shaft of the pinion, and converted to the plane of rotation by calculation. Another method consists of meshing a pair of gears tightly together on centers and observing the variation from the specified center distance. Such readings should also be converted to the plane of rotation and in a tangent direction at or near the pitch diameter for the reasons previously given.

Measurements of backlash may vary in the same pair of gears, depending on accuracy of manufacturing and assembling. Incorrect tooth profiles will cause a change of backlash at different phases of the tooth action. Eccentricity may cause a substantial difference between maximum and minimum backlash at different positions around the gears. In stating amounts of backlash, it should always be remembered that merely making allowances on tooth thickness does not guarantee the minimum amount of backlash that will exist in assembled gears.

*Fine-Pitch Gears:* The measurement of backlash of fine-pitch gears, when assembled, cannot be made in the same manner and by the same techniques employed for gears of coarser pitches. In the very fine pitches, it is virtually impossible to use indicating devices for measuring backlash. Sometimes a toolmaker's microscope is used for this purpose to good advantage on very small mechanisms.

Another means of measuring backlash in fine-pitch gears is to attach a beam to one of the shafts and measure the angular displacement in inches when one member is held stationary. The ratio of the length of the beam to the nominal pitch radius of the gear or pinion to which the beam is attached gives the approximate ratio of indicator reading to circular backlash. Because of the limited means of measuring backlash between a pair of fine-pitch gears, gear centers and tooth thickness of the gears when cut must be held to very close lim-

its. Tooth thickness of fine-pitch spur and helical gears can best be checked on a variable-center-distance fixture using a master gear. When checked in this manner, tooth thickness change =  $2 \times$  center distance change  $\times$  tangent of transverse pressure angle, approximately.

**Control of Backlash in Assemblies.**—Provision is often made for adjusting one gear relative to the other, thereby affording complete control over backlash at initial assembly and throughout the life of the gears. Such practice is most common in bevel gearing. It is fairly common in spur and helical gearing when the application permits slight changes between shaft centers. It is practical in worm gearing only for single thread worms with low lead angles. Otherwise faulty contact results.

Another method of controlling backlash quite common in bevel gears and less common in spur and helical gears is to match the high and low spots of the runout gears of one to one ratio and mark the engaging teeth at the point where the runout of one gear cancels the runout of the mating gear.

**Table 3. AGMA Backlash Allowance and Tolerance for Fine-Pitch Spur, Helical and Herringbone Gearing**

| Backlash Designation | Normal Diametral Pitch Range | Tooth Thinning to Obtain Backlash <sup>a</sup> |                           | Resulting Approximate Backlash (per Mesh) Normal Plane <sup>b</sup> Inch |
|----------------------|------------------------------|--|---------------------------|--|
|                      |                              | Allowance, per Gear, Inch                      | Tolerance, per Gear, Inch |  |
| A                    | 20 thru 45                   | .002   | 0 to .002                 | .004 to .008   |
|                      | 46 thru 70                   | .0015  | 0 to .002                 | .003 to .007   |
|                      | 71 thru 90                   | .001   | 0 to .00175               | .002 to .0055  |
|                      | 91 thru 200                  | .00075   | 0 to .00075               | .0015 to .003  |
| B                    | 20 thru 60                   | .001   | 0 to .001                 | .002 to .004   |
|                      | 61 thru 120                  | .00075   | 0 to .00075               | .0015 to .003  |
|                      | 121 thru 200                 | .0005  | 0 to .0005                | .001 to .002   |
| C                    | 20 thru 60                   | .0005  | 0 to .0005                | .001 to .002   |
|                      | 61 thru 120                  | .00035   | 0 to .0004                | .0007 to .0015   |
|                      | 121 thru 200                 | .0002  | 0 to .0003                | .0004 to .001  |
| D                    | 20 thru 60                   | .00025   | 0 to .00025               | .0005 to .001  |
|                      | 61 thru 120                  | .0002  | 0 to .0002                | .0004 to .0008   |
|                      | 121 thru 200                 | .0001  | 0 to .0001                | .0002 to .0004   |
| E                    | 20 thru 60                   |  | 0 to .00025               | 0 to .0005   |
|                      | 61 thru 120                  | Zero <sup>c</sup>                              | 0 to .0002                | 0 to .0004   |
|                      | 121 thru 200                 |  | 0 to .0001                | 0 to .0002   |

<sup>a</sup> These dimensions are shown primarily for the benefit of the gear manufacturer and represent the amount that the thickness of teeth should be reduced in the pinion and gear below the standard calculated value, to provide for backlash in the mesh. In some cases, particularly with pinions involving small numbers of teeth, it may be desirable to provide for total backlash by thinning the teeth in the gear member only by twice the allowance value shown in column (3). In this case both members will have the tolerance shown in column (4). In some cases, particularly in meshes with a small number of teeth, backlash may be achieved by an increase in basic center at distance. In such cases, neither member is reduced by the allowance shown in column (3).

<sup>b</sup> These dimensions indicate the approximate backlash that will occur in a mesh in which each of the mating pairs of gears have the teeth thinned by the amount referred to in Note 1, and are meshed on theoretical centers.

<sup>c</sup> Backlash in gear sets can also be achieved by increasing the center distance above nominal and using the teeth at standard tooth thickness. Class E backlash designation infers gear sets operating under these conditions.

*Backlash* in gears is the play between mating tooth surfaces. For purposes of measurement and calculation, backlash is defined as the amount by which a tooth space exceeds the thickness of an engaging tooth. When not otherwise specified, numerical values of backlash are understood to be measured at the tightest point of mesh on the pitch circle in a direction normal to the tooth surface when the gears are mounted in their specified position.

*Allowance* is the basic amount that a tooth is thinned from basic calculated circular tooth thickness to obtain the required backlash class.

*Tolerance* is the total permissible variation in the circular thickness of the teeth.

**Angular Backlash in Gears.**—When the backlash on the pitch circles of a meshing pair of gears is known, the angular backlash or angular play corresponding to this backlash may be computed from the following formulas.

$$\theta_D = \frac{6875B}{D} \text{ minutes} \quad \theta_d = \frac{6875B}{d} \text{ minutes}$$

In these formulas,  $B$  = backlash between gears, in inches;  $D$  = pitch diameter of larger gear, in inches;  $d$  = pitch diameter of smaller gear, in inches;  $\theta_D$  = angular backlash or angular movement of larger gear in minutes when smaller gear is held fixed and larger gear rocked back and forth; and  $\theta_d$  = angular backlash or angular movement of smaller gear, in minutes, when the larger gear is held fixed and the smaller gear rocked back and forth.

**Inspection of Gears.**—Perhaps the most widely used method of determining relative accuracy in a gear is to rotate the gear through at least one complete revolution in intimate contact with a master gear of known accuracy. The gear to be tested and the master gear are mounted on a variable-center-distance fixture and the resulting radial displacements or changes in center distance during rotation of the gear are measured by a suitable device. Except for the effect of backlash, this so-called “composite check” approximates the action of the gear under operating conditions and gives the combined effect of the following errors: runout; pitch error; tooth-thickness variation; profile error; and lateral runout (sometimes called wobble).

*Tooth-to-Tooth Composite Error*, illustrated below, is the error that shows up as flicker on the indicator of a variable-center-distance fixture as the gear being tested is rotated from tooth to tooth in intimate contact with the master gear. Such flicker shows the combined or composite effect of circular pitch error, tooth-thickness variation, and profile error.

Diagram Showing Nature of Composite Errors

*Total Composite Error*, shown above, is made up of runout, wobble, and the tooth-to-tooth composite error; it is the total center-distance displacement read on the indicating device of the testing fixture, as shown in the accompanying diagram.

**Pressure for Composite Checking of Fine-Pitch Gears.**—In using a variable-center-distance fixture, excessive pressure on fine-pitch gears of narrow face width will result in incorrect readings due to deflection of the teeth. Based on tests, the following checking pressures are recommended for gears of 0.100-inch face width: 20 to 29 diametral pitch, 28 ounces; 30 to 39 pitch, 24 ounces; 40 to 49 pitch, 20 ounces; 50 to 59 pitch, 16 ounces; 60 to 79 pitch, 12 ounces; 80 to 99 pitch, 8 ounces, 100 to 149 pitch, 4 ounces; and 150 and finer pitches, 2 ounces, minimum. These recommended checking pressures are based on the use of antifriction mountings for the movable head of the checking fixture and include the pressure of the indicating device. For face widths less than 0.100 inch, the recommended pressures should be reduced proportionately; for larger widths, no increase is necessary although the force may be increased safely in the proper proportion.

### Internal Gearing

**Internal Spur Gears.**—An internal gear may be proportioned like a standard spur gear turned “outside in” or with addendum and dedendum in reverse positions; however, to avoid interference or improve the tooth form and action, the internal diameter of the gear should be increased and the outside diameter of the mating pinion is also made larger than the size based upon standard or conventional tooth proportions. The extent of these enlargements will be illustrated by means of examples given following table, *Rules for Internal Gears—20-degree Full-Depth Teeth*. The 20-degree involute full-depth tooth form is recommended for internal gears; the 20-degree stub tooth and the 14½-degree full-depth tooth are also used.

**Methods of Cutting Internal Gears.**—Internal spur gears are cut by methods similar in principle to those employed for external spur gears.

They may be cut by one of the following methods: 1) By a generating process, as when using a Fellows gear shaper; 2) by using a formed cutter and milling the teeth; 3) by planing, using a machine of the template or form-copying type (especially applicable to gears of large pitch); and 4) by using a formed tool that reproduces its shape and is given a planing action either on a slotting or a planing type of machine.

Internal gears frequently have a web at one side that limits the amount of clearance space at the ends of the teeth. Such gears may be cut readily on a gear shaper. The most practical method of cutting very large internal gears is on a planer of the form-copying type. A regular spur gear planer is equipped with a special tool holder for locating the tool in the position required for cutting internal teeth.

**Formed Cutters for Internal Gears.**—When formed cutters are used, a special cutter usually is desirable, because the tooth spaces of an internal gear are not the same shape as the tooth spaces of external gearing having the same pitch and number of teeth. This difference is because an internal gear is a spur gear “turned outside in.” According to one rule, the standard No. 1 cutter for external gearing may be used for internal gears of 4 diametral pitch and finer, when there are 60 or more teeth. This No. 1 cutter, as applied to external gearing, is intended for all gears having from 135 teeth to a rack. The finer the pitch and the larger the number of teeth, the better the results obtained with a No. 1 cutter. The standard No. 1 cutter is considered satisfactory for jobbing work, and usually when the number of gears to be cut does not warrant obtaining a special cutter, although the use of the No. 1 cutter is not practicable when the number of teeth in the pinion is large in proportion to the number of teeth in the internal gear.

**Arc Thickness of Internal Gear Tooth.**—*Rule:* If internal diameter of an internal gear is enlarged as determined by Rules 1 and 2 for Internal Diameters (see *Rules for Internal Gears—20-degree Full-Depth Teeth*), the arc tooth thickness at the pitch circle equals 1.3888 divided by the diametral pitch, assuming a pressure angle of 20 degrees.

**Arc Thickness of Pinion Tooth.**—*Rule:* If the pinion for an internal gear is larger than conventional size (see Outside Diameter of Pinion for Internal Gear, under *Rules for Internal Gears—20-degree Full-Depth Teeth*), then the arc tooth thickness on the pitch circle equals 1.7528 divided by the diametral pitch, assuming a pressure angle of 20 degrees.

*Note:* For chordal thickness and chordal addendum, see rules and formulas for spur gears.

**Relative Sizes of Internal Gear and Pinion.**—If a pinion is too large or too near the size of its mating internal gear, serious interference or modification of the tooth shape may occur.

*Rule:* For internal gears having a 20-degree pressure angle and full-depth teeth, the difference between the numbers of teeth in gear and pinion should not be less than 12. For teeth of stub form, the smallest difference should be 7 or 8 teeth. For a pressure angle of 14½ degrees, the difference in tooth numbers should not be less than 15.

## Rules for Internal Gears—20-degree Full-Depth Teeth

| To Find  | Rule   |
|--|--|
| Pitch Diameter                                     | <i>Rule:</i> To find the pitch diameter of an internal gear, divide the number of internal gear teeth by the diametral pitch. The pitch diameter of the mating pinion also equals the number of pinion teeth divided by the diametral pitch, the same as for external spur gears.  |
| Internal Diameter (Enlarged to Avoid Interference) | <p><i>Rule 1:</i> For internal gears to mesh with pinions having 16 teeth or more, subtract 1.2 from the number of teeth and divide the remainder by the diametral pitch.</p> <p><i>Example:</i> An internal gear has 72 teeth of 6 diametral pitch and the mating pinion has 18 teeth; then</p> $\text{Internal diameter} = \frac{72 - 1.2}{6} = 11.8 \text{ inches}$ <p><i>Rule 2:</i> If circular pitch is used, subtract 1.2 from the number of internal gear teeth, multiply the remainder by the circular pitch, and divide the product by 3.1416.</p>   |
| Internal Diameter (Based upon Spur Gear Reversed)  | <p><i>Rule:</i> If the internal gear is to be designed to conform to a spur gear turned outside in, subtract 2 from the number of teeth and divide the remainder by the diametral pitch to find the internal diameter.</p> <p><i>Example:</i> (Same as Example above.)</p> $\text{Internal diameter} = \frac{72 - 2}{6} = 11.666 \text{ inches}$   |
| Outside Diameter of Pinion for Internal Gear       | <p><i>Note:</i> If the internal gearing is to be proportioned like standard spur gearing, use the rule or formula previously given for spur gears in determining the outside diameter. The rule and formula following apply to a pinion that is enlarged and intended to mesh with an internal gear enlarged as determined by the preceding Rules 1 and 2 above.</p> <p><i>Rule:</i> For pinions having 16 teeth or more, add 2.5 to the number of pinion teeth and divide by the diametral pitch.</p> <p><i>Example 1:</i> A pinion for driving an internal gear is to have 18 teeth (full depth) of 6 diametral pitch; then</p> $\text{Outside diameter} = \frac{18 + 2.5}{6} = 3.416 \text{ inches}$ <p>By using the rule for external spur gears, the outside diameter = 3.333 inches.</p> |
| Center Distance                                    | <i>Rule:</i> Subtract the number of pinion teeth from the number of internal gear teeth and divide the remainder by two times the diametral pitch.   |
| Tooth Thickness                                    | See paragraphs, <i>Arc Thickness of Internal Gear Tooth</i> and <i>Effect of Diameter of Cutting on Profile and Pressure Angle of Worms</i> , on previous page.  |

**British Standard for Spur and Helical Gears**

**British Standard For Spur And Helical Gears.**—BS 436: Part 1: 1967: Spur and Helical Gears, Basic Rack Form, Pitches and Accuracy for Diametral Pitch Series, now has sections concerned with basic requirements for general tooth form, standard pitches, accuracy and accuracy testing procedures, and the showing of this information on engineering drawings to make sure that the gear manufacturer receives the required data. The latest form of the standard complies with ISO agreements. The standard pitches are in accordance with ISO R54, and the basic rack form and its modifications are in accordance with the ISO R53 “Basic Rack of Cylindrical Gears for General Engineering and for Heavy Engineering Standard”.

Five grades of gear accuracy in previous versions are replaced by grades 3 to 12 of the draft ISO Standard. Grades 1 and 2 cover master gears that are not dealt with here. BS 436: Part 1: 1967 is a companion to the following British Standards:

BS 235 “Gears for Traction”

BS 545 “Bevel Gears (Machine Cut)”

BS 721 “Worm Gearing”

BS 821 “Iron Castings for Gears and Gear Blanks (Ordinary, Medium and High Grade)”

BS 978 “Fine Pitch Gears” Part 1, “Involute, Spur and Helical Gears”; Part 2, “Cycloidal Gears” (with addendum 1, PD 3376: “Double Circular Arc Type Gears.”; Part 3, “Bevel Gears”

BS 1807 “Gears for Turbines and Similar Drives” Part 1, “Accuracy” Part 2, “Tooth Form and Pitches”

BS 2519 “Glossary of Terms for Toothed Gearing”

BS 3027 “Dimensions for Worm Gear Units”

BS 3696 “Master Gears”

Part 1 of BS 436 applies to external and internal involute spur and helical gears on parallel shafts and having normal diametral pitch of 20 or coarser. The basic rack and tooth form are specified, also first and second preference standard pitches and fundamental tolerances that determine the grades of gear accuracy, and requirements for terminology and notation.

These requirements include: center distance  $a$ ; reference circle diameter  $d$ , for pinion  $d_1$  and wheel  $d_2$ ; tip diameter  $d_a$  for pinion  $d_{a1}$  and wheel  $d_{a2}$ ; center distance modification coefficient  $\gamma$ ; face width  $b$  for pinion  $b_1$  and wheel  $b_2$ ; addendum modification coefficient  $x$ ; for pinion  $x_1$  and wheel  $x_2$ ; length of arc  $l$ ; diametral pitch  $P$ ; normal diametral pitch  $p_n$ ; transverse pitch  $p_t$ ; number of teeth  $z$ , for pinion  $z_1$  and wheel  $z_2$ ; helix angle at reference cylinder  $\beta$ ; pressure angle at reference cylinder  $\alpha$ ; normal pressure angle at reference cylinder  $\alpha_n$ ; transverse pressure angle at reference cylinder  $\alpha_t$ ; and transverse pressure angle, working,  $\alpha_{tw}$ .

The basic rack tooth profile has a pressure angle of  $20^\circ$ . The Standard permits the total tooth depth to be varied within 2.25 to 2.40, so that the root clearance can be increased within the limits of 0.25 to 0.040 to allow for variations in manufacturing processes; and the root radius can be varied within the limits of 0.25 to 0.39. Tip relief can be varied within the limits shown at the right in the illustration.

*Standard normal diametral pitches  $P_n$* , BS 436 Part 1:1967, are in accordance with ISO R54. The preferred series, rather than the second choice, should be used where possible.

Preferred normal diametral pitches for spur and helical gears (second choices in parentheses) are: 20 (18), 16 (14), 12 (11), 10 (9), 8 (7), 6 (5.5), 5 (4.5), 4 (3.5), 3 (2.75), 2.5 (2.25), 2 (1.75), 1.5, 1.25, and 1.

*Information to be Given on Drawings:* British Standard BS 308, “Engineering Drawing Practice”, specifies data to be included on drawings of spur and helical gears. For all gears the data should include: number of teeth, normal diametral pitch, basic rack tooth form, axial pitch, tooth profile modifications, blank diameter, reference circle diameter, and helix angle at reference cylinder ( $0^\circ$  for straight spur gears), tooth thickness at reference

cylinder, grade of gear, drawing number of mating gear, working center distance, and backlash.

For single helical gears, the above data should be supplemented with hand and lead of the tooth helix; and for double helical gears, with the hand in relation to a specific part of the face width and the lead of tooth helix.

Inspection instructions should be included, care being taken to avoid conflicting requirements for accuracy of individual elements, and single- and dual-flank testing. Supplementary data covering specific design, manufacturing and inspection requirements or limitations may be needed, together with other dimensions and tolerances, material, heat treatment, hardness, case depth, surface texture, protective finishes, and drawing scale.

**Addendum Modification to Involute Spur and Helical Gears.**—The British Standards Institute guide PD 6457:1970 contains certain design recommendations aimed at making it possible to use standard cutting tools for some sizes of gears. Essentially, the guide covers addendum modification and includes formulas for both English and metric units.

*Addendum Modification* is an enlargement or reduction of gear tooth dimensions that results from displacement of the reference plane of the generating rack from its normal position. The displacement is represented by the coefficient  $X$ ,  $X_1$ , or  $X_2$ , where  $X$  is the equivalent dimension for gears of unit module or diametral pitch. The addendum modification establishes a datum tooth thickness at the reference circle of the gear but does not necessarily establish the height of either the reference addendum or the working addendum. In any pair of gears, the datum tooth thicknesses are those that always give zero backlash at the meshing center distance. Normal practice requires allowances for backlash for all unmodified gears.

Taking full advantage of the adaptability of the involute system allows various tooth design features to be obtained. Addendum modification has the following applications: avoiding undercut tooth profiles; achieving optimum tooth proportions and control of the proportion of receding to approaching contact; adapting a gear pair to a predetermined center distance without recourse to non-standard pitches; and permitting use of a range of working pressure angles using standard geometry tools.

**BS 436, Part 3:1986 "Spur and Helical Gears".**—This part provides methods for calculating contact and root bending stresses for metal involute gears, and is somewhat similar to the ANSI/AGMA Standard for calculating stresses in pairs of involute spur or helical gears. Stress factors covered in the British Standard include the following:

*Tangential Force* is the nominal force for contact and bending stresses.

*Zone Factor* accounts for the influence of tooth flank curvature at the pitch point on Hertzian stress.

*Contact Ratio Factor* takes account of the load-sharing influence of the transverse contact ratio and the overlap ratio on the specific loading.

*Elasticity Factor* takes into account the influence of the modulus of elasticity of the material and of Poisson's ratio on the Hertzian stress.

*Basic Endurance Limit* for contact makes allowance for the surface hardness.

*Material Quality* covers the quality of the material used.

*Lubricant Influence, Roughness, and Speed* The lubricant viscosity, surface roughness and pitch line speed affect the lubricant film thickness, which in turn, affects the Hertzian stresses.

*Work Hardening Factor* accounts for the increase in surface durability due to the meshing action.

*Size Factor* covers the possible influences of size on the material quality and its response to manufacturing processes.

*Life Factor* accounts for the increase in permissible stresses when the number of stress cycles is less than the endurance life.

*Application Factor* allows for load fluctuations from the mean load or loads in the load histogram caused by sources external to the gearing.

*Dynamic Factor* allows for load fluctuations arising from contact conditions at the gear mesh.

*Load Distribution* accounts for the increase in local load due to maldistribution of load across the face of the gear tooth caused by deflections, alignment tolerances and helix modifications.

*Minimum Demanded and Actual Safety Factor* The minimum demanded safety factor is agreed between the supplier and the purchaser. The actual safety factor is calculated.

*Geometry Factors* allow for the influence of the tooth form, the effect of the fillet and the helix angle on the nominal bending stress for the application of load at the highest point of single pair tooth contact.

*Sensitivity Factor* allows for the sensitivity of the gear material to the presence of notches such as the root fillet.

*Surface Condition Factor* accounts for reduction of the endurance limit due to flaws in the material and the surface roughness of the tooth root fillets.

**ISO TC/600.**—The ISO TC/600 Standard is similar to BS 436, Part 3:1986, but is far more comprehensive. For general gear design, the ISO Standard provides a complicated method of arriving at a conclusion similar to that reached by the less complex British Standard. Factors additional to the above that are included in the ISO Standard include the following

*Application Factor* account for dynamic overloads from sources external to the gearing.

*Dynamic Factor* allows for internally generated dynamic loads caused by vibrations of the pinion and wheel against each other.

*Load Distribution* makes allowance for the effects of non-uniform distribution of load across the face width, depending on the mesh alignment error of the loaded gear pair and the mesh stiffness.

*Transverse Load Distribution Factor* takes into account the effect of the load distribution on gear tooth contact stresses.

*Gear Tooth Stiffness Constants* are defined as the load needed to deform one or several meshing gear teeth having 1 mm face width, by an amount of  $1\ \mu\text{m}$  (0.00004 in).

*Allowable Contact Stress* is the permissible Hertzian pressure on the gear tooth face.

*Minimum demanded and Calculated Safety Factors* The minimum demanded safety factor is agreed between the supplier and the customer. The calculated safety factor is the actual safety factor of the gear pair.

*Zone Factor* accounts for the influence on the Hertzian pressure of the tooth flank curvature at the pitch point.

*Elasticity Factor* takes account of the influence of the material properties such as the modulus of elasticity and Poisson's ratio.

*Contact Ratio Factor* accounts for the influence of the transverse contact ratio and the overlap ratio on the specific surface load of the gears.

*Helix Angle Factor* makes allowance for influence of helix angle on surface durability.

*Endurance Limit* is the limit of repeated Hertzian stresses that can be permanently endured by a given material

*Life Factor* takes account of a higher permissible Hertzian stress if only limited durability is demanded.

*Lubrication Film Factor* The film of lubricant between the tooth flanks influences the surface load capacity. Factors include the oil viscosity, pitch line velocity and roughness of the tooth flanks.

*Work Hardening Factor* takes account of the increase in surface durability due to meshing a steel wheel with a hardened pinion having smooth tooth surfaces.

*Coefficient of Friction* The mean value of the local coefficient of friction depends on the lubricant, surface roughness, the lay of surface irregularities, material properties of the tooth flanks, and the force and size of tangential velocities.

*Bulk Temperature Thermal Flash Factor* is dependent on moduli of elasticity and thermal contact coefficients of pinion and wheel materials and geometry of the line of action.

*Welding Factor* Accounts for different tooth materials and heat treatments.

*Geometrical Factor* is defined as a function of the gear ratio and the dimensionless parameter on the line of action.

*Integral Temperature Criterion* The integral temperature of the gears depends on the lubricant viscosity and tendency toward cuffing and scoring of the gear materials.

Examination of the above factors shows the similarity in the approach of the British and the ISO Standards to that of the ANSI/AGMA Standards. Slight variations in the methods used to calculate the factors will result in different allowable stress figures. Experimental work using some of the stressing formulas has shown wide variations and designers must continue to rely on experience to arrive at satisfactory results.

### Standards Nomenclature

All standards are referenced and identified throughout this book by an alphanumeric prefix which designates the organization that administered the development work on the standard, and followed by a standards number.

All standards are reviewed by the relevant committees at regular time intervals, as specified by the overseeing standards organization, to determine whether the standard should be confirmed (reissued without changes other than correction of typographical errors), updated, or removed from service.

The following is for example use only. ANSI B18.8.2-1984, R1994 is a standard for Taper, Dowel, Straight, Grooved, and Spring Pins. ANSI refers to the American National Standards Institute that is responsible for overseeing the development or approval of the standard, and B18.8.2 is the number of the standard. The first date, 1984, indicates the year in which the standard was issued, and the sequence R1994 indicates that this standard was reviewed and reaffirmed in that 1994. The current designation of the standard, ANSI/ASME B18.8.2-1995, indicates that it was revised in 1995; it is ANSI approved; and, ASME (American Society of Mechanical Engineers) was the standards body responsible for development of the standard. This standard is sometimes also designated ASME B18.8.2-1995.

ISO (International Organization for Standardization) standards use a slightly different format, for example, ISO 5127-1:1983. The entire ISO reference number consists of a prefix ISO, a serial number, and the year of publication.

Aside from content, ISO standards differ from American National standards in that they often smaller focused documents, which in turn reference other standards or other parts of the same standard. Unlike the numbering scheme used by ANSI, ISO standards related to a particular topic often do not carry sequential numbers nor are they in consecutive series.

British Standards Institute standards use the following format: BS 1361: 1971 (1986). The first part is the organization prefix BS, followed by the reference number and the date of issue. The number in parenthesis is the date that the standard was most recently reconfirmed. British Standards may also be designated *withdrawn* (no longer to be used) and *obsolescent* (going out of use, but may be used for servicing older equipment).

**HYPOID AND BEVEL GEARING****Hypoid Gears**

Hypoid gears are offset and in effect, are spiral gears whose axes do not intersect but are staggered by an amount decided by the application. Due to the offset, contact between the teeth of the two gears does not occur along a surface line of the cones as it does with spiral bevels having intersecting axes, but along a curve in space inclined to the surface line. The basic solids of the hypoid gear members are not cones, as in spiral bevels, but are hyperboloids of revolution which cannot be projected into the common plane of ordinary flat gears, thus the name hypoid. The visualization of hypoid gears is based on an imaginary flat gear which is a substitute for the theoretically correct helical surface. If certain rules are observed during the calculations to fix the gear dimensions, the errors that result from the use of an imaginary flat gear as an approximation are negligible.

The staggered axes result in meshing conditions that are beneficial to the strength and running properties of the gear teeth. A uniform sliding action takes place between the teeth, not only in the direction of the tooth profile but also longitudinally, producing ideal conditions for movement of lubricants. With spiral gears, great differences in sliding motion arise over various portions of the tooth surface, creating vibration and noise. Hypoid gears are almost free from the problems of differences in these sliding motions and the teeth also have larger curvature radii in the direction of the profile. Surface pressures are thus reduced so that there is less wear and quieter operation.

The teeth of hypoid gears are 1.5 to 2 times stronger than those of spiral bevel gears of the same dimensions, made from the same material. Certain limits must be imposed on the dimensions of hypoid gear teeth so that their proportions can be calculated in the same way as they are for spiral bevel gears. The offset must not be larger than 1/7th of the ring gear outer diameter, and the tooth ratio must not be much less than 4 to 1. Within these limits, the tooth proportions can be calculated in the same way as for spiral bevel gears and the radius of lengthwise curvature can be assumed in such a way that the normal module is a maximum at the center of the tooth face width to produce stabilized tooth bearings.

If the offset is larger or the ratio is smaller than specified above, a tooth form must be selected that is better adapted to the modified meshing conditions. In particular, the curvature of the tooth length curve must be determined with other points in view. The limits are only guidelines since it is impossible to account for all other factors involved, including the pitch line speed of the gears, lubrication, loads, design of shafts and bearings, and the general conditions of operation.

Of the three different designs of hypoid bevel gears now available, the most widely used, especially in the automobile industry, is the Gleason system. Two other hypoid gear systems have been introduced by Oerlikon (Swiss) and Klingelberg (German). All three methods use the involute gear form, but they have teeth with differing curvatures, produced by the cutting method. Teeth in the Gleason system are arc shaped and their depth tapers. Both the European systems are designed to combine rolling with the sideways motion of the teeth and use a constant tooth depth. Oerlikon uses an epicycloidal tooth form and Klingelberg uses a true involute form.

With their circular arcuate tooth face curves, Gleason hypoid gears are produced with multi-bladed face milling cutters. The gear blank is rolled relative to the rotating cutter to make one inter-tooth groove, then the cutter is withdrawn and returned to its starting position while the blank is indexed into the position for cutting the next tooth. Both roughing and finishing cutters are kept parallel to the tooth root lines, which are at an angle to the gear pitch line. Depending on this angularity, plus the spiral angle, a correction factor must be calculated for both the leading and trailing faces of the gear tooth.

In operation, the convex faces of the teeth on one gear always bear on the concave faces of the teeth on the mating gear. For correct meshing between the pinion and gear wheel, the

spiral angles should not vary over the full face width. The tooth form generated is a logarithmic spiral and, as a compromise, the cutter radius is made equal to the mean radius of a corresponding logarithmic spiral.

The involute tooth face curves of the Klingelnberg system gears have constant-pitch teeth cut by (usually) a single-start taper hob. The machine is set up to rotate both the cutter and the gear blank at the correct relative speeds. The surface of the hob is set tangential to a circle radius, which is the gear base circle, from which all the parallel involute curves are struck. To keep the hob size within reasonable dimensions, the cone must lie a minimum distance within the teeth and this requirement governs the size of the module.

Both the module and the tooth depth are constant over the full face width and the spiral angle varies. The cutting speed variations, especially with regard to crown wheels, over the cone surface of the hob, make it difficult to produce a uniform surface finish on the teeth, so a finishing cut is usually made with a truncated hob which is tilted to produce the required amount of crowning automatically, for correct tooth marking and finishing. The dependence of the module, spiral angle and other features on the base circle radius, and the need for suitable hob proportions restrict the gear dimensions and the system cannot be used for gears with a low or zero angle. However, gears can be cut with a large root radius giving teeth of high strength. The favorable geometry of the tooth form gives quieter running and tolerance of inaccuracies in assembly.

Teeth of gears made by the Oerlikon system have elongated epicycloidal form, produced with a face-type rotating cutter. Both the cutter and the gear blank rotate continuously, with no indexing. The cutter head has separate groups of cutters for roughing, outside cutting and inside cutting so that tooth roots and flanks are cut simultaneously, but the feed is divided into two stages. As stresses are released during cutting, there is some distortion of the blank and this distortion will usually be worse for a hollow crown wheel than for a solid pinion.

All the heavy cuts are taken during the first stages of machining with the Oerlikon system and the second stage is used to finish the tooth profile accurately, so distortion effects are minimized. As with the Klingelnberg process, the Oerlikon system produces a variation in spiral angle and module over the width of the face, but unlike the Klingelnberg method, the tooth length curve is cycloidal. It is claimed that, under load, the tilting force in an Oerlikon gear set acts at a point 0.4 times the distance from the small diameter end of the gear and not in the mid-tooth position as in other gear systems, so that the radius is obviously smaller and the tilting moment is reduced, resulting in lower loading of the bearings.

Gears cut by the Oerlikon system have tooth markings of different shape than gears cut by other systems, showing that more of the face width of the Oerlikon tooth is involved in the load-bearing pattern. Thus, the surface loading is spread over a greater area and becomes lighter at the points of contact.

### Bevel Gearing

**Types of Bevel Gears.**—Bevel gears are conical gears, that is, gears in the shape of cones, and are used to connect shafts having intersecting axes. Hypoid gears are similar in general form to bevel gears, but operate on axes that are offset. With few exceptions, most bevel gears may be classified as being either of the straight-tooth type or of the curved-tooth type. The latter type includes spiral bevels, Zerol bevels, and hypoid gears. The following is a brief description of the distinguishing characteristics of the different types of bevel gears.

*Straight Bevel Gears:* The teeth of this most commonly used type of bevel gear are straight but their sides are tapered so that they would intersect the axis at a common point called the pitch cone apex if extended inward. The face cone elements of most straight bevel gears, however, are now made parallel to the root cone elements of the mating gear to obtain uniform clearance along the length of the teeth. The face cone elements of such

gears, therefore, would intersect the axis at a point inside the pitch cone. Straight bevel gears are the easiest to calculate and are economical to produce.

Straight bevel gear teeth may be generated for full-length contact or for localized contact. The latter are slightly convex in a lengthwise direction so that some adjustment of the gears during assembly is possible and small displacements due to load deflections can occur without undesirable load concentration on the ends of the teeth. This slight lengthwise rounding of the tooth sides need not be computed in the design but is taken care of automatically in the cutting operation on the newer types of bevel gear generators.

*Zerol Bevel Gears:* The teeth of Zerol bevel gears are curved but lie in the same general direction as the teeth of straight bevel gears. They may be thought of as spiral bevel gears of zero spiral angle and are manufactured on the same machines as spiral bevel gears. The face cone elements of Zerol bevel gears do not pass through the pitch cone apex but instead are approximately parallel to the root cone elements of the mating gear to provide uniform tooth clearance. The root cone elements also do not pass through the pitch cone apex because of the manner in which these gears are cut. Zerol bevel gears are used in place of straight bevel gears when generating equipment of the spiral type but not the straight type is available, and may be used when hardened bevel gears of high accuracy (produced by grinding) are required.

*Spiral Bevel Gears:* Spiral bevel gears have curved oblique teeth on which contact begins gradually and continues smoothly from end to end. They mesh with a rolling contact similar to straight bevel gears. As a result of their overlapping tooth action, however, spiral bevel gears will transmit motion more smoothly than straight bevel or Zerol bevel gears, reducing noise and vibration that become especially noticeable at high speeds.

One of the advantages associated with spiral bevel gears is the complete control of the localized tooth contact. By making a slight change in the radii of curvature of the mating tooth surfaces, the amount of surface over which tooth contact takes place can be changed to suit the specific requirements of each job. Localized tooth contact promotes smooth, quiet running spiral bevel gears, and permits some mounting deflections without concentrating the load dangerously near either end of the tooth. Permissible deflections established by experience are given under the heading *Mountings for Bevel Gears*.

Because their tooth surfaces can be ground, spiral bevel gears have a definite advantage in applications requiring hardened gears of high accuracy. The bottoms of the tooth spaces and the tooth profiles may be ground simultaneously, resulting in a smooth blending of the tooth profile, the tooth fillet, and the bottom of the tooth space. This feature is important from a strength standpoint because it eliminates cutter marks and other surface interruptions that frequently result in stress concentrations.

*Hypoid Gears:* In general appearance, hypoid gears resemble spiral bevel gears, except that the axis of the pinion is offset relative to the gear axis. If there is sufficient offset, the shafts may pass one another thus permitting the use of a compact straddle mounting on the gear and pinion. Whereas a spiral bevel pinion has equal pressure angles and symmetrical profile curvatures on both sides of the teeth, a hypoid pinion properly conjugate to a mating gear having equal pressure angles on both sides of the teeth must have nonsymmetrical profile curvatures for proper tooth action. In addition, to obtain equal arcs of motion for both sides of the teeth, it is necessary to use unequal pressure angles on hypoid pinions. Hypoid gears are usually designed so that the pinion has a larger spiral angle than the gear. The advantage of such a design is that the pinion diameter is increased and is stronger than a corresponding spiral bevel pinion. This diameter increment permits the use of comparatively high ratios without the pinion becoming too small to allow a bore or shank of adequate size. The sliding action along the lengthwise direction of their teeth in hypoid gears is a function of the difference in the spiral angles on the gear and pinion. This sliding effect makes such gears even smoother running than spiral bevel gears. Grinding of hypoid gears can be accomplished on the same machines used for grinding spiral bevel and Zerol bevel gears.

**Applications of Bevel and Hypoid Gears.**—Bevel and hypoid gears may be used to transmit power between shafts at practically any angle and speed. The particular type of gearing best suited for a specific job, however, depends on the mountings and the operating conditions.

*Straight and Zerol Bevel Gears:* For peripheral speeds up to 1000 feet per minute, where maximum smoothness and quietness are not the primary consideration, straight and Zerol bevel gears are recommended. For such applications, plain bearings may be used for radial and axial loads, although the use of antifriction bearings is always preferable. Plain bearings permit a more compact and less expensive design, which is one reason why straight and Zerol bevel gears are much used in differentials. This type of bevel gearing is the simplest to calculate and set up for cutting, and is ideal for small lots where fixed charges must be kept to a minimum.

Zerol bevel gears are recommended in place of straight bevel gears where hardened gears of high accuracy are required, because Zerol gears may be ground; and when only spiral-type equipment is available for cutting bevel gears.

*Spiral Bevel and Hypoid Gears:* Spiral bevel and hypoid gears are recommended for applications where peripheral speeds exceed 1000 feet per minute or 1000 revolutions per minute. In many instances, they may be used to advantage at lower speeds, particularly where extreme smoothness and quietness are desired. For peripheral speeds above 8000 feet per minute, ground gears should be used.

For large reduction ratios the use of spiral and hypoid gears will reduce the overall size of the installation because the continuous pitch line contact of these gears makes it practical to obtain smooth performance with a smaller number of teeth in the pinion than is possible with straight or Zerol bevel gears.

Hypoid gears are recommended for industrial applications: when maximum smoothness of operation is desired; for high reduction ratios where compactness of design, smoothness of operation, and maximum pinion strength are important; and for nonintersecting shafts.

Bevel and hypoid gears may be used for both speed-reducing and speed-increasing drives. In speed-increasing drives, however, the ratio should be kept as low as possible and the pinion mounted on antifriction bearings; otherwise bearing friction will cause the drive to lock.

**Notes on the Design of Bevel Gear Blanks.**—The quality of any finished gear is dependent, to a large degree, on the design and accuracy of the gear blank. A number of factors that affect manufacturing economy as well as performance must be considered.

A gear blank should be designed to avoid localized stresses and serious deflections within itself. Sufficient thickness of metal should be provided under the roots of gear teeth to give them proper support. As a general rule, the amount of metal under the root should equal the whole depth of the tooth; this metal depth should be maintained under the small ends of the teeth as well as under the middle. On webless-type ring gears, the minimum stock between the root line and the bottom of tap drill holes should be one-third the tooth depth. For heavily loaded gears, a preliminary analysis of the direction and magnitude of the forces is helpful in the design of both the gear and its mounting. Rigidity is also necessary for proper chucking when cutting the teeth. For this reason, bores, hubs, and other locating surfaces must be in proper proportion to the diameter and pitch of the gear. Small bores, thin webs, or any condition that necessitates excessive overhang in cutting should be avoided.

Other factors to be considered are the ease of machining and, in gears that are to be hardened, proper design to ensure the best hardening conditions. It is desirable to provide a locating surface of generous size on the backs of gears. This surface should be machined or ground square with the bore and is used both for locating the gear axially in assembly and for holding it when the teeth are cut. The front clamping surface must, of course, be flat and parallel to the back surface. In connection with cutting the teeth on Zerol bevel, spiral

bevel, and hypoid gears, clearance must be provided for face-mill type cutters; front and rear hubs should not intersect the extended root line of the gear or they will interfere with the path of the cutter. In addition, there must be enough room in the front of the gear for the clamp nut that holds the gear on the arbor, or in the chuck, while cutting the teeth. The same considerations must be given to straight bevel gears that are to be generated using a circular-type cutter instead of reciprocating tools.

**Mountings for Bevel Gears.**—Rigid mountings should be provided for bevel gears to keep the displacements of the gears under operating loads within recommended limits. To align gears properly, care should be taken to ensure accurately machined mountings, properly fitted keys, and couplings that run true and square.

As a result of deflection tests on gears and their mountings, and having observed these same units in service, the *Gleason Works* recommends that the following allowable deflections be used for gears from 6 to 15 inches in diameter: neither the pinion nor the gear should lift or depress more than 0.003 inch at the center of the face width; the pinion should not yield axially more than 0.003 inch in either direction; and the gear should not yield axially more than 0.003 inch in either direction on 1 to 1 ratio gears (miter gears), or near miters, or more than 0.010 inch away from the pinion on higher ratios.

When deflections exceed these limits, additional problems are involved in obtaining satisfactory gears. It becomes necessary to narrow and shorten the tooth contacts to suit the more flexible mounting. These changes decrease the bearing area, raise the unit tooth pressure, and reduce the number of teeth in contact, resulting in increased noise and the danger of surface failure as well as tooth breakage.

Spiral bevel and hypoid gears in general should be mounted on antifriction bearings in an oil-tight case. Designs for a given set of conditions may use plain bearings for radial and thrust loads, maintaining gears in satisfactory alignment is usually more easily accomplished with ball or roller bearings.

*Bearing Spacing and Shaft Stiffness:* Bearing spacing and shaft stiffness are extremely important if gear deflections are to be minimized. For both straddle mounted and overhung mounted gears the spread between bearings should never be less than 70 per cent of the pitch diameter of the gear. On overhung mounted gears the spread should be at least  $2\frac{1}{2}$  times the overhang and, in addition, the shaft diameter should be equal to or preferably greater than the overhang to provide sufficient shaft stiffness. When two spiral bevel or hypoid gears are mounted on the same shaft, the axial thrust should be taken at one place only and near the gear where the greater thrust is developed. Provision should be made for adjusting both the gear and pinion axially in assembly. Details on how this may be accomplished are given in the *Gleason Works* booklet, "Assembling Bevel Gears."

**Cutting Bevel Gear Teeth.**—A correctly formed bevel gear tooth has the same sectional shape throughout its length, but on a uniformly diminishing scale from the large to the small end. The only way to obtain this correct form is by using a generating type of bevel gear cutting machine. This accounts, in part, for the extensive use of generating type gear cutting equipment in the production of bevel gears.

Bevel gears too large to be cut by generating equipment (100 inches or over in diameter) may be produced by a form-copying type of gear planer. With this method, a template or former is used to mechanically guide a single cutting tool in the proper path to cut the profile of the teeth. Since the tooth profile produced by this method is dependent on the contour of the template used, it is possible to produce tooth profiles to suit a variety of requirements.

Although generating methods are to be preferred, there are still some cases where straight bevel gears are produced by milling. Milled gears cannot be produced with the accuracy of generated gears and generally are not suitable for use in high-speed applications or where angular motion must be transmitted with a high degree of accuracy. Milled gears are used chiefly as replacement gears in certain applications, and gears which are

subsequently to be finished on generating type equipment are sometimes roughed out by milling. Formulas and methods used for the cutting of bevel gears are given in the latter part of this section.

In producing gears by generating methods, the tooth curvature is generated from a straight-sided cutter or tool having an angle equal to the required pressure angle. This tool represents the side of a crown gear tooth. The teeth of a true involute crown gear, however, have sides which are very slightly curved. If the curvature of the cutting tool conforms to that of the involute crown gear, an involute form of bevel gear tooth will be obtained. The use of a straight-sided tool is more practical and results in a very slight change of tooth shape to what is known as the "octoid" form. Both the octoid and involute forms of bevel gear tooth give theoretically correct action.

Bevel gear teeth, like those for spur gears, differ as to pressure angle and tooth proportions. The whole depth and the addendum at the large end of the tooth may be the same as for a spur gear of equal pitch. Most bevel gears, however, both of the straight tooth and spiral-bevel types, have lengthened pinion addendums and shortened gear addendums as in the case of some spur gears, the amount of departure from equal addendums varying with the ratio of gearing. Long addendums on the pinion are used principally to avoid undercut and to increase tooth strength. In addition, where long and short addendums are used, the tooth thickness of the gear is decreased and that of the pinion increased to provide a better balance of strength. See the Gleason Works System for straight and spiral bevel gears and also the British Standard.

**Nomenclature for Bevel Gears.**—The accompanying diagram, [Fig. 1a](#), *Bevel Gear Nomenclature*, illustrates various angles and dimensions referred to in describing bevel gears. In connection with the face angles shown in the diagram, it should be noted that the face cones are made parallel to the root cones of the mating gears to provide uniform clearance along the length of the teeth. See also [Fig. 1b](#), page 2087.

**American Standard for Bevel Gears.**—American Standard ANSI/AGMA 2005-B88, Design Manual for Bevel Gears, replaces AGMA Standards 202.03, 208.03, 209.04, and 330.01, and provides standards for design of straight, zerol, and spiral bevel gears and hypoid gears with information on fabrication, inspection, and mounting. The information covers preliminary design, drawing formats, materials, rating, strength, inspection, lubrication, mountings, and assembly. Blanks for standard taper, uniform depth, duplex taper, and tilted root designs are included so that the material applies to users of Gleason, Klingenberg, and Oerlikon gear cutting machines.

**Formulas for Dimensions of Milled Bevel Gears.**—As explained earlier, most bevel gears are produced by generating methods. Even so, there are applications for which it may be desired to cut a pair of mating bevel gears by using rotary formed milling cutters. Examples of such applications include replacement gears for certain types of equipment and gears for use in experimental developments.

The tooth proportions of milled bevel gears differ in some respects from those of generated gears, the principal difference being that for milled bevel gears the tooth thicknesses of pinion and gear are made equal, and the addendum and dedendum of the pinion are respectively the same as those of the gear. The rules and formulas in the accompanying table may be used to calculate the dimensions of milled bevel gears with shafts at a right angle, an acute angle, and an obtuse angle.

In the accompanying diagrams, [Figs. 1a](#) and [1b](#), and list of notations, the various terms and symbols applied to milled bevel gears are as indicated.

- $N$  = number of teeth
- $P$  = diametral pitch
- $p$  = circular pitch
- $\alpha$  = pitch cone angle and edge angle
- $\Sigma$  = angle between shafts

## BEVEL GEARING

Fig. 1a. Bevel Gear Nomenclature

- $D$  = pitch diameter  
 $S$  = addendum  
 $S+A$  = dedendum ( $A$  = clearance)  
 $W$  = whole depth of tooth  
 $T$  = thickness of tooth at pitch line  
 $C$  = pitch cone radius  
 $F$  = width of face  
 $s$  = addendum at small end of tooth  
 $t$  = thickness of tooth at pitch line at small end  
 $\theta$  = addendum angle  
 $\phi$  = dedendum angle  
 $\gamma$  = face angle = pitch cone angle + addendum angle  
 $\delta$  = angle of compound rest  
 $\zeta$  = cutting angle  
 $K$  = angular addendum  
 $O$  = outside diameter  
 $J$  = vertex distance

$j$  = vertex distance at small end

$N'$  = number of teeth for which to select cutter

Fig. 1b. Bevel Gear Nomenclature

The formulas for milled bevel gears should be modified to make the clearance at the bottom of the teeth uniform instead of tapering toward the vertex. If this recommendation is followed, then the cutting angle (root angle) should be determined by subtracting the *addendum* angle from the pitch cone angle instead of subtracting the *dedendum* angle as in the formula given in the table.

#### Rules and Formulas for Calculating Dimensions of Milled Bevel Gears

| To Find                    | Rule   | Formula  |
|----------------------------|--|--|
| Pitch Cone Angle of Pinion | Divide the sine of the shaft angle by the sum of the cosine of the shaft angle and the quotient obtained by dividing the number of teeth in the gear by the number of teeth in the pinion; this gives the tangent. <i>Note:</i> For shaft angles greater than $90^\circ$ the cosine is negative. | $\tan \alpha_p = \frac{\sin \Sigma}{\frac{N_G}{N_P} + \cos \Sigma}$ For $90^\circ$ shaft angle,<br>$\tan \alpha_p = \frac{N_P}{N_G}$ |
| Pitch Cone Angle of Gear   | Subtract the pitch cone angle of the pinion from the shaft angle.  | $\alpha_G = \Sigma - \alpha_p$   |
| Pitch Diameter             | Divide the number of teeth by the diametral pitch.   | $D = N \div P$   |

**Rules and Formulas for Calculating Dimensions of Milled Bevel Gears (Continued)**

| To Find                                       | Rule   | Formula                                |
|---|--|--|
| Addendum                                      | Divide 1 by the diametral pitch.   | $S = 1 \div P$                         |
| Dedendum                                      | Divide 1.157 by the diametral pitch.   | $S + A = 1.157 \div P$                 |
| Whole Depth of Tooth                          | Divide 2.157 by the diametral pitch.   | $W = 2.157 \div P$                     |
| Thickness of Tooth at Pitch Line              | Divide 1.571 by the diametral pitch.   | $T = 1.571 \div P$                     |
| Pitch Cone Radius                             | Divide the pitch diameter by twice the sine of the pitch cone angle.   | $C = \frac{D}{2 \times \sin \alpha}$   |
| Addendum of Small End of Tooth                | Subtract the width of face from the pitch cone radius, divide the remainder by the pitch cone radius and multiply by the addendum.                             | $s = S \times \frac{C-F}{C}$           |
| Thickness of Tooth at Pitch Line at Small End | Subtract the width of face from the pitch cone radius, divide the remainder by the pitch cone radius and multiply by the thickness of the tooth at pitch line. | $t = T \times \frac{C-F}{C}$           |
| Addendum Angle                                | Divide the addendum by the pitch cone radius to get the tangent.   | $\tan \theta = \frac{S}{C}$            |
| Dedendum Angle                                | Divide the dedendum by the pitch cone radius to get the tangent.   | $\tan \phi = \frac{S+A}{C}$            |
| Face Width (Max.)                             | Divide the pitch cone radius by 3 or divide 8 by the diametral pitch, whichever gives the smaller value.   | $F = \frac{C}{3}$ or $F = \frac{8}{P}$ |
| Circular Pitch                                | Divide 3.1416 by the diametral pitch.  | $\rho = 3.1416 \div P$                 |
| Face Angle                                    | Add the addendum angle to the pitch cone angle   | $\gamma = \alpha + \theta$             |
| Compound Rest Angle for Turning Blank         | Subtract both the pitch cone angle and the addendum angle from 90 degrees.   | $\delta = 90^\circ - \alpha - \theta$  |
| Cutting Angle                                 | Subtract the dedendum angle from the pitch cone angle.   | $\zeta = \alpha - \phi$                |
| Angular Addendum                              | Multiply the addendum by the cosine of the pitch cone angle.   | $K = S \times \cos \alpha$             |
| Outside Diameter                              | Add twice the angular addendum to the pitch diameter.  | $O = D + 2K$                           |
| Vertex or Apex Distance                       | Multiply one-half the outside diameter by the cotangent of the face angle.   | $J = \frac{O}{2} \times \cot \gamma$   |
| Vertex Distance at Small End of Tooth         | Subtract the width of face from the pitch cone radius; divide the remainder by the pitch cone radius and multiply by the apex distance.                        | $j = J \times \frac{C-F}{C}$           |
| Number of Teeth for which to Select Cutter    | Divide the number of teeth by the cosine of the pitch cone angle.  | $N' = \frac{N}{\cos \alpha}$           |

These dimensions are the same for both gear and pinion.

Number of cutter for gear given first, followed by number for pinion. See text, page 2091

**Selecting Formed Cutters for Milling Bevel Gears.**—For milling  $14\frac{1}{2}$ -degree pressure angle bevel gears, the standard cutter series furnished by manufacturers of formed milling cutters is commonly used. There are 8 cutters in the series for each diametral pitch to cover the full range from a 12-tooth pinion to a crown gear. The difference between formed cutters used for milling spur gears and those used for bevel gears is that bevel gear cutters are thinner because they must pass through the narrow tooth space at the small end of the bevel gear; otherwise the shape of the cutter and hence, the cutter number, are the same.

To select the proper number of cutter to be used when a bevel gear is to be milled, it is necessary, first, to compute what is called the "Number of Teeth,  $N'$  for which to Select Cutter." This number of teeth can then be used to select the proper number of bevel gear cutter from the spur gear milling cutter table on page 2054. The value of  $N'$  may be computed using the last formula in the table on page 2087.

*Example 1:* What numbers of cutters are required for a pair of bevel gears of 4 diametral pitch and 70 degree shaft angle if the gear has 50 teeth and the pinion 20 teeth?

The pitch cone angle of the pinion is determined by using the first formula in the table on page 2087:

$$\tan \alpha_P = \frac{\sin \Sigma}{\frac{N_G}{N_P} + \cos \Sigma} = \frac{\sin 70^\circ}{\frac{50}{20} + \cos 70^\circ} = 0.33064; \alpha_P = 18^\circ 18'$$

The pitch cone angle of the gear is determined from the second formula in the table on page 2087:

$$\alpha_G = \Sigma - \alpha_P = 70^\circ - 18^\circ 18' = 51^\circ 42'$$

The numbers of teeth  $N'$  for which to select the cutters for the gear and pinion may now be determined from the last formula in the table on page 2087:

$$N' \text{ for the pinion} = \frac{N_P}{\cos \alpha_P} = \frac{20}{\cos 18^\circ 18'} = 21.1 \approx 21 \text{ teeth}$$

$$N' \text{ for the gear} = \frac{N_G}{\cos \alpha_G} = \frac{50}{\cos 51^\circ 42'} = 80.7 \approx 81 \text{ teeth}$$

From the table on page 2054 the numbers of the cutters for pinion and gear are found to be, respectively, 5 and 2.

*Example 2:* Required the cutters for a pair of bevel gears where the gear has 24 teeth and the pinion 12 teeth. The shaft angle is 90 degrees. As in the first example, the formulas given in the table on page 2087 will be used.

$$\tan \alpha_P = N_P \div N_G = 12 \div 24 = 0.5000 \text{ and } \alpha_P = 26^\circ 34'$$

$$\alpha_G = \Sigma - \alpha_P = 90^\circ - 26^\circ 34' = 63^\circ 26'$$

$$N' \text{ for pinion} = 12 \div \cos 26^\circ 34' = 13.4 \approx 13 \text{ teeth}$$

$$N' \text{ for gear} = 24 \div \cos 63^\circ 26' = 53.6 \approx 54 \text{ teeth}$$

And from the table on page 2054 the cutters for pinion and gear are found to be, respectively, 8 and 3.

**Use of Table for Selecting Formed Cutters for Milling Bevel Gears.**—The table beginning on page 2089 gives the numbers of cutters to use for milling various numbers of teeth in the gear and pinion. The table applies only to bevel gears with axes at right angles. Thus, in *Example 2* given above, the numbers of the cutters could have been obtained directly by entering the table with the actual numbers of teeth in the gear, 24, and the pinion, 12.

**Offset of Cutter for Milling Bevel Gears.**—When milling bevel gears with a rotary formed cutter, it is necessary to take two cuts through each tooth space with the gear blank slightly off center, first on one side and then on the other, to obtain a tooth of approximately the correct form. The gear blank is also rotated proportionately to obtain the proper tooth thickness at the large and small ends. The amount that the gear blank or cutter should be offset from the central position can be determined quite accurately by the use of the table *Factors for Obtaining Offset for Milling Bevel Gears* in conjunction with the following rule: Find the factor in the table corresponding to the number of cutter used and to the ratio of the pitch cone radius to the face width; then divide this factor by the diametral pitch and subtract the result from half the thickness of the cutter at the pitch line.

**Factors for Obtaining Offset for Milling Bevel Gears**

| No. of Cutter | Ratio of Pitch Cone Radius to Width of Face $\left(\frac{C}{F}\right)$ |                          |                          |                          |               |                          |                          |                          |               |                          |               |               |               |

Note.—For obtaining offset by above table, use formula:

$$\text{Offset} = \frac{T}{2} - \frac{\text{factor from table}}{P}$$

$P$  = diametral pitch of gear to be cut

$T$  = thickness of cutter used, measured at pitch line

To illustrate, what would be the amount of offset for a bevel gear having 24 teeth, 6 diametral pitch, 30-degree pitch cone angle and  $1\frac{1}{4}$ -inch face or tooth length? In order to obtain a factor from the table, the ratio of the pitch cone radius to the face width must be determined. The pitch cone radius equals the pitch diameter divided by twice the sine of the pitch cone angle =  $4 \div (2 \times 0.5) = 4$  inches. As the face width is 1.25, the ratio is  $4 \div 1.25$  or about  $3\frac{1}{4}$  to 1. The factor in the table for this ratio is 0.280 with a No. 4 cutter, which would be the cutter number for this particular gear. The thickness of the cutter at the pitch line is measured by using a vernier gear tooth caliper. The depth  $S + A$  (see Fig. 2;  $S$  = addendum;  $A$  = clearance) at which to take the measurement equals 1.157 divided by the diametral pitch; thus,  $1.157 \div 6 = 0.1928$  inch. The cutter thickness at this depth will vary with different cutters and even with the same cutter as it is ground away, because formed bevel gear cutters are commonly provided with side relief. Assuming that the thickness is 0.1745 inch, and substituting the values in the formula given, we have:

$$\text{Offset} = \frac{0.1745}{2} - \frac{0.280}{6} = 0.0406 \text{ inch}$$

**Adjusting the Gear Blank for Milling.**—After the offset is determined, the blank is adjusted laterally by this amount, and the tooth spaces are milled around the blank. After having milled one side of each tooth to the proper dimensions, the blank is set over in the opposite direction the same amount from a position central with the cutter, and is rotated to line up the cutter with a tooth space at the small end. A trial cut is then taken, which will leave the tooth being milled a little too thick, provided the cutter is thin enough—as it should be—to pass through the small end of the tooth space of the finished gear. This trial tooth is made the proper thickness by rotating the blank toward the cutter. To test the amount of offset, measure the tooth thickness (with a vernier caliper) at the large and small ends. The caliper should be set so that the addendum at the small end is in proper proportion to the addendum at the large end; that is, in the ratio,  $(C - F)/C$  (see Fig. 2).

Fig. 2.

In taking these measurements, if the thicknesses at both ends (which should be in the same ratio) are too great, rotate the tooth toward the cutter and take trial cuts until the proper thickness at either the large or small end is obtained. If the large end of the tooth is the right thickness and the small end too thick, the blank was offset too much; inversely, if the small end is correct and the large end too thick, the blank was not set enough off center, and, either way, its position should be changed accordingly. The formula and table previously referred to will enable a properly turned blank to be set accurately enough for general work. The dividing head should be set to the cutting angle  $\beta$  (see Fig. 2), which is found by subtracting the addendum angle  $\theta$  from the pitch cone angle  $\alpha$ . After a bevel gear is cut by the method described, the sides of the teeth at the small end should be filed as indicated by the shade lines at *E*; that is, by filing off a triangular area from the point of the tooth at the large end to the point at the small end, thence down to the pitch line and back diagonally to a point at the large end.

## Typical Steels Used for Bevel Gear Applications

| Nitriding Steels                         |  |  |  |                       |  |
| Nitralloy<br>H & G                       | Special Alloy                            | Anneal   | 163–192                                  |                       | Normal hardness range for cutting is 20–28 Rockwell C  |

Other steels with qualities equivalent to those listed in the table may also be used.

**Circular Thickness, Chordal Thickness, and Chordal Addendum of Milled Bevel Gear Teeth.**—In the formulas that follow,  $T$  = circular tooth thickness on pitch circle at large end of tooth;  $t$  = circular thickness at small end;  $T_c$  and  $t_c$  = chordal thickness at large and small ends, respectively;  $S_c$  and  $s_c$  = chordal addendum at large and small ends, respectively;  $D$  = pitch diameter at large end; and  $C, F, P, S, s,$  and  $\alpha$  are as defined on page 2085.

$$T = \frac{1.5708}{P} \quad T_c = T - \frac{T^3}{6D^2} \quad S_c = S + \frac{T^2 \cos \alpha}{4D}$$

$$t = \frac{T(C-F)}{C} \quad t_c = t - \frac{t^3}{6(D-2F \sin \alpha)^2} \quad s_c = s + \frac{t^2 \cos \alpha}{4(D-2F \sin \alpha)}$$

### Worm Gearing

**Worm Gearing.**—Worm gearing may be divided into two general classes, fine-pitch worm gearing, and coarse-pitch worm gearing. Fine-pitch worm gearing is segregated from coarse-pitch worm gearing for the following reasons:

- 1) Fine-pitch worms and wormgears are used largely to transmit motion rather than power. Tooth strength except at the coarser end of the fine-pitch range is seldom an important factor; durability and accuracy, as they affect the transmission of uniform angular motion, are of greater importance.
- 2) Housing constructions and lubricating methods are, in general, quite different for fine-pitch worm gearing.
- 3) Because fine-pitch worms and wormgears are so small, profile deviations and tooth bearings cannot be measured with the same accuracy as can those of coarse pitches.
- 4) Equipment generally available for cutting fine-pitch wormgears has restrictions which limit the diameter, the lead range, the degree of accuracy attainable, and the kind of tooth bearing obtainable.
- 5) Special consideration must be given to top lands in fine-pitch hardened worms and wormgear-cutting tools.
- 6) Interchangeability and high production are important factors in fine-pitch worm gearing; individual matching of the worm to the gear, as often practiced with coarse-pitch precision worms, is impractical in the case of fine-pitch worm drives.

**American Standard Design for Fine-pitch Worm Gearing (ANSI B6.9-1977).**—This standard is intended as a design procedure for fine-pitch worms and wormgears having axes at right angles. It covers cylindrical worms with helical threads, and wormgears hobbled for fully conjugate tooth surfaces. It does not cover helical gears used as wormgears.

**Hobs:** The hob for producing the gear is a duplicate of the mating worm with regard to tooth profile, number of threads, and lead. The hob differs from the worm principally in that the outside diameter of the hob is larger to allow for resharpening and to provide bottom clearance in the wormgear.

**Pitches:** Eight standard axial pitches have been established to provide adequate coverage of the pitch range normally required: 0.030, 0.040, 0.050, 0.065, 0.080, 0.100, 0.130, and 0.160 inch.

Axial pitch is used as a basis for this design standard because: 1) Axial pitch establishes lead which is a basic dimension in the production and inspection of worms; 2) the axial pitch of the worm is equal to the circular pitch of the gear in the central plane; and 3) only one set of change gears or one master lead cam is required for a given lead, regardless of lead angle, on commonly-used worm-producing equipment.

| <b>DIMENSIONS FOR BOTH WORM AND WORMGEAR</b>                 |                                 |  |  |
| Addendum   | $a = 0.3183P_n$                 | Tooth thickness                                | $t_n = 0.5P_n$   |
| Whole Depth  | $h_t = 0.7003P_n + 0.002$       | Approximate normal pressure angle <sup>c</sup> | $\phi_n = 20$ degrees  |
| Working Depth  | $h_k = 0.6366P_n$               | Center distance                                | $C = 0.5(d + D)$   |
| Clearance  | $c = h_t - h_k$                 |  |  |

<sup>a</sup> Current practice for fine-pitch worm gearing does not require the use of throated blanks. This results in the much simpler blank shown in the diagram which is quite similar to that for a spur or helical gear. The slight loss in contact resulting from the use of non-throated blanks has little effect on the load-carrying capacity of fine-pitch worm gears. It is sometimes desirable to use topping hobs for producing wormgears in which the size relation between the outside and pitch diameters must be closely controlled. In such cases the blank is made slightly larger than  $D_o$  by an amount (usually from 0.010 to 0.020) depending on the pitch. Topped wormgears will appear to have a small throat which is the result of the hobbing operation. For all intents and purposes, the throating is negligible and a blank so made is not to be considered as being a throated blank.

<sup>b</sup> This formula allows a sufficient length for fine-pitch worms.

<sup>c</sup> As stated in the text on page 2097, the actual pressure angle will be slightly greater due to the manufacturing process.

All dimensions in inches unless otherwise indicated.

**Lead Angles:** Fifteen standard lead angles have been established to provide adequate coverage: 0.5, 1, 1.5, 2, 3, 4, 5, 7, 9, 11, 14, 17, 21, 25, and 30 degrees.

This series of lead angles has been standardized to: 1) Minimize tooling; 2) permit obtaining geometric similarity between worms of different axial pitch by keeping the same lead angle; and 3) take into account the production distribution found in fine-pitch worm gearing applications.

For example, most fine-pitch worms have either one or two threads. This requires smaller increments at the low end of the lead angle series. For the less frequently used thread num-

bers, proportionately greater increments at the high end of the lead angle series are sufficient.

**Pressure Angle of Worm:** A pressure angle of 20 degrees has been selected as standard for cutters and grinding wheels used to produce worms within the scope of this Standard because it avoids objectionable undercutting regardless of lead angle.

Although the pressure angle of the cutter or grinding wheel used to produce the worm is 20 degrees, the normal pressure angle produced in the worm will actually be slightly greater, and will vary with the worm diameter, lead angle, and diameter of cutter or grinding wheel. A method for calculating the pressure angle change is given under the heading *Effect of Production Method on Worm Profile and Pressure Angle*.

**Pitch Diameter Range of Worms:** The minimum recommended worm pitch diameter is 0.250 inch and the maximum is 2.000 inches.

**Tooth Form of Worm and Wormgear:** The shape of the worm thread in the normal plane is defined as that which is produced by a symmetrical double-conical cutter or grinding wheel having straight elements and an included angle of 40 degrees.

Because worms and wormgears are closely related to their method of manufacture, it is impossible to specify clearly the tooth form of the wormgear without referring to the mating worm. For this reason, worm specifications should include the method of manufacture and the diameter of cutter or grinding wheel used. Similarly, for determining the shape of the generating tool, information about the method of producing the worm threads must be given to the manufacturer if the tools are to be designed correctly.

The worm profile will be a curve that departs from a straight line by varying amounts, depending on the worm diameter, lead angle, and the cutter or grinding wheel diameter. A method for calculating this deviation is given in the Standard. The tooth form of the wormgear is understood to be made fully conjugate to the mating worm thread.

#### Effect of Diameter of Cutting on Profile and Pressure Angle of Worms

**Effect of Production Method on Worm Profile and Pressure Angle.**—In worm gearing, tooth bearing is usually used as the means of judging tooth profile accuracy since direct profile measurements on fine-pitch worms or wormgears is not practical. According to AGMA 370.01, Design Manual for Fine-Pitch Gearing, a minimum of 50 per cent initial area of contact is suitable for most fine-pitch worm gearing, although in some cases, such as when the load fluctuates widely, a more restricted initial area of contact may be desirable.

Except where single-pointed lathe tools, end mills, or cutters of special shape are used in the manufacture of worms, the pressure angle and profile produced by the cutter are differ-

ent from those of the cutter itself. The amounts of these differences depend on several factors, namely, diameter and lead angle of the worm, thickness and depth of the worm thread, and diameter of the cutter or grinding wheel. The accompanying diagram shows the curvature and pressure angle effects produced in the worm by cutters and grinding wheels, and how the amount of variation in worm profile and pressure angle is influenced by the diameter of the cutting tool used.

**Materials for Worm Gearing.**—Worm gearing, especially for power transmission, should have steel worms and phosphor bronze wormgears. This combination is used extensively. The worms should be hardened and ground to obtain accuracy and a smooth finish.

The phosphor bronze wormgears should contain from 10 to 12 per cent of tin. The S.A.E. phosphor gear bronze (No. 65) contains 88–90% copper, 10–12% tin, 0.50% lead, 0.50% zinc (but with a maximum total lead, zinc and nickel content of 1.0 per cent), phosphorous 0.10–0.30%, aluminum 0.005%. The S.A.E. nickel phosphor gear bronze (No. 65 + Ni) contains 87% copper, 11% tin, 2% nickel and 0.2% phosphorous.

**Single-thread Worms.**—The ratio of the worm speed to the wormgear speed may range from 1.5 or even less up to 100 or more. Worm gearing having high ratios are not very efficient as transmitters of power; nevertheless high as well as low ratios often are required. Since the ratio equals the number of wormgear teeth divided by the number of threads or “starts” on the worm, single-thread worms are used to obtain a high ratio. As a general rule, a ratio of 50 is about the maximum recommended for a single worm and wormgear combination, although ratios up to 100 or higher are possible. When a high ratio is required, it may be preferable to use, in combination, two sets of worm gearing of the multi-thread type in preference to one set of the single-thread type in order to obtain the same total reduction and a higher combined efficiency.

Single-thread worms are comparatively inefficient because of the effect of the low lead angle; consequently, single-thread worms are not used when the primary purpose is to transmit power as efficiently as possible but they may be employed either when a large speed reduction with one set of gearing is necessary, or possibly as a means of adjustment, especially if “mechanical advantage” or self-locking are important factors.

**Multi-thread Worms.**—When worm gearing is designed primarily for transmitting power efficiently, the lead angle of the worm should be as high as is consistent with other requirements and preferably between, say, 25 or 30 and 45 degrees. This means that the worm must be multi-threaded. To obtain a given ratio, some number of wormgear teeth divided by some number of worm threads must equal the ratio. Thus, if the ratio is 6, combinations such as the following might be used:

$$\frac{24}{4}, \frac{30}{5}, \frac{36}{6}, \frac{42}{7}$$

The numerators represent the number of wormgear teeth and the denominators, the number of worm threads or “starts.” The number of wormgear teeth may not be an exact multiple of the number of threads on a multi-thread worm in order to obtain a “hunting tooth” action.

*Number of Threads or “Starts” on Worm:* The number of threads on the worm ordinarily varies from one to six or eight, depending upon the ratio of the gearing. As the ratio is increased, the number of worm threads is reduced, as a general rule. In some cases, however, the higher of two ratios may also have a larger number of threads. For example, a ratio of  $6\frac{1}{5}$  would have 5 threads whereas a ratio of  $6\frac{3}{6}$  would have 6 threads. Whenever the ratio is fractional, the number of threads on the worm equals the denominator of the fractional part of the ratio.

## HELICAL GEARING

**Basic Rules and Formulas for Helical Gear Calculations.**—The rules and formulas in the following table and elsewhere in this article are basic to helical gear calculations. The notation used in the formulas is:  $P_n$  = normal diametral pitch of cutter;  $D$  = pitch diameter;  $N$  = number of teeth;  $\alpha$  = helix angle;  $\gamma$  = center angle or angle between shafts;  $C$  = center distance;  $N'$  = number of teeth for which to select a formed cutter for milled teeth;  $L$  = lead of tooth helix;  $S$  = addendum;  $W$  = whole depth;  $T_n$  = normal tooth thickness at pitch line; and  $O$  = outside diameter.

## Rules and Formulas for Helical Gear Calculations

| No. | To Find                              | Rule   | Formula                         |
|-----|--------------------------------------|--|---------------------------------|
| 1   | Pitch Diameter                       | Divide the number of teeth by the product of the normal diametral pitch and the cosine of the helix angle. | $D = \frac{N}{P_n \cos \alpha}$ |
| 2   | Center Distance                      | Add together the two pitch diameters and divide by 2.  | $C = \frac{D_a + D_b}{2}$       |
| 3   | Lead of Tooth Helix                  | Multiply the pitch diameter by 3.1416 by the cotangent of the helix angle.                                 | $L = \pi D \cot \alpha$         |
| 4   | Addendum                             | Divide 1 by the normal diametral pitch.  | $S = \frac{1}{P_n}$             |
| 5   | Whole Depth of tooth                 | Divide 2.157 by the normal diametral pitch.  | $W = \frac{2.157}{P_n}$         |
| 6   | Normal Tooth Thickness at Pitch Line | Divide 1.5708 by the normal diametral pitch.   | $T_n = \frac{1.5708}{P_n}$      |
| 7   | Outside Diameter                     | Add twice the addendum to the pitch diameter.  | $O = D + 2S$                    |

**Determining Direction of Thrust.**—The first step in helical gear design is to determine the desired direction of the thrust. When the direction of the thrust has been determined and the relative positions of the driver and driven gears are known, then the direction of helix (right- or left-hand) may be found from the accompanying thrust diagrams, *Directions of Rotation and Resulting Thrust for Parallel Shaft and 90 Degree Shaft Angle Helical Gears*. The diagrams show the directions of rotation and the resulting thrust for parallel-

shaft and 90-degree shaft angle helical gears. The thrust bearings are located so as to take the thrust caused by the tooth loads. The direction of the thrust depends on the direction of the helix, the relative positions of driver and driven gears, and the direction of rotation. The thrust may be changed to the opposite direction by changing any one of the three conditions, namely, by changing the hand of the helix, by reversing the direction of rotation, or by exchanging of driver and driven gear positions.

Directions of Rotation and Resulting Thrust for Parallel Shaft and 90 Degree Shaft Angle Helical Gears

**Determining Helix Angles.**—The following rules should be observed for helical gears with shafts at any given angle. If each helix angle is less than the shaft angle, then the sum of the helix angles of the two gears will equal the angle between the shafts, and the helix angle is of the same hand for both gears; if the helix angle of one of the gears is larger than the shaft angle, then the difference between the helix angles of the two gears will be equal to the shaft angle, and the gears will be of opposite hand.

**Pitch of Cutter to be Used.**—The thickness of the cutter at the pitchline for cutting helical gears should equal one-half the *normal* circular pitch. The normal pitch varies with the helix angle, hence, the helix angle must be considered when selecting a cutter. The cutter should be of the same pitch as the *normal* diametral pitch of the gear. This normal pitch is found by dividing the transverse diametral pitch of the gear by the cosine of the helix angle. To illustrate, if the pitch diameter of a helical gear is 6.718 and there are 38 teeth having a helix angle of 45 degrees, the transverse diametral pitch equals 38 divided by 6.718 = 5.656; then the normal diametral pitch equals 5.656 divided by 0.707 = 8. A cutter, then, of 8 diametral pitch is the one to use for this particular gear.

Helical gears should preferably be cut on a generating-type gear cutting machine such as a hobber or shaper. Milling machines are used in some shops when hobbors or shapers are not available or when single, replacement gears are being made. In such instances, the pitch of the formed cutter used in milling a helical gear must not only conform to the normal diametral pitch of the gear, but the cutter number must also be determined. See *Selecting Cutter for Milling Helical Gears* starting on page 2108.

**1. Shafts Parallel, Center Distance Approximate.**—Given or assumed:

- 1) Position of gear having right- or left-hand helix, depending upon rotation and direction in which thrust is to be received
- 2)  $C_a$  = approximate center distance
- 3)  $P_n$  = normal diametral pitch
- 4)  $N$  = number of teeth in large gear
- 5)  $n$  = number of teeth in small gear
- 6)  $\alpha$  = angle of helix

To find:

$$1) D = \text{pitch diameter of large gear} = \frac{N}{P_n \cos \alpha}$$

$$2) d = \text{pitch diameter of small gear} = \frac{n}{P_n \cos \alpha}$$

$$3) O = \text{outside diameter of large gear} = D + \frac{2}{P_n}$$

$$4) o = \text{outside diameter of small gear} = d + \frac{2}{P_n}$$

$$5) T = \text{number of teeth marked on formed milling cutter (large gear)} = \frac{N}{\cos^3 \alpha}$$

$$6) t = \text{number of teeth marked on formed milling cutter (small gear)} = \frac{n}{\cos^3 \alpha}$$

$$7) L = \text{lead of helix on large gear} = \pi D \cot \alpha$$

$$8) l = \text{lead of helix on small gear} = \pi d \cot \alpha$$

$$9) C = \text{center distance (if not right, vary } \alpha) = \frac{1}{2}(D + d)$$

*Example:* Given or assumed: 1) See illustration; 2)  $C_a = 17$  inches; 3)  $P_n = 2$ ; 4)  $N = 48$ ; 5)  $n = 20$ ; and 6)  $\alpha = 20$ .

To find:

$$1) D = \frac{N}{P_n \cos \alpha} = \frac{48}{2 \times 0.9397} = 25.541 \text{ inches}$$

$$2) d = \frac{n}{P_n \cos \alpha} = \frac{20}{2 \times 0.9397} = 10.642 \text{ inches}$$

$$3) O = \frac{2}{P_n} = 25.541 + \frac{2}{2} = 26.541 \text{ inches}$$

$$4) o = d + \frac{2}{P_n} = 10.642 + \frac{2}{2} = 11.642 \text{ inches}$$

$$5) T = \frac{N}{\cos^3 \alpha} = \frac{48}{(0.9397)^3} = 57.8, \text{ say } 58 \text{ teeth}$$

$$6) t = \frac{n}{\cos^3 \alpha} = \frac{20}{(0.9397)^3} = 24.1, \text{ say } 24 \text{ teeth}$$

$$7) L = \pi D \cot \alpha = 3.1416 \times 25.541 \times 2.747 = 220.42 \text{ inches}$$

$$8) l = \pi d \cot \alpha = 3.1416 \times 10.642 \times 2.747 = 91.84 \text{ inches}$$

$$9) C = \frac{1}{2}(D + d) = \frac{1}{2}(25.541 + 10.642) = 18.091 \text{ inches}$$

**2. Shafts Parallel, Center Distance Exact.**—Given or assumed:

1) Position of gear having right- or left-hand helix, depending upon rotation and direction in which thrust is to be received

2)  $C$  = exact center distance

3)  $P_n$  = normal diametral pitch (pitch of cutter)

4)  $N$  = number of teeth in large gear

5)  $n$  = number of teeth in small gear

To find:

$$1) \cos \alpha = \frac{N + n}{2P_n C}$$

$$2) D = \text{pitch diameter of large gear} = \frac{N}{P_n \cos \alpha}$$

$$3) d = \text{pitch diameter of small gear} = \frac{n}{P_n \cos \alpha}$$

$$4) O = \text{outside diameter of large gear} = D + \frac{2}{P_n}$$

$$5) o = \text{outside diameter of small gear} = d + \frac{2}{P_n}$$

$$6) T = \text{number of teeth marked on formed milling cutter (large gear)} = \frac{N}{\cos^3 \alpha}$$

$$7) t = \text{number of teeth marked on formed milling cutter (small gear)} = \frac{n}{\cos^3 \alpha}$$

$$8) L = \text{lead of helix (large gear)} = \pi D \cot \alpha$$

$$9) l = \text{lead of helix (small gear)} = \pi d \cot \alpha$$

*Example:* Given or assumed: 1) See illustration; 2)  $C = 18.75$  inches; 3)  $P_n = 4$ ; 4)  $N = 96$ ; and 5)  $n = 48$ .

$$1) \cos \alpha = \frac{N + n}{2P_n C} = \frac{96 + 48}{2 \times 4 \times 18.75} = 0.96, \text{ or } \alpha = 16^\circ 16'$$

$$2) D = \frac{N}{P_n \cos \alpha} = \frac{96}{4 \times 0.96} = 25 \text{ inches}$$

$$3) d = \frac{n}{P_n \cos \alpha} = \frac{48}{4 \times 0.96} = 12.5 \text{ inches}$$

$$4) O = D + \frac{2}{P_n} = 25 + \frac{2}{4} = 25.5 \text{ inches}$$

$$5) o = d + \frac{2}{P_n} = 12.5 + \frac{2}{4} = 13 \text{ inches}$$

$$6) T = \frac{N}{\cos^3 \alpha} = \frac{96}{(0.96)^3} = 108 \text{ teeth}$$

$$7) t = \frac{n}{\cos^3 \alpha} = \frac{48}{(0.96)^3} = 54 \text{ teeth}$$

$$8) L = \pi D \cot \alpha = 3.1416 \times 25 \times 3.427 = 269.15 \text{ inches}$$

$$9) l = \pi d \cot \alpha = 3.1416 \times 12.5 \times 3.427 = 134.57 \text{ inches}$$

**3. Shafts at Right Angles, Center Distance Approx.**—Sum of helix angles of gear and pinion must equal 90 degrees.

Given or assumed:

- 1) Position of gear having right- or left-hand helix, depending on rotation and direction in which thrust is to be received
- 2)  $C_a$  = approximate center distance
- 3)  $P_n$  = normal diametral pitch (pitch of cutter)
- 4)  $R$  = ratio of gear to pinion size

$$5) n = \text{number of teeth in pinion} = \frac{1.41 C_a P_n}{R + 1} \text{ for 45 degrees;}$$

$$\text{and } \frac{2 C_a P_n \cos \alpha \cos \beta}{R \cos \beta + \cos \alpha} \text{ for any angle}$$

$$6) N = \text{number of teeth in gear} = nR$$

$$7) \alpha = \text{angle of helix of gear}$$

$$8) \beta = \text{angle of helix of pinion}$$

To find:

a) When helix angles are 45 degrees,

$$1) D = \text{pitch diameter of gear} = \frac{N}{0.70711 P_n}$$

$$2) d = \text{pitch diameter of pinion} = \frac{n}{0.70711 P_n}$$

$$3) O = \text{outside diameter of gear} = D + \frac{2}{P_n}$$

$$4) o = \text{outside diameter of pinion} = d + \frac{2}{P_n}$$

$$5) T = \text{number of formed cutter (gear)} = \frac{N}{0.353}$$

$$6) t = \text{number of formed cutter (pinion)} = \frac{n}{0.353}$$

$$7) L = \text{lead of helix of gear} = \pi D$$

$$8) l = \text{lead of helix of pinion} = \pi d$$

$$9) C = \text{center distance (exact)} = \frac{D + d}{2}$$

b) When helix angles are other than 45 degrees

$$1) D = \frac{N}{P_n \cos \alpha} \quad 2) d = \frac{n}{P_n \cos \beta} \quad 3) T = \frac{N}{\cos^3 \alpha}$$

$$4) t = \frac{n}{\cos^3 \beta} \quad 5) L = \pi D \cot \alpha \quad 6) l = \pi d \cot \beta$$

*Example:* Given or assumed: 1) See illustration; 2)  $C_a = 3.2$  inches; 3)  $P_n = 10$ ; and 4)  $R = 1.5$ .

$$5) n = \frac{1.41 C_a P_n}{R + 1} = \frac{1.41 \times 3.2 \times 10}{1.5 + 1} = \text{say 18 teeth.}$$

6)  $N = nR = 18 \times 1.5 = 27$  teeth; 7)  $\alpha = 45$  degrees; and 8)  $\beta = 45$  degrees.

To find:

$$1) D = \frac{N}{0.70711 P_n} = \frac{27}{0.70711 \times 10} = 3.818 \text{ inches}$$

$$2) d = \frac{n}{0.70711 P_n} = \frac{18}{0.70711 \times 10} = 2.545 \text{ inches}$$

$$3) O = D + \frac{2}{P_n} = 3.818 + \frac{2}{10} = 4.018 \text{ inches}$$

$$4) o = d + \frac{2}{P_n} = 2.545 + \frac{2}{10} = 2.745 \text{ inches}$$

$$5) T = \frac{N}{0.353} = \frac{27}{0.353} = 76.5, \text{ say } 76 \text{ teeth}$$

$$6) t = \frac{n}{0.353} = \frac{18}{0.353} = 51 \text{ teeth}$$

$$7) L = \pi D = 3.1416 \times 3.818 = 12 \text{ inches}$$

$$8) l = \pi d = 3.1416 \times 2.545 = 8 \text{ inches}$$

$$9) C = \frac{D + d}{2} = \frac{3.818 + 2.545}{2} = 3.182 \text{ inches}$$

**4A. Shafts at Right Angles, Center Distance Exact.**—Gears have same direction of helix. Sum of the helix angles will equal 90 degrees.

Given or assumed:

- 1) Position of gear having right- or left-hand helix depending on rotation and direction in which thrust is to be received
- 2)  $P_n$  = normal diametral pitch (pitch of cutter)
- 3)  $R$  = ratio of number of teeth in large gear to number of teeth in small gear
- 4)  $\alpha_a$  = approximate helix angle of large gear
- 5)  $C$  = exact center distance

To find:

$$1) n = \text{number of teeth in small gear nearest} = 2 CP_n \sin \alpha_a \div 1 + R \tan \alpha_a$$

$$2) N = \text{number of teeth in large gear} = Rn$$

$$3) \alpha = \text{exact helix angle of large gear, found by trial from } R \sec \alpha + \operatorname{cosec} \alpha = 2 CP_n \div n$$

$$4) \beta = \text{exact helix angle of small gear} = 90^\circ - \alpha$$

$$5) D = \text{pitch diameter of large gear} = \frac{N}{P_n \cos \alpha}$$

$$6) d = \text{pitch diameter of small gear} = \frac{n}{P_n \cos \beta}$$

$$7) O = \text{outside diameter of large gear} = D + \frac{2}{P_n}$$

$$8) o = \text{outside diameter of small gear} = d + \frac{2}{P_n}$$

9)  $N'$  and  $n'$  = numbers of teeth marked on cuttters for large and small gears (see page 2108)

$$10) L = \text{lead of helix on large gear} = \pi D \cot \alpha$$

$$11) l = \text{lead of helix on small gear} = \pi d \cot \beta$$

*Example:* Given or assumed: 1) See illustration; 2)  $P_n = 8$ ; 3)  $R = 3$ ; 4)  $\alpha_a = 45$  degrees; and 5)  $C = 10$  in.

To find:

$$1) n = \frac{2CP_n \sin \alpha_a}{1 + R \tan \alpha_a} = \frac{2 \times 10 \times 8 \times 0.70711}{1 + 3} = 28.25, \text{ say } 28 \text{ teeth}$$

$$2) N = Rn = 3 \times 28 = 84 \text{ teeth}$$

$$3) R \sec \alpha + \operatorname{cosec} \alpha = \frac{2CP_n}{n} = \frac{2 \times 10 \times 8}{28} = 5.714, \text{ or } \alpha = 46^\circ 6'$$

$$4) \beta = 90^\circ - \alpha = 90^\circ - 46^\circ 6' = 43^\circ 54'$$

$$5) D = \frac{N}{P_n \cos \alpha} = \frac{84}{8 \times 0.6934} = 15.143 \text{ inches}$$

$$6) d = \frac{n}{P_n \cos \beta} = \frac{28}{8 \times 0.72055} = 4.857 \text{ inches}$$

$$7) O = D + \frac{2}{P_n} = 15.143 + 0.25 = 15.393 \text{ inches}$$

$$8) o = d + \frac{2}{P_n} = 4.857 + 0.25 = 5.107 \text{ inches}$$

$$9) N' = 275; n' = 94 \text{ (see page 2108)}$$

$$10) L = \pi D \cot \alpha = 3.1416 \times 15.143 \times 0.96232 = 45.78 \text{ inches}$$

$$11) l = \pi d \cot \beta = 3.1416 \times 4.857 \times 1.0392 = 15.857 \text{ inches}$$

#### 4B. Shafts at Right Angles, Any Ratio, Helix Angle for Minimum Center Distance.—

Diagram similar to 4A. Gears have same direction of helix. The sum of the helix angles will equal 90 degrees.

For any given ratio of gearing  $R$  there is a helix angle  $\alpha$  for the larger gear and a helix angle  $\beta = 90^\circ - \alpha$  for the smaller gear that will make the center distance  $C$  a minimum. Helix angle  $\alpha$  is found from the formula  $\cot \alpha = R^{1/3}$ . As an example, using the data found in Case 4A, helix angles  $\alpha$  and  $\beta$  for minimum center distance would be:  $\cot \alpha = R^{1/3} = 1.4422$ ;  $\alpha = 34^\circ 44'$  and  $\beta = 90^\circ - 34^\circ 44' = 55^\circ 16'$ . Using these helix angles,  $D = 12.777$ ;  $d = 6.143$ ; and  $C = 9.460$  from the formulas for  $D$  and  $d$  given under Case 4A.

**5. Shafts at Any Angle, Center Distance Approx.—**

The sum of the helix angles of the two gears equals the shaft angle, and the gears are of the same hand, if each angle is less than the shaft angle. The difference between the helix angles equals the shaft angle, and the gears are of opposite hand, if either angle is greater than the shaft angle.

Given or assumed:

- 1) Hand of helix, depending on rotation and direction in which thrust is to be received
- 2)  $C_a$  = center distance
- 3)  $P_n$  = normal diametral pitch (pitch of cutter)

$$4) R = \text{ratio of gear to pinion} = \frac{N}{n}$$

5)  $\alpha$  = angle of helix, gear

6)  $\beta$  = angle of helix, pinion

$$7) n = \text{number of teeth in pinion nearest } \frac{2C_a P_n \cos \alpha \cos \beta}{R \cos \beta + \cos \alpha} \text{ for any angle}$$

$$\text{and } \frac{2C_a P_n \cos \alpha}{R + 1} \text{ when both angles are equal}$$

8)  $N$  = number of teeth in gear =  $Rn$

To find:

$$1) D = \text{pitch diameter of gear} = \frac{N}{P_n \cos \alpha}$$

$$2) d = \text{pitch diameter of pinion} = \frac{n}{P_n \cos \beta}$$

$$3) O = \text{outside diameter of gear} = D + \frac{2}{P_n}$$

$$4) o = \text{outside diameter of pinion} = d + \frac{2}{P_n}$$

$$5) T = \text{number of teeth marked on cutter for gear} = \frac{N}{\cos^3 \alpha}$$

$$6) t = \text{number of teeth marked on cutter for pinion} = \frac{n}{\cos^3 \beta}$$

7)  $L$  = lead of helix on gear =  $\pi D \cot \alpha$

8)  $l$  = lead of helix on pinion =  $\pi d \cot \beta$

$$9) C = \text{actual center distance} = \frac{D + d}{2}$$

*Example:* Given or assumed (angle of shafts, 60 degrees):

1) See illustration 2)  $C_a$  = 12 inches 3)  $P_n$  = 8

4)  $R$  = 4 5)  $\alpha$  = 30 degrees 6)  $\beta$  = 30 degrees

$$7) n = \frac{2C_a P_n \cos \alpha}{R + 1} = \frac{2 \times 12 \times 8 \times 0.86603}{4 + 1} = 33 \text{ teeth}$$

$$8) N = 4 \times 33 = 132 \text{ teeth}$$

To find:

$$1) D = \frac{N}{P_n \cos \alpha} = \frac{132}{8 \times 0.86603} = 19.052 \text{ inches}$$

$$2) d = \frac{n}{P_n \cos \beta} = \frac{33}{8 \times 0.86603} = 4.763 \text{ inches}$$

$$3) O = D + \frac{2}{P_n} = 19.052 + \frac{2}{8} = 19.302 \text{ inches}$$

$$4) o = d + \frac{2}{P_n} = 4.763 + \frac{2}{8} = 5.013 \text{ inches}$$

$$5) T = \frac{N}{\cos^3 \alpha} = \frac{132}{0.65} = 203 \text{ teeth}$$

$$6) t = \frac{n}{\cos^3 \beta} = \frac{33}{0.65} = 51 \text{ teeth}$$

$$7) L = \pi D \cot \alpha = \pi \times 19.052 \times 1.732 = 103.66 \text{ inches}$$

$$8) l = \pi d \cot \beta = \pi \times 4.763 \times 1.732 = 25.92 \text{ inches}$$

$$9) C = \frac{D + d}{2} = \frac{19.052 + 4.763}{2} = 11.9075 \text{ inches}$$

**6. Shafts at Any Angle, Center Distance Exact.**—The sum of the helix angles of

the two gears equals the shaft angle, and the gears are of the same hand, if each angle is less than the shaft angle. The difference between the helix angles equals the shaft angle, and the gears are of opposite hand, if either angle is greater than the shaft angle.

Given or assumed:

- 1) Hand of helix, depending on rotation and direction in which thrust is to be received
- 2)  $C$  = center distance
- 3)  $P_n$  = normal diametral pitch (pitch of cutter)

4)  $\alpha_a$  = approximate helix angle of gear

5)  $\beta_a$  = approximate helix angle of pinion

6)  $R$  = ratio of gear to pinion size =  $\frac{N}{n}$

7)  $n$  = number of pinion teeth nearest  $\frac{2CP_n \cos \alpha_a \cos \beta_a}{R \cos \beta_a + \cos \alpha_a}$

8)  $N$  = number of gear teeth =  $Rn$

To find:

1)  $\alpha$  and  $\beta$ , exact helix angles, found by trial from  $R \sec \alpha + \sec \beta = \frac{2CP_n}{n}$

$$2) D = \text{pitch diameter of gear} = \frac{N}{P_n \cos \alpha}$$

$$3) d = \text{pitch diameter of pinion} = \frac{n}{P_n \cos \beta}$$

$$4) O = \text{outside diameter of gear} = D + \frac{2}{P_n}$$

$$5) o = \text{outside diameter of pinion} = d + \frac{2}{P_n}$$

6)  $N'$  = number of teeth marked on formed cutter for gear (see below)

7)  $n'$  = number of teeth marked on formed cutter for pinion (see below)

8)  $L$  = lead of helix on gear =  $\pi D \cot \alpha$

9)  $l$  = lead of helix on pinion =  $\pi d \cot \beta$

**Selecting Cutter for Milling Helical Gears.**—The proper milling cutter to use for spur gears depends on the pitch of the teeth and also upon the number of teeth as explained on page 2052 but a cutter for milling helical gears is not selected with reference to the actual number of teeth in the gear, as in spur gearing, but rather with reference to a calculated number  $N'$  that takes into account the effect on the tooth profile of lead angle, normal diametral pitch, and cutter diameter.

In the helical gearing examples starting on page 2101 the number of teeth  $N'$  on which to base the selection of the cutter has been determined using the approximate formula  $N' = N \div \cos^3 \alpha$  or  $N' = N \sec^3 \alpha$ , where  $N$  = the actual number of teeth in the helical gear and  $\alpha$  = the helix angle. However, the use of this formula may, where a combination of high helix angle and low tooth number is involved, result in the selection of a higher number of cutter than should actually be used for greatest accuracy. This condition is most likely to occur when the aforementioned formula is used to calculate  $N'$  for gears of high helix angle and low number of teeth.

To avoid the possibility of error in choice of cutter number, the following formula, which gives theoretically correct results for all combinations of helix angle and tooth numbers, is to be preferred:

$$N' = N \sec^3 \alpha + P_n D_c \tan^2 \alpha \quad (1)$$

where:  $N'$  = number of teeth on which to base selection of cutter number from table on page 2054;  $N$  = actual number of teeth in helical gear;  $\alpha$  = helix angle;  $P_n$  = normal diametral pitch of gear and cutter; and  $D_c$  = pitch diameter of cutter.

To simplify calculations, Formula (1) may be written as follows:

$$N' = NK + QK' \quad (2)$$

In this formula,  $K$ ,  $K'$  and  $Q$  are constants obtained from the tables on page 2109.

*Example:* Helix angle = 30 degrees; number of teeth in helical gear = 15; and normal diametral pitch = 20. From the tables on page 2109  $K$ ,  $K'$ , and  $Q$  are, respectively, 1.540, 0.333, and 37.80.

$$\begin{aligned} N' &= (15 \times 1.540) + (37.80 \times 0.333) = 23.10 + 12.60 \\ &= 35.70, \text{ say, } 36 \end{aligned}$$

Hence, from page 2054 select a number 3 cutter. Had the approximate formula been used, then a number 5 cutter would have been selected on the basis of  $N' = 23$ .

## Factors for Selecting Cutters for Milling Helical Gears

| Helix Angle, $\alpha$ | $K$   | $K'$  | Helix Angle, $\alpha$ | $K$   | $K'$  | Helix Angle, $\alpha$ | $K$   | $K'$  | Helix Angle, $\alpha$ | $K$    | $K'$  |
|-----------------------|-------|-------|-----------------------|-------|-------|-----------------------|-------|-------|-----------------------|--------|-------|

| 2½                            | 5.750               | 4.83              | 12.08         | 12                            | 2.250               | 2.06              | 24.72         | 40                            | 1.750               | 1.70              | 68.00         |
| 3                             | 4.750               | 3.98              | 11.94         | 14                            | 2.125               | 1.96              | 27.44         | 48                            | 1.750               | 1.70              | 81.60         |
| 4                             | 4.250               | 3.67              | 14.68         | 16                            | 2.125               | 1.98              | 31.68         | ..                            | ...                 | ...               | ...           |
| 5                             | 3.750               | 3.29              | 16.45         | 18                            | 2.000               | 1.87              | 33.66         | ..                            | ...                 | ...               | ...           |

Pitch diameters shown in the table are computed from the formula:  $D_c = D_o - 2(1.57 \div P_n)$ . This same formula may be used to compute the pitch diameter of a non-standard outside diameter cutter when the normal diametral pitch  $P_n$  and the outside diameter  $D_o$  are known.

**Milling the Helical Teeth.**—The teeth of a helical gear are proportioned from the normal pitch and not the circular pitch. The whole depth of the tooth can be found by dividing 2.157 by the normal diametral pitch of the gear, which corresponds to the pitch of the cut-

ter. The thickness of the tooth at the pitch line equals 1.571 divided by the normal diametral pitch. After a tooth space has been milled, the cutter should be prevented from dragging through it when being returned for another cut. This can be done by lowering the blank slightly, or by stopping the machine and turning the cutter to such a position that the teeth will not touch the work. If the gear has teeth coarser than 10 or 12 diametral pitch, it is well to take a roughing and a finishing cut. When pressing a helical gear blank on the arbor, it should be remembered that it is more likely to slip when being milled than a spur gear, because the pressure of the cut, being at an angle, tends to rotate the blank on the arbor.

*Angular Position of Table:* When cutting a helical gear on a milling machine, the table is set to the helix angle of the gear. If the lead of the helical gear is known, but not the helix angle, the helix angle is determined by multiplying the pitch diameter of the gear by 3.1416 and dividing this product by the lead; the result is the tangent of the lead angle which may be obtained from trigonometric tables or a calculator.

**American National Standard Fine-Pitch Teeth For Helical Gears.**—This Standard, ANSI B6.7-1977, provides a 20-degree tooth form for both spur and helical gears of 20 diametral pitch and finer. Formulas for tooth parts are given on page 2039.

*Enlargement of Helical Pinions, 20-Degree Normal Pressure Angle:* Formula (4) and the accompanying graph are based on the use of hobs having sharp corners at their top lands. Pinions cut by shaper cutters may not require as much modification as indicated by (4) or the graph. The number 2.1 appearing in (4) results from the use of a standard tooth thickness rack having an addendum of  $1.05/P_n$  which will start contact at a roll angle 5 degrees above the base radius. The roll angle of 5 degrees is also reflected in Formula (4).

To avoid undercutting of the teeth and to provide more favorable contact conditions near the base of the tooth, it is recommended that helical pinions with less than 24 teeth be enlarged in accordance with the following graph and formulas. As with enlarged spur pinions, when an enlarged helical pinion is used it is necessary either to reduce the diameter of the mating gear or to increase the center distance. In the formulas that follow,  $\phi_n$  = normal pressure angle;  $\phi_t$  = transverse pressure angle;  $\psi$  = helix angle of pinion;  $P_n$  = normal diametral pitch;  $P_t$  = transverse diametral pitch;  $d$  = pitch diameter of pinion;  $d_o$  = outside diameter of enlarged pinion,  $K_h$  = enlargement for full depth pinions of 1 normal diametral pitch; and  $n$  = number of teeth in pinion.

To eliminate the need for making the calculations indicated in [Formulas \(3\) and \(4\)](#), the accompanying graph may be used to obtain the value of  $K_h$  directly for full-depth pinions of 20-degree normal pressure angle.

$$P_t = P_n \cos \psi \quad (1)$$

$$d = n \div P_t \quad (2)$$

$$\tan \psi_t = \tan \phi_n \div \cos \psi \quad (3)$$

$$K_h = 2.1 - \frac{n}{\cos \psi} (\sin \phi_t - \cos \phi_t \tan 5^\circ) \sin \phi_t \quad (4)$$

$$d_o = d + \frac{2 + K_h}{P_n} \quad (5)$$

*Example:* Find the outside diameter of a helical pinion having 12 teeth, 32 normal diametral pitch, 20-degree pressure angle, and 18-degree helix angle.

$$P_t = P_n \cos \psi = 32 \cos 18^\circ = 32 \times 0.95106 = 30.4339$$

$$d = n \div P_t = 12 \div 30.4339 = 0.3943 \text{ inch}$$

$$K_h = 0.851 \text{ (from graph)}$$

$$d_o = 0.3943 + \frac{2 + 0.851}{32} = 0.4834$$

**Center Distance at Which Modified Mating Helical Gears Will Mesh with no Backlash.**—If the helical pinion in the previous example on page 2111 had been made to standard dimensions, that is, not enlarged, and was in tight mesh with a standard 24-tooth mating gear, the center distance for tight mesh could be calculated from the formula on page 2039:

$$C = \frac{n + N}{2P_n \cos \psi} = \frac{12 + 24}{2 \times 32 \times \cos 18^\circ} = 0.5914 \text{ inch} \quad (1)$$

However, if the pinion is enlarged as in the example and meshed with the same standard 24-tooth gear, then the center distance for tight mesh will be increased. To calculate the new center distance, the following formulas and calculations are required:

First, calculate the transverse pressure angle  $\phi_t$  using [Formula \(2\)](#):

$$\tan \phi_t = \tan \phi_n \div \cos \psi = \tan 20^\circ \div \cos 18^\circ = 0.38270 \quad (2)$$

and from a calculator the angle  $\phi_t$  is found to be  $20^\circ 56' 30''$ . In the table on page 104,  $\text{inv } \phi_t$  is found to be 0.017196, and the cosine from a calculator as 0.93394.

Using [Formula \(3\)](#), calculate the pressure angle  $\phi$  at which the gears are in tight mesh:

$$\text{inv } \phi = \text{inv } \phi_t + \frac{(t_{nP} + t_{nG}) - \pi}{n + N} \quad (3)$$

In this formula, the value for  $t_{nP}$  for 1 diametral pitch is that found in [Table 9c](#) on page 2056, for a 12-tooth pinion, in the fourth column: 1.94703. The value of  $t_{nG}$  for 1 diametral pitch for a standard gear is always 1.5708.

$$\text{inv } \phi = 0.017196 + \frac{(1.94703 + 1.5708) - \pi}{12 + 24} = 0.027647$$

From the table on page 105, or a calculator, 0.027647 is the involute of  $24^\circ 22' 7''$  and the cosine corresponding to this angle is 0.91091.

Finally, using [Formula \(4\)](#), the center distance for tight mesh,  $C'$  is found:

$$C' = \frac{C \cos \phi_t}{\cos \phi} = \frac{0.5914 \times 0.93394}{0.91091} = 0.606 \text{ inch} \quad (4)$$

**Change-gears for Helical Gear Hobbing.**—If a gear-hobbing machine is not equipped with a differential, there is a fixed relation between the index and feed gears and it is necessary to compensate for even slight errors in the index gear ratio, to avoid excessive lead errors. This may be done readily (as shown by the example to follow) by modifying the ratio of the feed gears slightly, thus offsetting the index gear error and making very accurate leads possible.

*Machine Without Differential:* The formulas which follow may be applied in computing the index gear ratio.

$R$  = index-gear ratio

$L$  = lead of gear, inches

$F$  = feed per gear revolution, inch

$K$  = machine constant

$T$  = number of threads on hob

$N$  = number of teeth on gear

$P_n$  = normal diametral pitch

$P_{nc}$  = normal circular pitch

$A$  = helix angle, relative to axis

$M$  = feed gear constant

$$R = \frac{L \div F}{(L \div F) \pm 1} \times \frac{KT}{N} = \frac{L}{L \pm F} \times \frac{KT}{N} = \frac{\text{Driving gear sizes}}{\text{Driven gear sizes}} \quad (1)$$

Use minus (–) sign in [Formulas \(1\) and \(2\)](#) when gear and hob are the same “hand” and plus (+) sign when they are of opposite hand; when *climb* hobbing is to be used, reverse this rule.

$$R = \frac{KT}{N \pm \frac{P_n \times \sin A \times F}{\pi}} = \frac{KT}{N \pm \frac{\sin A \times F}{P_{nc}}} \quad (2)$$

$$\text{Ratio of feed gears} = \frac{F}{M} \quad F = \frac{L(NR - KT)}{NR} \quad (3)$$

$$L = \frac{FNR}{(NR - KT)} = \text{lead obtained with available index and feed gears} \quad (4)$$

*Note:* If gear and hob are of opposite hand, then in [Formulas \(3\) and \(4\)](#) change  $(NR - KT)$  to  $(KT - NR)$ . This change is also made if gear and hob are of same hand but *climb* hobbing is used.

*Example:* A right-hand helical gear with 48 teeth of 10 normal diametral pitch, has a lead of 44.0894 inches. The feed is to be 0.035 inch, with whatever slight adjustment may be necessary to compensate for the error in available index gears.  $K = 30$  and  $M = 0.075$ . A single-thread right-hand hob is to be used.

$$R = \frac{44.0894}{44.0894 - 0.035} \times \frac{30 \times 1}{48} = 0.62549654$$

Using the method of *Conjugate Fractions* beginning on page [12](#), several suitable ratios close to 0.62549654 were found. One of these,  $(34 \times 53)/(43 \times 67) = 0.625477264839$  will be used as the index ratio. Other usable ratios and their decimal values were found to be as follows:

$$\frac{32 \times 38}{27 \times 72} = 0.6255144 \quad \frac{27 \times 42}{42 \times 37} = 0.62548263$$

$$\frac{44 \times 29}{34 \times 60} = 0.6254902 \quad \frac{26 \times 97}{96 \times 42} = 0.62549603$$

$$\frac{20 \times 41}{23 \times 57} = 0.62547674$$

Index ratio error =  $0.62549654 - 0.62547726 = 0.00001928$ .

Now use [Formula \(3\)](#) to find slight change required in rate of feed. This change compensates sufficiently for the error in available index gears.

*Change in Feed Rate:* Insert in [Formula \(3\)](#) obtainable index ratio.

$$F = \frac{44.0894 \times (48 \times 0.62547726 - 30)}{48 \times 0.62547726} = 0.0336417$$

$$\text{Modified feed gear ratio} = \frac{F}{M} = \frac{0.0336417}{0.075} = 0.448556$$

$$\text{Log } 0.448556 = \bar{1}.651817 \quad \text{log of reciprocal} = 0.348183$$

To find close approximation to modified feed gear ratio, proceed as in finding suitable gears for index ratio, thus obtaining  $\frac{106}{71} \times \frac{112}{75}$ . Inverting, modified feed gear ratio =

$$\frac{71}{106} \times \frac{75}{112} = 0.448534.$$

Modified feed  $F$  = obtainable modified feed ratio  $\times M = 0.448534 \times 0.075 = 0.03364$  inch. If the feed rate is not modified, even a small error in the index gear ratio may result in an excessive lead error.

*Checking Accuracy of Lead:* The modified feed and obtainable index ratio are inserted in [Formula \(4\)](#). Desired lead = 44.0894 inches. Lead obtained = 44.087196 inches; hence the computed error =  $44.0894 - 44.087196 = 0.002204$  inch or about 0.00005 inch per inch of lead.

*Machine with Differential:* If a machine is equipped with a differential, the *lead gears* are computed in order to obtain the required helix angle and lead. The instructions of the hobbing machine manufacturer should be followed in computing the lead gears, because the ratio formula is affected by the location of the differential gears. If these gears are *ahead* of the index gears, the lead gear ratio is not affected by a change in the number of teeth to be cut (see [Formula \(5\)](#)); hence, the same lead gears are used when, for example, a gear and pinion are cut on the same machine. In the formulas which follow, the notation is the same as previously given, with these exceptions:  $R_d$  = lead gear ratio for machine with differential;  $P_a$  = axial or linear pitch of helical gear = distance from center of one tooth to center of next tooth measured parallel to gear axis = total lead  $L \div$  number of teeth  $N$ .

$$R_d = \frac{P_a \times T}{K} = \frac{L \times T}{N \times K} = \frac{\pi \times \text{cosec } A \times T}{P_n \times K} = \frac{\text{Driven gear sizes}}{\text{Driving gear sizes}} \quad (5)$$

The number of hob threads  $T$  is included in the formula because double-thread hobs are used sometimes, especially for roughing in order to reduce the hobbing time. Lead gears having a ratio sufficiently close to the required ratio may be determined by using the table of gear ratio logarithms as previously described in connection with the non-differential type of machine. When using a machine equipped with a differential, the effect of a lead-gear ratio error upon the lead of the gear is small in comparison with the effect of an index gear error when using a non-differential type of machine. The lead obtained with a given or

obtainable lead gear ratio may be determined by the following formula:  $L = (R_d NK) \div T$ . In this formula,  $R_d$  represents the ratio obtained with available gears. If the given lead is 44.0894 inches, as in the preceding example, then the desired ratio as obtained with **Formula (5)** would be 0.9185292 if  $K = 1$ . Assume that the lead gears selected by using logs of ratios have a ratio of 0.9184704; then this ratio error of 0.0000588 would result in a computed lead error of only 0.000065 inch per inch.

**Formula (5)**, as mentioned, applies to machines having the differential located *ahead* of the index gears. If the differential is located after the index gears, it is necessary to change lead gears whenever the index gears are changed for hobbing a different number of teeth, as indicated by the following formula which gives the lead gear ratio. In this formula,  $D =$  pitch diameter.

$$R_d = \frac{L \times T}{K} = \frac{D \times \pi \times T}{K \times \tan A} = \frac{\text{Driven gear sizes}}{\text{Driving gear sizes}} \quad (6)$$

**General Remarks on Helical Gear Hobbing.**—In cutting teeth having large angles, it is desirable to have the direction of helix of the hob the same as the direction of helix of the gear, or in other words, the gear and the hob of the same “hand.” Then the direction of the cut will come against the movement of the blank. At ordinary angles, however, one hob will cut both right- and left-hand gears. In setting up the hobbing machine for helical gears, care should be taken to see that the vertical feed does not trip until the machine has been stopped or the hob has fed down past the finished gear.

### Herringbone Gears

Double helical or herringbone gears are commonly used in parallel-shaft transmissions, especially when a smooth, continuous action (due to the gradual overlapping engagement of the teeth) is essential, as in high-speed drives where the pitch-line velocity may range from about 1000 to 3000 feet per minute in commercial gearing and up to 12,000 feet per minute or higher in more specialized installations. These relatively high speeds are encountered in marine reduction gears, in certain speed-reducing and speed-increasing units, and in various other transmissions, particularly in connection with steam turbine and electric motor drives.

**General Classes of Helical Gear Problems.**—There are two general classes of problems. In one, the problem is to design gears capable of transmitting a given amount of power at a given speed, safely and without excessive wear; hence, the required proportions must be determined. In the second, the proportions and speed are known and the power-transmitting capacity is required. The first is the more difficult and common problem.

**Causes of Herringbone Gear Failures.**—Where failure occurs in a herringbone gear transmission, it is rarely due to tooth breakage but usually to excessive wear or sub-surface failures, such as pitting and spalling; hence, it is common practice to base the design of such gears upon durability, or upon tooth pressures which are within the allowable limits for wear. In this connection, it seems to have been well established by tests of both spur gears and herringbone gears, that there is a critical surface pressure value for teeth having given physical properties and coefficient of friction. According to these tests, pressures above the critical value result in rapid wear and a short gear life, whereas when pressures are below the critical, wear is negligible. The yield point or endurance limit of the material marks the critical loading point, and in practical designing a reasonable factor of safety would, of course, be applied.

### Elliptic Gears

Gears of this type provide simple means of obtaining a quick-return motion but they present a rather cumbersome manufacturing problem and, as a general rule, it is preferable

to obtain quick-return motions by some other type of mechanism. When elliptic gears are used, the two gears that mesh with each other must be equal in size, and each gear must revolve about one of the foci of the ellipse forming the pitch line, as indicated by the diagram, in Fig. 1a. By the use of elliptic gears so mounted, it is possible to obtain a variable motion of the driven shaft, because the gear on the driving shaft, while revolving one half of a revolution, will engage with only a small portion of the circumference of the driven gear, while during the other half of its revolution, the driving gear will engage with a great deal more than one-half of the total number of teeth in the driven gear; hence, the cutting stroke of a machine tool, for example, may be made to have a slow motion, while the return stroke is at a rapid rate. The ellipse has two points, each of which is called a *focus*, located as indicated at *A* and *B*. The sum of the distance between the foci and the elliptic curve is constant at all points and is equal to the longer or major axis of the ellipse. On account of this peculiarity of the ellipse, two equal ellipses can be made to mesh with each other during a complete revolution about their axes, if one is mounted on a shaft at its focus *A* and the other at its focus *B*.

Fig. 1a. General Arrangement of Elliptic Gears.

### Planetary Gearing

Planetary or epicyclic gearing provides means of obtaining a compact design of transmission, with driving and driven shafts in line, and a large speed reduction when required. Typical arrangements of planetary gearing are shown by the following diagrams which are accompanied by speed ratio formulas. When planetary gears are arranged as shown by Figs. 5, 6, 9 and 12, the speed of the follower relative to the driver is increased, whereas Figs. 7, 8, 10, and 11 illustrate speed-reducing mechanisms.

**Direction of Rotation.**—In using the following formulas, if the final result is preceded by a minus sign (negative), this indicates that the driver and follower will rotate in opposite directions; otherwise, both will rotate in the same direction.

**Compound Drive.**—The formulas accompanying Figs. 19 through 22 are for obtaining the speed ratios when there are *two* driving members rotating at different speeds. For example, in Fig. 19, the central shaft with its attached link is one driver. The internal gear  $z$ , instead of being fixed, is also rotated. In Fig. 22, if  $z = 24$ ,  $B = 60$  and  $S = 3\frac{1}{2}$ , with both drivers rotating in the same direction, then  $F = 0$ , thus indicating, in this case, the point where a larger value of  $S$  will reverse follower rotation.

**Planetary Bevel Gears.**—Two forms of planetary gears of the bevel type are shown in Figs. 23 and 24. The planet gear in Fig. 23 rotates about a fixed bevel gear at the center of which is the driven shaft. Fig. 24 illustrates the Humpage reduction gear. This is sometimes referred to as cone-pulley back-gearing because of its use within the cone pulleys of certain types of machine tools.

**Ratios of Planetary or Epicyclic Gearing**

$D$  = rotation of *driver* per revolution of follower or driven member  
 $F$  = rotation of *follower* or driven member per revolution of driver. (In Figs. 1 through 4,  $F$  = rotation of planet type follower about its axis.)  
 $A$  = size of driving gear (use either number of teeth or pitch diameter). Note: When follower derives its motion both from  $A$  and from a secondary driving member,  $A$  = size of *initial* driving gear, and formula gives speed relationship between  $A$  and follower.  
 $B$  = size of *driven* gear or *follower* (use either pitch diameter or number of teeth)  
 $C$  = size of *fixed* gear (use either pitch diameter or number of teeth)  
 $x$  = size of *planet gear* as shown by diagram (use either pitch diameter or number of teeth)  
 $y$  = size of *planet gear* as shown by diagram (use either pitch diameter or number of teeth)  
 $z$  = size of secondary or *auxiliary driving gear*, when follower derives its motion from two driving members  
 $S$  = rotation of *secondary driver*, per revolution of *initial driver*.  $S$  is negative when secondary and initial drivers rotate in opposite directions. (Formulas in which  $S$  is used, give speed relationship between follower and the initial driver.)  
 Note: In all cases, if  $D$  is known,  $F = 1 \div D$ , or, if  $F$  is known,  $D = 1 \div F$ .

## Ratchet Gearing

Ratchet gearing may be used to transmit intermittent motion, or its only function may be to prevent the ratchet wheel from rotating backward. Ratchet gearing of this latter form is commonly used in connection with hoisting mechanisms of various kinds, to prevent the hoisting drum or shaft from rotating in a reverse direction under the action of the load.

## Types of Ratchet Gearing

Ratchet gearing in its simplest form consists of a toothed ratchet wheel *a* (see Fig. a), and a pawl or detent *b*, and it may be used to transmit intermittent motion or to prevent relative motion between two parts except in one direction. The pawl *b* is pivoted to lever *c* which, when given an oscillating movement, imparts an intermittent rotary movement to ratchet wheel *a*. Fig. b illustrates another application of the ordinary ratchet and pawl mechanism. In this instance, the pawl is pivoted to a stationary member and its only function is to prevent the ratchet wheel from rotating backward. With the stationary design, illustrated at

Fig. c, the pawl prevents the ratchet wheel from rotating in either direction, so long as it is in engagement with the wheel.

The principle of *multiple-pawl ratchet gearing* is illustrated at Fig. d, which shows the use of two pawls. One of these pawls is longer than the other, by an amount equal to one-half the pitch of the ratchet-wheel teeth, so that the practical effect is that of reducing the pitch one-half. By placing a number of driving pawls side by side and proportioning their lengths according to the pitch of the teeth, a very fine feed can be obtained with a ratchet wheel of comparatively coarse pitch.

This method of obtaining a fine feed from relatively coarse-pitch ratchets may be preferable to the use of single ratchets of fine pitch which, although providing the feed required, may have considerably weaker teeth.

The type of ratchet gearing shown at Fig. e is sometimes employed to impart a rotary movement to the ratchet wheel for both the forward and backward motions of the lever to which the two pawls are attached.

A simple form of *reversing ratchet* is illustrated at Fig. f. The teeth of the wheel are so shaped that either side may be used for driving by simply changing the position of the double-ended pawl, as indicated by the full and dotted lines.

Another form of reversible ratchet gearing for shapers is illustrated at Fig. g. The pawl, in this case, instead of being a pivoted latch, is in the form of a plunger which is free to move in the direction of its axis, but is normally held into engagement with the ratchet wheel by a small spring. When the pawl is lifted and turned one-half revolution, the driving face then engages the opposite sides of the teeth and the ratchet wheel is given an intermittent rotary motion in the opposite direction.

The *frictional type* of ratchet gearing differs from the designs previously referred to, in that there is no positive engagement between the driving and driven members of the ratchet mechanism, the motion being transmitted by frictional resistance. One type of frictional ratchet gearing is illustrated at Fig. h. Rollers or balls are placed between the ratchet wheel and an outer ring which, when turned in one direction, causes the rollers or balls to wedge between the wheel and ring as they move up the inclined edges of the teeth.

Fig. i illustrates one method of utilizing ratchet gearing for moving the driven member in a straight line, as in the case of a lifting jack. The pawl g is pivoted to the operating lever of the jack and does the lifting, whereas the pawl h holds the load while the lifting pawl g is being returned preparatory to another lifting movement.

**Shape of Ratchet Wheel Teeth.**—When designing ratchet gearing, it is important to so shape the teeth that the pawl will remain in engagement when a load is applied. The faces of the teeth which engage the end of the pawl should be in such relation with the center of the pawl pivot that a line perpendicular to the face of the engaging tooth will pass somewhere between the center of the ratchet wheel and the center of the pivot about which the pawl swings. This is true if the pawl *pushes* the ratchet wheel, or if the ratchet wheel *pushes* the pawl. However, if the pawl *pulls* the ratchet wheel or if the ratchet wheel *pulls* the pawl, the perpendicular from the face of the ratchet teeth should fall outside the pawl pivot center. Ratchet teeth may be either cut by a milling cutter having the correct angle, or hobbled in a gear-hobbing machine by the use of a special hob.

**Pitch of Ratchet Wheel Teeth.**—The pitch of ratchet wheels used for holding suspended loads may be calculated by the following formula, in which  $P$  = circular pitch, in inches, measured at the outside circumference;  $M$  = turning moment acting upon the ratchet wheel shaft, in inch-pounds;  $L$  = length of tooth face, in inches (thickness of ratchet gear);  $S$  = safe stress (for steel, 2500 pounds per square inch when subjected to shock, and 4000 pounds per square inch when not subjected to shock);  $N$  = number of teeth in ratchet wheel;  $F$  = a factor the value of which is 50 for ratchet gears with 12 teeth or less, 35 for gears having from 12 to 20 teeth, and 20 for gears having over 20 teeth:

$$P = \frac{\sqrt{FM}}{LSN}$$

This formula has been used in the calculation of ratchet gears for crane design.

**Gear Design Based upon Module System.**—The *module* of a gear is equal to the pitch diameter divided by the number of teeth, whereas *diametral pitch* is equal to the number of teeth divided by the pitch diameter. The module system (see accompanying table and diagram) is in general use in countries that have adopted the metric system; hence, the term module is usually understood to mean the pitch diameter *in millimeters* divided by the number of teeth. The module system, however, may also be based on inch measurements and then it is known as the English module to avoid confusion with the metric module. Module is an actual dimension, whereas diametral pitch is only a ratio. Thus, if the pitch diameter of a gear is 50 millimeters and the number of teeth 25, the module is 2, which means that there are 2 millimeters of pitch diameter for each tooth. The table *Tooth Dimensions Based Upon Module System* shows the relation among module, diametral pitch, and circular pitch.

#### German Standard Tooth Form for Spur and Bevel Gears DIN 867

| To Find                       | Module Known                      | Circular Pitch Known                       |
|-------------------------------|-----------------------------------|--|
| Addendum                      | Equals module                     | $0.31823 \times \text{Circular pitch}$     |
| Dedendum                      | $1.157 \times \text{module}^*$    | $0.3683 \times \text{Circular pitch}^*$    |
|                               | $1.167 \times \text{module}^{**}$ | $0.3714 \times \text{Circular pitch}^{**}$ |
| Working Depth                 | $2 \times \text{module}$          | $0.6366 \times \text{Circular pitch}$      |
| Total Depth                   | $2.157 \times \text{module}^*$    | $0.6866 \times \text{Circular pitch}^*$    |
|                               | $2.167 \times \text{module}^{**}$ | $0.6898 \times \text{Circular pitch}^{**}$ |
| Tooth Thickness on Pitch Line | $1.5708 \times \text{module}$     | $0.5 \times \text{Circular pitch}$         |

Formulas for dedendum and total depth, marked (\*) are used when clearance equals  $0.157 \times \text{module}$ . Formulas marked (\*\*) are used when clearance equals one-sixth module. It is common practice among American cutter manufacturers to make the clearance of metric or module cutters equal to  $0.157 \times \text{module}$ .

<sup>a</sup> Dedendum and total depth when clearance =  $0.1666 \times$  module, or one-sixth module.

<sup>b</sup> Total depth equivalent to American standard full-depth teeth. (Clearance =  $0.157 \times$  module.)

## Rules for Module System of Gearing

| To Find                                     | Rule  |
|---|---|
| Metric Module                               | <p><i>Rule 1:</i> To find the metric module, divide the pitch diameter in millimeters by the number of teeth.</p> <p><i>Example 1:</i> The pitch diameter of a gear is 200 millimeters and the number of teeth, 40; then</p> $\text{Module} = \frac{200}{40} = 5$ <p><i>Rule 2:</i> Multiply circular pitch in millimeters by 0.3183.</p> <p><i>Example 2:</i> (Same as Example 1. Circular pitch of this gear equals 15.708 millimeters.)</p> $\text{Module} = 15.708 \times 0.3183 = 5$ <p><i>Rule 3:</i> Divide outside diameter in millimeters by the number of teeth plus 2.</p> |
| English Module                              | <p><i>Note:</i> The module system is usually applied when gear dimensions are expressed in millimeters, but module may also be based on inch measurements.</p> <p><i>Rule:</i> To find the English module, divide pitch diameter in inches by the number of teeth.</p> <p><i>Example:</i> A gear has 48 teeth and a pitch diameter of 12 inches.</p> $\text{Module} = \frac{12}{48} = \frac{1}{4} \text{ module or 4 diametral pitch}$  |
| Metric Module Equivalent to Diametral Pitch | <p><i>Rule:</i> To find the metric module equivalent to a given diametral pitch, divide 25.4 by the diametral pitch.</p> <p><i>Example:</i> Determine metric module equivalent to 10 diametral pitch.</p> $\text{Equivalent module} = \frac{25.4}{10} = 2.54$ <p><i>Note:</i> The nearest standard module is 2.5.</p>   |
| Diametral Pitch Equivalent to Metric Module | <p><i>Rule:</i> To find the diametral pitch equivalent to a given module, divide 25.4 by the module. (25.4 = number of millimeters per inch.)</p> <p><i>Example:</i> The module is 12; determine equivalent diametral pitch.</p> $\text{Equivalent diametral pitch} = \frac{25.4}{12} = 2.117$ <p><i>Note:</i> A diametral pitch of 2 is the nearest <i>standard</i> equivalent.</p>  |
| Pitch Diameter                              | <p><i>Rule:</i> Multiply number of teeth by module.</p> <p><i>Example:</i> The metric module is 8 and the gear has 40 teeth; then</p> $D = 40 \times 8 = 320 \text{ millimeters} = 12.598 \text{ inches}$   |
| Outside Diameter                            | <p><i>Rule:</i> Add 2 to the number of teeth and multiply sum by the module.</p> <p><i>Example:</i> A gear has 40 teeth and module is 6. Find outside or blank diameter.</p> $\text{Outside diameter} = (40 + 2) \times 6 = 252 \text{ millimeters}$  |

For tooth dimensions, see table *Tooth Dimensions Based Upon Module System*; also formulas in *German Standard Tooth Form for Spur and Bevel Gears DIN 867*.

The module of a gear is the pitch diameter divided by the number of teeth. The module may be expressed in any units; but when no units are stated, it is understood to be in millimeters. The metric module, therefore, equals the pitch diameter in millimeters divided by the number of teeth. To find the metric module equivalent to a given diametral pitch, divide 25.4 by the diametral pitch. To find the diametral pitch equivalent to a given module, divide 25.4 by the module. (25.4 = number of millimeters per inch.)

## CHECKING GEAR SIZES

## Checking Gear Size by Measurement Over Wires or Pins

The wire or pin method of checking gear sizes is accurate, easily applied, and especially useful in shops with limited inspection equipment. Two cylindrical wires or pins of predetermined diameter are placed in diametrically opposite tooth spaces (see diagram). If the gear has an odd number of teeth, the wires are located as nearly opposite as possible, as shown by the diagram at the right. The overall measurement  $M$  is checked by using any sufficiently accurate method of measurement. The value of measurement  $M$  when the pitch diameter is correct can be determined easily and quickly by means of the calculated values in the accompanying tables.

**Measurements for Checking External Spur Gears when Wire Diameter Equals 1.728 Divided by Diametral Pitch.**—Tables 1 and 2 give measurements  $M$ , in inches, for checking the pitch diameters of external spur gears of 1 diametral pitch. For any other diametral pitch, divide the measurement given in the table by whatever diametral pitch is required. The result shows what measurement  $M$  should be when the pitch diameter is correct and there is no allowance for backlash. The procedure for obtaining a given amount of backlash will be explained later. Tables 1 through 4 inclusive are based on wire sizes conforming to the Van Keuren standard. For external spur gears, the wire size equals 1.728 divided by the diametral pitch. The wire diameters for various diametral pitches will be found in the left-hand section of Table 5.

**Even Number of Teeth:** Table 1 is for even numbers of teeth. To illustrate the use of the table, assume that a spur gear has 32 teeth of 4 diametral pitch and a pressure angle of 20 degrees. Table 1 shows that the measurement for 1 diametral pitch is 34.4130; hence, for 4 diametral pitch, the measurement equals  $34.4130 \div 4 = 8.6032$  inches. This dimension is the measurement over the wires when the pitch diameter is correct, provided there is no allowance for backlash. The wire diameter here equals  $1.728 \div 4 = 0.432$  inch (Table 5).

Measurement for even numbers of teeth above 170 and not in Table 1 may be determined as shown by the following example: Assume that number of teeth = 240 and pressure angle =  $14\frac{1}{2}$  degrees; then, for 1 diametral pitch, figure at left of decimal point = given No. of teeth + 2 =  $240 + 2 = 242$ . Figure at right of decimal point lies between decimal values given in table for 200 teeth and 300 teeth and is obtained by interpolation. Thus,  $240 - 200 = 40$  (change to 0.40);  $0.5395 - 0.5321 = 0.0074 =$  difference between decimal values for 300 and 200 teeth; hence, decimal required =  $0.5321 + (0.40 \times 0.0074) = 0.53506$ . Total dimension =  $242.53506$  divided by the diametral pitch required.

**Odd Number of Teeth:** Table 2 is for odd numbers of teeth. Measurement for odd numbers above 171 and not in Table 2 may be determined as shown by the following example: Assume that number of teeth = 335 and pressure angle = 20 degrees; then, for 1 diametral

CHECKING GEAR SIZES

pitch, figure at left of decimal point = given No. of teeth + 2 = 335 + 2 = 337. Figure at right of decimal point lies between decimal values given in table for 301 and 401 teeth. Thus, 335 - 301 = 34 (change to 0.34); 0.4565 - 0.4538 = 0.0027; hence, decimal required = 0.4538 + (0.34 × 0.0027) = 0.4547. Total dimension = 337.4547.

**Table 1. Checking External Spur Gear Sizes by Measurement Over Wires**

| EVEN NUMBERS OF TEETH  |                |         |         |         |         |

**Measurements for Checking Internal Gears when Wire Diameter Equals 1.44 Divided by Diametral Pitch.**—Tables 3 and 4 give measurements between wires for checking internal gears of 1 diametral pitch. For any other diametral pitch, divide the measurement given in the table by the diametral pitch required. These measurements are based upon the Van Keuren standard wire size, which, for internal spur gears, equals 1.44 divided by the diametral pitch (see Table 5).

*Even Number of Teeth:* For an even number of teeth above 170 and not in Table 3, proceed as shown by the following example: Assume that the number of teeth = 380 and pressure angle is  $14\frac{1}{2}$  degrees; then, for 1 diametral pitch, figure at left of decimal point = given number of teeth  $- 2 = 380 - 2 = 378$ . Figure at right of decimal point lies between decimal values given in table for 300 and 400 teeth and is obtained by interpolation. Thus,  $380 - 300 = 80$  (change to 0.80);  $0.8803 - 0.8795 = 0.0008$ ; hence, decimal required =  $0.8795 + (0.80 \times 0.0008) 0.88014$ . Total dimension = 378.88014.

*Odd Number of Teeth:* Table 4 is for internal gears having odd numbers of teeth. For tooth numbers above 171 and not in the table, proceed as shown by the following example: Assume that number of teeth = 337 and pressure angle is  $14\frac{1}{2}$  degrees; then, for 1 diametral pitch, figure at left of decimal point = given No. of teeth  $- 2 = 337 - 2 = 335$ . Figure at right of decimal point lies between decimal values given in table for 301 and 401 teeth and is obtained by interpolation. Thus,  $337 - 301 = 36$  (change to 0.36);  $0.8776 - 0.8759 = 0.0017$ ; hence, decimal required =  $0.8759 + (0.36 \times 0.0017) = 0.8765$ . Total dimension = 335.8765.

**Measurements for Checking External Spur Gears when Wire Diameter Equals 1.68 Divided by Diametral Pitch.**—Tables 7 and 8 give measurements  $M$ , in inches, for checking the pitch diameters of external spur gears of 1 diametral pitch. For any other diametral pitch, divide the measurement given in the table by whatever diametral pitch is required. The result shows what measurement  $M$  should be when the pitch diameter is correct and there is no allowance for backlash. The procedure for checking for a given amount of backlash when the diameter of the measuring wires equals 1.68 divided by the diametral pitch is explained under a subsequent heading. Tables 7 and 8 are based upon wire sizes equal to 1.68 divided by the diametral pitch. The corresponding wire diameters for various diametral pitches are given in Table 6.

**Table 6. Wire Diameters for Spur and Helical Gears Based upon 1.68 Constant**

| Diametral or Normal Diametral Pitch | Wire Diameter | Diametral or Normal Diametral Pitch | Wire Diameter | Diametral or Normal Diametral Pitch | Wire Diameter | Diametral or Normal Diametral Pitch | Wire Diameter |
|-------------------------------------|---------------|-------------------------------------|---------------|-------------------------------------|---------------|-------------------------------------|---------------|
| 2                                   | 0.840         | 8                                   | 0.210         | 18                                  | 0.09333       | 40                                  | 0.042         |
| $2\frac{1}{2}$                      | 0.672         | 9                                   | 0.18666       | 20                                  | 0.084         | 48                                  | 0.035         |

| 5                                   | 0.336         | 12                                  | 0.140         | 28                                  | 0.060         | 80                                  | 0.021         |
| 6                                   | 0.280         | 14                                  | 0.120         | 32                                  | 0.0525        | ...                                 | ...           |
| 7                                   | 0.240         | 16                                  | 0.105         | 36                                  | 0.04667       | ...                                 | ...           |

Pin diameter =  $1.68 \div$  diametral pitch for spur gears and  $1.68 \div$  normal diametral pitch for helical gears.

To find measurement  $M$  of an external spur gear using wire sizes equal to 1.68 inches divided by the diametral pitch, the same method is followed in using Tables 7 and 8 as that outlined for Tables 1 and 2.

**Table 7. Checking External Spur Gear Sizes by Measurement Over Wires**

| EVEN NUMBERS OF TEETH   |                |          |          |          |          |
|---|----------------|----------|----------|----------|----------|
| Dimensions in table are for 1 diametral pitch and 1.68-inch series wire sizes (a Van Keuren standard). For any other diametral pitch, divide dimension in table by given pitch. |                |          |          |          |          |
| Wire or pin diameter = $\frac{1.68}{\text{Diametral Pitch}}$  |                |          |          |          |          |

*Allowance for Backlash:* Tables 1, 2, 7, and 8 give measurements over wires when the pitch diameters are correct and there is no allowance for backlash or play between meshing teeth. Backlash is obtained by cutting the teeth somewhat deeper than standard, thus reducing the thickness. Usually, the teeth of both mating gears are reduced in thickness an amount equal to one-half of the total backlash desired. However, if the pinion is small, it is common practice to reduce the gear teeth the full amount of backlash and the pinion is made to standard size. The changes in measurements  $M$  over wires, for obtaining backlash in external spur gears, are listed in Table 9.

**Table 8. Checking External Spur Gear Sizes by Measurement Over Wires**

| ODD NUMBERS OF TEETH  |                |         |         |         |         |

*External Gears:* For each 0.001 inch reduction in pitch-line tooth thickness, *reduce* measurement over wires obtained from Tables 1, 2, 7, or 8 by the amount shown below.

*Internal Gears:* For each 0.001 inch reduction in pitch-line tooth thickness, *increase* measurement between wires obtained from Tables 3 or 4 by the amounts shown below.

Backlash on pitch line equals double tooth thickness reduction when teeth of *both* mating gears are reduced. If teeth of *one* gear only are reduced, backlash on pitch line equals amount of reduction.

*Example:* For a 30-tooth, 10-diametral pitch, 20-degree pressure angle, external gear the measurement over wires from Table 1 is  $32.4102 \div 10$ . For a backlash of 0.002 this measurement must be reduced by  $2 \times 0.0024$  to 3.2362 or (3.2410 - 0.0048).

**Measurements for Checking Helical Gears using Wires or Balls.**—Helical gears may be checked for size by using one wire, or ball; two wires, or balls; and three wires, depending on the case at hand. Three wires may be used for measurement of either even or odd tooth numbers provided that the face width and helix angle of the gear permit the arrangement of two wires in adjacent tooth spaces on one side of the gear and a third wire on the opposite side. The wires should be held between flat, parallel plates. The measurement between these plates, and perpendicular to the gear axis, will be the same for both even and odd numbers of teeth because the axial displacement of the wires with the odd numbers of teeth does not affect the perpendicular measurement between the plates. The calculation of measurements over three wires is the same as described for measurements over two wires for even numbers of teeth.

*Measurements over One Wire or One Ball for Even or Odd Numbers of Teeth:* This measurement is calculated by the method for measurement over two wires for even numbers of teeth and the result divided by two to obtain the measurement from over the wire or ball to the center of the gear mounted on an arbor.

*Measurement over Two Wires or Two Balls for Even Numbers of Teeth:* The measurement over two wires (or two balls kept in the same plane by holding them against a surface parallel to the face of the gear) is calculated as follows: First, calculate the pitch diameter of the helical gear from the formula  $D = \text{Number of teeth} \div \text{the product of the normal diametral pitch and the cosine of the helix angle}$ ,  $D = N \div (P_n \times \cos \psi)$ . Next, calculate the number of teeth,  $N_e$ , there would be in a spur gear for it to have the same tooth curvature as the helical gear has in the normal plane:  $N_e = N / \cos^3 \psi$ . Next, refer to Table 7 for spur gears with even tooth numbers and find, by interpolation, the *decimal* value of the constant for this number of teeth under the given *normal* pressure angle. Finally, add 2 to this decimal value and divide the sum by the normal diametral pitch  $P_n$ . The result of this calculation, added to the pitch diameter  $D$ , is the measurement over two wires or balls.

*Example:* A helical gear has 32 teeth of 6 normal diametral pitch, 20 degree pressure angle, and 23 degree helix angle. Determine the measurement over two wires,  $M$ , without allowance for backlash.

$D = 32 \div 6 \times \cos 23^\circ = 5.7939$ ;  $N_e = 32 \div \cos^3 23^\circ = 41.027$ ; and in Table 7, fourth column, the decimal part of the measurement for 40 teeth is .2473 and that for 42 teeth is .2485. The

decimal part for 41.027 teeth is, by interpolation,  $\frac{(41.027 - 40)}{(42 - 40)} \times (.2485 - .2473) + .2473 = 0.2479$ ;  $(0.2479 + 2) \div 6 = 0.3747$ ; and  $M = 0.3747 + 5.7939 = 6.1686$ .

This measurement over wires or balls is based upon the use of  $1.68/P_n$  wires or balls. If measurements over  $1.728/P_n$  diameter wires or balls are preferred, use Table 1 to find the decimal part described above instead of Table 7.

**Measurement over Two Wires or Two Balls for Odd Numbers of Teeth:** The procedure is similar to that for two wire or two ball measurement for even tooth numbers except that a correction is made in the final  $M$  value to account for the wires or balls not being diametrically opposite by one-half tooth interval. In addition, care must be taken to ensure that the balls or wires are kept in a plane of the gear's rotation as described previously.

**Example:** A helical gear has 13 teeth of 8 normal diametral pitch,  $14\frac{1}{2}$  degree pressure angle, and 45 degree helix angle. Determine measurement  $M$  without allowance for backlash based upon the use of  $1.728/P_n$  balls or wires.

As before,  $D = 13/8 \times \cos 45^\circ = 2.2981$ ;  $N_e = 13/\cos^3 45^\circ = 36.770$ ; and in the second column of Table 1 the decimal part of the measurement for 36 teeth is .4565 and that for 38 teeth is .4603. The decimal part for 36.770 teeth is, by interpolation,  $\frac{(36.770 - 36)}{(38 - 36)} \times (.4603 - .4565) + .4565 = 0.4580$ ;  $(0.4580 + 2)/8 = 0.3073$ ; and  $M = 0.3073 + 2.2981 = 2.6054$ . This measurement is correct for three-wire measurements but, for two balls or wires held in the plane of rotation of the gear,  $M$  must be corrected as follows:

$$\begin{aligned} M \text{ corrected} &= (M - \text{Ball Diam.}) \times \cos(90^\circ/N) + \text{Ball Diam.} \\ &= (2.6054 - 1.728/8) \times \cos(90^\circ/13) + 1.728/8 = 2.5880 \end{aligned}$$

### Checking Spur Gear Size by Chordal Measurement Over Two or More Teeth.—

Another method of checking gear sizes, that is generally available, is illustrated by the diagram accompanying Table 10. A vernier caliper is used to measure the distance  $M$  over two or more teeth. The diagram illustrates the measurement over two teeth (or with one intervening tooth space), but three or more teeth might be included, depending upon the pitch. The jaws of the caliper are merely held in contact with the sides or profiles of the teeth and perpendicular to the axis of the gear. Measurement  $M$  for involute teeth of the correct size is determined as follows

**General Formula for Checking External and Internal Spur Gears by Measurement Over Wires:** The following formulas may be used for pressure angles or wire sizes not covered by the tables. In these formulas,  $M$  = measurement over wires for external gears or measurement between wires for internal gears;  $D$  = pitch diameter;  $T$  = arc tooth thickness on pitch circle;  $W$  = wire diameter;  $N$  = number of gear teeth;  $A$  = pressure angle of gear;  $a$  = angle, the cosine of which is required in Formulas (2) and (3).

First determine the involute function of angle  $a$  ( $\text{inv } a$ ); then the corresponding angle  $a$  is found by referring to the tables of involute functions beginning on page 104,

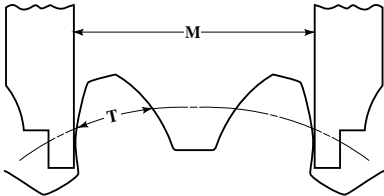

$$\text{inv } a = \text{inv } A \pm \frac{T}{D} \pm \frac{W}{D \cos A} \mp \frac{\pi}{N} \quad (1)$$

$$\text{For even numbers of teeth, } M = \frac{D \cos A}{\cos a} \pm W \quad (2)$$

$$\text{For odd numbers of teeth, } M = \left( \frac{D \cos A}{\cos a} \right) \left( \cos \frac{90^\circ}{N} \right) \pm W \quad (3)$$

**Note:** In Formulas (1), (2), and (3), use the upper sign for external and the lower sign for internal gears wherever a  $\pm$  or  $\mp$  appears in the formulas.

**Table 10. Chordal Measurements over Spur Gear Teeth of 1 Diametral Pitch**

| <p>Find value of <math>M</math> under pressure angle and opposite number of teeth; divide <math>M</math> by diametral pitch of gear to be measured and then subtract one-half total backlash to obtain a measurement <math>M</math> equivalent to given pitch and backlash. The number of teeth to gage or measure over is shown by Table 11.</p>  |                          |                      |                          |                      |                          |                      |                          |

*Table for Determining the Chordal Dimension:* Table 10 gives the chordal dimensions for one diametral pitch when measuring over the number of teeth indicated in Table 11. To obtain any chordal dimension, it is simply necessary to divide chord  $M$  in the table (opposite the given number of teeth) by the diametral pitch of the gear to be measured and then subtract from the quotient one-half the total backlash between the mating pair of gears. In cases where a small pinion is used with a large gear and all of the backlash is to be obtained by reducing the gear teeth, the total amount of backlash is subtracted from the chordal dimension of the gear and nothing from the chordal dimension of the pinion. The application of the tables will be illustrated by an example.

**Table 11. Number of Teeth Included in Chordal Measurement**

| Tooth Range for 14½° Pressure Angle | Tooth Range for 20° Pressure Angle | Number of Teeth to Gage Over | Tooth Range for 14½° Pressure Angle | Tooth Range for 20° Pressure Angle | Number of Teeth to Gage Over |
|-------------------------------------|------------------------------------|------------------------------|-------------------------------------|------------------------------------|------------------------------|
| 12 to 18                            | 12 to 18                           | 2                            | 63 to 75                            | 46 to 54                           | 6                            |
| 19 to 37                            | 19 to 27                           | 3                            | 76 to 87                            | 55 to 63                           | 7                            |
| 38 to 50                            | 28 to 36                           | 4                            | 88 to 100                           | 64 to 72                           | 8                            |
| 51 to 62                            | 37 to 45                           | 5                            | 101 to 110                          | 73 to 81                           | 9                            |

This table shows the number of teeth to be included between the jaws of the vernier caliper in measuring dimension  $M$  as explained in connection with Table 10.

*Example:* Determine the chordal dimension for checking the size of a gear having 30 teeth of 5 diametral pitch and a pressure angle of 20 degrees. A total backlash of 0.008 inch is to be obtained by reducing equally the teeth of both mating gears.

Table 10 shows that chordal distance for 30 teeth of one diametral pitch and a pressure angle of 20 degrees is 10.7526 inches; one-half of the backlash equals 0.004 inch; hence,

$$\text{Chordal dimension} = \frac{10.7526}{5} - 0.004 = 2.1465 \text{ inches}$$

Table 11 shows that this is the chordal dimension when the vernier caliper spans four teeth, this being the number of teeth to gage over whenever gears of 20-degree pressure angle have any number of teeth from 28 to 36, inclusive.

If it is considered necessary to leave enough stock on the gear teeth for a shaving or finishing cut, this allowance is simply added to the chordal dimension of the finished teeth to obtain the required measurement over the teeth for the roughing operation. It may be advisable to place this chordal dimension for rough machining on the detail drawing.

**Formula for Chordal Dimension  $M$ .**—The required measurement  $M$  over spur gear teeth may be obtained by the following formula in which  $R$  = pitch radius of gear,  $A$  = pressure angle,  $T$  = tooth thickness along pitch circle,  $N$  = number of gear teeth,  $S$  = number of tooth spaces between caliper jaws,  $F$  = a factor depending on the pressure angle = 0.01109 for 14½°; = 0.01973 for 17½°; = 0.0298 for 20°; = 0.04303 for 22½°; = 0.05995 for 25°. This factor  $F$  equals twice the involute function of the pressure angle.

$$M = R \times \cos A \times \left( \frac{T}{R} + \frac{6.2832 \times S}{N} + F \right)$$

*Example:* A spur gear has 30 teeth of 6 diametral pitch and a pressure angle of 14½ degrees. Determine measurement  $M$  over three teeth, there being two intervening tooth spaces.

The pitch radius = 2½ inches, the arc tooth thickness equivalent to 6 diametral pitch is 0.2618 inch (if no allowance is made for backlash) and factor  $F$  for 14½ degrees = 0.01109 inch.

$$M = 2.5 \times 0.96815 \times \left( \frac{0.2618}{2.5} + \frac{6.2832 \times 2}{30} + 0.01109 \right) = 1.2941 \text{ inches}$$

**Checking Enlarged Pinions by Measuring Over Pins or Wires.**—When the teeth of small spur gears or pinions would be undercut if generated by an unmodified straight-sided rack cutter or hob, it is common practice to make the outside diameter larger than standard. The amount of increase in outside diameter varies with the pressure angle and number of teeth, as shown by Table 7 on page 2050. The teeth are always cut to standard depth on a generating type of machine such as a gear hobber or gear shaper; and because the number of teeth and pitch are not changed, the pitch diameter also remains unchanged. The tooth thickness on the pitch circle, however, is increased and wire sizes suitable for standard gears are not large enough to extend above the tops of these enlarged gears or pinions; hence, the Van Keuren wire size recommended for these enlarged pinions equals  $1.92 \div$  diametral pitch. Table 12 gives measurements over wires of this size, for checking full-depth involute gears of 1 diametral pitch. For any other pitch, merely divide the measurement given in the table by the diametral pitch. Table 12 applies to pinions that have been enlarged by the same amounts as given in tables 7 and 8, starting on page 2050. These enlarged pinions will mesh with standard gears; but if the standard center distance is to be maintained, reduce the gear diameter below the standard size by as much as the pinion diameter is increased.

**Table 12. Checking Enlarged Spur Pinions by Measurement Over Wires**

| Measurements over wires are given in table for 1 diametral pitch. For any other diametral pitch, divide measurement in table by given pitch. Wire size equals $1.92 \div$ diametral pitch. |                                    |                                   |                        |  |                                    |                                   |                        |

**GEAR MATERIALS**

**Classification of Gear Steels.**—Gear steels may be divided into two general classes — the plain carbon and the alloy steels. Alloy steels are used to some extent in the industrial field, but heat-treated plain carbon steels are far more common. The use of untreated alloy steels for gears is seldom, if ever, justified, and then, only when heat-treating facilities are lacking. The points to be considered in determining whether to use heat-treated plain carbon steels or heat-treated alloy steels are: Does the service condition or design require the superior characteristics of the alloy steels, or, if alloy steels are not required, will the advantages to be derived offset the additional cost? For most applications, plain carbon steels, heat-treated to obtain the best of their qualities for the service intended, are satisfactory and quite economical. The advantages obtained from using heat-treated alloy steels in place of heat-treated plain carbon steels are as follows:

- 1) Increased surface hardness and depth of hardness penetration for the same carbon content and quench.
- 2) Ability to obtain the same surface hardness with a less drastic quench and, in the case of some of the alloys, a lower quenching temperature, thus giving less distortion.
- 3) Increased toughness, as indicated by the higher values of yield point, elongation, and reduction of area.
- 4) Finer grain size, with the resulting higher impact toughness and increased wear resistance.
- 5) In the case of some of the alloys, better machining qualities or the possibility of machining at higher hardnesses.

**Use of Casehardening Steels.**—Each of the two general classes of gear steels may be further subdivided as follows: 1) Casehardening steels; 2) full-hardening steels; and 3) steels that are heat-treated and drawn to a hardness that will permit machining.

The first two — casehardening and full-hardening steels — are interchangeable for some kinds of service, and the choice is often a matter of personal opinion. Casehardening steels with their extremely hard, fine-grained (when properly treated) case and comparatively soft and ductile core are generally used when resistance to wear is desired. Casehardening alloy steels have a fairly tough core, but not as tough as that of the full-hardening steels. In order to realize the greatest benefits from the core properties, casehardened steels should be double-quenched. This is particularly true of the alloy steels, because the benefits derived from their use seldom justify the additional expense, unless the core is refined and toughened by a second quench. The penalty that must be paid for the additional refinement is increased distortion, which may be excessive if the shape or design does not lend itself to the casehardening process.

**Use of “Thru-Hardening” Steels.**—Thru-hardening steels are used when great strength, high endurance limit, toughness, and resistance to shock are required. These qualities are governed by the kind of steel and treatment used. Fairly high surface hardnesses are obtainable in this group, though not so high as those of the casehardening steels. For that reason, the resistance to wear is not so great as might be obtained, but when wear resistance combined with great strength and toughness is required, this type of steel is superior to the others. Thru-hardening steels become distorted to some extent when hardened, the amount depending upon the steel and quenching medium used. For that reason, thru-hardening steels are not suitable for high-speed gearing where noise is a factor, or for gearing where accuracy is of paramount importance, except, of course, in cases where grinding of the teeth is practicable. The medium and high-carbon percentages require an oil quench, but a water quench may be necessary for the lower carbon contents, in order to obtain the highest physical properties and hardness. The distortion, however, will be greater with the water quench.

**Heat-Treatment that Permits Machining.**—When the grinding of gear teeth is not practicable and a high degree of accuracy is required, hardened steels may be drawn or tem-

pered to a hardness that will permit the cutting of the teeth. This treatment gives a highly refined structure, great toughness, and, in spite of the low hardness, excellent wearing qualities. The lower strength is somewhat compensated for by the elimination of the increment loads due to the impacts which are caused by inaccuracies. When steels that have a low degree of hardness penetration from surface to core are treated in this manner, the design cannot be based on the physical properties corresponding to the hardness at the surface. Since the physical properties are determined by the hardness, the drop in hardness from surface to core will give lower physical properties at the root of the tooth, where the stress is greatest. The quenching medium may be either oil, water, or brine, depending on the steel used and hardness penetration desired. The amount of distortion, of course, is immaterial, because the machining is done after heat-treating.

**Making Pinion Harder than Gear to Equalize Wear.**—Beneficial results from a wear standpoint are obtained by making the pinion harder than the gear. The pinion, having a lesser number of teeth than the gear, naturally does more work per tooth, and the differential in hardness between the pinion and the gear (the amount being dependent on the ratio) serves to equalize the rate of wear. The harder pinion teeth correct the errors in the gear teeth to some extent by the initial wear and then seem to burnish the teeth of the gear and increase its ability to withstand wear by the greater hardness due to the cold-working of the surface. In applications where the gear ratio is high and there are no severe shock loads, a casehardened pinion running with an oil-treated gear, treated to a Brinell hardness at which the teeth may be cut after treating, is an excellent combination. The pinion, being relatively small, is distorted but little, and distortion in the gear is circumvented by cutting the teeth after treatment.

**Forged and Rolled Carbon Steels for Gears.**—These compositions cover steel for gears in three groups, according to heat treatment, as follows:

- a) case-hardened gears
- b) unhardened gears, not heat treated after machining
- c) hardened and tempered gears

Forged and rolled carbon gear steels are purchased on the basis of the requirements as to chemical composition specified in [Table 1](#). Class N steel will normally be ordered in ten point carbon ranges within these limits. Requirements as to physical properties have been omitted, but when they are called for the requirements as to carbon shall be omitted. The steels may be made by either or both the open hearth and electric furnace processes.

**Table 1. Compositions of Forged and Rolled Carbon Steels for Gears**

| Heat Treatment          | Class | Carbon    | Manganese | Phosphorus | Sulfur    |
|-------------------------|-------|-----------|-----------|------------|-----------|
| Case-hardened           | C     | 0.15–0.25 | 0.40–0.70 | 0.045 max  | 0.055 max |
| Untreated               | N     | 0.25–0.50 | 0.50–0.80 | 0.045 max  | 0.055 max |
| Hardened (or untreated) | H     | 0.40–0.50 | 0.40–0.70 | 0.045 max  | 0.055 max |

**Forged and Rolled Alloy Steels for Gears.**—These compositions cover alloy steel for gears, in two classes according to heat treatment, as follows:

- a) casehardened gears
- b) hardened and tempered gears

Forged and rolled alloy gear steels are purchased on the basis of the requirements as to chemical composition specified in [Table 2](#). Requirements as to physical properties have been omitted. The steel shall be made by either or both the open hearth and electric furnace process.

<sup>b</sup> Both Nitralloy alloys contain aluminum 0.85–1.2%

**Steel Castings for Gears.**—It is recommended that steel castings for cut gears be purchased on the basis of chemical analysis and that only two types of analysis be used, one for case-hardened gears and the other for both untreated gears and those which are to be hardened and tempered. The steel is to be made by the open hearth, crucible, or electric furnace processes. The converter process is not recognized. Sufficient risers must be provided to secure soundness and freedom from undue segregation. Risers should not be broken off the unannealed castings by force. Where risers are cut off with a torch, the cut should be at least one-half inch above the surface of the castings, and the remaining metal removed by chipping, grinding, or other noninjurious method.

Steel for use in gears should conform to the requirements for chemical composition indicated in Table 3. All steel castings for gears must be thoroughly normalized or annealed, using such temperature and time as will entirely eliminate the characteristic structure of unannealed castings.

**Table 3. Compositions of Cast Steels for Gears**

| Steel Specification | Chemical Composition <sup>a</sup> |           |           |                    |
|---------------------|-----------------------------------|-----------|-----------|--------------------|
|                     | C                                 | Mn        | Si        |                    |
| SAE-0022            | 0.12–0.22                         | 0.50–0.90 | 0.60 Max. | May be carburized  |
| SAE-0050            | 0.40–0.50                         | 0.50–0.90 | 0.80 Max. | Hardenable 210–250 |

<sup>a</sup> C = carbon; Mn = manganese; and Si = silicon.

**Effect of Alloying Metals on Gear Steels.**—The effect of the various alloying elements on steel are here summarized to assist in deciding on the particular kind of alloy steel to use for specific purposes. The characteristics outlined apply only to heat-treated steels. When the effect of the addition of an alloying element is stated, it is understood that reference is made to alloy steels of a given carbon content, compared with a plain carbon steel of the same carbon content.

**Nickel:** The addition of nickel tends to increase the hardness and strength, with but little sacrifice of ductility. The hardness penetration is somewhat greater than that of plain carbon steels. Use of nickel as an alloying element lowers the critical points and produces less distortion, due to the lower quenching temperature. The nickel steels of the case-hardening group carburize more slowly, but the grain growth is less.

**Chromium:** Chromium increases the hardness and strength over that obtained by the use of nickel, though the loss of ductility is greater. Chromium refines the grain and imparts a

greater depth of hardness. Chromium steels have a high degree of wear resistance and are easier machined in spite of the fine grain.

*Manganese:* When present in sufficient amounts to warrant the use of the term alloy, the addition of manganese is very effective. It gives greater strength than nickel and a higher degree of toughness than chromium. Owing to its susceptibility to cold-working, it is likely to flow under severe unit pressures. Up to the present time, it has never been used to any great extent for heat-treated gears, but is now receiving an increasing amount of attention.

*Vanadium:* Vanadium has a similar effect to that of manganese—increasing the hardness, strength, and toughness. The loss of ductility is somewhat more than that due to manganese, but the hardness penetration is greater than for any of the other alloying elements. Owing to the extremely fine-grained structure, the impact strength is high; but vanadium tends to make machining difficult.

*Molybdenum:* Molybdenum has the property of increasing the strength without affecting the ductility. For the same hardness, steels containing molybdenum are more ductile than any other alloy steels, and having nearly the same strength, are tougher; in spite of the increased toughness, the presence of molybdenum does not make machining more difficult. In fact, such steels can be machined at a higher hardness than any of the other alloy steels. The impact strength is nearly as great as that of the vanadium steels.

*Chrome-Nickel Steels:* The combination of the two alloying elements chromium and nickel adds the beneficial qualities of both. The high degree of ductility present in nickel steels is complemented by the high strength, finer grain size, deep hardening, and wear-resistant properties imparted by the addition of chromium. The increased toughness makes these steels more difficult to machine than the plain carbon steels, and they are more difficult to heat treat. The distortion increases with the amount of chromium and nickel.

*Chrome-Vanadium Steels:* Chrome-vanadium steels have practically the same tensile properties as the chrome-nickel steels, but the hardening power, impact strength, and wear resistance are increased by the finer grain size. They are difficult to machine and become distorted more easily than the other alloy steels.

*Chrome-Molybdenum Steels:* This group has the same qualities as the straight molybdenum steels, but the hardening depth and wear resistance are increased by the addition of chromium. This steel is very easily heat treated and machined.

*Nickel-Molybdenum Steels:* Nickel-molybdenum steels have qualities similar to chrome-molybdenum steel. The toughness is said to be greater, but the steel is somewhat more difficult to machine.

**Sintered Materials.**—For high production of low and moderately loaded gears, significant production cost savings may be effected by the use of a sintered metal powder. With this material, the gear is formed in a die under high pressure and then sintered in a furnace. The primary cost saving comes from the great reduction in labor cost of machining the gear teeth and other gear blank surfaces. The volume of production must be high enough to amortize the cost of the die and the gear blank must be of such a configuration that it may be formed and readily ejected from the die.

**Bronze and Brass Gear Castings.**—These specifications cover nonferrous metals for spur, bevel, and worm gears, bushings and flanges for composition gears. This material shall be purchased on the basis of chemical composition. The alloys may be made by any approved method.

*Spur and Bevel Gears:* For spur and bevel gears, hard cast bronze is recommended (ASTM B-10-18; SAE No. 62; and the well-known 88-10-2 mixture) with the following limits as to composition: Copper, 86 to 89; tin, 9 to 11; zinc, 1 to 3; lead (max), 0.20; iron (max), 0.06 per cent. Good castings made from this bronze should have the following minimum physical characteristics: Ultimate strength, 30,000 pounds per square inch; yield point, 15,000 pounds per square inch; elongation in 2 inches, 14 per cent.

## Steels for Industrial Gearing

| Material Specification                     | Hardness |          | Typical Heat Treatment, Characteristics, and Uses   |
|--|----------|----------|---|
|  | Case Rc  | Core Bhn |   |
| Case-Hardening Steels                      |          |          |   |
| AISI 1020<br>AISI 1116                     | 55–60    | 160–230  | Carburize, harden, temper at 350°F.<br>For gears that must be wear-resistant. Normalized material is easily machined. Core is ductile but has little strength.  |
| AISI 4130<br>AISI 4140                     | 50–55    | 270–370  | Harden, temper at 900°F, Nitride.<br>For parts requiring greater wear resistance than that of through-hardened steels but cannot tolerate the distortion of carburizing. Case is shallow, core is tough.  |
| AISI 4615<br>AISI 4620                     | } 55–60  | 170–260  | Carburize, harden, temper at 350°F.<br>For gears requiring high fatigue resistance and strength. The 86xx series has better machinability.<br>The 20 point steels are used for coarser teeth.   |
| AISI 8615<br>AISI 8620                     |          | 200–300  |   |
| AISI 9310                                  | 58–63    | 250–350  | Carburize, harden, temper at 300°F.<br>Primarily for aerospace gears that are highly loaded and operate at high pitch line velocity and for other gears requiring high reliability under extreme operating conditions. This material is not used at high temperatures.<br><br>Harden, temper at 1200°F, Nitride.      |
| Nitralloy N<br>and Type 135<br>Mod. (15-N) | 90–94    | 300–370  | For gears requiring high strength and wear resistance that cannot tolerate the distortion of the carburizing process or that operate at high temperatures.<br>Gear teeth are usually finished before nitriding. Care must be exercised in running nitrided gears together to avoid crazing of case-hardened surfaces. |
| Through-Hardening Steels                   |          |          |   |
| AISI 1045<br>AISI 1140                     | 24–40    | ...      | Harden and temper to required hardness. Oil quench for lower hardness and water quench for higher hardness.<br>For gears of medium and large size requiring moderate strength and wear resistance. Gears that must have consistent, solid sections to withstand quenching.  |
| AISI 4140<br>AISI 4340                     | 24–40    | ...      | Harden (oil quench), temper to required hardness.<br>For gears requiring high strength and wear resistance, and high shock loading resistance. Use 41xx series for moderate sections and 43xx series for heavy sections. Gears must have consistent, solid sections to withstand quenching.                           |

*Worm Gears:* For bronze worm gears, two alternative analyses of phosphor bronze are recommended, SAE No. 65 and No. 63.

SAE No. 65 (called phosphor gear bronze) has the following composition: Copper, 88 to 90; tin, 10 to 12; phosphorus, 0.1 to 0.3; lead, zinc, and impurities (max) 0.5 per cent.

Good castings made of this alloy should have the following minimum physical characteristics: Ultimate strength, 35,000 pounds per square inch; yield point, 20,000 pounds per square inch; elongation in 2 inches, 10 per cent.

The composition of SAE No. 63 (called leaded gun metal) follows: copper, 86 to 89; tin, 9 to 11; lead, 1 to 2.5; phosphorus (max), 0.25; zinc and impurities (max), 0.50 per cent.

Good castings made of this alloy should have the following minimum physical characteristics: Ultimate strength, 30,000 pounds per square inch; yield point, 12,000 pounds per square inch; elongation in 2 inches, 10 per cent.

These alloys, especially No. 65, are adapted to chilling for hardness and refinement of grain. No. 65 is to be preferred for use with worms of great hardness and fine accuracy. No. 63 is to be preferred for use with unhardened worms.

*Gear Bushings:* For bronze bushings for gears, SAE No. 64 is recommended of the following analysis: copper, 78.5 to 81.5; tin, 9 to 11; lead, 9 to 11; phosphorus, 0.05 to 0.25; zinc (max), 0.75; other impurities (max), 0.25 per cent. Good castings of this alloy should have the following minimum physical characteristics: Ultimate strength, 25,000 pounds per square inch; yield point, 12,000 pounds per square inch; elongation in 2 inches, 8 per cent.

*Flanges for Composition Pinions:* For brass flanges for composition pinions ASTM B-30-32T, and SAE No. 40 are recommended. This is a good cast red brass of sufficient strength and hardness to take its share of load and wear when the design is such that the flanges mesh with the mating gear. The composition is as follows: copper, 83 to 86; tin, 4.5 to 5.5; lead, 4.5 to 5.5; zinc, 4.5 to 5.5; iron (max) 0.35; antimony (max), 0.25 per cent; aluminum, none. Good castings made from this alloy should have the following minimum physical characteristics: ultimate strength, 27,000 pounds per square inch; yield point, 12,000 pounds per square inch; elongation in 2 inches, 16 per cent.

**Materials for Worm Gearing.**—The Hamilton Gear & Machine Co. conducted an extensive series of tests on a variety of materials that might be used for worm gears, to ascertain which material is the most suitable. According to these tests chill-cast nickel-phosphor-bronze ranks first in resistance to wear and deformation. This bronze is composed of approximately 87.5 per cent copper, 11 per cent tin, 1.5 per cent nickel, with from 0.1 to 0.2 per cent phosphorus. The worms used in these tests were made from SAE-2315, 3½ per cent nickel steel, case-hardened, ground, and polished. The Shore scleroscope hardness of the worms was between 80 and 90. This nickel alloy steel was adopted after numerous tests of a variety of steels, because it provided the necessary strength, together with the degree of hardness required.

The material that showed up second best in these tests was a No. 65 SAE bronze. Navy bronze (88-10-2) containing 2 per cent zinc, with no phosphorus, and not chilled, performed satisfactorily at speeds of 600 revolutions per minute, but was not sufficiently strong at lower speeds. Red brass (85-5-5) proved slightly better at from 1500 to 1800 revolutions per minute, but would bend at lower speeds, before it would show actual wear.

**Non-metallic Gearing.**—Non-metallic or composition gearing is used primarily where quietness of operation at high speed is the first consideration. Non-metallic materials are also applied very generally to timing gears and numerous other classes of gearing. Rawhide was used originally for non-metallic gears, but other materials have been introduced that have important advantages. These later materials are sold by different firms under various trade names, such as Micarta, Textolite, Formica, Dilecto, Spauldite, Phenolite, Fibroc, Fabroil, Synthane, Celoron, etc. Most of these gear materials consist of layers of canvas or other material that is impregnated with plastics and forced together under hydraulic pressure, which, in conjunction with the application of heat, forms a dense rigid mass.

Although phenol resin gears in general are resilient, they are self-supporting and require no side plates or shrouds unless subjected to a heavy starting torque. The phenol resinoid element protects these gears from vermin and rodents.

The non-metallic gear materials referred to are generally assumed to have the power-transmitting capacity of cast iron. Although the tensile strength may be considerably less than that of cast iron, the resiliency of these materials enables them to withstand impact and

abrasion to a degree that might result in excessive wear of cast-iron teeth. Thus, composition gearing of impregnated canvas has often proved to be more durable than cast iron.

**Application of Non-metallic Gears.**—The most effective field of use for these non-metallic materials is for high-speed duty. At low speeds, when the starting torque may be high, or when the load may fluctuate widely, or when high shock loads may be encountered, these non-metallic materials do not always prove satisfactory. In general, non-metallic materials should not be used for pitch-line velocities below 600 feet per minute.

**Tooth Form:** The best tooth form for non-metallic materials is the 20-degree stub-tooth system. When only a single pair of gears is involved and the center distance can be varied, the best results will be obtained by making the non-metallic driving pinion of all-addendum form, and the driven metal gear with standard tooth proportions. Such a drive will carry from 50 to 75 per cent greater loads than one of standard tooth proportions.

**Material for Mating Gear:** For durability under load, the use of hardened steel (over 400 Brinell) for the mating metal gear appears to give the best results. A good second choice for the material of the mating member is cast iron. The use of brass, bronze, or soft steel (under 400 Brinell) as a material for the mating member of phenolic laminated gears leads to excessive abrasive wear.

**Power-Transmitting Capacity of Non-metallic Gears.**—The characteristics of gears made of phenolic laminated materials are so different from those of metal gears that they should be considered in a class by themselves. Because of the low modulus of elasticity, most of the effects of small errors in tooth form and spacing are absorbed at the tooth surfaces by the elastic deformation, and have but little effect on the strength of the gears.

If  $S$  = safe working stress for a given velocity

$S_s$  = allowable static stress

$V$  = pitch-line velocity in feet per minute

then, according to the recommended practice of the American Gear Manufacturers' Association,

$$S = S_s \times \left( \frac{150}{200 + V} + 0.25 \right)$$

The value of  $S_s$  for phenolic laminated materials is given as 6000 pounds per square inch. The accompanying table gives the safe working stresses  $S$  for different pitch-line velocities. When the value of  $S$  is known, the horsepower capacity is determined by substituting the value of  $S$  for  $S_s$  in the appropriate equations in the section on power-transmitting capacity of plastics gears starting on page 625.

**Safe Working Stresses for Non-metallic Gears**

| Pitch-Line Velocity, Feet per Minute, $V$ | Safe Working Stresses | Pitch-Line Velocity, Feet per Minute, $V$ | Safe Working Stresses | Pitch-Line Velocity, Feet per Minute, $V$ | Safe Working Stresses |
|---|-----------------------|---|-----------------------|---|-----------------------|
| 600                                       | 2625                  | 1800                                      | 1950                  | 4000                                      | 1714                  |
| 700                                       | 2500                  | 2000                                      | 1909                  | 4500                                      | 1691                  |
| 800                                       | 2400                  | 2200                                      | 1875                  | 5000                                      | 1673                  |
| 900                                       | 2318                  | 2400                                      | 1846                  | 5500                                      | 1653                  |
| 1000                                      | 2250                  | 2600                                      | 1821                  | 6000                                      | 1645                  |
| 1200                                      | 2143                  | 2800                                      | 1800                  | 6500                                      | 1634                  |
| 1400                                      | 2063                  | 3000                                      | 1781                  | 7000                                      | 1622                  |
| 1600                                      | 2000                  | 3500                                      | 1743                  | 7500                                      | 1617                  |

The tensile strength of the phenolic laminated materials used for gears is slightly less than that of cast iron. These materials are far softer than any metal, and the modulus of elasticity is about one-thirtieth that of steel. In other words, if the tooth load on a steel gear that causes a deformation of 0.001 inch were applied to the tooth of a similar gear made of phenolic laminated material, the tooth of the non-metallic gear would be deformed about  $\frac{1}{32}$  inch. Under these conditions, several things will happen. With all gears, regardless of the theoretical duration of contact, one tooth only will carry the load until the load is sufficient to deform the tooth the amount of the error that may be present. On metal gears, when the tooth has been deformed the amount of the error, the stresses set up in the materials may approach or exceed the elastic limit of the material. Hence, for standard tooth forms and those generated from standard basic racks, it is dangerous to calculate their strength as very much greater than that which can safely be carried on a single tooth. On gears made of phenolic laminated materials, on the other hand, the teeth will be deformed the amount of this normal error without setting up any appreciable stresses in the material, so that the load is actually supported by several teeth.

All materials have their own peculiar and distinct characteristics, so that under certain specific conditions, each material has a field of its own where it is superior to any other. Such fields may overlap to some extent, and only in such overlapping fields are different materials directly competitive. For example, steel is more or less ductile, has a high tensile strength, and a high modulus of elasticity. Cast iron, on the other hand, is not ductile, has a low tensile strength, but a high compressive strength, and a low modulus of elasticity. Hence, when stiffness and high tensile strength are essential, steel is far superior to cast iron. On the other hand, when these two characteristics are unimportant, but high compressive strength and a moderate amount of elasticity are essential, cast iron is superior to steel.

**Preferred Pitch for Non-metallic Gears.**—The pitch of the gear or pinion should bear a reasonable relation either to the horsepower or speed or to the applied torque, as shown by the accompanying table. The upper half of this table is based upon horsepower transmitted at a given pitch-line velocity. The lower half gives the torque in pounds-feet or the torque at a 1-foot radius. This torque  $T$  for any given horsepower and speed can be obtained from the following formula:

$$T = \frac{5252 \times \text{hp}}{\text{rpm}}$$

**Bore Sizes for Non-metallic Gears.**—For plain phenolic laminated pinions, that is, pinions without metal end plates, a drive fit of 0.001 inch per inch of shaft diameter should be used. For shafts above 2.5 inches in diameter, the fit should be constant at 0.0025 to 0.003 inch. When metal reinforcing end plates are used, the drive fit should conform to the same standards as used for metal.

The root diameter of a pinion of phenolic laminated type should be such that the minimum distance from the edge of the keyway to the root diameter will be at least equal to the depth of tooth.

**Keyway Stresses for Non-metallic Gears.**—The keyway stress should not exceed 3000 pounds per square inch on a plain phenolic laminated gear or pinion. The keyway stress is calculated by the formula

$$S = \frac{33,000 \times \text{hp}}{V \times A}$$

where  $S$  = unit stress in pounds per square inch

$hp$  = horsepower transmitted

$V$  = peripheral speed of shaft in feet per minute; and

$A$  = square inch area of keyway in pinion (length  $\times$  height)

## Preferred Pitches for Non-metallic Gears

| Diametral Pitch for Given Horsepower and Pitch Line Velocities |  |   |   |
|--|--|---|---|
| Horsepower Transmitted   | Pitch Line Velocity up to 1000 Feet per Minute | Pitch Line Velocity from 1000 to 2000 Feet per Minute | Pitch Line Velocity over 2000 Feet per Minute |
| ¼-1  | 8-10   | 10-12   | 12-16   |
| 1-2  | 7-8  | 8-10  | 10-12   |
| 2-3  | 6-7  | 7-8   | 8-10  |
| 3-7½   | 5-6  | 6-7   | 7-8   |
| 7½-10  | 4-5  | 5-6   | 6-7   |
| 10-15  | 3-4  | 4-5   | 5-6   |
| 15-25  | 2½-3   | 3-4   | 4-5   |
| 25-60  | 2-2½   | 2½-3  | 3-4   |
| 60-100   | 1¾-2   | 2-2½  | 2½-3  |
| 100-150  | 1½-1¾  | 1¾-2  | 2-2½  |

| Torque in Pounds-feet for Given Diametral Pitch |                       |         |                 |                       |         |
|---|-----------------------|---------|-----------------|-----------------------|---------|
| Diametral Pitch                                 | Torque in Pounds-feet |         | Diametral Pitch | Torque in Pounds-feet |         |
|   | Minimum               | Maximum |                 | Minimum               | Maximum |
| 16  | 1                     | 2       | 4               | 50                    | 100     |
| 12  | 2                     | 4       | 3               | 100                   | 200     |
| 10  | 4                     | 8       | 2½              | 200                   | 450     |
| 8   | 8                     | 15      | 2               | 450                   | 900     |
| 6   | 15                    | 30      | 1½              | 900                   | 1800    |
| 5   | 30                    | 50      | 1               | 1800                  | 3500    |

These preferred pitches are applicable both to rawhide and the phenolic laminated types of materials.

If the keyway stress formula is expressed in terms of shaft radius  $r$  and revolutions per minute, it will read

$$S = \frac{63,000 \times \text{hp}}{\text{rpm} \times r \times A}$$

When the design is such that the keyway stresses exceed 3000 pounds, metal reinforcing end plates may be used. Such end plates should not extend beyond the root diameter of the teeth. The distance from the outer edge of the retaining bolt to the root diameter of the teeth shall not be less than a full tooth depth. The use of drive keys should be avoided, but if required, metal end plates should be used on the pinion to take the wedging action of the key.

For phenolic laminated pinions, the face of the mating gear should be the same or slightly greater than the pinion face.

**Invention of Gear Teeth.**—The invention of gear teeth represents a gradual evolution from gearing of primitive form. The earliest evidence we have of an investigation of the problem of *uniform motion* from toothed gearing and the successful solution of that problem dates from the time of Olaf Roemer, the celebrated Danish astronomer, who, in the year 1674, proposed the epicycloidal form to obtain uniform motion. Evidently Robert Willis, professor at the University of Cambridge, was the first to make a practical application of the epicycloidal curve so as to provide for an interchangeable series of gears. Willis gives credit to Camus for conceiving the idea of interchangeable gears, but claims for himself its first application. The involute tooth was suggested as a theory by early scientists and mathematicians, but it remained for Willis to present it in a practical form. Perhaps the

earliest conception of the application of this form of teeth to gears was by Philippe de Lahire, a Frenchman, who considered it, in theory, equally suitable with the epicycloidal for tooth outlines. This was about 1695 and not long after Roemer had first demonstrated the epicycloidal form. The applicability of the involute had been further elucidated by Leonard Euler, a Swiss mathematician, born at Basel, 1707, who is credited by Willis with being the first to suggest it. Willis devised the Willis odontograph for laying out involute teeth.

A pressure angle of  $14\frac{1}{2}$  degrees was selected for three different reasons. First, because the sine of  $14\frac{1}{2}$  degrees is nearly  $\frac{1}{4}$ , making it convenient in calculation; second, because this angle coincided closely with the pressure angle resulting from the usual construction of epicycloidal gear teeth; third, because the angle of the straight-sided involute rack is the same as the 29-degree worm thread.

**Calculating Replacement-Gear Dimensions from Simple Measurements.**—The following Tables 1a, 1b, and 1c, provide formulas with which to calculate the dimensions needed to produce replacement spur, bevel, and helical gears when only the number of teeth, the outside diameter, and the tooth depth of the gear to be replaced are known.

For helical gears, exact helix angles can be obtained by the following procedure.

- 1) Using a common protractor, measure the approximate helix angle  $A$  at the approximate pitch line.
- 2) Place sample or its mating gear on the arbor of a gear hobbing machine.
- 3) Calculate the index and lead gears differentially for the angle obtained by the measurements, and set up the machine as though a gear is to be cut.
- 4) Attach a dial indicator on an adjustable arm to the vertical swivel head, with the indicator plunger in a plane perpendicular to the gear axis and in contact with the tooth face. Contact may be anywhere between the top and the root of the tooth.
- 5) With the power shut off, engage the starting lever and traverse the indicator plunger axially by means of the handwheel.
- 6) If angle  $A$  is correct, the indicator plunger will not move as it traverses the face width of the gear. If it does move from 0, note the amount. Divide the amount of movement by the width of the gear to obtain the tangent of the angle by which to correct angle  $A$ , plus or minus, depending on the direction of indicator movement.

**Table 1a. Formulas for Calculating Spur Gear Dimensions**

| Tooth Form and Pressure Angle                                | Diametral Pitch $P$   | Pitch Diameter $D$ | Circular Pitch $P_c$ | Outside Diameter $O$            | Addendum $J$    | Dedendum $K$       | Whole Tooth Depth $W$ | Clearance $K - J$  | Tooth Thickness on Pitch Circle |
|--|-----------------------|--------------------|----------------------|---------------------------------|-----------------|--------------------|-----------------------|--------------------|---------------------------------|
| American Standard $14\frac{1}{2}$ - and 20-degree full depth | $\frac{N + 2}{O}$     | $\frac{N}{P}$      | $\frac{3.1416}{P}$   | $\frac{N + 2}{P}$               | $\frac{1}{P}$   | $\frac{1.157}{P}$  | $\frac{2.157}{P}$     | $\frac{0.157}{P}$  | $\frac{1.5708}{P}$              |
| American Standard 20-degree stub                             | $\frac{N + 1.6}{O}$   | $\frac{N}{P}$      | $\frac{3.1416}{P}$   | $\frac{N + 1.6}{P}$             | $\frac{0.8}{P}$ | $\frac{1}{P}$      | $\frac{1.8}{P}$       | $\frac{0.2}{P}$    | $\frac{1.5708}{P}$              |
| Fellows 20-degree stub                                       | See Note <sup>a</sup> | $\frac{N}{P_N}$    | $\frac{3.1416}{P_N}$ | $\frac{N}{P_N} + \frac{2}{P_D}$ | $\frac{1}{P_D}$ | $\frac{1.25}{P_D}$ | $\frac{2.25}{P_D}$    | $\frac{0.25}{P_D}$ | $\frac{1.5708}{P_N}$            |

<sup>a</sup> In the Fellows stub-tooth system,  $P_N$  = diametral pitch in numerator of stub-tooth designation and is used to determine circular pitch and number of teeth, and  $P_D$  = diametral pitch in the denominator of stub-tooth designation and is used to determine tooth depth.

$N$  = number of teeth.

**Table 1b. Formulas for Calculating Dimensions of Milled Bevel Gears — 90 degree Shafts<sup>a</sup>**

| American Standard 20-degree stub                | $\frac{N_G}{N_P}$                             | $\frac{N_P}{N_G}$                               | $\frac{N_G + 1.6 \cos A}{O}$<br>or<br>$\frac{N_P + 1.6 \cos a}{o}$ | $\frac{N_G + 1.6 \cos A}{P}$<br>or<br>$\frac{N_P + 1.6 \cos a}{P}$                         | $\frac{D}{2 \sin A}$<br>or<br>$\frac{d}{2 \sin a}$   | $\frac{1.6 \sin A}{N_G}$<br>or<br>$\frac{1.6 \sin a}{N_P}$                         | $\frac{2 \sin A}{N_G}$<br>or<br>$\frac{2 \sin a}{N_P}$                                 | $\frac{(P \times O) - N_G}{1.6}$                          |
| Fellows 20-degree stub                          | $\frac{N_G}{N_P}$                             | $\frac{N_P}{N_G}$                               | ...  | $\frac{N_G}{P_N} + \frac{2 \cos A}{P_D}$<br>or<br>$\frac{N_P}{P_N} + \frac{2 \cos a}{P_D}$ | $\frac{D}{2 \sin A}$<br>or<br>$\frac{d}{2 \sin a}$   | $\frac{2P_N \sin A}{N_G \times P_D}$<br>or<br>$\frac{2P_N \sin a}{N_P \times P_D}$ | $\frac{2.5P_N \sin A}{N_G \times P_D}$<br>or<br>$\frac{2.5P_N \sin a}{N_P \times P_D}$ | $\frac{P_D[(O \times P_N) - N_G]}{2P_N}$                  |

<sup>a</sup>These formulas do not apply to Gleason System Gearing.

<sup>b</sup>These values are the same for both gear and pinion.

<sup>c</sup>The same formulas apply to the pinion, substituting  $N_P$  for  $N_G$  and  $o$  for  $O$ .

$N_G$  = number of teeth in gear;  $N_P$  = number of teeth in pinion;  $O$  = outside diameter of gear;  $o$  = outside diameter of pinion;  $D$  = pitch diameter of gear =  $N_G \div P$ ;  $d$  = pitch diameter of pinion =  $N_P \div P$ ;  $P_c$  = circular pitch;  $J$  = addendum;  $K$  = dedendum;  $W$  = whole depth.

See footnote in Table 1a for meaning of  $P_N$  and  $P_D$ . The tooth thickness on the pitch circle is found by means of the formulas in the last column under spur gears.

Table 1c. Formulas for Calculating Dimensions of Helical Gears

| Tooth Form and Pressure Angle                   | Normal Diametral Pitch $P_N$   | Diametral Pitch $P$                              | Outside Diameter of Blank $O$   | Pitch Diameter $D$                            | Cosine of Helix Angle $A$                                | Addendum  | Dedendum  | Whole Depth   |

| Fellows 20-degree stub                          | ...  | ...  | $\frac{N}{(P_N)_N \cos A} + \frac{2}{(P_N)_D}$                          | $\frac{N}{(P_N)_N \cos A}$                    | $\frac{N}{(P_N)_N \left( O - \frac{2}{(P_N)_D} \right)}$ | $\frac{1}{(P_N)_D}$                               | $\frac{1.25}{(P_N)_D}$                                | $\frac{2.25}{(P_N)_D}$                                |

$P_N$  = normal diametral pitch = normal diametral pitch of cutter or hob used to cut teeth

$P$  = diametral pitch

$O$  = outside diameter of blank

$D$  = pitch diameter

$A$  = helix angle

$N$  = number of teeth

$(P_N)_N$  = normal diametral pitch in numerator of stub-tooth designation, which determines thickness of tooth and number of teeth

$(P_N)_D$  = normal diametral pitch in denominator of stub-tooth designation, which determines the addendum, dedendum, and whole depth

**SPLINES AND SERRATIONS**

A splined shaft is one having a series of parallel keys formed integrally with the shaft and mating with corresponding grooves cut in a hub or fitting; this arrangement is in contrast to a shaft having a series of keys or feathers fitted into slots cut into the shaft. The latter construction weakens the shaft to a considerable degree because of the slots cut into it and consequently, reduces its torque-transmitting capacity.

Splined shafts are most generally used in three types of applications: 1) for coupling shafts when relatively heavy torques are to be transmitted without slippage; 2) for transmitting power to slidably-mounted or permanently-fixed gears, pulleys, and other rotating members; and 3) for attaching parts that may require removal for indexing or change in angular position.

Splines having straight-sided teeth have been used in many applications (see SAE Parallel Side Splines for Soft Broached Holes in Fittings); however, the use of splines with teeth of involute profile has steadily increased since 1) involute spline couplings have greater torque-transmitting capacity than any other type; 2) they can be produced by the same techniques and equipment as is used to cut gears; and 3) they have a self-centering action under load even when there is backlash between mating members.

**Involute Splines**

**American National Standard Involute Splines\*.**—These splines or multiple keys are similar in form to internal and external involute gears. The general practice is to form the external splines either by hobbing, rolling, or on a gear shaper, and internal splines either by broaching or on a gear shaper. The internal spline is held to basic dimensions and the external spline is varied to control the fit. Involute splines have maximum strength at the base, can be accurately spaced and are self-centering, thus equalizing the bearing and stresses, and they can be measured and fitted accurately.

In American National Standard ANSI B92.1-1970 (R 1993), many features of the 1960 standard are retained; plus the addition of three tolerance classes, for a total of four. The term “involute serration,” formerly applied to involute splines with 45-degree pressure angle, has been deleted and the standard now includes involute splines with 30-, 37.5-, and 45-degree pressure angles. Tables for these splines have been rearranged accordingly. The term “serration” will no longer apply to splines covered by this Standard.

The Standard has only one fit class for all side fit splines; the former Class 2 fit. Class 1 fit has been deleted because of its infrequent use. The major diameter of the flat root side fit spline has been changed and a tolerance applied to include the range of the 1950 and the 1960 standards. The interchangeability limitations with splines made to previous standards are given later in the section entitled “Interchangeability.”

There have been no tolerance nor fit changes to the major diameter fit section.

The Standard recognizes the fact that proper assembly between mating splines is dependent only on the spline being within effective specifications from the tip of the tooth to the form diameter. Therefore, on side fit splines, the internal spline major diameter now is shown as a maximum dimension and the external spline minor diameter is shown as a minimum dimension. The minimum internal major diameter and the maximum external minor diameter must clear the specified form diameter and thus do not need any additional control.

The spline specification tables now include a greater number of tolerance level selections. These tolerance classes were added for greater selection to suit end product needs. The selections differ only in the tolerance as applied to space width and tooth thickness.

\* See American National Standard ANSI B92.2M-1980 (R 1989), Metric Module Involute Splines; also see page 2176.

The tolerance class used in ASA B5.15-1960 is the basis and is now designated as tolerance Class 5. The new tolerance classes are based on the following formulas:

$$\text{Tolerance Class 4} = \text{Tolerance Class 5} \times 0.71$$

$$\text{Tolerance Class 6} = \text{Tolerance Class 5} \times 1.40$$

$$\text{Tolerance Class 7} = \text{Tolerance Class 5} \times 2.00$$

All dimensions listed in this standard are for the finished part. Therefore, any compensation that must be made for operations that take place during processing, such as heat treatment, must be taken into account when selecting the tolerance level for manufacturing.

The standard has the same internal minimum effective space width and external maximum effective tooth thickness for all tolerance classes and has two types of fit. For tooth side fits, the minimum effective space width and the maximum effective tooth thickness are of equal value. This basic concept makes it possible to have interchangeable assembly between mating splines where they are made to this standard regardless of the tolerance class of the individual members. A tolerance class "mix" of mating members is thus allowed, which often is an advantage where one member is considerably less difficult to produce than its mate, and the "average" tolerance applied to the two units is such that it satisfies the design need. For instance, assigning a Class 5 tolerance to one member and Class 7 to its mate will provide an assembly tolerance in the Class 6 range. The maximum effective tooth thickness is less than the minimum effective space width for major diameter fits to allow for eccentricity variations.

In the event the fit as provided in this standard does not satisfy a particular design need and a specific amount of effective clearance or press fit is desired, the change should be made only to the external spline by a reduction or an increase in effective tooth thickness and a like change in actual tooth thickness. The minimum effective space width, in this standard, is always basic. The basic minimum effective space width should always be retained when special designs are derived from the concept of this standard.

**Terms Applied to Involute Splines.**—The following definitions of involute spline terms, here listed in alphabetical order, are given in the American National Standard. Some of these terms are illustrated in the diagram in [Table 6](#).

*Active Spline Length ( $L_a$ )* is the length of spline that contacts the mating spline. On sliding splines, it exceeds the length of engagement.

*Actual Space Width ( $s$ )* is the circular width on the pitch circle of any single space considering an infinitely thin increment of axial spline length.

*Actual Tooth Thickness ( $t$ )* is the circular thickness on the pitch circle of any single tooth considering an infinitely thin increment of axial spline length.

*Alignment Variation* is the variation of the effective spline axis with respect to the reference axis (see [Fig. 1c](#)).

*Base Circle* is the circle from which involute spline tooth profiles are constructed.

*Base Diameter ( $D_b$ )* is the diameter of the base circle.

*Basic Space Width* is the basic space width for 30-degree pressure angle splines; half the circular pitch. The basic space width for 37.5- and 45-degree pressure angle splines, however, is greater than half the circular pitch. The teeth are proportioned so that the external tooth, at its base, has about the same thickness as the internal tooth at the form diameter. This proportioning results in greater minor diameters than those of comparable involute splines of 30-degree pressure angle.

*Circular Pitch ( $p$ )* is the distance along the pitch circle between corresponding points of adjacent spline teeth.

*Depth of Engagement* is the radial distance from the minor circle of the internal spline to the major circle of the external spline, minus corner clearance and/or chamfer depth.

*Diametral Pitch ( $P$ )* is the number of spline teeth per inch of pitch diameter. The diametral pitch determines the circular pitch and the basic space width or tooth thickness. In conjunction with the number of teeth, it also determines the pitch diameter. (See also Pitch.)

*Effective Clearance ( $c_v$ )* is the effective space width of the internal spline minus the effective tooth thickness of the mating external spline.

*Effective Space Width ( $S_v$ )* of an internal spline is equal to the circular tooth thickness on the pitch circle of an imaginary perfect external spline that would fit the internal spline without looseness or interference considering engagement of the entire axial length of the spline. The minimum effective space width of the internal spline is always basic, as shown in Table 3. Fit variations may be obtained by adjusting the tooth thickness of the external spline.

### Three types of involute spline variations

Fig. 1a. Lead Variation

Fig. 1b. Parallelism Variation

Fig. 1c. Alignment Variation

*Effective Tooth Thickness ( $t_v$ )* of an external spline is equal to the circular space width on the pitch circle of an imaginary perfect internal spline that would fit the external spline without looseness or interference, considering engagement of the entire axial length of the spline.

*Effective Variation* is the accumulated effect of the spline variations on the fit with the mating part.

*External Spline* is a spline formed on the outer surface of a cylinder.

*Fillet* is the concave portion of the tooth profile that joins the sides to the bottom of the space.

*Fillet Root Splines* are those in which a single fillet in the general form of an arc joins the sides of adjacent teeth.

*Flat Root Splines* are those in which fillets join the arcs of major or minor circles to the tooth sides.

*Form Circle* is the circle which defines the deepest points of involute form control of the tooth profile. This circle along with the tooth tip circle (or start of chamfer circle) determines the limits of tooth profile requiring control. It is located near the major circle on the internal spline and near the minor circle on the external spline.

*Form Clearance* ( $c_f$ ) is the radial depth of involute profile beyond the depth of engagement with the mating part. It allows for looseness between mating splines and for eccentricities between the minor circle (internal), the major circle (external), and their respective pitch circles.

*Form Diameter* ( $D_{Fe}$ ,  $D_{Fi}$ ) the diameter of the form circle.

*Internal Spline* is a spline formed on the inner surface of a cylinder.

*Involute Spline* is one having teeth with involute profiles.

*Lead Variation* is the variation of the direction of the spline tooth from its intended direction parallel to the reference axis, also including parallelism and alignment variations (see Fig. 1a). *Note:* Straight (nonhelical) splines have an infinite lead.

*Length of Engagement* ( $L_q$ ) is the axial length of contact between mating splines.

*Machining Tolerance* ( $m$ ) is the permissible variation in actual space width or actual tooth thickness.

*Major Circle* is the circle formed by the outermost surface of the spline. It is the outside circle (tooth tip circle) of the external spline or the root circle of the internal spline.

*Major Diameter* ( $D_o$ ,  $D_{ri}$ ) is the diameter of the major circle.

*Minor Circle* is the circle formed by the innermost surface of the spline. It is the root circle of the external spline or the inside circle (tooth tip circle) of the internal spline.

*Minor Diameter* ( $D_{re}$ ,  $D_i$ ) is the diameter of the minor circle.

*Nominal Clearance* is the actual space width of an internal spline minus the actual tooth thickness of the mating external spline. It does not define the fit between mating members, because of the effect of variations.

*Out of Roundness* is the variation of the spline from a true circular configuration.

*Parallelism Variation* is the variation of parallelism of a single spline tooth with respect to any other single spline tooth (see Fig. 1b).

*Pitch* ( $PIP_s$ ) is a combination number of a one-to-two ratio indicating the spline proportions; the upper or first number is the diametral pitch, the lower or second number is the stub pitch and denotes, as that fractional part of an inch, the basic radial length of engagement, both above and below the pitch circle.

*Pitch Circle* is the reference circle from which all transverse spline tooth dimensions are constructed.

*Pitch Diameter* ( $D$ ) is the diameter of the pitch circle.

*Pitch Point* is the intersection of the spline tooth profile with the pitch circle.

*Pressure Angle* ( $\phi$ ) is the angle between a line tangent to an involute and a radial line through the point of tangency. Unless otherwise specified, it is the standard pressure angle.

*Profile Variation* is any variation from the specified tooth profile normal to the flank.

*Spline* is a machine element consisting of integral keys (spline teeth) or keyways (spaces) equally spaced around a circle or portion thereof.

*Standard (Main) Pressure Angle* ( $\phi_D$ ) is the pressure angle at the specified pitch diameter.

*Stub Pitch* ( $P_s$ ) is a number used to denote the radial distance from the pitch circle to the major circle of the external spline and from the pitch circle to the minor circle of the internal spline. The stub pitch for splines in this standard is twice the diametral pitch.

*Total Index Variation* is the greatest difference in any two teeth (adjacent or otherwise) between the actual and the perfect spacing of the tooth profiles.

*Total Tolerance* ( $m + \lambda$ ) is the machining tolerance plus the variation allowance.

*Variation Allowance* ( $\lambda$ ) is the permissible effective variation.

**Tooth Proportions.**—There are 17 pitches: 2.5/5, 3/6, 4/8, 5/10, 6/12, 8/16, 10/20, 12/24, 16/32, 20/40, 24/48, 32/64, 40/80, 48/96, 64/128, 80/160, and 128/256. The numerator in this fractional designation is known as the diametral pitch and controls the pitch diameter; the denominator, which is always double the numerator, is known as the stub pitch and controls the tooth depth. For convenience in calculation, only the numerator is used in the formulas given and is designated as  $P$ . Diametral pitch, as in gears, means the number of teeth per inch of pitch diameter.

Table 1 shows the symbols and Table 2 the formulas for basic tooth dimensions of involute spline teeth of various pitches. Basic dimensions are given in Table 3.

**Table 1. American National Standard Involute Spline Symbols**  
ANSI B92.1-1970, R1993

|          |   |             |   |
|----------|---|-------------|---|
| $c_v$    | effective clearance                           | $M_i$       | measurement between pins, internal spline               |
| $c_F$    | form clearance                                | $N$         | number of teeth   |
| $D$      | pitch diameter                                | $P$         | diametral pitch   |
| $D_b$    | base diameter                                 | $P_s$       | stub pitch  |
| $D_{ci}$ | pin contact diameter, internal spline         | $p$         | circular pitch  |
| $D_{ce}$ | pin contact diameter, external spline         | $r_f$       | fillet radius   |
| $D_{Fe}$ | form diameter, external spline                | $s$         | actual space width, circular                            |
| $D_{Fi}$ | form diameter, internal spline                | $s_v$       | effective space width, circular                         |
| $D_i$    | minor diameter, internal spline               | $s_c$       | allowable compressive stress, psi                       |
| $D_o$    | major diameter, external spline               | $s_s$       | allowable shear stress, psi                             |
| $D_{re}$ | minor diameter, external spline (root)        | $t$         | actual tooth thickness, circular                        |
| $D_{ri}$ | major diameter, internal spline (root)        | $t_v$       | effective tooth thickness, circular                     |
| $d_e$    | diameter of measuring pin for external spline | $\lambda$   | variation allowance                                     |
| $d_i$    | diameter of measuring pin for internal spline | $\epsilon$  | involute roll angle                                     |
| $K_e$    | change factor for external spline             | $\phi$      | pressure angle  |
| $K_i$    | change factor for internal spline             | $\phi_D$    | standard pressure angle                                 |
| $L$      | spline length                                 | $\phi_{ci}$ | pressure angle at pin contact diameter, internal spline |
| $L_a$    | active spline length                          | $\phi_{ce}$ | pressure angle at pin contact diameter, external spline |
| $L_g$    | length of engagement                          | $\phi_i$    | pressure angle at pin center, internal spline           |
| $m$      | machining tolerance                           | $\phi_e$    | pressure angle at pin center, external spline           |
| $M_e$    | measurement over pins, external spline        | $\phi_F$    | pressure angle at form diameter                         |

**Tooth Numbers.**—The American National Standard covers involute splines having tooth numbers ranging from 6 to 60 with a 30- or 37.5-degree pressure angle and from 6 to 100 with a 45-degree pressure angle. In selecting the number of teeth for a given spline application, it is well to keep in mind that there are no advantages to be gained by using odd numbers of teeth and that the diameters of splines with odd tooth numbers, particularly internal splines, are troublesome to measure with pins since no two tooth spaces are diametrically opposite each other.

**Types and Classes of Involute Spline Fits.**—Two types of fits are covered by the American National Standard for involute splines, the side fit, and the major diameter fit. Dimensional data for flat root side fit, flat root major diameter fit, and fillet root side fit splines are tabulated in this standard for 30-degree pressure angle splines; but for only the fillet root side fit for 37.5- and 45-degree pressure angle splines.

*Side Fit:* In the side fit, the mating members contact only on the sides of the teeth; major and minor diameters are clearance dimensions. The tooth sides act as drivers and centralize the mating splines.

*Major Diameter Fit:* Mating parts for this fit contact at the major diameter for centralizing. The sides of the teeth act as drivers. The minor diameters are clearance dimensions.

The major diameter fit provides a minimum effective clearance that will allow for contact and location at the major diameter with a minimum amount of location or centralizing effect by the sides of the teeth. The major diameter fit has only one space width and tooth thickness tolerance which is the same as side fit Class 5.

A fillet root may be specified for an external spline, even though it is otherwise designed to the flat root side fit or major diameter fit standard. An internal spline with a fillet root can be used only for the side fit.

**Classes of Tolerances.**—This standard includes four classes of tolerances on space width and tooth thickness. This has been done to provide a range of tolerances for selection to suit a design need. The classes are variations of the former single tolerance which is now Class 5 and are based on the formulas shown in the footnote of Table 4. All tolerance classes have the same minimum effective space width and maximum effective tooth thickness limits so that a mix of classes between mating parts is possible.

**Table 4. Maximum Tolerances for Space Width and Tooth Thickness of Tolerance Class 5 Splines ANSI B92.1-1970, R1993**  
(Values shown in ten thousandths; 20 = 0.0020)

| No. of Teeth   | Pitch, $P/P_s$                 |              |               |                 |                 |                  |                   |          |    |    |    |    |

For other tolerance classes: Class 4 =  $0.71 \times$  Tabulated value

Class 5 = As tabulated in table

Class 6 =  $1.40 \times$  Tabulated value

Class 7 =  $2.00 \times$  Tabulated value

**Fillets and Chamfers.**—Spline teeth may have either a flat root or a rounded fillet root.

*Flat Root Splines:* are suitable for most applications. The fillet that joins the sides to the bottom of the tooth space, if generated, has a varying radius of curvature. Specification of this fillet is usually not required. It is controlled by the form diameter, which is the diameter at the deepest point of the desired true involute form (sometimes designated as TIF).

When flat root splines are used for heavily loaded couplings that are not suitable for fillet root spline application, it may be desirable to minimize the stress concentration in the flat root type by specifying an approximate radius for the fillet.

Because internal splines are stronger than external splines due to their broad bases and high pressure angles at the major diameter, broaches for flat root internal splines are normally made with the involute profile extending to the major diameter.

*Fillet Root Splines:* are recommended for heavy loads because the larger fillets provided reduce the stress concentrations. The curvature along any generated fillet varies and cannot be specified by a radius of any given value.

External splines may be produced by generating with a pinion-type shaper cutter or with a hob, or by cutting with no generating motion using a tool formed to the contour of a tooth space. External splines are also made by cold forming and are usually of the fillet root design. Internal splines are usually produced by broaching, by form cutting, or by generating with a shaper cutter. Even when full-tip radius tools are used, each of these cutting methods produces a fillet contour with individual characteristics. Generated spline fillets are curves related to the prolate epicycloid for external splines and the prolate hypocycloid for internal splines. These fillets have a minimum radius of curvature at the point where the fillet is tangent to the external spline minor diameter circle or the internal spline major diameter circle and a rapidly increasing radius of curvature up to the point where the fillet comes tangent to the involute profile.

*Chamfers and Corner Clearance:* In major diameter fits, it is always necessary to provide corner clearance at the major diameter of the spline coupling. This clearance is usually effected by providing a chamfer on the top corners of the external member. This method may not be possible or feasible because of the following:

- If the external member is roll formed by plastic deformation, a chamfer cannot be provided by the process.
- A semitopping cutter may not be available.
- When cutting external splines with small numbers of teeth, a semitopping cutter may reduce the width of the top land to a prohibitive point.

In such conditions, the corner clearance can be provided on the internal spline, as shown in Fig. 2.

When this option is used, the form diameter may fall in the protuberance area.

Fig. 2. Internal corner clearance.

**Spline Variations.**—The maximum allowable variations for involute splines are listed in Table 4.

*Profile Variation:* The reference profile, from which variations occur, passes through the point used to determine the actual space width or tooth thickness. This is either the pitch point or the contact point of the standard measuring pins.

Profile variation is positive in the direction of the space and negative in the direction of the tooth. Profile variations may occur at any point on the profile for establishing effective fits and are shown in Table 4.

*Lead Variations:* The lead tolerance for the total spline length applies also to any portion thereof unless otherwise specified.

*Out of Roundness:* This condition may appear merely as a result of index and profile variations given in Table 4 and requires no further allowance. However, heat treatment and deflection of thin sections may cause out of roundness, which increases index and profile variations. Tolerances for such conditions depend on many variables and are therefore not tabulated. Additional tooth and/or space width tolerance must allow for such conditions.

*Eccentricity:* Eccentricity of major and minor diameters in relation to the effective diameter of side fit splines should not cause contact beyond the form diameters of the mating splines, even under conditions of maximum effective clearance. This standard does not establish specific tolerances.

Eccentricity of major diameters in relation to the effective diameters of major diameter fit splines should be absorbed within the maximum material limits established by the tolerances on major diameter and effective space width or effective tooth thickness.

If the alignment of mating splines is affected by eccentricity of locating surfaces relative to each other and/or the splines, it may be necessary to decrease the effective and actual tooth thickness of the external splines in order to maintain the desired fit condition. This standard does not include allowances for eccentric location.

**Effect of Spline Variations.**—Spline variations can be classified as index variations, profile variations, or lead variations.

*Index Variations:* These variations cause the clearance to vary from one set of mating tooth sides to another. Because the fit depends on the areas with minimum clearance, index variations reduce the effective clearance.

*Profile Variations:* Positive profile variations affect the fit by reducing effective clearance. Negative profile variations do not affect the fit but reduce the contact area.

*Lead Variations:* These variations will cause clearance variations and therefore reduce the effective clearance.

*Variation Allowance:* The effect of individual spline variations on the fit (effective variation) is less than their total, because areas of more than minimum clearance can be altered without changing the fit. The variation allowance is 60 percent of the sum of twice the positive profile variation, the total index variation and the lead variation for the length of engagement. The variation allowances in Table 4 are based on a lead variation for an assumed length of engagement equal to one-half the pitch diameter. Adjustment may be required for a greater length of engagement.

**Effective and Actual Dimensions.**—Although each space of an internal spline may have the same width as each tooth of a perfect mating external spline, the two may not fit because of variations of index and profile in the internal spline. To allow the perfect external spline to fit in any position, all spaces of the internal spline must then be widened by the amount of interference. The resulting width of these tooth spaces is the *actual* space width of the internal spline. The *effective* space width is the tooth thickness of the perfect mating external spline. The same reasoning applied to an external spline that has variations of index and profile when mated with a perfect internal spline leads to the concept of effective

tooth thickness, which exceeds the actual tooth thickness by the amount of the effective variation.

The effective space width of the internal spline minus the effective tooth thickness of the external spline is the effective clearance and defines the fit of the mating parts. (This statement is strictly true only if high points of mating parts come into contact.) Positive effective clearance represents looseness or backlash. Negative effective clearance represents tightness or interference.

**Space Width and Tooth Thickness Limits.**—The variation of actual space width and actual tooth thickness within the machining tolerance causes corresponding variations of effective dimensions, so that there are four limit dimensions for each component part.

These variations are shown diagrammatically in Table 5.

**Table 5. Specification Guide for Space Width and Tooth Thickness**  
ANSI B92.1-1970, R1993

| Dimension                          | Dimension of Variations, Clearances, and Tolerances on Part |        | Dimensioning Method |              |          |
|------------------------------------|---|--------|---------------------|--------------|----------|
|                                    | Effective   | Actual | Standard            | Alternatives |          |
|                                    |   |        |                     | A            | B        |
| Space Width of Internal Spline     |   |        | Required            | Required     | Ref.     |
|                                    |   |        | Ref.                | Ref.         | Ref.     |
| (Basic)                            | $\pi$   |        | Ref.                | Required     | Required |
| Tooth Thickness of External Spline |   |        | Required            | Required     | Required |
|                                    |   |        | Ref.                | Required     | Required |
|                                    |   |        | Ref.                | Ref.         | Ref.     |
|                                    |   |        | Required            | Required     | Ref.     |

The minimum effective space width is always basic. The maximum effective tooth thickness is the same as the minimum effective space width except for the major diameter fit. The major diameter fit maximum effective tooth thickness is less than the minimum effective space width by an amount that allows for eccentricity between the effective spline and the major diameter. The permissible variation of the effective clearance is divided between the internal and external splines to arrive at the maximum effective space width and the minimum effective tooth thickness. Limits for the actual space width and actual tooth thickness are constructed from suitable variation allowances.

**Use of Effective and Actual Dimensions.**—Each of the four dimensions for space width and tooth thickness shown in Table 5 has a definite function.

*Minimum Effective Space Width and Maximum Effective Tooth Thickness:* These dimensions control the minimum effective clearance, and must always be specified.

*Minimum Actual Space Width and Maximum Actual Tooth Thickness:* These dimensions cannot be used for acceptance or rejection of parts. If the actual space width is less than the minimum without causing the effective space width to be undersized, or if the actual tooth thickness is more than the maximum without causing the effective tooth thickness to be oversized, the effective variation is less than anticipated; such parts are desirable and not defective. The specification of these dimensions as processing reference dimensions is optional. They are also used to analyze undersize effective space width or oversize effective tooth thickness conditions to determine whether or not these conditions are caused by excessive effective variation.

**Maximum Actual Space Width and Minimum Actual Tooth Thickness:** These dimensions control machining tolerance and limit the effective variation. The spread between these dimensions, reduced by the effective variation of the internal and external spline, is the maximum effective clearance. Where the effective variation obtained in machining is appreciably less than the variation allowance, these dimensions must be adjusted in order to maintain the desired fit.

**Maximum Effective Space Width and Minimum Effective Tooth Thickness:** These dimensions define the maximum effective clearance but they do not limit the effective variation. They may be used, in addition to the maximum actual space width and minimum actual tooth thickness, to prevent the increase of maximum effective clearance due to reduction of effective variations. The notation "inspection optional" may be added where maximum effective clearance is an assembly requirement, but does not need absolute control. It will indicate, without necessarily adding inspection time and equipment, that the actual space width of the internal spline must be held below the maximum, or the actual tooth thickness of the external spline above the minimum, if machining methods result in less than the allowable variations. Where effective variation needs no control or is controlled by laboratory inspection, these limits may be substituted for maximum actual space width and minimum actual tooth thickness.

**Combinations of Involute Spline Types.**—Flat root side fit internal splines may be used with fillet root external splines where the larger radius is desired on the external spline for control of stress concentrations. This combination of fits may also be permitted as a design option by specifying for the minimum root diameter of the external, the value of the minimum root diameter of the fillet root external spline and noting this as "optional root."

A design option may also be permitted to provide either flat root internal or fillet root internal by specifying for the maximum major diameter, the value of the maximum major diameter of the fillet root internal spline and noting this as "optional root."

**Interchangeability.**—Splines made to this standard may interchange with splines made to older standards. Exceptions are listed below.

**External Splines:** These external splines will mate with older internal splines as follows:

| Year              | Major Dia. Fit | Flat Root Side Fit  | Fillet Root Side Fit |
|-------------------|----------------|---------------------|----------------------|
| 1946              | Yes            | No (A) <sup>a</sup> | No (A)               |
| 1950 <sup>b</sup> | Yes (B)        | Yes (B)             | Yes (C)              |
| 1950 <sup>c</sup> | Yes (B)        | No (A)              | Yes (C)              |
| 1957 SAE          | Yes            | No (A)              | Yes (C)              |
| 1960              | Yes            | No (A)              | Yes (C)              |

<sup>a</sup> For exceptions A, B, C, see the paragraph on *Exceptions* that follows.

<sup>b</sup> Full dedendum.

<sup>c</sup> Short dedendum.

**Internal Splines:** These will mate with older external splines as follows:

| Year     | Major Dia. Fit      | Flat Root Side Fit | Fillet Root Side Fit |
|----------|---------------------|--------------------|----------------------|
| 1946     | No (D) <sup>a</sup> | No (E)             | No (D)               |
| 1950     | Yes (F)             | Yes                | Yes (C)              |
| 1957 SAE | Yes (G)             | Yes                | Yes                  |
| 1960     | Yes (G)             | Yes                | Yes                  |

<sup>a</sup> For exceptions C, D, E, F, G, see the paragraph on *Exceptions* that follows.

**Table 6. Spline Terms, Symbols, and Drawing Data, 30-Degree Pressure Angle, Flat Root Side Fit ANSI B92.1-1970, R1993**

The fit shown is used in restricted areas (as with tubular parts with wall thickness too small to permit use of fillet roots, and to allow hobbing closer to shoulders, etc.) and for economy (when hobbing, shaping, etc., and using shorter broaches for the internal member).

Press fits are not tabulated because their design depends on the degree of tightness desired and must allow for such factors as the shape of the blank, wall thickness, material, hardness, thermal expansion, etc. Close tolerances or selective size grouping may be required to limit fit variations.

**Drawing Data**

| Internal Involute Spline Data                       |              | External Involute Spline Data                       |              |

| The following information may be added as required: |              | The following information may be added as required: |              |
| Max Measurement Between Pins                        | x.xxx Ref    | Min Measurement Over Pins                           | x.xxxx Ref   |
| Pin Diameter  | x.xxxx       | Pin Diameter  | x.xxxx       |

The above drawing data are required for the spline specifications. The standard system is shown; for alternate systems, see Table 5. Number of x's indicates number of decimal places normally used.

*Exceptions:*

a) The external major diameter, unless chamfered or reduced, may interfere with the internal form diameter on flat root side fit splines. Internal splines made to the 1957 and 1960 standards had the same dimensions as shown for the major diameter fit splines in this standard.

b) For 15 teeth or less, the minor diameter of the internal spline, unless chamfered, will interfere with the form diameter of the external spline.

c) For 9 teeth or less, the minor diameter of the internal spline, unless chamfered, will interfere with form diameter of the external spline.

d) The internal minor diameter, unless chamfered, will interfere with the external form diameter.

e) The internal minor diameter, unless chamfered, will interfere with the external form diameter.

f) For 10 teeth or less, the minimum chamfer on the major diameter of the external spline may not clear the internal form diameter.

g) Depending upon the pitch of the spline, the minimum chamfer on the major diameter may not clear the internal form diameter.

**Drawing Data.**—It is important that uniform specifications be used to show complete information on detail drawings of splines. Much misunderstanding will be avoided by following the suggested arrangement of dimensions and data as given in [Table 6](#). The number of x's indicates the number of decimal places normally used. With this tabulated type of spline specifications, it is usually not necessary to show a graphic illustration of the spline teeth.

**Spline Data and Reference Dimensions.**—Spline data are used for engineering and manufacturing purposes. Pitch and pressure angle are not subject to individual inspection.

As used in this standard, *reference* is an added notation or modifier to a dimension, specification, or note when that dimension, specification, or note is:

- 1) Repeated for drawing clarification.
- 2) Needed to define a nonfeature datum or basis from which a form or feature is generated.
- 3) Needed to define a nonfeature dimension from which other specifications or dimensions are developed.
- 4) Needed to define a nonfeature dimension at which toleranced sizes of a feature are specified.
- 5) Needed to define a nonfeature dimension from which control tolerances or sizes are developed or added as useful information.

Any dimension, specification, or note that is noted "REF" should not be used as a criterion for part acceptance or rejection.

**Estimating Key and Spline Sizes and Lengths.**—[Fig. 3](#) may be used to estimate the size of American Standard involute splines required to transmit a given torque. It also may be used to find the outside diameter of shafts used with single keys. After the size of the shaft is found, the proportions of the key can be determined from [Table 1](#) on page [2363](#).

Curve A is for flexible splines with teeth hardened to Rockwell C 55–65. For these splines, lengths are generally made equal to or somewhat greater than the pitch diameter for diameters below 1¼ inches; on larger diameters, the length is generally one-third to two-thirds the pitch diameter. Curve A also applies for a single key used as a fixed coupling, the length of the key being one to one and one-quarter times the shaft diameter. The stress in the shaft, neglecting stress concentration at the keyway, is about 7500 pounds per square inch. See also *Effect of Keyways on Shaft Strength* starting on page [305](#).

Curve B represents high-capacity single keys used as fixed couplings for stresses of 9500 pounds per square inch, neglecting stress concentration. Key-length is one to one and one-quarter times shaft diameter and both shaft and key are of moderately hard heat-treated

Fig. 3. Chart for Estimating Involute Spline Size Based on Diameter-Torque Relationships

steel. This type of connection is commonly used to key commercial flexible couplings to motor or generator shafts.

Curve C is for multiple-key fixed splines with lengths of three-quarters to one and one-quarter times pitch diameter and shaft hardness of 200–300 BHN.

Curve D is for high-capacity splines with lengths one-half to one times the pitch diameter. Hardnesses up to Rockwell C 58 are common and in aircraft applications the shaft is generally hollow to reduce weight.

Curve E represents a solid shaft with 65,000 pounds per square inch shear stress. For hollow shafts with inside diameter equal to three-quarters of the outside diameter the shear stress would be 95,000 pounds per square inch.

*Length of Splines:* Fixed splines with lengths of one-third the pitch diameter will have the same shear strength as the shaft, assuming uniform loading of the teeth; however, errors in spacing of teeth result in only half the teeth being fully loaded. Therefore, for balanced strength of teeth and shaft the length should be two-thirds the pitch diameter. If weight is not important, however, this may be increased to equal the pitch diameter. In the case of flexible splines, long lengths do not contribute to load carrying capacity when there is misalignment to be accommodated. Maximum effective length for flexible splines may be approximated from Fig. 4.

**Formulas for Torque Capacity of Involute Splines.**—The formulas for torque capacity of 30-degree involute splines given in the following paragraphs are derived largely from an article “When Splines Need Stress Control” by D. W. Dudley, *Product Engineering*, Dec. 23, 1957.

In the formulas that follow the symbols used are as defined on page 2160 with the following additions:  $D_i$  = inside diameter of hollow shaft, inches;  $K_a$  = application factor from Table 7;  $K_m$  = load distribution factor from Table 8;  $K_f$  = fatigue life factor from Table 9;  $K_w$

Fig. 4. Maximum Effective Length for Fixed and Flexible Splines

= wear life factor from Table 10;  $L_e$  = maximum effective length from Fig. 4, to be used in stress formulas even though the actual length may be greater;  $T$  = transmitted torque, pound-inches. For fixed splines without helix modification, the effective length  $L_e$  should never exceed  $5000 D^{3.5} \div T$ .

Table 7. Spline Application Factors,  $K_a$ 

| Power Source                               | Type of Load                |   |   |  |
|--|-----------------------------|---|---|--|
|  | Uniform<br>(Generator, Fan) | Light Shock<br>(Oscillating<br>Pumps, etc.) | Intermittent<br>Shock<br>(Actuating<br>Pumps, etc.) | Heavy<br>Shock<br>(Punches,<br>Shears, etc.) |

|----------------------------------|-----------------------------------|------------------|------------------|------------------|
|                                  | $\frac{1}{2}$ -in. Face Width     | 1-in. Face Width | 2-in. Face Width | 4-in. Face Width |
| 0.001                            | 1                                 | 1                | 1                | $1 \frac{1}{2}$  |
| 0.002                            | 1                                 | 1                | $1 \frac{1}{2}$  | 2                |
| 0.004                            | 1                                 | $1 \frac{1}{2}$  | 2                | $2 \frac{1}{2}$  |
| 0.008                            | $1 \frac{1}{2}$                   | 2                | $2 \frac{1}{2}$  | 3                |

<sup>a</sup> For fixed splines,  $K_m = 1$ .

For fixed splines,  $K_m = 1$ .

**Table 9. Fatigue-Life Factors,  $K_f$ , for Splines**

| No. of Torque Cycles <sup>a</sup> | Fatigue-Life Factor, $K_f$ |                |
|-----------------------------------|----------------------------|----------------|
|                                   | Unidirectional             | Fully-reversed |
| 1,000                             | 1.8                        | 1.8            |
| 10,000                            | 1.0                        | 1.0            |
| 100,000                           | 0.5                        | 0.4            |
| 1,000,000                         | 0.4                        | 0.3            |
| 10,000,000                        | 0.3                        | 0.2            |

<sup>a</sup> A torque cycle consists of one start and one stop, not the number of revolutions.

**Table 10. Wear Life Factors,  $K_w$ , for Flexible Splines**

| Number of Revolutions of Spline | Life Factor, $K_w$ | Number of Revolutions of Spline | Life Factor, $K_w$ |
|---------------------------------|--------------------|---------------------------------|--------------------|
| 10,000                          | 4.0                | 100,000,000                     | 1.0                |
| 100,000                         | 2.8                | 1,000,000,000                   | 0.7                |
| 1,000,000                       | 2.0                | 10,000,000,000                  | 0.5                |
| 10,000,000                      | 1.4                | ...                             | ...                |

Wear life factors, unlike fatigue life factors given in Table 9, are based on the total number of revolutions of the spline, since each revolution of a flexible spline results in a complete cycle of rocking motion which contributes to spline wear.

*Definitions:* A *fixed* spline is one which is either shrink fitted or loosely fitted but piloted with rings at each end to prevent rocking of the spline which results in small axial movements that cause wear. A *flexible* spline permits some rocking motion such as occurs when the shafts are not perfectly aligned. This flexing or rocking motion causes axial movement and consequently wear of the teeth. Straight-toothed flexible splines can accommodate only small angular misalignments (less than 1 deg.) before wear becomes a serious problem. For greater amounts of misalignment (up to about 5 deg.), crowned splines are preferable to reduce wear and end-loading of the teeth.

*Shear Stress Under Roots of External Teeth:* For a transmitted torque  $T$ , the torsional shear stress induced in the shaft under the root diameter of an external spline is:

$$S_s = \frac{16TK_a}{\pi D_{re}^3 K_f} \quad \text{for a solid shaft} \quad (1)$$

$$S_s = \frac{16TD_{re}K_a}{\pi(D_{re}^4 - D_h^4)K_f} \quad \text{for a hollow shaft} \quad (2)$$

The computed stress should not exceed the values in Table 11.

**Table 11. Allowable Shear, Compressive, and Tensile Stresses for Splines**

| Material                                  | Hardness |            | Max. Allowable Stress |                         |         |                     |
|---|----------|------------|-----------------------|-------------------------|---------|---------------------|
|   |          |            | Shear Stress, psi     | Compressive Stress, psi |         | Tensile Stress, psi |

*Shear Stress at the Pitch Diameter of Teeth:* The shear stress at the pitch line of the teeth for a transmitted torque  $T$  is:

$$S_s = \frac{4TK_aK_m}{DNL_e t K_f} \quad (3)$$

The factor of 4 in (3) assumes that only half the teeth will carry the load because of spacing errors. For poor manufacturing accuracies, change the factor to 6.

The computed stress should not exceed the values in [Table 11](#).

*Compressive Stresses on Sides of Spline Teeth:* Allowable compressive stresses on splines are very much lower than for gear teeth since non-uniform load distribution and misalignment result in unequal load sharing and end loading of the teeth.

$$\text{For flexible splines, } S_c = \frac{2TK_mK_a}{DNL_e h K_w} \quad (4)$$

$$\text{For fixed splines, } S_c = \frac{2TK_mK_a}{9DNL_e h K_f} \quad (5)$$

In these formulas,  $h$  is the depth of engagement of the teeth, which for flat root splines is  $0.9/P$  and for fillet root splines is  $1/P$ , approximately.

The stresses computed from [Formulas \(4\)](#) and [\(5\)](#) should not exceed the values in [Table 11](#).

*Bursting Stresses on Splines:* Internal splines may burst due to three kinds of tensile stress: 1) tensile stress due to the radial component of the transmitted load; 2) centrifugal tensile stress; and 3) tensile stress due to the tangential force at the pitch line causing bending of the teeth.

$$\text{Radial load tensile stress, } S_1 = \frac{T \tan \phi}{\pi D t_w L} \quad (6)$$

where  $t_w$  = wall thickness of internal spline = outside diameter of spline sleeve minus spline major diameter, all divided by 2.  $L$  = full length of spline.

$$\text{Centrifugal tensile stress, } S_2 = \frac{1.656 \times (\text{rpm})^2 (D_{oi}^2 + 0.212 D_{ri}^2)}{1,000,000} \quad (7)$$

where  $D_{oi}$  = outside diameter of spline sleeve.

$$\text{Beam loading tensile stress, } S_3 = \frac{4T}{D^2 L_e Y} \quad (8)$$

In [Equation \(8\)](#),  $Y$  is the Lewis form factor obtained from a tooth layout. For internal splines of 30-deg. pressure angle a value of  $Y = 1.5$  is a satisfactory estimate. The factor 4 in (8) assumes that only half the teeth are carrying the load.

The total tensile stress tending to burst the rim of the external member is:

$S_t = [K_a K_m (S_1 + S_3) + S_2] / K_f$ ; and should be less than those in [Table 11](#).

**Crowned Splines for Large Misalignments.**—As mentioned on page [2172](#), crowned splines can accommodate misalignments of up to about 5 degrees. Crowned splines have considerably less capacity than straight splines of the same size if both are operating with precise alignment. However, when large misalignments exist, the crowned spline has greater capacity.

American Standard tooth forms may be used for crowned external members so that they may be mated with straight internal members of Standard form.

The accompanying diagram of a crowned spline shows the radius of the crown  $r_1$ ; the radius of curvature of the crowned tooth,  $r_2$ ; the pitch diameter of the spline,  $D$ ; the face width,  $F$ ; and the relief or crown height  $A$  at the ends of the teeth. The crown height  $A$  should always be made somewhat greater than one-half the face width multiplied by the tangent of the misalignment angle. For a crown height  $A$ , the approximate radius of curvature  $r_2$  is  $F^2 \div 8A$ , and  $r_1 = r_2 \tan \phi$ , where  $\phi$  is the pressure angle of the spline.

For a torque  $T$ , the compressive stress on the teeth is:

$$S_c = 2290 \sqrt{2T \div D N h r_2};$$

and should be less than the value in [Table 11](#).

**Fretting Damage to Splines and Other Machine Elements.**—Fretting is wear that occurs when cyclic loading, such as vibration, causes two surfaces in intimate contact to undergo small oscillatory motions with respect to each other. During fretting, high points or asperities of the mating surfaces adhere to each other and small particles are pulled out, leaving minute, shallow pits and a powdery debris. In steel parts exposed to air, the metallic debris oxidizes rapidly and forms a red, rustlike powder or sludge; hence, the coined designation “fretting corrosion.”

Fretting is mechanical in origin and has been observed in most materials, including those that do not oxidize, such as gold, platinum, and nonmetallics; hence, the corrosion accompanying fretting of steel parts is a secondary factor.

Fretting can occur in the operation of machinery subject to motion or vibration or both. It can destroy close fits; the debris may clog moving parts; and fatigue failure may be accelerated because stress levels to initiate fatigue in fretted parts are much lower than for undamaged material. Sites for fretting damage include interference fits; splined, bolted, keyed, pinned, and riveted joints; between wires in wire rope; flexible shafts and tubes; between leaves in leaf springs; friction clamps; small amplitude-of-oscillation bearings; and electrical contacts.

Vibration or cyclic loadings are the main causes of fretting. If these factors cannot be eliminated, greater clamping force may reduce movement but, if not effective, may actually worsen the damage. Lubrication may delay the onset of damage; hard plating or surface hardening methods may be effective, not by reducing fretting, but by increasing the fatigue strength of the material. Plating soft materials having inherent lubricity onto contacting surfaces is effective until the plating wears through.

**Involute Spline Inspection Methods.**—Spline gages are used for routine inspection of production parts.

Analytical inspection, which is the measurement of individual dimensions and variations, may be required:

- To supplement inspection by gages, for example, where NOT GO composite gages are used in place of NOT GO sector gages and variations must be controlled.
- To evaluate parts rejected by gages.
- For prototype parts or short runs where spline gages are not used.

d) To supplement inspection by gages where each individual variation must be restrained from assuming too great a portion of the tolerance between the minimum material actual and the maximum material effective dimensions.

**Inspection with Gages.**—A variety of gages is used in the inspection of involute splines.

*Types of Gages:* A composite spline gage has a full complement of teeth. A sector spline gage has two diametrically opposite groups of teeth. A sector plug gage with only two teeth per sector is also known as a “paddle gage.” A sector ring gage with only two teeth per sector is also known as a “snap ring gage.” A progressive gage is a gage consisting of two or more adjacent sections with different inspection functions. Progressive GO gages are physical combinations of GO gage members that check consecutively first one feature or one group of features, then their relationship to other features. GO and NOT GO gages may also be combined physically to form a progressive gage.

Fig. 5. Space width and tooth-thickness inspection.

*GO and NOT GO Gages:* GO gages are used to inspect maximum material conditions (maximum external, minimum internal dimensions). They may be used to inspect an individual dimension or the relationship between two or more functional dimensions. They control the minimum looseness or maximum interference.

NOT GO gages are used to inspect minimum material conditions (minimum external, maximum internal dimensions), thereby controlling the maximum looseness or minimum interference. Unless otherwise agreed upon, a product is acceptable only if the NOT GO gage does not enter or go on the part. A NOT GO gage can be used to inspect only one dimension. An attempt at simultaneous NOT GO inspection of more than one dimension could result in failure of such a gage to enter or go on (acceptance of part), even though all but one of the dimensions were outside product limits. In the event all dimensions are outside the limits, their relationship could be such as to allow acceptance.

*Effective and Actual Dimensions:* The effective space width and tooth thickness are inspected by means of an accurate mating member in the form of a composite spline gage.

The actual space width and tooth thickness are inspected with sector plug and ring gages, or by measurements with pins.

**Measurements with Pins.**—The actual space width of internal splines, and the actual tooth thickness of external splines, may be measured with pins. These measurements do not determine the fit between mating parts, but may be used as part of the analytic inspection of splines to evaluate the effective space width or effective tooth thickness by approximation.

*Formulas for 2-Pin Measurement Between Pins:* For measurement *between* pins of internal splines using the symbols given on page 2160:

1) Find involute of pressure angle at pin center:

$$\text{inv } \phi_i = \frac{s}{D} + \text{inv } \phi_d - \frac{d_i}{D_b}$$

2) Find the value of  $\phi_i$  in degrees, in the involute function tables beginning on page 104. Find  $\sec \phi_i = 1/\cosine \phi_i$  in the trig tables, pages 100 through 102, using interpolation to obtain higher accuracy.

3) Compute measurement,  $M_i$ , between pins:

For even numbers of teeth:  $M_i = D_b \sec \phi_i - d_i$

For odd numbers of teeth:  $M_i = (D_b \cos 90^\circ/N) \sec \phi_i - d_i$

where:  $d_i = 1.7280/P$  for  $30^\circ$  and  $37.5^\circ$  standard pressure angle ( $\phi_D$ ) splines

$d_i = 1.9200/P$  for  $45^\circ$  pressure angle splines

*Example:* Find the measurement between pins for *maximum* actual space width of an internal spline of  $30^\circ$  pressure angle, tolerance class 4,  $\frac{3}{6}$  diametral pitch, and 20 teeth.

The maximum actual space width to be substituted for  $s$  in Step 1 above is obtained as follows: In Table 5, page 2166, the maximum actual space width is the sum of the minimum effective space width (second column) and  $\lambda + m$  (third column). The minimum effective space width  $s_v$  from Table 2, page 2161, is  $\pi/2P = \pi/(2 \times 3)$ . The values of  $\lambda$  and  $m$  from Table 4, page 2163, are, for a class 4 fit,  $\frac{3}{6}$  diametral pitch, 20-tooth spline:  $\lambda = 0.0027 \times 0.71 = 0.00192$ ; and  $m = 0.00176 \times 0.71 = 0.00125$ , so that  $s = 0.52360 + 0.00192 + 0.00125 = 0.52677$ .

Other values required for Step 1 are:

$$D = N \div P = 20 \div 3 = 6.66666$$

$$\text{inv } \phi_D = \text{inv } 30^\circ = 0.053751 \text{ from a calculator}$$

$$d_i = 1.7280/3 = 0.57600$$

$$D_b = D \cos \phi_D = 6.66666 \times 0.86603 = 5.77353$$

The computation is made as follows:

$$1) \text{inv } \phi_i = 0.52677/6.66666 + 0.053751 - 0.57600/5.77353 = 0.03300$$

$$2) \text{ From a calculator, } \phi_i = 25^\circ 46.18' \text{ and } \sec \phi_i = 1.11044$$

$$3) M_i = 5.77353 \times 1.11044 - 0.57600 = 5.8352 \text{ inches}$$

*Formulas for 2-Pin Measurement Over Pins:* For measurement *over* pins of external splines:

1) Find involute of pressure angle at pin center:

$$\text{inv } \phi_e = \frac{t}{D} + \text{inv } \phi_D + \frac{d_e}{D_b} - \frac{\pi}{N}$$

2) Find the value of  $\phi_e$  and  $\sec \phi_e$  from the involute function tables beginning on page 104.

3) Compute measurement,  $M_e$ , over pins:

For even numbers of teeth:  $M_e = D_b \sec \phi_e + d_e$

For odd numbers of teeth:  $M_e = (D_b \cos 90^\circ/N) \sec \phi_e + d_e$

where  $d_e = 1.9200/P$  for all external splines

**American National Standard Metric Module Splines.**—ANSI B92.2M-1980 (R1989) is the American National Standards Institute version of the International Standards Organization involute spline standard. It is not a "soft metric" conversion of any previous, inch-based, standard,\* and splines made to this hard metric version are not intended for use with components made to the B92.1 or other, previous standards. The ISO 4156 Standard from

\* A "soft" conversion is one in which dimensions in inches, when multiplied by 25.4 will, after being appropriately rounded off, provide equivalent dimensions in millimeters. In a "hard" system the tools of production, such as hobs, do not bear a usable relation to the tools in another system; i.e., a 10 diametral pitch hob calculates to be equal to a 2.54 module hob in the metric module system, a hob that does not exist in the metric standard.

which this one is derived is the result of a cooperative effort between the ANSI B92 committee and other members of the ISO/TC 14-2 involute spline committee.

Many of the features of the previous standard, ANSI B92.1-1970 (R1993), have been retained such as: 30-, 37.5-, and 45-degree pressure angles; flat root and fillet root side fits; the four tolerance classes 4, 5, 6, and 7; tables for a single class of fit; and the effective fit concept.

Among the major differences are: use of modules of from 0.25 through 10 mm in place of diametral pitch; dimensions in millimeters instead of inches; the "basic rack"; removal of the major diameter fit; and use of ISO symbols in place of those used previously. Also, provision is made for calculating three defined clearance fits.

The Standard recognizes that proper assembly between mating splines is dependent only on the spline being within effective specifications from the tip of the tooth to the form diameter. Therefore, the internal spline major diameter is shown as a maximum dimension and the external spline minor diameter is shown as a minimum dimension. The minimum internal major diameter and the maximum external minor diameter must clear the specified form diameter and thus require no additional control. All dimensions are for the finished part; any compensation that must be made for operations that take place during processing, such as heat treatment, must be considered when selecting the tolerance level for manufacturing.

The Standard provides the same internal minimum effective space width and external maximum effective tooth thickness for all tolerance classes. This basic concept makes possible interchangeable assembly between mating splines regardless of the tolerance class of the individual members, and permits a tolerance class "mix" of mating members. This arrangement is often an advantage when one member is considerably less difficult to produce than its mate, and the "average" tolerance applied to the two units is such that it satisfies the design need. For example, by specifying Class 5 tolerance for one member and Class 7 for its mate, an assembly tolerance in the Class 6 range is provided.

If a fit given in this Standard does not satisfy a particular design need, and a specific clearance or press fit is desired, the change shall be made only to the external spline by a reduction of, or an increase in, the effective tooth thickness and a like change in the actual tooth thickness. The minimum effective space width is always basic and this basic width should always be retained when special designs are derived from the concept of this Standard.

*Spline Terms and Definitions:* The spline terms and definitions given for American National Standard ANSI B92.1-1970 (R1993) described in the preceding section, may be used in regard to ANSI B92.2M-1980 (R1989). The 1980 Standard utilizes ISO symbols in place of those used in the 1970 Standard; these differences are shown in [Table 12](#).

*Dimensions and Tolerances:* Dimensions and tolerances of splines made to the 1980 Standard may be calculated using the formulas given in [Table 13](#). These formulas are for metric module splines in the range of from 0.25 to 10 mm metric module of side-fit design and having pressure angles of 30-, 37.5-, and 45-degrees. The standard modules in the system are: 0.25; 0.5; 0.75; 1; 1.25; 1.5; 1.75; 2; 2.5; 3; 4; 5; 6; 8; and 10. The range of from 0.5 to 10 module applies to all splines except 45-degree fillet root splines; for these, the range of from 0.25 to 2.5 module applies.

*Fit Classes:* Four classes of side fit splines are provided: spline fit class H/h having a minimum effective clearance,  $c_v = es = 0$ ; classes H/f, H/e, and H/d having tooth thickness modifications,  $es$ , of  $f$ ,  $e$ , and  $d$ , respectively, to provide progressively greater effective clearance  $c_v$ . The tooth thickness modifications  $h$ ,  $f$ ,  $e$ , and  $d$  in [Table 14](#) are fundamental deviations selected from ISO R286, "ISO System of Limits and Fits." They are applied to the external spline by shifting the tooth thickness total tolerance below the basic tooth thickness by the amount of the tooth thickness modification to provide a prescribed minimum effective clearance  $c_v$ .

**Table 12. Comparison of Symbols Used in ANSI B92.2M-1980 (R1989) and Those in ANSI B92.1-1970, R1993**

| Symbol       |           | Meaning of Symbol                                    | Symbol               |                   | Meaning of Symbol  |

<sup>a</sup> Internal splines are fit class H and have space width modification from basic space width equal to zero; thus, an H/h fit class has effective clearance  $c_v = 0$ .

*Note:* The values listed in this table are taken from ISO R286 and have been computed on the basis of the geometrical mean of the size ranges shown. Values in **boldface** type do not comply with any documented rule for rounding but are those used by ISO R286; they are used in this table to comply with established international practice.

*Basic Rack Profiles:* The basic rack profile for the standard pressure angle splines are shown in Figs. 6a, 6b, 6c, and 6d. The dimensions shown are for maximum material condition and for fit class H/h.

**Spline Machining Tolerances and Variations.**—The total tolerance ( $T + \lambda$ ), Table 15, is the sum of Effective Variation,  $\lambda$ , and a Machining Tolerance,  $T$ .

**Table 15. Space Width and Tooth Thickness Total Tolerance,  $(T + \lambda)$ , in Millimeters**

| Spline Tolerance Class | Formula for Total Tolerance, $(T + \lambda)$ | Spline Tolerance Class | Formula for Total Tolerance, $(T + \lambda)$ | In these formulas, $i^*$ and $i^{**}$ are tolerance units based upon pitch diameter and tooth thickness, respectively:<br><br>$i^* = 0.001(0.45^3\sqrt{D} + 0.001D)$ for $D \leq 500$ mm<br>$= 0.001(0.004D + 2.1)$ for $D > 500$ mm<br><br>$i^{**} = 0.001(0.45^3\sqrt{S_{\text{bsc}}} + 0.001S_{\text{bsc}})$ |
|------------------------|--|------------------------|--|---|
| 4                      | $10i^* + 40i^{**}$                           | 6                      | $25i^* + 100i^{**}$                          |   |
| 5                      | $16i^* + 64i^{**}$                           | 7                      | $40i^* + 160i^{**}$                          |   |

*Effective Variation:* The effective variation,  $\lambda$ , is the combined effect that total index variation, positive profile variation, and tooth alignment variation has on the effective fit of mating involute splines. The effect of the individual variations is less than the sum of the allowable variations because areas of more than minimum clearance can have profile, tooth alignment, or index variations without changing the fit. It is also unlikely that these variations would occur in their maximum amounts simultaneously on the same spline. For this reason, total index variation, total profile variation, and tooth alignment variation are used to calculate the combined effect by the following formula:

$$\lambda = 0.6 \sqrt{(F_p)^2 + (f_f)^2 + (F_\beta)^2} \text{ millimeters}$$

The above variation is based upon a length of engagement equal to one-half the pitch diameter of the spline; adjustment of  $\lambda$  may be required for a greater length of engagement. Formulas for values of  $F_p$ ,  $f_f$ , and  $F_\beta$  used in the above formula are given in Table 16.

**Table 16. Formulas for  $F_p, f_f,$  and  $F_\beta$  used to calculate  $\lambda$**

| Spline Tolerance Class | Total Index Variation, in mm, $F_p$ | Total Profile Variation, in mm, $f_f$ | Total Lead Variation, in mm, $F_\beta$ |
|------------------------|-------------------------------------|---------------------------------------|--|
| 4                      | $0.001(2.5\sqrt{mZ\pi/2} + 6.3)$    | $0.001 [1.6m(1 + 0.0125Z) + 10]$      | $0.001(0.8\sqrt{g} + 4)$               |
| 5                      | $0.001(3.55\sqrt{mZ\pi/2} + 9)$     | $0.001 [2.5m(1 + 0.0125Z) + 16]$      | $0.001(1.0\sqrt{g} + 5)$               |
| 6                      | $0.001(5\sqrt{mZ\pi/2} + 12.5)$     | $0.001 [4m(1 + 0.0125Z) + 25]$        | $0.001(1.25\sqrt{g} + 6.3)$            |
| 7                      | $0.001(7.1\sqrt{mZ\pi/2} + 18)$     | $0.001 [6.3m(1 + 0.0125Z) + 40]$      | $0.001(2\sqrt{g} + 10)$                |

$g$  = length of spline in millimeters.

These values are used with the applicable formulas in Table 13.

**Machining Tolerance:** A value for machining tolerance may be obtained by subtracting the effective variation,  $\lambda$ , from the total tolerance ( $T + \lambda$ ). Design requirements or specific processes used in spline manufacture may require a different amount of machining tolerance in relation to the total tolerance.

**British Standard Straight Splines.**—British Standard BS 2059:1953, “Straight-sided Splines and Serrations”, was introduced because of the widespread development and use of splines and because of the increasing use of involute splines it was necessary to provide a separate standard for straight-sided splines. BS 2059 was prepared on the hole basis, the hole being the constant member, and provide for different fits to be obtained by varying the size of the splined or serrated shaft. Part 1 of the standard deals with 6 splines only, irrespective of the shaft diameter, with two depths termed shallow and deep. The splines are bottom fitting with top clearance.

The standard contains three different grades of fit, based on the principle of variations in the diameter of the shaft at the root of the splines, in conjunction with variations in the widths of the splines themselves. Fit 1 represents the condition of closest fit and is designed for minimum backlash. Fit 2 has a positive allowance and is designed for ease of assembly, and Fit 3 has a larger positive allowance for applications that can accept such clearances.

all these splines allow for clearance on the sides of the splines (the widths), but in Fit 1, the minor diameters of the hole and the shaft may be of identical size.

Assembly of a splined shaft and hole requires consideration of the designed profile of each member, and this consideration should concentrate on the maximum diameter of the shafts and the widths of external splines, in association with the minimum diameter of the hole and the widths of the internal splineways. In other words, both internal and external splines are in the maximum metal condition. The accuracy of spacing of the splines will affect the quality of the resultant fit. If angular positioning is inaccurate, or the splines are not parallel with the axis, there will be interference between the hole and the shaft.

Part 2 of the Standard deals with straight-sided 90° serrations having nominal diameters from 0.25 to 6.0 inches. Provision is again made for three grades of fits, the basic constant being the serrated hole size. Variations in the fits of these serrations is obtained by varying the sizes of the serrations on the shaft, and the fits are related to flank bearing, the depth of engagement being constant for each size and allowing positive clearance at crest and root.

Fit 1 is an interference fit intended for permanent or semi-permanent assemblies. Heating to expand the internally-serrated member is needed for assembly. Fit 2 is a transition fit intended for assemblies that require accurate location of the serrated members, but must allow disassembly. In maximum metal conditions, heating of the outside member may be needed for assembly. Fit 3 is a clearance or sliding fit, intended for general applications.

Maximum and minimum dimensions for the various features are shown in the Standard for each class of fit. Maximum metal conditions presupposes that there are no errors of form such as spacing, alignment, or roundness of hole or shaft. Any compensation needed for such errors may require reduction of a shaft diameter or enlargement of a serrated bore, but the measured effective size must fall within the specified limits.

British Standard BS 3550:1963, "Involute Splines", is complementary to BS 2059, and the basic dimensions of all the sizes of splines are the same as those in the ANSI/ASME B5.15-1960, for major diameter fit and side fit. The British Standard uses the same terms and symbols and provides data and guidance for design of straight involute splines of 30° pressure angle, with tables of limiting dimensions. The standard also deals with manufacturing errors and their effect on the fit between mating spline elements. The range of splines covered is:

Side fit, flat root, 2.5/5.0 to 32/64 pitch, 6 to 60 splines.

Major diameter, flat root, 3.0/6.0 to 16/32 pitch, 6 to 60 splines.

Side fit, fillet root, 2.5/5.0 to 48/96 pitch, 6 to 60 splines.

British Standard BS 6186, Part 1:1981, "Involute Splines, Metric Module, Side Fit" is identical with sections 1 and 2 of ISO 4156 and with ANSI B92.2M-1980 (R1989) "Straight Cylindrical Involute Splines, Metric Module, Side Fit – Generalities, Dimensions and Inspection".

**S.A.E. Standard Spline Fittings.**—The S.A.E. spline fittings (Tables 18 through 21 inclusive) have become an established standard for many applications in the agricultural, automotive, machine tool, and other industries. The dimensions given, in inches, apply only to soft broached holes. Dimensions are illustrated in Figs. 7a, 7b, and 7c. The tolerances given may be readily maintained by usual broaching methods. The tolerances selected for the large and small diameters may depend upon whether the fit between the mating part, as finally made, is on the large or the small diameter. The other diameter, which is designed for clearance, may have a larger manufactured tolerance. If the final fit between the parts is on the sides of the spline only, larger tolerances are permissible for both the large and small diameters. The spline should not be more than 0.006 inch per foot out of parallel with respect to the shaft axis. No allowance is made for corner radii to obtain clearance. Radii at the corners of the spline should not exceed 0.015 inch.

<sup>a</sup> *Torque Capacity of Spline Fittings:* The torque capacities of the different spline fittings are given in the columns headed "T." The torque capacity, per inch of bearing length at 1000 pounds pressure per square inch on the sides of the spline, may be determined by the following formula, in which *T* = torque capacity in inch-pounds per inch of length, *N* = number of splines, *R* = mean radius or radial distance from center of hole to center of spline, *h* = depth of spline:  $T = 1000NRh$

| Sixteen        | 0.098D              | 0.045D             | 0.910D   | 0.070D                     | 0.860D   | 0.095D                   | 0.810D   |

<sup>a</sup>Four splines for fits *A* and *B* only.

The formulas in the table above give the maximum dimensions for *W*, *h*, and *d*, as listed in Tables 18 through 21 inclusive.

**Polygon-Type Shaft Connections.**— Involute-form and straight-sided splines are used for both fixed and sliding connections between machine members such as shafts and gears. Polygon-type connections, so called because they resemble regular polygons but with curved sides, may be used similarly. German DIN Standards 32711 and 32712 include data for three- and four-sided metric polygon connections. Data for 11 of the sizes shown in those Standards, but converted to inch dimensions by Stoffel Polygon Systems, are given in the accompanying table.

### Dimensions of Three- and Four-Sided Polygon-type Shaft Connections

| 1.870   | 1.630          | 0.060        | 2.378                       | 0.850                        | 1.750   | 1.480          | 0.250        | 1.94                        | 0.64                         |
| 2.140   | 1.860          | 0.070        | 3.090                       | 1.260                        | 2.000   | 1.700          | 0.250        | 2.60                        | 0.92                         |

Dimensions *Q* and *R* shown on the diagrams are approximate and used only for drafting purposes:  $Q \approx 7.5e$ ;  $R \approx D_1/2 + 16e$ .

Dimension  $D_M = D_1 + 2e$ . Pressure angle  $B_{max}$  is approximately  $344e/D_M$  degrees for three sides, and  $299e/D_M$  degrees for four sides.

Tolerances: ISO H7 tolerances apply to bore dimensions. For shafts, g6 tolerances apply for sliding fits; k7 tolerances for tight fits.

**Choosing Between Three- and Four-Sided Designs:** Three-sided designs are best for applications in which no relative movement between mating components is allowed while torque is transmitted. If a hub is to slide on a shaft while under torque, four-sided designs, which have larger pressure angles  $B_{max}$  than those of three-sided designs, are better suited to sliding even though the axial force needed to move the sliding member is approximately 50 percent greater than for comparable involute spline connections.

*Strength of Polygon Connections:* In the formulas that follow,

$H_w$  = hub width, inches  $H_t$  = hub wall thickness, inches

$M_b$  = bending moment, lb-inch

$M_t$  = torque, lb-inch

$Z$  = section modulus, bending, in.<sup>3</sup>

=0.098 $D_M^4/D_A$  for three sides =0.15 $D_f^3$  for four sides

$Z_p$  = polar section modulus, torsion, in.<sup>3</sup>

=0.196 $D_M^4/D_A$  for three sides =0.196 $D_f^3$  for four sides

$D_A$  and  $D_M$ . See table footnotes.

$S_b$  = bending stress, allowable, lb/in.<sup>2</sup>

$S_s$  = shearing stress, allowable, lb/in.<sup>2</sup>

$S_t$  = tensile stress, allowable, lb/in.<sup>2</sup>

For shafts,  $M_t$  (maximum) =  $S_s Z_p$ ;

$M_b$  (maximum) =  $S_b Z$

For bores,

$$H_t(\text{minimum}) = K \sqrt{\frac{M_t}{S_t H_w}}$$

in which  $K = 1.44$  for three sides except that if  $D_M$  is greater than 1.375 inches, then  $K = 1.2$ ;  $K = 0.7$  for four sides.

Failure may occur in the hub of a polygon connection if the hoop stresses in the hub exceed the allowable tensile stress for the material used. The radial force tending to expand the rim and cause tensile stresses is calculated from

$$\text{Radial Force, lb} = \frac{2M_t}{D_f n \tan(B_{max} + 11.3)}$$

This radial force acting at  $n$  points may be used to calculate the tensile stress in the hub wall using formulas from strength of materials.

*Manufacturing:* Polygon shaft profiles may be produced using conventional machining processes such as hobbing, shaping, contour milling, copy turning, and numerically controlled milling and grinding. Bores are produced using broaches, spark erosion, gear shapers with generating cutters of appropriate form, and, in some instances, internal grinders of special design. Regardless of the production methods used, points on both of the mating profiles may be calculated from the following equations:

$$X = (D_f/2 + e) \cos \alpha - e \cos n \alpha \cos \alpha - n e \sin n \alpha \sin \alpha$$

$$Y = (D_f/2 + e) \sin \alpha - e \cos n \alpha \sin \alpha + n e \sin n \alpha \cos \alpha$$

In these equations,  $\alpha$  is the angle of rotation of the workpiece from any selected reference position;  $n$  is the number of polygon sides, either 3 or 4;  $D_f$  is the diameter of the inscribed circle shown on the diagram in the table; and  $e$  is the dimension shown on the diagram in the table and which may be used as a setting on special polygon grinding machines. The value of  $e$  determines the shape of the profile. A value of 0, for example, results in a circular shaft having a diameter of  $D_f$ . The values of  $e$  in the table were selected arbitrarily to provide suitable proportions for the sizes shown.

## CAMS AND CAM DESIGN

**Classes of Cams.**—Cams may, in general, be divided into two classes: uniform motion cams and accelerated motion cams. The uniform motion cam moves the follower at the same rate of speed from the beginning to the end of the stroke; but as the movement is started from zero to the full speed of the uniform motion and stops in the same abrupt way, there is a distinct shock at the beginning and end of the stroke, if the movement is at all rapid. In machinery working at a high rate of speed, therefore, it is important that cams are so constructed that sudden shocks are avoided when starting the motion or when reversing the direction of motion of the follower.

The uniformly accelerated motion cam is suitable for moderate speeds, but it has the disadvantage of sudden changes in acceleration at the beginning, middle and end of the stroke. A cycloidal motion curve cam produces no abrupt changes in acceleration and is often used in high-speed machinery because it results in low noise, vibration and wear. The cycloidal motion displacement curve is so called because it can be generated from a cycloid which is the locus of a point of a circle rolling on a straight line.\*

**Cam Follower Systems.**—The three most used cam and follower systems are radial and offset translating roller follower, Figs. 1a and 1b; and the swinging roller follower, Fig. 1c. When the cam rotates, it imparts a translating motion to the roller followers in Figs. 1a and 1b and a swinging motion to the roller follower in Fig. 1c. The motion of the follower is, of course, dependent on the shape of the cam; and the following section on displacement diagrams explains how a favorable motion is obtained so that the cam can rotate at high speed without shock.

Fig. 1a. Radial Translating Roller Follower

Fig. 1b. Offset Translating Roller Follower

Fig. 1c. Swinging Roller Follower

Fig. 2a. Closed-Track Cam

Fig. 2b. Closed-Track Cam With Two Rollers

The arrangements in Figs. 1a, 1b, and 1c show open-track cams. In Figs. 2a and 2b the roller is forced to move in a closed track. Open-track cams build smaller than closed-track

\* Jensen, P. W., *Cam Design and Manufacture*, Industrial Press Inc.

cams but, in general, springs are necessary to keep the roller in contact with the cam at all times. Closed-track cams do not require a spring and have the advantage of positive drive throughout the rise and return cycle. The positive drive is sometimes required as in the case where a broken spring would cause serious damage to a machine.

**Displacement Diagrams.**—Design of a cam begins with the displacement diagram. A simple displacement diagram is shown in Fig. 3. One cycle means one whole revolution of the cam; i.e., one cycle represents  $360^\circ$ . The horizontal distances  $T_1, T_2, T_3, T_4$  are expressed in units of time (seconds); or radians or degrees. The vertical distance,  $h$ , represents the maximum “rise” or stroke of the follower.

Fig. 3. A Simple Displacement Diagram

The displacement diagram of Fig. 3 is not a very favorable one because the motion from rest (the horizontal lines) to constant velocity takes place instantaneously and this means that accelerations become infinitely large at these transition points.

*Types of Cam Displacement Curves:* A variety of cam curves are available for moving the follower. In the following sections only the rise portions of the total time-displacement diagram are studied. The return portions can be analyzed in a similar manner. Complex cams are frequently employed which may involve a number of rise-dwell-return intervals in which the rise and return aspects are quite different. To analyze the action of a cam it is necessary to study its time-displacement and associated velocity and acceleration curves. The latter are based on the first and second time-derivatives of the equation describing the time-displacement curve:

$$y = \text{displacement} = f(t) \quad \text{or} \quad y = f(\phi)$$

$$v = \frac{dy}{dt} = \text{velocity} = \omega \frac{dy}{d\phi}$$

$$a = \frac{d^2y}{dt^2} = \text{acceleration} = \omega^2 \frac{d^2y}{d\phi^2}$$

*Meaning of Symbols and Equivalent Relations:*  $y$  = displacement of follower, inch

$h$  = maximum displacement of follower, inch

$t$  = time for cam to rotate through angle  $\phi$ , sec,  $= \phi/\omega$ , sec

$T$  = time for cam to rotate through angle  $\beta$ , sec,  $= \beta/\omega$ , or  $\beta/6N$ , sec

$\phi$  = cam angle rotation for follower displacement  $y$ , degrees

$\beta$  = cam angle rotation for total rise  $h$ , degrees

$v$  = velocity of follower, in./sec

$a$  = follower acceleration, in./sec<sup>2</sup>

$$t/T = \phi/\beta$$

$N$  = cam speed, rpm

$\omega$  = angular velocity of cam, degrees/sec  $= \beta/T = \phi/t = d\phi/dt = 6N$

$\omega_R$  = angular velocity of cam, radians/sec  $= \pi\omega/180$

$W$  = effective weight, lbs

- $g$  = gravitational constant = 386 in./sec<sup>2</sup>
- $f(t)$  = means a function of  $t$
- $f(\phi)$  = means a function of  $\phi$
- $R_{min}$  = minimum radius to the cam pitch curve, inch
- $R_{max}$  = maximum radius to the cam pitch curve, inch
- $r_f$  = radius of cam follower roller, inch
- $\rho$  = radius of curvature of cam pitch curve (path of center of roller follower), inch
- $R_c$  = radius of curvature of actual cam surface, in., =  $\rho - r_f$  for convex surface;  
=  $\rho + r_f$  for concave surface.

Fig. 4. Cam Displacement, Velocity, and Acceleration Curves for Constant Velocity Motion  
Four displacement curves are of the greatest utility in cam design.

1. Constant-Velocity Motion: (Fig. 4)

$$y = \frac{h t}{T} \quad \text{or} \quad y = \frac{h \phi}{\beta} \quad (1a)$$

$$v = \frac{dy}{dt} = \frac{h}{T} \quad \text{or} \quad v = \frac{h \omega}{\beta} \quad (1b)$$

$$a = \frac{d^2 y}{dt^2} = 0^* \quad (1c)$$

}  $0 < t < T$

\* Except at  $t = 0$  and  $t = T$  where the acceleration is theoretically infinite.

This motion and its disadvantages were mentioned previously. While in the unaltered form shown it is rarely used except in very crude devices, nevertheless, the advantage of uniform velocity is an important one and by modifying the start and finish of the follower stroke this form of cam motion can be utilized. Such modification is explained in the section Displacement Diagram Synthesis.

2. Parabolic Motion: (Fig. 5)

For  $0 \leq t \leq T/2$  and  $0 \leq \phi \leq \beta/2$

For  $T/2 \leq t \leq T$  and  $\beta/2 \leq \phi \leq \beta$

$$y = 2h(t/T)^2 = 2h(\phi/\beta)^2 \quad (2a)$$

$$y = h[1 - 2(1 - t/T)^2] = h[1 - 2(1 - \phi/\beta)^2] \quad (2d)$$

$$v = 4ht/T^2 = 4h\omega\phi/\beta^2 \quad (2b)$$

$$v = 4h/T(1 - t/T) = (4h\omega/\beta)(1 - \phi/\beta) \quad (2e)$$

$$a = 4h/T^2 = 4h(\omega/\beta)^2 \quad (2c)$$

$$a = -4h/T^2 = -4h(\omega/\beta)^2 \quad (2f)$$

Examination of the above formulas shows that the velocity is zero when  $t = 0$  and  $y = 0$ ; and when  $t = T$  and  $y = h$ .

Fig. 5. Cam Displacement, Velocity, and Acceleration Curves for Parabolic Motion

The most important advantage of this curve is that for a given angle of rotation and rise it produces the smallest possible acceleration. However, because of the sudden changes in acceleration at the beginning, middle, and end of the stroke, shocks are produced. If the follower system were perfectly rigid with no backlash or flexibility, this would be of little significance. But such systems are mechanically impossible to build and a certain amount of impact is caused at each of these changeover points.

Fig. 6. Cam Displacement, Velocity, and Acceleration Curves for Simple Harmonic Motion

### 3. Simple Harmonic Motion: (Fig. 6)

$$y = \frac{h}{2} \left[ 1 - \cos\left(\frac{180^\circ t}{T}\right) \right] \quad \text{or} \quad y = \frac{h}{2} \left[ 1 - \cos\left(\frac{180^\circ \phi}{\beta}\right) \right] \quad (3a)$$

$$v = \frac{h}{2} \cdot \frac{\pi}{T} \sin\left(\frac{180^\circ t}{T}\right) \quad \text{or} \quad v = \frac{h}{2} \cdot \frac{\pi \omega}{\beta} \sin\left(\frac{180^\circ \phi}{\beta}\right) \quad (3b) \quad \left. \begin{array}{l} \\ \end{array} \right\} 0 \leq t \leq T$$

$$a = \frac{h}{2} \cdot \frac{\pi^2}{T^2} \cos\left(\frac{180^\circ t}{T}\right) \quad \text{or} \quad a = \frac{h}{2} \cdot \left(\frac{\pi \omega}{\beta}\right)^2 \cos\left(\frac{180^\circ \phi}{\beta}\right) \quad (3c)$$

Smoothness in velocity and acceleration during the stroke is the advantage inherent in this curve. However, the instantaneous changes in acceleration at the beginning and end of the stroke tend to cause vibration, noise, and wear. As can be seen from Fig. 6, the maximum acceleration values occur at the ends of the stroke. Thus, if inertia loads are to be overcome by the follower, the resulting forces cause stresses in the members. These forces are in many cases much larger than the externally applied loads.

## 4. Cycloidal Motion: (Fig. 7)

$$y = h \left[ \frac{t}{T} - \frac{1}{2\pi} \sin \left( \frac{360^\circ t}{T} \right) \right] \quad \text{or} \quad y = h \left[ \frac{\phi}{\beta} - \frac{1}{2\pi} \sin \left( \frac{360^\circ \phi}{\beta} \right) \right] \quad (4a)$$

$$v = \frac{h}{T} \left[ 1 - \cos \left( \frac{360^\circ t}{T} \right) \right] \quad \text{or} \quad v = \frac{h\omega}{\beta} \left[ 1 - \cos \left( \frac{360^\circ \phi}{\beta} \right) \right] \quad (4b) \quad \left. \vphantom{\frac{h}{T}} \right\} 0 \leq t \leq T$$

$$a = \frac{2\pi h}{T^2} \sin \left( \frac{360^\circ t}{T} \right) \quad \text{or} \quad a = \frac{2\pi h\omega^2}{\beta^2} \sin \left( \frac{360^\circ \phi}{\beta} \right) \quad (4c)$$

Fig. 7. Cam Displacement, Velocity, and Acceleration Curves for Cycloidal Motion

This time-displacement curve has excellent acceleration characteristics; there are no abrupt changes in its associated acceleration curve. The maximum value of the acceleration of the follower for a given rise and time is somewhat higher than that of the simple harmonic motion curve. In spite of this, the cycloidal curve is used often as a basis for designing cams for high-speed machinery because it results in low levels of noise, vibration, and wear.

**Displacement Diagram Synthesis.**—The straight-line graph shown in Fig. 3 has the important advantage of uniform velocity. This is so desirable that many cams based on this graph are used. To avoid impact at the beginning and end of the stroke, a modification is introduced at these points. There are many different types of modifications possible, ranging from a simple circular arc to much more complicated curves. One of the better curves used for this purpose is the parabolic curve given by Equation (2a). As seen from the derived time graphs, this curve causes the follower to begin a stroke with zero velocity but having a finite and constant acceleration. We must accept the necessity of acceleration, but effort should be made to hold it to a minimum.

**Matching of Constant Velocity and Parabolic Motion Curves:** By matching a parabolic cam curve to the beginning and end of a straight-line cam displacement diagram it is possible to reduce the acceleration from infinity to a finite constant value to avoid impact loads. As illustrated in Fig. 8, it can be shown that for any parabola the vertex of which is at  $O$ , the tangent to the curve at the point  $P$  intersects the line  $OQ$  at its midpoint. This means that the tangent at  $P$  represents the velocity of the follower at time  $X_0$  as shown in Fig. 8. Since the tangent also represents the velocity of the follower over the constant velocity portion of the stroke, the transition from rest to the maximum velocity is accomplished with smoothness.

Fig. 8. The Tangent at  $P$  Bisects  $OQ$ , When Curve is a Parabola

*Example:* A cam follower is to rise  $\frac{1}{4}$  in. with constant acceleration;  $1\frac{1}{4}$  in. with constant velocity, over an angle of 50 degrees; and then  $\frac{1}{2}$  in. with constant deceleration.

In Fig. 9 the three rise distances are laid out,  $y_1 = \frac{1}{4}$  in.,  $y_2 = 1\frac{1}{4}$  in.,  $y_3 = \frac{1}{2}$  in., and horizontals drawn. Next, an arbitrary horizontal distance  $\phi_2$  proportional to 50 degrees is measured off and points  $A$  and  $B$  are located. The line  $AB$  is extended to  $M_1$  and  $M_2$ . By remembering that a tangent to a parabola, Fig. 8, will cut the abscissa axis at point  $(X_0/2, 0)$  where  $X_0$  is the abscissa of the point of tangency, the two values  $\phi_1 = 20^\circ$  and  $\phi_3 = 40^\circ$  will be found. Analytically,

$$\frac{M_1E}{\phi_2} = \frac{y_1}{y_2} \quad \frac{\frac{1}{2}\phi_1}{50^\circ} = \frac{0.25}{1.25} \quad \therefore \phi_1 = 20^\circ$$

$$\frac{FM_2}{\phi_2} = \frac{y_3}{y_2} \quad \frac{\frac{1}{2}\phi_3}{50^\circ} = \frac{0.50}{1.25} \quad \therefore \phi_3 = 40^\circ$$

In Fig. 9, the portions of the parabola have been drawn in; the details of this operation are as follows:

Assume that accuracy to the nearest thousandth of one inch is desired, and it is decided to plot values for every 5 degrees of cam rotation.

The formula for the acceleration portion of the parabolic curve is:

$$y = \frac{2h}{T^2}t^2 = 2h\left(\frac{\phi}{\beta}\right)^2 \quad (5)$$

Two different parabolas are involved in this example; one for accelerating the follower during a cam rotation of 20 degrees, the other for decelerating it in 40 degrees, these two being tangent, to opposite ends of the same line  $AB$ .

In Fig. 9 only the first half of a complete acceleration-deceleration parabolic curve is used to blend with the left end of the straight line  $AB$ . Therefore, in using the Formula (5) substitute  $2y_1$  for  $h$  and  $2\phi_1$  for  $\beta$  so that

$$y = \frac{2h\phi^2}{\beta^2} = \frac{(2)(2y_1)}{(2\phi_1)^2} \phi^2$$

For the right end of the straight line  $AB$ , the calculations are similar but, in using [Formula \(5\)](#), calculated  $y$  values are *subtracted* from the *total rise* of the cam ( $y_1 + y_2 + y_3$ ) to obtain the follower displacement.

Fig. 9. Matching a Parabola at Each End of Straight Line Displacement Curve  $AB$  to Provide More Acceptable Acceleration and Deceleration

[Table 1](#) shows the computations and resulting values for the cam displacement diagram described. The calculations are shown in detail so that if equations are programmed for a digital computer, the results can be verified easily. Obviously, the intermediate points are not needed to draw the straight line, but when the cam profile is later to be drawn or cut, these values will be needed since they are to be measured on radial lines.

The matching procedure when using cycloidal motion is exactly the same as for parabolic motion, because parabolic and cycloidal motion have the same maximum velocity for equal rise (or return) and lift angle (or return angle).

**Cam Profile Determination.**—In the cam constructions that follow an artificial device called an *inversion* is used. This represents a mental concept which is very helpful in performing the graphical work. The construction of a cam profile requires the drawing of many positions of the cam with the follower in each case in its related location. However, instead of revolving the cam, it is assumed that the follower rotates around the *fixed* cam. It requires the drawing of many follower positions, but since this is done more or less diagrammatically, it is relatively simple.

As part of the inversion process, the direction of rotation is important. In order to preserve the correct sequence of events, the artificial rotation of the follower must be the reverse of the cam's prescribed rotation. Thus, in [Fig. 10](#) the cam rotation is counterclockwise, whereas the artificial rotation of the follower is clockwise.

**Radial Translating Roller Follower:** The time-displacement diagram for a cam with a radial translating roller follower is shown in [Fig. 10\(a\)](#). This diagram is read from left to right as follows: For 100 degrees of cam shaft rotation the follower rises  $h$  inches ( $AB$ ), dwells in its upper position for 20 degrees ( $BC$ ), returns over 180 degrees ( $CD$ ), and finally dwells in its lowest position for 60 degrees ( $DE$ ). Then the entire cycle is repeated.

[Fig. 10\(b\)](#) shows the cam construction layout with the cam pitch curve as a dot and dash line. To locate a point on this curve, take a point on the displacement curve, as  $6'$  at the 60-degree position, and project this horizontally to point  $6''$  on the 0-degree position of the cam construction diagram. Using the center of cam rotation, an arc is struck from point  $6''$  to intercept the 60-degree position radial line which gives point  $6'''$  on the cam pitch curve. It will be seen that the smaller circle in the cam construction layout has a radius  $R_{\min}$  equal

to the smallest distance from the center of cam rotation to the pitch curve and, similarly, the larger circle has a radius  $R_{\max}$  equal to the largest distance to the pitch curve. Thus, the difference in radii of these two circles is equal to the maximum rise  $h$  of the follower.

The cam pitch curve is also the actual profile or working surface when a knife-edged follower is used. To get the profile or working surface for a cam with a roller follower, a series of arcs with centers on the pitch curve and radii equal to the radius of the roller are drawn and the inner envelope drawn tangent to these arcs is the cam working surface or profile shown as a solid line in Fig. 10(b).

**Table 1. Development of Modified Constant Velocity Cam with Parabolic Matching**

| Rise Angle          | $\phi$<br>Degrees | Computation                       | Follower Displacement<br>$y$ | Explanation   |
|---------------------|-------------------|-----------------------------------|------------------------------|---|
| $\phi_1 = 20^\circ$ | 0                 | 0                                 | 0                            | $\beta = 40^\circ h = 0.500$<br>$y = \frac{(2)(0.500)}{(40)^2} \phi^2$<br>$= 0.000625 \phi^2$   |

<sup>a</sup> Since the deceleration portion of a parabolic cam is the same shape as the acceleration portion, but inverted, Formula (5) may be used to calculate the  $y$  values by substituting  $2y_3$  for  $h$  and for  $\beta$  and the result subtracted from the total rise ( $y_1 + y_2 + y_3$ ) to obtain the follower displacement.

Fig. 10. (a) Time-Displacement Diagram for Cam to be Laid Out; (b) Construction of Contour of Cam With Radial Translating Roller Follower

**Offset Translating Roller Follower:** Given the time-displacement diagram Fig. 11(a) and an offset follower. The construction of the cam in this case is very similar to the foregoing case and is shown in Fig. 11(b). In this construction it will be noted that the angular position lines are not drawn radially from the cam shaft center but tangent to a circle having a radius equal to the amount of offset of the center line of the cam follower from the center of the cam shaft. For counterclockwise rotation of the cam, points 6', 6'', and 6''' are located in succession as indicated.

Fig. 11. (a) Time-Displacement Diagram for Cam to be Laid Out; (b) Construction of Contour of Cam With Offset Translating Roller Follower

**Swinging Roller Follower:** Given the time-displacement diagram Fig. 12(a) and the length of the swinging follower arm  $L_f$ , it is required that the displacement of the follower center along the circular arc that it describes be equal to the corresponding displacements in the time-displacement diagram. If  $\phi_0$  is known, the displacement  $h$  of Fig. 12(a) would be found from the formula  $h = \pi\phi_0 L_f / 180^\circ$ ; otherwise the maximum rise  $h$  of the follower is stepped off on the arc drawn with  $M$  as a center and starting at a point on the  $R_{\min}$  circle. Point  $M$  is the actual position of the pivot center of the swinging follower with respect to the cam shaft center. It is again required that the rotation of the cam be counterclockwise and therefore  $M$  is considered to have been rotated clockwise around the cam shaft center, whereby the points 2, 4, 6, etc., are obtained as shown in Fig. 12(b). Around each of the pivot points, 2, 4, 6, etc., circular arcs whose radii equal  $L_f$  are drawn between the  $R_{\min}$  and

$R_{\max}$  circles giving the points 2', 4', 6', etc. The  $R_{\min}$  circle with center at the cam shaft center is drawn through the lowest position of the center of the roller follower and the  $R_{\max}$  circle through the highest position as shown. The different points on the pitch curve are now located. Point 6''', for instance, is found by stepping off the  $y_6$  ordinate of the displacement diagram on arc 6' starting at the  $R_{\min}$  circle.

Fig. 12. (a) Time-Displacement Diagram for Cam to be Laid Out; (b) Construction of Contour of Cam With Swinging Roller Follower

**Pressure Angle and Radius of Curvature.**—The pressure angle at any point on the profile of a cam may be defined as the angle between the direction where the follower wants to go at that point and where the cam wants to push it. It is the angle between the tangent to the path of follower motion and the line perpendicular to the tangent of the cam profile at the point of cam-roller contact.

The size of the pressure angle is important because:

- 1) Increasing the pressure angle increases the side thrust and this increases the forces exerted on cam and follower.
- 2) Reducing the pressure angle increases the cam size and often this is not desirable because:
  - a) The size of the cam determines, to a certain extent, the size of the machine.
  - b) Larger cams require more precise cutting points in manufacturing and, therefore, an increase in cost.
  - c) Larger cams have higher circumferential speed and small deviations from the theoretical path of the follower cause additional acceleration, the size of which increases with the square of the cam size.
  - d) Larger cams mean more revolving weight and in high-speed machines this leads to increased vibrations in the machine.
  - e) The inertia of a large cam may interfere with quick starting and stopping.

The maximum pressure angle  $\alpha_m$  should, in general, be kept at or below 30 degrees for translating-type followers and at or below 45 degrees for swinging-type followers. These values are on the conservative side and in many cases may be increased considerably, but beyond these limits trouble could develop and an analysis is necessary.

In the following, graphical methods are described by which a cam mechanism can be designed with translating or swinging roller followers having specified maximum pressure angles for rise and return. These methods are applicable to any kind of time-displacement diagram.

Fig. 13. Displacement Diagram

**Determination of Cam Size for a Radial or an Offset Translating Follower.**—Fig. 13 shows a time-displacement diagram. The maximum displacement is preferably made to scale, but the length of the abscissa,  $L$ , can be chosen arbitrarily. The distance  $L$  from 0 to 360 degrees is measured and is set equal to  $2\pi k$  from which

$$k = \frac{L}{2\pi}$$

$k$  is calculated and laid out as length  $E$  to  $M$  in Fig. 14.

In Fig. 13 the two points  $P_1$  and  $P_2$  having the maximum angles of slope,  $\tau_1$ , and  $\tau_2$ , are located by inspection. In this example  $y_1$  and  $y_2$  are of equal length.

Angles  $\tau_1$  and  $\tau_2$  are laid out as shown in Fig. 14, and the points of intersection with a perpendicular to  $EM$  at  $M$  determine  $Q_1$  and  $Q_2$ . The measured distances

$$MQ_1 = k \tan \tau_1 \quad \text{and} \quad MQ_2 = k \tan \tau_2$$

are laid out in Fig. 15, which is constructed as follows:

Draw a vertical line  $R_u R_o$  of length  $h$  equal to the stroke of the roller follower,  $R_u$  being the lowest position and  $R_o$  the highest position of the center of the roller follower. From  $R_u$  lay out  $R_u R_{y_1} = y_1$  and  $R_u R_{y_2} = y_2$ ; these are equal lengths in this example. Next, if the rotation of the cam is counterclockwise, lay out  $k \tan \tau_1$ , to the left,  $k \tan \tau_2$  to the right from points  $R_{y_1}$  and  $R_{y_2}$ , respectively,  $R_{y_1}$  and  $R_{y_2}$  being the same point in this case.

Fig. 14. Construction to Find  $k \tan \tau_1$  and  $k \tan \tau_2$ 

The specified maximum pressure angle  $\alpha_1$  is laid out at  $E_1$  as shown, and a ray (line)  $E_1 F_1$  is determined. Any point on this ray chosen as the cam shaft center will proportion the cam so that the pressure angle at a point on the cam profile corresponding to point  $P_1$ , of the displacement diagram will be exactly  $\alpha_1$ .

Fig. 15. Finding Proportions of Cam; Offset Translating Follower

The angle  $\alpha_2$  is laid out at  $E_2$  as shown, and another ray  $E_2F_2$  is determined. Similarly, any point on this ray chosen as the cam shaft center will proportion the cam so that the pressure angle at a point on the cam profile corresponding to point  $P_2$  of the displacement diagram will be exactly  $\alpha_2$ .

Any point chosen within the cross-hatched area A as the cam center will yield a cam whose pressure angles at points corresponding to  $P_1$  and  $P_2$  will not exceed the specified values  $\alpha_1$  and  $\alpha_2$  respectively. If  $O_1$  is chosen as the cam shaft center, the pressure angles on the cam profile corresponding to points  $P_1$  and  $P_2$  are exactly  $\alpha_1$  and  $\alpha_2$ , respectively. Selection of point  $O_1$  also yields the smallest possible cam for the given requirements and requires an offset follower in which  $e$  is the offset distance.

If  $O_2$  is chosen as the cam shaft center, a radial translating follower is obtained (zero offset). In that case, the pressure angle  $\alpha_1$  for the rise is unchanged, whereas the pressure angle for the return is changed from  $\alpha_2$  to  $\alpha'_2$ . That is, the pressure angle on the return stroke is reduced at the point  $P_2$ . If point  $O_3$  had been selected, then  $\alpha_2$  would remain unchanged but  $\alpha_1$  would be decreased and the offset,  $e$ , increased.

Fig. 16. Construction of Cam Contour; Offset Translating Follower

Fig. 16 shows the shape of the cam when  $O_1$  from Fig. 15 is chosen as the cam shaft center, and it is seen that the pressure angle at a point on the cam profile corresponding to point  $P_1$  is  $\alpha_1$  and at a point corresponding to point  $P_2$  is  $\alpha_2$ .

In the foregoing, a cam mechanism has been so proportioned that the pressure angles  $\alpha_1$  and  $\alpha_2$  at points on the cam corresponding to points  $P_1$  and  $P_2$  were obtained. Even though  $P_1$  and  $P_2$  are the points of greatest slope on the displacement diagram, the pressure angles produced at some other points on the actual cam may be slightly greater.

However, if the pressure angles  $\alpha_1$  and  $\alpha_2$  are not to be exceeded at any point — i.e., they are to be maximum pressure angles — then  $P_1$  and  $P_2$  must be selected to be at the locations where these maximum pressure angles occur. If these locations are not known, then the graphical procedure described must be repeated, letting  $P_1$  take various positions on the curve for rise ( $AB$ ) and  $P_2$  various positions on the return curve ( $CD$ ) and then setting  $R_{\min}$  equal to the largest of the values determined from the various positions.

Fig. 17. Displacement Diagram

**Determination of Cam Size for Swinging Roller Follower.**—The proportioning of a cam with swinging roller follower having specific pressure angles at selected points follows the same procedure as that for a translating follower.

*Example:* Given the diagram for the roller displacement along its circular arc, Fig. 17 with  $h = 1.95$  in., the periods of rise and fall, respectively,  $\beta_1 = 160^\circ$  and  $\beta_2 = 120^\circ$ , the length of the swinging follower arm  $L_f = 3.52$  in., rotation of the cam away from pivot point  $M$ , and pressure angles  $\alpha_1 = \alpha_2 = 45^\circ$  (corresponding to the points  $P_1$  and  $P_2$  in the displacement diagram). Find the cam proportions.

*Solution:* Distances  $k \tan \tau_1$  and  $k \tan \tau_2$  are determined as in the previous example, Fig. 14. In Fig. 18,  $R_{y_1}$  is determined by making the distance  $R_u R_{y_1} = y_1$  along the arc  $R_u R_o$  and  $R_{y_2}$  by making  $R_u R_{y_2} = y_2$ . The arc  $R_u R_o = h$  and  $R_u$  indicates the lowest position of the center of the swinging roller follower and  $R_o$  the highest position.

Because the cam (i.e., the surface of the cam as it passes under the follower roller) rotates away from pivot point  $M$ ,  $k \tan \tau_1$  is laid out away from  $M$ , that is, from  $R_{y_1}$  to  $E_1$  and  $k \tan \tau_2$  is laid out toward  $M$  from  $R_{y_2}$  to  $E_2$ . Angle  $\alpha_1$  at  $E_1$  determines one ray and  $\alpha_2$  at  $E_2$  another ray, which together subtend an area  $A$  having the property that if the cam shaft center is chosen inside this area, the pressure angles at the points of the cam corresponding to  $P_1$  and  $P_2$  in the displacement diagram will not exceed the given values  $\alpha_1$  and  $\alpha_2$ , respectively. If the cam shaft center is chosen on the ray drawn from  $E_1$  at an angle  $\alpha_1 = 45^\circ$ , the pressure angle  $\alpha_1$  on the cam profile corresponding to point  $P_1$  will be exactly  $45^\circ$ , and if chosen on the ray from  $E_2$ , the pressure angle  $\alpha_2$  corresponding to  $P_2$  will be exactly  $45^\circ$ . If another point,  $O_2$  for example, is chosen as the cam shaft center, the pressure angle corresponding to  $P_1$  will be  $\alpha'_1$  and that corresponding to  $P_2$  will be  $\alpha_2$ .

Fig. 18. Finding Proportions of Cam; Swinging Roller Follower (CCW Rotation)

Fig. 19. Finding Proportions of Cam; Swinging Roller Follower (CW Rotation)

Fig. 19 shows the construction for rotation toward pivot point  $M$  (clockwise rotation of the cam in this case). The layout of the cam curve is made in a manner similar to that shown previously in Fig. 12.

In this example, the cam mechanism was so proportioned that the pressure angles at certain points (corresponding to  $P_1$  and  $P_2$ ) do not exceed certain specified values (namely  $\alpha_1$  and  $\alpha_2$ ).

To make sure that the pressure angle at *no point* along the cam profile exceeds the specified value, the previous procedure should be repeated for a series of points along the profile.

**Formulas for Calculating Pressure Angles.**—The graphical methods described previously are useful because they permit layout and measurement of pressure angles and radii of curvature of *any* cam profile. For cams of complicated profiles, and especially if the pro-

file cannot be represented by a simple formula, the graphical method may be the only practical solution. However, for some of the standard cam profiles utilizing *radial* translating roller followers, the following formulas may be used to determine key cam dimensions before laying out the cam. These formulas enable the designer to specify the maximum pressure angle (usually  $30^\circ$  or less) and, using the specified value, to calculate the minimum cam size that will satisfy the requirement.

The following symbols are in addition to those starting on page 2189.

$\alpha_{max}$  = specified maximum pressure angle, degrees

$R_{\alpha_{max}}$  = radius from cam center to point on pitch curve where  $\alpha_{max}$  is located, inches

$\phi_p$  = rise angle, in degrees, corresponding to  $\alpha_{max}$  and  $R_{\alpha_{max}}$

$\alpha$  = pressure angle at any selected point, degrees

$R_\alpha$  = radius from cam center to pitch curve at  $\alpha$ , inches

$\phi$  = rise angle, in degrees, corresponding to  $\alpha$  and  $R_\alpha$

For Uniform Velocity Motion:  $\alpha = \arctan \left[ \frac{180^\circ h}{\pi \beta R_\alpha} \right]$  at radius  $R_\alpha$  to the pitch curve (6a)

$\alpha_{max} = \arctan \left[ \frac{180^\circ h}{\pi \beta R_{min}} \right]$  at radius  $R_{min}$  of the pitch curve ( $\phi=0^\circ$ ). (6b)

If  $\alpha_{max}$  is specified, then the minimum radius to the lowest point on the pitch curve,  $R_{min}$ , is:

$R_{min} = \frac{180^\circ h}{\pi \beta \tan \alpha_{max}}$  which corresponds to  $\phi=0^\circ$ . (6c)

For Parabolic Motion:  $\alpha = \arctan \left[ \frac{720^\circ h \phi}{\pi \beta^2 R_\alpha} \right]$  at radius  $R_\alpha$  to the pitch curve at angle  $\phi$ ,

where  $0 \leq \phi \leq \beta/2$  (7a)

$\alpha = \arctan \left[ \frac{720^\circ h (1 - \phi/\beta)}{\pi \beta R_\alpha} \right]$  at radius  $R_\alpha$  to the pitch curve at angle  $\phi$ , where  $\beta/2 \leq \phi \leq \beta$ .

$\alpha = \arctan \left[ \frac{360^\circ h}{\pi \beta R_\alpha} \right]$  which occurs at  $\phi=\beta/2$  and  $R_\alpha=R_{min}+h/2$  (7b)

If  $\alpha_{max}$  is specified, then the minimum radius to the lowest point of the pitch curve is:

$R_{min} = \left[ \frac{360^\circ h}{\pi \beta \tan \alpha_{max}} - \frac{h}{2} \right]$  which corresponds to  $\phi=0^\circ$ . (7c)

For Simple Harmonic Motion:  $\alpha = \arctan \left[ \frac{90^\circ h}{\beta R_\alpha} \sin \left( \frac{180^\circ \phi}{\beta} \right) \right]$  at radius  $R_\alpha$  to the pitch curve at angle  $\phi$  (8a)

$\phi_p = \left( \frac{\beta}{180^\circ} \right) \left[ \arccot \left( \frac{\beta}{180^\circ} \tan \alpha_{max} \right) \right]$  = value of  $\phi$  where specified pressure angle  $\alpha_{max}$  occurs (8b)

$R_{\alpha_{max}} = \frac{h [\sin (180^\circ \phi_p / \beta)]^2}{2 \cos (180^\circ \phi_p / \beta)}$  at point where  $\alpha=\alpha_{max}$  and  $\phi=\phi_{max}$  (8c)

$$R_{\min} = R_{\alpha \max} - \frac{h}{2} \left[ 1 - \cos \left( \frac{180^\circ \phi_p}{\beta} \right) \right] \quad (8d)$$

For Cycloidal Motion:  $\alpha = \arctan \left[ \frac{180^\circ}{\pi \beta R_{\alpha}} \left[ 1 - \cos \left( \frac{360^\circ \phi}{\beta} \right) \right] \right]$  at radius  $R_{\alpha}$  to the pitch curve at angle  $\phi$  (9a)

$$\phi_p = \frac{\beta}{180^\circ} \left[ \operatorname{arccot} \left( \frac{\beta \tan \alpha_{\max}}{360^\circ} \right) \right] \quad \phi_p = \text{value of } \phi \text{ where specified pressure angle } \alpha_{\max} \text{ occurs} \quad (9b)$$

$$R_{\alpha \max} = \frac{h}{2\pi} \frac{[1 - \cos(360^\circ \phi_p / \beta)]^2}{\sin(360^\circ \phi_p / \beta)} \quad \text{at point where } \alpha = \alpha_{\max} \text{ and } \phi = \phi_p \quad (9c)$$

$$R_{\min} = R_{\alpha \max} - h \left[ \frac{\phi_p}{\beta} - \frac{1}{2\pi} \sin \left( \frac{360^\circ \phi_p}{\beta} \right) \right] \quad (9d)$$

**Radius of Curvature.**—The minimum radius of curvature of a cam should be kept as large as possible (1) to prevent undercutting of the convex portion of the cam and (2) to prevent too high surface stresses. Figs. 20(a), (b) and (c) illustrate how undercutting occurs.

Fig. 20. (a) No Undercutting. (b) Sharp Corner on Cam. (c) Undercutting

In Fig. 20(a) the radius of curvature of the path of the follower is  $\rho_{\min}$  and the cam will at that point have a radius of curvature  $R_c = \rho_{\min} - r_f$ .

In Fig. 20(b)  $\rho_{\min} = r_f$  and  $R_c = 0$ . Therefore, the actual cam will have a sharp corner which in most cases will result in too high surface stresses.

In Fig. 20(c) is shown the case where  $\rho_{\min} < r_f$ . This case is not possible because undercutting will occur and the actual motion of the roller follower will deviate from the desired one as shown.

Undercutting cannot occur at the *concave* portion of the cam profile (working surface), but caution should be exerted in not making the radius of curvature equal to the radius of the roller follower. This condition would occur if there is a cusp on the displacement diagram which, of course, should always be avoided. To enable milling or grinding of *concave* portions of a cam profile, the radius of curvature of concave portions of the cam,  $R_c = \rho_{\min} + r_f$  must be larger than the radius of the cutter to be used.

The radius of curvature is used in calculating surface stresses (see following section), and may be determined by measurement on the cam layout or, in the case of radial translating followers, may be calculated using the formulas that follow. Although these formulas are exact for radial followers, they may be used for offset and swinging followers to obtain an approximation.

Based upon polar coordinates, the radius of curvature is:

$$\rho = \frac{\left[ r^2 + \left( \frac{dr}{d\phi} \right)^2 \right]^{3/2}}{r^2 + 2 \left( \frac{dr}{d\phi} \right)^2 - r \left( \frac{d^2r}{d\phi^2} \right)} \quad (10)$$

\*Positive values (+) indicate convex curve; negative values (-), concave.

In Equation (10),  $r = (R_{\min} + y)$ , where  $R_{\min}$  is the smallest radius to the pitch curve (see Fig. 12) and  $y$  is the displacement of the follower from its lowest position given in terms of  $\phi$ , the angle of cam rotation. The following formulas for  $r$ ,  $dr/d\phi$ , and  $d^2r/d\phi^2$  may be substituted into Equation (10) to calculate the radius of curvature at any point of the cam pitch curve; however, to determine the possibility of undercutting of the convex portion of the cam, it is the minimum radius of curvature on the convex portion,  $\rho_{\min}$ , that is needed. The minimum radius of curvature occurs, generally, at the point of maximum *negative* acceleration.

*Parabolic motion:*

$$r = R_{\min} + h - 2h \left( 1 - \frac{\phi}{\beta} \right)^2 \quad (11a)$$

$$\frac{dr}{d\phi} = \frac{720^\circ h}{\pi \beta} \left( 1 - \frac{\phi}{\beta} \right) \quad (11b) \quad \left. \vphantom{\frac{dr}{d\phi}} \right\} \frac{\beta}{2} \leq \phi \leq \beta$$

$$\frac{d^2r}{d\phi^2} = \frac{-4(180^\circ)^2 h}{\pi^2 \beta^2} \quad (11c)$$

These equations are for the deceleration portion of the curve as explained in the footnote to Table 1.

The minimum radius of curvature can occur at either  $\phi = \beta/2$  or at  $\phi = \beta$ , depending on the magnitudes of  $h$ ,  $R_{\min}$ , and  $\beta$ . Therefore, to determine which is the case, make two calculations using Formula (10), one for  $\phi = \beta/2$ , and the other for  $\phi = \beta$ .

*Simple harmonic motion:*

$$r = R_{\min} + \frac{h}{2} \left[ 1 - \cos \left( \frac{180^\circ \phi}{\beta} \right) \right] \quad (12a)$$

$$\frac{dr}{d\phi} = \frac{180^\circ h}{2\beta} \sin \left( \frac{180^\circ \phi}{\beta} \right) \quad (12b) \quad \left. \vphantom{\frac{dr}{d\phi}} \right\} 0 \leq \phi \leq \beta$$

$$\frac{d^2r}{d\phi^2} = \frac{(180^\circ)^2 h}{2\beta^2} \cos \left( \frac{180^\circ \phi}{\beta} \right) \quad (12c)$$

The minimum radius of curvature can occur at either  $\phi = \beta/2$  or at  $\phi = \beta$ , depending on the magnitudes of  $h$ ,  $R_{\min}$ , and  $\beta$ . Therefore, to determine which is the case, make two calculations using Formula (10), one for  $\phi = \beta/2$ , and the other for  $\phi = \beta$ .

*Cycloidal motion:*

$$r = R_{\min} + h \left[ \frac{\phi}{\beta} - \frac{1}{2\pi} \sin \left( \frac{360^\circ \phi}{\beta} \right) \right] \quad (13a)$$

$$\frac{dr}{d\phi} = \frac{180^\circ h}{\pi \beta} \left[ 1 - \cos \left( \frac{360^\circ \phi}{\beta} \right) \right] \quad (13b) \quad \left. \vphantom{\frac{dr}{d\phi}} \right\} 0 \leq \phi \leq \beta$$

$$\frac{d^2r}{d\phi^2} = \frac{2(180^\circ)^2 h}{\pi\beta^2} \sin\left(\frac{360^\circ\phi}{\beta}\right) \quad (13c)$$

$$\rho_{\min} = \frac{[(R_{\min} + 0.91h)^2 + (180^\circ h/\pi\beta)^2]^{3/2}}{(R_{\min} + 0.91h)^2 + 2(180^\circ h/\pi\beta)^2 + (R_{\min} + 0.91h)[2(180^\circ)^2 h/\pi\beta^2]} \quad (13d)$$

( $\rho_{\min}$  occurs near  $\phi = 0.75\beta$ .)

*Example:* Given  $h = 1$  in.,  $R_{\min} = 2.9$  in., and  $\beta = 60^\circ$ . Find  $\rho_{\min}$  for parabolic motion, simple harmonic motion, and cycloidal motion.

*Solution:*  $\rho_{\min} = 2.02$  in. for parabolic motion, from Equation (10)

$\rho_{\min} = 1.8$  in. for simple harmonic motion, from Equation (10)

$\rho_{\min} = 1.6$  in. for cycloidal motion, from Equation (13d)

The value of  $\rho_{\min}$  on any cam may also be obtained by measurement on the layout of the cam using a compass.

**Cam Forces, Contact Stresses, and Materials.**—After a cam and follower configuration has been determined, the forces acting on the cam may be calculated or otherwise determined. Next, the stresses at the cam surface are calculated and suitable materials to withstand the stress are selected. If the calculated maximum stress is too great, it will be necessary to change the cam design.

Such changes may include: 1) increasing the cam size to decrease pressure angle and increase the radius of curvature; 2) changing to an offset or swinging follower to reduce the pressure angle; 3) reducing the cam rotation speed to reduce inertia forces; 4) increasing the cam rise angle,  $\beta$ , during which the rise,  $h$ , occurs; 5) increasing the thickness of the cam, provided that deflections of the follower are small enough to maintain uniform loading across the width of the cam; and 6) using a more suitable cam curve or modifying the cam curve at critical points.

Although parabolic motion seems to be the best with respect to minimizing the calculated maximum acceleration and, therefore, also the maximum acceleration forces, nevertheless, in the case of high speed cams, cycloidal motion yields the lower maximum acceleration forces. Thus, it can be shown that owing to the sudden change in acceleration (called *jerk* or *pulse*) in the case of parabolic motion, the actual forces acting on the cam are doubled and sometimes even tripled at high speed, whereas with cycloidal motion, owing to the gradually changing acceleration, the actual dynamic forces are only slightly higher than the theoretical. Therefore, the calculated force due to acceleration should be multiplied by at least a factor of 2 for parabolic and 1.05 for cycloidal motion to provide an allowance for the load-increasing effects of elasticity and backlash.

The main factors influencing cam forces are: 1) displacement and cam speed (forces due to acceleration); 2) dynamic forces due to backlash and flexibility; 3) linkage dimensions which affect weight and weight distribution; 4) pressure angle and friction forces; and 5) spring forces.

The main factors influencing stresses in cams are: 1) radius of curvature for cam and roller; and 2) materials.

*Acceleration Forces:* The formula for the force acting on a translating body given an acceleration  $a$  is:

$$R = \frac{Wa}{g} = \frac{Wa}{386} \quad (14)$$

In this formula,  $g = 386$  inches/second squared,  $a =$  acceleration of  $W$  in inches/second squared;  $R =$  resultant of all the external forces (except friction) acting on the weight  $W$ . For cam analysis purposes,  $W$ , in pounds, consists of the weight of the follower, a portion of the

weight of the return spring ( $\frac{1}{3}$ ), and the weight of the members of the external mechanism against which the follower pushes, for example, the weight of a piston:

$$W = W_f + \frac{1}{3}W_s + W_e \tag{15}$$

where  $W$  = equivalent single weight;  $W_f$  = follower weight;  $W_s$  = spring weight; and  $W_e$  = external weight, all in pounds.

*Spring Forces:* The return spring,  $K_s$ , shown in Fig. 21a must be strong enough to hold the follower against the cam at all times. At high cam speeds the main force attempting to separate the follower from the cam surface is the acceleration force  $R$  at the point of maximum negative acceleration. Thus, at that point the spring must exert a force  $F_s$ ,

$$F_s = R - W_f - F_e - F_f \tag{16}$$

where  $F_e$  = external force resisting motion of follower, and  $F_f$  = friction force from follower guide bushings and other sources.

When the follower is at its lowest position ( $R_{min}$  in Fig. 21a), it is usual practice to have the spring provide some estimated preload to account for "set" that takes place in a spring after repeated use and to prevent roller sliding at the start of movement.

The required spring constant,  $K_s$ , in pounds per inch of spring deflection is:

$$K_s = \frac{F_s - \text{preload}}{y_a} \tag{17}$$

where  $y_a$  = rise of cam from  $R_{min}$  to height at which maximum negative acceleration takes place.

The force,  $F_y$ , that the spring exerts at any height  $y$  above  $R_{min}$  is:

$$F_y = yK_s + \text{preload} \tag{18}$$

Fig. 21. (a) Radial Translating Follower and Cam System (b) Force Acting on a Translating Follower

*Pressure Angle and Friction Forces:* As shown in Fig. 21b, the pressure angle of the cam causes a sideways component  $F_n \sin \alpha$  which produces friction forces  $\mu F_1$  and  $\mu F_2$  in the guide bushing. If the follower rod is too flexible, bending of the follower will increase

these friction forces. The effect of the friction forces and the pressure angle are taken into account in the formula,

$$F_n = \frac{P}{\cos \alpha - \frac{\mu \sin \alpha}{l_2} (2l_1 + l_2 - \mu d)} \quad (19a)$$

where  $\mu$  = coefficient of friction in bushing;  $l_1$ ,  $l_2$ , and  $d$  are as shown in Fig. 21; and  $P$  = the sum of all the forces acting down against the upward motion of the follower (acceleration force + spring force + follower weight + external force)

$$P = \frac{W \times a}{386} + (yK_s + \text{preload}) + W_f + F_e \quad (19b)$$

**Cam Torque:** The follower pressing against the cam causes resisting torques during the rise period and assisting torques during the return period. The maximum value of the resisting torque determines the cam drive requirements. Instantaneous torque values may be calculated from

$$T_o = \frac{30vF_n \cos \alpha}{\pi N} = (R_{\min} + y)F_n \sin \alpha \quad (20)$$

in which  $T_o$  = instantaneous torque in pound-inches.

**Example of Force Analysis:** A radial translating follower system is shown in Fig. 21a. The follower is moved with cycloidal motion over a distance of 1 in. and an angle of lift  $\beta = 100^\circ$ . Cam speed  $N = 900$  rpm. The weight of the follower mass,  $W_f$  is 2 pounds. Both the spring weight  $W_s$  and the external weight  $W_e$  are negligible. The follower stem diameter is 0.75 in.,  $l_1 = 1.5$  in.,  $l_2 = 4$  in., coefficient of friction  $\mu = 0.05$ , external force  $F_e = 10$  lbs, and the pressure angle is not to exceed  $30^\circ$ .

(a) What is the smallest radius  $R_{\min}$  to the pitch curve?

From Formula (9b) the rise angle  $\phi_p$  to where the maximum pressure angle  $\alpha_{\max}$  exists is:

$$\begin{aligned} \phi_p &= \frac{\beta}{180^\circ} \left[ \operatorname{arccot} \left( \frac{\beta \tan \alpha_{\max}}{360^\circ} \right) \right] = \frac{100^\circ}{180^\circ} \left[ \operatorname{arccot} \left( \frac{100^\circ \times \tan 30^\circ}{360^\circ} \right) \right] \\ &= 44.94^\circ = 45^\circ \end{aligned}$$

From Formula (9c) the radius,  $R_{\alpha_{\max}}$ , at which the angle of rise is  $\phi_p$  is:

$$R_{\alpha_{\max}} = \frac{h}{2\pi} \frac{[1 - \cos(360^\circ \phi_p / \beta)]^2}{\sin(360^\circ \phi_p / \beta)} = \frac{1}{2\pi} \frac{[1 - \cos[(360^\circ \times 45^\circ) / 100^\circ]]^2}{\sin[(360^\circ \times 45^\circ) / 100^\circ]} = 1.96 \text{ in.}$$

From Formula (9d),  $R_{\min}$  is given by

$$\begin{aligned} R_{\min} &= R_{\alpha_{\max}} - h \left[ \frac{\phi_p}{\beta} - \frac{1}{2\pi} \sin \left( \frac{360^\circ \phi_p}{\beta} \right) \right] \\ &= 1.96 - 1 \times \left[ \frac{45^\circ}{100^\circ} - \frac{1}{2\pi} \sin \left( \frac{360^\circ \times 45^\circ}{100^\circ} \right) \right] = 1.560 \text{ in.} \end{aligned}$$

The same results could have been obtained graphically. If this  $R_{\min}$  is too small, i.e., if the cam bore and hub require a larger cam, then  $R_{\min}$  can be increased, in which case the maximum pressure angle will be less than  $30^\circ$ .

(b) If the return spring  $K_s$  is specified to provide a preload of 36 lbs when the follower is at  $R_{\min}$ , what is the spring constant required to hold the follower on the cam throughout the cycle?

The follower tends to leave the cam at the point of maximum *negative* acceleration. Fig. 7 shows this to be at  $\phi = \frac{3}{4}\beta = 75^\circ$ .

From Formula (4c),

$$a = \frac{2\pi h \omega^2}{\beta^2} \sin\left(\frac{360^\circ \phi}{\beta}\right) = \frac{2\pi \times 1 \times (6 \times 900)^2}{(100^\circ)^2} \sin\left(\frac{360^\circ \times 75^\circ}{100^\circ}\right) = -18,300 \text{ in./sec}^2$$

From Formulas (14) and (15),

$$R = \frac{Wa}{386} = \frac{(W_f + \frac{1}{3}W_s + W_e)a}{386} = \frac{(2 + 0 + 0)(-18,300)}{386} = 95 \text{ lbs (upward)}$$

Using Formula (16) to determine the spring force  $F_s$  to hold the follower on the cam,

$$F_s = R - W_f - F_e - F_f$$

as stated on page 2205, the value of  $R$  in the above formula should be multiplied by 1.05 for cycloidal motion to provide a factor of safety for dynamic pulses. Thus,

$$F_s = 1.05R - W_f - F_e - F_f = 1.05 \times 95 - 2 - 10 - 0 = 88 \text{ lbs (downward)}$$

The spring constant from Formula (17) is:

$$K_s = \frac{F_s - \text{preload}}{y_a} = \frac{88 - 36}{y_a}$$

and, from Formula (4a)  $y_a$  is:

$$y_a = h \left[ \frac{\phi}{\beta} - \frac{1}{2\pi} \sin\left(\frac{360^\circ \phi}{\beta}\right) \right] = 1 \times \left[ \frac{75^\circ}{100^\circ} - \frac{1}{2\pi} \sin\left(\frac{360^\circ \times 75^\circ}{100^\circ}\right) \right] = 0.909 \text{ in.}$$

so that  $K_s = (88 - 36)/0.909 = 57 \text{ lb/in.}$

(c) At the point where the pressure angle  $\alpha_{\max}$  is  $30^\circ$  ( $\phi = 45^\circ$ ) the rise of the follower is  $1.96 - 1.56 = 0.40 \text{ in.}$  What is the normal force,  $F_n$ , on the cam? From Formulas (19a) and (19b)

$$F_n = \frac{Wa/386 + yK_s + \text{preload} + W_f + F_e}{\cos \alpha - \frac{\mu \sin \alpha}{l_2} (2l_1 + l_2 - \mu d)}$$

using  $\phi = 45^\circ$ ,  $h = 1 \text{ in.}$ ,  $\beta = 100^\circ$ , and  $\omega = 6 \times 900 \text{ in}$  in Formula (4c) gives  $a = 5660 \text{ in./sec}^2$ . So that, with  $W = 2 \text{ lbs}$ ,  $y = 0.4$ ,  $K_s = 57$ , preload = 36 lbs,  $W_f = 2 \text{ lbs}$ ,  $F_e = 10 \text{ lbs}$ ,  $\alpha = 30^\circ$ ,  $\mu = 0.05$ ,  $l_1 = 1.5$ ,  $l_2 = 4$ , and  $d = 0.75$ ,

$$F_n = \frac{(2 \times 5660)/386 + 0.4 \times 57 + 36 + 2}{\cos 30^\circ - \frac{0.05 \times \sin 30^\circ}{4} (2 \times 1.5 + 4 - 0.05 \times 0.75)} = 110 \text{ lbs}$$

*Note:* If the coefficient of friction had been assumed to be 0, then  $F_n = 104$ ; on the other hand, if the follower is too flexible, so that sidewise bending occurs causing jamming in the bushing, the coefficient of friction may increase to, say, 0.5, in which case the calculated  $F_n = 200 \text{ lbs.}$

(d) Assuming that in the manufacture of this cam that an error or "bump" resulting from a chattermark or as a result of poor blending occurred, and that this "bump" rose to a height of 0.001 in. in a  $1^\circ$  rise of the cam in the vicinity of  $\phi = 45^\circ$ . What effect would this bump have on the acceleration force  $R$ ?

One formula that may be used to calculate the change in acceleration caused by such a cam error is:

$$\Delta a = \pm 2e \left( \frac{6N}{\Delta\phi} \right)^2 \quad (21)$$

where  $\Delta a$  = change in acceleration,

$e$  = error in inches,

$\Delta\phi$  = width of error in degrees. The plus (+) sign is used for a "bump" and the minus (-) sign for a dent or hollow in the surface

For  $e = 0.001$ ,  $\Delta\phi = 1^\circ$ , and  $N = 900$  rpm,

$$\Delta a = +2 \times 0.001 \left( \frac{6 \times 900}{1^\circ} \right)^2 = 58,320 \text{ in./sec}^2$$

which is 10 times the acceleration calculated for a perfect cam and would cause sufficient force  $F_n$  to damage the cam surface. On high speed cams, therefore, accuracy is of considerable importance.

(e) What is the cam torque at  $\phi = 45^\circ$ ?

From Formula (20),

$$\begin{aligned} T_o &= (R_{\min} + y) F_n \sin \alpha \\ &= (1.56 + 0.4) \times 110 \times \sin 30^\circ = 108 \text{ in.-lbs} \end{aligned}$$

(f) What is the radius of curvature at  $\phi = 45^\circ$ ?

From Formula (10),

$$\begin{aligned} \rho &= \frac{\left[ r^2 + \left( \frac{dr}{d\phi} \right)^2 \right]^{3/2}}{r^2 + 2 \left( \frac{dr}{d\phi} \right)^2 - r \left( \frac{d^2r}{d\phi^2} \right)} \\ r &= R_{\min} + y = 1.56 + 0.4 = 1.96 \end{aligned}$$

From Formula (13b),

$$\begin{aligned} \frac{dr}{d\phi} &= \frac{180^\circ h}{\pi \beta} \left[ 1 - \cos \left( \frac{360^\circ \phi}{\beta} \right) \right] = \frac{180^\circ \times 1}{\pi \times 100^\circ} \left[ 1 - \cos \left( \frac{360^\circ \times 45^\circ}{100^\circ} \right) \right] \\ &= 1.12 \end{aligned}$$

From Formula (13c),

$$\begin{aligned} \frac{d^2r}{d\phi^2} &= \frac{2(180^\circ)^2 h}{\pi \beta^2} \sin \left( \frac{360^\circ \phi}{\beta} \right) = \frac{2 \times (180^\circ)^2 \times 1}{\pi \times (100^\circ)^2} \sin \left( \frac{360^\circ \times 45^\circ}{100^\circ} \right) \\ &= 0.64 \\ \rho &= \frac{[(1.96)^2 + (1.12)^2]^{3/2}}{(1.96)^2 + 2(1.12)^2 - 1.96 \times 0.64} = 2.26 \text{ in.} \end{aligned}$$

**Calculation of Contact Stresses.**—When a roller follower is loaded against a cam, the compressive stress developed at the surface of contact may be calculated from

$$S_c = 2290 \sqrt{\frac{F_n}{b} \left( \frac{1}{r_f} \pm \frac{1}{R_c} \right)} \quad (22)$$

for a steel roller against a steel cam. For a steel roller on a cast iron cam, use 1850 instead of 2290 in Equation (22).

$S_c$  = maximum calculated compressive stress, psi

$F_n$  = normal load, lb

$b$  = width of cam, inch

$R_c$  = radius of curvature of cam surface, inch

$r_f$  = radius of roller follower, inch

The plus sign in (21) is used in calculating the maximum compressive stress when the roller is in contact with the convex portion of the cam profile and the minus sign is used when the roller is in contact with the concave portion. When the roller is in contact with the straight (flat) portion of the cam profile,  $R_c = \infty$  and  $1/R_c = 0$ . In practice, the greatest compressive stress is most apt to occur when the roller is in contact with that part of the cam profile which is convex and has the smallest radius of curvature.

*Example:* Given the previous cam example, the radius of the roller  $r_f = 0.25$  in., the convex radius of the cam  $R_c = (2.26 - 0.25)$  in., the width of contact  $b = 0.3$  in., and the normal load  $F_n = 110$  lbs. Find the maximum surface compressive stress. From (21),

$$S_c = 2290 \sqrt{\frac{110}{0.3} \left( \frac{1}{0.25} + \frac{1}{2.01} \right)} = 93,000 \text{ psi}$$

This calculated stress should be less than the allowable stress for the material selected from Table 2.

*Cam Materials:* In considering materials for cams it is difficult to select any single material as being the best for every application. Often the choice is based on custom or the machinability of the material rather than its strength. However, the failure of a cam or roller is commonly due to fatigue, so that an important factor to be considered is the limiting wear load, which depends on the surface endurance limits of the materials used and the relative hardnesses of the mating surfaces.

**Table 2. Cam Materials**

| Cam Materials for Use with Roller of Hardened Steel                                | Maximum Allowable Compressive Stress, psi |
|--|---|

Based on United Shoe Machinery Corp. data by Guy J. Talbourdet.

In Table 2 are given maximum permissible compressive stresses (surface endurance limits) for various cam materials when in contact with a roller of hardened steel. The stress values shown are based on 100,000,000 cycles or repetitions of stress for pure rolling. Where the repetitions of stress are considerably greater than 100,000,000, where there is appreciable misalignment, or where there is sliding, more conservative stress figures must be used.

**Layout of Cylinder Cams.**—In Fig. 22 is shown the development of a uniformly accelerated motion cam curve laid out on the surface of a cylindrical cam. This development is necessary for finding the projection on the cylindrical surface, as shown at *KL*. To construct the developed curve, first divide the base circle of the cylinder into, say, twelve equal parts. Set off these parts along line *ag*. Only one-half of the layout has been shown, as the other half is constructed in the same manner, except that the curve is here falling instead of rising. Divide line *aH* into the same number of divisions as the half circle, the divisions being in the proportion 1 : 3 : 5 : 5 : 3 : 1. Draw horizontal lines from these division points and vertical lines from *a, b, c, etc.* The intersections between the two sets of lines are points on the developed cam curve. These points are transferred to the cylindrical surface at the left by projection in the usual manner.

Fig. 22. Development of Cylindrical Cam

**Shape of Rolls for Cylinder Cams.**—The rolls for cylindrical cams working in a groove in the cam should be conical rather than cylindrical in shape, in order that they may rotate freely and without excessive friction. Fig. 23(a) shows a straight roll and groove, the action of which is faulty because of the varying surface speed at the top and bottom of the groove. Fig. 23(b) shows a roll with curved surface. For heavy work, however, the small bearing area is quickly worn down and the roll presses a groove into the side of the cam as well, thus destroying the accuracy of the movement and creating backlash. Fig. 23(c) shows the conical shape which permits a true rolling action in the groove. The amount of taper depends on the angle of spiral of the cam groove. As this angle, as a rule, is not constant for the whole movement, the roll and groove should be designed to meet the requirements on that section of the cam where the heaviest duty is performed. Frequently the cam groove is of a nearly even spiral angle for a considerable length. The method for determining the angle of the roll and groove to work correctly during the important part of the cycle is as follows:

In Fig. 23(d), *b* is the circumferential distance on the surface of the cam that includes the section of the groove for which correct rolling action is required. The throw of the cam for this circumferential movement is *a*. Line *OU* is the development of the movement of the

cam roll during the given part of the cycle, and  $c$  is the movement corresponding to  $b$ , but on a circle the diameter of which is equal to that of the cam at the bottom of the groove. With the same throw  $a$  as before, the line  $OV$  will be the development of the cam at the bottom of the groove.  $OU$  then is the length of the helix traveled by the top of the roll, while  $OV$  is the travel at the bottom of the groove. If, then, the top width and bottom width of the groove be made proportional to  $OU$  and  $OV$ , the groove will be properly proportioned.

Fig. 23. Shape of Rolls for Cylinder Cams

**Cam Milling.**—Plate cams having a constant rise, such as are used on automatic screw machines, can be cut in a universal milling machine, with the spiral head set at an angle  $\alpha$ , as shown by the illustration.

Fig. 24.

When the spiral head is set vertical, the “lead” of the cam (or its rise for one complete revolution) is the same as the lead for which the machine is geared; but when the spiral head and cutter are inclined, any lead or rise of the cam can be obtained, provided it is less than the lead for which the machine is geared, that is, less than the forward feed of the table for one turn of the spiral-head spindle. The cam lead, then, can be varied within certain limits by simply changing the inclination  $\alpha$  of the spiral head and cutter. The following formula is for determining this angle of inclination, for a given rise of cam and with the machine geared for a lead,  $L$ , selected from the tables beginning on page 1967,

$$\sin \alpha = \frac{360^\circ \times r}{\phi \times L}$$

where  $\alpha$  = angle to which index head and milling attachment are set from horizontal as shown in the accompanying diagram

$r$  = rise of cam in given part of circumference

$L$  = spiral lead for which milling machine is geared

$\phi$  = angle in which rise is required, expressed in degrees

For example, suppose a cam is to be milled having a rise of 0.125 inch in 300 degrees and that the machine is geared for the smallest possible lead, or 0.670 inch; then:

$$\sin \alpha = \frac{360^\circ \times 0.125}{300^\circ \times 0.670} = 0.2239$$

which is the sine of  $12^\circ 56'$ . Therefore, to secure a rise of 0.125 inch with the machine geared for 0.670 inch lead, the spiral head is elevated to an angle of  $12^\circ 56'$  and the vertical milling attachment is also swiveled around to locate the cutter in line with the spiral-head spindle, so that the edge of the finished cam will be parallel to its axis of rotation. In the example given, the lead used was 0.670. A larger lead, say 0.930, could have been selected from the table on page 1967. In that case,  $\alpha = 9^\circ 17'$ .

When there are several lobes on a cam, having different leads, the machine can be geared for a lead somewhat in excess of the greatest lead on the cam, and then all the lobes can be milled without changing the spiral head gearing, by simply varying the angle of the spiral head and cutter to suit the different cam leads. Whenever possible, it is advisable to mill on the under side of the cam, as there is less interference from chips; moreover, it is easier to see any lines that may be laid out on the cam face. To set the cam for a new cut, it is first turned back by operating the handle of the table feed screw, after which the index crank is disengaged from the plate and turned the required amount.

**Simple Method for Cutting Uniform Motion Cams.**—Some cams are laid out with dividers, machined and filed to the line; but for a cam that must advance a certain number of thousandths per revolution of spindle this method is not accurate. Cams are easily and accurately cut in the following manner.

Let it be required to make the heart cam shown in the illustration. The throw of this cam is 1.1 inch. Now, by setting the index on the milling machine to cut 200 teeth and also dividing 1.1 inch by 100, we find that we have 0.011 inch to recede from or advance towards the cam center for each cut across the cam. Placing the cam securely on an arbor, and the latter between the centers of the milling machine, and using a convex cutter set the proper distance from the center of the arbor, make the first cut across the cam. Then, by lowering the milling machine knee 0.011 inch and turning the index pin the proper number of holes on the index plate, take the next cut and so on.

## PLAIN BEARINGS

## Introduction

On the following pages are given data and procedures for designing full-film or hydrodynamically lubricated bearings of the journal and thrust types. However, before proceeding to these design methods, it is thought useful to first review those bearing aspects concerning the types of bearings available; lubricants and lubrication methods; hardness and surface finish; machining methods; seals; retainers; and typical length-to-diameter ratios for various applications.

The following paragraphs preceding the design sections provide guidance in these matters and suggest modifications in allowable loads when other than full-film operating conditions exist in a bearing.

**Classes of Plain Bearings.**—Bearings that provide sliding contact between mating surfaces fall into three general classes: *radial bearings* that support rotating shafts or journals; *thrust bearings* that support axial loads on rotating members; and *guide or slipper bearings* that guide moving parts in a straight line. Radial sliding bearings, more commonly called sleeve bearings, may be of several types, the most usual being the plain full journal bearing, which has 360-degree contact with its mating journal, and the partial journal bearing, which has less than 180-degree contact. This latter type is used when the load direction is constant and has the advantages of simplicity, ease of lubrication, and reduced frictional loss.

The relative motions between the parts of plain bearings may take place: 1) as pure sliding without the benefit of a liquid or gaseous lubricating medium between the moving surfaces such as with the dry operation of nylon or Teflon; 2) with hydrodynamic lubrication in which a wedge or film buildup of lubricating medium is produced, with either whole or partial separation of the bearing surfaces; 3) with hydrostatic lubrication in which a lubricating medium is introduced under pressure between the mating surfaces causing a force opposite to the applied load and a lifting or separation of these surfaces; and 4) with a hybrid form or combination of hydrodynamic and hydrostatic lubrication.

Listed below are some of the advantages and disadvantages of sliding contact (plain) bearings as compared with rolling contact (antifriction) bearings.

*Advantages:* 1) require less space; 2) are quieter in operation; 3) are lower in cost, particularly in high-volume production; 4) have greater rigidity; and 5) their life is generally not limited by fatigue.

*Disadvantages:* 1) have higher frictional properties resulting in higher power consumption; 2) are more susceptible to damage from foreign material in lubrication system; 3) have more stringent lubrication requirements; and 4) are more susceptible to damage from interrupted lubrication supply.

**Types of Journal Bearings.**—Many types of journal bearing configurations have been developed; some of these are shown in Fig. 1.

*Circumferential-groove bearings*, Fig. 1(a), have an oil groove extending circumferentially around the bearing. The oil is maintained under pressure in the groove. The groove divides the bearing into two shorter bearings that tend to run at a slightly greater eccentricity. However, the advantage in terms of stability is slight, and this design is most commonly used in reciprocating-load main and connecting-rod bearings because of the uniformity of oil distribution.

Short cylindrical bearings are a better solution than the circumferential-groove bearing for high-speed, low-load service. Often the bearing can be shortened enough to increase the unit loading to a substantial value, causing the shaft to ride at a position of substantial eccentricity in the bearing. Experience has shown that instability rarely results when the shaft eccentricity is greater than 0.6. Very short bearings are not often used for this type of

Fig. 1. Typical shapes of several types of pressure-fed bearings.

application, because they do not provide a high temporary rotating-load capacity in the event some unbalance should be created in the rotor during service.

*Cylindrical-overshot bearings*, Fig. 1(b), are used where surface speeds of 10,000 fpm or more exist, and where additional oil flow is desired to maintain a reasonable bearing temperature. This bearing has a wide circumferential groove extending from one axial oil groove to the other over the upper half of the bearing. Oil is usually admitted to the trailing-edge oil groove. An inlet orifice is used to control the oil flow. Cooler operation results from the elimination of shearing action over a large section of the upper half of the bearing and, to a great extent, from the additional flow of cool oil over the top half of the bearing.

*Pressure bearings*, Fig. 1(c), employ a groove over the top half of the bearing. The groove terminates at a sharp dam about 45 degrees beyond the vertical in the direction of shaft rotation. Oil is pumped into this groove by shear action from the rotation of the shaft and is then stopped by the dam. In high-speed operation, this situation creates a high oil pressure over the upper half of the bearing. The pressure created in the oil groove and surrounding upper half of the bearing increases the load on the lower half of the bearing. This self-generated load increases the shaft eccentricity. If the eccentricity is increased to 0.6 or greater, stable operation under high-speed, low-load conditions can result. The central oil groove can be extended around the lower half of the bearing, further increasing the effective loading. This design has one primary disadvantage: Dirt in the oil will tend to abrade the sharp edge of the dam and impair ability to create high pressures.

*Multiple-groove bearings*, Fig. 1(d), are sometimes used to provide increased oil flow. The interruptions in the oil film also appear to give this bearing some merit as a stable design.

*Elliptical bearings*, Fig. 1(e), are not truly elliptical, but are formed from two sections of a cylinder. This two-piece bearing has a large clearance in the direction of the split and a smaller clearance in the load direction at right angles to the split. At light loads, the shaft runs eccentric to both halves of the bearing, and hence, the elliptical bearing has a higher oil flow than the corresponding cylindrical bearing. Thus, the elliptical bearing will run cooler and will be more stable than a cylindrical bearing.

*Elliptical-overshot bearings* (not shown) are elliptical bearings in which the upper half is relieved by a wide oil groove connecting the axial oil grooves. They are analogous to cylindrical-overshot bearings.

*Displaced elliptical bearings*, Fig. 1(f), shift the centers of the two bearing arcs in both a horizontal and a vertical direction. This design has greater stiffness than a cylindrical bearing, in both horizontal and vertical directions, with substantially higher oil flow. It has not been extensively used, but offers the prospect of high stability and cool operation.

*Three-lobe bearings*, Fig. 1(g), are made up in cross section of three circular arcs. They are most effective as anti-whip bearings when the centers of curvature of each of the three lobes lie well outside the clearance circle that the shaft center can describe within the bearing. Three axial oil-feed grooves are used. It is a more difficult design to manufacture, because it is almost necessary to make it in three parts instead of two. The bore is machined with shims between each of the three parts. The shims are removed after machining is completed.

*Pivoted-shoe bearings*, Fig. 1(h), are one of the most stable bearings. The bearing surface is divided into three or more segments, each of which is pivoted at the center. In operation, each shoe tilts to form a wedge-shaped oil film, thus creating a force tending to push the shaft toward the center of the bearing. For single-direction rotation, the shoes are sometimes pivoted near one end and forced toward the shaft by springs.

*Nutcracker bearings*, Fig. 1(i), consist of two cylindrical half-bearings. The upper half-bearing is free to move in a vertical direction and is forced toward the shaft by a hydraulic cylinder. External oil pressure may be used to create load on the upper half of the bearing through the hydraulic cylinder. Or the high-pressure oil may be obtained from the lower half of the bearing by tapping a hole into the high-pressure oil film, thus creating a self-loading bearing. Either type can increase bearing eccentricity to the point where stable operation can be achieved.

**Hydrostatic Bearings.**—Hydrostatic bearings are used when operating conditions require full film lubrication that cannot be developed hydrodynamically. The hydrostatically lubricated bearing, either thrust or radial, is supplied with lubricant under pressure from an external source. Some advantages of the hydrostatic bearing over bearings of other types are: low friction; high load capacity; high reliability; high stiffness; and long life.

Hydrostatic bearings are used successfully in many applications including machine tools, rolling mills, and other heavily loaded slow-moving machinery. However, specialized techniques, including a thorough understanding of hydraulic components external to the bearing package is required. The designer is cautioned against use of this type of bearing without a full knowledge of all aspects of the problem. Determination of the operating performance of hydrostatic bearings is a specialized area of the lubrication field and is described in specialized reference books.

**Guide Bearings.**—This type of bearing is generally used as a positioning device or as a guide to linear motion such as in machine tools. Fig. 2 shows several examples of guide-way bearing designs. It is normal for this type of bearing to operate in the boundary lubrication region with either dry, dry film such as molybdenum disulfide ( $\text{MoS}_2$ ) or tetrafluorethylene (TFE), grease, oil, or gaseous lubrication. Hydrostatic lubrication is often used to improve performance, reduce wear, and increase stability. This type of design uses pumps to supply air or gas under pressure to pockets designed to produce a bearing film and maintain complete separation of the sliding surfaces.

Fig. 2. Types of Guide Bearings

**Design.**—The design of a sliding bearing is generally accomplished in one of two ways: 1) a bearing operating under similar conditions is used as a model or basis from which the new bearing is designed; and 2) in the absence of any previous experience with similar bearings in similar environments, certain assumptions concerning operating conditions and requirements are made and a tentative design prepared based on general design parameters or rules of thumb. Detailed lubrication analysis is then performed to establish design and operating details and requirements.

**Modes of Bearing Operation.**—The load-carrying ability of a sliding bearing depends upon the kind of fluid film that is formed between its moving surfaces. The formation of this film is dependent, in part, on the design of the bearing and, in part, on the speed of rotation. The bearing has three modes or regions of operation designated as *full-film*, *mixed-film*, and *boundary* lubrication with effects on bearing friction, as shown in Fig. 3.

In terms of physical bearing operation these three modes may be further described as follows:

Fig. 3. Three modes of bearing operation.

1) Full-film, or hydrodynamic, lubrication produces a complete physical separation of the sliding surfaces resulting in low friction and long wear-free service life.

To promote full-film lubrication in hydrodynamic operation, the following parameters should be satisfied: a) Lubricant selected has the correct viscosity for the proposed operation; b) proper lubricant flow rates are maintained; c) proper design methods and considerations have been utilized; and d) surface velocity in excess of 25 feet per minute is maintained.

When full-film lubrication is achieved, a coefficient of friction between 0.001 and 0.005 can be expected.

2) Mixed-film lubrication is a mode of operation between the full-film and boundary modes. With this mode, there is a partial separation of the sliding surfaces by the lubricant film; however, as in boundary lubrication, limitations on surface speed and wear will result. With this type of lubrication, a surface velocity in excess of 10 feet per minute is required with resulting coefficients of friction of 0.02 to 0.08.

3) Boundary lubrication takes place when the sliding surfaces are rubbing together with only an extremely thin film of lubricant present. This type of operation is acceptable only in applications with oscillating or slow rotary motion. In complete boundary lubrication, the oscillatory or rotary motion is usually less than 10 feet per minute with resulting coefficients of friction of 0.08 to 0.14. These bearings are usually grease lubricated or periodically oil lubricated.

In starting up and accelerating to its operating point, a journal bearing passes through all three modes of operation. At rest, the journal and bearing are in contact, and thus when starting, the operation is in the boundary lubrication region. As the shaft begins to rotate

more rapidly and the hydrodynamic film starts to build up, bearing operation enters the region of mixed-film lubrication. When design speeds and loads are reached, the hydrodynamic action in a properly designed bearing will promote full-film lubrication.

**Methods of Retaining Bearings.**—Several methods are available to ensure that a bearing remains in place within a housing. Which method to use depends upon the particular application but requires first that the unit lends itself to convenient assembly and disassembly; additionally, the bearing wall should be of uniform thickness to avoid introduction of weak points in the construction that may lead to elastic or thermal distortion.

*Press or Shrink Fit:* One common and satisfactory technique for retaining the bearing is to press or shrink the bearing in the housing with an interference fit. This method permits the use of bearings having uniform wall thickness over the entire bearing length.

Standard bushings with finished inside and outside diameters are available in sizes up to approximately 5 inches inside diameter. Stock bushings are commonly provided 0.002 to 0.003 inch over nominal on outside diameter sizes of 3 inches or less. For diameters greater than 3 inches, outside diameters are 0.003 to 0.005 inch over nominal. Because these tolerances are built into standard bushings, the amount of press fit is controlled by the housing-bore size.

As a result of a press or shrink fit, the bore of the bearing material “closes in” by some amount. In general, this diameter decrease is approximately 70 to 100 per cent of the amount of the interference fit. Any attempt to accurately predict the amount of reduction, in an effort to avoid final clearance machining, should be avoided.

Shrink fits may be accomplished by chilling the bearing in a mixture of dry ice and alcohol, or in liquid air. These methods are easier than heating the housing and are preferred. Dry ice in alcohol has a temperature of  $-110$  degrees F and liquid air boils at  $-310$  degrees F.

When a bearing is pressed into the housing, the driving force should be uniformly applied to the end of the bearing to avoid upsetting or peening of the bearing. Of equal importance, the mating surfaces must be clean, smoothly finished, and free of machining imperfections.

*Keying Methods:* A variety of methods can be used to fix the position of the bearing with respect to its housing by “keying” the two together. Possible keying methods are shown in Figs. 4a through 4f including: a) set screws; b) Woodruff keys; c) bolted bearing flanges; d) threaded bearings; e) dowel pins; and f) housing caps.

Factors to be considered when selecting one of these methods are as follows:

- 1) Maintaining uniform wall thickness of the bearing material, if possible, especially in the load-carrying region of the bearing.
- 2) Providing as much contact area as possible between bearing and housing. Mating surfaces should be clean, smooth, and free from imperfections to facilitate heat transfer.
- 3) Preventing any local deformation of the bearing that might result from the keying method. Machining after keying is recommended.
- 4) Considering the possibility of bearing distortion resulting from the effect of temperature changes on the particular keying method.

**Methods of Sealing.**—In applications where lubricants or process fluids are utilized in operation, provision must be made normally to prevent leakage to other areas. This provision is made by the use of static and dynamic type sealing devices. In general, three terms are used to describe the devices used for sealing:

*Seal:* A means of preventing migration of fluids, gases, or particles across a joint or opening in a container.

*Packing:* A dynamic seal, used where some form of relative motion occurs between rigid members of an assembly.

*Gaskets:* A static seal, used where there is no relative motion between joined parts.

## Methods of Bearing Retention

Fig. 4a. Set Screws

Fig. 4b. Woodruff Key

Fig. 4c. Bolts through Flange

Fig. 4d. Bearing Screwed into Housing

Fig. 4e. Dowel Pin

Fig. 4f. Housing Cap

Two major functions must be achieved by all sealing applications: prevent escape of fluid; and prevent migration of foreign matter from the outside.

The first determination in selecting the proper seal is whether the application is static or dynamic. To meet the requirements of a static application there must be no relative motion between the joining parts or between the seal and the mating part. If there is any relative motion, the application must be considered dynamic, and the seal selected accordingly.

Dynamic sealing requires control of fluids leaking between parts with relative motion. Two primary methods are used to this end: positive contact or rubbing seals; and controlled clearance noncontact seals.

*Positive Contact or Rubbing Seals:* These seals are used where positive containment of liquids or gases is required, or where the seal area is continuously flooded. If properly selected and applied, contact seals can provide zero leakage for most fluids. However, because they are sensitive to temperature, pressure, and speed, improper application can result in early failure. These seals are applicable to rotating and reciprocating shafts. In many assemblies, positive-contact seals are available as off-the-shelf items. In other instances, they are custom-designed to the special demands of a particular application. Custom design is offered by many seal manufacturers and, for extreme cases, probably offers the best solution to the sealing problem.

*Controlled Clearance Noncontact Seals:* Representative of the controlled-clearance seals, which includes all seals in which there is no rubbing contact between the rotating and

stationary members, are throttling bushings and labyrinths. Both types operate by fluid-throttling action in narrow annular or radial passages.

Clearance seals are frictionless and very insensitive to temperature and speed. They are chiefly effective as devices for limiting leakage rather than stopping it completely. Although they are employed as primary seals in many applications, the clearance seal also finds use as auxiliary protection in contact-seal applications. These seals are usually designed into the equipment by the designer himself, and they can take on many different forms.

Advantages of this seal are that friction is kept to an absolute minimum and there is no wear or distortion during the life of the equipment. However, there are two significant disadvantages: The seal has limited use when leakage rates are critical; and it becomes quite costly as the configuration becomes elaborate.

*Static Seals:* Static seals such as gaskets, "O" rings, and molded packings cover very broad ranges of both design and materials.

Some of the typical types are as follows: 1) Molded packings: a) lip type, and b) squeeze-molded; 2) simple compression packings; 3) diaphragm seals; 4) nonmetallic gaskets; 5) "O" rings; and 6) metallic gaskets and "O" rings.

Data on "O" rings are found starting on page 2502.

Detailed design information for specific products should be obtained directly from manufacturers.

**Hardness and Surface Finish.**—Even in well-lubricated full-film sleeve bearings, momentary contact between journal and bearing may occur under such conditions as starting, stopping, or overloading. In mixed-film and boundary-film lubricated sleeve bearings, continuous metal-to-metal contact occurs. Hence, to allow for any necessary wearing-in, the journal is usually made harder than the bearing material. This arrangement allows the effects of scoring or wearing to take place on the bearing, which is more easily replaced, rather than on the more expensive shaft. As a general rule, recommended Brinell (Bhn) hardness of the journal is at least 100 points harder than the bearing material.

The softer cast bronzes used for bearings are those with high lead content and very little tin. Such bronzes give adequate service in boundary- and mixed-film applications where full advantage is taken of their excellent "bearing" characteristics.

High-tin, low-lead content cast bronzes are the harder bronzes and these have high ultimate load-carrying capacity; higher journal hardnesses are required with these bearing bronzes. Aluminum bronze, for example, requires a journal hardness in the range of 550 to 600 Bhn.

In general, harder bearing materials require better alignment and more reliable lubrication to minimize local heat generation if and when the journal touches the shaft. Also, abrasives that find their way into the bearing are a problem for the harder bearing materials and greater care should be taken to exclude them.

*Surface Finish:* Whether bearing operation is complete boundary, mixed film, or fluid film, surface finishes of the journal and bearing must receive careful attention. In applications where operation is hydrodynamic or full-film, peak surface variations should be less than the expected minimum film thickness; otherwise, peaks on the journal surface will contact peaks on the bearing surface, with resulting high friction and temperature rise. Ranges of surface roughness obtained by various finishing methods are: boring, broaching, and reaming, 32 to 64 microinches, rms; grinding, 16 to 64 microinches, rms; and fine grinding, 4 to 16 microinches, rms.

In general, the better surface finishes are required for full-film bearings operating at high eccentricity ratios because full-film lubrication must be maintained with small clearances, and metal-to-metal contact must be avoided. Also, the harder the material, the better the surface finish required. For boundary- and mixed-film applications, surface finish requirements may be somewhat relaxed because bearing wear-in will in time smooth the surfaces.

Fig. 5 is a general guide to the ranges required for bearing and journal surface finishes. Selecting a particular surface finish in each range can be simplified by observing the general rule that smoother finishes are required for the harder materials, for high loads, and for high speeds.

Fig. 5. Recommended ranges of surface finish for the three types of sleeve bearing operations.

**Machining Bores.**—The methods most commonly used in finishing journal bearing bores are boring, broaching, reaming, and burnishing.

Broaching is a rapid finishing method providing good size and alignment control when adequate piloting is possible. Soft babbitt materials are particularly compatible with the broaching method. A third finishing method, reaming, facilitates good size and alignment control when piloting is utilized. Reaming can be accomplished both manually or by machine, the machine method being preferred. Burnishing is a fast sizing operation that gives good alignment control, but does not give as good size control as the cutting methods. It is not recommended for soft materials such as babbitt. Burnishing has an ironing effect that gives added seating of the bushing outside diameter in the housing bore; consequently, it is often used for this purpose, especially on a  $\frac{1}{32}$ -inch wall bushing, even if a further sizing operation is to be used subsequently.

Boring of journal bearings provides the best concentricity, alignment, and size control and is the finishing method of choice when close tolerances and clearances are desirable.

**Methods of Lubrication.**—There are numerous ways to supply lubricant to bearings. The more common of these are described in the following.

*Pressure lubrication*, in which an abundance of oil is fed to the bearing from a central groove, single or multiple holes, or axial grooves, is effective and efficient. The moving oil assists in flushing dirt from the bearing and helps keep the bearing cool. In fact, it removes heat faster than other lubricating methods and, therefore, permits thinner oil films and unimpaired load capacities. The oil-supply pressure needed for bushings carrying the basic load is directly proportional to the shaft speed, but for most installations, 50 psi will be adequate.

*Splash fed* applies to a variety of intermittently lubricated bushings. It includes everything from bearings spattered with oil from the action of other moving parts to bearings regularly dipped in oil. Like oil bath lubrication, splash feeding is practical when the housing can be made oiltight and when the moving parts do not churn the oil. The fluctuating

nature of the load and the intermittent oil supply in splash fed applications requires the designer to use experience and judgment when determining the probable load capacity of bearings lubricated in this way.

*Oil bath lubrication*, in which the bushing is submerged in oil, is the most reliable of all methods except pressure lubrication. It is practical if the housing can be made oil tight, and if the shaft speed is not so great as to cause excessive churning of the oil.

*Oil ring lubrication*, in which oil is supplied to the bearing by a ring in contact with the shaft, will, within reasonable limits, bring enough oil to the bearing to maintain hydrodynamic lubrication. If the shaft speed is too low, little oil will follow the ring to the bearing; and, if the speed is too high, the ring speed will not keep pace with the shaft. Also, a ring revolving at high speed will lose oil by centrifugal force. For best results, the peripheral speed of the shaft should be between 200 and 2000 feet per minute. Safe load to achieve hydrodynamic lubrication should be one-half of that for pressure fed bearings. Unless the load is light, hydrodynamic lubrication is doubtful. The safe load, then, to achieve hydrodynamic lubrication, should be one-quarter of that of pressure fed bearings.

*Wick or waste pack lubrication* delivers oil to a bushing by the capillary action of a wick or waste pack; the amount delivered is proportional to the size of the wick or pack.

*Lubricants:* The value of an oil as a lubricant depends mainly on its film-forming capacity, that is, its capability to maintain a film of oil between the bearing surfaces. The film-forming capacity depends to a large extent on the viscosity of the oil, but this should not be understood to mean that oil of the highest viscosity is always the most suitable lubricant. For practical reasons, an oil of the lowest viscosity that will retain an unbroken oil film between the bearing surfaces is the most suitable for purposes of lubrication. A higher viscosity than that necessary to maintain the oil film results in a waste of power due to the expenditure of energy necessary to overcome the internal friction of the oil itself.

Fig. 6 provides representative values of viscosity in centipoises for SAE mineral oils. Table 55a on page 2586 is provided as a means of converting viscosities of other units to centipoises.

Grease packed in a cavity surrounding the bushing is less adequate than an oil system, but it has the advantage of being more or less permanent. Although hydrodynamic lubrication is possible under certain very favorable circumstances, boundary lubrication is the usual state.

**Lubricant Selection.**—In selecting lubricants for journal bearing operation, several factors must be considered: 1) type of operation (full, mixed, or boundary film) anticipated; 2) surface speed; and 3) bearing loading.

Fig. 7 combines these factors and facilitates general selection of the proper lubricant viscosity range.

As an example of using these curves, consider a lightly loaded bearing operating at 2000 rpm. At the bottom of the figure, locate 2000 rpm and move vertically to intersect the light-load full-film lubrication curve, which indicates an SAE 5 oil.

As a general rule-of-thumb, heavier oils are recommended for high loads and lighter oils for high speeds.

In addition, other than using conventional lubrication oils, journal bearings may be lubricated with greases or solid lubricants. Some of the reasons for use of these lubricants are to:

- 1) Lengthen the period between relubrication;
- 2) Avoid contaminating surrounding equipment or material with "leaking" lubricating oil;
- 3) Provide effective lubrication under extreme temperature ranges;
- 4) Provide effective lubrication in the presence of contaminating atmospheres; and
- 5) Prevent intimate metal-to-metal contact under conditions of high unit pressure which might destroy boundary lubricating films.

## BEARING LUBRICANTS

Fig. 6. Viscosity vs. Temperature—SAE oils.

**Greases:** Where full-film lubrication is not possible or is impractical for slow-speed fairly high-load applications, greases are widely used as bearing lubricants. Although full-film lubrication with grease is possible, it is not normally considered since an elaborate pumping system is required to continuously supply a prescribed amount of grease to the bearing. Bearings supplied with grease are usually lubricated periodically. Grease lubrication, therefore, implies that the bearing will operate under conditions of complete boundary lubrication and should be designed accordingly.

Lubricating greases are essentially a combination of a mineral lubricating oil and a thickening agent, which is usually a metallic soap. When suitably mixed, they make excellent bearing lubricants. There are many different types of greases which, in general, may be classified according to the soap base used. Information on commonly used greases is shown in Table 3.

Fig. 7. Lubricant Selection Guide

Table 3. Commonly Used Greases and Solid Lubricants

| Type                 | Operating Temperature, Degrees F | Load     | Comments             |
|----------------------|----------------------------------|----------|----------------------|
| Greases              |                                  |          |                      |
| Calcium or lime soap | 160                              | Moderate | ...                  |
| Sodium soap          | 300                              | Wide     | For wide speed range |
| Aluminum soap        | 180                              | Moderate | ...                  |
| Lithium soap         | 300                              | Moderate | Good low temperature |
| Barium soap          | 350                              | Wide     | ...                  |
| Solid Lubricants     |                                  |          |                      |
| Graphite             | 1000                             | Wide     | ...                  |
| Molybdenum disulfide | -100 to 750                      | Wide     | ...                  |

Synthetic greases are composed of normal types of soaps but use synthetic hydrocarbons instead of normal mineral oils. They are available in a range of consistencies in both water-soluble and insoluble types. Synthetic greases can accommodate a wide range of variation in operating temperature; however, recommendations on special-purpose greases should be obtained from the lubricant manufacturer.

Application of grease is accomplished by one of several techniques depending upon grease consistency. These classifications are shown in Table 4 along with typical methods of application. Grooves for grease are generally greater in width, up to 1.5 times, than for oil.

Coefficients of friction for grease-lubricated bearings range from 0.08 to 0.16, depending upon consistency of the grease, frequency of lubrication, and type of grease. An average value of 0.12 may be used for design purposes.

*Solid Lubricants:* The need for effective high-temperature lubricants led to the development of several solid lubricants. Essentially, solid lubricants may be described as low-shear-strength solid materials. Their function within a bronze bearing is to act as an inter-

**Table 4. NLGI Consistency Numbers**

| NLGI <sup>a</sup><br>Consistency No. | Consistency<br>of Grease | Typical<br>Method of Application            |
|--------------------------------------|--------------------------|---|
| 0                                    | Semifluid                | Brush or gun                                |
| 1                                    | Very soft                | Pin-type cup or gun                         |
| 2                                    | Soft                     | Pressure gun or centralized pressure system |
| 3                                    | Light cup grease         | Pressure gun or centralized pressure system |
| 4                                    | Medium cup grease        | Pressure gun or centralized pressure system |
| 5                                    | Heavy cup grease         | Pressure gun or hand                        |
| 6                                    | Block grease             | Hand, cut to fit                            |

<sup>a</sup>NLGI is National Lubricating Grease Institute

mediary material between sliding surfaces. Since these solids have very low shear strength, they shear more readily than the bearing material and thereby allow relative motion. So long as solid lubricant remains between the moving surfaces, effective lubrication is provided and friction and wear are reduced to acceptable levels.

Solid lubricants provide the most effective boundary films in terms of reduced friction, wear, and transfer of metal from one sliding component to the other. However, there is a significant deterioration in these desirable properties as the operating temperature of the boundary film approaches the melting point of the solid film. At this temperature the friction may increase by a factor of 5 to 10 and the rate of metal transfer may increase by as much as 1000. What occurs is that the molecules of the lubricant lose their orientation to the surface that exists when the lubricant is solid. As the temperature further increases, additional deterioration sets in with the friction increasing by some additional small amount but the transfer of metal accelerates by an additional factor of 20 or more. The final effect of too high temperature is the same as metal-to-metal contact without benefit of lubricant. These changes, which are due to the physical state of the lubricant, are reversed when cooling takes place.

The effects just described also partially explain why fatty acid lubricants are superior to paraffin base lubricants. The fatty acid lubricants react chemically with the metallic surfaces to form a metallic soap that has a higher melting point than the lubricant itself, the result being that the breakdown temperature of the film, now in the form of a metallic soap is raised so that it acts more like a solid film lubricant than a fluid film lubricant.

### Journal or Sleeve Bearings

Although this type of bearing may take many shapes and forms, there are always three basic components: journal or shaft, bushing or bearing, and lubricant. Fig. 1 shows these components with the nomenclature generally used to describe a journal bearing:  $W$  = applied load,  $N$  = revolution,  $e$  = eccentricity of journal center to bearing center,  $\theta$  = attitude angle, which is the angle between the applied load and the point of minimum film thickness,  $d$  = diameter of the shaft,  $c_d$  = bearing clearance,  $d + c_d$  = diameter of the bearing and  $h_o$  = minimum film thickness.

**Grooving and Oil Feeding.**—Grooving in a journal bearing has two purposes:

- 1) to establish and maintain an efficient film of lubricant between the bearing moving surfaces and
- 2) to provide adequate bearing cooling

The obvious and only practical location for introducing lubricant to the bearing is in a region of low pressure. A typical pressure profile of a bearing is shown by Fig. 2. The arrow  $W$  shows the applied load. Typical grooving configurations used for journal bearings are shown in Figs. 3a through 3e.

Fig. 1. Basic components of a journal bearing.

Fig. 2. Typical pressure profile of journal bearing.

### Types of Journal Bearing Oil Grooving

Fig. 3a. Single inlet hole

Fig. 3b. Circular groove

Fig. 3c. Straight axial groove

Fig. 3d. Straight axial groove with feeder groove

Fig. 3e. Straight axial groove in shaft

**Heat Radiating Capacity.**—In a self-contained lubrication system for a journal bearing, the heat generated by bearing friction must be removed to prevent continued temperature rise to an unsatisfactory level. The heat-radiating capacity  $H_R$  of the bearing in foot-pounds per minute may be calculated from the formula  $H_R = Ld Ct_R$  in which  $C$  is a constant determined by O. Lasche, and  $t_R$  is temperature rise in degrees Fahrenheit.

Values for the product  $Ct_R$  may be found from the curves in Fig. 4 for various values of bearing temperature rise  $t_R$  and for three operating conditions. In this equation,  $L$  = total length of the bearing in inches and  $d$  = bearing diameter in inches.

Fig. 4. Heat-radiating capacity factor,  $C_{tR}$ , vs. bearing temperature rise,  $t_R$ —journal bearings.

**Journal Bearing Design Notation.**—The symbols used in the following step-by-step procedure for lubrication analysis and design of a plain sleeve or journal bearing are as follows:

- $c$  = specific heat of lubricant, Btu/lb/degree F
- $c_d$  = diametral clearance, inches
- $C_n$  = bearing capacity number
- $d$  = journal diameter, inches
- $e$  = eccentricity, inches
- $h_o$  = minimum film thickness, inch
- $K$  = constants
- $l$  = bearing length as defined in Fig. 5, inches
- $L$  = actual length of bearing, inches
- $m$  = clearance modulus
- $N$  = rpm
- $p_b$  = unit load, psi
- $p_s$  = oil supply pressure, psi
- $P_f$  = friction horsepower
- $P'$  = bearing pressure parameter
- $q$  = flow factor
- $Q_1$  = hydrodynamic flow, gpm
- $Q_2$  = pressure flow, gpm
- $Q$  = total flow, gpm
- $Q_{new}$  = new total flow, gpm
- $Q_R$  = total flow required, gpm

- $r$  = journal radius, inches  
 $\Delta t$  = actual temperature rise of oil in bearing, °F  
 $\Delta t_a$  = assumed temperature rise of oil in bearing, °F  
 $\Delta t_{new}$  = new assumed temperature rise of oil in bearing, °F  
 $t_b$  = bearing operating temperature, °F  
 $t_{in}$  = oil inlet temperature, °F  
 $T_f$  = friction torque, inch-pounds/inch  
 $T'$  = torque parameter  
 $W$  = load, pounds  
 $X$  = factor  
 $Z$  = viscosity, centipoises  
 $\epsilon$  = eccentricity ratio — ratio of eccentricity to radial clearance  
 $\alpha$  = oil density, lbs/inch<sup>3</sup>

Fig. 5. Length,  $l$ , of bearing for circular groove type (left) and single inlet hole type (right).

**Journal Bearing Lubrication Analysis.**—The following procedure leads to a complete lubrication analysis which forms the basis for the bearing design.

1) *Diameter of bearing  $d$* : This is usually determined by considering strength and/or deflection requirements for the shaft using principles of strength of materials.

2) *Length of bearing  $L$* : This is determined by an assumed  $l/d$  ratio in which  $l$  may or may not be equal to the overall length,  $L$  (See Step 6). Bearing pressure and the possibility of edge loading due to shaft deflection and misalignment are factors to be considered. In general, shaft misalignment resulting from location tolerances and/or shaft deflections should be maintained below 0.0003 inch per inch of length.

3) *Bearing pressure  $p_b$* : The unit load in pound per square inch is calculated from the formula:

$$p_b = \frac{W}{Kld}$$

where  $K = 1$  for single oil hole

$K = 2$  for central groove

$W$  = load, pounds

$l$  = bearing length as defined in Fig. 5, inches

$d$  = journal diameter, inches

Typical unit loads in service are shown in Table 5. These pressures can be used as a safe guide in selection. However, if space limitations impose a higher limit of loading, the complete lubrication analysis and evaluation of material properties will determine acceptability.

**Table 5. Allowable Sleeve Bearing Pressures for Various Classes of Bearings**

| Types of Bearing or Kind of Service           | Pressure <sup>a</sup><br>psi | Types of Bearing or Kind of Service | Pressure <sup>a</sup><br>psi |
|---|------------------------------|-------------------------------------|------------------------------|
| Electric Motor & Generator Bearings (General) | 100–200                      | Diesel Engine Rod                   | 1000–2000                    |
| Turbine & Reduction Gears                     | 100–250                      | Wrist Pins                          | 1800–2000                    |
| Heavy Line Shafting                           | 100–150                      | Automotive, Main Bearings           | 500–700                      |
| Locomotive Axles                              | 300–350                      | Automotive, Rod Bearings            | 1500–2500                    |
| Light Line Shafting                           | 15–35                        | Centrifugal Pumps                   | 80–100                       |
| Diesel Engine, Main                           | 800–1500                     | Aircraft Rod Bearings               | 700–3000                     |

<sup>a</sup>These pressures in pounds per square inch of area equal to length times diameter are intended as a general guide only. The allowable unit pressure depends upon operating conditions, especially in regard to lubrication, design of bearings, workmanship, velocity, and nature of load.

4) *Diametral clearance  $c_d$* : This is selected on a trial basis from Fig. 6 which shows suggested diametral clearance ranges for various shaft sizes and for two speed ranges. These are *hot* or *operating* clearances so that thermal expansion of journal and bearing to these temperatures must be taken into consideration in establishing machining dimensions. The optimum operating clearance should be determined on the basis of a complete lubrication analysis (See paragraph following Step (23)).

5) *Clearance modulus  $m$* : This is calculated from the formula:  $m = \frac{c_d}{d}$

6) *Length to diameter ratio  $l/d$* : This is usually between 1 and 2; however, with the modern trend toward higher speeds and more compact units, lower ratios down to 0.3 are used. In shorter bearings there is a consequent reduction in load carrying capacity due to excessive end or side leakage of lubricant. In longer bearings there may be a tendency towards edge loading. Length  $l$  for a single oil feed hole is taken as the total length of the bearing as shown in Fig. 5. For a central oil groove length,  $l$  is taken as one-half the total length.

Typical  $l/d$  ratio's use for various types of applications are given in Table 6.

7) *Assumed operating temperature  $t_b$* : A temperature rise of the lubricant as it passes through the bearing is assumed and the consequent operating temperature in degrees F is calculated from the formula:

$$t_b = t_{in} + \Delta t_a$$

where  $t_{in}$  = inlet temperature of oil in °F

$\Delta t_a$  = assumed temperature rise of oil in bearing in °F. An initial assumption of 20°F is usually made.

8) *Viscosity of lubricant  $Z$* : The viscosity in centipoises at the assumed bearing operating temperature is found from the curve in Fig. 6 which shows the viscosity of SAE grade oils versus temperature.

9) *Bearing pressure parameter  $P'$* : This value is required to find the eccentricity ratio and is calculated from the formula:

$$P' = \frac{6.9(1000m)^2 p_b}{ZN}$$

where  $N$  = rpm

| Type of Service   | $l/d$      | Type of Service               | $l/d$      |
|---|------------|-------------------------------|------------|
| Gasoline and diesel engine<br>main bearings and crankpins | 0.3 to 1.0 | Light shafting                | 2.5 to 3.5 |
| Generators and motors                                     | 1.2 to 2.5 | Heavy shafting                | 2.0 to 3.0 |
| Turbogenerators   | 0.8 to 1.5 | Steam engine<br>Main bearings | 1.5 to 2.5 |
| Machine tools   | 2.0 to 3.0 | Crank and wrist pins          | 1.0 to 1.3 |

10) *Eccentricity ratio*  $\epsilon$ : Using  $P'$  and  $l/d$ , the value of  $1/(1 - \epsilon)$  is determined from Fig. 7 and from this,  $\epsilon$  can be determined.

11) *Torque parameter*  $T'$ : This value is obtained from Fig. 8 or Fig. 9 using  $1/(1 - \epsilon)$  and  $l/d$ .

Fig. 7. Bearing parameter,  $P'$ , vs. eccentricity ratio,  $l/(1-\epsilon)$ —journal bearings.

12) *Friction torque*  $T$ : This value is calculated from the formula:

$$T = \frac{T' r^2 Z N}{6900(1000m)}$$

where  $r$  = journal radius, inches

13) *Friction horsepower*  $P_f$ : This value is calculated from the formula:

$$P_f = \frac{K T N l}{63,000}$$

where  $K = 1$  for single oil hole, 2 for central groove.

14) *Factor*  $X$ : This factor is used in the calculation of the lubricant flow and can either be obtained from [Table 7](#) or calculated from the formula:

$$X = 0.1837/\alpha c$$

where  $\alpha$  = oil density in pounds per cubic inch

$c$  = specific heat of lubricant in Btu/lb/°F

15) *Total flow of lubricant required*  $Q_R$ : This is calculated from the formula:

$$Q_R = \frac{X(P_f)}{\Delta t_a}$$

16) *Bearing capacity number*  $C_n$ : This value is needed to obtain the flow factor and is calculated from the formula:

$$C_n = \left(\frac{l}{d}\right)^2 / 60P'$$

17) *Flow factor*  $q$ : This value is obtained from the curve in [Fig. 10](#).

Fig. 8. Torque parameter,  $T'$ , vs. eccentricity ratio,  $1/(1-\epsilon)$  — journal bearings.

Fig. 9. Torque parameter,  $T'$ , vs. eccentricity ratio,  $1/(1-\epsilon)$  — journal bearings.

**Table 7. X Factor vs. Temperature of Mineral Oils**

| Temperature | X Factor |
|-------------|----------|
| 100         | 12.9     |
| 150         | 12.4     |
| 200         | 12.1     |
| 250         | 11.8     |
| 300         | 11.5     |

Fig. 10. Flow factor,  $q$ , vs. bearing capacity number,  $C_n$ —journal bearings.

18) *Hydrodynamic flow of lubricant  $Q_1$* : This flow in gallons per minute is calculated from the formula:

$$Q_1 = \frac{Nlc_dqd}{294}$$

19) *Pressure flow of lubricant  $Q_2$* : This flow in gallons per minute is calculated from the formula:

$$Q_2 = \frac{Kp_s c_d^3 d(1 + 1.5\epsilon^2)}{Zl}$$

where  $K = 1.64 \times 10^5$  for single oil hole

$K = 2.35 \times 10^5$  for central groove

$p_s$  = oil supply pressure

20) *Total flow of lubricant  $Q$* : This value is obtained by adding the hydrodynamic flow and the pressure flow.

$$Q = Q_1 + Q_2$$

21) *Bearing temperature rise  $\Delta t$* : This temperature rise in degrees F is obtained from the formula:

$$\Delta t = \frac{X(P_f)}{Q}$$

22) *Comparison of actual and assumed temperature rises*: At this point if  $\Delta t_a$  and  $\Delta t$  differ by more than 5 degrees F, Steps 7 through 22 are repeated using a  $\Delta t_{new}$  halfway between the former  $\Delta t_a$  and  $\Delta t$ .

23) *Minimum film thickness  $h_o$* : When Step 22 has been satisfied, the minimum film thickness in inches is calculated from the formula:  $h_o = \frac{1}{2}C_d(1 - \epsilon)$ .

A new diametral clearance  $c_d$  is now assumed and Steps 5 through 23 are repeated. When this repetition has been done for a sufficient number of values for  $c_d$ , the full lubrication study is plotted as shown in Fig. 11. From this chart a working range of diametral clearance can be determined that optimizes film thickness, differential temperature, friction horsepower and oil flow.

Fig. 11. Example of lubrication analysis curves for journal bearing.

**Use of Lubrication Analysis.**—Once the lubrication analysis has been completed and plotted as shown in Fig. 11, the following steps lead to the optimum bearing design, taking into consideration both basic operating requirements and requirements peculiar to the application.

1) Examine the curve (Fig. 11) for minimum film thickness and determine the acceptable range of diametral clearance,  $c_d$ , based on

- a) a minimum of  $200 \times 10^{-6}$  inches for small bearings under 1 inch diameter
- b) a minimum of  $500 \times 10^{-6}$  inches for bearings from 1 to 4 inches diameter
- c) a minimum of  $750 \times 10^{-6}$  inches for larger bearings.

More conservative designs would increase these requirements

2) Determine the minimum acceptable  $c_d$  based on a maximum  $\Delta t$  of 40°F from the oil temperature rise curve (Fig. 11).

3) If there are no requirements for maintaining low friction horsepower and oil flow, the possible limits of diametral clearance are now defined.

4) The required manufacturing tolerances can now be placed within this band to optimize  $h_o$  as shown by Fig. 11.

5) If oil flow and power loss are a consideration, the manufacturing tolerances may then be shifted, within the range permitted by the requirements for  $h_o$  and  $\Delta t$ .

Fig. 12. Full journal bearing example design.

*Example:* A full journal bearing, Fig. 12, 2.3 inches in diameter and 1.9 inches long is to carry a load of 6000 pounds at 4800 rpm, using SAE 30 oil supplied at 200°F through a single oil hole at 30 psi. Determine the operating characteristics of this bearing as a function of diametral clearance.

1) *Diameter of bearing*, given as 2.3 inches.

2) *Length of bearing*, given as 1.9 inches.

3) *Bearing pressure:*

$$p_b = \frac{6000}{1 \times 1.9 \times 2.3} = 1372 \text{ lbs. per sq. in.}$$

4) *Diametral clearance:* Assume  $c_d$  is equal to 0.003 inch from Fig. 6 on page 2235 for first calculation.

5) *Clearance modulus:*  $m = \frac{0.003}{2.3} = 0.0013$  inch

6) *Length-to-diameter ratio:*

$$\frac{l}{d} = \frac{1.9}{2.3} = 0.83$$

7) *Assumed operating temperature:* If the temperature rise  $\Delta t_a$  is assumed to be 20°F,

$$t_b = 200 + 20 = 220^\circ\text{F}$$

8) *Viscosity of lubricant:* From Fig. 6 on page 2228,  $Z = 7.7$  centipoises

9) *Bearing-pressure parameter:*

$$P' = \frac{6.9 \times 1.3^2 \times 1372}{7.7 \times 4800} = 0.43$$

10) *Eccentricity ratio:* From Fig. 7,  $\frac{1}{1 - \epsilon} = 6.8$  and  $\epsilon = 0.85$

11) *Torque parameter:* From Fig. 8,  $T' = 1.46$

12) *Friction torque:*

$$T_f = \frac{1.46 \times 1.15^2 \times 7.7 \times 4800}{6900 \times 1.3} = 7.96 \text{ inch-pounds per inch}$$

13) Friction horsepower:

$$P_f = \frac{1 \times 7.96 \times 4800 \times 1.9}{63,000} = 1.15 \text{ horsepower}$$

14) Factor X: From Table 7,  $X = 12$ , approximately

15) Total flow of lubricant required:

$$Q_R = \frac{12 \times 1.15}{20} = 0.69 \text{ gallon per minute}$$

16) Bearing-capacity number:

$$C_n = \frac{0.83^2}{60 \times 0.43} = 0.027$$

17) Flow factor: From Fig. 10,  $q = 1.43$

18) Actual hydrodynamic flow of lubricant:

$$Q_1 = \frac{4800 \times 1.9 \times 0.003 \times 1.43 \times 2.3}{294} = 0.306 \text{ gallon per minute}$$

19) Actual pressure flow of lubricant:

$$Q_2 = \frac{1.64 \times 10^5 \times 30 \times 0.003^3 \times 2.3 \times (1 + 1.5 \times 0.85^2)}{7.7 \times 1.9} = 0.044 \text{ gallon per min}$$

20) Actual total flow of lubricant:

$$Q = 0.306 + 0.044 = 0.350 \text{ gallon per minute}$$

21) Actual bearing-temperature rise:

$$\Delta t = \frac{12 \times 1.15}{0.350} = 39.4^\circ\text{F}$$

22) Comparison of actual and assumed temperature rises: Because  $\Delta t_a$  and  $\Delta t$  differ by more than  $5^\circ\text{F}$ , a new  $\Delta t_a$ , midway between these two, of  $30^\circ\text{F}$  is assumed and Steps 7 through 22 are repeated.

7a) Assumed operating temperature:

$$t_b = 200 + 30 = 230^\circ\text{F}$$

8a) Viscosity of lubricant: From Fig. 6,  $Z = 6.8$  centipoises

9a) Bearing-pressure parameter:

$$P' = \frac{6.9 \times 1.3^2 \times 1372}{6.8 \times 4800} = 0.49$$

10a) Eccentricity ratio: From Fig. 7,

$$\frac{1}{1 - \epsilon} = 7.4$$

and  $\epsilon = 0.86$

11a) Torque parameter: From Fig. 8,  $T' = 1.53$

12a) Friction torque:

$$T_f = \frac{1.53 \times 1.15^2 \times 6.8 \times 4800}{6900 \times 1.3} = 7.36 \text{ inch-pounds per inch}$$

13a) Friction horsepower:

$$P_f = \frac{1 \times 7.36 \times 4800 \times 1.9}{63,000} = 1.07 \text{ horsepower}$$

14a) Factor X: From Table 7,  $X = 11.9$  approximately

15a) Total flow of lubricant required:

$$Q_R = \frac{11.9 \times 1.07}{30} = 0.42 \text{ gallon per minute}$$

16a) *Bearing-capacity number:*

$$C_n = \frac{0.83^2}{60 \times 0.49} = 0.023$$

17a) *Flow factor:* From Fig. 10,  $q = 1.48$

18a) *Actual hydrodynamic flow of lubricant:*

$$Q_1 = \frac{4800 \times 1.9 \times 0.003 \times 1.48 \times 2.3}{294} = 0.317 \text{ gallon per minute}$$

19a) *Pressure flow:*

$$Q_2 = \frac{1.64 \times 10^5 \times 30 \times 0.003^3 \times 2.3 \times (1 + 1.5 \times 0.86^2)}{6.8 \times 1.9} = 0.050 \text{ gallon per minute}$$

20a) *Actual flow of lubricant:*

$$Q_{\text{new}} = 0.317 + 0.050 = 0.367 \text{ gallon per minute}$$

21a) *Actual bearing-temperature rise:*

$$\Delta t = \frac{11.9 \times 1.06}{0.367} = 34.4^\circ\text{F}$$

22a) *Comparison of actual and assumed temperature rises:* Now  $\Delta t$  and  $\Delta t_a$  are within 5 degrees F.

23) *Minimum film thickness:*

$$h_o = \frac{0.003}{2}(1 - 0.86) = 0.00021 \text{ inch}$$

This analysis may now be repeated for other values of  $c_d$  determined from Fig. 6 and a complete lubrication analysis performed and plotted as shown in Fig. 11. An operating range for  $c_d$  can then be determined to optimize minimum clearance, friction horsepower loss, lubricant flow, and temperature rise.

### Thrust Bearings

As the name implies, thrust bearings are used either to absorb axial shaft loads or to position shafts axially. Brief descriptions of the normal designs for these bearings follow with approximate design methods for each. The generally accepted load ranges for these types of bearings are given in Table 1 and the schematic configurations are shown in Fig. 1.

*The parallel or flat plate thrust bearing* is probably the most frequently used type. It is the simplest and lowest in cost of those considered; however, it is also the least capable of absorbing load, as can be seen from Table 1. It is most generally used as a positioning device where loads are either light or occasional.

*The step bearing*, like the parallel plate, is also a relatively simple design. This type of bearing will accept the normal range of thrust loads and lends itself to low-cost, high-volume production. However, this type of bearing becomes sensitive to alignment as its size increases.

*The tapered land thrust bearing*, as shown in Table 1, is capable of high load capacity. Where the step bearing is generally used for small sizes, the tapered land type can be used in larger sizes. However, it is more costly to manufacture and does require good alignment as size is increased.

*The tilting pad or Kingsbury thrust bearing* (as it is commonly referred to) is also capable of high thrust capacity. Because of its construction it is more costly, but it has the inherent advantage of being able to absorb significant amounts of misalignment.

Fig. 1. Types of thrust bearings.

**Table 1. Thrust Bearing Loads\***

| Type             | Normal Unit Loads,<br>Lb per Sq. In. | Maximum Unit Loads,<br>Lb per Sq. In. |
|------------------|--------------------------------------|---------------------------------------|
| Parallel surface | <75                                  | <150                                  |
| Step             | 200                                  | 500                                   |
| Tapered land     | 200                                  | 500                                   |
| Tilting pad      | 200                                  | 500                                   |

**Thrust Bearing Design Notation.**—The symbols used in the design procedures that follow for flat plate, step, tapered land, and tilting pad thrust bearings are as follows:

$a$  = radial width of pad, inches

$b$  = circumferential length of pad at pitch line, inches

$b_2$  = pad step length

$B$  = circumference of pitch circle, inches

$c$  = specific heat of oil, Btu/gal/°F

$D$  = diameter, inches

$e$  = depth of step, inch

$f$  = coefficient of friction

$g$  = depth of 45° chamfer, inches

$h$  = film thickness, inch

$i$  = number of pads

$J$  = power loss coefficient

$K$  = film thickness factor

$K_g$  = fraction of circumference occupied by the pads; usually, 0.8

$l$  = length of chamfer, inches

$M$  = horsepower per square inch

$N$  = revolutions per minute

$O$  = operating number

$p$  = bearing unit load, psi

$p_s$  = oil-supply pressure, psi

$P_f$  = friction horsepower

$Q$  = total flow, gpm

\* Reproduced with permission from Wilcock and Booser, *Bearing Design and Applications*, McGraw-Hill Book Co., Copyright © 1957.

- $Q_c$  = required flow per chamfer, gpm  
 $Q_c^o$  = uncorrected required flow per chamfer, gpm  
 $Q_F$  = film flow, gpm  
 $s$  = oil-groove width  
 $\Delta t$  = temperature rise, °F  
 $U$  = velocity, feet per minute  
 $V$  = effective width-to-length ratio for one pad  
 $W$  = applied load, pounds  
 $Y_G$  = oil-flow factor  
 $Y_L$  = leakage factor  
 $Y_S$  = shape factor  
 $Z$  = viscosity, centipoises  
 $\alpha$  = dimensionless film-thickness factor  
 $\delta$  = taper  
 $\xi$  = kinetic energy correction factor

*Note:* In the following, subscript 1 denotes inside diameter and subscript 2 denotes outside diameter. Subscript  $i$  denotes inlet and subscript  $o$  denotes outlet.

**Flat Plate Thrust Bearing Design.**—The following steps define the performance of a flat plate thrust bearing, one section of which is shown in Fig. 2. Although each bearing section is wedge shaped, as shown below right, for the purposes of design calculation, it is considered to be a rectangle with a length  $b$  equal to the circumferential length along the pitch line of the section being considered, and a width  $a$  equal to the difference in the external and internal radii.

*General Parameters:* a) From Table 1, the maximum unit load is between 75 and 100 pounds per square inch; and b) The outside diameter is usually between 1.5 and 2.5 times the inside diameter.

Fig. 2. Basic elements of flat plate thrust bearing.\*

Basic elements of flat plate thrust bearing.\*

- 1) *Inside diameter,  $D_1$ .* Determined by shaft size and clearance.
- 2) *Outside diameter,  $D_2$ .* Calculated by the formula

$$D_2 = \left( \frac{4W}{\pi K_g p} + D_1^2 \right)^{1/2}$$

where  $W$  = applied load, pounds

$K_g$  = fraction of circumference occupied by pads; usually, 0.8

$p$  = bearing unit load, psi

- 3) *Radial pad width,  $a$ .* Equal to one-half the difference between the inside and outside diameters.

$$a = \frac{D_2 - D_1}{2}$$

4) *Pitch line circumference, B.* Found from the pitch diameter.

$$B = \pi(D_2 - a)$$

5) *Number of pads, i.* Assume an oil groove width,  $s$ . If the length of pad is assumed to be optimum, i.e., equal to its width,

$$i_{\text{app}} = \frac{B}{a + s}$$

Take  $i$  as nearest even number.

6) *Length of pad, b.* If number of pads and oil groove width are known,

$$b = \frac{B - (i \times s)}{i}$$

7) *Actual unit load, p.* Calculated in pounds per square inch based on pad dimensions.

$$p = \frac{W}{iab}$$

8) *Pitch line velocity, U.* Found in feet per minute from

$$U = \frac{BN}{12}$$

where  $N = \text{rpm}$

9) *Friction power loss,  $P_f$ .* Friction power loss is difficult to calculate for this type of bearing because there is no theoretical method of determining the operating film thickness. However, a good approximation can be made using Fig. 3. From this curve, the value of  $M$ , horsepower loss per square inch of bearing surface, can be obtained. The total power loss,  $P_f$ , is then calculated from

$$P_f = iabM$$

10) *Oil flow required, Q.* May be estimated in gallons per minute for a given temperature rise from

$$Q = \frac{42.4P_f}{c\Delta t}$$

where  $c = \text{specific heat of oil in Btu/gal/}^\circ\text{F}$

$\Delta t = \text{temperature rise of the oil in } ^\circ\text{F}$

Note: A  $\Delta t$  of  $50^\circ\text{F}$  is an acceptable maximum.

Because there is no theoretical method of predicting the minimum film thickness in this type of bearing, only an approximation, based on experience, of the film flow can be made. For this reason and based on practical experience, it is desirable to have a minimum of one-half of the desired oil flow pass through the chamfer.

11) *Film flow,  $Q_F$ .* Calculated in gallons per minute from

$$Q_F = \frac{(1.5)(10^5)iVh^3p_s}{Z_2}$$

where  $V = \text{effective width-to-length ratio for one pad, } a/b$

$Z_2 = \text{oil viscosity at outlet temperature}$

$h = \text{film thickness}$

Note: Because  $h$  cannot be calculated, use  $h = 0.002$  inch.

12) *Required flow per chamfer,  $Q_c$ .* Readily found from the formula

## THRUST BEARINGS

Fig. 3. Friction power loss,  $M$ , vs. peripheral speed,  $U$  — thrust bearings.<sup>a</sup>

<sup>a</sup> See footnote on page 2243.

$$Q_c = \frac{Q}{i}$$

13) *Kinetic energy correction factor*,  $\xi$ . Found by assuming a chamfer length  $l$  and entering Fig. 4 with a value  $Z_2 l$  and  $Q_c$ .

14) *Uncorrected required flow per chamfer*,  $Q_c^0$ . Found from the formula

$$Q_c^0 = \frac{Q_c}{\xi}$$

15) *Depth of chamfer*,  $g$ . Found from the formula

$$g = \sqrt[4]{\frac{Q_c^0 / Z_2}{4.74 \times 10^4 p_s}}$$

*Example:* Design a flat plate thrust bearing to carry 900 pounds load at 4000 rpm using an SAE 10 oil with a specific heat of 3.5 Btu/gal/°F at 120°F and 30-psi inlet conditions. The

Fig. 4. Kinetic energy correction factor,  $\xi$ —thrust bearings.<sup>a</sup>

<sup>a</sup> See footnote on page 2243.

shaft is  $2\frac{3}{4}$  inches in diameter and the temperature rise is not to exceed 40°F. Fig. 5 shows the final design of this bearing.

1) *Inside diameter.* Assumed to be 3 inches to clear shaft.

2) *Outside diameter.* Assuming a unit bearing load of 75 pounds per square inch from Table 1,

$$D_2 = \sqrt{\frac{4 \times 900}{\pi \times 0.8 \times 75} + 3^2} = 5.30 \text{ inches}$$

Use  $5\frac{1}{2}$  inches.

3) *Radial pad width.*

$$a = \frac{5.5 - 3}{2} = 1.25 \text{ inches}$$

4) *Pitch-line circumference.*

$$B = \pi \times 4.25 = 13.35 \text{ inches}$$

5) *Number of pads.* Assume an oil groove width of  $\frac{3}{16}$  inch. If length of pad is assumed to be equal to width of pad, then

$$i_{\text{app}} = \frac{13.3}{1.25 + 0.1875} = 9+$$

If the number of pads,  $i$ , is taken as 10, then

## THRUST BEARINGS

$$6) \text{ Length of pad. } b = \frac{13.35 - (10 \times 0.1875)}{10} = 1.14 \text{ inches}$$

7) *Actual unit load.*

$$p = \frac{900}{10 \times 1.25 \times 1.14} = 63 \text{ psi}$$

8) *Pitch-line velocity.*

$$U = \frac{13.35 \times 4000}{12} = 4,430 \text{ ft per min.}$$

9) *Friction power loss.* From Fig. 3,  $M = 0.19$

$$P_f = 10 \times 1.25 \times 1.14 \times 0.19 = 2.7 \text{ horsepower}$$

10) *Oil flow required.*

$$Q = \frac{42.4 \times 2.7}{3.5 \times 40} = 0.82 \text{ gallon per minute}$$

(Assuming a temperature rise of 40°F—the maximum allowable according to the given condition—then the assumed operating temperature will be 120°F + 40°F = 160°F and the oil viscosity  $Z_2$  is found from Fig. 6 to be 9.6 centipoises.)

11) *Film flow.*

$$Q_F = \frac{1.5 \times 10^5 \times 10 \times 1 \times 0.002^3 \times 30}{9.6} = 0.038 \text{ gpm}$$

Because 0.038 gpm is a very small part of the required flow of 0.82 gpm, the bulk of the flow must be carried through the chamfers.

12) *Required flow per chamfer.* Assume that all the oil flow is to be carried through the chamfers.

$$Q_c = \frac{0.82}{10} = 0.082 \text{ gpm}$$

13) *Kinetic energy correction factor.* If  $l$ , the length of chamfer is made  $\frac{1}{8}$  inch, then  $Z_2 l = 9.6 \times \frac{1}{8} = 1.2$ . Entering Fig. 4 with this value and  $Q_c = 0.082$ ,

$$\xi = 0.44$$

14) *Uncorrected required oil flow per chamfer.*

$$Q_c^0 = \frac{0.082}{0.44} = 0.186 \text{ gpm}$$

15) *Depth of chamfer.*

$$g = 4 \sqrt[4]{\frac{0.186 \times 0.125 \times 9.6}{4.74 \times 10^4 \times 30}}$$

$$g = 0.02 \text{ inch}$$

A schematic drawing of this bearing is shown in Fig. 5.

Fig. 5. Flat plate thrust bearing example design.\*

**Step Thrust Bearing Design.**—The following steps define the performance of a step thrust bearing, one section of which is shown in Fig. 6.

Fig. 6. Basic elements of step thrust bearing.\*

Although each bearing section is wedge shaped, as shown at the right in Fig. 6, for the purposes of design calculation it is considered to be a rectangle with a length  $b$  equal to the circumferential length along the pitch line of the section being considered, and a width  $a$  equal to the difference in the external and internal radii.

*General Parameters:* For optimum proportions,  $a = b$ ,  $b_2 = 1.2b_1$ , and  $e = 0.7h$ .

1) *Internal diameter,  $D_1$ .* An internal diameter is assumed that is sufficient to clear the shaft.

2) *External diameter,  $D_2$ .* A unit bearing pressure is assumed from Table 1 and the external diameter is then found from the formula

$$D_2 = \sqrt{\frac{4W}{\pi K_g p} + D_1^2}$$

3) *Radial pad width,  $a$ .* Equal to the difference between the external and internal radii.

$$a = \frac{D_2 - D_1}{2}$$

\* See footnote on page 2243.

4) *Pitch-line circumference, B.* Found from the formula

$$B = \frac{\pi(D_1 + D_2)}{2}$$

5) *Number of pads, i.* Assume an oil groove width,  $s$  (0.062 inch may be taken as a minimum), and find the approximate number of pads, assuming the pad length is equal to  $a$ . Note that if a chamfer is found necessary to increase the oil flow (see Step 13), the oil groove width should be greater than the chamfer width.

$$i_{\text{app}} = \frac{B}{a + s}$$

Then  $i$  is taken as the nearest even number.

6) *Length of pad, b.* Readily determined from the number of pads and groove width.

$$b = \frac{B}{i} - s$$

7) *Pitch-line velocity, U.* Found in feet per minute from the formula  $U = \frac{BN}{12}$

8) *Film thickness, h.* Found in inches from the formula

$$h = \sqrt[4]{\frac{2.09 \times 10^{-9} i a^3 U Z}{W}}$$

9) *Depth of step, e.* According to the general parameter

$$e = 0.7h$$

10) *Friction power loss, P<sub>f</sub>.* Found from the formula

$$P_f = \frac{7.35 \times 10^{-13} i a^2 U^2 Z}{h}$$

11) *Pad step length, b<sub>2</sub>.* This distance, on the pitch line, from the leading edge of the pad to the step in inches is determined by the general parameters

$$b_2 = \frac{1.2b}{2.2}$$

12) *Hydrodynamic oil flow, Q.* Found in gallons per minute from the formula

$$Q = 6.65 \times 10^{-4} i a h U$$

13) *Temperature rise, Δt.* Found in degrees F from the formula

$$\Delta t = \frac{42.4 P_f}{c Q}$$

If the flow is insufficient, as indicated by too high a temperature rise, chamfers can be added to provide adequate flow as in Steps 12–15 of the flat plate thrust bearing design.

*Example:* Design a step thrust bearing for positioning a  $\frac{7}{8}$ -inch diameter shaft operating with a 25-pound thrust load and a speed of 5,000 rpm. The lubricating oil has a viscosity of 25 centipoises at the operating temperature of 160 deg. F and has a specific heat of 3.4 Btu per gal. per deg. F.

1) *Internal diameter.* Assumed to be 1 inch to clear the shaft.

2) *External diameter.* Because the example is a positioning bearing with low total load, unit load will be negligible and the external diameter is not established by using the formula given in Step 2 of the procedure, but a convenient size is taken to give the desired overall bearing proportions.

$$D_2 = 3 \text{ inches}$$

3) *Radial pad width.*

$$a = \frac{3-1}{2} = 1 \text{ inch}$$

4) *Pitch-line circumference.*

$$B = \frac{\pi(3+1)}{2} = 6.28 \text{ inches}$$

5) *Number of pads.* Assuming a minimum groove width of 0.062 inch,

$$i_{\text{app}} = \frac{6.28}{1+0.062} = 5.9$$

Take  $i = 6$ .

6) *Length of pad.*

$$b = \frac{6.28}{6} - 0.062 = 0.985$$

7) *Pitch-line velocity.*

$$U = \frac{6.28 \times 5,000}{12} = 2,620 \text{ fpm}$$

8) *Film thickness.*

$$h = \sqrt{\frac{2.09 \times 10^{-9} \times 6 \times 1^3 \times 2,620 \times 25}{25}} = 0.0057 \text{ inch}$$

9) *Depth of step.*

$$e = 0.7 \times 0.0057 = 0.004 \text{ inch}$$

10) *Power loss.*

$$P_f = \frac{7.35 \times 10^{-13} \times 6 \times 1^2 \times 2,620^2 \times 25}{0.0057} = 0.133 \text{ hp}$$

11) *Pad step length.*

$$b_2 = \frac{1.2 \times 0.985}{2.2} = 0.537 \text{ inch}$$

12) *Total hydrodynamic oil flow.*

$$Q = 6.65 \times 10^{-4} \times 6 \times 1 \times 0.0057 \times 2,620 = 0.060 \text{ gpm}$$

13) *Temperature rise.*

$$\Delta t = \frac{42.4 \times 0.133}{3.4 \times 0.060} = 28^\circ \text{ F}$$

**Tapered Land Thrust Bearing Design.**—The following steps define the performance of a tapered land thrust bearing, one section of which is shown in Fig. 7. Although each bearing section is wedge shaped, as shown in Fig. 7, right, for the purposes of design calculation, it is considered to be a rectangle with a length  $b$  equal to the circumferential length along the pitch line of the section being considered and a width  $a$  equal to the difference in the external and internal radii.

*General Parameters:* Usually, the taper extends to only 80 per cent of the pad length with the remainder being flat, thus:  $b_2 = 0.8b$  and  $b_1 = 0.2b$ .

## THRUST BEARINGS

Fig. 7. Basic elements of tapered land thrust bearing.\*

- 1) *Inside diameter,  $D_1$* . Determined by shaft size and clearance.
- 2) *Outside diameter,  $D_2$* . Calculated by the formula

$$D_2 = \left( \frac{4W}{\pi K_g P_a} + D_1^2 \right)^{1/2}$$

where  $K_g = 0.8$  or  $0.9$  and  $W =$  applied load, pounds

$P_a =$  assumed unit load from Table 1, page 2243

- 3) *Radial pad width,  $a$* . Equal to one-half the difference between the inside and outside diameters.

$$a = \frac{D_2 - D_1}{2}$$

- 4) *Pitch-line circumference,  $B$* . Found from the mean diameter:

$$B = \frac{\pi(D_1 + D_2)}{2}$$

- 5) *Number of pads,  $i$* . Assume an oil groove width,  $s$ , and find the approximate number of pads, assuming the pad length is equal to  $a$ .

$$i_{\text{app}} = \frac{B}{a + s}$$

Then  $i$  is taken as the nearest even number.

- 6) *Length of pad,  $b$* . Readily determined because the number of pads and groove width are known.

$$b = \frac{B - is}{i}$$

- 7) *Taper values,  $\delta_1$  and  $\delta_2$* . Can be taken from Table 2.

- 8) *Actual bearing unit load,  $p$* . Calculated in pounds per square inch from the formula

$$p = \frac{W}{iab}$$

- 9) *Pitch-line velocity,  $U$* . Found in feet per minute at the pitch circle from the formula

$$U = \frac{BN}{12}$$

where  $N =$  rpm

- 10) *Oil leakage factor,  $Y_L$* . Found either from Fig. 8 which shows curves for  $Y_L$  as functions of the pad width  $a$  and length of land  $b$  or from the formula

$$Y_L = \frac{b}{1 + (\pi^2 b^2 / 12 a^2)}$$

- 11) *Film thickness factor,  $K$* . Calculated using the formula

$$K = \frac{5.75 \times 10^6 p}{UY_L Z}$$

\* See footnote on page 2243.

12) *Minimum film thickness,  $h$ .* Using the value of  $K$  just determined and the selected taper values  $\delta_1$  and  $\delta_2$ ,  $h$  is found from Fig. 9. In general,  $h$  should be 0.001 inch for small bearings and 0.002 inch for larger and high-speed bearings.

13) *Friction power loss,  $P_f$ .* Using the film thickness  $h$ , the coefficient  $J$  can be obtained from Fig. 10. The friction loss in horsepower is then calculated from the formula

$$P_f = 8.79 \times 10^{-13} iabJU^2Z$$

14) *Required oil flow,  $Q$ .* May be estimated in gallons per minute for a given temperature rise  $\Delta_t$  from the formula

$$Q = \frac{42.4P_f}{c\Delta t}$$

where  $c$  = specific heat of the oil in Btu/gal/°F

Note: A  $\Delta t$  of 50°F is an acceptable maximum.

15) *Shape factor,  $Y_s$ .* Needed to compute the actual oil flow and calculated from

$$Y_s = \frac{8ab}{D_2^2 - D_1^2}$$

16) *Oil flow factor,  $Y_G$ .* Found from Fig. 11 using  $Y_s$  and  $D_1/D_2$ .

17) *Actual oil film flow,  $Q_F$ .* The amount of oil in gallons per minute that the bearing film will pass is calculated from the formula

$$Q_F = \frac{8.9 \times 10^{-4} i \delta_2 D_2^3 N Y_G Y_s^2}{D_2 - D_1}$$

18) If the flow is insufficient, the tapers can be increased or chamfers calculated to provide adequate flow, as in Steps 12–15 of the flat plate thrust bearing design procedure.

*Example:* Design a tapered land thrust bearing for 70,000 pounds at 3600 rpm. The shaft diameter is 6.5 inches. The oil inlet temperature is 110°F at 20 psi.

Fig. 8. Leakage factor,  $Y_L$ , vs. pad dimensions  $a$  and  $b$ —tapered land thrust bearings.\*

\* See footnote on page 2243.

THRUST BEARINGS

Fig. 9. Thickness,  $h$ , vs. factor  $K$ —tapered land thrust bearings.\*

Fig. 10. Power-loss coefficient,  $J$ , vs. film thickness,  $h$ —tapered land thrust bearings.\*

A maximum temperature rise of 50°F is acceptable and results in a viscosity of 18 centipoises. Use values of  $K_g = 0.9$  and  $c = 3.5$  Btu/gal/°F.

\* See footnote on page 2243.

1) *Internal diameter.* Assume  $D_1 = 7$  inches to clear shaft.

2) *External diameter.* Assume a unit bearing load  $p_a$  of 400 pounds per square inch from Table 1, then

$$D_2 = \sqrt{\frac{4 \times 70,000}{3.14 \times 0.9 \times 400}} + 7^2 = 17.2 \text{ inches}$$

Round off to 17 inches.

3) *Radial pad width.*

$$a = \frac{17 - 7}{2} = 5 \text{ inches}$$

4) *Pitch-line circumference.*

$$B = \frac{3.14(17 + 7)}{2} = 37.7 \text{ inches}$$

5) *Number of pads.* Assume groove width of 0.5 inch, then

$$i_{\text{app}} = \frac{37.7}{5 + 0.5} = 6.85$$

Take  $i = 6$ .

6) *Length of pad.*

$$b = \frac{37.7 - 6 \times 0.5}{6} = 5.78 \text{ inches}$$

Fig. 11. Oil-flow factor,  $Y_G$ , vs. diameter ratio  $D_1/D_2$ —tapered land bearings.\*

7) *Taper values.* Interpolate in Table 2 to obtain

$$\delta_1 = 0.008 \text{ inch} \quad \text{and} \quad \delta_2 = 0.005 \text{ inch}$$

8) *Actual bearing unit load.*

$$p = \frac{70,000}{6 \times 5 \times 5.78} = 404 \text{ psi}$$

\* See footnote on page 2243.

9) *Pitch-line velocity.*

$$U = \frac{37.7 \times 3600}{12} = 11,300 \text{ ft per min}$$

10) *Oil leakage factor.*

$$\text{From Fig. 8, } Y_L = 2.75$$

11) *Film-thickness factor.*

$$K = \frac{5.75 \times 10^6 \times 404}{11,300 \times 2.75 \times 18} = 4150$$

12) *Minimum film thickness.*

$$\text{From Fig. 9, } h = 2.2 \text{ mils}$$

13) *Friction power loss.* From Fig. 10,  $J = 260$ , then

$$P_f = 8.79 \times 10^{-13} \times 6 \times 5 \times 5.78 \times 260 \times 11,300^2 \times 18 = 91 \text{ hp}$$

14) *Required oil flow.*

$$Q = \frac{42.4 \times 91}{3.5 \times 50} = 22.0 \text{ gpm}$$

See footnote on page 2243.

15) *Shape factor.*

$$Y_S = \frac{8 \times 5 \times 5.78}{17^2 - 7^2} = 0.963$$

16) *Oil-flow factor.*

$$\text{From Fig. 11, } Y_G = 0.61$$

where  $D_1/D_2 = 0.41$

17) *Actual oil film flow.*

$$Q_F = \frac{8.9 \times 10^{-4} \times 6 \times 0.005 \times 17^3 \times 3600 \times 0.61 \times 0.963^2}{17 - 7} = 26.7 \text{ gpm}$$

Because calculated film flow exceeds required oil flow, chamfers are not necessary. However, if film flow were less than required, suitable chamfers would be needed.

**Table 2. Taper Values for Tapered Land Thrust Bearings**

| Pad Dimensions, Inches           | Taper, Inch                    |                                |
|----------------------------------|--------------------------------|--------------------------------|
|                                  | $\delta_1 = h_2 - h_1$ (at ID) | $\delta_2 = h_2 - h_1$ (at OD) |
| $\frac{1}{2} \times \frac{1}{2}$ | 0.0025                         | 0.0015                         |
| $1 \times 1$                     | 0.005                          | 0.003                          |
| $3 \times 3$                     | 0.007                          | 0.004                          |
| $7 \times 7$                     | 0.009                          | 0.006                          |

**Tilting Pad Thrust Bearing Design.**—The following steps define the performance of a tilting pad thrust bearing, one section of which is shown in Fig. 12. Although each bearing section is wedge shaped, as shown at the right below, for the purposes of design calculation, it is considered to be a rectangle with a length  $b$  equal to the circumferential length along the pitch line of the section being considered and a width  $a$  equal to the difference in the external and internal radii, as shown at left in Fig. 12. The location of the pivot shown in Fig. 12 is optimum. If shaft rotation in both directions is required, however, the pivot must be at the midpoint, which results in little or no detrimental effect on the performance.

Fig. 12. Basic elements of tilting pad thrust bearing.\*

- 1) *Inside diameter,  $D_1$* . Determined by shaft size and clearance.
- 2) *Outside diameter,  $D_2$* . Calculated from the formula

$$D_2 = \left( \frac{4W}{\pi K_g p} + D_1^2 \right)^{1/2}$$

where  $W$  = applied load, pounds

$$K_g = 0.8$$

$p$  = unit load from Table 1

- 3) *Radial pad width,  $a$* . Equal to one-half the difference between the inside and outside diameters:

$$a = \frac{D_2 - D_1}{2}$$

- 4) *Pitch-line circumference,  $B$* . Found from the mean diameter:

$$B = \pi \left( \frac{D_1 + D_2}{2} \right)$$

- 5) *Number of pads,  $i$* . The number of pads may be estimated from the formula

$$i = \frac{BK_g}{a}$$

Select the nearest even number.

- 6) *Length of pad,  $b$* . Found from the formula

$$b \cong \frac{BK_g}{i}$$

- 7) *Pitch-line velocity,  $U$* . Calculated in feet per minute from the formula

$$U = \frac{BN}{12}$$

- 8) *Bearing unit load,  $p$* . Calculated from the formula

$$p = \frac{W}{iab}$$

- 9) *Operating number,  $O$* . Calculated from the formula

$$O = \frac{1.45 \times 10^{-7} Z_2 U}{5pb}$$

10) where  $Z_2$  = viscosity of oil at outlet temperature (inlet temperature plus assumed temperature rise through the bearing).

\* See footnote on page 2243.

11) *Minimum film thickness,  $h_{\min}$* . By using the operating number, the value of  $\alpha$  = dimensionless film thickness is found from Fig. 13. Then the actual minimum film thickness is calculated from the formula:

$$h_{\min} = \alpha b$$

In general, this value should be 0.001 inch for small bearings and 0.002 inch for larger and high-speed bearings.

12) *Coefficient of friction,  $f$* . Found from Fig. 14.

13) *Friction power loss,  $P_f$* . This horsepower loss now is calculated by the formula

$$P_f = \frac{fWU}{33,000}$$

14) *Actual oil flow,  $Q$* . This flow over the pad in gallons per minute is calculated from the formula

$$Q = 0.0591 \alpha i a b U$$

15) *Temperature rise,  $\Delta t$* . Found from the formula

$$\Delta t = 0.0217 \frac{f p}{\alpha c}$$

where  $c$  = specific heat of oil in Btu/gal/°F

If the flow is insufficient, as indicated by too high a temperature rise, chamfers can be added to provide adequate flow, as in Steps 12–15 of the flat plate thrust bearing design.

*Example:* Design a tilting pad thrust bearing for 70,000 pounds thrust at 3600 rpm. The shaft diameter is 6.5 inches and a maximum OD of 15 inches is available. The oil inlet temperature is 110°F and the supply pressure is 20 pounds per square inch. A maximum temperature rise of 50°F is acceptable and results in a viscosity of 18 centipoises. Use a value of 3.5 Btu/gal/°F for  $c$ .

1) *Inside diameter*. Assume  $D_1 = 7$  inches to clear shaft.

2) *Outside diameter*. Given maximum  $D_2 = 15$  inches.

3) *Radial pad width*.

$$a = \frac{15 - 7}{2} = 4 \text{ inches}$$

4) *Pitch-line circumference*.

$$B = \pi \left( \frac{7 + 15}{2} \right) = 34.6 \text{ inches}$$

5) *Number of pads*.

$$i = \frac{34.6 \times 0.8}{4} = 6.9$$

Select 6 pads:  $i = 6$ .

6) *Length of pad*.

$$b = \frac{34.6 \times 0.8}{6} = 4.61 \text{ inches}$$

Make  $b = 4.75$  inches.

7) *Pitch-line velocity*.

$$U = \frac{34.6 \times 3600}{12} = 10,400 \text{ ft/min}$$

8) *Bearing unit load*.

$$p = \frac{70,000}{6 \times 4 \times 4.75} = 614 \text{ psi}$$

Fig. 13. Dimensionless minimum film thickness,  $\alpha$ , vs. operating number,  $O$ —tilting pad thrust bearings.\*

Fig. 14. Coefficient of friction  $f$  vs. dimensionless film thickness  $\alpha$  for tilting pad thrust bearings with optimum pivot location.\*

\* See footnote on page 2243.

9) *Operating number.*

$$O = \frac{1.45 \times 10^{-7} \times 18 \times 10,400}{5 \times 614 \times 4.75} = 1.86 \times 10^{-6}$$

10) *Minimum film thickness.* From Fig. 13,  $\alpha = 0.30 \times 10^{-3}$ .

$$h_{\min} = 0.00030 \times 4.75 = 0.0014 \text{ inch}$$

11) *Coefficient of friction.* From Fig. 14,  $f = 0.0036$ .

12) *Friction power loss.*

$$P_f = \frac{0.0036 \times 70,000 \times 10,400}{33,000} = 79.4 \text{ hp}$$

13) *Oil flow.*

$$Q = 0.0591 \times 6 \times 0.30 \times 10^{-3} \times 4 \times 4.75 \times 10,400 = 21.02 \text{ gpm}$$

14) *Temperature rise.*

$$\Delta t = \frac{0.0217 \times 0.0036 \times 614}{0.30 \times 10^{-3} \times 3.5} = 45.7^\circ \text{F}$$

Because this temperature is less than the 50°F, which is considered as the acceptable maximum, the design is satisfactory.

### Plain Bearing Materials

Materials used for sliding bearings cover a wide range of metals and nonmetals. To make the optimum selection requires a complete analysis of the specific application. The important general categories are: Babbitts, alkali-hardened lead, cadmium alloys, copper lead, aluminum bronze, silver, sintered metals, plastics, wood, rubber, and carbon graphite.

**Properties of Bearing Materials.**—For a material to be used as a plain bearing, it must possess certain physical and chemical properties that permit it to operate properly. If a material does not possess all of these characteristics to some degree, it will not function long as a bearing. It should be noted, however, that few, if any, materials are outstanding in all these characteristics. Therefore, the selection of the optimum bearing material for a given application is at best a compromise to secure the most desirable combination of properties required for that particular usage.

The seven properties generally acknowledged to be the most significant are: 1) Fatigue resistance; 2) Embeddability; 3) Compatibility; 4) Conformability; 5) Thermal conductivity; 6) Corrosion resistance; and 7) Load capacity.

These properties are described as follows:

1) *Fatigue resistance* is the ability of the bearing lining material to withstand repeated applications of stress and strain without cracking, flaking, or being destroyed by some other means.

2) *Embeddability* is the ability of the bearing lining material to absorb or embed within itself any of the larger of the small dirt particles present in a lubrication system. Poor embeddability permits particles circulating around the bearing to score both the bearing surface and the journal or shaft. Good embeddability will permit these particles to be trapped and forced into the bearing surface and out of the way where they can do no harm.

3) *Compatibility or antiscoring tendencies* permit the shaft and bearing to “get along” with each other. It is the ability to resist galling or seizing under conditions of metal-to-metal contact such as at startup. This characteristic is most truly a bearing property, because contact between the bearing and shaft in good designs occurs only at startup.

4) *Conformability* is defined as malleability or as the ability of the bearing material to creep or flow slightly under load, as in the initial stages of running, to permit the shaft and bearing contours to conform with each other or to compensate for nonuniform loading caused by misalignment.

**Table 3. Bearing and Bushing Alloys—Composition, Forms, Characteristics, and Applications SAE General Information**

| SAE No. and Alloy Grouping |     | Nominal Composition, Per cent          | Form of Use (1), Characteristics (2), and Applications (3)   |
|----------------------------|-----|--|--|
| Sn-Base Alloys             | 11  | Sn, 87.5; Sb, 6.75; Cu, 5.75           | (1) Cast on steel, bronze, or brass backs, or directly in the bearing housing. (2) Soft, corrosion-resistant with moderate fatigue resistance. (3) Main and connecting-rod bearings; motor bushings. Operates with either hard or soft journal.  |
|                            | 12  | Sn, 89; Sb, 7.5; Cu, 3.5               |  |
| Pb-Base Alloys             | 13  | Pb, 84; Sb, 10; Sn, 6                  | (1) SAE 13 and 14 are cast on steel, bronze, or brass, or in the bearing housing; SAE 15 is cast on steel; and SAE 16 is cast into and on a porous sintered matrix, usually copper-nickel bonded to steel. (2) Soft, moderately fatigue-resistant, corrosion-resistant. (3) Main and connecting-rod bearings. Operates with hard or soft journal with good finish.   |
|                            | 14  | Pb, 75; Sb, 15; Sn, 10                 |  |
|                            | 15  | Pb, 83; Sb, 15; Sn, 14; As, 1          |  |
| Pb-Sn Overlays             | 16  | Pb, 92; Sb, 3.5; Sn, 4.5               | (1) Electrodeposited as a thin layer on copper-lead or silver bearings faces. (2) Soft, corrosion-resistant. Bearings so coated run satisfactorily on soft shafts throughout the life of the coating. (3) Heavy-duty, high-speed main and connecting-rod bearings.   |
|                            | 19  | Pb, 90; Sn, 10                         |  |
| Cu-Pb Alloys               | 190 | Pb, 93; Sn, 7                          | (1) Cast or sintered on steel back with the exception of SAE 481, which is cast on steel back only. (2) Moderately hard. Somewhat subject to oil corrosion. Some oils minimize this; protection with overlay may be desirable. Fatigue resistance good to fairly good. Listed in order of decreasing hardness and fatigue resistance. (3) Main and connecting-rod bearings. The higher lead alloys can be used unplated against a soft shaft, although an overlay is helpful. The lower lead alloys may be used against a hard shaft, or with an overlay against a soft one. |
|                            | 49  | Cu, 76; Pb, 24                         |  |
|                            | 48  | Cu, 70; Pb, 30                         |  |
|                            | 480 | Cu, 65; Pb, 35                         |  |
| Cu-Pb-Sn-Alloys            | 481 | Cu, 60; Pb, 40                         | (1) Steel-backed and lined with a structure combining sintered copper alloy matrix with corrosion-resistant lead alloy. (2) Moderately hard. Corrosion resistance improved over copper-leads of equal lead content without tin. Fatigue resistance fairly good. Listed in order of decreasing hardness and fatigue resistance. (3) Main and connecting-rod bearings. Generally used without overlay. SAE 484 and 485 may be used with hard or soft shaft, and a hardened or cast shaft is recommended for SAE 482.   |
|                            | 482 | Cu, 67; Pb, 28; Sn, 5                  |  |
|                            | 484 | Cu, 55; Pb, 42; Sn, 3                  |  |
| Al-Base Alloys             | 485 | Cu, 46; Pb, 51; Sn, 3                  | (1) SAE 770 cast in permanent molds; work-hardened to improve physical properties. SAE 780 and 782 usually bonded to steel back but is procurable in strip form without steel backing. SAE 781 usually bonded to steel back but can be produced as castings or wrought strip without steel back. (2) Hard, extremely fatigue-resistant, resistant to oil corrosion. (3) Main and connecting-rod bearings. Generally used with suitable overlay. SAE 781 and 782 also used for bushings and thrust bearings with or without overlay.  |
|                            | 770 | Al, 91.75; Sn, 6.25; Cu, 1; Ni, 1      |  |
|                            | 780 | Al, 91; Sn, 6; Si, 1.5; Cu, 1; Ni, 0.5 |  |
|                            | 781 | Al, 95; Si, 4; Cd, 1                   |  |
| Other Cu-Base Alloys       | 782 | Al, 95; Cu, 1; Ni, 1; Cd, 3            | (1) Wrought solid bronze, (2) Hard, strong, good fatigue resistance, (3) Intermediate-load oscillating motion such as tie-rods and brake shafts.   |
|                            | 795 | Cu, 90; Zn, 9.5; Sn, 0.5               |  |
|                            | 791 | Cu, 88; Zn, 4; Sn, 4; Pb, 4            |  |
|                            | 793 | Cu, 84; Pb, 8; Sn, 4; Zn, 4            |  |
| Other Cu-Base Alloys       | 798 | Cu, 84; Pb, 8; Sn, 4; Zn, 4            | (1) SAE 791, wrought solid bronze; SAE 793, cast on steel back; SAE 798, sintered on steel back. (2) General-purpose bearing material, good shock and load capacity. Resistant to high temperatures. Hard shaft desirable. Less score-resistant than higher lead alloys. (3) Medium to high loads. Transmission bushings and thrust washers. SAE 791 also used for piston pin and 793 and 798 for chassis bushings.  |
|                            | 792 | Cu, 80; Sn, 10; Pb, 10                 |  |
|                            | 797 | Cu, 80; Sn, 10; Pb, 10                 |  |
|                            | 794 | Cu, 73.5; Pb, 23; Sn, 3.5              |  |
| Other Cu-Base Alloys       | 799 | Cu, 73.5; Pb, 23; Sn, 3.5              | (1) SAE 794, cast on steel back; SAE 799, sintered on steel back. (2) Higher lead content gives improved surface action for higher speeds but results in somewhat less corrosion resistance. (3) Intermediate load application for both oscillating and rotating shafts, that is, rocker-arm bushings, transmissions, and farm implements.   |
|                            | 799 | Cu, 73.5; Pb, 23; Sn, 3.5              |  |

5) *High thermal conductivity* is required to absorb and carry away the heat generated in the bearing. This conductivity is most important, not in removing frictional heat generated in the oil film, but in preventing seizures due to hot spots caused by local asperity breakthroughs or foreign particles.

6) *Corrosion resistance* is required to resist attack by organic acids that are sometimes formed in oils at operating conditions.

7) *Load capacity or strength* is the ability of the material to withstand the hydrodynamic pressures exerted upon it during operation.

**Babbitt or White Metal Alloys.**—Many different bearing metal compositions are referred to as babbitt metals. The exact composition of the original babbitt metal is not known; however, the ingredients were probably tin, copper, and antimony in approximately the following percentages: 89.3, 3.6, and 7.1. Tin and lead-base babbitts are probably the best known of all bearing materials. With their excellent embeddability and compatibility characteristics under boundary lubrication, babbitt bearings are used in a wide range of applications including household appliances, automobile and diesel engines, railroad cars, electric motors, generators, steam and gas turbines, and industrial and marine gear units.

**Table 4. White Metal Bearing Alloys—Composition and Properties**  
*ASTM B23-83, reapproved 1988*

| ASTM Alloy <sup>a</sup> Number | Nominal Composition, Per Cent |      |      |      | Compressive Yield Point, <sup>b</sup> psi |        | Ultimate Compressive Strength, <sup>c</sup> psi |        | Brinell Hardness <sup>d</sup> |        | Melting Point °F | Proper Pouring Temperature, °F |
|--------------------------------|-------------------------------|------|------|------|---|--------|---|--------|-------------------------------|--------|------------------|--------------------------------|
|                                | Sn                            | Sb   | Pb   | Cu   | 68 °F                                     | 212 °F | 68 °F   | 212 °F | 68 °F                         | 212 °F |                  |                                |
| 1                              | 91.0                          | 4.5  | ...  | 4.5  | 4400                                      | 2650   | 12,850  | 6950   | 17.0                          | 8.0    | 433              | 825                            |
| 2                              | 89.0                          | 7.5  | ...  | 3.5  | 6100                                      | 3000   | 14,900  | 8700   | 24.5                          | 12.0   | 466              | 795                            |

| 19                             | 5.0                           | 9.0  | 86.0 | ...  | ...                                       | ...    | 15,600  | 6100   | 17.7                          | 8.0    | 462              | 620                            |

<sup>a</sup> Data for ASTM alloys 1, 2, 3, 7, 8, and 15 appear in the Appendix of ASTM B23-83; the data for alloys 4, 5, 6, 10, 11, 12, 16, and 19 are given in ASTM B23-49. All values are for reference purposes only.

<sup>b</sup> The values for yield point were taken from stress-strain curves at the deformation of 0.125 per cent reduction of gage.

<sup>c</sup> The ultimate strength values were taken as the unit load necessary to produce a deformation of 25 per cent of the length of the specimen.

<sup>d</sup> These values are the average Brinell number of three impressions on each alloy using a 10-mm ball and a 500-kg load applied for 30 seconds.

<sup>e</sup> Also nominal arsenic, 0.45 per cent.

<sup>f</sup> Also nominal arsenic, 1 per cent.

The compression test specimens were cylinders 1.5 inches in length and 0.5 inch in diameter, machined from chill castings 2 inches in length and 0.75 inch in diameter. The Brinell tests were made on the bottom face of parallel machined specimens cast in a 2-inch diameter by 0.625-inch deep steel mold at room temperature.

Both the Society of Automotive Engineers and American Society for Testing and Materials have classified white metal bearing alloys. [Tables 3 and 4](#) give compositions and properties or characteristics for the two classifications.

In small bushings for fractional-horsepower motors and in automotive engine bearings, the babbitt is generally used as a thin coating over a flat steel strip. After forming oil distribution grooves and drilling required holes, the strip is cut to size, then rolled and shaped into the finished bearing. These bearings are available for shaft diameters from 0.5 to 5 inches. Strip bearings are turned out by the millions yearly in highly automated factories and offer an excellent combination of low cost with good bearing properties.

For larger bearings in heavy-duty equipment, a thicker babbitt is cast on a rigid backing of steel or cast iron. Chemical and electrolytic cleaning of the bearing shell, thorough rinsing, tinning, and then centrifugal casting of the babbitt are desirable for sound bonding of the babbitt to the bearing shell. After machining, the babbitt layer is usually  $\frac{1}{2}$  to  $\frac{1}{4}$  inch thick.

Compared to other bearing materials, babbitts generally have lower load-carrying capacity and fatigue strength, are a little higher in cost, and require a more complicated design. Also, their strength decreases rapidly with increasing temperature. These shortcomings can be avoided by using an intermediate layer of high-strength, fatigue-resistant material that is placed between a steel backing and a thin babbitt surface layer. Such composite bearings frequently eliminate any need for using alternate materials having poorer bearing characteristics.

Tin babbitt is composed of 80 to 90 per cent tin to which is added about 3 to 8 per cent copper and 4 to 14 per cent antimony. An increase in copper or antimony produces increased hardness and tensile strength with decreased ductility. However, if the percentages of these alloys are increased above those shown in [Table 4](#), the resulting alloy will have decreased fatigue resistance. These alloys have very little tendency to cause wear to their journals because of their ability to embed dirt. They resist the corrosive effects of acids, are not prone to oil-film failure, and are easily bonded and cast. Two drawbacks are encountered from use of these alloys because they have low fatigue resistance and their hardness and strength drop appreciably at low temperatures.

Lead babbitt compositions generally range from 10 to 15 per cent antimony and up to 10 per cent tin in combination with the lead. Like tin-base babbitts, these alloys have little tendency to cause wear to their journals, embed dirt well, resist the corrosive effects of acids, are not prone to oil-film failure and are easily bonded and cast. Their chief disadvantages when compared with tin-base alloys are a rather lower strength and a susceptibility to corrosion.

**Cadmium Base.**—Cadmium alloy bearings have a greater resistance to fatigue than babbitt bearings, but their use is very limited due to their poor corrosion resistance. These alloys contain 1 to 15 per cent nickel, or 0.4 to 0.75 per cent copper, and 0.5 to 2.0 per cent silver. Their prime attribute is their high-temperature capability. The load-carrying capacity and relative basic bearing properties are shown in [Table 5](#).

**Copper-Lead.**—Copper-lead bearings are a binary mixture of copper and lead containing from 20 to 40 per cent lead. Lead is practically insoluble in copper, so a cast microstructure consists of lead pockets in a copper matrix. A steel backing is commonly used with this material and high volume is achieved either by continuous casting or by powder metallurgy techniques. This material is very often used with an overplate such as lead-tin and lead-tin-copper to increase basic bearing properties. [Table 5](#) provides comparisons of material properties.

The combination of good fatigue strength, high-load capacity, and high-temperature performance has resulted in extensive use of this material for heavy-duty main and connecting-rod bearings as well as moderate-load and speed applications in turbines and electric motors.

**Table 5. Properties of Bearing Alloys and Bearing Characteristics Ratings**

| Material           | Recommended Shaft Hardness, Brinell | Load-Carrying Capacity, psi | Maximum Operating Temp., °F | Compatibility <sup>a</sup> | Conformability and Embeddability <sup>a</sup> | Corrosion Resistance <sup>a</sup> | Fatigue Strength <sup>a</sup> |
|--------------------|-------------------------------------|-----------------------------|-----------------------------|----------------------------|---|-----------------------------------|-------------------------------|
| Tin-Base Babbitt   | 150 or less                         | 800 – 1500                  | 300                         | 1                          | 1   | 1                                 | 5                             |
| Lead-Base Babbitt  | 150 or less                         | 800 – 1200                  | 300                         | 1                          | 1   | 3                                 | 5                             |
| Cadmium Base       | 200 – 250                           | 1200 – 2000                 | 500                         | 1                          | 2   | 5                                 | 4                             |
| Copper-Lead        | 300                                 | 1500 – 2500                 | 350                         | 2                          | 2   | 5                                 | 3                             |
| Tin-Bronze         | 300 – 400                           | 4000+                       | 500+                        | 3                          | 5   | 2                                 | 1                             |
| Lead-Bronze        | 300                                 | 3000 – 4500                 | 450 – 500                   | 3                          | 4   | 4                                 | 2                             |
| Aluminum           | 300                                 | 4000+                       | 225 – 300                   | 5                          | 3   | 1                                 | 2                             |
| Silver-Overplate   | 300                                 | 4000+                       | 500                         | 2                          | 3   | 1                                 | 1                             |
| Trimetal-Overplate | 230 or less                         | 2000 – 4000+                | 225 – 300                   | 1                          | 2   | 2                                 | 3                             |

<sup>a</sup>Note: 1 is best; 5 is worst.

**Leaded Bronze and Tin-Bronze.**—Leaded and tin-bronzes contain up to 25 per cent lead or approximately 10 per cent tin, respectively. Cast leaded bronze bearings offer good compatibility, excellent casting, and easy machining characteristics, low cost, good structural properties and high-load capacity, usefulness as a single material that requires neither a separate overlay nor a steel backing. Bronzes are available in standard bar stock, sand or permanent molds, investment, centrifugal or continuous casting. Leaded bronzes have better compatibility than tin-bronzes because the spheroids of lead smear over the bearing surface under conditions of inadequate lubrication. These alloys are generally a first choice at intermediate loads and speeds. Table 5 provides comparisons of basic bearing properties of these materials.

**Aluminum.**—Aluminum bearings are either cast solid aluminum, aluminum with a steel backing, or aluminum with a suitable overlay. The aluminum is usually alloyed with small amounts of tin, silicon, cadmium, nickel, or copper, as shown in Table 3. An aluminum bearing alloy with 20 to 30 per cent tin alloy and up to 3 per cent copper has shown promise as a substitute for bronzes in some industrial applications.

These bearings are best suited for operation with hard journals. Owing to the high thermal expansion of the metal (resulting in diametral contraction when it is confined as a bearing in a rigid housing), large clearances are required, which tend to make the bearing noisy, especially on starting. Overlays of lead-tin, lead, or lead-tin-copper may be applied to aluminum bearings to facilitate their use with soft shafts.

Aluminum alloys are available with properties specifically designed for bearing applications, such as high load-carrying capacity, fatigue strength, and thermal conductivity, in addition to excellent corrosion resistance and low cost.

**Silver.**—Silver bearings were developed for and have an excellent record in heavy-duty applications such as aircraft master rod and diesel engine main bearings. Silver has a higher fatigue rating than any of the other bearing materials; the steel backing used with this material may show evidence of fatigue before the silver. The advent of overlays, or more commonly called overplates, made it possible for silver to be used as a bearing material. Silver by itself does not possess any of the desirable bearing qualities except high fatigue resistance and high thermal conductivity. The overlays such as lead, lead-tin, or lead-indium improve the embeddability and antiscoring properties of silver. The relative basic properties of this material, when used as an overplate, are shown in Table 5.

**Cast Iron.**—Cast iron is an inexpensive bearing material capable of operation at light loads and low speeds, i.e., up to 130 ft/min and 150 lb/in.<sup>2</sup> These bearings must be well

lubricated and have a rather large clearance so as to avoid scoring from particles torn from the cast iron that ride between bearing and journal. A journal hardness of between 150 and 250 Brinell has been found to be best when using cast-iron bearings.

**Porous Metals.**—Porous metal self-lubricating bearings are usually made by sintering metals such as plain or leaded bronze, iron, and stainless steel. The sintering produces a spongelike structure capable of absorbing fairly large quantities of oil, usually 10–35 per cent of the total volume. These bearings are used where lubrication supply is difficult, inadequate, or infrequent. This type of bearing should be flooded from time to time to resaturate the material. Another use of these porous materials is to meter a small quantity of oil to the bearings such as in drip feed systems. The general design operating characteristics of this class of materials are shown in [Table 6](#).

**Table 6. Application Limits — Sintered Metal and Nonmetallic Bearings**

| Bearing Material      | Load Capacity (psi) | Maximum Temperature (°F) | Surface Speed, $V_{max}$ (max. fpm) | PV Limit $P = \text{psi load}$<br>$V = \text{surface ft/min}$ |
|-----------------------|---------------------|--------------------------|-------------------------------------|---|
| Acetal                | 1000                | 180                      | 1000                                | 3000  |
| Graphite (dry)        | 600                 | 750                      | 2500                                | 15,000  |
| Graphite (lubricated) | 600                 | 750                      | 2500                                | 150,000   |

| Porous metals         | 4000–8000           | 150                      | 1500                                | 50,000  |
| Virgin Teflon (TFE)   | 500                 | 500                      | 50                                  | 1000  |
| Reinforced Teflon     | 2500                | 500                      | 1000                                | 10,000–15,000   |
| TFE fabric            | 60,000              | 500                      | 150                                 | 25,000  |
| Rubber                | 50                  | 150                      | 4000                                | 15,000  |
| Maple & Lignum Vitae  | 2000                | 150                      | 2000                                | 15,000  |

[Tables 7](#), [8](#), and [9](#) give the chemical compositions, permissible loads, interference fits, and running clearances of bronze-base and iron-base metal-powder sintered bearings that are specified in the ASTM specifications for oil-impregnated metal-powder sintered bearings (B438-83a and B439-83).

**Plastics Bearings.**—Plastics are finding increased use as bearing materials because of their resistance to corrosion, quiet operation, ability to be molded into many configurations, and their excellent compatibility, which minimizes or eliminates the need for lubrication. Many plastics are capable of operating as bearings, especially phenolic, tetrafluoroethylene (TFE), and polyamide (nylon) resins. The general application limits for these materials are shown in [Table 6](#).

*Laminated Phenolics:* These composite materials consist of cotton fabric, asbestos, or other fillers bonded with phenolic resin. They have excellent compatibility with various fluids as well as strength and shock resistance. However, precautions must be taken to maintain adequate bearing cooling because the thermal conductivity of these materials is low.

*Nylon:* This material has the widest use for small, lightly loaded applications. It has low frictional properties and requires no lubrication.

*Teflon:* This material, with its exceptional low coefficient of friction, self-lubricating characteristics, resistance to attack by almost any chemicals, and its wide temperature

range, is one of the most interesting of the plastics for bearing use. High cost combined with low load capacity cause Teflon to be selected mostly in modified form, where other less expensive materials have proved inadequate for design requirements.

Bearings made of laminated phenolics, nylon, or Teflon are all unaffected by acids and alkalis except if highly concentrated and therefore can be used with lubricants containing dilute acids or alkalis. Water is used to lubricate most phenolic laminate bearings but oil, grease, and emulsions of grease and water are also used. Water and oil are used as lubricants for nylon and Teflon bearings. Almost all types of plastic bearings absorb water and oil to some extent. In some the dimensional change caused by the absorption may be as much as three per cent in one direction. This means that bearings have to be treated before use so that proper clearances will be kept. This may be done by boiling in water, for water lubricated bearings. Boiling in water makes bearings swell the maximum amount. Clearances for phenolic bearings are kept at about 0.001 inch per inch of diameter on treated bearings. Partially lubricated or dry nylon bearings are given a clearance of 0.004 to 0.006 inches for a one-inch diameter bearing.

*Rubber:* Rubber bearings give excellent performance on propeller shafts and rudders of ships, hydraulic turbines, pumps, sand and gravel washers, dredges and other industrial equipment that handle water or slurries. The resilience of rubber helps to isolate vibration and provide quiet operation, allows running with relatively large clearances and helps to compensate for misalignment. In these bearings a fluted rubber structure is supported by a metal shell. The flutes or scallops in the rubber form a series of grooves through which lubricant or, as generally used, water and foreign material such as sand may pass through the bearing.

**Wood.**—Bearings made from such woods as lignum vitae, rock maple, or oak offer self-lubricating properties, low cost, and clean operation. However, they have frequently been displaced in recent years by various plastics, rubber and sintered-metal bearings. General applications are shown in [Table 6](#).

**Carbon-Graphite.**—Bearings of molded and machined carbon-graphite are used where regular maintenance and lubrication cannot be given. They are dimensionally stable over a wide range of temperatures, may be lubricated if desired, and are not affected by chemicals. These bearings may be used up to temperatures of 700 to 750 degrees F. in air or 1200 degrees F. in a non-oxidizing atmosphere, and generally are operated at a maximum load of 20 pounds per square inch. In some instances a metal or metal alloy is added to the carbon-graphite composition to improve such properties as compressive strength and density. The temperature limitation depends upon the melting point of the metal or alloy and the maximum load is generally 350 pounds per square inch when used with no lubrication or 600 pounds per square inch when used with lubrication.

Normal running clearances for both types of carbon-graphite bearings used with steel shafts and operating at a temperature of less than 200 degrees F. are as follows: 0.001 inch for bearings of 0.187 to 0.500-inch inside diameter, 0.002 inch for bearings of 0.501 to 1.000-inch inside diameter, 0.003 inch for bearings of 1.001 to 1.250-inch inside diameter, 0.004 inch for bearings of 1.251 to 1.500-inch diameter, and 0.005 inch for bearings of 1.501 to 2.000-inch inside diameter. Speeds depend upon too many variables to list specifically so it can only be stated here that high loads require a low number of rpm and low loads permit a high number of rpm. Smooth journals are necessary in these bearings as rough ones tend to abrade the bearings quickly. Cast iron and hard chromium-plate steel shafts of 400 Brinell and over, and phosphor-bronze shafts over 135 Brinell are recommended.

<sup>a</sup> Abbreviations used for the alloying elements are as follows: Cu, copper; Fe, iron; Sn, tin; Pb, lead; Zn, zinc; Ni, nickel; Sb, antimony; Si, silicon; Al, aluminum; and C, carbon.

<sup>b</sup> Total of iron plus copper shall be 97 per cent, minimum.

<sup>c</sup> Combined carbon (on basis of iron only) may be a metallographic estimate of the carbon in the iron.

| Over 100 to 150       | 365            | 325    | 365         | Over 100 to 150       | 300          | 400          |
| Over 150 to 200       | 280            | 250    | 280         | Over 150 to 200       | 225          | 300          |
| Over 200              |                | a      | a           | a                     | Over 200     | a            |

<sup>a</sup> For shaft velocities over 200 fpm, the permissible loads may be calculated as follows:  $P = 50,000/V$ ; where  $P$  = safe load, psi of projected area; and  $V$  = shaft velocity, fpm. With a shaft velocity of less than 50 fpm and a permissible load greater than 1,000 psi, an extreme pressure lubricant should be used; with heat dissipation and removal techniques, higher  $PV$  ratings can be obtained.

<sup>a</sup> Standard and special tolerances are specified for diameters, thicknesses, and parallellism. Special tolerances should not be specified unless required because they require additional or secondary operations and, therefore, are costlier. Thrust bearings (¼ inch thickness, max.) have a standard thickness tolerance of ±0.005 inch and a special thickness tolerance of ±0.0025 inch for all diameters.

All dimensions in inches except where otherwise noted.

## BALL, ROLLER, AND NEEDLE BEARINGS

### Rolling Contact Bearings

Rolling contact bearings substitute a rolling element, ball or roller, for a hydrodynamic or hydrostatic fluid film to carry an impressed load without wear and with reduced friction. Because of their greatly reduced starting friction, when compared to the conventional journal bearing, they have acquired the common designation of "anti-friction" bearings. Although normally made with hardened rolling elements and races, and usually utilizing a separator to space the rolling elements and reduce friction, many variations are in use throughout the mechanical and electrical industries. The most common anti-friction bearing application is that of the deep-groove ball bearing with ribbon-type separator and sealed-grease lubrication used to support a shaft with radial and thrust loads in rotating equipment. This shielded or sealed bearing has become a standard and commonplace item ordered from a supplier's catalogue in much the same manner as nuts and bolts. Because of the simple design approach and the elimination of a separate lubrication system or device, this bearing is found in as many installations as the wick-fed or impregnated porous plain bushing.

Currently, a number of manufacturers produce a complete range of ball and roller bearings in a fully interchangeable series with standard dimensions, tolerances and fits as specified in Anti-Friction Bearing Manufacturers Association (AFBMA) Standards. Except for deep-groove ball bearings, performance standards are not so well defined and sizing and selection must be done in close conformance with the specific manufacturer's catalogue requirements. In general, desired functional features should be carefully gone over with the vendor's representatives.

Rolling contact bearings are made to high standards of accuracy and with close metallurgical control. Balls and rollers are normally held to diametral tolerances of .0001 inch or less within one bearing and are often used as "gage" blocks in routine toolroom operations. This accuracy is essential to the performance and durability of rolling-contact bearings and in limiting runout, providing proper radial and axial clearances, and ensuring smoothness of operation.

Because of their low friction, both starting and running, rolling-contact bearings are utilized to reduce the complexity of many systems that normally function with journal bearings. Aside from this advantage and that of precise radial and axial location of rotating elements, however, they also are desirable because of their reduced lubrication requirements and their ability to function during brief interruptions in normal lubrication.

In applying rolling-contact bearings it is well to appreciate that their life is limited by the fatigue life of the material from which they are made and is modified by the lubricant used. In rolling-contact fatigue, precise relationships among life, load, and design characteristics are not predictable, but a statistical function described as the "probability of survival" is used to relate them according to equations recommended by the AFBMA. Deviations from these formulas result when certain extremes in applications such as speed, deflection, temperature, lubrication, and internal geometry must be dealt with.

**Types of Anti-friction Bearings.**—The general types are usually determined by the shape of the rolling element, but many variations have been developed that apply conventional elements in unique ways. Thus it is well to know that special bearings can be procured with races adapted to specific applications, although this is not practical for other than high volume configurations or where the requirements cannot be met in a more economical manner. "Special" races are appreciably more expensive. Quite often, in such situations, races are made to incorporate other functions of the mechanism, or are "submerged" in the surrounding structure, with the rolling elements supported by a shaft or housing that has been hardened and finished in a suitable manner. Typical anti-friction bearing types are shown in [Tables 1a](#) through [1g](#).

**Table 1a. Types of Rolling Element Bearings and Their Symbols**

**Types of Ball Bearings.**—Most types of ball bearings originate from three basic designs: the single-row radial, the single-row angular contact, and the double-row angular contact.

*Single-row Radial, Non-filling Slot:* This is probably the most widely used ball bearing and is employed in many modified forms. It is also known as the “Conrad” type or “Deep-groove” type. It is a symmetrical unit capable of taking combined radial and thrust loads in which the thrust component is relatively high, but is not intended for pure thrust loads, however. Because this type is not self-aligning, accurate alignment between shaft and housing bore is required.

*Single-row Radial, Filling Slot:* This type is designed primarily to carry radial loads. Bearings of this type are assembled with as many balls as can be introduced by eccentric displacement of the rings, as in the non-filling slot type, and then several more balls are inserted through the loading slot, aided by a slight spreading of the rings and heat expansion of the outer ring, if necessary. This type of bearing will take a certain degree of thrust when in combination with a radial load but is not recommended where thrust loads exceed 60 per cent of the radial load.

|   | Symbol   | Description   |   |  |
|   | BS   | Raceway of outer ring spherical   |  |  |

<sup>a</sup> A line through the ball contact points forms an acute angle with a perpendicular to the bearing axis.

**Single-row Angular-contact:** This type is designed for combined radial and thrust loads where the thrust component may be large and axial deflection must be confined within very close limits. A high shoulder on one side of the outer ring is provided to take the thrust, while the shoulder on the other side is only high enough to make the bearing non-separable. Except where used for a pure thrust load in one direction, this type is applied either in pairs (duplex) or one at each end of the shaft, opposed.

**Double-row Bearings:** These are, in effect, two single-row angular-contact bearings built as a unit with the internal fit between balls and raceway fixed at the time of bearing assembly. This fit is therefore not dependent upon mounting methods for internal rigidity. These bearings usually have a known amount of internal preload built in for maximum resistance to deflection under combined loads with thrust from either direction. Thus, with balls and races under compression before an external load is applied, due to this internal preload, the bearings are very effective for radial loads where bearing deflection must be minimized.

**Other Types:** Modifications of these basic types provide arrangements for self-sealing, location by snap ring, shielding, etc., but the fundamentals of mounting are not changed. A special type is the *self-aligning* ball bearing which can be used to compensate for an appreciable degree of misalignment between shaft and housing due to shaft deflections, mount-

ing inaccuracies, or other causes commonly encountered. With a single row of balls, alignment is provided by a spherical outer surface on the outer ring; with a double row of balls, alignment is provided by a spherical raceway on the outer ring. Bearings in the wide series have a considerable amount of thrust capacity.

**Types of Roller Bearings.**—Types of roller bearings are distinguished by the design of rollers and raceways to handle axial, combined axial and thrust, or thrust loads.

**Cylindrical Roller:** These bearings have solid or helically wound hollow cylindrical rollers. The free ring may have a restraining flange to provide some restraint to endwise movement in one direction or may be without a flange so that the bearing rings may be displaced axially with respect to each other. Either rolls or roller path on the races may be slightly crowned to prevent edge loading under slight shaft misalignment. Low friction makes this type suitable for relatively high speeds.

**Barrel Roller:** These bearings have rollers that are barrel-shaped and symmetrical. They are furnished in both single- and double-row mountings. As with cylindrical roller bearings, the single-row mounting type has a low thrust capacity, but angular mounting of rolls in the double-row type permits its use for combined axial and thrust loads.

**Spherical Roller:** These bearings are usually furnished in a double-row, self-aligning mounting. Both rows of rollers have a common spherical outer raceway. The rollers are

barrel-shaped with one end smaller than the other to provide a small thrust to keep the rollers in contact with the center guide flange. This type of roller bearing has a high radial and thrust load carrying capacity with the ability to maintain this capacity under some degree of misalignment of shaft and bearing housing.

**Tapered Roller:** In this type, straight tapered rollers are held in accurate alignment by means of a guide flange on the inner ring. The basic characteristic of these bearings is that the apexes of the tapered working surfaces of both rollers and races, if extended, would coincide on the bearing axis. These bearings are separable. They have a high radial and thrust carrying capacity.

**Types of Ball and Roller Thrust Bearings.**—Are designed to take thrust loads alone or in combination with radial loads.

**One-direction Ball Thrust:** These bearings consist of a shaft ring and a flat or spherical housing ring with a single row of balls between. They are capable of carrying pure thrust loads in one direction only. They cannot carry any radial load.

**Two-direction Ball Thrust:** These bearings consist of a shaft ring with a ball groove in either side, two sets of balls, and two housing rings so arranged that thrust loads in either direction can be supported. No radial loads can be carried.

<sup>a</sup> Inch dimensioned only.

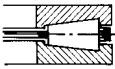

**Spherical Roller Thrust:** This type is similar in design to the radial spherical roller bearing except that it has a much larger contact angle. The rollers are barrel shaped with one end smaller than the other. This type of bearing has a very high thrust load carrying capacity and can also carry radial loads.

**Tapered Roller Thrust:** In this type the rollers are tapered and several different arrangements of housing and shaft are used.

**Roller Thrust:** In this type the rollers are straight and several different arrangements of housing and shaft are used.

**Types of Needle Bearings.**—Needle bearings are characterized by their relatively small size rollers, usually not above  $\frac{1}{4}$  inch in diameter, and a relatively high ratio of length to diameter, usually ranging from about 3 to 1 and 10 to 1. Another feature that is characteris-

tic of several types of needle bearings is the absence of a cage or separator for retaining the individual rollers. Needle bearings may be divided into three classes: loose-roller, outer race and retained roller, and non-separable units.

**Loose-roller:** This type of bearing has no integral races or retaining members, the needles being located directly between the shaft and the outer bearing bore. Usually both shaft and outer bore bearing surfaces are hardened and retaining members that have smooth unbroken surfaces are provided to prevent endwise movement. Compactness and high radial load capacity are features of this type.

**Outer Race and Retained Roller:** There are two types of outer race and retained roller bearings. In the *Drawn Shell* type, the needle rollers are enclosed by a hardened shell that acts as a retaining member and as a hardened outer race. The needles roll directly on the shaft, the bearing surface of which should be hardened. The capacity for given roller length and shaft diameter is about two-thirds that of the loose roller type. It is mounted in the housing with a press fit.

In the *Machined Race* type, the outer race consists of a heavy machined member. Various modifications of this type provide heavy ends or faces for end location of the needle rollers, or open end construction with end washers for roller retention, or a cage that maintains alignment of the rollers and is itself held in place by retaining rings. An auxiliary outer member with spherical seat that holds the outer race may be provided for self-alignment.

<sup>a</sup> Symbols with I, as NIB, are inch-dimensioned, and those without the I, as NB, are metric dimensioned.

This type is applicable where split housings occur or where a press fit of the bearing into the housing is not possible.

**Non-separable:** This type consists of a non-separable unit of outer race, rollers and inner race. These bearings are used where high static or oscillating motion loads are expected as in certain aircraft components and where both outer and inner races are necessary.

**Special or Unconventional Types.**—Rolling contact bearings have been developed for many highly specialized applications. They may be constructed of non-corrosive materials, non-magnetic materials, plastics, ceramics, and even wood. Although the materials are chosen to adapt more conventional configurations to difficult applications or environments, even greater ingenuity has been applied in utilizing rolling contact for solving particular problems. Thus, linear or recirculating bearings are available to provide low friction, accurate location, and simplified lubrication features to such applications as machine ways, axial motion devices, jack-screws, steering linkages, collets, and chucks. This type of bearing utilizes the “full-complement” style of loading the rolling elements between “races” or ways without a cage and with each element advancing by the action of “races” in the loaded areas and by contact with the adjacent element in the unloaded areas. The “races” may not be cylindrical or bodies of revolution but plane surfaces, with suitable interruptions to free the rolling elements so that they can follow a return trough or slot back to the entry-point at the start of the “race” contact area. Combinations of radial and thrust bearings are available for the user with special requirements.

**Plastics Bearings.**—A more recent development has been the use of Acetal resin rollers and balls in applications where abrasive, corrosive and difficult-to-lubricate conditions exist. Although these bearings do not have the load carrying capacity nor the low friction factor of their hard steel counterparts, they do offer freedom from indentation, wear, and corrosion, while at the same time providing significant weight savings.

Of additional value are: 1) their resistance to indentation from shock loads or oscillation; and 2) their self-lubricating properties.

Usually these bearings are not available from stock, but must be designed and produced in accordance with the data made available by the plastics processor.

**Pillow Block and Flanged Housing Bearings.**—Of great interest to the shop man and particularly adaptable to “line-shafting” applications are a series of ball and roller bearings supplied with their own housings, adapters, and seals. Often called pre-mounted bearings, they come with a wide variety of flange mountings permitting location on faces parallel to or perpendicular to the shaft axis.

Inner races can be mounted directly on ground shafts, or can be adapter-mounted to “drill-rod” or to commercial shafting. For installations sensitive to imbalance and vibration, the use of accurately ground shaft seats is recommended.

Most pillow block designs incorporate self-aligning types of bearings so they do not require the precision mountings utilized with more normal bearing installations.

**Conventional Bearing Materials.**—Most rolling contact bearings are made with all load carrying members of full hard steel, either through- or case-hardened. For greater reliability this material is controlled and selected for cleanliness and alloying practices in conformity with rigid specifications in order to reduce anomalies and inclusions that could limit the useful fatigue life. Magnaflux inspection is employed to ensure that elements are free from both material defects and cracks. Likewise, a light etch is employed between rough and finish grinding to allow detection of burns due to heavy stock removal and associated decarburization in finished pieces.

**Cage Materials.**—Standard bearings are normally made with cages of free-machining brass or low carbon sulfurized steel. In high-speed applications or where lubrication may be intermittent or marginal, special materials may be employed. Iron-silicon-bronze, laminated phenolics, silver-plating, over-lays, solid-film baked-on coatings, carbon-graphite inserts, and, in extreme cases, sintered or even impregnated materials are used in separators.

Commercial bearings usually rely on stamped steel with or without a phosphate treatment; some low cost varieties are found with snap-in plastic or metallic cages.

So long as lubrication is adequate and speeds are both reasonable and steady, the materials and design of the cage are of secondary importance when compared with those of the rolling elements and their contacts with the races. In spite of this tolerance, a good portion of all rolling bearing failures encountered can be traced to cage failures resulting from inadequate lubrication. It can never be overemphasized that *no bearing can be designed to run continuously without lubrication!*

**Standard Method of Bearing Designation.**—The Anti-Friction Bearing Manufacturers Association has adopted a standard identification code that provides a specific designation for each different ball, roller, and needle bearing. Thus, for any given bearing, a uniform designation is provided for manufacturer and user alike, so that the confusion of different company designations can be avoided.

In this identification code there is a “basic number” for each bearing that consists of three elements: a one- to four-digit number to indicate the size of the bore in numbers of millimeters (metric series); a two- or three-letter symbol to indicate the type of bearing; and a two-digit number to identify the dimension series to which the bearing belongs.

In addition to this “basic number” other numbers and letters are added to designate type of tolerance, cage, lubrication, fit up, ring modification, addition of shields, seals, mounting accessories, etc. Thus, a complete designating symbol might be *50BC02JPXE0A10*, for example. The basic number is *50BC02* and the remainder is the supplementary number. For a radial bearing, this latter consists of up to four letters to indicate modification of design, one or two digits to indicate internal fit and tolerances, a letter to indicate lubricants and preservatives, and up to three digits to indicate special requirements.

For a thrust bearing the supplementary number would consist of two letters to indicate modifications of design, one digit to indicate tolerances, one letter to indicate lubricants and preservatives, and up to three digits to indicate special requirements.

For a needle bearing the supplementary number would consist of up to three letters indicating cage material or integral seal information or whether the outer ring has a crowned outside surface and one letter to indicate lubricants or preservatives.

*Dimension Series:* Annular ball, cylindrical roller, and self-aligning roller bearings are made in a series of different outside diameters for every given bore diameter and in a series of different widths for every given outside diameter. Thus, each of these bearings belongs to a dimension series that is designated by a two-digit number such as 08, 23, 93, etc. The first digit (8, 0, 1, 2, 3, 4, 5, 6 and 9) indicates the *width series* and the second digit (7, 8, 9, 0, 1, 2, 3, and 4) the *diameter series* to which the bearing belongs. Similar types of identification codes are used for ball and roller thrust bearings and needle roller bearings.

### Bearing Tolerances

**Ball and Roller Bearings.**—In order to provide standards of precision for proper application of ball or roller bearings in all types of equipment, five classes of tolerances have been established by the Anti-Friction Bearing Manufacturers Association for ball bearings, three for cylindrical roller bearings and one for spherical roller bearings. These tolerances are given in [Tables 2, 3, 4, 5, and 6](#). They are designated as ABEC-1, ABEC-3, ABEC-5, ABEC-7 and ABEC-9 for ball bearings, the ABEC-9 being the most precise, RBEC-1, RBEC-3, and RBEC-5 for roller bearings. In general, bearings to specifications closer than ABEC-1 or RBEC-1 are required because of the need for very precise fits on shaft or housing, to reduce eccentricity or runout of shaft or supported part, or to permit operation at very high speeds. All five classes include tolerances for bore, outside diameter, ring width, and radial runouts of inner and outer rings. ABEC-5, ABEC-7 and ABEC-9 provide added tolerances for parallelism of sides, side runout and groove parallelism with sides.

**Thrust Bearings.**—Anti-Friction Bearing Manufacturers Association and American National Standard tolerance limits for metric single direction thrust ball and roller bearings are given in [Table 8](#). Tolerance limits for single direction thrust ball bearings, inch dimensioned are given in [Table 7](#), and for cylindrical thrust roller bearings, inch dimensioned in [Table 9](#).

Only one class of tolerance limits is established for metric thrust bearings.

**Radial Needle Roller Bearings.**—Tolerance limits for needle roller bearings, drawn cup, without inner ring, inch types NIB, NIBM, NIY, NIYM, NIH, and NIHM are given in [Table 10](#) and for metric types NB, NBM, NY, NYM, NH and NHM in [Table 11](#). Standard tolerance limits for needle roller bearings, with cage, machined ring, without inner ring, inch type NIA are given in [Table 12](#) and for needle roller bearings inner rings, inch type NIR in [Table 13](#).

<sup>a</sup> Single inner ring width deviation from basic.  $\Delta_{Cs}$  (single outer ring width deviation from basic) is identical to  $\Delta_{Bs}$  of inner ring of same bearing.

<sup>b</sup> Refers to the rings of single bearings made for paired or stack mounting.

All units are micrometers, unless otherwise indicated. For sizes beyond range of this table, see Standard. This table does not cover tapered roller bearings.

<sup>a</sup> Outside diameter variation in a single radial plane. Applies before mounting and after removal of internal or external snap ring.

<sup>b</sup> Single plane mean outside diameter deviation from basic.

<sup>c</sup> Radial runout of assembled bearing outer ring.

<sup>d</sup> No values have been established for diameter series 7, 8, 9, 0, and 1.

<sup>a</sup> Single inner ring width deviation from basic.  $\Delta_{Cs}$  (single outer ring width deviation from basic) is identical to  $\Delta_{Bs}$  of inner ring of same bearing.

<sup>b</sup> Refers to the rings of single bearings made for paired or stack mounting.

All units are micrometers, unless otherwise indicated. For sizes beyond range of this table, see Standard. This table does not cover tapered roller bearings.

<sup>a</sup> Bore ( $V_{dp}$ ) and outside diameter ( $V_{Dp}$ ) variation in a single radial plane.

<sup>b</sup> Single plane mean bore ( $\Delta_{dmp}$ ) and outside diameter ( $\Delta_{Dmp}$ ) deviation from basic. (For a basically tapered bore,  $\Delta_{dmp}$  refers only to the theoretical small end of the bore.)

<sup>c</sup> Axial runout of assembled bearing with inner ring  $S_{ia}$ . Applies to groove-type ball bearings only.

<sup>d</sup> Single bore ( $\Delta_{Bs}$ ) and outer ring ( $\Delta_{Cs}$ ) width variation.

<sup>e</sup> Inner ( $V_{Bs}$ ) and outer ( $V_{Cs}$ ) ring width deviation from basic.

<sup>f</sup> Applies to the rings of single bearings made for paired or stack mounting.

<sup>a</sup> Bore ( $V_{dp}$ ) and outside diameter ( $V_{Dp}$ ) variation in a single radial plane.

<sup>b</sup> Single plane mean bore ( $\Delta_{dmp}$ ) and outside diameter ( $\Delta_{Dmp}$ ) deviation from basic. (For a basically tapered bore,  $\Delta_{dmp}$  refers only to the theoretical small end of the bore.)

<sup>c</sup> Single bore ( $\Delta_{ds}$ ) and outside diameter ( $\Delta_{Ds}$ ) deviations from basic. These deviations apply to diameter series 0, 1, 2, 3, and 4 only.

<sup>d</sup> Axial run out of assembled bearing with inner ring  $S_{ia}$ . Applies to groove-type ball bearings only.

<sup>e</sup> Single bore ( $\Delta_{Bs}$ ) and outer ring ( $\Delta_{Cs}$ ) width deviation from basic.

<sup>f</sup> Inner ( $V_{Bs}$ ) and outer ( $V_{Cs}$ ) ring width variation.

<sup>g</sup> Applies to the rings of single bearings made for paired or stack mounting.

- <sup>a</sup> Bore ( $V_{dp}$ ) and outside diameter ( $V_{Dp}$ ) variation in a single radial plane.
- <sup>b</sup> Single plane mean bore ( $\Delta_{Dmp}$ ) and outside diameter ( $\Delta_{Dmp}$ ) deviation from basic. (For a basically tapered bore,  $\Delta_{Dmp}$  refers to the theoretical small end of the bore.)
- <sup>c</sup> Single bore diameter ( $\Delta_{Ds}$ ) and outside diameter ( $\Delta_{Ds}$ ) deviation from basic.
- <sup>d</sup> Applies to groove-type ball bearings only.
- <sup>e</sup> Single bore ( $\Delta_{Bs}$ ) and outer ring ( $\Delta_{Cs}$ ) width variation from basic.
- <sup>f</sup> Inner ( $V_{Bs}$ ) and outer ( $V_{Cs}$ ) ring width variation.

<sup>a</sup> Single plane mean bore diameter deviation of central shaft washer ( $\Delta d_{mp}$ ) and outside diameter ( $\Delta D_{mp}$ ) variation.

<sup>b</sup> Raceway parallelism with the face, housing-mounted ( $S_r$ ) and boremounted ( $S_c$ ) race or washer.

<sup>c</sup> Deviation of the actual bearing height.

All dimensions in micrometers, unless otherwise indicated. Tolerances are for normal tolerance class only. For sizes beyond the range of this table and for other tolerance class values, see Standard. All entries apply to type TA bearings; boldface entries also apply to type TS bearings.

**Table 9. Tolerance Limits for Cylindrical Roller Thrust Bearings—Inch Design ANSI/ABMA 24.2-1998**

| Basic Bore Dia., <i>d</i>  |        | $\Delta d_{mp}^a$ |        | $\Delta T_r^b$ |        | Basic Outside dia., <i>D</i> |        | $\Delta D_{mp}^c$ |        |
|----------------------------|--------|-------------------|--------|----------------|--------|------------------------------|--------|-------------------|--------|
| Over                       | Incl.  | Low               | High   | High           | Low    | Over                         | Incl.  | High              | Low    |
| EXTRA LIGHT SERIES—TYPE TP |        |                   |        |                |        |                              |        |                   |        |
| 0                          | 0.9375 | +0.040            | +0.060 | +0.050         | -0.050 | 0                            | 4.7188 | +0                | -0.030 |

<sup>a</sup> The bore diameter under needle rollers can be measured only when bearing is pressed into a ring gage, which rounds and sizes the bearing.

For fitting and mounting practice, see Table 19.

For fitting and mounting practice, see [Table 21](#).

**Metric Radial Ball and Roller Bearing Shaft and Housing Fits.**—To select the proper fits, it is necessary to consider the type and extent of the load, bearing type, and certain other design and performance requirements.

The required shaft and housing fits are indicated in [Tables 14](#) and [15](#). The terms “Light,” “Normal,” and “Heavy” loads refer to radial loads that are generally within the following limits, with some overlap ( $C$  being the Basic Load Rating computed in accordance with AFBMA-ANSI Standards):

| Bearing Type       | Radial Load    |                          |              |
|--------------------|----------------|--------------------------|--------------|
|                    | Light          | Normal                   | Heavy        |
| Ball               | Up to $0.075C$ | From $0.075C$ to $0.15C$ | Over $0.15C$ |
| Cylindrical Roller | Up to $0.075C$ | From $0.075C$ to $0.2C$  | Over $0.15C$ |
| Spherical Roller   | Up to $0.075C$ | From $0.070C$ to $0.25C$ | Over $0.15C$ |

**Shaft Fits:** [Table 14](#) indicates the initial approach to shaft fit selection. Note that for most normal applications where the shaft rotates and the radial load direction is constant, an interference fit should be used. Also, the heavier the load, the greater is the required interference. For stationary shaft conditions and constant radial load direction, the inner ring may be moderately loose on the shaft.

For pure thrust (axial) loading, heavy interference fits are not necessary; only a moderately loose to tight fit is needed.

The upper part of [Table 16](#) shows how the shaft diameters for various ANSI shaft limit classifications deviate from the basic bore diameters.

[Table 17](#) gives metric values for the shaft diameter and housing bore tolerance limits given in [Table 16](#).

The lower parts of [Tables 16](#) and [17](#) show how housing bores for various ANSI hole limit classifications deviate from the basic shaft outside diameters.

**Table 14. Selection of Shaft Tolerance Classifications for Metric Radial Ball and Roller Bearings of ABEC-1 and RBEC-1 Tolerance Classes ANSI/ABMA 7-1995**

| Operating Conditions   |              |  | Ball Bearings          |               | Cylindrical Roller Bearings  |               | Spherical Roller Bearings |                 | Tolerance Symbol <sup>a</sup> |

| Pure Thrust Load   |              |  | All diam.              | All diam.     | Consult Bearing Manufacturer |               |                           |                 | j6                            |

<sup>a</sup> For solid steel shafts. For hollow or nonferrous shafts, tighter fits may be needed.

<sup>b</sup> When greater accuracy is required, use j5, k5, and m5 instead of j6, k6, and m6, respectively.

Numerical values are given in [Tables 16](#) and [17](#).

**Table 15. Selection of Housing Tolerance Classifications for Metric Radial Ball and Roller Bearings of ABEC-1 and RBEC-1 Tolerance Classes**

| Design and Operating Conditions                     |   |  |                               | Tolerance Classification <sup>a</sup> |
|---|---|--|-------------------------------|---------------------------------------|
| Rotational Conditions                               | Loading                                 | Outer Ring Axial Displacement Limitations      | Other Conditions              |                                       |
| Outer ring stationary in relation to load direction | Light<br>Normal<br>and<br>Heavy         | Outer ring must be easily axially displaceable | Heat input through shaft      | G7                                    |
|   |   |  | Housing split axially         | H7 <sup>b</sup>                       |
|   | Shock with temporary complete unloading | Transitional Range <sup>c</sup>                | Housing not split axially     | split housing not recommended         |
| J6 <sup>b</sup>                                     |   |  |                               |                                       |
| Load direction is indeterminate                     | Light and normal                        | Transitional Range <sup>c</sup>                | split housing not recommended | K6 <sup>b</sup>                       |
|   | Normal and Heavy                        |  |                               | M6 <sup>b</sup>                       |
|   | Heavy Shock                             |  |                               | N6 <sup>b</sup>                       |
| Outer ring rotating in relation to load direction   | Light                                   | Outer ring need not be axially displaceable    | Thin wall housing not split   | M6 <sup>b</sup>                       |
|   | Normal and Heavy                        |  |                               | N6 <sup>b</sup>                       |
|   | Heavy                                   | P6 <sup>b</sup>                                |                               |                                       |

<sup>a</sup>For cast iron or steel housings. For housings of nonferrous alloys tighter fits may be needed.

<sup>b</sup>Where wider tolerances are permissible, use tolerance classifications P7, N7, M7, K7, J7, and H7, in place of P6, N6, M6, K6, J6, and H6, respectively.

<sup>c</sup>The tolerance zones are such that the outer ring may be either tight or loose in the housing.

**Table 16. AFBMA and American National Standard Shaft Diameter and Housing Bore Tolerance Limits ANSI/ABMA 7-1995**

Based on ANSI B4.1-1967 (R1994) Preferred Limits and Fits for Cylindrical Parts. Symbols g6, h6, etc., are shaft and G7, H7, etc., hole limits designations. For larger diameters and metric values see AFBMA Standard 7.

**Design and Installation Considerations.**—Interference fitting will reduce bearing radial internal clearance, so it is recommended that prospective users consult bearing manufacturers to make certain that the required bearings are correctly specified to satisfy all mounting, environmental and other operating conditions and requirements. This check is particularly necessary where heat sources in associated parts may further diminish bearing clearances in operation.

Standard values of radial internal clearances of radial bearings are listed in AFBMA-ANSI Standard 20.

**Allowance for Axial Displacement.**—Consideration should be given to axial displacement of bearing components owing to thermal expansion or contraction of associated parts. Displacement may be accommodated either by the internal construction of the bearing or by allowing one of the bearing rings to be axially displace-able. For unusual applications consult bearing manufacturers.

**Needle Roller Bearing Fitting and Mounting Practice.**—The tolerance limits required for shaft and housing seat diameters for needle roller bearings with inner and outer rings as well as limits for raceway diameters where inner or outer rings or both are omitted and rollers operate directly upon these surfaces are given in Tables 18 through 21, inclusive. Unusual design and operating conditions may require a departure from these practices. In such cases, bearing manufacturers should be consulted.

*Needle Roller Bearings, Drawn Cup:* These bearings without inner ring, Types NIB, NB, NIBM, NBM, NIY, NY, NIYM, NYM, NIH, NH, NIHM, NHM, and Inner Rings, Type NIR depend on the housings into which they are pressed for their size and shape. Therefore, the housings must not only have the proper bore dimensions but also must have sufficient strength. Tables 18 and 19, show the bore tolerance limits for rigid housings such as those made from cast iron or steel of heavy radial section equal to or greater than the ring gage section given in AFBMA Standard 4, 1984. The bearing manufacturers should be consulted for recommendations if the housings must be of lower strength materials such as aluminum or even of steel of thin radial section. The shape of the housing bores should be such that when the mean bore diameter of a housing is measured in each of several radial planes, the maximum difference between these mean diameters should not exceed 0.0005 inch (0.013 mm) or one-half the housing bore tolerance limit, if smaller. Also, the radial deviation from circular form should not exceed 0.00025 inch (0.006 mm). The housing bore surface finish should not exceed 125 micro-inches (3.2 micrometers) arithmetical average.

**Table 18. AFBMA and American National Standard Tolerance Limits for Shaft Raceway and Housing Bore Diameters—Needle Roller Bearings, Drawn Cup, Without Inner Ring, Inch Types NIB, NIBM, NIY, NIYM, NIH, and NIHM ANSI/ABMA 18.2-1982 (R1993)**

<sup>a</sup> See text for additional requirements.

For inner ring tolerance limits, see [Table 13](#).

Most needle roller bearings do not use inner rings, but operate directly on the surfaces of shafts. When shafts are used as inner raceways, they should be made of bearing quality steel hardened to Rockwell C 58 minimum. [Tables 15](#) and [19](#) show the shaft raceway tolerance limits and [Table 21](#) shows the shaft seat tolerance limits when inner rings are used. However, whether the shaft surfaces are used as inner raceways or as seats for inner rings, the mean outside diameter of the shaft surface in each of several radial planes should be determined. The difference between these mean diameters should not exceed 0.0003 inch (0.008 mm) or one-half the diameter tolerance limit, if smaller. The radial deviation from circular form should not exceed 0.0001 inch (0.0025 mm), for diameters up to and including 1 in. (25.4 mm). Above one inch the allowable deviation is 0.0001 times the shaft diameter. The surface finish should not exceed 16 micro-inches (0.4 micrometer) arithmetical average. The housing bore and shaft diameter tolerance limits depend upon whether the load rotates relative to the shaft or the housing.

*Needle Roller Bearing With Cage, Machined Ring, Without Inner Ring:* The following covers needle roller bearings Type NIA and inner rings Type NIR. The shape of the housing bores should be such that when the mean bore diameter of a housing is measured in each of several radial planes, the maximum difference between these mean diameters does not exceed 0.0005 inch (0.013 mm) or one-half the housing bore tolerance limit, if smaller. Also, the radial deviation from circular form should not exceed 0.00025 inch (0.006 mm). The housing bore surface finish should not exceed 125 micro-inches (3.2 micrometers) arithmetical average. [Table 21](#) shows the housing bore tolerance limits.

When shafts are used as inner raceways their requirements are the same as those given above for Needle Roller Bearings, Drawn Cup. [Table 20](#) shows the shaft raceway tolerance limits and [Table 21](#) shows the shaft seat tolerance limits when inner rings are used.

*Needle Roller and Cage Assemblies, Types NIM and NM:* For information concerning boundary dimensions, tolerance limits, and fitting and mounting practice, reference should be made to ANSI/ABMA 18.1-1982 (R1994) and ANSI/ABMA 18.2-1982 (R1993).

### Bearing Mounting Practice

Because of their inherent design and material rigidity, rolling contact bearings must be mounted with careful control of their alignment and runout. Medium-speed or slower (400,000  $DN$  values or less where  $D$  is the bearing bore in millimeters and  $N$  is the bearing speed in revolutions per minute), and medium to light load ( $C/P$  values of 7 or greater where  $C$  is the bearing specific dynamic capacity in pounds and  $P$  is the average bearing load in pounds) applications can endure misalignments equivalent to those acceptable for high-capacity, precision journal bearings utilizing hard bearing materials such as silver, copper-lead, or aluminum. In no case, however, should the maximum shaft deflection exceed .001 inch per inch for well-crowned roller bearings, and .003 inch per inch for deep-groove ball-bearings. Except for self-aligning ball-bearings and spherical or barrel roller bearings, all other types require shaft alignments with deflections no greater than .0002 inch per inch. With preloaded ball bearings, this same limit is recommended as a maximum. Close-clearance tapered bearings or thrust bearings of most types require the same shaft alignment also.

Of major importance for all bearings requiring good reliability, is the location of the races on the shaft and in the housing.

Assembly methods must insure: 1) that the faces are square, before the cavity is closed; 2) that the cover face is square to the shoulder and pulled in evenly; and 3) that it will be located by a face parallel to it when finally seated against the housing.

These requirements are shown in the accompanying [Table 22](#). In applications not controlled by automatic tooling with closely controlled fixtures and bolt torquing mechanisms, races should be checked for squareness by sweeping with a dial indicator mounted as shown below. For commercial applications with moderate life and reliability requirements, outer race runouts should be held to .0005 inch per inch of radius and inner race runout to .0004 inch per inch of radius. In preloaded and precision applications, these tolerances must be cut in half. In regard to the question of alignment, it must be recognized that rolling-contact bearings, being made of fully-hardened steel, do not wear in as may certain journal bearings when carefully applied and initially operated. Likewise, rolling contact bearings absorb relatively little deflection when loaded to  $C/P$  values of 6 or less. At such stress levels the rolling element-race deformation is generally not over .0002 inch. Consequently, proper mounting and control of shaft deflections are imperative for reliable bearing performance. Aside from inadequate lubrication, these factors are the most frequent causes of premature bearing failures.

**Mountings for Precision and Quiet-running Applications.**—In applications of rolling-element bearings where vibration or smoothness of operation is critical, special precautions must be taken to eliminate those conditions which can serve to initiate radial and axial motions. These exciting forces can result in shaft excursions which are in resonance with shaft or housing components over a range of frequencies from well below shaft speed to as much as 100 times above it. The more sensitive the configuration, the greater is the need for precision bearings and mountings to be used.

Precision bearings are normally made to much closer tolerances than standard and therefore benefit from better finishing techniques. Special inspection operations are required, however, to provide races and rolling elements with smoothness and runouts compatible with the needs of the application. Similarly, shafts and housings must be carefully controlled.

Among the important elements to be controlled are shaft, race, and housing roundness; squareness of faces, diameters, shoulders, and rolling paths. Though not readily appreciated, grinding chatter, lobular and compensating out-of-roundness, waviness, and flats of less than .0005 inch deviation from the average or mean diameter can cause significant roughness. To detect these and insure the selection of good pieces, three-point electronic indicator inspection must be made. For ultra-precise or quiet applications, pieces are often

checked on a "Talyrod" or a similar continuous recording instrument capable of measuring to within a few millionths of an inch. Though this may seem extreme, it has been found that shaft deformities will be reflected through inner races shrunk onto them. Similarly, tight-fit outer races pick up significant deviations in housings. In many instrument and in missile guidance applications, such deviations and deformities may have to be limited to less than .00002 inch.

In most of these precision applications, bearings are used with rolling elements controlled to less than 5 millionths of an inch deviation from roundness and within the same range for diameter.

Special attention is required both in housing design and in assembly of the bearing to shaft and housing. Housing response to axial excursions forced by bearing wobble (which in itself is a result of out-of-square mounting) has been found to be a major source of small electric and other rotating equipment noise and howl. Stiffer, more massive housings and careful alignment of bearing races can make significant improvements in applications where noise or vibration has been found to be objectionable.

**Table 22. Commercial Application Alignment Tolerances**

| Feature  | Location | Tolerance   |
|--|----------|---|
| <b>Housing Face Runout</b>                         | 1        | Square to shaft center within .0004 inch/inch of radius full indicator reading.   |
| <b>Outer Race Face Runout</b>                      | 2        | Square to shaft center within .0004 inch/inch of radius full indicator reading and complementary to the housing runout (not opposed). |
| <b>Inner Race Face Runout</b>                      | 3        | Square to shaft center within .0003 inch/inch of radius full indicator reading.   |
| <b>Cover and Closure Mounting Face Parallelism</b> | 4 and 5  | Parallel within .001.   |
| <b>Housing Mounting Face Parallelism</b>           | 6        | Parallel within .001  |

**Squareness and Alignment.**—In addition to the limits for roundness and wall variation of the races and their supports, squareness of end faces and shoulders must be closely controlled. Tolerances of .0001 inch full indicator reading per inch of diameter are normally required for end faces and shoulders, with appropriately selected limits for fillet eccentricities. The latter must also fall within specified limits for radii tolerances to prevent interference and the resulting cocking of the race. Reference should be made to the bearing dimension tables which list corner radii for typical bearings. Shoulders must also be of a sufficient height to insure proper support for the races, since they are of hardened steel and are less capable of absorbing shock loads and abuse. The general subject of squareness and alignment is of primary importance to the life of rolling element bearings.

The following recommendations for shaft and housing design are given by the New Departure Division of General Motors Corporation.\*

“As a rule, there is little trouble experienced with inaccuracies in shafts. Bearings seats and locating shoulders are turned and ground to size with the shaft held on centers and, with ordinary care, there is small chance for serious out-of-roundness or taper. Shaft shoulders should present sufficient surface in contact with the bearing face to assure positive and accurate location.

“Where an undercut must be made for wheel runout in grinding a bearing seat, care should be exercised that no sharp corners are left, for it is at such points that fatigue is most likely to result in shaft breakage. It is best to undercut as little as possible and to have the undercut end in a fillet instead of a sharp corner.

“Where clamping nuts are to be used, it is important to cut the threads as true and square as possible in order to insure even pressure at all points on the bearing inner ring faces when the nuts are set up tight. It is also important not to cut threads so far into the bearing seat as to leave part of the inner ring unsupported or carried on the threads. Excessive deflection is usually the result of improperly designed or undersized machine parts. With a weak shaft, it is possible to seriously affect bearing operation through misalignment due to shaft deflection. Where shafts are comparatively long, the diameter between bearings must be great enough to properly resist bending. In general, the use of more than two bearings on a single shaft should be avoided, owing to the difficulty of securing accurate alignment. With bearings mounted close to each other, this can result in extremely heavy bearing loads.

“Design is as important as careful machining in construction of accurate bearing housings. There should be plenty of metal in the wall sections and large, thin areas should be avoided as much as possible, since they are likely to permit deflection of the boring tool when the housing is being finish-machined.

“Wherever possible, it is best to design a housing so that the radial load placed on the bearing is transmitted as directly as possible to the wall or rib supporting the housing. Diaphragm walls connecting an offset housing to the main wall or side of a machine are apt to deflect unless made thick and well braced.

“When two bearings are to be mounted opposed, but in separate housings, the housings should be so reinforced with fins or webs as to prevent deflection due to the axial load under which the bearings are opposed.

“Where housings are deep and considerable overhang of the boring tool is required, there is a tendency to produce out-of-roundness and taper, unless the tool is very rigid and light finishing cuts are taken. In a too roughly bored housing there is a possibility for the ridges of metal to peen down under load, thus eventually resulting in too loose a fit for the bearing outer ring.”

**Soft Metal and Resilient Housings.**—In applications relying on bearing housings made of soft materials (aluminum, magnesium, light sheet metal, etc.) or those which lose their fit because of differential thermal expansion, outer race mounting must be approached in a cautious manner. Of first importance is the determination of the possible consequences of race loosening and turning. In conjunction with this, the type of loading must be considered for it may serve to magnify the effect of race loosening. It must be remembered that generally, balancing processes do not insure zero unbalance at operating speeds, but rather an “acceptable” maximum. This force exerted by the rotating element on the outer race can initiate a precession which will aggravate the race loosening problem by causing further attrition through wear, pounding, and abrasion. Since this force is generally of an order greater than the friction forces in effect between the outer race, housing, and closures (retaining nuts also), no foolproof method can be recommended for securing outer races in housings which deform significantly under load or after appreciable service wear. Though

\*New Departure Handbook. Vol. II—1951.

many such “fixes” are offered, the only sure solution is to press the race into a housing of sufficient stiffness with the heaviest fit consistent with the installed and operating clearances. In many cases, inserts, or liners of cast iron or steel are provided to maintain the desired fit and increase useful life of both bearing and housing.

**Quiet or Vibration-free Mountings.**—In seeming contradiction is the approach to bearing mountings in which all shaft or rotating element excursions must be isolated from the frame, housing, or supporting structure. Here bearing outer races are often supported on elastomeric or metallic springs. Fundamentally, this is an isolation problem and must be approached with caution to insure solution of the primary bearing objective — location and restraint of the rotating body, as well as the reduction or elimination of the dynamic problem. Again, the danger of skidding rolling elements must be considered and reference to the resident engineers or sales engineers of the numerous bearing companies is recommended, as this problem generally develops requirements for special, or non-catalog-type bearings.

**General Mounting Precautions.**—Since the last operations involving the bearing application — mounting and closing — have such important effects on bearing performance, durability, and reliability, it must be cautioned that more bearings are abused or “killed” in this early stage of their life than wear out or “die” under conditions for which they were designed. Hammer and chisel “mechanics” invariably handle bearings as though no blow could be too hard, no dirt too abrasive, and no misalignment of any consequence. Proper tools, fixtures, and techniques are a must for rolling bearing application, and it is the responsibility of the design engineer to provide for this in his design, advisory notes, mounting instructions, and service manuals. Nicks, dents, scores, scratches, corrosion staining, and dirt must be avoided if reliability, long life, and smooth running are to be expected of rolling bearings. All manufacturers have pertinent service instructions available for the bearing user. These should be followed for best performance. In a later section, methods for inspecting bearings and descriptions of most common bearing deficiencies will be given.

**Seating Fits for Bearings.**—Anti-Friction Bearing Manufacturers Association (AFBMA) standard shaft and housing bearing seat tolerances are given in [Tables 13 through 18](#), inclusive.

**Clamping and Retaining Methods.**—Various methods of clamping bearings to prevent axial movement on the shaft are employed, one of the most common being a nut screwed on the end of the shaft and held in place by a tongued lock washer (see [Table 23](#)). The shaft thread for the clamping nut (see [Table 24](#)) should be cut in accurate relation to bearing seats and shoulders if bearing stresses are to be avoided. The threads used are of American National Form, Class 3; special diameters and data for these are given in [Tables 25 and 26](#). Where somewhat closer than average accuracy is required, the washers and locknut faces may be obtained ground for closer alignment with the threads. For a high degree of accuracy the shaft threads are ground and a more precise clamping means is employed. Where a bearing inner ring is to be clamped, it is important to provide a sufficiently high shoulder on the shaft to locate the bearing positively and accurately. If the difference between bearing bore and maximum shaft diameter gives a low shoulder which would enter the corner of the radius of the bearing, a shoulder ring that extends above the shoulder and well into the shaft corner is employed. A shoulder ring with snap wire fitting into a groove in the shaft is sometimes used where no locating shaft shoulder is present. A snap ring fitting into a groove is frequently employed to prevent endwise movement of the bearing away from the locating shoulder where tight clamping is not required. Such a retaining ring should not be used where a slot in the shaft surface might lead to fatigue failure. Snap rings are also used to locate the outer bearing ring in the housing. Dimensions of snap rings used for this latter purpose are given in AFBMA and ANSI standards.

<sup>a</sup> *Tolerances:* On width,  $T$ ,  $-.010$  inch for Types W-00 to W-03 and TW-100 to TW-103;  $-.020$  inch for W-04 to W-07 and TW-104 to TW-107;  $-.030$  inch for all others shown. On Projection  $V$ ,  $+.031$  inch for all sizes up through W-13 and TW-113;  $+.062$  inch for all others shown.

All dimensions in inches. For dimensions in millimeters, multiply inch values by 25.4 and round result to two decimal places.

Data for sizes larger than shown are given in ANSI/AFBMA Standard 8.2-1991.

**Table 24. AFBMA Standard Locknuts (Series N-00) for Ball Bearings and Cylindrical and Spherical Roller Bearings and (Series TN-00) for Tapered Roller Bearings. Inch Design.**

Runout and parallelism of faces measured on a tight fitting threaded arbor.

N-00 to N-06 = .002 Max.  
N-07 to AN-15 = .004 Max.

TN-065 to TAN-15 = .002 Max.

Surface Finish Note

TN-065 to TN-11, 100 $\mu$  in., max.  
TN-12 to TAN-15, 120 $\mu$  in., max.

N-00 through AN-15

All dimensions in inches. For dimensions in millimeters, multiply inch values, except thread diameters, by 25.4 and round result to two decimal places.

Threads are American National form, Class 3.

Typical steels for locknuts are: AISI, C1015, C1018, C1020, C1025, C1035, C1117, C1118, C1212, C1213, and C1215. Minimum hardness, tensile strength, yield strength and elongation are given in ANSI/ABMA 8.2-1991 which also lists larger sizes of locknuts.

**Table 25. AFBMA Standard for Shafts for Locknuts (series N-00) for Ball Bearings and Cylindrical and Spherical Roller Bearings. Inch Design.**

Min. Bearing Width  $-0.016''$  (0.41 mm)

Threads (see footnotes)

<sup>a</sup>Threads are American National form Class 3.

All dimensions in inches. For dimensions in millimeters, multiply inch values, except thread diameters, by 25.4 and round results to two decimal places. These data apply to steel. When either the nut or the shaft is made of stainless steel, aluminum, or other material having a tendency to seize, it is recommended that the maximum thread diameter of the shaft, both major and pitch, be reduced by 20 per cent of the pitch diameter tolerance listed in the Standard. For sizes larger than shown, see ANSI/ABMA 8.2-1991.

**Bearing Closures.**—Shields, seals, labyrinths, and slingers are employed to retain the lubricant in the bearing and to prevent the entry of dirt, moisture, or other harmful substances. The type selected for a given application depends upon the lubricant, shaft, speed, and the atmospheric conditions in which the unit is to operate. The shields or seals may be located in the bearing itself. Shields differ from seals in that they are attached to one bearing race but there is a definite clearance between the shield and the other, usually the inner, race. When a shielded bearing is placed in a housing in which the grease space has been filled, the bearing in running will tend to expel excess grease past the shields or to accept grease from the housing when the amount in the bearing itself is low.

Seals of leather, rubber, cork, felt, or plastic composition may be used. Since they must bear against the rotating member, excessive pressure should be avoided and some lubricant must be allowed to flow into the area of contact in order to prevent seizing and burning of the seal and scoring of the rotating member. Some seals are made up in the form of cartridges which can be pressed into the end of the bearing housing.

Leather seals may be used over a wide range of speeds. Although lubricant is best retained with a leather cupped inward toward the bearing, this arrangement is not suitable at high speeds due to danger of burning the leather. At high speeds where abrasive dust is present, the seal should be arranged with the leather cupped outward to lead some lubricant into the contact area. Only light pressure of leather against the shaft should be maintained.

**Bearing Fits.**—The slipping or creeping of a bearing ring on a rotating shaft or in a rotating housing occurs when the fit of the ring on the shaft or in the housing is loose. Such slipping or creeping action may cause rapid wear of both shaft and bearing ring when the surfaces are dry and highly loaded. To prevent this action the bearing is customarily mounted with the rotating ring a press fit and the stationary ring a push fit, the tightness or looseness depending upon the service intended. Thus, where shock or vibratory loads are to be encountered, fits should be made somewhat tighter than for ordinary service. The stationary ring, if correctly fitted, is allowed to creep very slowly so that prolonged stressing of one part of the raceway is avoided.

To facilitate the assembly of a bearing on a shaft it may become necessary to expand the inner ring by heating. This should be done in clean oil or in a temperature-controlled furnace at a temperature of between 200 and 250°F. The utmost care must be used to make sure that the temperature does not exceed 250°F. as overheating will tend to reduce the hardness of the rings. Prelubricated bearings should not be mounted by this method.

### Design Considerations

**Friction Losses in Rolling Element Bearings.**—The static and kinematic torques of rolling element bearings are generally small and in many applications are not significant. Bearing torque is a measure of the frictional resistance of the bearing to rotation and is the sum of three components: the torque due to the applied load; the torque due to viscous forces in lubricated rolling element bearings; and the torque due to roller end motions, for example, thrust loads against flanges. The friction or torque data may be used to calculate power absorption or heat generation within the bearing and can be utilized in efficiency or system-cooling studies.

Empirical equations have been developed for each of the torque components. These equations are influenced by such factors as bearing load, lubrication environment, and bearing design parameters. These design parameters include sliding friction from contact between the rolling elements and separator surfaces or between adjacent rolling elements; rolling friction from material deformations during the passage of the rolling elements over the race path; skidding or sliding of the Hertzian contact; and windage friction as a function of speed.

Starting or breakaway torques are also of interest in some situations. Breakaway torques tend to be between 1.5 and 1.8 times the running or kinetic torques.

When evaluating the torque requirements of a system under design, it should be noted that other components of the bearing package, such as seals and closures, can increase the overall system torque significantly. Seal torques have been shown to vary from a fraction of the bearing torque to several times that torque. In addition, the torque values given can vary significantly when load, speed of rotation, temperature, or lubrication are outside normal ranges.

For small instrument bearings friction torque has implications more critical than for larger types of bearings. These bearings have three operating friction torques to consider: starting torque, normal running torque, and peak running torque. These torque levels may vary between manufacturers and among lots from a given manufacturer.

Instrument bearings are even more critically dependent on design features — radial play, retainer type, and race conformity — than larger bearings. Typical starting torque values for small bearings are given in the accompanying table, extracted from the New Departure General Catalog.

Finally, if accurate control of friction torque is critical to a particular application, tests of the selected bearings should be conducted to evaluate performance.

#### Starting Torque — ABEC7

| Bearing Bore<br>(in.) | Max. Starting<br>Torque<br>(g cm) | Thrust<br>Load<br>(g) | Minimum Radial Play Range (inches)             |                                      |
|-----------------------|-----------------------------------|-----------------------|--|--------------------------------------|
|                       |                                   |                       | High Carbon Chrome<br>Steel and All Miniatures | Stainless Steel<br>Except Miniatures |
| 0.125                 | 0.10                              | 75                    | 0.0003–0.0005                                  | —                                    |
|                       | 0.14                              | 75                    | 0.0002–0.0004                                  | 0.0004–0.0006                        |

**Selection of Ball and Roller Bearings.**—As compared with sleeve bearings, ball and roller bearings offer the following advantages: 1) Starting friction is low; 2) Less axial space is required; 3) Relatively accurate shaft alignment can be maintained; 4) Both radial and axial loads can be carried by certain types; 5) Angle of load application is not restricted; 6) Replacement is relatively easy; 7) Comparatively heavy overloads can be carried momentarily; 8) Lubrication is simple; and 9) Design and application can be made with the assistance of bearing supplier engineers.

In selecting a ball or roller bearing for a specific application five choices must be made: 1) the bearing series; 2) the type of bearing; 3) the size of bearing; 4) the method of lubrication; and 5) the type of mounting.

Naturally these considerations are modified or affected by the anticipated operating conditions, expected life, cost, and overhaul philosophy.

It is well to review the possible history of the bearing and its function in the machine it will be applied to, thus: 1) Will it be expected to endure removal and reapplication?; 2) Must it be free from maintenance attention during its useful life?; 3) Can wear of the housing or shaft be tolerated during the overhaul period?; 4) Must it be adjustable to take up wear, or to change shaft location?; 5) How accurately can the load spectrum be estimated? and; and 6) Will it be relatively free from abuse in operation?.

Though many cautions could be pointed out, it should always be remembered that inadequate design approaches limit the utilization of rolling element bearings, reduce customer satisfaction, and reduce reliability. Time spent in this stage of design is the most rewarding effort of the bearing engineer, and here again he can depend on the bearing manufacturers' field organization for assistance.

*Type:* Where loads are low, ball bearings are usually less expensive than roller bearings in terms of unit-carrying capacity. Where loads are high, the reverse is usually true.

For a purely radial load, almost any type of radial bearing can be used, the actual choice being determined by other factors. To support a combination of thrust and radial loads, several types of bearings may be considered. If the thrust load component is large, it may be most economical to provide a separate thrust bearing. When a separate thrust bearing cannot be used due to high speed, lack of space, or other factors, the following types may be considered: angular contact ball bearing, deep groove ball bearing without filling slot, tapered roller bearing with steep contact angle, and self-aligning bearing of the wide type. If movement or deflection in an axial direction must be held to a minimum, then a separate thrust bearing or a preloaded bearing capable of taking considerable thrust load is required. To minimize deflection due to a moment in an axial plane, a rigid bearing such as a double row angular contact type with outwardly converging load lines is required. In such cases, the resulting stresses must be taken into consideration in determining the proper size of the bearing.

For shock loads or heavy loads of short duration, roller bearings are usually preferred.

Special bearing designs may be required where accelerations are usually high as in planetary or crank motions.

Where the problem of excessive shaft deflection or misalignment between shaft and housing is present, a self-aligning type of bearing may be a satisfactory solution.

It should be kept in mind that a great deal of difficulty can be avoided if standard types of bearings are used in preference to special designs, wherever possible.

*Size:* The size of bearing required for a given application is determined by the loads that are to be carried and, in some cases, by the amount of rigidity that is necessary to limit deflection to some specified amount.

The forces to which a bearing will be subjected can be calculated by the laws of engineering mechanics from the known loads, power, operating pressure, etc. Where loads are irregular, varying, or of unknown magnitude, it may be difficult to determine the actual forces. In such cases, empirical determination of such forces, based on extensive experience in bearing design, may be needed to attack the problem successfully. Where such experience is lacking, the bearing manufacturer should be consulted or the services of a bearing expert obtained.

If a ball or roller bearing is to be subjected to a combination of radial and thrust loads, an *equivalent radial load* is computed in the case of radial or angular type bearings and an *equivalent thrust load* is computed in the case of thrust bearings.

**Method of Lubrication.**—If speeds are high, relubrication difficult, the shaft angle other than horizontal, the application environment incompatible with normal lubrication, leakage cannot be tolerated; if other elements of the mechanism establish the lubrication requirements, bearing selection must be made with these criteria as controlling influences. Modern bearing types cover a wide selection of lubrication means. Though the most popular type is the "cartridge" type of sealed grease ball bearing, many applications have requirements which dictate against them. Often, operating environments may subject bearings to temperatures too high for seals utilized in the more popular designs. If minute leakage or the accumulation of traces of dirt at seal lips cannot be tolerated by the application (as in baking industry machinery), then the selections of bearings must be made with other sealing and lubrication systems in mind.

High shaft speeds generally dictate bearing selection based on the need for cooling, the suppression of churning or aeration of conventional lubricants, and most important of all, the inherent speed limitations of certain bearing types. An example of the latter is the effect of cage design and of the roller-end thrust-flange contact on the lubrication requirements in commercial taper roller bearings, which limit the speed they can endure and the thrust load they can carry. Reference to the manufacturers' catalog and application-design manuals is recommended before making bearing selections.

See *Anti-friction Bearing Lubrication* on page 2339 for more information on this topic.

**Type of Mounting.**—Many bearing installations are complicated because the best adapted type was not selected. Similarly, performance, reliability, and maintenance operations are restricted because the mounting was not thoroughly considered. There is no universally adaptable bearing for all needs. Careful reviews of the machine requirements should be made before designs are implemented. In many cases complicated machining, redundant shaft and housings, and use of an oversize bearing can be eliminated if the proper bearing in a well-thought-out mounting is chosen.

Advantage should be taken of the many race variations available in "standard" series of bearings. Puller grooves, tapered sleeves, ranged outer races, split races, fully demountable rolling-element and cage assemblies, flexible mountings, hydraulic removal features, relubrication holes and grooves, and many other innovations are available beyond the obvious advantages which are inherent in the basic bearing types.

**Radial and Axial Clearance.**—In designing the bearing mounting, a major consideration is to provide running clearances consistent with the requirements of the application. Race fits must be expected to absorb some of the original bearing clearance so that allowance should be made for approximately 80 per cent of the actual interference showing up in the diameter of the race. This will increase for heavy, stiff housings or for extra light series races shrunk onto solid shafts, while light metal housings (aluminum, magnesium, or sheet metal) and tubular shafts with wall sections less than the race wall thickness will cause a lesser change in the race diameter.

Where the application will impose heat losses through housing or shaft, or where a temperature differential may be expected, allowances must be made in the proper direction to insure proper operating clearance. Some compromises are required in applications where the indicated modification cannot be fully accommodated without endangering the bearing performance at lower speeds, during starting, or under lower temperature conditions than anticipated. Some leeway can be relied on with ball bearings since they can run with moderate preloads (.0005 inch, max.) without affecting bearing life or temperature rise. Roller bearings, however, have a lesser tolerance for preloading, and must be carefully controlled to avoid overheating and resulting self-destruction.

In all critical applications axial and radial clearances should be checked with feeler gages or dial indicators to insure mounted clearances within tolerances established by the design engineer. Since chips, scores, race misalignment, shaft or housing denting, housing distortion, end cover (closure) off-squareness, and mismatch of rotor and housing axial dimensions can rob the bearing of clearance, careful checks of running clearance is recommended.

For precision applications, taper-sleeve mountings, opposed ball or tapered-roller bearings with adjustable or shimmed closures are employed to provide careful control of radial and/or axial clearances. This practice requires skill and experience as well as the initial assistance of the bearing manufacturer's field engineer.

Tapered bore bearings are often used in applications such as these, again requiring careful and well worked-out assembly procedures. They can be assembled on either tapered shafts or on adapter sleeves. Advancement of the inner race over the tapered shaft can be done either by controlled heating (to expand the race as required) or by the use of a hydraulic jack. The adapter sleeve is supplied with a lock-nut which is used to advance the race on

the tapered sleeve. With the heavier fits normally required to effect the clearance changes compatible with such mountings, hydraulic removal devices are normally recommended.

For the conventional application, with standard fits, clearances provided in the standard bearing are suitable for normal operation. To insure that the design conditions are "normal," a careful review of the application requirements, environments, operating speed range, anticipated abuses, and design parameters must be made.

**General Bearing Handling Precautions.**—To insure that rolling element bearings are capable of achieving their design life and that they perform without objectionable noise, temperature rise, or shaft excursions, the following precautions are recommended:

- 1) Use the best bearing available for the application, consistent with the value of the application. Remember, the cost of the best bearing is generally small compared to the replacement costs of the rotating components that can be destroyed if a bearing fails or malfunctions.
- 2) If questions arise in designing the bearing application, seek out the assistance of the bearing manufacturer's representative.
- 3) Handle bearings with care, keeping them in the sealed, original container until ready to use.
- 4) Follow the manufacturer's instructions in handling and assembling the bearings.
- 5) Work with clean tools, clean dry hands, and in clean surroundings.
- 6) Do not wash or wipe bearings prior to installation unless special instructions or requirements have been established to do so.
- 7) Place unwrapped bearings on clean paper and keep them similarly covered until applied, if they cannot be kept in the original container.
- 8) Don't use wooden mallets, brittle or chipped tools, or dirty fixtures and tools in mounting bearings.
- 9) Don't spin uncleaned bearings, nor spin *any* bearing with an air blast.
- 10) Use care not to scratch or nick bearings.
- 11) Don't strike or press on race flanges.
- 12) Use adapters for mounting which provide uniform steady pressure rather than hammering on a drift or sleeve.
- 13) Insure that races are started onto shafts and into housings evenly so as to prevent cocking.
- 14) Inspect shafts and housings before mounting bearing to insure that proper fits will be maintained.
- 15) When removing bearings, clean housings, covers, and shafts before exposing the bearings. All dirt can be considered an abrasive, dangerous to the reuse of any rolling bearing.
- 16) Treat used bearings, which may be reused, as new ones.
- 17) Protect dismantled bearings from dirt and moisture.
- 18) Use clean, lint-free rags if bearings are wiped.
- 19) Wrap bearings in clean, oil-proof paper when not in use.
- 20) Use clean filtered, water-free Stoddard's solvent or flushing oil to clean bearings.
- 21) In heating bearings for mounting onto shafts, follow manufacturer's instructions.
- 22) In assembling bearings onto shafts *never* strike the outer race, or press on it to force the inner race. Apply the pressure on the inner race only. In dismantling follow the same precautions.
- 23) Do not press, strike, or otherwise force the seal or shield on factory-sealed bearings.

**Bearing Failures, Deficiencies, and Their Origins.**—The general classifications of failures and deficiencies requiring bearing removal are:

1) Overheating due to a) Inadequate or insufficient lubrication; b) Excessive lubrication; c) Grease liquefaction or aeration; d) Oil foaming; e) Abrasive or corrosive action due to contaminants in bearing; f) Distortion of housing due to warping, or out-of-round; g) Seal rubbing or failure; h) Inadequate or blocked scavenge oil passages; i) Inadequate bearing-clearance or bearing-preload; j) Race turning; k) Cage wear; and l) Shaft expansion—loss of bearing or seal clearance.

2) Vibration due to a) Dirt or chips in bearing; b) Fatigued race or rolling elements; c) Race turning; d) Rotor unbalance; e) Out-of-round shaft; f) Race misalignment; g) Housing resonance; h) Cage wear; i) Flats on races or rolling elements; j) Excessive clearance; k) Corrosion; l) False-brinelling or indentation of races; m) Electrical discharge (similar to corrosion effects); n) Mixed rolling element diameters; and o) Out-of-square rolling paths in races.

3) Turning on shaft due to a) Growth of race due to overheating; b) Fretting wear; c) Improper initial fit; d) Excessive shaft deflection; e) Initially coarse shaft finish; and f) Seal rub on inner race.

4) Binding of the shaft due to a) Lubricant breakdown; b) Contamination by abrasive or corrosive matter; c) Housing distortion or out-of-round pinching bearing; d) Uneven shimming of housing with loss of clearance; e) Tight rubbing seals; f) Preloaded bearings; g) Cocked races; h) Loss of clearance due to excessive tightening of adapter; i) Thermal expansion of shaft or housing; and j) Cage failure.

5) Noisy bearing due to a) Lubrication breakdown, inadequate lubrication, stiff grease; b) Contamination; c) Pinched bearing; d) Seal rubbing; e) Loss of clearance and preload; f) Bearing slipping on shaft or in housing; g) Flatted roller or ball; h) Brinelling due to assembly abuse, handling, or shock loads; i) Variation in size of rolling elements; j) Out-of-round or lobular shaft; k) Housing bore waviness; and l) Chips or scores under bearing race seat.

6) Displaced shaft due to a) Bearing wear; b) Improper housing or closure assembly; c) Overheated and shifted bearing; d) Inadequate shaft or housing shoulder; e) Lubrication and cage failure permitting rolling elements to bunch; f) Loosened retainer nut or adapter; g) Excessive heat application in assembling inner race, causing growth and shifting on shaft; and h) Housing pounding out.

7) Lubricant leakage due to a) Overfilling of lubricant; b) Grease churning due to use of too soft a consistency; c) Grease deterioration due to excessive operating temperature; d) Operating life longer than grease life (grease breakdown, aeration, and purging); e) Seal wear; f) Wrong shaft attitude (bearing seals designed for horizontal mounting only); g) Seal failure; h) Clogged breather; i) Oil foaming due to churning or air flow through housing; j) Gasket (O-ring) failure or misapplication; k) Porous housing or closure; and l) Lubricator set at wrong flow rate.

### Load Ratings and Fatigue Life

**Ball and Roller Bearing Life.**—The performance of ball and roller bearings is a function of many variables. These include the bearing design, the characteristics of the material from which the bearings are made, the way in which they are manufactured, as well as many variables associated with their application. The only sure way to establish the satisfactory operation of a bearing selected for a specific application is by actual performance in the application. As this is often impractical, another basis is required to estimate the suitability of a particular bearing for a given application. Two factors are taken into consideration: the bearing fatigue life, and its ability to withstand static loading.

*Life Criterion:* Even if a ball or roller bearing is properly mounted, adequately lubricated, protected from foreign matter and not subjected to extreme operating conditions, it

can ultimately fatigue. Under ideal conditions, the repeated stresses developed in the contact areas between the balls or rollers and the raceways eventually can result in the fatigue of the material which manifests itself with the spalling of the load-carrying surfaces. In most applications the fatigue life is the maximum useful life of a bearing.

*Static Load Criterion:* A static load is a load acting on a non-rotating bearing. Permanent deformations appear in balls or rollers and raceways under a static load of moderate magnitude and increase gradually with increasing load. The permissible static load is, therefore, dependent upon the permissible magnitude of permanent deformation. It has been found that for ball and roller bearings suitably manufactured from hardened alloy steel, deformations occurring under maximum contact stress of 4,000 megapascals (580,000 pounds per square inch) acting at the center of contact (in the case of roller bearings, of a uniformly loaded roller) do not greatly impair smoothness or friction. Depending on requirements for smoothness of operation, friction, or sound level, higher or lower static load limits may be tolerated.

**Ball Bearing Types Covered.**—AFBMA and American National Standard ANSI/ABMA 9-1990 sets forth the method of determining ball bearing Rating Life and Static Load Rating and covers the following types:

1) *Radial, deep groove and angular contact ball bearings* whose inner ring raceways have a cross-sectional radius not larger than 52 percent of the ball diameter and whose outer ring raceways have a cross-sectional radius not larger than 53 percent of the ball diameter.

2) *Radial, self-aligning ball bearings* whose inner ring raceways have cross-sectional radii not larger than 53 percent of the ball diameter.

3) *Thrust ball bearings* whose washer raceways have cross-sectional radii not larger than 54 percent of the ball diameter.

4) *Double row, radial and angular contact ball bearings* and double direction thrust ball bearings are presumed to be symmetrical.

**Limitations for Ball Bearings.**—The following limitations apply:

1) *Truncated contact area.* This standard\* may not be safely applied to ball bearings subjected to loading which causes the contact area of the ball with the raceway to be truncated by the raceway shoulder. This limitation depends strongly on details of bearing design which are not standardized.

2) *Material.* This standard applies only to ball bearings fabricated from hardened good quality steel.

3) *Types.* The  $f_c$  factors specified in the basic load rating formulas are valid only for those ball bearing types specified above.

4) *Lubrication.* The Rating Life calculated according to this standard is based on the assumption that the bearing is adequately lubricated. The determination of adequate lubrication depends upon the bearing application.

5) *Ring support and alignment.* The Rating Life calculated according to this standard assumes that the bearing inner and outer rings are rigidly supported and the inner and outer ring axes are properly aligned.

6) *Internal clearance.* The radial ball bearing Rating Life calculated according to this standard is based on the assumption that only a nominal interior clearance occurs in the mounted bearing at operating speed, load and temperature.

7) *High speed effects.* The Rating Life calculated according to this standard does not account for high speed effects such as ball centrifugal forces and gyroscopic moments. These effects tend to diminish fatigue life. Analytical evaluation of these effects frequently requires the use of high speed digital computation devices and hence is not covered in the standard.

\* All references to "standard" are to AFBMA and American National Standard "Load Ratings and Fatigue Life for Ball Bearings" ANSI/ABMA 9-1990.

8) *Groove radii.* If groove radii are smaller than those specified in the bearing types covered, the ability of a bearing to resist fatigue is not improved; however, it is diminished by the use of larger radii.

**Ball Bearing Rating Life.**—According to the Anti-Friction Bearing Manufacturers Association standards the Rating Life  $L_{10}$  of a group of apparently identical ball bearings is the life in millions of revolutions that 90 percent of the group will complete or exceed. For a single bearing,  $L_{10}$  also refers to the life associated with 90 percent reliability.

*Radial and Angular Contact Ball Bearings:* The magnitude of the Rating Life  $L_{10}$  in millions of revolutions, for a radial or angular contact ball bearing application is given by the formula:

$$L_{10} = \left( \frac{C}{P} \right)^3 \quad (1)$$

where  $C$  = basic load rating, newtons (pounds). See Formulas (2), (3a) and (3b)

$P$  = equivalent radial load, newtons (pounds). See Formula (4)

**Table 27. Values of  $f_c$  for Radial and Angular Contact Ball Bearings**

| $\frac{D \cos \alpha}{d_m}$ | Single Row Radial Contact; Single and Double Row Angular Contact, Groove Type <sup>a</sup> |                   | Double Row Radial Contact Groove Type |                   | Self-Aligning       |                   |
|-----------------------------|--|-------------------|---------------------------------------|-------------------|---------------------|-------------------|
|                             | Metric <sup>b</sup>  | Inch <sup>c</sup> | Metric <sup>b</sup>                   | Inch <sup>c</sup> | Metric <sup>b</sup> | Inch <sup>c</sup> |
| 0.05                        | 46.7   | 3550              | 44.2                                  | 3360              | 17.3                | 1310              |

<sup>a</sup> A. When calculating the basic load rating for a unit consisting of two similar, single row, radial contact ball bearings, in a duplex mounting, the pair is considered as one, double row, radial contact ball bearing.

B. When calculating the basic load rating for a unit consisting of two, similar, single row, angular contact ball bearings in a duplex mounting, "face-to-face" or "back-to-back," the pair is considered as one, double row, angular contact ball bearing.

C. When calculating the basic load rating for a unit consisting of two or more similar, single angular contact ball bearings mounted "in tandem," properly manufactured and mounted for equal load distribution, the rating of the combination is the number of bearings to the 0.7 power times the rating of a single row ball bearing. If the unit may be treated as a number of individually interchangeable single row bearings, this footnote "C" does not apply.

<sup>b</sup> Use to obtain  $C$  in newtons when  $D$  is given in mm.

<sup>c</sup> Use to obtain  $C$  in pounds when  $D$  is given in inches.

**Table 28. Values of X and Y for Computing Equivalent Radial Load P of Radial and Angular Contact Ball Bearings**

| Contact Angle, $\alpha$               | Table Entering Factors <sup>a</sup>    |              |            | Single Row Bearings <sup>b</sup> |   |                       | Double Row Bearings |                    |      |                    |

<sup>a</sup> Symbol definitions are given on the following page.

<sup>b</sup> For single row bearings when  $F_d/F_r \leq e$ , use  $X = 1, Y = 0$ . Two similar, single row, angular contact ball bearings mounted face-to-face or back-to-back are considered as one double row, angular contact bearing.

Values of X, Y, and e for a load or contact angle other than shown are obtained by linear interpolation. Values of X, Y, and e do not apply to filling slot bearings for applications in which ball-raceway

contact areas project substantially into the filling slot under load. Symbol Definitions:  $F_a$  is the applied axial load in newtons (pounds);  $C_o$  is the static load rating in newtons (pounds) of the bearing under consideration and is found by [Formula \(20\)](#);  $i$  is the number of rows of balls in the bearing;  $Z$  is the number of balls per row in a radial or angular contact bearing or the number of balls in a single row, single direction thrust bearing;  $D$  is the ball diameter in millimeters (inches); and  $F_r$  is the applied radial load in newtons (pounds).

For radial and angular contact ball bearings with balls not larger than 25.4 mm (1 inch) in diameter,  $C$  is found by the formula:

$$C = f_c (i \cos \alpha)^{0.7} Z^{2/3} D^{1.8} \quad (2)$$

and with balls larger than 25.4 mm (1 inch) in diameter  $C$  is found by the formula:

$$C = 3.647 f_c (i \cos \alpha)^{0.7} Z^{2/3} D^{1.4} \quad (\text{metric}) \quad (3a)$$

$$C = f_c (i \cos \alpha)^{0.7} Z^{2/3} D^{1.4} \quad (\text{inch}) \quad (3b)$$

where  $f_c$  = a factor which depends on the geometry of the bearing components, the accuracy to which the various bearing parts are made and the material. Values of  $f_c$  are given in [Table 27](#)

$i$  = number of rows of balls in the bearing

$\alpha$  = nominal contact angle, degrees

$Z$  = number of balls per row in a radial or angular contact bearing

$D$  = ball diameter, mm (inches)

The magnitude of the equivalent radial load,  $P$ , in newtons (pounds) for radial and angular contact ball bearings, under combined constant radial and constant thrust loads is given by the formula:

$$P = XF_r + YF_a \quad (4)$$

where  $F_r$  = the applied radial load in newtons (pounds)

$F_a$  = the applied axial load in newtons (pounds)

$X$  = radial load factor as given in [Table 30](#)

$Y$  = axial load factor as given in [Table 30](#)

**Thrust Ball Bearings:** The magnitude of the Rating Life  $L_{10}$  in millions of revolutions for a thrust ball bearing application is given by the formula:

$$L_{10} = \left( \frac{C_a}{P_a} \right)^3 \quad (5)$$

where  $C_a$  = the basic load rating, newtons (pounds). See [Formulas \(6\) to \(10\)](#)

$P_a$  = equivalent thrust load, newtons (pounds). See [Formula \(11\)](#)

For single row, single and double direction, thrust ball bearing with balls not larger than 25.4 mm (1 inch) in diameter,  $C_a$  is found by the formulas:

$$\text{for } \alpha = 90 \text{ degrees, } C_a = f_c Z^{2/3} D^{1.8} \quad (6)$$

$$\text{for } \alpha \neq 90 \text{ degrees, } C_a = f_c (\cos \alpha)^{0.7} Z^{2/3} D^{1.8} \tan \alpha \quad (7)$$

and with balls larger than 25.4 mm (1 inch) in diameter,  $C_a$  is found by the formulas:

$$\text{for } \alpha = 90 \text{ degrees, } C_a = 3.647 f_c Z^{2/3} D^{1.4} \quad (\text{metric}) \quad (8a)$$

$$C_a = f_c Z^{2/3} D^{1.4} \quad (\text{inch}) \quad (8b)$$

$$\text{for } \alpha \neq 90 \text{ degrees, } C_a = 3.647 f_c (\cos \alpha)^{0.7} Z^{2/3} D^{1.4} \tan \alpha \quad (\text{metric}) \quad (9a)$$

$$C_a = f_c (\cos \alpha)^{0.7} Z^{2/3} D^{1.4} \tan \alpha \quad (9b)$$

where  $f_c$  = a factor which depends on the geometry of the bearing components, the accuracy to which the various bearing parts are made, and the material. Values of  $f_c$  are given in Table 29

$Z$  = number of balls per row in a single row, single direction thrust ball bearing

$D$  = ball diameter, mm (inches)

$\alpha$  = nominal contact angle, degrees

**Table 29. Values of  $f_c$  for Thrust Ball Bearings**

<sup>a</sup> Use to obtain  $C_a$  in newtons when  $D$  is given in mm.

<sup>b</sup> Use to obtain  $C_a$  in pounds when  $D$  is given in inches.

For thrust ball bearings with two or more rows of similar balls carrying loads in the same direction, the basic load rating,  $C_a$ , in newtons (pounds) is found by the formula:

$$C_a = (Z_1 + Z_2 + \dots + Z_n) \left[ \left( \frac{Z_1}{C_{a1}} \right)^{10/3} + \left( \frac{Z_2}{C_{a2}} \right)^{10/3} + \dots + \left( \frac{Z_n}{C_{an}} \right)^{10/3} \right]^{-0.3} \quad (10)$$

where  $Z_1, Z_2, \dots, Z_n$  = number of balls in respective rows of a single-direction multi-row thrust ball bearing

$C_{a1}, C_{a2}, \dots, C_{an}$  = basic load rating per row of a single-direction, multi-row thrust ball bearing, each calculated as a single-row bearing with  $Z_1, Z_2, \dots, Z_n$  balls, respectively

The magnitude of the equivalent thrust load,  $P_a$ , in newtons (pounds) for thrust ball bearings with  $\alpha \neq 90$  degrees under combined constant thrust and constant radial loads is found by the formula:

$$P_a = XF_r + YF_a \quad (11)$$

where  $F_r$  = the applied radial load in newtons (pounds)

$F_a$  = the applied axial load in newtons (pounds)

$X$  = radial load factor as given in Table 30

$Y$  = axial load factor as given in Table 30

**Table 30. Values of X and Y for Computing Equivalent Thrust Load  $P_a$  for Thrust Ball Bearings**

| Contact Angle<br>$\alpha$ | $e$  | Single Direction Bearings |   | Double Direction Bearings |      |                       |   |
|---------------------------|------|---------------------------|---|---------------------------|------|-----------------------|---|
|                           |      | $\frac{F_a}{F_r} > e$     |   | $\frac{F_a}{F_r} \leq e$  |      | $\frac{F_a}{F_r} > e$ |   |
|                           |      | X                         | Y | X                         | Y    | X                     | Y |
| 45°                       | 1.25 | 0.66                      | 1 | 1.18                      | 0.59 | 0.66                  | 1 |
| 60°                       | 2.17 | 0.92                      | 1 | 1.90                      | 0.54 | 0.92                  | 1 |
| 75°                       | 4.67 | 1.66                      | 1 | 3.89                      | 0.52 | 1.66                  | 1 |

For  $\alpha = 90^\circ$ ,  $F_r = 0$  and  $Y = 1$ .

**Roller Bearing Types Covered.**—This standard\* applies to *cylindrical, tapered and self-aligning radial and thrust roller bearings* and to *needle roller bearings*. These bearings are presumed to be within the size ranges shown in the AFBMA dimensional standards, of good quality and produced in accordance with good manufacturing practice.

Roller bearings vary considerably in design and execution. Since small differences in relative shape of contacting surfaces may account for distinct differences in load carrying ability, this standard does not attempt to cover all design variations, rather it applies to basic roller bearing designs.

The following limitations apply:

1) *Truncated contact area.* This standard may not be safely applied to roller bearings subjected to application conditions which cause the contact area of the roller with the raceway to be severely truncated by the edge of the raceway or roller.

2) *Stress concentrations.* A cylindrical, tapered or self-aligning roller bearing must be expected to have a basic load rating less than that obtained using a value of  $f_c$  taken from Table 31 or 32 if, under load, a stress concentration is present in some part of the roller-raceway contact. Such stress concentrations occur in the center of nominal point contacts, at the contact extremities for line contacts and at inadequately blended junctions of a rolling surface profile. Stress concentrations can also occur if the rollers are not accurately guided such as in bearings without cages and bearings not having rigid integral flanges. Values of  $f_c$  given in Tables 31 and 32 are based upon bearings manufactured to achieve optimized contact. For no bearing type or execution will the factor  $f_c$  be greater than that obtained in Tables 31 and 32.

3) *Material.* This standard applies only to roller bearings fabricated from hardened, good quality steel.

4) *Lubrication.* Rating Life calculated according to this standard is based on the assumption that the bearing is adequately lubricated. Determination of adequate lubrication depends upon the bearing application.

5) *Ring support and alignment.* Rating Life calculated according to this standard assumes that the bearing inner and outer rings are rigidly supported, and that the inner and outer ring axes are properly aligned.

6) *Internal clearance.* Radial roller bearing Rating Life calculated according to this standard is based on the assumption that only a nominal internal clearance occurs in the mounted bearing at operating speed, load, and temperature.

7) *High speed effects.* The Rating Life calculated according to this standard does not account for high speed effects such as roller centrifugal forces and gyroscopic moments: These effects tend to diminish fatigue life. Analytical evaluation of these effects frequently requires the use of high speed digital computation devices and hence, cannot be included.

\* All references to "standard" are to AFBMA and American National Standard "Load Ratings and Fatigue Life for Roller Bearings" ANSI/AFBMA Std 11-1990.

<sup>a</sup> Use to obtain  $C_a$  in newtons when  $l_{eff}$  and  $D$  are given in mm.

<sup>b</sup> Use to obtain  $C_a$  in pounds when  $l_{eff}$  and  $D$  are given in inches.

**Roller Bearing Rating Life.**—The Rating Life  $L_{10}$  of a group of apparently identical roller bearings is the life in millions of revolutions that 90 percent of the group will complete or exceed. For a single bearing,  $L_{10}$  also refers to the life associated with 90 percent reliability.

**Radial Roller Bearings:** The magnitude of the Rating Life,  $L_{10}$ , in millions of revolutions, for a radial roller bearing application is given by the formula:

$$L_{10} = \left(\frac{C}{P}\right)^{10/3} \quad (12)$$

where  $C$  = the basic load rating in newtons (pounds), see [Formula \(13\)](#); and,  $P$  = equivalent radial load in newtons (pounds), see [Formula \(14\)](#).

For radial roller bearings,  $C$  is found by the formula:

$$C = f_c(i l_{eff} \cos \alpha)^{7/9} Z^{3/4} D^{29/27} \quad (13)$$

where  $f_c$  = a factor which depends on the geometry of the bearing components, the accuracy to which the various bearing parts are made, and the material. Maximum values of  $f_c$  are given in [Table 31](#)

$i$  = number of rows of rollers in the bearing

$l_{eff}$  = effective length, mm (inches)     $\alpha$  = nominal contact angle, degrees

$Z$  = number of rollers per row in a radial roller bearing

$D$  = roller diameter, mm (inches) (mean diameter for a tapered roller, major diameter for a spherical roller)

When rollers are longer than  $2.5D$ , a reduction in the  $f_c$  value must be anticipated. In this case, the bearing manufacturer may be expected to establish load ratings accordingly.

In applications where rollers operate directly on a shaft surface or a housing surface, such a surface must be equivalent in all respects to the raceway it replaces to achieve the basic load rating of the bearing.

When calculating the basic load rating for a unit consisting of two or more similar single-row bearings mounted "in tandem," properly manufactured and mounted for equal load distribution, the rating of the combination is the number of bearings to the  $7/9$  power times the rating of a single-row bearing. If, for some technical reason, the unit may be treated as a number of individually interchangeable single-row bearings, this consideration does not apply.

The magnitude of the equivalent radial load,  $P$ , in newtons (pounds), for radial roller bearings, under combined constant radial and constant thrust loads is given by the formula:

$$P = XF_r + YF_a \quad (14)$$

where  $F_r$  = the applied radial load in newtons (pounds)

$F_a$  = the applied axial load in newtons (pounds)

$X$  = radial load factor as given in [Table 33](#)

$Y$  = axial load factor as given in [Table 33](#)

**Table 33. Values of  $X$  and  $Y$  for Computing Equivalent Radial Load  $P$  for Radial Roller Bearing**

| Bearing Type   | $\frac{F_a}{F_r} \leq e$         |                    | $\frac{F_a}{F_r} > e$ |                    |
|--|----------------------------------|--------------------|-----------------------|--------------------|
|  | $X$                              | $Y$                | $X$                   | $Y$                |
| Self-Aligning<br>and<br>Tapered<br>Roller Bearings <sup>a</sup><br>$\alpha \neq 0^\circ$ | Single Row Bearings              |                    |                       |                    |
|  | 1                                | 0                  | 0.4                   | $0.4 \cot \alpha$  |

### Typical Bearing Life for Various Design Applications

| Uses   | Design life in hours | Uses  | Design life in hours |
|--|----------------------|---|----------------------|
| Agricultural equipment   | 3000 – 6000          | Gearing units   |                      |
| Aircraft equipment   | 500 – 2000           | Automotive  | 600 – 5000           |
| Automotive   |                      | Multipurpose  | 8000 – 15000         |
| Race car   | 500 – 800            | Machine tools   | 20000                |
| Light motor cycle  | 600 – 1200           | Rail Vehicles   | 15000 – 25000        |
| Heavy motor cycle  | 1000 – 2000          | Heavy rolling mill  | > 50000              |
| Light cars   | 1000 – 2000          | Machines  |                      |
| Heavy cars   | 1500 – 2500          | Beater mills  | 20000 – 30000        |
| Light trucks   | 1500 – 2500          | Briquette presses   | 20000 – 30000        |
| Heavy trucks   | 2000 – 2500          | Grinding spindles   | 1000 – 2000          |
| Buses  | 2000 – 5000          | Machine tools   | 10000 – 30000        |
| Electrical   |                      | Mining machinery  | 4000 – 15000         |
| Household appliances   | 1000 – 2000          | Paper machines  | 50000 – 80000        |
| Motors ≤ ½ hp  | 1000 – 2000          | Rolling mills   |                      |
| Motors ≤ 3 hp  | 8000 – 10000         | Small cold mills  | 5000 – 6000          |
| Motors, medium   | 10000 – 15000        | Large multipurpose mills  | 8000 – 10000         |
| Motors, large  | 20000 – 30000        | Rail vehicle axle   |                      |
| Elevator cables sheaves  | 40000 – 60000        | Mining cars   | 5000                 |
| Mine ventilation fans  | 40000 – 50000        | Motor rail cars   | 16000 – 20000        |
| Propeller thrust bearings  | 15000 – 25000        | Open-pit mining cars  | 20000 – 25000        |
| Propeller shaft bearings   | > 80000              | Streetcars  | 20000 – 25000        |
| Gear drives  |                      | Passenger cars  | 26000                |
| Boat gearing units   | 3000 – 5000          | Freight cars  | 35000                |
| Gear drives  | > 50000              | Locomotive outer bearings   | 20000 – 25000        |
| Ship gear drives   | 20000 – 30000        | Locomotive inner bearings   | 30000 – 40000        |
| Machinery for 8 hour service which are not always fully utilized | 14000 – 20000        | Machinery for short or intermittent operation where service interruption is of minor importance | 4000 – 8000          |
| Machinery for 8 hour service which are fully utilized            | 20000 – 30000        | Machinery for intermittent service where reliable operation is of great importance              | 8000 – 14000         |
| Machinery for continuous 24 hour service                         | 50000 – 60000        | Instruments and apparatus in frequent use   | 0 – 500              |

Roller bearings are generally designed to achieve optimized contact; however, they usually support loads other than the loading at which optimized contact is maintained. The  $10/3$  exponent in Rating Life Formulas (12) and (15) was selected to yield satisfactory Rating Life estimates for a broad spectrum from light to heavy loading. When loading exceeds that which develops optimized contact, e.g., loading greater than  $C/4$  or  $C_d/4$  to  $C_d/2$ , the user should consult the bearing manufacturer to establish the adequacy of the Rating Life formulas for the particular application.

**Thrust Roller Bearings:** The magnitude of the Rating Life,  $L_{10}$ , in millions of revolutions for a thrust roller bearing application is given by the formula:

$$L_{10} = \left( \frac{C_a}{P_a} \right)^{10/3} \quad (15)$$

where  $C_a$  = basic load rating, newtons (pounds). See Formulas (16) to (18)

$P_a$  = equivalent thrust load, newtons (pounds). See Formula (19)

For single row, single and double direction, thrust roller bearings, the magnitude of the basic load rating,  $C_a$ , in newtons (pounds), is found by the formulas:

$$\text{for } \alpha = 90^\circ, C_a = f_c l_{eff}^{7/9} Z^{3/4} D^{29/27} \quad (16)$$

$$\text{for } \alpha \neq 90^\circ, C_a = f_c (l_{eff} \cos \alpha)^{7/9} Z^{3/4} D^{29/27} \tan \alpha \quad (17)$$

where  $f_c$  = a factor which depends on the geometry of the bearing components, the accuracy to which the various parts are made, and the material. Values of  $f_c$  are given in [Table 32](#)

$l_{eff}$  = effective length, mm (inches)

$Z$  = number of rollers in a single row, single direction, thrust roller bearing

$D$  = roller diameter, mm (inches) (mean diameter for a tapered roller, major diameter for a spherical roller)

$\alpha$  = nominal contact angle, degrees

For thrust roller bearings with two or more rows of rollers carrying loads in the same direction the magnitude of  $C_a$  is found by the formula:

$$C_a = (Z_1 l_{eff1} + Z_2 l_{eff2} \dots Z_n l_{effn}) \left\{ \left[ \frac{Z_1 l_{eff1}}{C_{a1}} \right]^{9/2} + \left[ \frac{Z_2 l_{eff2}}{C_{a2}} \right]^{9/2} + \dots \right. \\ \left. \left[ \frac{Z_n l_{effn}}{C_{an}} \right]^{9/2} \right\}^{-2/9} \quad (18)$$

Where  $Z_1, Z_2 \dots Z_n$  = the number of rollers in respective rows of a single direction, multi-row bearing

$C_{a1}, C_{a2} \dots C_{an}$  = the basic load rating per row of a single direction, multi-row, thrust roller bearing, each calculated as a single row bearing with  $Z_1, Z_2 \dots Z_n$  rollers respectively

$l_{eff1}, l_{eff2} \dots l_{effn}$  = effective length, mm (inches), or rollers in the respective rows

In applications where rollers operate directly on a surface supplied by the user, such a surface must be equivalent in all respects to the washer raceway it replaces to achieve the basic load rating of the bearing.

In case the bearing is so designed that several rollers are located on a common axis, these rollers are considered as one roller of a length equal to the total effective length of contact of the several rollers. Rollers as defined above, or portions thereof which contact the same washer-raceway area, belong to one row.

When the ratio of the individual roller effective length to the pitch diameter (at which this roller operates) is too large, a reduction of the  $f_c$  value must be anticipated due to excessive slip in the roller-raceway contact.

When calculating the basic load rating for a unit consisting of two or more similar single row bearings mounted "in tandem," properly manufactured and mounted for equal load distribution, the rating of the combination is defined by [Formula \(18\)](#). If, for some technical reason, the unit may be treated as a number of individually interchangeable single-row bearings, this consideration does not apply.

The magnitude of the equivalent thrust load,  $P_a$ , in pounds, for thrust roller bearings with  $\alpha$  not equal to 90 degrees under combined constant thrust and constant radial loads is given by the formula:

$$P_a = XF_r + YF_a \quad (19)$$

where  $F_r$  = applied radial load, newtons (pounds)

$F_a$  = applied axial load, newtons (pounds)

$X$  = radial load factor as given in [Table 34](#)

$Y$  = axial load factor as given in [Table 34](#)

**Table 34. Values of X and Y for Computing Equivalent Thrust Load  $P_a$  for Thrust Roller Bearings**

| Bearing Type   | Single Direction Bearings |   | Double Direction Bearings |      |                       |   |
|--|---------------------------|---|---------------------------|------|-----------------------|---|
|  | $\frac{F_a}{F_r} > e$     |   | $\frac{F_a}{F_r} \leq e$  |      | $\frac{F_a}{F_r} > e$ |   |
|  | X                         | Y | X                         | Y    | X                     | Y |
| Self-Aligning Tapered Thrust Roller Bearings <sup>a</sup><br>$\alpha \neq 0$ | $\tan \alpha$             | 1 | $1.5 \tan \alpha$         | 0.67 | $\tan \alpha$         | 1 |

<sup>a</sup> For  $\alpha = 90^\circ$ ,  $F_r = 0$  and  $Y = 1$ .

$$e = 1.5 \tan \alpha$$

**Life Adjustment Factors.**—In certain applications of ball or roller bearings it is desirable to specify life for a reliability other than 90 per cent. In other cases the bearings may be fabricated from special bearing steels such as vacuum-degassed and vacuum-melted steels, and improved processing techniques. Finally, application conditions may indicate other than normal lubrication, load distribution, or temperature. For such conditions a series of life adjustment factors may be applied to the fatigue life formula. This is fully explained in AFBMA and American National Standard "Load Ratings and Fatigue Life for Ball Bearings" ANSI/AFBMA Std 9–1990 and AFBMA and American National Standard "Load Ratings and Fatigue Life for Roller Bearings" ANSI/AFBMA Std 11–1990. In addition to consulting these standards it may be advantageous to also obtain information from the bearing manufacturer.

*Life Adjustment Factor for Reliability:* For certain applications, it is desirable to specify life for a reliability greater than 90 per cent which is the basis of the Rating Life.

To determine the bearing life of ball or roller bearings for reliability greater than 90 per cent, the Rating Life must be adjusted by a factor  $a_1$  such that  $L_n = a_1 L_{10}$ . For a reliability of 95 per cent, designated as  $L_5$ , the life adjustment factor  $a_1$  is 0.62; for 96 per cent,  $L_4$ ,  $a_1$  is 0.53; for 97 per cent,  $L_3$ ,  $a_1$  is 0.44; for 98 per cent,  $L_2$ ,  $a_1$  is 0.33; and for 99 per cent,  $L_1$ ,  $a_1$  is 0.21.

*Life Adjustment Factor for Material:* For certain types of ball or roller bearings which incorporate improved materials and processing, the Rating Life can be adjusted by a factor  $a_2$  such that  $L_{10}' = a_2 L_{10}$ . Factor  $a_2$  depends upon steel analysis, metallurgical processes, forming methods, heat treatment, and manufacturing methods in general. Ball and roller bearings fabricated from consumable vacuum remelted steels and certain other special analysis steels, have demonstrated extraordinarily long endurance. These steels are of exceptionally high quality, and bearings fabricated from these are usually considered special manufacture. Generally,  $a_2$  values for such steels can be obtained from the bearing manufacturer. However, all of the specified limitations and qualifications for the application of the Rating Life formulas still apply.

*Life Adjustment Factor for Application Condition:* Application conditions which affect ball or roller bearing life include: 1) lubrication; 2) load distribution (including effects of clearance, misalignment, housing and shaft stiffness, type of loading, and thermal gradients); and 3) temperature.

Items 2 and 3 require special analytical and experimental techniques, therefore the user should consult the bearing manufacturer for evaluations and recommendations.

Operating conditions where the factor  $a_3$  might be less than 1 include: a) exceptionally low values of  $Nd_m$  (rpm times pitch diameter, in mm); e.g.,  $Nd_m < 10,000$ ; b) lubricant viscosity at less than 70 SSU for ball bearings and 100 SSU for roller bearings at operating temperature; and c) excessively high operating temperatures.

When  $a_3$  is less than 1 it may not be assumed that the deficiency in lubrication can be overcome by using an improved steel. When this factor is applied,  $L_{10}' = a_3 L_{10}$ .

In most ball and roller bearing applications, lubrication is required to separate the rolling surfaces, i.e., rollers and raceways, to reduce the retainer-roller and retainer-land friction and sometimes to act as a coolant to remove heat generated by the bearing.

*Factor Combinations:* A fatigue life formula embodying the foregoing life adjustment factors is  $L_{10}' = a_1 a_2 a_3 L_{10}$ . Indiscriminate application of the life adjustment factors in this formula may lead to serious overestimation of bearing endurance, since fatigue life is only one criterion for bearing selection. Care must be exercised to select bearings which are of sufficient size for the application.

**Ball Bearing Static Load Rating.**—For ball bearings suitably manufactured from hardened alloy steels, the static radial load rating is that uniformly distributed static radial bearing load which produces a maximum contact stress of 4,000 megapascals (580,000 pounds per square inch). In the case of a single row, angular contact ball bearing, the static radial load rating refers to the radial component of that load which causes a purely radial displacement of the bearing rings in relation to each other. The static axial load rating is that uniformly distributed static centric axial load which produces a maximum contact stress of 4,000 megapascals (580,000 pounds per square inch).

*Radial and Angular Contact Groove Ball Bearings:* The magnitude of the static load rating  $C_o$  in newtons (pounds) for radial ball bearings is found by the formula:

$$C_o = f_o i Z D^2 \cos \alpha \quad (20)$$

where  $f_o$  = a factor for different kinds of ball bearings given in [Table 35](#)

$i$  = number of rows of balls in bearing

$Z$  = number of balls per row

$D$  = ball diameter, mm (inches)

$\alpha$  = nominal contact angle, degrees

This formula applies to bearings with a cross sectional raceway groove radius not larger than  $0.52 D$  in radial and angular contact groove ball bearing inner rings and  $0.53 D$  in radial and angular contact groove ball bearing outer rings and self-aligning ball bearing inner rings.

The load carrying ability of a ball bearing is not necessarily increased by the use of a smaller groove radius but is reduced by the use of a larger radius than those indicated above.

*Radial or Angular Contact Ball Bearing Combinations:* The basic static load rating for two similar single row radial or angular contact ball bearings mounted side by side on the same shaft such that they operate as a unit (duplex mounting) in “back-to-back” or “face-to-face” arrangement is two times the rating of one single row bearing.

The basic static radial load rating for two or more single row radial or angular contact ball bearings mounted side by side on the same shaft such that they operate as a unit (duplex or stack mounting) in “tandem” arrangement, properly manufactured and mounted for equal load distribution, is the number of bearings times the rating of one single row bearing.

*Thrust Ball Bearings:* The magnitude of the static load rating  $C_{oa}$  for thrust ball bearings is found by the formula:

$$C_{oa} = f_o Z D^2 \cos \alpha \quad (21)$$

where  $f_o$  = a factor given in [Table 35](#)

$Z$  = number of balls carrying the load in one direction

$D$  = ball diameter, mm (inches)

$\alpha$  = nominal contact angle, degrees

This formula applies to thrust ball bearings with a cross sectional raceway radius not larger than  $0.54 D$ . The load carrying ability of a bearing is not necessarily increased by use of a smaller radius, but is reduced by use of a larger radius.

**Roller Bearing Static Load Rating:** For roller bearings suitably manufactured from hardened alloy steels, the static radial load rating is that uniformly distributed static radial bearing load which produces a maximum contact stress of 4,000 megapascals (580,000 pounds per square inch) acting at the center of contact of the most heavily loaded rolling element. The static axial load rating is that uniformly distributed static centric axial load which produces a maximum contact stress of 4,000 megapascals (580,000 pounds per square inch) acting at the center of contact of each rolling element.

**Table 35.  $f_o$  for Calculating Static Load Rating for Ball Bearings**

| $\frac{D \cos \alpha}{d_m}$ | Radial and Angular Contact Groove Type |                   | Radial Self-Aligning |                   | Thrust              |                   |

**Table 35. (Continued)  $f_o$  for Calculating Static Load Rating for Ball Bearings**

| $\frac{D \cos \alpha}{d_m}$ | Radial and Angular Contact Groove Type |                   | Radial Self-Aligning |                   | Thrust              |                   |
|-----------------------------|--|-------------------|----------------------|-------------------|---------------------|-------------------|
|                             | Metric <sup>a</sup>                    | Inch <sup>b</sup> | Metric <sup>a</sup>  | Inch <sup>b</sup> | Metric <sup>a</sup> | Inch <sup>b</sup> |
| 0.46                        | 7.1                                    | 1030              | 2.8                  | 399               | 23.5                | 3400              |
| 0.47                        | 6.9                                    | 1000              | 2.8                  | 404               | 22.9                | 3320              |
| 0.48                        | 6.7                                    | 977               | 2.8                  | 410               | 22.4                | 3240              |
| 0.49                        | 6.6                                    | 952               | 2.9                  | 415               | 21.8                | 3160              |
| 0.50                        | 6.4                                    | 927               | 2.9                  | 421               | 21.2                | 3080              |

<sup>a</sup> Use to obtain  $C_o$  or  $C_{oa}$  in newtons when  $D$  is given in mm.

<sup>b</sup> Use to obtain  $C_o$  or  $C_{oa}$  in pounds when  $D$  is given in inches.

Note: Based on modulus of elasticity =  $2.07 \times 10^5$  megapascals ( $30 \times 10^6$  pounds per square inch) and Poisson's ratio = 0.3.

**Radial Roller Bearings:** The magnitude of the static load rating  $C_o$  in newtons (pounds) for radial roller bearings is found by the formulas:

$$C_o = 44 \left( 1 - \frac{D \cos \alpha}{d_m} \right) i Z l_{eff} D \cos \alpha \quad (\text{metric}) \quad (22a)$$

$$C_o = 6430 \left( 1 - \frac{D \cos \alpha}{d_m} \right) i Z l_{eff} D \cos \alpha \quad (\text{inch}) \quad (22b)$$

where  $D$  = roller diameter, mm (inches); mean diameter for a tapered roller and major diameter for a spherical roller

$d_m$  = mean pitch diameter of the roller complement, mm (inches)

$i$  = number of rows of rollers in bearing

$Z$  = number of rollers per row

$l_{eff}$  = effective length, mm (inches); overall roller length minus roller chamfers or minus grinding undercuts at the ring where contact is shortest

$\alpha$  = nominal contact angle, degrees

**Radial Roller Bearing Combinations:** The static load rating for two similar single row roller bearings mounted side by side on the same shaft such that they operate as a unit is two times the rating of one single row bearing.

The static radial load rating for two or more similar single row roller bearings mounted side by side on the same shaft such that they operate as a unit (duplex or stack mounting) in "tandem" arrangement, properly manufactured and mounted for equal load distribution, is the number of bearings times the rating of one single row bearing.

**Thrust Roller Bearings:** The magnitude of the static load rating  $C_{oa}$  in newtons (pounds) for thrust roller bearings is found by the formulas:

$$C_{oa} = 220 \left( 1 - \frac{D \cos \alpha}{d_m} \right) Z l_{eff} D \sin \alpha \quad (\text{metric}) \quad (23a)$$

$$C_{oa} = 32150 \left( 1 - \frac{D \cos \alpha}{d_m} \right) Z l_{eff} D \sin \alpha \quad (\text{inch}) \quad (23b)$$

where the symbol definitions are the same as for **Formulas (22a) and (22b)**.

**Thrust Roller Bearing Combination:** The static axial load rating for two or more similar single direction thrust roller bearings mounted side by side on the same shaft such that they operate as a unit (duplex or stack mounting) in "tandem" arrangement, properly manufactured and mounted for equal load distribution, is the number of bearings times the rating of one single direction bearing. The accuracy of this formula decreases in the case of single direction bearings when  $F_r > 0.44 F_a \cot \alpha$  where  $F_r$  is the applied radial load in newtons (pounds) and  $F_a$  is the applied axial load in newtons (pounds).

**Ball Bearing Static Equivalent Load.**—For ball bearings the static equivalent radial load is that calculated static radial load which produces a maximum contact stress equal in magnitude to the maximum contact stress in the actual condition of loading. The static equivalent axial load is that calculated static centric axial load which produces a maximum contact stress equal in magnitude to the maximum contact stress in the actual condition of loading.

*Radial and Angular Contact Ball Bearings:* The magnitude of the static equivalent radial load  $P_o$  in newtons (pounds) for radial and angular contact ball bearings under combined thrust and radial loads is the greater of:

$$P_o = X_o F_r + Y_o F_a \quad (24)$$

$$P_o = F_r \quad (25)$$

where  $X_o$  = radial load factor given in [Table 36](#)

$Y_o$  = axial load factor given in [Table 36](#)

$F_r$  = applied radial load, newtons (pounds)

$F_a$  = applied axial load, newtons (pounds)

**Table 36. Values of  $X_o$  and  $Y_o$  for Computing Static Equivalent Radial Load  $P_o$  of Ball Bearings**

| Contact Angle                                 | Single Row Bearings <sup>a</sup> |                    | Double Row Bearings |                    |
|---|----------------------------------|--------------------|---------------------|--------------------|
|   | $X_o$                            | $Y_o$ <sup>b</sup> | $X_o$               | $Y_o$ <sup>b</sup> |
| RADIAL CONTACT GROOVE BEARINGS <sup>c,a</sup> |                                  |                    |                     |                    |
| $\alpha = 0^\circ$                            | 0.6                              | 0.5                | 0.6                 | 0.5                |
| ANGULAR CONTACT GROOVE BEARINGS               |                                  |                    |                     |                    |
| $\alpha = 15^\circ$                           | 0.5                              | 0.47               | 1                   | 0.94               |
| $\alpha = 20^\circ$                           | 0.5                              | 0.42               | 1                   | 0.84               |
| $\alpha = 25^\circ$                           | 0.5                              | 0.38               | 1                   | 0.76               |
| $\alpha = 30^\circ$                           | 0.5                              | 0.33               | 1                   | 0.66               |
| $\alpha = 35^\circ$                           | 0.5                              | 0.29               | 1                   | 0.58               |
| $\alpha = 40^\circ$                           | 0.5                              | 0.26               | 1                   | 0.52               |
| SELF-ALIGNING BEARINGS                        |                                  |                    |                     |                    |
| ...   | 0.5                              | $0.22 \cot \alpha$ | 1                   | $0.44 \cot \alpha$ |

<sup>a</sup>  $P_o$  is always  $\geq F_r$ .

<sup>b</sup> Values of  $Y_o$  for intermediate contact angles are obtained by linear interpolation.

<sup>c</sup> Permissible maximum value of  $F_d/C_o$  (where  $F_d$  is applied axial load and  $C_o$  is static radial load rating) depends on the bearing design (groove depth and internal clearance).

*Thrust Ball Bearings:* The magnitude of the static equivalent axial load  $P_{oa}$  in newtons (pounds) for thrust ball bearings with contact angle  $\alpha \neq 90^\circ$  under combined radial and thrust loads is found by the formula:

$$P_{oa} = F_a + 2.3 F_r \tan \alpha \quad (26)$$

where the symbol definitions are the same as for [Formulas \(24\)](#) and [\(25\)](#). This formula is valid for all load directions in the case of double direction ball bearings. For single direction ball bearings, it is valid where  $F_r/F_a \leq 0.44 \cot \alpha$  and gives a satisfactory but less conservative value of  $P_{oa}$  for  $F_r/F_a$  up to  $0.67 \cot \alpha$ .

Thrust ball bearings with  $\alpha = 90^\circ$  can support axial loads only. The static equivalent load for this type of bearing is  $P_{oa} = F_a$ .

**Roller Bearing Static Equivalent Load.**—The static equivalent radial load for roller bearings is that calculated, static radial load which produces a maximum contact stress acting at the center of contact of a uniformly loaded rolling element equal in magnitude to the maximum contact stress in the actual condition of loading. The static equivalent axial load is that calculated, static centric axial load which produces a maximum contact stress acting

at the center of contact of a uniformly loaded rolling element equal in magnitude to the maximum contact stress in the actual condition of loading.

**Radial Roller Bearings:** The magnitude of the static equivalent radial load  $P_o$  in newtons (pounds) for radial roller bearings under combined radial and thrust loads is the greater of:

$$P_o = X_o F_r + Y_o F_a \quad (27)$$

$$P_o = F_r \quad (28)$$

where  $X_o$  = radial factor given in Table 37

$Y_o$  = axial factor given in Table 37

$F_r$  = applied radial load, newtons (pounds)

$F_a$  = applied axial load, newtons (pounds)

**Table 37. Values of  $X_o$  and  $Y_o$  for Computing Static Equivalent Radial Load  $P_o$  for Self-Aligning and Tapered Roller Bearings**

| Bearing Type                                 | Single Row <sup>a</sup> |                    | Double Row |                    |
|--|-------------------------|--------------------|------------|--------------------|
|  | $X_o$                   | $Y_o$              | $X_o$      | $Y_o$              |
| Self-Aligning and Tapered<br>$\alpha \neq 0$ | 0.5                     | $0.22 \cot \alpha$ | 1          | $0.44 \cot \alpha$ |

<sup>a</sup>  $P_o$  is always  $\geq F_r$ .

The static equivalent radial load for radial roller bearings with  $\alpha = 0^\circ$  and subjected to radial load only is  $P_{or} = F_r$ .

Note: The ability of radial roller bearings with  $\alpha = 0^\circ$  to support axial loads varies considerably with bearing design and execution. The bearing user should therefore consult the bearing manufacturer for recommendations regarding the evaluation of equivalent load in cases where bearings with  $\alpha = 0^\circ$  are subjected to axial load.

**Radial Roller Bearing Combinations:** When calculating the static equivalent radial load for two similar single row angular contact roller bearings mounted side by side on the same shaft such that they operate as a unit (duplex mounting) in "back-to-back" or "face-to-face" arrangement, use the  $X_o$  and  $Y_o$  values for a double row bearing and the  $F_r$  and  $F_a$  values for the total loads on the arrangement.

When calculating the static equivalent radial load for two or more similar single row angular contact roller bearings mounted side by side on the same shaft such that they operate as a unit (duplex or stack mounting) in "tandem" arrangement, use the  $X_o$  and  $Y_o$  values for a single row bearing and the  $F_r$  and  $F_a$  values for the total loads on the arrangement.

**Thrust Roller Bearings:** The magnitude of the static equivalent axial load  $P_{oa}$  in newtons (pounds) for thrust roller bearings with contact angle  $\alpha \neq 90^\circ$ , under combined radial and thrust loads is found by the formula:

$$P_{oa} = F_a + 2.3 F_r \tan \alpha \quad (29)$$

where  $F_a$  = applied axial load, newtons (pounds)

$F_r$  = applied radial load, newtons (pounds)

$\alpha$  = nominal contact angle, degrees

The accuracy of this formula decreases for single direction thrust roller bearings when  $F_r > 0.44 F_a \cot \alpha$ .

**Thrust Roller Bearing Combinations:** When calculating the static equivalent axial load for two or more thrust roller bearings mounted side by side on the same shaft such that they operate as a unit (duplex or stack mounting) in "tandem" arrangement, use the  $F_r$  and  $F_a$  values for the total loads acting on the arrangement.

## STANDARD METAL BALLS

**Standard Metal Balls.**—American National Standard ANSI/AFBMA Std 10-1989 provides information for the user of metal balls permitting them to be described readily and accurately. It also covers certain measurable characteristics affecting ball quality.

On the following pages, tables taken from this Standard cover standard balls for bearings and other purposes by type of material, grade, and size range; preferred ball sizes; ball hardness corrections for curvature; various tolerances, marking increments, and maximum surface roughnesses by grades; total hardness ranges for various materials; and minimum case depths for carbon steel balls. The numbers of balls per pound and per kilogram for ferrous and nonferrous metals are also shown.

**Definitions and Symbols.**—The following definitions and symbols apply to American National Standard metal balls.

*Nominal Ball Diameter,  $D_w$ :* The diameter value that is used for the general identification of a ball size, e.g.,  $\frac{1}{4}$  inch, 6 mm, etc.

*Single Diameter of a Ball,  $D_{ws}$ :* The distance between two parallel planes tangent to the surface of a ball.

*Mean Diameter of a Ball,  $D_{wm}$ :* The arithmetical mean of the largest and smallest single diameters of a ball.

*Ball Diameter Variation,  $V_{Dws}$ :* The difference between the largest and smallest single diameters of one ball.

*Deviation from Spherical Form,  $\Delta R_w$ :* The greatest radial distance in any radial plane between a sphere circumscribed around the ball surface and any point on the ball surface.

*Lot:* A definite quantity of balls manufactured under conditions that are presumed uniform, considered and identified as an entirety.

*Lot Mean Diameter,  $D_{wmL}$ :* The arithmetical mean of the mean diameter of the largest ball and that of the smallest ball in the lot.

*Lot Diameter Variation,  $V_{DwL}$ :* The difference between the mean diameter of the largest ball and that of the smallest ball in the lot.

*Nominal Ball Diameter Tolerance:* The maximum allowable deviation of any ball lot mean diameter from the Nominal Ball Diameter.

*Container Marking Increment:* The Standard unit steps in millionths of an inch or in micrometers used to express the Specific Diameter.

*Specific Diameter:* The amount by which the lot mean diameter ( $D_{wmL}$ ) differs from the nominal diameter ( $D_w$ ), accurate to the container marking increment for that grade; the specific diameter should be marked on the unit container.

*Ball Gage Deviation,  $\Delta S$ :* The difference between the lot mean diameter and the sum of the nominal mean diameter and the ball gage.

*Surface Roughness,  $R_a$ :* Surface roughness consists of all those irregularities that form surface relief and are conventionally defined within the area where deviations of form and waviness are eliminated. (See Handbook Surface Texture Section.)

**Ordering Specifications.**—Unless otherwise agreed between producer and user, orders for metal balls should provide the following information: quantity, material, nominal ball diameter, grade, and ball gage. A *ball grade* embodies a specific combination of dimensional form, and surface roughness tolerances. A *ball gage(s)* is the prescribed small amount, expressed with the proper algebraic sign, by which the lot mean diameter (arithmetical mean of the mean diameters of the largest and smallest balls in the lot) should differ from the nominal diameter, this amount being one of an established series of amounts as shown in the table below. The 0 ball gage is commonly referred to as "OK".

## Preferred Ball Gages for Grades 3 to 200

| Grade  | Ball Gages (in 0.0001-in. units) |    |                        | Ball Gages (in 1 $\mu$ m units)    |    |                                    |
|--------|----------------------------------|----|------------------------|------------------------------------|----|------------------------------------|
|        | Minus                            | OK | Plus                   | Minus                              | OK | Plus                               |
| 3, 5   | - 3 - 2 - 1                      | 0  | + 1 + 2 + 3            | - 8 - 7 - 6 - 5<br>- 4 - 3 - 2 - 1 | 0  | + 1 + 2 + 3 + 4<br>+ 5 + 6 + 7 + 8 |
| 10, 16 | - 4 - 3 - 2 - 1                  | 0  | + 1 + 2 + 3 + 4        | - 10 - 8 - 6<br>- 4 - 2            | 0  | + 2 + 4 + 6<br>+ 8 + 10            |
| 24     | - 5 - 4 - 3<br>- 2 - 1           | 0  | + 1 + 2 + 3<br>+ 4 + 5 | - 12 - 10 - 8<br>- 6 - 4 - 2       | 0  | + 2 + 4 + 6<br>+ 8 + 10 + 12       |
| 48     | - 6 - 4 - 2                      | 0  | + 2 + 4 + 6            | - 16 - 12 - 8 - 4                  | 0  | + 4 + 8 + 12 + 16                  |
| 100    |                                  | 0  |                        |                                    | 0  |                                    |
| 200    |                                  | 0  |                        |                                    | 0  |                                    |

Table 1. AFBMA Standard Balls — Tolerances for Individual Balls and for Lots of Balls

| Grade       | Allowable Ball Diameter Variation | Allowable Deviation from Spherical Form | Maximum Surface Roughness $R_a$ | Allowable Lot Diameter Variation | Nominal Ball Diameter Tolerance ( $\pm$ ) | Container Marking Increments |
|-------------|-----------------------------------|---|---------------------------------|----------------------------------|---|------------------------------|
|             | For Individual Balls              |   |                                 | For Lots of Balls                |   |                              |
| Grade       | Millionths of an Inch             |   |                                 |                                  |   |                              |
| 3           | 3                                 | 3                                       | 0.5                             | 5                                | a   | 10                           |
| 5           | 5                                 | 5                                       | 0.8                             | 10                               | a   | 10                           |

<sup>a</sup> Not applicable.

Allowable ball gage (see text) deviation is for Grade 3: + 0.000030, - 0.000030 inch (+0.75, - 0.75  $\mu$ m); for Grades 5, 10, and 16: + 0.000050, - 0.000040 inch (+ 1.25, - 1  $\mu$ m); and for Grade 24: + 0.000100, - 0.000100 inch (+ 2.5, - 2.5  $\mu$ m). Other grades not given.

*Examples:* A typical order, in inch units, might read as follows: 80,000 pieces, chrome alloy steel,  $\frac{1}{4}$ -inch Nominal Diameter, Grade 16, and Ball Gage to be -0.0002 inch.

A typical order, in metric units, might read as follows: 80,000 pieces, chrome alloy steel, 6 mm Nominal Diameter, Grade 16, and Ball Gage to be  $-4 \mu\text{m}$ .

**Package Marking:** The ball manufacturer or supplier will identify packages containing each lot with information provided on the orders, as given above. In addition, the specific diameter of the contents shall be stated. Container marking increments are listed in [Table 1](#).

**Examples:** Balls supplied to the order of the first of the previous examples would, if perfect size, be  $D_{wml} = 0.249800$  inch. In Grade 16 these balls would be acceptable with  $D_{wml}$  from 0.249760 to 0.249850 inch. If they actually measured 0.249823 (which would be rounded off to 0.249820), each package would be marked: 5,000 Balls, Chrome Alloy Steel,  $\frac{1}{4}$ " Nominal Diameter, Grade 16,  $-0.0002$  inch Ball Gage, and  $-0.000180$  inch Specific Diameter.

Balls supplied to the order of the second of the two previous examples would, if perfect size, be  $D_{wml} = 5.99600$  mm. In Grade 16 these balls would be acceptable with a  $D_{wml}$  from 5.99500 to 5.99725 mm. If they actually measured 5.99627 mm (which would be rounded off to 5.99625 mm), each package would be marked: 5,000 Balls, Chrome Alloy Steel, 6 mm Nominal Diameter, Grade 16,  $-4 \mu\text{m}$  Ball Gage, and  $-3.75 \mu\text{m}$  Specific Diameter.

For complete details as to material requirements, quality specifications, quality assurance provisions, and methods of hardness testing, reference should be made to the Standard.

<sup>a</sup> Rockwell Hardness Tests shall be conducted on parallel flats in accordance with ASTM Standard E18 unless otherwise specified.

<sup>b</sup> Hardness readings taken on spherical surfaces are subject to the corrections shown in Table 5. Hardness readings for carbon steel balls smaller than 5 mm (¼ inch) shall be taken by the microhardness method (detailed in ANSI/AFBMA Std 10-1989) or as agreed between manufacturer and purchaser.

<sup>c</sup> Hardness of balls in any one lot shall be within 3 points on Rockwell C scale.

<sup>d</sup> When microhardness method (see ANSI/AFBMA Std 10-1989) is used, the Rockwell hardness values given are converted to DPH in accordance with ASTM Standard E 140, “Standard Hardness Conversion Tables for Metals.”

<sup>e</sup> Choice of carbon steels shown to be at ball manufacturer's option.

<sup>f</sup> Hardness of balls in any one lot shall be within 4 points on Rockwell C scale.

<sup>g</sup> Annealed hardness of 75–90 “B” is available when specified.

## STANDARD METAL BALLS

Table 4. Preferred Ball Sizes

| Nominal Ball Sizes Metric | Diameter mm | Diameter Inches | Nominal Ball Sizes Inch | Nominal Ball Sizes Metric | Diameter mmm | Diameter Inches | Nominal Ball Sizes Inch |
|---------------------------|-------------|-----------------|-------------------------|---------------------------|--------------|-----------------|-------------------------|
| 0.3                       | 0.300 00    | 0.011 810       |                         |                           | 0.793 75     | 0.031 250       | $\frac{1}{32}$          |

Corrections to be added to Rockwell C readings obtained on spherical surfaces of chrome alloy steel, corrosion resisting hardened and unhardened steel, and carbon steel balls. For other ball sizes and hardness readings, interpolate between correction values shown.

Table 6. Number of Metal Balls per Pound

| Nom. Dia., <sup>a</sup> Inches | Material Density, Pounds per Cubic Inch |         |         |         |         |         |         |         |         |         |         |         |         |

| 2 5/8                          | 22.9                                    | 8.46    | 8.37    | 8.31    | 8.19    | 8.16    | 8.10    | 8.05    | 7.70    | 7.62    | 7.57    | 7.27    | 4.29    |
| 2 3/4                          | 20.8                                    | 7.67    | 7.58    | 7.53    | 7.42    | 7.40    | 7.35    | 7.29    | 6.98    | 6.91    | 6.87    | 6.59    | 3.89    |
| 3                              | 18.9                                    | 6.97    | 6.89    | 6.85    | 6.75    | 6.72    | 6.68    | 6.63    | 6.35    | 6.28    | 6.24    | 5.99    | 3.54    |

<sup>a</sup> For sizes above 1 in. diameter, use the following formula: No. balls per pound =  $1.91 \div [(\text{nom. dia., in.})^3 \times (\text{material density, lbs. per cubic in.})]$ .

Ball material densities in pounds per cubic inch: aluminum .101; aluminum bronze .274; corrosion resisting hardened steel .277; AISI M-50 and silicon molybdenum steels .279; chrome alloy steel .283; carbon steel .284; AISI 302 corrosion resisting unhardened steel .286; AISI 316 corrosion resisting unhardened steel .288; bronze .304; brass and K-Monel metal .306; Monel metal .319; and tungsten carbide .540.

Table 7. Number of Metal Balls per Kilogram

| Nom. Dia., <sup>a</sup><br>mm | Material Density, Grams per Cubic Centimeter |           |           |           |           |           |           |           |           |           |           |           |           |

<sup>a</sup>For sizes above 17 mm diameter, use the following formula: No. balls per kilogram =  $1,910,000 \div [(\text{nom. dia., mm})^3 \times (\text{material density, grams per cu. cm})]$ .

Ball material densities in grams per cubic centimeter: aluminum, 2.796; aluminum bronze, 7.584; corrosion-resisting hardened steel, 7.677; AISI M-50 and silicon molybdenum steel, 7.723; chrome alloy steel, 7.833; carbon steel, 7.861; AISI 302 corrosion-resisting unhardened steel, 7.916; AISI 316 corrosion-resisting unhardened steel, 7.972; bronze, 8.415; brass and K-Monel metal, 8.470; Monel metal, 8.830; tungsten carbide, 14.947.

**LUBRICANTS AND LUBRICATION**

A lubricant is used for one or more of the following purposes: to reduce friction; to prevent wear; to prevent adhesion; to aid in distributing the load; to cool the moving elements; and to prevent corrosion.

The range of materials used as lubricants has been greatly broadened over the years, so that in addition to oils and greases, many plastics and solids and even gases are now being applied in this role. The only limitations on many of these materials are their ability to replenish themselves, to dissipate frictional heat, their reaction to high environmental temperatures, and their stability in combined environments. Because of the wide selection of lubricating materials available, great care is advisable in choosing the material and the method of application. The following types of lubricants are available: petroleum fluids, synthetic fluids, greases, solid films, working fluids, gases, plastics, animal fat, metallic and mineral films, and vegetable oils.

**Lubricating Oils.**—The most versatile and best-known lubricant is mineral oil. When applied in well-designed applications that provide for the limitations of both mechanical and hydraulic elements, oil is recognized as the most reliable lubricant. Concurrently, it is offered in a wide selection of stocks, carefully developed to meet the requirements of the specific application.

Lubricating oils are seldom marketed without additives blended for a narrow range of applications. These “additive packages” are developed for particular applications, so it is advisable to consult the sales-engineering representatives of a reputable petroleum company on the proper selection for the conditions under consideration. The following are the most common types of additives: wear preventive, oxidation inhibitor, rust inhibitor, detergent-dispersant, viscosity index improver, defoaming agent, and pour-point depressant.

A more recent development in the field of additives is a series of organic compounds that leave no ash when heated to a temperature high enough to evaporate or burn off the base oil. Initially produced for internal-combustion-engine applications these additives have found ready acceptance in those other applications where metallic or mineral trace elements would promote catalytic, corrosive, deposition, or degradation effects on mechanism materials.

Additives usually are not stable over the entire temperature and shear-rate ranges considered acceptable for the base stock oil application. Because of this problem, additive type oils must be carefully monitored to ensure that they are not continued in service after their principal capabilities have been diminished or depleted. Of primary importance in this regard is the action of the detergent-dispersant additives that function so well to reduce and control degradation products that would otherwise deposit on the operating parts and oil cavity walls. Because the materials cause the oil to carry a higher than normal amount of the breakdown products in a fine suspension, they may cause an accelerated deposition rate or foaming when they have been depleted or degenerated by thermal or contamination action. Ingestion of water by condensation or leaking can cause markedly harmful effects.

Viscosity index improvers serve to modify oils so that their change in viscosity is reduced over the operating temperature range. These materials may be used to improve both a heavy or a light oil; however, the original stock will tend to revert to its natural state when the additive has been depleted or degraded due to exposure to high temperatures or to the high shear rates normally encountered in the load-carrying zones of bearings and gears. In heavy-duty installations, it is generally advisable to select a heavier or a more highly refined oil (and one that is generally more costly) rather than to rely on a less stable viscosity-index-improvement product. Viscosity-index-improved oils are generally used in applications where the shear rate is well below 1,000,000 reciprocal seconds, as determined by the following formula:

$$\text{Shear rate}(s^{-1}) = \frac{DN}{60t}$$

where  $D$  is the journal diameter in inches,  $N$  is the journal speed in rpm, and  $t$  is the film thickness in inches.

**Types of Oils.**—Aside from being aware of the many additives available to satisfy particular application requirements and improve the performance of fluids, the designer must also be acquainted with the wide variety of oils, natural and synthetic, which are also available. Each oil has its own special features that make it suitable for specific applications and limit its utility in others. Though a complete description of each oil and its application feasibility cannot be given here, reference to major petroleum and chemical company sales engineers will provide full descriptions and sound recommendations. In some applications, however, it must be accepted that the interrelation of many variables, including shear rate, load, and temperature variations, prohibit precise recommendations or predictions of fluid durability and performance. Thus, prototype and rig testing are often required to ensure the final selection of the most satisfactory fluid.

The following table lists the major classifications and properties of available commercial petroleum oils.

### Properties of Commercial Petroleum Oils and Their Applications

| Automotive. With increased additives, diesel and marine reciprocating engines. |                        |       |                       | Gear trains and transmissions. With E. P. additives, hypoid gears. |                        |       |                       |
|--|------------------------|-------|-----------------------|--|------------------------|-------|-----------------------|
| Type   | Viscosity, Centistokes |       | Density, g/cc at 60°F | Type   | Viscosity, Centistokes |       | Density, g/cc at 60°F |

**Viscosity.**—As noted before, fluids used as lubricants are generally categorized by their viscosity at 100 and 210 deg. F. Absolute viscosity is defined as a fluid's resistance to shear or motion—its internal friction in other words. This property is described in several ways, but basically it is the force required to move a plane surface of unit area with unit speed parallel to a second plane and at unit distance from it. In the metric system, the unit of viscosity is called the "poise" and in the English system is called the "reyn." One reyn is equal to 68,950 poises. One poise is the viscosity of a fluid, such that one dyne force is required to move a surface of one square centimeter with a speed of one centimeter per second, the distance between surfaces being one centimeter. The range of kinematic viscosity for a series of typical fluids is shown in the table on page 2333. Kinematic viscosity is related directly to the flow time of a fluid through the viscosimeter capillary. By multiplying the kinematic viscosity by the density of the fluid at the test temperature, one can determine the absolute viscosity. Because, in the metric system, the mass density is equal to the specific gravity, the conversion from kinematic to absolute viscosity is generally made in this sys-

tem and then converted to English units where required. The densities of typical lubricating fluids with comparable viscosities at 100 deg. F and 210 deg. F are shown in this same table.

The following conversion table may be found helpful.

### Viscosity Conversion Factors

| Multiply   | By                                      | To Get   |
|--|---|--|
| Centipoises, $Z, \frac{\text{dyne-s}}{100 \text{ cm}^2}$ | $1.45 \times 10^{-7}$                   | Reyns, $\mu, \frac{\text{lb force-s}}{\text{in.}^2}$     |
| Centistokes, $v, \frac{\text{cm}^2}{100 \text{ s}}$      | Density in $\frac{\text{g}}{\text{cc}}$ | Centipoises, $Z, \frac{\text{dyne-s}}{100 \text{ cm}^2}$ |
| Saybolt Universal Seconds, $t_s$                         | $0.22 t_s - \frac{180}{t_s}$            | Centistokes, $v, \frac{\text{cm}^2}{100 \text{ s}}$      |

Also see page 2586 for addittional conversion factors.

**Finding Specific Gravity of Oils at Different Temperatures.**—The standard practice in the oil industry is to obtain a measure of specific gravity at 60 deg. F on an arbitrary scale, in degrees API, as specified by the American Petroleum Institute. As an example, API gravity,  $\rho_{\text{API}}$ , may be expressed as 27.5 degrees at 60 deg. F.

The relation between gravity in API degrees and specific gravity (grams of mass per cubic centimeter) at 60 deg. F,  $\rho_{60}$ , is

$$\rho_{60} = \frac{141.5}{131.5 + \rho_{\text{API}}}$$

The specific gravity,  $\rho_T$ , at some other temperature,  $T$ , is found from the equation

$$\rho_T = \rho_{60} - 0.00035(T - 60)$$

Normal values of specific gravity for sleeve-bearing lubricants range from 0.75 to 0.95 at 60 deg. F. If the API rating is not known, an assumed value of 0.85 may be used.

**Application of Lubricating Oils.**—In the selection and application of lubricating oils, careful attention must be given to the temperature in the critical operating area and its effect on oil properties. Analysis of each application should be made with detailed attention given to cooling, friction losses, shear rates, and contaminants.

Many oil selections are found to result in excessive operating temperatures because of a viscosity that is initially too high, which raises the friction losses. As a general rule, the lightest-weight oil that can carry the maximum load should be used. Where it is felt that the load carrying capacity is borderline, lubricity improvers may be employed rather than an arbitrarily higher viscosity fluid. It is well to remember that in many mechanisms the thicker fluid may increase friction losses sufficiently to lower the operating viscosity into the range provided by an initially lighter fluid. In such situations also, improved cooling, such as may be accomplished by increasing the oil flow, can improve the fluid properties in the load zone.

Similar improvements can be accomplished in many gear trains and other mechanisms by reducing churning and aeration through improved scavenging, direction of oil jets, and elimination of obstacles to the flow of the fluid. Many devices, such as journal bearings, are extremely sensitive to the effects of cooling flow and can be improved by greater flow rates with a lighter fluid. In other cases it is well to remember that the load carrying capacity of a petroleum oil is affected by pressure, shear rate, and bearing surface finish as well as initial viscosity and therefore these must be considered in the selection of the fluid. Detailed explanation of these factors is not within the scope of this text; however the technical representatives of the petroleum companies can supply practical guides for most applications.

Other factors to consider in the selection of an oil include the following: 1) Compatibility with system materials; 2) Water absorption properties; 3) Break-in requirements; 4) Detergent requirements; 5) Corrosion protection; 6) Low temperature properties; 7) Foaming tendencies; 8) Boundary lubrication properties; 9) Oxidation resistance (high temperature properties); and 10) Viscosity/temperature stability (Viscosity Temperature Index)..

Generally, the factors listed above are those which are usually modified by additives as described earlier. Since additives are used in limited amounts in most petroleum products, blended oils are not as durable as the base stock and must therefore be used in carefully worked-out systems. Maintenance procedures must be established to monitor the oil so that it may be replaced when the effect of the additive is noted or expected to degrade. In large systems supervised by a lubricating engineer, sampling and associated laboratory analysis can be relied on, while in customer-maintained systems as in automobiles and reciprocating engines, the design engineer must specify a safe replacement period which takes into account any variation in type of service or utilization.

Some large systems, such as turbine-power units, have complete oil systems which are designed to filter, cool, monitor, meter, and replenish the oil automatically. In such facilities, much larger oil quantities are used and they are maintained by regularly assigned lubricating personnel. Here reliance is placed on conservatively chosen fluids with the expectation that they will endure many months or even years of service.

**Centralized Lubrication Systems.**—Various forms of centralized lubrication systems are used to simplify and render more efficient the task of lubricating machines. In general, a central reservoir provides the supply of oil, which is conveyed to each bearing either through individual lines of tubing or through a single line of tubing that has branches extending to each of the different bearings. Oil is pumped into the lines either manually by a single movement of a lever or handle, or automatically by mechanical drive from some revolving shaft or other part of the machine. In either case, all bearings in the central system are lubricated simultaneously. Centralized force-feed lubrication is adaptable to various classes of machine tools such as lathes, planers, and milling machines and to many other types of machines. It permits the use of a lighter grade of oil, especially where complete coverage of the moving parts is assured.

**Gravity Lubrication Systems.**—Gravity systems of lubrication usually consist of a small number of distributing centers or manifolds from which oil is taken by piping as directly as possible to the various surfaces to be lubricated, each bearing point having its own independent pipe and set of connections. The aim of the gravity system, as of all lubrication systems, is to provide a reliable means of supplying the bearing surfaces with the proper amount of lubricating oil. The means employed to maintain this steady supply of oil include drip feeds, wick feeds, and the wiping type of oiler. Most manifolds are adapted to use either or both drip and wick feeds.

*Drip-feed Lubricators:* A drip feed consists of a simple cup or manifold mounted in a convenient position for filling and connected by a pipe or duct to each bearing to be oiled. The rate of feed in each pipe is regulated by a needle or conical valve. A loose-fitting cover is usually fitted to the manifold in order to prevent cinders or other foreign matter from becoming mixed with the oil. When a cylinder or other chamber operating under pressure is to be lubricated, the oil-cup takes the form of a lubricator having a tight-fitting screw cover and a valve in the oil line. To fill a lubricator of this kind, it is only necessary to close the valve and unscrew the cover.

*Operation of Wick Feeds:* For a wick feed, the siphoning effect of strands of worsted yarn is employed. The worsted wicks give a regular and reliable supply of oil and at the same time act as filters and strainers. A wick composed of the proper number of strands is fitted into each oil-tube. In order to insure using the proper sizes of wicks, a study should be made of the oil requirements of each installation, and the number of strands necessary to

meet the demands of bearings at different rates of speed should be determined. When the necessary data have been obtained, a table should be prepared showing the size of wick or the number of strands to be used for each bearing of the machine.

*Oil-conducting Capacity of Wicks:* With the oil level maintained at a point  $\frac{3}{8}$  to  $\frac{3}{4}$  inch below the top of an oil-tube, each strand of a clean worsted yarn will carry slightly more than one drop of oil a minute. A twenty-four-strand wick will feed approximately thirty drops a minute, which is ordinarily sufficient for operating a large bearing at high speed. The wicks should be removed from the oil-tubes when the machinery is idle. If left in place, they will continue to deliver oil to the bearings until the supply in the cup is exhausted, thus wasting a considerable quantity of oil, as well as flooding the bearing. When bearings require an extra supply of oil temporarily, it may be supplied by dipping the wicks or by pouring oil down the tubes from an oil-can or, in the case of drip feeds, by opening the needle valves. When equipment that has remained idle for some time is to be started up, the wicks should be dipped and the moving parts oiled by hand to insure an ample initial supply of oil. The oil should be kept at about the same level in the cup, as otherwise the rate of flow will be affected. Wicks should be lifted periodically to prevent dirt accumulations at the ends from obstructing the flow of oil.

*How Lubricating Wicks are Made:* Wicks for lubricating purposes are made by cutting worsted yarn into lengths about twice the height of the top of the oil-tube above the bottom of the oil-cup, plus 4 inches. Half the required number of strands are then assembled and doubled over a piece of soft copper wire, laid across the middle of the strands. The free ends are then caught together by a small piece of folded sheet lead, and the copper wire twisted together throughout its length. The lead serves to hold the lower end of the wick in place, and the wire assists in forcing the other end of the wick several inches into the tube. When the wicks are removed, the free end of the copper wire may be hooked over the tube end to indicate which tube the wick belongs to. Dirt from the oil causes the wick to become gummy and to lose its filtering effect. Wicks that have thus become clogged with dirt should be cleaned or replaced by new ones. The cleaning is done by boiling the wicks in soda water and then rinsing them thoroughly to remove all traces of the soda. Oil-pipes are sometimes fitted with openings through which the flow of oil can be observed. In some installations, a short glass tube is substituted for such an opening.

*Wiper-type Lubricating Systems:* Wiper-type lubricators are used for out-of-the-way oscillating parts. A wiper consists of an oil-cup with a central blade or plate extending above the cup, and is attached to a moving part. A strip of fibrous material fed with oil from a source of supply is placed on a stationary part in such a position that the cup in its motion scrapes along the fibrous material and wipes off the oil, which then passes to the bearing surfaces.

Oil manifolds, cups, and pipes should be cleaned occasionally with steam conducted through a hose or with boiling soda water. When soda water is used, the pipes should be disconnected, so that no soda water can reach the bearings.

**Oil Mist Systems.**—A very effective system for both lubricating and cooling many elements which require a limited quantity of fluid is found in a device which generates a mist of oil, separates out the denser and larger (wet) oil particles, and then distributes the mist through a piping or conduit system. The mist is delivered into the bearing, gear, or lubricated element cavity through a condensing or spray nozzle, which also serves to meter the flow. In applications which do not encounter low temperatures or which permit the use of visual devices to monitor the accumulation of solid oil, oil mist devices offer advantages in providing cooling, clean lubricant, pressurized cavities which prevent entrance of contaminants, efficient application of limited lubricant quantities, and near-automatic performance. These devices are supplied with fluid reservoirs holding from a few ounces up to several gallons of oil and with accommodations for either accepting shop air or working

from a self-contained compressor powered by electricity. With proper control of the fluid temperature, these units can atomize and dispense most motor and many gear oils.

**Lubricating Greases.**—In many applications, fluid lubricants cannot be used because of the difficulty of retention, relubrication, or the danger of churning. To satisfy these and other requirements such as simplification, greases are applied. These formulations are usually petroleum oils thickened by dispersions of soap, but may consist of synthetic oils with soap or inorganic thickeners, or oil with siliceous dispersions. In all cases, the thickener, which must be carefully prepared and mixed with the fluid, is used to immobilize the oil, serving as a storehouse from which the oil bleeds at a slow rate. Though the thickener very often has lubricating properties itself, the oil bleeding from the bulk of the grease is the determining lubricating function. Thus, it has been shown that when the oil has been depleted to the level of 50 per cent of the total weight of the grease, the lubricating ability of the material is no longer reliable. In some applications requiring an initially softer and wetter material, however, this level may be as high as 60 per cent.

**Grease Consistency Classifications.**—To classify greases as to mobility and oil content, they are divided into Grades by the NLGI (National Lubricating Grease Institute). These grades, ranging from 0, the softest, up through 6, the stiffest, are determined by testing in a penetrometer, with the depth of penetration of a specific cone and weight being the controlling criterion. To insure proper averaging of specimen resistance to the cone, most specifications include a requirement that the specimen be worked in a sieve-like device before being packed into the penetrometer cup for the penetration test. Since many greases exhibit thixotropic properties (they soften with working, as they often do in an application with agitation of the bulk of the grease by the working elements or accelerations), this penetration of the worked specimen should be used as a guide to compare the material to the original manufactured condition of it and other greases, rather than to the exact condition in which it will be found in the application. Conversely, many greases are found to stiffen when exposed to high shear rates at moderate loads as in automatic grease dispensing equipment. The application of a grease, therefore must be determined by a carefully planned cut-and-try procedure. Most often this is done by the original equipment manufacturer with the aid of the petroleum company representatives, but in many cases it is advisable to include the bearing engineer as well. In this general area it is well to remember that shock loads, axial or thrust movement within or on the grease cavity can cause the grease to contact the moving parts and initiate softening due to the shearing or working thus induced. To limit this action, grease-lubricated bearing assemblies often utilize dams or dividers to keep the bulk of the grease contained and unchanged by this working. Successful application of a grease depends however, on a relatively small amount of mobile lubricant (the oil bled out of the bulk) to replenish that small amount of lubricant in the element to be lubricated. If the space between the bulk of the mobile grease and the bearing is too large, then a critical delay period (which will be regulated by the grease bleed rate and the temperature at which it is held) will ensue before lubricant in the element can be resupplied. Since most lubricants undergo some attrition due to thermal degradation, evaporation, shearing, or decomposition in the bearing area to which applied, this delay can be fatal.

To prevent this from leading to failure, grease is normally applied so that the material in the cavity contacts the bearing in the lower quadrants, insuring that the excess originally packed into it impinges on the material in the reservoir. With the proper selection of a grease which does not slump excessively, and a reservoir construction to prevent churning, the initial action of the bearing when started into operation will be to purge itself of excess grease, and to establish a flow path for bleed oil to enter the bearing. For this purpose, most greases selected will be of a grade 2 or 3 consistency, falling into the "channelling" variety or designation.

**Types of Grease.**—Greases are made with a variety of soaps and are chosen for many particular characteristics. Most popular today, however, are the lithium, or soda-soap grease

and the modified-clay thickened materials. For high temperature applications (250 deg. F. and above) certain finely divided dyes and other synthetic thickeners are applied. For all-around use the lithium soap greases are best for moderate temperature applications (up to 225 deg. F.) while a number of soda-soap greases have been found to work well up to 285 deg. F. Since the major suppliers offer a number of different formulations for these temperature ranges it is recommended that the user contact the engineering representatives of a reputable petroleum company before choosing a grease. Greases also vary in volatility and viscosity according to the oil used. Since the former will affect the useful life of the bulk applied to the bearing and the latter will affect the load carrying capacity of the grease, they must both be considered in selecting a grease.

For application to certain gears and slow-speed journal bearings, a variety of greases are thickened with carbon, graphite, molybdenum disulfide, lead, or zinc oxide. Some of these materials are likewise used to inhibit fretting corrosion or wear in sliding or oscillating mechanisms and in screw or thread applications. One material used as a "gear grease" is a residual asphaltic compound which is known as a "Crater Compound." Being extremely stiff and having an extreme temperature-viscosity relationship, its application must also be made with careful consideration of its limitations and only after careful evaluation in the actual application. Its oxidation resistance is limited and its low mobility in winter temperature ranges make it a material to be used with care. However, it is used extensively in the railroad industry and in other applications where containment and application of lubricants is difficult. In such conditions its ability to adhere to gear and chain contact surfaces far outweighs its limitations and in some extremes it is "painted" onto the elements at regular intervals.

**Temperature Effects on Grease Life.**—Since most grease applications are made where long life is important and relubrication is not too practical, operating temperatures must be carefully considered and controlled. Being a hydro-carbon, and normally susceptible to oxidation, grease is subject to the general rule that: Above a critical threshold temperature, each 15- to 18-deg. F. rise in temperature reduces the oxidation life of the lubricant by half. For this reason, it is vital that all elements affecting the operating temperature of the application be considered, correlated, and controlled. With sealed-for-life bearings, in particular, grease life must be determined for representative bearings and limits must be established for all subsequent applications.

Most satisfactory control can be established by measuring bearing temperature rise during a controlled test, at a consistent measuring point or location. Once a base line and limiting range are determined, all deviating bearings should be dismantled, inspected, and reassembled with fresh lubricant for retest. In this manner mavericks or faulty assemblies will be ferreted out and the reliability of the application established. Generally, a well lubricated grease packed bearing will have a temperature rise above ambient, as measured at the outer race, of from 10 to 50 deg. F. In applications where heat is introduced into the bearing through the shaft or housing, a temperature rise must be added to that of the frame or shaft temperature.

In bearing applications care must be taken not to fill the cavity too full. The bearing should have a practical quantity of grease worked into it with the rolling elements thoroughly coated and the cage covered, but the housing (cap and cover) should be no more than 75 per cent filled; with softer greases, this should be no more than 50 per cent. Excessive packing is evidenced by overheating, churning, aerating, and eventual purging with final failure due to insufficient lubrication. In grease lubrication, *never* add a bit more for good luck — hold to the prescribed amount and determine this with care on a number of representative assemblies.

**Relubricating with Grease.**—In some applications, sealed-grease methods are not applicable and addition of grease at regular intervals is required. Where this is recommended by the manufacturer of the equipment, or where the method has been worked out as part of a development program, the procedure must be carefully followed. *First*, use the proper

lubricant — the same as recommended by the manufacturer or as originally applied (grease performance can be drastically impaired if contaminated with another lubricant). *Second*, clean the lubrication fitting thoroughly with materials which will not affect the mechanism or penetrate into the grease cavity. *Third*, remove the cap (and if applicable, the drain or purge plug). *Fourth*, clean and inspect the drain or scavenge cavity. *Fifth*, weigh the grease gun or calibrate it to determine delivery rate. *Sixth*, apply the directed quantity or fill until grease is detected coming out the drain or purge hole. *Seventh*, operate the mechanism with the drain open so that excess grease is purged. *Last*, continue to operate the mechanism while determining the temperature rise and insure that it is within limits. Where there is access to a laboratory, samples of the purged material may be analyzed to determine the deterioration of the lubricant and to search for foreign material which may be evidence of contamination or of bearing failure.

Normally, with modern types of grease and bearings, lubrication need only be considered at overhaul periods or over intervals of three to ten years.

**Solid Film Lubricants.**—Solids such as graphite, molybdenum disulfide, polytetrafluoroethylene, lead, babbitt, silver, or metallic oxides are used to provide dry film lubrication in high-load, slow-speed or oscillating load conditions. Though most are employed in conjunction with fluid or grease lubricants, they are often applied as the primary or sole lubricant where their inherent limitations are acceptable. Of foremost importance is their inability to carry away heat. Second, they cannot replenish themselves, though they generally do lay down an oriented film on the contacting interface. Third, they are relatively immobile and must be bonded to the substrate by a carrier, by plating, fusing, or by chemical or thermal deposition.

Though these materials do not provide the low coefficient of friction associated with fluid lubrication, they do provide coefficients in the range of 0.4 down to 0.02, depending on the method of application and the material against which they rub. Polytetrafluoroethylene, in normal atmospheres and after establishing a film on both surfaces has been found to exhibit a coefficient of friction down to 0.02. However, this material is subject to cold flow and must be supported by a filler or on a matrix to continue its function. Since it can now be cemented in thin sheets and is often supplied with a fine glass fiber filler, it is practical in a number of installations where the speed and load do not combine to melt the bond or cause the material to sublime.

Bonded films of molybdenum disulfide, using various resins and ceramic combinations as binders, are deposited over phosphate treated steel, aluminum, or other metals with good success. Since its action produces a gradual wear of the lubricant, its life is limited by the thickness which can be applied (not over a thousandth or two in the conventional application). In most applications this is adequate if the material is used to promote break-in, prevent galling or pick-up, and to reduce fretting or abrasion in contacts otherwise impossible to separate.

In all applications of solid film lubricants, the performance of the film is limited by the care and preparation of the surface to which they are applied. If they can't adhere properly, they cannot perform, coming off in flakes and often jamming under flexible components. The best advice is to seek the assistance of the supplier's field engineer and set up a close control of the surface preparation and solid film application procedure. It should be noted that the functions of a good solid film lubricant cannot overcome the need for better surface finishing. Contacting surfaces should be smooth and flat to insure long life and minimum friction forces. Generally, surfaces should be finished to no more than 24 micro-inches AA with wariness no greater than 0.00002 inch.

**Anti-friction Bearing Lubrication.**—The limiting factors in bearing lubrication are the load and the linear velocity of the centers of the balls or rollers. Since these are difficult to evaluate, a speed factor which consists of the inner race bore diameter  $\times$  RPM is used as a

criterion. This factor will be referred to as  $S_i$ , where the bore diameter is in inches and  $S_m$  where it is in millimeters.

For use in anti-friction bearings, grease must have the following properties:

- 1) Freedom from chemically or mechanically active ingredients such as uncombined metals or oxides, and similar mineral or solid contaminants.
- 2) The slightest possible tendency of change in consistency, such as thickening, separation of oil, evaporation or hardening.
- 3) A melting point considerably higher than the operating temperatures.

The choice of lubricating oils is easier. They are more uniform in their characteristics and if resistant to oxidation, gumming and evaporation, can be selected primarily with regard to a suitable viscosity.

*Grease Lubrication:* Anti-friction bearings are normally grease lubricated, both because grease is much easier than oil to retain in the housing over a long period and because it acts to some extent as a seal against the entry of dirt and other contaminants into the bearings. For almost all applications, a No. 2 soda-base grease or a mixed-base grease with up to 5 per cent calcium soap to give a smoother consistency, blended with an oil of around 250 to 300 SSU (Saybolt Universal Seconds) at 100 degrees F. is suitable. In cases where speeds are high, say  $S_i$  is 5000 or over, a grease made with an oil of about 150 SSU at 100 degrees F. may be more suitable especially if temperatures are also high. In many cases where bearings are exposed to large quantities of water, it has been found that a standard soda-base ball-bearing grease, although classed as water soluble gives better results than water-insoluble types. Greases are available that will give satisfactory lubrication over a temperature range of -40 degrees to +250 degrees F.

Conservative grease renewal periods will be found in the accompanying chart. Grease should not be allowed to remain in a bearing for longer than 48 months or if the service is very light and temperatures low, 60 months, irrespective of the number of hours' operation during that period as separation of the oil from the soap and oxidation continue whether the bearing is in operation or not.

Before renewing the grease in a hand-packed bearing, the bearing assembly should be removed and washed in clean kerosene, degreasing fluid or other solvent. As soon as the bearing is quite clean it should be washed at once in clean light mineral oil, preferably rust-inhibited. The bearing should *not be spun* before or while it is being oiled. Caustic solutions may be used if the old grease is hard and difficult to remove, but the best method is to soak the bearing for a few hours in light mineral oil, preferably warmed to about 130 degrees F., and then wash in cleaning fluid as described above. The use of chlorinated solvents is best avoided.

When replacing the grease, it should be forced with the fingers between the balls or rollers, dismantling the bearing, if convenient. The available space inside the bearing should be filled completely and the bearing then spun by hand. Any grease thrown out should be wiped off. The space on each side of the bearing in the housing should be not more than half-filled. Too much grease will result in considerable churning, high bearing temperatures and the possibility of early failure. Unlike any other kind of bearing, anti-friction bearings more often give trouble due to over-rather than to under-lubrication.

Grease is usually not very suitable for speed factors over 12,000 for  $S_i$  or 300,000 for  $S_m$  (although successful applications have been made up to an  $S_i$  of 50,000) or for temperatures much over 210 degrees F., 300 degrees F. being the extreme practical upper limit, even if synthetics are used. For temperatures above 210 degrees F., the grease renewal periods are very short.

*Oil Lubrication:* Oil lubrication is usually adopted when speeds and temperatures are high or when it is desired to adopt a central oil supply for the machine as a whole. Oil for anti-friction bearing lubrication should be well refined with high film strength and good resistance to oxidation and good corrosion protection. Anti-oxidation additives do no harm

but are not really necessary at temperatures below about 200 degrees F. Anti-corrosion additives are always desirable. The accompanying table gives recommended viscosities of oil for ball bearing lubrication other than by an air-distributed oil mist. Within a given temperature and speed range, an oil towards the lighter end of the grade should be used, if convenient, as speeds increase. Roller bearings usually require an oil one grade heavier than do ball bearings for a given speed and temperature range. Cooled oil is sometimes circulated through an anti-friction bearing to carry off excess heat resulting from high speeds and heavy loads.

### Oil Viscosities and Temperature Ranges for Ball Bearing Lubrication

| Maximum Temperature Range Degrees F. | Optimum Temperature Range, Degrees F. | Speed Factor, $S_p^a$       |                            |
|--------------------------------------|---------------------------------------|-----------------------------|----------------------------|
|                                      |                                       | Under 1000                  | Over 1000                  |
|                                      |                                       | Viscosity                   |                            |
| -40 to +100                          | -40 to -10                            | 80 to 90 SSU <sup>b</sup>   | 70 to 80 SSU <sup>b</sup>  |
| -10 to +100                          | -10 to +30                            | 100 to 115 SSU <sup>b</sup> | 80 to 100 SSU <sup>b</sup> |
| +30 to +150                          | +30 to +150                           | SAE 20                      | SAE 10                     |
| +30 to +200                          | +150 to +200                          | SAE 40                      | SAE 30                     |
| +50 to +300                          | +200 to +300                          | SAE 70                      | SAE 60                     |

Not applicable to air-distributed oil mist lubrication.

### Aerodynamic Lubrication

A natural extension of hydrodynamic lubrication consists in using air or some other gas as the lubricant. The viscosity of air is 1,000 times smaller than that of a very thin mineral oil. Consequently, the viscous resistance to motion is very much less. However, the distance of nearest approach, i.e. the closest distance between the shaft and the bearing is also correspondingly smaller, so that special precautions must be taken.

To obtain full benefit from such aerodynamic lubrication, the surfaces must have a very fine finish, the alignment must be very good, the speeds must be high and the loading relatively low. If all these conditions are fulfilled extremely successful bearing system can be made to run at very low coefficients of friction. They may also operate at very high temperatures since chemical degradation of the lubricant need not occur. Furthermore, if air is used as the lubricant, it costs nothing. This type of lubrication mechanism is very important for oil-free compressors and gas turbines. Another area of growing application for aerodynamic bearings is in data recording heads for computers. Air is used as the lubricant for the recording heads which are designed to be separated from the magnetic recording disc by a thin air film. The need for high recording densities in magnetic discs necessitates the smallest possible air film thickness between the head and disc. A typical thickness is around  $1\mu\text{m}$ .

The analysis of aerodynamic bearings is very similar to liquid hydrodynamic bearings. The main difference, however, is that the gas compressibility is now a distinctive feature and has to be incorporated into the analysis.

**Elastohydrodynamic Lubrication.**—In the arrangement of the shaft and bearing it is usually assumed that the surfaces are perfectly rigid and retain their geometric shape during operation. However, a question might be posed: what is the situation if the geometry or mechanical properties of the materials are such that appreciable elastic deformation of the surfaces occurs? Suppose a steel shaft rests on a rubber block. It deforms the block elastically and provides an approximation to a half-bearing (see Figure 1 a).

Fig. 1a.

Fig. 1b.

If a lubricant is applied to the system it will be dragged into the interface and, if the conditions are right, it will form a hydrodynamic film. However, the pressures developed in the oil film will now have to match up with the elastic stresses in the rubber. In fact the shape of the rubber will be changed as indicated in Figure 1 b.

This type of lubrication is known as elastohydrodynamic lubrication. It occurs between rubber seals and shafts. It also occurs, rather surprisingly, in the contact between a windshield wiper blade and a windshield in the presence of rain. The geometry of the deformable member, its elastic properties, the load, the speed and the viscosity of the liquid and its dependence on the contact pressure are all important factors in the operation of elastohydrodynamic lubrication.

With conventional journals and bearings the average pressure over the bearing is of the order of  $7 \times 10^{-6} \text{ N/rn}^2$ . With elastohydrodynamic bearings using a material such as rubber the pressures are perhaps 10 to 20 times smaller. At the other end of pressure spectrum, for instance in gear teeth, contact pressures of the order of  $700 \times 10^6 \text{ N/in}^2$  may easily be

reached. Because the metals used for gears are very hard this may still be within the range of elastic deformation. With careful alignment of the engaging gear teeth and appropriate surface finish, gears can in fact run successfully under these conditions using an ordinary mineral oil as the lubricant. If the thickness of the elastohydrodynamic film formed at such pressures is calculated it will be found that it is less than an atomic diameter. Since even the smoothest metal surfaces are far rougher than this (a millionth of an inch is about 100 atomic diameters) it seems hard to understand why lubrication is effective in these circumstances.

The explanation was first provided by A.N. Grubin in 1949 and a little later (1958) by A.W. Crook. With most mineral oils the application of a high pressure can lead to an enormous increase in viscosity. For example, at a pressure of  $700 \times 10^6 \text{ N/m}^2$  the viscosity may be increased 10,000-fold. The oil entering the gap between the gear teeth is trapped between the surfaces and at the high pressures existing in the contact region behaves virtually like a solid separating layer. This process explains why many mechanisms in engineering practice operate under much severer conditions than the classical theory would allow.

This type of elastohydrodynamic lubrication becomes apparent only when the film thickness is less than about 0.25 to 1  $\mu\text{m}$ . To be exploited successfully it implies that the surfaces must be very smooth and very carefully aligned. If these conditions are met systems such as gears or cams and tappets can operate effectively at very high contact pressures without any metallic contact occurring. The coefficient of friction depends on the load, contact geometry, speed, etc., but generally it lies between about  $\mu = 0.01$  at the lightest pressures and  $\mu = 0.1$  at the highest pressures. The great success of elastohydrodynamic theory in explaining effective lubrication at very high contact pressures also raises a problem that has not yet been satisfactorily resolved: why do lubricants ever fail, since the harder they are squeezed the harder it is to extrude them? It is possible that high temperature flashes are responsible; alternatively the high rates of shear can actually fracture the lubricant film since when it is trapped between the surfaces it is, instantaneously, more like a wax than an oil.

It is clear that in this type of lubrication the effect of pressure on viscosity is a factor of major importance. It turns out that mineral oils have reasonably good pressure-viscosity characteristics. It appears that synthetic oils do not have satisfactory pressure-viscosity characteristics.

In engineering, two most frequently encountered types of contact are line contact and point contact.

The film thickness for line contact (gears, cam-tappet) can be estimated from:

$$h_o = 2.65 \frac{\alpha^{0.54} (\eta_o U)^{0.7} R_e^{0.43}}{w^{0.13} E_e^{0.03}}$$

In the case of point contact (ball bearings), the film thickness is given by:

$$h_o = 0.84 \alpha \eta_o U^{0.74} 0.41 R_e \left( \frac{E_e}{W} \right)^{0.074}$$

In the above equations the symbols used are defined as:

$\alpha$  = the pressure-viscosity coefficient. A typical value for mineral oil is  $1.8 \times 10^{-8} \text{ m}^2/\text{N}$

$\nu$  = the viscosity of the lubricant at atmospheric pressure  $\text{Ns/m}^2$

$U$  = the entraining surface velocity,  $U = (U_A + U_B)/2 \text{ m/s}$ , where the subscripts  $A$  and  $B$  refer to the velocities of bodies 'A' and 'B' respectively.

$W$  = the load on the contact,  $\text{N}$

$w$  = the load per unit width of line contact,  $\text{N/m}$

LUBRICANTS

$E_o$  = the reduced Young's modulus  $\frac{1}{E_e} = \frac{1}{2} \left( \frac{1 - \nu_A^2}{E_A} + \frac{1 - \nu_B^2}{E_B} \right)$  N/m<sup>2</sup> where ' $\nu_A$

and  $\nu_B$  are the Poisson's ratios of the contacting bodies 'A' and 'B' respectively;  $E_A$  and  $E_B$  are the Young's moduli of the contacting bodies 'A' and 'B' respectively.

$R_e$  = is the reduced radius of curvature (meters) and is given by different equations for different contact configurations.

In ball bearings (see Figure 2) the reduced radius is given by:

- contact between the ball and inner race:  $R_e = \frac{rR_1}{R_1 + r}$
- contact between the ball and outer race:  $R_e = \frac{r(R_1 + 2r)}{R_1 + r}$

Fig. 2.

For involute gears it can readily be shown that the contact at a distance  $s$  from the pitch point can be represented by two cylinders of radii  $R_{1,2} \sin \psi + s$  rotating with the angular velocity of the wheels (see Fig. 3b). In the expression below  $R_1$  or  $R_2$  represent pitch radii of the wheels and  $\psi$  is the pressure angle. Thus,

$$R_e = \frac{(R_1 \sin \psi + s)(R_2 \sin \psi + s)}{(R_1 + R_2) \sin \psi}$$

The thickness of the film developed in the contact zone between smooth surfaces must be related to the topography of the actual surfaces. The most commonly used parameter for this purpose is the specific film thickness defined as the ratio of the minimum film thickness for smooth surfaces (given by the above equations) to the roughness parameter of the contacting surfaces.

$$\lambda = \frac{h_o}{\sqrt{R_{m1}^2 + R_{m2}^2}}$$

where  $R_m = 1.11R_a$  is the root-mean-square height of surface asperities, and  $R_a$  is the centre-line-average height of surface asperities.

If  $\lambda$  is greater than 3 then it is usually assumed that there is full separation of contacting bodies by an elastohydrodynamic film.

Fig. 3a.

Fig. 3b.

**Viscosity-pressure relationship.**—Lubricant viscosity increases with pressure. For most lubricants this effect is considerably larger than the effect of temperature or shear when the pressure is appreciably above atmospheric. This is of fundamental importance in the lubrication of highly loaded concentrated contacts such as in rolling contact bearings, gears and cam-tappet systems.

The best known equation to calculate the viscosity of a lubricant at moderate pressures is the Barus equation.

$$\eta_p = \eta_o e^{\alpha p}$$

where  $\eta$  is the viscosity at pressure  $p$  ( $\text{Ns/m}^2$ ),  $\eta_o$  is the viscosity at atmospheric pressure ( $\text{Ns/in}^2$ ),  $\alpha$  is the pressure-viscosity coefficient ( $\text{m}^2/\text{N}$ ) which can be obtained by plotting the natural logarithm of dynamic viscosity  $\eta$  measured at pressure  $p$ . The slope of the graph is  $\alpha$  and  $p$  is the pressure of concern ( $\text{N/m}^2$ ).

Values of dynamic viscosity  $\eta$  and pressure-viscosity coefficient  $\alpha$  for most commonly used lubricants are given in Table 1.

**Table 1. Dynamic Viscosity  $\eta$  and Pressure-viscosity Coefficient  $\alpha$  for Lubricants**

| Lubricant            | Dynamic viscosity $\eta$ measured at atmospheric pressure and room temperature $\eta \times 10^{-3}$ Ns/m <sup>2</sup> | Pressure-viscosity coefficient $\alpha$ measured at room temperature $\alpha \times 10^{-3}$ m <sup>2</sup> /N |
|----------------------|--|--|
| Light machine oil    | 45   | 28   |
| Heavy machine oil    | 153  | 23.7   |
| Cylinder oil         | 810  | 34   |
| Spindle oil          | 18.6   | 20   |
| Medicinal whale oil  | 107  | 29.5   |
| Castor oil           | 360  | 15.9   |
| Glycerol (glycerine) | 535  | 5.9  |

COUPLINGS AND CLUTCHES

**Connecting Shafts.**—For couplings to transmit up to about 150 horsepower, simple flange-type couplings of appropriate size, as shown in the table, are commonly used. The design shown is known as a safety flange coupling because the bolt heads and nuts are shrouded by the flange, but such couplings today are normally shielded by a sheet metal or other cover.

Safety Flange Couplings

| A      | B       | C      | D  | E       | F     | G      | H    | J     | K     | Bolts |         |

| 10 1/2 | 18 3/8  | 22 1/2 | 35 | 4 1/4   | 2 5/8 | 13 1/8 | 5/16 | 11/32 | 3/4   | 10    | 1 3/8   |
| 11     | 19 1/4  | 23 3/8 | 36 | 4 7/16  | 2 3/4 | 13 1/2 | 5/16 | 11/32 | 7/8   | 10    | 1 11/16 |
| 11 1/2 | 20 1/8  | 24 3/4 | 37 | 4 3/8   | 2 7/8 | 13 7/8 | 5/16 | 11/32 | 7/8   | 10    | 1 3/4   |
| 12     | 21      | 25 7/8 | 38 | 4 13/16 | 3     | 14 1/4 | 5/16 | 11/32 | 1     | 10    | 1 13/16 |

For small sizes and low power applications, a setscrew may provide the connection between the hub and the shaft, but higher power usually requires a key and perhaps two setscrews, one of them above the key. A flat on the shaft and some means of locking the set-screw(s) in position are advisable. In the AGMA Class I and II fits the shaft tolerances are  $-0.0005$  inch from  $\frac{1}{2}$  to  $1\frac{1}{2}$  inches diameter and  $-0.001$  inch on larger diameters up to 7 inches.

Class I coupling bore tolerances are  $+0.001$  inch up to  $1\frac{1}{2}$  inches diameter, then  $+0.0015$  inch to 7 inches diameter. Class II coupling bore tolerances are  $+0.002$  inch on sizes up to 3 inches diameter,  $+0.003$  inch on sizes from  $3\frac{1}{4}$  through  $3\frac{3}{4}$  inches diameter, and  $+0.004$  inch on larger diameters up to 7 inches.

**Interference Fits.**—Components of couplings transmitting over 150 horsepower often are made an interference fit on the shafts, which may reduce fretting corrosion. These couplings may or may not use keys, depending on the degree of interference. Keys may range in size from  $\frac{1}{8}$  inch wide by  $\frac{1}{16}$  inch high for  $\frac{1}{2}$ -inch diameter shafts to  $1\frac{3}{4}$  inches wide by  $\frac{7}{8}$  inch high for 7-inch diameter shafts. Couplings transmitting high torque or operating at high speeds or both may use two keys. Keys must be a good fit in their keyways to ensure good transmission of torque and prevent failure. AGMA standards provide recommendations for square parallel, rectangular section, and plain tapered keys, for shafts of  $\frac{5}{16}$  through 7 inches diameter, in three classes designated commercial, precision, and fitted. These standards also cover keyway offset, lead, parallelism, finish and radii, and face keys and splines. (See also ANSI and other Standards in Keys and Keyways section of this Handbook.)

**Double-cone Clamping Couplings.**—As shown in the table, double-cone clamping couplings are made in a range of sizes for shafts from  $1\frac{1}{16}$  to 6 inches in diameter, and are easily assembled to shafts. These couplings provide an interference fit, but they usually cost more and have larger overall dimensions than regular flanged couplings.

Double-cone Clamping Couplings

| A                | B               | C               | D               | E              | F             | G               | H                | J              | K              | L               | M             | No. of Bolts | No. of Keys |

**Flexible Couplings.**—Shafts that are out of alignment laterally or angularly can be connected by any of several designs of flexible couplings. Such couplings also permit some degree of axial movement in one or both shafts. Some couplings use disks or diaphragms to transmit the torque. Another simple form of flexible coupling consists of two flanges connected by links or endless belts made of leather or other strong, pliable material. Alternatively, the flanges may have projections that engage spacers of molded rubber or other flexible materials that accommodate uneven motion between the shafts. More highly developed flexible couplings use toothed flanges engaged by correspondingly toothed elements, permitting relative movement. These couplings require lubrication unless one or more of the elements is made of a self-lubricating material. Other couplings use diaphragms or bellows that can flex to accommodate relative movement between the shafts.

**The Universal Joint.**—This form of coupling, originally known as a Cardan or Hooke's coupling, is used for connecting two shafts the axes of which are not in line with each other, but which merely intersect at a point. There are many different designs of universal joints or couplings, which are based on the principle embodied in the original design. One well-known type is shown by the accompanying diagram.

As a rule, a universal joint does not work well if the angle  $\alpha$  (see illustration) is more than 45 degrees, and the angle should preferably be limited to about 20 degrees or 25 degrees, excepting when the speed of rotation is slow and little power is transmitted.

*Variation in Angular Velocity of Driven Shaft:* Owing to the angularity between two shafts connected by a universal joint, there is a variation in the angular velocity of one shaft during a single revolution, and because of this, the use of universal couplings is sometimes prohibited. Thus, the angular velocity of the driven shaft will not be the same at all points of the revolution as the angular velocity of the driving shaft. In other words, if the driving shaft moves with a uniform motion, then the driven shaft will have a variable motion and, therefore, the universal joint should not be used when absolute uniformity of motion is essential for the driven shaft.

*Determining Maximum and Minimum Velocities:* If shaft *A* (see diagram) runs at a constant speed, shaft *B* revolves at maximum speed when shaft *A* occupies the position shown in the illustration, and the minimum speed of shaft *B* occurs when the fork of the driving shaft *A* has turned 90 degrees from the position illustrated. The maximum speed of the driven shaft may be obtained by multiplying the speed of the driving shaft by the secant of angle  $\alpha$ . The minimum speed of the driven shaft equals the speed of the driver multiplied by cosine  $\alpha$ . Thus, if the driver rotates at a constant speed of 100 revolutions per minute and the shaft angle is 25 degrees, the maximum speed of the driven shaft is at a rate equal to  $1.1034 \times 100 = 110.34$  rpm. The minimum speed rate equals  $0.9063 \times 100 = 90.63$ ; hence, the extreme variation equals  $110.34 - 90.63 = 19.71$  rpm.

**Use of Intermediate Shaft between Two Universal Joints.**—The lack of uniformity in the speed of the driven shaft resulting from the use of a universal coupling, as previously explained, is objectionable for some forms of mechanisms. This variation may be avoided if the two shafts are connected with an intermediate shaft and two universal joints, provided the latter are properly arranged or located. Two conditions are necessary to obtain a constant speed ratio between the driving and driven shafts. First, the shafts must make the same angle with the intermediate shaft; second, the universal joint forks (assuming that the fork design is employed) on the intermediate shaft must be placed relatively so that when the plane of the fork at the left end coincides with the center lines of the intermediate shaft and the shaft attached to the left-hand coupling, the plane of the right-hand fork must also coincide with the center lines of the intermediate shaft and the shaft attached to the right-hand coupling; therefore the driving and the driven shafts may be placed in a variety of positions. One of the most common arrangements is with the driving and driven shafts parallel. The forks on the intermediate shafts should then be placed in the same plane.

This intermediate connecting shaft is frequently made telescoping, and then the driving and driven shafts can be moved independently of each other within certain limits in longitudinal and lateral directions. The telescoping intermediate shaft consists of a rod which enters a sleeve and is provided with a suitable spline, to prevent rotation between the rod and sleeve and permit a sliding movement. This arrangement is applied to various machine tools.

**Knuckle Joints.**—Movement at the joint between two rods may be provided by knuckle joints, for which typical proportions are seen in the table *Proportions of Knuckle Joints* that follows.

**Friction Clutches.**—Clutches which transmit motion from the driving to the driven member by the friction between the engaging surfaces are built in many different designs, although practically all of them can be classified under four general types, namely, conical clutches; radially expanding clutches; contracting-band clutches; and friction disk clutches in single and multiple types. There are many modifications of these general classes, some of which combine the features of different types. The proportions of various sizes of cone clutches are given in the table "Cast-iron Friction Clutches." The multicone friction clutch is a further development of the cone clutch. Instead of having a single cone-shaped surface, there is a series of concentric conical rings which engage annular grooves formed by corresponding rings on the opposite clutch member. The internal-expanding type is provided with shoes which are forced outward against an enclosing drum by the action of levers connecting with a collar free to slide along the shaft. The engaging shoes are commonly lined with wood or other material to increase the coefficient of friction. Disk clutches are based on the principle of multiple-plane friction, and use alternating plates or disks so arranged that one set engages with an outside cylindrical case and the other set with the shaft. When these plates are pressed together by spring pressure, or by other means, motion is transmitted from the driving to the driven members connected to the clutch. Some disk clutches have a few rather heavy or thick plates and others a relatively large number of thinner plates. Clutches of the latter type are common in automobile transmissions. One set of disks may be of soft steel and the other set of phosphor-bronze, or some other combination may be employed. For instance, disks are sometimes provided with cork inserts, or one set or series of disks may be faced with a special friction material such as asbestos-wire fabric, as in "dry plate" clutches, the disks of which are not lubricated like the disks of a clutch having, for example, the steel and phosphor-bronze combination. It is common practice to hold the driving and driven members of friction clutches in engagement by means of spring pressure, although pneumatic or hydraulic pressure may be employed.

Proportions of Knuckle Joints

**Power Transmitting Capacity of Friction Clutches.**—When selecting a clutch for a given class of service, it is advisable to consider any overloads that may be encountered and base the power transmitting capacity of the clutch upon such overloads. When the load varies or is subject to frequent release or engagement, the clutch capacity should be greater than the actual amount of power transmitted. If the power is derived from a gas or gasoline engine, the horsepower rating of the clutch should be 75 or 100 per cent greater than that of the engine.

**Power Transmitted by Disk Clutches.**—The approximate amount of power that a disk clutch will transmit may be determined from the following formula, in which *H* = horsepower transmitted by the clutch;  $\mu$  = coefficient of friction; *r* = mean radius of engaging surfaces; *F* = axial force in pounds (spring pressure) holding disks in contact; *N* = number of frictional surfaces; *S* = speed of shaft in revolutions per minute:

$$H = \frac{\mu r F N S}{63,000}$$

## Cast-iron Friction Clutches

For sizes not given below:

$$a = 2D$$

$$b = 4 \text{ to } 8D$$

$$c = 2\frac{1}{4}D$$

$$t = 1\frac{1}{2}D$$

$$e = \frac{3}{8}D$$

$$h = \frac{1}{2}D$$

$$s = \frac{5}{16}D, \text{ nearly}$$

$$k = \frac{1}{4}D$$

Note: The angle  $\phi$  of the cone may be from 4 to 10 degrees

**Frictional Coefficients for Clutch Calculations.**—While the frictional coefficients used by designers of clutches differ somewhat and depend upon variable factors, the following values may be used in clutch calculations: For greasy leather on cast iron about 0.20 or 0.25, leather on metal that is quite oily 0.15; metal and cork on oily metal 0.32; the same on dry metal 0.35; metal on dry metal 0.15; disk clutches having lubricated surfaces 0.10.

**Formulas for Cone Clutches.**—In cone clutch design, different formulas have been developed for determining the horsepower transmitted. These formulas, at first sight, do not seem to agree, there being a variation due to the fact that in some of the formulas the friction clutch surfaces are assumed to engage without slip, whereas, in others, some allowance is made for slip. The following formulas include both of these conditions:

$H.P.$  = horsepower transmitted

$N$  = revolutions per minute

$r$  = mean radius of friction cone, in inches

$r_1$  = large radius of friction cone, in inches

$r_2$  = small radius of friction cone, in inches

$R_1$  = outside radius of leather band, in inches

$R_2$  = inside radius of leather band, in inches

$V$  = velocity of a point at distance  $r$  from the center, in feet per minute

$F$  = tangential force acting at radius  $r$ , in pounds

$P_n$  = total normal force between cone surfaces, in pounds

$P_s$  = spring force, in pounds

$\alpha$  = angle of clutch surface with axis of shaft = 7 to 13 degrees

$\beta$  = included angle of clutch leather, when developed, in degrees

$f$  = coefficient of friction = 0.20 to 0.25 for greasy leather on iron

$p$  = allowable pressure per square inch of leather band = 7 to 8 pounds

$W$  = width of clutch leather, in inches

### DEVELOPMENT OF CLUTCH LEATHER

$$R_1 = \frac{r_1}{\sin \alpha} \quad R_2 = \frac{r_2}{\sin \alpha}$$

$$\beta = \sin \alpha \times 360 \quad r = \frac{r_1 + r_2}{2}$$

$$V = \frac{2\pi r N}{12}$$

$$F = \frac{HP \times 33,000}{V}$$

$$W = \frac{P_n}{2\pi r p}$$

$$HP = \frac{P_n f r N}{63,025}$$

For engagement with some slip:

$$P_n = \frac{P_s}{\sin \alpha}$$

$$P_s = \frac{HP \times 63,025 \sin \alpha}{f r N}$$

For engagement without slip:

$$P_n = \frac{P_s}{\sin \alpha + f \cos \alpha}$$

$$P_s = \frac{HP \times 63,025 (\sin \alpha + f \cos \alpha)}{f r N}$$

**Angle of Cone.**—If the angle of the conical surface of the cone type of clutch is too small, it may be difficult to release the clutch on account of the wedging effect, whereas, if the angle is too large, excessive spring force will be required to prevent slipping. The minimum angle for a leather-faced cone is about 8 or 9 degrees and the maximum angle about 13 degrees. An angle of  $12 \frac{1}{2}$  degrees appears to be the most common and is generally con-

sidered good practice. These angles are given with relation to the clutch axis and are one-half the included angle.

**Magnetic Clutches.**—Many disk and other clutches are operated electromagnetically with the magnetic force used only to move the friction disk(s) and the clutch disk(s) into or out of engagement against spring or other pressure. On the other hand, in a magnetic particle clutch, transmission of power is accomplished by magnetizing a quantity of metal particles enclosed between the driving and the driven components, forming a bond between them. Such clutches can be controlled to provide either a rigid coupling or uniform slip, useful in wire drawing and manufacture of cables.

Another type of magnetic clutch uses eddy currents induced in the input member which interact with the field in the output rotor. Torque transmitted is proportional to the coil current, so precise control of torque is provided. A third type of magnetic clutch relies on the hysteresis loss between magnetic fields generated by a coil in an input drum and a close-fitting cup on the output shaft, to transmit torque. Torque transmitted with this type of clutch also is proportional to coil current, so close control is possible.

Permanent-magnet types of clutches also are available, in which the engagement force is exerted by permanent magnets when the electrical supply to the disengagement coils is cut off. These types of clutches have capacities up to five times the torque-to-weight ratio of spring-operated clutches. In addition, if the controls are so arranged as to permit the coil polarity to be reversed instead of being cut off, the combined permanent magnet and electromagnetic forces can transmit even greater torque.

**Centrifugal and Free-wheeling Clutches.**—Centrifugal clutches have driving members that expand outward to engage a surrounding drum when speed is sufficient to generate centrifugal force. Free-wheeling clutches are made in many different designs and use balls, cams or sprags, ratchets, and fluids to transmit motion from one member to the other. These types of clutches are designed to transmit torque in only one direction and to take up the drive with various degrees of gradualness up to instantaneously.

**Slipping Clutch/Couplings.**—Where high shock loads are likely to be experienced, a slipping clutch or coupling or both should be used. The most common design uses a clutch plate that is clamped between the driving and driven plates by spring pressure that can be adjusted. When excessive load causes the driven member to slow, the clutch plate surfaces slip, allowing reduction of the torque transmitted. When the overload is removed, the drive is taken up automatically. Switches can be provided to cut off current supply to the driving motor when the driven shaft slows to a preset limit or to signal a warning or both. The slip or overload torque is calculated by taking 150 per cent of the normal running torque.

**Wrapped-spring Clutches.**—For certain applications, a simple steel spring sized so that its internal diameter is a snug fit on both driving and driven shafts will transmit adequate torque in one direction. The tightness of grip of the spring on the shafts increases as the torque transmitted increases. Disengagement can be effected by slight rotation of the spring, through a projecting tang, using electrical or mechanical means, to wind up the spring to a larger internal diameter, allowing one of the shafts to run free within the spring.

Normal running torque  $T_r$  in lb-ft = (required horsepower  $\times$  5250)  $\div$  rpm. For heavy shock load applications, multiply by a 200 per cent or greater overload factor. (See Motors, factors governing selection.)

The clutch starting torque  $T_c$ , in lb-ft, required to accelerate a given inertia in a specific time is calculated from the formula:

$$T_c = \frac{WR^2 \times \Delta N}{308t}$$

where  $WR^2$  = total inertia encountered by clutch in lb-ft<sup>2</sup> ( $W$  = weight and  $R$  = radius of gyration of rotating part)

$\Delta N$  = final rpm – initial rpm

308 = = constant (see *Factors Governing Motor Selection* on page 2473)

$t$  = time to required speed in seconds

Example: If the inertia is 80 lb-ft<sup>2</sup>, and the speed of the driven shaft is to be increased from 0 to 1500 rpm in 3 seconds, find the clutch starting torque in lb-ft.

$$T_c = \frac{80 \times 1500}{308 \times 3} = 130 \text{ lb-ft}$$

The heat  $E$ , in BTU, generated in one engagement of a clutch can be calculated from the formula:

$$E = \frac{T_c \times WR^2 \times (N_1^2 - N_2^2)}{(T_c - T_1) \times 4.7 \times 10^6}$$

where:  $WR^2$  = total inertia encountered by clutch in lb-ft.<sup>2</sup>

$N_1$  = final rpm     $N_2$  = initial rpm

$T_c$  = clutch torque in lb-ft     $T_1$  = torque load in lb-ft

Example: Calculate the heat generated for each engagement under the conditions cited for the first example.

$$E = \frac{130 \times 80 \times (1500)^2}{(130 - 10) \times 4.7 \times 10^6} = 41.5 \text{ BTU}$$

The preferred location for a clutch is on the high- rather than on the low-speed shaft because a smaller-capacity unit, of lower cost and with more rapid dissipation of heat, can be used. However, the heat generated may also be more because of the greater slippage at higher speeds, and the clutch may have a shorter life. For light-duty applications, such as to a machine tool, where cutting occurs after the spindle has reached operating speed, the calculated torque should be multiplied by a safety factor of 1.5 to arrive at the capacity of the clutch to be used. Heavy-duty applications such as frequent starting of a heavily loaded vibratory-finishing barrel require a safety factor of 3 or more.

**Positive Clutches.**—When the driving and driven members of a clutch are connected by the engagement of interlocking teeth or projecting lugs, the clutch is said to be “positive” to distinguish it from the type in which the power is transmitted by frictional contact. The positive clutch is employed when a sudden starting action is not objectionable and when the inertia of the driven parts is relatively small. The various forms of positive clutches differ merely in the angle or shape of the engaging surfaces. The least positive form is one having planes of engagement which incline backward, with respect to the direction of motion. The tendency of such a clutch is to disengage under load, in which case it must be held in position by axial pressure.

Fig. 1. Types of Clutch Teeth

This pressure may be regulated to perform normal duty, permitting the clutch to slip and disengage when over-loaded. Positive clutches, with the engaging planes parallel to the axis of rotation, are held together to obviate the tendency to jar out of engagement, but they provide no safety feature against over-load. So-called “under-cut” clutches engage more tightly the heavier the load, and are designed to be disengaged only when free from load. The teeth of positive clutches are made in a variety of forms, a few of the more common

styles being shown in Fig. 1. Clutch *A* is a straight-toothed type, and *B* has angular or saw-shaped teeth. The driving member of the former can be rotated in either direction: the latter is adapted to the transmission of motion in one direction only, but is more readily engaged. The angle  $\theta$  of the cutter for a saw-tooth clutch *B* is ordinarily 60 degrees. Clutch *C* is similar to *A*, except that the sides of the teeth are inclined to facilitate engagement and disengagement. Teeth of this shape are sometimes used when a clutch is required to run in either direction without backlash. Angle  $\theta$  is varied to suit requirements and should not exceed 16 or 18 degrees. The straight-tooth clutch *A* is also modified to make the teeth engage more readily, by rounding the corners of the teeth at the top and bottom. Clutch *D* (commonly called a "spiral-jaw" clutch) differs from *B* in that the surfaces *e* are helicoidal. The driving member of this clutch can transmit motion in only one direction.

Fig. 2. Diagrammatic View Showing Method of Cutting Clutch Teeth

Fig. 3.

Clutches of this type are known as right- and left-hand, the former driving when turning to the right, as indicated by the arrow in the illustration. Clutch *E* is the form used on the back-shaft of the Brown & Sharpe automatic screw machines. The faces of the teeth are radial and incline at an angle of 8 degrees with the axis, so that the clutch can readily be disengaged. This type of clutch is easily operated, with little jar or noise. The 2-inch diameter size has 10 teeth. Height of working face,  $\frac{1}{8}$  inch.

**Cutting Clutch Teeth.**—A common method of cutting a straight-tooth clutch is indicated by the diagrams *A*, *B* and *C*, Fig. 2, which show the first, second and third cuts required for forming the three teeth. The work is held in the chuck of a dividing-head, the latter being set at right angles to the table. A plain milling cutter may be used (unless the corners of the teeth are rounded), the side of the cutter being set to exactly coincide with the center-line. When the number of teeth in the clutch is odd, the cut can be taken clear across the blank as shown, thus finishing the sides of two teeth with one passage of the cutter. When the number of teeth is even, as at *D*, it is necessary to mill all the teeth on one side and then set the cutter for finishing the opposite side. Therefore, clutches of this type commonly have an odd number of teeth. The maximum width of the cutter depends upon the width of the space at the narrow ends of the teeth. If the cutter must be quite narrow in order to pass the narrow ends, some stock may be left in the tooth spaces, which must be removed by a separate cut. If the tooth is of the modified form shown at *C*, Fig. 1, the cutter should be set as

indicated in Fig. 3; that is, so that a point *a* on the cutter at a radial distance *d* equal to one-half the depth of the clutch teeth lies in a radial plane. When it is important to eliminate all backlash, point *a* is sometimes located at a radial distance *d* equal to six-tenths of the depth of the tooth, in order to leave clearance spaces at the bottoms of the teeth; the two clutch members will then fit together tightly. Clutches of this type must be held in mesh.

Fig. 4.

**Angle of Dividing-head for Milling V-shaped Teeth with Single-angle Cutter**

$$\cos \alpha = \frac{\tan(360^\circ/N) \times \cot \theta}{2}$$

$\alpha$  is the angle shown in Fig. 4 and is the angle shown by the graduations on the dividing head.  $\theta$  is the included angle of a single cutter, see Fig. 1.

| No. of Teeth, <i>N</i> | Angle of Single-angle Cutter, $\theta$ |       |           |           | No. of Teeth, <i>N</i> | Angle of Single-angle Cutter, $\theta$ |           |           |  |
|------------------------|--|-------|-----------|-----------|------------------------|--|-----------|-----------|--|

| 11                     | 79                                     | 18.5  | 83 17     | 86 45.1   | 24                     | 85 33.8                                | 87 12.3   | 88 38.8   |  |
| 12                     | 80                                     | 24.4  | 83 58.1   | 87 4.94   | 25                     | 85 45                                  | 87 19.3   | 88 42.2   |  |
| 13                     | 81                                     | 17.1  | 84 31.1   | 87 20.9   | 26                     | 85 55.2                                | 87 25.7   | 88 45.3   |  |
| 14                     | 82                                     | .536  | 84 58.3   | 87 34     | 27                     | 86 4.61                                | 87 31.7   | 88 48.2   |  |
| 15                     | 82                                     | 36.9  | 85 21.2   | 87 45     | 28                     | 86 13.3                                | 87 37.2   | 88 50.8   |  |
| 16                     | 83                                     | 7.95  | 85 40.6   | 87 54.4   | 29                     | 86 21.4                                | 87 42.3   | 88 53.3   |  |
| 17                     | 83                                     | 34.7  | 85 57.4   | 88 2.56   | 30                     | 86 28.9                                | 87 47     | 88 55.6   |  |

**Cutting Saw-tooth Clutches:** When milling clutches having angular teeth as shown at B, Fig. 1, the axis of the clutch blank should be inclined a certain angle  $\alpha$  as shown at A in Fig. 4. If the teeth were milled with the blank vertical, the tops of the teeth would incline towards the center as at D, whereas, if the blank were set to such an angle that the tops of the teeth were square with the axis, the bottoms would incline upwards as at E. In either case,

the two clutch members would not mesh completely: the engagement of the teeth cut as shown at  $D$  and  $E$  would be as indicated at  $D_1$  and  $E_1$  respectively. As will be seen, when the outer points of the teeth at  $D_1$  are at the bottom of the grooves in the opposite member, the inner ends are not together, the contact area being represented by the dotted lines. At  $E_1$  the inner ends of the teeth strike first and spaces are left between the teeth around the outside of the clutch. To overcome this objectionable feature, the clutch teeth should be cut as indicated at  $B$ , or so that the bottoms and tops of the teeth have the same inclination, converging at a central point  $x$ . The teeth of both members will then engage across the entire width as shown at  $C$ . The angle  $\alpha$  required for cutting a clutch as at  $B$  can be determined by the following formula in which  $\alpha$  equals the required angle,  $N$  = number of teeth,  $\theta$  = cutter angle, and  $360^\circ/N$  = angle between teeth:

$$\cos \alpha = \frac{\tan(360^\circ/N) \times \cot \theta}{2}$$

The angles  $\alpha$  for various numbers of teeth and for 60-, 70- or 80-degree single-angle cutters are given in the table on page 2356. The following table is for double-angle cutters used to cut V-shaped teeth.

#### Angle of Dividing-head for Milling V-shaped Teeth with Double-angle Cutter

$$\cos \alpha = \frac{\tan(180^\circ/N) \times \cot(\theta/2)}{2}$$

This is the angle ( $\alpha$ , Fig. 4) shown by graduations on the dividing-head.  $\theta$  is the included angle of a double-angle cutter, see Fig. 1.

| No. of Teeth, $N$ | Included Angle of Cutter, $\theta$ |         | No. of Teeth, $N$ | Included Angle of Cutter, $\theta$ |           |

| 27                | 84 11.4                            | 86 39   | 48                | 86 44.8                            | 88 7.32   |
| 28                | 84 24                              | 86 46.2 | 49                | 86 48.8                            | 88 9.63   |
| 29                | 84 35.7                            | 86 53   | 50                | 86 52.6                            | 88 11.8   |
| 30                | 84 46.7                            | 86 59.3 | 51                | 86 56.3                            | 88 14     |

The angles given in the table above are applicable to the milling of V-shaped grooves in brackets, etc., which must have toothed surfaces to prevent the two members from turning relative to each other, except when unclamped for angular adjustment

**FRICION BRAKES**

**Formulas for Band Brakes.**—In any band brake, such as shown in Fig. 1, in the tabulation of formulas, where the brake wheel rotates in a clockwise direction, the tension in that part of the band marked *x* equals  $P \frac{1}{e^{\mu\theta} - 1}$

The tension in that part marked *y* equals  $P \frac{e^{\mu\theta}}{e^{\mu\theta} - 1}$ .

*P* = tangential force in pounds at rim of brake wheel

*e* = base of natural logarithms = 2.71828

$\mu$  = coefficient of friction between the brake band and the brake wheel

$\theta$  = angle of contact of the brake band with the brake wheel expressed in

radians (one radian =  $\frac{180 \text{ deg.}}{\pi \text{ radians}} = 57.296 \frac{\text{deg.}}{\text{radian}}$ ).

For simplicity in the formulas presented, the tensions at *x* and *y* (Fig. 1) are denoted by  $T_1$  and  $T_2$  respectively, for clockwise rotation. When the direction of the rotation is reversed, the tension in *x* equals  $T_2$ , and the tension in *y* equals  $T_1$ , which is the reverse of the tension in the clockwise direction.

The value of the expression  $e^{\mu\theta}$  in these formulas may be most easily found by using a hand-held calculator of the scientific type; that is, one capable of raising 2.71828 to the power  $\mu\theta$ . The following example outlines the steps in the calculations.

**Table of Values of  $e^{\mu\theta}$**

| Proportion of Contact to Whole Circumference, $\frac{\theta}{2\pi}$ | Steel Band on Cast Iron, $\mu = 0.18$ | Leather Belt on               |                           |                               |                    |
|---|---------------------------------------|-------------------------------|---------------------------|-------------------------------|--------------------|
|   |                                       | Wood                          | Cast Iron                 |                               |                    |
|   |                                       | Slightly Greasy; $\mu = 0.47$ | Very Greasy; $\mu = 0.12$ | Slightly Greasy; $\mu = 0.28$ | Damp; $\mu = 0.38$ |
| 0.1   | 1.12                                  | 1.34                          | 1.08                      | 1.19                          | 1.27               |
| 0.2   | 1.25                                  | 1.81                          | 1.16                      | 1.42                          | 1.61               |
| 0.3   | 1.40                                  | 2.43                          | 1.25                      | 1.69                          | 2.05               |
| 0.4   | 1.57                                  | 3.26                          | 1.35                      | 2.02                          | 2.60               |

## Formulas for Simple and Differential Band Brakes

$F$  = force in pounds at end of brake handle;  $P$  = tangential force in pounds at rim of brake wheel;  $e$  = base of natural logarithms = 2.71828;  $\mu$  = coefficient of friction between the brake band and the brake wheel;  $\theta$  = angle of contact of the brake band with the brake wheel, expressed in radians (one radian = 57.296 degrees).

$$T_1 = P \frac{1}{e^{\mu\theta} - 1} \quad T_2 = P \frac{e^{\mu\theta}}{e^{\mu\theta} - 1}$$

## Simple Band Brake

Fig. 1.

For clockwise rotation:

$$F = \frac{bT_2}{a} = \frac{Pb}{a} \left( \frac{e^{\mu\theta}}{e^{\mu\theta} - 1} \right)$$

For counter clockwise rotation:

$$F = \frac{bT_1}{a} = \frac{Pb}{a} \left( \frac{1}{e^{\mu\theta} - 1} \right)$$

Fig. 2.

For clockwise rotation:

$$F = \frac{bT_1}{a} = \frac{Pb}{a} \left( \frac{1}{e^{\mu\theta} - 1} \right)$$

For counter clockwise rotation:

$$F = \frac{bT_2}{a} = \frac{Pb}{a} \left( \frac{e^{\mu\theta}}{e^{\mu\theta} - 1} \right)$$

## Differential Band Brake

Fig. 3.

For clockwise rotation:

$$F = \frac{b_2T_2 - b_1T_1}{a} = \frac{P}{a} \left( \frac{b_2e^{\mu\theta} - b_1}{e^{\mu\theta} - 1} \right)$$

For counter clockwise rotation:

$$F = \frac{b_2T_1 - b_1T_2}{a} = \frac{P}{a} \left( \frac{b_2 - b_1e^{\mu\theta}}{e^{\mu\theta} - 1} \right)$$

In this case, if  $b_2$  is equal to, or less than,  $b_1e^{\mu\theta}$ , the force  $F$  will be 0 or negative and the band brake works automatically.

Fig. 4.

For clockwise rotation:

$$F = \frac{b_2T_2 + b_1T_1}{a} = \frac{P}{a} \left( \frac{b_2e^{\mu\theta} + b_1}{e^{\mu\theta} - 1} \right)$$

For counter clockwise rotation:

$$F = \frac{b_1T_2 + b_2T_1}{a} = \frac{P}{a} \left( \frac{b_1e^{\mu\theta} + b_2}{e^{\mu\theta} - 1} \right)$$

If  $b_2 = b_1$ , both of the above formulas reduce to  $F = \frac{Pb_1}{a} \left( \frac{e^{\mu\theta} + 1}{e^{\mu\theta} - 1} \right)$ .

In this case, the same force  $F$  is required for rotation in either direction.

*Example:* In a band brake of the type in Fig. 1, dimension  $a = 24$  inches, and  $b = 4$  inches; force  $P = 100$  pounds; coefficient  $\mu = 0.2$ , and angle of contact = 240 degrees, or

$$\theta = \frac{240}{180} \times \pi = 4.18$$

The rotation is clockwise. Find force  $F$  required.

$$\begin{aligned}
 F &= \frac{Pb}{a} \left( \frac{e^{\mu\theta}}{e^{\mu\theta} - 1} \right) \\
 &= \frac{100 \times 4}{24} \left( \frac{2.71828^{0.2 \times 4.18}}{2.71828^{0.2 \times 4.18} - 1} \right) \\
 &= \frac{400}{24} \times \frac{2.71828^{0.836}}{2.71828^{0.836} - 1} = 16.66 \times \frac{2.31}{2.31 - 1} = 29.4
 \end{aligned}$$

If a hand-held calculator is not used, determining the value of  $e^{\mu\theta}$  is rather tedious, and the table on page 2358 will save calculations.

**Coefficient of Friction in Brakes.**—The coefficients of friction that may be assumed for friction brake calculations are as follows: Iron on iron, 0.25 to 0.3 leather on iron, 0.3; cork on iron, 0.35. Values somewhat lower than these should be assumed when the velocities exceed 400 feet per minute at the beginning of the braking operation.

For brakes where wooden brake blocks are used on iron drums, poplar has proved the best brake-block material. The best material for the brake drum is wrought iron. Poplar gives a high coefficient of friction, and is little affected by oil. The average coefficient of friction for poplar brake blocks and wrought-iron drums is 0.6; for poplar on cast iron, 0.35 for oak on wrought iron, 0.5; for oak on cast iron, 0.3; for beech on wrought iron, 0.5; for beech on cast iron, 0.3; for elm on wrought iron, 0.6; and for elm on cast iron, 0.35. The objection to elm is that the friction decreases rapidly if the friction surfaces are oily. The coefficient of friction for elm and wrought iron, if oily, is less than 0.4.

**Calculating Horsepower from Dynamometer Tests.**—When a dynamometer is arranged for measuring the horsepower transmitted by a shaft, as indicated by the diagrammatic view in Fig. 5, the horsepower may be obtained by the formula:

$$HP = \frac{2\pi LPN}{33000}$$

in which H.P. = horsepower transmitted;  $N$  = number of revolutions per minute;  $L$  = distance (as shown in illustration) from center of pulley to point of action of weight  $P$ , in feet;  $P$  = weight hung on brake arm or read on scale.

Fig. 5.

By adopting a length of brake arm equal to 5 feet 3 inches, the formula may be reduced to the simple form:

$$HP = \frac{NP}{1000}$$

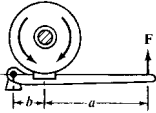

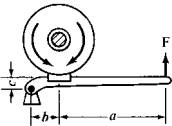

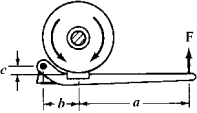

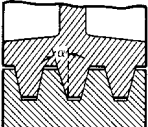

If a length of brake arm equal to 2 feet 7½ inches is adopted as a standard, the formula takes the form:

$$HP = \frac{NP}{2000}$$

The *transmission* type of dynamometer measures the power by transmitting it through the mechanism of the dynamometer from the apparatus in which it is generated, or to the

apparatus in which it is to be utilized. Dynamometers known as *indicators* operate by simultaneously measuring the pressure and volume of a confined fluid. This type may be used for the measurement of the power generated by steam or gas engines or absorbed by refrigerating machinery, air compressors, or pumps. An electrical dynamometer is for measuring the power of an electric current, based on the mutual action of currents flowing in two coils. It consists principally of one fixed and one movable coil, which, in the normal position, are at right angles to each other. Both coils are connected in series, and, when a current traverses the coils, the fields produced are at right angles; hence, the coils tend to take up a parallel position. The movable coil with an attached pointer will be deflected, the deflection measuring directly the electric current.

**Formulas for Block Brakes**

|  |  |
|--|--|
| <p><math>F</math> = force in pounds at end of brake handle;<br/> <math>P</math> = tangential force in pounds at rim of brake wheel;<br/> <math>\mu</math> = coefficient of friction between the brake block and brake wheel.</p> |  |
|  <p>Fig. 1.</p>   | <p>Block brake.<br/>                 For rotation in either direction:</p> $F = P \frac{b}{a+b} \times \frac{1}{\mu} = \frac{Pb}{a+b} \left( \frac{1}{\mu} \right)$  |
|  <p>Fig. 2.</p>   | <p>Block brake.<br/>                 For clockwise rotation:</p> $F = \frac{Pb - Pc}{a+b} = \frac{Pb}{a+b} \left( \frac{1}{\mu} - \frac{c}{b} \right)$ <p>For counter clockwise rotation:</p> $F = \frac{Pb + Pc}{a+b} = \frac{Pb}{a+b} \left( \frac{1}{\mu} + \frac{c}{b} \right)$  |
|  <p>Fig. 3.</p>   | <p>Block brake.<br/>                 For clockwise rotation:</p> $F = \frac{Pb + Pc}{a+b} = \frac{Pb}{a+b} \left( \frac{1}{\mu} + \frac{c}{b} \right)$ <p>For counter clockwise rotation:</p> $F = \frac{Pb - Pc}{a+b} = \frac{Pb}{a+b} \left( \frac{1}{\mu} - \frac{c}{b} \right)$  |
|  <p>Fig. 4.</p>   | <p>The brake wheel and friction block of the block brake are often grooved as shown in Fig. 4. In this case, substitute for <math>\mu</math> in the above equations the value <math>\frac{\mu}{\sin \alpha + \mu \cos \alpha}</math> where <math>\alpha</math> is one-half the angle included by the faces of the grooves.</p> |

**Friction Wheels for Power Transmission**

When a rotating member is driven intermittently and the rate of driving does not need to be positive, friction wheels are frequently used, especially when the amount of power to be transmitted is comparatively small. The driven wheels in a pair of friction disks should always be made of a harder material than the driving wheels, so that if the driven wheel

should be held stationary by the load, while the driving wheel revolves under its own pressure, a flat spot may not be rapidly worn on the driven wheel. The driven wheels, therefore, are usually made of iron, while the driving wheels are made of or covered with, rubber, paper, leather, wood or fiber. The safe working force per inch of face width of contact for various materials are as follows: Straw fiber, 150; leather fiber, 240; tarred fiber, 240; leather, 150; wood, 100 to 150; paper, 150. Coefficients of friction for different combinations of materials are given in the following table. Smaller values should be used for exceptionally high speeds, or when the transmission must be started while under load.

**Horsepower of Friction Wheels.**—Let  $D$  = diameter of friction wheel in inches;  $N$  = Number of revolutions per minute;  $W$  = width of face in inches;  $f$  = coefficient of friction;  $P$  = force in pounds, per inch width of face. Then:

$$\text{H.P.} = \frac{3.1416 \times D \times N \times P \times W \times f}{33,000 \times 12}$$

Assume

$$\frac{3.1416 \times P \times f}{33,000 \times 12} = C$$

then,

for  $P = 100$  and  $f = 0.20$ ,  $C = 0.00016$

for  $P = 150$  and  $f = 0.20$ ,  $C = 0.00024$

for  $P = 200$  and  $f = 0.20$ ,  $C = 0.00032$

**Working Values of Coefficient of Friction**

| Materials                   | Coefficient of Friction | Materials                 | Coefficient of Friction |
|-----------------------------|-------------------------|---------------------------|-------------------------|
| Straw fiber and cast iron   | 0.26                    | Tarred fiber and aluminum | 0.18                    |
| Straw fiber and aluminum    | 0.27                    | Leather and cast iron     | 0.14                    |
| Leather fiber and cast iron | 0.31                    | Leather and aluminum      | 0.22                    |
| Leather fiber and aluminum  | 0.30                    | Leather and typemetal     | 0.25                    |
| Tarred fiber and cast iron  | 0.15                    | Wood and metal            | 0.25                    |
| Paper and cast iron         | 0.20                    |                           |                         |

The horsepower transmitted is then:

$$\text{HP} = D \times N \times W \times C$$

*Example:* Find the horsepower transmitted by a pair of friction wheels; the diameter of the driving wheel is 10 inches, and it revolves at 200 revolutions per minute. The width of the wheel is 2 inches. The force per inch width of face is 150 pounds, and the coefficient of friction 0.20.

$$\text{HP} = 10 \times 200 \times 2 \times 0.00024 = 0.96 \text{ horsepower}$$

**Horsepower Which May be Transmitted by Means of a Clean Paper Friction Wheel of One-inch Face when Run Under a Force of 150 Pounds (Rockwood Mfg. Co.)**

| Dia. of Friction Wheel | Revolutions per Minute |       |       |       |       |       |       |       |       |      |       |

## KEYS AND KEYSEATS

**ANSI Standard Keys and Keyseats.**—American National Standard, B17.1 Keys and Keyseats, based on current industry practice, was approved in 1967, and reaffirmed in 1989. This standard establishes a uniform relationship between shaft sizes and key sizes for parallel and taper keys as shown in [Table 1](#). Other data in this standard are given in [Tables 2](#) and [3](#) through [7](#). The sizes and tolerances shown are for single key applications only.

The following definitions are given in the standard:

**Key:** A demountable machinery part which, when assembled into keyseats, provides a positive means for transmitting torque between the shaft and hub.

**Keyseat:** An axially located rectangular groove in a shaft or hub.

This standard recognizes that there are two classes of stock for parallel keys used by industry. One is a close, plus toleranced key stock and the other is a broad, negative toleranced bar stock. Based on the use of two types of stock, two classes of fit are shown:

**Class 1:** A clearance or metal-to-metal side fit obtained by using bar stock keys and keyseat tolerances as given in [Table 4](#). This is a relatively free fit and applies only to parallel keys.

**Class 2:** A side fit, with possible interference or clearance, obtained by using key stock and keyseat tolerances as given in [Table 4](#). This is a relatively tight fit.

**Class 3:** This is an interference side fit and is not tabulated in [Table 4](#) since the degree of interference has not been standardized. However, it is suggested that the top and bottom fit range given under Class 2 in [Table 4](#), for parallel keys be used.

**Table 1. Key Size Versus Shaft Diameter ANSI B17.1-1967 (R1998)**

| Nominal Shaft Diameter   |                | Nominal Key Size |                |                | Normal Keyseat Depth |                |
|--|----------------|------------------|----------------|----------------|----------------------|----------------|
| Over   | To (Incl.)     | Width, W         | Height, H      |                | H/2                  |                |
|  |                |                  | Square         | Rectangular    | Square               | Rectangular    |
| $\frac{3}{16}$   | $\frac{7}{16}$ | $\frac{3}{32}$   | $\frac{3}{32}$ | ...            | $\frac{3}{64}$       | ...            |

| 9  | 11             | $2\frac{1}{2}$   | $2\frac{1}{2}$ | $1\frac{3}{4}$ | $1\frac{1}{4}$       | $\frac{7}{8}$  |

<sup>a</sup> Some key standards show  $1\frac{1}{4}$  inches; preferred height is  $1\frac{1}{2}$  inches.

All dimensions are given in inches. For larger shaft sizes, see *ANSI Standard Woodruff Keys and Keyseats*.

**Key Size vs. Shaft Diameter:** Shaft diameters are listed in [Table 1](#) for identification of various key sizes and are not intended to establish shaft dimensions, tolerances or selections. For a stepped shaft, the size of a key is determined by the diameter of the shaft at the

point of location of the key. Up through 6½-inch diameter shafts square keys are preferred; rectangular keys are preferred for larger shafts.

If special considerations dictate the use of a keyseat in the hub shallower than the preferred nominal depth shown, it is recommended that the tabulated preferred nominal standard keyseat always be used in the shaft.

**Keyseat Alignment Tolerances:** A tolerance of 0.010 inch, max is provided for offset (due to parallel displacement of keyseat centerline from centerline of shaft or bore) of keyseats in shaft and bore. The following tolerances for maximum lead (due to angular displacement of keyseat centerline from centerline of shaft or bore and measured at right angles to the shaft or bore centerline) of keyseats in shaft and bore are specified: 0.002 inch for keyseat length up to and including 4 inches; 0.0005 inch per inch of length for keyseat lengths above 4 inches to and including 10 inches; and 0.005 inch for keyseat lengths above 10 inches. For the effect of keyways on shaft strength, see *Effect of Keyways on Shaft Strength* on page 305.

**Table 2. Depth Control Values *S* and *T* for Shaft and Hub**  
*ANSI B17.1-1967 (R1998)*

| Nominal Shaft Diameter | Shafts, Parallel and Taper |             | Hubs, Parallel |             | Hubs, Taper |             |

All dimensions are given in inches.

\*For locating position of dimension H. Tolerance does not apply.

For larger sizes the following relationships are suggested as guides for establishing A and B: A = 1.8H and B = 1.2H.

All dimensions are given in inches.

The Key numbers indicate normal key dimensions. The last two digits give the nominal diameter  $B$  in eighths of an inch and the digits preceding the last two give the nominal width  $W$  in thirty-seconds of an inch.

All dimensions are given in inches.

The key numbers indicate nominal key dimensions. The last two digits give the nominal diameter  $B$  in eighths of an inch and the digits preceding the last two give the nominal width  $W$  in thirty-seconds of an inch.

The key numbers with the -1 designation, while representing the nominal key size have a shorter length  $F$  and due to a greater distance below center  $E$  are less in height than the keys of the same number without the -1 designation.

**Table 10. ANSI Keyseat Dimensions for Woodruff Keys**  
ANSI B17.2-1967 (R1998)

<sup>a</sup> These Width *A* values were set with the maximum keyseat (shaft) width as that figure which will receive a key with the greatest amount of looseness consistent with assuring the key's sticking in the keyseat (shaft). Minimum keyseat width is that figure permitting the largest shaft distortion acceptable when assembling maximum key in minimum keyseat. Dimensions *A*, *B*, *C*, *D* are taken at side intersection.

All dimensions are given in inches.

The following definitions are given in this standard:

**Woodruff Key:** A demountable machinery part which, when assembled into key-seats, provides a positive means for transmitting torque between the shaft and hub.

**Woodruff Key Number:** An identification number by which the size of key may be readily determined.

**Woodruff Keyseat—Shaft:** The circular pocket in which the key is retained.

**Woodruff Keyseat—Hub:** An axially located rectangular groove in a hub. (This has been referred to as a keyway.)

**Woodruff Keyseat Milling Cutter:** An arbor type or shank type milling cutter normally used for milling Woodruff keyseats in shafts (see page 820).

Taper Shaft Ends with Slotted Nuts SAE Standard

TAPER PER FOOT =  $1.500^{+0.002}$  IN.  
 H IS MEASURED PERPENDICULAR TO KEY.  
 C, COTTER-PIN HOLE HAS CENTERLINE  
 DISPLACED 90° FROM KEYWAY CENTER

**Chamfered Keys and Filleted Keyseats.**—In general practice, chamfered keys and filleted keyseats are not used. However, it is recognized that fillets in keyseats decrease stress concentration at corners. When used, fillet radii should be as large as possible without causing excessive bearing stresses due to reduced contact area between the key and its mating parts. Keys must be chamfered or rounded to clear fillet radii. Values in Table 5 assume general conditions and should be used only as a guide when critical stresses are encountered.

**Depths for Milling Keyseats.**—Table 11 on page 2375 has been compiled to facilitate the accurate milling of keyseats. This table gives the distance  $M$  (see illustration accompanying table) between the top of the shaft and a line passing through the upper corners or edges of the keyseat. Dimension  $M$  is calculated by the formula:  $M = \frac{1}{2}(S - \sqrt{S^2 - E^2})$  where  $S$  is diameter of shaft, and  $E$  is width of keyseat. A simple approximate formula that gives  $M$  to within 0.001 inch is  $M = E^2 \div 4S$ .

**Cotters.**—A cotter is a form of key that is used to connect rods, etc., that are subjected either to tension or compression or both, the cotter being subjected to shearing stresses at two transverse cross-sections. When taper cotters are used for drawing and holding parts together, if the cotter is held in place by the friction between the bearing surfaces, the taper should not be too great. Ordinarily a taper varying from  $\frac{1}{4}$  to  $\frac{1}{2}$  inch per foot is used for plain cotters. When a set-screw or other device is used to prevent the cotter from backing out of its slot, the taper may vary from  $1\frac{1}{2}$  to 2 inches per foot.

### British Keys and Keyways

**British Standard Metric Keys and Keyways.**—This British Standard, BS 4235:Part 1:1972 (1986), covers square and rectangular parallel keys and keyways, and square and rectangular taper keys and keyways. Plain and gib-head taper keys are specified. There are three classes of fit for the square and rectangular parallel keys and keyways, designated free, normal, and close. A *free fit* is applied when the application requires the hub of an assembly to slide over the key; a *normal fit* is employed when the key is to be inserted in the keyway with the minimum amount of fitting, as may be required in mass-production assembly work; and a *close fit* is applied when accurate fitting of the key is required under maximum material conditions, which may involve selection of components.

The Standard does not provide for misalignment or offset greater than can be accommodated within the dimensional tolerances. If an assembly is to be heavily stressed, a check should be made to ensure that the cumulative effect of misalignment or offset, or both, does not prevent satisfactory bearing on the key. Radii and chamfers are not normally provided on keybar and keys as supplied, but they can be produced during manufacture by agreement between the user and supplier.

Unless otherwise specified, keys in compliance with this Standard are manufactured from steel made to BS 970 having a tensile strength of not less than 550 MN/m<sup>2</sup> in the finished condition. BS 970, Part 1, lists the following steels and maximum section sizes, respectively, that meet this tensile strength requirement: 070M20, 25 × 14 mm; 070M26, 36 × 20 mm; 080M30, 90 × 45 mm; and 080M40, 100 × 50 mm.

At the time of publication of this Standard, the demand for metric keys was not sufficient to enable standard ranges of lengths to be established. The lengths given in the accompanying table are those shown as standard in ISO Recommendations R773: 1969, "Rectangular or Square Parallel Keys and their Corresponding Keyways (Dimensions in Millimeters)," and R 774: 1969, "Taper Keys and their Corresponding Keyways—with or without Gib Head (Dimensions in Millimeters)."

Tables 12 through 15 on the following pages cover the dimensions and tolerances of square and rectangular keys and keyways, and square and rectangular taper keys and keyways.

**Table 11. Finding Depth of Keyseat and Distance from Top of Key to Bottom of Shaft**

For milling keyseats, the total depth to feed cutter in from outside of shaft to bottom of keyseat is  $M + D$ , where  $D$  is depth of keyseat.

For checking an assembled key and shaft, caliper measurement  $J$  between top of key and bottom of shaft is used.

$$J = S - (M + D) + C$$

where  $C$  is depth of key. For Woodruff keys, dimensions  $C$  and  $D$  can be found in Tables 8 through 10. Assuming shaft diameter  $S$  is normal size, the tolerance on dimension  $J$  for Woodruff keys in keyslots are  $+0.000, -0.010$  inch.

| Dia. of Shaft, S, Inches | Width of Keyseat, E |       |       |       |       |       |       |       |       |       |       |       |       |       |       |     |

<sup>a</sup> The tolerance on the width and thickness of square taper keys is h9, and on the width and thickness of rectangular taper keys, h9 and h11 respectively, in accordance with ISO metric limits and fits. Does not apply to gib head dimensions.

*British Standard Keys and Keyways:* Tables 16 through 21 from BS 46:Part 1:1958 (1985) (obsolescent) provide data for rectangular parallel keys and keyways, square parallel keys and keyways, plain and gib head rectangular taper keys and keyways, plain and gib head square taper keys and keyways, and Woodruff keys and keyways.

*Parallel Keys:* These keys are used for transmitting unidirectional torques in transmissions not subject to heavy starting loads and where periodic withdrawal or sliding of the hub member may be required. In many instances, particularly couplings, a gib-head cannot be accommodated, and there is insufficient room to drift out the key from behind. It is then necessary to withdraw the component over the key and a parallel key is essential. Parallel square and rectangular keys are normally side fitting with top clearance and are usually retained in the shaft rather more securely than in the hub. The rectangular key is the general-purpose key for shafts greater than 1 inch in diameter; the square key is intended for

use with shafts up to and including 1-inch diameter or for shafts up to 6-inch diameter where it is desirable to have a greater key depth than is provided by rectangular keys. In stepped shafts, the larger diameters are usually required by considerations other than torque, e.g., resistance to bending. Where components such as fans, gears, impellers, etc., are attached to the larger shaft diameter, the use of a key smaller than standard for that diameter may be permissible. As this results in unequal disposition of the key in the shaft and its related hub, the dimensions  $H$  and  $h$  must be recalculated to maintain the  $T/2$  relationship.

**British Standard Preferred Lengths of Metric Keys BS 4235:Part 1:1972 (1986)**

| Length | Type of key |       |           |             | Length | Type of key |       |           |             |

**Taper Keys:** These keys are used for transmitting heavy unidirectional, reversing, or vibrating torques and in applications where periodic withdrawal of the key may be necessary. Taper keys are usually top fitting, but may be top and side fitting where required, and the keyway in the hub should then have the same width value as the keyway in the shaft. Taper keys of rectangular section are used for general purposes and are of less depth than square keys; square sections are for use with shafts up to and including 1-inch diameter or for shafts up to 6-inch diameter where it is desirable to have greater key depth.

**Woodruff Keys:** These keys are used for light applications or the angular location of associated parts on tapered shaft ends. They are not recommended for other applications, but if so used, corner radii in the shaft and hub keyways are advisable to reduce stress concentration.

**Dimensions and Tolerances for British Parallel and Taper Keys and Keyways:** Dimensions and tolerances for key and keyway widths given in Tables 16, 17, 18, and 19 are based on the width of key  $W$  and provide a fitting allowance. The fitting allowance is designed to permit an interference between the key and the shaft keyway and a slightly easier condition between the key and the hub keyway. In shrink and heavy force fits, it may be found necessary to depart from the width and depth tolerances specified. Any variation in the width of the keyway should be such that the greatest width is at the end from which the key enters and any variation in the depth of the keyway should be such that the greatest depth is at the end from which the key enters.

Keys and keybar normally are not chamfered or radiused as supplied, but this may be done at the time of fitting. Radii and chamfers are given in Tables 16, 17, 18, and 19. Corner radii are recommended for keyways to alleviate stress concentration.

Table 16. British Standard Rectangular Parallel Keys, Keyways, and Keybars B.S. 46: Part I: 1958

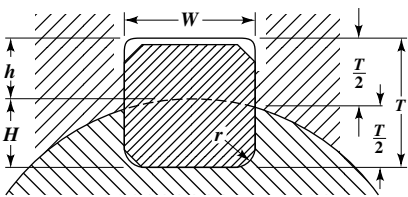

| Diameter of Shaft |                     | Key               |            |       |                | Keyway in Shaft |             |       |           | Keyway in Hub |             |       |           | Nominal Keyway Radius, $r^3$ | Keybar |       |       |       |       |

<sup>a</sup>The key chamfer shall be the minimum to clear the keyway radius. Nominal values shall be given.

<sup>b</sup>Dimensions A, B, C, D, and R pertain to gib-head keys only.

All dimensions in inches.

<sup>a</sup>The key chamfer shall be the minimum to clear the keyway radius. Nominal values shall be given.

<sup>b</sup>Dimensions *A*, *B*, *C*, *D*, and *R* pertain to gib-head keys only.

All dimensions in inches.

**Dimensions and Tolerances of British Woodruff Keys and Keyways.**—Dimensions and tolerances are shown in Table 20. An optional alternative design of the Woodruff key that differs from the normal form in its depth is given in the illustration accompanying the table. The method of designating British Woodruff Keys is the same as the American method explained in the footnote on page 2369.

**Table 20. British Standard Woodruff Keys and Keyways BS 46: Part 1: 1958**

All dimension are in inches

**FLEXIBLE BELTS AND SHEAVES**

Flexible belt drives are used in industrial power transmission applications, especially when the speeds of the driver and driven shafts must be different or when shafts must be widely separated. The trend toward higher speed prime movers and the need to achieve a slower, useful driven speed are additional factors favoring the use of belts. Belts have numerous advantages over other means of power transmission; these advantages include overall economy, cleanliness, no need for lubrication, lower maintenance costs, easy installation, dampening of shock loads, and the abilities to be used for clutching and variable speed power transmission between widely spaced shafts.

**Calculations for Belts and Pulleys**

Belt speed plays an important role in the amount of load a friction drive system can transmit. Higher speeds will require higher preloads (increased belt tension) to compensate for the higher centrifugal force. In positive drive (toothed belt) systems, higher speeds generate dynamic forces caused by unavoidable tolerance errors that may result in increased tooth or pin stresses and shorter belt life.

**Pulley Diameters and Drive Ratios.**—Minimum pulley diameters determined by belt manufacturers are based on the minimum radius that a belt can wrap around a pulley without stressing the load-carrying members. For positive drive systems, minimum pulley diameters are also determined by the minimum number of teeth that must be engaged with the sprocket to guarantee the operating load.

Diameters of driving and driven pulleys determine the velocity ratio of the input relative to the output shaft and are derived from the following formulas: for all belt systems, velocity ratio  $V = D_{pi}/D_{po}$ , and for positive (toothed) drive systems, velocity ratio  $V = N_i/N_o$ , where  $D_{pi}$  is the pitch diameter of the driving pulley,  $D_{po}$  is the pitch diameter of the driven pulley,  $N_i$  is the number of teeth on the driving pulley, and  $N_o$  is the number of teeth on the driven pulley. For most drive systems, a velocity ratio of 8:1 is the largest that should be attempted with a single reduction drive, and 6:1 is a reasonable maximum.

**Wrap Angles and Center-to-Center Distances.**—The radial distance for which the belt is in contact with the pulley surface, or the number of teeth in engagement for positive drive belts, is called the wrap angle. Belt and sprocket combinations should be chosen to ensure a wrap angle of about  $120^\circ$  around the smaller pulley. The wrap angle should not be less than  $90^\circ$ , especially with positive drive belts, because if too few teeth are in engagement, the belt may jump a tooth or pin and timing or synchronization may be lost.

For flat belts, the minimum allowable center-to-center distance (CD) for any belt-and-sprocket combination should be chosen to ensure a minimum wrap angle around the smaller pulley. For high-velocity systems, a good rule of thumb is a minimum CD equal to the sum of the pitch diameter of the larger sprocket and one-half the pitch diameter of the smaller sprocket. This formula ensures a minimum wrap angle of approximately  $120^\circ$ , which is generally sufficient for friction drives and will ensure that positive drive belts do not jump teeth.

**Pulley Center Distances and Belt Lengths.**—Maximum center distances of pulleys should be about 15 to 20 times the pitch diameter of the smaller pulley. Greater spacing requires tight control of the belt tension because a small amount of stretch will cause a large drop in tension. Constant belt tension can be obtained by application of an adjustable tensioning pulley applied to the slack side of the belt. Friction drive systems using flat belts require much more tension than positive drive belt systems.

Belt length can be calculated from:  $L = 2C + \pi(D_2 + D_1)/2 + (D_2 - D_1)^2/4C$  for friction drives, and length  $L = 2C + \pi(D_2 + D_1)/2 + (D_2 + D_1)^2/4C$  for crossed belt friction belt drives, where  $C$  is the center distance,  $D_1$  is the pitch diameter of the small pulley, and  $D_2$  is

the pitch diameter of the large pulley. For serrated belt drives, the length determined by use of these equations should be divided by the serration pitch. The belt length must then be adjusted to provide a whole number of serrations.

**Pulley Diameters and Speeds.**—If  $D$  = diameter of driving pulley,  $d$  = diameter of driven pulley,  $S$  = speed of driving pulley, and  $s$  = speed of driven pulley:

$$D = \frac{d \times s}{S}, \quad d = \frac{D \times S}{s}, \quad S = \frac{d \times s}{D}, \quad \text{and} \quad s = \frac{D \times S}{d}$$

*Example 1:* If the diameter of the driving pulley  $D$  is 24 inches, its speed is 100 rpm, and the driven pulley is to run at 600 rpm, the diameter of the driven pulley,  $d = 24 \times 100/600 = 4$  inches.

*Example 2:* If the diameter of the driven pulley  $d$  is 36 inches, its required speed is to be 150 rpm, and the speed of the driving pulley is to be 600 rpm, the diameter of the driving pulley  $D = 36 \times 150/600 = 9$  inches.

*Example 3:* If the diameter of the driven pulley  $d$  is 4 inches, its required speed is 800 rpm, and the diameter of the driving pulley  $D$  is 26 inches, the speed of the driving pulley  $= 4 \times 800/26 = 123$  rpm.

*Example 4:* If the diameter of the driving pulley  $D$  is 15 inches and its speed is 180 rpm, and the diameter of the driven pulley  $d$  is 9 inches, then the speed of the driven pulley  $= 15 \times 180/9 = 300$  rpm.

**Pulley Diameters in Compound Drive.**—If speeds of driving and driven pulleys,  $A$ ,  $B$ ,  $C$ , and  $D$  (see illustration) are known, the first step in finding their diameters is to form a fraction with the driving pulley speed as the numerator and the driven pulley speed as the denominator, and then reduce this fraction to its lowest terms. Resolve the numerator and the denominator into two pairs of factors (a pair being one factor in the numerator and one in the denominator) and, if necessary, multiply each pair by a trial number that will give pulleys of suitable diameters.

*Example 5:* If the speed of pulley  $A$  is 260 rpm and the required speed of pulley  $D$  is 720 rpm, find the diameters of the four pulleys. Reduced to its lowest terms, the fraction  $260/720 = 13/36$ , which represents the required speed ratio. Resolve this ratio  $13/36$  into two factors:

$$\frac{13}{36} = \frac{1 \times 13}{2 \times 18}$$

Multiply by trial numbers 12 and 1 to get:

$$\frac{(1 \times 12) \times (13 \times 1)}{(2 \times 12) \times (18 \times 1)} = \frac{12 \times 13}{24 \times 18}$$

Compound Drive with Four Pulleys.

The values 12 and 13 in the numerator represent the diameters of the *driven* pulleys,  $B$  and  $D$ , and the values 24 and 18 in the denominator represent the diameters of the *driving* pulleys,  $A$  and  $C$ , as shown in the illustration.

**Speed of Driven Pulley in Compound Drive.**—If diameters of pulleys  $A$ ,  $B$ ,  $C$ , and  $D$  (see illustration above), and speed of pulley  $A$  are known, the speed of the driven pulley  $D$  is found from:

$$\frac{\text{driving pulley diameter}}{\text{driven pulley diameter}} \times \frac{\text{driving pulley diameter}}{\text{driven pulley diameter}} \times \text{speed of first driving pulley}$$

*Example 6:* If the diameters of driving pulleys  $A$  and  $C$  are 18 and 24 inches, diameters of driven pulleys  $B$  and  $D$  are 12 and 13 inches, and the speed of driving pulley  $A$  is 260 rpm, speed of driven pulley

$$D = \frac{18 \times 24}{12 \times 13} \times 260 = 720 \text{ rpm}$$

**Length of Belt Traversing Three Pulleys.**—The length  $L$  of a belt traversing three pulleys, as shown in the diagram below, and touching them on one side only, can be found by the following formula.

Flat Belt Traversing Three Pulleys.

Referring to the diagram,  $R_1$ ,  $R_2$ , and  $R_3$  are the radii of the three pulleys;  $C_{12}$ ,  $C_{13}$ , and  $C_{23}$  are the center distances; and  $\alpha_1$ ,  $\alpha_2$ , and  $\alpha_3$  are the angles, in radians, of the triangle formed by the center distances. Then:

$$L = C_{12} + C_{13} + C_{23} + \frac{1}{2} \left[ \frac{(R_2 - R_1)^2}{C_{12}} + \frac{(R_3 - R_1)^2}{C_{13}} + \frac{(R_3 - R_2)^2}{C_{23}} \right] + \pi(R_1 + R_2 + R_3) - (\alpha_1 R_1 + \alpha_2 R_2 + \alpha_3 R_3)$$

*Example 7:* Assume  $R_1 = 1$ ,  $R_2 = 2$ ,  $R_3 = 4$ ,  $C_{12} = 10$ ,  $C_{13} = 6$ ,  $C_{23} = 8$ ,  $\alpha_1 = 53.13$  degrees or 0.9273 radian,  $\alpha_2 = 36.87$  degrees or 0.6435 radian, and  $\alpha_3 = 90$  degrees or 1.5708 radians. Then:

$$\begin{aligned} L &= 10 + 6 + 8 + \frac{1}{2} \left[ \frac{(2-1)^2}{10} + \frac{(4-1)^2}{6} + \frac{(4-2)^2}{8} \right] \\ &\quad + \pi(1 + 2 + 4) + (0.9273 \times 1 + 0.6435 \times 2 + 1.5708 \times 4) \\ &= 24 + 1.05 + 21.9911 - 8.4975 = 38.5436 \end{aligned}$$

**Power Transmitted By Belts.**—With belt drives, the force that produces work acts on the rim of a pulley or sheave and causes it to rotate. Since a belt on a drive must be tight enough to prevent slip, there is a belt pull on both sides of a driven wheel. When a drive is stationary or operating with no power transmitted, the pulls on both sides of the driven wheel are equal. When the drive is transmitting power, however, the pulls are not the same. There is a tight side tension  $T_T$  and a slack side tension,  $T_S$ . The difference between these two pulls ( $T_T - T_S$ ) is called *effective pull* or *net pull*. This effective pull is applied at the rim of the pulley and is the force that produces work.

Net pull equals horsepower (HP)  $\times$  33,000  $\div$  belt speed (fpm). Belt speed in fpm can be set by changing the pulley, sprocket, or sheave diameter. The shaft speeds remain the same. Belt speed is directly related to pulley diameter. Double the diameter and the total belt pull is cut in half, reducing the load on the shafts and bearings.

A belt experiences three types of tension as it rotates around a pulley: working tension (tight side – slack side), bending tension, and centrifugal tension.

The *tension ratio* ( $R$ ) equals tight side divided by slack side tension (measured in pounds). The larger  $R$  is, the closer a V-belt is to slipping—the belt is too loose. (Synchronous belts do not slip, because they depend on the tooth grip principle.)

In addition to working tension (tight side – slack side), two other tensions are developed in a belt when it is operating on a drive. *Bending tension*  $T_B$  occurs when the belt bends around the pulley. One part of the belt is in tension and the other is in compression, so compressive stresses also occur. The amount of tension depends on the belt's construction and the pulley diameter. *Centrifugal tension* ( $T_C$ ) occurs as the belt rotates around the drive and is calculated by  $T_C = MV^2$ , where  $T_C$  is centrifugal tension in pounds,  $M$  is a constant dependent on the belt's weight, and  $V$  is the belt velocity in feet per minute. Neither the bending nor centrifugal tensions are imposed on the pulley, shaft, or bearing—only on the belt.

Combining these three types of tension results in *peak tension* which is important in determining the degree of performance or belt life:  $T_{\text{peak}} = T_T + T_B + T_C$ .

**Measuring the Effective Length.**—The effective length of a V-belt is determined by placing the belt on a measuring device having two equal diameter sheaves with standard groove dimensions. The shaft of one of the sheaves is fixed. A specified measuring tension is applied to the housing for the shaft of the other sheave, moving it along a graduated scale. The belt is rotated around the sheaves at least two revolutions of the belt to seat it properly in the sheave grooves and to divide the total tension equally between the two strands of the belt.

The effective length of the belt is obtained by adding the effective (outside) circumference of one of the measuring sheaves to twice the center distance. Synchronous belts are measured in a similar manner.

The following sections cover common belts used in industrial applications for power transmission and specified in Rubber Manufacturers Association (RMA), Mechanical Power Transmission Association (MPTA), and The Rubber Association of Canada (RAC) standards. The information presented does not apply to automotive or agricultural drives, for which other standards exist. The belts covered in this section are Narrow, Classical, Double, and Light-Duty V-Belts, V-Ribbed Belts, Variable-Speed Belts, 60 deg V-Belts, and Synchronous (Timing) Belts.

### Flat Belting

Flat belting was originally made from leather because it was the most durable material available and could easily be cut and joined to make a driving belt suitable for use with cylindrical or domed pulleys. This type of belting was popular because it could be used to

transmit high torques over long distances and it was employed in factories to drive many small machines from a large common power source such as a steam engine. As electric motors became smaller, more efficient, and more powerful, and new types of belts and chains were made possible by modern materials and manufacturing processes, flat belts fell out of favor. Flat belts are still used for some drive purposes, but leather has been replaced by other natural and synthetic materials such as urethanes, which can be reinforced by high-strength polyamide or steel fabrics to provide properties such as resistance to stretching. The high modulus of elasticity in these flat belts eliminates the need for periodic retensioning that is usually necessary with V-belts.

Driving belts can be given a coating of an elastomer with a high coefficient of friction, to enable belts to grip pulleys without the degree of tension common with earlier materials. Urethanes are commonly used for driving belts where high resistance to abrasion is required, and also resist attack by chemical solvents of most kinds. Flat belts having good resistance to high temperatures are also available. Typical properties of polyurethane belts include tensile strength up to 40,000 psi, depending on reinforcement type and Shore hardness of 85 to 95. Most polyurethane belts are installed under tension. The amount of tension varies with the belt cross-section, being greater for belts of small section. Belt tension can be measured by marking lines 10 inches apart on an installed belt, then applying tension until the separation increases by the desired percentage. For 2 per cent tension, lines on the tensioned belt would be 10.2 inches apart. Mechanical failure may result when belt tensioning is excessive, and 2 to 2.5 per cent elongation should be regarded as the limit.

Flat belts offer high load capacities and are capable of transmitting power over long distances, maintaining relative rotational direction, can operate without lubricants, and are generally inexpensive to maintain or replace when worn. Flat belt systems will operate with little maintenance and only periodic adjustment. Because they transmit motion by friction, flat belts have the ability to slip under excessive loads, providing a fail-safe action to guard against malfunctions. This advantage is offset by the problem that friction belts can both slip and creep so that they do not offer exact, consistent velocity ratios nor precision timing between input and output shafts. Flat belts can be made to any desired length, being joined by reliable chemical bonding processes.

Increasing centrifugal force has less effect on the load-carrying capacity of flat belts at high speeds than it has on V-belts, for instance. The low thickness of a flat belt, compared with a V-belt, places its center of gravity near the pulley surface. Flat belts therefore may be run at surface speeds of up to 16,000 or even 20,000 ft/min (81.28 and 101.6 m/s), although ideal speeds are in the range of 3,000 to 10,000 ft/min (15.25 to 50.8 m/s). Elastomeric drive surfaces on flat belts have eliminated the need for belt dressings that were often needed to keep leather belts in place. These surface coatings can also contain antistatic materials. Belt pulley wear and noise are low with flat belts shock and vibration are damped, and efficiency is generally greater than 98 per cent compared with 96 per cent for V-belts.

Driving belt load capacities can be calculated from torque  $T = F(d/2)$  and horsepower  $HP = T \times rpm/396,000$ , where  $T$  is the torque in in-lb,  $F$  is the force transmitted in lb, and  $d$  is the pulley diameter in inches. Pulley width is usually about 10 per cent larger than the belt, and for good tracking, pulleys are often crowned by 0.012 to 0.10 inch for diameters in the range of 1.5 to 80 inches.

Before a belt specification is written, the system should be checked for excessive startup and shut-down loads, which sometimes are more than 10 per cent above operating conditions. In overcoming such loads, the belt will transmit considerably more force than during normal operation. Large starting and stopping forces will also shorten belt life unless they are taken into account during the design stage.

**Flat Belt Pulleys.**— Flat belt pulleys are usually made of cast iron, fabricated steel, paper, fiber, or various kinds of wood. They may be solid or split and in either case the hub may be split for clamping to the shaft.

Pulley face widths are nominally the same as the widths of the belts they are to carry. The pulley face should be approximately one inch more than the belt width for belts under 12 inches wide, 2 inches more for belts from 12 to 24 inches wide, and 3 inches more for belts over 24 inches in width.

Belts may be made to center themselves by the use of crowned pulleys. The usual amount of crowning is  $\frac{1}{8}$  inch per foot of pulley width. Thus, the difference in maximum and minimum radii of a crowned 6-inch wide pulley would be  $\frac{1}{16}$  inch. Crowned pulleys have a rim section either with a convex curve or a flat V form. Flanges on the sides of flat belt pulleys are in general undesirable as the belt tends to crawl against them. Too much crown is undesirable because of the tendency to "break the belt's back." This is particularly true for riding idlers close to driving pulleys where the curvature of the belt changes rapidly from one pulley to the other. Here, the idler should under no circumstances be crowned and the adjacent pulley should have very little crown. Pulleys carrying shifting belts are not crowned.

Open belt drives connecting pulleys on short centers with one pulley considerably larger than the other may be unsatisfactory due to the small angle of wrap on the smaller pulley. This angle may be increased by the use of idler pulleys on one or both sides of the belt.

### V-Belts

**Narrow V-Belts ANSI/RMA IP-22.**—Narrow V-belts serve the same applications as multiple, classical V-belts, but allow for a lighter, more compact drive. Three basic cross sections—3V and 3VX, 5V and 5VX, and 8V—are provided, as shown in Fig. 1. The 3VX and 5VX are molded, notched V-belts that have greater power capacity than conventional belts. Narrow V-belts are specified by cross section and effective length and have top widths ranging from  $\frac{3}{8}$  to 1 inch.

Narrow V-belts usually provide substantial weight and space savings over classical belts. Some narrow belts can transmit up to three times the horsepower of conventional belts in the same drive space, or the same horsepower in one-third to one-half the space. These belts are designed to operate in multiples and are also available in the joined configuration.

*Belt Cross Sections:* Nominal dimensions of the three cross sections are given in Fig. 1.

*Belt Size Designation:* Narrow V-belt sizes are identified by a standard belt number. The first figure of this number followed by the letter V denotes the belt cross section. An X following the V indicates a notched cross section. The remaining figures show the effective belt length in tenths of an inch. For example, the number 5VX1400 designates a notched V-belt with a 5V cross section and an effective length of 140.0 in. Standard effective lengths of narrow V-belts are shown in Table 1.

Fig. 1. Nominal Narrow V-Belt Dimensions

*Sheave Dimensions:* Groove angles and dimensions for sheaves and face widths of sheaves for multiple belt drives are given in Tables 2a and 2b, along with various tolerance values. Standard sheave outside diameters are given in Table 3.

**Table 1. Narrow V-Belt Standard Effective Lengths ANSI/RMA IP-22 (1983)**

| Standard Length Designation <sup>a</sup> | Standard Effective Outside Length |       |       | Permissible Deviation from Standard Length | Matching Limits for One Set | Standard Length Designation <sup>a</sup> | Standard Effective Outside Length |       |       | Permissible Deviation from Standard Length | Matching Limits for One Set |
|--|-----------------------------------|-------|-------|--|-----------------------------|--|-----------------------------------|-------|-------|--|-----------------------------|
|  | Cross Section                     |       |       |  |                             |  | Cross Section                     |       |       |  |                             |

<sup>a</sup>To specify belt size, use the Standard Length Designation prefixed by the cross section, for example, 5 V850.

All dimensions in inches.

Table 2a. Narrow V-Belt Standard Sheave and Groove Dimensions ANSI/RMA IP-22 (1983)

Face Width of Standard and Deep Groove Sheaves =  $s_g(N_g - 1) + 2s_e$ , where  $N_g$  = number of grooves

<sup>a</sup>Deep groove sheaves are intended for drives with belt offset such as quarter-turn or vertical shaft drives. They may also be necessary where oscillations in the center distance may occur. Joined belts will not operate in deep groove sheaves.

<sup>b</sup>Summation of the deviations from  $S_g$  for all grooves in any one sheave should not exceed  $\pm 0.031$  in. The variations in pitch diameter between the grooves in any one sheave must be within the following limits: Up through 19.9 in. outside diameter and up through 6 grooves—0.010 in. (add 0.0005 in. for each additional groove). 20.0 in. and over on outside diameter and up through 10 grooves—0.015 in. (add 0.0005 in. for each additional groove). This variation can be obtained by measuring the distance across two measuring balls or rods placed in the grooves diametrically opposite each other. Comparing this “diameter over balls or rods” measurement between grooves will give the variation in pitch diameter.

| Other Sheave Tolerances  |   |   |
|--|---|---|
| Outside Diameter   | Radial Runout <sup>a</sup>  | Axial Runout <sup>a</sup>   |
| Up through 8.0 in. outside diameter $\pm 0.020$ in.<br>For each additional inch of outside diameter add $\pm 0.0025$ in. | Up through 10.0 in. outside diameter 0.010 in.<br>For each additional inch of outside diameter add 0.0005 in. | Up through 5.0 in. outside diameter 0.005 in.<br>For each additional inch of outside diameter add 0.001 in. |

All dimensions in inches. The nominal diameters were selected from R40 and R80 preferred numbers (see page 689).

**Minimum Sheave Size:** The recommended minimum sheave size depends on the rpm of the faster shaft. Minimum sheave diameters for each belt cross-section are listed in [Table 3](#).

**Cross Section Selection:** The chart ([Fig. 2](#), on page 2398) is a guide to the V-belt cross section to use for any combination of design horsepower and speed of the faster shaft. When the intersection of the design horsepower and speed of the faster shaft falls near a line between two areas on the chart, it is advisable to investigate the possibilities in both areas. Special circumstances (such as space limitations) may lead to a choice of belt cross section different from that indicated in the chart.

**Horsepower Ratings:** The horsepower ratings of narrow V-belts can be calculated using the following formula:

$$HP = d_p r [K_1 - K_2/d_p - K_3(d_p r)^2 - K_4 \log(d_p r)] + K_{SR} r$$

where  $d_p$  = the pitch diameter of the small sheave, in.;  $r$  = rpm of the faster shaft divided by 1000;  $K_{SR}$ , speed ratio correction factor ([Table 4](#)), and  $K_1$ ,  $K_2$ ,  $K_3$ , and  $K_4$ , cross section parameters, are listed in the accompanying [Table 5](#). This formula gives the basic horsepower rating, corrected for the speed ratio. To obtain the horsepower per belt for an arc of contact other than 180° and for belts shorter or longer than average length, multiply the horsepower obtained from this formula by the length correction factor ([Table 7](#)) and the arc of contact correction factor ([Table 6](#)).

*Arc of Contact:* Arc of contact on the small sheave may be determined by the formulas.

*Exact formula:* Arc of Contact (deg) =  $2 \cos^{-1} \left( \frac{D_e - d_e}{2C} \right)$

*Approximate formula:* Arc of Contact (deg) =  $180 - \frac{(D_e - d_e)60}{C}$

where:  $D_e$  = Effective diameter of large sheave, inch

$d_e$  = Effective diameter of small sheave, inch

$C$  = Center distance, inch

**Number of Belts:** The number of belts required for an application is obtained by dividing the design horsepower by the corrected horsepower rating for one belt.

**Classical V-Belts ANSI/RMA IP-20.**—Classical V-belts are most commonly used in heavy-duty applications and include these standard cross sections: A, AX, B, BX, C, CX, D, and DX (Fig. 3, page 2403). Top widths range from  $\frac{1}{2}$  to  $1\frac{1}{4}$  in. and are specified by cross section and nominal length. Classical belts can be teamed in multiples of two or more. These multiple drives can transmit up to several hundred horsepower continuously and absorb reasonable shock loads.

**Belt Cross Sections:** Nominal dimensions of the four cross sections are given in Fig. 3.

**Belt Size Designation:** Classical V-belt sizes are identified by a standard belt number consisting of a letter-numeral combination. The letter identifies the cross section; the numeral identifies the length as shown in Table 8. For example, A60 indicates an A cross section and a standard length designation of 60. An X following the section letter designation indicates a molded notch cross section, for example, AX60.

*Sheave Dimensions:* Groove angles and dimensions for sheaves and the face widths of sheaves for multiple belt drives are given in Table 9, along with various tolerance values.

**Table 8. Classical V-Belt Standard Datum Length ANSI/RMA IP-20, 1988**

| Standard Length Designation <sup>a</sup> | Standard Datum lengths |       |       |       | Permissible Deviations from Std. Datum Length | Matching Limits for One Set |
|--|------------------------|-------|-------|-------|---|-----------------------------|
|  | Cross Section          |       |       |       |   |                             |
|  | A, AX                  | B, BX | C, CX | D     |   |                             |

<sup>a</sup>To specify belt size use the Standard Length Designation prefixed by the letter indicating the cross section, e.g., B90.

All dimensions in inches.

Table 9. Classical V-Belt Sheave and Groove Dimensions ANSI/RMA IP-20, 1988

Face Width of Standard and Deep Groove Sheaves =  $S_g (N_g - 1) + 2S_e$ , where  $N_g$  = number of grooves

<sup>a</sup> The A/AX, B/BX combination groove should be used when deep grooves are required for A or AX belts.

<sup>b</sup> Summation of the deviations from  $S_g$  for all grooves in any one sheave should not exceed  $\pm 0.050$  in. The variation in datum diameter between the grooves in any one sheave must be within the following limits: Through 19.9 in. outside diameter and through 6 grooves: 0.010 in. (add 0.0005 in. for each additional groove). 20.0 in. and over on outside diameter and through 10 grooves: 0.015 in. (add 0.0005 in. for each additional groove). This variation can be obtained by measuring the distance across two measuring balls or rods placed diametrically opposite each other in a groove. Comparing this "diameter over balls or rods" measurement between grooves will give the variation in datum diameter.

<sup>c</sup> Diameters shown for combination grooves are outside diameters. A specific datum diameter does not exist for either A or B belts in combination grooves.

<sup>d</sup> The  $b_d$  value shown for combination grooves is the "constant width" point, but does not represent a datum width for either A or B belts ( $2h_d = 0.340$  ref).

<sup>e</sup>  $2h_d$  values for combination grooves are calculated based on  $b_d$  for A and B grooves.

<sup>f</sup> Deep groove sheaves are intended for drives with belt offset such as quarter-turn or vertical shaft drives. Joined belts will not operate in deep groove sheaves. Also, A and AX joined belts will not operate in A/AX and B/BX combination grooves.

| Other Sheave Tolerances   |   |   |
|---|---|---|
| Outside Diameter  | Radial Runout <sup>a</sup>  | Axial Runout <sup>a</sup>   |
| Through 8.0 in. outside diameter $\pm 0.020$ in. For each additional inch of outside diameter add $\pm 0.005$ in. | Through 10.0 in. outside diameter 0.010 in. For each additional inch of outside diameter add 0.0005 in. | Through 5.0 in. outside diameter 0.005 in. For each additional inch of outside diameter add 0.001 in. |

<sup>a</sup> Total indicator readings.

**A, AX & B, BX Combin.** All dimensions in inches.

**Minimum Sheave Size:** The recommended minimum sheave size depends on the rpm of the faster shaft. Minimum sheave diameters for each cross-section belt are listed in Table 9.

**Cross Section Selection:** Use the chart (Fig. 4) as a guide to the Classical V-belt cross section for any combination of design horsepower and speed of the faster shaft. When the intersection of the design horsepower and speed of the faster shaft falls near a line between two areas on the chart, the possibilities in both areas should be investigated. Special circumstances (such as space limitations) may lead to a choice of belt cross section different from that indicated in the chart.

Fig. 3. Classical V-Belt Cross Sections

**Horsepower Ratings:** The horsepower rating formulas for classical V-belts are:

$$\begin{aligned} \mathbf{A:HP} = d_p r \left[ 1.004 - \frac{1.652}{d_p} - 1.547 \times 10^{-4} (d_p r)^2 - 0.2126 \log(d_p r) \right] \\ + 1.652 r \left( 1 - \frac{1}{K_{SR}} \right) \end{aligned}$$

$$\begin{aligned} \mathbf{AX:HP} = d_p r \left[ 1.462 - \frac{2.239}{d_p} - 2.198 \times 10^{-4} (d_p r)^2 - 0.4238 \log(d_p r) \right] \\ + 2.239 r \left( 1 - \frac{1}{K_{SR}} \right) \end{aligned}$$

$$\begin{aligned} \mathbf{B:HP} = d_p r \left[ 1.769 - \frac{4.372}{d_p} - 3.081 \times 10^{-4} (d_p r)^2 - 0.3658 \log(d_p r) \right] \\ + 4.372 r \left( 1 - \frac{1}{K_{SR}} \right) \end{aligned}$$

## CLASSICAL V-BELTS

$$\text{BX:HP} = d_p r \left[ 2.051 - \frac{3.532}{d_p} - 3.097 \times 10^{-4} (d_p r)^2 - 0.5735 \log(d_p r) \right] + 3.532 r \left( 1 - \frac{1}{K_{SR}} \right)$$

$$\text{C:HP} = d_p r \left[ 3.325 - \frac{12.07}{d_p} - 5.828 \times 10^{-4} (d_p r)^2 - 0.6886 \log(d_p r) \right] + 12.07 r \left( 1 - \frac{1}{K_{SR}} \right)$$

$$\text{CX:HP} = d_p r \left[ 3.272 - \frac{6.655}{d_p} - 5.298 \times 10^{-4} (d_p r)^2 - 0.8637 \log(d_p r) \right] + 6.655 r \left( 1 - \frac{1}{K_{SR}} \right)$$

$$\text{D:HP} = d_p r \left[ 7.160 - \frac{43.21}{d_p} - 1.384 \times 10^{-3} (d_p r)^2 - 1.454 \log(d_p r) \right] + 43.21 r \left( 1 - \frac{1}{K_{SR}} \right)$$

Fig. 4. Selection of Classic V-Belt Cross Sections

In these equations,  $d_p$  = pitch diameter of small sheave, in.;  $r$  = rpm of the faster shaft divided by 1000;  $K_{SR}$  = speed ratio factor given in the accompanying Table 10. These formulas give the basic horsepower rating, corrected for the speed ratio. To obtain the horsepower per belt for an arc of contact other than 180 degrees and for belts shorter or longer than average length, multiply the horsepower obtained from these formulas by the length correction factor (Table 11) and the arc of contact correction factor (Table 12).

**Table 10. Speed Ratio Correction Factors**

| Speed Ratio <sup>a</sup> Range | $K_{SR}$ | Speed Ratio <sup>a</sup> Range | $K_{SR}$ |
|--------------------------------|----------|--------------------------------|----------|
| 1.00–1.01                      | 1.0000   | 1.15–1.20                      | 1.0586   |
| 1.02–1.04                      | 1.0112   | 1.21–1.27                      | 1.0711   |
| 1.05–1.07                      | 1.0226   | 1.28–1.39                      | 1.0840   |
| 1.08–1.10                      | 1.0344   | 1.40–1.64                      | 1.0972   |
| 1.11–1.14                      | 1.0463   | Over 1.64                      | 1.1106   |

<sup>a</sup>  $D_p/d_p$ , where  $D_p$  ( $d_p$ ) is the pitch diameter of the large (small) sheave.

**Number of Belts:** The number of belts required for an application is obtained by dividing the design horsepower by the corrected horsepower rating for one belt.

**Arc of Contact:** Arc of contact on the small sheave may be determined by the formulas.

$$\text{Exact formula: Arc of Contact (deg)} = 2 \cos^{-1} \left( \frac{D_d - d_d}{2C} \right)$$

$$\text{Approximate formula: Arc of Contact (deg)} = 180 - \left( \frac{(D_d - d_d)60}{C} \right)$$

where  $D_d$  = Datum diameter of large sheave or flat pulley, inch;  $d_d$  = Datum diameter of small sheave, inch; and,  $C$  = Center distance, inch.

**Table 12. Arc of Contact Correction Factors**

| $\frac{D_d - d_d}{C}$ | Arc of Contact,<br>$\theta$ , Small<br>Sheave (deg) | Correction Factor |                     | $\frac{D_d - d_d}{C}$ | Arc of Contact,<br>$\theta$ Small<br>Sheave (deg) | Correction Factor |                     |

| 0.70                  | 139   | 0.89              | 0.84                | 1.50                  | 83  | 0.65              | 0.65                |

<sup>a</sup> A V-flat drive is one using a small sheave and a large diameter flat pulley.

**Double V-Belts ANSI/RMA IP-21.**—Double V-belts or hexagonal belts are used when power input or takeoff is required on both sides of the belt. Designed for use on “serpentine” drives, which consist of sheaves rotating in opposite directions, the belts are available in AA, BB, CC, and DD cross sections and operate in standard classical sheaves. They are specified by cross section and nominal length.

*Belt Cross Sections:* Nominal dimensions of the four cross sections are given in Fig. 5.

*Belt Size Designation:* Double V-belt sizes are identified by a standard belt number, consisting of a letter-numeral combination. The letters identify the cross section; the numbers identify length as shown in Column 1 of Table 13. For example, AA51 indicates an AA cross section and a standard length designation of 51.

**Table 13. Double V-Belt Standard Effective Lengths ANSI/RMA IP-21, 1984**

| Standard Length Designation <sup>a</sup> | Standard Effective Length |       |       |       | Permissible Deviation from Standard Effective Length | Matching Limits for One Set |
|--|---------------------------|-------|-------|-------|--|-----------------------------|
|  | Cross Section             |       |       |       |  |                             |
|  | AA                        | BB    | CC    | DD    |  |                             |
| 51                                       | 53.1                      | 53.9  | ...   | ...   | ±0.7   | 0.15                        |

<sup>a</sup> To specify belt size use the Standard Length Designation prefixed by the letters indicating cross section; for example, BB90.

All dimensions in inches.

*Sheave Dimensions:* Groove angles and dimensions for sheaves and face widths of sheaves for multiple belt drives are given in Table 14, along with various tolerance values.

Table 14. Double V-Belt Sheave and Groove Dimensions ANSI/RMA IP-21, 1984

Face Width of Standard and Deep Groove Sheaves =  $S_g(N_g - 1) + 2S_e$ , where  $N_g$  = number of grooves

<sup>a</sup> Summation of the deviations from  $S_g$  for all grooves in any one sheave shall not exceed  $\pm 0.050$  in. The variation in pitch diameter between the grooves in any one sheave must be within the following limits: Up through 19.9 in. outside diameter and up through 6 grooves: 0.010 in. (add 0.005 in. for each additional groove). 20.0 in. and over on outside diameter and up through 10 grooves: 0.015 in. (add 0.0005 in. for each additional groove). This variation can be obtained easily by measuring the distance across two measuring balls or rods placed diametrically opposite each other in a groove. Comparing this "diameter over balls or rods" measurement between grooves will give the variation in pitch diameter.

<sup>b</sup> The  $a_p$  values shown for the A/B combination sheaves are the geometrically derived values. These values may be different from those shown in manufacturer's catalogs.

<sup>c</sup> Deep groove sheaves are intended for drives with belt offset such as quarter-turn or vertical shaft drives.

| Other Sheave Tolerances   |   |   |
|---|---|---|
| Outside Diameter  | Radial Runout <sup>a</sup>  | Axial Runout <sup>a</sup>   |
| Up through 4.0 in. outside diameter $\pm 0.020$ in.<br>For each additional inch of outside diameter add $\pm 0.005$ in. | Up through 10.0 in. outside diameter $\pm 0.010$ in.<br>For each additional inch of outside diameter add 0.0005 in. | Up through 5.0 in. outside diameter 0.005 in.<br>For each additional inch of outside diameter add 0.001 in. |

<sup>a</sup> Total indicator reading.  
All dimensions in inches.

**Cross Section Selection:** Use the chart (Fig. 6) as a guide to the double V-belt cross section for any combination of design horsepower and speed of the faster shaft. When the intersection of the design horsepower and speed of the faster shaft falls near a line between two areas on the chart, it is best to investigate the possibilities in both areas. Special circumstances (such as space limitations) may lead to a choice of belt cross section different from that indicated in the chart.

Fig. 5. Double-V Belt Cross Section

Fig. 6. Selection of Double V-Belt Cross Section

**Effective Diameter Determination:** Fig. 6 shows the relationship of effective diameter, outside diameter, and nomenclature diameter. Nomenclature diameter is used when ordering sheaves for double V-belt drives. The effective diameter is determined as follows:

$$\text{Effective diameter} = \text{Nomenclature diameter} + 2h_d - 2a_p$$

The values of  $2h_d$  and  $2a_p$  are given in Table 14.

**Double V-belt Length Determination:** The effective belt length of a specific drive may be determined by making a scaled layout of the drive. Draw the sheaves in terms of their effective diameters and in the position when a new belt is applied and first brought to driv-

ing tension. Next, measure the tangents and calculate the effective arc length ( $AL_e$ ) of each sheave (see Table 15 for a glossary of terms):

$$AL_e = \frac{d_e \theta}{115}$$

The effective length of the belt will then be the sum of the tangents and the connecting arc lengths. Manufacturers may be consulted for mathematical calculation of effective belt length for specific drive applications.

**Table 15. Glossary of Terms for Double V-belt Calculations**

|  |  |
|--|--|
| $AL_e$ = Length, arc, effective, in.   | $R$ = Ratio, tight side to slack side tension  |
| $2a_p$ = Diameter, differential, pitch to outside, in.                             | $R/(R - 1)$ = Factor, tension ratio            |
| $d$ = Diameter, pitch, in. (same as effective diameter)                            | $r$ = Angular velocity, faster shaft, rpm/1000 |
| $d_e$ = Diameter, effective, in.   | $S$ = Speed, belt, fpm/1000                    |
| $2h_d$ = Diameter differential, nomenclature to outside, in.                       | $T_e$ = Tension, effective pull, lbf           |
| $K_f$ = Factor, length - flex correction   | $T_r$ = Tension, allowable tight side, lbf     |
| $L_e$ = Length, effective, in.   | $T_s$ = Tension, slack side, lbf               |
| $n$ = Sheaves, number on drive   | $T_T$ = Tension, tight side, lbf               |
| $P_d$ = Power, design, horsepower (transmitted horsepower $\times$ service factor) | $\theta$ = Angle, arc of belt contact, deg     |

Fig. 7. Effective, Outside, and Nomenclature Sheave Diameters

**Number of Belts Determination:** The number of belts required may be determined on the basis of allowable tight side tension rating ( $T_r$ ) at the most severe sheave. The allowable tight side tensions per belt are given in Tables 16 through 19, and must be multiplied by the length-flex correction factors ( $K_f$ ) listed in Table 20. To select the allowable tight side tension from the tables for a given sheave, the belt speed and effective diameter of the sheave in question are required.

**Double V-Belt Drive Design Method:** The fourteen drive design steps are as follows:

1) Number the sheaves starting from the driver in the opposite direction to belt rotation; include the idlers.

2) Select the proper service factor for each loaded driven unit.

3) Multiply the horsepower requirement for each loaded driven sheave by the corresponding service factor. This is the design horsepower at each sheave.

4) Calculate driver design horsepower. This hp is equal to the sum of all the driven design horsepower.

5) Calculate belt speed ( $S$ ) in thousands of feet per minute:  $S = rd/3.820$ .

6) Calculate effective tension ( $T_e$ ) for each loaded sheave:  $T_e = 33P_d/S$ .

7) Determine minimum  $R/(R - 1)$  for each loaded sheave from Table 21 using the arc of contact determined from the drive layout.

8) In most drives, slippage will occur first at the driver sheave. Assume this to be true and calculate  $T_T$  and  $T_S$  for the driver:  $T_T = T_e [R/(R - 1)]$  and  $T_S = T_T - T_e$ . Use  $R/(R - 1)$  from Step 7 and  $T_e$  from Step 6 for the driver sheave.

9) Starting with the first driven sheave, determine  $T_T$  and  $T_S$  for each segment of the drive. The  $T_T$  for the driver becomes  $T_S$  for that sheave and is equal to  $T_T - T_e$ . Proceed around the drive in like manner.

10) Calculate actual  $R/(R - 1)$  for each sheave using:  $R/(R - 1) = T_T/T_e = T_T/(T_T - T_S)$ . The  $T_T$  and  $T_S$  values are for those determined in Step 9. If these values are equal to or greater than those determined in Step 7, the assumption that slippage will first occur at the driver is correct and the next two steps are not necessary. If the value is less, the assumption was not correct, so proceed with Step 11.

11) Take the sheave where the actual value  $R/(R - 1)$  (Step 10) is less than the minimum, as determined in Step 7, and calculate a new  $T_T$  and  $T_S$  for this sheave using the minimum  $R/(R - 1)$  as determined in Step 7:  $T_T = T_e [R/(R - 1)]$  and  $T_S = T_T - T_e$ .

12) Start with this sheave and recalculate the tension in each segment of the drive as in Step 9.

13) The length-flex factor ( $K_f$ ) is taken from Table 20. Before using this table, calculate the value of  $L_e/n$ . Be sure to use the appropriate belt cross-section column when selecting the correction factor.

14) Beginning with the driver sheave, determine the number of belts ( $N_b$ ) needed to satisfy the conditions at each loaded sheave using:  $N_b = T_T/T_r K_f$ . Note:  $T_T$  is tight side tension as determined in Step 9 or 11 and 12.  $T_r$  is allowable tight side tension as shown in Tables 18-21.  $K_f$  is the length-flex correction factor from Table 20. The sheave that requires the largest number of belts is the number of belts required for the drive. Any fraction of a belt should be treated as a whole belt.

**Table 16. Allowable Tight Side Tension for an AA Section**

| Belt Speed<br>(fpm) | Sheave Effective Diameter (in.) |     |     |     |     |     |     |     |

The allowable tight side tension must be evaluated for each sheave in the system (see Step 14). Values must be corrected by  $K_f$  from Table 20.

**Table 20. Length-Flex Correction Factors  $K_f$** 

| $\frac{L_e}{n}$ | Belt Cross Section |      |      |      | $\frac{L_e}{n}$ | Belt Cross Section |      |      |      |

**Tension Ratings:** The tension rating formulas are:

$$\text{AA } T_r = 118.5 - \frac{318.2}{d} - 0.8380S^2 - 25.76 \log S$$

$$\text{BB } T_r = 186.3 - \frac{665.1}{d} - 1.269S^2 - 39.02 \log S$$

$$CC \quad T_r = 363.9 - \frac{2060}{d} - 2.400S^2 - 73.77 \log S$$

$$DD \quad T_r = 783.1 - \frac{7790}{d} - 5.078S^2 - 156.1 \log S$$

where  $T_r$  = The allowable tight side tension for a double-V belt drive, lbf (not corrected for tension ratio or length-flex correction factor)

$d$  = Pitch diameter of small sheave, inch

$S$  = Belt speed, fpm/1000

**Table 21. Tension Ratio/Arc of Contact Factors**

| Arc of Contact,<br>$\theta$ (deg.) | Design<br>$\frac{R}{R-1}$ | Arc of Contact,<br>$\theta$ (deg.) | Design<br>$\frac{R}{R-1}$ |

| 180                                | 1.25                      | 50                                 | 2.77                      |

**Minimum Sheave Size:** The recommended minimum sheave size depends on the rpm of the faster shaft. Minimum groove diameters for each belt cross section are listed in [Table 14](#).

**Light Duty V-Belts ANSI/RMA IP-23.**—Light duty V-belts are typically used with fractional horsepower motors or small engines, and are designed primarily for fractional horsepower service. These belts are intended and specifically designed for use with small diameter sheaves and drives of loads and service requirements that are within the capacity of a single belt.

Fig. 8. Light Duty V-Belt Cross Sections

The four belt cross sections and sheave groove sizes are 2L, 3L, 4L, and 5L. The 2L is generally used only by OEMs and is not covered in the RMA standards.

**Belt Cross Sections.**—Nominal dimensions of the four cross sections are given in [Fig. 8](#).

**Belt Size Designation.**—V-belt sizes are identified by a standard belt number, consisting of a letter-numeral combination. The first number and letter identify the cross section; the remaining numbers identify length as shown in [Table 22](#). For example, a 3L520 belt has a 3L cross section and a length of 52.0 in.

**Table 22. Light Duty V-Belt Standard Dimensions ANSI/RMA IP-23, 1968**

| Standard Effective Outside Length (in.) |     |     |     | Permissible Deviation From Standard Effective Length (in.) | Standard Effective Outside Length (in.) |     |     |     | Permissible Deviation From Standard Effective Length (in.) |
|---|-----|-----|-----|--|---|-----|-----|-----|--|
| Cross Section                           |     |     |     |  | Cross Section                           |     |     |     |  |

<sup>a</sup>The diameter used in calculating speed ratio and belt speed is obtained by subtracting the  $2a$  value from the Effective Outside Diameter of the sheave.

| Other Sheave Tolerances                               |  |   |
|---|--|---|
| Outside Diameters                                     | Outside Diameter Eccentricity <sup>a</sup>                   | Groove Side Wobble & Runout <sup>a</sup>  |
| For outside diameters under 6.0 in. $\pm 0.015$ in.   | For outside diameters 10.0 in. and under 0.010 in.           | For outside diameters 20.0 in. and under 0.0015 in. per inch of outside diameter. |
| For outside diameters 6.0 to 12.0 in. $\pm 0.020$ in. | For each additional inch of outside diameter, add 0.0005 in. | For each additional inch of outside diameter, add 0.0005 in.                      |
| For outside diameters over 12.0 in. $\pm 0.040$ in.   |  |   |

<sup>a</sup>Total indicator reading.

All dimensions in inches.

**Horsepower Ratings:** The horsepower ratings for light duty V-belts can be calculated from the following formulas:

$$3L \quad \text{HP} = r \left( \frac{0.2164d^{0.91}}{r^{0.09}} - 0.2324 - 0.0001396r^2d^3 \right)$$

$$4L \quad \text{HP} = r \left( \frac{0.4666d^{0.91}}{r^{0.09}} - 0.7231 - 0.0002286r^2d^3 \right)$$

$$5L \quad \text{HP} = r \left( \frac{0.7748d^{0.91}}{r^{0.09}} - 1.727 - 0.0003641r^2d^3 \right)$$

where  $d = d_0 - 2a$ ;  $d_0$  = effective outside diameter of small sheave, in.;  $r$  = rpm of the faster shaft divided by 1000. The corrected horsepower rating is obtained by dividing the horsepower rating by the combined correction factor (Table 24), which accounts for drive geometry and service factor requirements.

**Table 24. Combined Correction Factors**

| Type of Driven Unit       | Speed Ratio   |              |
|---------------------------|---------------|--------------|
|                           | Less than 1.5 | 1.5 and Over |
| Fans and blowers          | 1.0           | 0.9          |
| Domestic laundry machines | 1.1           | 1.0          |
| Centrifugal pumps         | 1.1           | 1.0          |
| Generators                | 1.2           | 1.1          |
| Rotary compressors        | 1.2           | 1.1          |
| Machine tools             | 1.3           | 1.2          |
| Reciprocating pumps       | 1.4           | 1.3          |
| Reciprocating compressors | 1.4           | 1.3          |
| Wood working machines     | 1.4           | 1.3          |

**V-Ribbed Belts ANSI/RMA IP-26.**—V-ribbed belts are a cross between flat belts and V-belts. The belt is basically flat with V-shaped ribs projecting from the bottom, which guide the belt and provide greater stability than that found in a flat belt. The ribs operate in grooved sheaves.

V-ribbed belts do not have the wedging action of a V-belt and thus operate at higher tensions. This design provides excellent performance in high-speed and serpentine applications, and in drives that utilize small diameter sheaves. The V-ribbed belt comes in five cross sections: H, J, K, L, and M, specified by effective length, cross section and number of ribs.

*Belt Cross Sections:* Nominal dimensions of the five cross sections are given in Table 25.

**Table 25. Nominal Dimensions of V-Ribbed Belt Cross Sections**  
ANSI/RMA IP-26, 1977

| Cross Section | $h_b$ | $S_g$ | Standard Number of Ribs      |
|---------------|-------|-------|------------------------------|
| H             | 0.12  | 0.063 | ...                          |
| J             | 0.16  | 0.092 | 4, 6, 10, 16, 20             |
| K             | 0.24  | 0.140 | ...                          |
| L             | 0.38  | 0.185 | 6, 8, 10, 12, 14, 16, 18, 20 |
| M             | 0.66  | 0.370 | 6, 8, 10, 12, 14, 16, 18, 20 |

$b_b = N_r \times S_g$ , where  $N_r$  = number of ribs and  $S_g$  is sheave groove spacing

All dimensions in inches.

**Table 26. V-Ribbed Belt Sheave and Groove Dimensions ANSI/RMA IP-26, 1977**

<sup>a</sup> Summation of the deviations from  $S_g$  for all grooves in any one sheave shall not exceed  $\pm 0.010$  in.

| Other Sheave Tolerances <sup>a</sup>  |  |  |
|---|--|--|
| Outside Diameter  | Radial Runout <sup>b</sup>   | Axial Runout <sup>b</sup>              |
| Up through 2.9 in. outside diameter $\pm 0.010$ in.                             | Up through 2.9 in. outside diameter 0.005 in.                              | 0.001 in. per inch of outside diameter |
| Over 2.9 in. to and including 8.0 in. outside diameter $\pm 0.020$ in.          | Over 2.9 in. to and including 10.0 in. outside diameter 0.010 in.          |  |
| For each additional inch of outside diameter over 8.0 in., add $\pm 0.0025$ in. | For each additional inch of outside diameter over 10.0 in., add 0.0005 in. |  |

<sup>a</sup> Variations in pitch diameter between the grooves in any one sheave must be within the following limits: Up through 2.9 in. outside diameter and up through 6 grooves, 0.002 in. (add 0.001 in. for each additional groove); over 2.9 in. to and including 19.9 in. and up through 10 grooves, 0.005 in. (add 0.0002 in. for each additional groove); over 19.9 in. and up through 10 grooves, 0.010 in. (add 0.0005 in. for each additional groove). This variation can be obtained by measuring the distance across two measuring balls or rods placed in the grooves diametrically opposite each other. Comparing this "diameter-over-balls or -rods" measurement between grooves will give the variation in pitch diameter.

<sup>b</sup> Total indicator reading.

All dimensions in inches

**Belt Size Designation:** Belt sizes are identified by a standard belt number, which consists of belt effective length to the nearest tenth of an inch, a letter designating cross section, and the number of ribs. For example, 540L6 signifies a 54.0 in. effective length, L belt, six ribs wide.

**Sheave Dimensions.:** Groove angles and dimensions for sheaves and face widths of sheaves for multiple belt drives are given in Table 26, along with various tolerance values.

**Cross Section Selection.:** Use the chart (Fig. 9) as a guide to the V-ribbed belt cross section for any combination of design horsepower and speed of the faster shaft. When the intersection of the design horsepower and speed of the faster shaft falls near a line between two areas on the chart, the possibilities in both areas should be explored. Special circumstances (such as space limitations) may lead to a choice of belt cross section different from that indicated in the chart. H and K cross sections are not included because of their specialized use. Belt manufacturers should be contacted for specific data.

Fig. 9. Selection of V-Ribbed Belt Cross Section

**Horsepower Ratings.:** The horsepower rating formulas are:

$$\mathbf{J:HP} = d_p r \left[ \frac{0.1240}{(d_p r)^{0.09}} - \frac{0.08663}{d_p} - 0.2318 \times 10^{-4} (d_p r)^2 \right] + 0.08663 r \left[ 1 - \frac{1}{K_{SR}} \right]$$

$$\mathbf{L:HP} = d_p r \left[ \frac{0.5761}{(d_p r)^{0.09}} - \frac{0.8987}{d_p} - 1.018 \times 10^{-4} (d_p r)^2 \right] + 0.8987 r \left[ 1 - \frac{1}{K_{SR}} \right]$$

$$\mathbf{M:HP} = d_p r \left[ \frac{1.975}{(d_p r)^{0.09}} - \frac{6.597}{d_p} - 3.922 \times 10^{-4} (d_p r)^2 \right] + 6.597 r \left[ 1 - \frac{1}{K_{SR}} \right]$$

In these equations,  $d_p$  = pitch diameter of the small sheave, in.;  $r$  = rpm of the faster shaft divided by 1000;  $K_{SR}$  = speed ratio factor given in the accompanying Table 30. These formulas give the maximum horsepower per rib recommended, corrected for the speed ratio. To obtain the horsepower per rib for an arc of contact other than 180 degrees, and for belts longer or shorter than the average length, multiply the horsepower obtained from these formulas by the length correction factor (Table 28) and the arc of contact correction factor (Table 29).

**Table 27. V-Ribbed Belt Standard Effective Lengths ANSI/RMA IP-26, 1977**

**Table 29. Arc of Contact Correction Factors**

| $\frac{D_o - d_o}{C}$ | Arc of Contact, $\theta$ ,<br>on Small Sheave, (deg) | Correction Factor |
|-----------------------|--|-------------------|
| 0.00                  | 180  | 1.00              |
| 0.10                  | 174  | 0.98              |
| 0.20                  | 169  | 0.97              |
| 0.30                  | 163  | 0.95              |
| 0.40                  | 157  | 0.94              |
| 0.50                  | 151  | 0.92              |
| 0.60                  | 145  | 0.90              |
| 0.70                  | 139  | 0.88              |
| 0.80                  | 133  | 0.85              |
| 0.90                  | 127  | 0.83              |
| 1.00                  | 120  | 0.80              |
| 1.10                  | 113  | 0.77              |
| 1.20                  | 106  | 0.74              |
| 1.30                  | 99   | 0.71              |
| 1.40                  | 91   | 0.67              |
| 1.50                  | 83   | 0.63              |

*Number of Ribs:* The number of ribs required for an application is obtained by dividing the design horsepower by the corrected horsepower rating for one rib.

Arc of contact on the small sheave may be determined by the following formulas:

$$\text{Exact Formula: Arc of Contact (deg)} = 2 \cos^{-1} \left( \frac{D_o - d_o}{2C} \right)$$

$$\text{Approximate Formula: Arc of Contact (deg)} = 180 - \frac{(D_o - d_o)60}{C} \text{ where}$$

$D_o$  = Effective outside diameter of large sheave, in;  $d_o$  = Effective outside diameter of small sheave, in; and,  $C$  = Center distance, inch.

**Table 30. Speed Ratio Correction Factors**

| Speed Ratio <sup>a</sup>    | $K_{SR}$ |
|-----------------------------|----------|
| 1.00 to and incl. 1.10      | 1.0000   |
| Over 1.01 to and incl. 1.04 | 1.0136   |
| Over 1.04 to and incl. 1.08 | 1.0276   |
| Over 1.08 to and incl. 1.12 | 1.0419   |
| Over 1.12 to and incl. 1.18 | 1.0567   |
| Over 1.18 to and incl. 1.24 | 1.0719   |
| Over 1.24 to and incl. 1.34 | 1.0875   |
| Over 1.34 to and incl. 1.51 | 1.1036   |
| Over 1.51 to and incl. 1.99 | 1.1202   |
| Over 1.99                   | 1.1373   |

<sup>a</sup>  $D_p/d_p$ , where  $D_p$  ( $d_p$ ) is the pitch diameter of the large (small) sheave.

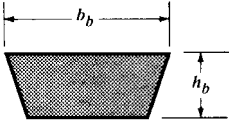

**Variable Speed Belts ANSI/RMA IP-25.**—For drives that require more speed variation than can be obtained with conventional industrial V-belts, standard-line variable-speed drives are available. These drives use special wide, thin belts. Package units of standard-line variable-speed belts and sheaves, combined with the motor and output gearbox are available in ranges from approximately  $\frac{1}{2}$  through 100 horsepower.

The speed ranges of variable-speed drives can be much greater than those drives using classical V-belts. Speed ranges up to 10:1 can be obtained on lower horsepower units.

This section covers 12 variable speed belt cross sections and sheave groove sizes designed 1422V, 1922V, 2322V 1926V, 2926V, 3226V, 2530V, 3230V, 4430V, 4036V, 4436V, and 4836V. The industry supplies many other sizes that are not listed in this section.

*Belt Cross Sections and Lengths:* Nominal dimensions of the 12 cross sections are given in [Table 31](#), and lengths in [Table 32](#).

**Table 31. Normal Variable-Speed Belt Dimensions ANSI/RMA IP-25, 1982**

|  |       |       |           |               |       |       |           |
|---|-------|-------|-----------|---------------|-------|-------|-----------|
| Cross Section   | $b_b$ | $h_b$ | $h_b/b_b$ | Cross Section | $b_b$ | $h_b$ | $h_b/b_b$ |
| 1422V   | 0.88  | 0.31  | 0.35      | 2530V         | 1.56  | 0.59  | 0.38      |
| 1922V   | 1.19  | 0.38  | 0.32      | 3230V         | 2.00  | 0.62  | 0.31      |
| 2322V   | 1.44  | 0.44  | 0.31      | 4430V         | 2.75  | 0.69  | 0.25      |
| 1926V   | 1.19  | 0.44  | 0.37      | 4036V         | 2.50  | 0.69  | 0.28      |
| 2926V   | 1.81  | 0.50  | 0.28      | 4436V         | 2.75  | 0.72  | 0.26      |
| 3226V   | 2.0   | 0.53  | 0.27      | 4836V         | 3.00  | 0.75  | 0.25      |

All dimensions in inches.

**Table 32. Variable-Speed V-Belt Standard Belt Lengths ANSI/RMA IP-25, 1982**

| Standard Pitch Length Designation | Standard Effective Lengths |       |       |       |       |       |       |       |       |       |       |       | Permissible Deviations From Standard Length |

<sup>a</sup>The effective width ( $b_e$ ), a reference dimension, is the same as the ideal top width of closed variable-speed sheave ( $b_g$ ) and the ideal top width of the companion sheave ( $b_g$ ).

| Other Sheave Tolerances  |                 |   |  |
|--|-----------------|---|--|
| Outside Diameter   |                 | Radial Runout <sup>a</sup>                                  | Axial Runout <sup>a</sup>                                  |
| Up through 4.0 in. outside diameter                              | $\pm 0.020$ in. | Up through 10.0 in. outside diameter                        | 0.010 in.  |
| For each additional inch of outside diameter add $\pm 0.005$ in. |                 | For each additional inch of outside diameter add 0.0005 in. | Up through 5.0 in. outside diameter                        |
|  |                 |   | For each additional inch of outside diameter add 0.001 in. |

<sup>a</sup>Total indicator reading.

| Surface Finish                    |   |  |   |
|-----------------------------------|---|--|---|
| Machined Surface Area             | Max Surface Roughness Height, $R_v$ (AA) ( $\mu$ in.) | Machined Surface Area  | Max Surface Roughness Height, $R_v$ (AA) ( $\mu$ in.) |
| V-Sheave groove sidewalls         | 125   | Straight bores with 0.002 in. or less total tolerance        | 125   |
| Rim edges and ID, Hub ends and OD | 500   | Taper and straight bores with total tolerance over 0.002 in. | 250   |

All dimensions in inches, except where noted.

**Belt Size Designation:** Variable-speed belt sizes are identified by a standard belt number. The first two digits denote the belt top width in sixteenths of an inch; the third and fourth digits indicate the angle of the groove in which the belt is designed to operate. Letter V (for variable) follows the first four digits. The digits after the V indicate pitch length to the nearest 0.1 in. For example, 1422V450 is a belt of  $\frac{7}{8}$  in. ( $\frac{14}{16}$  in.) nominal top width designed to operate in a sheave of 22 degree groove angle and having a pitch length of 45.0 in.

**Sheave Groove Data:** A variable speed sheave is an assembly of movable parts, designed to permit one or both flanges of the sheave to be moved axially causing a radial movement of the variable speed belt in the sheave groove. This radial movement permits stepless speed variation within the physical limits of the sheave and the belt. A companion sheave may be a solid sheave having a constant diameter and groove profile or another variable sheave. Variable speed sheave designs should conform to the dimensions in Table 33 and Fig. 10. The included angle of the sheaves, top width, and clearance are boundary dimensions. Groove angles and dimensions of companion sheaves should conform to Table 33 and Fig. 11. Various tolerance values are also given in Table 33.

Fig. 10. Variable Sheaves

**Variable-Speed Drive Design:** Variable-speed belts are designed to operate in sheaves that are an assembly of movable parts. The sheave design permits one or both flanges of the sheave to be moved axially, causing a radial movement of the variable-speed belt in the sheave groove. The result is a stepless speed variation within the physical limits of the sheave and the variable-speed belt. Therefore, besides transmitting power, variable-speed belt drives provide speed variation.

## VARIABLE SPEED BELTS

Fig. 11. Companion Sheaves

The factors that determine the amount of pitch diameter change on variable-speed sheaves are belt top width, belt thickness, and sheave angle. This pitch diameter change, combined with the selected operating pitch diameters for a sheave, determines the possible speed variation.

The range of output speeds from a variable-speed sheave drive is established by the companion sheave and is a function of the ratio of the pitch diameter of the companion sheave to the maximum and minimum pitch diameters of the variable sheave. Speed variation is usually obtained by varying the center distance between the two sheaves. This type of drive seldom exceeds a speed variation of 3:1.

For a single variable-speed sheave drive, the speed variation

$$\text{Speed variation} = \frac{\text{PD Max}}{\text{PD Min}} \quad (\text{of variable sheave})$$

For a dual variable-speed sheave drive, which is frequently referred to as a compound drive because both sheaves are variable, the speed variation is

$$\text{Speed variation} = \frac{DR(DN)}{dr(dn)}$$

where  $DR$  = Max driver PD

$DN$  = Max driven PD

$dr$  = Min driver PD

$dn$  = Min driven PD

With this design, the center distance is generally fixed and speed variation is usually accomplished by mechanically altering the pitch diameter of one sheave. In this type of drive, the other sheave is spring loaded to make an opposite change in the pitch diameter and to provide the correct belt tension. Speed variations of up to 10:1 are common on this type of drive.

**Speed Ratio Adjustment:** All speed ratio changes must be made while the drives are running. Attempting to make adjustments while the unit is stopped creates unnecessary and possibly destructive forces on both the belt and sheaves. In stationary control drives, the belt tension should be released to allow the flanges to adjust without belt force interference.

**Cross Section Selection:** Selection of a variable speed belt cross section is based on the drive design horsepower and speed variation. Table 33 shows the maximum pitch diameter variation ( $2av$ ) that each cross section can attain.

**Horsepower Ratings:** The general horsepower formulas for variable-speed belts are:

$$1422 \text{ V HP} = d_p r \left[ 0.4907 (d_p r)^{-0.09} - \frac{0.8378}{d_p} - 0.000337 (d_p r)^2 \right] + 0.8378 r \left( 1 - \frac{1}{K_{SR}} \right)$$

$$1922 \text{ VHP} = d_p r \left[ 0.8502(d_p r)^{-0.09} - \frac{1.453}{d_p} - 0.000538(d_p r)^2 \right] + 1.453r \left( 1 - \frac{1}{K_{SR}} \right)$$

$$2322 \text{ VHP} = d_p r \left[ 1.189(d_p r)^{-0.09} - \frac{2.356}{d_p} - 0.000777(d_p r)^2 \right] + 2.356r \left( 1 - \frac{1}{K_{SR}} \right)$$

$$1926 \text{ VHP} = d_p r \left[ 1.046(d_p r)^{-0.09} - \frac{1.833}{d_p} - 0.000589(d_p r)^2 \right] + 1.833r \left( 1 - \frac{1}{K_{SR}} \right)$$

$$2926 \text{ VHP} = d_p r \left[ 1.769(d_p r)^{-0.09} - \frac{4.189}{d_p} - 0.001059(d_p r)^2 \right] + 4.189r \left( 1 - \frac{1}{K_{SR}} \right)$$

$$3226 \text{ VHP} = d_p r \left[ 2.073(d_p r)^{-0.09} - \frac{5.236}{d_p} - 0.001217(d_p r)^2 \right] + 5.236r \left( 1 - \frac{1}{K_{SR}} \right)$$

$$2530 \text{ VHP} = d_p r \left[ 2.395(d_p r)^{-0.09} - \frac{6.912}{d_p} - 0.001148(d_p r)^2 \right] + 6.912r \left( 1 - \frac{1}{K_{SR}} \right)$$

$$3230 \text{ VHP} = d_p r \left[ 2.806(d_p r)^{-0.09} - \frac{7.854}{d_p} - 0.001520(d_p r)^2 \right] + 7.854r \left( 1 - \frac{1}{K_{SR}} \right)$$

$$4430 \text{ VHP} = d_p r \left[ 3.454(d_p r)^{-0.09} - \frac{7.854}{d_p} - 0.002196(d_p r)^2 \right] + 9.818r \left( 1 - \frac{1}{K_{SR}} \right)$$

$$4036 \text{ VHP} = d_p r \left[ 3.566(d_p r)^{-0.09} - \frac{9.687}{d_p} - 0.002060(d_p r)^2 \right] + 9.687r \left( 1 - \frac{1}{K_{SR}} \right)$$

$$4436 \text{ VHP} = d_p r \left[ 4.041(d_p r)^{-0.09} - \frac{11.519}{d_p} - 0.002297(d_p r)^2 \right] + 11.519r \left( 1 - \frac{1}{K_{SR}} \right)$$

$$4836 \text{ VHP} = d_p r \left[ 4.564(d_p r)^{-0.09} - \frac{13.614}{d_p} - 0.002634(d_p r)^2 \right] + 13.614r \left( 1 - \frac{1}{K_{SR}} \right)$$

In these equations,  $d_p$  = pitch diameter of small sheave, in.;  $r$  = rpm of faster shaft divided by 1000;  $K_{SR}$  = speed ratio factor given in the accompanying Table 34. These formulas give the basic horsepower rating, corrected for the speed ratio. To obtain the horsepower for arcs of contact other than 180 degrees and for belts longer or shorter than average length, multiply the horsepower obtained from these formulas by the arc of contact correction factor (Table 36) and the length correction factor (Table 35).

**Table 34. Speed Ratio Correction Factors**

| Speed Ratio <sup>a</sup> | $K_{SR}$ | Speed Ratio <sup>a</sup> | $K_{SR}$ |
|--------------------------|----------|--------------------------|----------|
| 1.00–1.01                | 1.0000   | 1.19–1.24                | 1.0719   |
| 1.02–1.04                | 1.0136   | 1.25–1.34                | 1.0875   |
| 1.05–1.08                | 1.0276   | 1.35–1.51                | 1.1036   |
| 1.09–1.12                | 1.0419   | 1.52–1.99                | 1.1202   |
| 1.13–1.18                | 1.0567   | 2.0 and over             | 1.1373   |

<sup>a</sup>  $D_p/d_p$ , where  $D_p$  ( $d_p$ ) is the pitch diameter of the large (small) sheave.

**Rim Speed:** The material and design selected for sheaves must be capable of withstanding the high rim speeds that may occur in variable-speed drives. The rim speed is calculated as follows: Rim speed (fpm) =  $(\pi/12) (D_o)$  (rpm).

**Arc of Contact:** Arc of contact on the small sheave may be determined by the formulas:

$$\text{Exact Formula: Arc of Contact (deg)} = 2 \cos^{-1} \left( \frac{D-d}{2C} \right)$$

$$\text{Approximate Formula: Arc of Contact (deg)} = 180 - \frac{(D-d)60}{C}$$

where  $D$  = Pitch diameter of large sheave or flat pulley, inch

$d$  = Pitch diameter of small sheave, inch

$C$  = Center distance, inch

**Table 36. Arc of Contact Correction Factors**

| $\frac{D-d}{C}$ | Arc of Contact, $\theta$ ,<br>on Small Sheave,<br>(deg) | Correction<br>Factor | $\frac{D-d}{C}$ | Arc of Contact, $\theta$ ,<br>on Small Sheave,<br>(deg) | Correction<br>Factor |

| 0.70            | 139   | 0.89                 | 1.50            | 1.50  | 0.65                 |

**60 Degree V-Belts.**—60 degree V-belts are ideal for compact drives. Their 60 degree angle and ribbed top are specifically designed for long life on small diameter sheaves. These belts offer extremely smooth operation at high speeds (in excess of 10,000 rpm) and can be used on drives with high speed ratios. They are available in 3M, 5M, 7M, and 11M (3, 5, 7, 11 mm) cross sections (top widths) and are commonly found in the joined configuration, which provides extra stability and improved performance. They are specified by cross section and nominal length; for example, a 5M315 designation indicates a belt having a 5 mm cross section and an effective length of 315 mm.

Industry standards have not yet been published for 60 degree V-belts. Therefore, belt manufacturers should be contacted for specific applications, specifications, and additional information.

**SAE Standard V-Belts.**—The data for V-belts and pulleys shown in Table 37 cover nine sizes, three of which — 0.250, 0.315, and 0.440 — were added in 1977 to conform to existing practice. This standard was reaffirmed in 1987.

V-belts are produced in a variety of constructions in a basic trapezoidal shape and are to be dimensioned in such a way that they are functional in pulleys dimensioned as described in the standard. Standard belt lengths are in increments of  $\frac{1}{2}$  inch up to and including 80 inches. Standard lengths above 80 inches up to and including 100 inches are in increments of 1 inch, without fractions. Standard belt length tolerances are based on the center distance and are as follows: For belt lengths of 50 inches or less,  $\pm 0.12$  inch; over 50 to 60 inches, inclusive,  $\pm 0.16$  inch; over 60 to 80 inches, inclusive,  $\pm 0.19$ ; and over 80 to 100 inches, inclusive,  $\pm 0.22$ .

**Belt Storage and Handling.**—To achieve maximum belt performance, proper belt storage procedures should always be practiced. If belts are not stored properly, their performance can be adversely affected. Four key rules are:

- 1) Do not store belts on floors unless they are protected by appropriate packaging.
- 2) Do not store belts near windows where the belts may be exposed to direct sunlight or moisture.

Table 37. SAE V-Belt and Pulley Dimensions

| SAE Size                       | Recommended Min. Eff Dia <sup>a</sup> | A Groove Angle (deg) ±0.5 | W Eff. Groove Width | D Groove Depth Min | d Ball or Rod Dia (±0.0005) | 2K 2 × Ball Extension | 2X <sup>b</sup> | S Groove <sup>c</sup> Spacing (±0.015) |
|--------------------------------|---------------------------------------|---------------------------|---------------------|--------------------|-----------------------------|-----------------------|-----------------|--|

All dimensions in inches.

<sup>a</sup> Pulley effective diameters below those recommended should be used with caution, because power transmission and belt life may be reduced.

<sup>b</sup> The  $X$  dimension is radial;  $2X$  is to be subtracted from the effective diameter to obtain "pitch diameter" for speed ratio calculations.

<sup>c</sup> These values are intended for adjacent grooves of the same effective width ( $W$ ). Choice of pulley manufacture or belt design parameter may justify variance from these values. The  $S$  dimension should be the same on all multiple groove pulleys in a drive using matched belts. © 1990, SAE, Inc.

3) Do not store belts near electrical devices that may generate ozone (transformers, electric motors, etc.).

4) Do not store belts in areas where solvents or chemicals are present in the atmosphere.

Belts should be stored in a cool, dry environment. When stacked on shelves, the stacks should be short enough to avoid excess weight on the bottom belts, which may cause distortion. When stored in containers, the container size and contents should be sufficiently limited to avoid distortion.

**V-Belts:** A common method is to hang the belts on pegs or pin racks. Very long belts stored this way should use sufficiently large pins or crescent shaped "saddles" to prevent their weight from causing distortion.

**Table 38. Service Factors for V-Belts**

The machines listed above are representative samples only. Select the group listed above whose load characteristics most closely approximate those of the machine being considered.

**Joined V-belts, Synchronous Belts, V-Ribbed Belts:** Like V-belts, these belts may be stored on pins or saddles with precautions taken to avoid distortion. However, belts of this type up to approximately 120 in. are normally shipped in a “nested” configuration and should be stored in the same manner. Nests are formed by laying a belt on its side on a flat surface and placing as many belts inside the first belt as possible without undue force. When the nests are tight and are stacked with each rotated 180° from the one below, they may be stacked without damage.

Belts of this type over 120 in. may be “rolled up” and tied for shipment. These rolls may be stacked for easy storage. Care should be taken to avoid small bend radii which could damage the belts.

**Variable Speed Belts:** Variable speed belts are more sensitive to distortion than most other belts, and should not be hung from pins or racks but stored on shelves in the sleeves in which they are shipped.

**Service Factors:** Service factors for V-belts are listed in [Table 38](#).

### Synchronous Belts

**Synchronous Belts ANSI/RMA IP-24.**—Synchronous belts are also known as timing belts. These belts have evenly spaced teeth on their surfaces, which mesh with teeth on pulleys or sprockets to produce a positive, no-slip transmission of power. Such designs should not be confused with molded notched V-belts, which transmit power by means of the wedging action of the V-shape. Synchronous belts are used where driven shaft speeds must be synchronized to the rotation of the driver shaft and to eliminate the noise and maintenance problems of chain drives.

**Standard Timing Belts:** Conventional trapezoidal, or rectangular tooth, timing belts come in six cross sections, which relate to the pitch of the belt. Pitch is the distance from center to center of the teeth. The six basic cross sections or pitches are MXL (mini extra light), XL (extra light), L (light), H (heavy), XH (extra heavy), and XXH (double extra heavy) (Fig. 12). Belts are specified by pitch length, cross section (pitch), and width.

Double-sided timing belts have identical teeth on both sides of the belt and are used where synchronization is required from each belt face. They are available in XL, L, and H cross sections.

**Size Designations:** Synchronous belt sizes are identified by a standard number. The first digits specify the belt length to 0.1 in. followed by the belt section (pitch) designation. The digits following the belt section designation represent the nominal belt width times 100. For example, an L section belt 30.000 in. pitch length and 0.75 in. in width would be specified as a 300L075 synchronous belt.

Fig. 12. Standard Synchronous Belt Sections

The RMA nomenclature for double-sided belts is the same as for single-sided belts with the addition of the prefix "D" in front of the belt section. However, some manufacturers use their own designation system for double-sided belts.

**Standard Sections:** Belt sections are specified in terms of pitch. Table 40 gives the Standard Belt Sections and their corresponding pitches.

Synchronous belts will not slip, and therefore must be belted for the highest loadings anticipated in the system. A minimum service factor of 2.0 is recommended for equipment subject to chocking.

**Pitch Lengths:** Standard belt pitch lengths, belt length designations, and numbers of teeth are shown in [Table 42](#). Belt length tolerances are also given in this table; these tolerances apply to all belt sections and represent the total manufacturing tolerance on belt length.

**Nominal Tooth Dimensions:** [Table 40](#) shows the nominal tooth dimensions for each of the standard belt sections. Tooth dimensions for single- and double-sided belts are identical.

SYNCHRONOUS BELTS

**Table 40. Synchronous Belt Nominal Tooth and Section Dimensions**  
ANSI/RMA IP-24, 1983

| Belt Section (Pitch) | Tooth Angle | Single-Sided Belts |       |       |       |       |       | Double-Sided Belts |       |       |       |       |       |      |       |

*Widths.*: Standard belt widths, width designations, and width tolerances are shown in Table 43.

*Length Determination.*: The pitch length of a synchronous belt is determined by placing the belt on a measuring fixture having two pulleys of equal diameter, a method of applying force, and a means of measuring the center distance between the two pulleys. The position of one of the two pulleys is fixed and the other is movable along a graduated scale.

*Synchronous Belt Pulley Diameters:* Table 44 lists the standard pulley diameters by belt section (pitch). Fig. 13 defines the pitch, pitch diameter, outside diameter and pitch line differential.

All dimensions in inches.

\* Usually not available in all widths — consult supplier.

**Widths:** Standard pulley widths for each belt section are shown in Table 41. The nominal pulley width is specified in terms of the maximum standard belt width the pulley will accommodate. The minimum pulley width, whether flanged or unflanged, is also shown in Table 41, along with flange dimensions and various pulley tolerances.

**Pulley Size Designation:** Synchronous belt pulleys are designated by the number of grooves, the belt section, and a number representing 100 times the nominal width. For example, a 30 groove L section pulley with a nominal width of 0.75 in. would be designated by 30L075. Pulley tolerances are shown in Table 45.

**Table 45. Pulley Tolerances (All Sections)**

| Outside Diameter Range   | Outside Diameter Tolerance | Pitch to Pitch Tolerance   |                              |
|--|----------------------------|--|------------------------------|

| Radial Runout <sup>a</sup>   |                            | Axial Runout <sup>b</sup>  |                              |
| For outside diameters 8.0 in. and under 0.005 in.<br>For each additional inch of outside diameter add 0.0005 in. |                            | For outside diameters 1.0 in. and under 0.001 in.<br>For each additional inch of outside diameter up through 10.0 in., add 0.001 in.<br>For each additional inch of outside diameter over 10.0 in., add 0.0005 in. |                              |

<sup>a</sup> Flange outside diameter equals pulley outside diameter plus twice flange height.

<sup>b</sup> Total indicator reading.

All dimensions in inches.

**Cross Section Selection:** The chart (Fig. 14) may be used as a guide to the selection of a synchronous belt for any combination of design horsepower and speed of the faster shaft. When the intersection of the design horsepower and speed of the faster shaft falls near a line between two areas on the chart, the possibilities in both areas should be explored. Special circumstances (such as space limitations) may result in selection of a belt cross section different from that indicated in the chart. Belt manufacturers should be contacted for specific data.

**Torque Ratings:** It is customary to use torque load requirements rather than horsepower load when designing drives using the small pitch MXL section belts. These belts operate on small diameters resulting in relatively low belt speeds, so torque is essentially constant for all rpm. The torque rating formulas for MXL sections are:

$$Q_r = d[1.13 - 1.38 \times 10^{-3} d^2] \text{ for belt width} = 0.12 \text{ in.}$$

$$Q_r = d[1.88 - 2.30 \times 10^{-3} d^2] \text{ for belt width} = 0.19 \text{ in.}$$

$$Q_r = d[2.63 - 3.21 \times 10^{-3} d^2] \text{ for belt width} = 0.25 \text{ in.}$$

where  $Q_r$  = the maximum torque rating (lbf-in.) for a belt of specified width having six or more teeth in mesh and a pulley surface speed of 6500 fpm or less. Torque ratings for drives with less than six teeth in mesh must be corrected as shown in Table 46.  $d$  = pitch diameter of smaller pulley, inch.

Fig. 14. Selection of Synchronous Belt Cross Section

Table 46. Teeth in Mesh Factor

| Teeth in Mesh | Factor $K_z$ | Teeth in Mesh | Factor $K_z$ |
|---------------|--------------|---------------|--------------|
| 6 or more     | 1.00         | 3             | 0.40         |
| 5             | 0.80         | 2             | 0.20         |
| 4             | 0.60         |               |              |

**Horsepower Rating Formulas:** The horsepower rating formulas for synchronous belts, other than the MLX section, are determined from the following formulas, where the number in parentheses is the belt width in inches.

$$XL(0.38)HP = dr[0.0916 - 7.07 \times 10^{-5}(dr)^2]$$

$$L(1.00)HP = dr[0.436 - 3.01 \times 10^{-4}(dr)^2]$$

$$H(3.00)HP = dr[3.73 - 1.41 \times 10^{-3}(dr)^2]$$

$$XH(4.00)HP = dr[7.21 - 4.68 \times 10^{-3}(dr)^2]$$

$$XXH(5.00)HP = dr[11.4 - 7.81 \times 10^{-3}(dr)^2]$$

where HP = the maximum horsepower rating recommended for the specified standard belt width having six or more teeth in mesh and a pulley surface speed of 6500 fpm or less. Horsepower ratings for drives with less than six teeth in mesh must be corrected as shown in Table 46.  $d$  = pitch diameter of smaller pulley, in.  $r$  = rpm of faster shaft divided by 1000. Total horsepower ratings are the same for double-sided as for single-sided belts. Contact manufacturers for percentage of horsepower available for each side of the belt.

**Finding the Required Belt Width:** The belt width should not exceed the small pulley diameter or excessive side thrust will result.

**Torque Rating Method (MXL Section):** Divide the design torque by the teeth in mesh factor to obtain the corrected design torque. Compare the corrected design torque with the torque rating given in Table 47 for the pulley diameter being considered. Select the narrowest belt width that has a torque rating equal to or greater than the corrected design torque.

**Table 47. Torque Rating for MXL Section (0.080 in. Pitch)**

| Belt Width, (in.) | Rated Torque (lbf-in.) for Small Pulley (Number of Grooves and Pitch Diameter, in.) |                |                |                |                |                |                |                |                |                |
|-------------------|---|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|----------------|
|                   | 10MXL<br>0.255  | 12MXL<br>0.306 | 14MXL<br>0.357 | 16MXL<br>0.407 | 18MXL<br>0.458 | 20MXL<br>0.509 | 22MXL<br>0.560 | 24MXL<br>0.611 | 28MXL<br>0.713 | 30MXL<br>0.764 |
| 0.12              | 0.29  | 0.35           | 0.40           | 0.46           | 0.52           | 0.57           | 0.63           | 0.69           | 0.81           | 0.86           |
| 0.19              | 0.48  | 0.58           | 0.67           | 0.77           | 0.86           | 0.96           | 1.05           | 1.15           | 1.34           | 1.44           |
| 0.25              | 0.67  | 0.80           | 0.94           | 1.07           | 1.20           | 1.34           | 1.47           | 1.61           | 1.87           | 2.01           |

**Horsepower Rating Method (XL, L, H, XH, and XXH Sections):** Multiply the horsepower rating for the widest standard belt of the selected section by the teeth in mesh factor to obtain the corrected horsepower rating. Divide the design horsepower by the corrected horsepower rating to obtain the required belt width factor. Compare the required belt width factor with those shown in [Table 48](#). Select the narrowest belt width that has a width factor equal to or greater than the required belt width factor.

**Table 48. Belt Width Factor**

| Belt Section | Belt Width (in.) |      |      |      |      |      |      |      |      |      |      |      |
|--------------|------------------|------|------|------|------|------|------|------|------|------|------|------|
|              | 0.12             | 0.19 | 0.25 | 0.38 | 0.50 | 0.75 | 1.00 | 1.50 | 2.00 | 3.00 | 4.00 | 5.00 |

| L (0.375)    | ...              | ...  | ...  | ...  | 0.45 | 0.72 | 1.00 | ...  | ...  | ...  | ...  | ...  |
| H (0.500)    | ...              | ...  | ...  | ...  | ...  | 0.21 | 0.29 | 0.45 | 0.63 | 1.00 | ...  | ...  |
| XH (0.875)   | ...              | ...  | ...  | ...  | ...  | ...  | ...  | ...  | 0.45 | 0.72 | 1.00 | ...  |
| XXH (1.250)  | ...              | ...  | ...  | ...  | ...  | ...  | ...  | ...  | 0.35 | 0.56 | 0.78 | 1.00 |

**Drive Selection:** Information on design and selection of synchronous belt drives is available in engineering manuals published by belt manufacturers. Manufacturers should be consulted on such matters as preferred stock sizes, desirable speeds, center distances, etc.

**Minimum Pulley Size:** The recommended minimum pulley size depends on the rpm of the faster shaft. Minimum sheave diameters for each cross-section belt are listed in [Table 44](#).

**Selection of Flanged Pulleys:** To determine when to use flanged pulleys, consider the following conditions:

1) On all two-pulley drives, the minimum flanging requirements are two flanges on one pulley, or one flange on each pulley on opposite sides.

2) On drives where the center distance is more than eight times the diameter of the small pulley, both pulleys should be flanged on both sides.

3) On vertical shaft drives, one pulley should be flanged on both sides and other pulleys in the system should be flanged on the bottom side only.

4) On drives with more than two pulleys, the minimum flanging requirements are two flanges on every other pulley, or one flange on every pulley, alternating sides around the system.

**Service Factors:** Service factors for synchronous belts in [Table 39](#).

## TRANSMISSION CHAINS

### Types of Chains

In addition to the standard roller and inverted tooth types, a wide variety of drive chains of different construction is available. Such chains are manufactured to various degrees of precision ranging from unfinished castings or forgings to chains having certain machined parts. Practically all of these chains as well as standard roller chains can be equipped with attachments to fit them for conveyor use. A few such types are briefly described in the following paragraphs. Detailed information about them can be obtained from the manufacturers.

**Types of Chains.**—*Detachable Chains:* The links of this type of chain, which are identical, are easily detachable. Each has a hook-shaped end in which the bar of the adjacent link articulates. These chains are available in malleable iron or pressed steel. The chief advantage is the ease with which any link can be removed.

*Cast Roller Chains:* Cast roller chains are constructed, wholly or partly, of cast metal parts and are available in various styles. In general the rollers and side bars are accurately made castings without machine finish. The links are usually connected by means of forged pins secured by nuts or cotters. Such chains are used for slow speeds and moderate loads, or where the precision of standard roller chains is not required.

*Pintle Chains:* Unlike the roller chain, the pintle chain is composed of hollow-cored cylinders cast or forged integrally with two offset side bars and each link identical. The links are joined by pins inserted in holes in the ends of the side bars and through the cored holes in the adjacent links. Lugs prevent turning of the pins in the side bars ensuring articulation of the chain between the pin and the cored cylinder.

### Standard Roller Transmission Chains

A roller chain is made up of two kinds of links: roller links and pin links alternately spaced throughout the length of the chain as shown in [Table 1](#).

Roller chains are manufactured in several types, each designed for the particular service required. All roller chains are so constructed that the rollers are evenly spaced throughout the chain. The outstanding advantage of this type of chain is the ability of the rollers to rotate when contacting the teeth of the sprocket. Two arrangements of roller chains are in common use: the single-strand type and the multiple-strand type. In the latter type, two or more chains are joined side by side by means of common pins which maintain the alignment of the rollers in the different strands.

**Types of Roller Chains.**—*Standard roller chains* are manufactured to the specifications in the American National Standard for precision power transmission roller chains, attachments, and sprockets ANSI/ASME B29.1M-1993 and, where indicated, the data in the subsequent tables have been taken from this standard. These roller chains and sprockets are commonly used for the transmission of power in industrial machinery, machine tools, motor trucks, motorcycles, tractors, and similar applications. In tabulating the dimensional information in ANSI/ASME B29.1M, customary inch-pound units were used. Metric (SI) units are given in separate tabulations in the Standard.

*Nonstandard roller chains*, developed individually by various manufacturers prior to the adoption of the ANSI standard, are similar in form and construction to standard roller chains but do not conform dimensionally to standard chains. Some sizes are still available from the originating manufacturers for replacement on existing equipment. They are not recommended for new installations, since their manufacture is being discontinued as rapidly as possible.

**Table 1. ANSI Nomenclature for Roller Chain Parts** ANSI/ASME B29.1M-1993

*Roller Link D.* — An inside link consisting of two inside plates, two bushings, and two rollers.

*Pin Link G and E.* — An outside link consisting of two pin-link plates assembled with two pins.

*Inside Plate A.* — One of the plates forming the tension members of a roller link.

*Pin Link Plate E.* — One of the plates forming the tension members of a pin link.

*Pin F.* — A stud articulating within a bushing of an inside link and secured at its ends by the pin-link plates.

*Bushing B.* — A cylindrical bearing in which the pin turns.

*Roller C.* — A ring or thimble which turns over a bushing.

*Assembled Pins G.* — Two pins assembled with one pin-link plate.

*Connecting-Link G and I.* — A pin link having one side plate detachable.

*Connecting-Link Plate I.* — The detachable pin-link plate belonging to a connecting link. It is retained by cotter pins or by a one-piece spring clip (not shown).

*Connecting Link Assembly M.* — A unit designed to connect two roller links.

*Offset Link L.* — A link consisting of two offset plates assembled with a bushing and roller at one end and an offset link pin at the other.

*Offset Plate J.* — One of the plates forming the tension members of the offset link.

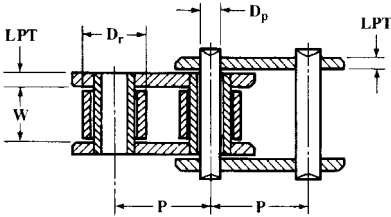

*Offset Link Pin K.* — A pin used in offset links.

*Standard double-pitch roller chains* are like standard roller chains, except that their link plates have twice the pitch of the corresponding standard-pitch chain. Their design conforms to specifications in the ANSI Standard for double-pitch power transmission roller chains and sprockets ANSI/ASME B29.3M-1994. They are especially useful for low speeds, moderate loads, or long center distances.

## Transmission Roller Chain

**Standard Roller Chain Nomenclature, Dimensions and Loads.**—Standard nomenclature for roller chain parts are given in Table 1. Dimensions for Standard Series roller chain are given in Table 2.

Table 2. ANSI Roller Chain Dimensions ASME/ANSI B29.1M-1986

| Pitch<br>$P$ | Max. Roller Diameter<br>$D_r$ | Standard Series    |              |                       |                                   |                                     | Heavy Series                      |
|--------------|-------------------------------|--------------------|--------------|-----------------------|-----------------------------------|-------------------------------------|-----------------------------------|
|              |                               | Standard Chain No. | Width<br>$W$ | Pin Diameter<br>$D_p$ | Thickness of Link Plates<br>$LPT$ | Measuring Load, <sup>†</sup><br>Lb. | Thickness of Link Plates<br>$LPT$ |

<sup>a</sup> Bushing diameter. This size chain has no rollers.

All dimensions are in inches.

Roller Diameters  $D_r$  are approximately  $\frac{5}{8}P$ .

The width  $W$  is defined as the distance between the link plates. It is approximately  $\frac{5}{8}$  of the chain pitch.

Pin Diameters  $D_p$  are approximately  $\frac{5}{16}P$  or  $\frac{1}{2}$  of the roller diameter.

Thickness  $LPT$  of Inside and Outside Link Plates for the standard series is approximately  $\frac{1}{8}P$ .

Thickness of Link Plates for the heavy series of any pitch is approximately that of the next larger pitch Standard Series chain.

Maximum Height of Roller Link Plates =  $0.95P$ .

Maximum Height of Pin Link Plates =  $0.82P$ .

Maximum Pin Diameter = nominal pin diameter + 0.0005 inch.

Minimum Hole in Bushing = nominal pin diameter + 0.0015 inch.

Maximum Width of Roller Link = nominal width of chain +  $(2.12 \times \text{nominal link plate thickness.})$

Minimum Distance between Pin Link Plates = maximum width of roller link + 0.002 inch.

**Chain Pitch:** Distance in inches between centers of adjacent joint members. Other dimensions are proportional to the pitch.

**Tolerances for Chain Length:** New chains, under standard measuring load, must not be underlength. Overlength tolerance is  $0.001/(\text{pitch in inches})^2 + 0.015$  inch per foot. Length measurements are to be taken over a length of at least 12 inches.

**Measuring Load:** The load in pounds under which a chain should be measured for length. It is equal to one per cent of the ultimate tensile strength, with a minimum of 18 pounds and a maximum of 1000 pounds for both single and multiple-strand chain.

**Minimum Ultimate Tensile Strength:** For single-strand chain, equal to or greater than  $12,500 \times (\text{pitch in inches})^2$  pounds. The minimum tensile strength or breaking strength of a multiple-strand chain is equal to that of a single-strand chain multiplied by the number of strands. Minimum ultimate tensile strength is indicative only of the tensile strength quality of the chain, not the maximum load that can be applied.

**Standard Roller Chain Numbers.**—The right-hand figure in the chain number is zero for roller chains of the usual proportions, 1 for a lightweight chain, and 5 for a rollerless bushing chain. The numbers to the left of the right-hand figure denote the number of  $\frac{1}{8}$  inches in the pitch. The letter *H* following the chain number denotes the heavy series; thus the number 80 *H* denotes a 1-inch pitch heavy chain. The hyphenated number 2 suffixed to the chain number denotes a double strand, 3 a triple strand, 4 a quadruple strand chain and so on.

**Heavy Series:** These chains, made in  $\frac{3}{4}$ -inch and larger pitches, have thicker link plates than those of the regular standard. Their value is only in the acceptance of higher loads at lower speeds.

**Light-weight Machinery Chain:** This chain is designated as No. 41. It is  $\frac{1}{2}$  inch pitch;  $\frac{1}{4}$  inch wide; has 0.306-inch diameter rollers and a 0.141-inch pin diameter. The minimum ultimate tensile strength is 1500 pounds.

**Multiple-strand Chain:** This is essentially an assembly of two or more single-strand chains placed side by side with pins that extend through the entire width to maintain alignment of the different strands.

**Types of Sprockets.**—Four different designs or types of roller-chain sprockets are shown by the sectional views, Fig. 1. Type *A* is a plain plate; type *B* has a hub on one side only; type *C*, a hub on both sides; and type *D*, a detachable hub. Also used are shear pin and slip clutch sprockets designed to prevent damage to the drive or to other equipment caused by overloads or stalling.

Fig. 1. Types of Sprockets

**Attachments.**—Modifications to standard chain components to adapt the chain for use in conveying, elevating, and timing operations are known as "attachments." The components commonly modified are: 1) the link plates, which are provided with extended lugs which may be straight or bent; and 2) the chain pins, which are extended in length so as to project substantially beyond the outer surface of the pin link plates.

Hole diameters, thicknesses, hole locations and offset dimensions for straight link and bent link plate extensions and lengths and diameters of extended pins are given in Table 3.

**Table 3. Straight and Bent Link Plate Extensions and Extended Pin Dimensions**  
ANSI/ASME B29.1M-1993

| Chain No. | Straight Link Plate Extension |          |          | Bent Link Plate Extension |          |          |          | Extended Pin                 |          |

All dimensions are in inches.

**Sprocket Classes.**—The American National Standard ANSI/ASME B29.1M-1993 provides for two classes of sprockets designated as Commercial and Precision. The selection of either is a matter of drive application judgment. The usual moderate to slow speed commercial drive is adequately served by Commercial sprockets. Where extreme high speed in combination with high load is involved, or where the drive involves fixed centers, critical timing, or register problems, or close clearance with outside interference, then the use of Precision sprockets may be more appropriate.

As a general guide, drives requiring Type A or Type B lubrication (see page 2463) would be served by Commercial sprockets. Drives requiring Type C lubrication may require Precision sprockets; the manufacturer should be consulted.

**Keys, Keyways, and Set Screws.**—To secure sprockets to the shaft, both keys and set screws should be used. The key is used to prevent rotation of the sprocket on the shaft. Keys should be fitted carefully in the shaft and sprocket keyways to eliminate all backlash, especially on the fluctuating loads. A set screw should be located over a flat key to secure it against longitudinal displacement.

Where a set screw is to be used with a parallel key, the following sizes are recommended by the American Chain Association. For a sprocket bore and shaft diameter in the range of

$\frac{1}{2}$  through  $\frac{7}{8}$  inch, a  $\frac{1}{4}$ -inch set screw

$\frac{15}{16}$  through  $1\frac{3}{4}$  inches, a  $\frac{3}{8}$ -inch set screw

$1\frac{13}{16}$  through  $2\frac{1}{4}$  inches, a  $\frac{1}{2}$ -inch set screw

$2\frac{5}{16}$  through  $3\frac{1}{4}$  inches, a  $\frac{5}{8}$ -inch set screw

$3\frac{3}{8}$  through  $4\frac{1}{2}$  inches, a  $\frac{3}{4}$ -inch set screw

$4\frac{3}{4}$  through  $5\frac{1}{2}$  inches, a  $\frac{7}{8}$ -inch set screw

$5\frac{3}{4}$  through  $7\frac{3}{8}$  inches, a 1-inch set screw

$7\frac{1}{2}$  through  $12\frac{1}{2}$  inches, a  $1\frac{1}{4}$ -inch set screw

**Sprocket Diameters.**—The various diameters of roller chain sprockets are shown in Fig. 2. These are defined as follows.

*Pitch Diameter:* The pitch diameter is the diameter of the pitch circle that passes through the centers of the link pins as the chain is wrapped on the sprocket.

Fig. 2. Sprocket Diameters

Because the chain pitch is measured on a straight line between the centers of adjacent pins, the chain pitch lines form a series of chords of the sprocket pitch circle. Sprocket pitch diameters for one-inch pitch and for 9 to 108 teeth are given in Table 4. For lower (5 to 8) or higher (109 to 200) numbers of teeth use the following formula in which  $P$  = pitch,  $N$  = number of teeth: Pitch Diameter =  $P \div \sin(180^\circ \div N)$ .

**Table 4. ANSI Roller Chain Sprocket Diameters ANSI/ASME B29.1M-1993**

These diameters and caliper factors apply only to chain of 1-inch pitch. For any other pitch, multiply the values given below by the pitch.

Caliper Dia. (even teeth) = Pitch Diameter – Roller Dia.

Caliper Dia. (odd teeth) = Caliper factor × Pitch – Roller Dia.

See Table 5 for tolerances on Caliper Diameters.

| No. Teeth <sup>a</sup> | Pitch Diameter | Outside Diameter |                 | Caliper Factor | No. Teeth <sup>a</sup> | Pitch Diameter | Outside Diameter |                 | Caliper Factor |
|------------------------|----------------|------------------|-----------------|----------------|------------------------|----------------|------------------|-----------------|----------------|

<sup>a</sup> For 5 – 8 and 109–200 teeth see text, pages 2446, 2448.

**Bottom Diameter:** The bottom diameter is the diameter of a circle tangent to the curve (called the seating curve) at the bottom of the tooth gap. It equals the pitch diameter minus the diameter of the roller.

**Caliper Diameter:** The caliper diameter is the same as the bottom diameter for a sprocket with an even number of teeth. For a sprocket with an odd number of teeth, it is defined as the distance from the bottom of one tooth gap to that of the nearest opposite tooth gap. The caliper diameter for an even tooth sprocket is equal to pitch diameter–roller diameter. The caliper diameter for an odd tooth sprocket is equal to caliper factor–roller diameter. Here, the caliper factor =  $PD[\cos(90^\circ \div N)]$ , where  $PD$  = pitch diameter and  $N$  = number of teeth. Caliper factors for 1-in. pitch and sprockets having 9–108 teeth are given in Table 4. For other tooth numbers use above formula. Caliper diameter tolerances are minus only and are equal to  $0.002P\sqrt{N} + 0.006$  inch for the Commercial sprockets and  $0.001P\sqrt{N} + 0.003$  inch for Precision sprockets. Tolerances are given in Table 5.

**Table 5. Minus Tolerances on the Caliper Diameters of Precision Sprockets**  
ANSI/ASME B29.1M-1993

Minus tolerances for Commercial sprockets are twice those shown in this table.

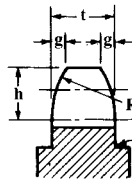

**Outside Diameter:** OD is the diameter over the tips of teeth. Sprocket ODs for 1-in. pitch and 9–108 teeth are given in Table 4. For other tooth numbers the OD may be determined by the following formulas in which  $O$  = approximate OD;  $P$  = pitch of chain;  $N$  = number of sprocket teeth:  $O = P[0.6 + \cot(180^\circ \div N)]$ , for turned sprocket;  $O$  = pitch diameter – roller diameter +  $2 \times$  whole depth of topping hob cut, for topping hob cut sprocket.\*

**Table 6. American National Standard Roller Chain Sprocket Flange Thickness and Tooth Section Profile Dimension ANSI/ASME B29.1M-1993**

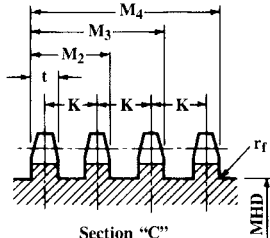

Flange chamfer may be either as in Section "A" or Section "B" or anything in between.

**Section "A"**

**Section "B"**

**Section "C"**

All dimensions are in inches.  $r_f \text{ max} = 0.04 P$  for max. hub diameter.

\*This dimension was added in 1984 as a desirable goal for the future. It should in no way obsolete existing tools or sprockets. The whole depth  $WD$  is found from the formula:  $WD = \frac{1}{2}D_r + P[0.3 - \frac{1}{2} \tan(90 \text{ deg} \div N_a)]$ , where  $N_a$  is the intermediate number of teeth for the topping hob. For teeth range 5,  $N_a = 5$ ; 6, 6; 7-8, 7.47; 9-11, 9.9; 12-17, 14.07; 18-34, 23.54; 35 and over, 56.

**Proportions of Sprockets.**—Typical proportions of single-strand and multiple-strand cast roller chain sprockets, as provided by the American Chain Association, are shown in Table 7. Typical proportions of roller chain bar-steel sprockets, also provided by this association, are shown in Table 8.

**Table 7. Typical Proportions of Single-Strand and Multiple-Strand Cast Roller Chain Sprockets**

**Table 8. Typical Proportions of Roller Chain Bar-steel Sprockets**

When sprocket wheels are designed with spokes, the usual assumptions made in order to determine suitable proportions are as follows: 1) That the maximum torque load acting on a sprocket is the chain tensile strength times the sprocket pitch radius; 2) That the torque load is equally divided between the arms by the rim; and 3) That each arm acts as a cantilever beam.

The arms are generally elliptical in cross section, the major axis twice the minor axis.

**Selection of Chain and Sprockets.**—The smallest applicable pitch of roller chain is desirable for quiet operation and high speed. The horsepower capacity varies with the chain pitch as shown in Table 9. However, short pitch with high working load can often be obtained by the use of multiple-strand chain.

The small sprocket selected must be large enough to accommodate the shaft. Table 10 gives maximum bore and hub diameters consistent with commercial practice for sprockets with up to 25 teeth.

After selecting the small sprocket, the number of teeth in the larger sprocket is determined by the desired ratio of the shaft speed. Overemphasis on the exactness in the speed ratio may result in a cumbersome and expensive installation. In most cases, satisfactory operation can be obtained with a minor change in speed of one or both shafts.

**Table 9. Horsepower Ratings for Roller Chain—1986**

|   |  |      |      |      |      |      |      |        |      |      |      |      |      |      |

| To properly use this table the following factors must be taken into consideration:  |  |      |      |      |      |      |      |        |      |      |      |      |      |      |
| 1) Service factors  |  |      |      |      |      |      |      |        |      |      |      |      |      |      |
| 2) Multiple Strand Factors  |  |      |      |      |      |      |      |        |      |      |      |      |      |      |
| 3) Lubrication  |  |      |      |      |      |      |      |        |      |      |      |      |      |      |
| Service Factors: See Table 15.  |  |      |      |      |      |      |      |        |      |      |      |      |      |      |
| Multiple Strand Factors: For two strands, the multiple strand factor is 1.7; for three strands, it is 2.5; and for four strands, it is 3.3.                           |  |      |      |      |      |      |      |        |      |      |      |      |      |      |
| Lubrication:  |  |      |      |      |      |      |      |        |      |      |      |      |      |      |
| Required type of lubrication is indicated at the bottom of each roller chain size section of the table. For a description of each type of lubrication, see page 2463. |  |      |      |      |      |      |      |        |      |      |      |      |      |      |
| Type A — Manual or Drip Lubrication   |  |      |      |      |      |      |      |        |      |      |      |      |      |      |
| Type B — Bath or Disc Lubrication   |  |      |      |      |      |      |      |        |      |      |      |      |      |      |
| Type C — Oil Stream Lubrication   |  |      |      |      |      |      |      |        |      |      |      |      |      |      |
| To find the required horsepower table rating, use the following formula:  |  |      |      |      |      |      |      |        |      |      |      |      |      |      |
| $\text{Required hp Table Rating} = \frac{\text{hp to be Transmitted} \times \text{Service Factor}}{\text{Multiple-Strand Factor}}$                                    |  |      |      |      |      |      |      |        |      |      |      |      |      |      |

**Center Distance between Sprockets.**—The center-to-center distance between sprockets, as a general rule, should not be less than  $1\frac{1}{2}$  times the diameter of the larger sprocket and not less than thirty times the pitch nor more than about 50 times the pitch, although much depends upon the speed and other conditions. A center distance equivalent to 80 pitches may be considered an approved maximum. Very long center distances result in catenary tension in the chain. If roller-chain drives are designed correctly, the center-to-center distance for some transmissions may be so short that the sprocket teeth nearly touch each other, assuming that the load is not too great and the number of teeth is not too small. To

avoid interference of the sprocket teeth, the center distance must, of course, be somewhat greater than one-half the sum of the outside diameters of the sprockets. The chain should extend around at least 120 degrees of the pinion circumference, and this minimum amount of contact is obtained for all center distances provided the ratio is less than  $3\frac{1}{2}$  to 1. Other things being equal, a fairly long chain is recommended in preference to the shortest one allowed by the sprocket diameters, because the rate of chain elongation due to natural wear is inversely proportional to the length, and also because the greater elasticity of the longer strand tends to absorb irregularities of motion and to decrease the effect of shocks.

If possible, the center distance should be adjustable in order to take care of slack due to elongation from wear and this range of adjustment should be at least one and one-half pitches. A little slack is desirable as it allows the chain links to take the best position on the sprocket teeth and reduces the wear on the bearings. Too much sag or an excessive distance between the sprockets may cause the chain to whip up and down — a condition detrimental to smooth running and very destructive to the chain. The sprockets should run in a vertical plane, the sprocket axes being approximately horizontal, unless an idler is used on the slack side to keep the chain in position. The most satisfactory results are obtained when the slack side of the chain is on the bottom.

**Center Distance for a Given Chain Length.**—When the distance between the driving and driven sprockets can be varied to suit the length of the chain, this center distance for a tight chain may be determined by the following formula, in which  $c$  = center-to-center distance in inches;  $L$  = chain length in pitches;  $P$  = pitch of chain;  $N$  = number of teeth in large sprocket;  $n$  = number of teeth in small sprocket.

$$c = \frac{P}{8}(2L - N - n + \sqrt{(2L - N - n)^2 - 0.810(N - n)^2})$$

This formula is approximate, but the error is less than the variation in the length of the best chains. The length  $L$  in pitches should be an even number for a roller chain, so that the use of an offset connecting link will not be necessary.

**Idler Sprockets.**—When sprockets have a fixed center distance or are non-adjustable, it may be advisable to use an idler sprocket for taking up the slack. The idler should preferably be placed against the slack side between the two strands of the chain. When a sprocket is applied to the tight side of the chain to reduce vibration, it should be on the lower side and so located that the chain will run in a straight line between the two main sprockets. A sprocket will wear excessively if the number of teeth is too small and the speed too high, because there is impact between the teeth and rollers even though the idler carries practically no load.

**Length of Driving Chain.**—The total length of a block chain should be given in multiples of the pitch, whereas for a roller chain, the length should be in multiples of twice the pitch, because the ends must be connected with an outside and inside link. The length of a chain can be calculated accurately enough for ordinary practice by the use of the following formula, in which  $L$  = chain length in pitches;  $C$  = center distance in pitches;  $N$  = number of teeth in large sprocket;  $n$  = number of teeth in small sprocket:

$$L = 2C + \frac{N}{2} + \frac{n}{2} + \left(\frac{N-n}{2\pi}\right)^2 \times \frac{1}{C}$$

| 3        | 3.033                | 0.810    | 0.090    | 9 3/4 | 11 1/4   | 2.000 | 1/2 × 3/8  | 8          |

Hobs designed for a given roller diameter ( $D_r$ ) and chain pitch ( $P$ ) will cut any number of teeth.

$P$  = Pitch of Chain

$P_n$  = Normal Pitch of Hob = 1.011  $P$  inches

$D_s$  = Minimum Diameter of Seating Curve = 1.005  $D_r$  + 0.003 inches

$F$  = Radius Center for Arc  $GK$ ;  $TO = OU = P_n \div 2$

$H = 0.27 P$ ;  $E = 0.03 P$  = Radius of Fillet Circle

$Q$  is located on line passing through  $F$  and  $J$ . Point  $J$  is intersection of line  $XY$  with circle of diameter  $D_s$ .  $R$  is found by trial and the arc of this radius is tangent to arc  $GK$  at  $K$  and to fillet radius.

$OD$  = Outside Diameter = 1.7 (Bore +  $D_r$  + 0.7  $P$ ) approx.

$D_n$  = Pitch Diameter =  $OD - D_s$ ;  $M$  = Helix Angle;  $\sin M = P_n \div \pi D_n$

$L$  = Lead =  $P_n \div \cos M$ ;  $W$  = Width = Not less than  $2 \times$  Bore, or  $6 D_r$ , or  $3.2 P$

To the length obtained by this formula, add enough to make a whole number (and for a roller chain, an even number) of pitches. If a roller chain has an odd number of pitches, it will be necessary to use an offset connecting link.

Another formula for obtaining chain length in which  $D$  = distance between centers of shafts;  $R$  = pitch radius of large sprocket;  $r$  = pitch radius of small sprocket;  $N$  = number of teeth in large sprocket;  $n$  = number of teeth in small sprocket;  $P$  = pitch of chain and sprockets; and  $l$  = required chain length in inches, is:

$$l = \frac{180^\circ + 2\alpha}{360^\circ} NP + \frac{180^\circ - 2\alpha}{360^\circ} nP + 2D \cos \alpha \quad \text{where } \sin \alpha = \frac{R - r}{D}$$

**Cutting Standard Sprocket Tooth Form.**—The proportions and seating curve data for the standard sprocket tooth form for roller chain are given in Table 11. Either formed or generating types of sprocket cutters may be employed.

**Hobs:** Only one hob will be required to cut any number of teeth for a given pitch and roller diameter. All hobs should be marked with pitch and roller diameter to be cut. Formulas and data for standard hob design are given in Table 12.

**Space Cutters:** Five cutters of this type will be required to cut from 7 teeth up for any given roller diameter. The ranges are, respectively, 7–8, 9–11, 12–17, 18–34, and 35 teeth and over. If less than 7 teeth is necessary, special cutters conforming to the required number of teeth should be used.

The regular cutters are based upon an intermediate number of teeth  $N_a$ , equal to  $2N_1N_2 \div (N_1 + N_2)$  in which  $N_1$  = minimum number of teeth and  $N_2$  = maximum number of teeth for which cutter is intended; but the topping curve radius  $F$  (see diagram in Table 13) is designed to produce adequate tooth height on a sprocket of  $N_2$  teeth. The values of  $N_a$  for the several cutters are, respectively, 7.47, 9.9, 14.07, 23.54, and 56. Formulas and construction data for space cutter layout are given in Table 13 and recommended cutter sizes are given in Table 14.

**Table 13. Standard Space Cutters for Roller-Chain Sprockets**

| Data for Laying Out Space Cutter |                       |                       |              |                |
|----------------------------------|-----------------------|-----------------------|--------------|----------------|
| Range of Teeth                   | M                     | T                     | W            | V              |
| 7-8                              | $0.5848 D_r$          | $0.5459 D_r$          | $1.2790 D_r$ | $0.5694 D_r$   |
| 9-11                             | $0.6032 D_r$          | $0.5255 D_r$          | $1.3302 D_r$ | $0.4365 D_r$   |
| 12-17                            | $0.6194 D_r$          | $0.5063 D_r$          | $1.3694 D_r$ | $0.2911 D_r$   |
| 18-34                            | $0.6343 D_r$          | $0.4875 D_r$          | $1.3947 D_r$ | $0.1220 D_r$   |
| 35 up                            | $0.6466 D_r$          | $0.4710 D_r$          | $1.4000 D_r$ | 0              |
| Range of Teeth                   | F                     | Chord xy              | yz           | Angle Yab      |
| 7-8                              | $0.8686 D_r - 0.0015$ | $0.2384 D_r + 0.0003$ | $0.0618 D_r$ | $24^\circ$     |
| 9-11                             | $0.8554 D_r - 0.0015$ | $0.2800 D_r + 0.0003$ | $0.0853 D_r$ | $18^\circ 10'$ |

| 18-34                            | $0.8073 D_r - 0.0015$ | $0.3540 D_r + 0.0004$ | $0.1922 D_r$ | $5^\circ$      |
| 35 up                            | $0.7857 D_r - 0.0015$ | $0.3850 D_r + 0.0004$ | $0.2235 D_r$ | $0^\circ$      |

$E$  (same for all ranges) =  $1.3025 D_r + 0.0015$ ;  $G$  (same for all ranges) =  $1.4 D_r$

See Table 14 for recommended cutter sizes.

Angle  $Yab$  is equal to  $180^\circ \div N$  when the cutter is made for a specific number of teeth. For the design of cutters covering a range of teeth, angle  $Yab$  was determined by layout to ensure chain roller clearance and to avoid pointed teeth on the larger sprockets of each range. It has values as given below for cutters covering the range of teeth shown. The following formulas are for cutters covering the standard ranges of teeth where  $N_a$  equals intermediate values given on page 2460.

$$W = 1.4D_r \cos Yab \quad V = 1.4D_r \sin Yab$$

$$yz = D_r \left[ 1.4 \sin \left( 17^\circ + \frac{116^\circ}{N_a} - Yab \right) - 0.8 \sin \left( 18^\circ - \frac{56^\circ}{N_a} \right) \right]$$

$$F = D_r \left[ 0.8 \cos \left( 18^\circ - \frac{56^\circ}{N_a} \right) + 1.4 \cos \left( 17^\circ + \frac{116^\circ}{N_a} - Yab \right) - 1.3025 \right] - 0.0015 \text{ in.}$$

For other points, use the value of  $N_a$  for  $N$  in the standard formulas in Table 11.

Where the same roller diameter is commonly used with chains of two different pitches it is recommended that stock cutters be made wide enough to cut sprockets for both chains.

**Marking of Cutters.**—All cutters are to be marked, giving pitch, roller diameter and range of teeth to be cut.

**Bores for Sprocket Cutters** (recommended practice) are approximately as calculated from the formula:

$$\text{Bore} = 0.7 \sqrt{(\text{Width of Cutter} + \text{Roller Diameter} + 0.7 \text{ Pitch})}$$

and are equal to 1 inch for  $\frac{1}{4}$ - through  $\frac{3}{4}$ -inch pitches;  $1\frac{1}{4}$  inches for 1- through  $1\frac{1}{2}$ -inch for  $1\frac{3}{4}$ - through  $2\frac{1}{4}$ -inch pitches;  $1\frac{3}{4}$  inches for  $2\frac{1}{2}$ -inch pitch; and 2 inches for 3-inch pitch.

**Minimum Outside Diameters of Space Cutters** for 35 teeth and over (recommended practice) are approximately as calculated from the formula:

$$\text{Outside Diameter} = 1.2(\text{Bore} + \text{Roller Diameter} + 0.7 \text{ Pitch}) + 1 \text{ in.}$$

**Shaper Cutters:** Only one will be required to cut any number of teeth for a given pitch and roller diameter. The manufacturer should be referred to for information concerning the cutter form design to be used.

**Sprocket Manufacture.**—Cast sprockets have cut teeth, and the rim, hub face, and bore are machined. The smaller sprockets are generally cut from steel bar stock, and are finished all over. Sprockets are often made from forgings or forged bars. The extent of finishing depends on the particular specifications that are applicable. Many sprockets are made by welding a steel hub to a steel plate. This process produces a one-piece sprocket of desired proportions and one that can be heat-treated.

**Sprocket Materials.**—For large sprockets, cast iron is commonly used, especially in drives with large speed ratios, since the teeth of the larger sprocket are subjected to fewer chain engagements in a given time. For severe service, cast steel or steel plate is preferred.

The smaller sprockets of a drive are usually made of steel. With this material the body of the sprocket can be heat-treated to produce toughness for shock resistance, and the tooth surfaces can be hardened to resist wear.

Stainless steel or bronze may be used for corrosion resistance, and Formica, nylon or other suitable plastic materials for special applications.

**Roller Chain Drive Ratings.**—In 1961, under auspices of The American Sprocket Chain Manufacturers Association (now called American Chain Association), a joint research program was begun to study pin-bushing interaction at high speeds and to gain further data on the phenomenon of chain joint galling among other research areas. These studies have shown that a separating film of lubricant is formed in chain joints in a manner similar to that found in journal bearings. These developments appear in ANSI/ASME B29.1M-1993, and are contained in Table 9. The ratings shown in Table 9 are below the galling range.

The horsepower ratings in Table 9 apply to lubricated, single-pitch, single-strand roller chains, both ANSI Standard and Heavy series. To obtain ratings of multiple-strand chains, a multiple-strand factor is applied.

The ratings in Table 9 are based upon: 1) A service factor of 1.; 2) A chain length of approximately 100 pitches.; 3) Use of recommended lubrication methods.; and 4) A drive arrangement where two aligned sprockets are mounted on parallel shafts in a horizontal plane.

Under these conditions, approximately 15,000 hours of service life at full load operation may be expected.

**Table 15. Roller Chain Drive Service Factors**

| Type of Driven Load | Type of Input Power                             |                           |  |
|---------------------|---|---------------------------|--|
|                     | Internal Combustion Engine with Hydraulic Drive | Electric Motor or Turbine | Internal Combustion Engine with Mechanical Drive |
| Smooth              | 1.0   | 1.0                       | 1.2  |
| Moderate Shock      | 1.2   | 1.3                       | 1.4  |
| Heavy Shock         | 1.4   | 1.5                       | 1.7  |

Substantial increases in rated speed loads can be utilized, as when a service life of less than 15,000 hours is satisfactory, or when full load operation is encountered only during a portion of the required service life. Chain manufacturers should be consulted for assistance with any special application requirements.

The horsepower ratings shown in Table 9 relate to the speed of the smaller sprocket and drive selections are made on this basis, whether the drive is speed reducing or speed increasing. Drives with more than two sprockets, idlers, composite duty cycles, or other unusual conditions often require special consideration. Where quietness or extra smooth operation are of special importance, small-pitch chain operating over large diameter sprockets will minimize noise and vibration.

When making drive selection, consideration is given to the loads imposed on the chain by the type of input power and the type of equipment to be driven. Service factors are used to compensate for these loads and the *required* horsepower rating of the chain is determined by the following formula:

$$\text{Required hp Table Rating} = \frac{\text{hp to be Transmitted} \times \text{Service Factor}}{\text{Multiple-Strand Factor}}$$

*Service Factors:* The service factors in Table 15 are for normal chain loading. For unusual or extremely severe operating conditions not shown in this table, it is desirable to use larger service factors.

*Multiple-Strand Factors:* The horsepower ratings for multiple-strand chains equal single-strand ratings multiplied by these factors: for two strands, a factor of 1.7; for three strands, 2.5; and for four strands, 3.3.

**Lubrication.**—It has been shown that a separating wedge of fluid lubricant is formed in operating chain joints much like that formed in journal bearings. Therefore, fluid lubricant must be applied to ensure an oil supply to the joints and minimize metal-to-metal contact. If supplied in sufficient volume, lubrication also provides effective cooling and impact damping at higher speeds. For this reason, it is important that lubrication recommendations be followed. *The ratings in Table 9 apply only to drives lubricated in the manner specified in this table.*

Chain drives should be protected against dirt and moisture and the oil supply kept free of contamination. Periodic oil change is desirable. A good grade of non-detergent petroleum base oil is recommended. Heavy oils and greases are generally too stiff to enter and fill the chain joints. The following lubricant viscosities are recommended: For temperatures of 20° to 40°F, use SAE 20 lubricant; for 40° to 100°, use SAE 30; for 100° to 120°, use SAE 40; and for 120° to 140°, use SAE 50.

There are three basic types of lubrication for roller chain drives. The recommended type shown in Table 9 as Type A, Type B, or Type C is influenced by the chain speed and the amount of power transmitted. These are *minimum* lubrication requirements and the use of a better type (for example, Type C instead of Type B) is acceptable and may be beneficial. Chain life can vary appreciably depending upon the way the drive is lubricated. The better the chain lubrication, the longer the chain life. For this reason, it is important that the lubrication recommendations be followed when using the ratings given in Table 9. The types of lubrication are as follows:

*Type A — Manual or Drip Lubrication:* In manual lubrication, oil is applied copiously with a brush or spout can at least once every eight hours of operation. Volume and frequency should be sufficient to prevent overheating of the chain or discoloration of the chain joints. In drip lubrication, oil drops from a drip lubricator are directed between the link plate edges. The volume and frequency should be sufficient to prevent discoloration of the lubricant in the chain joints. Precautions must be taken against misdirection of the drops by windage.

*Type B — Bath or Disc Lubrication:* In bath lubrication, the lower strand of the chain runs through a sump of oil in the drive housing. The oil level should reach the pitch line of the chain at its lowest point while operating. In disc lubrication, the chain operates above the oil level. The disc picks up oil from the sump and deposits it onto the chain, usually by means of a trough. The diameter of the disc should be such as to produce rim speeds of between 600 and 8000 feet per minute.

*Type C — Oil Stream Lubrication:* The lubricant is usually supplied by a circulating pump capable of supplying each chain drive with a continuous stream of oil. The oil should be applied inside the chain loop evenly across the chain width, and directed at the slack strand.

The chain manufacturer should be consulted when it appears desirable to use a type of lubricant other than that recommended.

**Installation and Alignment.**—Sprockets should have the tooth form, thickness, profile, and diameters conforming to ASME/ANSI B29.1M. For maximum service life small sprockets operating at moderate to high speeds, or near the rated horsepower, should have hardened teeth. Normally, large sprockets should not exceed 120 teeth.

In general a center distance of 30 to 50 chain pitches is most desirable. The distance between sprocket centers should provide at least a 120 degree chain wrap on the smaller sprocket. Drives may be installed with either adjustable or fixed center distances. Adjustable centers simplify the control of chain slack. Sufficient housing clearance must always be provided for the chain slack to obtain full chain life.

Accurate alignment of shafts and sprocket tooth faces provides uniform distribution of the load across the entire chain width and contributes substantially to optimum drive life.

Shafting, bearings, and foundations should be suitable to maintain the initial alignment. Periodic maintenance should include an inspection of alignment.

**Example of Roller Chain Drive Design Procedure.**—The selection of a roller chain and sprockets for a specific design requirement is best accomplished by a systematic step-by-step procedure such as is used in the following example.

*Example:* Select a roller chain drive to transmit 10 horsepower from a countershaft to the main shaft of a wire drawing machine. The countershaft is  $1\frac{5}{16}$ -inches diameter and operates at 1000 rpm. The main shaft is also  $1\frac{5}{16}$ -inches diameter and must operate between 378 and 382 rpm. Shaft centers, once established, are fixed and by initial calculations must be approximately  $22\frac{1}{2}$  inches. The load on the main shaft is uneven and presents “peaks,” which place it in the heavy shock load category. The input power is supplied by an electric motor. The driving head is fully enclosed and all parts are lubricated from a central system.

*Step 1. Service Factor:* From Table 15 the service factor for heavy shock load and an electric motor drive is 1.5.

*Step 2. Design Horsepower:* The horsepower upon which the chain selection is based (design horsepower) is equal to the specified horsepower multiplied by the service factor,  $10 \times 1.5 = 15$  hp.

*Step 3. Chain Pitch and Small Sprocket Size for Single-Strand Drive:* In Table 9 under 1000 rpm, a  $\frac{5}{8}$ -inch pitch chain with a 24-tooth sprocket or a  $\frac{3}{4}$ -inch pitch chain with a 15-tooth sprocket are possible choices.

*Step 4. Check of Chain Pitch and Sprocket Selection:* From Table 10 it is seen that only the 24-tooth sprocket in Step 3 can be bored to fit the  $1\frac{5}{16}$ -inch diameter main shaft. In Table 9 a  $\frac{5}{8}$ -pitch chain at a small sprocket speed of 1000 rpm is rated at 15.5 hp for a 24-tooth sprocket.

*Step 5. Selection of Large Sprocket:* Since the driver is to operate at 1000 rpm and the driven at a minimum of 378 rpm, the speed ratio  $1000/378 = 2.646$ . Therefore the large sprocket should have  $24 \times 2.646 = 63.5$  (use 63) teeth.

This combination of 24 and 63 teeth will produce a main drive shaft speed of 381 rpm which is within the limitation of 378 to 382 rpm established in the original specification.

*Step 6. Computation of Chain Length:* Since the 24- and 63-tooth sprockets are to be placed on  $22\frac{1}{2}$ -inch centers, the chain length is determined from the formula:

$$L = 2C + \frac{N}{2} + \frac{n}{2} + \left(\frac{N-n}{2\pi}\right)^2 \times \frac{1}{C}$$

where  $L$  = chain length in pitches;  $C$  = shaft center distance in pitches;  $N$  = number of teeth in large sprocket; and  $n$  = number of teeth in small sprocket.

$$L = 2 \times 36 + \frac{63 + 24}{2} + \left(\frac{63 - 24}{6.28}\right)^2 \times \frac{1}{36} = 116.57 \text{ pitches}$$

*Step 7. Correction of Center Distance:* Since the chain is to couple at a whole number of pitches, 116 pitches will be used and the center distance recomputed based on this figure using the formula on page 2457 where  $c$  is the center distance in inches and  $P$  is the pitch.

$$c = \frac{P}{8}(2L - N - n + \sqrt{(2L - N - n)^2 - 0.810(N - n)^2})$$

$$c = \frac{5}{64}(2 \times 116 - 63 - 24 + \sqrt{(2 \times 116 - 63 - 24)^2 - 0.810(63 - 24)^2})$$

$$c = \frac{5}{64}(145 + 140.69) = 22.32 \text{ inches, say } 22\frac{3}{8} \text{ inches}$$

## STANDARDS FOR ELECTRIC MOTORS

**Classes of NEMA Standards.**—National Electrical Manufacturers Association Standards, available from the Association at 2101 L Street, NW, Washington, DC 20037, are of two classes: 1) *NEMA Standard*, which relates to a product commercially standardized and subject to repetitive manufacture, which standard has been approved by at least 90 per cent of the members of the Subdivision eligible to vote thereon; and 2) *Suggested Standard for Future Design*, which may not have been regularly applied to a commercial product, but which suggests a sound engineering approach to future development and has been approved by at least two-thirds of the members of the Subdivision eligible to vote thereon.

*Authorized Engineering Information* consists of explanatory data and other engineering information of an informative character not falling within the classification of NEMA Standard or Suggested Standard for Future Design.

**Mounting Dimensions and Frame Sizes for Electric Motors.**—Dimensions for foot-mounted electric motors as standardized in the United States by the National Electrical Manufacturers Association (NEMA) include the spacing of bolt holes in the feet of the motor, the distance from the bottom of the feet to the center-line of the motor shaft, the size of the conduit, the length and diameter of shaft, and other dimensions likely to be required by designers or manufacturers of motor-driven equipment. The Standard provides dimensions for face-mounted and flange-mounted motors by means of standard motor frame numbers.

Standard dimensions also are given where the motor is to be mounted upon a belt-tightening base or upon rails.

The NEMA standards also prescribe lettering for dimension drawings, mounting and terminal housing locations and dimensions, symbols and terminal connections, and provision for grounding of field wiring. In addition, the standards give recommended knock-out and clearance hole dimensions; tolerances on shaft extension diameters and keyseats; methods of measuring shaft run-out and eccentricity, also face runout of mounting surfaces; and tolerances of face-mounted and flanged-mounted motors.

**Design Letters of Polyphase Integral-horsepower Motors.**—Designs A, B, C, and D motors are squirrel-cage motors designed to withstand full voltage starting and developing locked-rotor torque and breakdown torque, drawing locked-rotor current, and having a slip as specified below:

*Design A:* Locked-rotor torque as shown in [Table 2](#), breakdown torque as shown in [Table 3](#), locked-rotor current higher than the values shown in [Table 1](#), and a slip at rated load of less than 5 per cent. Motors with 10 or more poles may have a slightly greater slip.

**Table 1. NEMA Standard Locked-rotor Current of 3-phase 60-hertz Integral-horsepower Squirrel-cage Induction Motors Rated at 230 Volts**

| Horse-power | Locked-rotor Current, Amps. | Design Letters | Horse-power | Locked-rotor Current, Amps. | Design Letters | Horse-power | Locked-rotor Current, Amps. | Design Letters |
|-------------|-----------------------------|----------------|-------------|-----------------------------|----------------|-------------|-----------------------------|----------------|
| ½           | 20                          | B, D           | 7½          | 127                         | B, C, D        | 50          | 725                         | B, C, D        |
| ¾           | 25                          | B, D           | 10          | 162                         | B, C, D        | 60          | 870                         | B, C, D        |
| 1           | 30                          | B, D           | 15          | 232                         | B, C, D        | 75          | 1085                        | B, C, D        |

| 2           | 50                          | B, D           | 25          | 365                         | B, C, D        | 125         | 1815                        | B, C, D        |
| 3           | 64                          | B, C, D        | 30          | 435                         | B, C, D        | 150         | 2170                        | B, C, D        |
| 5           | 92                          | B, C, D        | 40          | 580                         | B, C, D        | 200         | 2900                        | B, C           |

*Note:* The locked-rotor current of a motor is the steady-state current taken from the line with the rotor locked and with rated voltage and frequency applied to the motor.

For motors designed for voltages other than 230 volts, the locked-rotor current is inversely proportional to the voltages. For motors larger than 200 hp, see NEMA Standard MG 1-12.34.

**Table 2. NEMA Standard Locked-rotor Torque of Single-speed Polyphase 60- and 50-hertz Squirrel-cage Integral-horsepower Motors with Continuous Ratings**

| 75                                       | 105                    | 140  | 135  | 125  | 120 | 115 | 110 |                                    |          |      |     |
| 100                                      | 105                    | 125  | 125  | 125  | 120 | 115 | 110 |                                    |          |      |     |
| 125                                      | 100                    | 110  | 125  | 120  | 115 | 115 | 110 |                                    |          |      |     |
| 150                                      | 100                    | 110  | 120  | 120  | 115 | 115 | ... |                                    |          |      |     |
| 200                                      | 100                    | 100  | 120  | 120  | 115 | ... | ... |                                    |          |      |     |
|  |                        |      |      |      |     |     |     | For Design D motors, see footnote. |          |      |     |

<sup>a</sup> These values represent the upper limit of application for these motors.

*Note:* The locked-rotor torque of a motor is the minimum torque which it will develop at rest for all angular positions of the rotor, with rated voltage applied at rated frequency.

The locked-rotor torque of Design D, 60- and 50-hertz 4-, 6-, and 8-pole single-speed, polyphase squirrel-cage motors rated 150 hp and smaller, with rated voltage and frequency applied is 275 per cent of full-load torque, which represents the upper limit of application for these motors.

For motors larger than 200 hp, see NEMA Standard MG 1-12.37.

<sup>a</sup> Design A values are in excess of those shown.

These values represent the upper limit of the range of application for these motors. For above 200 hp, see NEMA Standard MG1-12.38.

*Design B:* Locked-rotor torque as shown in Table 2, breakdown torque as shown in Table 3, locked-rotor current not exceeding that in Table 1, and a slip at rated load of less than 5 per cent. Motors with 10 or more poles may have a slightly greater slip.

*Design C:* Locked-rotor torque for special high-torque applications up to values shown in Table 2, breakdown torque up to values shown in Table 3, locked-rotor current not exceeding values shown in Table 1 and a slip at rated load of less than 5 per cent.

*Design D:* Locked-rotor torque as indicated in Table 2, locked-rotor current not greater than that shown in Table 1 and a slip at rated load of 5 per cent or more.

**Torque and Current Definitions.**—The definitions which follow have been adopted as standard by the National Electrical Manufacturers Association.

*Locked-Rotor or Static Torque:* The locked-rotor torque of a motor is the minimum torque which it will develop at rest for all angular positions of the rotor, with rated voltage applied at rated frequency.

*Breakdown Torque:* The breakdown torque of a motor is the maximum torque which the motor will develop, with rated voltage applied at rated frequency, without an abrupt drop in speed (see Table 4).

*Full-Load Torque:* The full-load torque of a motor is the torque necessary to produce its rated horsepower at full load speed. In pounds at 1-foot radius, it is equal to the horsepower times 5252 divided by the full-load speed.

*Pull-Out Torque:* The pull-out torque of a synchronous motor is the maximum sustained torque which the motor will develop at synchronous speed with rated voltage applied at rated frequency and with normal excitation.

*Pull-In Torque:* The pull-in torque of a synchronous motor is the maximum constant torque under which the motor will pull its connected inertia load into synchronism at rated voltage and frequency, when its field excitation is applied.

*Pull-Up Torque:* The pull-up torque of an alternating current motor is the minimum torque developed by the motor during the period of acceleration from rest to the speed at which breakdown torque occurs. For motors which do not have a definite breakdown torque, the pull-up torque is the minimum torque developed up to rated speed.

*Locked Rotor Current:* The locked rotor current of a motor is the steady-state current taken from the line with the rotor locked and with rated voltage (and rated frequency in the case of alternating-current motors) applied to the motor.

**Table 4. NEMA Standard Breakdown Torque of Polyphase Wound-rotor Motors with Continuous Ratings — 60- and 50-hertz**

| Horsepower | Speed, rpm                   |      |     | Horsepower    | Speed, rpm                   |      |     |
|------------|------------------------------|------|-----|---------------|------------------------------|------|-----|
|            | 1800                         | 1200 | 900 |               | 1800                         | 1200 | 900 |
|            | Per cent of Full-load Torque |      |     |               | Per cent of Full-load Torque |      |     |
| 1          | ...                          | ...  | 250 | 7½            | 275                          | 250  | 225 |
| 1½         | ...                          | ...  | 250 | 10            | 275                          | 250  | 225 |
| 2          | 275                          | 275  | 250 | 15            | 250                          | 225  | 225 |
| 3          | 275                          | 275  | 250 | 20–200, incl. | 225                          | 225  | 225 |
| 5          | 275                          | 275  | 250 | ...           | ...                          | ...  | ... |

These values represent the upper limit of the range of application for these motors.

**Standard Direction of Motor Rotation.**—The standard direction of rotation for all non-reversing direct-current motors, all alternating-current single-phase motors, all synchronous motors, and all universal motors, is *counterclockwise* when facing that end of the motor opposite the drive.

This rule does not apply to two- and three-phase induction motors, as in most applications the phase sequence of the power lines is rarely known.

**Motor Types According to Variability of Speed.**—Five types of motors classified according to variability of speed are:

*Constant-speed Motors:* In this type of motor the normal operating speed is constant or practically constant; for example, a synchronous motor, an induction motor with small slip, or a direct-current shunt-wound motor.

*Varying-speed Motor:* In this type of motor, the speed varies with the load, ordinarily decreasing when the load increases; such as a series-wound or repulsion motor.

*Adjustable-speed Motor:* In this type of motor, the speed can be varied gradually over a considerable range, but when once adjusted remains practically unaffected by the load; such as a direct-current shunt-wound motor with field resistance control designed for a considerable range of speed adjustment.

The base speed of an adjustable-speed motor is the lowest rated speed obtained at rated load and rated voltage at the temperature rise specified in the rating.

*Adjustable Varying-speed Motor:* This type of motor is one in which the speed can be adjusted gradually, but when once adjusted for a given load will vary in considerable degree with the change in load; such as a direct-current compound-wound motor adjusted by field control or a wound-rotor induction motor with rheostatic speed control.

*Multispeed Motor:* This type of motor is one which can be operated at any one of two or more definite speeds, each being practically independent of the load; such as a direct-current motor with two armature windings or an induction motor with windings capable of various pole groupings. In the case of multispeed permanent-split capacitor and shaded pole motors, the speeds are dependent upon the load.

**Pull-up Torque.**—NEMA Standard pull up torques for single-speed, polyphase, squirrel-cage integral-horsepower motors, Designs A and B, with continuous ratings and with rated voltage and frequency applied are as follows: When the locked-rotor torque given in Table 2 is 110 per cent or less, the pull-up torque is 90 per cent of the locked-rotor torque; when the locked-rotor torque is greater than 110 per cent but less than 145 per cent, the pull-up torque is 100 per cent of full-load torque; and when the locked-rotor torque is 145 per cent or more, the pull-up torque is 70 per cent of the locked-rotor torque.

For Design C motors, with rated voltage and frequency applied, the pull-up torque is not less than 70 per cent of the locked-rotor torque as given in Table 2.

### Types and Characteristics of Electric Motors

**Types of Direct-Current Motors.**—Direct-current motors may be grouped into three general classes: series-wound; shunt-wound; and compound-wound.

In the *series-wound motor* the field windings, which are fixed in the stator frame, and the armature windings, which are placed around the rotor, are connected in series so that all current passing through the armature also passes through the field. In the *shunt-wound motor*, both armature and field are connected across the main power supply so that the armature and field currents are separate. In the *compound-wound motor*, both series and shunt field windings are provided and these may be connected so that the currents in both are flowing in the same direction, called *cumulative compounding*, or so that the currents in each are flowing in opposite directions, called *differential compounding*.

**Characteristics of Series-wound Direct-Current Motors.**—In the series-wound motor, any increase in load results in more current passing through the armature and the field windings. As the field is strengthened by this increased current, the motor speed decreases. Conversely, as the load is decreased the field is weakened and the speed increases and at very light loads may become excessive. For this reason, series-wound direct-current motors are usually directly connected or geared to the load to prevent “run-away.” (A series-wound motor, designated as series-shunt wound, is sometimes provided with a light shunt field winding to prevent dangerously high speeds at light loads.) The increase in armature current with increasing load produces increased torque, so that the

series-wound motor is particularly suited to heavy starting duty and where severe overloads may be expected. Its speed may be adjusted by means of a variable resistance placed in series with the motor, but due to variation with load, the speed cannot be held at any constant value. This variation of speed with load becomes greater as the speed is reduced. Series-wound motors are used where the load is practically constant and can easily be controlled by hand. They are usually limited to traction and lifting service.

**Shunt-wound Direct-Current Motors.**—In the shunt-wound motor, the strength of the field is not affected appreciably by change in the load, so that a fairly constant speed (about 10 to 12 per cent drop from no load to full load speed) is obtainable. This type of motor may be used for the operation of machines requiring an approximately constant speed and imposing low starting torque and light overload on the motor.

The shunt-wound motor becomes an adjustable-speed motor by means of field control or by armature control. If a variable resistance is placed in the field circuit, the amount of current in the field windings and hence the speed of rotation can be controlled. As the speed increases, the torque decreases proportionately, resulting in nearly constant horsepower. A speed range of 6 to 1 is possible using field control, but 4 to 1 is more common. Speed regulation is somewhat greater than in the constant-speed shunt-wound motors, ranging from about 15 to 22 per cent. If a variable resistance is placed in the armature circuit, the voltage applied to the armature can be reduced and hence the speed of rotation can be reduced over a range of about 2 to 1. With armature control, speed regulation becomes poorer as speed is decreased, and is about 100 per cent for a 2 to 1 speed range. Since the current through the field remains unchanged, the torque remains constant.

*Machine Tool Applications:* The adjustable-speed shunt-wound motors are useful on larger machines of the boring mill, lathe, and planer type and are particularly adapted to spindle drives because constant horsepower characteristics permit heavy cuts at low speed and light or finishing cuts at high speed. They have long been used for planer drives because they can provide an adjustable low speed for the cutting stroke and a high speed for the return stroke. Their application has been limited, however, to plants in which direct-current power is available.

**Adjustable-voltage Shunt-wound Motor Drive.**—More extensive use of the shunt-wound motor has been made possible by a combination drive that includes a means of converting alternating current to direct current. This conversion may be effected by a self-contained unit consisting of a separately excited direct-current generator driven by a constant speed alternating-current motor connected to the regular alternating-current line, or by an electronic rectifier with suitable controls connected to the regular alternating-current supply lines. The latter has the advantage of causing no vibration when mounted directly on the machine tool, an important factor in certain types of grinders.

In this type of adjustable-speed, shunt-wound motor drive, speed control is effected by varying the voltage applied to the armature while supplying constant voltage to the field. In addition to providing for the adjustment of the voltage supplied by the conversion unit to the armature of the shunt-wound motor, the amount of current passing through the motor field may also be controlled. In fact, a single control may be provided to vary the motor speed from minimum to base speed (speed of the motor at full load with rated voltage on armature and field) by varying the voltage applied to the armature and from base speed to maximum speed by varying the current flowing through the field. When so controlled, the motor operates at constant torque up to base speed and at constant horsepower above base speed.

*Speed Range:* Speed ranges of at least 20 to 1 below base speed and 4 or 5 to 1 above base speed (a total range of 100 to 1, or more) are obtainable as compared with about 2 to 1 below normal speed and 3 or 4 to 1 above normal speed for the conventional type of control. Speed regulation may be as great as 25 per cent at high speeds. Special electronic controls, when used with this type shunt motor drive, make possible maintenance of motor

speeds with as little variation as  $\frac{1}{2}$  to 1 per cent of full load speed from full load to no load over a line voltage variation of  $\pm 10$  per cent and over any normal variation in motor temperature and ambient temperature.

*Applications:* These direct-current, adjustable-voltage drives, as they are sometimes called, have been applied successfully to such machine tools as planers, milling machines, boring mills and lathes, as well as to other industrial machines where wide, stepless speed control, uniform speed under all operating conditions, constant torque acceleration and adaptability to automatic operation are required.

**Compound-wound Motors.**—In the compound-wound motor, the speed variation due to load changes is much less than in the series-wound motor, but greater than in the shunt-wound motor (ranging up to 25 per cent from full load to no load). It has a greater starting torque than the shunt-wound motor, is able to withstand heavier overloads, but has a narrower adjustable speed range. Standard motors of this type have a cumulative-compound winding, the differential-compound winding being limited to special applications. They are used where the starting load is very heavy or where the load changes suddenly and violently as with reciprocating pumps, printing presses and punch presses.

**Types of Polyphase Alternating-Current Motors.**—The most widely used polyphase motors are of the induction type. The “*squirrel cage*” induction motor consists of a wound stator which is connected to an external source of alternating-current power and a laminated steel core rotor with a number of heavy aluminum or copper conductors set into the core around its periphery and parallel to its axis. These conductors are connected together at each end of the rotor by a heavy ring, which provides closed paths for the currents induced in the rotor to circulate. The rotor bars form, in effect, a “squirrel cage” from which the motor takes its name.

*Wound-rotor type of Induction motor:* This type has in addition to a squirrel cage, a series of coils set into the rotor which are connected through slip-rings to external variable resistors. By varying the resistance of the wound-rotor circuits, the amount of current flowing in these circuits and hence the speed of the motor can be controlled. Since the rotor of an induction motor is not connected to the power supply, the motor is said to operate by transfer action and is analogous to a transformer with a short-circuited secondary that is free to rotate. Induction motors are built with a wide range of speed and torque characteristics which are discussed under “Operating Characteristics of Squirrel-cage Induction Motors.”

*Synchronous Motor:* The other type of polyphase alternating-current motor used industrially is the *synchronous motor*. In contrast to the induction motor, the rotor of the synchronous motor is connected to a direct-current supply which provides a field that rotates in step with the alternating-current field in the stator. After having been brought up to synchronous speed, which is governed by the frequency of the power supply and the number of poles in the rotor, the synchronous motor operates at this constant speed throughout its entire load range.

**Operating Characteristics of Squirrel-cage Induction Motors.**—In general, squirrel-cage induction motors are simple in design and construction and offer rugged service. They are essentially constant-speed motors, their speed changing very little with load and not being subject to adjustment. They are used for a wide range of industrial applications calling for integral horsepower ratings. According to the NEMA (National Electrical Manufacturers Association) Standards, there are four classes of squirrel-cage induction motors designated respectively as *A*, *B*, *C*, and *D*.

*Design A* motors are not commonly used since *Design B* has similar characteristics with the advantage of lower starting current.

*Design B:* motors may be designated as a general purpose type suitable for the majority of polyphase alternating-current applications such as blowers, compressors, drill presses, grinders, hammer mills, lathes, planers, polishers, saws, screw machines, shakers, stokers,

etc. The starting torque at 1800 R.P.M. is 250 to 275 per cent of full load torque for 3 H.P. and below; for 5 H.P. to 75 H. P. ratings the starting torque ranges from 185 to 150 per cent of full load torque. They have low starting current requirements, usually no more than 5 to 6 times full load current and can be started at full voltage. Their slip (difference between synchronous speed and actual speed at rated load) is relatively low.

*Design C:* motors have high starting torque (up to 250 per cent of full load torque) but low starting current. They can be started at full voltage. Slip at rated load is relatively low. They are used for compressors requiring a loaded start, heavy conveyors, reciprocating pumps and other applications requiring high starting torque.

*Design D:* motors have high slip at rated load, that is, the motor speed drops off appreciably as the load increases, permitting use of the stored energy of a flywheel. They provide heavy starting torque, up to 275 per cent of full load torque, are quiet in operation and have relatively low starting current. Applications are for impact, shock and other high peak loads or flywheel drives such as trains, elevators, hoists, punch and drawing presses, shears, etc.

*Design F:* motors are no longer standard. They had low starting torque, about 125 per cent of full-load torque, and low starting current. They were used to drive machines which required infrequent starting at no load or at very light load.

**Multiple-Speed Induction Motors.**—This type has a number of windings in the stator so arranged and connected that the number of effective poles and hence the speed can be changed. These motors are for the same types of starting conditions as the conventional squirrel-cage induction motors and are available in designs that provide constant horsepower at all rated speeds and in designs that provide constant torque at all rated speeds.

Typical speed combinations obtainable in these motors are 600, 900, 1200 and 1800 R.P.M.; 450, 600, 900 and 1200 R.P.M.; and 600, 720, 900 and 1200 R.P.M.

Where a gradual change in speed is called for, a wound rotor may be provided in addition to the multiple stator windings.

**Wound-Rotor Induction Motors.**—These motors are designed for applications where extremely low starting current with high starting torque are called for, such as in blowers, conveyors, compressors, fans and pumps. They may be employed for adjustable-varying speed service where the speed range does not extend below 50 per cent of synchronous speed, as for steel plate-forming rolls, printing presses, cranes, blowers, stokers, lathes and milling machines of certain types. The speed regulation of a wound rotor induction motor ranges from 5 to 10 per cent at maximum speed and from 18 to 30 per cent at low speed. They are also employed for reversing service as in cranes, gates, hoists and elevators.

**High-Frequency Induction Motors.**—This type is used in conjunction with frequency changers when very high speeds are desired, as on grinders, drills, routers, portable tools or woodworking machinery. These motors have an advantage over the series-wound or universal type of high speed motor in that they operate at a relatively constant speed over the entire load range. A motor-generator set, a two-unit frequency converter or a single unit inductor frequency converter may be used to supply three-phase power at the frequency required. The single unit frequency converter may be obtained for delivering any one of a number of frequencies ranging from 360 to 2160 cycles and it is self-driven and self-excited from the general polyphase power supply.

**Synchronous Motors.**—These are widely used in electric timing devices; to drive machines that must operate in synchronism; and also to operate compressors, rolling mills, crushers which are started without load, paper mill screens, shredders, vacuum pumps and motor-generator sets. Synchronous motors have an inherently high power factor and are often employed to make corrections for the low power factor of other types of motors on the same system.

**Types of Single-Phase Alternating-Current Motors.**—Most of the single-phase alternating-current motors are basically induction motors distinguished by different arrangements for starting. (A single-phase induction motor with only a squirrel-cage rotor has no starting torque.) In the *capacitor-start* single-phase motor, an auxiliary winding in the stator is connected in series with a capacitor and a centrifugal switch. During the starting and accelerating period the motor operates as a two-phase induction motor. At about two-thirds full-load speed, the auxiliary circuit is disconnected by the switch and the motor then runs as a single-phase induction motor. In the *capacitor-start, capacitor-run* motor, the auxiliary circuit is arranged to provide high effective capacity for high starting torque and to remain connected to the line but with reduced capacity during the running period. In the *single-value capacitor* or *capacitor split-phase* motor, a relatively small continuously-rated capacitor is permanently connected in one of the two stator windings and the motor both starts and runs like a two-phase motor.

In the *repulsion-start* single-phase motor, a drum-wound rotor circuit is connected to a commutator with a pair of short-circuited brushes set so that the magnetic axis of the rotor winding is inclined to the magnetic axis of the stator winding. The current flowing in this rotor circuit reacts with the field to produce starting and accelerating torques. At about two-thirds full load speed the brushes are lifted, the commutator is short circuited and the motor runs as a single-phase squirrel-cage motor. The *repulsion* motor employs a repulsion winding on the rotor for both starting and running. The *repulsion-induction* motor has an outer winding on the rotor acting as a repulsion winding and an inner squirrel-cage winding. As the motor comes up to speed, the induced rotor current partially shifts from the repulsion winding to the squirrel-cage winding and the motor runs partly as an induction motor.

In the *split-phase* motor, an auxiliary winding in the stator is used for starting with either a resistance connected in series with the auxiliary winding (*resistance-start*) or a reactor in series with the main winding (*reactor-start*).

The *series-wound* single-phase motor has a rotor winding in series with the stator winding as in the series-wound direct-current motor. Since this motor may also be operated on direct current, it is called a *universal* motor.

**Characteristics of Single-Phase Alternating-Current Motors.**—Single-phase motors are used in sizes up to about  $7\frac{1}{2}$  horsepower for heavy starting duty chiefly in home and commercial appliances for which polyphase power is not available. The *capacitor-start* motor is available in normal starting torque designs for such applications as centrifugal pumps, fans, and blowers and in high-starting torque designs for reciprocating compressors, pumps, loaded conveyors, or belts. The *capacitor-start, capacitor-run* motor is exceptionally quiet in operation when loaded to at least 50 per cent of capacity. It is available in low-torque designs for fans and centrifugal pumps and in high-torque designs for applications similar to those of the capacitor-start motor.

The *capacitor split-phase* motor requires the least maintenance of all single-phase motors, but has very low starting torque. Its high maximum torque makes it potentially useful in floor sanders or in grinders where momentary overloads due to excessive cutting pressure are experienced. It is also used for slow-speed direct connected fans.

The *repulsion-start, induction-run* motor has higher starting torque than the capacitor motors, although for the same current, the capacitor motors have equivalent pull-up and maximum torque. Electrical and mechanical noise and the extra maintenance sometimes required are disadvantages. These motors are used for compressors, conveyors and stokers starting under full load. The *repulsion-induction* motor has relatively high starting torque and low starting current. It also has a smooth speed-torque curve with no break and a greater ability to withstand long accelerating periods than capacitor type motors. It is particularly suitable for severe starting and accelerating duty and for high inertia loads such as laundry extractors. Brush noise is, however, continuous.

The *repulsion* motor has no limiting synchronous speed and the speed changes with the load. At certain loads, slight changes in load cause wide changes in speed. A brush shifting arrangement may be provided to adjust the speed which may have a range of 4 to 1 if full rated constant torque is applied but a decreasing range as the torque falls below this value. This type of motor may be reversed by shifting the brushes beyond the neutral point. These motors are suitable for machines requiring constant-torque and adjustable speed.

The *split-phase* and *universal* motors are limited to about  $\frac{1}{2}$  H.P. ratings and are used chiefly for small appliance and office machine applications.

**Motors with Built-in Speed Reducers.**—Electric motors having built-in speed-changing units are compact and the design of these motorized speed reducers tends to improve the appearance of the machines which they drive. There are several types of these speed reducers; they may be classified according to whether they are equipped with worm gearing, a regular gear train with parallel shafts, or planetary gearing.

The claims made for the worm gearing type of reduction unit are that the drive is quiet in operation and well adapted for use where the slow-speed shaft must be at right angles to the motor shaft and where a high speed ratio is essential.

For very low speeds, the double reduction worm gearing units are suitable. In these units two sets of worm gearing form the gear train, and both the slow-speed shaft and the armature shaft are parallel. The intermediate worm gear shaft can be built to extend from the housing, if required, so as to make two countershaft speeds available on the same unit.

In the parallel-shaft type of speed reducer, the slow-speed shaft is parallel with the armature shaft. The slow-speed shaft is rotated by a pinion on the armature shaft, this pinion meshing with a larger gear on the slow-speed shaft.

Geared motors having built-in speed-changing units are available with constant-mesh change gears for varying the speed ratio.

Planetary gearing permits a large speed reduction with few parts; hence, it is well adapted for geared-head motor units where economy and compactness are essential. The slow-speed shaft is in line with the armature shaft.

### Factors Governing Motor Selection

**Speed, Horsepower, Torque and Inertia Requirements.**—Where more than one speed or a range of speeds are called for, one of the following types of motors may be selected, depending upon other requirements: For direct-current, the standard shunt-wound motor with field control has a 2 to 1 range in some designs; the adjustable speed motor may have a range of from 3 to 1 up to 6 to 1; the shunt motor with adjustable voltage supply has a range up to 20 to 1 or more below base speed and 4 or 5 to 1 above base speed, making a total range of up to 100 to 1 or more. For polyphase alternating current, multi-speed squirrel-cage induction motors have 2, 3 or 4 fixed speeds; the wound-rotor motor has a 2 to 1 range. The two-speed wound-rotor motor has a 4 to 1 range. The brush-shifting shunt motor has a 4 to 1 range. The brush-shifting series motor has a 3 to 1 range; and the squirrel-cage motor with a variable-frequency supply has a very wide range. For single-phase alternating current, the brush-shifting repulsion motor has a  $2\frac{1}{2}$  to 1 range; the capacitor motor with tapped winding has a 2 to 1 range and the multi-speed capacitor motor has 2 or 3 fixed speeds. Speed regulation (variation in speed from no load to full load) is greatest with motors having series field windings and entirely absent with synchronous motors.

**Horsepower:** Where the load to be carried by the motor is not constant but follows a definite cycle, a horsepower-time curve enables the peak horsepower to be determined as well as the root-mean-square-average horsepower, which indicates the proper motor rating from a heating standpoint. Where the load is maintained at a constant value for a period of from 15 minutes to 2 hours depending on the size, the horsepower rating required will usually not be less than this constant value. When selecting the size of an induction motor, it should be kept in mind that this type of motor operates at maximum efficiency when it is

loaded to full capacity. Where operation is to be at several speeds, the horsepower requirement for each speed should be considered.

*Torque:* Starting torque requirements may vary from 10 per cent of full load to 250 per cent of full load torque depending upon the type of machine being driven. Starting torque may vary for a given machine because of frequency of start, temperature, type and amount of lubricant, etc., and such variables should be taken into account. The motor torque supplied to the machine must be well above that required by the driven machine at all points up to full speed. The greater the excess torque, the more rapid the acceleration. The approximate time required for acceleration from rest to full speed is given by the formula:

$$\text{Time} = \frac{N \times WR^2}{T_a \times 308} \text{ seconds}$$

where  $N$  = Full load speed in R.P.M.

$T_a$  = Torque = average foot-pounds available for acceleration.

$WR^2$  = Inertia of rotating part in pounds feet squared ( $W$  = weight and  $R$  = radius of gyration of rotating part).

308 = Combined constant converting minutes into seconds, weight into mass and radius into circumference.

If the time required for acceleration is greater than 20 seconds, special motors or starters may be required to avoid overheating.

The running torque  $T_r$  is found by the formula:

$$T_r = \frac{5250 \times \text{HP}}{N} \text{ foot pounds}$$

where  $H.P.$  = Horsepower being supplied to the driven machine

$N$  = Running speed in R.P.M.

5250 = Combined constant converting horsepower to foot-pounds per minute and work per revolution into torque.

The peak horsepower determines the maximum torque required by the driven machine and the motor must have a maximum running torque in excess of this value.

*Inertia:* The inertia or flywheel effect of the rotating parts of a driven machine will, if large, appreciably affect the accelerating time and, hence, the amount of heating in the motor. If synchronous motors are used, the inertia ( $WR^2$ ) of both the motor rotor and the rotating parts of the machine must be known since the pull-in torque (torque required to bring the driven machine up to synchronous speed) varies approximately as the square root of the total inertia of motor and load.

**Space Limitations in Motor Selection.**—If the motor is to become an integral part of the machine which it drives and space is at a premium, a partial motor may be called for. A complete motor is one made up of a stator, a rotor, a shaft, and two end shields with bearings. A *partial motor* is without one or more of these elements. One common type is furnished without drive-end end shield and bearing and is directly connected to the end or side of the machine which it drives, such as the headstock of a lathe. A so-called *shaftless type of motor* is supplied without shaft, end shields or bearings and is intended for built-in application in such units as multiple drilling machines, precision grinders, deep well pumps, compressors and hoists where the rotor is actually made a part of the driven machine. Where a partial motor is used, however, proper ventilation, mounting, alignment and bearings must be arranged for by the designer of the machine to which it is applied.

Sometimes it is possible to use a motor having a smaller frame size and wound with Class B insulation, permitting it to be subjected to a higher temperature rise than the larger-frame Class A insulated motor having the same horsepower rating.

**Temperatures.**—The applicability of a given motor is limited not only by its load starting and carrying ability, but also by the temperature which it reaches under load. Motors are given temperature ratings which are based upon the type of insulation (Class A or Class B are the most common) used in their construction and their type of frame (open, semien-closed, or enclosed).

*Insulating Materials:* Class A materials are: cotton, silk, paper, and similar organic materials when either impregnated or immersed in a liquid dielectric; molded and laminated materials with cellulose filler, phenolic resins, and other resins of similar properties; films and sheets of cellulose acetate and other cellulose derivatives of similar properties; and varnishes (enamel) as applied to conductors.

Class B insulating materials are: materials or combinations of materials such as mica, glass fiber, asbestos, etc., with suitable bonding substances. Other materials shown capable of operation at Class B temperatures may be included.

*Ambient Temperature and Allowable Temperature Rise:* Normal ambient temperature is taken to be 40°C (104°F). For open general-purpose motors with Class A insulation, the normal temperature rise on which the performance guarantees are based is 40°C (104°F).

Motors with Class A insulation having protected, semiprotected, drip-proof, or splash-proof, or drip-proof protected enclosures have a 50°C (122°F) rise rating.

Motors with Class A insulation and having totally enclosed, fan-cooled, explosion-proof, waterproof, dust-tight, submersible, or dust-explosion-proof enclosures have a 55°C (131°F) rise rating.

Motors with Class B insulation are permissible for total temperatures up to 110 degrees C (230°F) for open motors and 115°C (239°F) for enclosed motors.

**Motors Exposed to Injurious Conditions.**—Where motors are to be used in locations imposing unusual operating conditions, the manufacturer should be consulted, especially where any of the following conditions apply: exposure to chemical fumes; operation in damp places; operation at speeds in excess of specified overspeed; exposure to combustible or explosive dust; exposure to gritty or conducting dust; exposure to lint; exposure to steam; operation in poorly ventilated rooms; operation in pits, or where entirely enclosed in boxes; exposure to inflammable or explosive gases; exposure to temperatures below 10°C (50°F); exposure to oil vapor; exposure to salt air; exposure to abnormal shock or vibration from external sources; where the departure from rated voltage is excessive; and or where the alternating-current supply voltage is unbalanced.

Improved insulating materials and processes and greater mechanical protection against falling materials and liquids make it possible to use general-purpose motors in many locations where special-purpose motors were previously considered necessary. *Splash-proof motors* having well-protected ventilated openings and specially treated windings are used where they are to be subjected to falling and splashing water or are to be washed down as with a hose. Where climatic conditions are not severe, this type of motor is also successfully used in unprotected outdoor installations.

If the surrounding atmosphere carries abnormal quantities of metallic, abrasive, or non-explosive dust or acid or alkali fumes, a *totally enclosed fan-cooled motor* may be called for. In this type, the motor proper is completely enclosed but air is blown through an outer shell that completely or partially surrounds the inner case. If the dust in the atmosphere tends to pack or solidify and close the air passages of open splash-proof or totally enclosed fan-cooled motors, *totally enclosed (nonventilated) motors* are used. This type, which is limited to low horsepower ratings, is also used for outdoor service in mild or severe climates.

**Table 1. Characteristics and Applications of D.C. Motors, 1–300 hp**

| Type                                    | Starting Duty   | Maximum Momentary Running Torque    | Speed Regulation   | Speed Control <sup>a</sup>   | Applications  |
|---|---|-------------------------------------|--|--|---|
| Shunt-wound, constant-speed             | Medium starting torque. Varies with voltage supplied to armature, and is limited by starting resistor to 125 to 200% full-load torque | 125 to 200%. Limited by commutation | 8 to 12%   | Basic speed to 200% basic speed by field control                         | Drives where starting requirements are not severe. Use constant-speed or adjustable-speed, depending on speed required. Centrifugal pumps, fans, blowers, conveyors, elevators, wood- and metalworking machines |
| Shunt-wound, adjustable speed           |   |                                     | 10 to 20%, increases with weak fields                              | Basic speed to 60% basic speed (lower for some ratings) by field control |   |
| Shunt-wound, adjustable voltage control |   |                                     | Up to 25%. Less than 5% obtainable with special rotating regulator | Basic speed to 2% basic speed and basic speed to 200% basic speed        | Drives where wide, stepless speed control, uniform speed, constant-torque acceleration and adaptability to automatic operation are required. Planers, milling machines, boring machines, lathes, etc.           |
| Compound wound, constant-speed          | Heavy starting torque, Limited by starting resistor to 130 to 260% of full-load torque  | 130 to 260%. Limited by commutation | Standard compounding 25%. Depends on amount of series winding      | Basic speed to 125% basic speed by field control                         | Drives requiring high starting torque and fairly constant speed. Pulsating loads. Shears, bending rolls, pumps, conveyors, crushers, etc.   |
| Series-wound, varying-speed             | Very heavy starting torque. Limited to 300 to 350% full-load torque   | 300 to 350%. Limited by commutation | Very high. Infinite no-load speed                                  | From zero to maximum speed, depending on control and load                | Drives where very high starting torque is required and speed can be regulated. Cranes, hoists, gates, bridges, car dumpers, etc.  |

<sup>a</sup>Minimum speed below basic speed by armature control limited by heating.

**Table 2. Characteristics and Applications of Polyphase AC Motors**

| Polyphase Type  | Ratings hp              | Speed Regulation  | Speed Control   | Starting Torque  | Breakdown Torque   | Applications   |
|---|-------------------------|---|---|--|--|--|
| General-purpose squirrel cage, normal stg current, normal stg torque. Design B      | 0.5 to 200              | Less than 5%  | None, except multi-speed types, designed for two to four fixed speeds                         | 100 to 250% of full-load   | 200 to 300% of full-load   | Constant-speed service where starting torque is not excessive. Fans, blowers, rotary compressors, centrifugal pumps, woodworking machines, machine tools, line shafts  |
| Full-voltage starting, high stg torque, normal stg current, squirrel-cage, Design C | 3 to 150                | Less than 5%  | None except multi-speed types, designed for two to four fixed speeds                          | 200 to 250% of full-load   | 190 to 225% of full-load   | Constant-speed service where fairly high starting torque is required at infrequent intervals with starting current of about 500% full-load. Reciprocating pumps and compressors, conveyors, crushers, pulverizers, agitators, etc. |
| Full-voltage starting, high stg-torque, high-slip squirrel cage, Design D           | 0.5 to 150              | Drops about 7 to 12% from no load to full load                                  | None, except multi-speed types, designed for two to four fixed speeds                         | 275% of full-load depending on speed and rotor resistance                                | 275% of full-load<br>Will usually not stall until loaded to its maximum torque, which occurs at standstill | Constant-speed service and high-starting torque if starting not too frequent, and for taking high-peak loads with or without flywheels. Punch presses, die stamping, shears, bulldozers, bailers, hoists, cranes, elevators, etc.  |
| Wound-rotor, external-resistance starting   | 0.5 to several thousand | With rotor rings short-circuited drops about 3% for large to 5% for small sizes | Speed can be reduced to 50% of normal by rotor resistance. Speed varies inversely as the load | Up to 300% depending on external resistance in rotor circuit and how distributed         | 200% when rotor slip rings are short circuited   | Where high-starting torque with low-starting current or where limited speed control is required. Fans, centrifugal and plunger pumps, compressors, conveyors, hoists, cranes, ball mills, gate hoists, etc.                        |
| Synchronous   | 25 to several thousand  | Constant  | None, except special motors designed for two fixed speeds                                     | 40% for slow speed to 160% for medium speed 80% p-f designs. Special high-torque designs | Pull-out torque of unity-p-f motors 170%; 80%-p-f motors 225%. Special designs up to 300%                  | For constant-speed service, direct connection to slow-speed machines and where power-factor correction is required.  |

In addition to these special-purpose motors, there are two types of *explosion-proof motors* designed for hazardous locations. One type is for operation in hazardous dust locations (Class II, Group *G* of the National Electrical Code) and the other is for atmospheres containing explosive vapors and fumes classified as Class I, Group *D* (gasoline, naphtha, alcohols, acetone, lacquer-solvent vapors, natural gas).

### Electric Motor Maintenance

**Electric Motor Inspection Schedule.**—Frequency and thoroughness of inspection depend upon such factors as 1) importance of the motor in the production scheme; 2) percentage of days the motor operates; 3) nature of service; and 4) winding conditions.

The following schedules, recommended by the General Electric Company, and covering both AC and DC motors are based on average conditions in so far as duty and dirt are concerned.

**Weekly Inspection.**—1) *Surroundings.* Check to see if the windings are exposed to any dripping water, acid or alcoholic fumes; also, check for any unusual amount of dust, chips, or lint on or about the motor. See if any boards, covers, canvas, etc., have been misplaced that might interfere with the motor ventilation or jam moving parts.

2) *Lubrication of sleeve-bearing motors.* In sleeve-bearing motors check oil level, if a gage is used, and fill to the specified line. If the journal diameter is less than 2 inches, the motor should be stopped before checking the oil level. For special lubricating systems, such as wool-packed, forced lubrication, flood and disk lubrication, follow instruction book. Oil should be added to bearing housing only when motor is at rest. A check should be made to see if oil is creeping along the shaft toward windings where it may harm the insulation.

3) *Mechanical condition.* Note any unusual noise that may be caused by metal-to-metal contact or any odor as from scorching insulation varnish.

4) *Ball or roller bearings.* Feel ball- or roller-bearing housings for evidence of vibration, and listen for any unusual noise. Inspect for creepage of grease on inside of motor.

5) *Commutators and brushes.* Check brushes and commutator for sparking. If the motor is on cyclic duty it should be observed through several cycles. Note color and surface condition of the commutator. A stable copper oxide-carbon film (as distinguished from a pure copper surface) on the commutator is an essential requirement for good commutation. Such a film may vary in color all the way from copper to straw, chocolate to black. It should be clean and smooth and have a high polish. All brushes should be checked for wear and pigtail connections for looseness. The commutator surface may be cleaned by using a piece of dry canvas or other hard, nonlinting material that is wound around and securely fastened to a wooden stick, and held against the rotating commutator.

6) *Rotors and armatures.* The air gap on sleeve-bearing motors should be checked, especially if they have been recently overhauled. After installing new bearings, make sure that the average reading is within 10 per cent, provided reading should be less than 0.020 inch. Check air passages through punchings and make sure they are free of foreign matter.

7) *Windings.* If necessary clean windings by suction or mild blowing. After making sure that the motor is dead, wipe off windings with dry cloth, note evidence of moisture, and see if any water has accumulated in the bottom of frame. Check if any oil or grease has worked its way up to the rotor or armature windings. Clean with carbon tetrachloride in a well-ventilated room.

8) *General.* This is a good time to check the belt, gears, flexible couplings, chain, and sprockets for excessive wear or improper location. The motor starting should be checked to make sure that it comes up to proper speed each time power is applied.

**Monthly or Bimonthly Inspection.**—1) *Windings.* Check shunt, series, and commutating field windings for tightness. Try to move field spools on the poles, as drying out may have caused some play. If this condition exists, a service shop should be consulted. Check motor cable connections for tightness.

2) *Brushes.* Check brushes in holders for fit and free play. Check the brush-spring pressure. Tighten brush studs in holders to take up slack from drying out of washers, making sure that studs are not displaced, particularly on DC motors. Replace brushes that are worn down almost to the brush rivet, examine brush faces for chipped toes or heels, and for heat cracks. Damaged brushes should be replaced immediately.

3) *Commutators.* Examine commutator surface for high bars and high mica, or evidence of scratches or roughness. See that the risers are clean and have not been damaged.

4) *Ball or roller bearings.* On hard-driven, 24-hour service ball- or roller-bearing motors, purge out old grease through drain hole and apply new grease. Check to make sure grease or oil is not leaking out of the bearing housing. If any leakage is present, correct the condition before continuing to operate.

5) *Sleeve bearings.* Check sleeve bearings for wear, including end-play bearing surfaces. Clean out oil wells if there is evidence of dirt or sludge. Flush with lighter oil before refilling.

6) *Enclosed gears.* For motors with enclosed gears, open drain plug and check oil flow for presence of metal scale, sand, or water. If condition of oil is bad, drain, flush, and refill as directed. Rock rotor to see if slack or backlash is increasing.

7) *Loads.* Check loads for changed conditions, bad adjustment, poor handling, or control.

8) *Couplings and other drive details.* Note if belt-tightening adjustment is all used up. Shorten belt if this condition exists. See if belt runs steadily and close to inside (motor edge) of pulley. Chain should be checked for evidence of wear and stretch. Clean inside of chain housing. Check chain-lubricating system. Note inclination of slanting base to make sure it does not cause oil rings to rub on housing.

**Annual or Biannual Inspection.**—1) *Windings.* Check insulation resistance by using either a megohmmeter or a voltmeter having a resistance of about 100 ohms per volt. Check insulation surfaces for dry cracks and other evidence of need for coatings of insulating material. Clean surfaces and ventilating passages thoroughly if inspection shows accumulation of dust. Check for mold or water standing in frame to determine if windings need to be dried out, varnished, and baked.

2) *Air gap and bearings.* Check air gap to make sure that average reading is within 10 per cent, provided reading should be less than 0.020 inch. All bearings, ball, roller, and sleeve should be thoroughly checked and defective ones replaced. Waste-packed and wick-oiled bearings should have waste or wicks renewed, if they have become glazed or filled with metal or dirt, making sure that new waste bears well against shaft.

3) *Rotors (squirrel-cage).* Check squirrel-cage rotors for broken or loose bars and evidence of local heating. If fan blades are not cast in place, check for loose blades. Look for marks on rotor surface indicating foreign matter in air gap or a worn bearing.

4) *Rotors (wound).* Clean wound rotors thoroughly around collector rings, washers, and connections. Tighten connections if necessary. If rings are rough, spotted, or eccentric, refer to service shop for refinishing. See that all top sticks or wedges are tight. If any are loose, refer to service shop.

5) *Armatures.* Clean all armature air passages thoroughly if any are obstructed. Look for oil or grease creeping along shaft, checking back to bearing. Check commutator for surface condition, high bars, high mica, or eccentricity. If necessary, remachine the commutator to secure a smooth fresh surface.

6) *Loads.* Read load on motor with instruments at no load, full load, or through an entire cycle, as a check on the mechanical condition of the driven machine.

## ADHESIVES AND SEALANTS

By strict definition, an adhesive is any substance that fastens or bonds materials to be joined (adherends) by means of surface attachment. The bond durability depends on the strength of the adhesive to the substrate (adhesion) and the strength within the adhesive (cohesion). Besides bonding a joint, an adhesive may serve as a seal against foreign matter. When an adhesive performs both bonding and sealing functions, it is usually referred to as an adhesive sealant. Joining materials with adhesives offers significant benefits compared with mechanical methods of uniting two materials.

Among these benefits are that an adhesive distributes a load over an area rather than concentrating it at a point, resulting in a more even distribution of stresses. The adhesive bonded joint is therefore more resistant to flexural and vibrational stresses than, for example, a bolted, riveted, or welded joint. Another benefit is that an adhesive forms a seal as well as a bond. This seal prevents the corrosion that may occur with dissimilar metals, such as aluminum and magnesium, or mechanically fastened joints, by providing a dielectric insulation between the substrates. An adhesive also joins irregularly shaped surfaces more easily than does a mechanical fastener. Other benefits include negligible weight addition and virtually no change to part dimensions or geometry.

Most adhesives are available in liquids, gels, pastes, and tape forms. The growing variety of adhesives available can make the selection of the proper adhesive or sealant a challenging experience. In addition to the technical requirements of the adhesive, time and costs are also important considerations. Proper choice of an adhesive is based on knowledge of the suitability of the adhesive or sealant for the particular substrates. Appropriate surface preparation, curing parameters, and matching the strength and durability characteristics of the adhesive to its intended use are essential. The performance of an adhesive-bonded joint depends on a wide range of these factors, many of them quite complex. Adhesive suppliers can usually offer essential expertise in the area of appropriate selection.

Adhesives can be classified as structural or nonstructural. In general, an adhesive can be considered structural when it is capable of supporting heavy loads; nonstructural when it cannot support such loads. Many adhesives and sealants, under various brand names, may be available for a particular bonding application. It is always advisable to check the adhesive manufacturers' information before making an adhesive sealant selection. Also, testing under end-use conditions is always suggested to help ensure bonded or sealed joints meet or exceed expected performance requirements.

Though not meant to be all-inclusive, the following information correlates the features of some successful adhesive compositions available in the marketplace.

### Bonding Adhesives

Reactive-type bonding adhesives are applied as liquids and react (cure) to solids under appropriate conditions. The cured adhesive is either a thermosetting or thermoplastic polymer. These adhesives are supplied as two-component no-mix, two-component mix, and one-component no-mix types, which are discussed in the following paragraphs.

### Two-Component No-Mix Adhesives

**Types of Adhesives.**—*Anaerobic (Urethane Methacrylate Ester) Structural Adhesives:* Anaerobic structural adhesives are mixtures of acrylic esters that remain liquid when exposed to air but harden when confined between metal substrates. These adhesives can be used for large numbers of industrial purposes where high reliability of bond joints is required. Benefits include: no mixing is required (no pot-life or waste problems), flexible/durable bonds are made that withstand thermal cycling, have excellent resistance to solvents and severe environments, and rapid cure at room temperatures (eliminating

expensive ovens). The adhesives are easily dispensed with automatic equipment. An activator is usually required to be present on one surface to initiate the cure for these adhesives. Applications for these adhesives include bonding of metals, magnets (ferrites), glass, thermosetting plastics, ceramics, and stone.

*Acrylic Adhesives:* Acrylic adhesives are composed of a polyurethane polymer backbone with acrylate end groups. They can be formulated to cure through heat or the use of an activator applied to the substrate surface, but many industrial acrylic adhesives are cured by light. Light-cured adhesives are used in applications where the bond geometry allows light to reach the adhesive and the production rate is high enough to justify the capital expense of a light source. Benefits include: no mixing is required (no pot-life or waste problems); formulations cure (solidify) with activator, heat, or light; the adhesive will bond to a variety of substrates, including metal and most thermoplastics; and tough and durable bonds are produced with a typical resistance to the effects of temperatures up to 180°C. Typical applications include automobile body parts (steel stiffeners), assemblies subjected to paint-baking cycles, speaker magnets to pole plates, and bonding of motor magnets, sheet steel, and many other structural applications. Other applications include bonding glass, sheet metal, magnets (ferrite), thermosetting and thermoplastic plastics, wood, ceramics, and stone.

### Two-Component Mix Adhesives

**Types of Adhesives.**—*Epoxy Adhesives:* Two-component epoxy adhesives are well-established adhesives that offer many benefits in manufacturing. The reactive components of these adhesives are separated prior to use, so they usually have a good shelf life without refrigeration. Polymerization begins upon mixing, and a thermoset polymer is formed. Epoxy adhesives cure to form thermosetting polymers made up of a base side with the polymer resin and a second part containing the catalyst. The main benefit of these systems is that the depth of cure is unlimited. As a result, large volume can be filled for work such as potting, without the cure being limited by the need for access to an external influence such as moisture or light to activate the curing process.

For consistent adhesive performance, it is important that the mix ratio remain constant to eliminate variations in adhesive performance. Epoxies can be handled automatically, but the equipment involves initial and maintenance costs. Alternatively, adhesive components can be mixed by hand. However, this approach involves labor costs and the potential for human error. The major disadvantage of epoxies is that they tend to be very rigid and consequently have low peel strength. This lack of peel strength is less of a problem when bonding metal to metal than it is when bonding flexible substrates such as plastics.

Applications of epoxy adhesives include bonding, potting, and coating of metals, bonding of glass, rigid plastics, ceramics, wood, and stone.

*Polyurethane Adhesives:* Like epoxies, polyurethane adhesives are available as two-part systems or as one-component frozen premixes. They are also available as one-part moisture-cured systems. Polyurethane adhesives can provide a wide variety of physical properties. Their flexibility is greater than that of most epoxies. Coupled with the high cohesive strength, this flexibility provides a tough polymer able to achieve better peel strength and lower flexural modulus than most epoxy systems. This superior peel resistance allows use of polyurethanes in applications that require high flexibility. Polyurethanes bond very well to a variety of substrates, though a primer may be needed to prepare the substrate surface. These primers are moisture-reactive and require several hours to react sufficiently for the parts to be used. Such a time requirement may cause a production bottleneck if the bond-strength requirements are such that a primer is needed.

Applications for polyurethane adhesives include bonding of metals, glass, rubber, thermosetting and thermoplastic plastics, and wood.

**One-Component No-Mix Adhesives**

**Types of Adhesives.**—*Light-Curable Adhesives:* Light-curing systems use a unique curing mechanism. The adhesives contain photoinitiators that absorb light energy and dissociate to form radicals. These radicals then initiate the polymerization of the polymers, oligomers, and monomers in the adhesive. The photoinitiator acts as a chemical solar cell, converting the light energy into chemical energy for the curing process. Typically, these systems are formulated for use with ultraviolet light sources. However, newer products have been formulated for use with visible light sources.

One of the biggest benefits that light-curing adhesives offer to the manufacturer is the elimination of the work time to work-in-progress trade-off, which is embodied in most adhesive systems. With light-curing systems, the user can take as much time as needed to position the part without fear of the adhesive curing. Upon exposure to the appropriate light source, the adhesive then can be fully cured in less than 1 minute, minimizing the costs associated with work in progress. Adhesives that utilize light as the curing mechanism are often one-part systems with good shelf life, which makes them even more attractive for manufacturing use.

Applications for light-curable adhesives include bonding of glass, and glass to metal, tacking of wires, surface coating, thin-film encapsulation, clear substrate bonding, and potting of components,

*Cyanoacrylate Adhesives (Instant Adhesives):* Cyanoacrylates or instant adhesives are often called Superglue™. Cyanoacrylates are one-part adhesives that cure rapidly, as a result of the presence of surface moisture, to form high-strength bonds, when confined between two substrates. Cyanoacrylates have excellent adhesion to many substrates, including most plastics and they achieve fixture strength in seconds and full strength within 24 hours. These qualities make cyanoacrylates suitable for use in automated production environments. They are available in viscosities ranging from water-thin liquids to thixotropic gels.

Because cyanoacrylates are a relatively mature adhesive family, a wide variety of specialty formulations is now available to help the user address difficult assembly problems. One of the best examples is the availability of polyolefin primers, which allow users to obtain high bond strengths on difficult-to-bond plastics such as polyethylene and polypropylene. One common drawback of cyanoacrylates is that they form a very rigid polymer matrix, resulting in very low peel strengths. To address this problem, formulations have been developed that are rubber-toughened. Although the rubber toughening improves the peel strength of the system to some extent, peel strength remains a weak point for this system, and, therefore, cyanoacrylates are poor candidates for joint designs that require high peel resistance. In manufacturing environments with low relative humidity, the cure of the cyanoacrylate can be significantly retarded.

This problem can be addressed in one of two ways. One approach is to use accelerators that deposit active species on the surface to initiate the cure of the product. The other approach is to use specialty cyanoacrylate formulations that have been engineered to be surface-insensitive. These formulations can cure rapidly even on dry or slightly acidic surfaces.

Applications for cyanoacrylate adhesives include bonding of thermoplastic and thermosetting plastics, rubber, metals, wood, and leather, also strain relief of wires.

*Hot-Melt Adhesives:* Hot-melt adhesives are widely used in assembly applications. In general, hot-melt adhesives permit fixturing speeds that are much faster than can be achieved with water- or solvent-based adhesives. Usually supplied in solid form, hot-melt adhesives liquify when exposed to elevated temperatures. After application, they cool quickly, solidifying and forming a bond between two mating substrates. Hot-melt adhesives have been used successfully for a wide variety of adherends and can greatly reduce both the need for clamping and the length of time for curing. Some drawbacks with hot-

melt adhesives are their tendency to string during dispensing and relatively low-temperature resistance.

Applications for hot-melt adhesives are bonding of fabrics, wood, paper, plastics, and cardboard.

**Rubber-Based Solvent Cements:** Rubber-based solvent cements are adhesives made by combining one or more rubbers or elastomers in a solvent. These solutions are further modified with additives to improve the tack or stickiness, the degree of peel strength, flexibility, and the viscosity or body. Rubber-based adhesives are used in a wide variety of applications such as contact adhesive for plastics laminates like counter tops, cabinets, desks, and tables. Solvent-based rubber cements have also been the mainstay of the shoe and leather industry for many years.

Applications for rubber-based solvent cements include bonding of plastics laminates, wood, paper, carpeting, fabrics, and leather.

**Moisture-Cured Polyurethane Adhesives:** Like heat-curing systems, moisture-cured polyurethanes have the advantage of a very simple curing process. These adhesives start to cure when moisture from the atmosphere diffuses into the adhesive and initiates the polymerization process. In general, these systems will cure when the relative humidity is above 25 per cent, and the rate of cure will increase as the relative humidity increases.

The dependence of these systems on the permeation of moisture through the polymer is the source of their most significant process limitations. As a result of this dependence, depth of cure is limited to between 0.25 and 0.5 in. (6.35 and 12.7 mm). Typical cure times are in the range of 12 to 72 hours. The biggest use for these systems is for windshield bonding in automobile bodies.

Applications for moisture-cured polyurethane adhesives include bonding of metals, glass, rubber, thermosetting and thermoplastic plastics, and wood.

### Retaining Compounds

The term *retaining compounds* is used to describe adhesives used in circumferential assemblies joined by inserting one part into the other. In general, retaining compounds are anaerobic adhesives composed of mixtures of acrylic esters that remain liquid when exposed to air but harden when confined between cylindrical machine components. A typical example is a bearing held in an electric motor housing with a retaining compound. The first retaining compounds were launched in 1963, and the reaction among users of bearings was very strong because these retaining compounds enabled buyers of new bearings to salvage worn housings and minimize their scrap rate.

The use of retaining compounds has many benefits, including elimination of bulk needed for high friction forces, ability to produce more accurate assemblies and to augment or replace press fits, increased strength in heavy press fits, and reduction of machining costs. Use of these compounds also helps in dissipating heat through assembly, and eliminating distortion when installing drill bushings, fretting corrosion and backlash in keys and splines, and bearing seizure during operation.

The major advantages of retaining compounds for structural assemblies are that they require less severe machining tolerances and no securing of parts. Components are assembled quickly and cleanly, and they transmit high forces and torques, including dynamic forces. Retaining compounds also seal, insulate, and prevent micromovements so that neither fretting corrosion nor stress corrosion occurs. The adhesive joint can be taken apart easily after heating above 450°F (230°C) for a specified time.

Applications for retaining compounds include mounting of bearings in housings or on shafts, avoiding distortion of precision tooling and machines, mounting of rotors on shafts, inserting drill jig bushings, retaining cylinder linings, holding oil filter tubes in castings, retaining engine-core plugs, restoring accuracy to worn machine tools, and eliminating keys and set screws.

### Threadlocking

The term *threadlocker* is used to describe adhesives used in threaded assemblies for locking the threaded fasteners by filling the spaces between the nut and bolt threads with a hard, dense material that prevents loosening. In general, thread-lockers are anaerobic adhesives comprising mixtures of acrylic esters that remain liquid when exposed to air but harden when confined between threaded components. A typical example is a mounting bolt on a motor or a pump. Threadlocker strengths range from very low strength (removable) to high strength (permanent).

It is important that the total length of the thread is coated and that there is no restriction to the curing of the threadlocker material. (Certain oils or cleaning systems can impede or even completely prevent the adhesive from curing by anaerobic reaction.) The liquid threadlocker may be applied by hand or with special dispensing devices. Proper coating (wetting) of a thread is dependent on the size of the thread, the viscosity of the adhesive, and the geometry of the parts. With blind-hole threads, it is essential that the adhesive be applied all the way to the bottom of the threaded hole. The quantity must be such that after assembly, the displaced adhesive fills the whole length of the thread.

Some threadlocking products cured by anaerobic reaction have a positive influence on the coefficient of friction in the thread. The values are comparable with those of oiled bolts. Prestress and installation torque therefore can be defined exactly. This property allows threadlocking products cured by anaerobic reaction to be integrated into automated production lines using existing assembly equipment. The use of thread-lockers has many benefits including ability to lock and seal all popular bolt and nut sizes with all industrial finishes, and to replace mechanical locking devices. The adhesive can seal against most industrial fluids and will lubricate threads so that the proper clamp load is obtained. The materials also provide vibration-resistant joints that require handtool dismantling for servicing, prevent rusting of threads, and cure (solidify) without cracking or shrinking.

The range of applications includes such uses as locking and sealing nuts on hydraulic pistons, screws on vacuum cleaner bell housings, track bolts on bulldozers, hydraulic-line fittings, screws on typewriters, oil-pressure switch assembly, screws on carburetors, rocker nuts, machinery driving keys, and on construction equipment.

### Sealants

The primary role of a sealant composition is the prevention of leakage from or access by dust, fluids, and other materials to assembly structures. Acceptable leak rates can range from a slight drip to bubbletight to molecular diffusion through the base materials. Equipment users in the industrial market want trouble-free operation, but it is not always practical to specify zero leak rates. Factors influencing acceptable leak rates are toxicity, product or environmental contamination, combustibility, economics, and personnel considerations. All types of fluid seals perform the same basic function: they seal the process fluid (gas, liquid, or vapor) and keep it where it belongs. A general term for these assembly approaches is gasketing. Many products are being manufactured that are capable of sealing a variety of substrates.

**Types of Sealants.**—*Anaerobic Formed-in-Place Gasketing Materials:* Mechanical assemblies that require the joining of metal-to-metal flange surfaces have long been designed with prefabricated, precut materials required to seal the imperfect surfaces of the assembly. Numerous gasket materials that have been used to seal these assemblies include paper, cork, asbestos, wood, metals, dressings, and even plastics. Fluid seals are divided into static and dynamic systems, depending on whether or not the parts move in relationship to each other. Flanges are classed as static systems, although they may be moved relative to each other by vibration, temperature, and/or pressure changes, shocks, and impacts.

The term *anaerobic formed-in-place gasketing* is used to describe sealants that are used in flanged assemblies to compensate for surface imperfections of metal-to-metal compo-

nents by filling the space between the substrates with a flexible, nonrunning material. In general, anaerobic formed-in-place gaskets are sealants made up of mixtures of acrylic esters that remain liquid when exposed to air but harden when confined between components. A typical example is sealing two halves of a split crankcase.

The use of anaerobic formed-in-place gaskets has many benefits, including the ability to seal all surface imperfections, allow true metal-to-metal contact, eliminate compression set and fastener loosening, and add structural strength to assemblies. These gaskets also help improve torque transmission between bolted flange joints, eliminate bolt retorquing needed with conventional gaskets, permit use of smaller fasteners and lighter flanges, and provide for easy disassembly and cleaning.

Applications in which formed-in-place gasketing can be used to produce leakproof joints include pipe flanges, split crankcases, pumps, compressors, power takeoff covers, and axle covers. These types of gaskets may also be used for repairing damaged conventional gaskets and for coating soft gaskets.

*Silicone Rubber Formed-in-Place Gasketing:* Another type of formed-in-place gasket uses room-temperature vulcanizing (RTV) silicone rubbers. These materials are one-component sealants that cure on exposure to atmospheric moisture. They have excellent properties for vehicle use such as flexibility, low volatility, good adhesion, and high resistance to most automotive fluids. The materials will also withstand temperatures up to 600°F (320°C) for intermittent operation.

RTV silicones are best suited for fairly thick section (gap) gasketing applications where flange flexing is greatest. In the form of a very thin film, for a rigid metal-to-metal seal, the cured elastomer may abrade and eventually fail under continual flange movement. The RTV silicone rubber does not unitize the assembly, and it requires relatively clean, oil-free surfaces for sufficient adhesion and leakproof seals.

Because of the silicone's basic polymeric structure, RTV silicone elastomers have several inherent characteristics that make them useful in a wide variety of applications. These properties include outstanding thermal stability at temperatures from 400 to 600°F (204 to 320°C), and good low-temperature flexibility at -85 to -165°F (-65 to -115°C). The material forms an instant seal, as is required of all liquid gaskets, and will fill large gaps up to 0.250 in. (6.35 mm) for stamped metal parts and flanges. The rubber also has good stability in ultraviolet light and excellent weathering resistance.

Applications for formed-in-place RTV silicones in the automotive field are valve, camshaft and rocker covers, manual transmission (gearbox) flanges, oil pans, sealing panels, rear axle housings, timing chain covers, and window plates. The materials are also used on oven doors and flues.

### **Tapered Pipe-thread Sealing**

Thread sealants are used to prevent leakage of gases and liquids from pipe joints. All joints of this type are considered to be dynamic because of vibration, changing pressures, or changing temperatures.

Several types of sealants are used on pipe threads including noncuring pipe dopes, which are one of the oldest methods of sealing the spiral leak paths of threaded joints. In general, pipe dopes are pastes made from oils and various fillers. They lubricate joints and jam threads but provide no locking advantage. They also squeeze out under pressure, and have poor solvent resistance. Noncuring pipe dopes are not suitable for use on straight threads.

Another alternative is solvent-drying pipe dopes, which are an older method of sealing tapered threaded joints. These types of sealant offer the advantages of providing lubrication and orifice jamming and they also extrude less easily than noncuring pipe dopes. One disadvantage is that they shrink during cure as the solvents evaporate and fittings must be retorqued to minimize voids. These materials generally lock the threaded joint together by friction. A third type of sealer is the trapped elastomer supplied in the form of a thin tape

incorporating polytetrafluorethylene (PTFE). This tape gives a good initial seal and resists chemical attack, and is one of the only materials used for sealing systems that will seal against oxygen gas.

Some other advantages of PTFE are that it acts as a lubricant, allows for high torquing, and has a good resistance to various solvents. Some disadvantages are that it may not provide a true seal between the two threaded surfaces, and it lubricates in the off direction, so it may allow fittings to loosen. In dynamic joints, tape may allow creep, resulting in leakage over time. The lubrication effect may allow overtightening, which can add stress or lead to breakage. Tape also may be banned in some hydraulic systems due to shredding, which may cause clogging of key orifices.

**Anaerobic Pipe Sealants.**—*Anaerobic Pipe Sealants:* The term *anaerobic pipe sealants* is used to describe anaerobic sealants used in tapered threaded assemblies for sealing and locking threaded joints. Sealing and locking are accomplished by filling the space between the threads with the sealant. In general, these pipe sealants are anaerobic adhesives consisting of mixtures of acrylic esters that remain liquid when exposed to air but harden when confined between threaded components to form an insoluble tough plastics. The strength of anaerobic pipe sealants is between that of elastomers and yielding metal.

Clamp loads need be only tight enough to prevent separation in use. Because they develop strength by curing after they are in place, these sealants are generally forgiving of tolerances, tool marks, and slight misalignment. These sealants are formulated for use on metal substrates. If the materials are used on plastics, an activator or primer should be used to prepare the surfaces.

Among the advantages of these anaerobic sealers are that they lubricate during assembly, they seal regardless of assembly torque, and they make seals that correspond with the burst rating of the pipe. They also provide controlled disassembly torque, do not cure outside the joint, and are easily dispensed on the production line. These sealants also have the lowest cost per sealed fitting. Among the disadvantages are that the materials are not suitable for oxygen service, for use with strong oxidizing agents, or for use at temperatures above 200°C. The sealants also are typically not suitable for diameters over M80 (approximately 3 inches).

The many influences faced by pipe joints during service should be known and understood at the design stage, when sealants are selected. Sealants must be chosen for reliability and long-term quality. Tapered pipe threads must remain leak-free under the severest vibration and chemical attack, also under heat and pressure surges.

Applications of aerobic sealants are found in industrial plant fluid power systems, the textile industry, chemical processing, utilities and power generation facilities, petroleum refining, and in marine, automotive, and industrial equipment. The materials are also used in the pulp and paper industries, in gas compression and distribution, and in waste-treatment facilities.

## MOTION CONTROL

The most important factor in the manufacture of accurately machined components is the control of motion, whatever power source is used. For all practical purposes, motion control is accomplished by electrical or electronic circuits, energizing or deenergizing actuators such as electric motors or solenoid valves connected to hydraulic or pneumatic cylinders or motors. The accuracy with which a machine tool slide, for example, may be brought to a required position, time after time, controls the dimensions of the part being machined. This accuracy is governed by the design of the motion control system in use.

There is a large variety of control systems, with power outputs from milliwatts to megawatts, and they are used for many purposes besides motion control. Such a system may control a mechanical positioning unit, which may be linear or rotary, its velocity, acceleration, or combinations of these motion parameters. A control system may also be used to set voltage, tension, and other manufacturing process variables and to actuate various types of solenoid-operated valves. The main factors governing design of control systems are whether they are to be open- or closed-loop; what kinds and amounts of power are available; and the function requirements.

Factors governing selection of control systems are listed in [Table 1](#).

**Table 1. Control System Application Factors**

|                          |   |
|--------------------------|---|
| Type of System           | Nature of required control motion, i.e., position, velocity, acceleration   |
| Accuracy                 | Controlled output versus input  |
| Mechanical Load          | Viscous friction, coulomb friction, starting friction, load inertia   |
| Impact Loads             | Hitting mechanical stops and load disturbances  |
| Ratings                  | Torque or force, and speed  |
| Torque                   | Peak instantaneous torque   |
| Duty Cycle               | Load response, torque level, and duration and effect on thermal response  |
| Ambient Temperature      | Relation to duty cycle and internal temperature rise, and to the effect of temperature on the sensor  |
| Speed of Response        | Time to reach commanded condition. Usually defined by a response to a stepped command   |
| Frequency Response       | Output to input ratio versus frequency, for varying frequency and specified constant input amplitude. Usually expressed in decibels   |
| No-Load Speed            | Frequently applies to maximum kinetic energy and to impact on stops; avoiding overspeeding  |
| Backdriving              | With power off, can the load drive the motor? Is a fail-safe brake required? Can the load backdrive with power on without damage to the control electronics? (Electric motor acting as a generator) |
| Power Source             | Range of voltage and frequency within which the system must work. Effect of line transients   |
| Environmental Conditions | Range of nonoperating and operating conditions, reliability and serviceability, scheduled maintenance   |

**Open-Loop Systems.**—The term open-loop typically describes use of a rheostat or variable resistance to vary the input voltage and thereby adjust the speed of an electric motor, a low-accuracy control method because there is no output sensor to measure the performance. However, use of stepper motors (see [Table 2](#), and page 2493) in open-loop systems can make them very accurate. Shafts of stepper motors are turned through a fixed angle for every electrical pulse transmitted to them. The maximum pulse rate can be high, and the shaft can be coupled with step-down gear drives to form inexpensive, precise drive units

with wide speed ranges. Although average speed with stepper motors is exact, speed modulation can occur at low pulse rates and drives can incur serious resonance problems.

**Table 2. Control Motor Types**

|                            |   |
|----------------------------|---|
| AC Motors                  | Induction motors, simplest, lowest cost, most rugged, can work directly off the ac line or through an inexpensive, efficient, and compact thyristor controller. Useful in fan and other drives where power increases rapidly with speed as well as in simple speed regulation. Ac motors are larger than comparable permanent-magnet motors |
| Two-Phase Induction Motors | Often used as control motors in small electromechanical control systems. Power outputs range from a few milliwatts to tens of watts   |
| Split-Field Series Motors  | Work on both ac and dc. Feature high starting torque, low cost, uniform power output over a wide speed range, and are easily reversed with a single-pole three-position switch. Very easy to use with electric limit switches for controlling angle of travel   |
| Permanent-Magnet Motors    | Operate on dc, with high power output and high efficiency. The most powerful units use rare-earth magnets and are more expensive than conventional types. Lower-cost ferrite magnets are much less expensive and require higher gear-reduction ratios, but at their higher rated speeds are very efficient                                  |
| Brushless DC Motors        | Use electrical commutation and may be applied as simple drive motors or as four-quadrant control motors. The absence of brushes for commutation ensures high reliability and low electromagnetic interference   |
| Stepper Motors             | Index through a fixed angle for each input pulse so that speed is in exact proportion to pulse rate and the travel angle increases uniformly with the number of pulses. Proper application in systems with backlash and load inertia requires special care  |
| Wound-Field DC Motors      | For subfractional to integral horsepower applications where size is not significant. Cost is moderate because permanent magnets are not required. Depending on the windings, output characteristics can be adjusted for specific applications   |

Open-loop systems are only as accurate as the input versus output requirement can be calibrated, including the effects of changes in line voltage, temperature, and other operating conditions.

**Closed-Loop Systems.**—Table 3 shows some parameters and characteristics of closed-loop systems, and a simple example of such a system is shown below. A command may be input by a human operator, it may be derived from another piece of system equipment, or it may be generated by a computer. Generally, the command is in the form of an electrical signal. The system response is converted by the output sensor to a compatible, scaled electrical signal that may be compared with the input command, the difference constituting an error signal. It is usually required that the error be small, so it is amplified and applied to an appropriate driving unit. The driver may take many forms, but for motion control it is usually a motor.

The amplified error voltage drives the motor to correct the error. If the input command is constant, the system is a closed-loop regulator.

Closed-loop systems use feedback sensors that measure system output and give instructions to the power drive components, based on the measured values. A typical closed-loop speed control, for instance, uses a tachometer as a feedback sensor and will correct automatically for differences between the tachometer output and the commanded speed. All motion control systems require careful design to achieve good practical performance. Closed-loop systems generally cost more than open-loop systems because of the extra cost

of the tachometer or transducer used for output measurement. Faster response components also increase cost.

**Table 3. Closed-Loop System Parameters and Characteristics**

|  |  |
|--|--|
| Step Response                                | The response of the system to a step change in the input command. The response to a large step, which can saturate the system amplifier, is different from the response to a small nonsaturating step. Initial overshoots may not be permissible in some types of equipment  |
| Frequency Response                           | System response to a specified small-amplitude sinusoidal command where frequency is varied over the range of interest. The response is in decibels (dB), where $\text{dB} = 20 \log_{10}(\text{output}/\text{input})$ . This characteristic determines whether the system is responsive enough to meet requirements                                 |
| Bandwidth                                    | The effective range of input frequencies within which the control system responds well. The bandwidth is often described by the point where the frequency response is down by three decibels. Bandwidth is usually defined in Hz (cycles/sec) or $\omega = 2\pi \times \text{Hz}$ (radians/sec)  |
| Loading                                      | The torque required to drive the load and the load inertia. The amplifier must supply enough power to meet acceleration as well as output power requirements. If the load is nonlinear, its effect on error must be within specifications. Behavior may vary considerably, depending on whether the load aids or opposes motor torque, as in a hoist |
| Output Stiffness                             | A measure of the system's response to load disturbances. Dynamic stiffness measures the system's response to a rapidly varying load  |
| Resonant Peaks                               | Can show up in frequency-response testing as sharp (undamped) resonances. These resonances cannot be tolerated in the normal frequency range of the control system because they can lead to oscillation and vibration  |
| No load, or maximum speed and maximum torque | Can be controlled by voltage or current limiting in the electronic amplifier. A slip clutch can also be used for torque limiting, particularly to avoid impact damage  |

Fig. 1. General Arrangement of a Closed-Loop Control System

Accuracy of closed-loop systems is directly related to the accuracy of the sensor, so that choosing between open-loop and closed-loop controls may mean choosing between low price and consistent, accurate repeatability. In the closed-loop arrangement in Fig. 1, the sensor output is compared with the input command and the difference is amplified and applied to the motor to produce a correction. When the amplifier gain is high (the difference is greatly enlarged), even a small error will generate a correction. However, a high gain can lead to an unstable system due to inherent delays between the electrical inputs and outputs, especially with the motor.

Response accuracy depends not only on the precision of the feedback sensor and the gain of the amplifier, but also on the rate at which the command signal changes. The ability of the control system to follow rapidly changing inputs is naturally limited by the maximum motor speed and acceleration.

Amplified corrections cannot be applied to the motor instantaneously, and the motor does not respond immediately. Overshoots and oscillations can occur and the system must be adjusted or tuned to obtain acceptable performance. This adjustment is called damping the system response. Table 4 lists a variety of methods of damping, some of which require specialized knowledge.

**Table 4. Means of Damping System Response**

|                    |   |
|--------------------|---|
| Network Damping    | Included in the electrical portion of the closed loop. The networks adjust amplitude and phase to minimize control system feedback oscillations. Notch networks are used to reduce gain at specific frequencies to avoid mechanical resonance oscillations  |
| Tachometer Damping | Feedback proportional to output velocity is added to the error signal for system stabilization  |
| Magnetic Damping   | Viscous or inertial dampers on the motor rear shaft extension for closed-loop stabilization. Similar dampers use silicone fluid instead of magnetic means to provide damping  |
| Nonlinear Damping  | Used for special characteristics. Inverse error damping provides low damping for large errors, permitting fast slewing toward zero and very stable operation at zero. Other nonlinearities meet specific needs, for example, coulomb friction damping works well in canceling backlash oscillations |
| Damping Algorithms | With information on output position or velocity, or both, sampled data may be used with appropriate algorithms to set motor voltage for an optimum system response  |

The best damping methods permit high error amplification and accuracy, combined with the desired degree of stability. Whatever form the output takes, it is converted by the output sensor to an electrical signal of compatible form that can be compared with the input command. The error signal thus generated is amplified before being applied to the driving unit.

**Drive Power.**—Power for the control system often depends on what is available and may vary from single- and three-phase ac 60 or 400 Hz, through dc and other types. Portable or mobile equipment is usually battery-powered dc or an engine-driven electrical generator. Hydraulic and pneumatic power may also be available. Cost is often the deciding factor in the choice.

**Table 5. Special Features of Controllers**

|                                 |  |
|---------------------------------|--|
| Linear or Pulse-Width Modulated | Linear is simpler, PWM is more complex and can generate electromagnetic interference, but is more efficient  |
| Current Limiting                | Sets limits to maximum line or motor current. Limits the torque output of permanent magnet motors. Can reduce starting transients and current surges |
| Voltage Limiting                | Sets limits to maximum motor speed. Permits more uniform motor performance over a wide range of line voltages  |
| Energy Absorption               | Ability of the controller to absorb energy from a dc motor drive, back-driven by the load  |
| EMI Filtering                   | Especially important when high electrical gain is required, as in thermocouple circuits, for example   |
| Isolation                       | Of input and output, sometimes using optoisolators, or transformers, when input and output circuits require a high degree of isolation               |

**Control Function.**—The function of the control is usually set by the designer of the equipment and needs careful definition because it is the basis for the overall design. For instance, in positioning a machine tool table, such aspects as speed of movement and permissible variations in speed, accuracy of positioning, repeatability, and overshoot are among dozens of factors that must be considered. Some special features of controllers are

listed in [Table 5](#). Complex electromechanical systems require more knowledge of design and debugging than are needed for strictly mechanical systems.

**Electromechanical Control Systems.**—Wiring is the simplest way to connect components, so electromechanical controls are more versatile than pure hydraulic or pneumatic controls. The key to this versatility is often in the controller, the fundamental characteristic of which is its power output. The power output must be compatible with motor and load requirements. Changes to computer chips or software can usually change system performance to suit the application.

When driving a dc motor, for instance, the controller must supply sufficient power to match load requirements as well as motor operating losses, at minimum line voltage and maximum ambient temperature. The system's wiring must not be greatly sensitive to transient or steady-state electrical interference, and power lines must be separated from control signal lines, or appropriately shielded and isolated to avoid cross-coupling. Main lines to the controller must often include electrical interference filters so that the control system does not affect the power source, which may influence other equipment connected to the same source. For instance, an abruptly applied step command can be smoothed out so that heavy motor inrush currents are avoided. The penalty is a corresponding delay in response.

Use of current limiting units in a controller will not only set limits to line currents, but will also limit motor torque. Electronic torque limiting can frequently avoid the need for mechanical torque limiting. An example of the latter is using a slip clutch to avoid damage due to overtravel, the impact of which usually includes the kinetic energy of the moving machine elements. In many geared systems, most of the kinetic energy is in the motor. Voltage limiting is less useful than current limiting but may be needed to isolate the motor from voltage transients on the power line, to prevent overspeeding, as well as to protect electronic components.

**Mechanical Stiffness.**—When output motion must respond to a rapidly changing input command, the control system must have a wide bandwidth. Where the load mass (in linear motion systems) or the polar moment of inertia (in rotary systems) is high, there is a possibility of resonant oscillations. For the most stable and reliable systems, with a defined load, a high system mechanical stiffness is preferred. To attain this stiffness requires strengthening shafts, preloading bearings, and minimizing free play or backlash. In the best-performing systems, motor and load are coupled without intervening compliant members. Even tightly bolted couplings can introduce compliant oscillations resulting from extremely minute slippages caused by the load motions.

Backlash is a factor in the effective compliance of any coupling but has little effect on the resonant frequency because little energy is exchanged as the load is moved through the backlash region. However, even in the absence of significant torsional resonance, a high-gain control system can “buzz” in the backlash region. Friction is often sufficient to eliminate this small-amplitude, high-frequency component.

The difficulty with direct-drive control systems lies in matching motor to load. Most electric motors deliver rated power at higher speeds than are required by the driven load, so that load power must be delivered by the direct-drive motor operating at a slow and relatively inefficient speed. Shaft power at low speed involves a correspondingly high torque, which requires a large motor and a high-power controller. Motor copper loss (heating) is high in delivering the high motor torque. However, direct-drive motors provide maximum load velocity and acceleration, and can position massive loads within seconds of arc (rotational) or tenths of thousandths of an inch (linear) under dynamic conditions.

Where performance requirements are moderate, the required load torque can be traded off against speed by using a speed-changing transmission, typically, a gear train. The transmission effectively matches the best operating region of the motor to the required operating region of the load, and both motor and controller can be much smaller than would be needed for a comparable direct drive.

**Torsional Vibration.**—Control system instabilities can result from insufficient stiffness between the motor and the inertia of the driven load. The behavior of such a system is similar to that of a torsional pendulum, easily excited by commanded motions of the control system. If frictional losses are moderate to low, sustained oscillations will occur. In spite of the complex dynamics of the closed-loop system, the resonant frequency, as for a torsional pendulum, is given to a high degree of accuracy by the formula:

$$f_n = \frac{1}{2\pi} \times \sqrt{\frac{K}{J_L}}$$

where  $f_n$  is in hertz,  $K$  is torsional stiffness in in.-lb/rad, and  $J_L$  is load inertia in in.-lb-sec<sup>2</sup>/rad. If this resonant frequency falls within the bandwidth of the control system, self-sustained oscillations are likely to occur. These oscillations are often overlooked by control systems analysts because they do not appear in simple control systems, and they are very difficult to correct.

Friction inherently reduces the oscillation by dissipating the energy in the system inertia. If there is backlash between motor and load, coulomb friction (opposing motion but independent of speed) is especially effective in damping out the oscillation. However, the required friction for satisfactory damping can be excessive, introducing positioning error and adding to motor (and controller) power requirements. Friction also varies with operating conditions and time.

The most common method of eliminating torsional oscillation is to introduce a filter in the error channel of the control system to shape the gain characteristic as a function of frequency. If the torsional resonance is within the required system bandwidth, little can be done except stiffening the mechanical system and increasing the resonant frequency. If the filter reduces the gain within the required bandwidth, it will reduce performance. This method will work only if the natural resonance is above the minimum required performance bandwidth.

The simplest shaping network is the notch network (Table 4, network damping), which, in effect, is a band-rejection filter that sharply reduces gain at the notch frequency. By locating the notch frequency so as to balance out the torsional resonance peak, the oscillation can be eliminated. Where there are several modes of oscillation, several filter networks can be connected in series.

**Electric Motors.**—Electric motors for control systems must suit the application. Motors used in open-loop systems (excluding stepper motors) need not respond quickly to input command changes. Where the command is set by a human, response times of hundreds of milliseconds to several seconds may be acceptable. Slow response does not lead to the instabilities that time delays can introduce into closed-loop systems.

Closed-loop systems need motors with fast response, of which the best are permanent-magnet dc units, used where wide bandwidth, efficient operation, and high power output are required. Table 2 lists some types of control motors and their characteristics. An important feature of high-performance, permanent-magnet motors using high-energy, rare-earth magnets is that their maximum torque output capacity can be 10 to 20 or more times higher than their rated torque. In intermittent or low-duty-cycle applications, very high torque loads can be driven by a given motor. However, when rare-earth magnets (samarium cobalt or neodymium) are not used, peak torque capability may be limited by the possibility of demagnetization. Rare-earth magnets are relatively expensive, so it is important to verify peak torque capabilities for lower-cost motors that may use weaker Alnico or ferrite magnets.

Duty-cycle calculations are an aspect of thermal analysis that are well understood and are not covered here. Motor manufacturers usually supply information on thermal characteristics including thermal time constants and temperature rise per watt of internal power dissipation.

Fig. 2. Idealized Control Motor Characteristics for a Consistent Set of Units

Characteristics of permanent-magnet motors are defined with fair accuracy by relatively few parameters. The most important characteristics are:  $D_M$  motor damping in lb-in.-sec/rad;  $J_M$  motor inertia in lb-in.-sec<sup>2</sup>/rad; and  $R$  winding resistance in ohms. Fig. 1 shows other control motor characteristics,  $T_{STO}$  stall torque with no current limiting;  $T_L$  maximum torque with current limiting;  $\omega_{NL}$  no-load speed;  $\omega_R$  rated speed. Other derived motor parameters include  $V$  rated voltage in volts;  $I_{STO} = V/R$  current in amperes at stall with no current limiting;  $I_L$  ampere limit, adjusted in amplifier;  $I_R$  rated current;  $K_T = T_{STO}/I_{STO}$  torque constant in in.-lb/ampere;  $K_E = V/\omega_{NL}$  voltage constant in volt/rad/sec;

$K_M = K_T/\sqrt{R}$ , torque per square root of winding resistance;  $D_M = T_{STO}/\omega_{NL}$  motor damping in in.-lb/rad/sec; and  $T_M = J_M/D_M$  motor mechanical time constant in seconds.

**Stepper Motors.**—In a stepper motor, power is applied to a wound stator, causing the brushless rotor to change position to correspond with the internal magnetic field. The rotor maintains its position relative to the internal magnetic field at all times. In its most common mode of operation, the stepper motor is energized by an electronic controller whose current output to the motor windings defines the position of the internally generated magnetic field. Applying a command pulse to the controller will change the motor currents to reposition the rotor. A series of pulses, accompanied by a direction command, will cause rotation in uniformly spaced steps in the specified direction.

If the pulses are applied at a sufficiently high frequency, the rotor will be carried along with the system's inertia and will rotate relatively uniformly but with a modulated velocity. At the other extreme, the response to a single pulse will be a step followed by an overshoot and a decaying oscillation. Where the application cannot permit the oscillation, damping can be included in the controller.

Stepper motors are often preferred because positions of the rotor are known from the number of pulses and the step size. An initial index point is required as an output position reference, and care is required in the electronic circuits to avoid introducing random pulses that will cause false positions. As a minimum, the output index point on an appropriate shaft can verify the step count during operation.

**Gearing.**—In a closed-loop system, gearing may be used to couple a high-speed, low-torque motor to a lower-speed, higher-torque load. The gearing must meet requirements for accuracy, strength, and reliability to suit the application. In addition, the closed loop requires minimum backlash at the point where the feedback sensor is coupled. In a velocity-controlled system, the feedback sensor is a tachometer that is usually coupled directly to the rotor shaft. Backlash between motor and tachometer, as well as torsional compliance, must be minimized for stable operation of a high-performance system. Units combining motor and tachometer on a single shaft can usually be purchased as an assembly.

By contrast, a positioning system may use a position feedback sensor that is closely coupled to the shaft being positioned. As with the velocity system, backlash between the motor and feedback sensor must be minimized for closed-loop stability. Antibacklash gearing is frequently used between the gearing and the position feedback sensor. When the position

feedback sensor is a limited rotation device, it may be coupled to a gear that turns faster than the output gear to allow use of its full range. Although this step-up gearing enhances it, accuracy is ultimately limited by the errors in the intermediate gearing between the position sensor and the output.

When an appreciable load inertia is being driven, it is important that the mechanical stiffness between the position sensor coupling point and the load be high enough to avoid natural torsional resonances in the passband.

**Feedback Transducers.**—Controlled variables are measured by feedback transducers and are the key to accuracy in operation of closed-loop systems. When the accuracy of a carefully designed control system approaches the accuracy of the feedback transducer, the need for precision in the other system components is reduced.

Transducers may measure the quantity being controlled in digital or analog form, and are available for many different parameters such as pressure and temperature, as well as distance traveled or degrees of rotation. Machine designers generally need to measure and control linear or rotary motion, velocity, position, and sometimes acceleration. Although some transducers are nonlinear, a linear relationship between the measured variable and the (usually electrical) output is most common.

Output characteristics of an analog linear-position transducer are shown in Fig. 2. By dividing errors into components, accuracy can be increased by external adjustments, and slope error and zero offsets are easily trimmed in. Nonlinearity is controlled by the manufacturer. In Fig. 2 are seen the discrete error components that can be distinguished because of the ease with which they can be canceled out individually by external adjustments. The most common compensation is for zero-position alignment, so that when the machine has been set to the start position for a sequence, the transducer can be positioned to read zero output. Alternatively, with all components in fixed positions, a small voltage can be inserted in series with the transducer output for a very accurate alignment of mechanical and electrical zeros. This method helps in canceling long-term drift, particularly in the mechanical elements.

The second most common adjustment of a position transducer is of its output gradient, that is, transducer output volts per degree. Depending on the type of analog transducer, it is usually possible to add a small adjustment to the electrical input, to introduce a proportional change in output gradient. As with the zero-position adjustment, the gradient may be set very accurately initially and during periodic maintenance. The remaining errors shown in Fig. 2, such as intrinsic nonlinearity or nonconformity, result from limitations in design and manufacture of the transducer.

Fig. 3. Output Characteristics of a General Linear Position Transducer

Greater accuracy can be achieved in computer-controlled systems by using the computer to cancel out transducer errors. The system's mechanical values and corresponding transducer values are stored in a lookup table in the computer and referred to as necessary.

Accuracies approaching the inherent repeatability and stability of the system can thus be secured. If necessary, recalibration can be performed at frequent intervals.

**Analog Transducers.**—The simplest analog position transducer is the resistance potentiometer, the resistance element in which is usually a deposited-film rather than a wire-wound type. Very stable resistance elements based on conductive plastics, with resolution to a few microinches and operating lives in the 100 million rotations, are available, capable of working in severe environments with high vibrations and shock and at temperatures of 150 to 200°C. Accuracies of a few hundredths, and stability of thousandths, of a per cent, can be obtained from these units by trimming the plastics resistance element as a function of angle.

Performance of resistance potentiometers deteriorates when they operate at high speeds, and prolonged operation at speeds above 10 rpm causes excessive wear and increasing output noise. An alternative to the resistance potentiometer is the variable differential transformer, which uses electrical coupling between ac magnetic elements to measure angular or linear motion without sliding contacts. These units have unlimited resolution with accuracy comparable to the best resistance potentiometers but are more expensive and require compatible electronic circuits.

A variable differential transformer needs ac energization, so an ac source is required. A precision demodulator is frequently used to change the ac output to dc. Sometimes the ac output is balanced against an ac command signal whose input is derived from the same ac source. In dealing with ac signals, phase-angle matching and an accurate amplitude-scale factor are required for proper operation. Temperature compensation also may be required, primarily due to changes in resistance of the copper windings. Transducer manufacturers will supply full sets of compatible electronic controls.

**Synchros and Resolvers.**—Synchros and resolvers are transducers that are widely used for sensing of angles at accuracies down to 10 to 20 arc-seconds. More typically, and at much lower cost, their accuracies are 1 to 2 arc-minutes. Cost is further reduced when accuracies of 0.1 degree or higher are acceptable.

Synchros used as angle-position transducers are made as brush types with slip rings and in brushless types. These units can rotate continuously at high speeds, the operating life of brushless designs being limited only by the bearing life. Synchros have symmetrical three-wire stator windings that facilitate transmission of angle data over long distances (thousands of feet). Such a system is also highly immune to noise and coupled signals. Practically the only trimming required for very long line systems is matching the line-to-line capacitances.

Because synchros can rotate continuously, they can be used in multispeed arrangements, where, for example, full-scale system travel may be represented by 36 or 64 full rotations. When reduced by gearing to a single, full-scale turn, a synchro's electrical inaccuracy is the typical 0.1° error divided by 36 or 64 or whatever gear ratio is used. This error is insignificant compared with the error of the gearing coupling the high-speed synchro and the single speed (1 rotation for full scale) output shaft. The accuracy is dependable and stable, using standard synchros and gearing.

### Hydraulic and Pneumatic Systems

In Fig. 1 is shown a schematic of a hydraulic cylinder and the relationships between force and area that govern all hydraulic systems. Hydraulic actuators that drive the load may be cylinders or motors, depending on whether linear or rotary motion is required. The load must be defined by its torque-speed characteristics and inertia, and a suitable hydraulic actuator selected before the remaining system components can be chosen. Fluid under pressure and suitable valves are needed to control motion. Both single- and double-acting hydraulic cylinders are available, and the latter type is seen in Fig. 1.

Pressure can be traded off against velocity, if desired, by placing a different effective area at each side of the piston. The same pressure on a smaller area will move the piston at a higher speed but lower force for a given rate of fluid delivery. The cylinder shown in Fig. 1 can drive loads in either direction. The simple formulas of plane geometry relate cylinder areas, force, fluid flow, and rate of movement. Other configurations can develop equal forces and speeds in both directions.

The rotary equivalent of the cylinder is the hydraulic motor, which is defined by the fluid displacement required to turn the output shaft through one revolution, by the output torque, and by the load requirements of torque and speed. Output torque is proportional to fluid pressure, which can be as high as safety permits. Output speed is defined by the number of gallons per minute supplied to the motor. As an example, if 231 cu. in. = 1 gallon, an input of 6 gallons/min (gpm) with a 5-cu. in. displacement gives a mean speed of  $6 \times 231/5 = 277$  rpm. The motor torque must be defined by lb-in. per 100 lb<sub>f</sub>/in.<sup>2</sup> (typically) from which the required pressure can be determined. Various motor types are available.

**Hydraulic Pumps.**—The most-used hydraulic pump is the positive-displacement type, which delivers a fixed amount of fluid for every cycle. These pumps are also called hydrostatic because they deliver energy by static pressure rather than by the kinetic energy of a moving fluid. Positive-displacement pumps are rated by the gpm delivered at a stated speed and by the maximum pressure, which are the key parameters defining the power capacity of the hydraulic actuator. Delivered gpm are reduced under load due to leakage, and the reduction is described by the volumetric efficiency, which is the ratio of actual to theoretical output.

**Hydraulic Fluids.**—The hydraulic fluid is the basic means of transmitting power, and it also provides lubrication and cooling when passed through a heat exchanger. The fluid must be minimally compressible to avoid springiness and delay in response. The total system inertia reacts with fluid compliance to generate a resonant frequency, much as inertia and mechanical compliance react in an electromechanical system. Compliance must be low enough that resonances do not occur in the active bandwidth of the servomechanism, and that unacceptable transients do not occur under shock loads. Seal friction and fluid viscosity tend to damp out resonant vibrations. Shock-absorbing limit stops or cushions are usually located at the travel limits to minimize transient impact forces.

$$F = \text{force (lb)} = \text{pressure} \times \text{area}$$

$$P_1 \text{ and } P_2 = \text{line pressure on either side of piston in lb}_f/\text{in.}^2$$

$$d_1 \text{ and } d_2 = \text{diameters of piston rod and piston in in.}$$

$$F_1 = \frac{\pi}{4} (d_2^2 - d_1^2) \times P_1 = 0.7854 P_1 (d_2^2 - d_1^2)$$

$$F_2 = \frac{\pi}{4} d_2^2 P_2 = 0.7854 P_2 d_2^2$$

Fig. 1. Elementary Hydraulic Force/Area Formulas

Hydraulic fluids with special additives for lubrication minimize wear between moving parts. An auxiliary function is prevention of corrosion and pitting. Hydraulic fluids must also be compatible with gaskets, seals, and other nonmetallic materials.

Viscosity is another critical parameter of hydraulic fluids as high viscosity means high resistance to fluid flow with a corresponding power loss and heating of the fluid, pressure drop in the hydraulic lines, difficulty in removing bubbles, and sometimes overdamped operation. Unfortunately, viscosity falls very rapidly with increasing temperature, which can lead to reduction of the lubrication properties and excessive wear as well as increasing leakage. For hydraulic actuators operating at very low temperatures, the fluid pour point is important. Below this temperature, the hydraulic fluid will not flow. Design guidelines similar to those used with linear or rotating bearings are applicable in these conditions.

Fire-resistant fluids are available for use in certain conditions such as in die casting, where furnaces containing molten metal are often located near hydraulic systems.

A problem with hydraulic systems that is absent in electromechanical systems is that of dirt, air bubbles, and contaminants in the fluid. Enclosed systems are designed to keep out contaminants, but the main problem is with the reservoir or fluid storage unit. A suitable sealer must be used in the reservoir to prevent corrosion and a filter should be used during filling. Atmospheric pressure is required on the fluid surface in the reservoir except where a pressurized reservoir is used. Additional components include coarse and fine filters to remove contaminants and these filters may be rated to remove micron sized particles (1 micron = 0.00004 in.).

Very fine filters are sometimes used in high-pressure lines, where dirt might interfere with the operation of sensitive valves. Where a high-performance pump is used, a fine filter is a requirement. Usually, only coarse filters are used on fluid inlet lines because fine filters might introduce excessive pressure drop.

Aside from the reservoir used for hydraulic fluid storage, line connections, fittings, and couplings are needed. Expansion of these components under pressure increases the mechanical compliance of the system, reducing the frequencies of any resonances and possibly interfering with the response of wide-band systems.

Formulas relating fluid flow and mechanical power follow. These formulas supplement the general force, torque, speed, and power formulas of mechanical systems.

$$F = P \times A$$

$$A = 0.7854 \times d^2$$

$$hp = 0.000583q \times \text{pressure in lb}_f/\text{in.}^2$$

$$1 \text{ gallon of fluid flow/min at } 1 \text{ lb}_f/\text{in.}^2 \text{ pressure} = 0.000582 \text{ hp.}$$

For rotary outputs,

$$hp = \text{torque} \times \text{rpm}/63,025$$

where torque is in lb-in. (Theoretical hp output must be multiplied by the efficiency of the hydraulic circuits to determine actual output.)

In the preceding equations,

$$P = \text{pressure in lb}_f/\text{in.}^2$$

$$A = \text{piston area in in.}^2$$

$$F = \text{force in lb}$$

$$q = \text{fluid flow in gallons/min}$$

$$d = \text{piston diameter in inches}$$

**Hydraulic and Pneumatic Control Systems.**—Control systems for hydraulic and pneumatic circuits are more mature than those for electromechanical systems because they have been developed over many more years. Hydraulic components are available at moderate prices from many sources. Although their design is complex, application and servicing of these systems are usually more straightforward than with electromechanical systems.

Electromechanical and hydraulic/pneumatic systems may be analyzed by similar means. The mathematical requirements for accuracy and stability are analogous, as are most performance features, although nonlinearities are caused by different physical attributes. Nonlinear friction, backlash, and voltage and current limiting are common to both types of system, but hydraulic/pneumatic systems also have the behavior characteristics of fluid-driven systems such as thermal effects and fluid flow dynamics including turbulence, leakage caused by imperfect seals, and contamination.

Both control types require overhead equipment that does not affect performance but adds to overall cost and complexity. For instance, electromechanical systems require electrical power sources and power control components, voltage regulators, fuses and circuit breakers, relays and switches, connectors, wiring and related devices. Hydraulic/pneumatic sys-

tems require fluid stored under pressure, motor-driven pumps or compressors, valves, pressure regulators/limiters, piping and fasteners, as well as hydraulic/pneumatic motors and cylinders. Frequently, the optimum system is selected on the basis of overhead equipment already available.

Electromechanical systems are generally slower and heavier than hydraulic systems and less suited to controlling heavy loads. The bandwidths of hydraulic control systems can respond to input signals of well over 100 Hz as easily as an electromechanical system can respond to, say, 10 to 20 Hz. Hydraulic systems can drive very high torque loads without intermediate transmissions such as the gear trains often used with electromechanical systems. Also, hydraulic/pneumatic systems using servo valves and piston/cylinder arrangements are inherently suited to linear motion operation, whereas electromechanical controls based on conventional electrical machines are more naturally suited to driving rotational loads.

Until recently, electromechanical systems were limited to system bandwidths of about 10 Hz, with power outputs of a few hundred watts. However, their capabilities have now been sharply extended through the use of rare-earth motor magnets having much higher energies than earlier designs. Similarly, semiconductor power components deliver much higher output power at lower prices than earlier equipment. Electromechanical control systems are now suited to applications of more than 100 hp with bandwidths up to 40 Hz and sometimes up to 100 Hz.

Although much depends on the specific design, the edge in reliability, even for high-power, fast-response needs, is shifting toward electromechanical systems. Basically, there are more things that can go wrong in hydraulic/pneumatic systems, as indicated by the shift to more electrical systems in aircraft.

**Hydraulic Control Systems.**—Using essentially incompressible fluid, hydraulic systems are suited to a wide range of applications, whereas pneumatic power is generally limited to simpler uses. In Fig. 2 are shown the essential features of a simple linear hydraulic control system and a comparable system for driving a rotating load.

Fig. 2. (left) A Simple Linear Hydraulic Control System in Which the Load Force Returns the Piston and (right) a Comparable System for Driving a Rotating Load

Hydraulic controls of the type shown have fast response and very high load capacities. In a linear actuator, for example, each  $\text{lb}/\text{in}^2$  of system pressure acts against the area of the piston to generate the force applied. Hydraulic pressures of up to  $3000 \text{ lb}/\text{in}^2$  are readily obtained from hydraulic pumps, so that cylinders can exert forces of hundreds of tons without the need for speed-reducing transmission systems to increase the force. The hydraulic fluid distributes heat, so it helps cool the system.

Systems similar to those in Fig. 2 can be operated in open- or closed-loop modes. Open-loop operation can be controlled by programming units that initiate each step by operating relays, limit switches, solenoid valves, and other components to generate the forces over

the required travel ranges. Auxiliary components are used to ensure safe operation and make such systems flexible and reliable, as shown in Fig. 3.

Fig. 3. Some of the Auxiliary Components Used in a Practical Hydraulic System

In the simplest mode, whether open- or closed-loop, hydraulic system operation may be discontinuous or proportional. Discontinuous operation, sometimes called bang-bang, or on-off, works well, is widely used in low- to medium-accuracy systems, and is easy to maintain. In this closed-loop mode, accuracy is limited; if the response to error is set too high, the system will oscillate between on-off modes, with average output at about the desired value. This oscillation, however, can be noisy, introduces system transients, and may cause rapid wear of system components.

Another factor to be considered in on-off systems is the shock caused by sudden opening and closing of high-pressure valves, which introduce transient pulses in the fluid flow and can cause high stresses in components. These problems can be addressed by the use of pressure-limiting relief valves and other units.

**Proportional Control Systems.**—Where the highest accuracy is required, perhaps in two directions, and with aiding or opposing forces or torques, a more sophisticated proportional control, closed-loop system is preferred. As shown in Fig. 4, the amplifier and electric servomotor used in electromechanical closed-loop systems is replaced in the closed-loop hydraulic system by an electronically controlled servo-valve. In its simplest form, the valve uses a linear motor to position the spool that determines the flow path for the hydraulic fluid. In some designs, the linear motor may be driven by a solenoid against a bias spring on the valve spool. In other arrangements, the motor may be a bidirectional unit that permits a fluid flow depending on the polarity and amplitude of the voltage supplied to the motor.

Fig. 4.

Such designs can be used in proportional control systems to achieve smooth operation and minimum nonlinearities, and will give the maximum accuracy required by the best machine tool applications. Where very high power must be controlled, use is often made of a two-stage valve in which the output from the first stage is used to drive the second-stage valve, as shown in Fig. 5.

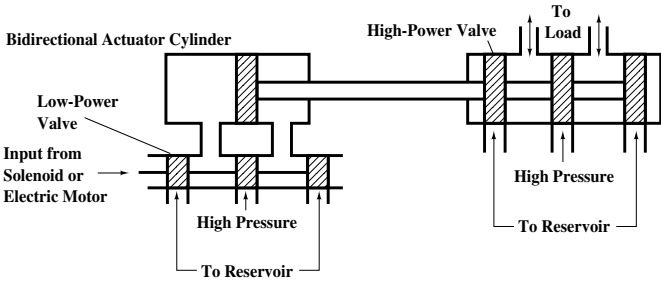

Fig. 5. Two-Stage Valve for Large-Power Control from a Low-Power Input

**Electronic Controls.**—An error-sensing electronic amplifier drives the solenoid motor of Fig. 5, which provides automatic output correction in a closed-loop system. The input is an ideal place to introduce electrical control features, adding greatly to the versatility of the control system. The electronic amplifier can provide the necessary driving power using pulse-width modulation as required, for minimum heating. The output can respond to signals in the low-microvolt range.

A major decision is whether to use analog or digital control. Although analog units are simple, they are much less versatile than their digital counterparts. Digital systems can be readjusted for total travel, speed, and acceleration by simple reprogramming. Use of appropriate feedback sensors can match accuracy to any production requirement, and a single digital system can be easily adapted to a great variety of similar applications. This adaptability is an important cost-saving feature for moderate-sized production runs. Modern microprocessors can integrate the operation of sets of systems.

Because nonlinearities and small incremental motions are easy to implement, digital systems are capable of very smooth acceleration, which avoids damaging shocks and induced leaks, and enhances reliability so that seals and hose connections last longer. The accuracy of digital control systems depends on transducer availability, and a full range of such devices has been developed and is now available.

Other features of digital controls are their capacity for self-calibration, easy digital read-out, and periodic self-compensation. For example, it is easy to incorporate backlash compensation. Inaccuracies can be corrected by using lookup tables that may themselves be updated as necessary. Digital outputs can be used as part of an inspection plan, to indicate need for tool changing, adjustment or sharpening, or for automatic record keeping. Despite continuing improvements in analog systems, digital control of hydraulic systems is favored in large plants.

**Pneumatic Systems.**—Hydraulic systems transmit power by means of the flow of an essentially incompressible fluid. Pneumatic systems use a highly compressible gas. For this reason, a pneumatic system is slower in responding to loads, especially sudden output loads, than a hydraulic system. Similarly, torque or force requires time and output motion to build up. Response to sudden output loads shows initial overshoot. Much more complex networks or other damping means are required to develop stable response in closed-loop systems. On the other hand, there are no harmful shock waves analogous to the transients that can occur in hydraulic systems, and pneumatic system components last comparatively longer.

Notwithstanding their performance deficiencies, pneumatic systems have numerous desirable features. Pneumatic systems avoid some fire hazards compared with the most preferred hydraulic fluids. Air can be vented to the atmosphere so a flow line only is needed, reducing the complexity, cost, and weight of the overall system. Pneumatic lines,

couplings, and fittings are lighter than their hydraulic counterparts, often a significant advantage. The gaseous medium also is lighter than hydraulic fluid, and pneumatic systems are usually easier to clean, assemble, and generally maintain. Fluid viscosity and its temperature variations are virtually negligible with pneumatic systems.

Among drawbacks with pneumatics are that lubrication must be carefully designed in, and more power is needed to achieve a desired pressure when the fluid medium is a compressible gas. Gas under high pressure can cause an explosion if its storage tank is damaged, so storage must have substantial safety margins. Gas compressibility makes pneumatic systems 1 or 2 orders of magnitude slower than hydraulic systems.

The low stiffness of pneumatic systems is another indicator of the long response time. Resonances occur between the compressible gas and equivalent system inertias at lower frequencies. Even the relatively low speed of sound in connecting lines contributes to response delay, adding to the difficulty of closed-loop stabilization. Fortunately, it is possible to construct pneumatic analogs to electrical networks to simplify stabilization at the exact point of the delays. Such pneumatic stabilizing means are commercially available and are important elements of closed-loop pneumatic control systems.

In contrast with hydraulic systems, where speed may be controlled by varying pump output, pneumatic system control is almost exclusively by valves, which control the flow from a pneumatic accumulator or pressure source. The pressure is maintained between limits by an intermittently operated pump. Low-pressure outlet ports must be large enough to accommodate the high volume of the expanded gas. In Fig. 6 is shown a simplified system for closed-loop position control applied to an air cylinder, in which static accuracy is controlled by the position sensor. Proper design requires a good theoretical analysis and attention to practical design if good, stable, closed-loop response is to be achieved.

Fig. 6. A Pneumatic Closed-Loop Linear Control System

## O-RINGS

An O-ring is a one-piece molded elastomeric seal with a circular cross-section that seals by distortion of its resilient elastic compound. Dimensions of O-rings are given in ANSI/SAE AS568A, Aerospace Size Standard for O-rings. The standard ring sizes have been assigned identifying dash numbers that, in conjunction with the compound (ring material), completely specifies the ring. Although the ring sizes are standardized, ANSI/SAE AS568A does not cover the compounds used in making the rings; thus, different manufacturers will use different designations to identify various ring compounds. For example, 230-8307 represents a standard O-ring of size 230 (2.484 in. ID by 0.139 in. width) made with compound 8307, a general-purpose nitrile compound. O-ring material properties are discussed at the end of this section.

When properly installed in a groove, an O-ring is normally slightly deformed so that the naturally round cross-section is squeezed diametrically out of round prior to the application of pressure. This compression ensures that under static conditions, the ring is in contact with the inner and outer walls enclosing it, with the resiliency of the rubber providing a zero-pressure seal. When pressure is applied, it tends to force the O-ring across the groove, causing the ring to further deform and flow up to the fluid passage and seal it against leakage, as in Fig. 1(a). As additional pressure is applied, the O-ring deforms into a D shape, as in Fig. 1(b). If the clearance gap between the sealing surface and the groove corners is too large or if the pressure exceeds the deformation limits of the O-ring material (compound), the O-ring will extrude into the clearance gap, reducing the effective life of the seal. For very low-pressure static applications, the effectiveness of the seal can be improved by using a softer durometer compound or by increasing the initial squeeze on the ring, but at higher pressures, the additional squeeze may reduce the ring's dynamic sealing ability, increase friction, and shorten ring life.

Fig. 1.

The initial diametral squeeze of the ring is very important in the success of an O-ring application. The squeeze is the difference between the ring width  $W$  and the gland depth  $F$  (Fig. 2) and has a great effect on the sealing ability and life of an O-ring application.

Fig. 2. Groove and Ring Details

The ideal squeeze varies according to the ring cross-section, with the average being about 20 per cent, i.e., the ring's cross-section  $W$  is about 20 per cent greater than the gland depth  $F$  (groove depth plus clearance gap). The groove width is normally about 1.5 times larger than the ring width  $W$ . When installed, an O-ring compresses slightly and distorts into the free space within the groove. Additional expansion or swelling may also occur due to contact of the ring with fluid or heat. The groove must be large enough to accommodate the maximum expansion of the ring or the ring may extrude into the clearance gap or rupture the assembly. In a dynamic application, the extruded ring material will quickly wear and fray, severely limiting seal life.

To prevent O-ring extrusion or to correct an O-ring application, reduce the clearance gap by modifying the dimensions of the system, reduce the system operating pressure, install antiextrusion backup rings in the groove with the O-ring, as in Fig. 3, or use a harder O-ring compound. A harder compound may result in higher friction and a greater tendency of the seal to leak at low pressures. Backup rings, frequently made of leather, Teflon, metal, phenolic, hard rubber, and other hard materials, prevent extrusion and nibbling where large clearance gaps and high pressure are necessary.

Fig. 3. Preferred Use of Backup Washers

The most effective and reliable sealing is generally provided by using the diametrical clearances given in manufacturers' literature. However, the information in Table 1 may be used to estimate the gland depth (groove depth plus radial clearance) required in O-ring applications. The radial clearance used (radial clearance equals one-half the diametrical clearance) also depends on the system pressure, the ring compound and hardness, and specific details of the application.

**Table 1. Gland Depth for O-Ring Applications**

| Standard O-Ring Cross-Sectional Diameter (in.) | Gland Depth (in.)   |                |
|--|---------------------|----------------|
|  | Reciprocating Seals | Static Seals   |
| 0.070  | 0.055 to 0.057      | 0.050 to 0.052 |
| 0.103  | 0.088 to 0.090      | 0.081 to 0.083 |
| 0.139  | 0.121 to 0.123      | 0.111 to 0.113 |
| 0.210  | 0.185 to 0.188      | 0.170 to 0.173 |
| 0.275  | 0.237 to 0.240      | 0.226 to 0.229 |

Source: Auburn Manufacturing Co. When possible, use manufacturer recommendations for clearance gaps and groove depth.

Fig. 4 indicates conditions where O-ring seals may be used, depending on the fluid pressure and the O-ring hardness. If the conditions of use fall to the right of the curve, extrusion of the O-ring into the surrounding clearance gap will occur, greatly reducing the life of the ring. If conditions fall to the left of the curve, no extrusion of the ring will occur, and the ring may be used under these conditions. For example, in an O-ring application with a 0.004-in. diametrical clearance and 2500-psi pressure, extrusion will occur with a 70 durometer O-ring but not with an 80 durometer O-ring. As the graph indicates, high-pressure applications require lower clearances and harder O-rings for effective sealing.

Fig. 4. Extrusion Potential of O-Rings as a Function of Hardness and Clearance

Recommended groove width, clearance dimensions, and bottom-of-groove radius for O-ring numbers up to 475 (25.940-in. ID by 0.275-in. width) can be found using Table 2 in conjunction with Fig. 5. In general, except for ring cross-sections smaller than  $\frac{1}{16}$  in., the groove width is approximately  $1.5W$ , where  $W$  is the ring cross-sectional diameter. Straight-sided grooves are best for preventing extrusion of the ring or nibbling; however, for low-pressure applications (less than 1500 psi) sloped sides with an angle up to  $5^\circ$  can be used to simplify machining of the groove. The groove surfaces should be free of burrs, nicks, or scratches. For static seals (i.e., no contact between the O-ring and any moving parts), the groove surfaces should have a maximum roughness of 32 to 63  $\mu\text{in. rms}$  for liquid-sealing applications and 16 to 32  $\mu\text{in. rms}$  for gaseous-sealing applications. In dynamic seals, relative motion exists between the O-ring and one or more parts and the maximum groove surface roughness should be 8 to 16  $\mu\text{in. rms}$  for sliding contact applications (reciprocating seals, for example) and 16 to 32  $\mu\text{in. rms}$  for rotary contact applications (rotating and oscillating seals).

In dynamic seal applications, the roughness of surfaces in contact with O-rings (bores, pistons, and shafts, for example) should be 8 to 16  $\mu\text{in. rms}$ , without longitudinal or circumferential scratches. Surface finishes of less than 5  $\mu\text{in. rms}$  are too smooth to give a good seal life because they wipe too clean, causing the ring to wear against the housing in the absence of a lubricating film. The best-quality surfaces are honed, burnished, or hard chromium plated. Soft and stringy metals such as aluminum, brass, bronze, Monel, or free machining stainless steel should not be used in contact with moving seals. In static applica-

tions, O-ring contacting surfaces should have a maximum surface roughness of 64 to 125  $\mu\text{in. rms}$ .

**Table 2. Diametral Clearance and Groove Sizes for O-Ring Applications**

| ANSI/SAE<br>AS568<br>Number | Tolerances       |                  | Diametral Clearance, $D$        |                      | Groove Width, $G$ |       |       | Bottom of<br>Groove<br>Radius, $R$ |

Source: Auburn Manufacturing Co. All dimensions are in inches. Clearances listed are minimum and maximum values; standard groove widths may be reduced by about 10 per cent for use with ring compounds that free swell less than 15 per cent. Dimension A is the ID of any surface contacted by the outside circumference of the ring; B is the OD of any surface contacted by the inside circumference of the ring.

Fig. 5. Installation data for use with Table 2. Max and Min are maximum and minimum piston and bore diameters for O.D. and I.D., respectively.

The preferred bore materials are steel and cast iron, and pistons should be softer than the bore to avoid scratching them. The bore sections should be thick enough to resist expansion and contraction under pressure so that the radial clearance gap remains constant, reducing the chance of damage to the O-ring by extrusion and nibbling. Some compatibility problems may occur when O-rings are used with plastics parts because certain compounding ingredients may attack the plastics, causing crazing of the plastics surface.

O-rings are frequently used as driving belts in round bottom or V-grooves with light tension for low-power drive elements. Special compounds are available with high resistance to stress relaxation and fatigue for these applications. Best service is obtained in drive belt applications when the initial belt tension is between 80 and 200 psi and the initial installed stretch is between 8 and 25 per cent of the circumferential length. Most of the compounds used for drive belts operate best between 10 and 15 per cent stretch, although polyurethane has good service life when stretched as much as 20 to 25 per cent.

**Table 3. Typical O-Ring Compounds**

|                            |  |
|----------------------------|--|
| Nitrile                    | General-purpose compound for use with most petroleum oils, greases, gasoline, alcohols and glycols, LP gases, propane and butane fuels. Also for food service to resist vegetable and animal fats. Effective temperature range is about $-40^{\circ}$ to $250^{\circ}$ F. Excellent compression set, tear and abrasion resistance, but poor resistance to ozone, sunlight and weather. Higher-temperature nitrile compounds with similar properties are also available.  |
| Hydrogenated Nitrile       | Similar to general-purpose nitrile compounds with improved high-temperature performance, resistance to aging, and petroleum product compatibility.   |
| Polychloroprene (Neoprene) | General-purpose compound with low compression set and good resistance to elevated temperatures. Good resistance to sunlight, ozone, and weathering, and fair oil resistance. Frequently used for refrigerator gases such as Freon. Effective temperature range is about $-40^{\circ}$ to $250^{\circ}$ F.  |
| Ethylene Propylene         | General-purpose compound with excellent resistance to polar fluids such as water, steam, ketones, and phosphate esters, and brake fluids, but not resistant to petroleum oils and solvents. Excellent resistance to ozone and flexing. Recommended for belt-drive applications. Continuous duty service in temperatures up to $250^{\circ}$ F.   |
| Silicon                    | Widest temperature range ( $-150^{\circ}$ to $500^{\circ}$ F) and best low-temperature flexibility of all elastomeric compounds. Not recommended for dynamic applications, due to low strength, or for use with most petroleum oils. Shrinkage characteristics similar to organic rubber, allowing existing molds to be used.  |
| Polyurethane               | Toughest of the elastomers used for O-rings, characterized by high tensile strength, excellent abrasion resistance, and tear strength. Compression set and heat resistance are inferior to nitrile. Suitable for hydraulic applications that anticipate abrasive contaminants and shock loads. Temperature service range of $-65^{\circ}$ to $212^{\circ}$ F.  |
| Fluorosilicone             | Wide temperature range ( $-80^{\circ}$ to $450^{\circ}$ F) for continuous duty and excellent resistance to petroleum oils and fuels. Recommended for static applications only, due to limited strength and low abrasion resistance.  |
| Polyacrylate               | Heat resistance better than nitrile compounds, but inferior low temperature, compression set, and water resistance. Often used in power steering and transmission applications due to excellent resistance to oil, automatic transmission fluids, oxidation, and flex cracking. Temperature service range of $-20^{\circ}$ to $300^{\circ}$ F.   |
| Fluorocarbon (Viton)       | General-purpose compound suitable for applications requiring resistance to aromatic or halogenated solvents or to high temperatures ( $-20^{\circ}$ to $500^{\circ}$ F with limited service to $600^{\circ}$ F). Outstanding resistance to blended aromatic fuels, straight aromatics, and halogenated hydrocarbons and other petroleum products. Good resistance to strong acids (temperature range in acids $-20^{\circ}$ to $250^{\circ}$ F), but not effective for use with very hot water, steam, and brake fluids. |

**Ring Materials.**—Thousands of O-ring compounds have been formulated for specific applications. Some of the most common types of compounds and their typical applications are given in [Table 3](#). The Shore A durometer is the standard instrument used for measuring the hardness of elastomeric compounds. The softest O-rings are 50 and 60 Shore A and stretch more easily, exhibit lower breakout friction, seal better on rough surfaces, and need less clamping pressure than harder rings. For a given squeeze, the higher the durometer hardness of a ring, the greater the associated friction because a greater compressive force is exerted by hard rings than soft rings.

The most widely used rings are medium-hard O-rings with 70 Shore A hardness, which have the best wear resistance and frictional properties for running seals. Applications that involve oscillating or rotary motion frequently use 80 Shore A materials. Rings with a hardness above 85 Shore A often leak more because of less effective wiping action. These harder rings have a greater resistance to extrusion, but for small sizes may break easily during installation. O-ring hardness varies inversely with temperature, but when used for continuous service at high temperatures, the hardness may eventually increase after an initial softening of the compound.

O-ring compounds have thermal coefficients of expansion in the range of 7 to 20 times that of metal components, so shrinkage or expansion with temperature change can pose problems of leakage past the seal at low temperatures and excessive pressures at high temperatures when a ring is installed in a tight-fitting groove. Likewise, when an O-ring is immersed in a fluid, the compound usually absorbs some of the fluid and consequently increases in volume. Manufacturer's data give volumetric increase data for compounds completely immersed in various fluids. For confined rings (those with only a portion of the ring exposed to fluid), the size increase may be considerably lower than for rings completely immersed in fluid. Certain fluids can also cause ring shrinkage during "idle" periods, i.e., when the seal has a chance to dry out. If this shrinkage is more than 3 to 4 per cent, the seal may leak.

Excessive swelling due to fluid contact and high temperatures softens all compounds approximately 20 to 30 Shore A points from room temperature values and designs should anticipate the expected operating conditions. At low temperatures, swelling may be beneficial because fluid absorption may make the seal more flexible. However, the combination of low temperature and low pressure makes a seal particularly difficult to maintain. A soft compound should be used to provide a resilient seal at low temperatures. Below  $-65^{\circ}\text{F}$ , only compounds formulated with silicone are useful; other compounds are simply too stiff, especially for use with air and other gases.

Compression set is another material property and a very important sealing factor. It is a measure of the shape memory of the material, that is, the ability to regain shape after being deformed. Compression set is a ratio, expressed as a percentage, of the unrecovered to original thickness of an O-ring compressed for a specified period of time between two heated plates and then released. O-rings with excessive compressive set will fail to maintain a good seal because, over time, the ring will be unable to exert the necessary compressive force (squeeze) on the enclosing walls. Swelling of the ring due to fluid contact tends to increase the squeeze and may partially compensate for the loss due to compression set. Generally, compression set varies by compound and ring cross-sectional diameter, and increases with the operating temperature.

## ROLLED STEEL SECTIONS, WIRE, AND SHEET-METAL GAGES

### Rolled Steel Sections

**Lengths of Angles Bent to Circular Shape.**—To calculate the length of an angle-iron used either inside or outside of a tank or smokestack, the following table of constants may be used: Assume, for example, that a stand-pipe, 20 feet inside diameter, is provided with a 3 by 3 by  $\frac{3}{8}$  inch angle-iron on the inside at the top. The circumference of a circle 20 feet in diameter is 754 inches. From the table of constants, find the constant for a 3 by 3 by  $\frac{3}{8}$  inch angle-iron, which is 4.319. The length of the angle then is  $754 - 4.319 = 749.681$  inches. Should the angle be on the outside, add the constant instead of subtracting it; thus,  $754 + 4.319 = 758.319$  inches.

| Size of Angle  | Const. | Size of Angle   | Const. | Size of Angle                   | Const. |
|--|--------|---|--------|---------------------------------|--------|
| $\frac{1}{4} \times 2 \times 2$                        | 2.879  | $\frac{5}{16} \times 3 \times 3$                      | 4.123  | $\frac{1}{2} \times 5 \times 5$ | 6.804  |
| $\frac{5}{16} \times 2 \times 2$                       | 3.076  | $\frac{3}{8} \times 3 \times 3$                       | 4.319  | $\frac{3}{8} \times 6 \times 6$ | 7.461  |
| $\frac{3}{8} \times 2 \times 2$                        | 3.272  | $\frac{1}{2} \times 3 \times 3$                       | 4.711  | $\frac{1}{2} \times 6 \times 6$ | 7.854  |
| $\frac{1}{4} \times 2\frac{1}{2} \times 2\frac{1}{2}$  | 3.403  | $\frac{3}{8} \times 3\frac{1}{2} \times 3\frac{1}{2}$ | 4.843  | $\frac{3}{4} \times 6 \times 6$ | 8.639  |
| $\frac{5}{16} \times 2\frac{1}{2} \times 2\frac{1}{2}$ | 3.600  | $\frac{1}{2} \times 3\frac{1}{2} \times 3\frac{1}{2}$ | 5.235  | $\frac{1}{2} \times 8 \times 8$ | 9.949  |
| $\frac{3}{8} \times 2\frac{1}{2} \times 2\frac{1}{2}$  | 3.796  | $\frac{3}{8} \times 4 \times 4$                       | 5.366  | $\frac{3}{4} \times 8 \times 8$ | 10.734 |
| $\frac{1}{2} \times 2\frac{1}{2} \times 2\frac{1}{2}$  | 4.188  | $\frac{1}{2} \times 4 \times 4$                       | 5.758  | $1 \times 8 \times 8$           | 11.520 |
| $\frac{1}{4} \times 3 \times 3$                        | 3.926  | $\frac{3}{8} \times 5 \times 5$                       | 6.414  | ...                             | ...    |

**Standard Designations of Rolled Steel Shapes.**—Through a joint effort, the American Iron and Steel Institute (AISI) and the American Institute of Steel Construction (AISC) have changed most of the designations for their hot-rolled structural steel shapes. The present designations, standard for steel producing and fabricating industries, should be used when designing, detailing, and ordering steel. The accompanying Table 1 compares the present designations with the previous descriptions.

**Table 1. Hot-Rolled Structural Steel Shape Designations (AISI and AISC)**

| Present Designation                    | Type of Shape                   | Previous Designation                   |
|--|---------------------------------|--|
| W 24 × 76                              | W shape                         | 24 WF 76                               |
| W 14 × 26                              | W shape                         | 14 B 26                                |
| S 24 × 100                             | S shape                         | 24 I 100                               |
| M 8 × 18.5                             | M shape                         | 8 M 18.5                               |
| M 10 × 9                               | M shape                         | 10 JR 9.0                              |
| M 8 × 34.3                             | M shape                         | 8 × 8 M 34.3                           |

Table 2a. Steel Wide-Flange Sections

Wide-flange sections are designated, in order, by a section letter, nominal depth of the member in inches, and the nominal weight in pounds per foot; thus:

**W 18 × 64**

indicates a wide-flange section having a nominal depth of 18 inches, and a nominal weight per foot of 64 pounds. Actual geometry for each section can be obtained from the values below.

| Designation       | Area, A<br>inch <sup>2</sup> | Depth, d<br>inch | Flange                        |                                   | Web Thickness, t <sub>w</sub><br>inch | Axis X-X               |                        |           | Axis Y-Y               |                        |           |
|-------------------|------------------------------|------------------|-------------------------------|-----------------------------------|---------------------------------------|------------------------|------------------------|-----------|------------------------|------------------------|-----------|
|                   |                              |                  | Width, b <sub>f</sub><br>inch | Thickness, t <sub>f</sub><br>inch |                                       | I<br>inch <sup>4</sup> | S<br>inch <sup>3</sup> | r<br>inch | I<br>inch <sup>4</sup> | S<br>inch <sup>3</sup> | r<br>inch |

Consult the AISC Manual, noted above, for W steel shapes having nominal depths greater than 27 inches.

Symbols: I = moment of inertia; S = section modulus; r = radius of gyration.

Data taken from the "Manual of Steel Construction," 8th Edition, 1980, with permission of the American Institute of Steel Construction.

Table 2b. Steel Wide-Flange Sections

Wide-flange sections are designated, in order, by a section letter, nominal depth of the member in inches, and the nominal weight in pounds per foot. Thus:  
**W 16 × 78**  
 indicates a wide-flange section having a nominal depth of 16 inches, and a nominal weight per foot of 78 pounds. Actual geometry for each section can be obtained from the values below.

| Designation | Area, $A$<br>inch <sup>2</sup> | Depth, $d$<br>inch | Flange               |                          | Web Thickness, $t_w$<br>inch | Axis X-X                 |                          |             | Axis Y-Y                 |                          |             |
|-------------|--------------------------------|--------------------|----------------------|--------------------------|------------------------------|--------------------------|--------------------------|-------------|--------------------------|--------------------------|-------------|

Table 2c. Steel Wide-Flange Sections

Wide-flange sections are designated, in order, by a section letter, nominal depth of the member in inches, and the nominal weight in pounds per foot. Thus:

**W 14 × 38**
