## Solution of Oblique-Angled Triangles

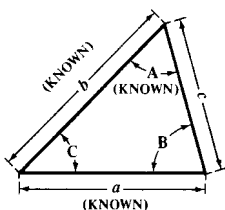

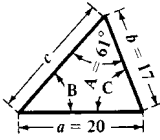

## One Side and Two Angles Known (Law of Sines):

|   |  |
|---|--|
|  <p>One Side and Two Angles Known</p> | <p>Call the known side <math>a</math>, the angle opposite it <math>A</math>, and the other known angle <math>B</math>. Then, <math>C = 180^\circ - (A + B)</math>. If angles <math>B</math> and <math>C</math> are given, but not <math>A</math>, then <math>A = 180^\circ - (B + C)</math>.</p> $C = 180^\circ - (A + B)$ $b = \frac{a \times \sin B}{\sin A} \quad c = \frac{a \times \sin C}{\sin A}$ $\text{Area} = \frac{a \times b \times \sin C}{2}$                      |
|  <p>Side and Angles Known</p>         | <p><math>a = 5</math> centimeters; <math>A = 80^\circ</math>; <math>B = 62^\circ</math></p> $C = 180^\circ - (80^\circ + 62^\circ) = 180^\circ - 142^\circ = 38^\circ$ $b = \frac{a \times \sin B}{\sin A} = \frac{5 \times \sin 62^\circ}{\sin 80^\circ} = \frac{5 \times 0.88295}{0.98481}$ $= 4.483 \text{ centimeters}$ $c = \frac{a \times \sin C}{\sin A} = \frac{5 \times \sin 38^\circ}{\sin 80^\circ} = \frac{5 \times 0.61566}{0.98481}$ $= 3.126 \text{ centimeters}$ |

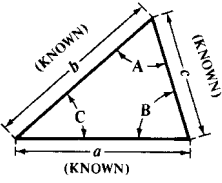

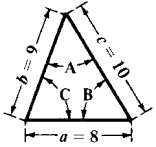

## Two Sides and the Angle Between Them Known:

|   |  |
|---|--|
|  <p>Two Sides and the Angle Between Them Known</p> | <p>Call the known sides <math>a</math> and <math>b</math>, and the known angle between them <math>C</math>. Then,</p> $\tan A = \frac{a \times \sin C}{b - (a \times \cos C)}$ $B = 180^\circ - (A + C) \quad c = \frac{a \times \sin C}{\sin A}$ <p>Side <math>c</math> may also be found directly as below:</p> $c = \sqrt{a^2 + b^2 - (2ab \times \cos C)}$ $\text{Area} = \frac{a \times b \times \sin C}{2}$  |
|  <p>Sides and Angle Known</p>                     | <p><math>a = 9</math> inches; <math>b = 8</math> inches; <math>C = 35^\circ</math>.</p> $\tan A = \frac{a \times \sin C}{b - (a \times \cos C)} = \frac{9 \times \sin 35^\circ}{8 - (9 \times \cos 35^\circ)}$ $= \frac{9 \times 0.57358}{8 - (9 \times 0.81915)} = \frac{5.16222}{0.62765} = 8.22468$ <p>Hence, <math>A = 83^\circ 4'</math></p> $B = 180^\circ - (A + C) = 180^\circ - 118^\circ 4' = 61^\circ 56'$ $c = \frac{a \times \sin C}{\sin A} = \frac{9 \times 0.57358}{0.99269} = 5.2 \text{ inches}$ |

## Two Sides and the Angle Opposite One of the Sides Known:

|   |  |
|---|--|
|  <p>Two Sides and the Angle Opposite One of the Sides Known</p> | <p>Call the known angle <math>A</math>, the side opposite it <math>a</math>, and the other known side <math>b</math>. Then,</p> $\sin B = \frac{b \times \sin A}{a} \quad C = 180^\circ - (A + B)$ $c = \frac{a \times \sin C}{\sin A} \quad \text{Area} = \frac{a \times b \times \sin C}{2}$ <p>If, in the above, angle <math>B &gt; \text{angle } A</math> but <math>&lt; 90^\circ</math>, then a second solution <math>B_2, C_2, c_2</math> exists for which: <math>B_2 = 180^\circ - B</math>; <math>C_2 = 180^\circ - (A + B_2)</math>; <math>c_2 = (a \times \sin C_2) \div \sin A</math>; area = <math>(a \times b \times \sin C_2) \div 2</math>. If <math>a \geq b</math>, then the first solution only exists. If <math>a &lt; b \times \sin A</math>, then no solution exists.</p> |
|  <p>Sides and Angle Known</p>                                  | <p><math>a = 20</math> centimeters; <math>b = 17</math> centimeters; <math>A = 61^\circ</math>.</p> $\sin B = \frac{b \times \sin A}{a} = \frac{17 \times \sin 61^\circ}{20}$ $= \frac{17 \times 0.87462}{20} = 0.74343$ <p>Hence, <math>B = 48^\circ 1'</math></p> $C = 180^\circ - (A + B) = 180^\circ - 109^\circ 1' = 70^\circ 59'$ $c = \frac{a \times \sin C}{\sin A} = \frac{20 \times \sin 70^\circ 59'}{\sin 61^\circ} = \frac{20 \times 0.94542}{0.87462}$ $= 21.62 \text{ centimeters}$   |

## All Three Sides are Known:

|  |  |
|--|--|
|  <p>All Three Sides Known</p>   | <p>Call the sides <math>a, b</math>, and <math>c</math>, and the angles opposite them, <math>A, B</math>, and <math>C</math>. Then,</p> $\cos A = \frac{b^2 + c^2 - a^2}{2bc} \quad \sin B = \frac{b \times \sin A}{a}$ $C = 180^\circ - (A + B) \quad \text{Area} = \frac{a \times b \times \sin C}{2}$   |
|  <p>Sides and Angle Known</p> | <p><math>a = 8</math> inches; <math>b = 9</math> inches; <math>c = 10</math> inches.</p> $\cos A = \frac{b^2 + c^2 - a^2}{2bc} = \frac{9^2 + 10^2 - 8^2}{2 \times 9 \times 10}$ $= \frac{81 + 100 - 64}{180} = \frac{117}{180} = 0.65000$ <p>Hence, <math>A = 49^\circ 27'</math></p> $\sin B = \frac{b \times \sin A}{a} = \frac{9 \times 0.75984}{8} = 0.85482$ <p>Hence, <math>B = 58^\circ 44'</math></p> $C = 180^\circ - (A + B) = 180^\circ - 108^\circ 11' = 71^\circ 49'$ |

ANGULAR CONVERSIONS

**Conversion Tables of Angular Measure.**—The accompanying tables of degrees, minutes, and seconds into radians; radians into degrees, minutes, and seconds; radians into degrees and decimals of a degree; and minutes and seconds into decimals of a degree and vice versa facilitate the conversion of measurements.

*Example 1:* The Degrees, Minutes, and Seconds into Radians table is used to find the number of radians in 324 degrees, 25 minutes, 13 seconds as follows:

|             |                    |
|-------------|--------------------|
| 300 degrees | = 5.235988 radians |
| 20 degrees  | = 0.349066 radian  |
| 4 degrees   | = 0.069813 radian  |
| 25 minutes  | = 0.007272 radian  |
| 13 seconds  | = 0.000063 radian  |
| 324°25'13"  | = 5.662202 radians |

*Example 2:* The Radians into Degrees and Decimals of a Degree, and Radians into Degrees, Minutes and Seconds tables are used to find the number of decimal degrees or degrees, minutes and seconds in 0.734 radian as follows:

|                                |                                      |
|--------------------------------|--------------------------------------|
| 0.7 radian = 40.1070 degrees   | 0.7 radian = 40° 6'25"               |
| 0.03 radian = 1.7189 degrees   | 0.03 radian = 1°43'8"                |
| 0.004 radian = 0.2292 degree   | 0.004 radian = 0°13'45"              |
| 0.734 radian = 42.0551 degrees | 0.734 radian = 41°62'78" or 42°3'18" |

**Degrees, Minutes, and Seconds into Radians (Based on 180 degrees = π radians)**

| Degrees into Radians |            |      |           |      |          |      |          |      |          |

|                                   |        |      |        |                                   |        | 57   | 0.0158 |
|                                   |        |      |        |                                   |        | 58   | 0.0161 |
|                                   |        |      |        |                                   |        | 59   | 0.0164 |
|                                   |        |      |        |                                   |        | 60   | 0.0167 |

*Example 3:* Convert 11°37" to decimals of a degree. From the left table, 11° = 0.1833 degree. From the right table, 37" = 0.0103 degree. Adding, 11°37" = 0.1833 + 0.0103 = 0.1936 degree.

*Example 4:* Convert 0.1234 degree to minutes and seconds. From the left table, 0.1167 degree = 7'. Subtracting 0.1167 from 0.1234 gives 0.0067. From the right table, 0.0067 = 24" so that 0.1234 = 7°24".

## SOLUTION OF TRIANGLES

Fig. 1. Signs of Trigonometric Functions, Fractions of  $\pi$ , and Degree-Radian Conversion

**Graphic Illustrations of the Functions of Angles.**—In graphically illustrating the functions of angles, it is assumed that all distances measured in the horizontal direction to the right of line  $AB$  are positive. Those measured horizontally to the left of  $AB$  are negative. All distances measured vertically, are positive above line  $CD$  and negative below it. It can then be readily seen that the sine is positive for all angles less than 180 degrees. For angles larger than 180 degrees, the sine would be measured below  $CD$ , and is negative. The cosine is positive up to 90 degrees, but for angles larger than 90 but less than 270 degrees, the cosine is measured to the left of line  $AB$  and is negative.

The table *Useful Relationships Among Angles* that follows is arranged to show directly whether the function of any given angle is positive or negative. It also gives the limits between which the numerical values of the function vary. For example, it will be seen from the table that the cosine of an angle between 90 and 180 degrees is negative, and that its value will be somewhere between 0 and  $-1$ . In the same way, the cotangent of an angle between 180 and 270 degrees is positive and has a value between infinity and 0; in other words, the cotangent for 180 degrees is infinitely large and then the cotangent gradually decreases for increasing angles, so that the cotangent for 270 degrees equals 0.

The sine is positive for all angles up to 180 degrees. The cosine, tangent and cotangent for angles between 90 and 180 degrees, while they have the same numerical values as for angles from 0 to 90 degrees, are negative. These should be preceded by a minus sign; thus  $\tan 123$  degrees 20 minutes  $= -1.5204$ .

Graphic Illustration of the Functions of Angles

**Tables of Trigonometric Functions.**—The trigonometric (trig) tables on the following pages give numerical values for sine, cosine, tangent, and cotangent functions of angles from 0 to 90 degrees. Function values for all other angles can be obtained from the tables by applying the rules for signs of trigonometric functions and the useful relationships among angles given in the following. Secant and cosecant functions can be found from  $\sec A = 1/\cos A$  and  $\csc A = 1/\sin A$ .

The trig tables are divided by a double line. The body of each half table consists of four labeled columns of data between columns listing angles. The angles listed to the left of the data increase moving down the table, and angles listed to the right of the data increase moving up the table. Labels above the data identify the trig functions corresponding to angles listed in the left column of each half table. Labels below the data correspond to angles listed in the right column of each half table. To find the value of a function for a particular angle, first locate the angle in the table, then find the appropriate function label across the top or bottom row of the table, and find the function value at the intersection of the angle row and label column. Angles opposite each other are complementary angles (i.e., their sum equals  $90^\circ$ ) and related. For example,  $\sin 10^\circ = \cos 80^\circ$  and  $\cos 10^\circ = \sin 80^\circ$ .

All the trig functions of angles between  $0^\circ$  and  $90^\circ$  have positive values. For other angles, consult the chart below to find the sign of the function in the quadrant where the angle is located. To determine trig functions of angles greater than  $90^\circ$  subtract 90, 180, 270, or 360 from the angle to get an angle less than  $90^\circ$  and use Table 1 to find the equivalent first-quadrant function and angle to look up in the trig tables.

**Table 1. Useful Relationships Among Angles**

| Angle Function | $\theta$      | $-\theta$      | $90^\circ \pm \theta$ | $180^\circ \pm \theta$ | $270^\circ \pm \theta$ | $360^\circ \pm \theta$ |
|----------------|---------------|----------------|-----------------------|------------------------|------------------------|------------------------|
| sin            | $\sin \theta$ | $-\sin \theta$ | $+\cos \theta$        | $\mp \sin \theta$      | $-\cos \theta$         | $\pm \sin \theta$      |
| cos            | $\cos \theta$ | $+\cos \theta$ | $\mp \sin \theta$     | $-\cos \theta$         | $\pm \sin \theta$      | $+\cos \theta$         |
| tan            | $\tan \theta$ | $-\tan \theta$ | $\mp \cot \theta$     | $\pm \tan \theta$      | $\mp \cot \theta$      | $\pm \tan \theta$      |
| cot            | $\cot \theta$ | $-\cot \theta$ | $\mp \tan \theta$     | $\pm \cot \theta$      | $\mp \tan \theta$      | $\pm \cot \theta$      |
| sec            | $\sec \theta$ | $+\sec \theta$ | $\mp \csc \theta$     | $-\sec \theta$         | $\pm \csc \theta$      | $+\sec \theta$         |
| csc            | $\csc \theta$ | $-\csc \theta$ | $+\sec \theta$        | $\mp \csc \theta$      | $-\sec \theta$         | $\pm \csc \theta$      |

Examples:  $\cos (270^\circ - \theta) = -\sin \theta$ ;  $\tan (90^\circ + \theta) = -\cot \theta$ .

**Example:** Find the cosine of  $336^\circ 40'$ . The diagram in *Signs of Trigonometric Functions, Fractions of  $p$ , and Degree–Radian Conversion* shows that the cosine of every angle in Quadrant IV ( $270^\circ$  to  $360^\circ$ ) is positive. To find the angle and trig function to use when entering the trig table, subtract 270 from 336 to get  $\cos 336^\circ 40' = \cos (270^\circ + 66^\circ 40')$  and then find the intersection of the cos row and the  $270 \pm \theta$  column in Table 1. Because  $\cos (270 \pm \theta)$  in the fourth quadrant is equal to  $\pm \sin \theta$  in the first quadrant, find  $\sin 66^\circ 40'$  in the trig table. Therefore,  $\cos 336^\circ 40' = \sin 66^\circ 40' = 0.918216$ .

|        | cos      | sin      | cot      | tan      | Angle   |        | cos      | sin      | cot      | tan      | Angle   |

For angles 0° to 15° 0' (angles found in a column to the left of the data), use the column labels at the top of the table; for angles 75° to 90° 0' (angles found in a column to the right of the data), use the column labels at the bottom of the table.

## Trigonometric Functions of Angles from 15° to 30° and 60° to 75°

| 10      | 0.604136 | 0.796882 | 0.758125 | 1.319044 |       | 50      | 0.702981 | 0.711209 | 0.988432 | 1.011704 | 20      |
| 20      | 0.606451 | 0.795121 | 0.762716 | 1.311105 |       | 40      | 0.705047 | 0.709161 | 0.994199 | 1.005835 | 10      |
| 37° 30' | 0.608761 | 0.793353 | 0.767327 | 1.303225 |       | 52° 30' | 0.707107 | 0.707107 | 1.000000 | 1.000000 | 45° 0'  |
|         | cos      | sin      | cot      | tan      | Angle |         | cos      | sin      | cot      | tan      | Angle   |

For angles 30° to 45° 0' (angles found in a column to the left of the data), use the column labels at the top of the table; for angles 45° to 60° 0' (angles found in a column to the right of the data), use the column labels at the bottom of the table.

**Using a Calculator to Find Trig Functions.**—A scientific calculator is quicker and more accurate than tables for finding trig functions and angles corresponding to trig functions. On scientific calculators, the keys labeled **sin**, **cos**, and **tan** are used to find the common trig functions. The other functions can be found by using the same keys and the **1/x** key, noting that  $\csc A = 1/\sin A$ ,  $\sec A = 1/\cos A$ , and  $\cot A = 1/\tan A$ . The specific keystrokes used will vary slightly from one calculator to another. To find the angle corresponding to a given trig function use the keys labeled **sin<sup>-1</sup>**, **cos<sup>-1</sup>**, and **tan<sup>-1</sup>**. On some other calculators, the **sin**, **cos**, and **tan** are used in combination with the **INV**, or inverse, key to find the number corresponding to a given trig function.

If a scientific calculator or computer is not available, tables are the easiest way to find trig values. However, trig function values can be calculated very accurately without a scientific calculator by using the following formulas:

$$\begin{aligned}\sin A &= A - \frac{A^3}{3!} + \frac{A^5}{5!} - \frac{A^7}{7!} \pm \dots & \cos A &= 1 - \frac{A^2}{2!} + \frac{A^4}{4!} - \frac{A^6}{6!} \pm \dots \\ \sin^{-1} A &= \frac{1}{2} \times \frac{A^3}{3} + \frac{1}{2} \times \frac{3}{4} \times \frac{A^5}{5} + \dots & \tan^{-1} A &= A - \frac{A^3}{3} + \frac{A^5}{5} - \frac{A^7}{7} \pm \dots\end{aligned}$$

where the angle  $A$  is expressed in radians (convert degrees to radians by multiplying degrees by  $\pi/180 = 0.0174533$ ). The three dots at the ends of the formulas indicate that the expression continues with more terms following the sequence established by the first few terms. Generally, calculating just three or four terms of the expression is sufficient for accuracy. In these formulas, a number followed by the symbol **!** is called a factorial (for example,  $3!$  is three factorial). Except for  $0!$ , which is defined as 1, a factorial is found by multiplying together all the integers greater than zero and less than or equal to the factorial number wanted. For example:  $3! = 1 \times 2 \times 3 = 6$ ;  $4! = 1 \times 2 \times 3 \times 4 = 24$ ;  $7! = 1 \times 2 \times 3 \times 4 \times 5 \times 6 \times 7 = 5040$ ; etc.

**Versed Sine and Versed Cosine.**—These functions are sometimes used in formulas for segments of a circle and may be obtained using the relationships:

$$\text{versed } \sin \theta = 1 - \cos \theta; \text{ versed } \cos \theta = 1 - \sin \theta.$$

**Sevolute Functions.**—Sevolute functions are used in calculating the form diameter of involute splines. They are computed by subtracting the involute function of an angle from the secant of the angle ( $1/\cosine = \text{secant}$ ). Thus, sevolute of 20 degrees = secant of 20 degrees - involute function of 20 degrees =  $1.064178 - 0.014904 = 1.049274$ .

**Involute Functions.**—Involute functions are used in certain formulas relating to the design and measurement of gear teeth as well as measurement of threads over wires. See, for example, pages 1901 through 1904, 2111, and 2175.

The tables on the following pages provide values of involute functions for angles from 14 to 51 degrees in increments of 1 minute. These involute functions were calculated from the following formulas: Involute of  $\theta = \tan \theta - \theta$ , for  $\theta$  in radians, and involute of  $\theta = \tan \theta - \pi \times \theta/180$ , for  $\theta$  in degrees.

*Example:* For an angle of 14 degrees and 10 minutes, the involute function is found as follows: 10 minutes =  $10/60 = 0.166666$  degrees,  $14 + 0.166666 = 14.166666$  degree, so that the involute of 14.166666 degrees =  $\tan 14.166666 - \pi \times 14.166666/180 = 0.252420 - 0.247255 = 0.005165$ . This value is the same as that in the table *Involute Functions for Angles from 14 to 23 Degrees* for 14 degrees and 10 minutes. The same result would be obtained from using the conversion tables beginning on page 96 to convert 14 degrees and 10 minutes to radians and then applying the first of the formulas given above.

## INVOLUTE FUNCTIONS

## Involute Functions for Angles from 14 to 23 Degrees

| Minutes | Degrees            |          |          |          |          |          |          |          |          |
|---------|--------------------|----------|----------|----------|----------|----------|----------|----------|----------|
|         | 14                 | 15       | 16       | 17       | 18       | 19       | 20       | 21       | 22       |

## Compound Angles

Three types of compound angles are illustrated by Figs. 1 through 6. The first type is shown in Figs. 1, 2, and 3; the second in Fig. 4; and the third in Figs. 5 and 6.

In Fig. 1 is shown what might be considered as a thread-cutting tool without front clearance.  $A$  is a known angle in plane  $y-y$  of the top surface.  $C$  is the corresponding angle in plane  $x-x$  that is at some given angle  $B$  with plane  $y-y$ . Thus, angles  $A$  and  $B$  are components of the compound angle  $C$ .

*Example Problem Referring to Fig. 1:* Angle  $2A$  in plane  $y-y$  is known, as is also angle  $B$  between planes  $x-x$  and  $y-y$ . It is required to find compound angle  $2C$  in plane  $x-x$ .

*Solution:* Let  $2A = 60$  and  $B = 15$

$$\begin{aligned} \text{Then} \quad \tan C &= \tan A \cos B = \tan 30 \cos 15 \\ \tan C &= 0.57735 \times 0.96592 = 0.55767 \\ C &= 29 \text{ } 8.8' & 2C &= 58 \text{ } 17.6' \end{aligned}$$

Fig. 2 shows a thread-cutting tool with front clearance angle  $B$ . Angle  $A$  equals one-half the angle between the cutting edges in plane  $y-y$  of the top surface and compound angle  $C$  is one-half the angle between the cutting edges in a plane  $x-x$  at right angles to the inclined front edge of the tool. The angle between planes  $y-y$  and  $x-x$  is, therefore, equal to clearance angle  $B$ .

*Example Problem Referring to Fig. 2:* Find the angle  $2C$  between the front faces of a thread-cutting tool having a known clearance angle  $B$ , which will permit the grinding of these faces so that their top edges will form the desired angle  $2A$  for cutting the thread.

*Solution:* Let  $2A = 60$  and  $B = 15$

$$\begin{aligned} \text{Then} \quad \tan C &= \frac{\tan A}{\cos B} = \frac{\tan 30^\circ}{\cos 15^\circ} = \frac{0.57735}{0.96592} \\ \tan C &= 0.59772 \\ C &= 30 \text{ } 52' & 2C &= 61 \text{ } 44' \end{aligned}$$

In Fig. 3 is shown a form-cutting tool in which the angle  $A$  is one-half the angle between the cutting edges in plane  $y-y$  of the top surface;  $B$  is the front clearance angle; and  $C$  is one-half the angle between the cutting edges in plane  $x-x$  at right angles to the front edges of the tool. The formula for finding angle  $C$  when angles  $A$  and  $B$  are known is the same as that for Fig. 2.

*Example Problem Referring to Fig. 3:* Find the angle  $2C$  between the front faces of a form-cutting tool having a known clearance angle  $B$  that will permit the grinding of these faces so that their top edges will form the desired angle  $2A$  for form cutting.

*Solution:* Let  $2A = 46$  and  $B = 12$

$$\begin{aligned} \text{Then} \quad \tan C &= \frac{\tan A}{\cos B} = \frac{\tan 23^\circ}{\cos 12^\circ} = \frac{0.42447}{0.97815} \\ \tan C &= 0.43395 \\ C &= 23 \text{ } 27.5' & 2C &= 46 \text{ } 55' \end{aligned}$$

In Fig. 4 is shown a wedge-shaped block, the top surface of which is inclined at compound angle  $C$  with the base in a plane at right angles with the base and at angle  $R$  with the front edge. Angle  $A$  in the vertical plane of the front of the plate and angle  $B$  in the vertical plane of one side that is at right angles to the front are components of angle  $C$ .

*Example Problem Referring to Fig. 4:* Find the compound angle  $C$  of a wedge-shaped block having known component angles  $A$  and  $B$  in sides at right angles to each other.

Formulas for Compound Angles

$C$  = compound angle in plane  $x-x$  and is the resultant of angles  $A$  and  $B$

*Solution:* Let  $A = 47^{\circ}14'$  and  $B = 38^{\circ}10'$

Then

$$\tan R = \frac{\tan B}{\tan A} = \frac{\tan 38^{\circ}10'}{\tan 47^{\circ}14'} = \frac{0.78598}{1.0812} = 0.72695 \quad R = 36^{\circ}09'$$

$$\tan C = \frac{\tan A}{\cos R} = \frac{\tan 47^{\circ}14'}{\cos 36^{\circ}09'} = \frac{1.0812}{0.80887} = 1.3367 \quad C = 53^{\circ}12'$$

In Fig. 5 is shown a four-sided block, two sides of which are at right angles to each other and to the base of the block. The other two sides are inclined at an oblique angle with the base. Angle  $C$  is a compound angle formed by the intersection of these two inclined sides and the intersection of a vertical plane passing through  $x-x$ , and the base of the block. The components of angle  $C$  are angles  $A$  and  $B$  and angle  $R$  is the angle in the base plane of the block between the plane of angle  $C$  and the plane of angle  $A$ .

*Example Problem Referring to Fig. 5:* Find the angles  $C$  and  $R$  in the block shown in Fig. 5 when angles  $A$  and  $B$  are known.

*Solution:* Let angle  $A = 27^{\circ}$  and  $B = 36^{\circ}$

Then

$$\cot C = \sqrt{\cot^2 A + \cot^2 B} = \sqrt{1.9626^2 + 1.3764^2} = \sqrt{5.74627572} = 2.3971$$

$$C = 22^{\circ}38.6'$$

$$\tan R = \frac{\cot B}{\cot A} = \frac{\cot 36^{\circ}}{\cot 27^{\circ}} = \frac{1.3764}{1.9626} = 0.70131 \quad R = 35^{\circ}2.5'$$

*Example Problem Referring to Fig. 6:* A rod or pipe is inserted into a rectangular block at an angle. Angle  $C_1$  is the compound angle of inclination (measured from the vertical) in a plane passing through the center line of the rod or pipe and at right angles to the top surface of the block. Angles  $A_1$  and  $B_1$  are the angles of inclination of the rod or pipe when viewed respectively in the front and side planes of the block. Angle  $R$  is the angle between the plane of angle  $C_1$  and the plane of angle  $B_1$ . Find angles  $C_1$  and  $R$  when a rod or pipe is inclined at known angles  $A_1$  and  $B_1$ .

*Solution:* Let  $A_1 = 39^{\circ}$  and  $B_1 = 34^{\circ}$

Then

$$\tan C_1 = \sqrt{\tan^2 A_1 + \tan^2 B_1} = \sqrt{0.80978^2 + 0.67451^2} = 1.0539$$

$$C_1 = 46^{\circ}30.2'$$

$$\tan R = \frac{\tan A_1}{\tan B_1} = \frac{0.80978}{0.67451} = 1.2005 \quad R = 50^{\circ}12.4'$$

**Interpolation.**—In mathematics, interpolation is the process of finding a value in a table or in a mathematical expression which falls between two given tabulated or known values. In engineering handbooks, the values of trigonometric functions are usually given to degrees and minutes; hence, if the given angle is to degrees, minutes and seconds, the value of the function is determined from the nearest given values, by interpolation.

*Interpolation to Find Functions of an Angle:* Assume that the sine of  $14^{\circ}22'26''$  is to be determined. It is evident that this value lies between the sine of  $14^{\circ}22'$  and the sine of  $14^{\circ}23'$ . Sine  $14^{\circ}23' = 0.24841$  and sine  $14^{\circ}22' = 0.24813$ . The difference =  $0.24841 - 0.24813 = 0.00028$ . Consider this difference as a whole number (28) and multiply it by a fraction having as its numerator the number of seconds (26) in the given angle, and as its denominator 60 (number of seconds in one minute). Thus  $\frac{26}{60} \times 28 = 12$  nearly; hence, by adding 0.00012 to sine of  $14^{\circ}22'$  we find that sine  $14^{\circ}22'26'' = 0.24813 + 0.00012 = 0.24825$ . The correction value (represented in this example by 0.00012) is *added* to the function of the *smaller* angle nearest the given angle in dealing with *sines* or *tangents* but this correction value is *subtracted* in dealing with *cosines* or *cotangents*.

## LOGARITHMS

Logarithms have long been used to facilitate and shorten calculations involving multiplication, division, the extraction of roots, and obtaining powers of numbers; however, since the advent of hand-held calculators logarithms are rarely used for multiplication and division problems. Logarithms still come up in other problems, and the following properties of logarithms are useful:

$$\begin{aligned} \log_c c &= 1 & \log_c c^p &= p & \log_c 1 &= 0 \\ \log_c (a \times b) &= \log_c a + \log_c b & \log_c (a \div b) &= \log_c a - \log_c b \\ \log_c (a^p) &= p \log_c a & \log_c (\sqrt[p]{a}) &= 1/p \log_c a \end{aligned}$$

The logarithm of a number is defined as the exponent of a base number raised to a power. For example,  $\log_{10} 3.162277 = 0.500$  means the logarithm of 3.162277 is equal to 0.500. Another way of expressing the same relationship is  $10^{0.500} = 3.162277$ , where 10 is the base number and the exponent 0.500 is the logarithm of 3.162277. A common example of a logarithmic expression  $10^2 = 100$  means that the base 10 logarithm of 100 is 2, that is,  $\log_{10} 100 = 2.00$ . There are two standard systems of logarithms in use: the "common" system (base 10) and the so-called "natural" system (base  $e = 2.71828\dots$ ). Logarithms to base  $e$  are frequently written using "ln" instead of " $\log_e$ " such as  $\ln 6.1 = 1.808289$ . Logarithms of a number can be converted between the natural- and common-based systems as follows:  $\ln_e A = 2.3026 \times \log_{10} A$  and  $\log_{10} A = 0.43430 \times \ln_e A$ . Additional information on the use of "natural logarithms" is given at the end of this section.

A logarithm consists of two parts, a whole number and a decimal. The whole number, which may be positive, negative, or zero, is called the characteristic; the decimal is called the mantissa. As a rule, only the decimal or mantissa is given in tables of common logarithms; tables of natural logarithms give both the characteristic and mantissa. The tables given in this section are abbreviated, but very accurate results can be obtained by using the method of interpolation described in *Interpolation from the Tables* on page 112. These tables are especially useful for finding logarithms and calculating powers and roots of numbers on calculators without these functions built in.

## Evaluating Logarithms

**Common Logarithms.**—For common logarithms, the characteristic is prefixed to the mantissa according to the following rules: For numbers greater than or equal to 1, the characteristic is one less than the number of places to the left of the decimal point. For example, the characteristic of the logarithm of 237 is 2, and of 2536.5 is 3. For numbers smaller than 1 and greater than 0, the characteristic is negative and its numerical value is one more than the number of zeros immediately to the right of the decimal point. For example, the characteristic of the logarithm of 0.036 is  $-2$ , and the characteristic of the logarithm of 0.0006 is  $-4$ . The minus sign is usually written over the figure, as in  $\bar{2}$  to indicate that the minus sign refers only to the characteristic and not to the mantissa, which is never negative. The logarithm of 0 does not exist.

The table of common logarithms in this section gives the mantissas of the logarithms of numbers from 1 to 10 and from 1.00 to 1.01. When finding the mantissa, the decimal point in a number is disregarded. The mantissa of the logarithms of 2716, 271.6, 27.16, 2.716, or 0.02716, for example, is the same. The tables give directly the mantissas of logarithms of numbers with three figures or less; the logarithms for numbers with four or more figures can be found by interpolation, as described in *Interpolation from the Tables* on page 112 and illustrated in the examples. All the mantissas in the common logarithmic tables are decimals and the decimal point has been omitted in the table. However, a decimal point should always be put before the mantissa as soon as it is taken from the table. Logarithmic

tables are sufficient for many purposes, but electronic calculators and computers are faster, simpler, and more accurate than tables.

To find the common logarithm of a number from the tables, find the left-hand column of the table and follow down to locate the first two figures of the number. Then look at the top row of the table, on the same page, and follow across it to find the third figure of the number. Follow down the column containing this last figure until opposite the row on which the first two figures were found. The number at the intersection of the row and column is the mantissa of the logarithm. If the logarithm of a number with less than three figures is being obtained, add extra zeros to the right of the number so as to obtain three figures. For example, if the mantissa of the logarithm of 6 is required, find the mantissa of 600.

**Interpolation from the Tables.**—If the logarithm of a number with more than three figures is needed, linear interpolation is a method of using two values from the table to estimate the value of the logarithm desired. To find the logarithm of a number not listed in the tables, find the mantissa corresponding to the first three digits of the given number (disregarding the decimal point and leading zeros) and find the mantissa of the first three digits of the given number plus one. For example, to find the logarithm of 601.2, 60.12, or 0.006012, find the mantissa of 601 and find the mantissa of 602 from the tables. Then subtract the mantissa of the smaller number from the mantissa of the larger number and multiply the result by a decimal number made from the remaining (additional greater than 3) figures of the original number. Add the result to the mantissa of the smaller number. Find the characteristic as described previously.

*Example:* Find the logarithm of 4032. The characteristic portion of the logarithm found in the manner described before is 3. Find the mantissa by locating 40 in the left-hand column of the logarithmic tables and then follow across the top row of the table to the column headed 3. Follow down the 3 column to the intersection with the 40 row and read the mantissa. The mantissa of the logarithm of 4030 is 0.605305. Because 4032 is between 4030 and 4040, the logarithm of 4032 is the logarithm of 4030 plus two tenths of the difference in the logarithms of 4030 and 4040. Find the mantissa of 4040 and then subtract from it the mantissa of 4030. Multiply the difference obtained by 0.2 and add the result to the mantissa of the logarithm of 4030. Finally, add the characteristic portion of the logarithm. The result is  $\log_{10} 4032 = 3 + 0.605305 + 0.2 \times (0.606381 - 0.605305) = 3.60552$ .

**Finding a Number Whose Logarithm Is Given.**—When a logarithm is given and it is required to find the corresponding number, find the number in the body of the table equal to the value of the mantissa. This value may appear in any column 0 to 9. Follow the row on which the mantissa is found across to the left to read the first two digits of the number sought. Read the third digit of the number from the top row of the table by following up the column on which the mantissa is found to the top. If the characteristic of the logarithm is positive, the number of figures to the left of the decimal in the number is one greater than the value of the characteristic. For example, if the figures corresponding to a given mantissa are 376 and the characteristic is 5, then the number sought has six figures to the left of the decimal point and is 376,000. If the characteristic had been  $\bar{3}$ , then the number sought would have been 0.00376. If the mantissa is not exactly obtainable in the tables, find the mantissa in the table that is nearest to the one given and determine the corresponding number. This procedure usually gives sufficiently accurate results. If more accuracy is required, find the two mantissas in the tables nearest to the mantissa given, one smaller and the other larger. For each of the two mantissas, read the three corresponding digits from the left column and top row to obtain the first three figures of the number as described before. The exact number sought lies between the two numbers found in this manner.

Next: 1) subtract the smaller mantissa from the given mantissa and; and 2) subtract the smaller mantissa from the larger mantissa.

Divide the result of (1) by the result of (2) and add the quotient to the number corresponding to the smaller mantissa.

*Example:* Find the number whose logarithm is 2.70053. First, find the number closest to the mantissa 70053 in the body of the tables. The closest mantissa listed in the tables is 700704, so read across the table to the left to find the first two digits of the number sought (50) and up the column to find the third digit of the number (2). The characteristic of the logarithm given is 2, so the number sought has three digits to the left of the decimal point. Therefore, the number sought is slightly less than 502 and greater than 501. If greater accuracy is required, find the two mantissas in the table closest to the given mantissa (699838 and 700704). Subtract the smaller mantissa from the mantissa of the given logarithm and divide the result by the smaller mantissa subtracted from the larger mantissa. Add the result to the number corresponding to the smaller mantissa. The resulting answer is  $501 + (700530 - 699838) \div (700704 - 699838) = 501 + 0.79 = 501.79$ .

**Natural Logarithms.**—In certain formulas and in some branches of mathematical analysis, use is made of logarithms (formerly also called Napierian or hyperbolic logarithms). As previously mentioned, the base of this system,  $e = 2.7182818284\dots$ , is the limit of certain mathematical series. The logarithm of a number  $A$  to the base  $e$  is usually written  $\log_e A$  or  $\ln A$ . Tables of natural logarithms for numbers ranging from 1 to 10 and 1.00 to 1.01 are given in this Handbook after the table of common logarithms. To obtain natural logs of numbers less than 1 or greater than 10, proceed as in the following examples:  $\log_e 0.239 = \log_e 2.39 - \log_e 10$ ;  $\log_e 0.0239 = \log_e 2.39 - 2 \log_e 10$ ;  $\log_e 239 = \log_e 2.39 + 2 \log_e 10$ ;  $\log_e 2390 = \log_e 2.39 + 3 \log_e 10$ , etc.

**Using Calculators to Find Logarithms.**—A scientific calculator is usually the quickest and most accurate method of finding logarithms and numbers corresponding to given logarithms. On most scientific calculators, the key labeled **log** is used to find common logarithms (base 10) and the key labeled **ln** is used for finding natural logarithms (base  $e$ ). The keystrokes to find a logarithm will vary slightly from one calculator to another, so specific instructions are not given. To find the number corresponding to a given logarithm: use the key labeled **10<sup>x</sup>** if a common logarithm is given or use the key labeled **e<sup>x</sup>** if a natural logarithm is given; calculators without the **10<sup>x</sup>** or **e<sup>x</sup>** keys may have a key labeled **x<sup>y</sup>** that can be used by substituting 10 or  $e$  (2.718281...), as required, for  $x$  and substituting the logarithm whose corresponding number is sought for  $y$ . On some other calculators, the **log** and **ln** keys are used to find common and natural logarithms, and the same keys in combination with the **INV**, or inverse, key are used to find the number corresponding to a given logarithm.

**Obtaining the Powers of Numbers.**—A number may be raised to any power by simply multiplying the logarithm of the number by the exponent of the number. The product gives the logarithm of the value of the power.

*Example 1:* Find the value of  $6.51^3$

$$\begin{aligned}\log 6.51 &= 0.81358 \\ 3 \times 0.81358 &= 2.44074\end{aligned}$$

The logarithm 2.44074 is the logarithm of  $6.51^3$ . Hence,  $6.51^3$  equals the number corresponding to this logarithm, as found from the tables, or  $6.51^3 = 275.9$ .

*Example 2:* Find the value of  $12^{1.29}$

$$\begin{aligned}\log 12 &= 1.07918 \\ 1.29 \times 1.07918 &= 1.39214\end{aligned}$$

Hence,  $12^{1.29} = 24.67$ .

Raising a decimal to a decimal power presents a somewhat more difficult problem because of the negative characteristic of the logarithm and the fact that the logarithm must be multiplied by a decimal exponent. The method for avoiding the use of negative charac-

teristics, that is adding a number to and subtracting it from the characteristic, as shown below, is helpful here.

*Example 3:* Find the value of  $0.0813^{0.46}$

$$\log 0.0813 = \bar{2}.91009 = 8.91009 - 10$$

$$\log 0.0813^{0.46} = 0.46 \times (8.91009 - 10) = 4.09864 - 4.6$$

Subtract and add 0.6 to make the characteristic a whole number:

$$\begin{array}{r} 4.09864 - 4.6 \\ \underline{-0.6} \quad + 0.6 \end{array}$$

$$\log 0.0813^{0.46} = 3.49864 - 4 = \bar{1}.49864$$

Hence,  $0.0813^{0.46} = 0.3152$ .

**Extracting Roots by Logarithms.**—Roots of numbers, for example,  $\sqrt[5]{37}$ , can be extracted easily by means of logarithms. The small (<sup>5</sup>) in the radical ( $\sqrt{\quad}$ ) of the root sign is called the index of the root. Any root of a number may be found by dividing its logarithm by the index of the root; the quotient is the logarithm of the root.

*Example 1:* Find  $\sqrt[3]{276}$

$$\begin{array}{r} \log 276 \quad = 2.44091 \\ 2.44091 \div 3 = 0.81364 \end{array}$$

Hence,  $\log \sqrt[3]{276} = 0.81364$       and       $\sqrt[3]{276} = 6.511$

*Example 2:* Find  $\sqrt[3]{0.67}$

$$\log 0.67 = \bar{1}.82607$$

Here it is not possible to divide directly, because there is a negative characteristic and a positive mantissa, another instance where the method of avoiding the use of negative characteristics, previously outlined, is helpful. The preferred procedure is to add and subtract some number to the characteristic that is evenly divisible by the index of the root. The root index is 3, so 9 can be added to and subtracted from the characteristic, and the resulting logarithm divided by 3.

$$\log 0.67 = \bar{1}.82607 = 8.82607 - 9$$

$$\log \sqrt[3]{0.67} = \frac{8.82607 - 9}{3} = 2.94202 - 3$$

$$\log \sqrt[3]{0.67} = 2.94202 - 3 = \bar{1}.94202$$

Hence,  $\sqrt[3]{0.67} = 0.875$

*Example 3:* Find  $\sqrt[1.7]{0.2}$

$$\log 0.2 = \bar{1}.30103 = 16.30103 - 17$$

$$\log \sqrt[1.7]{0.2} = \frac{16.30103 - 17}{1.7} = 9.58884 - 10 = \bar{1}.58884$$

Hence,

$$\sqrt[1.7]{0.2} = 0.388$$

## MATRICES

A matrix is a set of real numbers arranged in rows and columns to form a rectangular array. A matrix with  $m$  rows and  $n$  columns is an  $m \times n$  matrix ( $m$  by  $n$ ) and may be written as

$$A_{mn} = \begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1n} \\ a_{21} & a_{22} & \cdots & a_{2n} \\ \cdots & \cdots & \cdots & \cdots \\ a_{m1} & a_{m2} & \cdots & a_{mn} \end{bmatrix}$$

The  $a_{ij}$  terms are called the entries or elements of the matrix. The first subscript  $i$  identifies the row position of an entry, and the second subscript  $j$  identifies the column position in the matrix.

Some common matrix types have special names, as follows:

*Column Matrix:* A matrix that has only one column ( $m \times 1$ ).

*Diagonal Matrix:* A square matrix in which all values are zero except for those on one of the diagonals. If the diagonal entries are all 1, the matrix is an *identity* matrix.

*Identity Matrix:* A diagonal matrix in which the diagonal entries are all 1.

*Row Matrix:* A matrix that has only one row ( $1 \times n$ ).

*Square Matrix:* A matrix in which the number of rows and columns are equal, i.e.,  $m = n$ .

*Zero Matrix:* A matrix in which all the entries of the matrix are zero. The zero matrix is also called the *null* matrix.

## Matrix Operations

**Matrix Addition and Subtraction.**—Matrices can be added or subtracted if they have the same shape, that is, if number of columns in each matrix is the same, and the number of rows in each matrix is the same. The sum or difference of the matrices are determined by adding or subtracting the corresponding elements of each matrix. Thus, each element in the resultant matrix is formed using  $c_{ij} = a_{ij} \pm b_{ij}$  as illustrated below:

$$\begin{bmatrix} c_{11} & c_{12} & c_{13} \\ c_{21} & c_{22} & c_{23} \\ c_{31} & c_{32} & c_{33} \end{bmatrix} = \begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{bmatrix} \pm \begin{bmatrix} b_{11} & b_{12} & b_{13} \\ b_{21} & b_{22} & b_{23} \\ b_{31} & b_{32} & b_{33} \end{bmatrix} = \begin{bmatrix} (a_{11} \pm b_{11}) & (a_{12} \pm b_{12}) & (a_{13} \pm b_{13}) \\ (a_{21} \pm b_{21}) & (a_{22} \pm b_{22}) & (a_{23} \pm b_{23}) \\ (a_{31} \pm b_{31}) & (a_{32} \pm b_{32}) & (a_{33} \pm b_{33}) \end{bmatrix}$$

## Example 1

$$\begin{bmatrix} 4 & 6 & -5 \\ 5 & -7 & 8 \\ -8 & 6 & -7 \end{bmatrix} + \begin{bmatrix} 8 & -2 & 6 \\ -6 & 9 & 5 \\ 9 & -2 & 2 \end{bmatrix} = \begin{bmatrix} (4+8) & (6-2) & (-5+6) \\ (5-6) & (-7+9) & (8+5) \\ (-8+9) & (6-2) & (-7+2) \end{bmatrix} = \begin{bmatrix} 12 & 4 & 1 \\ -1 & 2 & 13 \\ 1 & 4 & -5 \end{bmatrix}$$

**Matrix Multiplication.**—Two matrices can be multiplied *only* when the number of columns in the first matrix is equal to the number of rows of the second matrix. Matrix multiplication is not commutative, thus,  $A \times B$  is not necessarily equal to  $B \times A$ .

Each resulting entry  $c_{ij}$  in the product matrix,  $C = A \times B$ , is the sum of the products of each element in the  $i^{\text{th}}$  row of matrix  $A$  multiplied by the corresponding element in the  $j^{\text{th}}$  column of matrix  $B$ , as illustrated in the following:

$$\begin{bmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{bmatrix} \times \begin{bmatrix} b_{11} & b_{12} & b_{13} \\ b_{21} & b_{22} & b_{23} \\ b_{31} & b_{32} & b_{33} \end{bmatrix}$$

$$= \begin{bmatrix} (a_{11}b_{11} + a_{12}b_{21} + a_{13}b_{31}) & (a_{11}b_{12} + a_{12}b_{22} + a_{13}b_{32}) & (a_{11}b_{13} + a_{12}b_{23} + a_{13}b_{33}) \\ (a_{21}b_{11} + a_{22}b_{21} + a_{23}b_{31}) & (a_{21}b_{12} + a_{22}b_{22} + a_{23}b_{32}) & (a_{21}b_{13} + a_{22}b_{23} + a_{23}b_{33}) \\ (a_{31}b_{11} + a_{32}b_{21} + a_{33}b_{31}) & (a_{31}b_{12} + a_{32}b_{22} + a_{33}b_{32}) & (a_{31}b_{13} + a_{32}b_{23} + a_{33}b_{33}) \end{bmatrix}$$

**Example 2**

$$\begin{bmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 3 & 2 & 1 \end{bmatrix} \times \begin{bmatrix} 7 & 8 & 9 \\ 1 & 2 & 3 \\ 4 & 5 & 7 \end{bmatrix} = \begin{bmatrix} (1 \cdot 7 + 2 \cdot 1 + 3 \cdot 4) & (1 \cdot 8 + 2 \cdot 2 + 3 \cdot 5) & (1 \cdot 9 + 2 \cdot 3 + 3 \cdot 7) \\ (4 \cdot 7 + 5 \cdot 1 + 6 \cdot 4) & (4 \cdot 8 + 5 \cdot 2 + 6 \cdot 5) & (4 \cdot 9 + 5 \cdot 3 + 6 \cdot 7) \\ (3 \cdot 7 + 2 \cdot 1 + 1 \cdot 4) & (3 \cdot 8 + 2 \cdot 2 + 1 \cdot 5) & (3 \cdot 9 + 2 \cdot 3 + 1 \cdot 7) \end{bmatrix}$$

$$= \begin{bmatrix} (7 + 2 + 12) & (8 + 4 + 15) & (9 + 6 + 21) \\ (28 + 5 + 24) & (32 + 10 + 30) & (36 + 15 + 42) \\ (21 + 2 + 4) & (24 + 4 + 5) & (27 + 6 + 7) \end{bmatrix} = \begin{bmatrix} 21 & 27 & 36 \\ 57 & 72 & 93 \\ 27 & 33 & 40 \end{bmatrix}$$

**Transpose of a Matrix.**— If the rows of a matrix  $A_{mn}$  are interchanged with its columns, the new matrix is called the transpose of matrix  $A$ , or  $A^T_{nm}$ . The first row of the matrix becomes the first column in the transposed matrix, the second row of the matrix becomes second column, and the third row of the matrix becomes third column.

**Example 3:**

$$A = \begin{bmatrix} 21 & 27 & 36 \\ 57 & 72 & 93 \\ 27 & 33 & 40 \end{bmatrix} \quad A^T = \begin{bmatrix} 21 & 57 & 27 \\ 27 & 72 & 33 \\ 36 & 93 & 40 \end{bmatrix}$$

**Determinant of a Square Matrix.**— Every square matrix  $A$  is associated with a real number, its determinant, which may be written  $\det(A)$  or  $|A|$ .

For  $A = \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix}$ , the determinant of  $A$  is

$$\det(A) = |A| = \begin{vmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{vmatrix} = a_{11}a_{22} - a_{12}a_{21}$$

For a  $3 \times 3$  matrix  $B$ , the determinant is

$$\det(B) = \begin{vmatrix} b_{11} & b_{12} & b_{13} \\ b_{21} & b_{22} & b_{23} \\ b_{31} & b_{32} & b_{33} \end{vmatrix}$$

$$= (b_{11}b_{22}b_{33} - b_{11}b_{23}b_{32}) - (b_{12}b_{23}b_{31} - b_{12}b_{21}b_{33}) + (b_{13}b_{21}b_{32} - b_{13}b_{22}b_{31})$$

$$= b_{11}(b_{22}b_{33} - b_{23}b_{32}) - b_{12}(b_{23}b_{31} - b_{21}b_{33}) + b_{13}(b_{21}b_{32} - b_{22}b_{31})$$

The determinant of an  $n \times n$  matrix results in  $n$  successive terms with alternating signs (+ or -). The troublesome task of keeping track of the proper sign for each term can be avoided by multiplying each term by  $(-1)^{i+j}$  and adding all the terms. For example, using this rule, the last line of the previous equation can be rewritten as follows:

$$= (-1)^{(1+1)}b_{11}(b_{22}b_{33} - b_{23}b_{32}) + (-1)^{(1+2)}b_{12}(b_{23}b_{31} - b_{21}b_{33}) + (-1)^{(1+3)}b_{13}(b_{21}b_{32} - b_{22}b_{31})$$

**Example 4:** Find the determinant of the following matrix.

$$A = \begin{bmatrix} 5 & 6 & 7 \\ 1 & 2 & 3 \\ 4 & 5 & 6 \end{bmatrix}$$

*Solution:*

$$\begin{aligned} \det(A) &= (-1)^{(1+1)} \cdot 5 \cdot [(2 \times 6) - (5 \times 3)] \\ &\quad + (-1)^{(1+2)} \cdot 6 \cdot [(1 \times 6) - (4 \times 3)] \\ &\quad + (-1)^{(1+3)} \cdot 7 \cdot [(1 \times 5) - (2 \times 4)] \\ \det(A) &= 5(12 - 15) - 6(6 - 12) + 7(5 - 8) \\ &= 5(-3) - 6(-6) + 7(-3) = -15 + 36 - 21 = 0 \end{aligned}$$

**Minors and Cofactors.**— The minor  $M_{ij}$  of a matrix  $A$  is the determinant of a submatrix resulting from the elimination of row  $i$  and of column  $j$ . If  $A$  is a square matrix, the minor  $M_{ij}$  of the entry  $a_{ij}$  is the determinant of the matrix obtained by deleting the  $i^{\text{th}}$  row and  $j^{\text{th}}$  column of  $A$ .

The cofactor  $C_{ij}$  of the entry  $a_{ij}$  is given by  $C_{ij} = (-1)^{(i+j)}M_{ij}$ . When the matrix is formed by the cofactors, then it is called a cofactors matrix.

*Example 5:* Find the minors and cofactors of

$$A = \begin{bmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 3 & 2 & 1 \end{bmatrix}$$

*Solution:* To determine the minor  $M_{11}$ , delete the first row and first column of  $A$  and find the determinant of the resulting matrix.

$$M_{11} = \begin{vmatrix} 5 & 6 \\ 2 & 1 \end{vmatrix} = (5 \times 1) - (6 \times 2) = 5 - 12 = -7$$

Similarly to find  $M_{12}$ , delete the first row and second column of  $A$  and find the determinant of the resulting matrix.

$$M_{12} = \begin{vmatrix} 4 & 6 \\ 3 & 1 \end{vmatrix} = (4 \times 1) - (6 \times 3) = 4 - 18 = -14$$

Continuing this way, we obtain the following minors:

$$\begin{array}{lll} M_{11} = -7 & M_{12} = -14 & M_{13} = -7 \\ M_{21} = -4 & M_{22} = -8 & M_{23} = -4 \\ M_{31} = -3 & M_{32} = -6 & M_{33} = -3 \end{array}$$

To find the cofactor  $C_{ij} = (-1)^{(i+j)} \times M_{ij}$ , thus  $C_{11} = (-1)^{(1+1)} \times M_{11} = 1 \times (-7) = -7$

Similarly  $C_{12} = (-1)^{(1+2)} \times M_{12} = -1 \times -14 = 14$ , and continuing this way we obtain the following cofactors

$$\begin{array}{lll} C_{11} = -7 & C_{12} = 14 & C_{13} = -7 \\ C_{21} = 4 & C_{22} = -8 & C_{23} = 4 \\ C_{31} = -3 & C_{32} = 6 & C_{33} = -3 \end{array}$$

**Adjoint of a Matrix.**— The transpose of cofactor matrix is called the adjoint matrix. First determine the cofactor matrix and then transpose it to obtain the adjoint matrix.

*Example 6:* Find the adjoint matrix of  $A$

$$A = \begin{bmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \\ 3 & 2 & 1 \end{bmatrix}$$

**Solution:** The cofactor matrix from the above example is shown below at the left, and the adjoint matrix on the right.

$$\text{Cofactor}(A) = \begin{bmatrix} -7 & 14 & -7 \\ 4 & -8 & 4 \\ -3 & 6 & -3 \end{bmatrix} \quad \text{Adjoint}(A) = \begin{bmatrix} -7 & 14 & -7 \\ 4 & -8 & 4 \\ -3 & 6 & -3 \end{bmatrix}^T = \begin{bmatrix} -7 & 4 & -3 \\ 14 & -8 & 6 \\ -7 & 4 & -3 \end{bmatrix}$$

**Singularity and Rank of a Matrix.**—A singular matrix is one whose determinant is zero. The rank of a matrix is the maximum number of linearly independent row or column vectors.

**Inverse of a Matrix.**—A square non-singular matrix  $A$  has an inverse  $A^{-1}$  such that the product of matrix  $A$  and inverse matrix  $A^{-1}$ , is the identity matrix  $I$ . Thus,  $AA^{-1} = I$ . The inverse is the ratio of adjoint of the matrix and the determinant of that matrix.

$$A^{-1} = \frac{\text{Adjoint}(A)}{|A|}$$

**Example 7:** What is the inverse of the following matrix?

$$A = \begin{bmatrix} 2 & 3 & 5 \\ 4 & 1 & 6 \\ 1 & 4 & 0 \end{bmatrix}$$

**Solution:** The basic formula of an inverse of a matrix is

$$A^{-1} = \frac{\text{Adjoint}(A)}{|A|}$$

The determinant of  $A$  is

$$\begin{aligned} |A| &= 2(1 \times 0 - 4 \times 6) - 3(4 \times 0 - 1 \times 6) + 5(4 \times 4 - 1 \times 1) \\ &= 2(0 - 24) - 3(0 - 6) + 5(16 - 1) \\ &= -48 + 18 + 75 = 45 \end{aligned}$$

The cofactors are

$$\begin{aligned} a_{11} &= (-1)^{1+1} \begin{vmatrix} 1 & 6 \\ 4 & 0 \end{vmatrix} = -24 & a_{12} &= (-1)^{1+2} \begin{vmatrix} 4 & 6 \\ 1 & 0 \end{vmatrix} = 6 & a_{13} &= (-1)^{1+3} \begin{vmatrix} 4 & 1 \\ 1 & 4 \end{vmatrix} = 15 \\ a_{21} &= (-1)^{2+1} \begin{vmatrix} 3 & 5 \\ 4 & 0 \end{vmatrix} = 20 & a_{22} &= (-1)^{2+2} \begin{vmatrix} 2 & 5 \\ 1 & 0 \end{vmatrix} = -5 & a_{23} &= (-1)^{2+3} \begin{vmatrix} 2 & 3 \\ 1 & 4 \end{vmatrix} = -5 \\ a_{31} &= (-1)^{3+1} \begin{vmatrix} 3 & 5 \\ 1 & 6 \end{vmatrix} = 13 & a_{32} &= (-1)^{3+2} \begin{vmatrix} 2 & 5 \\ 4 & 6 \end{vmatrix} = 8 & a_{33} &= (-1)^{3+3} \begin{vmatrix} 2 & 3 \\ 4 & 1 \end{vmatrix} = -10 \end{aligned}$$

The matrix of cofactors is  $\begin{bmatrix} -24 & 6 & 15 \\ 20 & -5 & -5 \\ 13 & 8 & -10 \end{bmatrix}$  and the adjoint matrix is  $\begin{bmatrix} -24 & 20 & 13 \\ 6 & -5 & 8 \\ 15 & -5 & -10 \end{bmatrix}$

Then the inverse of matrix  $A$  is

$$A^{-1} = \frac{\text{Adjoint}(A)}{|A|} = \frac{1}{45} \begin{bmatrix} -24 & 20 & 13 \\ 6 & -5 & 8 \\ 15 & -5 & -10 \end{bmatrix}$$

**Simultaneous Equations.**—Matrices can be used to solve systems of simultaneous equations with a large number of unknowns. Generally, this method is less cumbersome than

using substitution methods. The coefficients of the equations are placed in matrix form. The matrix is then manipulated into the Identity matrix, see below, to yield a solution.

$$\begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

Identity Matrix

*Example 8:* Solve the three simultaneous equations using matrix operations.

$$-4x_1 + 8x_2 + 12x_3 = 16$$

$$3x_1 - x_2 + 2x_3 = 5$$

$$x_1 + 7x_2 + 6x_3 = 10$$

*Solution:* First, place the equation coefficients and constants into matrix form. The object is to transform the coefficient matrix into the form shown below, thereby obtaining a solution to the system of equations.

$$\begin{bmatrix} -4 & 8 & 12 & 16 \\ 3 & -1 & 2 & 5 \\ 1 & 7 & 6 & 10 \end{bmatrix} \Leftrightarrow \begin{bmatrix} 1 & 0 & 0 & x_1 \\ 0 & 1 & 0 & x_2 \\ 0 & 0 & 1 & x_3 \end{bmatrix}$$

Transform the coefficient matrix so that element  $c_{11}$  is 1 and all other elements in the first column are 0, as follows: a) Divide *Row 1* ( $R_1$ ) by  $-4$ ; b) multiply new  $R_1$  by  $-3$ , then add to  $R_2$ ; and c) multiply  $R_1$  by  $-1$ , then add to  $R_3$ .

$$\begin{bmatrix} -4 & 8 & 12 & 16 \\ -4 & -4 & -4 & -4 \\ 3 & -1 & 2 & 5 \\ 1 & 7 & 6 & 10 \end{bmatrix} \Rightarrow \begin{bmatrix} 1 & -2 & -3 & -4 \\ (3-3) & (-1+6) & (2+9) & (5+12) \\ (1-1) & (7+2) & (6+3) & (10+4) \end{bmatrix} \Rightarrow \begin{bmatrix} 1 & -2 & -3 & -4 \\ 0 & 5 & 11 & 17 \\ 0 & 9 & 9 & 14 \end{bmatrix}$$

Transform the resulting matrix so that element  $c_{22}$  is 1 and all other elements in the second column are 0, as follows: a) Divide  $R_2$  by 9; b) multiply new  $R_2$  by  $-5$ , then add to  $R_1$ ; c) multiply  $R_2$  by 2, then add to  $R_3$ ; and d) swap  $R_2$  and  $R_3$ .

$$\begin{bmatrix} 1 & -2 & -3 & -4 \\ 0 & 5 & 11 & 17 \\ 0 & 9 & 9 & 14 \\ \frac{9}{9} & \frac{9}{9} & \frac{9}{9} & \frac{9}{9} \end{bmatrix} \Rightarrow \begin{bmatrix} 1 & (-2+2) & (-3+2) & (-4+\frac{28}{9}) \\ 0 & (5-5) & (11-5) & (17-\frac{70}{9}) \\ 0 & 1 & 1 & \frac{14}{9} \end{bmatrix} \Rightarrow \begin{bmatrix} 1 & 0 & -1 & -\frac{8}{9} \\ 0 & 0 & 6 & \frac{83}{9} \\ 0 & 1 & 1 & \frac{14}{9} \end{bmatrix} \Rightarrow \begin{bmatrix} 1 & 0 & -1 & -\frac{8}{9} \\ 0 & 1 & 1 & \frac{14}{9} \\ 0 & 0 & 6 & \frac{83}{9} \end{bmatrix}$$

Transform the resulting matrix so that element  $c_{33}$  is 1 and all other elements in the third column are 0, as follows: a) Divide  $R_3$  by 6; b) multiply new  $R_3$  by  $-1$ , then add to  $R_2$ ; and c) add  $R_3$  to  $R_1$ .

$$\begin{bmatrix} 1 & 0 & -1 & -\frac{8}{9} \\ 0 & 1 & 1 & \frac{14}{9} \\ 0 & 0 & \frac{6}{6} & \frac{83}{9(6)} \end{bmatrix} \Rightarrow \begin{bmatrix} 1 & 0 & (-1+1) & (-\frac{8}{9} + \frac{83}{54}) \\ 0 & 1 & (1-1) & (\frac{14}{9} - \frac{83}{54}) \\ 0 & 0 & 1 & \frac{83}{54} \end{bmatrix} \Rightarrow \begin{bmatrix} 1 & 0 & 0 & \frac{35}{54} \\ 0 & 1 & 0 & \frac{1}{54} \\ 0 & 0 & 1 & \frac{83}{54} \end{bmatrix}$$

Finally, when the identity matrix has been formed, the last column contains the values of  $x_1$ ,  $x_2$ , and  $x_3$  that satisfy the original equations.

$$x_1 = \frac{35}{54} \quad x_2 = \frac{1}{54} \quad x_3 = \frac{83}{54}$$

Checking the solutions:

$$\begin{array}{rcl} -4x_1 + 8x_2 + 12x_3 = 16 & 3x_1 - x_2 + 2x_3 = 5 & x_1 + 7x_2 + 6x_3 = 10 \\ 16 = 16 & 5 = 5 & 10 = 10 \end{array}$$

**Example 9:** Use matrix operations to find the currents ( $I_1$ ,  $I_2$ ,  $I_3$ ) in the following electrical network.

By Kirchoff's Current Law:

$$\begin{array}{l} I_2 + I_3 = I_1 \\ I_1 - I_2 - I_3 = 0 \end{array}$$

By Kirchoff's Voltage Law, and Ohm's Law:

$$\begin{array}{l} 2I_1 + 5I_3 - 40 = 0 \\ 10I_2 + 5I_3 - 30 = 0 \end{array}$$

By combining all the above equations, a linear system of three independent equations is formed. Solve the system for the currents  $I_1$ ,  $I_2$ , and  $I_3$ .

$$\begin{array}{l} I_1 - I_2 - I_3 = 0 \\ 2I_1 + 5I_3 = 40 \\ 10I_2 - 5I_3 = 30 \end{array}$$

**Solution:** If  $A$  is the matrix of coefficients of the currents,  $B$  is the matrix of currents (variables), and  $C$  be the matrix of constants from the right side of the equations, then the problem can be written in the following form:  $AB = C$ , and  $B = A^{-1}C$ , where  $A^{-1}$  is the inverse of matrix  $A$ .

Thus,

$$A = \begin{bmatrix} 1 & -1 & -1 \\ 2 & 0 & 5 \\ 0 & 10 & -5 \end{bmatrix} \quad B = \begin{bmatrix} I_1 \\ I_2 \\ I_3 \end{bmatrix} \quad C = \begin{bmatrix} 0 \\ 40 \\ 30 \end{bmatrix} \quad \text{and} \quad \begin{bmatrix} I_1 \\ I_2 \\ I_3 \end{bmatrix} = \begin{bmatrix} 1 & -1 & -1 \\ 2 & 0 & 5 \\ 0 & 10 & -5 \end{bmatrix}^{-1} \begin{bmatrix} 0 \\ 40 \\ 50 \end{bmatrix}$$

Using the method of [Example 7](#), the inverse of matrix  $A$  is

$$A^{-1} = \begin{bmatrix} 1 & -1 & -1 \\ 2 & 0 & 5 \\ 0 & 10 & -5 \end{bmatrix}^{-1} = -\frac{1}{80} \begin{bmatrix} -50 & -15 & -5 \\ 10 & -5 & -7 \\ 20 & -10 & 2 \end{bmatrix} = \begin{bmatrix} \frac{5}{8} & \frac{3}{16} & \frac{1}{16} \\ -\frac{1}{8} & \frac{1}{16} & \frac{7}{80} \\ -\frac{1}{4} & \frac{1}{8} & -\frac{1}{40} \end{bmatrix}$$

and finally, matrix  $B$  can be found as follows:

$$B = A^{-1}C = \begin{bmatrix} \frac{5}{8} & \frac{3}{16} & \frac{1}{16} \\ -\frac{1}{8} & \frac{1}{16} & \frac{7}{80} \\ -\frac{1}{4} & \frac{1}{8} & -\frac{1}{40} \end{bmatrix} \begin{bmatrix} 0 \\ 40 \\ 50 \end{bmatrix} = \begin{bmatrix} 9.375 \\ 5.125 \\ 4.25 \end{bmatrix}$$

Thus,  $I_1 = 9.375$  amps,  $I_2 = 5.125$  amps, and  $I_3 = 4.25$  amps

## ENGINEERING ECONOMICS

Engineers, managers, purchasing agents, and others are often required to plan and evaluate project alternatives, and make economic decisions that may greatly affect the success or failure of a project.

The goals of a project, such as reducing manufacturing cost or increasing production, selection of machine tool alternatives, or reduction of tooling, labor and other costs, determine which of the available alternatives may bring the most attractive economic return.

Various cost analysis techniques that may be used to obtain the desired outcome are discussed in the material that follows.

### Interest

Interest is money paid for the use of money lent for a certain time. *Simple* interest is the interest paid on the principal (money lent) only. When simple interest that is due is not paid, and its amount is added to the interest-bearing principal, the interest calculated on this new principal is called *compound* interest. The compounding of the interest into the principal may take place yearly or more often, according to circumstances.

**Interest Formulas.**—The symbols used in the formulas to calculate various types of interest are:

$P$  = principal or amount of money lent

$I$  = nominal annual interest rate stated as a percentage, i.e., 10 per cent per annum

$I_e$  = effective annual interest rate when interest is compounded more often than once a year (see *Nominal vs. Effective Interest Rates*)

$i$  = nominal annual interest rate per cent expressed as a decimal, i.e., if  $I = 12$  per cent, then  $i = 12/100 = 0.12$

$n$  = number of annual interest periods

$m$  = number of interest compounding periods in one year

$F$  = a sum of money at the end of  $n$  interest periods from the present date that is equivalent to  $P$  with added interest  $i$

$A$  = the payment at the end of each period in a uniform series of payments continuing for  $n$  periods, the entire series equivalent to  $P$  at interest rate  $i$

*Note:* The exact amount of interest for one day is  $1/365$  of the interest for one year. Banks, however, customarily take the year as composed of 12 months of 30 days, making a total of 360 days to a year. This method is also used for home-mortgage-type payments, so that the interest rate per month is  $30/360 = 1/12$  of the annual interest rate. For example, if  $I$  is a 12 per cent per annum nominal interest rate, then for a 30-day period, the interest rate is  $(12 \times 1/12) = 1.0$  per cent per month. The decimal rate per month is then  $1.0/100 = 0.01$ .

**Simple Interest.**—The formulas for simple interest are:

$$\text{Interest for } n \text{ years} = P \times i \times n$$

$$\text{Total amount after } n \text{ years, } S = P + P \times i \times n$$

*Example:* For \$250 that has been lent for three years at 6 per cent simple interest:  $P = 250$ ;  $I = 6$ ;  $i = I/100 = 0.06$ ;  $n = 3$ .

$$F = 250 + (250 \times 0.06 \times 3) = 250 + 45 = \$295$$

**Compound Interest.**—The following formulas apply when compound interest is to be computed and assuming that the interest is compounded annually.

$$F = P(1 + i)^n$$

$$P = F/(1 + i)^n$$

$$i = (F/P)^{1/n} - 1$$

$$n = (\log F - \log P)/\log(1 + i)$$

*Example:* At 10 per cent interest compounded annually for 10 years, a principal amount  $P$  of \$1000 becomes a sum  $F$  of

$$F = 1000(1 + 10/100)^{10} = \$2,593.74$$

If a sum  $F = \$2593.74$  is to be accumulated, beginning with a principal  $P = \$1,000$  over a period  $n = 10$  years, the interest rate  $i$  to accomplish this would have to be  $i = (2593.74/1000)^{1/10} - 1 = 0.09999$ , which rounds to 0.1, or 10 per cent.

For a principal  $P = \$500$  to become  $F = \$1,000$  at 6 per cent interest compounded annually, the number of years  $n$  would have to be

$$\begin{aligned} n &= (\log 1000 - \log 500)/\log(1 + 0.06) \\ &= (3 - 2.69897)/0.025306 = 11.9 \text{ years} \end{aligned}$$

To triple the principal  $P = \$500$  to become  $F = \$1,500$ , the number of years would have to be

$$\begin{aligned} n &= (\log 1500 - \log 500)/\log(1 + 0.06) \\ &= (3.17609 - 2.69897)/0.025306 = 18.85 \text{ years} \end{aligned}$$

**Interest Compounded More Often Than Annually.**—If interest is payable  $m$  times a year, it will be computed  $m$  times during each year, or  $nm$  times during  $n$  years. The rate for each compounding period will be  $i/m$  if  $i$  is the nominal annual decimal interest rate. Therefore, at the end of  $n$  years, the amount  $F$  will be:  $F = P(1 + i/m)^{nm}$ .

As an example, if  $P = \$1,000$ ;  $n$  is 5 years, the interest payable quarterly, and the annual rate is 6 per cent, then  $n = 5$ ;  $m = 4$ ;  $i = 0.06$ ;  $i/m = 0.06/4 = 0.015$ ; and  $nm = 5 \times 4 = 20$ , so that

$$F = 1000(1 + 0.015)^{20} = \$1,346.86$$

**Nominal vs. Effective Interest Rates.**—Deposits in savings banks, automobile loans, interest on bonds, and many other transactions of this type involve computation of interest due and payable more often than once a year. For such instances, there is a difference between the *nominal* annual interest rate stated to be the cost of borrowed money and the *effective* rate that is actually charged.

For example, a loan with interest charged at 1 per cent per month is described as having an interest rate of 12 per cent per annum. To be precise, this rate should be stated as being a *nominal* 12 per cent per annum compounded monthly; the actual or *effective* rate for monthly payments is 12.7 per cent. For quarterly compounding, the effective rate would be 12.6 per cent:

$$I_e = (1 + I/m)^m - 1$$

In this formula,  $I_e$  is the effective annual rate,  $I$  is the nominal annual rate, and  $m$  is the number of times per year the money is compounded.

*Example:* For a nominal per annum rate of 12 per cent, with monthly compounding, the effective per annum rate is

$$I_e = (1 + 0.12/12)^{12} - 1 = 0.1268 = 12.7 \text{ per cent effective per annum rate}$$

*Example:* Same as before but with quarterly compounding:

$$I_e = (1 + 0.12/4)^4 - 1 = 0.1255 = 12.6 \text{ per cent effective per annum rate}$$

**Finding Unknown Interest Rates.**—If a single payment of  $P$  dollars is to produce a sum of  $F$  dollars after  $n$  annual compounding periods, the per annum decimal interest rate is found using:

$$i = \sqrt[n]{\frac{F}{P}} - 1$$

### Cash Flow and Equivalence

The sum of money receipts or disbursement in a project's financial report are called cash flows. Due to the time value of money, the timing of cash flows over the project life plays a vital role in project success. Engineering economy problems involve the following four patterns of cash flow, both separately and in combination. Two cash flow patterns are said to be equivalent if they have the same value at a particular time.

**Present Value and Discount.**—The present value or present worth  $P$  of a given amount  $F$  is the amount  $P$  that, when placed at interest  $i$  for a given time  $n$ , will produce the given amount  $F$ .

$$\text{At simple interest, } P = F / (1 + ni)$$

$$\text{At compound interest, } P = F / (1 + i)^n$$

The *true discount*  $D$  is the difference between  $F$  and  $P$ :  $D = F - P$ .

These formulas are for an annual interest rate. If interest is payable other than annually, modify the formulas as indicated in the formulas in the section *Interest Compounded More Often Than Annually* on page 126.

*Example:* Find the present value and discount of \$500 due in six months at 6 per cent simple interest. Here,  $F = 500$ ;  $n = 6/12 = 0.5$  year;  $i = 0.06$ . Then,  $P = 500 / (1 + 0.5 \times 0.06) = \$485.44$ .

*Example:* Find the sum that, placed at 5 per cent compound interest, will in three years produce \$5,000. Here,  $F = 5000$ ;  $i = 0.05$ ;  $n = 3$ . Then,

$$P = 5000 / (1 + 0.05)^3 = \$4,319.19$$

**Annuities.**—An annuity is a fixed sum paid at regular intervals. In the formulas that follow, yearly payments are assumed. It is customary to calculate annuities on the basis of compound interest. If an annuity  $A$  is to be paid out for  $n$  consecutive years, the interest rate being  $i$ , then the present value  $P$  of the annuity is

$$P = A \frac{(1+i)^n - 1}{i(1+i)^n}$$

If at the *beginning* of each year a sum  $A$  is set aside at an interest rate  $i$ , the total value  $F$  of the sum set aside, with interest, at the end of  $n$  years, will be

$$F = A \frac{(1+i)[(1+i)^n - 1]}{i}$$

If at the *end* of each year a sum  $A$  is set aside at an interest rate  $i$ , then the total value  $F$  of the principal, with interest, at the end of  $n$  years will be

$$F = A \frac{(1+i)^n - 1}{i}$$

If a principal  $P$  is increased or decreased by a sum  $A$  at the end of each year, then the value of the principal after  $n$  years will be

$$F = P(1+i)^n \pm A \frac{(1+i)^n - 1}{i}$$

If the sum  $A$  by which the principal  $P$  is decreased each year is greater than the total yearly interest on the principal, then the principal, with the accumulated interest, will be entirely used up in  $n$  years:

$$n = \frac{\log A - \log(A - iP)}{\log(1 + i)}$$

*Example:* If an annuity of \$200 is to be paid for 10 years, what is the present amount of money that needs to be deposited if the interest is 5 per cent. Here,  $A = 200$ ;  $i = 0.05$ ;  $n = 10$ :

$$P = 200 \frac{(1 + 0.05)^{10} - 1}{0.05(1 + 0.05)^{10}} = \$1,544.35$$

The annuity a principal  $P$  drawing interest at the rate  $i$  will give for a period of  $n$  years is

$$A = P \frac{i(1 + i)^n}{(1 + i)^n - 1}$$

*Example:* A sum of \$10,000 is placed at 4 per cent. What is the amount of the annuity payable for 20 years out of this sum: Here,  $P = 10000$ ;  $i = 0.04$ ;  $n = 20$ :

$$A = 10,000 \frac{0.04(1 + 0.04)^{20}}{(1 + 0.04)^{20} - 1} = \$735.82$$

**Sinking Funds.**—Amortization is “the extinction of debt, usually by means of a sinking fund.” The sinking fund is created by a fixed investment  $A$  placed each year at compound interest for a term of years  $n$ , and is therefore an annuity of sufficient size to produce at the end of the term of years the amount  $F$  necessary for the repayment of the principal of the debt, or to provide a definite sum for other purposes. Then,

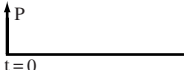

$$F = A \frac{(1 + i)^n - 1}{i} \quad \text{and} \quad A = F \frac{i}{(1 + i)^n - 1}$$

*Example:* If \$2,000 is invested annually for 10 years at 4 per cent compound interest, as a sinking fund, what would be the total amount of the fund at the expiration of the term? Here,  $A = 2000$ ;  $n = 10$ ;  $i = 0.04$ :

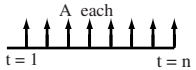

$$F = 2000 \frac{(1 + 0.04)^{10} - 1}{0.04} = \$24,012.21$$

**Cash Flow Diagrams.**—The following conventions are used to standardize cash flow diagrams. The horizontal (time) axis is marked off in equal increments, one per period, up to the duration of the project. Receipts are represented by arrows directed upwards and disbursements are represented by arrows directed downwards. The arrow length is proportional to the magnitude of cash flow. In the following,  $i$  = interest rate, and  $n$  = number of payments or periods.

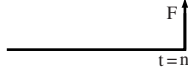

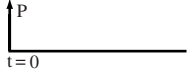

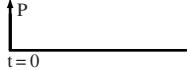

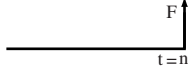

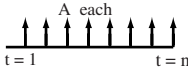

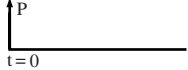

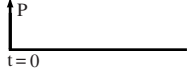

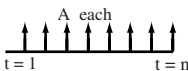

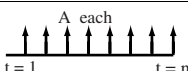

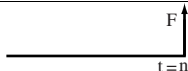

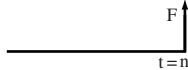

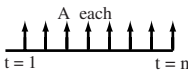

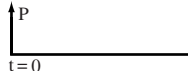

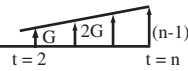

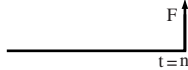

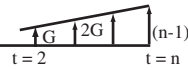

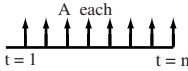

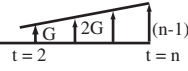

**Table 1. Cash Flow Patterns**

|                                     |   |   |
|-------------------------------------|---|---|
| $P$ -pattern<br>$P$ = present value | A single amount $P$ occurring at the beginning of $n$ years. $P$ represents “Present” amount. |  |
| $F$ -pattern<br>$F$ = future value  | A single amount $F$ occurring at the end of $n$ years. $F$ represents “Future” amount.        |  |

**Table 1. (Continued) Cash Flow Patterns**

|  |   |   |
|--|---|---|
| <p>A-pattern<br/>A = annual value</p>                | <p>Equal amounts <i>A</i> occurring at the end of each of <i>n</i> years. <i>A</i> represents "annual" amount.</p>        |  |
| <p>G-pattern<br/>G = uniform gradient of expense</p> | <p><i>G</i> is increasing by an equal amount over the period of life <i>n</i>. <i>G</i> represents "Gradient" amount.</p> |  |

**Table 2. Standard Cash Flow Factors**

| Symbol   | To Find | Formula   | Given | Symbol  |
|--|---------|---|-------|---|
|    | F       | $(P/F, i\%, n)$ $F = P(1+i)^n$  | P     |    |
|    | P       | $(F/P, i\%, n)$ $P = \frac{F}{(1+i)^n}$   | F     |    |
|    | A       | $(A/P, i\%, n)$ $A = P \frac{i(1+i)^n}{(1+i)^n - 1}$  | P     |    |
|    | P       | $(P/A, i\%, n)$ $P = A \frac{(1+i)^n - 1}{i(1+i)^n}$  | A     |    |
|   | A       | $(A/F, i\%, n)$ $A = F \frac{i}{(1+i)^n - 1}$   | F     |   |
|  | F       | $(F/A, i\%, n)$ $F = A \left[ \frac{(1+i)^n - 1}{i} \right]$  | A     |  |
|  | P       | $(P/G, i\%, n)$ $P = G \frac{1}{i} \left[ \frac{(1+i)^n - 1}{i(1+i)^n} - \frac{n}{(1+i)^n} \right]$ | G     |  |
|  | F       | $(F/G, i\%, n)$ $F = G \frac{1}{i} \left[ \frac{(1+i)^n - 1}{i} - n \right]$                        | G     |  |
|  | A       | $(A/G, i\%, n)$ $A = G \left[ \frac{1}{i} - \frac{n}{(1+i)^n - 1} \right]$                          | G     |  |

*Example:* A rental property pays \$2000/month with a \$10 per month increase starting the second year. Based on 10 year period and 8% annual interest, compute the unified average annuity, considering the gradient.

*Solution*

$$\begin{aligned} \text{Average rental} &= G \left[ \frac{1}{i} - \frac{n}{(1+i)^n - 1} \right] + A \\ &= 10 \left[ \frac{1}{(8/1200)} - \frac{120}{(1+8/1200)^{120} - 1} \right] + 2000 \\ &= 516 + 2000 = \$2516 \end{aligned}$$

**Depreciation**

Depreciation is the allocation of the cost of an asset over its depreciable life. A machine may decline in value because it is wearing out and no longer performing its function as well as when it is new. Depreciation is an economical technique that spreads the purchase price of an asset or other property over a number of years. Tax regulations do not allow the cost of an asset to be treated as a deductible expense in the year of purchase. Portions of the expense must be allocated to each of the years of the asset's depreciation period. The amount that is allocated each year is called the depreciation.

**Straight Line Depreciation.**—Straight line depreciation is a constant depreciation charge over the period of life. If  $P$  is the principal value,  $L$  is the salvage value and  $n$  is the period of life. The depreciation will be

$$\text{Depreciation at } x\text{th year} \quad D_x = \frac{P-L}{n}$$

$$\text{Book Value after } x \text{ years} \quad BV_x = \frac{(P-L)(n-x)}{n} + L$$

$$\text{After Tax Depreciation Recovery} \quad ATDR = TR \left( \frac{P-L}{n} \right) \left( \frac{(1+i)^n - 1}{i(1+i)^n} \right)$$

**Sum of the Years Digits.**—Another method for allocating the cost of an asset minus salvage value over its useful life is called sum of the years digits depreciation. This method results in larger than straight line depreciation charges during the early years of an asset and smaller charges near the end period.

$$\text{Depreciation at } x\text{th year} \quad D_x = \frac{2(P-L)(n-x+1)}{n(n+1)}$$

$$\text{Book Value after } x \text{ years} \quad BV_x = P - (P-L)(2n-x+1) \frac{x}{n(n+1)}$$

**Double Declining Balance Method.**—A constant depreciation is applied to the book value of the property.

$$\text{Depreciation at } x\text{th year} \quad D_x = 2 \left( \frac{P}{n} \right) \left( \frac{n-2}{n} \right)^{(x-1)}$$

$$\text{Book Value after } x \text{ years} \quad BV_x = P \left( \frac{n-2}{n} \right)^x$$

**Statutory Depreciation System.**—The latest depreciation method is used in U.S. income tax purpose is called accelerated cost recovery system (ACRS) depreciation. The first step in ACRS is to determine the property class of the asset being depreciated. All personal property falls into one of six classes.

$$\text{Depreciation at } x\text{th year} \quad D_x = P \times \text{Factor}$$

**Table 3. Property Class and Factor**

| ACRS Classes of Depreciable Property |  | Year<br>(x) | Depreciation Rate for Recovery Period (n) |         |         |          |
|--------------------------------------|--|-------------|---|---------|---------|----------|
| Property<br>Class                    | Personal Property  |             | 3 Years                                   | 5 Years | 7 Years | 10 Years |
| 3                                    | Handling device for food and beverage manufacture, plastic products, fabricated metal products             | 1           | 33.33%                                    | 20.00%  | 14.29%  | 10.00%   |
|                                      |  | 2           | 44.45%                                    | 32.00%  | 24.49%  | 18.00%   |
|                                      |  | 3           | 14.81%                                    | 19.20%  | 17.49%  | 14.40%   |
| 5                                    | Automobiles, trucks, computer, aircraft, petroleum drilling equipment, research and experimentation equip. | 4           | 7.41%                                     | 11.52%  | 12.49%  | 11.52%   |
|                                      |  | 5           |   | 11.52%  | 8.93%   | 9.22%    |
| 7                                    | Office furniture, fixtures, and equip.   | 6           |   | 5.76%   | 8.92%   | 7.37%    |
| 10                                   | Railroad cars, manufacture of tobacco products   | 7           |   |         | 8.93%   | 6.55%    |
|                                      |  | 8           |   |         | 4.46%   | 6.55%    |
| 15                                   | Telephone distribution line, municipal sewers plant  | 9           |   |         |         | 6.56%    |
|                                      |  | 10          |   |         |         | 6.55%    |
| 20                                   | Municipal sewers   | 11          |   |         |         | 3.28%    |

### Evaluating Alternatives

Two or more mutually exclusive investments compete for limited funds. There are a number of ways for selecting the superior alternative from a group of proposals. This section concerns strategies for selecting alternatives in such a way that net value is maximized.

**Net Present Value.**—One of the easiest way to compare mutually exclusive alternatives is to resolve their consequences to the present time. It is most frequently used to determine the present value of future money receipts and disbursements. There are three economic criteria for present worth analysis described in the table that follows. If investment cost is same, consider only the output money. If the output result is known, then minimize the investment cost. If neither input nor output is fixed, then maximize the output minus the input. This method is widely applied when alternatives have the same period of time.

$$\text{With uniform annual expense before tax} \quad NPV = -P + (AR - AE) \left( \frac{(1+i)^n - 1}{i(1+i)^n} \right) + \frac{L}{(1+i)^n}$$

$$\text{With uniform gradient on annual expense before tax} \quad NPV = -P + (AR - AE - (A/G, i, n)G) \left( \frac{(1+i)^n - 1}{i(1+i)^n} \right) + \frac{L}{(1+i)^n}$$

$$\text{With uniform annual expense after tax} \quad NPV = -P + (AR - AE)(1 - TR) \left( \frac{(1+i)^n - 1}{i(1+i)^n} \right) + \frac{L}{(1+i)^n}$$

$$\text{With uniform gradient on annual expense after tax} \quad NPV = -P + (AR - AE - (A/G, i, n)G)(1 - TR) \left( \frac{(1+i)^n - 1}{i(1+i)^n} \right) + \frac{L}{(1+i)^n}$$

The symbol used in this table are defined as follows:

$P$  = Present value     $NPV$  = Net present value     $AR$  = Annual revenue  
 $AE$  = Annual expense     $G$  = Uniform gradient of expense     $TR$  = Tax rate as percentage  
 $i$  = Interest rate     $n$  = Number of payments or periods

The previous formulas do not consider depreciation. To include depreciation, the after tax depreciation recovery (ATDR) must be added to get the net present value.

**Example 10:** A pharmaceutical company produces a product from different chemical compositions. Two mixing processes, batch and continuous, are available.

## INVESTMENTS

| Process                | Continuous | Batch   |
|------------------------|------------|---------|
| Initial cost           | \$75000    | \$35000 |
| Lifetime (years)       | 10         | 10      |
| Maintenance (per year) | \$5000     | \$8000  |
| Capacity (units/year)  | 25000      | 20000   |

The company uses straight line depreciation, pays 40% of its net income as income tax, and has an after tax minimum attractive rate of return of 15%. The company can sell the product at \$1.00 per unit. Which manufacturing process should the company invest in?

**Solution:** Because the lifetimes are equal, we can make a comparison using the present worth method by applying the formulas for  $NPV$  and also for  $ATDR$ .

$$\begin{aligned}
 NPV_{Continuous} &= -P + (AR - AE)(1 - TR) \left( \frac{(1+i)^n - 1}{i(1+i)^n} \right) + TR \left( \frac{P-L}{n} \right) \left( \frac{(1+i)^n - 1}{i(1+i)^n} \right) \\
 &= -75000 + (25000 \times 1 - 5000)(1 - 0.40) \left( \frac{\left(1 + \frac{15}{100}\right)^{10} - 1}{\left(\frac{15}{100}\right)\left(1 + \frac{15}{100}\right)^{10}} \right) + 0.40 \left( \frac{75000}{10} \right) \left( \frac{\left(1 + \frac{15}{100}\right)^{10} - 1}{\left(\frac{15}{100}\right)\left(1 + \frac{15}{100}\right)^{10}} \right) \\
 &= -14775 + 15056 = 281
 \end{aligned}$$

$$\begin{aligned}
 NPV_{Batch} &= -P + (AR - AE)(1 - TR) \left( \frac{(1+i)^n - 1}{i(1+i)^n} \right) + TR \left( \frac{P-L}{n} \right) \left( \frac{(1+i)^n - 1}{i(1+i)^n} \right) \\
 &= -35000 + [(20000 \times 1) - 8000](1 - 0.40) \left( \frac{\left(1 + \frac{15}{100}\right)^{10} - 1}{\left(\frac{15}{100}\right)\left(1 + \frac{15}{100}\right)^{10}} \right) + 0.40 \left( \frac{35000}{10} \right) \left( \frac{\left(1 + \frac{15}{100}\right)^{10} - 1}{\left(\frac{15}{100}\right)\left(1 + \frac{15}{100}\right)^{10}} \right) \\
 &= 1135 + 7026 = 8161
 \end{aligned}$$

Based on above calculations, the batch production process is selected because it gives a greater net present value ( $NPV$ ) than the continuous process.

**Capitalized Cost.**—In governmental analyses, there are some circumstances where a service is required for an infinite period of time such as with roads, dams, pipelines, etc. Present worth of a project with an infinite life is known as capitalized cost. Capitalized cost is the amount of money at  $n = 0$  needed to perpetually support the projection the earned interest only. Capitalized cost is the present sum of money that would need to be set aside now, at some interest rate, to yield the funds required to provide the service.

$$CC = P + A(P/A, i\%, n) - L(P/F, i\%, n) + G(P/G, i\%, n)$$

$$\text{Without Periodical Replacement} \quad CC = P + \frac{A}{i}$$

$$\text{With 100\% Periodical Replacement} \quad CC = P + \frac{P-L}{(1+i)^n - 1} + \frac{A}{i}$$

$$\text{With Periodical Renovation Cost} \quad CC = P + \frac{RC}{(1+i)^n - 1} + \frac{A}{i}$$

where  $CC$  = capitalized cost;  $P$  = initial cost;  $L$  = salvage value;  $A$  = annual cost;  $RC$  = renovation cost;  $i$  = interest rate; and,  $n$  = effective period of time.

**Equivalent Uniform Annual Cost.**—This method is applied when the alternatives have unequal periods of life. To avoid unequal periods of time, the present value and future value is converted to an annual value. The alternatives must be mutually exclusive and repeatedly renewed up to the duration of the longest lived alternative.

$$A = P(A/P, i\%, n) - L(A/F, i\%, n) + G(A/G, i\%, n) + AE$$

$$\text{With Sinking Fund Depreciation} \quad A = (P - L) \frac{i(1+i)^n}{(1+i)^n - 1} + Li + AE$$

$$\text{With Sinking Fund Depreciation and Uniform Gradient G} \quad A = (P - L) \frac{i(1+i)^n}{(1+i)^n - 1} + Li + AE + G \left( \frac{1}{i} - \frac{n}{(1+i)^n - 1} \right)$$

$$\text{Straight Line Depreciation} \quad A = \frac{P - L}{n} + Li + AE + \frac{(P - L)(n + 1)i}{2n}$$

*Example 11:* An investment of \$15,000 is being considered to reduce labor and labor-associated costs in a materials handling operation from \$8,200 a year to \$3,300. This operation is expected to be used for 10 years before being changed or discontinued entirely. In addition to the initial investment of \$15,000 and the annual cost of \$3,300 for labor, there are additional annual costs for power, maintenance, insurance, and property taxes of \$1,800 associated with the revised operation. Based on comparisons of annual costs, should the \$15,000 investment be made or the present operation continued?

The present annual cost of the operation is \$8,200 for labor and labor-associated costs. The proposed operation has an annual cost of \$3,300 for labor and labor extras plus \$1,800 for additional power, maintenance, insurance, and taxes, plus the annual cost of recovering the initial investment of \$15,000 at some interest rate (minimum acceptable rate of return).

Assuming that 10 per cent would be an acceptable rate of return on this investment over a period of 10 years, the annual amount to be recovered on the initial investment would be \$15,000 multiplied by the capital recovery factor.

Putting this value into  $(A/P, i\%, n)$  yields:

$$A = \frac{i(1+i)^n}{(1+i)^n - 1} P + AE = \frac{(10/100)(1 + 10/100)^{10}}{(1 + 10/100)^{10} - 1} 15000 + 5100 = 7541.18$$

Adding this amount to the \$5,100 annual cost associated with the investment (\$3,300 + \$1,800 = \$5,100) gives a total annual cost of \$7,542, which is less than the present annual cost of \$8,200. Thus, the investment is justified unless there are other considerations such as the effects of income taxes, salvage values, expected life, uncertainty about the required rate of return, changes in the cost of borrowed funds, and others.

A tabulation of annual costs of alternative plans A, B, C, etc., is a good way to compare costs item by item. For this example:

| Item |                                    | Plan A     | Plan B     |
|------|------------------------------------|------------|------------|
| 1    | Labor and labor extras             | \$8,200.00 | \$3,300.00 |
| 2    | Annual cost of \$15,000 investment |            | 2,442.00   |
| 3    | Power                              |            | 400.00     |
| 4    | Maintenance                        |            | 1,100.00   |
| 5    | Property taxes and insurance       |            | 300.00     |
|      | Total annual cost                  | \$8,200.00 | \$7,542.00 |

*Example 12, (Annual Cost Considering Salvage Value):* If in [Example 11](#) the salvage value of the equipment installed was \$5,000 at the end of 10 years, what effect does this have on the annual cost of the proposed investment of \$15,000?

The only item in the annual cost of [Example 11](#) that will be affected is the capital recovery amount of \$2,442. The following formula gives the amount of annual capital recovery when salvage value is considered:

$$A = (P - L) \frac{i(1+i)^n}{(1+i)^n - 1} + Li + AE$$

$$= (15000 - 5000) \frac{\left(\frac{10}{100}\right) \left(1 + \frac{10}{100}\right)^{10}}{\left(1 + \frac{10}{100}\right)^{10} - 1} + 5000 \left(\frac{10}{100}\right) + 5100 = 7227.45$$

Adding this amount to the \$5,100 annual cost determined previously gives a total annual cost of \$7,227, which is \$315 less than the previous annual cost of \$7,542 for the proposed investment.

**Rate of Return.**—The estimated interest rate produced by an investment. Rate of return is the interest rate at which the benefits are equivalent to the costs. It is defined as the interest rate paid on the unpaid balance of a loan such that the payment schedule makes the unpaid loan balance equal to zero when the final payment is made. It may be computed by finding the interest rate in such a way that the estimated expenditures are equal to the capital gain. *Net Present Worth = 0, or PW of benefits - PW of costs = 0*

$$\frac{((1 + ror)^n - 1)}{ror(1 + ror)^n} (AR - AE) + \frac{L}{(1 + ror)^n} = P$$

The rate of return can only be calculated by trial and error solution. To find out the present worth, select a reasonable interest rate, calculate the present worth. Choose another rate, calculate the present worth. Interpolate or extrapolate the value of *ROR* to find the zero value of present worth.

**Benefit-Cost Ratio.**—It is the ratio of present worth of benefit and present worth of cost. This method is applied to municipal project evaluations where benefits (*B*) and costs (*C*) accrue to different segments of the community. The project is considered acceptable if the ratio equals or exceeds 1. For fixed input maximize the  $B/C \geq 1$  and for fixed output maximize the  $B/C \geq 1$  and if neither input nor output is fixed, to compute the incremental benefit cost ratio ( $\Delta B/\Delta C$ ), choose  $\Delta B/\Delta C \geq 1$ .

*Example 13:* To build a bridge over a river costs \$1,200,000, benefits of \$2,000,000, and disbenefits of \$500,000. (a) What is the benefit cost ratio? (b) What is the excess of benefits over costs?

$$\text{Solution: The benefit cost ratio is } B/C = \frac{B - D}{D} = \frac{2,000,000 - 500,000}{500,000} = 3$$

The excess of benefits over cost equal  $2,000,000 - 1,200,000 - 500,000 = 300,000$ .

**Payback Period.**—This is the period of time required for the profit or other benefits of an investment to equal the cost of investment. The criterion in all situations is to minimize the payback period.

**Break-Even Analysis.**—Break-even analysis is a method of comparing two or more alternatives to determine which works best. Frequently, cost is the basis of the comparison, with the least expensive alternative being the most desirable. Break-even analysis can be applied in situations such as: to determine if it is more efficient and cost effective to use HSS, carbide, or ceramic tooling; to compare coated versus uncoated carbide tooling; to

decide which of several machines should be used to produce a part; or to decide whether to buy a new machine for a particular job or to continue to use an older machine. The techniques used to solve any of these problems are the same; however, the details will be different, depending on the type of comparison being made. The remainder of this section deals with break-even analysis based on comparing the costs of manufacturing a product using different machines.

*Choosing a Manufacturing Method:* The object of this analysis is to decide which of several machines can produce parts at the lowest cost. In order to compare the cost of producing a part, all the costs involved in making that part must be considered. The cost of manufacturing any number of parts can be expressed as the sum:  $C_T = C_F + n \times C_V$ , where  $C_T$  is the total cost of manufacturing one part,  $C_F$  is the sum of the fixed costs of making the parts,  $n$  is the number of parts made, and  $C_V$  is the total variable costs per piece made.

Fixed costs are manufacturing costs that have to be paid whatever the number of parts is produced and usually before any parts can be produced. They include the cost of drafting and CNC part programs, the cost of special tools and equipment required to make the part, and the cost of setting up the machine for the job. Fixed costs are generally one-time charges that occur at the beginning of a job or are recurrent charges that do not depend on the number of pieces made, such as those that might occur each time a job is run again.

Variable costs depend on the number of parts produced and are expressed as the cost per part made. The variable costs include the cost of materials, the cost of machine time, the cost of the labor directly involved in making the part, and the portion of the overhead that is attributable to production of the part. Variable costs can be expressed as:  $C_V =$  material cost + machine cost + labor cost + overhead cost. When comparing alternatives, if the same cost is incurred by each alternative, then that cost can be eliminated from the analysis without affecting the result. For example, the cost of material is frequently omitted from a manufacturing analysis if each machine is going to make parts from the same stock and if there is not going to be a significant difference in the amount of scrap produced by each method. The time to produce one part is needed to determine the machine, labor, and overhead costs. The total time expressed in hours per part is  $t_T = t_f + t_s$ , where  $t_f$  equals the floor-to-floor production time for one part and  $t_s$  the setup time per part. The setup time,  $t_s$ , is the time spent setting up the machine and periodically reconditioning tooling, divided by the number of parts made per setup.

*Material cost* equals the cost of the materials divided by the number of parts made.

*Machine cost* is the portion of a machine's total cost that is charged toward the production of each part. It is found by multiplying the machine rate (cost of the machine per hour) by the machine time per part,  $t_f$ . The machine hourly rate is calculated by dividing the lifetime costs (including purchase price, insurance, maintenance, etc.) by the estimated lifetime hours of operation of the machine. The total operating hours may be difficult to determine but a reasonable number can be based on experience and dealer information.

*Labor costs* are the wages paid to people who are directly involved in the manufacture of the part. The labor cost per part is the labor rate per hour multiplied by the time needed to manufacture each part,  $t_T$ . Indirect labor, which supports but is not directly involved in the manufacture of the part, is charged as overhead.

*Overhead cost* is the cost of producing an item that is not directly related to the cost of manufacture. Overhead includes the cost of management and other support personnel, building costs, heating and cooling, and similar expenses. Often, overhead is estimated as a percentage of the largest component cost of producing a part. For example, if direct labor is the largest expense in producing a part, the overhead can be estimated as a percentage of the direct labor costs. On the other hand, if equipment costs are higher, the overhead would be based on a percentage of the machine cost. Depending on the company, typical overhead charges range from about 150 to 800 per cent of the highest variable cost.

Most of the time, the decision to use one machine or another for making parts depends on how many pieces are needed. For example, given three machines *A*, *B*, and *C*, if only a few parts need to be produced, then, in terms of cost, machine *A* might be the best; if hundreds of parts are needed, then machine *B* might be best; and, if thousands of components are to be manufactured, then machine *C* may result in the lowest cost per part. Break-even analysis reveals how many components need to be produced before a particular machine becomes more cost effective than another.

To use break-even analysis, the cost of operating each machine needs to be established. The costs are plotted on a graph as a function of the number of components to be manufactured to learn which machine can make the required parts for the least cost. The following graph is a plot of the fixed and variable costs of producing a quantity of parts on two different machines, *Machine 1* and *Machine 2*. Fixed costs for each machine are plotted on the vertical *cost* axis. Variable costs for each machine are plotted as a line that intersects the cost axis at the fixed cost for each respective machine. The variable cost line is constructed with a slope that is equal to the cost per part, that is, for each part made, the line rises by an amount equal to the cost per part. If the calculations necessary to produce the graph are done carefully, the total cost of producing any quantity of parts can be found from the data plotted on the graph.

As an example, the graph shown in Fig. 7 is a comparison of the cost of manufacturing a quantity of a small part on a manually operated milling machine (*Machine 1*) and on a CNC machining center (*Machine 2*). The fixed costs (fixed costs = lead time  $\times$  lead time rate + setup time  $\times$  setup rate) for the manual machine are \$190 and the fixed costs for the CNC machine are higher at \$600. The fixed cost for each machine is the starting point of the line representing the cost of manufacturing a quantity of parts with that machine. The variable costs plotted are: \$18 per piece for the manual machine and \$5 per piece for the CNC mill.

Fig. 7. Quantity of Parts

The variable costs are calculated using the machine, labor, and overhead costs. The cost of materials is not included because it is assumed that materials cost will be the same for parts made on either machine and there will be no appreciable difference in the amount of scrap generated. The original cost of *Machine 1* (the manual milling machine) is \$19,000 with an estimated operating life of 16,000 hours, so the hourly operating cost is  $19,000/16,000 = \$1.20$  per hour. The labor rate is \$17 per hour and the overhead is estimated as 1.6 times the labor rate, or  $17 \times 1.6 = \$27.20$  per hour. The time,  $t_p$ , needed to complete each part on *Machine 1* is estimated as 24 minutes (0.4 hour). Therefore, by using *Machine 1*, the variable cost per part excluding material is  $(1.20 + 17.00 + 27.20) \text{ \$/h} \times 0.4 \text{ h/part} = \$18$  per part. For *Machine 2* (the CNC machining center), the machine cost is calculated at \$3 per hour, which is based on a \$60,000 initial cost (including installation, maintenance,

insurance, etc.) and 20,000 hours of estimated lifetime. The cost of labor is \$15 per hour for *Machine 2* and the overhead is again calculated at 1.6 times the labor rate, or \$24 per hour. Each part is estimated to take 7.2 minutes (0.12 h) to make, so the variable cost per part made on *Machine 2* is  $(3 + 15 + 24) \$/h \times 0.12 \text{ h/part} = \$5$  per part.

The lines representing the variable cost of operating each machine intersect at only one point on the graph. The intersection point corresponds to a quantity of parts that can be made by either the CNC or manual machine for the same cost, which is the break-even point. In the figure, the break-even point is 31.5 parts and the cost of those parts is \$757, or about \$24 apiece, excluding materials. The graph shows that if fewer than 32 parts need to be made, the total cost will be lowest if the manual machine is used because the line representing *Machine 1* is lower (representing lower cost) than the line representing *Machine 2*. On the other hand, if more than 31 parts are going to be made, the CNC machine will produce them for a lower cost. It is easy to see that the per piece cost of manufacturing is lower on the CNC machine because the line for *Machine 2* rises at a slower rate than the line for *Machine 1*. For producing only a few parts, the manual machine will make them less expensively than the CNC because the fixed costs are lower, but once the CNC part program has been written, the CNC can also run small batches efficiently because very little setup work is required.

The quantity of parts corresponding to the break-even point is known as the break-even quantity  $Q_b$ . The break-even quantity can be found without the use of the graph by using the following break-even equation:  $Q_b = (C_{F1} - C_{F2}) / (C_{V2} - C_{V1})$ . In this equation, the  $C_{F1}$  and  $C_{F2}$  are the fixed costs for *Machine 1* and *Machine 2*, respectively;  $C_{V1}$  and  $C_{V2}$  are the variable costs for *Machine 1* and *Machine 2*, respectively.

Break-even analysis techniques are also useful for comparing performance of more than two machines. Plot the manufacturing costs for each machine on a graph as before and then compare the costs of the machines in pairs using the techniques described. For example, if an automatic machine such as a rotary transfer machine is included as *Machine 3* in the preceding analysis, then three lines representing the costs of operating each machine would be plotted on the graph. The equation to find the break-even quantities is applied three times in succession, for *Machines 1* and 2, for *Machines 1* and 3, and again for *Machines 2* and 3. The result of this analysis will show the region (range of quantities) within which each machine is most profitable.

**Overhead Expenses.—Machine-Hour Distribution:** The machine-hour rate method consists of distributing all the manufacturing expenses of an establishment by a charge to each job of the overhead cost of operating the machines and other facilities used on that job. This overhead charge is not an average for the whole plant or department, but is, as nearly as possible, the actual overhead cost of maintaining and operating each of the machines, group of machines, benches, etc., which are found in the plant. By the proper use of this method it is possible to show the difference between the expense cost of a boring mill and a lathe, a gear-cutter and a splining machine, etc.

**Man-Hour Distribution:** The man-hour method of distributing overhead has for its base the number of hours spent on a job instead of the amount of wages paid. The assumption is made that the overhead expenses have a fixed ratio to the number of hours of time spent on a job. Certain items of expense bear a direct relation to the number of hours worked, and include the expenses of the payroll, compensation, insurance, and supervision.

**Man-Rate Distribution:** The man-rate method of distributing overhead costs is the one in most general use because of its simplicity. To use this method, find the ratio of total expenses to total labor for a given business, and to apply this ratio to the labor cost of each job. For a factory making one kind of product, this method of distributing overhead is quite satisfactory, but where the product itself is varied and the tools used are different for each of the products, this method is incorrect and misleading as to final results.

## MECHANICS

Throughout this section in this Handbook, both English and metric SI data and formulas are given to cover the requirements of working in either system of measurement. Except for the passage entitled *The Use of the Metric SI System in Mechanics Calculations*, formulas and text relating exclusively to SI are given in bold face type.

### Terms and Definitions

**Definitions.**—The science of mechanics deals with the effects of forces in causing or preventing motion. *Statics* is the branch of mechanics that deals with bodies in equilibrium, i.e., the forces acting on them cause them to remain at rest or to move with uniform velocity. *Dynamics* is the branch of mechanics that deals with bodies not in equilibrium, i.e., the forces acting on them cause them to move with non-uniform velocity. *Kinetics* is the branch of dynamics that deals with both the forces acting on bodies and the motions that they cause. *Kinematics* is the branch of dynamics that deals only with the motions of bodies without reference to the forces that cause them.

Definitions of certain terms and quantities as used in mechanics follow:

*Force* may be defined simply as a push or a pull; the push or pull may result from the force of contact between bodies or from a force, such as magnetism or gravitation, in which no direct contact takes place.

*Matter* is any substance that occupies space; gases, liquids, solids, electrons, atoms, molecules, etc., all fit this definition.

*Inertia* is the property of matter that causes it to resist any change in its motion or state of rest.

*Mass* is a measure of the inertia of a body.

*Work*, in mechanics, is the product of force times distance and is expressed by a combination of units of force and distance, as foot-pounds, inch-pounds, meter-kilograms, etc. **The metric SI unit of work is the joule, which is the work done when the point of application of a force of one newton is displaced through a distance of one meter in the direction of the force.**

*Power*, in mechanics, is the product of force times distance divided by time; it measures the performance of a given amount of work in a given time. It is the rate of doing work and as such is expressed in foot-pounds per minute, foot-pounds per second, kilogram-meters per second, etc. **The metric SI unit is the watt, which is one joule per second.**

*Horsepower* is the unit of power that has been adopted for engineering work. One horsepower is equal to 33,000 foot-pounds per minute or 550 foot-pounds per second. The *kilowatt*, used in electrical work, equals 1.34 horsepower; or 1 horsepower equals 0.746 kilowatt. **However, in the metric SI, the term horsepower is not used, and the basic unit of power is the watt. This unit, and the derived units milliwatt and kilowatt, for example, are the same as those used in electrical work.**

*Torque or moment* of a force is a measure of the tendency of the force to rotate the body upon which it acts about an axis. The magnitude of the moment due to a force acting in a plane perpendicular to some axis is obtained by multiplying the force by the perpendicular distance from the axis to the line of action of the force. (If the axis of rotation is not perpendicular to the plane of the force, then the components of the force in a plane perpendicular to the axis of rotation are used to find the resultant moment of the force by finding the moment of each component and adding these component moments algebraically.) Moment or torque is commonly expressed in pound-feet, pound-inches, kilogram-meters, etc. **The metric SI unit is the newton-meter (N · m).**

*Velocity* is the time-rate of change of distance and is expressed as distance divided by time, that is, feet per second, miles per hour, centimeters per second, meters per second, etc.

*Acceleration* is defined as the time-rate of change of velocity and is expressed as velocity divided by time or as distance divided by time squared, that is, in feet per second, per second or feet per second squared; inches per second, per second or inches per second squared; centimeters per second, per second or centimeters per second squared; etc. **The metric SI unit is the meter per second squared.**

**Unit Systems.**—In mechanics calculations, both *absolute* and *gravitational* systems of units are employed. The fundamental units in absolute systems are *length*, *time*, and *mass*, and from these units, the dimension of force is derived. Two absolute systems which have been in use for many years are the cgs (centimeter-gram-second) and the MKS (meter-kilogram-second) systems. Another system, known as MKSA (meter-kilogram-second-ampere), links the MKS system of units of mechanics with electro magnetic units.

**The Conference General des Poids et Mesures (CGPM), which is the body responsible for all international matters concerning the metric system, adopted in 1954 a rationalized and coherent system of units based on the four MKSA units and including the kelvin as the unit of temperature, and the candela as the unit of luminous intensity. In 1960, the CGPM formally named this system the 'Système International d'Unites,' for which the abbreviation is SI in all languages. In 1971, the 14th CGPM adopted a seventh base unit, the mole, which is the unit of quantity ("amount of substance"). Further details of the SI are given in the section *MEASURING UNITS* starting on page 2544, and its application in mechanics calculations, contrasted with the use of the English system, is considered on page 142.**

The fundamental units in gravitational systems are *length*, *time*, and *force*, and from these units, the dimension of mass is derived. In the gravitational system most widely used in English measure countries, the units of length, time, and force are, respectively, the foot, the second, and the pound. The corresponding unit of mass, commonly called the *slug*, is equal to 1 pound second<sup>2</sup> per foot and is derived from the formula,  $M = W \div g$  in which  $M$  = mass in slugs,  $W$  = weight in pounds, and  $g$  = acceleration due to gravity, commonly taken as 32.16 feet per second<sup>2</sup>. A body that weighs 32.16 lbs. on the surface of the earth has, therefore, a mass of one slug.

Many engineering calculations utilize a system of units consisting of the inch, the second, and the pound. The corresponding units of mass are pounds second<sup>2</sup> per inch and the value of  $g$  is taken as 386 inches per second<sup>2</sup>.

In a gravitational system that has been widely used in metric countries, the units of length, time, and force are, respectively, the meter, the second, and the kilogram. The corresponding units of mass are kilograms second<sup>2</sup> per meter and the value of  $g$  is taken as 9.81 meters per second<sup>2</sup>.

**Acceleration of Gravity  $g$  Used in Mechanics Formulas.**—The acceleration of a freely falling body has been found to vary according to location on the earth's surface as well as with height, the value at the equator being 32.09 feet per second, per second while at the poles it is 32.26 ft/sec<sup>2</sup>. In the United States it is customary to regard 32.16 as satisfactory for most practical purposes in engineering calculations.

*Standard Pound Force:* For use in defining the magnitude of a standard unit of force, known as the *pound force*, a fixed value of 32.1740 ft/sec<sup>2</sup>, designated by the symbol  $g_0$ , has been adopted by international agreement. As a result of this agreement, whenever the term mass,  $M$ , appears in a mechanics formula and the substitution  $M = W/g$  is made, use of the standard value  $g_0 = 32.1740$  ft/sec<sup>2</sup> is implied although as stated previously, it is customary to use approximate values for  $g$  except where extreme accuracy is required.

**The Use of the Metric SI System in Mechanics Calculations.**—The SI system is a development of the traditional metric system based on decimal arithmetic; fractions are avoided. For each physical quantity, units of different sizes are formed by multiplying or dividing a single base value by powers of 10. Thus, changes can be made very simply by

adding zeros or shifting decimal points. For example, the meter is the basic unit of length; the kilometer is a multiple (1,000 meters); and the millimeter is a sub-multiple (one-thousandth of a meter).

In the older metric system, the simplicity of a series of units linked by powers of 10 is an advantage for plain quantities such as length, but this simplicity is lost as soon as more complex units are encountered. For example, in different branches of science and engineering, energy may appear as the erg, the calorie, the kilogram-meter, the liter-atmosphere, or the horsepower-hour. In contrast, the SI provides only one basic unit for each physical quantity, and universality is thus achieved.

There are seven base-units, and in mechanics calculations three are used, which are for the basic quantities of length, mass, and time, expressed as the meter (m), the kilogram (kg), and the second (s). The other four base-units are the ampere (A) for electric current, the kelvin (K) for thermodynamic temperature, the candela (cd) for luminous intensity, and the mole (mol) for amount of substance.

The SI is a coherent system. A system of units is said to be coherent if the product or quotient of any two unit quantities in the system is the unit of the resultant quantity. For example, in a coherent system in which the foot is a unit of length, the square foot is the unit of area, whereas the acre is not. Further details of the SI, and definitions of the units, are given in the section *MEASURING UNITS* starting on page 2544, near the end of the book.

Other physical quantities are derived from the base-units. For example, the unit of velocity is the meter per second (m/s), which is a combination of the base-units of length and time. The unit of acceleration is the meter per second squared ( $m/s^2$ ). By applying Newton's second law of motion — force is proportional to mass multiplied by acceleration — the unit of force is obtained, which is the  $kg \cdot m/s^2$ . This unit is known as the newton, or N. Work, or force times distance, is the  $kg \cdot m^2/s^2$ , which is the joule, (1 joule = 1 newton-meter) and energy is also expressed in these terms. The abbreviation for joule is J. Power, or work per unit time, is the  $kg \cdot m^2/s^3$ , which is the watt (1 watt = 1 joule per second = 1 newton-meter per second). The abbreviation for watt is W.

More information on Newton's laws may be found in the section *Newton's Laws of Motion* on page 167.

The coherence of SI units has two important advantages. The first, that of uniqueness and therefore universality, has been explained. The second is that it greatly simplifies technical calculations. Equations representing physical principles can be applied without introducing such numbers as 550 in power calculations, which, in the English system of measurement have to be used to convert units. Thus conversion factors largely disappear from calculations carried out in SI units, with a great saving in time and labor.

*Mass, Weight, Force, Load:* SI is an absolute system (see *Unit Systems* on page 142), and consequently it is necessary to make a clear distinction between mass and weight. The *mass* of a body is a measure of its inertia, whereas the *weight* of a body is the *force* exerted on it by gravity. In a fixed gravitational field, weight is directly proportional to mass, and the distinction between the two can be easily overlooked. However, if a body is moved to a different gravitational field, for example, that of the moon, its weight alters, but its mass remains unchanged. Since the gravitational field on earth varies from place to place by only a small amount, and weight is proportional to mass, it is practical to use the weight of unit mass as a unit of force, and this procedure is adopted in both the English and older metric systems of measurement. In common usage, they are given the same names, and we say that a mass of 1 pound has a weight of 1 pound. In the former case the pound is being used as a unit of mass, and in the latter case, as a unit of force. This procedure is convenient in some branches of engineering, but leads to confusion in others.

As mentioned earlier, Newton's second law of motion states that force is proportional to mass times acceleration. Because an unsupported body on the earth's surface falls with acceleration  $g$  ( $32 \text{ ft/s}^2$  approximately), the pound (force) is that force which will impart an

acceleration of  $g$  ft/s<sup>2</sup> to a pound (mass). Similarly, the kilogram (force) is that force which will impart an acceleration of  $g$  (9.8 meters per second<sup>2</sup> approximately), to a mass of one kilogram. In the SI, the *newton* is that force which will impart unit acceleration (1 m/s<sup>2</sup>) to a mass of one kilogram. It is therefore smaller than the kilogram (force) in the ratio 1: $g$  (about 1:9.8). This fact has important consequences in engineering calculations. The factor  $g$  now disappears from a wide range of formulas in dynamics, but appears in many formulas in statics where it was formerly absent. It is however not quite the same  $g$ , for reasons which will now be explained.

In the article on page 171, the mass of a body is referred to as  $M$ , but it is immediately replaced in subsequent formulas by  $W/g$ , where  $W$  is the weight in pounds (force), which leads to familiar expressions such as  $WV^2/2g$  for kinetic energy. In this treatment, the  $M$  which appears briefly is really expressed in terms of the slug (page 142), a unit normally used only in aeronautical engineering. In everyday engineers' language, weight and mass are regarded as synonymous and expressions such as  $WV^2/2g$  are used without pondering the distinction. Nevertheless, on reflection it seems odd that  $g$  should appear in a formula which has nothing to do with gravity at all. In fact the  $g$  used here is not the true, local value of the acceleration due to gravity, but an arbitrary standard value which has been chosen as part of the definition of the pound (force) and is more properly designated  $g_0$  (page 142). Its function is not to indicate the strength of the local gravitational field, but to convert from one unit to another.

In the SI the unit of mass is the *kilogram*, and the unit of force (and therefore weight) is the *newton*.

The following are typical statements in dynamics expressed in SI units:

A force of  $R$  newtons acting on a mass of  $M$  kilograms produces an acceleration of  $R/M$  meters per second<sup>2</sup>. The kinetic energy of a mass of  $M$  kg moving with velocity  $V$  m/s is  $\frac{1}{2}MV^2$  kg (m/s)<sup>2</sup> or  $\frac{1}{2}MV^2$  joules. The work done by a force of  $R$  newtons moving a distance  $L$  meters is  $RL$  Nm, or  $RL$  joules. If this work were converted entirely into kinetic energy we could write  $RL = \frac{1}{2}MV^2$  and it is instructive to consider the units. Remembering that the N is the same as the kg · m/s<sup>2</sup>, we have (kg · m/s<sup>2</sup>) × m = kg (m/s)<sup>2</sup>, which is obviously correct. It will be noted that  $g$  does not appear anywhere in these statements.

In contrast, in many branches of engineering where the weight of a body is important, rather than its mass, using SI units,  $g$  does appear where formerly it was absent. Thus, if a rope hangs vertically supporting a mass of  $M$  kilograms the tension in the rope is  $Mg$  N. Here  $g$  is the acceleration due to gravity, and its units are m/s<sup>2</sup>. The ordinary numerical value of 9.81 will be sufficiently accurate for most purposes on earth. The expression is still valid elsewhere, for example, on the moon, provided the proper value of  $g$  is used. The maximum tension the rope can safely withstand (and other similar properties) will also be specified in terms of the newton, so that direct comparison may be made with the tension predicted.

Words like load and weight have to be used with greater care. In everyday language we might say "a lift carries a load of five people of average weight 70 kg," but in precise technical language we say that if the average mass is 70 kg, then the average weight is 70g N, and the total load (that is force) on the lift is 350g N.

If the lift starts to rise with acceleration  $a$  · m/s<sup>2</sup>, the load becomes 350( $g + a$ ) N; both  $g$  and  $a$  have units of m/s<sup>2</sup>, the mass is in kg, so the load is in terms of kg · m/s<sup>2</sup>, which is the same as the newton.

*Pressure and stress:* These quantities are expressed in terms of force per unit area. In the SI the unit is the pascal (Pa), which expressed in terms of SI derived and base units is the newton per meter squared (N/m<sup>2</sup>). The pascal is very small—it is only equivalent to 0.15 × 10<sup>-3</sup> lb/in<sup>2</sup>—hence the kilopascal (kPa = 1000 pascals), and the megapascal (MPa = 10<sup>6</sup>

pascals) may be more convenient multiples in practice. Thus, note: 1 newton per millimeter squared = 1 meganewton per meter squared = 1 megapascal.

In addition to the pascal, the bar, a non-SI unit, is in use in the field of pressure measurement in some countries, including England. Thus, in view of existing practice, the International Committee of Weights and Measures (CIPM) decided in 1969 to retain this unit for a limited time for use with those of SI. The bar =  $10^5$  pascals and the hectobar =  $10^7$  pascals.

### Force Systems

**Scalar and Vector Quantities.**—The quantities dealt with in mechanics are of two kinds according to whether magnitude alone or direction as well as magnitude must be known in order to completely specify them. Quantities such as time, volume and density are completely specified when their magnitude is known. Such quantities are called *scalar* quantities. Quantities such as force, velocity, acceleration, moment, and displacement which must, in order to be specified completely, have a specific direction as well as magnitude, are called *vector* quantities.

**Graphical Representation of Forces.**—A force has three characteristics which, when known, determine it. They are *direction*, *point of application*, and *magnitude*. The direction of a force is the direction in which it tends to move the body upon which it acts. The point of application is the place on the line of action where the force is applied. Forces may conveniently be represented by straight lines and arrow heads. The arrow head indicates the direction of the force, and the length of the line, its magnitude to any suitable scale. The point of application may be at any point on the line, but it is generally convenient to assume it to be at one end. In the accompanying illustration, a force is supposed to act along line *AB* in a direction from left to right. The length of line *AB* shows the magnitude of the force. If point *A* is the point of application, the force is exerted as a pull, but if point *B* be assumed to be the point of application, it would indicate that the force is exerted as a push.

Vector

Velocities, moments, displacements, etc. may similarly be represented and manipulated graphically because they are all of the same class of quantities called vectors. (See *Scalar and Vector Quantities*.)

**Addition and Subtraction of Forces:** The resultant of two forces applied at the same point and acting in the same direction, is equal to the sum of the forces. For example, if the two forces *AB* and *AC*, one equal to two and the other equal to three pounds, are applied at point *A*, then their resultant *AD* equals the sum of these forces, or five pounds.

Fig. 1.

Fig. 2.

If two forces act in opposite directions, then their resultant is equal to their difference, and the direction of the resultant is the same as the direction of the greater of the two forces. For example: *AB* and *AC* are both applied at point *A*; then, if *AB* equals four and *AC* equals six pounds, the resultant *AD* equals two pounds and acts in the direction of *AC*.

**Parallelogram of Forces:** If two forces applied at a point are represented in magnitude and direction by the adjacent sides of a parallelogram (*AB* and *AC* in Fig. 3), their resultant

will be represented in magnitude and direction by the diagonal  $AR$  drawn from the intersection of the two component forces.

Fig. 3.

Fig. 4.

Fig. 5.

If two forces  $P$  and  $Q$  do not have the same point of application, as in Fig. 4, but the lines indicating their directions intersect, the forces may be imagined as applied at the point of intersection between the lines (as at  $A$ ), and the resultant of the two forces may be found by constructing the parallelogram of forces. Line  $AR$  shows the direction and magnitude of the resultant, the point of application of which may be assumed to be at any point on line  $AR$  or its extension.

If the resultant of three or more forces having the same point of application is to be found, as in Fig. 5, first find the resultant of any two of the forces ( $AB$  and  $AC$ ) and then find the resultant of the resultant just found ( $AR_1$ ) and the third force ( $AD$ ). If there are more than three forces, continue in this manner until the resultant of all the forces has been found.

**Parallel Forces:** If two forces are parallel and act in the same direction, as in Fig. 6, then their resultant is parallel to both lines, is located between them, and is equal to the sum of the two components. The point of application of the resultant divides the line joining the points of application of the components inversely as the magnitude of the components. Thus,

$$AB : CE = CD : AD$$

The resultant of two parallel and unequal forces acting in opposite directions, Fig. 7, is parallel to both lines, is located outside of them on the side of the greater of the components, has the same direction as the greater component, and is equal in magnitude to the difference between the two components. The point of application on the line  $AC$  produced is found from the proportion:

$$AB : CD = CE : AE$$

Fig. 6.

Fig. 7.

**Polygon of Forces:** When several forces are applied at a point and act in a single plane, Fig. 8, their resultant may be found more simply than by the method just described, as follows: From the extreme end of the line representing the first force, draw a line representing the second force, parallel to it and of the same length and in the direction of the second force. Then through the extreme end of this line draw a line parallel to, and of the same length and direction as the third force, and continue this until all the forces have been thus

represented. Then draw a line from the point of application of the forces (as  $A$ ) to the extreme point (as  $5_1$ ) of the line last drawn. This line ( $A 5_1$ ) is the resultant of the forces.

Fig. 8.

Fig. 9.

**Moment of a Force:** The moment of a force with respect to a point is the product of the force multiplied by the perpendicular distance from the given point to the direction of the force. In Fig. 9, the moment of the force  $P$  with relation to point  $A$  is  $P \times AB$ . The perpendicular distance  $AB$  is called the lever-arm of the force. The moment is the measure of the tendency of the force to produce rotation about the given point, which is termed the center of moments. If the force is measured in pounds and the distance in inches, the moment is expressed in inch-pounds. **In metric SI units, the moment is expressed in newton-meters ( $N \cdot m$ ), or newton-millimeters ( $N \cdot mm$ ).**

The moment of the resultant of any number of forces acting together in the same plane is equal to the algebraic sum of the moments of the separate forces.

**Couples.**—If the forces  $AB$  and  $CD$  are equal and parallel but act in opposite directions, then the resultant equals 0, or, in other words, the two forces have no resultant and are called a couple. A couple tends to produce rotation. The measure of this tendency is called the moment of the couple and is the product of one of the forces multiplied by the distance between the two.

Two Examples of Couples

As a couple has no resultant, no single force can balance or counteract the tendency of the couple to produce rotation. To prevent the rotation of a body acted upon by a couple, two other forces are therefore required, forming a second couple. In the illustration,  $E$  and  $F$  form one couple and  $G$  and  $H$  are the balancing couple. The body on which they act is in equilibrium if the moments of the two couples are equal and tend to rotate the body in opposite directions. A couple may also be represented by a vector in the direction of the axis about which the couple acts. The length of the vector, to some scale, represents the magnitude of the couple, and the direction of the vector is that in which a right-hand screw would advance if it were to be rotated by the couple.

**Composition of a Single Force and Couple.**—A single force and a couple in the same plane or in parallel planes may be replaced by another single force equal and parallel to the first force, at a distance from it equal to the moment of the couple divided by the magnitude of the force. The new single force is located so that the moment of the resultant about the point of application of the original force is of the same sign as the moment of the couple.

In the next figure, with the couple  $N-N$  in the position shown, the resultant of  $P, -N$ , and  $N$  is  $O$  (which equals  $P$ ) acting on a line through point  $c$  so that  $(P-N) \times ac = N \times bc$ .

Thus, it follows that,

$$ac = \frac{N(ac + bc)}{P} = \frac{\text{Moment of Couple}}{P}$$

Single Force and Couple Composition

**Algebraic Composition and Resolution of Force Systems.**—The graphical methods given beginning on page 145 are convenient for solving problems involving force systems in which all of the forces lie in the same plane and only a few forces are involved. If many forces are involved, however, or the forces do not lie in the same plane, it is better to use algebraic methods to avoid complicated space diagrams. Systematic procedures for solving force problems by algebraic methods are outlined beginning on page 148. In connection with the use of these procedures, it is necessary to define several terms applicable to force systems in general.

The single force which produces the same effect upon a body as two or more forces acting together is called their *resultant*. The separate forces which can be so combined are called the *components*. Finding the resultant of two or more forces is called the *composition of forces*, and finding two or more components of a given force, the *resolution of forces*. Forces are said to be *concurrent* when their lines of action can be extended to meet at a common point; forces that are *parallel* are, of course, *nonconcurrent*. Two forces having the same line of action are said to be *collinear*. Two forces equal in magnitude, parallel, and in opposite directions constitute a *couple*. Forces all in the same plane are said to be *coplanar*; if not in the same plane, they are called *noncoplanar* forces.

The *resultant* of a system of forces is the simplest equivalent system that can be determined. It may be a single force, a couple, or a noncoplanar force and a couple. This last type of resultant, a noncoplanar force and a couple, may be replaced, if desired, by two *skewed* forces (forces that are nonconcurrent, nonparallel, and noncoplanar). When the resultant of a system of forces is zero, the system is in equilibrium, that is, the body on which the force system acts remains at rest or continues to move with uniform velocity.

**Algebraic Solution of Force Systems—All Forces in the Same Plane**

*Finding Two Concurrent Components of a Single Force:*

|  |   |
|--|---|
|  | <p>Case I: To find two components <math>F_1</math> and <math>F_2</math> at angles <math>\theta</math> and <math>\phi</math>, <math>\phi</math> not being <math>90^\circ</math>.</p> $F_1 = \frac{F \sin \theta}{\sin \phi}$ $F_2 = \frac{F \sin(\phi - \theta)}{\sin \phi}$ |
|  | <p>Case II: Components <math>F_1</math> and <math>F_2</math> form <math>90^\circ</math> angle.</p> $F_1 = F \sin \theta$ $F_2 = F \cos \theta$  |

*Finding the Resultant of Two Concurrent Forces:*

|  |  |
|--|--|
|  | <p>Case I: Forces <math>F_1</math> and <math>F_2</math> do not form <math>90^\circ</math> angle.</p> $R = \frac{F_1 \sin \phi}{\sin \theta} \text{ or } R = \frac{F_2 \sin \phi}{\sin(\phi - \theta)} \text{ or}$ $R = \sqrt{F_1^2 + F_2^2 + 2F_1F_2 \cos \phi}$ $\tan \theta = \frac{F_1 \sin \phi}{F_1 \cos \phi + F_2}$ |
|  | <p>Case II: Forces <math>F_1</math> and <math>F_2</math> form <math>90^\circ</math> angle.</p> $R = \frac{F_2}{\cos \theta} \text{ or } R = \frac{F_1}{\sin \theta} \text{ or}$ $R = \sqrt{F_1^2 + F_2^2}$ $\tan \theta = \frac{F_1}{F_2}$   |

*Finding the Resultant of Three or More Concurrent Forces:*

|       | <p>To determine resultant of forces <math>F_1, F_2, F_3</math>, etc. making angles, respectively, of <math>\theta_1, \theta_2, \theta_3</math>, etc. with the <math>x</math> axis, find the <math>x</math> and <math>y</math> components <math>F_x</math> and <math>F_y</math> of each force and arrange in a table similar to that shown below for a system of three forces. Find the algebraic sum of the <math>F_x</math> and <math>F_y</math> components (<math>\Sigma F_x</math> and <math>\Sigma F_y</math>) and use these to determine resultant <math>R</math>.</p> <table border="1" data-bbox="502 1215 968 1371"> <thead> <tr> <th>Force</th> <th><math>F_x</math></th> <th><math>F_y</math></th> </tr> </thead> <tbody> <tr> <td><math>F_1</math></td> <td><math>F_1 \cos \theta_1</math></td> <td><math>F_1 \sin \theta_1</math></td> </tr> <tr> <td><math>F_2</math></td> <td><math>F_2 \cos \theta_2</math></td> <td><math>F_2 \sin \theta_2</math></td> </tr> <tr> <td><math>F_3</math></td> <td><math>F_3 \cos \theta_3</math></td> <td><math>F_3 \sin \theta_3</math></td> </tr> <tr> <td></td> <td><math>\Sigma F_x</math></td> <td><math>\Sigma F_y</math></td> </tr> </tbody> </table> $R = \sqrt{(\Sigma F_x)^2 + (\Sigma F_y)^2}$ $\cos \theta_R = \frac{\Sigma F_x}{R}$ <p>or <math>\tan \theta_R = \frac{\Sigma F_y}{\Sigma F_x}</math></p> | Force               | $F_x$ | $F_y$ | $F_1$ | $F_1 \cos \theta_1$ | $F_1 \sin \theta_1$ | $F_2$ | $F_2 \cos \theta_2$ | $F_2 \sin \theta_2$ | $F_3$ | $F_3 \cos \theta_3$ | $F_3 \sin \theta_3$ |  | $\Sigma F_x$ | $\Sigma F_y$ |
|-------|--|---------------------|-------|-------|-------|---------------------|---------------------|-------|---------------------|---------------------|-------|---------------------|---------------------|--|--------------|--------------|
| Force | $F_x$  | $F_y$               |       |       |       |                     |                     |       |                     |                     |       |                     |                     |  |              |              |
| $F_1$ | $F_1 \cos \theta_1$  | $F_1 \sin \theta_1$ |       |       |       |                     |                     |       |                     |                     |       |                     |                     |  |              |              |
| $F_2$ | $F_2 \cos \theta_2$  | $F_2 \sin \theta_2$ |       |       |       |                     |                     |       |                     |                     |       |                     |                     |  |              |              |
| $F_3$ | $F_3 \cos \theta_3$  | $F_3 \sin \theta_3$ |       |       |       |                     |                     |       |                     |                     |       |                     |                     |  |              |              |
|       | $\Sigma F_x$   | $\Sigma F_y$        |       |       |       |                     |                     |       |                     |                     |       |                     |                     |  |              |              |

*Finding a Force and a Couple Which Together are Equivalent to a Single Force:*

To resolve a single force  $F$  into a couple of moment  $M$  and a force  $P$  passing through any chosen point  $O$  at a distance  $d$  from the original force  $F$ , use the relations

$$P = F$$

$$M = F \times d$$

The moment  $M$  must, of course, tend to produce rotation about  $O$  in the same direction as the original force. Thus, as seen in the diagram,  $F$  tends to produce clockwise rotation; hence  $M$  is shown clockwise.

*Finding the Resultant of a Single Force and a Couple:*

The resultant of a single force  $F$  and a couple  $M$  is a single force  $R$  equal in magnitude and direction to  $F$  and parallel to it at a distance  $d$  to the left or right of  $F$ .

$$R = F$$

$$d = M \div R$$

Resultant  $R$  is placed to the left or right of point of application  $O$  of the original force  $F$  depending on which position will give  $R$  the same direction of moment about  $O$  as the original couple  $M$ .

*Finding the Resultant of a System of Parallel Forces:*

To find the resultant of a system of coplanar parallel forces, proceed as indicated below.

1) Select any convenient point  $O$  from which perpendicular distances  $d_1, d_2, d_3$ , etc. to parallel forces  $F_1, F_2, F_3$ , etc. can be specified or calculated.

2) Find the algebraic sum of all the forces; this will give the magnitude of the resultant of the system.

$$R = \Sigma F = F_1 + F_2 + F_3 + \dots$$

3) Find the algebraic sum of the moments of the forces about  $O$ ; clockwise moments may be taken as negative and counterclockwise moments as positive:

$$\Sigma M_O = F_1 d_1 + F_2 d_2 + \dots$$

4) Calculate the distance  $d$  from  $O$  to the line of action of resultant  $R$ :

$$d = \Sigma M_O \div R$$

This distance is measured to the left or right from  $O$  depending on which position will give the moment of  $R$  the same direction of rotation about  $O$  as the couple  $\Sigma M_O$ , that is, if  $\Sigma M_O$  is negative, then  $d$  is left or right of  $O$  depending on which direction will make  $R \times d$  negative.

*Note Concerning Interpretation of Results:* If  $R = 0$ , then the resultant of the system is a couple  $\Sigma M_O$ ; if  $\Sigma M_O = 0$  then the resultant is a single force  $R$ ; if both  $R$  and  $\Sigma M_O = 0$ , then the system is in equilibrium.

## Finding the Resultant of Forces Not Intersecting at a Common Point:

To determine the resultant of a coplanar, nonconcurrent, nonparallel force system as shown in the diagram, proceed as shown below.

1) Draw a set of  $x$  and  $y$  coordinate axes through any convenient point  $O$  in the plane of the forces as shown in the diagram.

2) Determine the  $x$  and  $y$  coordinates of any convenient point on the line of action of each force and the angle  $\theta$ , measured in a counterclockwise direction, that each line of action makes with the positive  $x$  axis. For example, in the diagram, coordinates  $x_4, y_4$ , and  $\theta_4$  are shown for  $F_4$ . Similar data should be known for each of the forces of the system.

3) Calculate the  $x$  and  $y$  components ( $F_x, F_y$ ) of each force and the moment of each component about  $O$ . Counterclockwise moments are considered positive and clockwise moments are negative. Tabulate all results in a manner similar to that shown below for a system of three forces and find  $\Sigma F_x, \Sigma F_y, \Sigma M_O$  by algebraic addition.

| Force<br>$F$ | Coordinates of $F$ |       |            | Components of $F$   |                     | Moment of $F$ about $O$                         |
|--------------|--------------------|-------|------------|---------------------|---------------------|---|
|              | $x$                | $y$   | $\theta$   | $F_x$               | $F_y$               | $M_O = xF_y - yF_x$                             |
| $F_1$        | $x_1$              | $y_1$ | $\theta_1$ | $F_1 \cos \theta_1$ | $F_1 \sin \theta_1$ | $x_1 F_1 \sin \theta_1 - y_1 F_1 \cos \theta_1$ |
| $F_2$        | $x_2$              | $y_2$ | $\theta_2$ | $F_2 \cos \theta_2$ | $F_2 \sin \theta_2$ | $x_2 F_2 \sin \theta_2 - y_2 F_2 \cos \theta_2$ |
| $F_3$        | $x_3$              | $y_3$ | $\theta_3$ | $F_3 \cos \theta_3$ | $F_3 \sin \theta_3$ | $x_3 F_3 \sin \theta_3 - y_3 F_3 \cos \theta_3$ |
|              |                    |       |            | $\Sigma F_x$        | $\Sigma F_y$        | $\Sigma M_O$                                    |

4. Compute the resultant of the system and the angle  $\theta_R$  it makes with the  $x$  axis by using the formulas:

$$R = \sqrt{(\Sigma F_x)^2 + (\Sigma F_y)^2}$$

$$\cos \theta_R = \Sigma F_x \div R \text{ or } \tan \theta_R = \Sigma F_y \div \Sigma F_x$$

5. Calculate the distance  $d$  from  $O$  to the line of action of the resultant  $R$ :

$$d = \Sigma M_O \div R$$

Distance  $d$  is in such direction from  $O$  as will make the moment of  $R$  about  $O$  have the same sign as  $\Sigma M_O$ .

*Note Concerning Interpretation of Results:* If  $R = 0$ , then the resultant is a couple  $\Sigma M_O$ ; if  $\Sigma M_O = 0$ , then  $R$  passes through  $O$ ; if both  $R = 0$  and  $\Sigma M_O = 0$ , then the system is in equilibrium.

*Example:* Find the resultant of three coplanar nonconcurrent forces for which the following data are given.

$$F_1 = 10 \text{ lbs; } x_1 = 5 \text{ in.; } y_1 = -1 \text{ in.; } \theta_1 = 270^\circ$$

$$F_2 = 20 \text{ lbs; } x_2 = 4 \text{ in.; } y_2 = 1.5 \text{ in.; } \theta_2 = 50^\circ$$

$$F_3 = 30 \text{ lbs; } x_3 = 2 \text{ in.; } y_3 = 2 \text{ in.; } \theta_3 = 60^\circ$$

$$F_{x_1} = 10 \cos 270^\circ = 10 \times 0 = 0 \text{ lbs.}$$

$$F_{x_2} = 20 \cos 50^\circ = 20 \times 0.64279 = 12.86 \text{ lbs.}$$

$$F_{x_3} = 30 \cos 60^\circ = 30 \times 0.5000 = 15.00 \text{ lbs.}$$

$$F_{y_1} = 10 \times \sin 270^\circ = 10 \times (-1) = -10.00 \text{ lbs.}$$

$$F_{y_2} = 20 \times \sin 50^\circ = 20 \times 0.76604 = 15.32 \text{ lbs.}$$

$$F_{y_3} = 30 \times \sin 60^\circ = 30 \times 0.86603 = 25.98 \text{ lbs.}$$

$$M_{o_1} = 5 \times (-10) - (-1) \times 0 = -50 \text{ in. lbs.}$$

$$M_{o_2} = 4 \times 15.32 - 1.5 \times 12.86 = 41.99 \text{ in. lbs.}$$

$$M_{o_3} = 2 \times 25.98 - 2 \times 15 = 21.96 \text{ in. lbs.}$$

**Note:** When working in metric SI units, pounds are replaced by newtons (N); inches by meters or millimeters, and inch-pounds by newton-meters (N · m) or newton-millimeters (N · mm).

| Force<br>$F$ | Coordinates of $F$ |     |             | Components of $F$    |                      | Moment<br>of $F$ about $O$ |
|--------------|--------------------|-----|-------------|----------------------|----------------------|----------------------------|
|              | $x$                | $y$ | $\theta$    | $F_x$                | $F_y$                |                            |
| $F_1 = 10$   | 5                  | -1  | $270^\circ$ | 0                    | -10.00               | -50.00                     |
| $F_2 = 20$   | 4                  | 1.5 | $50^\circ$  | 12.86                | 15.32                | 41.99                      |
| $F_3 = 30$   | 2                  | 2   | $60^\circ$  | 15.00                | 25.98                | 21.96                      |
|              |                    |     |             | $\Sigma F_x = 27.86$ | $\Sigma F_y = 31.30$ | $\Sigma M_O = 13.95$       |

$$R = \sqrt{(27.86)^2 + (31.30)^2}$$

$$= 41.90 \text{ lbs.}$$

$$\tan \theta_R = \frac{31.30}{27.86} = 1.1235$$

$$\theta_R = 48^\circ 20'$$

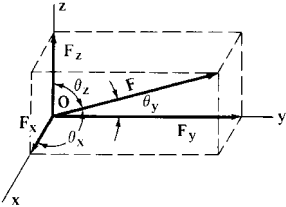

$$d = \frac{13.95}{41.90} = 0.33 \text{ inches}$$

measured as shown on the diagram.

### Algebraic Solution of Force Systems — Forces Not in Same Plane

#### Resolving a Single Force Into Its Three Rectangular Components:

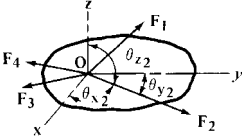

$F_x = F \cos \theta_x$   
 $F_y = F \cos \theta_y$   
 $F_z = F \cos \theta_z$   
 $F = \sqrt{F_x^2 + F_y^2 + F_z^2}$

The diagram shows how a force  $F$  may be resolved at any point  $O$  on its line of action into three concurrent components each of which is perpendicular to the other two.

The  $x, y, z$  components  $F_x, F_y, F_z$  of force  $F$  are determined from the accompanying relations in which  $\theta_x, \theta_y, \theta_z$  are the angles that the force  $F$  makes with the  $x, y, z$  axes.

#### Finding the Resultant of Any Number of Concurrent Forces:

To find the resultant of any number of noncoplanar concurrent forces  $F_1, F_2, F_3$ , etc., use the procedure outlined below.

- 1) Draw a set of  $x, y, z$  axes at  $O$ , the point of concurrency of the forces. The angles each force makes measured counterclockwise from the positive  $x, y$ , and  $z$  coordinate axes must be known in addition to the magnitudes of the forces. For force  $F_2$ , for example, the angles are  $\theta_{x2}, \theta_{y2}, \theta_{z2}$  as indicated on the diagram.
- 2) Apply the first three formulas given under the heading "Resolving a Single Force Into Its Three Rectangular Components" to each force to find its  $x, y$ , and  $z$  components. Tabulate these calculations as shown below for a system of three forces. Algebraically add the calculated components to find  $\Sigma F_x, \Sigma F_y$ , and  $\Sigma F_z$  which are the components of the resultant.

| Force<br>$F$ | Angles        |               |               | Components of Forces   |                        |                        |
|--------------|---------------|---------------|---------------|------------------------|------------------------|------------------------|
|              | $\theta_x$    | $\theta_y$    | $\theta_z$    | $F_x$                  | $F_y$                  | $F_z$                  |
| $F_1$        | $\theta_{x1}$ | $\theta_{y1}$ | $\theta_{z1}$ | $F_1 \cos \theta_{x1}$ | $F_1 \cos \theta_{y1}$ | $F_1 \cos \theta_{z1}$ |
| $F_2$        | $\theta_{x2}$ | $\theta_{y2}$ | $\theta_{z2}$ | $F_2 \cos \theta_{x2}$ | $F_2 \cos \theta_{y2}$ | $F_2 \cos \theta_{z2}$ |
| $F_3$        | $\theta_{x3}$ | $\theta_{y3}$ | $\theta_{z3}$ | $F_3 \cos \theta_{x3}$ | $F_3 \cos \theta_{y3}$ | $F_3 \cos \theta_{z3}$ |
|              |               |               |               | $\Sigma F_x$           | $\Sigma F_y$           | $\Sigma F_z$           |

3. Find the resultant of the system from the formula  $R = \sqrt{(\Sigma F_x)^2 + (\Sigma F_y)^2 + (\Sigma F_z)^2}$

4. Calculate the angles  $\theta_{xR}, \theta_{yR}$ , and  $\theta_{zR}$  that the resultant  $R$  makes with the respective coordinate axes:

$$\cos \theta_{xR} = \frac{\Sigma F_x}{R}$$

$$\cos \theta_{yR} = \frac{\Sigma F_y}{R}$$

$$\cos \theta_{zR} = \frac{\Sigma F_z}{R}$$

*Finding the Resultant of Parallel Forces Not in the Same Plane:*

In the diagram, forces  $F_1, F_2$ , etc. represent a system of noncoplanar parallel forces. To find the resultant of such systems, use the procedure shown below.

1) Draw a set of  $x, y$ , and  $z$  coordinate axes through any point  $O$  in such a way that one of these axes, say the  $z$  axis, is parallel to the lines of action of the forces. The  $x$  and  $y$  axes then will be perpendicular to the forces.

2) Set the distances of each force from the  $x$  and  $y$  axes in a table as shown below. For example,  $x_1$  and  $y_1$  are the  $x$  and  $y$  distances for  $F_1$  shown in the diagram.

3) Calculate the moment of each force about the  $x$  and  $y$  axes and set the results in the table as shown for a system consisting of three forces. The algebraic sums of the moments  $\sum M_x$  and  $\sum M_y$  are then obtained. (In taking moments about the  $x$  and  $y$  axes, assign counterclockwise moments a plus (+) sign and clockwise moments a minus (-) sign. In deciding whether a moment is counterclockwise or clockwise, look from the positive side of the axis in question toward the negative side.)

| Force      | Coordinates of Force $F$ |       | Moments $M_x$ and $M_y$ due to $F$ |              |
|------------|--------------------------|-------|------------------------------------|--------------|
|            | $x$                      | $y$   | $M_x$                              | $M_y$        |
| $F_1$      | $x_1$                    | $y_1$ | $F_1 y_1$                          | $F_1 x_1$    |
| $F_2$      | $x_2$                    | $y_2$ | $F_2 y_2$                          | $F_2 x_2$    |
| $F_3$      | $x_3$                    | $y_3$ | $F_3 y_3$                          | $F_3 x_3$    |
| $\Sigma F$ |                          |       | $\Sigma M_x$                       | $\Sigma M_y$ |

4. Find the algebraic sum  $\Sigma F$  of all the forces; this will be the resultant  $R$  of the system.

$$R = \Sigma F = F_1 + F_2 + \dots$$

5. Calculate  $x_R$  and  $y_R$ , the moment arms of the resultant:

$$x_R = \Sigma M_y \div R$$

$$y_R = \Sigma M_x \div R$$

These moment arms are measured in such direction along the  $x$  and  $y$  axes as will give the resultant a moment of the same direction of rotation as  $\Sigma M_x$  and  $\Sigma M_y$ .

*Note Concerning Interpretation of Results:* If  $\Sigma M_x$  and  $\Sigma M_y$  are both 0, then the resultant is a single force  $R$  along the  $z$  axis; if  $R$  is also 0, then the system is in equilibrium. If  $R$  is 0 but  $\Sigma M_x$  and  $\Sigma M_y$  are not both 0, then the resultant is a couple

$$M_R = \sqrt{(\Sigma M_x)^2 + (\Sigma M_y)^2}$$

that lies in a plane parallel to the  $z$  axis and making an angle  $\theta_R$  measured in a counterclockwise direction from the positive  $x$  axis and calculated from the following formula:

$$\sin \theta_R = \frac{\Sigma M_x}{M_R}$$

## Finding the Resultant of Nonparallel Forces Not Meeting at a Common Point:

The diagram shows a system of noncoplanar, nonparallel, nonconcurrent forces  $F_1, F_2$ , etc. for which the resultant is to be determined. Generally speaking, the resultant will be a noncoplanar force and a couple which may be further combined, if desired, into two forces that are skewed.

This is the most general force system that can be devised, so each of the other systems so far described represents a special, simpler case of this general force system. The method of solution described below for a system of three forces applies for any number of forces.

- 1) Select a set of coordinate  $x, y$ , and  $z$  axes at any desired point  $O$  in the body as shown in the diagram.
- 2) Determine the  $x, y$ , and  $z$  coordinates of any convenient point on the line of action of each force as shown for  $F_2$ . Also determine the angles,  $\theta_x, \theta_y, \theta_z$  that each force makes with each coordinate axis. These angles are measured counterclockwise from the positive direction of the  $x, y$ , and  $z$  axes. The data is tabulated, as shown in the table accompanying Step 3, for convenient use in subsequent calculations.
- 3) Calculate the  $x, y$ , and  $z$  components of each force using the formulas given in the accompanying table. Add these components algebraically to get  $\Sigma F_x, \Sigma F_y$  and  $\Sigma F_z$  which are the components of the resultant,  $R$ , given by the formula,

$$R = \sqrt{(\Sigma F_x)^2 + (\Sigma F_y)^2 + (\Sigma F_z)^2}$$

| Force<br>$F$ | Coordinates of Force $F$ |       |       |               |               |               | Components of $F$      |                        |                        |
|--------------|--------------------------|-------|-------|---------------|---------------|---------------|------------------------|------------------------|------------------------|
|              | $x$                      | $y$   | $z$   | $\theta_x$    | $\theta_y$    | $\theta_z$    | $F_x$                  | $F_y$                  | $F_z$                  |
| $F_1$        | $x_1$                    | $y_1$ | $z_1$ | $\theta_{x1}$ | $\theta_{y1}$ | $\theta_{z1}$ | $F_1 \cos \theta_{x1}$ | $F_1 \cos \theta_{y1}$ | $F_1 \cos \theta_{z1}$ |
| $F_2$        | $x_2$                    | $y_2$ | $z_2$ | $\theta_{x2}$ | $\theta_{y2}$ | $\theta_{z2}$ | $F_2 \cos \theta_{x2}$ | $F_2 \cos \theta_{y2}$ | $F_2 \cos \theta_{z2}$ |
| $F_3$        | $x_3$                    | $y_3$ | $z_3$ | $\theta_{x3}$ | $\theta_{y3}$ | $\theta_{z3}$ | $F_3 \cos \theta_{x3}$ | $F_3 \cos \theta_{y3}$ | $F_3 \cos \theta_{z3}$ |
|              |                          |       |       |               |               |               | $\Sigma F_x$           | $\Sigma F_y$           | $\Sigma F_z$           |

The resultant force  $R$  makes angles of  $\theta_{xR}, \theta_{yR}$ , and  $\theta_{zR}$  with the  $x, y$ , and  $z$  axes, respectively, and passes through the selected point  $O$ . These angles are determined from the formulas,

$$\cos \theta_{xR} = \Sigma F_x \div R$$

$$\cos \theta_{yR} = \Sigma F_y \div R$$

$$\cos \theta_{zR} = \Sigma F_z \div R$$

4. Calculate the moments  $M_x, M_y, M_z$  about  $x, y,$  and  $z$  axes, respectively, due to the  $F_x, F_y,$  and  $F_z$  components of each force and set them in tabular form. The formulas to use are given in the accompanying table.

In interpreting moments about the  $x, y,$  and  $z$  axes, consider counterclockwise moments a plus (+) sign and clockwise moments a minus (-) sign. In deciding whether a moment is counterclockwise or clockwise, look from the positive side of the axis in question toward the negative side.

| Force | Moments of Components of $F (F_x, F_y, F_z)$ about $x, y, z$ axes |                                  |                                  |
|-------|---|----------------------------------|----------------------------------|
| $F$   | $M_x = yF_z - zF_y$   | $M_y = zF_x - xF_z$              | $M_z = xF_y - yF_x$              |
| $F_1$ | $M_{x1} = y_1F_{z1} - z_1F_{y1}$                                  | $M_{y1} = z_1F_{x1} - x_1F_{z1}$ | $M_{z1} = x_1F_{y1} - y_1F_{x1}$ |
| $F_2$ | $M_{x2} = y_2F_{z2} - z_2F_{y2}$                                  | $M_{y2} = z_2F_{x2} - x_2F_{z2}$ | $M_{z2} = x_2F_{y2} - y_2F_{x2}$ |
| $F_3$ | $M_{x3} = y_3F_{z3} - z_3F_{y3}$                                  | $M_{y3} = z_3F_{x3} - x_3F_{z3}$ | $M_{z3} = x_3F_{y3} - y_3F_{x3}$ |
|       | $\Sigma M_x$  | $\Sigma M_y$                     | $\Sigma M_z$                     |

5. Add the component moments algebraically to get  $\Sigma M_x, \Sigma M_y,$  and  $\Sigma M_z$  which are the components of the resultant couple,  $M$ , given by the formula,

$$M = \sqrt{(\Sigma M_x)^2 + (\Sigma M_y)^2 + (\Sigma M_z)^2}$$

The resultant couple  $M$  will tend to produce rotation about an axis making angles of  $\beta_x, \beta_y,$  and  $\beta_z$  with the  $x, y, z$  axes, respectively. These angles are determined from the formulas,

$$\cos \beta_x = \frac{\Sigma M_x}{M} \quad \cos \beta_y = \frac{\Sigma M_y}{M} \quad \cos \beta_z = \frac{\Sigma M_z}{M}$$

*General Method of Locating Resultant When Its Components are Known:* To determine the position of the resultant force of a system of forces, proceed as follows:

From the origin, point  $O$ , of a set of coordinate axes  $x, y, z,$  lay off on the  $x$  axis a length  $A$  representing the algebraic sum  $\Sigma F_x$  of the  $x$  components of all the forces. From the end of line  $A$  lay off a line  $B$  representing  $\Sigma F_y$ , the algebraic sum of the  $y$  components; this line  $B$  is drawn in a direction parallel to the  $y$  axis. From the end of line  $B$  lay off a line  $C$  representing  $\Sigma F_z$ . Finally, draw a line  $R$  from  $O$  to the end of  $C$ ;  $R$  will be the resultant of the system.

### Friction

**Properties of Friction.**—Friction is the resistance to motion that takes place when one body is moved upon another, and is generally defined as “that force which acts between two bodies at their surface of contact, so as to resist their sliding on each other.” According to the conditions under which sliding occurs, the force of friction,  $F$ , bears a certain relation to the force between the two bodies called the normal force  $N$ . The relation between force of friction and normal force is given by the *coefficient of friction*, generally denoted by the Greek letter  $\mu$ . Thus:

$$F = \mu \times N \quad \text{and} \quad \mu = \frac{F}{N}$$

*Example:* A body weighing 28 pounds rests on a horizontal surface. The force required to keep it in motion along the surface is 7 pounds. Find the coefficient of friction.

$$\mu = \frac{F}{N} = \frac{7}{28} = 0.25$$

If a body is placed on an inclined plane, the friction between the body and the plane will prevent it from sliding down the inclined surface, provided the angle of the plane with the horizontal is not too great. There will be a certain angle, however, at which the body will just barely be able to remain stationary, the frictional resistance being very nearly overcome by the tendency of the body to slide down. This angle is termed the angle of repose, and the tangent of this angle equals the coefficient of friction. The angle of repose is frequently denoted by the Greek letter  $\theta$ . Thus,  $\mu = \tan \theta$ .

A greater force is required to start a body moving from a state of rest than to merely keep it in motion, because the *friction of rest* is greater than the *friction of motion*.

**Laws of Friction.**—The laws of friction for unlubricated or dry surfaces are summarized in the following statements.

1) For low pressures (normal force per unit area) the friction is directly proportional to the normal force between the two surfaces. As the pressure increases, the friction does not rise proportionally; but when the pressure becomes abnormally high, the friction increases at a rapid rate until seizing takes place.

2) The friction both in its total amount and its coefficient is independent of the areas in contact, so long as the normal force remains the same. This is true for moderate pressures only. For high pressures, this law is modified in the same way as in the first case.

3) At very low velocities the friction is independent of the velocity of rubbing. As the velocities increase, the friction decreases.

*Lubricated Surfaces:* For well lubricated surfaces, the laws of friction are considerably different from those governing dry or poorly lubricated surfaces.

1) The frictional resistance is almost independent of the pressure (normal force per unit area) if the surfaces are flooded with oil.

2) The friction varies directly as the speed, at low pressures; but for high pressures the friction is very great at low velocities, approaching a minimum at about two feet per second linear velocity, and afterwards increasing approximately as the square root of the speed.

3) For well lubricated surfaces the frictional resistance depends, to a very great extent, on the temperature, partly because of the change in the viscosity of the oil and partly because, for a journal bearing, the diameter of the bearing increases with the rise of temperature more rapidly than the diameter of the shaft, thus relieving the bearing of side pressure.

4) If the bearing surfaces are flooded with oil, the friction is almost independent of the nature of the material of the surfaces in contact. As the lubrication becomes less ample, the coefficient of friction becomes more dependent upon the material of the surfaces.

**Influence of Friction on the Efficiency of Small Machine Elements.**—Friction between machine parts lowers the efficiency of a machine. Average values of the efficiency, in per cent, of the most common machine elements when carefully made are ordi-

nary bearings, 95 to 98; roller bearings, 98; ball bearings, 99; spur gears with cut teeth, including bearings, 99; bevel gears with cut teeth, including bearings, 98; belting, from 96 to 98; high-class silent power transmission chain, 97 to 99; roller chains, 95 to 97.

**Coefficients of Friction.**—Tables 1 and 2 provide representative values of static friction for various combinations of materials with dry (clean, unlubricated) and lubricated surfaces. The values for static or breakaway friction shown in these tables will generally be higher than the subsequent or sliding friction. Typically, the steel-on-steel static coefficient of 0.8 unlubricated will drop to 0.4 when sliding has been initiated; with oil lubrication, the value will drop from 0.16 to 0.03.

Many factors affect friction, and even slight deviations from normal or test conditions can produce wide variations. Accordingly, when using friction coefficients in design calculations, due allowance or factors of safety should be considered, and in critical applications, specific tests conducted to provide specific coefficients for material, geometry, and/or lubricant combinations.

**Table 1. Coefficients of Static Friction for Steel on Various Materials**

| Material          | Coefficient of Friction, $\mu$ |            | Material         | Coefficient of Friction, $\mu$ |            |
|-------------------|--------------------------------|------------|------------------|--------------------------------|------------|
|                   | Clean                          | Lubricated |                  | Clean                          | Lubricated |
| Steel             | 0.8                            | 0.16       | Hard carbon      | 0.14                           | 0.11–0.14  |
| Copper-lead alloy | 0.22                           | ...        | Graphite         | 0.1                            | 0.1        |
| Phosphor-bronze   | 0.35                           | ...        | Tungsten carbide | 0.4–0.6                        | 0.1–0.2    |
| Aluminum-bronze   | 0.45                           | ...        | Plexiglas        | 0.4–0.5                        | 0.4–0.5    |
| Brass             | 0.35                           | 0.19       | Polystyrene      | 0.3–0.35                       | 0.3–0.35   |
| Cast iron         | 0.4                            | 0.21       | Polythene        | 0.2                            | 0.2        |
| Bronze            | ...                            | 0.16       | Teflon           | 0.04                           | 0.04       |
| Sintered bronze   | ...                            | 0.13       |                  |                                |            |

**Rolling Friction.**—When a body rolls on a surface, the force resisting the motion is termed *rolling friction* or *rolling resistance*. Let  $W$  = total weight of rolling body or load on wheel, in pounds;  $r$  = radius of wheel, in inches;  $f$  = coefficient of rolling resistance, in inches. Then: resistance to rolling, in pounds =  $(W \times f) \div r$ .

The coefficient of rolling resistance varies with the conditions. For wood on wood it may be assumed as 0.06 inch; for iron on iron, 0.02 inch; iron on granite, 0.085 inch; iron on asphalt, 0.15 inch; and iron on wood, 0.22 inch.

The coefficient of rolling resistance,  $f$ , is in inches and is not the same as the sliding or static coefficient of friction given in Tables 1 and 2, which is a dimensionless ratio between frictional resistance and normal load. Various investigators are not in close agreement on the true values for these coefficients and the foregoing values should only be used for the approximate calculation of rolling resistance.

## Mechanisms

### Lever

| Types of Levers   | Examples   |
|---|--|
|  <p> <math>F:W = l:L</math> <math>F \times L = W \times l</math><br/> <math>F = \frac{W \times l}{L}</math> <math>W = \frac{F \times L}{l}</math><br/> <math>L = \frac{W \times a}{W + F} = \frac{W \times l}{F}</math> <math>l = \frac{F \times a}{W + F} = \frac{F \times L}{W}</math> </p>  | <p>A pull of 80 pounds is exerted at the end of the lever, at <math>W</math>; <math>l = 12</math> inches and <math>L = 32</math> inches.</p> <p>Find the value of force <math>F</math> required to balance the lever.</p> $F = \frac{80 \times 12}{32} = \frac{960}{32} = 30 \text{ pounds}$ <p>If <math>F = 20</math>; <math>W = 180</math>; and <math>l = 3</math>; how long must <math>L</math> be made to secure equilibrium?</p> $L = \frac{180 \times 3}{20} = 27$                                   |
|  <p> <math>F:W = l:L</math> <math>F \times L = W \times l</math><br/> <math>F = \frac{W \times l}{L}</math> <math>W = \frac{F \times L}{l}</math><br/> <math>L = \frac{W \times a}{W - F} = \frac{W \times l}{F}</math> <math>l = \frac{F \times a}{W - F} = \frac{F \times L}{W}</math> </p> | <p>Total length <math>L</math> of a lever is 25 inches. A weight of 90 pounds is supported at <math>W</math>; <math>l</math> is 10 inches.</p> <p>Find the value of <math>F</math>.</p> $F = \frac{90 \times 10}{25} = 36 \text{ pounds}$ <p>If <math>F = 100</math> pounds, <math>W = 2200</math> pounds, and <math>a = 5</math> feet, what should <math>L</math> equal to secure equilibrium?</p> $L = \frac{2200 \times 5}{2200 - 100} = 5.24 \text{ feet}$   |
|  <p>When three or more forces act on lever:</p> $F \times x = W \times a + P \times b + Q \times c$ $x = \frac{W \times a + P \times b + Q \times c}{F}$ $F = \frac{W \times a + P \times b + Q \times c}{x}$  | <p>Let <math>W = 20</math>, <math>P = 30</math>, and <math>Q = 15</math> pounds; <math>a = 4</math>, <math>b = 7</math>, and <math>c = 10</math> inches.</p> <p>If <math>x = 6</math> inches, find <math>F</math>.</p> $F = \frac{20 \times 4 + 30 \times 7 + 15 \times 10}{6} = 73\frac{1}{3} \text{ lbs}$ <p>Assuming <math>F = 20</math> pounds in the example above, how long must lever arm <math>x</math> be made?</p> $x = \frac{20 \times 4 + 30 \times 7 + 15 \times 10}{20} = 22 \text{ inches}$ |

The above formulas are valid using metric SI units, with forces expressed in newtons, and lengths in meters. However, it should be noted that the weight of a mass  $W$  kilograms is equal to a force of  $Wg$  newtons, where  $g$  is approximately  $9.81 \text{ m/s}^2$ . Thus, supposing that in the first

example  $l = 0.4$  m,  $L = 1.2$  m, and  $W = 30$  kg, then the weight of  $W$  is 30g newtons, so that the force  $F$  required to balance the lever is  $F = \frac{30g \times 0.4}{1.2} = 10g = 98.1$  newtons.

This force could be produced by suspending a mass of 10 kg at  $F$ .

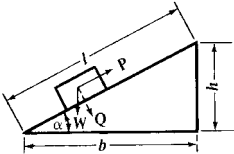

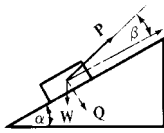

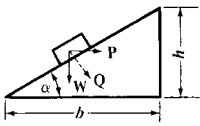

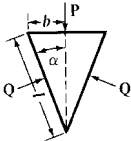

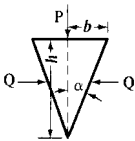

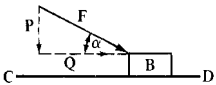

**Table of Forces on Inclined Planes**

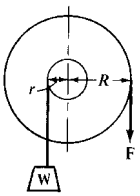

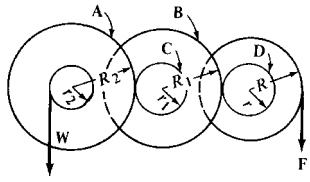

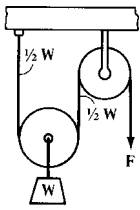

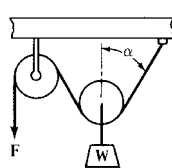

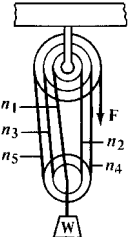

| Per Cent of Grade. Rise, Ft. per 100 Ft. | Angle $\alpha$ | Tension $P$ in Cable per Ton of 2000 Lbs. | Perpendicular Pressure $Q$ on Plane per Ton of 2000 Lbs. | Per Cent of Grade. Rise, Ft. per 100 Ft. | Angle $\alpha$ | Tension $P$ in Cable per Ton of 2000 Lbs. | Perpendicular Pressure $Q$ on Plane per Ton of 2000 Lbs. |
|--|----------------|---|--|--|----------------|---|--|

|   | <p><b>Force Moving Body on Horizontal Plane.</b>—<math>F</math> tends to move <math>B</math> along line <math>CD</math>; <math>Q</math> is the component which actually moves <math>B</math>; <math>P</math> is the pressure, due to <math>F</math>, of the body on <math>CD</math>.</p> $Q = F \times \cos \alpha \quad P = \sqrt{F^2 - Q^2}$   |

**Wheels and Pulleys**

|  |  |
|--|--|
|  $F:W = r:R$ $F \times R = W \times r$ $F = \frac{W \times r}{R}$ $W = \frac{F \times R}{r}$ $R = \frac{W \times r}{F}$ $r = \frac{F \times R}{W}$   | <p>The radius of a drum on which is wound the lifting rope of a windlass is 2 inches. What force will be exerted at the periphery of a gear of 24 inches diameter, mounted on the same shaft as the drum and transmitting power to it, if one ton (2000 pounds) is to be lifted? Here <math>W = 2000</math>; <math>R = 12</math>; <math>r = 2</math>.</p> $F = \frac{2000 \times 2}{12} = 333 \text{ pounds}$  |
|  <p>A, B, C and D are the pitch circles of gears.</p> $F = \frac{W \times r \times r_1 \times r_2}{R \times R_1 \times R_2}$ $W = \frac{F \times R \times R_1 \times R_2}{r \times r_1 \times r_2}$  | <p>Let the pitch diameters of gears A, B, C and D be 30, 28, 12 and 10 inches, respectively. Then <math>R_2 = 15</math>; <math>R_1 = 14</math>; <math>r_1 = 6</math>; and <math>r = 5</math>. Let <math>R = 12</math>, and <math>r_2 = 4</math>. Then the force <math>F</math> required to lift a weight <math>W</math> of 2000 pounds, friction being neglected, is:</p> $F = \frac{2000 \times 5 \times 6 \times 4}{12 \times 14 \times 15} = 95 \text{ pounds}$ |
|  $F = \frac{1}{2} W$ <p>The velocity with which weight <math>W</math> will be raised equals one-half the velocity of the force applied at <math>F</math>.</p>   |  $F:W = \sec \alpha:2$ $F = \frac{W \times \sec \alpha}{2}$ $W = 2F \times \cos \alpha$  |
|  <p><math>n</math> = number of strands or parts of rope (<math>n_1, n_2</math>, etc.).</p> $F = \frac{1}{n} \times W$ <p>The velocity with which <math>W</math> will be raised equals <math>\frac{1}{n}</math> of the velocity of the force applied at <math>F</math>.</p> | <p>In the illustration is shown a combination of a double and triple block. The pulleys each turn freely on a pin as axis, and are drawn with different diameters, to show the parts of the rope more clearly. There are 5 parts of rope. Therefore, if 200 pounds is to be lifted, the force <math>F</math> required at the end of the rope is:</p> $F = \frac{1}{5} \times 200 = 40 \text{ pounds}$  |

Note: The above formulas are valid using metric SI units, with forces expressed in newtons, and lengths in meters or millimeters. (See note on page 159 concerning weight and mass.)

Differential Pulley

|  |   |
|--|---|
|  | <p>In the differential pulley a chain must be used, engaging sprockets, so as to prevent the chain from slipping over the pulley faces.</p> $P \times R = \frac{1}{2} W(R - r)$ $P = \frac{W(R - r)}{2R}$ $W = \frac{2PR}{R - r}$ |
|--|---|

|   |  |
|---|--|
| <p style="text-align: center;">Chinese Windlass</p> | <p>The Chinese windlass is of the differential motion principle, in that the resultant motion is the difference between two original motions. The hoisting rope is arranged to unwind from one part of a drum or pulley onto another part differing somewhat in diameter. The distance that the load or hook moves for one revolution of the compound hoisting drum is equal to half the difference between the circumferences of the two drum sections.</p> |
|---|--|

Screw

|  |  |
|--|--|
|  | <p><math>F</math> = force at end of handle or wrench; <math>R</math> = lever-arm of <math>F</math>; <math>r</math> = pitch radius of screw; <math>p</math> = lead of thread; <math>Q</math> = load. Then, neglecting friction:</p> $F = Q \times \frac{p}{6.2832R} \quad Q = F \times \frac{6.2832R}{p}$ <p>If <math>\mu</math> is the coefficient of friction, then:<br/>         For motion in direction of load <math>Q</math> which <i>assists</i> it:</p> $F = Q \times \frac{6.2832\mu r - p}{6.2832r + \mu p} \times \frac{r}{R}$ <p>For motion opposite load <math>Q</math> which <i>resists</i> it:</p> $F = Q \times \frac{p + 6.2832\mu r}{6.2832r - \mu p} \times \frac{r}{R}$ |
|--|--|

Geneva Wheel

|  |  |
|--|--|
|  | <p>Geneva wheels are frequently used on machine tools for indexing or rotating some part of the machine through a fractional part of a revolution.</p> <p>The driven wheel shown in the illustration has four radial slots located 90 degrees apart, and the driver carries a roller <math>k</math> which engages one of these slots each time it makes a revolution, thus turning the driven wheel one-quarter revolution. The concentric surface <math>b</math> engages the concave surface <math>c</math> between each pair of slots before the driving roller is disengaged from the driven wheel, which prevents the latter from rotating while the roller is moving around to engage the next successive slot. The circular boss <math>b</math> on the driver is cut away at <math>d</math> to provide a clearance space for the projecting arms of the driven wheel. In designing gearing of the general type illustrated, it is advisable to so proportion the driving and driven members that the angle <math>a</math> will be approximately 90 degrees.</p> <p>The radial slots in the driven part will then be tangent to the circular path of the driving roller at the time the roller enters and leaves the slot. When the gearing is designed in this way, the driven wheel is started gradually from a state of rest and the motion is also gradually checked.</p> |
|--|--|

**Toggle Joint**

A link mechanism commonly known as a toggle joint is applied to machines of different types, such as drawing and embossing presses, stone crushers, etc., for securing great pressure. The principle of the toggle joint is shown by Fig. 10. There are two links, *b* and *c*, which are connected at the center. Link *b* is free to swivel about a fixed pin or bearing at *d*, and link *e* is connected to a sliding member *e*. Rod *f* joins links *b* and *c* at the central connection. When force is applied to rod *f* in a direction at right angles to center-line *xx*, along which the driven member *e* moves, this force is greatly multiplied at *e*, because a movement at the joint *g* produces a relatively slight movement at *e*. As the angle  $\alpha$  becomes less, motion at *e* decreases and the force increases until the links are in line. If *R* = the resistance at *e*, *P* = the applied power or force, and  $\alpha$  = the angle between each link, and a line *x-x* passing through the axes of the pins, then:

Fig. 10. Toggle Joint Principle

If arms *ED* and *EH* are of unequal length then  
 $P = (F \times a) \div b$   
 The relation between *P* and *F* changes constantly as *F* moves downward.  
 If arms *ED* and *EH* are equal, then  
 $P = (F \times a) \div 2h$   
 A double toggle-joint does not increase the pressure exerted so long as the relative distances moved by *F* and *P* remain the same.

**Toggle-joints with Equal Arms**

$2P \sin \alpha = F \cos \alpha$   
 $\frac{P}{F} = \frac{\cos \alpha}{2 \sin \alpha} = \text{coefficient}$   
 $P = F \times \text{coefficient}$   
 where *F* = force applied; *P* = resistance; and,  $\alpha$  = given angle.

Equivalent expressions (see diagram):  
 $P = \frac{FS}{4h} \quad P = \frac{Fs}{H}$

To use the table, measure angle  $\alpha$ , and find the coefficient in the table corresponding to the angle found. The coefficient is the ratio of the resistance to the force applied, and multiplying the force applied by the coefficient gives the resistance, neglecting friction.

### Pendulums

A *compound* or *physical* pendulum consists of any rigid body suspended from a fixed horizontal axis about which the body may oscillate in a vertical plane due to the action of gravity.

A *simple* or *mathematical* pendulum is similar to a compound pendulum except that the mass of the body is concentrated at a single point which is suspended from a fixed horizontal axis by a weightless cord. Actually, a simple pendulum cannot be constructed since it is impossible to have either a weightless cord or a body whose mass is entirely concentrated at one point. A good approximation, however, consists of a small, heavy bob suspended by a light, fine wire. If these conditions are not met by the pendulum, it should be considered as a compound pendulum.

A *conical* pendulum is similar to a simple pendulum except that the weight suspended by the cord moves at a uniform speed around the circumference of a circle in a horizontal plane instead of oscillating back and forth in a vertical plane. The principle of the conical pendulum is employed in the Watt fly-ball governor.

#### Four Types of Pendulum

Physical Pendulum

Simple Pendulum

Conical Pendulum

Torsional Pendulum

$W$  = Weight of Disk

A *torsional* pendulum in its simplest form consists of a disk fixed to a slender rod, the other end of which is fastened to a fixed frame. When the disk is twisted through some angle and released, it will then oscillate back and forth about the axis of the rod because of the torque exerted by the rod.

**Pendulum Formulas.**—From the formulas that follow, the period of vibration or time required for one complete cycle back and forth may be determined for the types of pendulums shown in the accompanying diagram.

For a *simple* pendulum,

$$T = 2\pi \sqrt{\frac{l}{g}} \quad (1)$$

where  $T$  = period in seconds for one complete cycle;  $g$  = acceleration due to gravity = 32.17 feet per second per second (approximately); and  $l$  is the length of the pendulum in feet as shown on the accompanying diagram.

For a *physical* or *compound* pendulum,

$$T = 2\pi \sqrt{\frac{k_o^2}{gr}} \quad (2)$$

where  $k_o$  = radius of gyration of the pendulum about the axis of rotation, in feet, and  $r$  is the distance from the axis of rotation to the center of gravity, in feet.

**The metric SI units that can be used in the two above formulas are  $T$  = seconds;  $g$  = approximately 9.81 meters per second squared, which is the value for acceleration due to gravity;  $l$  = the length of the pendulum in meters;  $k_o$  = the radius of gyration in meters, and  $r$  = the distance from the axis of rotation to the center of gravity, in meters.**

**Formulas (1) and (2)** are accurate when the angle of oscillation  $\theta$  shown in the diagram is very small. For  $\theta$  equal to 22 degrees, these formulas give results that are too small by 1 per cent; for  $\theta$  equal to 32 degrees, by 2 per cent.

For a *conical* pendulum, the time in seconds for one revolution is:

$$T = 2\pi \sqrt{\frac{l \cos \phi}{g}} \quad (3a) \quad \text{or} \quad T = 2\pi \sqrt{\frac{r \cot \phi}{g}} \quad (3b)$$

For a *torsional* pendulum consisting of a thin rod and a disk as shown in the figure

$$T = \frac{2}{3} \sqrt{\frac{\pi W r^2 l}{g d^4 G}} \quad (4)$$

where  $W$  = weight of disk in pounds;  $r$  = radius of disk in feet;  $l$  = length of rod in feet;  $d$  = diameter of rod in feet; and  $G$  = modulus of elasticity in shear of the rod material in pounds per square inch.

**The formula using metric SI units is:**

$$T = 8 \sqrt{\frac{\pi M r^2 l}{d^4 G}}$$

where  $T$  = time in seconds for one complete oscillation;  $M$  = mass in kilograms;  $r$  = radius in meters;  $l$  = length of rod in meters;  $d$  = diameter of rod in meters;  $G$  = modulus of elasticity in shear of the rod material in pascals (newtons per meter squared). **The same formula can be applied using millimeters, providing dimensions are expressed in millimeters throughout, and the modulus of elasticity in megapascals (newtons per millimeter squared).**

**Harmonic.**—A harmonic is any component of a periodic quantity which is an integral multiple of the fundamental frequency. For example, a component the frequency of which is twice the fundamental frequency is called the second harmonic.

A harmonic, in electricity, is an alternating-current electromotive force wave of higher frequency than the fundamental, and superimposed on the same so as to distort it from a true sine-wave shape. It is caused by the slots, the shape of the pole pieces, and the pulsation of the armature reaction. The third and the fifth harmonics, i.e., with a frequency three and five times the fundamental, are generally the predominating ones in three-phase machines.

## VELOCITY, ACCELERATION, WORK, AND ENERGY

### Velocity and Acceleration

Motion is a progressive change of position of a body. Velocity is the rate of motion, that is, the rate of change of position. When the velocity of a body is the same at every moment during which the motion takes place, the latter is called *uniform* motion. When the velocity is variable and constantly increasing, the rate at which it changes is called *acceleration*; that is, acceleration is the rate at which the velocity of a body changes in a unit of time, as the change in feet per second, in one second. When the motion is decreasing instead of increasing, it is called *retarded* motion, and the rate at which the motion is retarded is frequently called the *deceleration*. If the acceleration is uniform, the motion is called *uniformly accelerated* motion. An example of such motion is found in that of falling bodies.

**Newton's Laws of Motion.**—The first clear statement of the fundamental relations existing between force and motion was made in the seventeenth century by Sir Isaac Newton, the English mathematician and physicist. It was put in the form of three laws, which are given as originally stated by Newton:

- 1) Every body continues in its state of rest, or uniform motion in a straight line, except in so far as it may be compelled by force to change that state.
- 2) Change of motion is proportional to the force applied and takes place in the direction in which that force acts.
- 3) To every action there is always an equal reaction; or, the mutual actions of two bodies are always equal and oppositely directed.

**Motion with Constant Velocity.**—In the formulas that follow,  $S$  = distance moved;  $V$  = velocity;  $t$  = time of motion,  $\theta$  = angle of rotation, and  $\omega$  = angular velocity; the usual units for these quantities are, respectively, feet, feet per second, seconds, radians, and radians per second. Any other consistent set of units may be employed.

*Constant Linear Velocity:*

$$S = V \times t \quad V = S \div t \quad t = S \div V$$

*Constant Angular Velocity:*

$$\theta = \omega t \quad \omega = \theta \div t \quad t = \theta \div \omega$$

*Relation between Angular Motion and Linear Motion:* The relation between the angular velocity of a rotating body and the linear velocity of a point at a distance  $r$  feet from the center of rotation is:

$$V(\text{ft per sec}) = r(\text{ft}) \times \omega(\text{radians per sec})$$

Similarly, the distance moved by the point during rotation through angle  $\theta$  is:

$$S(\text{ft}) = r(\text{ft}) \times \theta(\text{radians})$$

**Linear Motion with Constant Acceleration.**—The relations between distance, velocity, and time for linear motion with constant or uniform acceleration are given by the formulas in the accompanying Table 1. In these formulas, the acceleration is assumed to be in the same direction as the initial velocity; hence, if the acceleration in a particular problem should happen to be in a direction opposite that of the initial velocity, then  $a$  should be replaced by  $-a$ . Thus, for example, the formula  $V_f = V_o + at$  becomes  $V_f = V_o - at$  when  $a$  and  $V_o$  are opposite in direction.

*Example:* A car is moving at 60 mph when the brakes are suddenly locked and the car begins to skid. If it takes 2 seconds to slow the car to 30 mph, at what rate is it being decelerated, how long is it before the car comes to a halt, and how far will it have traveled?

The initial velocity  $V_o$  of the car is 60 mph or 88 ft/sec and the acceleration  $a$  due to braking is opposite in direction to  $V_o$ , since the car is slowed to 30 mph or 44 ft/sec.

|   | <i>V<sub>o</sub>, a, S</i>             | $V_f = \sqrt{V_o^2 + 2aS}$         | <i>Meanings of Symbols</i>   |  |                               |
| <i>V<sub>o</sub></i>  | <i>S, a, t</i>                         | $V_f = (S \div t) + \frac{1}{2}at$ | <i>S</i> = distance moved in feet<br><i>V<sub>f</sub></i> = final velocity, feet per second<br><i>V<sub>o</sub></i> = initial velocity, feet per second<br><i>a</i> = acceleration, feet per second per second<br><i>t</i> = time of acceleration in seconds |  |                               |
|   | <i>V<sub>f</sub>, a, S</i>             | $V_o = \sqrt{V_f^2 - 2aS}$         |  |  |                               |
|   | <i>V<sub>f</sub>, S, t</i>             | $V_o = (2S \div t) - V_f$          |  |  |                               |
|   | <i>V<sub>f</sub>, a, t</i>             | $V_o = V_f - at$                   |  |  |                               |
|   | <i>S, a, t</i>                         | $V_o = (S \div t) - \frac{1}{2}at$ |  |  |                               |

Since  $V_o$ ,  $V_f$ , and  $t$  are known,  $a$  can be determined from the formula

$$a = (V_f - V_o) \div t = (44 - 88) \div 2 = -22 \text{ ft/sec}^2$$

The time required to stop the car can be determined from the formula

$$t = (V_f - V_o) \div a = (0 - 88) \div (-22) = 4 \text{ seconds}$$

The distance traveled by the car is obtained from the formula

$$S = V_o t + \frac{1}{2}at^2 = (88 \times 4) + \left(\frac{1}{2} \times (-22) \times 4^2\right) = (352 - 176) = 176 \text{ feet}$$

**Angular Velocity of Rotating Bodies.**—The angular velocity of a rotating body is the angle through which the body turns in a unit of time. Angular velocity is commonly expressed in terms of revolutions per minute, but in certain engineering applications it is necessary to express it as radians per second. By definition there are  $2\pi$  radians in 360 degrees, or one revolution, so that one radian =  $360 \div 2\pi = 57.3$  degrees. To convert angular velocity in revolutions per minute,  $n$ , to angular velocity in radians per second,  $\omega$ , multiply by  $\pi$  and divide by 30:

$$\omega = \frac{\pi n}{30} \quad (1)$$

The following Table 2 may be used to obtain angular velocity in radians per second for all numbers of revolutions per minute from 1 to 239.

**Table 2. Angular Velocity in Revolutions per Minute  
Converted to Radians per Second**

| R.P.M. | Angular Velocity in Radians per Second |       |       |       |       |       |       |       |       |       |

*Example:* To find the angular velocity in radians per second of a flywheel making 97 revolutions per minute, locate 90 in the left-hand column and 7 at the top of the columns; at the intersection of the two lines, the angular velocity is read off as equal to 10.16 radians per second.

**Linear Velocity of Points on a Rotating Body.**—The linear velocity,  $v$ , of any point on a rotating body expressed in feet per second may be found by multiplying the angular velocity of the body in radians per second,  $\omega$ , by the radius,  $r$ , in feet from the center of rotation to the point:

$$v = \omega r \quad (2)$$

**The metric SI units are  $v$  = meters per second;  $\omega$  = radians per second,  $r$  = meters.**

**Rotary Motion with Constant Acceleration.**—The relations among angle of rotation, angular velocity, and time for rotation with constant or uniform acceleration are given in the accompanying Table 3.

In these formulas, the acceleration is assumed to be in the same direction as the initial angular velocity; hence, if the acceleration in a particular problem should happen to be in a direction opposite that of the initial angular velocity, then  $\alpha$  should be replaced by  $-\alpha$ . Thus, for example, the formula  $\omega_f = \omega_o + \alpha t$  becomes  $\omega_f = \omega_o - \alpha t$  when  $\alpha$  and  $\omega_o$  are opposite in direction.

*Linear Acceleration of a Point on a Rotating Body:* A point on a body rotating about a fixed axis has a linear acceleration  $a$  that is the resultant of two component accelerations. The first component is the centripetal or normal acceleration which is directed from the point  $P$  toward the axis of rotation; its magnitude is  $\omega^2 r$  where  $r$  is the radius from the axis to the point  $P$  and  $\omega$  is the angular velocity of the body at the time acceleration  $a$  is to be

**Table 3. Rotary Motion with Constant Acceleration**

| $\omega_o, \omega_f, \theta$                                  | $t = 2\theta \div (\omega_f + \omega_o)$ |  |  |                              |   |

determined. The second component of  $a$  is the tangential acceleration which is equal to  $r\alpha$  where  $\alpha$  is the angular acceleration of the body.

The acceleration of point  $P$  is the resultant of  $r\omega^2$  and  $r\alpha$  and is given by the formula

$$a = \sqrt{(r\omega^2)^2 + (r\alpha)^2}$$

When  $\alpha = 0$ , this formula reduces to:  $a = r\omega^2$

*Example:* A flywheel on a press rotating at 120 rpm is slowed to 102 rpm during a punching operation that requires  $\frac{3}{4}$  second for the punching portion of the cycle. What angular deceleration does the flywheel experience?

From the table on page 169, the angular velocities corresponding to 120 rpm and 102 rpm, respectively, are 12.57 and 10.68 radians per second. Therefore, using the formula

$$\alpha = (\omega_f - \omega_o) \div t$$

$$\alpha = (10.68 - 12.57) \div \frac{3}{4} = -1.89 \div \frac{3}{4}$$

$$\alpha = -2.52 \text{ radians per second per second}$$

which is, from the table on page 169, -24 rpm per second. The minus sign in the answer indicates that the acceleration  $\alpha$  acts to slow the flywheel, that is, the flywheel is being decelerated.

### Force, Work, Energy, and Momentum

**Accelerations Resulting from Unbalanced Forces.**—In the section describing the resolution and composition of forces it was stated that when the resultant of a system of forces is zero, the system is in equilibrium, that is, the body on which the force system acts remains at rest or continues to move with uniform velocity. If, however, the resultant of a system of forces is not zero, the body on which the forces act will be accelerated in the direction of the unbalanced force. To determine the relation between the unbalanced force and the resulting acceleration, Newton's laws of motion must be applied. These laws may be stated as follows:

*First Law:* Every body continues in a state of rest or in uniform motion in a straight line, until it is compelled by a force to change its state of rest or motion.

*Second Law:* Change of motion is proportional to the force applied, and takes place along the straight line in which the force acts. The "force applied" represents the resultant of *all* the forces acting on the body. This law is sometimes worded: An unbalanced force acting on a body causes an acceleration of the body in the direction of the force and of magnitude proportional to the force and inversely proportional to the mass of the body. Stated as a formula,  $R = Ma$  where  $R$  is the resultant of *all* the forces acting on the body,  $M$  is the mass of the body (mass = weight  $W$  divided by acceleration due to gravity  $g$ ), and  $a$  is the acceleration of the body resulting from application of force  $R$ .

*Third Law:* To every action there is always an equal reaction, or, in other words, if a force acts to change the state of motion of a body, the body offers a resistance equal and directly opposite to the force.

Newton's second law may be used to calculate linear and angular accelerations of a body produced by unbalanced forces and torques acting on the body; however, it is necessary first to use the methods described under *Algebraic Composition and Resolution of Force Systems* starting on page 148 to determine the magnitude and direction of the resultant of *all* forces acting on the body. Then, for a body moving with pure translation,

$$R = Ma = \frac{W}{g}a$$

where  $R$  is the resultant force in pounds acting on a body weighing  $W$  pounds;  $g$  is the gravitational constant, usually taken as 32.16 ft/sec<sup>2</sup>, approximately; and  $a$  is the resulting acceleration in ft/sec<sup>2</sup> of the body due to  $R$  and in the same direction as  $R$ .

**Using metric SI units, the formula is  $R = Ma$ , where  $R$  = force in newtons (N),  $M$  = mass in kilograms, and  $a$  = acceleration in meters/second squared. It should be noted that the weight of a body of mass  $M$  kg is  $Mg$  newtons, where  $g$  is approximately 9.81 m/s<sup>2</sup>.**

*Free Body Diagram:* In order to correctly determine the effect of forces on the motion of a body it is necessary to resort to what is known as a *free body diagram*. This diagram shows 1) the body removed or isolated from contact with all other bodies that exert force on the body and; and 2) *all* the forces acting on the body.

Thus, for example, in Fig. 1a the block being pulled up the plane is acted upon by certain forces; the free body diagram of this block is shown at Fig. 1b. Note that all forces acting on the block are indicated. These forces include: 1) the force of gravity (weight); 2) the pull of the cable,  $P$ ; 3) the normal component,  $W \cos \phi$ , of the force exerted on the block by the plane; and 4) the friction force,  $\mu W \cos \phi$ , of the plane on the block.

Fig. 1a.

Fig. 1b.

In preparing a free body diagram, it is important to realize that only those forces exerted on the body being considered are shown; forces exerted by the body on other bodies are disregarded. This feature makes the free body diagram an invaluable aid in the solution of problems in mechanics.

*Example:* A 100-pound body is being hoisted by a winch, the tension in the hoisting cable being kept constant at 110 pounds. At what rate is the body accelerated?

Two forces are acting on the body, its weight, 100 pounds downward, and the pull of the cable, 110 pounds upward. The resultant force  $R$ , from a free body diagram, is therefore  $110 - 100$ . Thus, applying Newton's second law,

$$110 - 100 = \frac{100}{32.16}a$$

$$a = \frac{32.16 \times 10}{100} = 3.216 \text{ ft/sec}^2 \text{ upward}$$

It should be noted that since in this problem the resultant force  $R$  was positive ( $110 - 100 = +10$ ), the acceleration  $a$  is also positive, that is,  $a$  is in the same direction as  $R$ , which is in accord with Newton's second law.

*Example using SI metric units:* A body of mass 50 kilograms is being hoisted by a winch, and the tension in the cable is 600 newtons. What is the acceleration? The weight of the 50 kg body is 50g newtons, where  $g =$  approximately  $9.81 \text{ m/s}^2$  (see *Note* on page 179). Applying the formula  $R = Ma$ , the calculation is:  $(600 - 50g) = 50a$ . Thus,

$$a = \frac{600 - 50g}{50} = \frac{600 - (50 \times 9.81)}{50} = 2.19 \text{ m/s}^2$$

*Formulas Relating Torque and Angular Acceleration:* For a body rotating about a fixed axis the relation between the unbalanced torque acting to produce rotation and the resulting angular acceleration may be determined from any one of the following formulas, each based on Newton's second law:

$$T_o = J_M \alpha$$

$$T_o = M k_o^2 \alpha$$

$$T_o = \frac{W k_o^2 \alpha}{g} = \frac{W k_o^2 \alpha}{32.16}$$

where  $T_o$  is the unbalanced torque in pounds-feet;  $J_M$  in ft-lbs-sec<sup>2</sup> is the moment of inertia of the body about the axis of rotation;  $k_o$  in feet is the radius of gyration of the body with respect to the axis of rotation, and  $\alpha$  in radians per second, per second is the angular acceleration of the body.

*Example:* A flywheel has a diameter of 3 feet and weighs 1000 pounds. What torque must be applied, neglecting bearing friction, to accelerate the flywheel at the rate of 100 revolutions per minute, per second?

From page 250 the moment of inertia of a solid cylinder with respect to a gravity axis at right angles to the circular cross-section is given as  $\frac{1}{2}Mr^2$ . From page 169, 100 rpm = 10.47 radians per second, hence an acceleration of 100 rpm per second = 10.47 radians per second, per second. Therefore, using the first of the preceding formulas,

$$T_o = J_M\alpha = \left(\frac{1}{2}\right)\frac{1000}{32.16}\left(\frac{3}{2}\right)^2 \times 10.47 = 366 \text{ ft-lbs}$$

Using metric SI units, the formulas are:  $T_o = J_M\alpha = Mk_o^2\alpha$ , where  $T_o$  = torque in newton-meters;  $J_M$  = the moment of inertia in  $\text{kg} \cdot \text{m}^2$ , and  $\alpha$  = the angular acceleration in radians per second squared.

**Example:** A flywheel has a diameter of 1.5 m, and a mass of 800 kg. What torque is needed to produce an angular acceleration of 100 revolutions per minute, per second? As in the preceding example,  $\alpha = 10.47 \text{ rad/s}^2$ . Thus:

$$J_M = \frac{1}{2}Mr^2 = \frac{1}{2} \times 800 \times 0.75^2 = 225 \text{ kg} \cdot \text{m}^2$$

Therefore:  $T_o = J_M\alpha = 225 \times 10.47 = 2356 \text{ N} \cdot \text{m}$ .

**Energy.**—A body is said to possess energy when it is capable of doing work or overcoming resistance. The energy may be either mechanical or non-mechanical, the latter including chemical, electrical, thermal, and atomic energy.

Mechanical energy includes *kinetic energy* (energy possessed by a body because of its motion) and *potential energy* (energy possessed by a body because of its position in a field of force and/or its elastic deformation).

**Kinetic Energy:** The motion of a body may be one of pure translation, pure rotation, or a combination of rotation and translation. By translation is meant motion in which every line in the body remains parallel to its original position throughout the motion, that is, no rotation is associated with the motion of the body.

The kinetic energy of a translating body is given by the formula

$$\text{Kinetic Energy in ft-lbs due to translation} = E_{KT} = \frac{1}{2}MV^2 = \frac{WV^2}{2g} \quad (3a)$$

where  $M$  = mass of body ( $= W \div g$ );  $V$  = velocity of the center of gravity of the body in feet per second;  $W$  = weight of body in pounds; and  $g$  = acceleration due to gravity = 32.16 feet per second, per second.

The kinetic energy of a body rotating about a fixed axis  $O$  is expressed by the formula:

$$\text{Kinetic Energy in ft-lbs due to rotation} = E_{KR} = \frac{1}{2}J_{MO}\omega^2 \quad (3b)$$

where  $J_{MO}$  is the moment of inertia of the body about the fixed axis  $O$  in pounds-feet-seconds<sup>2</sup>, and  $\omega$  = angular velocity in radians per second.

For a body that is moving with both translation and rotation, the total kinetic energy is given by the following formula as the sum of the kinetic energy due to translation of the center of gravity and the kinetic energy due to rotation about the center of gravity:

$$\begin{aligned} \text{Total Kinetic Energy in ft-lbs} &= E_T = \frac{1}{2}MV^2 + \frac{1}{2}J_{MG}\omega^2 \\ &= \frac{WV^2}{2g} + \frac{1}{2}J_{MG}\omega^2 = \frac{WV^2}{2g} + \frac{1}{2}\frac{Wk^2\omega^2}{g} = \frac{W}{2g}(V^2 + k^2\omega^2) \end{aligned} \quad (3c)$$

where  $J_{MG}$  is the moment of inertia of the body about its gravity axis in pounds-feet-seconds<sup>2</sup>,  $k$  is the radius of gyration in feet with respect to an axis through the center of gravity, and the other quantities are as previously defined.

**In the metric SI system, energy is expressed as the joule (J). One joule = 1 newton-meter. The kinetic energy of a translating body is given by the formula  $E_{KT} = \frac{1}{2}MV^2$ ,**

where  $M$  = mass in kilograms, and  $V$  = velocity in meters per second. Kinetic energy due to rotation is expressed by the formula  $E_{KR} = \frac{1}{2}J_{MO}\omega^2$ , where  $J_{MO}$  = moment of inertia in  $\text{kg} \cdot \text{m}^2$ , and  $\omega$  = the angular velocity in radians per second. Total kinetic energy  $ET = \frac{1}{2}MV^2 + \frac{1}{2}J_{MO}\omega^2$  joules =  $\frac{1}{2}M(V^2 + k^2\omega^2)$  joules, where  $k$  = radius of gyration in meters.

*Potential Energy:* The most common example of a body having potential energy because of its position in a field of force is that of a body elevated to some height above the earth. Here the field of force is the gravitational field of the earth and the potential energy  $E_{PF}$  of a body weighing  $W$  pounds elevated to some height  $S$  in feet above the surface of the earth is  $WS$  foot-pounds. If the body is permitted to drop from this height its potential energy  $E_{PF}$  will be converted to kinetic energy. Thus, after falling through height  $S$  the kinetic energy of the body will be  $WS$  ft-lbs.

**In metric SI units, the potential energy  $E_{PF}$  of a body of mass  $M$  kilograms elevated to a height of  $S$  meters, is  $MgS$  joules. After it has fallen a distance  $S$ , the kinetic energy gained will thus be  $MgS$  joules.**

Another type of potential energy is elastic potential energy, such as possessed by a spring that has been compressed or extended. The amount of work in ft lbs done in compressing the spring  $S$  feet is equal to  $KS^2/2$ , where  $K$  is the spring constant in pounds per foot. Thus, when the spring is released to act against some resistance, it can perform  $KS^2/2$  ft-lbs of work which is the amount of elastic potential energy  $E_{PE}$  stored in the spring.

**Using metric SI units, the amount of work done in compressing the spring a distance  $S$  meters is  $KS^2/2$  joules, where  $K$  is the spring constant in newtons per meter.**

**Work Performed by Forces and Couples.**—The work  $U$  done by a force  $F$  in moving an object along some path is the product of the distance  $S$  the body is moved and the component  $F \cos \alpha$  of the force  $F$  in the direction of  $S$ .

$$U = FS \cos \alpha$$

where  $U$  = work in ft-lbs;  $S$  = distance moved in feet;  $F$  = force in lbs; and  $\alpha$  = angle between line of action of force and the path of  $S$ .

If the force is in the same direction as the motion, then  $\cos \alpha = \cos 0 = 1$  and this formula reduces to:

$$U = FS$$

Similarly, the work done by a couple  $T$  turning an object through an angle  $\theta$  is:

$$U = T\theta$$

where  $T$  = torque of couple in pounds-feet and  $\theta$  = the angular rotation in radians.

**The above formulas can be used with metric SI units:  $U$  is in joules;  $S$  is in meters;  $F$  is in newtons, and  $T$  is in newton-meters.**

**Relation between Work and Energy.**—Theoretically, when work is performed on a body and there are no energy losses (such as due to friction, air resistance, etc.), the energy acquired by the body is equal to the work performed on the body; this energy may be either potential, kinetic, or a combination of both.

In actual situations, however, there may be energy losses that must be taken into account. Thus, the relation between work done on a body, energy losses, and the energy acquired by the body can be stated as:

$$\text{Work Performed} - \text{Losses} = \text{Energy Acquired}$$

$$U - \text{Losses} = E_T$$

*Example 1:* A 12-inch cube of steel weighing 490 pounds is being moved on a horizontal conveyor belt at a speed of 6 miles per hour (8.8 feet per second). What is the kinetic energy of the cube?

Since the block is not rotating, **Formula (3a)** for the kinetic energy of a body moving with pure translation applies:

$$\text{Kinetic Energy} = \frac{WV^2}{2g} = \frac{490 \times (8.8)^2}{2 \times 32.16} = 590 \text{ ft-lbs}$$

**A similar example using metric SI units is as follows: If a cube of mass 200 kg is being moved on a conveyor belt at a speed of 3 meters per second, what is the kinetic energy of the cube? It is:**

$$\text{Kinetic Energy} = \frac{1}{2}MV^2 = \frac{1}{2} \times 200 \times 3^2 = 900 \text{ joules}$$

*Example 2:* If the conveyor in **Example 1** is brought to an abrupt stop, how long would it take for the steel block to come to a stop and how far along the belt would it slide before stopping if the coefficient of friction  $\mu$  between the block and the conveyor belt is 0.2 and the block slides without tipping over?

The only force acting to slow the motion of the block is the friction force between the block and the belt. This force  $F$  is equal to the weight of the block,  $W$ , multiplied by the coefficient of friction;  $F = \mu W = 0.2 \times 490 = 98 \text{ lbs}$ .

The time required to bring the block to a stop can be determined from the impulse-momentum **Formula (4c)** on page 176.

$$R \times t = \frac{W}{g}(V_f - V_o) = (-98)t = \frac{490}{32.16} \times (0 - 8.8)$$

$$t = \frac{490 \times 8.8}{98 \times 32.16} = 1.37 \text{ seconds}$$

The distance the block slides before stopping can be determined by equating the kinetic energy of the block and the work done by friction in stopping it:

$$\text{Kinetic energy of block} (WV^2/2g) = \text{Work done by friction} (F \times S)$$

$$590 = 98 \times S$$

$$S = \frac{590}{98} = 6.0 \text{ feet}$$

**If metric SI units are used, the calculation is as follows (for the cube of 200 kg mass): The friction force =  $\mu$  multiplied by the weight  $Mg$  where  $g =$  approximately  $9.81 \text{ m/s}^2$ . Thus,  $\mu Mg = 0.2 \times 200g = 392.4$  newtons. The time  $t$  required to bring the block to a stop is  $(-392.4)t = 200(0 - 3)$ . Therefore,**

$$t = \frac{200 \times 3}{392.4} = 1.53 \text{ seconds}$$

**The kinetic energy of the block is equal to the work done by friction, that is  $392.4 \times S = 900$  joules. Thus, the distance  $S$  which the block moves before stopping is**

$$S = \frac{900}{392.4} = 2.29 \text{ meters}$$

**Force of a Blow.**—A body that weighs  $W$  pounds and falls  $S$  feet from an initial position of rest is capable of doing  $WS$  foot-pounds of work. The work performed during its fall may be, for example, that necessary to drive a pile a distance  $d$  into the ground. Neglecting losses in the form of dissipated heat and strain energy, the work done in driving the pile is equal to the product of the impact force acting on the pile and the distance  $d$  which the pile is driven. Since the impact force is not accurately known, an average value, called the

"average force of the blow," may be assumed. Equating the work done on the pile and the work done by the falling body, which in this case is a pile driver:

$$\text{Average force of blow} \times d = WS$$

$$\text{or,} \quad \text{Average force of blow} = \frac{WS}{d}$$

where,  $S$  = total height in feet through which the driver falls, including the distance  $d$  that the pile is driven

$W$  = weight of driver in pounds

$d$  = distance in feet which pile is driven

**When using metric SI units, it should be noted that a body of mass  $M$  kilograms has a weight of  $Mg$  newtons, where  $g$  = approximately  $9.81 \text{ m/s}^2$ . If the body falls a distance  $S$  meters, it can do work equal to  $MgS$  joules. The average force of the blow is  $MgS/d$  newtons, where  $d$  is the distance in meters that the pile is driven.**

*Example:* A pile driver weighing 200 pounds strikes the top of the pile after having fallen from a height of 20 feet. It forces the pile into the ground a distance of  $\frac{1}{2}$  foot. Before the ram is brought to rest, it will  $200 \times (20 + \frac{1}{2}) = 4100$  foot-pounds of work, and as this energy is expended in a distance of one-half foot, the average force of the blow equals  $4100 \div \frac{1}{2} = 8200$  pounds.

**A similar example using metric SI units is as follows: A pile driver of mass 100 kilograms falls 10 meters and moves the pile a distance of 0.3 meters. The work done =  $100g(10 + 0.3)$  joules, and it is expended in 0.3 meters. Thus, the average force is**

$$\frac{100g \times 10.3}{0.3} = 33680 \text{ newtons or } 33.68 \text{ kN}$$

**Impulse and Momentum.**—The *linear momentum* of a body is defined as the product of the mass  $M$  of the body and the velocity  $V$  of the center of gravity of the body:

$$\text{Linear momentum} = MV \text{ or since } M = W \div g$$

$$\text{Linear momentum} = \frac{WV}{g} \quad (4a)$$

It should be noted that linear momentum is a vector quantity, the momentum being in the same direction as  $V$ .

*Linear impulse* is defined as the product of the resultant  $R$  of all the forces acting on a body and the time  $t$  that the resultant acts:

$$\text{Linear Impulse} = Rt \quad (4b)$$

The change in the linear momentum of a body is numerically equal to the linear impulse that causes the change in momentum:

$$\text{Linear Impulse} = \text{change in Linear Momentum}$$

$$Rt = \frac{W}{g}V_f - \frac{W}{g}V_o = \frac{W}{g}(V_f - V_o) \quad (4c)$$

where  $V_f$ , the final velocity of the body after time  $t$ , and  $V_o$ , the initial velocity of the body, are both in the same direction as the applied force  $R$ . If  $V_o$ , and  $V_f$  are in opposite directions, then the minus sign in the formula becomes a plus sign.

**In metric SI units, the formulas are: Linear Momentum =  $MV$  kg · m/s, where  $M$  = mass in kg, and  $V$  = velocity in meters per second; and Linear Impulse =  $Rt$  newton-seconds, where  $R$  = force in newtons, and  $t$  = time in seconds. In [Formula \(4c\)](#) above,  $W/g$  is replaced by  $M$  when SI units are used.**

*Example:* A 1000-pound block is pulled up a 2-degree incline by a cable exerting a constant force  $F$  of 600 pounds. If the coefficient of friction  $\mu$  between the block and the plane is 0.5, how fast will the block be moving up the plane 10 seconds after the pull is applied?

The resultant force  $R$  causing the body to be accelerated up the plane is the difference between  $F$ , the force acting up the plane, and  $P$ , the force acting to resist motion up the plane. This latter force for a body on a plane is given by the formula at the top of page 161 as  $P = W(\mu \cos \alpha + \sin \alpha)$  where  $\alpha$  is the angle of the incline.

$$\begin{aligned}\text{Thus, } R &= F - P = F - W(\mu \cos \alpha + \sin \alpha) \\ &= 600 - 1000(0.5 \cos 2^\circ + \sin 2^\circ) = 600 - 1000(0.5 \times 0.99939 + 0.03490) \\ R &= 600 - 535 = 65 \text{ pounds.}\end{aligned}$$

**Formula (4c)** can now be applied to determine the speed at which the body will be moving up the plane after 10 seconds.

$$\begin{aligned}Rt &= \frac{W}{g}V_f - \frac{W}{g}V_o \\ 65 \times 10 &= \frac{1000}{32.2}V_f - \frac{1000}{32.2} \times 0 \\ V_f &= \frac{65 \times 10 \times 32.2}{1000} = 20.9 \text{ ft per sec} = 14.3 \text{ miles per hour}\end{aligned}$$

**A similar example using metric SI units is as follows: A 500 kg block is pulled up a 2 degree incline by a constant force  $F$  of 4 kN. The coefficient of friction  $\mu$  between the block and the plane is 0.5. How fast will the block be moving 10 seconds after the pull is applied?**

The resultant force  $R$  is:

$$\begin{aligned}R &= F - Mg(\mu \cos \alpha + \sin \alpha) \\ &= 4000 - 500 \times 9.81(0.5 \times 0.99939 + 0.03490) = 1378\text{N or } 1.378 \text{ kN}\end{aligned}$$

**Formula (4c)** can now be applied to determine the speed at which the body will be moving up the plane after 10 seconds. Replacing  $W/g$  by  $M$  in the formula, the calculation is:

$$\begin{aligned}Rt &= MV_f - MV_o \\ 1378 \times 10 &= 500(V_f - 0) \\ V_f &= \frac{1378 \times 10}{500} = 27.6 \text{ m/s}\end{aligned}$$

*Angular Impulse and Momentum:* In a manner similar to that for linear impulse and moment, the formulas for angular impulse and momentum for a body rotating about a fixed axis are:

$$\text{Angular momentum} = J_M \omega \quad (5a)$$

$$\text{Angular impulse} = T_o t \quad (5b)$$

where  $J_M$  is the moment of inertia of the body about the axis of rotation in pounds-feet-seconds<sup>2</sup>,  $\omega$  is the angular velocity in radians per second,  $T_o$  is the torque in pounds-feet about the axis of rotation, and  $t$  is the time in seconds that  $T_o$  acts.

The change in angular momentum of a body is numerically equal to the angular impulse that causes the change in angular momentum:

$$\begin{aligned}\text{Angular Impulse} &= \text{Change in Angular Momentum} \\ T_o t &= J_M \omega_f - J_M \omega_o = J_M (\omega_f - \omega_o)\end{aligned} \quad (5c)$$

where  $\omega_f$  and  $\omega_o$  are the final and initial angular velocities, respectively.

*Example:* A flywheel having a moment of inertia of 25 lbs-ft-sec<sup>2</sup> is revolving with an angular velocity of 10 radians per second when a constant torque of 20 lbs-ft is applied to reverse its direction of rotation. For what length of time must this constant torque act to stop the flywheel and bring it up to a reverse speed of 5 radians per second?

Applying [Formula \(5c\)](#),

$$\begin{aligned} T_o t &= J_M(\omega_f - \omega_o) \\ 20t &= 25(10 - [-5]) = 250 + 125 \\ t &= 375 \div 20 = 18.8 \text{ seconds} \end{aligned}$$

A similar example using metric SI units is as follows: A flywheel with a moment of inertia of 20 kilogram-meters<sup>2</sup> is revolving with an angular velocity of 10 radians per second when a constant torque of 30 newton-meters is applied to reverse its direction of rotation. For what length of time must this constant torque act to stop the flywheel and bring it up to a reverse speed of 5 radians per second? Applying [Formula \(5c\)](#), the calculation is:

$$\begin{aligned} T_o t &= J_M(\omega_f - \omega_o), \\ 30t &= 20(10 - [-5]). \end{aligned}$$

Thus,  $t = \frac{20 \times 15}{30} = 10 \text{ seconds}$

**Formulas for Work and Power.**—The formulas in the accompanying [Table 4](#) may be used to determine work and power in terms of the applied force and the velocity at the point of application of the force.

**Table 4. Formulas<sup>a</sup> for Work and Power**

| To Find | Known    | Formula                               | To Find   | Known                        | Formula                               |

| K       | K, S     | $F = K \div S$                        |   |                              |                                       |
|         | K, V, t  | $F = K \div (V \times t)$             |   |                              |                                       |
| V       | V, hp    | $F = 550 \times hp \div V$            |   |                              |                                       |
|         | F, V     | $P = F \times V$                      |   |                              |                                       |
| P       | F, S, t  | $P = F \times S \div t$               |   |                              |                                       |
|         | K, t     | $P = K \div t$                        |   |                              |                                       |
|         | hp       | $P = 550 \times hp$                   |   |                              |                                       |

<sup>a</sup> *Note:* The metric SI unit of work is the joule (one joule = 1 newton-meter), and the unit of power is the watt (one watt = 1 joule per second = 1 N · m/s). The term horsepower is not used. Thus, those formulas above that involve horsepower and the factor 550 are not applicable when working in SI units. The remaining formulas can be used, and the units are:  $S$  = distance in meters;  $V$  = constant or average velocity in meters per second;  $t$  = time in seconds;  $F$  = force in newtons;  $P$  = power in watts;  $K$  = work in joules.

*Example:* A casting weighing 300 pounds is to be lifted by means of an overhead crane. The casting is lifted 10 feet in 12 seconds. What is the horsepower developed? Here  $F = 300$ ;  $S = 10$ ;  $t = 12$ .

$$\text{hp} = \frac{F \times S}{550t} = \frac{300 \times 10}{550 \times 12} = 0.45$$

A similar example using metric SI units is as follows: A casting of mass 150 kg is lifted 4 meters in 15 seconds by means of a crane. What is the power? Here  $F = 150g$  N,  $S = 4$  m, and  $t = 15$  s. Thus:

$$\text{Power} = \frac{FS}{t} = \frac{150g \times 4}{15} = \frac{150 \times 9.81 \times 4}{15} = 392 \text{ watts or } 0.392 \text{ kW}$$

### Centrifugal Force

**Centrifugal Force.**—When a body rotates about any axis other than one at its center of mass, it exerts an outward radial force called centrifugal force upon the axis or any arm or cord from the axis that restrains it from moving in a straight (tangential) line. In the following formulas:

$F$  = centrifugal force in pounds

$W$  = weight of revolving body in pounds

$v$  = velocity at radius  $R$  on body in feet per second

$n$  = number of revolutions per minute

$g$  = acceleration due to gravity = 32.16 feet per second per second

$R$  = perpendicular distance in feet from axis of rotation to center of mass, or for practical use, to center of gravity of revolving body

*Note:* If a body rotates about its own center of mass,  $R$  equals zero and  $v$  equals zero. This means that the *resultant* of the centrifugal forces of all the elements of the body is equal to zero or, in other words, no centrifugal force is exerted on the axis of rotation. The centrifugal force of any part or element of such a body is found by the equations given below, where  $R$  is the radius to the center of gravity of the part or element. In a flywheel rim,  $R$  is the mean radius of the rim because it is the radius to the center of gravity of a thin radial section.

$$F = \frac{Wv^2}{gR} = \frac{Wv^2}{32.16R} = \frac{4WR\pi^2n^2}{60 \times 60g} = \frac{WRn^2}{2933} = 0.000341 WRn^2$$

$$W = \frac{FRg}{v^2} = \frac{2933F}{Rn^2} \qquad v = \sqrt{\frac{FRg}{W}}$$

$$R = \frac{Wv^2}{Fg} = \frac{2933F}{Wn^2} \qquad n = \sqrt{\frac{2933F}{WR}}$$

(If  $n$  is the number of revolutions per second instead of per minute, then  $F = 1227WRn^2$ .)

If metric SI units are used in the foregoing formulas,  $W/g$  is replaced by  $M$ , which is the mass in kilograms;  $F$  = centrifugal force in newtons;  $v$  = velocity in meters per second;  $n$  = number of revolutions per minute; and  $R$  = the radius in meters. Thus:

$$F = Mv^2/R = \frac{Mn^2(2\pi R^2)}{60^2 R} = 0.01097 MRn^2$$

If the rate of rotation is expressed as  $n_1 =$  revolutions per second, then  $F = 39.48 MRn_1^2$ ; if it is expressed as  $\omega$  radians per second, then  $F = MR\omega^2$ .

**Calculating Centrifugal Force.**—In the ordinary formula for centrifugal force,  $F = 0.000341 WRn^2$ ; the mean radius  $R$  of the flywheel or pulley rim is given in feet. For small dimensions, it is more convenient to have the formula in the form:

$$F = 0.2842 \times 10^{-4} Wrn^2$$

in which  $F$  = centrifugal force, in pounds;  $W$  = weight of rim, in pounds;  $r$  = mean radius of rim, in inches;  $n$  = number of revolutions per minute.

In this formula let  $C = 0.000028416n^2$ . This, then, is the centrifugal force of one pound, one inch from the axis. The formula can now be written in the form,

$$F = WrC$$

$C$  is calculated for various values of the revolutions per minute  $n$ , and the calculated values of  $C$  are given in Table 5. To find the centrifugal force in any given case, simply find the value of  $C$  in the table and multiply it by the product of  $W$  and  $r$ , the four multiplications in the original formula given thus having been reduced to two.

*Example:* A cast-iron flywheel with a mean rim radius of 9 inches, is rotated at a speed of 800 revolutions per minute. If the weight of the rim is 20 pounds, what is the centrifugal force?

From Table 5, for  $n = 800$  revolutions per minute, the value of  $C$  is 18.1862.

Thus,

$$F = WrC = 20 \times 9 \times 18.1862 = 3273.52 \text{ pounds}$$

Using metric SI units,  $0.01097n^2$  is the centrifugal force acting on a body of 1 kilogram mass rotating at  $n$  revolutions per minute at a distance of 1 meter from the axis. If this value is designated  $C_1$ , then the centrifugal force of mass  $M$  kilograms rotating at this speed at a distance from the axis of  $R$  meters, is  $C_1MR$  newtons. To simplify calculations, values for  $C_1$  are given in Table 6. If it is required to work in terms of millimeters, the force is  $0.001 C_1MR_1$  newtons, where  $R_1$  is the radius in millimeters.

*Example:* A steel pulley with a mean rim radius of 120 millimeters is rotated at a speed of 1100 revolutions per minute. If the mass of the rim is 5 kilograms, what is the centrifugal force?

From Table 6, for  $n = 1100$  revolutions per minute, the value of  $C_1$  is 13,269.1.

Thus,

$$F = 0.001 C_1MR_1 = 0.001 \times 13,269.1 \times 5 \times 120 = 7961.50 \text{ newtons}$$

**Centrifugal Casting.**—The centrifugal casting of metals is an old art. This process has become important in such work as the manufacture of paper-mill rolls, railroad car wheels, and cast-iron pipe. The centrifugal casting process has been successfully applied in the production of non-metallic tubes, such as concrete pipe, in the production of solid castings by locating the molds around the rim of a spinning wheel, and to a limited extent in the production of solid ingots by a largely similar process. Hollow objects such as cast-iron pipe are cast by introducing molten metal into a spinning mold. If the chilling of the metal is extremely rapid, for example in casting cast-iron pipe against a water-cooled chilled mold, it is imperative to use a movable spout. The particular feature that determines the field of application of hot-mold centrifugal casting is the ability to produce long cast shapes of comparatively thin metal.

**Table 5. Factors *C* for Calculating Centrifugal Force (English units)**

| <i>n</i> | <i>C</i> | <i>n</i> | <i>C</i> | <i>n</i> | <i>C</i> | <i>n</i> | <i>C</i> |
|----------|----------|----------|----------|----------|----------|----------|----------|
| 50       | 0.07104  | 100      | 0.28416  | 470      | 6.2770   | 5200     | 768.369  |
| 51       | 0.07391  | 101      | 0.28987  | 480      | 6.5470   | 5300     | 798.205  |
| 52       | 0.07684  | 102      | 0.29564  | 490      | 6.8227   | 5400     | 828.611  |

## FLYWHEELS

### Classification of Flywheels

Flywheels may be classified as *balance wheels* or as *flywheel pulleys*. The object of all flywheels is to equalize the energy exerted and the work done and thereby prevent excessive or sudden changes of speed. The permissible speed variation is an important factor in all flywheel designs. The allowable speed change varies considerably for different classes of machinery; for instance, it is about 1 or 2 per cent in steam engines, while in punching and shearing machinery a speed variation of 20 per cent may be allowed.

The function of a balance wheel is to absorb and equalize energy in case the resistance to motion, or driving power, varies throughout the cycle. Therefore, the rim section is generally quite heavy and is designed with reference to the energy that must be stored in it to prevent excessive speed variations and, with reference to the strength necessary to withstand safely the stresses resulting from the required speed. The rims of most balance wheels are either square or nearly square in section, but flywheel pulleys are commonly made wide to accommodate a belt and relatively thin in a radial direction, although this is not an invariable rule.

Flywheels, in general, may either be formed of a solid or one-piece section, or they may be of sectional construction. Flywheels in diameters up to about eight feet are usually cast solid, the hubs sometimes being divided to relieve cooling stresses. Flywheels ranging from, say, eight feet to fifteen feet in diameter, are commonly cast in half sections, and the larger sizes in several sections, the number of which may equal the number of arms in the wheel. Sectional flywheels may be divided into two general classes. One class includes cast wheels which are formed of sections principally because a solid casting would be too large to transport readily. The second class includes wheels of sectional construction which, by reason of the materials used and the special arrangement of the sections, enables much higher peripheral speeds to be obtained safely than would be possible with ordinary sectional wheels of the type not designed especially for high speeds. Various designs have been built to withstand the extreme stresses encountered in some classes of service. The rims in some designs are laminated, being partly or entirely formed of numerous segment-shaped steel plates. Another type of flywheel, which is superior to an ordinary sectional wheel, has a solid cast-iron rim connected to the hub by disk-shaped steel plates instead of cast spokes.

Steel wheels may be divided into three distinct types, including 1) those having the center and rim built up entirely of steel plates; 2) those having a cast-iron center and steel rim; and 3) those having a cast-steel center and rim formed of steel plates.

Wheels having wire-wound rims have been used to a limited extent when extremely high speeds have been necessary.

When the rim is formed of sections held together by joints it is very important to design these joints properly. The ordinary bolted and flanged rim joints located between the arms average about 20 per cent of the strength of a solid rim and about 25 per cent is the maximum strength obtainable for a joint of this kind. However, by placing the joints at the ends of the arms instead of between them, an efficiency of 50 per cent of the strength of the rim may be obtained, because the joint is not subjected to the outward bending stresses between the arms but is directly supported by the arm, the end of which is secured to the rim just beneath the joint. When the rim sections of heavy balance wheels are held together by steel links shrunk into place, an efficiency of 60 per cent may be obtained; and by using a rim of box or I-section, a link type of joint connection may have an efficiency of 100 per cent.

## Flywheel Calculations

**Energy Due to Changes of Velocity.**—When a flywheel absorbs energy from a variable driving force, as in a steam engine, the velocity increases; and when this stored energy is given out, the velocity diminishes. When the driven member of a machine encounters a variable resistance in performing its work, as when the punch of a punching machine is passing through a steel plate, the flywheel gives up energy while the punch is at work, and, consequently, the speed of the flywheel is reduced. The total energy that a flywheel would give out if brought to a standstill is given by the formula:

$$E = \frac{Wv^2}{2g} = \frac{Wv^2}{64.32}$$

in which  $E$  = total energy of flywheel, in foot-pounds

$W$  = weight of flywheel rim, in pounds

$v$  = velocity at mean radius of flywheel rim, in feet per second

$g$  = acceleration due to gravity = 32.16 ft/s<sup>2</sup>

If the velocity of a flywheel changes, the energy it will absorb or give up is proportional to the difference between the squares of its initial and final speeds, and is equal to the difference between the energy that it would give out if brought to a full stop and the energy that is still stored in it at the reduced velocity. Hence:

$$E_1 = \frac{Wv_1^2}{2g} - \frac{Wv_2^2}{2g} = \frac{W(v_1^2 - v_2^2)}{64.32}$$

in which  $E_1$  = energy in foot-pounds that a flywheel will give out while the speed is reduced from  $v_1$  to  $v_2$

$W$  = weight of flywheel rim, in pounds

$v_1$  = velocity at mean radius of flywheel rim before any energy has been given out, in feet per second

$v_2$  = velocity of flywheel rim at end of period during which the energy has been given out, in feet per second

Ordinarily, the effects of the arms and hub do not enter into flywheel calculations, and only the weight of the rim is considered. In computing the velocity, the mean radius of the rim is commonly used.

**Using metric SI units, the formulas are  $E = \frac{1}{2}Mv^2$ , and  $E_1 = \frac{1}{2}M(v_1^2 - v_2^2)$ , where  $E$  and  $E_1$  are in joules;  $M$  = the mass of the rim in kilograms; and  $v$ ,  $v_1$ , and  $v_2$  = velocities in meters per second. Note: In the SI, the unit of mass is the kilogram. If the weight of the flywheel rim is given in kilograms, the value referred to is the mass,  $M$ . Should the weight be given in newtons,  $N$ , then**

$$M = \frac{W(\text{newtons})}{g}$$

where  $g$  is approximately 9.81 meters per second squared.

**General Procedure in Flywheel Design.**—The general method of designing a flywheel is to determine first the value of  $E_1$  or the energy the flywheel must either supply or absorb for a given change in velocity, which, in turn, varies for different classes of service. The mean diameter of the flywheel may be assumed, or it may be fixed within certain limits by the general design of the machine. Ordinarily the speed of the flywheel shaft is known, at least approximately; the values of  $v_1$  and  $v_2$  can then be determined, the latter depending upon the allowable percentage of speed variation. When these values are known, the weight of the rim and the cross-sectional area required to obtain this weight may be computed. The general procedure will be illustrated more in detail by considering the design of flywheels for punching and shearing machinery.

**Flywheels for Presses, Punches, Shears, Etc.**—In these classes of machinery, the work that the machine performs is of an intermittent nature and is done during a small part of the time required for the driving shaft of the machine to make a complete revolution. To distribute the work of the machine over the entire period of revolution of the driving shaft, a heavy-rimmed flywheel is placed on the shaft, giving the belt an opportunity to perform an almost uniform amount of work during the whole revolution. During the greater part of the revolution of the driving shaft, the belt power is used to accelerate the speed of the flywheel. During the part of the revolution when the work is done, the energy thus stored up in the flywheel is given out at the expense of its velocity. The problem is to determine the weight and cross-sectional area of the rim when the conditions affecting the design of the flywheel are known.

*Example:* A flywheel is required for a punching machine capable of punching  $\frac{3}{4}$ -inch holes through structural steel plates  $\frac{3}{4}$  inch thick. This machine (see accompanying diagram) is of the general type having a belt-driven shaft at the rear which carries a flywheel and a pinion that meshes with a large gear on the main shaft at the top of the machine. It is assumed that the relative speeds of the pinion and large gear are 7 to 1, respectively, and that the slide is to make 30 working strokes per minute. The preliminary layout shows that the flywheel should have a mean diameter (see enlarged detail) of about 30 inches. Find the weight of the flywheel and the remaining rim dimensions.

Punch Press and Flywheel Detail

*Energy Supplied by Flywheel:* The energy that the flywheel must give up for a given change in velocity, and the weight of rim necessary to supply that energy, must be determined. The maximum force for shearing a  $\frac{3}{4}$ -inch hole through  $\frac{3}{4}$ -inch structural steel equals approximately the circumference of the hole multiplied by the thickness of the stock multiplied by the tensile strength, which is nearly the same as the shearing resistance of the steel. Thus, in this case,  $3.1416 \times \frac{3}{4} \times \frac{3}{4} \times 60,000 = 106,000$  pounds. The average force will be much less than the maximum. Some designers assume that the average force is about one-half the maximum, although experiments show that the material is practically sheared off when the punch has entered the sheet a distance equal to about one-third the sheet thickness. On this latter basis, the average energy  $E_a$  is 2200 foot-pounds for the example given. Thus:

$$E_a = \frac{106,000 \times \frac{1}{3} \times \frac{3}{4}}{12} = \frac{106,000}{4 \times 12} = 2200 \text{ foot-pounds.}$$

If the efficiency of the machine is taken as 85 per cent, the energy required will equal  $2200/0.85 = 2600$  foot-pounds nearly. Assume that the energy supplied by the belt while the punch is at work is determined by calculation to equal 175 foot-pounds. Then the flywheel must supply  $2600 - 175 = 2425$  foot-pounds =  $E_1$ .

## Dimensions of Flywheels for Punches and Shears

| A   | B  | C  | D   | E  | F  | G  | H   | J  | Max.<br>R.P.M. |
|-----|----|----|-----|----|----|----|-----|----|----------------|
| 24  | 3  | 3½ | 6   | 1¼ | 1⅜ | 2¾ | 3¼  | 3½ | 955            |
| 30  | 3½ | 4  | 7   | 1⅜ | 1½ | 3  | 3¾  | 4  | 796            |
| 36  | 4  | 4½ | 8   | 1½ | 1¾ | 3¼ | 4¼  | 4½ | 637            |
| 42  | 4¼ | 4¾ | 9   | 1¾ | 2  | 3½ | 4½  | 5  | 557            |
| 48  | 4½ | 5  | 10  | 1¾ | 2  | 3¾ | 4¾  | 5½ | 478            |
| 54  | 4¾ | 5½ | 11  | 2  | 2¼ | 4  | 5   | 6  | 430            |
| 60  | 5  | 6  | 12  | 2¼ | 2½ | 4½ | 5½  | 6½ | 382            |
| 72  | 5½ | 7  | 13  | 2½ | 2¾ | 5  | 6½  | 7  | 318            |
| 84  | 6  | 8  | 14  | 3  | 3½ | 5½ | 7½  | 8  | 273            |
| 96  | 7  | 9  | 15  | 3½ | 4  | 6  | 9   | 9  | 239            |
| 108 | 8  | 10 | 16½ | 3¾ | 4½ | 6½ | 10½ | 10 | 212            |
| 120 | 9  | 11 | 18  | 4  | 5  | 7½ | 12  | 12 | 191            |

The maximum number of revolutions per minute given in this table should never be exceeded for cast-iron flywheels.

**Rim Velocity at Mean Radius:** When the mean radius of the flywheel is known, the velocity of the rim at the mean radius, in feet per second, is:

$$v = \frac{2 \times 3.1416 \times R \times n}{60}$$

in which  $v$  = velocity at mean radius of flywheel, in feet per second

$R$  = mean radius of flywheel rim, in feet

$n$  = number of revolutions per minute

According to the preliminary layout the mean diameter in this example should be about 30 inches and the driving shaft is to make 210 rpm, hence,

$$v = \frac{2 \times 3.1416 \times 1.25 \times 210}{60} = 27.5 \text{ feet per second}$$

*Weight of Flywheel Rim:* Assuming that the allowable variation in velocity when punching is about 15 per cent, and values of  $v_1$  and  $v_2$  are respectively 27.5 and 23.4 feet per second ( $27.5 \times 0.85 = 23.4$ ), the weight of a flywheel rim necessary to supply a given amount of energy in foot-pounds while the speed is reduced from  $v_1$  to  $v_2$  would be:

$$W = \frac{E_1 \times 64.32}{v_1^2 - v_2^2} = \frac{2425 \times 64.32}{27.5^2 - 23.4^2} = 750 \text{ pounds}$$

*Size of Rim for Given Weight:* Since 1 cubic inch of cast iron weighs 0.26 pound, a flywheel rim weighing 750 pounds contains  $750/0.26 = 2884$  cubic inches. The cross-sectional area of the rim in square inches equals the total number of cubic inches divided by the mean circumference, or  $2884/94.25 = 31$  square inches nearly, which is approximately the area of a rim  $5\frac{1}{8}$  inches wide and 6 inches deep.

**Simplified Flywheel Calculations.**—Calculations for designing the flywheels of punches and shears are simplified by the following formulas and the accompanying table of constants applying to different percentages of speed reduction. In these formulas let:

HP = horsepower required

N = number of strokes per minute

E = total energy required per stroke, in foot-pounds

$E_1$  = energy given up by flywheel, in foot-pounds

T = time in seconds per stroke

$T_1$  = time in seconds of actual cut

W = weight of flywheel rim, in pounds

D = mean diameter of flywheel rim, in feet

R = maximum allowable speed of flywheel in revolutions per minute

C and  $C_1$  = speed reduction values as given in table

a = width of flywheel rim

b = depth of flywheel rim

y = ratio of depth to width of rim

$$HP = \frac{EN}{33,000} = \frac{E}{T \times 550} \quad E_1 = E \left(1 - \frac{T_1}{T}\right)$$

$$W = \frac{E_1}{CD^2R^2} \quad a = \sqrt{\frac{1.22W}{12Dy}} \quad b = ay$$

For cast-iron flywheels, with a maximum stress of 1000 pounds per square inch:

$$W = C_1 E_1 \quad R = 1940 \div D$$

#### Values of C and $C_1$ in the Previous Formulas

| Per Cent Reduction | C          | $C_1$  | Per Cent Reduction | C          | $C_1$  |
|--------------------|------------|--------|--------------------|------------|--------|
| 2½                 | 0.00000213 | 0.1250 | 10                 | 0.00000810 | 0.0328 |
| 5                  | 0.00000426 | 0.0625 | 15                 | 0.00001180 | 0.0225 |
| 7½                 | 0.00000617 | 0.0432 | 20                 | 0.00001535 | 0.0173 |

*Example 1:* A hot slab shear is required to cut a slab  $4 \times 15$  inches which, at a shearing stress of 6000 pounds per square inch, gives a force between the knives of 360,000 pounds. The total energy required for the cut will then be  $360,000 \times \frac{1}{2} = 120,000$  foot-pounds. The shear is to make 20 strokes per minute; the actual cutting time is 0.75 second, and the balance of the stroke is 2.25 seconds.

The flywheel is to have a mean diameter of 6 feet 6 inches and is to run at a speed of 200 rpm; the reduction in speed to be 10 per cent per stroke when cutting.

$$HP = \frac{120,000 \times 20}{33,000} = 72.7 \text{ horsepower}$$

$$E_1 = 120,000 \times \left(1 - \frac{0.75}{3}\right) = 90,000 \text{ foot-pounds}$$

$$W = \frac{90,000}{0.0000081 \times 6.5^2 \times 200^2} = 6570 \text{ pounds}$$

Assuming a ratio of 1.22 between depth and width of rim,

$$a = \sqrt{\frac{6570}{12 \times 6.5}} = 9.18 \text{ inches}$$

$$b = 1.22 \times 9.18 = 11.2 \text{ inches}$$

or size of rim, say,  $9 \times 11\frac{1}{2}$  inches.

*Example 2:* Suppose that the flywheel in [Example 1](#) is to be made with a stress due to centrifugal force of 1000 pounds per square inch of rim section.

$$C_1 \text{ for 10 per cent} = 0.0328$$

$$W = 0.0328 \times 90,000 = 2950 \text{ pounds}$$

$$R = \frac{1940}{D} \quad \text{If } D = 6 \text{ feet,} \quad R = \frac{1940}{6} = 323 \text{ rpm}$$

Assuming a ratio of 1.22 between depth and width of rim, as before:

$$a = \sqrt{\frac{2950}{12 \times 6}} = 6.4 \text{ inches}$$

$$b = 1.22 \times 6.4 = 7.8 \text{ inches}$$

or size of rim, say,  $6\frac{1}{4} \times 8$  inches.

**Centrifugal Stresses in Flywheel Rims.**—In general, high speed is desirable for flywheels in order to avoid using wheels that are unnecessarily large and heavy. The centrifugal tension or hoop tension stress, that tends to rupture a flywheel rim of given area, depends solely upon the rim velocity and is independent of the rim radius. The bursting velocity of a flywheel, based on hoop stress alone (not considering bending stresses), is related to the tensile stress in the flywheel rim by the following formula which is based on the centrifugal force formula from mechanics.

$$V = \sqrt{10 \times s} \quad \text{or,} \quad s = V^2 \div 10$$

where  $V$  = velocity of outside circumference of rim in feet per second, and  $s$  is the tensile strength of the rim material in pounds per square inch.

For cast iron having a tensile strength of 19,000 pounds per square inch the bursting speed would be:

$$V = \sqrt{10 \times 19,000} = 436 \text{ feet per second}$$

*Built-up Flywheels:* Flywheels built up of solid disks of rolled steel plate stacked and bolted together on a through shaft have greater speed capacity than other types. The maximum hoop stress is at the bore and is given by the formula,

$$s = 0.0194V^2[4.333 + (d/D)^2]$$

In this formula,  $s$  and  $V$  are the stress and velocity as previously defined and  $d$  and  $D$  are the bore and outside diameters, respectively.

Assuming the plates to be of steel having a tensile strength of 60,000 pounds per square inch and a safe working stress of 24,000 pounds per square inch (using a factor of safety of 2.5 on stress or  $\sqrt{2.5}$  on speed) and taking the worst condition (when  $d$  approaches  $D$ ), the safe rim speed for this type of flywheel is 500 feet per second or 30,000 feet per minute.

**Combined Stresses in Flywheels.**—The bending stresses in the rim of a flywheel may exceed the centrifugal (hoop tension) stress predicted by the simple formula  $s = V^2/10$  by a considerable amount. By taking into account certain characteristics of flywheels, relatively simple formulas have been developed to determine the stress due to the combined effect of hoop tension and bending stress. Some of the factors that influence the magnitude of the maximum combined stress acting at the rim of a flywheel are:

1) *The number of spokes.* Increasing the number of spokes decreases the rim span between spokes and hence decreases the bending moment. Thus an eight-spoke wheel can be driven to a considerably higher speed before bursting than a six-spoke wheel having the same rim.

2) *The relative thickness of the spokes.* If the spokes were extremely thin, like wires, they could offer little constraint to the rim in expanding to its natural diameter under centrifugal force, and hence would cause little bending stress. Conversely, if the spokes were extremely heavy in proportion to the rim, they would restrain the rim thereby setting up heavy bending stresses at the junctions of the rim and spokes.

3) *The relative thickness of the rim to the diameter.* If the rim is quite thick (i.e., has a large section modulus in proportion to span), its resistance to bending will be great and bending stress small. Conversely, thin rims with a section modulus small in comparison with diameter or span have little resistance to bending, thus are subject to high bending stresses.

4) *Residual stresses.* These include shrinkage stresses, impact stresses, and stresses caused by operating torques and imperfections in the material. Residual stresses are taken into account by the use of a suitable factor of safety. (See *Factors of Safety for Flywheels.*)

The formulas that follow give the maximum combined stress at the rim of flywheels having 6, 8, and 10 spokes. These formulas are for flywheels with *rectangular rim sections* and take into account the first three of the four factors listed as influencing the magnitude of the combined stress in flywheels.

$$\text{For 6 spokes:} \quad s = \frac{V^2}{10} \left[ 1 + \left( \frac{0.56B - 1.81}{3Q + 3.14} \right) Q \right]$$

$$\text{For 8 spokes:} \quad s = \frac{V^2}{10} \left[ 1 + \left( \frac{0.42B - 2.53}{4Q + 3.14} \right) Q \right]$$

$$\text{For 10 spokes:} \quad s = \frac{V^2}{10} \left[ 1 + \left( \frac{0.33B - 3.22}{5Q + 3.14} \right) Q \right]$$

In these formulas,  $s$  = maximum combined stress in pounds per square inch;  $Q$  = ratio of mean spoke cross-section area to rim cross-section area;  $B$  = ratio of outside diameter of rim to rim thickness; and  $V$  = velocity of flywheel rim in feet per second.

**Thickness of Cast Iron Flywheel Rims.**—The mathematical analysis of the stresses in flywheel rims is not conclusive owing to the uncertainty of shrinkage stresses in castings or the strength of the joint in sectional wheels. When a flywheel of ordinary design is revolving at high speed, the tendency of the rim is to bend or bow outward between the arms, and the bending stresses may be serious, especially if the rim is wide and thin and the spokes are rather widely spaced. When the rims are thick, this tendency does not need to be considered, but in a thin rim running at high speed, the stress in the middle might become suf-

ficiently great to cause the wheel to fail. The proper thickness of a cast-iron rim to resist this tendency is given for solid rims by [Formula \(1\)](#) and for a jointed rim by [Formula \(2\)](#).

$$t = \frac{0.475d}{n^2 \left( \frac{6000}{v^2} - \frac{1}{10} \right)} \quad (1)$$

$$t = \frac{0.95d}{n^2 \left( \frac{6000}{v^2} - \frac{1}{10} \right)} \quad (2)$$

In these formulas,  $t$  = thickness of rim, in inches;  $d$  = diameter of flywheel, in inches;  $n$  = number of arms;  $v$  = peripheral speed, in feet per second.

**Factors of Safety for Flywheels.**—Cast-iron flywheels are commonly designed with a factor of safety of 10 to 13. A factor of safety of 10 applied to the tensile strength of a flywheel material is equivalent to a factor of safety of  $\sqrt{10}$  or 3.16 on the speed of the flywheel because the stress on the rim of a flywheel increases as the square of the speed. Thus, a flywheel operating at a speed twice that for which it was designed would undergo rim stresses four times as great as at the design speed.

**Tables of Safe Speeds for Flywheels.**—The accompanying [Table 1](#), prepared by T. C. Rathbone of The Fidelity and Casualty Company of New York, gives general recommendations for safe rim speeds for flywheels of various constructions. [Table 2](#) shows the number of revolutions per minute corresponding to the rim speeds in [Table 1](#).

**Table 1. Safe Rim Speeds for Flywheels**

| Type of Wheel                               | Safe Rim Speed |               |
|---|----------------|---------------|
|   | Feet per Sec.  | Feet per Min. |
| Solid cast iron (balance wheels—heavy rims) | 110            | 6,600         |
| Solid cast iron (pulley wheels—thin rims)   | 85             | 5,100         |
| Wheels with shrink link joints              | 77.5           | 4,650         |
| Wheels with pad type joints                 | 70.7           | 4,240         |
| Wheels with bolted flange joints            | 50             | 3,000         |
| Solid cast steel wheels                     | 200            | 12,000        |
| Wheels built up of stacked steel plates     | 500            | 30,000        |

To find the safe speed in revolutions per minute, divide the safe rim speed in feet per minute by 3.14 times the outside diameter of the flywheel rim in feet. For flywheels up to 15 feet in diameter, see [Table 2](#).

**Table 2. Safe Speeds of Rotation for Flywheels**

| Outside Diameter of Rim (feet) | Safe Rim Speed in Feet per Minute (from Table 1) |       |       |       |       |        |        |
|--------------------------------|--|-------|-------|-------|-------|--------|--------|
|                                | 6,600  | 5,100 | 4,650 | 4,240 | 3,000 | 12,000 | 30,000 |
|                                | Safe Speed of Rotation in Revolutions per Minute |       |       |       |       |        |        |
| 1                              | 2100   | 1623  | 1480  | 1350  | 955   | 3820   | 9549   |
| 2                              | 1050   | 812   | 740   | 676   | 478   | 1910   | 4775   |
| 3                              | 700  | 541   | 493   | 450   | 318   | 1273   | 3183   |
| 4                              | 525  | 406   | 370   | 338   | 239   | 955    | 2387   |
| 5                              | 420  | 325   | 296   | 270   | 191   | 764    | 1910   |
| 6                              | 350  | 271   | 247   | 225   | 159   | 637    | 1592   |
| 7                              | 300  | 232   | 211   | 193   | 136   | 546    | 1364   |
| 8                              | 263  | 203   | 185   | 169   | 119   | 478    | 1194   |
| 9                              | 233  | 180   | 164   | 150   | 106   | 424    | 1061   |
| 10                             | 210  | 162   | 148   | 135   | 96    | 382    | 955    |
| 11                             | 191  | 148   | 135   | 123   | 87    | 347    | 868    |
| 12                             | 175  | 135   | 123   | 113   | 80    | 318    | 796    |
| 13                             | 162  | 125   | 114   | 104   | 73    | 294    | 735    |
| 14                             | 150  | 116   | 106   | 97    | 68    | 273    | 682    |
| 15                             | 140  | 108   | 99    | 90    | 64    | 255    | 637    |

Safe speeds of rotation are based on safe rim speeds shown in Table 1.

**Safe Speed Formulas for Flywheels and Pulleys.**—No simple formula can accommodate all the various types and proportions of flywheels and pulleys and at the same time provide a uniform factor of safety for each. Because of considerations of safety, such a formula would penalize the better constructions to accommodate the weaker designs.

One formula that has been used to check the maximum rated operating speed of flywheels and pulleys and which takes into account material properties, construction, rim thickness, and joint efficiencies is the following:

$$N = \frac{CAMEK}{D}$$

In this formula,

$N$  = maximum rated operating speed in revolutions per minute

$C$  = 1.0 for wheels driven by a constant speed electric motor (i.e., a-c squirrel-cage induction motor or a-c synchronous motor, etc.)

0.90 for wheels driven by variable speed motors, engines or turbines where overspeed is not over 110 per cent of rated operating speed

$A$  = 0.90 for 4 arms or spokes

1.00 for 6 arms or spokes

1.08 for 8 arms or spokes

1.50 for disc type

$M$  = 1.00 for cast iron of 20,000 psi tensile strength, or unknown

1.12 for cast iron of 25,000 psi tensile strength

1.22 for cast iron of 30,000 psi tensile strength

1.32 for cast iron of 35,000 psi tensile strength

2.20 for nodular iron of 60,000 psi tensile strength

2.45 for cast steel of 60,000 psi tensile strength

2.75 for plate or forged steel of 60,000 psi tensile strength

$E$  = joint efficiency

1.0 for solid rim

0.85 for link or prison joints

0.75 for split rim — bolted joint at arms

0.70 for split rim — bolted joint between arms

|  |
|--|
| $K = 1355$ for rim thickness equal to 1 per cent of outside diameter |
| 1650 for rim thickness equal to 2 per cent of outside diameter       |
| 1840 for rim thickness equal to 3 per cent of outside diameter       |
| 1960 for rim thickness equal to 4 per cent of outside diameter       |
| 2040 for rim thickness equal to 5 per cent of outside diameter       |
| 2140 for rim thickness equal to 7 per cent of outside diameter       |
| 2225 for rim thickness equal to 10 per cent of outside diameter      |
| 2310 for rim thickness equal to 15 per cent of outside diameter      |
| 2340 for rim thickness equal to 20 per cent of outside diameter      |

$D$  = outside diameter of rim in feet

*Example:* A six-spoke solid cast iron balance wheel 8 feet in diameter has a rectangular rim 10 inches thick. What is the safe speed, in revolutions per minute, if driven by a constant motor?

In this instance,  $C = 1$ ;  $A = 1$ ;  $M = 1$ , since tensile strength is unknown;  $E = 1$ ;  $K = 2225$  since the rim thickness is approximately 10 per cent of the wheel diameter; and  $D = 8$  feet. Thus,

$$N = \frac{1 \times 1 \times 1 \times 2225}{8} = 278 \text{ rpm}$$

(*Note:* This safe speed is slightly greater than the value of 263 rpm obtainable directly from Tables 1 and 2.)

**Tests to Determine Flywheel Bursting Speeds.**—Tests made by Prof. C. H. Benjamin, to determine the bursting speeds of flywheels, showed the following results:

*Cast-iron Wheels with Solid Rims:* Cast-iron wheels having solid rims burst at a rim speed of 395 feet per second, corresponding to a centrifugal tension of about 15,600 pounds per square inch.

*Wheels with Jointed Rims:* Four wheels were tested with joints and bolts inside the rim, using the familiar design ordinarily employed for band wheels, but with the joints located at points one-fourth of the distance from one arm to the next. These locations represent the points of least bending moment, and, consequently, the points at which the deflection due to centrifugal force would be expected to have the least effect. The tests, however, did not bear out this conclusion. The wheels burst at a rim speed of 194 feet per second, corresponding to a centrifugal tension of about 3750 pounds per square inch. These wheels, therefore, were only about one-quarter as strong as the wheels with solid rims, and burst at practically the same speed as wheels in a previous series of tests in which the rim joints were midway between the arms.

*Bursting Speed for Link Joints:* Another type of wheel with deep rim, fastened together at the joints midway between the arms by links shrunk into recesses, after the manner of flywheels for massive engines, gave much superior results. This wheel burst at a speed of 256 feet per second, indicating a centrifugal tension of about 6600 pounds per square inch.

*Wheel having Tie-rods:* Tests were made on a band wheel having joints inside the rim, midway between the arms, and in all respects like others of this design previously tested, except that tie-rods were used to connect the joints with the hub. This wheel burst at a speed of 225 feet per second, showing an increase of strength of from 30 to 40 per cent over similar wheels without the tie-rods.

*Wheel Rim of I-section:* Several wheels of special design, not in common use, were also tested, the one giving the greatest strength being an English wheel, with solid rim of I-section, made of high-grade cast iron and with the rim tied to the hub by steel wire spokes. These spokes were adjusted to have a uniform tension. The wheel gave way at a rim speed of 424 feet per second, which is slightly higher than the speed of rupture of the solid rim wheels with ordinary style of spokes.

*Tests on Flywheel of Special Construction:* A test was made on a flywheel 49 inches in diameter and weighing about 900 pounds. The rim was  $6\frac{3}{4}$  inches wide and  $1\frac{1}{8}$  inches thick, and was built of ten segments, the material being cast steel. Each joint was secured by three "prisoners" of an I-section on the outside face, by link prisoners on each edge, and by a dovetailed bronze clamp on the inside, fitting over lugs on the rim. The arms were of phosphor-bronze, twenty in number, ten on each side, and were cross-shaped in section. These arms came midway between the rim joints and were bolted to plane faces on the polygonal hub. The rim was further reinforced by a system of diagonal bracing, each section of the rim being supported at five points on each side, in such a way as to relieve it almost entirely from bending. The braces, like the arms, were of phosphor-bronze, and all bolts and connecting links were of steel. This wheel was designed as a model of a proposed 30-foot flywheel. On account of the excessive air resistance the wheel was enclosed at the sides between sheet-metal disks. This wheel burst at 1775 revolutions per minute or at a linear speed of 372 feet per second. The hub and main spokes of the wheel remained nearly in place, but parts of the rim were found 200 feet away. This sudden failure of the rim casting was unexpected, as it was thought the flange bolts would be the parts to give way first. The tensile strength of the casting at the point of fracture was about four times the strength of the wheel rim at a solid section.

**Stresses in Rotating Disks.**—When a disk of uniform width is rotated, the maximum stress  $S_t$  is tangential and at the bore of the hub, and the tangential stress is always greater than the radial stress at the same point on the disk. If  $S_t$  = maximum tangential stress in pounds per sq. in.;  $w$  = weight of material, lb. per cu. in.;  $N$  = rev. per min.;  $m$  = Poisson's ratio = 0.3 for steel;  $R$  = outer radius of disk, inches;  $r$  = inner radius of disk or radius of bore, inches.

$$S_t = 0.000071 w N^2 [(3 + m)R^2 + (1 - m)r^2]$$

**Steam Engine Flywheels.**—The variable amount of energy during each stroke and the allowable percentage of speed variation are of special importance in designing steam engine flywheels. The earlier the point of cut-off, the greater the variation in energy and the larger the flywheel that will be required. The weight of the reciprocating parts and the length of the connecting-rod also affect the variation. The following formula is used for computing the weight of the flywheel rim:

Let  $W$  = weight of rim in pounds

$D$  = mean diameter of rim in feet

$N$  = number of revolutions per minute

$\frac{1}{n}$  = allowable variation in speed (from  $\frac{1}{50}$  to  $\frac{1}{100}$ )

$E$  = excess and deficiency of energy in foot-pounds

$c$  = factor of energy excess, from the accompanying table

$HP$  = indicated horsepower

Then, if the indicated horsepower is given:

$$W = \frac{387,587,500 \times cn \times HP}{D^2 N^3} \quad (1)$$

If the work in foot-pounds is given, then:

$$W = \frac{11,745nE}{D^2 N^2} \quad (2)$$

In the second formula,  $E$  equals the average work in foot-pounds done by the engine in one revolution, multiplied by the decimal given in the accompanying table, "*Factors for Engine Flywheel Calculations*," which covers both condensing and non-condensing engines:

## Factors for Engine Flywheel Calculations

| Condensing Engines                           |               |               |               |               |               |               |
|--|---------------|---------------|---------------|---------------|---------------|---------------|
| Fraction of stroke at which steam is cut off | $\frac{1}{3}$ | $\frac{1}{4}$ | $\frac{1}{5}$ | $\frac{1}{6}$ | $\frac{1}{7}$ | $\frac{1}{8}$ |
| Factor of energy excess                      | 0.163         | 0.173         | 0.178         | 0.184         | 0.189         | 0.191         |
| Non-condensing Engines                       |               |               |               |               |               |               |
| Steam cut off at                             |               | $\frac{1}{2}$ | $\frac{1}{3}$ | $\frac{1}{4}$ | $\frac{1}{5}$ |               |
| Factor of energy excess                      |               | 0.160         | 0.186         | 0.209         | 0.232         |               |

*Example 1:* A non-condensing engine of 150 indicated horsepower is to make 200 revolutions per minute, with a speed variation of 2 per cent. The average cut-off is to be at one-quarter stroke, and the flywheel is to have a mean diameter of 6 feet. Find the necessary weight of the rim in pounds.

From the table  $c = 0.209$ , and from the data given  $HP = 150$ ;  $N = 200$ ;  $1/n = 1/50$  or  $n = 50$ ; and,  $D = 6$ .

Substituting these values in [Equation \(1\)](#):

$$W = \frac{387,587,500 \times 0.209 \times 50 \times 150}{6^2 \times 200^3} = 2110 \text{ pounds, nearly}$$

*Example 2:* A condensing engine,  $24 \times 42$  inches, cuts off at one-third stroke and has a mean effective pressure of 50 pounds per square inch. The flywheel is to be 18 feet in mean diameter and make 75 revolutions per minute with a variation of 1 per cent. Find the required weight of the rim.

The work done on the piston in one revolution is equal to the pressure on the piston multiplied by the distance traveled or twice the stroke in feet. The area of the piston is 452.4 square inches, and twice the stroke is 7 feet. The work done on the piston in one revolution is, therefore,  $452.4 \times 50 \times 7 = 158,340$  foot-pounds. From the table  $c = 0.163$ , and therefore:

$$E = 158,340 \times 0.163 = 25,810 \text{ foot-pounds}$$

From the data given:  $n = 100$ ;  $D = 18$ ;  $N = 75$ . Substituting these values in [Equation \(2\)](#):

$$W = \frac{11,745 \times 100 \times 25,810}{18^2 \times 75^2} = 16,650 \text{ pounds, nearly}$$

**Spokes or Arms of Flywheels.**—Flywheel arms are usually of elliptical cross-section. The major axis of the ellipse is in the plane of rotation to give the arms greater resistance to bending stresses and reduce the air resistance which may be considerable at high velocity. The stresses in the arms may be severe, due to the inertia of a heavy rim when sudden load changes occur. The strength of the arms should equal three-fourths the strength of the shaft in torsion.

If  $W$  equals the width of the arm at the hub (length of major axis) and  $D$  equals the shaft diameter, then  $W$  equals  $1.3D$  for a wheel having 6 arms; and for an 8-arm wheel  $W$  equals  $1.2D$ . The thickness of the arm at the hub (length of minor axis) equals one-half the width. The arms usually taper toward the rim. The cross-sectional area at the rim should not be less than two-thirds the area at the hub.

### Critical Speeds

**Critical Speeds of Rotating Bodies and Shafts.**—If a body or disk mounted upon a shaft rotates about it, the center of gravity of the body or disk must be at the center of the shaft, if a perfect running balance is to be obtained. In most cases, however, the center of gravity of the disk will be slightly removed from the center of the shaft, owing to the difficulty of perfect balancing. Now, if the shaft and disk be rotated, the centrifugal force generated by the heavier side will be greater than that generated by the lighter side geometrically opposite to it, and the shaft will deflect toward the heavier side, causing the center of the disk to rotate in a small circle. A rotating shaft without a body or disk mounted on it can also become dynamically unstable, and the resulting vibrations and deflections can result in damage not only to the shaft but to the machine of which it is a part. These conditions hold true up to a comparatively high speed; but a point is eventually reached (at several thousand revolutions per minute) when momentarily there will be excessive vibration, and then the parts will run quietly again. The speed at which this occurs is called the *critical speed* of the wheel or shaft, and the phenomenon itself for the shaft-mounted disk or body is called the *settling* of the wheel. The explanation of the settling is that at this speed the axis of rotation changes, and the wheel and shaft, instead of rotating about their geometrical center, begin to rotate about an axis through their center of gravity. The shaft itself is then deflected so that for every revolution its geometrical center traces a circle around the center of gravity of the rotating mass.

Critical speeds depend upon the magnitude or location of the load or loads carried by the shaft, the length of the shaft, its diameter and the kind of supporting bearings. The normal operating speed of a machine may or may not be higher than the critical speed. For instance, some steam turbines exceed the critical speed, although they do not run long enough at the critical speed for the vibrations to build up to an excessive amplitude. The practice of the General Electric Co. at Schenectady is to keep below the critical speeds. It is assumed that the maximum speed of a machine may be within 20 per cent high or low of the critical speed without vibration troubles. Thus, in a design of steam turbine sets, critical speed is a factor that determines the size of the shafts for both the generators and turbines. Although a machine may run very close to the critical speed, the alignment and play of the bearings, the balance and construction generally, will require extra care, resulting in a more expensive machine; moreover, while such a machine may run smoothly for a considerable time, any looseness or play that may develop later, causing a slight imbalance, will immediately set up excessive vibrations.

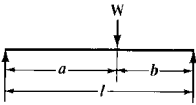

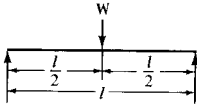

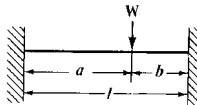

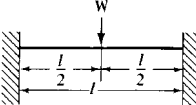

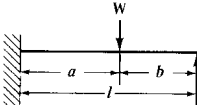

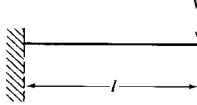

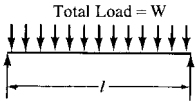

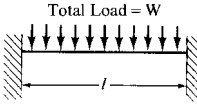

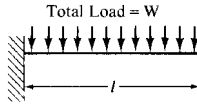

The formulas commonly used to determine critical speeds are sufficiently accurate for general purposes. There are cases, however, where the torque applied to a shaft has an important effect on its critical speed. Investigations have shown that the critical speeds of a uniform shaft are decreased as the applied torque is increased, and that there exist critical torques which will reduce the corresponding critical speed of the shaft to zero. A detailed analysis of the effects of applied torques on critical speeds may be found in a paper, "Critical Speeds of Uniform Shafts under Axial Torque," by Golumb and Rosenberg, presented at the First U.S. National Congress of Applied Mechanics in 1951.

**Formulas for Critical Speeds.**—The critical speed formulas given in the accompanying table (from the paper on Critical Speed Calculation presented before the ASME by S. H. Weaver) apply to (1) shafts with single concentrated loads and (2) shafts carrying uniformly distributed loads. These formulas also cover different conditions as regards bearings. If the bearings are self-aligning or very short, the shaft is considered supported at the ends; whereas, if the bearings are long and rigid, the shaft is considered fixed. These formulas, for both concentrated and distributed loads, apply to vertical shafts as well as horizontal shafts, the critical speeds having the same value in both cases. The data required for the solution of critical speed problems are the same as for shaft deflection. As the shaft is usually of variable diameter and its stiffness is increased by a long hub, an ideal shaft of uniform diameter and equal stiffness must be assumed.

**CRITICAL SPEEDS**

**Critical Speed Formulas**

| Formulas for Single Concentrated Load  |  |   |
|--|--|---|
|  $N = 387,000 \frac{d^2}{ab} \sqrt{\frac{l}{W}}$ <p>Bearings supported</p>   |  $N = 1,550,500 \frac{d^2}{l \sqrt{Wl}}$ <p>Bearings supported</p>  |  $N = 387,000 \frac{d^2 l}{ab} \sqrt{\frac{l}{Wab}}$ <p>Bearings fixed</p>   |
|  $N = 3,100,850 \frac{d^2}{l \sqrt{Wl}}$ <p>Bearings fixed</p>   |  $N = 775,200 \frac{d^2 l}{ab} \sqrt{\frac{l}{Wa(3l+b)}}$ <p>One-fixed — One supported</p>                            |  $N = 387,000 \frac{d^2}{l \sqrt{Wl}}$ <p>One fixed — One free end</p>   |
| Formulas for Distributed Loads—First Critical Speed  |  |   |
| <p>Total Load = W</p>  $N = 2,232,500 \frac{d^2}{l \sqrt{Wl}}$ $N_1 = 4,760,000 \frac{d}{l^2}$ <p>Bearings supported</p> | <p>Total Load = W</p>  $N = 4,979,250 \frac{d^2}{l \sqrt{Wl}}$ $N_1 = 10,616,740 \frac{d}{l^2}$ <p>Bearings fixed</p> | <p>Total Load = W</p>  $N = 795,200 \frac{d^2}{l \sqrt{Wl}}$ $N_1 = 1,695,500 \frac{d}{l^2}$ <p>One fixed—One free end</p> |

$N$  = critical speed, RPM

$N_1$  = critical speed of shaft alone

$d$  = diameter of shaft, in inches

$W$  = load applied to shaft, in pounds

$l$  = distance between centers of bearings, in inches

$a$  and  $b$  = distances from bearings to load

In calculating critical speeds, the weight of the shaft is either neglected or, say, one-half to two-thirds of the weight is added to the concentrated load. The formulas apply to steel shafts having a modulus of elasticity  $E = 29,000,000$ . Although a shaft carrying a number of loads or a distributed load may have an infinite number of critical speeds, ordinarily it is the first critical speed that is of importance in engineering work. The first critical speed is obtained by the formulas given in the distributed loads portion of the table [Critical Speed Formulas](#).

### Balancing Rotating Parts

**Static Balancing.**—There are several methods of testing the standing or static balance of a rotating part. A simple method that is sometimes used for flywheels, etc., is illustrated by the diagram, Fig. 1. An accurate shaft is inserted through the bore of the finished wheel, which is then mounted on carefully leveled "parallels" A. If the wheel is in an unbalanced state, it will turn until the heavy side is downward. When it will stand in any position as the result of counterbalancing and reducing the heavy portions, it is said to be in standing or static balance. Another test which is used for disk-shaped parts is shown in Fig. 2. The disk D is mounted on a vertical arbor attached to an adjustable cross-slide B. The latter is carried by a table C, which is supported by a knife-edged bearing. A pendulum having an adjustable screw-weight W at the lower end is suspended from cross-slide B. To test the static balance of disk D, slide B is adjusted until pointer E of the pendulum coincides with the center of a stationary scale F. Disk D is then turned halfway around without moving the slide, and if the indicator remains stationary, it shows that the disk is in balance for this particular position. The test is then repeated for ten or twelve other positions, and the heavy sides are reduced, usually by drilling out the required amount of metal. Several other devices for testing static balance are designed on this same principle.

Fig. 1.

Fig. 2.

Fig. 3.

**Running or Dynamic Balance.**—A cylindrical body may be in perfect static balance and not be in a balanced state when rotating at high speed. If the part is in the form of a thin disk, static balancing, if carefully done, may be accurate enough for high speeds, but if the rotating part is long in proportion to its diameter, and the unbalanced portions are at opposite ends or in different planes, the balancing must be done so as to counteract the centrifugal force of these heavy parts when they are rotating rapidly. This process is known as a running balance or dynamic balancing. To illustrate, if a heavy section is located at H (Fig. 3), and another correspondingly heavy section at  $H_1$ , one may exactly counterbalance the other when the cylinder is stationary, and this static balance may be sufficient for a part rigidly mounted and rotating at a comparatively slow speed; but when the speed is very high, as in turbine rotors, etc., the heavy masses H and  $H_1$ , being in different planes, are in an unbalanced state owing to the effect of centrifugal force, which results in excessive strains and injurious vibrations. Theoretically, to obtain a perfect running balance, the exact positions of the heavy sections should be located and the balancing effected either by reducing their weight or by adding counterweights opposite each section and in the same plane at the proper radius; but if the rotating part is rigidly mounted on a stiff shaft, a running balance that is sufficiently accurate for practical purposes can be obtained by means of comparatively few counterbalancing weights located with reference to the unbalanced parts.

**Balancing Calculations.**—As indicated previously, centrifugal forces caused by an unbalanced mass or masses in a rotating machine member cause additional loads on the bearings which are transmitted to the housing or frame and to other machine members. Such dynamically unbalanced conditions can occur even though static balance (balance at

zero speed) exists. Dynamic balance can be achieved by the addition of one or two masses rotating about the same axis and at the same speed as the unbalanced masses. A single unbalanced mass can be balanced by one counterbalancing mass located 180 degrees opposite and in the same plane of rotation as the unbalanced mass, if the product of their respective radii and masses are equal; i.e.,  $M_1r_1 = M_2r_2$ . Two or more unbalanced masses rotating in the same plane can be balanced by a single mass rotating in the same plane, or by two masses rotating about the same axis in two separate planes. Likewise, two or more unbalanced masses rotating in different planes about a common axis can be balanced by two masses rotating about the same axis in separate planes. When the unbalanced masses are in separate planes they may be in static balance but not in dynamic balance; i.e., they may be balanced when not rotating but unbalanced when rotating. If a system is in dynamic balance, it will remain in balance at all speeds, although this is not strictly true at the critical speed of the system. (See *Critical Speeds* on page 195.)

In all the equations that follow, the symbol  $M$  denotes either mass in kilograms or in slugs, or weight in pounds. Either mass or weight units may be used and the equations may be used with metric or with customary English units without change; however, in a given problem the units must be all metric or all customary English.

**Counterbalancing Several Masses Located in a Single Plane.**—In all balancing problems, it is the product of counterbalancing mass (or weight) and its radius that is calculated; it is thus necessary to select either the mass or the radius and then calculate the other value from the product of the two quantities. Design considerations usually make this decision self-evident. The angular position of the counterbalancing mass must also be calculated. Referring to Fig. 4:

$$M_B r_B = \sqrt{(\sum Mr \cos \theta)^2 + (\sum Mr \sin \theta)^2} \quad (1)$$

$$\tan \theta_B = \frac{-\sum Mr \sin \theta}{-\sum Mr \cos \theta} = \frac{y}{x} \quad (2)$$

Fig. 4.

**Table 1. Relationship of the Signs of the Functions of the Angle with Respect to the Quadrant in Which They Occur**

|        |                        |                 |                 |                 |                 |
|--------|------------------------|-----------------|-----------------|-----------------|-----------------|
|        | Angle $\theta$         |                 |                 |                 |                 |
|        |                        | 0° to 90°       | 90° to 180°     | 180° to 270°    | 270° to 360°    |
|        | Signs of the Functions |                 |                 |                 |                 |
|        | tan                    | $\frac{+y}{+x}$ | $\frac{+y}{-x}$ | $\frac{-y}{-x}$ | $\frac{-y}{+x}$ |
| sine   | $\frac{+y}{+r}$        | $\frac{+y}{+r}$ | $\frac{-y}{+r}$ | $\frac{-y}{+r}$ |                 |
| cosine | $\frac{+x}{+r}$        | $\frac{-x}{+r}$ | $\frac{-x}{+r}$ | $\frac{+x}{+r}$ |                 |

where:

$M_1, M_2, M_3, \dots M_n$  = any unbalanced mass or weight, kg or lb

$M_B$  = counterbalancing mass or weight, kg or lb

$r$  = radius to center of gravity of any unbalanced mass or weight, mm or inch

$r_B$  = radius to center of gravity of counterbalancing mass or weight, mm or inch

$\theta$  = angular position of  $r$  of any unbalanced mass or weight, degrees

$\theta_B$  = angular position of  $r_B$  of counterbalancing mass or weight, degrees

$x$  and  $y$  = see Table 1

Table 1 is helpful in finding the angular position of the counterbalancing mass or weight. It indicates the range of the angles within which this angular position occurs by noting the plus and minus signs of the numerator and the denominator of the terms in Equation (2). In a like manner, Table 1 is helpful in determining the sign of the sine or cosine functions for angles ranging from 0 to 360 degrees. Balancing problems are usually solved most conveniently by arranging the arithmetical calculations in a tabular form.

Example: Referring to Fig. 4, the particular values of the unbalanced weights have been entered in the table below. Calculate the magnitude of the counterbalancing weight if its radius is to be 10 inches.

| $M$ |     | $r$<br>in. | $\theta$<br>deg. | cos $\theta$ | sin $\theta$ | $Mr \cos \theta$                 | $Mr \sin \theta$               |
|-----|-----|------------|------------------|--------------|--------------|----------------------------------|--------------------------------|
| No. | lb. |            |                  |              |              |                                  |                                |
| 1   | 10  | 10         | 30               | 0.8660       | 0.5000       | 86.6                             | 50.0                           |
| 2   | 5   | 20         | 120              | -0.5000      | 0.8660       | -50.0                            | 86.6                           |
| 3   | 15  | 15         | 200              | -0.9397      | -0.3420      | -211.4                           | -77.0                          |
|     |     |            |                  |              |              | -174.8 = $\Sigma Mr \cos \theta$ | 59.6 = $\Sigma Mr \sin \theta$ |

$$M_B = \frac{\sqrt{(\Sigma Mr \cos \theta)^2 + (\Sigma Mr \sin \theta)^2}}{r_B} = \frac{\sqrt{(-174.8)^2 + (59.6)^2}}{10}$$

$$M_B = 18.5 \text{ lb}$$

$$\tan \theta_B = \frac{-\Sigma Mr \sin \theta}{-\Sigma Mr \cos \theta} = \frac{-(59.6)}{-(-174.8)} = \frac{-y}{+x}; \theta_B = 341^\circ 10'$$

Fig. 5.

**Counterbalancing Masses Located in Two or More Planes.**—Unbalanced masses or weights rotating about a common axis in two separate planes of rotation form a couple, which must be counterbalanced by masses or weights, also located in two separate planes, call them planes A and B, and rotating about the same common axis (see *Couples*, page 147). In addition, they must be balanced in the direction perpendicular to the axis, as before. Since two counterbalancing masses are required, two separate equations are required to calculate the product of each mass or weight and its radius, and two additional equations are required to calculate the angular positions. The planes A and B selected as balancing planes may be any two planes separated by any convenient distance  $c$ , along the axis of rotation. In Fig. 5:

For balancing plane A:

$$M_A r_A = \frac{\sqrt{(\sum M r b \cos \theta)^2 + (\sum M r b \sin \theta)^2}}{c} \quad (3)$$

$$\tan \theta_A = \frac{-(\sum M r b \sin \theta)}{-(\sum M r b \cos \theta)} = \frac{y}{x} \quad (4)$$

For balancing plane B:

$$M_B r_B = \frac{\sqrt{(\sum M r a \cos \theta)^2 + (\sum M r a \sin \theta)^2}}{c} \quad (5)$$

$$\tan \theta_B = \frac{-(\sum M r a \sin \theta)}{-(\sum M r a \cos \theta)} = \frac{y}{x} \quad (6)$$

Where:  $M_A$  and  $M_B$  are the mass or weight of the counterbalancing masses in the balancing planes A and B, respectively;  $r_A$  and  $r_B$  are the radii; and  $\theta_A$  and  $\theta_B$  are the angular positions of the balancing masses in these planes.  $M$ ,  $r$ , and  $\theta$  are the mass or weight, radius, and angular positions of the unbalanced masses, with the subscripts defining the particular mass to which the values are assigned. The length  $c$ , the distance between the balancing planes, is always a positive value. The axial dimensions,  $a$  and  $b$ , may be either positive or negative, depending upon their position relative to the balancing plane; for example, in Fig. 5, the dimension  $b_2$  would be negative.

*Example:* Referring to Fig. 5, a set of values for the masses and dimensions has been selected and put into convenient table form below. The separation of balancing planes,  $c$ , is assumed as being 15 inches. If in balancing plane A, the radius of the counterbalancing

weight is selected to be 10 inches; calculate the magnitude of the counterbalancing mass and its position. If in balancing plane *B*, the counterbalancing mass is selected to be 10 lb; calculate its radius and position.

For balancing plane *A*:

| Plane    | <i>M</i><br>lb | <i>r</i><br>in. | $\theta$<br>deg. | Balancing Plane <i>A</i> |            |                             |                             |
|----------|----------------|-----------------|------------------|--------------------------|------------|-----------------------------|-----------------------------|
|          |                |                 |                  | <i>b</i><br>in.          | <i>Mrb</i> | <i>Mrb</i> cos $\theta$     | <i>Mrb</i> sin $\theta$     |
| 1        | 10             | 8               | 30               | 6                        | 480        | 415.7                       | 240.0                       |
| 2        | 8              | 10              | 135              | -6                       | -480       | 339.4                       | -339.4                      |
| 3        | 12             | 9               | 270              | 12                       | 1296       | <u>0.0</u>                  | <u>-1296.0</u>              |
| <i>A</i> | ?              | 10              | ?                | 15 <sup>a</sup>          | ...        | 755.1                       | -1395.4                     |
| <i>B</i> | 10             | ?               | ?                | 0                        | ...        | = $\Sigma Mrb$ cos $\theta$ | = $\Sigma Mrb$ sin $\theta$ |

<sup>a</sup> 15 inches = distance *c* between planes *A* and *B*.

$$M_A = \frac{\sqrt{(\Sigma Mrb \cos \theta)^2 + (\Sigma Mrb \sin \theta)^2}}{r_A c} = \frac{\sqrt{(755.1)^2 + (-1395.4)^2}}{10(15)}$$

$$M_A = 10.6 \text{ lb}$$

$$\tan \theta_A = \frac{-\Sigma Mrb \sin \theta}{-\Sigma Mrb \cos \theta} = \frac{-(-1395.4)}{-(755.1)} = \frac{+y}{-x}$$

$$\theta_A = 118^\circ 25'$$

For balancing plane *B*:

| Plane    | <i>M</i><br>lb | <i>r</i><br>in. | $\theta$<br>deg. | Balancing Plane <i>B</i> |            |                             |                             |
|----------|----------------|-----------------|------------------|--------------------------|------------|-----------------------------|-----------------------------|
|          |                |                 |                  | <i>a</i><br>in.          | <i>Mra</i> | <i>Mra</i> cos $\theta$     | <i>Mra</i> sin $\theta$     |
| 1        | 10             | 8               | 30               | 9                        | 720        | 623.5                       | 360.0                       |
| 2        | 8              | 10              | 135              | 21                       | 1680       | -1187.9                     | 1187.9                      |
| 3        | 12             | 9               | 270              | 3                        | 324        | <u>0.0</u>                  | <u>-324.0</u>               |
| <i>A</i> | ?              | 10              | ?                | 0                        | ...        | -564.4                      | 1223.9                      |
| <i>B</i> | 10             | ?               | ?                | 15 <sup>a</sup>          | ...        | = $\Sigma Mra$ cos $\theta$ | = $\Sigma Mra$ sin $\theta$ |

<sup>a</sup> 15 inches = distance *c* between planes *A* and *B*.

$$r_B = \frac{\sqrt{(\Sigma Mra \cos \theta)^2 + (\Sigma Mra \sin \theta)^2}}{M_B c} = \frac{\sqrt{(-564.4)^2 + (1223.9)^2}}{10(15)}$$

$$= 8.985 \text{ in.}$$

$$\tan \theta_B = \frac{-\Sigma Mra \sin \theta}{-\Sigma Mra \cos \theta} = \frac{-(1223.9)}{-(-564.4)} = \frac{-y}{+x}$$

$$\theta_B = 294^\circ 45'$$

**Balancing Lathe Fixtures.**—Lathe fixtures rotating at a high speed require balancing. Often it is assumed that the center of gravity of the workpiece and fixture, and of the counterbalancing masses are in the same plane; however, this is not usually the case. Counterbalancing masses are required in two separate planes to prevent excessive vibration or bearing loads at high speeds.

Fig. 6.

Usually a single counterbalancing mass is placed in one plane selected to be 180 degrees directly opposite the combined center of gravity of the workpiece and the fixture. Two equal counterbalancing masses are then placed in the second counterbalancing plane, equally spaced on each side of the fixture. Referring to Fig. 6, the two counterbalancing masses  $M_A$  and the two angles  $\theta$  are equal. For the design in this illustration, the following formulas can be used to calculate the magnitude of the counterbalancing masses. Since their angular positions are fixed by the design, they are not calculated.

$$M_B = \frac{M_w r_w (l_1 + l_2)}{r_B l_1} \quad (7)$$

$$M_A = \frac{M_B r_B - M_w r_w}{2 r_A \sin \theta} \quad (8)$$

In these formulas  $M_w$  and  $r_w$  denote the mass or weight and the radius of the combined center of gravity of the workpiece and the fixture.

In Fig. 6 the combined weight of the workpiece and the fixture is 18.5 lb. The following dimensions were determined from the layout of the fixture and by calculating the centers of gravity:  $r_w = 2$  in.;  $r_A = 6.25$  in.;  $r_B = 6$  in.;  $l_1 = 3$  in.;  $l_2 = 5$  in.; and  $\theta = 30^\circ$ . Calculate the weights of the counterbalancing masses.

$$M_B = \frac{M_w r_w (l_1 + l_2)}{r_B l_1} = \frac{18.5 \times 2 \times 8}{6 \times 3} = 16.44 \text{ lb}$$

$$M_A = \frac{M_B r_B - M_w r_w}{2 r_A \sin \theta} = \frac{(16.44 \times 6) - (18.5 \times 2)}{(2 \times 6.25) \sin 30^\circ} = 9.86 \text{ lb (each weight)}$$

## STRENGTH OF MATERIALS

### Introduction

Strength of materials deals with the relations between the external forces applied to elastic bodies and the resulting deformations and stresses. In the design of structures and machines, the application of the principles of strength of materials is necessary if satisfactory materials are to be utilized and adequate proportions obtained to resist functional forces.

Forces are produced by the action of gravity, by accelerations and impacts of moving parts, by gasses and fluids under pressure, by the transmission of mechanical power, etc. In order to analyze the stresses and deflections of a body, the magnitudes, directions and points of application of forces acting on the body must be known. Information given in the Mechanics section provides the basis for evaluating force systems.

The time element in the application of a force on a body is an important consideration. Thus a force may be static or change so slowly that its maximum value can be treated as if it were static; it may be suddenly applied, as with an impact; or it may have a repetitive or cyclic behavior.

The environment in which forces act on a machine or part is also important. Such factors as high and low temperatures; the presence of corrosive gases, vapors and liquids; radiation, etc. may have a marked effect on how well parts are able to resist stresses.

**Throughout the Strength of Materials section in this Handbook, both English and metric SI data and formulas are given to cover the requirements of working in either system of measurement. Formulas and text relating exclusively to SI units are given in bold-face type.**

**Mechanical Properties of Materials.**—Many mechanical properties of materials are determined from tests, some of which give relationships between stresses and strains as shown by the curves in the accompanying figures.

*Stress* is force per unit area and is usually expressed in pounds per square inch. If the stress tends to stretch or lengthen the material, it is called *tensile* stress; if to compress or shorten the material, a *compressive* stress; and if to shear the material, a *shearing* stress. Tensile and compressive stresses always act at right-angles to (normal to) the area being considered; shearing stresses are always in the plane of the area (at right-angles to compressive or tensile stresses).

Fig. 1. Stress-strain curves

**In the SI, the unit of stress is the pascal (Pa), the newton per meter squared ( $\text{N}/\text{m}^2$ ). The megapascal (newtons per millimeter squared) is often an appropriate sub-multiple for use in practice.**

*Unit strain* is the amount by which a dimension of a body changes when the body is subjected to a load, divided by the original value of the dimension. The simpler term *strain* is often used instead of unit strain.

*Proportional limit* is the point on a stress-strain curve at which it begins to deviate from the straight-line relationship between stress and strain.

*Elastic limit* is the maximum stress to which a test specimen may be subjected and still return to its original length upon release of the load. A material is said to be stressed within the *elastic region* when the working stress does not exceed the elastic limit, and to be stressed in the *plastic region* when the working stress does exceed the elastic limit. The elastic limit for steel is for all practical purposes the same as its proportional limit.

*Yield point* is a point on the stress-strain curve at which there is a sudden increase in strain without a corresponding increase in stress. Not all materials have a yield point. Some representative values of the yield point (in ksi) are as follows:

|                            |       |   |        |
|----------------------------|-------|---|--------|
| Aluminum, wrought, 2014-T6 | 60    | Titanium, pure                                      | 55-70  |
| Aluminum, wrought, 6061-T6 | 35    | Titanium, alloy, 5Al, 2.5Sn                         | 110    |
| Beryllium copper           | 140   | Steel for bridges and buildings,                    | 33     |
| Brass, naval               | 25-50 | ASTM A7-61T, all shapes                             |        |
| Cast iron, malleable       | 32-45 | Steel, castings, high strength, for structural pur- | 40-145 |
| Cast iron, nodular         | 45-65 | poses, ASTM A148.60 (seven grades)                  |        |
| Magnesium, AZ80A-T5        | 38    | Steel, stainless (0.08-0.2C, 17Cr, 7Ni) 1/4 hard    | 78     |

*Yield strength,  $S_y$* , is the maximum stress that can be applied without permanent deformation of the test specimen. This is the value of the stress at the elastic limit for materials for which there is an elastic limit. Because of the difficulty in determining the elastic limit, and because many materials do not have an elastic region, yield strength is often determined by the offset method as illustrated by the accompanying figure at (3). Yield strength in such a case is the stress value on the stress-strain curve corresponding to a definite amount of permanent set or strain, usually 0.1 or 0.2 per cent of the original dimension. Yield strength data for various materials are given in tables starting on pages 417, 419, 463, 464, 466, 468, 472, 554, 556, 560, 569, 570, 575, 580, 588, 590, 591, and elsewhere.

*Ultimate strength,  $S_u$* , (also called *tensile strength*) is the maximum stress value obtained on a stress-strain curve.

*Modulus of elasticity,  $E$* , (also called *Young's modulus*) is the ratio of unit stress to unit strain within the proportional limit of a material in tension or compression. Some representative values of Young's modulus (in  $10^6$  psi) are as follows:

|                             |      |  |      |
|-----------------------------|------|--|------|
| Aluminum, cast, pure        | 9    | Magnesium, AZ80A-T5                            | 6.5  |
| Aluminum, wrought, 2014-T6  | 10.6 | Titanium, pure                                 | 15.5 |
| Beryllium copper            | 19   | Titanium, alloy, 5 Al, 2.5 Sn                  | 17   |
| Brass, naval                | 15   | Steel for bridges and buildings,               | 29   |
| Bronze, phosphor, ASTM B159 | 15   | ASTM A7-61T, all shapes                        |      |
| Cast iron, malleable        | 26   | Steel, castings, high strength, for structural | 29   |
| Cast iron, nodular          | 23.5 | purposes, ASTM A148-60 (seven grades)          |      |

*Modulus of elasticity in shear,  $G$* , is the ratio of unit stress to unit strain within the proportional limit of a material in shear.

*Poisson's ratio,  $\mu$* , is the ratio of lateral strain to longitudinal strain for a given material subjected to uniform longitudinal stresses within the proportional limit. The term is found in certain equations associated with strength of materials. Values of Poisson's ratio for common materials are as follows:

|                  |       |                 |       |
|------------------|-------|-----------------|-------|
| Aluminum         | 0.334 | Nickel silver   | 0.322 |
| Beryllium copper | 0.285 | Phosphor bronze | 0.349 |
| Brass            | 0.340 | Rubber          | 0.500 |
| Cast iron, gray  | 0.211 | Steel, cast     | 0.265 |
| Copper           | 0.340 | high carbon     | 0.295 |
| Inconel          | 0.290 | mild            | 0.303 |
| Lead             | 0.431 | nickel          | 0.291 |
| Magnesium        | 0.350 | Wrought iron    | 0.278 |
| Monel metal      | 0.320 | Zinc            | 0.331 |

**Compressive Properties.**—From compression tests, *compressive yield strength*,  $S_{cy}$ , and *compressive ultimate strength*,  $S_{cu}$ , are determined. Ductile materials under compression loading merely swell or buckle without fracture, hence do not have a compressive ultimate strength.

**Shear Properties.**—The properties of *shear yield strength*,  $S_{sy}$ , *shear ultimate strength*,  $S_{su}$ , and the *modulus of rigidity*,  $G$ , are determined by direct shear and torsional tests. The modulus of rigidity is also known as the modulus of elasticity in shear. It is the ratio of the shear stress,  $\tau$ , to the shear strain,  $\gamma$ , in radians, within the proportional limit:  $G = \tau/\gamma$ .

**Creep.**—Continuing changes in dimensions of a stressed material over time is called creep, and it varies with different materials and periods under stress, also with temperature. Creep tests may take some time as it is necessary to apply a constant tensile load to a specimen under a selected temperature. Measurements are taken to record the resulting elongation at time periods sufficiently long for a relationship to be established. The data are then plotted as elongation against time. The load is applied to the specimen only after it has reached the testing temperature, and causes an initial elastic elongation that includes some plastic deformation if the load is above the proportional limit for the material.

Some combinations of stress and temperature may cause failure of the specimen. Others show initial high rates of deformation, followed by decreasing, then constant, rates over long periods. Generally testing times to arrive at the constant rate of deformation are over 1000 hours.

**Creep Rupture.**—Tests for creep rupture are similar to creep tests but are prolonged until the specimen fails. Further data to be obtained from these tests include time to rupture, amount of elongation, and reduction of area. Stress-rupture tests are performed without measuring the elongation, so that no strain data are recorded, time to failure, elongation and reduction of area being sufficient. Sometimes, a V-notch is cut in the specimen to allow measurement of notch sensitivity under the testing conditions.

**Stress Analysis.**—Stresses, deflections, strains, and loads may be determined by application of strain gages or lacquers to the surface of a part, then applying loads simulating those to be encountered in service. Strain gages are commercially available in a variety of configurations and are usually cemented to the part surface. The strain gages are then calibrated by application of a known moment, load, torque, or pressure. The electrical characteristics of the strain gages change in proportion to the amount of strain, and the magnitude of changes in these characteristics under loads to be applied in service indicate changes caused by stress in the shape of the components being tested.

Lacquers are compounded especially for stress analysis and are applied to the entire part surface. When the part is loaded, and the lacquer is viewed under light of specific wavelength, stresses are indicated by color shading in the lacquer. The presence and intensity of the strains can then be identified and measured on the part(s) or on photographs of the setup. From such images, it is possible to determine the need for thicker walls, strengthening ribs and other modifications to component design that will enable the part to withstand stresses in service.

Most of these tests have been standardized by the American Society for Testing and Materials (ASTM), and are published in their *Book of Standards* in separate sections for metals, plastics, rubber, and wood. Many of the test methods are also adopted by the American National Standards Institute (ANSI).

**Fatigue Properties.**—When a material is subjected to many cycles of stress reversal or fluctuation (variation in magnitude without reversal), failure may occur, even though the maximum stress at any cycle is considerably less than the value at which failure would occur if the stress were constant. Fatigue properties are determined by subjecting test specimens to stress cycles and counting the number of cycles to failure. From a series of such tests in which maximum stress values are progressively reduced, S-N diagrams can be

plotted as illustrated by the accompanying figures. The S-N diagram Fig. 2a shows the behavior of a material for which there is an *endurance limit*,  $S_{en}$ . Endurance limit is the stress value at which the number of cycles to failure is infinite. Steels have endurance limits that vary according to hardness, composition, and quality; but many non-ferrous metals do not. The S-N diagram Fig. 2b does not have an endurance limit. For a metal that does not have an endurance limit, it is standard practice to specify fatigue strength as the stress value corresponding to a specific number of stress reversals, usually 100,000,000 or 500,000,000.

Fig. 2a. S-N endurance limit

Fig. 2b. S-N no endurance limit

**The Influence of Mean Stress on Fatigue.**—Most published data on the fatigue properties of metals are for completely reversed alternating stresses, that is, the mean stress of the cycle is equal to zero. However, if a structure is subjected to stresses that fluctuate between different values of tension and compression, then the mean stress is not zero.

When fatigue data for a specified mean stress and design life are not available for a material, the influence of nonzero mean stress can be estimated from empirical relationships that relate failure at a given life, under zero mean stress, to failure at the same life under zero mean cyclic stress. One widely used formula is Goodman's linear relationship, which is

$$S_a = S(1 - S_m/S_u)$$

where  $S_a$  is the alternating stress associated with some nonzero mean stress,  $S_m$ .  $S$  is the alternating fatigue strength at zero mean stress.  $S_u$  is the ultimate tensile strength.

Goodman's linear relationship is usually represented graphically on a so-called *Goodman Diagram*, shown in Fig. 3a. The alternating fatigue strength or the alternating stress for a given number of endurance cycles is plotted on the ordinate (y-axis) and the static tensile strength is plotted on the abscissa (x-axis). The straight line joining the alternating fatigue strength,  $S$ , and the tensile strength,  $S_u$ , is the Goodman line.

The value of an alternating stress  $S_{ax}$  at a known value of mean stress  $S_{mx}$  is determined as shown by the dashed lines on the diagram.

Fig. 3a. Goodman Diagram

Fig. 3b. Mean Tensile Stress

For ductile materials, the Goodman law is usually conservative, since approximately 90 per cent of actual test data for most ferrous and nonferrous alloys fall above the Goodman line, even at low endurance values where the yield strength is exceeded. For many brittle

materials, however, actual test values can fall below the Goodman line, as illustrated in Fig. 3b

As a rule of thumb, materials having an elongation of less than 5 per cent in a tensile test may be regarded as brittle. Those having an elongation of 5 per cent or more may be regarded as ductile.

**Cumulative Fatigue Damage.**—Most data are determined from tests at a constant stress amplitude. This is easy to do experimentally, and the data can be presented in a straightforward manner. In actual engineering applications, however, the alternating stress amplitude usually changes in some way during service operation. Such changes, referred to as “spectrum loading,” make the direct use of standard S-N fatigue curves inappropriate. A problem exists, therefore, in predicting the fatigue life under varying stress amplitude from conventional, constant-amplitude S-N fatigue data.

The assumption in predicting spectrum loading effects is that operation at a given stress amplitude and number of cycles will produce a certain amount of permanent fatigue damage and that subsequent operation at different stress amplitude and number of cycles will produce additional fatigue damage and a sequential accumulation of total damage, which at a critical value will cause fatigue failure. Although the assumption appears simple, the amount of damage incurred at any stress amplitude and number of cycles has proven difficult to determine, and several “cumulative damage” theories have been advanced.

One of the first and simplest methods for evaluating cumulative damage is known as Miner's law or the linear damage rule, where it is assumed that  $n_1$  cycles at a stress of  $S_1$ , for which the average number of cycles to failure is  $N_1$ , cause an amount of damage  $n_1/N_1$ . Failure is predicted to occur when

$$\Sigma n/N = 1$$

The term  $n/N$  is known as the “cycle ratio” or the damage fraction.

The greatest advantages of the Miner rule are its simplicity and prediction reliability, which approximates that of more complex theories. For these reasons the rule is widely used. It should be noted, however, that it does not account for all influences, and errors are to be expected in failure prediction ability.

**Modes of Fatigue Failure.**—Several modes of fatigue failure are:

*Low/High-Cycle Fatigue:* This fatigue process covers cyclic loading in two significantly different domains, with different physical mechanisms of failure. One domain is characterized by relatively low cyclic loads, strain cycles confined largely to the elastic range, and long lives or a high number of cycles to failure; traditionally, this has been called “high-cycle fatigue.” The other domain has cyclic loads that are relatively high, significant amounts of plastic strain induced during each cycle, and short lives or a low number of cycles to failure. This domain has commonly been called “low-cycle fatigue” or cyclic strain-controlled fatigue.

The transition from low- to high-cycle fatigue behavior occurs in the range from approximately 10,000 to 100,000 cycles. Many define low-cycle fatigue as failure that occurs in 50,000 cycles or less.

*Thermal Fatigue:* Cyclic temperature changes in a machine part will produce cyclic stresses and strains if natural thermal expansions and contractions are either wholly or partially constrained. These cyclic strains produce fatigue failure just as though they were produced by external mechanical loading. When strain cycling is produced by a fluctuating temperature field, the failure process is termed “thermal fatigue.”

While thermal fatigue and mechanical fatigue phenomena are very similar, and can be mathematically expressed by the same types of equations, the use of mechanical fatigue results to predict thermal fatigue performance must be done with care. For equal values of plastic strain range, the number of cycles to failure is usually up to 2.5 times lower for thermally cycled than for mechanically cycled samples.

**Corrosion Fatigue:** Corrosion fatigue is a failure mode where cyclic stresses and a corrosion-producing environment combine to initiate and propagate cracks in fewer stress cycles and at lower stress amplitudes than would be required in a more inert environment. The corrosion process forms pits and surface discontinuities that act as stress raisers to accelerate fatigue cracking. The cyclic loads may also cause cracking and flaking of the corrosion layer, baring fresh metal to the corrosive environment. Each process accelerates the other, making the cumulative result more serious.

**Surface or Contact Fatigue:** Surface fatigue failure is usually associated with rolling surfaces in contact, and results in pitting, cracking, and spalling of the contacting surfaces from cyclic Hertz contact stresses that cause the maximum values of cyclic shear stresses to be slightly below the surface. The cyclic subsurface shear stresses generate cracks that propagate to the contacting surface, dislodging particles in the process.

**Combined Creep and Fatigue:** In this failure mode, all of the conditions for both creep failure and fatigue failure exist simultaneously. Each process influences the other in producing failure, but this interaction is not well understood.

**Factors of Safety.**—There is always a risk that the working stress to which a member is subjected will exceed the strength of its material. The purpose of a factor of safety is to minimize this risk.

Factors of safety can be incorporated into design calculations in many ways. For most calculations the following equation is used:

$$s_w = S_m / f_s \quad (1)$$

where  $f_s$  is the factor of safety,  $S_m$  is the strength of the material in pounds per square inch, and  $S_w$  is the allowable working stress, also in pounds per square inch. Since the factor of safety is greater than 1, the allowable working stress will be less than the strength of the material.

In general,  $S_m$  is based on yield strength for ductile materials, ultimate strength for brittle materials, and fatigue strength for parts subjected to cyclic stressing. Most strength values are obtained by testing standard specimens at 68°F. in normal atmospheres. If, however, the character of the stress or environment differs significantly from that used in obtaining standard strength data, then special data must be obtained. If special data are not available, standard data must be suitably modified.

General recommendations for values of factors of safety are given in the following list.

| $f_s$   | Application  |
|---------|--|
| 1.3–1.5 | For use with highly reliable materials where loading and environmental conditions are not severe, and where weight is an important consideration.  |
| 1.5–2   | For applications using reliable materials where loading and environmental conditions are not severe.   |
| 2–2.5   | For use with ordinary materials where loading and environmental conditions are not severe.   |
| 2.5–3   | For less tried and for brittle materials where loading and environmental conditions are not severe.  |
| 3–4     | For applications in which material properties are not reliable and where loading and environmental conditions are not severe, or where reliable materials are to be used under difficult loading and environmental conditions. |

**Working Stress.**—Calculated working stresses are the products of calculated nominal stress values and stress concentration factors. Calculated nominal stress values are based on the assumption of idealized stress distributions. Such nominal stresses may be simple stresses, combined stresses, or cyclic stresses. Depending on the nature of the nominal stress, one of the following equations applies:

$$s_w = K\sigma \quad (2) \qquad s_w = K\sigma' \quad (4) \qquad s_w = K\sigma_{cy} \quad (6)$$

$$s_w = K\tau \quad (3) \qquad s_w = K\tau' \quad (5) \qquad s_w = K\tau_{cy} \quad (7)$$

where  $K$  is a stress concentration factor;  $\sigma$  and  $\tau$  are, respectively, simple normal (tensile or compressive) and shear stresses;  $\sigma'$  and  $\tau'$  are combined normal and shear stresses;  $\sigma_{cy}$  and  $\tau_{cy}$  are cyclic normal and shear stresses.

Where there is uneven stress distribution, as illustrated in the table (on page 213) of simple stresses for Cases 3, 4 and 6, the maximum stress is the one to which the stress concentration factor is applied in computing working stresses. The location of the maximum stress in each case is discussed under the section *Simple Stresses* and the formulas for these maximum stresses are given in the *Table of Simple Stresses* on page 213.

**Stress Concentration Factors.**—Stress concentration is related to type of material, the nature of the stress, environmental conditions, and the geometry of parts. When stress concentration factors that specifically match all of the foregoing conditions are not available, the following equation may be used:

$$K = 1 + q(K_t - 1) \quad (8)$$

$K_t$  is a theoretical stress concentration factor that is a function only of the geometry of a part and the nature of the stress;  $q$  is the *index of sensitivity* of the material. If the geometry is such as to provide no theoretical stress concentration,  $K_t = 1$ .

Curves for evaluating  $K_t$  are on pages 209 through 212. For constant stresses in cast iron and in ductile materials,  $q = 0$  (hence  $K = 1$ ). For constant stresses in brittle materials such as hardened steel,  $q$  may be taken as 0.15; for very brittle materials such as steels that have been quenched but not drawn,  $q$  may be taken as 0.25. When stresses are suddenly applied (impact stresses)  $q$  ranges from 0.4 to 0.6 for ductile materials; for cast iron it is taken as 0.5; and, for brittle materials, 1.

**Simple Stresses.**—Simple stresses are produced by constant conditions of loading on elements that can be represented as beams, rods, or bars. The table on page 213 summarizes information pertaining to the calculation of simple stresses. Following is an explanation of the symbols used in simple stress formulae:  $\sigma$  = simple normal (tensile or compressive) stress in pounds per square inch;  $\tau$  = simple shear stress in pounds per square inch;  $F$  = external force in pounds;  $V$  = shearing force in pounds;  $M$  = bending moment in inch-pounds;  $T$  = torsional moment in inch-pounds;  $A$  = cross-sectional area in square inches;  $Z$  = section modulus in inches<sup>3</sup>;  $Z_p$  = polar section modulus in inches<sup>3</sup>;  $I$  = moment of inertia in inches<sup>4</sup>;  $J$  = polar moment of inertia in inches<sup>4</sup>;  $a$  = area of the web of wide flange and I beams in square inches;  $y$  = perpendicular distance from axis through center of gravity of cross-sectional area to stressed fiber in inches;  $c$  = radial distance from center of gravity to stressed fiber in inches.

Table 2. Table of Simple Stresses

| Case | Type of Loading    | Illustration  | Stress Distribution   | Stress Equations   |
|------|--------------------|---|---|--|
| 1    | Direct tension     |    | Uniform   | $\sigma = \frac{F}{A}$ (9)   |
| 2    | Direct compression |    | Uniform   | $\sigma = -\frac{F}{A}$ (10)   |
| 3    | Bending            |    | Neutral plane   | $\sigma = \pm \frac{M}{Z} = \pm \frac{My}{I}$ (11)   |
| 4    | Shear              |   | Neutral plane   | For beams of rectangular cross-section:<br>$\tau = \frac{3V}{2A}$ (12)<br>For beams of solid circular cross-section:<br>$\tau = \frac{4V}{3A}$ (13)<br>For wide flange and I beams (approximately):<br>$\tau = \frac{V}{a}$ (14) |
| 5    | Direct shear       |  | Uniform   | $\tau = \frac{F}{A}$ (15)  |
| 6    | Torsion            |  |  | $\tau = \frac{T}{Z_p} = \frac{Tc}{J}$ (16)   |

SI metric units can be applied in the calculations in place of the English units of measurement without changes to the formulas. The SI units are the newton (N), which is the unit of force; the meter; the meter squared; the pascal (Pa) which is the

newton per meter squared ( $\text{N}/\text{m}^2$ ); and the newton-meter ( $\text{N} \cdot \text{m}$ ) for moment of force. Often in design work using the metric system, the millimeter is employed rather than the meter. In such instances, the dimensions can be converted to meters before the stress calculations are begun. Alternatively, the same formulas can be applied using millimeters in place of the meter, providing the treatment is consistent throughout. In such instances, stress and strength properties must be expressed in megapascals (MPa), which is the same as newtons per millimeter squared ( $\text{N}/\text{mm}^2$ ), and moments in newton-millimeters ( $\text{N} \cdot \text{mm}^2$ ). *Note:*  $1 \text{ N}/\text{mm}^2 = 1 \text{ N}/10^{-6}\text{m}^2 = 10^6 \text{ N}/\text{m}^2 = 1 \text{ meganewton}/\text{m}^2 = 1 \text{ megapascal}$ .

For direct tension and direct compression loading, Cases 1 and 2 in the table on page 213, the force  $F$  must act along a line through the center of gravity of the section at which the stress is calculated. The equation for direct compression loading applies only to members for which the ratio of length to least radius of gyration is relatively small, approximately 20, otherwise the member must be treated as a column.

The table *Stresses and Deflections in Beams* starting on page 261 give equations for calculating stresses due to bending for common types of beams and conditions of loading. Where these tables are not applicable, stress may be calculated using Equation (11) in the table on page 213. In using this equation it is necessary to determine the value of the bending moment at the point where the stress is to be calculated. For beams of constant cross-section, stress is ordinarily calculated at the point coinciding with the maximum value of bending moment. Bending loading results in the characteristic stress distribution shown in the table for Case 3. It will be noted that the maximum stress values are at the surfaces farthest from the neutral plane. One of the surfaces is stressed in tension and the other in compression. It is for this reason that the  $\pm$  sign is used in Equation (11). Numerous tables for evaluating section moduli are given in the section starting on page 236.

Shear stresses caused by bending have maximum values at neutral planes and zero values at the surfaces farthest from the neutral axis, as indicated by the stress distribution diagram shown for Case 4 in the *Table of Simple Stresses*. Values for  $V$  in Equations (12), (13) and (14) can be determined from shearing force diagrams. The shearing force diagram shown in Case 4 corresponds to the bending moment diagram for Case 3. As shown in this diagram, the value taken for  $V$  is represented by the greatest vertical distance from the  $x$  axis. The shear stress caused by direct shear loading, Case 5, has a uniform distribution. However, the shear stress caused by torsion loading, Case 6, has a zero value at the axis and a maximum value at the surface farthest from the axis.

**Deflections.**—For direct tension and direct compression loading on members with uniform cross sections, deflection can be calculated using Equation (17). For direct tension loading,  $e$  is an elongation; for direct compression loading,  $e$  is a contraction. Deflection is in inches when the load  $F$  is in pounds, the length  $L$  over which deflection occurs is in inches, the cross-sectional area  $A$  is in square inches, and the modulus of elasticity  $E$  is in pounds per square inch. The angular deflection of members with uniform circular cross sections subject to torsion loading can be calculated with Equation (18).

$$e = FL/AE \qquad (17) \qquad \theta = TL/GJ \qquad (18)$$

The angular deflection  $\theta$  is in radians when the torsional moment  $T$  is in inch-pounds, the length  $L$  over which the member is twisted is in inches, the modulus of rigidity  $G$  is in pounds per square inch, and the polar moment of inertia  $J$  is in inches<sup>4</sup>.

**Metric SI units can be used in Equations (17) and (18), where  $F$  = force in newtons (N);  $L$  = length over which deflection or twisting occurs in meters;  $A$  = cross-sectional area in meters squared;  $E$  = the modulus of elasticity in (newtons per meter squared);  $\theta$  = radians;  $T$  = the torsional moment in newton-meters (N·m);  $G$  = modulus of rigidity, in pascals; and  $J$  = the polar moment of inertia in meters<sup>4</sup>. If the load ( $F$ ) is applied as a weight, it should be noted that the weight of a mass  $M$  kilograms is  $Mg$  newtons,**

where  $g = 9.81 \text{ m/s}^2$ . Millimeters can be used in the calculations in place of meters, providing the treatment is consistent throughout.

**Combined Stresses.**—A member may be loaded in such a way that a combination of simple stresses acts at a point. Three general cases occur, examples of which are shown in the accompanying illustration Fig. 11.

*Superposition of Stresses:* Fig. 11 at (1) illustrates a common situation that results in simple stresses combining by superposition at points **a** and **b**. The equal and opposite forces  $F_1$  will cause a compressive stress  $\sigma_1 = -F_1/A$ . Force  $F_2$  will cause a bending moment  $M$  to exist in the plane of points **a** and **b**. The resulting stress  $\sigma_2 = \pm M/Z$ . The combined stress at point **a**,

$$\sigma'_a = -\frac{F_1}{A} - \frac{M}{Z} \quad (19) \quad \text{and at } \mathbf{b}, \quad \sigma'_b = -\frac{F_1}{A} + \frac{M}{Z} \quad (20)$$

where the minus sign indicates a compressive stress and the plus sign a tensile stress. Thus, the stress at **a** will be compressive and at **b** either tensile or compressive depending on which term in the equation for  $\sigma'_b$  has the greatest value.

*Normal Stresses at Right Angles:* This is shown in Fig. 11 at (2). This combination of stresses occurs, for example, in tanks subjected to internal or external pressure. The principle normal stresses are  $\sigma_x = F_1/A_1$ ,  $\sigma_y = F_2/A_2$ , and  $\sigma_z = 0$  in this plane stress problem. Determine the values of these three stresses with their signs, order them algebraically, and then calculate the maximum shear stress:

$$\tau = (\sigma_{\text{largest}} - \sigma_{\text{smallest}})/2 \quad (21)$$

*Normal and Shear Stresses:* The example in Fig. 11 at (3) shows a member subjected to a torsional shear stress,  $\tau = T/Z_p$ , and a direct compressive stress,  $\sigma = -F/A$ . At some point **a** on the member the principal normal stresses are calculated using the equation,

$$\sigma' = \frac{\sigma}{2} \pm \sqrt{\left(\frac{\sigma}{2}\right)^2 + \tau^2} \quad (22)$$

The maximum shear stress is calculated by using the equation,

$$\tau' = \sqrt{\left(\frac{\sigma}{2}\right)^2 + \tau^2} \quad (23)$$

The point **a** should ordinarily be selected where stress is a maximum value. For the example shown in the figure at (3), the point **a** can be anywhere on the cylindrical surface because the combined stress has the same value anywhere on that surface.

Fig. 11. Types of Combined Loading

**Tables of Combined Stresses.**—Beginning on page 216, these tables list equations for maximum nominal tensile or compressive (normal) stresses, and maximum nominal shear stresses for common machine elements. These equations were derived using general Equations (19), (20), (22), and (23). The equations apply to the critical points indicated on the

figures. Cases 1, 2, 3, and 4 are cantilever beams. These may be loaded with a combination of a vertical and horizontal force, or by a single oblique force. If the single oblique force  $F$  and the angle  $\theta$  are given, then horizontal and vertical forces can be calculated using the equations  $F_x = F \cos \theta$  and  $F_y = F \sin \theta$ . In cases 9 and 10 of the table, the equations for  $\sigma_a'$  can give a tensile and a compressive stress because of the  $\pm$  sign in front of the radical. Equations involving direct compression are valid only if machine elements have relatively short lengths with respect to their sections, otherwise column equations apply.

*Calculation of Worst Stress Condition:* Stress failure can occur at any critical point if either the tensile, compressive, or shear stress properties of the material are exceeded by the corresponding working stress. It is necessary to evaluate the factor of safety for each possible failure condition.

The following rules apply to calculations using equations in the *Table of Simple Stresses* on page 213, and to calculations based on Equations (19) and (20). *Rule 1:* For every calculated normal stress there is a corresponding induced shear stress; the value of the shear stress is equal to half that of the normal stress. *Rule 2:* For every calculated shear stress there is a corresponding induced normal stress; the value of the normal stress is equal to that of the shear stress. The tables of combined stress formulas, below, include equations for calculating both maximum nominal tensile or compressive stresses, and maximum nominal shear stresses.

**Formulas for Combined Stresses**

*(1) Circular Cantilever Beam in Direct Compression and Bending:*

| Type of Beam and Loading | Maximum Nominal Tensile or Compressive Stress  | Maximum Nominal Shear Stress                        |
|--------------------------|--|---|
|                          | $\sigma'_a = \frac{1.273}{d^2} \left( \frac{8LF_y}{d} - F_x \right)$ $\sigma'_b = -\frac{1.273}{d^2} \left( \frac{8LF_y}{d} + F_x \right)$ | $\tau'_a = 0.5 \sigma'_a$ $\tau'_b = 0.5 \sigma'_b$ |

*(2) Circular Cantilever Beam in Direct Tension and Bending:*

| Type of Beam and Loading | Maximum Nominal Tensile or Compressive Stress   | Maximum Nominal Shear Stress                        |
|--------------------------|---|---|
|                          | $\sigma'_a = \frac{1.273}{d^2} \left( F_x + \frac{8LF_y}{d} \right)$ $\sigma'_b = \frac{1.273}{d^2} \left( F_x - \frac{8LF_y}{d} \right)$ | $\tau'_a = 0.5 \sigma'_a$ $\tau'_b = 0.5 \sigma'_b$ |

*(3) Rectangular Cantilever Beam in Direct Compression and Bending:*

| Type of Beam and Loading | Maximum Nominal Tensile or Compressive Stress  | Maximum Nominal Shear Stress                        |
|--------------------------|--|---|
|                          | $\sigma'_a = \frac{1}{bh} \left( \frac{6LF_y}{h} - F_x \right)$ $\sigma'_b = -\frac{1}{bh} \left( \frac{6LF_y}{h} + F_x \right)$ | $\tau'_a = 0.5 \sigma'_a$ $\tau'_b = 0.5 \sigma'_b$ |

(4) Rectangular Cantilever Beam in Direct Tension and Bending:

| Type of Beam and Loading | Maximum Nominal Tensile or Compressive Stress   | Maximum Nominal Shear Stress                      |
|--------------------------|---|---|
|                          | $\sigma'_a = \frac{1}{bh} \left( F_x + \frac{6LF_y}{h} \right)$ $\sigma'_b = \frac{1}{bh} \left( F_x - \frac{6LF_y}{h} \right)$ | $\tau'_a = 0.5\sigma'_a$ $\tau'_b = 0.5\sigma'_b$ |

(5) Circular Beam or Shaft in Direct Compression and Bending:

| Type of Beam and Loading | Maximum Nominal Tensile or Compressive Stress  | Maximum Nominal Shear Stress                      |
|--------------------------|--|---|
|                          | $\sigma'_a = -\frac{1.273}{d^2} \left( \frac{2LF_y}{d} + F_x \right)$ $\sigma'_b = \frac{1.273}{d^2} \left( \frac{2LF_y}{d} - F_x \right)$ | $\tau'_a = 0.5\sigma'_a$ $\tau'_b = 0.5\sigma'_b$ |

(6) Circular Beam or Shaft in Direct Tension and Bending:

| Type of Beam and Loading | Maximum Nominal Tensile or Compressive Stress   | Maximum Nominal Shear Stress                      |
|--------------------------|---|---|
|                          | $\sigma'_a = \frac{1.273}{d^2} \left( F_x - \frac{2LF_y}{d} \right)$ $\sigma'_b = \frac{1.273}{d^2} \left( F_x + \frac{2LF_y}{d} \right)$ | $\tau'_a = 0.5\sigma'_a$ $\tau'_b = 0.5\sigma'_b$ |

(7) Rectangular Beam or Shaft in Direct Compression and Bending:

| Type of Beam and Loading | Maximum Nominal Tensile or Compressive Stress   | Maximum Nominal Shear Stress                      |
|--------------------------|---|---|
|                          | $\sigma'_a = -\frac{1}{bh} \left( \frac{3LF_y}{2h} + F_x \right)$ $\sigma'_b = \frac{1}{bh} \left( -\frac{3LF_y}{2h} - F_x \right)$ | $\tau'_a = 0.5\sigma'_a$ $\tau'_b = 0.5\sigma'_b$ |

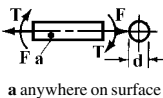

(8) Rectangular Beam or Shaft in Direct Tension and Bending:

| Type of Beam and Loading | Maximum Nominal Tensile or Compressive Stress   | Maximum Nominal Shear Stress                      |
|--------------------------|---|---|
|                          | $\sigma'_a = \frac{1}{bh} \left( F_x - \frac{3LF_y}{2h} \right)$ $\sigma'_b = \frac{1}{bh} \left( F_x + \frac{3LF_y}{2h} \right)$ | $\tau'_a = 0.5\sigma'_a$ $\tau'_b = 0.5\sigma'_b$ |

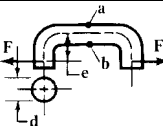

(9) Circular Shaft in Direct Compression and Torsion:

| Type of Beam and Loading     | Maximum Nominal Tensile or Compressive Stress  | Maximum Nominal Shear Stress  |
|------------------------------|--|---|
| <p>a anywhere on surface</p> | $\sigma'_a = -\frac{0.637}{d^2} \left[ F \pm \sqrt{F^2 + \left( \frac{8T}{d} \right)^2} \right]$ | $\tau'_a = -\frac{0.637}{d^2} \sqrt{F^2 + \left( \frac{8T}{d} \right)^2}$ |

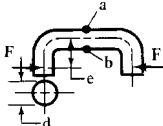

(10) Circular Shaft in Direct Tension and Torsion:

| Type of Beam and Loading   | Maximum Nominal Tensile or Compressive Stress   | Maximum Nominal Shear Stress   |
|--|---|--|
|  <p>a anywhere on surface</p> | $\sigma'_a = \frac{0.637}{d^2} \left[ F \pm \sqrt{F^2 + \left(\frac{8T}{d}\right)^2} \right]$ | $\tau'_a = \frac{0.637}{d^2} \sqrt{F^2 + \left(\frac{8T}{d}\right)^2}$ |

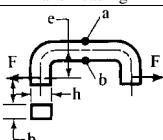

(11) Offset Link, Circular Cross Section, in Direct Tension:

| Type of Beam and Loading  | Maximum Nominal Tensile or Compressive Stress   | Maximum Nominal Shear Stress                      |
|---|---|---|
|  | $\sigma'_a = \frac{1.273F}{d^2} \left(1 - \frac{8e}{d}\right)$ $\sigma'_b = \frac{1.273F}{d^2} \left(1 + \frac{8e}{d}\right)$ | $\tau'_a = 0.5\sigma'_a$ $\tau'_b = 0.5\sigma'_b$ |

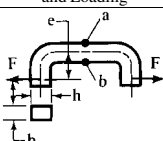

(12) Offset Link, Circular Cross Section, in Direct Compression:

| Type of Beam and Loading  | Maximum Nominal Tensile or Compressive Stress  | Maximum Nominal Shear Stress                      |
|---|--|---|
|  | $\sigma'_a = \frac{1.273F}{d^2} \left(\frac{8e}{d} - 1\right)$ $\sigma'_b = -\frac{1.273F}{d^2} \left(\frac{8e}{d} + 1\right)$ | $\tau'_a = 0.5\sigma'_a$ $\tau'_b = 0.5\sigma'_b$ |

(13) Offset Link, Rectangular Section, in Direct Tension:

| Type of Beam and Loading  | Maximum Nominal Tensile or Compressive Stress   | Maximum Nominal Shear Stress                      |
|---|---|---|
|  | $\sigma'_a = \frac{F}{bh} \left(1 - \frac{6e}{h}\right)$ $\sigma'_b = \frac{F}{bh} \left(1 + \frac{6e}{h}\right)$ | $\tau'_a = 0.5\sigma'_a$ $\tau'_b = 0.5\sigma'_b$ |

(14) Offset Link, Rectangular Section, in Direct Compression:

| Type of Beam and Loading  | Maximum Nominal Tensile or Compressive Stress  | Maximum Nominal Shear Stress                      |
|---|--|---|
|  | $\sigma'_a = \frac{F}{bh} \left(\frac{6e}{h} - 1\right)$ $\sigma'_b = -\frac{F}{bh} \left(\frac{6e}{h} + 1\right)$ | $\tau'_a = 0.5\sigma'_a$ $\tau'_b = 0.5\sigma'_b$ |

Formulas from the simple and combined stress tables, as well as tension and shear factors, can be applied without change in calculations using metric SI units. Stresses are given in newtons per meter squared (N/m<sup>2</sup>) or in N/mm<sup>2</sup>.

**Three-Dimensional Stress.**—Three-dimensional or triaxial stress occurs in assemblies such as a shaft press-fitted into a gear bore or in pipes and cylinders subjected to internal or external fluid pressure. Triaxial stress also occurs in two-dimensional stress problems if the loads produce normal stresses that are either both tensile or both compressive. In either case the calculated maximum shear stress, based on the corresponding two-dimensional theory, will be less than the true maximum value because of three-dimensional effects. Therefore, if the stress analysis is to be based on the maximum-shear-stress theory of failure, the triaxial stress cubic equation should first be used to calculate the three principal stresses and from these the true maximum shear stress. The following procedure provides the principal maximum normal tensile and compressive stresses and the true maximum shear stress at any point on a body subjected to any combination of loads.

The basis for the procedure is the stress cubic equation

$$S^3 - AS^2 + BS - C = 0$$

in which:

$$A = S_x + S_y + S_z$$

$$B = S_x S_y + S_y S_z + S_z S_x - S_{xy}^2 - S_{yz}^2 - S_{zx}^2$$

$$C = S_x S_y S_z + 2S_{xy} S_{yz} S_{zx} - S_x S_{yz}^2 - S_y S_{zx}^2 - S_z S_{xy}^2$$

and  $S_x$ ,  $S_y$ , etc., are as shown in Fig. 12.

The coordinate system  $XYZ$  in Fig. 12 shows the positive directions of the normal and shear stress components on an elementary cube of material. Only six of the nine components shown are needed for the calculations: the normal stresses  $S_x$ ,  $S_y$ , and  $S_z$  on three of the faces of the cube; and the three shear stresses  $S_{xy}$ ,  $S_{yz}$ , and  $S_{zx}$ . The remaining three shear stresses are known because  $S_{yx} = S_{xy}$ ,  $S_{zy} = S_{yz}$ , and  $S_{xz} = S_{zx}$ . The normal stresses  $S_x$ ,  $S_y$ , and  $S_z$  are shown as positive (tensile) stresses; the opposite direction is negative (compressive). The first subscript of each shear stress identifies the coordinate axis perpendicular to the plane of the shear stress; the second subscript identifies the axis to which the stress is parallel. Thus,  $S_{xy}$  is the shear stress in the  $YZ$  plane to which the  $X$  axis is perpendicular, and the stress is parallel to the  $Y$  axis.

Fig. 12.  $XYZ$  Coordinate System Showing Positive Directions of Stresses

Step 1. Draw a diagram of the hardware to be analyzed, such as the shaft shown in Fig. 13, and show the applied loads  $P$ ,  $T$ , and any others.

Step 2. For any point at which the stresses are to be analyzed, draw a coordinate diagram similar to Fig. 12 and show the magnitudes of the stresses resulting from the applied loads (these stresses may be calculated by using standard basic equations from strength of materials, and should include any stress concentration factors).

Step 3. Substitute the values of the six stresses  $S_x$ ,  $S_y$ ,  $S_z$ ,  $S_{xy}$ ,  $S_{yz}$ , and  $S_{zx}$ , including zero values, into the formulas for the quantities  $A$  through  $K$ . The quantities  $I$ ,  $J$ , and  $K$  represent the principal normal stresses at the point analyzed. As a check, if the algebraic sum  $I + J + K$  equals  $A$ , within rounding errors, then the calculations up to this point should be correct.

$$D = A^2/3 - B \quad E = A \times B/3 - C - 2 \times A^3/27$$

$$F = \sqrt{(D^3/27)} \quad G = \arccos(-E/(2 \times F))$$

$$H = \sqrt{(D/3)} \quad I = 2 \times H \times \cos(G/3) + A/3$$

$$J = 2 \times H \times [\cos(G/3 + 120^\circ)] + A/3 \quad K = 2 \times H \times [\cos(G/3 + 240^\circ)] + A/3$$

Step 4. Calculate the true maximum shear stress,  $S_{s(\max)}$  using the formula

$$S_{s(\max)} = 0.5 \times (S_{\text{large}} - S_{\text{small}})$$

in which  $S_{\text{large}}$  is equal to the algebraically largest of the calculated principal stresses  $I$ ,  $J$ , or  $K$  and  $S_{\text{small}}$  is algebraically the smallest.

The maximum principal normal stresses and the maximum true shear stress calculated above may be used with any of the various theories of failure.

Fig. 13. Example of Triaxial Stress on an Element  $a$  of Shaft Surface Caused by Load  $P$ , Torque  $T$ , and 5000 psi Hydraulic Pressure

*Example:* A torque  $T$  on the shaft in Fig. 13 causes a shearing stress  $S_{xy}$  of 8000 psi in the outer fibers of the shaft; and the loads  $P$  at the ends of the shaft produce a tensile stress  $S_x$  of 4000 psi. The shaft passes through a hydraulic cylinder so that the shaft circumference is subjected to the hydraulic pressure of 5000 psi in the cylinder, causing compressive stresses  $S_y$  and  $S_z$  of -5000 psi on the surface of the shaft. Find the maximum shear stress at any point  $A$  on the surface of the shaft.

From the statement of the problem  $S_x = +4000$  psi,  $S_y = -5000$  psi,  $S_z = -5000$  psi,  $S_{xy} = +8000$  psi,  $S_{yz} = 0$  psi, and  $S_{zx} = 0$  psi.

$$A = 4000 - 5000 - 5000 = -6000$$

$$B = (4000 \times -5000) + (-5000 \times -5000) + (-5000 \times 4000) - 8000^2 - 0^2 - 0^2 = -7.9 \times 10^7$$

$$C = (4000 \times -5000 \times -5000) + 2 \times 8000 \times 0 \times 0 - (4000 \times 0^2) - (-5000 \times 0^2) - (-5000 \times 8000^2) = 4.2 \times 10^{11}$$

$$D = A^2/3 - B = 9.1 \times 10^7 \quad E = A \times B/3 - C - 2 \times A^3/27 = -2.46 \times 10^{11}$$

$$F = \sqrt{(D^3/27)} = 1.6706 \times 10^{11} \quad G = \arccos(-E/(2 \times F)) = 42.586 \text{ degrees}$$

$$H = \sqrt{(D/3)} = 5507.57 \quad I = 2 \times H \times \cos(G/3 + A/3) = 8678.8, \text{ say, } 8680 \text{ psi}$$

$$J = 2 \times H \times [\cos(G/3 + 120^\circ)] + A/3 = -9678.78, \text{ say, } -9680 \text{ psi}$$

$$K = 2 \times H [\cos(G/3 + 240^\circ)] + A/3 = -5000 \text{ psi}$$

Check:  $8680 + (-9680) + (-5000) = -6000$  within rounding error.

$$S_{s(\max)} = 0.5 \times (8680 - (-9680)) = 9180 \text{ psi}$$

**Sample Calculations.**—The following examples illustrate some typical strength of materials calculations, using both English and metric SI units of measurement.

*Example 1(a):* A round bar made from SAE 1025 low carbon steel is to support a direct tension load of 50,000 pounds. Using a factor of safety of 4, and assuming that the stress concentration factor  $K = 1$ , a suitable standard diameter is to be determined. Calculations are to be based on a yield strength of 40,000 psi.

Because the factor of safety and strength of the material are known, the allowable working stress  $s_w$  may be calculated using Equation (1):  $40,000/4 = 10,000$  psi. The relationship between working stress  $s_w$  and nominal stress  $\sigma$  is given by Equation (2). Since  $K = 1$ ,  $\sigma = 10,000$  psi. Applying Equation (9) in the *Table of Simple Stresses*, the area of the bar can be solved for:  $A = 50,000/10,000$  or 5 square inches. The next largest standard diameter corresponding to this area is  $2\frac{9}{16}$  inches.

*Example 1(b):* A similar example to that given in 1(a), using metric SI units is as follows. A round steel bar of 300 meganewtons/meter<sup>2</sup> yield strength, is to withstand a direct tension of 200 kilonewtons. Using a safety factor of 4, and assuming that the stress concentration factor  $K = 1$ , a suitable diameter is to be determined.

Because the factor of safety and the strength of the material are known, the allowable working stress  $s_w$  may be calculated using Equation (1):  $300/4 = 75$  mega-newtons/meter<sup>2</sup>. The relationship between working stress and nominal stress  $\sigma$  is given by Equation (2). Since  $K = 1$ ,  $\sigma = 75$  MN/m<sup>2</sup>. Applying Equation (9) in the , the area of the bar can be determined from:

$$A = \frac{200 \text{ kN}}{75 \text{ MN/m}^2} = \frac{200,000 \text{ N}}{75,000,000 \text{ N/m}^2} = 0.00267 \text{ m}^2$$

The diameter corresponding to this area is 0.058 meters, or approximately 0.06 m.

Millimeters can be employed in the calculations in place of meters, providing the treatment is consistent throughout. In this instance the diameter would be 60 mm.

*Note:* If the tension in the bar is produced by hanging a mass of  $M$  kilograms from its end, the value is  $Mg$  newtons, where  $g$  = approximately 9.81 meters per second<sup>2</sup>.

*Example 2(a):* What would the total elongation of the bar in Example 1(a) be if its length were 60 inches? Applying Equation (17),

$$e = \frac{50,000 \times 60}{5.157 \times 30,000,000} = 0.019 \text{ inch}$$

*Example 2(b):* What would be the total elongation of the bar in Example 1(b) if its length were 1.5 meters? The problem is solved by applying Equation (17) in which  $F = 200$  kilonewtons;  $L = 1.5$  meters;  $A = \pi \cdot 0.06^2/4 = 0.00283 \text{ m}^2$ . Assuming a modulus of elasticity  $E$  of 200 giganewtons/meter<sup>2</sup>, then the calculation is:

$$e = \frac{200,000 \times 1.5}{0.00283 \times 200,000,000,000} = 0.000530 \text{ m}$$

The calculation is less unwieldy if carried out using millimeters in place of meters; then  $F = 200$  kN;  $L = 1500$  mm;  $A = 2830 \text{ mm}^2$ , and  $E = 200,000 \text{ N/mm}^2$ . Thus:

$$e = \frac{200,000 \times 1500}{2830 \times 200,000} = 0.530 \text{ mm}$$

**Example 3(a):** Determine the size for the section of a square bar which is to be held firmly at one end and is to support a load of 3000 pounds at the outer end. The bar is to be 30 inches long and is to be made from SAE 1045 medium carbon steel with a yield point of 60,000 psi. A factor of safety of 3 and a stress concentration factor of 1.3 are to be used.

From Equation (1) the allowable working stress  $s_w = 60,000/3 = 20,000$  psi. The applicable equation relating working stress and nominal stress is Equation (2); hence,  $\sigma = 20,000/1.3 = 15,400$  psi. The member must be treated as a cantilever beam subject to a bending moment of  $30 \times 3000$  or 90,000 inch-pounds. Solving Equation (11) in the for section modulus:  $Z = 90,000/15,400 = 5.85$  inch<sup>3</sup>. The section modulus for a square section with neutral axis equidistant from either side is  $a^3/6$ , where  $a$  is the dimension of the square, so  $a = \sqrt[3]{35.1} = 3.27$  inches. The size of the bar can therefore be  $3\frac{5}{16}$  inches.

**Example 3(b):** A similar example to that given in Example 3(a), using metric SI units is as follows. Determine the size for the section of a square bar which is to be held firmly at one end and is to support a load of 1600 kilograms at the outer end. The bar is to be 1 meter long, and is to be made from steel with a yield strength of 500 newtons/mm<sup>2</sup>. A factor of safety of 3, and a stress concentration factor of 1.3 are to be used. The calculation can be performed using millimeters throughout.

From Equation (1) the allowable working stress  $s_w = 500 \text{ N/mm}^2/3 = 167 \text{ N/mm}^2$ . The formula relating working stress and nominal stress is Equation (2); hence  $\sigma = 167/1.3 = 128 \text{ N/mm}^2$ . Since a mass of 1600 kg equals a weight of 1600 g newtons, where  $g = 9.81$  meters/second<sup>2</sup>, the force acting on the bar is 15,700 newtons. The bending moment on the bar, which must be treated as a cantilever beam, is thus  $1000 \text{ mm} \times 15,700 \text{ N} = 15,700,000 \text{ N} \cdot \text{mm}$ . Solving Equation (11) in the for section modulus:  $Z = M/\sigma = 15,700,000/128 = 123,000 \text{ mm}^3$ . Since the section modulus for a square section with neutral axis equidistant from either side is  $a^3/6$ , where  $a$  is the dimension of the square,

$$a = \sqrt[3]{6 \times 123,000} = 90.4 \text{ mm}$$

**Example 4(a):** Find the working stress in a 2-inch diameter shaft through which a transverse hole  $\frac{1}{4}$  inch in diameter has been drilled. The shaft is subject to a torsional moment of 80,000 inch-pounds and is made from hardened steel so that the index of sensitivity  $q = 0.2$ .

The polar section modulus is calculated using the equation shown in the stress concentration curve for a Round Shaft in Torsion with Transverse Hole, Fig. 7, page 211.

$$\frac{J}{c} = Z_p = \frac{\pi \times 2^3}{16} - \frac{2^2}{4 \times 6} = 1.4 \text{ inches}^3$$

The nominal shear stress due to the torsion loading is computed using Equation (16) in the :

$$\tau = 80,000/1.4 = 57,200 \text{ psi}$$

Referring to the previously mentioned stress concentration curve on page 211,  $K_t$  is 2.82 since  $d/D$  is 0.125. The stress concentration factor may now be calculated by means of Equation (8):  $K = 1 + 0.2(2.82 - 1) = 1.36$ . Working stress calculated with Equation (3) is  $s_w = 1.36 \times 57,200 = 77,800$  psi.

**Example 4(b):** A similar example to that given in 4(a), using metric SI units is as follows. Find the working stress in a 50 mm diameter shaft through which a transverse hole 6 mm in diameter has been drilled. The shaft is subject to a torsional moment of 8000 newton-meters, and has an index of sensitivity of  $q = 0.2$ . If the calculation is made in millimeters, the torsional moment is 8,000,000 N · mm.

The polar section modulus is calculated using the equation shown in the stress concentration curve for a Round Shaft in Torsion with Transverse Hole, Fig. 7, page 211:

$$\frac{J}{c} = Z_p = \frac{\pi \times 50^3}{16} - \frac{6 \times 50^2}{6} = 24,544 - 2500 = 22,044 \text{ mm}^3$$

The nominal shear stress due to torsion loading is computed using Equation (16) in the :

$$\tau = 8,000,000/22,000 = 363 \text{ N/mm}^2 = 363 \text{ megapascals}$$

Referring to the previously mentioned stress concentration curve on page 211,  $K_t$  is 2.85, since  $a/d = 6/50 = 0.12$ . The stress concentration factor may now be calculated by means of Equation (8):  $K = 1 + 0.2(2.85 - 1) = 1.37$ . From Equation (3), working stress  $s_w = 1.37 \times 363 = 497 \text{ N/mm}^2 = 497 \text{ megapascals}$ .

Example 5(a): For Case 3 in the *Tables of Combined Stresses*, calculate the least factor of safety for a 5052-H32 aluminum beam is 10 inches long, one inch wide, and 2 inches high. Yield strengths are 23,000 psi tension; 21,000 psi compression; 13,000 psi shear. The stress concentration factor is 1.5;  $F_y$  is 600 lbs;  $F_x$  500 lbs.

From *Tables of Combined Stresses*, Case 3:

$$\sigma_b' = -\frac{1}{1 \times 2} \left( \frac{6 \times 10 \times 600}{2} + 500 \right) = -9250 \text{ psi (in compression)}$$

The other formulas for Case 3 give  $\sigma_a' = 8750$  psi (in tension);  $\tau_a' = 4375$  psi, and  $\tau_b' = 4625$  psi. Using Equation (4) for the nominal compressive stress of 9250 psi:  $S_w = 1.5 \times 9250 = 13,900$  psi. From Equation (1)  $f_s = 21,000/13,900 = 1.51$ . Applying Equations (1), (4) and (5) in appropriate fashion to the other calculated nominal stress values for tension and shear will show that the factor of safety of 1.51, governed by the compressive stress at  $b$  on the beam, is minimum.

Example 5(b): What maximum  $F$  can be applied in Case 3 if the aluminum beam is 200 mm long; 20 mm wide; 40 mm high;  $\theta = 30^\circ$ ;  $f_s = 2$ , governing for compression,  $K = 1.5$ , and  $S_m = 144 \text{ N/mm}^2$  for compression.

From Equation (1)  $S_w = -144 \text{ N/mm}^2$ . Therefore, from Equation (4),  $\sigma_b' = -72/1.5 = -48 \text{ N/mm}^2$ . Since  $F_x = F \cos 30^\circ = 0.866F$ , and  $F_y = F \sin 30^\circ = 0.5F$ :

$$-48 = -\frac{1}{20 \times 40} \left( 0.866F + \frac{6 \times 200 \times 0.5F}{40} \right) \quad F = 2420 \text{ N}$$

**Stresses and Deflections in a Loaded Ring.**—For *thin* rings, that is, rings in which the dimension  $d$  shown in the accompanying diagram is small compared with  $D$ , the maximum stress in the ring is due primarily to bending moments produced by the forces  $P$ . The maximum stress due to bending is:

$$S = \frac{PDd}{4\pi I} \quad (24)$$

For a ring of circular cross section where  $d$  is the diameter of the bar from which the ring is made,

$$S = \frac{1.621PD}{d^3} \quad \text{or} \quad P = \frac{0.617Sd^3}{D} \quad (25)$$

The increase in the vertical diameter of the ring due to load  $P$  is:

$$\text{Increase in vertical diameter} = \frac{0.0186PD^3}{EI} \text{ inches} \quad (26)$$

The *decrease* in the horizontal diameter will be about 92% of the increase in the vertical diameter given by [Formula \(26\)](#). In the above formulas,  $P$  = load on ring in pounds;  $D$  = mean diameter of ring in inches;  $S$  = tensile stress in pounds per square inch,  $I$  = moment of inertia of section in inches<sup>4</sup>; and  $E$  = modulus of elasticity of material in pounds per square inch.

**Strength of Taper Pins.**—The mean diameter of taper pin required to safely transmit a known torque, may be found from the formulas:

$$d = 1.13 \sqrt{\frac{T}{DS}} \quad (27) \quad \text{and} \quad d = 283 \sqrt{\frac{HP}{NDS}} \quad (28a)$$

in which formulas  $T$  = torque in inch-pounds;  $S$  = safe unit stress in pounds per square inch; HP = horsepower transmitted;  $N$  = number of revolutions per minute; and  $d$  and  $D$  denote dimensions shown in the figure.

[Formula \(27\)](#) can be used with metric SI units where  $d$  and  $D$  denote dimensions shown in the figure in millimeters;  $T$  = torque in newton-millimeters ( $N \cdot \text{mm}$ ); and  $S$  = safe unit stress in newtons per millimeter<sup>2</sup> ( $\text{N}/\text{mm}^2$ ). [Formula \(28a\)](#) is replaced by:

$$d = 110.3 \sqrt{\frac{\text{Power}}{NDS}} \quad (28b)$$

where  $d$  and  $D$  denote dimensions shown in the figure in millimeters;  $S$  = safe unit stress in  $\text{N}/\text{mm}^2$ ;  $N$  = number of revolutions per minute, and Power = power transmitted in watts.

*Example 6(a):* A lever secured to a 2-inch round shaft by a steel tapered pin (dimension  $d = \frac{3}{8}$  inch) has a pull of 50 pounds at a 30-inch radius from shaft center. Find  $S$ , the unit working stress on the pin. By rearranging [Formula \(27\)](#):

$$S = \frac{1.27T}{Dd^2} = \frac{1.27 \times 50 \times 30}{2 \times \left(\frac{3}{8}\right)^2} \cong 6770 \text{ psi}$$

6770 pounds per square inch is a safe unit working stress for machine steel in shear.

Let  $P = 50$  pounds,  $R = 30$  inches,  $D = 2$  inches, and  $S = 6000$  pounds unit working stress. Using [Formula \(27\)](#) to find  $d$ :

$$d = 1.13 \sqrt{\frac{T}{DS}} = 1.13 \sqrt{\frac{50 \times 30}{2 \times 6000}} = 1.13 \sqrt{\frac{1}{8}} = 0.4 \text{ inch}$$

*Example 6(b):* A similar example using SI units is as follows: A lever secured to a 50 mm round shaft by a steel tapered pin ( $d = 10$  mm) has a pull of 200 newtons at a radius of 800 mm. Find  $S$ , the working stress on the pin. By rearranging [Formula \(27\)](#):

$$S = \frac{1.27T}{Dd^2} = \frac{1.27 \times 200 \times 800}{50 \times 10^2} = 40.6 \text{ N}/\text{mm}^2 = 40.6 \text{ megapascals}$$

If a shaft of 50 mm diameter is to transmit power of 12 kilowatts at a speed of 500 rpm, find the mean diameter of the pin for a material having a safe unit stress of 40  $\text{N}/\text{mm}^2$ . Using [Equation \(28b\)](#):

$$\begin{aligned} d &= 110.3 \sqrt{\frac{\text{Power}}{NDS}} & \text{then } d &= 110.3 \sqrt{\frac{12,000}{500 \times 50 \times 40}} \\ &= 110.3 \times 0.1096 = 12.09 \text{ mm} \end{aligned}$$

## PROPERTIES OF BODIES

### Center of Gravity

**Center of Gravity.**—The center of gravity of a body, volume, area, or line is that point at which if the body, volume, area, or line were suspended it would be perfectly balanced in all positions. For symmetrical bodies of uniform material it is at the geometric center. The center of gravity of a uniform round rod, for example, is at the center of its diameter half-way along its length; the center of gravity of a sphere is at the center of the sphere. For solids, areas, and arcs that are not symmetrical, the determination of the center of gravity may be made experimentally or may be calculated by the use of formulas.

The tables that follow give such formulas for some of the more important shapes. For more complicated and unsymmetrical shapes the methods outlined on page 231 may be used.

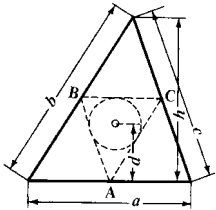

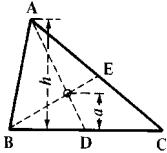

*Example:* A piece of wire is bent into the form of a semi-circular arc of 10-inch radius. How far from the center of the arc is the center of gravity located?

Accompanying the *Circular Arc* diagram on page 226 is a formula for the distance from the center of gravity of an arc to the center of the arc:  $a = 2r \div \pi$ . Therefore,

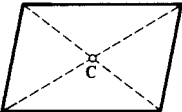

$$a = 2 \times 10 \div 3.1416 = 6.366 \text{ inches}$$

### Formulas for Center of Gravity

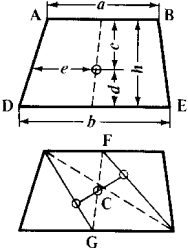

*Triangle:*

|   |   |
|---|---|
|   | <p><i>Perimeter</i></p> <p>If <math>A, B</math> and <math>C</math> are the middle points of the sides of the triangle, then the center of gravity is at the center of the circle that can be inscribed in triangle <math>ABC</math>. The distance <math>d</math> of the center of gravity from side <math>a</math> is:</p> $d = \frac{h(b+c)}{2(a+b+c)}$ <p>where <math>h</math> is the height perpendicular to <math>a</math>.</p> |
|  | <p><i>Area</i></p> <p>The center of gravity is at the intersection of lines <math>AD</math> and <math>BE</math>, which bisect the sides <math>BC</math> and <math>AC</math>. The perpendicular distance from the center of gravity to any one of the sides is equal to one-third the height perpendicular to that side. Hence, <math>a = h \div 3</math>.</p>   |

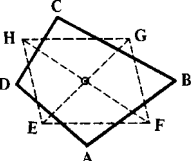

*Perimeter or Area of a Parallelogram :*

|   |   |
|---|---|
|  | <p>The center of gravity is at the intersection of the diagonals.</p> |
|---|---|

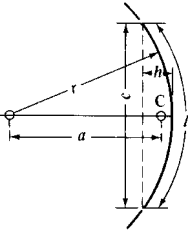

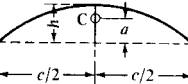

## Area of Trapezoid:

|   |  |
|---|--|
|  | <p>The center of gravity is on the line joining the middle points of parallel lines <math>AB</math> and <math>DE</math>.</p> $c = \frac{h(a+2b)}{3(a+b)} \quad d = \frac{h(2a+b)}{3(a+b)}$ $e = \frac{a^2 + ab + b^2}{3(a+b)}$ <p>The trapezoid can also be divided into two triangles. The center of gravity is at the intersection of the line joining the centers of gravity of the triangles, and the middle line <math>FG</math>.</p> |
|---|--|

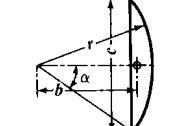

## Any Four-sided Figure :

|   |  |
|---|--|
|  | <p>Two cases are possible, as shown in the illustration. To find the center of gravity of the four-sided figure <math>ABCD</math>, each of the sides is divided into three equal parts. A line is then drawn through each pair of division points next to the points of intersection <math>A, B, C</math>, and <math>D</math> of the sides of the figure. These lines form a parallelogram <math>EFGH</math>; the intersection of the diagonals <math>EG</math> and <math>FH</math> locates center of gravity.</p> |
|---|--|

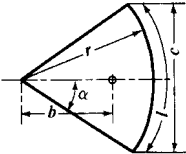

## Circular Arc:

|   |  |
|---|--|
|   | <p>The center of gravity is on the line that bisects the arc, at a distance <math>a = \frac{r \times c}{l} = \frac{c(c^2 + 4h^2)}{8lh}</math> from the center of the circle.</p> <p>For an arc equal to one-half the periphery:</p> $a = 2r \div \pi = 0.6366r$ <p>For an arc equal to one-quarter of the periphery:</p> $a = 2r \cdot \sqrt{2} \div \pi = 0.9003r$ <p>For an arc equal to one-sixth of the periphery:</p> $a = 3r \div \pi = 0.9549r$ |
|  | <p>An approximate formula is very nearly exact for all arcs less than one-quarter of the periphery is:</p> $a = \frac{2}{3}h$ <p>The error is only about one per cent for a quarter circle, and decreases for smaller arcs.</p>  |

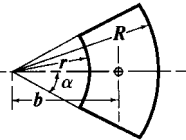

## Circle Segment :

|   |   |
|---|---|
|  | <p>The distance of the center of gravity from the center of the circle is:</p> $b = \frac{c^3}{12A} = \frac{2}{3} \times \frac{r^3 \sin^3 \alpha}{A}$ <p>in which <math>A</math> = area of segment.</p> |
|---|---|

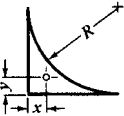

Circle Sector :

|   |   |
|---|---|

|  | <p>For a solid portion of a cylinder, as shown, the center of gravity is determined by:</p> $a = \frac{3}{16} \times 3.1416r \quad b = \frac{3}{32} \times 3.1416h$ <p>For the cylindrical surface only:</p> $a = \frac{1}{4} \times 3.1416r \quad b = \frac{1}{8} \times 3.1416h$ <p>If the cylinder is hollow, the center of gravity of the solid shell is found by:</p> $a = \frac{3}{16} \times 3.1416 \frac{R^4 - r^4}{R^3 - r^3}$ $b = \frac{3}{32} \times 3.1416 \frac{H^4 - h^4}{H^3 - h^3}$ |
|--|--|

*Center of Gravity of Two Bodies :*

If the weights of the bodies are  $P$  and  $Q$ , and the distance between their centers of gravity is  $a$ , then:

$$b = \frac{Qa}{P+Q} \quad c = \frac{Pa}{P+Q}$$

*Pyramid :*

In a solid pyramid the center of gravity is located on the line joining the apex with the center of gravity of the base surface, at a distance from the base equal to one-quarter of the height; or  $a = \frac{1}{4}h$ .

The center of gravity of the triangular surfaces forming the pyramid is located on the line joining the apex with the center of gravity of the base surface, at a distance from the base equal to one-third of the height; or  $a = \frac{1}{3}h$ .

*Frustum of Pyramid :*

The center of gravity is located on the line that joins the centers of gravity of the end surfaces. If  $A_1$  = area of base surface, and  $A_2$  = area of top surface,

$$a = \frac{h(A_1 + 2\sqrt{A_1 \times A_2} + 3A_2)}{4(A_1 + \sqrt{A_1 \times A_2} + A_2)}$$

*Cone :*

The same rules apply as for the pyramid. For the solid cone:

$$a = \frac{1}{4}h$$

For the conical surface:

$$a = \frac{1}{2}h$$

*Frustum of Cone :*

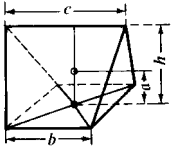

The same rules apply as for the frustum of a pyramid. For a solid frustum of a circular cone the formula below is also used:

$$a = \frac{h(R^2 + 2Rr + 3r^2)}{4(R^2 + Rr + r^2)}$$

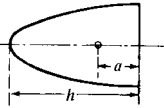

The location of the center of gravity of the conical surface of a frustum of a cone is determined by:

$$a = \frac{h(R + 2r)}{3(R + r)}$$

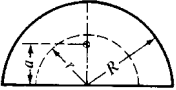

Wedge :

|   |  |
|---|--|
|  | <p>The center of gravity is on the line joining the center of gravity of the base with the middle point of the edge, and is located at:</p> $a = \frac{h(b+c)}{2(2b+c)}$ |
|---|--|

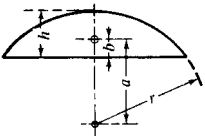

Paraboloid :

|   |  |
|---|--|
|  | <p>The center of gravity of a solid paraboloid of rotation is at:</p> $a = \frac{1}{3}h$ |
|---|--|

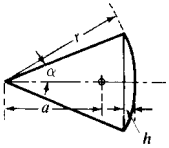

Half of a Hollow Sphere :

|   |   |
|---|---|
|  | <p>The center of gravity is located at:</p> $a = \frac{3(R^4 - r^4)}{8(R^3 - r^3)}$ |
|---|---|

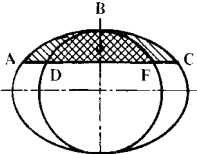

Spherical Segment :

|  |   |
|--|---|
|  | <p>The center of gravity of a solid segment is determined by:</p> $a = \frac{3(2r-h)^2}{4(3r-h)}$ $b = \frac{h(4r-h)}{4(3r-h)}$ <p>For a half-sphere, <math>a = b = \frac{3}{8}r</math></p> |
|--|---|

Spherical Sector :

|   |   |
|---|---|
|  | <p>The center of gravity of a solid sector is at:</p> $a = \frac{3}{8}(1 + \cos \alpha)r = \frac{3}{8}(2r - h)$ |
|---|---|

Segment of Ellipsoid or Spheroid :

|   |   |
|---|---|
|  | <p>The center of gravity of a solid segment <math>ABC</math>, symmetrical about the axis of rotation, coincides with the center of gravity of the segment <math>DBF</math> of a sphere, the diameter of which is equal to the axis of rotation of the spheroid.</p> |
|---|---|

**Center of Gravity of Figures of any Outline.**—If the figure is symmetrical about a center line, as in Fig. 1, the center of gravity will be located on that line. To find the exact location on that line, the simplest method is by taking moments with reference to any convenient axis at right angles to this center line. Divide the area into geometrical figures, the centers of gravity of which can be easily found. In the example shown, divide the figure into three rectangles KLMN, EFGH and OPRS. Call the areas of these rectangles  $A$ ,  $B$  and  $C$ , respectively, and find the center of gravity of each. Then select any convenient axis, as  $X-X$ , at right angles to the center line  $Y-Y$ , and determine distances  $a$ ,  $b$  and  $c$ . The distance  $y$  of the center of gravity of the complete figure from the axis  $X-X$  is then found from the equation:

$$y = \frac{Aa + Bb + Cc}{A + B + C}$$

Fig. 1.

Fig. 2.

As an example, assume that the area  $A$  is 24 square inches,  $B$ , 14 square inches, and  $C$ , 16 square inches, and that  $a = 3$  inches,  $b = 7.5$  inches, and  $c = 12$  inches. Then:

$$y = \frac{24 \times 3 + 14 \times 7.5 + 16 \times 12}{24 + 14 + 16} = \frac{369}{54} = 6.83 \text{ inches}$$

If the figure, the center of gravity of which is to be found, is not symmetrical about any axis, as in Fig. 2, then moments must be taken with relation to two axes  $X-X$  and  $Y-Y$ , centers of gravity of which can be easily found, the same as before. The center of gravity is determined by the equations:

$$x = \frac{Aa_1 + Bb_1 + Cc_1}{A + B + C} \quad y = \frac{Aa + Bb + Cc}{A + B + C}$$

As an example, let  $A = 14$  square inches,  $B = 18$  square inches, and  $C = 20$  square inches. Let  $a = 3$  inches,  $b = 7$  inches, and  $c = 11.5$  inches. Let  $a_1 = 6.5$  inches,  $b_1 = 8.5$  inches, and  $c_1 = 7$  inches. Then:

$$x = \frac{14 \times 6.5 + 18 \times 8.5 + 20 \times 7}{14 + 18 + 20} = \frac{384}{52} = 7.38 \text{ inches}$$

$$y = \frac{14 \times 3 + 18 \times 7 + 20 \times 11.5}{14 + 18 + 20} = \frac{398}{52} = 7.65 \text{ inches}$$

In other words, the center of gravity is located at a distance of 7.65 inches from the axis  $X-X$  and 7.38 inches from the axis  $Y-Y$ .

RADIUS OF GYRATION

Radius of Gyration

The radius of gyration with reference to an axis is that distance from the axis at which the entire mass of a body may be considered as concentrated, the moment of inertia, meanwhile, remaining unchanged. If  $W$  is the weight of a body;  $J_M$ , its moment of inertia with respect to some axis; and  $k_o$ , the radius of gyration with respect to the same axis, then:

$$k_o = \sqrt{\frac{J_M g}{W}} \quad \text{and} \quad J_M = \frac{W k_o^2}{g}$$

When using metric SI units, the formulas are:

$$k_o = \sqrt{\frac{J_M}{M}} \quad \text{and} \quad J_M = M k_o^2$$

where  $k_o$  = the radius of gyration in meters,  $J_M$  = kilogram-meter squared, and  $M$  = mass in kilograms.

To find the radius of gyration of an area, such as for the cross-section of a beam, divide the moment of inertia of the area by the area and extract the square root.

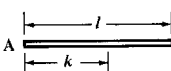

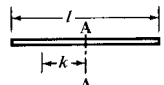

When the axis, the reference to which the radius of gyration is taken, passes through the center of gravity, the radius of gyration is the least possible and is called the *principal* radius of gyration. If  $k$  is the radius of gyration with respect to such an axis passing through the center of gravity of a body, then the radius of gyration,  $k_o$ , with respect to a parallel axis

at a distance  $d$  from the gravity axis is given by:  $k_o = \sqrt{k^2 + d^2}$

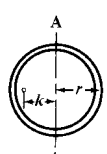

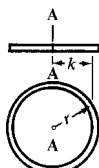

Tables of radii of gyration for various bodies and axes follows.

Formulas for Radius of Gyration

**Center and Radius of Oscillation.**—If a body oscillates about a horizontal axis which does not pass through its center of gravity, there will be a point on the line drawn from the center of gravity, perpendicular to the axis, the motion of which will be the same as if the whole mass were concentrated at that point. This point is called the *center of oscillation*. The *radius of oscillation* is the distance between the center of oscillation and the point of suspension. In a straight line, or in a bar of small diameter, suspended at one end and oscillating about it, the center of oscillation is at two-thirds the length of the rod from the end by which it is suspended.

When the vibrations are perpendicular to the plane of the figure, and the figure is suspended by the vertex of an angle or its uppermost point, the radius of oscillation of an isosceles triangle is equal to  $\frac{3}{4}$  of the height of the triangle; of a circle,  $\frac{5}{8}$  of the diameter; of a parabola,  $\frac{5}{7}$  of the height.

If the vibrations are in the plane of the figure, then the radius of oscillation of a circle equals  $\frac{3}{4}$  of the diameter; of a rectangle, suspended at the vertex of one angle,  $\frac{2}{3}$  of the diagonal.

**Center of Percussion.**—For a body that moves without rotation, the resultant of all the forces acting on the body passes through the center of gravity. On the other hand, for a body that rotates about some *fixed axis*, the resultant of all the forces acting on it does not pass through the center of gravity of the body but through a point called the *center of percussion*.

sion. The center of percussion is useful in determining the position of the resultant in mechanics problems involving angular acceleration of bodies about a fixed axis.

*Finding the Center of Percussion when the Radius of Gyration and the Location of the Center of Gravity are Known:* The center of percussion lies on a line drawn through the center of rotation and the center of gravity. The distance from the axis of rotation to the center of percussion may be calculated from the following formula

$$q = k_o^2 \div r$$

in which  $q$  = distance from the axis of rotation to the center of percussion;  $k_o$  = the radius of gyration of the body with respect to the axis of rotation; and  $r$  = the distance from the axis of rotation to the center of gravity of the body.

### Moment of Inertia

An important property of areas and solid bodies is the moment of inertia. Standard formulas are derived by multiplying elementary particles of area or mass by the squares of their distances from reference axes. Moments of inertia, therefore, depend on the location of reference axes. Values are minimum when these axes pass through the centers of gravity.

Three kinds of moments of inertia occur in engineering formulas:

1) *Moments of inertia of plane area,  $I$* , in which the axis is in the plane of the area, are found in formulas for calculating deflections and stresses in beams. When dimensions are given in inches, the units of  $I$  are inches<sup>4</sup>. A table of formulas for calculating the  $I$  of common areas can be found beginning on page 238.

2) *Polar moments of inertia of plane areas,  $J$* , in which the axis is at right angles to the plane of the area, occur in formulas for the torsional strength of shafting. When dimensions are given in inches, the units of  $J$  are inches<sup>4</sup>. If moments of inertia,  $I$ , are known for a plane area with respect to both  $x$  and  $y$  axes, then the polar moment for the  $z$  axis may be calculated using the equation,  $J_z = I_x + I_y$

A table of formulas for calculating  $J$  for common areas can be found on page 249 in this section.

**When metric SI units are used, the formulas referred to in (1) and (2) above, are valid if the dimensions are given consistently in meters or millimeters. If meters are used, the units of  $I$  and  $J$  are in meters<sup>4</sup>; if millimeters are used, these units are in millimeters<sup>4</sup>.**

3) *Polar moments of inertia of masses,  $J_M$* <sup>\*</sup>, appear in dynamics equations involving rotational motion.  $J_M$  bears the same relationship to angular acceleration as mass does to linear acceleration. If units are in the foot-pound-second system, the units of  $J_M$  are ft-lbs-sec<sup>2</sup> or slug-ft<sup>2</sup>. (1 slug = 1 pound second<sup>2</sup> per foot.) If units are in the inch-pound-second system, the units of  $J_M$  are inch-lbs-sec<sup>2</sup>.

**If metric SI values are used, the units of  $J_M$  are kilogram-meter squared.** Formulas for calculating  $J_M$  for various bodies are given beginning on page 250. If the polar moment of inertia  $J$  is known for the area of a body of constant cross section,  $J_M$  may be calculated using the equation,

$$J_M = \frac{\rho L}{g} J$$

where  $\rho$  is the density of the material,  $L$  the length of the part, and  $g$  the gravitational constant. If dimensions are in the foot-pound-second system,  $\rho$  is in lbs per ft<sup>3</sup>,  $L$  is in ft,  $g$  is

<sup>\*</sup> In some books the symbol  $I$  denotes the polar moment of inertia of masses;  $J_M$  is used in this handbook to avoid confusion with moments of inertia of plane areas.

32.16 ft per sec<sup>2</sup>, and  $J$  is in ft<sup>4</sup>. If dimensions are in the inch-pound-second system,  $\rho$  is in lbs per in<sup>3</sup>,  $L$  is in inches,  $g$  is 386 inches per sec<sup>2</sup>, and  $J$  is in inches<sup>4</sup>.

Using metric SI units, the above formula becomes  $J_M = \rho L J$ , where  $\rho$  = the density in kilograms/meter<sup>3</sup>,  $L$  = the length in meters, and  $J$  = the polar moment of inertia in meters<sup>4</sup>. The units of  $J_M$  are kg · m<sup>2</sup>.

**Moment of Inertia of Built-up Sections.**—The usual method of calculating the moment of inertia of a built-up section involves the calculations of the moment of inertia for each element of the section about its own neutral axis, and the transferring of this moment of inertia to the previously found neutral axis of the whole built-up section. A much simpler method that can be used in the case of any section which can be divided into rectangular elements bounded by lines parallel and perpendicular to the neutral axis is the so-called tabular method based upon the formula:  $I = b(h_1^3 - h^3)/3$  in which  $I$  = the moment of inertia about axis  $DE$ , Fig. 1, and  $b$ ,  $h$  and  $h_1$  are dimensions as given in the same illustration.

*Example:* The method may be illustrated by applying it to the section shown in Fig. 2, and for simplicity of calculation shown “massed” in Fig. 3. The calculation may then be tabulated as shown in the accompanying table. The distance from the axis  $DE$  to the neutral axis  $xx$  (which will be designated as  $d$ ) is found by dividing the sum of the geometrical moments by the area. The moment of inertia about the neutral axis is then found in the usual way by subtracting the area multiplied by  $d^2$  from the moment of inertia about the axis  $DE$ .

**Tabulated Calculation of Moment of Inertia**

| Section | Breadth<br>$b$ | Height<br>$h_1$ | Area<br>$b(h_1 - h)$ | $h_1^2$ | Moment<br>$\frac{b(h_1^2 - h^2)}{2}$ | $h_1^3$ | $I$ about axis $DE$<br>$\frac{b(h_1^3 - h^3)}{3}$ |
|---------|----------------|-----------------|----------------------|---------|--------------------------------------|---------|---|
| A       | 1.500          | 0.125           | 0.187                | 0.016   | 0.012                                | 0.002   | 0.001   |
| B       | 0.531          | 0.625           | 0.266                | 0.391   | 0.100                                | 0.244   | 0.043   |
| C       | 0.219          | 1.500           | 0.191                | 2.250   | 0.203                                | 3.375   | 0.228   |
|         |                |                 | $\Sigma A = 0.644$   |         | $\Sigma M = 0.315$                   |         | $\Sigma I_{DE} = 0.272$                           |

The distance  $d$  from  $DE$ , the axis at the base of the configuration, to the neutral axis  $xx$  is:

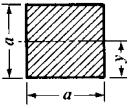

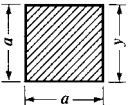

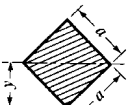

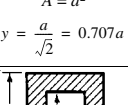

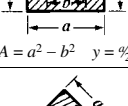

$$d = \frac{M}{A} = \frac{0.315}{0.644} = 0.49$$

The moment of inertia of the entire section with reference to the neutral axis  $xx$  is:

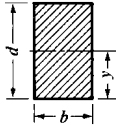

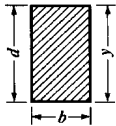

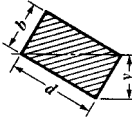

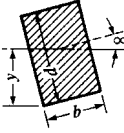

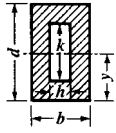

$$\begin{aligned} I_N &= I_{DE} - Ad^2 \\ &= 0.272 - 0.644 \times 0.49^2 \\ &= 0.117 \end{aligned}$$

**Formulas for Moments of Inertia, Section Moduli, etc.**—On the following pages are given formulas for the moments of inertia and other properties of forty-two different cross-sections. The formulas give the area of the section  $A$ , and the distance  $y$  from the neutral axis to the extreme fiber, for each example. Where the formulas for the section modulus and radius of gyration are very lengthy, the formula for the section modulus, for example, has been simply given as  $I \div y$ . The radius of gyration is sometimes given as  $\sqrt{I \div A}$  to save space.

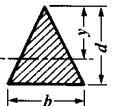

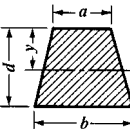

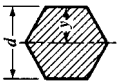

### Moments of Inertia, Section Moduli, and Radii of Gyration

| Section<br>$A = \text{area}$<br>$y = \text{distance from axis to extreme fiber}$   | Moment of Inertia<br>$I$ | Section Modulus<br>$Z = \frac{I}{y}$                              | Radius of Gyration<br>$k = \sqrt{\frac{I}{A}}$             |

**Polar Area Moment of Inertia and Section Modulus.**—The *polar moment of inertia*,  $J$ , of a cross-section with respect to a polar axis, that is, an axis at right angles to the plane of the cross-section, is defined as the moment of inertia of the cross-section with respect to the point of intersection of the axis and the plane. The polar moment of inertia may be found by taking the sum of the moments of inertia about two perpendicular axes lying in the plane of the cross-section and passing through this point. Thus, for example, the polar moment of inertia of a circular or a square area with respect to a polar axis through the center of gravity is equal to two times the moment of inertia with respect to an axis lying in the plane of the cross-section and passing through the center of gravity.

The polar moment of inertia with respect to a polar axis through the center of gravity is required for problems involving the torsional strength of shafts since this axis is usually the axis about which twisting of the shaft takes place.

The *polar section modulus* (also called section modulus of torsion),  $Z_p$ , for *circular* sections may be found by dividing the polar moment of inertia,  $J$ , by the distance  $c$  from the center of gravity to the most remote fiber. This method may be used to find the *approximate* value of the polar section modulus of sections that are *nearly* round. For other than circular cross-sections, however, the polar section modulus *does not* equal the polar moment of inertia divided by the distance  $c$ .

The accompanying table *Polar Moment of Inertia and Polar Section Modulus* on page 249 gives formulas for the polar section modulus for several different cross-sections. The polar section modulus multiplied by the allowable torsional shearing stress gives the allowable twisting moment to which a shaft may be subjected, see [Formula \(7\)](#) on page 300.

**Mass Moments of Inertia\***,  $J_M$ .—Starting on page 250, formulas for mass moment of inertia of various solids are given in a series of tables. The example that follows illustrates the derivation of  $J_M$  for one of the bodies given on page 250.

*Example, Polar Mass Moment of Inertia of a Hollow Circular Section:* Referring to the figure *Hollow Cylinder* on page 250, consider a strip of width  $dr$  on a hollow circular section, whose inner radius is  $r$  and outer radius is  $R$ .

The mass of the strip =  $2\pi r dr \rho$ , where  $\rho$  is the density of material. In order to get the mass of an individual section, integrate the mass of the strip from  $r$  to  $R$ .

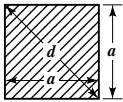

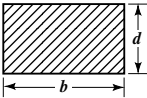

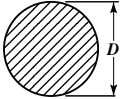

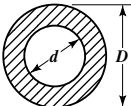

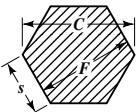

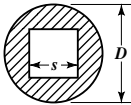

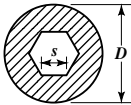

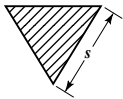

$$\begin{aligned} M &= \int_r^R 2\pi r(dr)\rho = 2\pi\rho \int_r^R r(dr) = 2\pi\rho \left[ \frac{r^2}{2} \right]_r^R \\ &= 2\pi\rho \left( \frac{R^2}{2} - \frac{r^2}{2} \right) = \pi\rho(R^2 - r^2) \end{aligned}$$

The 2nd moment of the strip about the AA axis =  $2\pi r dr \rho r^2$ . To find the polar moment of inertia about the AA axis, integrate the 2nd moment from  $r$  to  $R$ .

$$\begin{aligned} J_M &= \int_r^R 2\pi r(dr)\rho r^2 = 2\pi\rho \int_r^R r^3(dr) = 2\pi\rho \left[ \frac{r^4}{4} \right]_r^R \\ &= 2\pi\rho \left( \frac{R^4}{4} - \frac{r^4}{4} \right) = \frac{\pi\rho}{2}(R^2 - r^2)(R^2 + r^2) \\ &= \left( \pi\rho(R^2 - r^2) \right) \frac{(R^2 + r^2)}{2} = \frac{M(R^2 + r^2)}{2} \end{aligned}$$

\* In some books the symbol  $I$  denotes the polar moment of inertia of masses;  $J_M$  is used in this handbook to avoid confusion with moments of inertia of plane areas.

## Polar Moment of Inertia and Polar Section Modulus

|  | <p>With reference to axis A - A: <math>J_M = \frac{M}{5}(b^2 + c^2)</math></p> <p>With reference to axis B - B: <math>J_M = \frac{M}{5}(a^2 + c^2)</math></p> <p>With reference to axis C - C: <math>J_M = \frac{M}{5}(a^2 + b^2)</math></p> |
|--|--|

Cone:

|  |   |
|--|---|
|  | <p>With reference to axis A - A: <math>J_M = \frac{3M}{10} r^2</math></p> <p>With reference to axis B - B (through the center of gravity):</p> $J_M = \frac{3M}{20} \left( r^2 + \frac{h^2}{4} \right)$ |
|--|---|

Frustrum of Cone:

|  |   |
|--|---|
|  | <p>With reference to axis A - A: <math>J_M = \frac{3M(R^5 - r^5)}{10(R^3 - r^3)}</math></p> |
|--|---|

Moments of Inertia of Complex Areas and Masses may be evaluated by the addition and subtraction of elementary areas and masses. For example, the accompanying figure shows a complex mass at (1); its mass polar moment of inertia can be determined by adding together the moments of inertia of the bodies shown at (2) and (3), and subtracting that at (4).

Thus,  $J_{M1} = J_{M2} + J_{M3} - J_{M4}$ . All of these moments of inertia are with respect to the axis of rotation  $z - z$ . Formulas for  $J_{M2}$  and  $J_{M3}$  can be obtained from the tables beginning on page 250. The moment of inertia for the body at (4) can be evaluated by using the following transfer-axis equation:  $J_{M4} = J_{M4}' + d^2M$ . The term  $J_{M4}'$  is the moment of inertia with respect to axis  $z' - z'$ ; it may be evaluated using the same equation that applies to  $J_{M2}$  where  $d$  is the distance between the  $z - z$  and the  $z' - z'$  axes, and  $M$  is the mass of the body (= weight in lbs  $\div$  g).

Moments of Inertia of Complex Masses

Similar calculations can be made when calculating  $I$  and  $J$  for complex areas using the appropriate transfer-axis equations  $I = I' + d^2A$  and  $J = J' + d^2A$ . The primed term,  $I'$  or  $J'$ , is with respect to the center of gravity of the corresponding area  $A$ ;  $d$  is the distance between the axis through the center of gravity and the axis to which  $I$  or  $J$  is referred.

**Moments of Inertia and Section Moduli  
for Rectangles and Round Shafts**

Moments of inertia and section modulus values shown here are for rectangles 1 millimeter wide. To obtain moment of inertia or section modulus for rectangle of given side length, multiply appropriate table value by given width. (See the text starting on page 238 for basic formulas.)

**Moments of Inertia and Section Moduli for Rectangles (Metric Units)**

| Length of Side (mm) | Moment of Inertia | Section Modulus | Length of Side (mm) | Moment of Inertia | Section Modulus | Length of Side (mm) | Moment of Inertia | Section Modulus |

Section modulus values are shown for rectangles 1 inch wide. To obtain section modulus for rectangle of given side length, multiply value in table by given width.

## Section Moduli and Moments of Inertia for Round Shafts

In this and succeeding tables, the *Polar Section Modulus* for a shaft of given diameter can be obtained by multiplying its section modulus by 2. Similarly, its *Polar Moment of Inertia* can be obtained by multiplying its moment of inertia by 2.

## Section Moduli and Moments of Inertia for Round Shafts (English or Metric Units)

| Dia. | Section Modulus | Moment of Inertia | Dia. | Section Modulus | Moment of Inertia | Dia. | Section Modulus | Moment of Inertia |

## BEAMS

## Beam Calculations

**Reaction at the Supports.**—When a beam is loaded by vertical loads or forces, the sum of the reactions at the supports equals the sum of the loads. In a simple beam, when the loads are symmetrically placed with reference to the supports, or when the load is uniformly distributed, the reaction at each end will equal one-half of the sum of the loads. When the loads are not symmetrically placed, the reaction at each support may be ascertained from the fact that the algebraic sum of the moments must equal zero. In the accompanying illustration, if moments are taken about the support to the left, then:  $R_2 \times 40 - 8,000 \times 10 - 10,000 \times 16 - 20,000 \times 20 = 0$ ;  $R_2 = 16,000$  pounds. In the same way, moments taken about the support at the right give  $R_1 = 22,000$  pounds.

The sum of the reactions equals 38,000 pounds, which is also the sum of the loads. If part of the load is uniformly distributed over the beam, this part is first equally divided between the two supports, or the uniform load may be considered as concentrated at its center of gravity.

**If metric SI units are used for the calculations, distances may be expressed in meters or millimeters, providing the treatment is consistent, and loads in newtons. Note: If the load is given in kilograms, the value referred to is the mass. A mass of  $M$  kilograms has a weight (applies a force) of  $Mg$  newtons, where  $g =$  approximately 9.81 meters per second<sup>2</sup>.**

**Stresses and Deflections in Beams.**—On the following pages [Table 1](#) gives an extensive list of formulas for stresses and deflections in beams, shafts, etc. It is assumed that all the dimensions are in inches, all loads in pounds, and all stresses in pounds per square inch. **The formulas are also valid using metric SI units, with all dimensions in millimeters, all loads in newtons, and stresses and moduli in newtons per millimeter<sup>2</sup> (N/mm<sup>2</sup>).** *Note: A load due to the weight of a mass of  $M$  kilograms is  $Mg$  newtons, where  $g =$  approximately 9.81 meters per second<sup>2</sup>.* In the tables:

$E$  = modulus of elasticity of the material

$I$  = moment of inertia of the cross-section of the beam

$Z$  = section modulus of the cross-section of the beam =  $I \div$  distance from neutral axis to extreme fiber

$W$  = load on beam

$s$  = stress in extreme fiber, or maximum stress in the cross-section considered, due to load  $W$ . A positive value of  $s$  denotes tension in the upper fibers and compression in the lower ones (as in a cantilever). A negative value of  $s$  denotes the reverse (as in a beam supported at the ends). The greatest safe load is that value of  $W$  which causes a maximum stress equal to, but not exceeding, the greatest safe value of  $s$

$y$  = deflection measured from the position occupied if the load causing the deflection were removed. A positive value of  $y$  denotes deflection below this position; a negative value, deflection upward

$u, v, w, x$  = variable distances along the beam from a given support to any point

**Table 1. Stresses and Deflections in Beams**

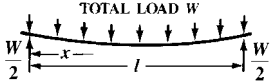

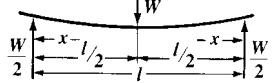

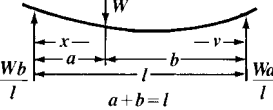

| Type of Beam  | Stresses   |  | Deflections  |  |
|---|--|--|--|--|
|   | General Formula for Stress at any Point  | Stresses at Critical Points  | General Formula for Deflection at any Point <sup>a</sup>   | Deflections at Critical Points <sup>a</sup>  |

<sup>a</sup>The deflections apply only to cases where the cross section of the beam is constant for its entire length.

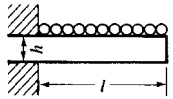

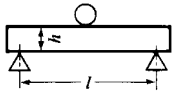

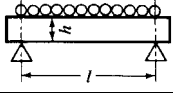

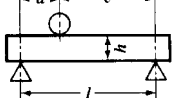

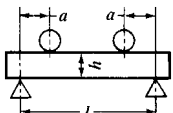

In the diagrammatical illustrations of the beams and their loading, the values indicated near, but below, the supports are the "reactions" or upward forces at the supports. For Cases 1 to 12, inclusive, the reactions, as well as the formulas for the stresses, are the same whether the beam is of constant or variable cross-section. For the other cases, the reactions and the stresses given are for constant cross-section beams only.

The bending moment at any point in inch-pounds is  $s \times Z$  and can be found by omitting the divisor  $Z$  in the formula for the stress given in the tables. A positive value of the bending moment denotes tension in the upper fibers and compression in the lower ones. A negative value denotes the reverse. The value of  $W$  corresponding to a given stress is found by transposition of the formula. For example, in Case 1, the stress at the critical point is  $s = -Wl \div 8Z$ . From this formula we find  $W = -8Zs \div l$ . Of course, the negative sign of  $W$  may be ignored.

In Table 1, if there are several kinds of loads, as, for instance, a uniform load and a load at any point, or separate loads at different points, the total stress and the total deflection at any point is found by adding together the various stresses or deflections at the point considered due to each load acting by itself. If the stress or deflection due to any one of the loads is negative, it must be subtracted instead of added.

Tables 2a and 2b give expressions for determining dimensions of rectangular and round beams in terms of beam stresses and load.

**Table 2a. Rectangular Solid Beams**

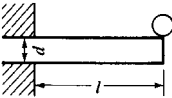

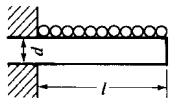

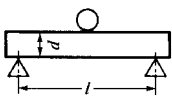

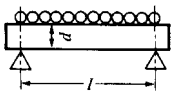

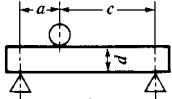

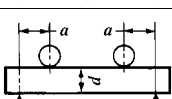

| Style of Loading and Support   | Breadth of Beam, <i>b</i><br>inch (mm) | Beam Height, <i>h</i><br>inch (mm) | Stress in Extreme Fibers, <i>f</i><br>lb/in <sup>2</sup> (N/mm <sup>2</sup> ) | Beam Length, <i>l</i><br>inch (mm)                | Total Load, <i>W</i><br>lb (N) |

**Deflection of Beam Uniformly Loaded for Part of Its Length.**—In the following formulas, lengths are in inches, weights in pounds. *W* = total load; *L* = total length between supports; *E* = modulus of elasticity; *I* = moment of inertia of beam section; *a* = fraction of length of beam at each end, that is not loaded = *b* ÷ *L*; and *f* = deflection.

$$f = \frac{WL^3}{384EI(1 - 2a)}(5 - 24a^2 + 16a^4)$$

The expression for maximum bending moment is:  $M_{\max} = \frac{1}{8}WL(1 + 2a)$ .

Table 2b. Round Solid Beams

| Style of Loading and Support  | Diameter of Beam, $d$<br>inch (mm)                     | Stress in Extreme<br>Fibers, $f$<br>lb/in <sup>2</sup> (N/mm <sup>2</sup> ) | Beam Length, $l$<br>inch (mm)                 | Total Load, $W$<br>lb (N)   |
|---|--|---|---|-----------------------------|
|   | Beam fixed at one end, loaded at the other             |   |   |                             |

|   | $\sqrt[3]{\frac{1.273Wl}{f}} = d$                      | $\frac{1.273Wl}{d^3} = f$   | $\frac{d^3f}{1.273W} = l$                     | $\frac{d^3f}{1.273l} = W$   |
|   | Beam supported at both ends, single unsymmetrical load |   |   |                             |
|   | $\sqrt[3]{\frac{10.18Wac}{fl}} = d$                    | $\frac{10.18Wac}{d^3l} = f$   | $a + c = l$                                   | $\frac{d^3fl}{10.18ac} = W$ |
|  | Beam supported at both ends, two symmetrical loads     |   |   |                             |
|   | $\sqrt[3]{\frac{5.092Wa}{f}} = d$                      | $\frac{5.092Wa}{d^3} = f$   | $l$ , any length<br>$\frac{d^3f}{5.092W} = a$ | $\frac{d^3f}{5.092a} = W$   |

These formulas apply to simple beams resting on supports at the ends.

If the formulas are used with metric SI units,  $W$  = total load in newtons;  $L$  = total length between supports in millimeters;  $E$  = modulus of elasticity in newtons per millimeter<sup>2</sup>;  $I$  = moment of inertia of beam section in millimeters<sup>4</sup>;  $a$  = fraction of length of beam at each end, that is not loaded =  $b \div L$ ; and  $f$  = deflection in millimeters. The bending moment  $M_{\max}$  is in newton-millimeters (N · mm).

Note: A load due to the weight of a mass of  $M$  kilograms is  $Mg$  newtons, where  $g$  = approximately 9.81 meters per second<sup>2</sup>.

**Bending Stress Due to an Oblique Transverse Force.**—The following illustration shows a beam and a channel being subjected to a transverse force acting at an angle  $\phi$  to the center of gravity. To find the bending stress, the moments of inertia  $I$  around axes 3-3 and 4-4 are computed from the following equations:  $I_3 = I_x \sin^2 \phi + I_y \cos^2 \phi$ , and  $I_4 = I_x \cos^2 \phi + I_y \sin^2 \phi$ .

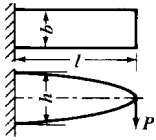

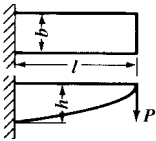

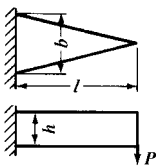

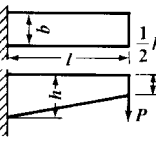

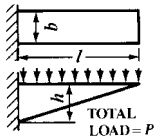

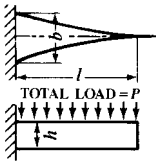

The computed bending stress  $f_b$  is then found from  $f_b = M \left( \frac{y}{I_x} \sin \phi + \frac{x}{I_y} \cos \phi \right)$  where  $M$  is the bending moment due to force  $F$ .

**Beams of Uniform Strength Throughout Their Length.**—The bending moment in a beam is generally not uniform throughout its length, but varies. Therefore, a beam of uniform cross-section which is made strong enough at its most strained section, will have an excess of material at every other section. Sometimes it may be desirable to have the cross-section uniform, but at other times the metal can be more advantageously distributed if the beam is so designed that its cross-section varies from point to point, so that it is at every point just great enough to take care of the bending stresses at that point. Tables 3a and 3b are given showing beams in which the load is applied in different ways and which are supported by different methods, and the shape of the beam required for uniform strength is indicated. It should be noted that the shape given is the theoretical shape required to resist bending only. It is apparent that sufficient cross-section of beam must also be added either at the points of support (in beams supported at both ends), or at the point of application of the load (in beams loaded at one end), to take care of the vertical shear.

It should be noted that the theoretical shapes of the beams given in the two tables that follow are based on the stated assumptions of uniformity of width or depth of cross-section, and unless these are observed in the design, the theoretical outlines do not apply without modifications. For example, in a cantilever with the load at one end, the outline is a parabola only when the width of the beam is uniform. It is not correct to use a strictly parabolic shape when the thickness is not uniform, as, for instance, when the beam is made of an I- or T-section. In such cases, some modification may be necessary; but it is evident that whatever the shape adopted, the correct depth of the section can be obtained by an investigation of the bending moment and the shearing load at a number of points, and then a line can be drawn through the points thus ascertained, which will provide for a beam of practically uniform strength whether the cross-section be of uniform width or not.

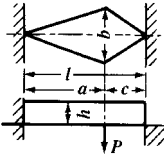

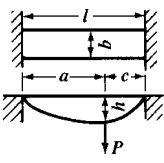

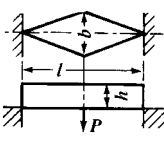

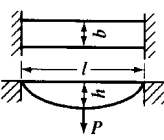

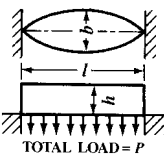

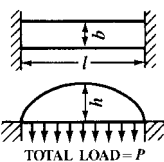

**Table 3a. Beams of Uniform Strength Throughout Their Length**

| Type of Beam   | Description   | Formula <sup>a</sup>   |
|--|---|------------------------|
|    | <p>Load at one end. Width of beam uniform. Depth of beam decreasing towards loaded end. Outline of beam-shape, parabola with vertex at loaded end.</p>  | $P = \frac{Sbh^2}{6l}$ |
|    | <p>Load at one end. Width of beam uniform. Depth of beam decreasing towards loaded end. Outline of beam, one-half of a parabola with vertex at loaded end. Beam may be reversed so that upper edge is parabolic.</p>                | $P = \frac{Sbh^2}{6l}$ |
|    | <p>Load at one end. Depth of beam uniform. Width of beam decreasing towards loaded end. Outline of beam triangular, with apex at loaded end.</p>  | $P = \frac{Sbh^2}{6l}$ |
|   | <p>Beam of <i>approximately</i> uniform strength. Load at one end. Width of beam uniform. Depth of beam decreasing towards loaded end, but not tapering to a sharp point.</p>   | $P = \frac{Sbh^2}{6l}$ |
|  | <p>Uniformly distributed load. Width of beam uniform. Depth of beam decreasing towards outer end. Outline of beam, right-angled triangle.</p>   | $P = \frac{Sbh^2}{3l}$ |
|  | <p>Uniformly distributed load. Depth of beam uniform. Width of beam gradually decreasing towards outer end. Outline of beam is formed by two parabolas which tangent each other at their vertices at the outer end of the beam.</p> | $P = \frac{Sbh^2}{3l}$ |

<sup>a</sup> In the formulas,  $P$  = load in pounds;  $S$  = safe stress in pounds per square inch; and  $a, b, c, h,$  and  $l$  are in inches. If metric SI units are used,  $P$  is in newtons;  $S$  = safe stress in  $N/mm^2$ ; and  $a, b, c, h,$  and  $l$  are in millimeters.

Table 3b. Beams of Uniform Strength Throughout Their Length

| Type of Beam   | Description  | Formula <sup>a</sup>     |
|--|--|--------------------------|
|                          | <p>Beam supported at both ends. Load concentrated at any point. Depth of beam uniform. Width of beam maximum at point of loading. Outline of beam, two triangles with apexes at points of support.</p>                     | $P = \frac{Sbh^2l}{6ac}$ |
|                          | <p>Beam supported at both ends. Load concentrated at any point. Width of beam uniform. Depth of beam maximum at point of loading. Outline of beam is formed by two parabolas with their vertexes at points of support.</p> | $P = \frac{Sbh^2l}{6ac}$ |
|                          | <p>Beam supported at both ends. Load concentrated in the middle. Depth of beam uniform. Width of beam maximum at point of loading. Outline of beam, two triangles with apexes at points of support.</p>                    | $P = \frac{2Sbh^2}{3l}$  |
|                         | <p>Beam supported at both ends. Load concentrated at center. Width of beam uniform. Depth of beam maximum at point of loading. Outline of beam, two parabolas with vertexes at points of support.</p>                      | $P = \frac{2Sbh^2}{3l}$  |
|  <p>TOTAL LOAD = P</p> | <p>Beam supported at both ends. Load uniformly distributed. Depth of beam uniform. Width of beam maximum at center. Outline of beam, two parabolas with vertexes at middle of beam.</p>                                    | $P = \frac{4Sbh^2}{3l}$  |
|  <p>TOTAL LOAD = P</p> | <p>Beam supported at both ends. Load uniformly distributed. Width of beam uniform. Depth of beam maximum at center. Outline of beam one-half of an ellipse.</p>  | $P = \frac{4Sbh^2}{3l}$  |

<sup>a</sup> For details of English and metric SI units used in the formulas, see footnote on page 275.

**Deflection as a Limiting Factor in Beam Design.**—For some applications, a beam must be stronger than required by the maximum load it is to support, in order to prevent excessive deflection. Maximum allowable deflections vary widely for different classes of service, so a general formula for determining them cannot be given. When exceptionally stiff girders are required, one rule is to limit the deflection to 1 inch per 100 feet of span; hence, if  $l$  = length of span in inches, deflection =  $l \div 1200$ . According to another formula, deflection limit =  $l \div 360$  where beams are adjacent to materials like plaster which would be broken by excessive beam deflection. Some machine parts of the beam type must be very rigid to maintain alignment under load. For example, the deflection of a punch press column may be limited to 0.010 inch or less. These examples merely illustrate variations in practice. It is impracticable to give general formulas for determining the allowable deflection in any specific application, because the allowable amount depends on the conditions governing each class of work.

*Procedure in Designing for Deflection:* Assume that a deflection equal to  $l \div 1200$  is to be the limiting factor in selecting a wide-flange (W-shape) beam having a span length of 144 inches. Supports are at both ends and load at center is 15,000 pounds. Deflection  $y$  is to be limited to  $144 \div 1200 = 0.12$  inch. According to the formula on page 261 (Case 2), in which  $W$  = load on beam in pounds,  $l$  = length of span in inches,  $E$  = modulus of elasticity of material,  $I$  = moment of inertia of cross section:

$$\text{Deflection } y = \frac{Wl^3}{48EI} \quad \text{hence, } I = \frac{Wl^3}{48yE} = \frac{15,000 \times 144^3}{48 \times 0.12 \times 29,000,000} = 268.1$$

A structural wide-flange beam, see *Steel Wide-Flange Sections* on page 2511, having a depth of 12 inches and weighing 35 pounds per foot has a moment of inertia  $I$  of 285 and a section modulus ( $Z$  or  $S$ ) of 45.6. Checking now for maximum stress  $s$  (Case 2, page 261):

$$s = \frac{Wl}{4Z} = \frac{15,000 \times 144}{4 \times 46.0} = 11,842 \text{ lbs/in}^2$$

Although deflection is the limiting factor in this case, the maximum stress is checked to make sure that it is within the allowable limit. As the limiting deflection is decreased, for a given load and length of span, the beam strength and rigidity must be increased, and, consequently, the maximum stress is decreased. Thus, in the preceding example, if the maximum deflection is 0.08 inch instead of 0.12 inch, then the calculated value for the moment of inertia  $I$  will be 402; hence a W 12  $\times$  53 beam having an  $I$  value of 426 could be used (nearest value above 402). The maximum stress then would be reduced to 7640 pounds per square inch and the calculated deflection is 0.076 inch.

A similar example using metric SI units is as follows. Assume that a deflection equal to  $l \div 1000$  millimeters is to be the limiting factor in selecting a W-beam having a span length of 5 meters. Supports are at both ends and the load at the center is 30 kilonewtons. Deflection  $y$  is to be limited to  $5000 \div 1000 = 5$  millimeters. The formula on page 261 (Case 2) is applied, and  $W$  = load on beam in newtons;  $l$  = length of span in mm;  $E$  = modulus of elasticity (assume 200,000 N/mm<sup>2</sup> in this example); and  $I$  = moment of inertia of cross-section in millimeters<sup>4</sup>. Thus,

$$\text{Deflection } y = \frac{Wl^3}{48EI}$$

hence

$$I = \frac{Wl^3}{48yE} = \frac{30,000 \times 5000^3}{48 \times 5 \times 200,000} = 78,125,000 \text{ mm}^4$$

Although deflection is the limiting factor in this case, the maximum stress is checked to make sure that it is within the allowable limit, using the formula from page 261 (Case 2):

$$s = \frac{Wl}{4Z}$$

The units of  $s$  are newtons per square millimeter;  $W$  is the load in newtons;  $l$  is the length in mm; and  $Z$  = section modulus of the cross-section of the beam =  $I \div$  distance in mm from neutral axis to extreme fiber.

**Curved Beams.**—The formula  $S = Mc/I$  used to compute stresses due to bending of beams is based on the assumption that the beams are straight before any loads are applied. In beams having initial curvature, however, the stresses may be considerably higher than predicted by the ordinary straight-beam formula because the effect of initial curvature is to shift the neutral axis of a curved member in from the gravity axis toward the center of curvature (the concave side of the beam). This shift in the position of the neutral axis causes an increase in the stress on the concave side of the beam and decreases the stress at the outside fibers.

Hooks, press frames, and other machine members which as a rule have a rather pronounced initial curvature may have a maximum stress at the inside fibers of up to about  $3\frac{1}{2}$  times that predicted by the ordinary straight-beam formula.

*Stress Correction Factors for Curved Beams:* A simple method for determining the maximum fiber stress due to bending of curved members consists of 1) calculating the maximum stress using the straight-beam formula  $S = Mc/I$ ; and; and 2) multiplying the calculated stress by a stress correction factor. Table 4 on page 279 gives stress correction factors for some of the common cross-sections and proportions used in the design of curved members.

An example in the application of the method using English units of measurement is given at the bottom of the table. **A similar example using metric SI units is as follows: The fiber stresses of a curved rectangular beam are calculated as 40 newtons per millimeter<sup>2</sup>, using the straight beam formula,  $S = Mc/I$ . If the beam is 150 mm deep and its radius of curvature is 300 mm, what are the true stresses?  $R/c = 300/75 = 4$ . From Table 4 on page 279, the  $K$  factors corresponding to  $R/c = 4$  are 1.20 and 0.85. Thus, the inside fiber stress is  $40 \times 1.20 = 48 \text{ N/mm}^2 = 48$  megapascals; and the outside fiber stress is  $40 \times 0.85 = 34 \text{ N/mm}^2 = 34$  megapascals.**

*Approximate Formula for Stress Correction Factor:* The stress correction factors given in Table 4 on page 279 were determined by Wilson and Quereau and published in the University of Illinois Engineering Experiment Station Circular No. 16, "A Simple Method of Determining Stress in Curved Flexural Members." In this same publication the authors indicate that the following empirical formula may be used to calculate the value of the stress correction factor for the *inside* fibers of sections not covered by the tabular data to within 5 per cent accuracy except in triangular sections where up to 10 per cent deviation may be expected. However, for most engineering calculations, this formula should prove satisfactory for general use in determining the factor for the inside fibers.

$$K = 1.00 + 0.5 \frac{I}{bc^2} \left[ \frac{1}{R-c} + \frac{1}{R} \right]$$

(Use 1.05 instead of 0.5 in this formula for circular and elliptical sections.)

$I$  = Moment of inertia of section about centroidal axis

$b$  = maximum width of section

$c$  = distance from centroidal axis to inside fiber, i.e., to the extreme fiber nearest the center of curvature

$R$  = radius of curvature of centroidal axis of beam

**Table 4. Values of Stress Correction Factor K for Various Curved Beam Sections**

| Section | $R/c$ | Factor K     |               | $y_0^a$ | Section  | $R/c$ | Factor K     |               | $y_0^a$ |
|---------|-------|--------------|---------------|---------|--|-------|--------------|---------------|---------|

<sup>a</sup>  $y_0$  is the distance from the centroidal axis to the neutral axis of curved beams subjected to pure bending and is measured from the centroidal axis toward the center of curvature.

*Example:* The accompanying diagram shows the dimensions of a clamp frame of rectangular cross-section. Determine the maximum stress at points *A* and *B* due to a clamping force of 1000 pounds.

The cross-sectional area =  $2 \times 4 = 8$  square inches; the bending moment at section *AB* is  $1000(24 + 6 + 2) = 32,000$  inch pounds; the distance from the center of gravity of the section at *AB* to point *B* is  $c = 2$  inches; and using the formula on page 239, the moment of inertia of the section is  $2 \times (4)^3 \div 12 = 10.667$  inches<sup>4</sup>.

Using the straight-beam formula, page 278, the stress at points *A* and *B* due to the bending moment is:

$$S = \frac{Mc}{I} = \frac{32,000 \times 2}{10.667} = 6000 \text{ psi}$$

The stress at *A* is a compressive stress of 6000 psi and that at *B* is a tensile stress of 6000 psi.

These values must be corrected to account for the curvature effect. In Table 4 on page 279 for  $R/c = (6 + 2)/(2) = 4$ , the value of  $K$  is found to be 1.20 and 0.85 for points *B* and *A* respectively. Thus, the actual stress due to bending at point *B* is  $1.20 \times 6000 = 7200$  psi in tension and the stress at point *A* is  $0.85 \times 6000 = 5100$  psi in compression.

To these stresses at *A* and *B* must be added, algebraically, the direct stress at section *AB* due to the 1000-pound clamping force. The direct stress on section *AB* will be a tensile stress equal to the clamping force divided by the section area. Thus  $1000 \div 8 = 125$  psi in tension.

The maximum unit stress at *A* is, therefore,  $5100 - 125 = 4975$  psi in compression and the maximum unit stress at *B* is  $7200 + 125 = 7325$  psi in tension.

The following is a similar calculation using metric SI units, assuming that it is required to determine the maximum stress at points *A* and *B* due to clamping force of 4 kilonewtons acting on the frame. The frame cross-section is 50 by 100 millimeters, the radius  $R = 200$  mm, and the length of the straight portions is 600 mm. Thus, the cross-sectional area =  $50 \times 100 = 5000$  mm<sup>2</sup>; the bending moment at *AB* is  $4000(600 + 200) = 3,200,000$  newton-millimeters; the distance from the center of gravity of the section at *AB* to point *B* is  $c = 50$  mm; and the moment of inertia of the section is, using the formula on page 239,  $50 \times (100)^3 = 4,170,000$  mm<sup>4</sup>.

Using the straight-beam formula, page 278, the stress at points *A* and *B* due to the bending moment is:

$$\begin{aligned} s &= \frac{Mc}{I} = \frac{3,200,000 \times 50}{4,170,000} \\ &= 38.4 \text{ newtons per millimeter}^2 = 38.4 \text{ megapascals} \end{aligned}$$

The stress at *A* is a compressive stress of 38.4 N/mm<sup>2</sup>, while that at *B* is a tensile stress of 38.4 N/mm<sup>2</sup>. These values must be corrected to account for the curvature

effect. From the table on page 279, the  $K$  factors are 1.20 and 0.85 for points  $A$  and  $B$  respectively, derived from  $R/c = 200/50 = 4$ . Thus, the actual stress due to bending at point  $B$  is  $1.20 \times 38.4 = 46.1 \text{ N/mm}^2$  (46.1 megapascals) in tension; and the stress at point  $A$  is  $0.85 \times 38.4 = 32.6 \text{ N/mm}^2$  (32.6 megapascals) in compression.

To these stresses at  $A$  and  $B$  must be added, algebraically, the direct stress at section  $AB$  due to the 4 kN clamping force. The direct stress on section  $AB$  will be a tensile stress equal to the clamping force divided by the section area. Thus,  $4000/5000 = 0.8 \text{ N/mm}^2$ . The maximum unit stress at  $A$  is, therefore,  $32.61 - 0.8 = 31.8 \text{ N/mm}^2$  (31.8 megapascals) in compression, and the maximum unit stress at  $B$  is  $46.1 + 0.8 = 46.9 \text{ N/mm}^2$  (46.9 megapascals) in tension.

**Size of Rail Necessary to Carry a Given Load.**—The following formulas may be employed for determining the size of rail and wheel suitable for carrying a given load. Let,  $A$  = the width of the head of the rail in inches;  $B$  = width of the tread of the rail in inches;  $C$  = the wheel-load in pounds;  $D$  = the diameter of the wheel in inches.

Then the width of the tread of the rail in inches is found from the formula:

$$B = \frac{C}{1250D} \quad (1)$$

The width  $A$  of the head equals  $B + \frac{5}{8}$  inch. The diameter  $D$  of the smallest track wheel that will safely carry the load is found from the formula:

$$D = \frac{C}{A \times K} \quad (2)$$

in which  $K = 600$  to  $800$  for steel castings;  $K = 300$  to  $400$  for cast iron.

As an example, assume that the wheel-load is 10,000 pounds; the diameter of the wheel is 20 inches; and the material is cast steel. Determine the size of rail necessary to carry this load. From [Formula \(1\)](#):

$$B = \frac{10,000}{1250 \times 20} = 0.4 \text{ inch}$$

The width of the rail required equals  $0.4 + \frac{5}{8}$  inch = 1.025 inch. Determine also whether a wheel 20 inches in diameter is large enough to safely carry the load. From [Formula \(2\)](#):

$$D = \frac{10,000}{1.025 \times 600} = 16\frac{1}{4} \text{ inches}$$

This is the smallest diameter of track wheel that will safely carry the load; hence a 20-inch wheel is ample.

**American Railway Engineering Association Formulas.**—The American Railway Engineering Association recommends for safe operation of steel cylinders rolling on steel plates that the allowable load  $p$  in pounds per inch of length of the cylinder should not exceed the value calculated from the formula

$$p = \frac{y.s. - 13,000}{20,000} 600d \text{ for diameter } d \text{ less than 25 inches}$$

This formula is based on steel having a yield strength, y.s., of 32,000 pounds per square inch. For roller or wheel diameters of up to 25 inches, the Hertz stress (contact stress) resulting from the calculated load  $p$  will be approximately 76,000 pounds per square inch.

For a 10-inch diameter roller the safe load per inch of roller length is

$$p = \frac{32,000 - 13,000}{20,000} 600 \times 10 = 5700 \text{ lbs per inch of length}$$

Therefore, to support a 10,000 pound load the roller or wheel would need to be  $10,000/5700 = 1.75$  inches wide.

### Stresses Produced by Shocks

**Stresses in Beams Produced by Shocks.**—Any elastic structure subjected to a shock will deflect until the product of the average resistance, developed by the deflection, and the distance through which it has been overcome, has reached a value equal to the energy of the shock. It follows that for a given shock, the average resisting stresses are inversely proportional to the deflection. If the structure were perfectly rigid, the deflection would be zero, and the stress infinite. The effect of a shock is, therefore, to a great extent dependent upon the elastic property (the springiness) of the structure subjected to the impact.

The energy of a body in motion, such as a falling body, may be spent in each of four ways:

- 1) In deforming the body struck as a whole.
- 2) In deforming the falling body as a whole.
- 3) In partial deformation of both bodies on the surface of contact (most of this energy will be transformed into heat).
- 4) Part of the energy will be taken up by the supports, if these are not perfectly rigid and inelastic.

How much energy is spent in the last three ways it is usually difficult to determine, and for this reason it is safest to figure as if the whole amount were spent as in Case 1. If a reliable judgment is possible as to what percentage of the energy is spent in other ways than the first, a corresponding fraction of the total energy can be assumed as developing stresses in the body subjected to shocks.

One investigation into the stresses produced by shocks led to the following conclusions:

- 1) A suddenly applied load will produce the same deflection, and, therefore, the same stress as a static load twice as great; and 2) The unit stress  $p$  (see formulas in [Table 1](#), "*Stresses Produced in Beams by Shocks*") for a given load producing a shock, varies directly as the square root of the modulus of elasticity  $E$ , and inversely as the square root of the length  $L$  of the beam and the area of the section.

Thus, for instance, if the sectional area of a beam is increased by four times, the unit stress will diminish only by half. This result is entirely different from those produced by static loads where the stress would vary inversely with the area, and within certain limits be practically independent of the modulus of elasticity.

In [Table 1](#), the expression for the approximate value of  $p$ , which is applicable whenever the deflection of the beam is small as compared with the total height  $h$  through which the body producing the shock is dropped, is always the same for beams supported at both ends and subjected to shock at *any* point between the supports. In the formulas all dimensions are in inches and weights in pounds.

**Table 1. Stresses Produced in Beams by Shocks**

| Method of Support and Point Struck by Falling Body | Fiber (Unit) Stress $p$ produced by Weight $Q$ Dropped Through a Distance $h$ | Approximate Value of $p$       |
|--|---|--------------------------------|
| Supported at both ends; struck in center.          | $p = \frac{QaL}{4I} \left( 1 + \sqrt{1 + \frac{96hEI}{QL^3}} \right)$         | $p = a \sqrt{\frac{6QhE}{LI}}$ |
| Fixed at one end; struck at the other.             | $p = \frac{QaL}{I} \left( 1 + \sqrt{1 + \frac{6hEI}{QL^3}} \right)$           | $p = a \sqrt{\frac{6QhE}{LI}}$ |
| Fixed at both ends; struck in center.              | $p = \frac{QaL}{8I} \left( 1 + \sqrt{1 + \frac{384hEI}{QL^3}} \right)$        | $p = a \sqrt{\frac{6QhE}{LI}}$ |

$I$  = moment of inertia of section;  $a$  = distance of extreme fiber from neutral axis;  $L$  = length of beam;  $E$  = modulus of elasticity.

If metric SI units are used,  $p$  is in newtons per square millimeter;  $Q$  is in newtons;  $E$  = modulus of elasticity in  $\text{N/mm}^2$ ;  $I$  = moment of inertia of section in millimeters<sup>4</sup>; and  $h$ ,  $a$ , and  $L$  in millimeters. Note: If  $Q$  is given in kilograms, the value referred to is mass. The weight  $Q$  of a mass  $M$  kilograms is  $Mg$  newtons, where  $g$  = approximately 9.81 meters per second<sup>2</sup>.

*Examples of How Formulas for Stresses Produced by Shocks are Derived:* The general formula from which specific formulas for shock stresses in beams, springs, and other machine and structural members are derived is:

$$p = p_s \left( 1 + \sqrt{1 + \frac{2h}{y}} \right) \quad (1)$$

In this formula,  $p$  = stress in pounds per square inch due to shock caused by impact of a moving load;  $p_s$  = stress in pounds per square inch resulting when moving load is applied statically;  $h$  = distance in inches that load falls before striking beam, spring, or other member;  $y$  = deflection, in inches, resulting from static load.

As an example of how Formula (1) may be used to obtain a formula for a specific application, suppose that the load  $W$  shown applied to the beam in Case 2 on page 261 were dropped on the beam from a height of  $h$  inches instead of being gradually applied (static loading). The maximum stress  $p_s$  due to load  $W$  for Case 2 is given as  $Wl \div 4Z$  and the maximum deflection  $y$  is given as  $Wl^3 \div 48EI$ . Substituting these values in Formula (1),

$$p = \frac{Wl}{4Z} \left( 1 + \sqrt{1 + \frac{2h}{Wl^3 \div 48EI}} \right) = \frac{Wl}{4Z} \left( 1 + \sqrt{1 + \frac{96hEI}{Wl^3}} \right) \quad (2)$$

If in Formula (2) the letter  $Q$  is used in place of  $W$  and if  $Z$ , the section modulus, is replaced by its equivalent,  $I \div$  distance  $a$  from neutral axis to extreme fiber of beam, then Formula (2) becomes the first formula given in the accompanying Table 1, *Stresses Produced in Beams by Shocks*

**Stresses in Helical Springs Produced by Shocks.**—A load suddenly applied on a spring will produce the same deflection, and, therefore, also the same unit stress, as a static load twice as great. When the load drops from a height  $h$ , the stresses are as given in the accompanying Table 2. The approximate values are applicable when the deflection is small as compared with the height  $h$ . The formulas show that the fiber stress for a given shock will be greater in a spring made from a square bar than in one made from a round bar, if the diameter of coil be the same and the side of the square bar equals the diameter of the round

bar. It is, therefore, more economical to use round stock for springs which must withstand shocks, due to the fact that the deflection for the same fiber stress for a square bar spring is smaller than that for a round bar spring, the ratio being as 4 to 5. The round bar spring is therefore capable of storing more energy than a square bar spring for the same stress.

**Table 2. Stresses Produced in Springs by Shocks**

| Form of Bar from Which Spring is Made | Fiber (Unit) Stress $f$ Produced by Weight $Q$ Dropped a Height $h$ on a Helical Spring | Approximate Value of $f$            |
|---------------------------------------|---|-------------------------------------|
| Round                                 | $f = \frac{8QD}{\pi d^3} \left( 1 + \sqrt{1 + \frac{Ghd^4}{4QD^3n}} \right)$            | $f = 1.27 \sqrt{\frac{QhG}{Dd^2n}}$ |
| Square                                | $f = \frac{9QD}{4d^3} \left( 1 + \sqrt{1 + \frac{Ghd^4}{0.9\pi QD^3n}} \right)$         | $f = 1.34 \sqrt{\frac{QhG}{Dd^2n}}$ |

$G$  = modulus of elasticity for torsion;  $d$  = diameter or side of bar;  $D$  = mean diameter of spring;  $n$  = number of coils in spring.

**Shocks from Bodies in Motion.**—The formulas given can be applied, in general, to shocks from bodies in motion. A body of weight  $W$  moving horizontally with the velocity of  $v$  feet per second, has a stored-up energy:

$$E_K = \frac{1}{2} \times \frac{Wv^2}{g} \text{ foot-pounds} \quad \text{or} \quad \frac{6Wv^2}{g} \text{ inch-pounds}$$

This expression may be substituted for  $Qh$  in the tables in the equations for unit stresses containing this quantity, and the stresses produced by the energy of the moving body thereby determined.

The formulas in the tables give the maximum value of the stresses, providing the designer with some definitive guidance even where there may be justification for assuming that only a part of the energy of the shock is taken up by the member under stress.

**The formulas can also be applied using metric SI units. The stored-up energy of a body of mass  $M$  kilograms moving horizontally with the velocity of  $v$  meters per second is:**

$$E_K = \frac{1}{2}Mv^2 \text{ newton-meters}$$

**This expression may be substituted for  $Qh$  in the appropriate equations in the tables. For calculation in millimeters,  $Qh = 1000 E_K$  newton-millimeters.**

**Fatigue Stresses.**—So-called "fatigue ruptures" occur in parts that are subjected to continually repeated shocks or stresses of small magnitude. Machine parts that are subjected to continual stresses in varying directions, or to repeated shocks, even if of comparatively small magnitude, may fail ultimately if designed, from a mere knowledge of the behavior of the material under a steady stress, such as is imposed upon it by ordinary tensile stress testing machines. Examinations of numerous cases of machine parts, broken under actual working conditions, indicate that at least 80 per cent of these ruptures are caused by fatigue stresses. Most fatigue ruptures are caused by bending stresses, and frequently by a revolving bending stress. Hence, to test materials for this class of stress, the tests should be made to stress the material in a manner similar to that in which it will be stressed under actual working conditions. See *Fatigue Properties* on page 205 for more on this topic.

## COLUMNS

## Strength of Columns or Struts

Structural members which are subject to compression may be so long in proportion to the diameter or lateral dimensions that failure may be the result 1) of both compression and bending; and 2) of bending or buckling to such a degree that compression stress may be ignored.

In such cases, the *slenderness ratio* is important. This ratio equals the length  $l$  of the column in inches divided by the least radius of gyration  $r$  of the cross-section. Various formulas have been used for designing columns which are too slender to be designed for compression only.

**Rankine or Gordon Formula.**—This formula is generally applied when slenderness ratios range between 20 and 100, and sometimes for ratios up to 120. The notation, in English and metric SI units of measurement, is given on page 287.

$$p = \frac{S}{1 + K\left(\frac{l}{r}\right)^2} = \text{ultimate load, lbs. per sq. in.}$$

Factor  $K$  may be established by tests with a given material and end condition, and for the probable range of  $l/r$ . If determined by calculation,  $K = S/C\pi^2E$ . Factor  $C$  equals 1 for either rounded or pivoted column ends, 4 for fixed ends, and 1 to 4 for square flat ends. The factors 25,000, 12,500, etc., in the Rankine formulas, arranged as on page 287, equal  $1/K$ , and have been used extensively.

**Straight-line Formula.**—This general type of formula is often used in designing compression members for buildings, bridges, or similar structural work. It is convenient especially in designing a number of columns that are made of the same material but vary in size, assuming that factor  $B$  is known. This factor is determined by tests.

$$p = S_y - B\left(\frac{l}{r}\right) = \text{ultimate load, lbs. per sq. in.}$$

$S_y$  equals yield point, lbs. per square inch, and factor  $B$  ranges from 50 to 100. Safe unit stress =  $p \div$  factor of safety.

**Formulas of American Railway Engineering Association.**—The formulas that follow apply to structural steel having an ultimate strength of 60,000 to 72,000 pounds per square inch.

For building columns having  $l/r$  ratios not greater than 120, allowable unit stress =  $17,000 - 0.485 l^2/r^2$ . For columns having  $l/r$  ratios greater than 120, allowable unit stress

$$\text{allowable unit stress} = \frac{18,000}{1 + l^2/18,000r^2}$$

For bridge compression members centrally loaded and with values of  $l/r$  not greater than 140:

$$\text{Allowable unit stress, riveted ends} = 15,000 - \frac{1}{4} \frac{l^2}{r^2}$$

$$\text{Allowable unit stress, pin ends} = 15,000 - \frac{1}{3} \frac{l^2}{r^2}$$

**Euler Formula.**—This formula is for columns that are so slender that bending or buckling action predominates and compressive stresses are not taken into account.

$$P = \frac{C\pi^2IE}{l^2} = \text{total ultimate load, in pounds}$$

The notation, in English and metric SI units of measurement, is given in the table *Rankine's and Euler's Formulas for Columns* on page 287. Factors  $C$  for different end conditions are included in the Euler formulas at the bottom of the table. According to a series of experiments, Euler formulas should be used if the values of  $l/r$  exceed the following ratios: Structural steel and flat ends, 195; hinged ends, 155; round ends, 120; cast iron with flat ends, 120; hinged ends, 100; round ends, 75; oak with flat ends, 130. The *critical slenderness ratio*, which marks the dividing line between the shorter columns and those slender enough to warrant using the Euler formula, depends upon the column material and its end conditions. If the Euler formula is applied when the slenderness ratio is too small, the *calculated* ultimate strength will exceed the yield point of the material and, obviously, will be incorrect.

**Eccentrically Loaded Columns.**—In the application of the column formulas previously referred to, it is assumed that the action of the load coincides with the axis of the column. If the load is offset relative to the column axis, the column is said to be eccentrically loaded, and its strength is then calculated by using a modification of the Rankine formula, the quantity  $cz/r^2$  being added to the denominator, as shown in the table on the next page. This modified formula is applicable to columns having a slenderness ratio varying from 20 or 30 to about 100.

**Machine Elements Subjected to Compressive Loads.**—As in structural compression members, an unbraced machine member that is relatively slender (i.e., its length is more than, say, six times the least dimension perpendicular to its longitudinal axis) is usually designed as a column, because failure due to overloading (assuming a compressive load centrally applied in an axial direction) may occur by buckling or a combination of buckling and compression rather than by direct compression alone. In the design of unbraced steel machine “columns” which are to carry compressive loads applied along their longitudinal axes, two formulas are in general use:

$$\text{(Euler)} \quad P_{cr} = \frac{S_y A r^2}{Q} \quad (1)$$

$$\text{(J. B. Johnson)} \quad P_{cr} = A S_y \left( 1 - \frac{Q}{4r^2} \right) \quad (2) \quad \text{where} \quad Q = \frac{S_y l^2}{n \pi^2 E} \quad (3)$$

In these formulas,  $P_{cr}$  = critical load in pounds that would result in failure of the column;  $A$  = cross-sectional area, square inches;  $S_y$  = yield point of material, pounds per square inch;  $r$  = least radius of gyration of cross-section, inches;  $E$  = modulus of elasticity, pounds per square inch;  $l$  = column length, inches; and  $n$  = coefficient for end conditions. For both ends fixed,  $n = 4$ ; for one end fixed, one end free,  $n = 0.25$ ; for one end fixed and the other end free but guided,  $n = 2$ ; for round or pinned ends, free but guided,  $n = 1$ ; and for flat ends,  $n = 1$  to 4. It should be noted that these values of  $n$  represent ideal conditions that are seldom attained in practice; for example, for both ends fixed, a value of  $n = 3$  to 3.5 may be more realistic than  $n = 4$ .

If metric SI units are used in these formulas,  $P_{cr}$  = critical load in newtons that would result in failure of the column;  $A$  = cross-sectional area, square millimeters;  $S_y$  = yield point of the material, newtons per square mm;  $r$  = least radius of gyration of cross-section, mm;  $E$  = modulus of elasticity, newtons per square mm;  $l$  = column length, mm; and  $n$  = a coefficient for end conditions. The coefficients given are valid for calculations in metric units.

**Rankine's and Euler's Formulas for Columns**

| Symbol | Quantity  | English Unit        | Metric SI Units          |
|--------|---|---------------------|--------------------------|
| $p$    | Ultimate unit load  | Lbs./sq. in.        | Newtons/sq. mm.          |
| $P$    | Total ultimate load   | Pounds              | Newtons                  |
| $S$    | Ultimate compressive strength of material   | Lbs./sq. in.        | Newtons/sq. mm.          |
| $l$    | Length of column or strut   | Inches              | Millimeters              |
| $r$    | Least radius of gyration  | Inches              | Millimeters              |
| $I$    | Least moment of inertia   | Inches <sup>4</sup> | Millimeters <sup>4</sup> |
| $r^2$  | Moment of inertia/area of section   | Inches <sup>2</sup> | Millimeters <sup>2</sup> |
| $E$    | Modulus of elasticity of material   | Lbs./sq. in.        | Newtons/sq. mm.          |
| $c$    | Distance from neutral axis of cross-section to side under compression                 | Inches              | Millimeters              |
| $z$    | Distance from axis of load to axis coinciding with center of gravity of cross-section | Inches              | Millimeters              |

**Rankine's Formulas**

| Material     | Both Ends of Column Fixed                 | One End Fixed and One End Rounded         | Both Ends Rounded                       |
|--------------|---|---|---|
| Steel        | $p = \frac{S}{1 + \frac{l^2}{25,000r^2}}$ | $p = \frac{S}{1 + \frac{l^2}{12,500r^2}}$ | $p = \frac{S}{1 + \frac{l^2}{6250r^2}}$ |
| Cast Iron    | $p = \frac{S}{1 + \frac{l^2}{5000r^2}}$   | $p = \frac{S}{1 + \frac{l^2}{2500r^2}}$   | $p = \frac{S}{1 + \frac{l^2}{1250r^2}}$ |
| Wrought Iron | $p = \frac{S}{1 + \frac{l^2}{35,000r^2}}$ | $p = \frac{S}{1 + \frac{l^2}{17,500r^2}}$ | $p = \frac{S}{1 + \frac{l^2}{8750r^2}}$ |
| Timber       | $p = \frac{S}{1 + \frac{l^2}{3000r^2}}$   | $p = \frac{S}{1 + \frac{l^2}{1500r^2}}$   | $p = \frac{S}{1 + \frac{l^2}{750r^2}}$  |

**Formulas Modified for Eccentrically Loaded Columns**

| Material | Both Ends of Column Fixed                                  | One End Fixed and One End Rounded                          | Both Ends Rounded  |
|----------|--|--|--|
| Steel    | $p = \frac{S}{1 + \frac{l^2}{25,000r^2} + \frac{cz}{r^2}}$ | $p = \frac{S}{1 + \frac{l^2}{12,500r^2} + \frac{cz}{r^2}}$ | $p = \frac{S}{1 + \frac{l^2}{6250r^2} + \frac{cz}{r^2}}$ |

For materials other than steel, such as cast iron, use the Rankine formulas given in the upper table and add to the denominator the quantity  $cz/r^2$

**Euler's Formulas for Slender Columns**

| Both Ends of Column Fixed  | One End Fixed and One End Rounded | Both Ends Rounded         | One End Fixed and One End Free |
|----------------------------|-----------------------------------|---------------------------|--------------------------------|
| $P = \frac{4\pi^2IE}{l^2}$ | $P = \frac{2\pi^2IE}{l^2}$        | $P = \frac{\pi^2IE}{l^2}$ | $P = \frac{\pi^2IE}{4l^2}$     |

*Allowable Working Loads for Columns:* To find the total allowable working load for a given section, divide the total ultimate load  $P$  (or  $p \times$  area), as found by the appropriate formula above, by a suitable factor of safety.

*Factor of Safety for Machine Columns:* When the conditions of loading and the physical qualities of the material used are accurately known, a factor of safety as low as 1.25 is sometimes used when minimum weight is important. Usually, however, a factor of safety of 2 to 2.5 is applied for steady loads. The factor of safety represents the ratio of the critical load  $P_{cr}$  to the working load.

*Application of Euler and Johnson Formulas:* To determine whether the Euler or Johnson formula is applicable in any particular case, it is necessary to determine the value of the quantity  $Q \div r^2$ . If  $Q \div r^2$  is greater than 2, then the Euler Formula (1) should be used; if  $Q \div r^2$  is less than 2, then the J. B. Johnson formula is applicable. Most compression members in machine design are in the range of proportions covered by the Johnson formula. For this reason a good procedure is to design machine elements on the basis of the Johnson formula and then as a check calculate  $Q \div r^2$  to determine whether the Johnson formula applies or the Euler formula should have been used.

*Example 1, Compression Member Design:* A rectangular machine member 24 inches long and  $\frac{1}{2} \times 1$  inch in cross-section is to carry a compressive load of 4000 pounds along its axis. What is the factor of safety for this load if the material is machinery steel having a yield point of 40,000 pounds per square inch, the load is steady, and each end of the rod has a ball connection so that  $n = 1$ ?

From Formula (3)

$$Q = \frac{40,000 \times 24 \times 24}{1 \times 3.1416 \times 3.1416 \times 30,000,000} = 0.0778$$

(The values 40,000 and 30,000,000 were obtained from the table *Strength Data for Iron and Steel* on page 474.)

The radius of gyration  $r$  for a rectangular section (page 239) is  $0.289 \times$  the dimension in the direction of bending. In columns, bending is most apt to occur in the direction in which the section is the weakest, the  $\frac{1}{2}$ -inch dimension in this example. Hence, least radius of gyration  $r = 0.289 \times \frac{1}{2} = 0.145$  inch.

$$\frac{Q}{r^2} = \frac{0.0778}{(0.145)^2} = 3.70$$

which is more than 2 so that the Euler formula will be used.

$$P_{cr} = \frac{s_y A r^2}{Q} = \frac{40,000 \times \frac{1}{2} \times 1}{3.70}$$

$$= 5400 \text{ pounds so that the factor of safety is } 5400 \div 4000 = 1.35$$

*Example 2, Compression Member Design:* In the preceding example, the column formulas were used to check the adequacy of a column of known dimensions. The more usual problem involves determining what the dimensions should be to resist a specified load. For example,:

A 24-inch long bar of rectangular cross-section with width  $w$  twice its depth  $d$  is to carry a load of 4000 pounds. What must the width and depth be if a factor of safety of 1.35 is to be used?

First determine the critical load  $P_{cr}$ :

$$\begin{aligned} P_{cr} &= \text{working load} \times \text{factor of safety} \\ &= 4000 \times 1.35 = 5400 \text{ pounds} \end{aligned}$$

Next determine  $Q$  which, as in [Example 1](#), will be 0.0778.

Assume [Formula \(2\)](#) applies:

$$P_{cr} = A s_y \left( 1 - \frac{Q}{4r^2} \right)$$

$$5400 = w \times d \times 40,000 \left( 1 - \frac{0.0778}{4r^2} \right)$$

$$= 2d^2 \times 40,000 \left( 1 - \frac{0.01945}{r^2} \right)$$

$$\frac{5400}{40,000 \times 2} = d^2 \left( 1 - \frac{0.01945}{r^2} \right)$$

As mentioned in [Example 1](#) the least radius of gyration  $r$  of a rectangle is equal to 0.289 times the least dimension,  $d$ , in this case. Therefore, substituting for  $d$  the value  $r \div 0.289$ ,

$$\frac{5400}{40,000 \times 2} = \left( \frac{r}{0.289} \right)^2 \left( 1 - \frac{0.01945}{r^2} \right)$$

$$\frac{5400 \times 0.289 \times 0.289}{40,000 \times 2} = r^2 - 0.01945$$

$$0.005638 = r^2 - 0.01945$$

$$r^2 = 0.0251$$

Checking to determine if  $Q \div r^2$  is greater or less than 2,

$$\frac{Q}{r^2} = \frac{0.0778}{0.0251} = 3.1$$

therefore [Formula \(1\)](#) should have been used to determine  $r$  and dimensions  $w$  and  $d$ . Using [Formula \(1\)](#),

$$5400 = \frac{40,000 \times 2d^2 \times r^2}{Q} = \frac{40,000 \times 2 \times \left( \frac{r}{0.289} \right)^2 r^2}{0.0778}$$

$$r^4 = \frac{5400 \times 0.0778 \times 0.289 \times 0.289}{40,000 \times 2} = 0.0004386$$

$$d = \frac{0.145}{0.289} = 0.50 \text{ inch}$$

and  $w = 2d = 1$  inch as in the previous example.

**American Institute of Steel Construction.**—For main or secondary compression members with  $l/r$  ratios up to 120, safe unit stress =  $17,000 - 0.485l^2/r^2$ . For columns and bracing or other secondary members with  $l/r$  ratios above 120,

Safe unit stress, psi =  $\frac{18,000}{1 + l^2/18,000r^2}$  for bracing and secondary members. For main

members, safe unit stress, psi =  $\frac{18,000}{1 + l^2/18,000r^2} \times \left( 1.6 - \frac{l/r}{200} \right)$

*Pipe Columns:* Allowable concentric loads for steel pipe columns based on the above formulas are given in the table on page [290](#).

## Allowable Concentric Loads for Steel Pipe Columns

| STANDARD STEEL PIPE                      |   |       |       |       |       |       |       |       |
|--|---|-------|-------|-------|-------|-------|-------|-------|
| Nominal Diameter, Inches                 | 12  | 10    | 8     | 6     | 5     | 4     | 3½    | 3     |
| Wall Thickness, Inch                     | 0.375   | 0.365 | 0.322 | 0.280 | 0.258 | 0.237 | 0.226 | 0.216 |
| Weight per Foot, Pounds                  | 49.56   | 40.48 | 28.55 | 18.97 | 14.62 | 10.79 | 9.11  | 7.58  |
| Effective Length (KL), Feet <sup>a</sup> | Allowable Concentric Loads in Thousands of Pounds |       |       |       |       |       |       |       |
| 6  | 303   | 246   | 171   | 110   | 83    | 59    | 48    | 38    |
| 7  | 301   | 243   | 168   | 108   | 81    | 57    | 46    | 36    |

<sup>a</sup> With respect to radius of gyration. The effective length (KL) is the actual unbraced length, L, in feet, multiplied by the effective length factor (K) which is dependent upon the restraint at the ends of the unbraced length and the means available to resist lateral movements. K may be determined by referring to the last portion of this table.

**Allowable Concentric Loads for Steel Pipe Columns (Continued)**

Load tables are given for 36 ksi yield stress steel. No load values are given below the heavy horizontal lines, because the  $Kl/r$  ratios (where  $l$  is the actual unbraced length in inches and  $r$  is the governing radius of gyration in inches) would exceed 200.

## PLATES, SHELLS, AND CYLINDERS

**Flat Stayed Surfaces.**—Large flat areas are often held against pressure by stays distributed at regular intervals over the surface. In boiler work, these stays are usually screwed into the plate and the projecting end riveted over to insure steam tightness. The U.S. Board of Supervising Inspectors and the American Boiler Makers Association rules give the following formula for flat stayed surfaces:

$$P = \frac{C \times t^2}{S^2}$$

in which  $P$  = pressure in pounds per square inch

$C$  = a constant, which equals

112 for plates  $\frac{7}{16}$  inch and under

120, for plates over  $\frac{7}{16}$  inch thick

140, for plates with stays having a nut and bolt on the inside and outside

160, for plates with stays having washers of at least one-half the thickness of the plate, and with a diameter at least one-half of the greatest pitch

$t$  = thickness of plate in 16ths of an inch (thickness =  $\frac{7}{16}$ ,  $t = 7$ )

$S$  = greatest pitch of stays in inches

**Strength and Deflection of Flat Plates.**—Generally, the formulas used to determine stresses and deflections in flat plates are based on certain assumptions that can be closely approximated in practice. These assumptions are:

- 1) the thickness of the plate is not greater than one-quarter the least width of the plate;
- 2) the greatest deflection when the plate is loaded is less than one-half the plate thickness;
- 3) the maximum tensile stress resulting from the load does not exceed the elastic limit of the material; and
- 4) all loads are perpendicular to the plane of the plate.

Plates of ductile materials fail when the maximum stress resulting from deflection under load exceeds the yield strength; for brittle materials, failure occurs when the maximum stress reaches the ultimate tensile strength of the material involved.

**Square and Rectangular Flat Plates.**—The formulas that follow give the maximum stress and deflection of flat steel plates supported in various ways and subjected to the loading indicated. These formulas are based upon a modulus of elasticity for steel of 30,000,000 pounds per square inch and a value of Poisson's ratio of 0.3. If the formulas for maximum stress,  $S$ , are applied without modification to other materials such as cast iron, aluminum, and brass for which the range of Poisson's ratio is about 0.26 to 0.34, the maximum stress calculations will be in error by not more than about 3 per cent. The deflection formulas may also be applied to materials other than steel by substituting in these formulas the appropriate value for  $E$ , the modulus of elasticity of the material (see pages 474 and 554). The deflections thus obtained will not be in error by more than about 3 per cent.

In the stress and deflection formulas that follow,

$p$  = uniformly distributed load acting on plate, pounds per square inch

$W$  = total load on plate, pounds;  $W = p \times$  area of plate

$L$  = distance between supports (length of plate), inches. For rectangular plates,  $L$  = long side,  $l$  = short side

$t$  = thickness of plate, inches

$S$  = maximum tensile stress in plate, pounds per square inch

$d$  = maximum deflection of plate, inches

$E$  = modulus of elasticity in tension.  $E = 30,000,000$  pounds per square inch for steel

If metric SI units are used in the formulas, then,

$W$  = total load on plate, newtons

$L$  = distance between supports (length of plate), millimeters. For rectangular plates,  $L$  = long side,  $l$  = short side

$t$  = thickness of plate, millimeters

$S$  = maximum tensile stress in plate, newtons per mm squared

$d$  = maximum deflection of plate, mm

$E$  = modulus of elasticity, newtons per mm squared

a) Square flat plate supported at top and bottom of all four edges and a uniformly distributed load over the surface of the plate.

$$S = \frac{0.29 W}{t^2} \quad (1)$$

$$d = \frac{0.0443 WL^2}{Et^3} \quad (2)$$

b) Square flat plate supported at the bottom only of all four edges and a uniformly distributed load over the surface of the plate.

$$S = \frac{0.28 W}{t^2} \quad (3)$$

$$d = \frac{0.0443 WL^2}{Et^3} \quad (4)$$

c) Square flat plate with all edges firmly fixed and a uniformly distributed load over the surface of the plate.

$$S = \frac{0.31 W}{t^2} \quad (5)$$

$$d = \frac{0.0138 WL^2}{Et^3} \quad (6)$$

d) Square flat plate with all edges firmly fixed and a uniform load over small circular area at the center. In Equations (7) and (9),  $r_0$  = radius of area to which load is applied. If  $r_0 < 1.7t$ , use  $r_s$  where  $r_s = \sqrt{1.6r_0^2 + t^2} - 0.675t$ .

$$S = \frac{0.62 W}{t^2} \log_e \left( \frac{L}{2r_0} \right) \quad (7)$$

$$d = \frac{0.0568 WL^2}{Et^3} \quad (8)$$

e) Square flat plate with all edges supported above and below, or below only, and a concentrated load at the center. (See Case 4, above, for definition of  $r_0$ ).

$$S = \frac{0.62 W}{t^2} \left[ \log_e \left( \frac{L}{2r_0} \right) + 0.577 \right] \quad (9)$$

$$d = \frac{0.1266 WL^2}{Et^3} \quad (10)$$

f) Rectangular plate with all edges supported at top and bottom and a uniformly distributed load over the surface of the plate.

$$S = \frac{0.75 W}{t^2 \left( \frac{L}{l} + 1.61 \frac{l^2}{L^2} \right)} \quad (11)$$

$$d = \frac{0.1422 W}{Et^3 \left( \frac{L}{l^3} + \frac{2.21}{L^2} \right)} \quad (12)$$

g) Rectangular plate with all edges fixed and a uniformly distributed load over the surface of the plate.

$$S = \frac{0.5 W}{t^2 \left( \frac{L}{l} + \frac{0.623 l^5}{L^5} \right)} \quad (13)$$

$$d = \frac{0.0284 W}{Et^3 \left( \frac{L}{l^3} + \frac{1.056 l^2}{L^4} \right)} \quad (14)$$

**Circular Flat Plates.**—In the following formulas,  $R$  = radius of plate to supporting edge in inches;  $W$  = total load in pounds; and other symbols are the same as used for square and rectangular plates.

**If metric SI units are used,  $R$  = radius of plate to supporting edge in millimeters, and the values of other symbols are the same as those used for square and rectangular plates.**

a) Edge supported around the circumference and a uniformly distributed load over the surface of the plate.

$$S = \frac{0.39W}{t^2} \quad (15) \quad d = \frac{0.221WR^2}{Et^3} \quad (16)$$

b) Edge fixed around circumference and a uniformly distributed load over the surface of the plate.

$$S = \frac{0.24W}{t^2} \quad (17) \quad d = \frac{0.0543WR^2}{Et^3} \quad (18)$$

c) Edge supported around the circumference and a concentrated load at the center.

$$S = \frac{0.48W}{t^2} \left[ 1 + 1.3 \log_e \frac{R}{0.325t} - 0.0185 \frac{t^2}{R^2} \right] \quad (19) \quad d = \frac{0.55WR^2}{Et^3} \quad (20)$$

d) Edge fixed around circumference and a concentrated load at the center.

$$S = \frac{0.62W}{t^2} \left[ \log_e \frac{R}{0.325t} + 0.0264 \frac{t^2}{R^2} \right] \quad (21) \quad d = \frac{0.22WR^2}{Et^3} \quad (22)$$

**Strength of Cylinders Subjected to Internal Pressure.**—In designing a cylinder to withstand internal pressure, the choice of formula to be used depends on 1) the kind of material of which the cylinder is made (whether brittle or ductile); 2) the construction of the cylinder ends (whether open or closed); and 3) whether the cylinder is classed as a thin- or a thick-walled cylinder.

A cylinder is considered to be thin-walled when the ratio of wall thickness to inside diameter is 0.1 or less and thick-walled when this ratio is greater than 0.1. Materials such as cast iron, hard steel, cast aluminum are considered to be brittle materials; low-carbon steel, brass, bronze, etc. are considered to be ductile.

In the formulas that follow,  $p$  = internal pressure, pounds per square inch;  $D$  = inside diameter of cylinder, inches;  $t$  = wall thickness of cylinder, inches;  $\mu$  = Poisson's ratio, = 0.3 for steel, 0.26 for cast iron, 0.34 for aluminum and brass; and  $S$  = allowable tensile stress, pounds per square inch.

**Metric SI units can be used in Formulas (23), (25), (26), and (27), where  $p$  = internal pressure in newtons per square millimeter;  $D$  = inside diameter of cylinder, millimeters;  $t$  = wall thickness, mm;  $\mu$  = Poisson's ratio, = 0.3 for steel, 0.26 for cast iron, and 0.34 for aluminum and brass; and  $S$  = allowable tensile stress, N/mm<sup>2</sup>. For the use of metric SI units in Formula (24), see below.**

*Thin-walled Cylinders:* 
$$t = \frac{Dp}{2S} \quad (23)$$

For low-pressure cylinders of cast iron such as are used for certain engine and press applications, a formula in common use is

$$t = \frac{Dp}{2500} + 0.3 \quad (24)$$

This formula is based on allowable stress of 1250 pounds per square inch and will give a wall thickness 0.3 inch greater than [Formula \(23\)](#) to allow for variations in metal thickness that may result from the casting process.

**If metric SI units are used in [Formula \(24\)](#),  $t$  = cylinder wall thickness in millimeters;  $D$  = inside diameter of cylinder, mm; and the allowable stress is in newtons per square millimeter. The value of 0.3 inches additional wall thickness is 7.62 mm, and the next highest number in preferred metric basic sizes is 8 mm.**

*Thick-walled Cylinders of Brittle Material, Ends Open or Closed:* Lamé's equation is used when cylinders of this type are subjected to internal pressure.

$$t = \frac{D}{2} \left( \sqrt{\frac{S+p}{S-p}} - 1 \right) \quad (25)$$

The table *Ratio of Outside Radius to Inside Radius, Thick Cylinders* on page 296 is for convenience in calculating the dimensions of cylinders under high internal pressure without the use of [Formula \(25\)](#).

*Example, Use of the Table:* Assume that a cylinder of 10 inches inside diameter is to withstand a pressure of 2500 pounds per square inch; the material is cast iron and the allowable stress is 6000 pounds per square inch. To solve the problem, locate the allowable stress per square inch in the left-hand column of the table and the working pressure at the top of the columns. Then find the ratio between the outside and inside radii in the body of the table. In this example, the ratio is 1.558, and hence the outside diameter of the cylinder should be  $10 \times 1.558$ , or about 15½ inches. The thickness of the cylinder wall will therefore be  $(15.558 - 10)/2 = 2.779$  inches.

Unless very high-grade material is used and sound castings assured, cast iron should not be used for pressures exceeding 2000 pounds per square inch. It is well to leave more metal in the bottom of a hydraulic cylinder than is indicated by the results of calculations, because a hole of some size must be cored in the bottom to permit the entrance of a boring bar when finishing the cylinder, and when this hole is subsequently tapped and plugged it often gives trouble if there is too little thickness.

For steady or gradually applied stresses, the maximum allowable fiber stress  $S$  may be assumed to be from 3500 to 4000 pounds per square inch for cast iron; from 6000 to 7000 pounds per square inch for brass; and 12,000 pounds per square inch for steel castings. For intermittent stresses, such as in cylinders for steam and hydraulic work, 3000 pounds per square inch for cast iron; 5000 pounds per square inch for brass; and 10,000 pounds per square inch for steel castings, is ordinarily used. These values give ample factors of safety.

**Note: In metric SI units, 1000 pounds per square inch equals 6.895 newtons per square millimeter.**

*Thick-walled Cylinders of Ductile Material, Closed Ends:* Clavarino's equation is used:

$$t = \frac{D}{2} \left[ \sqrt{\frac{S + (1 - 2\mu)p}{S - (1 + \mu)p}} - 1 \right] \quad (26)$$

*Thick-walled Cylinders of Ductile Material, Open Ends:* Birnie's equation is used:

$$t = \frac{D}{2} \left[ \sqrt{\frac{S + (1 - \mu)p}{S - (1 + \mu)p}} - 1 \right] \quad (27)$$

**Spherical Shells Subjected to Internal Pressure.—Let:**

$D$  = internal diameter of shell in inches

$p$  = internal pressure in pounds per square inch

$S$  = safe tensile stress per square inch

$t$  = thickness of metal in the shell, in inches.

**Ratio of Outside Radius to Inside Radius, Thick Cylinders**

| Allowable Stress in Metal per Sq. In. of Section | Working Pressure in Cylinder, Pounds per Square Inch |       |       |       |       |       |       |
|--|--|-------|-------|-------|-------|-------|-------|

| 10,500   | ...  | 1.212 | 1.341 | 1.493 | 1.678 | 1.915 | 2.236 |
| 11,000   | ...  | 1.201 | 1.322 | 1.464 | 1.633 | 1.844 | 2.121 |
| 11,500   | ...  | 1.193 | 1.306 | 1.437 | 1.593 | 1.784 | 2.027 |
| 12,000   | ...  | 1.183 | 1.291 | 1.414 | 1.558 | 1.732 | 1.949 |
| 12,500   | ...  | ...   | 1.277 | 1.393 | 1.527 | 1.687 | 1.878 |
| 13,000   | ...  | ...   | 1.264 | 1.374 | 1.500 | 1.647 | 1.825 |
| 13,500   | ...  | ...   | 1.253 | 1.357 | 1.475 | 1.612 | 1.775 |
| 14,000   | ...  | ...   | 1.243 | 1.341 | 1.453 | 1.581 | 1.732 |
| 14,500   | ...  | ...   | 1.233 | 1.327 | 1.432 | 1.553 | 1.693 |
| 15,000   | ...  | ...   | 1.224 | 1.314 | 1.414 | 1.527 | 1.658 |
| 16,000   | ...  | ...   | 1.209 | 1.291 | 1.381 | 1.483 | 1.599 |

$$\text{Then, } t = \frac{pD}{4S}$$

This formula also applies to hemi-spherical shells, such as the hemi-spherical head of a cylindrical container subjected to internal pressure, etc.

**If metric SI units are used, then:**

$D$  = internal diameter of shell in millimeters

$p$  = internal pressure in newtons per square millimeter

$S$  = safe tensile stress in newtons per square millimeter

$t$  = thickness of metal in the shell in millimeters

**Meters can be used in the formula in place of millimeters, providing the treatment is consistent throughout.**

*Example:* Find the thickness of metal required in the hemi-spherical end of a cylindrical vessel, 2 feet in diameter, subjected to an internal pressure of 500 pounds per square inch. The material is mild steel and a tensile stress of 10,000 pounds per square inch is allowable.

$$t = \frac{500 \times 2 \times 12}{4 \times 10,000} = 0.3 \text{ inch}$$

**A similar example using metric SI units is as follows: find the thickness of metal required in the hemi-spherical end of a cylindrical vessel, 750 mm in diameter, subjected to an internal pressure of 3 newtons/mm<sup>2</sup>. The material is mild steel and a tensile stress of 70 newtons/mm<sup>2</sup> is allowable.**

$$t = \frac{3 \times 750}{4 \times 70} = 8.04 \text{ mm}$$

If the radius of curvature of the domed head of a boiler or container subjected to internal pressure is made equal to the diameter of the boiler, the thickness of the cylindrical shell and of the spherical head should be made the same. For example, if a boiler is 3 feet in diameter, the radius of curvature of its head should also be 3 feet, if material of the same thickness is to be used and the stresses are to be equal in both the head and cylindrical portion.

**Collapsing Pressure of Cylinders and Tubes Subjected to External Pressures.**—The following formulas may be used for finding the collapsing pressures of lap-welded Bessemer steel tubes:

$$P = 86,670 \frac{t}{D} - 1386 \quad (28)$$

$$P = 50,210,000 \left( \frac{t}{D} \right)^3 \quad (29)$$

in which  $P$  = collapsing pressure in pounds per square inch;  $D$  = outside diameter of tube or cylinder in inches;  $t$  = thickness of wall in inches.

**Formula (28)** is for values of  $P$  greater than 580 pounds per square inch, and **Formula (29)** is for values of  $P$  less than 580 pounds per square inch. These formulas are substantially correct for all lengths of pipe greater than six diameters between transverse joints that tend to hold the pipe to a circular form. The pressure  $P$  found is the actual collapsing pressure, and a suitable factor of safety must be used. Ordinarily, a factor of safety of 5 is sufficient. In cases where there are repeated fluctuations of the pressure, vibration, shocks and other stresses, a factor of safety of from 6 to 12 should be used.

**If metric SI units are used the formulas are:**

$$P = 597.6 \frac{t}{D} - 9.556 \quad (30)$$

$$P = 346,200 \left( \frac{t}{D} \right)^3 \quad (31)$$

where  $P$  = collapsing pressure in newtons per square millimeter;  $D$  = outside diameter of tube or cylinder in millimeters; and  $t$  = thickness of wall in millimeters. **Formula (30)** is for values of  $P$  greater than 4 N/mm<sup>2</sup>, and **Formula (31)** is for values of  $P$  less than 4 N/mm<sup>2</sup>.

The table *Tubes Subjected to External Pressure* is based upon the requirements of the Steam Boat Inspection Service of the Department of Commerce and Labor and gives the permissible working pressures and corresponding minimum wall thickness for long, plain, lap-welded and seamless steel flues subjected to external pressure only. The table thicknesses have been calculated from the formula:

$$t = \frac{[(F \times p) + 1386]D}{86,670}$$

in which  $D$  = outside diameter of flue or tube in inches;  $t$  = thickness of wall in inches;  $p$  = working pressure in pounds per square inch;  $F$  = factor of safety. The formula is applicable to working pressures greater than 100 pounds per square inch, to outside diameters from 7 to 18 inches, and to temperatures less than 650°F.

The preceding [Formulas \(28\) and \(29\)](#) were determined by Prof. R. T. Stewart, Dean of the Mechanical Engineering Department of the University of Pittsburgh, in a series of experiments carried out at the plant of the National Tube Co., McKeesport, Pa.

The apparent fiber stress under which the different tubes failed varied from about 7000 pounds per square inch for the relatively thinnest to 35,000 pounds per square inch for the relatively thickest walls. The average yield point of the material tested was 37,000 pounds and the tensile strength 58,000 pounds per square inch, so it is evident that the strength of a tube subjected to external fluid collapsing pressure is not dependent alone upon the elastic limit or ultimate strength of the material from which it is made.

### Tubes Subjected to External Pressure

| Outside Diameter of Tube, Inches | Working Pressure in Pounds per Square Inch    |       |       |       |       |       |       |
|----------------------------------|---|-------|-------|-------|-------|-------|-------|
|                                  | 100   | 120   | 140   | 160   | 180   | 200   | 220   |
|                                  | Thickness of Tube in Inches. Safety Factor, 5 |       |       |       |       |       |       |
| 7                                | 0.152   | 0.160 | 0.168 | 0.177 | 0.185 | 0.193 | 0.201 |

## SHAFTS

## Shaft Calculations

**Torsional Strength of Shafting.**—In the formulas that follow,

$\alpha$  = angular deflection of shaft in degrees

$c$  = distance from center of gravity to extreme fiber

$D$  = diameter of shaft in inches

$G$  = torsional modulus of elasticity = 11,500,000 pounds per square inch for steel

$J$  = polar moment of inertia of shaft cross-section (see table)

$l$  = length of shaft in inches

$N$  = angular velocity of shaft in revolutions per minute

$P$  = power transmitted in horsepower

$S_s$  = allowable torsional shearing stress in pounds per square inch

$T$  = torsional or twisting moment in inch-pounds

$Z_p$  = polar section modulus (see table page 249)

The allowable twisting moment for a shaft of any cross-section such as circular, square, etc., is:

$$T = S_s \times Z_p \quad (1)$$

For a shaft delivering  $P$  horsepower at  $N$  revolutions per minute the twisting moment  $T$  being transmitted is:

$$T = \frac{63,000P}{N} \quad (2)$$

The twisting moment  $T$  as determined by this formula should be less than the value determined by using [Formula \(7\)](#) if the maximum allowable stress  $S_s$  is not to be exceeded.

The diameter of a solid circular shaft required to transmit a given torque  $T$  is:

$$D = \sqrt[3]{\frac{5.1T}{S_s}} \quad (3a) \quad \text{or} \quad D = \sqrt[3]{\frac{321,000P}{NS_s}} \quad (3b)$$

The allowable stresses that are generally used in practice are: 4000 pounds per square inch for main power-transmitting shafts; 6000 pounds per square inch for lineshafts carrying pulleys; and 8500 pounds per square inch for small, short shafts, countershafts, etc. Using these allowable stresses, the horsepower  $P$  transmitted by a shaft of diameter  $D$ , or the diameter  $D$  of a shaft to transmit a given horsepower  $P$  may be determined from the following formulas:

For main power-transmitting shafts:

$$P = \frac{D^3 N}{80} \quad (4a) \quad \text{or} \quad D = \sqrt[3]{\frac{80P}{N}} \quad (4b)$$

For lineshafts carrying pulleys:

$$P = \frac{D^3 N}{53.5} \quad (5a) \quad \text{or} \quad D = \sqrt[3]{\frac{53.5P}{N}} \quad (5b)$$

For small, short shafts:

$$P = \frac{D^3 N}{38} \quad (6a) \quad \text{or} \quad D = \sqrt[3]{\frac{38P}{N}} \quad (6b)$$

Shafts that are subjected to shocks, such as sudden starting and stopping, should be given a greater factor of safety resulting in the use of lower allowable stresses than those just mentioned.

*Example:* What should be the diameter of a lineshaft to transmit 10 horsepower if the shaft is to make 150 revolutions per minute? Using [Formula \(5b\)](#),

$$D = \sqrt[3]{\frac{53.5 \times 10}{150}} = 1.53 \text{ or, say, } 1\frac{1}{16} \text{ inches}$$

*Example:* What horsepower would be transmitted by a short shaft, 2 inches in diameter, carrying two pulleys close to the bearings, if the shaft makes 300 revolutions per minute? Using [Formula \(6a\)](#),

$$P = \frac{2^3 \times 300}{38} = 63 \text{ horsepower}$$

**Torsional Strength of Shafting, Calculations in Metric SI Units.**—The allowable twisting moment for a shaft of any cross-section such as circular, square, etc., can be calculated from:

$$T = S_s \times Z_p \quad (7)$$

where  $T$  = torsional or twisting moment in newton-millimeters;  $S_s$  = allowable torsional shearing stress in newtons per square millimeter; and  $Z_p$  = polar section modulus in millimeters<sup>3</sup>.

For a shaft delivering power of  $P$  kilowatts at  $N$  revolutions per minute, the twisting moment  $T$  being transmitted is:

$$T = \frac{9.55 \times 10^6 P}{N} \quad (8) \quad \text{or} \quad T = \frac{10^6 P}{\omega} \quad (8a)$$

where  $T$  is in newton-millimeters, and  $\omega$  = angular velocity in radians per second.

The diameter  $D$  of a solid circular shaft required to transmit a given torque  $T$  is:

$$D = \sqrt[3]{\frac{5.1T}{S_s}} \quad (9a) \quad \text{or} \quad D = \sqrt[3]{\frac{48.7 \times 10^6 P}{NS_s}} \quad (9b)$$

$$\text{or} \quad D = \sqrt[3]{\frac{5.1 \times 10^6 P}{\omega S_s}} \quad (9c)$$

where  $D$  is in millimeters;  $T$  is in newton-millimeters;  $P$  is power in kilowatts;  $N$  = revolutions per minute;  $S_s$  = allowable torsional shearing stress in newtons per square millimeter, and  $\omega$  = angular velocity in radians per second.

If 28 newtons/mm<sup>2</sup> and 59 newtons/mm<sup>2</sup> are taken as the generally allowed stresses for main power-transmitting shafts and small short shafts, respectively, then using these allowable stresses, the power  $P$  transmitted by a shaft of diameter  $D$ , or the diameter  $D$  of a shaft to transmit a given power  $P$  may be determined from the following formulas:

For main power-transmitting shafts:

$$P = \frac{D^3 N}{1.77 \times 10^6} \quad (10a) \quad \text{or} \quad D = 3\sqrt{\frac{1.77 \times 10^6 P}{N}} \quad (10b)$$

For small, short shafts:

$$P = \frac{D^3 N}{0.83 \times 10^6} \quad (11a) \quad \text{or} \quad D = 3\sqrt{\frac{0.83 \times 10^6 P}{N}} \quad (11b)$$

where  $P$  is in kilowatts,  $D$  is in millimeters, and  $N$  = revolutions per minute.

*Example:* What should be the diameter of a power-transmitting shaft to transmit 150 kW at 500 rpm?

$$D = 3\sqrt{\frac{1.77 \times 10^6 \times 150}{500}} = 81 \text{ millimeters}$$

*Example:* What power would a short shaft, 50 millimeters in diameter, transmit at 400 rpm?

$$P = \frac{50^3 \times 400}{0.83 \times 10^6} = 60 \text{ kilowatts}$$

**Torsional Deflection of Circular Shafts.**—Shafting must often be proportioned not only to provide the strength required to transmit a given torque, but also to prevent torsional deflection (twisting) through a greater angle than has been found satisfactory for a given type of service.

For a solid circular shaft the torsional deflection in degrees is given by:

$$\alpha = \frac{584 T l}{D^4 G} \quad (12)$$

*Example:* Find the torsional deflection for a solid steel shaft 4 inches in diameter and 48 inches long, subjected to a twisting moment of 24,000 inch-pounds. By [Formula \(12\)](#),

$$\alpha = \frac{584 \times 24,000 \times 48}{4^4 \times 11,500,000} = 0.23 \text{ degree}$$

**Formula (12)** can be used with metric SI units, where  $\alpha$  = angular deflection of shaft in degrees;  $T$  = torsional moment in newton-millimeters;  $l$  = length of shaft in millimeters;  $D$  = diameter of shaft in millimeters; and  $G$  = torsional modulus of elasticity in newtons per square millimeter.

*Example:* Find the torsional deflection of a solid steel shaft, 100 mm in diameter and 1300 mm long, subjected to a twisting moment of  $3 \times 10^6$  newton-millimeters. The torsional modulus of elasticity is 80,000 newtons/mm<sup>2</sup>. By [Formula \(12\)](#)

$$\alpha = \frac{584 \times 3 \times 10^6 \times 1300}{100^4 \times 80,000} = 0.285 \text{ degree}$$

The diameter of a shaft that is to have a maximum torsional deflection  $\alpha$  is given by:

$$D = 4.9 \times 4\sqrt[4]{\frac{Tl}{G\alpha}} \quad (13)$$

**Formula (13)** can be used with metric SI units, where  $D$  = diameter of shaft in millimeters;  $T$  = torsional moment in newton-millimeters;  $l$  = length of shaft in millime-

ters;  $G$  = torsional modulus of elasticity in newtons per square millimeter; and  $\alpha$  = angular deflection of shaft in degrees.

According to some authorities, the allowable twist in steel transmission shafting should not exceed 0.08 degree per foot length of the shaft. The diameter  $D$  of a shaft that will permit a maximum angular deflection of 0.08 degree per foot of length for a given torque  $T$  or for a given horsepower  $P$  can be determined from the formulas:

$$D = 0.29\sqrt[4]{T} \quad (14a) \quad \text{or} \quad D = 4.6 \times \sqrt[4]{\frac{P}{N}} \quad (14b)$$

Using metric SI units and assuming an allowable twist in steel transmission shafting of 0.26 degree per meter length, Formulas (14a) and (14b) become:

$$D = 2.26\sqrt[4]{T} \quad \text{or} \quad D = 125.7 \times \sqrt[4]{\frac{P}{N}}$$

where  $D$  = diameter of shaft in millimeters;  $T$  = torsional moment in newton-millimeters;  $P$  = power in kilowatts; and  $N$  = revolutions per minute.

Another rule that has been generally used in mill practice limits the deflection to 1 degree in a length equal to 20 times the shaft diameter. For a given torque or horsepower, the diameter of a shaft having this maximum deflection is given by:

$$D = 0.1\sqrt[3]{T} \quad (15a) \quad \text{or} \quad D = 4.0 \times \sqrt[3]{\frac{P}{N}} \quad (15b)$$

*Example:* Find the diameter of a steel lineshaft to transmit 10 horsepower at 150 revolutions per minute with a torsional deflection not exceeding 0.08 degree per foot of length. By Formula (14b),

$$D = 4.6 \times \sqrt[4]{\frac{10}{150}} = 2.35 \text{ inches}$$

This diameter is larger than that obtained for the same horsepower and rpm in the example given for Formula (5b) in which the diameter was calculated for strength considerations only. The usual procedure in the design of shafting which is to have a specified maximum angular deflection is to compute the diameter first by means of Formulas (13), (14a), (14b), (15a), or (15b) and then by means of Formulas (3a), (3b), (4b), (5b), or (6b), using the larger of the two diameters thus found.

**Linear Deflection of Shafting.**—For steel line shafting, it is considered good practice to limit the linear deflection to a maximum of 0.010 inch per foot of length. The maximum distance in feet between bearings, for average conditions, in order to avoid excessive linear deflection, is determined by the formulas:

$$L = 8.95\sqrt[3]{D^2} \text{ for shafting subject to no bending action except its own weight}$$

$$L = 5.2\sqrt[3]{D^2} \text{ for shafting subject to bending action of pulleys, etc.}$$

in which  $D$  = diameter of shaft in inches and  $L$  = maximum distance between bearings in feet. Pulleys should be placed as close to the bearings as possible.

In general, shafting up to three inches in diameter is almost always made from cold-rolled steel. This shafting is true and straight and needs no turning, but if keyways are cut in the shaft, it must usually be straightened afterwards, as the cutting of the keyways relieves the tension on the surface of the shaft produced by the cold-rolling process. Sizes of shafting from three to five inches in diameter may be either cold-rolled or turned, more frequently the latter, and all larger sizes of shafting must be turned because cold-rolled shafting is not available in diameters larger than 5 in.

**Diameters of Finished Shafting (former American Standard ASA B17.1)**

| Diameters, Inches     |                    | Minus Tolerances, Inches <sup>a</sup> | Diameters, Inches     |                    | Minus Tolerances, Inches <sup>a</sup> | Diameters, Inches     |                    | Minus Tolerances, Inches <sup>a</sup> |

|                       | 1 ¾                | 0.003                                 |                       | 3 5/8              | 0.004                                 | ...                   | ...                | ...                                   |

<sup>a</sup> Note:—These tolerances are *negative* or minus and represent the maximum allowable variation below the exact nominal size. For instance the maximum diameter of the 1 15/16 inch shaft is 1.938 inch and its minimum allowable diameter is 1.935 inch. Stock lengths of finished transmission shafting shall be: 16, 20 and 24 feet.

**Design of Transmission Shafting.**—The following guidelines for the design of shafting for transmitting a given amount of power under various conditions of loading are based upon formulas given in the former American Standard ASA B17c Code for the Design of Transmission Shafting. These formulas are based on the *maximum-shear theory* of failure which assumes that the elastic limit of a *ductile* ferrous material in shear is practically one-half its elastic limit in tension. This theory agrees, very nearly, with the results of tests on ductile materials and has gained wide acceptance in practice.

The formulas given apply in all shaft designs including shafts for special machinery. The limitation of these formulas is that they provide only for the strength of shafting and are not concerned with the torsional or lineal deformations which may, in shafts used in machine design, be the controlling factor (see *Torsional Deflection of Circular Shafts* on page 301 and *Linear Deflection of Shafting* on page 302 for deflection considerations). In the formulas that follow,

$$B = \sqrt[3]{1 \div (1 - K^4)} \text{ (see Table 3)}$$

$D$  = outside diameter of shaft in inches

$D_i$  = inside diameter of a hollow shaft in inches

$K_m$  = shock and fatigue factor to be applied in every case to the computed bending moment (see Table 1)

$K_t$  = combined shock and fatigue factor to be applied in every case to the computed torsional moment (see Table 1)

$M$  = maximum bending moment in inch-pounds

$N$  = revolutions per minute

$P$  = maximum power to be transmitted by the shaft in horsepower

$p_t$  = maximum allowable shearing stress under combined loading conditions in pounds per square inch (see Table 2)

$S$  = maximum allowable flexural (bending) stress, in either tension or compression in pounds per square inch (see Table 2)

$S_s$  = maximum allowable torsional shearing stress in pounds per square inch (see Table 2)

$T$  = maximum torsional moment in inch-pounds

$V$  = maximum transverse shearing load in pounds

For shafts subjected to pure torsional loads only,

$$D = B \sqrt[3]{\frac{5.1 K_t T}{S_s}} \quad (16a) \quad \text{or} \quad D = B \sqrt[3]{\frac{321,000 K_t P}{S_s N}} \quad (16b)$$

For stationary shafts subjected to bending only,

$$D = B \sqrt[3]{\frac{10.2 K_m M}{S}} \quad (17)$$

For shafts subjected to combined torsion and bending,

$$D = B \sqrt[3]{\frac{5.1}{p_t} \sqrt{(K_m M)^2 + (K_t T)^2}} \quad (18a)$$

or

$$D = B \sqrt[3]{\frac{5.1}{p_t} \sqrt{(K_m M)^2 + \left(\frac{63,000 K_t P}{N}\right)^2}} \quad (18b)$$

Formulas (16a) to (18b) may be used for solid shafts or for hollow shafts. For solid shafts the factor  $B$  is equal to 1, whereas for hollow shafts the value of  $B$  depends on the value of  $K$  which, in turn, depends on the ratio of the inside diameter of the shaft to the outside diameter ( $D_1 \div D = K$ ). Table 3 gives values of  $B$  corresponding to various values of  $K$ .

For short solid shafts subjected only to heavy transverse shear, the diameter of shaft required is:

$$D = \sqrt[3]{\frac{1.7V}{S_s}} \quad (19)$$

Formulas (16a), (17), (18a) and (19), can be used unchanged with metric SI units. Formula (16b) becomes:

$$D = B \sqrt[3]{\frac{48.7 K_t P}{S_s N}} \quad \text{and Formula (18b) becomes:}$$

$$D = B \sqrt[3]{\frac{5.1}{p_t} \sqrt{(K_m M)^2 + \left(\frac{9.55 K_t P}{N}\right)^2}}$$

Throughout the formulas,  $D$  = outside diameter of shaft in millimeters;  $T$  = maximum torsional moment in newton-millimeters;  $S_s$  = maximum allowable torsional shearing stress in newtons per millimeter squared (see Table 2);  $P$  = maximum power to be transmitted in milliwatts;  $N$  = revolutions per minute;  $M$  = maximum bending moment in newton-millimeters;  $S$  = maximum allowable flexural (bending) stress, either in tension or compression in newtons per millimeter squared (see Table 2);  $p_t$  = maximum allowable shearing stress under combined loading conditions in newtons

per millimeter squared; and  $V$  = maximum transverse shearing load in kilograms. The factors  $K_m$ ,  $K_r$ , and  $B$  are unchanged, and  $D_1$  = the inside diameter of a hollow shaft in millimeters.

**Table 1. Recommended Values of the Combined Shock and Fatigue Factors for Various Types of Load**

| Type of Load                        | Stationary Shafts |         | Rotating Shafts |         |
|-------------------------------------|-------------------|---------|-----------------|---------|
|                                     | $K_m$             | $K_r$   | $K_m$           | $K_r$   |
| Gradually applied and steady        | 1.0               | 1.0     | 1.5             | 1.0     |
| Suddenly applied, minor shocks only | 1.5–2.0           | 1.5–2.0 | 1.5–2.0         | 1.0–1.5 |
| Suddenly applied, heavy shocks      | ...               | ...     | 2.0–3.0         | 1.5–3.0 |

**Table 2. Recommended Maximum Allowable Working Stresses for Shafts Under Various Types of Load**

| Material                                       | Type of Load             |                          |                          |
|--|--------------------------|--------------------------|--------------------------|
|  | Simple Bending           | Pure Torsion             | Combined Stress          |
| "Commercial Steel" shafting without keyways    | $S = 16,000$             | $S_s = 8000$             | $p_t = 8000$             |
| "Commercial Steel" shafting with keyways       | $S = 12,000$             | $S_s = 6000$             | $p_t = 6000$             |
| Steel purchased under definite physical specs. | (See note <sup>a</sup> ) | (See note <sup>b</sup> ) | (See note <sup>b</sup> ) |

<sup>a</sup>  $S = 60$  per cent of the elastic limit in tension but not more than 36 per cent of the ultimate tensile strength.

<sup>b</sup>  $S_s$  and  $p_t = 30$  per cent of the elastic limit in tension but not more than 18 per cent of the ultimate tensile strength.

If the values in the Table are converted to metric SI units, note that 1000 pounds per square inch = 6.895 newtons per square millimeter.

**Table 3. Values of the Factor  $B$  Corresponding to Various Values of  $K$  for Hollow Shafts**

|                                  |      |      |      |      |      |      |      |      |      |      |
|----------------------------------|------|------|------|------|------|------|------|------|------|------|
| $K = \frac{D_1}{D} =$            | 0.95 | 0.90 | 0.85 | 0.80 | 0.75 | 0.70 | 0.65 | 0.60 | 0.55 | 0.50 |
| $B = \sqrt[3]{1 \div (1 - K^4)}$ | 1.75 | 1.43 | 1.28 | 1.19 | 1.14 | 1.10 | 1.07 | 1.05 | 1.03 | 1.02 |

For solid shafts,  $B = 1$  because  $K = 0$ , as follows:  $B = \sqrt[3]{1 \div (1 - K^4)} = \sqrt[3]{1 \div (1 - 0)} = 1$

**Effect of Keyways on Shaft Strength.**—Keyways cut into a shaft reduce its load carrying ability, particularly when impact loads or stress reversals are involved. To ensure an adequate factor of safety in the design of a shaft with standard keyway (width, one-quarter, and depth, one-eighth of shaft diameter), the former Code for Transmission Shafting tentatively recommended that shafts with keyways be designed on the basis of a solid circular shaft using not more than 75 per cent of the working stress recommended for the solid shaft. See also page 2363.

**Formula for Shafts of Brittle Materials.**—The preceding formulas are applicable to ductile materials and are based on the maximum-shear theory of failure which assumes that the elastic limit of a ductile material in shear is one-half its elastic limit in tension.

Brittle materials are generally stronger in shear than in tension; therefore, the maximum-shear theory is not applicable. The maximum-normal-stress theory of failure is now generally accepted for the design of shafts made from brittle materials. A material may be considered to be brittle if its elongation in a 2-inch gage length is less than 5 per cent. Materials such as cast iron, hardened tool steel, hard bronze, etc., conform to this rule. The diameter of a shaft made of a brittle material may be determined from the following formula which is based on the maximum-normal-stress theory of failure:

$$D = B \sqrt[3]{\frac{5.1}{S_t} \left[ (K_m M) + \sqrt{(K_m M)^2 + (K_t T)^2} \right]}$$

where  $S_t$  is the maximum allowable tensile stress in pounds per square inch and the other quantities are as previously defined.

**The formula can be used unchanged with metric SI units, where  $D$  = outside diameter of shaft in millimeters;  $S_t$  = the maximum allowable tensile stress in newtons per millimeter squared;  $M$  = maximum bending moment in newton-millimeters; and  $T$  = maximum torsional moment in newton-millimeters. The factors  $K_m$ ,  $K_t$ , and  $B$  are unchanged.**

**Critical Speed of Rotating Shafts.**—At certain speeds, a rotating shaft will become dynamically unstable and the resulting vibrations and deflections can result in damage not only to the shaft but to the machine of which it is a part. The speeds at which such dynamic instability occurs are called the critical speeds of the shaft. On page 196 are given formulas for the critical speeds of shafts subject to various conditions of loading and support. A shaft may be safely operated either above or below its critical speed, good practice indicating that the operating speed be at least 20 per cent above or below the critical.

The formulas commonly used to determine critical speeds are sufficiently accurate for general purposes. However, the torque applied to a shaft has an important effect on its critical speed. Investigations have shown that the critical speeds of a uniform shaft are decreased as the applied torque is increased, and that there exist critical torques which will reduce the corresponding critical speed of the shaft to zero. A detailed analysis of the effects of applied torques on critical speeds may be found in a paper, "Critical Speeds of Uniform Shafts under Axial Torque," by Golomb and Rosenberg presented at the First U.S. National Congress of Applied Mechanics in 1951.

**Shaft Couplings.**—A shaft coupling is a device for fastening together the ends of two shafts, so that the rotary motion of one causes rotary motion of the other. One of the most simple and common forms of coupling is the flange coupling **Figs. 1a** and **1b**. It consists of two flanged sleeves or hubs, each of which is keyed to the end of one of the two shafts to be connected. The sleeves are held together and prevented from rotating relative to each other by bolts through the flanges as indicated.

### Flange Coupling

Fig. 1a.

Fig. 1b.

**Flexible Couplings:** Flexible couplings are the most common mechanical means of compensating for unavoidable errors in alignment of shafts and shafting. When correctly applied, they are highly efficient for joining lengths of shafting without causing loss of power from bearing friction due to misalignment, and for use in direct motor drives for all kinds of machinery. Flexible couplings are not intended to be used for connecting a driven shaft and a driving shaft that are purposely placed in different planes or at an angle but are intended simply to overcome slight unavoidable errors in alignment that develop in service. There is a wide variety of flexible coupling designs; most of them consist essentially

of two flanged members or hubs, fastened to the shafts and connected by some yielding arrangement. Balance is an important factor in coupling selection or design; it is not sufficient that the coupling be perfectly balanced when installed, but it must remain in balance after wear has taken place.

**Comparison of Hollow and Solid Shafting with Same Outside Diameter.**—Table 4 that follows gives the per cent decrease in strength and weight of a hollow shaft relative to the strength and weight of a solid shaft of the same diameter. The upper figures in each line give the per cent decrease in strength and the lower figures give the per cent decrease in weight.

*Example:* A 4-inch shaft, with a 2-inch hole through it, has a weight 25 per cent less than a solid 4-inch shaft, but its strength is decreased only 6.25 per cent.

**Table 4. Comparative Torsional Strengths and Weights of Hollow and Solid Shafting with Same Outside Diameter**

| Dia. of Solid and Hollow Shaft, Inches | Diameter of Axial Hole in Hollow Shaft, Inches |       |       |       |       |       |       |       |       |       |
|--|--|-------|-------|-------|-------|-------|-------|-------|-------|-------|
|  | 1  | 1¼    | 1½    | 1¾    | 2     | 2½    | 3     | 3½    | 4     | 4½    |

|  | 2.04   | 3.19  | 4.59  | 6.25  | 8.16  | 12.76 | 18.36 | 25.00 | 32.66 | 41.33 |
| 7½                                     | 0.04   | 0.08  | 0.16  | 0.30  | 0.51  | 1.24  | 2.56  | 4.75  | 8.09  | 12.96 |
|  | 1.77   | 2.77  | 4.00  | 5.44  | 7.11  | 11.11 | 16.00 | 21.77 | 28.45 | 36.00 |
| 8                                      | 0.03   | 0.06  | 0.13  | 0.23  | 0.40  | 0.96  | 1.98  | 3.68  | 6.25  | 10.02 |
|  | 1.56   | 2.44  | 3.51  | 4.78  | 6.25  | 9.77  | 14.06 | 19.14 | 25.00 | 31.64 |

The upper figures in each line give number of per cent decrease in strength; the lower figures give per cent decrease in weight.

## SPRINGS

## Introduction to Spring Design

Many advances have been made in the spring industry in recent years. For example: developments in materials permit longer fatigue life at higher stresses; simplified design procedures reduce the complexities of design, and improved methods of manufacture help to speed up some of the complicated fabricating procedures and increase production. New types of testing instruments and revised tolerances also permit higher standards of accuracy. Designers should also consider the possibility of using standard springs now available from stock. They can be obtained from spring manufacturing companies located in different areas, and small shipments usually can be made quickly.

Designers of springs require information in the following order of precedence to simplify design procedures.

- 1) Spring materials and their applications
- 2) Allowable spring stresses
- 3) Spring design data with tables of spring characteristics, tables of formulas, and tolerances.

Only the more commonly used types of springs are covered in detail here. Special types and designs rarely used such as torsion bars, volute springs, Belleville washers, constant force, ring and spiral springs and those made from rectangular wire are only described briefly. Belleville and disc springs are discussed in the section *DISC SPRINGS* starting on page 354

**Notation.**—The following symbols are used in spring equations:

$AC$  = Active coils

$b$  = Widest width of rectangular wire, inches

$CL$  = Compressed length, inches

$D$  = Mean coil diameter, inches =  $OD - d$

$d$  = Diameter of wire or side of square, inches

$E$  = Modulus of elasticity in tension, pounds per square inch

$F$  = Deflection, for  $N$  coils, inches

$F^\circ$  = Deflection, for  $N$  coils, rotary, degrees

$f$  = Deflection, for one active coil

$FL$  = Free length, unloaded spring, inches

$G$  = Modulus of elasticity in torsion, pounds per square inch

$IT$  = Initial tension, pounds

$K$  = Curvature stress correction factor

$L$  = Active length subject to deflection, inches

$N$  = Number of active coils, total

$P$  = Load, pounds

$p$  = pitch, inches

$R$  = Distance from load to central axis, inches

$SorS_t$  = Stress, torsional, pounds per square inch

$S_b$  = Stress, bending, pounds per square inch

$SH$  = Solid height

$S_{it}$  = Stress, torsional, due to initial tension, pounds per square inch

$T$  = Torque =  $P \times R$ , pound-inches

$TC$  = Total coils

$t$  = Thickness, inches

$U$  = Number of revolutions =  $F^\circ/360^\circ$

### Spring Materials

The spring materials most commonly used include high-carbon spring steels, alloy spring steels, stainless spring steels, copper-base spring alloys, and nickel-base spring alloys.

**High-Carbon Spring Steels in Wire Form.**—These spring steels are the most commonly used of all spring materials because they are the least expensive, are easily worked, and are readily available. However, they are not satisfactory for springs operating at high or low temperatures or for shock or impact loading. The following wire forms are available:

*Music Wire, ASTM A228* (0.80–0.95 per cent carbon): This is the most widely used of all spring materials for small springs operating at temperatures up to about 250 degrees F. It is tough, has a high tensile strength, and can withstand high stresses under repeated loading. The material is readily available in round form in diameters ranging from 0.005 to 0.125 inch and in some larger sizes up to  $\frac{3}{16}$  inch. It is not available with high tensile strengths in square or rectangular sections. Music wire can be plated easily and is obtainable pretinned or preplated with cadmium, but plating after spring manufacture is usually preferred for maximum corrosion resistance.

*Oil-Tempered MB Grade, ASTM A229* (0.60–0.70 per cent carbon): This general-purpose spring steel is commonly used for many types of coil springs where the cost of music wire is prohibitive and in sizes larger than are available in music wire. It is readily available in diameters ranging from 0.125 to 0.500 inch, but both smaller and larger sizes may be obtained. The material should not be used under shock and impact loading conditions, at temperatures above 350 degrees F., or at temperatures in the sub-zero range. Square and rectangular sections of wire are obtainable in fractional sizes. Annealed stock also can be obtained for hardening and tempering after coiling. This material has a heat-treating scale that must be removed before plating.

*Oil-Tempered HB Grade, SAE 1080* (0.75–0.85 per cent carbon): This material is similar to the MB Grade except that it has a higher carbon content and a higher tensile strength. It is obtainable in the same sizes and is used for more accurate requirements than the MB Grade, but is not so readily available. In lieu of using this material it may be better to use an alloy spring steel, particularly if a long fatigue life or high endurance properties are needed. Round and square sections are obtainable in the oil-tempered or annealed conditions.

*Hard-Drawn MB Grade, ASTM A227* (0.60–0.70 per cent carbon): This grade is used for general-purpose springs where cost is the most important factor. Although increased use in recent years has resulted in improved quality, it is best not to use it where long life and accuracy of loads and deflections are important. It is available in diameters ranging from 0.031 to 0.500 inch and in some smaller and larger sizes also. The material is available in square sections but at reduced tensile strengths. It is readily plated. Applications should be limited to those in the temperature range of 0 to 250 degrees F.

**High-Carbon Spring Steels in Flat Strip Form.**—Two types of thin, flat, high-carbon spring steel strip are most widely used although several other types are obtainable for specific applications in watches, clocks, and certain instruments. These two compositions are used for over 95 per cent of all such applications. Thin sections of these materials under 0.015 inch having a carbon content of over 0.85 per cent and a hardness of over 47 on the Rockwell C scale are susceptible to hydrogen-embrittlement even though special plating and heating operations are employed. The two types are described as follows:

*Cold-Rolled Spring Steel, Blue-Tempered or Annealed, SAE 1074, also 1064, and 1070* (0.60 to 0.80 per cent carbon): This very popular spring steel is available in thicknesses ranging from 0.005 to 0.062 inch and in some thinner and thicker sections. The material is available in the annealed condition for forming in 4-slide machines and in presses, and can

readily be hardened and tempered after forming. It is also available in the heat-treated or blue-tempered condition. The steel is obtainable in several finishes such as straw color, blue color, black, or plain. Hardnesses ranging from 42 to 46 Rockwell C are recommended for spring applications. Uses include spring clips, flat springs, clock springs, and motor, power, and spiral springs.

*Cold-Rolled Spring Steel, Blue-Tempered Clock Steel, SAE 1095* (0.90 to 1.05 per cent carbon): This popular type should be used principally in the blue-tempered condition. Although obtainable in the annealed condition, it does not always harden properly during heat-treatment as it is a "shallow" hardening type. It is used principally in clocks and motor springs. End sections of springs made from this steel are annealed for bending or piercing operations. Hardnesses usually range from 47 to 51 Rockwell C.

Other materials available in strip form and used for flat springs are brass, phosphor-bronze, beryllium-copper, stainless steels, and nickel alloys.

**Alloy Spring Steels.**—These spring steels are used for conditions of high stress, and shock or impact loadings. They can withstand both higher and lower temperatures than the high-carbon steels and are obtainable in either the annealed or pretempered conditions.

*Chromium Vanadium, ASTM A231:* This very popular spring steel is used under conditions involving higher stresses than those for which the high-carbon spring steels are recommended and is also used where good fatigue strength and endurance are needed. It behaves well under shock and impact loading. The material is available in diameters ranging from 0.031 to 0.500 inch and in some larger sizes also. In square sections it is available in fractional sizes. Both the annealed and pretempered types are available in round, square, and rectangular sections. It is used extensively in aircraft-engine valve springs and for springs operating at temperatures up to 425 degrees F.

*Silicon Manganese:* This alloy steel is quite popular in Great Britain. It is less expensive than chromium-vanadium steel and is available in round, square, and rectangular sections in both annealed and pretempered conditions in sizes ranging from 0.031 to 0.500 inch. It was formerly used for knee-action springs in automobiles. It is used in flat leaf springs for trucks and as a substitute for more expensive spring steels.

*Chromium Silicon, ASTM A401:* This alloy is used for highly stressed springs that require long life and are subjected to shock loading. It can be heat-treated to higher hardnesses than other spring steels so that high tensile strengths are obtainable. The most popular sizes range from 0.031 to 0.500 inch in diameter. Very rarely are square, flat, or rectangular sections used. Hardnesses ranging from 50 to 53 Rockwell C are quite common and the alloy may be used at temperatures up to 475 degrees F. This material is usually ordered specially for each job.

**Stainless Spring Steels.**—The use of stainless spring steels has increased and several compositions are available all of which may be used for temperatures up to 550 degrees F. They are all corrosion resistant. Only the stainless 18-8 compositions should be used at sub-zero temperatures.

*Stainless Type 302, ASTM A313* (18 per cent chromium, 8 per cent nickel): This stainless spring steel is very popular because it has the highest tensile strength and quite uniform properties. It is cold-drawn to obtain its mechanical properties and cannot be hardened by heat treatment. This material is nonmagnetic only when fully annealed and becomes slightly magnetic due to the cold-working performed to produce spring properties. It is suitable for use at temperatures up to 550 degrees F. and for sub-zero temperatures. It is very corrosion resistant. The material best exhibits its desirable mechanical properties in diameters ranging from 0.005 to 0.1875 inch although some larger diameters are available. It is also available as hard-rolled flat strip. Square and rectangular sections are available but are infrequently used.

*Stainless Type 304, ASTM A313* (18 per cent chromium, 8 per cent nickel): This material is quite similar to Type 302, but has better bending properties and about 5 per cent lower tensile strength. It is a little easier to draw, due to the slightly lower carbon content.

*Stainless Type 316, ASTM A313* (18 per cent chromium, 12 per cent nickel, 2 per cent molybdenum): This material is quite similar to Type 302 but is slightly more corrosion resistant because of its higher nickel content. Its tensile strength is 10 to 15 per cent lower than Type 302. It is used for aircraft springs.

*Stainless Type 17-7 PH ASTM A313* (17 per cent chromium, 7 per cent nickel): This alloy, which also contains small amounts of aluminum and titanium, is formed in a moderately hard state and then precipitation hardened at relatively low temperatures for several hours to produce tensile strengths nearly comparable to music wire. This material is not readily available in all sizes, and has limited applications due to its high manufacturing cost.

*Stainless Type 414, SAE 51414* (12 per cent chromium, 2 per cent nickel): This alloy has tensile strengths about 15 per cent lower than Type 302 and can be hardened by heat-treatment. For best corrosion resistance it should be highly polished or kept clean. It can be obtained hard drawn in diameters up to 0.1875 inch and is commonly used in flat cold-rolled strip for stampings. The material is not satisfactory for use at low temperatures.

*Stainless Type 420, SAE 51420* (13 per cent chromium): This is the best stainless steel for use in large diameters above 0.1875 inch and is frequently used in smaller sizes. It is formed in the annealed condition and then hardened and tempered. It does not exhibit its stainless properties until after it is hardened. Clean bright surfaces provide the best corrosion resistance, therefore the heat-treating scale must be removed. Bright hardening methods are preferred.

*Stainless Type 431, SAE 51431* (16 per cent chromium, 2 per cent nickel): This spring alloy acquires high tensile properties (nearly the same as music wire) by a combination of heat-treatment to harden the wire plus cold-drawing after heat-treatment. Its corrosion resistance is not equal to Type 302.

**Copper-Base Spring Alloys.**—Copper-base alloys are important spring materials because of their good electrical properties combined with their good resistance to corrosion. Although these materials are more expensive than the high-carbon and the alloy steels, they nevertheless are frequently used in electrical components and in sub-zero temperatures.

*Spring Brass, ASTM B 134* (70 per cent copper, 30 per cent zinc): This material is the least expensive and has the highest electrical conductivity of the copper-base alloys. It has a low tensile strength and poor spring qualities, but is extensively used in flat stampings and where sharp bends are needed. It cannot be hardened by heat-treatment and should not be used at temperatures above 150 degrees F., but is especially good at sub-zero temperatures. Available in round sections and flat strips, this hard-drawn material is usually used in the "spring hard" temper.

*Phosphor Bronze, ASTM B 159* (95 per cent copper, 5 per cent tin): This alloy is the most popular of this group because it combines the best qualities of tensile strength, hardness, electrical conductivity, and corrosion resistance with the least cost. It is more expensive than brass, but can withstand stresses 50 per cent higher. The material cannot be hardened by heat-treatment. It can be used at temperatures up to 212 degrees F. and at sub-zero temperatures. It is available in round sections and flat strip, usually in the "extra-hard" or "spring hard" tempers. It is frequently used for contact fingers in switches because of its low arcing properties. An 8 per cent tin composition is used for flat springs and a superfine grain composition called "Duraflex," has good endurance properties.

*Beryllium Copper, ASTM B 197* (98 per cent copper, 2 per cent beryllium): This alloy can be formed in the annealed condition and then precipitation hardened after forming at

temperatures around 600 degrees F, for 2 to 3 hours. This treatment produces a high hardness combined with a high tensile strength. After hardening, the material becomes quite brittle and can withstand very little or no forming. It is the most expensive alloy in the group and heat-treating is expensive due to the need for holding the parts in fixtures to prevent distortion. The principal use of this alloy is for carrying electric current in switches and in electrical components. Flat strip is frequently used for contact fingers.

**Nickel-Base Spring Alloys.**—Nickel-base alloys are corrosion resistant, withstand both elevated and sub-zero temperatures, and their non-magnetic characteristic makes them useful for such applications as gyroscopes, chronoscopes, and indicating instruments. These materials have a high electrical resistance and therefore should not be used for conductors of electrical current.

*Monel*\* (67 per cent nickel, 30 per cent copper): This material is the least expensive of the nickel-base alloys. It also has the lowest tensile strength but is useful due to its resistance to the corrosive effects of sea water and because it is nearly non-magnetic. The alloy can be subjected to stresses slightly higher than phosphor bronze and nearly as high as beryllium copper. Its high tensile strength and hardness are obtained as a result of cold-drawing and cold-rolling only, since it can not be hardened by heat-treatment. It can be used at temperatures ranging from -100 to +425 degrees F. at normal operating stresses and is available in round wires up to  $\frac{3}{16}$  inch in diameter with quite high tensile strengths. Larger diameters and flat strip are available with lower tensile strengths.

*"K" Monel*\* (66 per cent nickel, 29 per cent copper, 3 per cent aluminum): This material is quite similar to Monel except that the addition of the aluminum makes it a precipitation-hardening alloy. It may be formed in the soft or fairly hard condition and then hardened by a long-time age-hardening heat-treatment to obtain a tensile strength and hardness above Monel and nearly as high as stainless steel. It is used in sizes larger than those usually used with Monel, is non-magnetic and can be used in temperatures ranging from -100 to +450 degrees F. at normal working stresses under 45,000 pounds per square inch.

*Inconel*\* (78 per cent nickel, 14 per cent chromium, 7 per cent iron): This is one of the most popular of the non-magnetic nickel-base alloys because of its corrosion resistance and because it can be used at temperatures up to 700 degrees F. It is more expensive than stainless steel but less expensive than beryllium copper. Its hardness and tensile strength is higher than that of "K" Monel and is obtained as a result of cold-drawing and cold-rolling only. It cannot be hardened by heat treatment. Wire diameters up to  $\frac{1}{4}$  inch have the best tensile properties. It is often used in steam valves, regulating valves, and for springs in boilers, compressors, turbines, and jet engines.

*Inconel "X"*\* (70 per cent nickel, 16 per cent chromium, 7 per cent iron): This material is quite similar to Inconel but the small amounts of titanium, columbium and aluminum in its composition make it a precipitation-hardening alloy. It can be formed in the soft or partially hard condition and then hardened by holding it at 1200 degrees F. for 4 hours. It is non-magnetic and is used in larger sections than Inconel. This alloy is used at temperatures up to 850 degrees F. and at stresses up to 55,000 pounds per square inch.

*Duranickel*\* ("*Z*" Nickel) (98 per cent nickel): This alloy is non-magnetic, corrosion resistant, has a high tensile strength and is hardenable by precipitation hardening at 900 degrees F. for 6 hours. It may be used at the same stresses as Inconel but should not be used at temperatures above 500 degrees F.

**Nickel-Base Spring Alloys with Constant Moduli of Elasticity.**—Some special nickel alloys have a constant modulus of elasticity over a wide temperature range. These materials are especially useful where springs undergo temperature changes and must exhibit uniform spring characteristics. These materials have a low or zero thermo-elastic coefficient

\*Trade name of the International Nickel Company.

and therefore do not undergo variations in spring stiffness because of modulus changes due to temperature differentials. They also have low hysteresis and creep values which makes them preferred for use in food-weighing scales, precision instruments, gyroscopes, measuring devices, recording instruments and computing scales where the temperature ranges from  $-50$  to  $+150$  degrees F. These materials are expensive, none being regularly stocked in a wide variety of sizes. They should not be specified without prior discussion with spring manufacturers because some suppliers may not fabricate springs from these alloys due to the special manufacturing processes required. All of these alloys are used in small wire diameters and in thin strip only and are covered by U.S. patents. They are more specifically described as follows:

*Elinvar*\* (nickel, iron, chromium): This alloy, the first constant-modulus alloy used for hairsprings in watches, is an austenitic alloy hardened only by cold-drawing and cold-rolling. Additions of titanium, tungsten, molybdenum and other alloying elements have brought about improved characteristics and precipitation-hardening abilities. These improved alloys are known by the following trade names: Elinvar Extra, Durinval, Modular and Nivarox.

*Ni-Span C*\* (nickel, iron, chromium, titanium): This very popular constant-modulus alloy is usually formed in the 50 per cent cold-worked condition and precipitation-hardened at 900 degrees F. for 8 hours, although heating up to 1250 degrees F. for 3 hours produces hardnesses of 40 to 44 Rockwell C, permitting safe torsional stresses of 60,000 to 80,000 pounds per square inch. This material is ferromagnetic up to 400 degrees F; above that temperature it becomes non-magnetic.

*Iso-Elastic*† (nickel, iron, chromium, molybdenum): This popular alloy is relatively easy to fabricate and is used at safe torsional stresses of 40,000 to 60,000 pounds per square inch and hardnesses of 30 to 36 Rockwell C. It is used principally in dynamometers, instruments, and food-weighing scales.

*Elgiloy*‡ (nickel, iron, chromium, cobalt): This alloy, also known by the trade names 8J Alloy, Durapower, and Cobenium, is a non-magnetic alloy suitable for sub-zero temperatures and temperatures up to about 1000 degrees F., provided that torsional stresses are kept under 75,000 pounds per square inch. It is precipitation-hardened at 900 degrees F. for 8 hours to produce hardnesses of 48 to 50 Rockwell C. The alloy is used in watch and instrument springs.

*Dynavar*\*\* (nickel, iron, chromium, cobalt): This alloy is a non-magnetic, corrosion-resistant material suitable for sub-zero temperatures and temperatures up to about 750 degrees F., provided that torsional stresses are kept below 75,000 pounds per square inch. It is precipitation-hardened to produce hardnesses of 48 to 50 Rockwell C and is used in watch and instrument springs.

### Spring Stresses

**Allowable Working Stresses for Springs.**—The safe working stress for any particular spring depends to a large extent on the following items:

- 1) Type of spring — whether compression, extension, torsion, etc.
- 2) Size of spring — small or large, long or short
- 3) Spring material
- 4) Size of spring material
- 5) Type of service — light, average, or severe
- 6) Stress range — low, average, or high

\*Trade name of Soc. Anon. de Commentry Fourchambault et Decazeville, Paris, France.

†Trade name of John Chatillon & Sons.

‡Trade name of Elgin National Watch Company.

\*\*Trade name of Hamilton Watch Company.

- 7) Loading — static, dynamic, or shock
- 8) Operating temperature
- 9) Design of spring — spring index, sharp bends, hooks.

Consideration should also be given to other factors that affect spring life: corrosion, buckling, friction, and hydrogen embrittlement decrease spring life; manufacturing operations such as high-heat stress-equalizing, presetting, and shot-peening increase spring life.

Item 5, the type of service to which a spring is subjected, is a major factor in determining a safe working stress once consideration has been given to type of spring, kind and size of material, temperature, type of loading, and so on. The types of service are:

**Light Service:** This includes springs subjected to static loads or small deflections and seldom-used springs such as those in bomb fuses, projectiles, and safety devices. This service is for 1,000 to 10,000 deflections.

**Average Service:** This includes springs in general use in machine tools, mechanical products, and electrical components. Normal frequency of deflections not exceeding 18,000 per hour permit such springs to withstand 100,000 to 1,000,000 deflections.

**Severe Service:** This includes springs subjected to rapid deflections over long periods of time and to shock loading such as in pneumatic hammers, hydraulic controls and valves. This service is for 1,000,000 deflections, and above. Lowering the values 10 per cent permits 10,000,000 deflections.

Figs. 1 through 6 show curves that relate the three types of service conditions to allowable working stresses and wire sizes for compression and extension springs, and safe values are provided. Figs. 7 through 10 provide similar information for helical torsion springs. In each chart, the values obtained from the curves may be increased by 20 per cent (but not beyond the top curves on the charts if permanent set is to be avoided) for springs that are baked, and shot-peened, and compression springs that are pressed. Springs stressed slightly above the Light Service curves will take a permanent set.

A curvature correction factor is included in all curves, and is used in spring design calculations (see examples beginning page 321). The curves may be used for materials other than those designated in Figs. 1 through 10, by applying multiplication factors as given in Table 1.

**Table 1. Correction Factors for Other Materials**

| Compression and Tension Springs |  |                                 |  |
|---------------------------------|--|---------------------------------|--|
| Material                        | Factor   | Material                        | Factor   |
| Silicon-manganese               | Multiply the values in the chromium-vanadium curves (Fig. 6) by 0.90         | Stainless Steel, 316            | Multiply the values in the corrosion-resisting steel curves (Fig. 5) by 0.90 |
| Valve-spring quality wire       | Use the values in the chromium-vanadium curves (Fig. 6)                      |                                 |  |
| Stainless Steel, 304 and 420    | Multiply the values in the corrosion-resisting steel curves (Fig. 5) by 0.95 | Stainless Steel, 431 and 17-7PH | Multiply the values in the music wire curves (Fig. 2) by 0.90                |
| Helical Torsion Springs         |  |                                 |  |
| Material                        | Factor <sup>a</sup>  | Material                        | Factor <sup>a</sup>  |
| Hard Drawn MB                   | 0.70   | Stainless Steel, 431            |  |
| Stainless Steel, 316            |  | Up to 1/32 inch diameter        | 0.80   |
| Up to 1/32 inch diameter        | 0.75   | Over 1/32 to 1/16 inch          | 0.85   |
| Over 1/32 to 3/16 inch          | 0.70   | Over 1/16 to 1/8 inch           | 0.95   |
| Over 3/16 to 1/4 inch           | 0.65   | Over 1/8 inch                   | 1.00   |
| Over 1/4 inch                   | 0.50   | Chromium-Vanadium               |  |
| Stainless Steel, 17-7 PH        |  | Up to 1/16 inch diameter        | 1.05   |
| Up to 1/8 inch diameter         | 1.00   | Over 1/16 inch                  | 1.10   |
| Over 1/8 to 3/16 inch           | 1.07   | Phosphor Bronze                 |  |
| Over 3/16 inch                  | 1.12   | Up to 1/8 inch diameter         | 0.45   |
| Stainless Steel, 420            |  | Over 1/8 inch                   | 0.55   |
| Up to 1/32 inch diameter        | 0.70   | Beryllium Copper <sup>b</sup>   |  |
| Over 1/32 to 1/16 inch          | 0.75   | Up to 1/32 inch diameter        | 0.55   |
| Over 1/16 to 1/8 inch           | 0.80   | Over 1/32 to 1/16 inch          | 0.60   |
| Over 1/8 to 3/16 inch           | 0.90   | Over 1/16 to 1/8 inch           | 0.70   |
| Over 3/16 inch                  | 1.00   | Over 1/8 inch                   | 0.80   |

<sup>a</sup> Multiply the values in the curves for oil-tempered MB grade ASTM A229 Type 1 steel (Fig. 8) by these factors to obtain required values.

<sup>b</sup> Hard drawn and heat treated after coiling.

For use with design stress curves shown in Figs. 2, 5, 6, and 8.

**Endurance Limit for Spring Materials.**—When a spring is deflected continually it will become “tired” and fail at a stress far below its elastic limit. This type of failure is called *fatigue failure* and usually occurs without warning. *Endurance limit* is the highest stress, or range of stress, in pounds per square inch that can be repeated indefinitely without failure of the spring. Usually ten million cycles of deflection is called “infinite life” and is satisfactory for determining this limit.

For severely worked springs of long life, such as those used in automobile or aircraft engines and in similar applications, it is best to determine the allowable working stresses by referring to the endurance limit curves seen in Fig. 11. These curves are based principally upon the range or difference between the stress caused by the first or initial load and the stress caused by the final load. Experience with springs designed to stresses within the limits of these curves indicates that they should have infinite or unlimited fatigue life. All values include Wahl curvature correction factor. The stress ranges shown may be increased 20 to 30 per cent for springs that have been properly heated, pressed to remove set, and then shot peened, provided that the increased values are lower than the torsional elastic limit by at least 10 per cent.

Fig. 11. Endurance Limit Curves for Compression Springs

*Notes:* For commercial spring materials with wire diameters up to  $\frac{1}{4}$  inch except as noted. Stress ranges may be increased by approximately 30 per cent for properly heated, preset, shot-peened springs.

Materials preceded by \* are not ordinarily recommended for long continued service under severe operating conditions.

**Working Stresses at Elevated Temperatures.**—Since modulus of elasticity decreases with increase in temperature, springs used at high temperatures exert less load and have larger deflections under load than at room temperature. The torsional modulus of elasticity for steel may be 11,200,000 pounds per square inch at room temperature, but it will drop to 10,600,000 pounds per square inch at 400°F. and will be only 10,000,000 pounds per square inch at 600°F. Also, the elastic limit is reduced, thereby lowering the permissible working stress.

Design stresses should be as low as possible for all springs used at elevated temperatures. In addition, corrosive conditions that usually exist at high temperatures, especially with steam, may require the use of corrosion-resistant material. Table 2 shows the permissible elevated temperatures at which various spring materials may be operated, together with the maximum recommended working stresses at these temperatures. The loss in load at the temperatures shown is less than 5 per cent in 48 hours; however, if the temperatures listed are increased by 20 to 40 degrees, the loss of load may be nearer 10 per cent. Maximum stresses shown in the table are for compression and extension springs and may be increased

by 75 per cent for torsion and flat springs. In using the data in Table 2 it should be noted that the values given are for materials in the heat-treated or spring temper condition.

**Table 2. Recommended Maximum Working Temperatures and Corresponding Maximum Working Stresses for Springs**

| Spring Material       | Max. Working Temp., °F | Max. Working Stress, psi | Spring Material              | Max. Working Temp., °F | Max. Working Stress, psi |
|-----------------------|------------------------|--------------------------|------------------------------|------------------------|--------------------------|
| Brass Spring Wire     | 150                    | 30,000                   | Permanickel <sup>a</sup>     | 500                    | 50,000                   |
| Phosphor Bronze       | 225                    | 35,000                   | Stainless Steel 18-8         | 550                    | 55,000                   |
| Music Wire            | 250                    | 75,000                   | Stainless Chromium 431       | 600                    | 50,000                   |
| Beryllium-Copper      | 300                    | 40,000                   | Inconel                      | 700                    | 50,000                   |

Loss of load at temperatures shown is less than 5 per cent in 48 hours.

### Spring Design Data

**Spring Characteristics.**—This section provides tables of spring characteristics, tables of principal formulas, and other information of a practical nature for designing the more commonly used types of springs.

*Standard wire gages for springs:* Information on wire gages is given in the section beginning on page 2519, and gages in decimals of an inch are given in the table on page 2520. It should be noted that the range in this table extends from Number 7/0 through Number 80. However, in spring design, the range most commonly used extends only from Gage Number 4/0 through Number 40. When selecting wire use Steel Wire Gage or Washburn and Moen gage for all carbon steels and alloy steels except music wire; use Brown & Sharpe gage for brass and phosphor bronze wire; use Birmingham gage for flat spring steels, and cold rolled strip; and use piano or music wire gage for music wire.

*Spring index:* The spring index is the ratio of the mean coil diameter of a spring to the wire diameter ( $D/d$ ). This ratio is one of the most important considerations in spring design because the deflection, stress, number of coils, and selection of either annealed or tempered material depend to a considerable extent on this ratio. The best proportioned springs have an index of 7 through 9. Indexes of 4 through 7, and 9 through 16 are often used. Springs with values larger than 16 require tolerances wider than standard for manufacturing; those with values less than 5 are difficult to coil on automatic coiling machines.

*Direction of helix:* Unless functional requirements call for a definite hand, the helix of compression and extension springs should be specified as optional. When springs are designed to operate, one inside the other, the helices should be opposite hand to prevent intermeshing. For the same reason, a spring that is to operate freely over a threaded member should have a helix of opposite hand to that of the thread. When a spring is to engage with a screw or bolt, it should, of course, have the same helix as that of the thread.

**Helical Compression Spring Design.**—After selecting a suitable material and a safe stress value for a given spring, designers should next determine the type of end coil formation best suited for the particular application. Springs with unground ends are less expensive but they do not stand perfectly upright; if this requirement has to be met, closed ground ends are used. Helical compression springs with different types of ends are shown in Fig. 12.

Fig. 12. Types of Helical Compression Spring Ends

*Spring design formulas:* Table 3 gives formulas for compression spring dimensional characteristics, and Table 4 gives design formulas for compression and extension springs.

*Curvature correction:* In addition to the stress obtained from the formulas for load or deflection, there is a direct shearing stress and an increased stress on the inside of the section due to curvature. Therefore, the stress obtained by the usual formulas should be multiplied by a factor  $K$  taken from the curve in Fig. 13. The corrected stress thus obtained is used only for comparison with the allowable working stress (fatigue strength) curves to determine if it is a safe stress and should not be used in formulas for deflection. The curvature correction factor  $K$  is for compression and extension springs made from round wire. For square wire reduce the  $K$  value by approximately 4 per cent.

*Design procedure:* The limiting dimensions of a spring are often determined by the available space in the product or assembly in which it is to be used. The loads and deflections on a spring may also be known or can be estimated, but the wire size and number of coils are usually unknown. Design can be carried out with the aid of the tabular data that appears later in this section (see Table 5, which is a simple method, or by calculation alone using the formulas in Tables 3 and 4.

*Example:* A compression spring with closed and ground ends is to be made from ASTM A229 high carbon steel wire, as shown in Fig. 14. Determine the wire size and number of coils.

*Method 1, using table:* Referring to Table 5, starting on page 325, locate the spring outside diameter ( $1\frac{3}{16}$  inches, from Fig. 14) in the left-hand column. Note from the drawing that the spring load is 36 pounds. Move to the right in the table to the figure nearest this value, which is 41.7 pounds. This is somewhat above the required value but safe. Immediately above the load value, the deflection  $f$  is given, which in this instance is 0.1594 inch. This is the deflection of one coil under a load of 41.7 pounds with an uncorrected torsional stress  $S$  of 100,000 pounds per square inch for ASTM A229 oil-tempered MB steel. For other spring materials, see the footnotes to Table 5 on page 325. Moving vertically in Table 5 from the load entry, the wire diameter is found to be 0.0915 inch.

The remaining spring design calculations are completed as follows:

*Step 1:* The stress with a load of 36 pounds is obtained by proportion, as follows: The 36 pound load is 86.3 per cent of the 41.7 pound load; therefore, the stress  $S$  at 36 pounds =  $0.863 \times 100,000 = 86,300$  pounds per square inch.

**Table 3. Formulas for Compression Springs**

| Feature                        | Type of End                    |                                    |                                   |                                   |
|--------------------------------|--------------------------------|------------------------------------|-----------------------------------|-----------------------------------|
|                                | Open or Plain (not ground)     | Open or Plain (with ends ground)   | Squared or Closed (not ground)    | Closed and Ground                 |
|                                | Formula <sup>a</sup>           |                                    |                                   |                                   |
| Pitch ( $p$ )                  | $\frac{FL-d}{N}$               | $\frac{FL}{TC}$                    | $\frac{FL-3d}{N}$                 | $\frac{FL-2d}{N}$                 |
| Solid Height (SH)              | $(TC+1)d$                      | $TC \times d$                      | $(TC+1)d$                         | $TC \times d$                     |
| Number of Active Coils ( $N$ ) | $N = TC$<br>$= \frac{FL-d}{p}$ | $N = TC-1$<br>$= \frac{FL}{p} - 1$ | $N = TC-2$<br>$= \frac{FL-3d}{p}$ | $N = TC-2$<br>$= \frac{FL-2d}{p}$ |
| Total Coils (TC)               | $\frac{FL-d}{p}$               | $\frac{FL}{p}$                     | $\frac{FL-3d}{p} + 2$             | $\frac{FL-2d}{p} + 2$             |

<sup>a</sup>The symbol notation is given on page 308.

**Table 4. Formulas for Compression and Extension Springs**

| Feature  | Formula <sup>a, b</sup>                                 |  |
|--|---|--|
|  | Springs made from round wire                            | Springs made from square wire                            |
| Load, $P$<br>Pounds                              | $P = \frac{0.393Sd^3}{D} = \frac{Gd^4F}{8ND^3}$         | $P = \frac{0.416Sd^3}{D} = \frac{Gd^4F}{5.58ND^3}$       |
| Stress, Torsional, $S$<br>Pounds per square inch | $S = \frac{GdF}{\pi ND^2} = \frac{PD}{0.393d^3}$        | $S = \frac{GdF}{2.32ND^2} = P \frac{D}{0.416d^3}$        |
| Deflection, $F$<br>Inch                          | $F = \frac{8PND^3}{Gd^4} = \frac{\pi SND^2}{Gd}$        | $F = \frac{5.58PND^3}{Gd^4} = \frac{2.32SND^2}{Gd}$      |
| Number of Active Coils, $N$                      | $N = \frac{Gd^4F}{8PD^3} = \frac{GdF}{\pi SD^2}$        | $N = \frac{Gd^4F}{5.58PD^3} = \frac{GdF}{2.32SD^2}$      |
| Wire Diameter, $d$<br>Inch                       | $d = \frac{\pi SND^2}{GF} = \sqrt[3]{\frac{2.55PD}{S}}$ | $d = \frac{2.32SND^2}{GF} = \sqrt[3]{\frac{PD}{0.416S}}$ |
| Stress due to Initial Tension, $S_{it}$          | $S_{it} = \frac{S}{P} \times IT$                        | $S_{it} = \frac{S}{P} \times IT$                         |

<sup>a</sup>The symbol notation is given on page 308.

<sup>b</sup>Two formulas are given for each feature, and designers can use the one found to be appropriate for a given design. The end result from either of any two formulas is the same.

**Step 2:** The 86.3 per cent figure is also used to determine the deflection per coil  $f$  at 36 pounds load:  $0.863 \times 0.1594 = 0.1375$  inch.

**Step 3:** The number of active coils  $AC = \frac{F}{f} = \frac{1.25}{0.1375} = 9.1$

Fig. 13. Compression and Extension Spring-Stress Correction for Curvature<sup>a</sup>

<sup>a</sup> For springs made from round wire. For springs made from square wire, reduce the  $K$  factor values by approximately 4 per cent.

Fig. 14. Compression Spring Design Example

Step 4: Total Coils  $TC = AC + 2$  (Table 3) =  $9 + 2 = 11$

Therefore, a quick answer is: 11 coils of 0.0915 inch diameter wire. However, the design procedure should be completed by carrying out these remaining steps:

Step 5: From Table 3, Solid Height =  $SH = TC \times d = 11 \times 0.0915 \cong 1$  inch

Therefore, Total Deflection =  $FL - SH = 1.5$  inches

$$\text{Step 6: Stress Solid} = \frac{86,300}{1.25} \times 1.5 = 103,500 \text{ pounds per square inch}$$

$$\text{Step 7: Spring Index} = \frac{O.D.}{d} - 1 = \frac{0.8125}{0.0915} - 1 = 7.9$$

Step 8: From Fig. 13, the curvature correction factor  $K = 1.185$

Step 9: Total Stress at 36 pounds load =  $S \times K = 86,300 \times 1.185 = 102,300$  pounds per square inch. This stress is below the 117,000 pounds per square inch permitted for 0.0915 inch wire shown on the middle curve in Fig. 3, so it is a safe working stress.

Step 10: Total Stress at Solid =  $103,500 \times 1.185 = 122,800$  pounds per square inch. This stress is also safe, as it is below the 131,000 pounds per square inch shown on the top curve Fig. 3, and therefore the spring will not set.

*Method 2, using formulas:* The procedure for design using formulas is as follows (the design example is the same as in Method 1, and the spring is shown in Fig. 14):

Step 1: Select a safe stress  $S$  below the middle fatigue strength curve Fig. 8 for ASTM A229 steel wire, say 90,000 pounds per square inch. Assume a mean diameter  $D$  slightly below the  $\frac{13}{16}$ -inch  $O.D.$ , say 0.7 inch. Note that the value of  $G$  is 11,200,000 pounds per square inch (Table 20).

Step 2: A trial wire diameter  $d$  and other values are found by formulas from Table 4 as follows:

$$\begin{aligned} d &= \sqrt[3]{\frac{2.55PD}{S}} = \sqrt[3]{\frac{2.55 \times 36 \times 0.7}{90,000}} \\ &= \sqrt[3]{0.000714} = 0.0894 \text{ inch} \end{aligned}$$

Note: Table 21 can be used to avoid solving the cube root.

Step 3: From the table on page 2520, select the nearest wire gauge size, which is 0.0915 inch diameter. Using this value, the mean diameter  $D = \frac{13}{16}$  inch  $- 0.0915 = 0.721$  inch.

$$\text{Step 4: The stress } S = \frac{PD}{0.393d^3} = \frac{36 \times 0.721}{0.393 \times 0.0915^3} = 86,300 \text{ lb/in}^2$$

Step 5: The number of active coils is

$$N = \frac{GdF}{\pi SD^2} = \frac{11,200,000 \times 0.0915 \times 1.25}{3.1416 \times 86,300 \times 0.721^2} = 9.1 \text{ (say 9)}$$

The answer is the same as before, which is to use 11 total coils of 0.0915-inch diameter wire. The total coils, solid height, etc., are determined in the same manner as in Method 1.

**Table of Spring Characteristics.**—Table 5 gives characteristics for compression and extension springs made from ASTM A229 oil-tempered MB spring steel having a torsional modulus of elasticity  $G$  of 11,200,000 pounds per square inch, and an uncorrected torsional stress  $S$  of 100,000 pounds per square inch. The deflection  $f$  for one coil under a load  $P$  is shown in the body of the table. The method of using these data is explained in the problems for compression and extension spring design. The table may be used for other materials by applying factors to  $f$ . The factors are given in a footnote to the table.

<sup>a</sup>This table is for ASTM A229 oil tempered spring steel with a torsional modulus  $G$  of 11,200,000 psi, and an uncorrected torsional stress of 100,000 psi. For other materials use the following factors: stainless steel, multiply  $f$  by 1.067; spring brass, multiply  $f$  by 2.24; phosphor bronze, multiply  $f$  by 1.867; Monel metal, multiply  $f$  by 1.244; beryllium copper, multiply  $f$  by 1.725; Inconel (non-magnetic), multiply  $f$  by 1.045.

<sup>b</sup>Round wire. For square wire, multiply  $f$  by 0.707, and  $p$ , by 1.2

<sup>c</sup>The upper figure is the deflection and the lower figure the load as read against each spring size. *Note:* Intermediate values can be obtained within reasonable accuracy by interpolation.

Table 5. (Continued) Compression and Extension Spring Deflections<sup>a</sup>

<sup>a</sup>This table is for ASTM A229 oil tempered spring steel with a torsional modulus  $G$  of 11,200,000 psi, and an uncorrected torsional stress of 100,000 psi. For other materials, and other important footnotes, see page 325.

**Extension Springs.**—About 10 per cent of all springs made by many companies are of this type, and they frequently cause trouble because insufficient consideration is given to stress due to initial tension, stress and deflection of hooks, special manufacturing methods, secondary operations and overstretching at assembly. Fig. 15 shows types of ends used on these springs.

**This Group of Special Ends Requires Special Tools**

Fig. 15. Types of Helical Extension Spring Ends

*Initial tension:* In the spring industry, the term "Initial tension" is used to define a force or load, measurable in pounds or ounces, which presses the coils of a close wound extension spring against one another. This force must be overcome before the coils of a spring begin to open up.

Initial tension is wound into extension springs by bending each coil as it is wound away from its normal plane, thereby producing a slight twist in the wire which causes the coil to spring back tightly against the adjacent coil. Initial tension can be wound into cold-coiled

## SPRING DESIGN

Fig. 16. Permissible Torsional Stress Caused by Initial Tension in Coiled Extension Springs for Different Spring Indexes

extension springs only. Hot-wound springs and springs made from annealed steel are hardened and tempered after coiling, and therefore initial tension cannot be produced. It is possible to make a spring having initial tension only when a high tensile strength, obtained by cold drawing or by heat-treatment, is possessed by the material as it is being wound into springs. Materials that possess the required characteristics for the manufacture of such springs include hard-drawn wire, music wire, pre-tempered wire, 18-8 stainless steel, phosphor-bronze, and many of the hard-drawn copper-nickel, and nonferrous alloys. Permissible torsional stresses resulting from initial tension for different spring indexes are shown in Fig. 16.

**Hook failure:** The great majority of breakages in extension springs occurs in the hooks. Hooks are subjected to both bending and torsional stresses and have higher stresses than the coils in the spring.

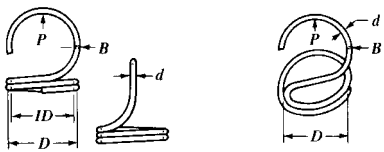

**Stresses in regular hooks:** The calculations for the stresses in hooks are quite complicated and lengthy. Also, the radii of the bends are difficult to determine and frequently vary between specifications and actual production samples. However, regular hooks are more

highly stressed than the coils in the body and are subjected to a bending stress at section B (see Table 6.) The bending stress  $S_b$  at section B should be compared with allowable stresses for torsion springs and with the elastic limit of the material in tension (See Figs. 7 through 10.)

*Stresses in cross over hooks:* Results of tests on springs having a normal average index show that the cross over hooks last longer than regular hooks. These results may not occur on springs of small index or if the cross over bend is made too sharply.

In as much as both types of hooks have the same bending stress, it would appear that the fatigue life would be the same. However, the large bend radius of the regular hooks causes some torsional stresses to coincide with the bending stresses, thus explaining the earlier breakages. If sharper bends were made on the regular hooks, the life should then be the same as for cross over hooks.

**Table 6. Formula for Bending Stress at Section B**

| Type of Hook   | Stress in Bending                    |
|--|--------------------------------------|
|  <p data-bbox="158 781 282 803">Regular Hook</p> <p data-bbox="446 781 595 803">Cross-over Hook</p> | $S_b = \frac{5PD^2}{I.D. \cdot d^3}$ |

*Stresses in half hooks:* The formulas for regular hooks can also be used for half hooks, because the smaller bend radius allows for the increase in stress. It will therefore be observed that half hooks have the same stress in bending as regular hooks.

Frequently overlooked facts by many designers are that one full hook deflects an amount equal to one half a coil and each half hook deflects an amount equal to one tenth of a coil. Allowances for these deflections should be made when designing springs. Thus, an extension spring, with regular full hooks and having 10 coils, will have a deflection equal to 11 coils, or 10 per cent more than the calculated deflection.

**Extension Spring Design.**—The available space in a product or assembly usually determines the limiting dimensions of a spring, but the wire size, number of coils, and initial tension are often unknown.

*Example:* An extension spring is to be made from spring steel ASTM A229, with regular hooks as shown in Fig. 17. Calculate the wire size, number of coils and initial tension.

*Note:* Allow about 20 to 25 per cent of the 9 pound load for initial tension, say 2 pounds, and then design for a 7 pound load (not 9 pounds) at  $\frac{5}{8}$  inch deflection. Also use lower stresses than for a compression spring to allow for overstretching during assembly and to obtain a safe stress on the hooks. Proceed as for compression springs, but locate a load in the tables somewhat higher than the 9 pound load.

*Method 1, using table:* From Table 5 locate  $\frac{3}{4}$  inch outside diameter in the left column and move to the right to locate a load  $P$  of 13.94 pounds. A deflection  $f$  of 0.212 inch appears above this figure. Moving vertically from this position to the top of the column a suitable wire diameter of 0.0625 inch is found.

The remaining design calculations are completed as follows:

*Step 1:* The stress with a load of 7 pounds is obtained as follows:  
The 7 pound load is 50.2 per cent of the 13.94 pound load. Therefore, the stress  $S$  at 7 pounds = 0.502 per cent  $\times$  100,000 = 50,200 pounds per square inch.

Fig. 17. Extension Spring Design Example

Step 2: The 50.2 per cent figure is also used to determine the deflection per coil  $f$ :  $0.502$  per cent  $\times 0.212 = 0.1062$  inch.

Step 3: The number of active coils. (say 6)

$$AC = \frac{F}{f} = \frac{0.625}{0.1062} = 5.86$$

This result should be reduced by 1 to allow for deflection of 2 hooks (see notes 1 and 2 that follow these calculations.) Therefore, a quick answer is: 5 coils of 0.0625 inch diameter wire. However, the design procedure should be completed by carrying out the following steps:

Step 4: The body length  $= (TC + 1) \times d = (5 + 1) \times 0.0625 = \frac{3}{8}$  inch.

Step 5: The length from the body to inside hook

$$= \frac{FL - \text{Body}}{2} = \frac{1.4375 - 0.375}{2} = 0.531 \text{ inch}$$

$$\text{Percentage of I.D.} = \frac{0.531}{\text{I.D.}} = \frac{0.531}{0.625} = 85 \text{ per cent}$$

This length is satisfactory, see Note 3 following this procedure.

Step 6:

$$\text{The spring index} = \frac{\text{O.D.}}{d} - 1 = \frac{0.75}{0.0625} - 1 = 11$$

Step 7: The initial tension stress is

$$S_{it} = \frac{S \times IT}{P} = \frac{50,200 \times 2}{7} = 14,340 \text{ pounds per square inch}$$

This stress is satisfactory, as checked against curve in Fig. 16.

Step 8: The curvature correction factor  $K = 1.12$  (Fig. 13).

Step 9: The total stress  $= (50,200 + 14,340) \times 1.12 = 72,285$  pounds per square inch

This result is less than 106,250 pounds per square inch permitted by the middle curve for 0.0625 inch wire in Fig. 3 and therefore is a safe working stress that permits some additional deflection that is usually necessary for assembly purposes.

*Step 10:* The large majority of hook breakage is due to high stress in bending and should be checked as follows:

From Table 6, stress on hook in bending is:

$$S_b = \frac{5PD^2}{\text{I.D.} \cdot d^3} = \frac{5 \times 9 \times 0.6875^2}{0.625 \times 0.0625^3} = 139,200 \text{ pounds per square inch}$$

This result is less than the top curve value, Fig. 8, for 0.0625 inch diameter wire, and is therefore safe. Also see Note 5 that follows.

*Notes:* The following points should be noted when designing extension springs:

- 1) All coils are active and thus  $AC = TC$ .
- 2) Each full hook deflection is approximately equal to  $\frac{1}{2}$  coil. Therefore for 2 hooks, reduce the total coils by 1. (Each half hook deflection is nearly equal to  $\frac{1}{10}$  of a coil.)
- 3) The distance from the body to the inside of a regular full hook equals 75 to 85 per cent (90 per cent maximum) of the I.D. For a cross over center hook, this distance equals the I.D.
- 4) Some initial tension should usually be used to hold the spring together. Try not to exceed the maximum curve shown on Fig. 16. Without initial tension, a long spring with many coils will have a different length in the horizontal position than it will when hung vertically.
- 5) The hooks are stressed in bending, therefore their stress should be less than the maximum bending stress as used for torsion springs — use top fatigue strength curves Figs. 7 through 10.

*Method 2, using formulas:* The sequence of steps for designing extension springs by formulas is similar to that for compression springs. The formulas for this method are given in Table 3.

**Tolerances for Compression and Extension Springs.**—Tolerances for coil diameter, free length, squareness, load, and the angle between loop planes for compression and extension springs are given in Tables 7 through 12. To meet the requirements of load, rate, free length, and solid height, it is necessary to vary the number of coils for compression springs by  $\pm 5$  per cent. For extension springs, the tolerances on the numbers of coils are: for 3 to 5 coils,  $\pm 20$  per cent; for 6 to 8 coils,  $\pm 30$  per cent; for 9 to 12 coils,  $\pm 40$  per cent. For each additional coil, a further  $1\frac{1}{2}$  per cent tolerance is added to the extension spring values. Closer tolerances on the number of coils for either type of spring lead to the need for trimming after coiling, and manufacturing time and cost are increased. Fig. 18 shows deviations allowed on the ends of extension springs, and variations in end alignments.

**Table 7. Compression and Extension Spring Coil Diameter Tolerances**

| Wire Diameter, Inch | Spring Index          |       |       |       |       |       |       |
|---------------------|-----------------------|-------|-------|-------|-------|-------|-------|
|                     | 4                     | 6     | 8     | 10    | 12    | 14    | 16    |
|                     | Tolerance, $\pm$ inch |       |       |       |       |       |       |

<sup>a</sup> Slenderness Ratio =  $FL \div D$

Springs with closed and ground ends, in the free position. Squareness tolerances closer than those shown require special process techniques which increase cost. Springs made from fine wire sizes, and with high spring indices, irregular shapes or long free lengths, require special attention in determining appropriate tolerance and feasibility of grinding ends.

<sup>a</sup> From free length to loaded position.

**Torsion Spring Design.**—Fig. 19 shows the types of ends most commonly used on torsion springs. To produce them requires only limited tooling. The straight torsion end is the least expensive and should be used whenever possible. After determining the spring load or torque required and selecting the end formations, the designer usually estimates suitable space or size limitations. However, the space should be considered approximate until the wire size and number of coils have been determined. The wire size is dependent principally upon the torque. Design data can be developed with the aid of the tabular data, which is a simple method, or by calculation alone, as shown in the following sections. Many other factors affecting the design and operation of torsion springs are also covered in the section, *Torsion Spring Design Recommendations* on page 341. Design formulas are shown in Table 13.

*Curvature correction:* In addition to the stress obtained from the formulas for load or deflection, there is a direct shearing stress on the inside of the section due to curvature. Therefore, the stress obtained by the usual formulas should be multiplied by the factor  $K$

**Table 12. Extension Spring Normal Load Tolerances**

| Spring Index | $\frac{FL}{F}$ | Wire Diameter (inch)              |       |       |       |       |       |       |       |       |       |       |

$FL/F$  = the ratio of the spring free length  $FL$  to the deflection  $F$ .

Fig. 19. The Most Commonly Used Types of Ends for Torsion Springs

Fig. 20. Torsion Spring Stress Correction for Curvature

obtained from the curve in Fig. 20. The corrected stress thus obtained is used only for comparison with the allowable working stress (fatigue strength) curves to determine if it is a safe value, and should not be used in the formulas for deflection.

**Torque:** Torque is a force applied to a moment arm and tends to produce rotation. Torsion springs exert torque in a circular arc and the arms are rotated about the central axis. It should be noted that the stress produced is in bending, not in torsion. In the spring industry it is customary to specify torque in conjunction with the deflection or with the arms of a spring at a definite position. Formulas for torque are expressed in pound-inches. If ounce-inches are specified, it is necessary to divide this value by 16 in order to use the formulas.

When a load is specified at a distance from a centerline, the torque is, of course, equal to the load multiplied by the distance. The load can be in pounds or ounces with the distances in inches or the load can be in grams or kilograms with the distance in centimeters or millimeters, but to use the design formulas, all values must be converted to pounds and inches. Design formulas for torque are based on the tangent to the arc of rotation and presume that a rod is used to support the spring. The stress in bending caused by the moment  $P \times R$  is identical in magnitude to the torque  $T$ , provided a rod is used.

Theoretically, it makes no difference how or where the load is applied to the arms of torsion springs. Thus, in Fig. 21, the loads shown multiplied by their respective distances pro-

**Table 13. Formulas for Torsion Springs**

| Feature  | Springs made from round wire                         | Springs made from square wire                        |

<sup>a</sup> Where two formulas are given for one feature, the designer should use the one found to be appropriate for the given design. The end result from either of any two formulas is the same.

<sup>b</sup> The symbol notation is given on page 308.

duce the same torque; i.e.,  $20 \times 0.5 = 10$  pound-inches;  $10 \times 1 = 10$  pound-inches; and  $5 \times 2 = 10$  pound-inches. To further simplify the understanding of torsion spring torque, observe in both Fig. 22 and Fig. 23 that although the turning force is in a circular arc the torque is not equal to  $P$  times the radius. The torque in both designs equals  $P \times R$  because the spring rests against the support rod at point  $a$ .

*Design Procedure:* Torsion spring designs require more effort than other kinds because consideration has to be given to more details such as the proper size of a supporting rod, reduction of the inside diameter, increase in length, deflection of arms, allowance for friction, and method of testing.

Fig. 21. Right-Hand Torsion Spring

Fig. 22. Left-Hand Torsion Spring

The Torque is  $T = P \times R$ , Not  $P \times \text{Radius}$ , because the Spring is Resting Against the Support Rod at Point  $a$

Fig. 23. Left-Hand Torsion Spring

As with the Spring in Fig. 22, the Torque is  $T = P \times R$ , Not  $P \times \text{Radius}$ , Because the Support Point Is at  $a$

*Example:* What music wire diameter and how many coils are required for the torsion spring shown in Fig. 24, which is to withstand at least 1000 cycles? Determine the corrected stress and the reduced inside diameter after deflection.

Fig. 24. Torsion Spring Design Example. The Spring Is to be Assembled on a  $\frac{7}{16}$ -Inch Support Rod

*Method 1, using table:* From Table 14, page 343, locate the  $\frac{1}{2}$  inch inside diameter for the spring in the left-hand column. Move to the right and then vertically to locate a torque value nearest to the required 10 pound-inches, which is 10.07 pound-inches. At the top of the same column, the music wire diameter is found, which is Number 31 gauge (0.085 inch). At the bottom of the same column the deflection for one coil is found, which is 15.81 degrees. As a 90-degree deflection is required, the number of coils needed is  $\frac{90}{15.81} = 5.69$  (say  $5\frac{3}{4}$  coils).

The spring index  $\frac{D}{d} = \frac{0.500 + 0.085}{0.085} = 6.88$  and thus the curvature correction factor

$K$  from Fig. 20 = 1.13. Therefore the corrected stress equals  $167,000 \times 1.13 = 188,700$  pounds per square inch which is below the Light Service curve (Fig. 7) and therefore should provide a fatigue life of over 1,000 cycles. The reduced inside diameter due to deflection is found from the formula in Table 13:

$$ID_1 = \frac{N(ID \text{ free})}{N + \frac{F}{360}} = \frac{5.75 \times 0.500}{5.75 + \frac{90}{360}} = 0.479 \text{ in.}$$

This reduced diameter easily clears a suggested  $\frac{7}{16}$  inch diameter supporting rod:  $0.479 - 0.4375 = 0.041$  inch clearance, and it also allows for the standard tolerance. The overall length of the spring equals the total number of coils plus one, times the wire diameter. Thus,  $6\frac{3}{4} \times 0.085 = 0.574$  inch. If a small space of about  $\frac{1}{64}$  in. is allowed between the coils to eliminate coil friction, an overall length of  $\frac{21}{32}$  inch results.

Although this completes the design calculations, other tolerances should be applied in accordance with the Torsion Spring Tolerance Tables 16 through 17 shown at the end of this section.

*Longer fatigue life:* If a longer fatigue life is desired, use a slightly larger wire diameter. Usually the next larger gage size is satisfactory. The larger wire will reduce the stress and still exert the same torque, but will require more coils and a longer overall length.

*Percentage method for calculating longer life:* The spring design can be easily adjusted for longer life as follows:

1) Select the next larger gage size, which is Number 32 (0.090 inch) from [Table 14](#). The torque is 11.88 pound-inches, the design stress is 166,000 pounds per square inch, and the deflection is 14.9 degrees per coil. As a percentage the torque is  $10/11.88 \times 100 = 84$  per cent.

2) The new stress is  $0.84 \times 166,000 = 139,440$  pounds per square inch. This value is under the bottom or Severe Service curve, [Fig. 7](#), and thus assures longer life.

3) The new deflection per coil is  $0.84 \times 14.97 = 12.57$  degrees. Therefore, the total number of coils required =  $90/12.57 = 7.16$  (say  $7 \frac{1}{8}$ ). The new overall length =  $8 \frac{1}{8} \times 0.090 = 0.73$  inch (say  $\frac{3}{4}$  inch). A slight increase in the overall length and new arm location are thus necessary.

*Method 2, using formulas:* When using this method, it is often necessary to solve the formulas several times because assumptions must be made initially either for the stress or for a wire size. The procedure for design using formulas is as follows (the design example is the same as in Method 1, and the spring is shown in [Fig. 24](#)):

*Step 1:* Note from [Table 13](#), page 338 that the wire diameter formula is:

$$d = \sqrt[3]{\frac{10.18T}{S_b}}$$

*Step 2:* Referring to [Fig. 7](#), select a trial stress, say 150,000 pounds per square inch.

*Step 3:* Apply the trial stress, and the 10 pound-inches torque value in the wire diameter formula:

$$d = \sqrt[3]{\frac{10.18T}{S_b}} = \sqrt[3]{\frac{10.18 \times 10}{150,000}} = \sqrt[3]{0.000679} = 0.0879 \text{ inch}$$

The nearest gauge sizes are 0.085 and 0.090 inch diameter. *Note:* [Table 21](#), page 351, can be used to avoid solving the cube root.

*Step 4:* Select 0.085 inch wire diameter and solve the equation for the actual stress:

$$S_b = \frac{10.18T}{d^3} = \frac{10.18 \times 10}{0.085^3} = 165,764 \text{ pounds per square inch}$$

*Step 5:* Calculate the number of coils from the equation, [Table 13](#):

$$N = \frac{EdF^{\circ}}{392S_bD} = \frac{28,500,000 \times 0.085 \times 90}{392 \times 165,764 \times 0.585} = 5.73 \text{ (say } 5 \frac{3}{4}\text{)}$$

*Step 6:* Calculate the total stress. The spring index is 6.88, and the correction factor  $K$  is 1.13, therefore total stress =  $165,764 \times 1.13 = 187,313$  pounds per square inch. *Note:* The corrected stress should not be used in any of the formulas as it does not determine the torque or the deflection.

**Torsion Spring Design Recommendations.**—The following recommendations should be taken into account when designing torsion springs:

*Hand:* The hand or direction of coiling should be specified and the spring designed so deflection causes the spring to wind up and to have more coils. This increase in coils and overall length should be allowed for during design. Deflecting the spring in an unwinding direction produces higher stresses and may cause early failure. When a spring is sighted down the longitudinal axis, it is "right hand" when the direction of the wire into the spring takes a clockwise direction or if the angle of the coils follows an angle similar to the threads

of a standard bolt or screw, otherwise it is "left hand." A spring must be coiled right-handed to engage the threads of a standard machine screw.

*Rods:* Torsion springs should be supported by a rod running through the center whenever possible. If unsupported, or if held by clamps or lugs, the spring will buckle and the torque will be reduced or unusual stresses may occur.

*Diameter Reduction:* The inside diameter reduces during deflection. This reduction should be computed and proper clearance provided over the supporting rod. Also, allowances should be considered for normal spring diameter tolerances.

*Winding:* The coils of a spring may be closely or loosely wound, but they seldom should be wound with the coils pressed tightly together. Tightly wound springs with initial tension on the coils do not deflect uniformly and are difficult to test accurately. A small space between the coils of about 20 to 25 per cent of the wire thickness is desirable. Square and rectangular wire sections should be avoided whenever possible as they are difficult to wind, expensive, and are not always readily available.

*Arm Length:* All the wire in a torsion spring is active between the points where the loads are applied. Deflection of long extended arms can be calculated by allowing one third of the arm length, from the point of load contact to the body of the spring, to be converted into coils. However, if the length of arm is equal to or less than one-half the length of one coil, it can be safely neglected in most applications.

*Total Coils:* Torsion springs having less than three coils frequently buckle and are difficult to test accurately. When thirty or more coils are used, light loads will not deflect all the coils simultaneously due to friction with the supporting rod. To facilitate manufacturing it is usually preferable to specify the total number of coils to the nearest fraction in eighths or quarters such as  $5 \frac{1}{8}$ ,  $5 \frac{1}{4}$ ,  $5 \frac{1}{2}$ , etc.

*Double Torsion:* This design consists of one left-hand-wound series of coils and one series of right-hand-wound coils connected at the center. These springs are difficult to manufacture and are expensive, so it often is better to use two separate springs. For torque and stress calculations, each series is calculated separately as individual springs; then the torque values are added together, but the deflections are not added.

*Bends:* Arms should be kept as straight as possible. Bends are difficult to produce and often are made by secondary operations, so they are therefore expensive. Sharp bends raise stresses that cause early failure. Bend radii should be as large as practicable. Hooks tend to open during deflection; their stresses can be calculated by the same procedure as that for tension springs.

*Spring Index:* The spring index must be used with caution. In design formulas it is  $D/d$ . For shop measurement it is  $O.D./d$ . For arbor design it is  $I.D./d$ . Conversions are easily performed by either adding or subtracting 1 from  $D/d$ .

*Proportions:* A spring index between 4 and 14 provides the best proportions. Larger ratios may require more than average tolerances. Ratios of 3 or less, often cannot be coiled on automatic spring coiling machines because of arbor breakage. Also, springs with smaller or larger spring indexes often do not give the same results as are obtained using the design formulas.

**Table of Torsion Spring Characteristics.**—Table 14 shows design characteristics for the most commonly used torsion springs made from wire of standard gauge sizes. The deflection for one coil at a specified torque and stress is shown in the body of the table. The figures are based on music wire (ASTM A228) and oil-tempered MB grade (ASTM A229), and can be used for several other materials which have similar values for the modulus of elasticity  $E$ . However, the design stress may be too high or too low, and the design stress, torque, and deflection per coil should each be multiplied by the appropriate correction factor in Table 15 when using any of the materials given in that table.

Table 14. Torsion Spring Deflections

<sup>a</sup> For sizes up to 26 gauge, the table values are for music wire with a modulus  $E$  of 29,500,000 psi; for sizes from 27 to  $\frac{1}{8}$  inch diameter the table values are for music wire with a modulus of 28,500,000 psi; for sizes from 10 gauge to  $\frac{1}{8}$  inch diameter, the values are for oil-tempered MB with a modulus of 28,500,000 psi.

<sup>b</sup> Gauges 31 through 37 are AMW gauges. Gauges 10 through 5 are Washburn and Moen.

Table 14. (Continued) Torsion Spring Deflections

<sup>a</sup>For sizes up to 26 gauge, the table values are for music wire with a modulus  $E$  of 29,500,000 psi; for sizes from 27 to  $\frac{1}{8}$  inch diameter the table values are for music wire with a modulus of 28,500,000 psi; for sizes from 10 gauge to  $\frac{1}{8}$  inch diameter, the values are for oil-tempered MB with a modulus of 28,500,000 psi.

For an example in the use of the table, see the example starting on page 340. Note: Intermediate values may be interpolated within reasonable accuracy.

**Table 15. Correction Factors for Other Materials**

| Material <sup>a</sup>         | Factor | Material <sup>a</sup>          | Factor |
|-------------------------------|--------|--------------------------------|--------|
| Hard Drawn MB                 | 0.75   | Stainless 316                  |        |
| Chrome-vanadium               | 1.10   | Up to 1/8 inch diameter        | 0.75   |
| Chrome-silicon                | 1.20   | Over 1/8 to 1/4 inch diameter  | 0.65   |
| Stainless 302 and 304         |        | Over 1/4 inch diameter         | 0.65   |
| Up to 1/8 inch diameter       | 0.85   | Stainless 17-7 PH              |        |
| Over 1/8 to 1/4 inch diameter | 0.75   | Up to 1/8 inch diameter        | 1.00   |
| Over 1/4 inch diameter        | 0.65   | Over 1/8 to 3/16 inch diameter | 1.07   |
| Stainless 431                 | 0.80   | Over 3/16 inch diameter        | 1.12   |
| Stainless 420                 | 0.85   | ...                            | ...    |

<sup>a</sup>For use with values in Table 14. *Note:* The figures in Table 14 are for music wire (ASTM A228) and oil-tempered MB grade (ASTM A229) and can be used for several other materials that have a similar modulus of elasticity  $E$ . However, the design stress may be too high or too low, and therefore the design stress, torque, and deflection per coil should each be multiplied by the appropriate correction factor when using any of the materials given in this table (Table 15).

**Torsion Spring Tolerances.**—Torsion springs are coiled in a different manner from other types of coiled springs and therefore different tolerances apply. The commercial tolerance on loads is  $\pm 10$  per cent and is specified with reference to the angular deflection. For example: 100 pound-inches  $\pm 10$  per cent at 45 degrees deflection. One load specified usually suffices. If two loads and two deflections are specified, the manufacturing and testing times are increased. Tolerances smaller than  $\pm 10$  per cent require each spring to be individually tested and adjusted, which adds considerably to manufacturing time and cost. Tables 16, 17, and 18 give, respectively, free angle tolerances, tolerances on the number of coils, and coil diameter tolerances.

**Table 16. Torsion Spring Tolerances for Angular Relationship of Ends**

| Number of Coils (N) | Spring Index                        |    |      |      |      |      |      |      |     |
|---------------------|-------------------------------------|----|------|------|------|------|------|------|-----|
|                     | 4                                   | 6  | 8    | 10   | 12   | 14   | 16   | 18   | 20  |
|                     | Free Angle Tolerance, $\pm$ degrees |    |      |      |      |      |      |      |     |
| 1                   | 2                                   | 3  | 3.5  | 4    | 4.5  | 5    | 5.5  | 5.5  | 6   |
| 2                   | 4                                   | 5  | 6    | 7    | 8    | 8.5  | 9    | 9.5  | 10  |

**Miscellaneous Springs.**— This section provides information on various springs, some in common use, some less commonly used.

*Conical compression:* These springs taper from top to bottom and are useful where an increasing (instead of a constant) load rate is needed, where solid height must be small, and where vibration must be damped. Conical springs with a uniform pitch are easiest to coil. Load and deflection formulas for compression springs can be used – using the average mean coil diameter, and providing the deflection does not cause the largest active coil to lie against the bottom coil. When this happens, each coil must be calculated separately, using the standard formulas for compression springs.

*Constant force springs:* Those springs are made from flat spring steel and are finding more applications each year. Complicated design procedures can be eliminated by selecting a standard design from thousands now available from several spring manufacturers.

*Spiral, clock, and motor springs:* Although often used in wind-up type motors for toys and other products, these springs are difficult to design and results cannot be calculated with precise accuracy. However, many useful designs have been developed and are available from spring manufacturing companies.

*Flat springs:* These springs are often used to overcome operating space limitations in various products such as electric switches and relays. Table 19 lists formulas for designing flat springs. The formulas are based on standard beam formulas where the deflection is small.

**Table 19. Formulas for Flat Springs**

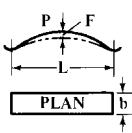

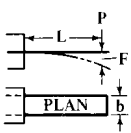

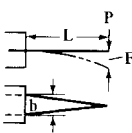

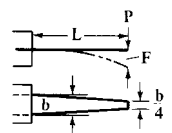

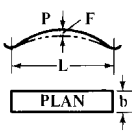

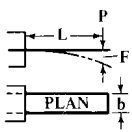

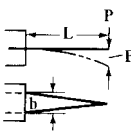

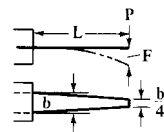

| Feature                      |  |  |  |  |
|------------------------------|---|---|---|---|
| Deflect., <i>f</i><br>Inches | $f = \frac{PL^3}{4Ebt^3}$<br>$= \frac{S_b L^2}{6Et}$                                | $f = \frac{4PL^3}{Ebt^3}$<br>$= \frac{2S_b L^2}{3Et}$                               | $f = \frac{6PL^3}{Ebt^3}$<br>$= \frac{S_b L^2}{Et}$                                 | $f = \frac{5.22PL^3}{Ebt^3}$<br>$= \frac{0.87S_b L^2}{Et}$                          |
| Load, <i>P</i><br>Pounds     | $P = \frac{2S_b bt^2}{3L}$<br>$= \frac{4Ebt^3 F}{L^3}$                              | $P = \frac{S_b bt^2}{6L}$<br>$= \frac{Ebt^3 F}{4L^3}$                               | $P = \frac{S_b bt^2}{6L}$<br>$= \frac{Ebt^3 F}{6L^3}$                               | $P = \frac{S_b bt^2}{6L}$<br>$= \frac{Ebt^3 F}{5.22L^3}$                            |

Table 19. (Continued) Formulas for Flat Springs

|                                 |   |   |   |   |
|---------------------------------|---|---|---|---|
| Feature                         |  |  |  |  |
| Stress, $S_b$<br>Bending<br>psi | $S_b = \frac{3PL}{2bt^2}$<br>$= \frac{6EtF}{L^2}$                                 | $S_b = \frac{6PL}{bt^2}$<br>$= \frac{3EtF}{2L^2}$                                 | $S_b = \frac{6PL}{bt^2}$<br>$= \frac{EtF}{L^2}$                                   | $S_b = \frac{6PL}{bt^2}$<br>$= \frac{EtF}{0.87L^2}$                               |
| Thickness, $t$<br>Inches        | $t = \frac{S_b L^2}{6EF}$<br>$= \sqrt[3]{\frac{PL^3}{4EbF}}$                      | $t = \frac{2S_b L^2}{3EF}$<br>$= \sqrt[3]{\frac{4PL^3}{EbF}}$                     | $t = \frac{S_b L^2}{EF}$<br>$= \sqrt[3]{\frac{6PL^3}{EbF}}$                       | $t = \frac{0.87S_b L^2}{EF}$<br>$= \sqrt[3]{\frac{5.22PL^3}{EbF}}$                |

Based on standard beam formulas where the deflection is small.

See page 308 for notation.

*Note:* Where two formulas are given for one feature, the designer should use the one found to be appropriate for the given design. The result from either of any two formulas is the same.

*Belleville washers or disc springs:* These washer type springs can sustain relatively large loads with small deflections, and the loads and deflections can be increased by stacking the springs.

Information on springs of this type is given in the section *DISC SPRINGS* starting on page 354.

*Volute springs:* These springs are often used on army tanks and heavy field artillery, and seldom find additional uses because of their high cost, long production time, difficulties in manufacture, and unavailability of a wide range of materials and sizes. Small volute springs are often replaced with standard compression springs.

*Torsion bars:* Although the more simple types are often used on motor cars, the more complicated types with specially forged ends are finding fewer applications as time goes.

**Moduli of Elasticity of Spring Materials.**—The modulus of elasticity in tension, denoted by the letter  $E$ , and the modulus of elasticity in torsion, denoted by the letter  $G$ , are used in formulas relating to spring design. Values of these moduli for various ferrous and nonferrous spring materials are given in Table 20.

**General Heat Treating Information for Springs.**—The following is general information on the heat treatment of springs, and is applicable to pre-tempered or hard-drawn spring materials only.

*Compression springs* are baked after coiling (before setting) to relieve residual stresses and thus permit larger deflections before taking a permanent set.

*Extension springs* also are baked, but heat removes some of the initial tension. Allowance should be made for this loss. Baking at 500 degrees F for 30 minutes removes approximately 50 per cent of the initial tension. The shrinkage in diameter however, will slightly increase the load and rate.

*Outside diameters shrink* when springs of music wire, pretempered MB, and other carbon or alloy steels are baked. Baking also slightly increases the free length and these changes produce a little stronger load and increase the rate.

*Outside diameters expand* when springs of stainless steel (18-8) are baked. The free length is also reduced slightly and these changes result in a little lighter load and a decrease the spring rate.

*Inconel, Monel, and nickel alloys* do not change much when baked.

*Beryllium-copper shrinks and deforms* when heated. Such springs usually are baked in fixtures or supported on arbors or rods during heating.

*Brass and phosphor bronze* springs should be given a light heat only. Baking above 450 degrees F will soften the material. Do not heat in salt pots.

*Torsion springs* do not require baking because coiling causes residual stresses in a direction that is helpful, but such springs frequently are baked so that jarring or handling will not cause them to lose the position of their ends.

**Table 20. Moduli of Elasticity in Torsion and Tension of Spring Materials**

| Ferrous Materials             |  |                         | Nonferrous Materials          |  |                         |
|-------------------------------|--|-------------------------|-------------------------------|--|-------------------------|

| Type 431                      | 11,400,000                               | 29,500,000              |                               |  |                         |

<sup>a</sup> Note: Modulus *G* (shear modulus) is used for compression and extension springs; modulus *E* (Young's modulus) is used for torsion, flat, and spiral springs.

<sup>b</sup> Trade name of International Nickel Company.

<sup>c</sup> May be 2,000,000 pounds per square inch less if material is not fully hard.

<sup>d</sup> Trade name of Hamilton Watch Company.

<sup>e</sup> Trade name of John Chatillon & Sons.

*Spring brass and phosphor bronze* springs that are not very highly stressed and are not subject to severe operating use may be stress relieved after coiling by immersing them in boiling water for a period of 1 hour.

*Positions of loops* will change with heat. Parallel hooks may change as much as 45 degrees during baking. Torsion spring arms will alter position considerably. These changes should be allowed for during looping or forming.

*Quick heating* after coiling either in a high-temperature salt pot or by passing a spring through a gas flame is not good practice. Samples heated in this way will not conform with production runs that are properly baked. A small, controlled-temperature oven should be used for samples and for small lot orders.

*Plated springs* should always be baked before plating to relieve coiling stresses and again after plating to relieve hydrogen embrittlement.

*Hardness* values fall with high heat—but music wire, hard drawn, and stainless steel will increase 2 to 4 points Rockwell C.

**Table 21. Squares, Cubes, and Fourth Powers of Wire Diameters**

**Spring Failure.**—Spring failure may be breakage, high permanent set, or loss of load. The causes are listed in groups in [Table 22](#). Group 1 covers causes that occur most frequently; Group 2 covers causes that are less frequent; and Group 3 lists causes that occur occasionally.

**Table 22. Causes of Spring Failure**

|         | Cause                  | Comments and Recommendations  |
|---------|------------------------|---|
| Group 1 | High stress            | The majority of spring failures are due to high stresses caused by large deflections and high loads. High stresses should be used only for statically loaded springs. Low stresses lengthen fatigue life.   |
|         | Hydrogen embrittlement | Improper electroplating methods and acid cleaning of springs, without proper baking treatment, cause spring steels to become brittle, and are a frequent cause of failure. Nonferrous springs are immune.   |
|         | Sharp bends and holes  | Sharp bends on extension, torsion, and flat springs, and holes or notches in flat springs, cause high concentrations of stress, resulting in failure. Bend radii should be as large as possible, and tool marks avoided.  |
|         | Fatigue                | Repeated deflections of springs, especially above 1,000,000 cycles, even with medium stresses, may cause failure. Low stresses should be used if a spring is to be subjected to a very high number of operating cycles.   |
| Group 2 | Shock loading          | Impact, shock, and rapid loading cause far higher stresses than those computed by the regular spring formulas. High-carbon spring steels do not withstand shock loading as well as do alloy steels.   |
|         | Corrosion              | Slight rusting or pitting caused by acids, alkalis, galvanic corrosion, stress corrosion cracking, or corrosive atmosphere weakens the material and causes higher stresses in the corroded area.  |
|         | Faulty heat treatment  | Keeping spring materials at the hardening temperature for longer periods than necessary causes an undesirable growth in grain structure, resulting in brittleness, even though the hardness may be correct.   |
|         | Faulty material        | Poor material containing inclusions, seams, slivers, and flat material with rough, slit, or torn edges is a cause of early failure. Overdrawn wire, improper hardness, and poor grain structure also cause early failure.   |
| Group 3 | High temperature       | High operating temperatures reduce spring temper (or hardness) and lower the modulus of elasticity, thereby causing lower loads, reducing the elastic limit, and increasing corrosion. Corrosion-resisting or nickel alloys should be used.   |
|         | Low temperature        | Temperatures below $-40$ degrees F reduce the ability of carbon steels to withstand shock loads. Carbon steels become brittle at $-70$ degrees F. Corrosion-resisting, nickel, or nonferrous alloys should be used.   |
|         | Friction               | Close fits on rods or in holes result in a wearing away of material and occasional failure. The outside diameters of compression springs expand during deflection but they become smaller on torsion springs.   |
|         | Other causes           | Enlarged hooks on extension springs increase the stress at the bends. Carrying too much electrical current will cause failure. Welding and soldering frequently destroy the spring temper. Tool marks, nicks, and cuts often raise stresses. Deflecting torsion springs outwardly causes high stresses and winding them tightly causes binding on supporting rods. High speed of deflection, vibration, and surging due to operation near natural periods of vibration or their harmonics cause increased stresses. |

**Table 23. Arbor Diameters for Springs Made from Music Wire**

| Wire Dia. (inch) | Spring Outside Diameter (inch) |       |       |       |       |       |       |       |       |       |       |       |       |     |
|------------------|--------------------------------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-----|
|                  | 1/16                           | 3/32  | 1/8   | 5/32  | 3/16  | 7/32  | 1/4   | 9/32  | 5/16  | 11/32 | 3/8   | 7/16  | 1/2   |     |
|                  | Arbor Diameter (inch)          |       |       |       |       |       |       |       |       |       |       |       |       |     |

## DISC SPRINGS

## Performance of Disc Springs

**Introduction.**—Disc springs, also known as Belleville springs, are conically formed from washers and have rectangular cross section. The disc spring concept was invented by a Frenchman Louis Belleville in 1865. His springs were relatively thick and had a small amount of cone height or “dish”, which determined axial deflection. At that time, these springs were used in the buffer parts of railway rolling stock, for recoil mechanisms of guns, and some other applications. The use of disc springs will be advantageous when space is limited and high force is required, as these conditions cannot be satisfied by using coil springs. Load-deflection characteristics of disc springs are linear and regressive depending on their dimensions and the type of stacking. A large number of standard sizes are available from disc spring manufacturers and distributors, so that custom sizes may not be required. Therefore, disc springs are widely used today in virtually all branches of engineering with possibilities of new applications.

**Disc Spring Nomenclature.**—Disc spring manufacturers assign their own part number for each disc spring, but the catalog numbers for disc springs are similar, so each item can often be identified regardless of the manufacturer. The disc spring identification number is a numerical code that provides basic dimensions in millimeters. Identification numbers representing the primary dimensions of the disc spring and consist of one, two, or three numbers separated from each other by dash marks or spaces. Disc spring manufacturers in the United States also provide dimensions in inches. Dimensions of several typical disc springs are shown in the following table. Basic nomenclature is illustrated in Fig. 1.

| Catalog Number (mm) | Outside Diameter $D$ (mm) | Inside Diameter $d$ (mm) | Thickness $t$ (mm) | Equivalent Catalog Number (inch) |
|---------------------|---------------------------|--------------------------|--------------------|----------------------------------|
| 8-4.2-0.4           | 8                         | 4.2                      | 0.4                | 0.315-0.165-0.0157               |
| 50-25.4-2           | 50                        | 25.4                     | 2                  | 1.97-1.00-0.0787                 |
| 200-102-12          | 200                       | 102                      | 12                 | 7.87-4.02-0.472                  |

Additional dimensions shown in catalogs are cone (dish) height  $h$  at unloaded condition, and overall height  $H = h + t$ , that combines the cone height and the thickness of a disc spring.

Fig. 1. Disc Spring Nomenclature

**Disc Spring Group Classification.**—Forces and stresses generated by compression depend on disc spring thickness much more than on any other dimensions. Standard DIN 2093 divides all disc springs into three groups in accordance with their thickness:

*Group 1* includes all disc springs with thickness less than 1.25 mm (0.0492 inch).

*Group 2* includes all disc springs with thickness between 1.25 mm and 6.0 mm (0.0492 inch and 0.2362 inch).

*Group 3* includes disc springs with thickness greater than 6.0 mm (0.2362 inch).

There are 87 standard disc spring items, which are manufactured in accordance with Standard DIN 2093 specifications for dimensions and quality requirements. There are 30 standard disc spring items in *Group 1*. The smallest and the largest disc springs in this

group are 8–4.2–0.2 and 40–20.4–1 respectively. *Group 2* has 45 standard disc spring items. The smallest and the largest disc springs are 22.5–11.2–1.25 and 200–102–5.5 respectfully. *Group 3* includes 12 standard disc spring items. The smallest and the largest disc springs of this group are 125–64–8 and 250–127–14 respectively.

#### Summary of Disc Spring Sizes Specified in DIN 2093

| Classification | OD                   |                      | ID                    |                       | Thickness             |                      |
|----------------|----------------------|----------------------|-----------------------|-----------------------|-----------------------|----------------------|
|                | Min.                 | Max.                 | Min.                  | Max.                  | Min.                  | Max.                 |
| <i>Group 1</i> | 6 mm<br>(0.236 in)   | 40 mm<br>(1.575 in)  | 3.2 mm<br>(0.126 in)  | 20.4 mm<br>(0.803 in) | 0.2 mm<br>(0.008 in)  | 1.2 mm<br>(0.047 in) |
| <i>Group 2</i> | 20 mm<br>(0.787 in)  | 225 mm<br>(8.858 in) | 10.2 mm<br>(0.402 in) | 112 mm<br>(4.409 in)  | 1.25 mm<br>(0.049 in) | 6 mm<br>(0.236 in)   |
| <i>Group 3</i> | 125 mm<br>(4.921 in) | 250 mm<br>(9.843 in) | 61 mm<br>(2.402 in)   | 127 mm<br>(5.000 in)  | 6.5 mm<br>(0.256 in)  | 16 mm<br>(0.630 in)  |

The number of catalog items by disc spring dimensions depends on the manufacturer. Currently, the smallest disc spring is 6–3.2–0.3 and the largest is 250–127–16. One of the U.S. disc spring manufacturers, Key Bellevilles, Inc. offers 190 catalog items. The greatest number of disc spring items can be found in Christian Bauer GmbH + Co. catalog. There are 291 disc spring catalog items in all three groups.

**Disc Spring Contact Surfaces.**—Disc springs are manufactured with and without contact (also called load-bearing) surfaces. Contact surfaces are small flats at points 1 and 3 in Fig. 2, adjacent to the corner radii of the spring. The width of the contact surfaces  $w$  depends on the outside diameter  $D$  of the spring, and its value is approximately  $w = D/150$ .

Fig. 2. Disc Spring with Contact Surfaces

Disc springs of *Group 1* and *Group 2*, that are contained in the DIN 2093 Standard, do not have contact surfaces, although some *Group 2* disc springs not included in DIN 2093 are manufactured with contact surfaces. All disc springs of *Group 3* (standard and nonstandard) are manufactured with contact surfaces. Almost all disc springs with contact surfaces are manufactured with reduced thickness.

Disc springs without contact surfaces have a corner radii  $r$  whose value depends on the spring thickness,  $t$ . One disc spring manufacturers recommends the following relationship:

$$r = t/6$$

**Disc Spring Materials.**—A wide variety of materials are available for disc springs, but selection of the material depends mainly on application. High-carbon steels are used only for *Group 1* disc springs. AISI 1070 and AISI 1095 carbon steels are used in the U.S. Similar high-carbon steels such as DIN 1.1231 and DIN 1.1238 (Germany), and BS 060 A67 and BS 060 A78 (Great Britain) are used in other countries. The most common materials for *Groups 2* and *3* springs operating under normal conditions are chromium-vanadium alloy steels such as AISI 6150 used in the U.S. Similar alloys such as DIN 1.8159 and DIN

1.7701 (Germany) and BS 735 A50 (Great Britain) are used in foreign countries. Some disc spring manufacturers in the U.S. also use chromium alloy steel AISI 5160. The hardness of disc springs in *Groups 2 and 3* should be 42 to 52 HRC. The hardness of disc springs in *Group 1* tested by the Vickers method should be 412 to 544 HV.

If disc springs must withstand corrosion and high temperatures, stainless steels and heat-resistant alloys are used. Most commonly used stainless steels in the United States are AISI types 301, 316, and 631, which are similar to foreign material numbers DIN 1.4310, DIN 1.4401, and DIN 1.4568, respectively. The operating temperature range for 631 stainless steel is  $-330$  to  $660^{\circ}\text{F}$  ( $-200$  to  $350^{\circ}\text{C}$ ). Among heat-resistant alloys, Inconel 718 and Inconel X750 (similar to DIN 2.4668 and DIN 2.4669, respectively) are the most popular. Operating temperature range for Inconel 718 is  $-440$  to  $1290^{\circ}\text{F}$  ( $-260$  to  $700^{\circ}\text{C}$ ).

When disc springs are stacked in large numbers and their total weight becomes a major concern, titanium  $\alpha$ - $\beta$  alloys can be used to reduce weight. In such cases, Ti-6Al-4V alloy is used.

If nonmagnetic and corrosion resistant properties are required and material strength is not an issue, phosphor bronzes and beryllium-coppers are the most popular copper alloys for disc springs. Phosphor bronze C52100, which is similar to DIN material number 2.1030, is used at the ordinary temperature range. Beryllium-coppers C17000 and C17200, similar to material numbers DIN 2.1245 and DIN 2.1247 respectively, works well at very low temperatures.

Strength properties of disc spring materials are characterized by moduli of elasticity and Poisson's ratios. These are summarized in [Table 1](#).

**Table 1. Strength Characteristics of Disc Spring Materials**

| Material                                       | Modulus of Elasticity |                   | Poisson's Ratio |
|--|-----------------------|-------------------|-----------------|
|  | $10^6$ psi            | N/mm <sup>2</sup> |                 |
| All Steels                                     | 28–31                 | 193,000–213,700   | 0.30            |
| Heat-resistant Alloys                          |                       |                   | 0.28–0.29       |
| $\alpha$ - $\beta$ Titanium Alloys (Ti-6Al-4V) | 17                    | 117,200           | 0.32            |
| Phosphor Bronze (C52100)                       | 16                    | 110,300           | 0.35            |
| Beryllium-copper (C17000)                      | 17                    | 117,200           | 0.30            |
| Beryllium-copper (C17200)                      | 18                    | 124,100           | 0.30            |

**Stacking of Disc Springs.**—Individual disc springs can be arranged in series and parallel stacks. Disc springs in series stacking, [Fig. 3](#), provide larger deflection  $S_{total}$  under the same load  $F$  as a single disc spring would generate. Disc springs in parallel stacking, [Fig. 4](#), generate higher loads  $F_{total}$  with the same deflection  $s$ , that a single disc spring would have.

$n$  = number of disc springs in stack

$s$  = deflection of single spring

$S_{total}$  = total deflection of stack of  $n$  springs

$F$  = load generated by a single spring

$F_{total}$  = total load generated by springs in stack

$L_0$  = length of unloaded spring stack

*Series:* For  $n$  disc springs arranged in series as in [Fig. 3](#), the following equations are applied:

$$F_{total} = F$$

$$S_{total} = s \times n$$

$$L_0 = H \times n = (t \div h) \times n \quad (1)$$

Fig. 3. Disc Springs in Series Stacking

$L_{1,2}$  indices indicate length of spring stack under minimum and maximum load

**Parallel:** Parallel stacking generates a force that is directly proportional to number of springs arranged in parallel. Two springs in parallel will double the force, three springs in parallel will triple the force, and so on. However, it is a common practice to use two springs in parallel in order to keep the frictional forces between the springs as low as possible. Otherwise, the actual spring force cannot be accurately determined due to deviation from its theoretical value.

For  $n$  disc springs arranged in parallel as in Fig. 4, the following equations are applied:

$$F_{total} = F \times n$$

$$S_{total} = s$$

$$L_0 = H + t(n - 1) = (h + t) + tn - t = h + tn \quad (2)$$

Fig. 4. Disc Springs in Parallel Stacking

**Parallel-Series:** When both higher force and greater deflection are required, disc springs must be arranged in a combined parallel-series stacking as illustrated in Fig. 5.

Fig. 5. Disc Springs in Parallel-Series Stacking

Normally, two springs in parallel are nested in series stacking. Two springs in parallel, called a pair, double the force, and the number of pairs,  $n_p$ , determines the total deflection,  $S_{total}$ .

For  $n_p$  disc spring pairs arranged in series, the following equations are applied:

$$\begin{aligned} F_{total} &= 2 \times F \\ S_{total} &= s \times n_p \\ L_0 &= H \times n_p = (2t + h) \times n_p \end{aligned} \quad (3)$$

### Disc Spring Forces and Stresses

Several methods of calculating forces and stresses for given disc spring configurations exist, some very complicated, others of limited accuracy. The theory which is widely used today for force and stress calculations was developed more than 65 years ago by Almen and Laszlo.

The theory is based on the following assumptions: cross sections are rectangular without radii, over the entire range of spring deflection; no stresses occur in the radial direction; disc springs are always under elastic deformation during deflection; and due to small cone angles of unloaded disc springs (between  $3.5^\circ$  and  $8.6^\circ$ ), mathematical simplifications are applied.

The theory provides accurate results for disc springs with the following ratios: outside-to-inside diameter,  $D/d = 1.3$  to  $2.5$ ; and cone height-to-thickness,  $h/t$  is up to  $1.5$ .

**Force Generated by Disc Springs Without Contact Surfaces.**—Disc springs in *Group 1* and most of disc springs in *Group 2* are manufactured without contact (load-bearing) surfaces, but have corner radii.

A single disc spring force applied to points 1 and 3 in Fig. 6 can be found from Equation (4) in which corner radii are not considered:

$$F = \frac{4 \cdot E \cdot s}{(1 - \mu^2) \cdot K_I \cdot D^2} \left[ \left( h - \frac{s}{2} \right) \cdot (h - s) \cdot t + t^3 \right] \quad (4)$$

where  $F$  = disc spring force;  $E$  = modulus of elasticity of spring material;  $\mu$  = Poisson's ratio of spring material;  $K_I$  = constant depending on outside-to-inside diameter ratio;  $D$  = disc spring nominal outside diameter;  $h$  = cone (dish) height;  $s$  = disc spring deflection; and,  $t$  = disc spring thickness.

Fig. 6. Schematic of Applied Forces

It has been found that the theoretical forces calculated using Equation (4) are lower than the actual (measured) spring forces, as illustrated in Fig. 7. The difference between theoretical (trace 1) and measured force values (trace 3) was significantly reduced (trace 2) when the actual outside diameter of the spring in loaded condition was used in the calculations.

DISC SPRING FORCES AND STRESSES

Fig. 7. Force–Deflection Relationships (80–36–3.6 Disc Springs)

- 1 – Theoretical Force Calculated by Equation (4)
- 2 – Theoretical Force Calculated by Equation (10)
- 3 – Measured Force

The actual outside diameter  $D_a$  of a disc spring contact circle is smaller than the nominal outside diameter  $D$  due to cone angle  $\alpha$  and corner radius  $r$ , as shown in Fig. 8. Diameter  $D_a$  cannot be measured, but can be calculated by Equation (9) developed by the author.

Fig. 8. Conventional Shape of Disc Spring

From Fig. 8,

$$\frac{D_a}{2} = \frac{D}{2} - (a + b) \tag{5}$$

where  $a = t \times \sin \alpha$  and  $b = r \times \cos \alpha$ . Substitution of  $a$  and  $b$  values into Equation (5) gives:

$$\frac{D_a}{2} = \frac{D}{2} - (t \sin \alpha + r \cos \alpha) \tag{6}$$

The cone angle  $\alpha$  is found from:

$$\tan \alpha = \frac{h}{\frac{D}{2} - \frac{d}{2}} = \frac{2h}{D - d} \quad \alpha = \text{atan}\left(\frac{2h}{D - d}\right) \tag{7}$$

Substituting  $\alpha$  from Equation (7) and  $r = t/6$  into Equation (6) gives:

$$\frac{D_a}{2} = \frac{D}{2} - t \left\{ \sin \left[ \text{atan}\left(\frac{2h}{D - d}\right) \right] + \frac{1}{6} \cos \left[ \text{atan}\left(\frac{2h}{D - d}\right) \right] \right\} \tag{8}$$

Finally,

$$D_a = D - 2t \left\{ \sin \left[ \text{atan}\left(\frac{2h}{D - d}\right) \right] + \frac{1}{6} \cos \left[ \text{atan}\left(\frac{2h}{D - d}\right) \right] \right\} \tag{9}$$

Substituting  $D_a$  from Equation (9) for  $D$  in Equation (4) yields Equation (10), that provides better accuracy for calculating disc spring forces.

$$F = \frac{4 \cdot E \cdot s}{(1 - \mu^2) \cdot K_1 \cdot D_a^2} \left[ \left( h - \frac{s}{2} \right) \cdot (h - s) \cdot t + t^3 \right] \tag{10}$$

The constant  $K_1$  depends on disc spring outside diameter  $D$ , inside diameter  $d$ , and their ratio  $\delta = D/d$ :

$$K_1 = \frac{\left( \frac{\delta - 1}{\delta} \right)^2}{\pi \cdot \left( \frac{\delta + 1}{\delta - 1} - \frac{2}{\ln \delta} \right)} \tag{11}$$

Table 2 compares the spring force of a series of disc springs deflected by 75% of their cone height, i.e.,  $s = 0.75h$ , as determined from manufacturers catalogs calculated in accordance with Equation (4), calculated forces by use of Equation (10), and measured forces.

Comparison made at 75% deflection, in Newtons (N) and pounds (lbf)

The difference between disc spring forces calculated by Equation (10) and the measured forces varies from  $-5.7\%$  (maximum) to  $+0.5\%$  (minimum). Disc spring forces calculated by Equation (4) and shown in manufacturers catalogs are less than measured forces by  $-11\%$  (maximum) to  $-6\%$  (minimum).

**Force Generated by Disc Spring with Contact Surfaces.**—Some of disc springs in Group 2 and all disc springs in Group 3 are manufactured with small contact (load-bearing) surfaces or flats in addition to the corner radii. These flats provide better contact between disc springs, but, at the same time, they reduce the springs outside diameter and generate higher spring force because in Equation (4) force  $F$  is inversely proportional to the square of outside diameter  $D^2$ . To compensate for the undesired force increase, the disc spring thickness is reduced from  $t$  to  $t'$ . Thickness reduction factors  $t'/t$  are approximately 0.94 for disc spring series A and B, and approximately 0.96 for series C springs. With such reduction factors, the disc spring force at 75% deflection is the same as for equivalent disc spring without contact surfaces. Equation (12), which is similar to Equation (10), has an additional constant  $K_4$  that correlates the increase in spring force due to contact surfaces. If disc springs do not have contact surfaces, then  $K_4^2 = K_4 = 1$ .

$$F = \frac{4 \cdot E \cdot K_4^2 \cdot s}{(1 - \mu^2) \cdot K_1 \cdot D_a^2} \left[ K_4^2 \cdot \left( h' - \frac{s}{2} \right) \cdot (h' - s) \cdot t' + (t')^3 \right] \quad (12)$$

where  $t'$  = reduced thickness of a disc spring

$h'$  = cone height adjusted to reduced thickness:  $h' = H - t'$  ( $h' > h$ )

$K_4$  = constant applied to disc springs with contact surfaces.

$K_4^2$  can be calculated as follows:

$$K_4^2 = \frac{-b + \sqrt{b^2 - 4ac}}{2a} \quad (13)$$

where  $a = t'(H - 4t' + 3t)(5H - 8t' + 3t)$ ;  $b = 32(t')^3$ ; and,  $c = -t[5(H - t)^2 + 32t^2]$ .

**Disc Spring Functional Stresses.**—Disc springs are designed for both static and dynamic load applications. In static load applications, disc springs may be under constant or fluctuating load conditions that change up to 5,000 or 10,000 cycles over long time intervals. Dynamic loads occur when disc springs are under continuously changing deflection between pre-load (approximately 15% to 20% of the cone height) and the maximum deflection values over short time intervals. Both static and dynamic loads cause compressive and tensile stresses. The position of critical stress points on a disc spring cross section are shown in Fig. 9.

Fig. 9. Critical Stress Points

$s$  is deflection of spring by force  $F$ ;  $h - s$  is a cone height of loaded disc spring

Compressive stresses are acting at points 0 and 1, that are located on the top surface of the disc spring. Point 0 is located on the cross-sectional mid-point diameter, and point 1 is located on the top inside diameter. Tensile stresses are acting at points 2 and 3, which are located on the bottom surface of the disc spring. Point 2 is on the bottom inside diameter, and point 3 is on the bottom outside diameter. The following equations are used to calcu-

late stresses. The minus sign “-” indicates that compressive stresses are acting in a direction opposite to the tensile stresses.

$$\text{Point 0: } \sigma_0 = -\frac{3}{\pi} \cdot \frac{4E \cdot t \cdot s \cdot K_4}{(1 - \mu^2) \cdot K_1 \cdot D_a^2} \quad (14)$$

$$\text{Point 1: } \sigma_1 = -\frac{4E \cdot K_4 \cdot s \cdot \left[ K_4 \cdot K_2 \cdot \left( h - \frac{s}{2} \right) + K_3 \cdot t \right]}{(1 - \mu^2) \cdot K_1 \cdot D_a^2} \quad (15)$$

$$\text{Point 2: } \sigma_2 = \frac{4E \cdot K_4 \cdot s \cdot \left[ K_3 \cdot t - K_2 \cdot K_4 \cdot \left( h - \frac{s}{2} \right) \right]}{(1 - \mu^2) \cdot K_1 \cdot D_a^2} \quad (16)$$

$$\text{Point 3: } \sigma_3 = \frac{4E \cdot K_4 \cdot s \cdot \left[ K_4 \cdot (2K_3 - K_2) \cdot \left( h - \frac{s}{2} \right) + K_3 \cdot t \right]}{(1 - \mu^2) \cdot K_1 \cdot D_a^2 \cdot \delta} \quad (17)$$

$K_2$  and  $K_3$  are disc spring dimensional constants, defined as follows:

$$K_2 = \frac{6 \left( \frac{\delta - 1}{\ln \delta} - 1 \right)}{\pi \cdot \ln \delta} \quad (18) \quad K_3 = \frac{3 \cdot (\delta - 1)}{\pi \cdot \ln \delta} \quad (19)$$

where  $\delta = D/d$  is the outside-to-inside diameter ratio.

In static application, if disc springs are fully flattened (100% deflection), compressive stress at point 0 should not exceed the tensile strength of disc spring materials. For most spring steels, the permissible value is  $\sigma_0 \leq 1600 \text{ N/mm}^2$  or 232,000 psi.

In dynamic applications, certain limitations on tensile stress values are recommended to obtain controlled fatigue life of disc springs utilized in various stacking. Maximum tensile stresses at points 2 and 3 depend on the *Group* number of the disc springs. Stresses  $\sigma_2$  and  $\sigma_3$  should not exceed the following values:

|  | Group 1                                 | Group 2                                 | Group 3                                 |
|--|---|---|---|
| Maximum allowable tensile stresses at points 2 and 3 | 1300 N/mm <sup>2</sup><br>(188,000 psi) | 1250 N/mm <sup>2</sup><br>(181,000 psi) | 1200 N/mm <sup>2</sup><br>(174,000 psi) |

**Fatigue Life of Disc Springs.**—Fatigue life is measured in terms of the maximum number of cycles that dynamically loaded disc springs can sustain prior to failure. Dynamically loaded disc springs are divided into two groups: disc springs with unlimited fatigue life, which exceeds  $2 \times 10^6$  cycles without failure, and disc springs with limited fatigue life between  $10^4$  cycles and less than  $2 \times 10^6$  cycles.

Typically, fatigue life is estimated from three diagrams, each representing one of the three Groups of disc springs (Figs. 10, 11, and 12). Fatigue life is found at the intersection of the vertical line representing minimum tensile stress  $\sigma_{\min}$  with the horizontal line, which represents maximum tensile stress  $\sigma_{\max}$ . The point of intersection of these two lines defines fatigue life expressed in number of cycles  $N$  that can be sustained prior to failure.

*Example:* For *Group 2* springs in Fig. 11, the intersection point of the  $\sigma_{\min} = 500 \text{ N/mm}^2$  line with the  $\sigma_{\max} = 1200 \text{ N/mm}^2$  line, is located on the  $N = 10^5$  cycles line. The estimated fatigue life is  $10^5$  cycles.

DISC SPRING FATIGUE LIFE

Fig. 10. Group 1 Diagram for Estimating Fatigue Life of Disc Springs ( $0.2 \leq t < 1.25$  mm)

Fig. 11. Group 2 Diagram for Estimating Fatigue Life of Disc Springs ( $1.25 \leq t \leq 6$  mm)

Fig. 12. Group 3 Diagram for Estimating Fatigue Life of Disc Springs ( $6 < t \leq 16$  mm)

When the intersection points of the minimum and maximum stress lines fall inside the areas of each cycle line, only the approximate fatigue life can be estimated by extrapolating the distance from the point of intersection to the nearest cycle line. The extrapolation cannot provide accurate values of fatigue life, because the distance between the cycle lines is expressed in logarithmic scale, and the distance between tensile strength values is expressed in linear scale (Figs. 10, 11, and 12), therefore linear-to-logarithmic scales ratio is not applicable.

When intersection points of minimum and maximum stress lines fall outside the cycle lines area, especially outside the  $N = 10^5$  cycles line, the fatigue life cannot be estimated.

Thus, the use of the fatigue life diagrams should be limited to such cases when the minimum and maximum tensile stress lines intersect exactly with each of the cycle lines.

To calculate fatigue life of disc springs without the diagrams, the following equations developed by the author can be used.

$$\text{Disc Springs in Group 1} \quad N = 10^{10.29085532 - 0.00542096(\sigma_{max} - 0.5\sigma_{min})} \quad (20)$$

$$\text{Disc Springs in Group 2} \quad N = 10^{10.10734911 - 0.00537616(\sigma_{max} - 0.5\sigma_{min})} \quad (21)$$

$$\text{Disc Springs in Group 3} \quad N = 10^{13.23985664 - 0.01084192(\sigma_{max} - 0.5\sigma_{min})} \quad (22)$$

As can be seen from Equations (20), (21), and (22), the maximum and minimum tensile stress range affects the fatigue life of disc springs. Since tensile stresses at Points 2 and 3 have different values, see Equations (16) and (17), it is necessary to determine at which critical point the minimum and maximum stresses should be used for calculating fatigue life. The general method is based on the diagram, Fig. 9, from which Point 2 or Point 3 can be found in relationship with disc spring outside-to-inside diameters ratio  $D_o/D_i$  and disc spring cone height-to-thickness ratio  $h/r$ . This method requires intermediate calculations of  $D_o/D_i$  and  $h/r$  ratios and is applicable only to disc springs without contact surfaces. The method is not valid for Group 3 disc springs or for disc springs in Group 2 that have contact surfaces and reduced thickness.

A simple and accurate method, that is valid for all disc springs, is based on the following statements:

if  $(\sigma_{2max} - 0.5\sigma_{2min}) > (\sigma_{3max} - 0.5\sigma_{3min})$ , then Point 2 is used, otherwise

if  $(\sigma_{3max} - 0.5\sigma_{3min}) > (\sigma_{2max} - 0.5\sigma_{2min})$ , then Point 3 is used

The maximum and minimum tensile stress range for disc springs in Groups 1, 2, and 3 is found from the following equations.

For disc springs in Group 1:

$$\sigma_{max} - 0.5\sigma_{min} = \frac{10.29085532 - \log N}{0.00542096} \quad (23)$$

For disc springs in Group 2:

$$\sigma_{max} - 0.5\sigma_{min} = \frac{10.10734911 - \log N}{0.00537616} \quad (24)$$

For disc springs in Group 3:

$$\sigma_{max} - 0.5\sigma_{min} = \frac{13.23985664 - \log N}{0.01084192} \quad (25)$$

Thus, Equations (23), (24), and (25) can be used to design any spring stack that provides required fatigue life. The following example illustrates how a maximum-minimum stress range is calculated in relationship with fatigue life of a given disc spring stack.

*Example:* A dynamically loaded stack, which utilizes disc springs in *Group 2*, must have the fatigue life of  $5 \times 10^5$  cycles. The maximum allowable tensile stress at Points 2 or 3 is  $1250 \text{ N/mm}^2$ . Find the minimum tensile stress value to sustain  $N = 5 \times 10^5$  cycles.

*Solution:* Substitution of  $\sigma_{\max} = 1250$  and  $N = 5 \times 10^5$  in Equation (24) gives:

$$1250 - 0.5\sigma_{\min} = \frac{10.10734911 - \log(5 \times 10^5)}{0.00537616} = \frac{10.10734911 - 5.69897}{0.00537616} = 820$$

from which  $\sigma_{\min} = \frac{1250 - 820}{0.5} = 860 \text{ N/mm}^2$  (124,700 psi)

**Recommended Dimensional Characteristics of Disc Springs.**—Dimensions of disc springs play a very important role in their performance. It is imperative to check selected disc springs for dimensional ratios, that should fall within the following ranges:

- 1) Diameters ratio,  $\delta = D_o/D_i = 1.7$  to  $2.5$ .
- 2) Cone height-to-thickness ratio,  $h_o/t = 0.4$  to  $1.3$ .
- 3) Outside diameter-to-thickness ratio,  $D_o/t = 18$  to  $40$ .

Small values of  $\delta$  correspond with small values of the other two ratios. The  $h_o/t$  ratio determines the shape of force-deflection characteristic graphs, that may be nearly linear or strongly curved. If  $h_o/t = 0.4$  the graph is almost linear during deflection of a disc spring up to its flat position. If  $h_o/t = 1.6$  the graph is strongly curved and its maximum point is at 75% deflection. Disc spring deflection from 75% to 100% slightly reduces spring force. Within the  $h_o/t = 0.4 - 1.3$  range, disc spring forces increase with the increase in deflection and reach maximum values at 100% deflection. In a stack of disc springs with a ratio  $h_o/t > 1.3$  deflection of individual springs may be unequal, and only one disc spring should be used if possible.

### Example Applications of Disc Springs

*Example 1, Disc Springs in Group 2 (no contact surfaces):* A mechanical device that works under dynamic loads must sustain a minimum of 1,000,000 cycles. The applied load varies from its minimum to maximum value every 30 seconds. The maximum load is approximately 20,000N (4,500 lbf). A 40-mm diameter guide rod is a receptacle for the disc springs. The rod is located inside a hollow cylinder. Deflection of the disc springs under minimum load should not exceed 5.5 mm (0.217 inch) including a 20 per cent pre-load deflection. Under maximum load, the deflection is limited to 8 mm (0.315 inch) maximum. Available space for the disc spring stack inside the cylinder is 35 to 40 mm (1.38 to 1.57 inch) in length and 80 to 85 mm (3.15 to 3.54 inch) in diameter.

Select the disc spring catalog item, determine the number of springs in the stack, the spring forces, the stresses at minimum and maximum deflection, and actual disc spring fatigue life.

*Solution:* 1) Disc spring standard inside diameter is 41 mm (1.61 inch) to fit the guide rod. The outside standard diameter is 80 mm (3.15 in) to fit the cylinder inside diameter. Disc springs with such diameters are available in various thickness: 2.25, 3.0, 4.0, and 5.0 mm (0.089, 0.118, 0.157, and 0.197 inch). The 2.25- and 3.0-mm thick springs do not fit the applied loads, since the maximum force values for disc springs with such thickness are 7,200N and 13,400N (1,600 lbf and 3,000 lbf) respectively. A 5.0-mm thick disc spring should not be used because its  $D_o/t$  ratio,  $80/5 = 16$ , is less than 18 and is considered as unfavorable. Disc spring selection is narrowed to an 80–41–4 catalog item.

2) Checking 80–41–4 disc spring for dimensional ratios:

$$\delta = D_o/D_i = 80/41 = 1.95 \quad h_o/t = 22/4 = 0.55 \quad D_o/t = 80/4 = 20$$

Because the dimensional ratios are favorable, the 80–41–4 disc springs are selected.

## DISC SPRING EXAMPLE

3) The number of springs in the stack is found from Equation (1):

$$n = L_o / (t + h) = 40 / (4 + 2.2) = \frac{40}{6.2} = 6.45.$$

Rounding  $n$  to the nearest integer gives  $n = 6$ . The actual length of unloaded spring stack is  $L_o = 6.2 \times 6 = 37.2$  mm (1.465 inch) and it satisfies the  $L_o < 40$  mm condition.

4) Calculating the cone angle  $\alpha$  from Equation (7) and actual outside diameter  $D_a$  from Equation (9) gives:

$$\alpha = \text{atan}\left(\frac{2 \times 2.2}{80 - 41}\right) = \text{atan}(0.11282) = 6.4^\circ$$

$$D_a = 80 - 2 \times 4 \left( \sin[\text{atan}(0.11282)] + \frac{1}{6} \cos[\text{atan}(0.11282)] \right)$$

$$D_a = 77.78 \text{ mm (3.062 in)}$$

5) Calculating constant  $K_1$  from Equation (11):

$$\delta = \frac{D}{d} = 1.95122$$

$$K_1 = \frac{\left(\frac{1.95122 - 1}{1.95122}\right)^2}{\pi \cdot \left[ \frac{1.95122 + 1}{1.95122 - 1} - \frac{2}{\ln(1.95122)} \right]} = 0.6841$$

6) Calculating minimum and maximum forces,  $F_{min}$  and  $F_{max}$  from Equation (10):

Based on the design requirements, the disc spring stack is deflecting by 5.5 mm (0.217 in) under minimum load, and each individual disc spring is deflecting by  $5.5/6 \cong 0.92$  mm (0.036 in). A single disc spring deflection  $s_{min} = 0.9$  mm (0.035 in) is used to calculate  $F_{min}$ . Under maximum load, the disc spring stack is permitted maximum deflection of 8 mm (0.315 in), and each individual disc spring deflects by  $8/6 \cong 1.33$  mm (0.0524 in). A disc spring deflection  $s_{max} = 1.32$  mm (0.052 in) will be used to calculate  $F_{max}$ . If disc springs are made of AISI 6150 alloy steel, then modulus of elasticity  $E = 206,000 \text{ N/mm}^2$  ( $30 \times 10^6$  psi) and Poisson's ratio  $\mu = 0.3$ .

$$F_{min} = \frac{4 \cdot 206000}{(1 - 0.3^2)(0.6841)(77.78)^2} \left[ \left(2.2 - \frac{0.9}{2}\right) \cdot (2.2 - 0.9) \cdot 4 + 4^3 \right] 0.9$$

$$F_{min} = 14390 \text{ N (3235 lbf)}$$

$$F_{max} = \frac{4 \cdot 206000}{(1 - 0.3^2)(0.6841)(77.78)^2} \left[ \left(2.2 - \frac{1.32}{2}\right) \cdot (2.2 - 1.32) \cdot 4 + 4^3 \right] 1.32$$

$$F_{max} = 20050 \text{ N (4510 lbf)}$$

7) Calculating constant  $K_2$ , Equation (18):

$$\delta = \frac{D}{d} = \frac{80}{41} = 1.95122$$

$$K_2 = \frac{6 \left( \frac{\delta - 1}{\ln \delta} - 1 \right)}{\pi \cdot \ln \delta} = \frac{6 \left( \frac{1.95122 - 1}{\ln(1.95122)} - 1 \right)}{\pi \cdot \ln(1.95122)} = 1.2086$$

8) Calculating constant  $K_3$  (Equation (19)):

$$K_3 = \frac{3 \cdot (\delta - 1)}{\pi \cdot \ln \delta} = \frac{3 \cdot (1.95122 - 1)}{\pi \cdot \ln(1.95122)} = 1.3589$$

9) Compressive stress  $\sigma_0$  at point 0 due to maximum deflection, Equation (14):

$$\sigma_0 = \frac{3}{\pi} \cdot \frac{4E \cdot t \cdot s \cdot K_4}{(1 - \mu^2) \cdot K_1 \cdot D_a^2} = \frac{3}{\pi} \cdot \frac{4 \cdot 206000 \cdot 4 \cdot 1.32 \cdot 1}{(1 - 0.3^2) \cdot 0.6841 \cdot 77.78^2}$$

$$\sigma_0 = 1103 \text{ N/mm}^2 = 160000 \text{ psi}$$

Because the compressive stress at point 0 does not exceed 1600 N/mm<sup>2</sup>, its current value satisfies the design requirement.

10) Tensile stress  $\sigma_2$  at point 2 due to minimum deflection  $s = 0.9$  mm, Equation (16):

$$\sigma_{2min} = \frac{4E \cdot K_4 \cdot s \cdot \left[ K_3 \cdot t - K_2 \cdot K_4 \cdot \left( h - \frac{s}{2} \right) \right]}{(1 - \mu^2) \cdot K_1 \cdot D_a^2} =$$

$$\frac{4 \cdot 206000 \cdot 1 \cdot 0.9 \cdot \left[ 1.3589 \cdot 4 - 1.2086 \cdot 1 \cdot \left( 2.2 - \frac{0.9}{2} \right) \right]}{(1 - 0.3^2) \cdot 0.6841 \cdot 77.78^2} = 654 \text{ N/mm}^2$$

11) Tensile stress  $\sigma_2$  at point 2 due to maximum deflection  $s = 1.32$  mm, Equation (16):

$$\sigma_{2max} = \frac{4E \cdot K_4 \cdot s \cdot \left[ K_3 \cdot t - K_2 \cdot K_4 \cdot \left( h - \frac{s}{2} \right) \right]}{(1 - \mu^2) \cdot K_1 \cdot D_a^2} =$$

$$\frac{4 \cdot 206000 \cdot 1 \cdot 1.32 \cdot \left[ 1.3589 \cdot 4 - 1.2086 \cdot 1 \cdot \left( 2.2 - \frac{1.32}{2} \right) \right]}{(1 - 0.3^2) \cdot 0.6841 \cdot 77.78^2} = 1032 \text{ N/mm}^2$$

Thus,  $\sigma_{2min} = 654 \text{ N/mm}^2$  (94,850 psi) and  $\sigma_{2max} = 1032 \text{ N/mm}^2$  (149,700 psi).

12) Tensile stress  $\sigma_3$  at point 3 due to minimum deflection  $s = 0.9$  mm, Equation (17):

$$\sigma_{3min} = \frac{4E \cdot K_4 \cdot s \cdot \left[ K_4 \cdot (2K_3 - K_2) \cdot \left( h - \frac{s}{2} \right) + K_3 \cdot t \right]}{(1 - \mu^2) \cdot K_1 \cdot D_a^2 \cdot \delta} =$$

$$\frac{4 \cdot 206000 \cdot 1 \cdot 0.9 \cdot \left[ 1 \cdot (2 \cdot 1.3589 - 1.2086) \cdot \left( 2.2 - \frac{0.9}{2} \right) + 1.3589 \cdot 4 \right]}{(1 - 0.3^2) \cdot 0.6841 \cdot 77.78^2 \cdot 1.95122} = 815 \text{ N/mm}^2$$

13) Tensile stress  $\sigma_3$  at point 3 due to maximum deflection  $s = 1.32$  mm, Equation (17):

$$\sigma_{3max} = \frac{4E \cdot K_4 \cdot s \cdot \left[ K_4 \cdot (2K_3 - K_2) \cdot \left( h - \frac{s}{2} \right) + K_3 \cdot t \right]}{(1 - \mu^2) \cdot K_1 \cdot D_a^2 \cdot \delta} =$$

$$\frac{4 \cdot 206000 \cdot 1 \cdot 1.32 \cdot \left[ 1 \cdot (2 \cdot 1.3589 - 1.2086) \cdot \left( 2.2 - \frac{1.32}{2} \right) + 1.3589 \cdot 4 \right]}{(1 - 0.3^2) \cdot 0.6841 \cdot 77.78^2 \cdot 1.95122} = 1149 \text{ N/mm}^2$$

Thus,  $\sigma_{3min} = 815 \text{ N/mm}^2$  (118,200 psi) and  $\sigma_{3max} = 1149 \text{ N/mm}^2$  (166,600 psi).

14) Functional tensile stress range at critical points 2 and 3.

Point 2:  $\sigma_{2max} - 0.5\sigma_{2min} = 1032 - 0.5 \times 654 = 705 \text{ N/mm}^2$

Point 3:  $\sigma_{3max} - 0.5\sigma_{3min} = 1149 - 0.5 \times 815 = 741.5 \text{ N/mm}^2$

Because  $\sigma_{3max} - 0.5\sigma_{3min} > \sigma_{2max} - 0.5\sigma_{2min}$ , the tensile stresses at point 3 are used for fatigue life calculations.

15) Fatigue life of selected disc springs, Equation (21):

$$N = 10^{[10.10734911 - 0.00537616(1149 - 0.5 \times 815)]} = 10^{10.10734911 - 3.98642264} = 10^{6.12092647}$$

$N = 1,321,000$  cycles. Thus, the calculated actual fatigue life exceeds required minimum number of cycles by 32%.

In conclusion, the six 80–41–4 disc springs arranged in series stacking, satisfy the requirements and will provide a 32 % longer fatigue life than required by the design criteria.

*Example 2:* A company wishes to use *Group 3* disc springs with contact surfaces on couplings to absorb bumping impacts between railway cars.

Given:

$D = 200$  mm, disc spring outside diameter

$d = 102$  mm, disc spring inside diameter

$t = 14$  mm, spring standard thickness

$t' = 13.1$  mm, spring reduced thickness

$h = 4.2$  mm, cone height of unloaded spring

$n = 22$ , number of springs in series stacking

$S_i = 33.9$  mm, initial deflection of the pack

$S_a = 36.0$  mm, additional deflection of the pack

Find the fatigue life in cycles and determine if the selected springs are suitable for the application.

The calculations are performed in the following sequence:

1) Determine the minimum  $s_{min}$  and maximum  $s_{max}$  deflections of a single disc spring:

$$s_{max} = \frac{(S_i + S_a)}{n} = \frac{(33.9 + 36)}{22} = 3.18 \text{ mm}$$

$$s_{min} = \frac{S_i}{n} = \frac{33.9}{22} = 1.54 \text{ mm}$$

2) Use Equations (16) and (17) to calculate tensile stresses  $\sigma_2$  and  $\sigma_3$  at  $s_{min}$  and  $s_{max}$  deflections:

$$\sigma_{2min} = 674 \text{ N/mm}^2, \sigma_{2max} = 1513 \text{ N/mm}^2, \sigma_{3min} = 707 \text{ N/mm}^2, \sigma_{3max} = 1379 \text{ N/mm}^2$$

3) Determine critical stress points:

$$\sigma_{2max} - 0.5\sigma_{2min} = 1513 - 0.5 \times 674 = 1176 \text{ N/mm}^2$$

$$\sigma_{3max} - 0.5\sigma_{3min} = 1379 - 0.5 \times 707 = 1025.5 \text{ N/mm}^2$$

Because  $(\sigma_{2max} - 0.5\sigma_{2min}) > (\sigma_{3max} - 0.5\sigma_{3min})$ , then tensile stresses at Point 2 are used to calculate fatigue life.

4) Fatigue life  $N$  is calculated using Equation (22):

$$N = 10^{[13.23985664 - (0.01084192 \times 1176)]} = 10^{0.49} = 3 \text{ cycles}$$

The selected disc springs at the above-mentioned minimum and maximum deflection values will not sustain any number of cycles. It is imperative to check the selected disc springs for dimensional ratios:

Outside-to-inside diameters ratio,  $200/102 = 1.96$ ; within recommended range.

Cone height-to-thickness ratio is  $4.2/13.1 = 0.3$ ; out of range, the minimum ratio is 0.4.

Outside diameter-to-thickness ratio is  $200/13.1 = 15$ ; out of range, the minimum ratio is 18. Thus, only one of the dimensional ratios satisfies the requirements for the best disc spring performance.

## WIRE ROPE, CHAIN, ROPE, AND HOOKS

### Strength and Properties of Wire Rope

**Wire Rope Construction.**—Essentially, a wire rope is made up of a number of strands laid helically about a metallic or non-metallic core. Each strand consists of a number of wires also laid helically about a metallic or non-metallic center. Various types of wire rope have been developed to meet a wide range of uses and operating conditions. These types are distinguished by the kind of core; the number of strands; the number, sizes, and arrangement of the wires in each strand; and the way in which the wires and strands are wound or laid about each other. The following descriptive material is based largely on information supplied by the Bethlehem Steel Co.

*Rope Wire Materials:* Materials used in the manufacture of rope wire are, in order of increasing strength: iron, phosphor bronze, traction steel, plow steel, improved plow steel, and bridge rope steel. Iron wire rope is largely used for low-strength applications such as elevator ropes not used for hoisting, and for stationary guy ropes.

Phosphor bronze wire rope is used occasionally for elevator governor-cable rope and for certain marine applications as life lines, clearing lines, wheel ropes and rigging.

Traction steel wire rope is used primarily as hoist rope for passenger and freight elevators of the traction drive type, an application for which it was specifically designed.

Ropes made of galvanized wire or wire coated with zinc by the electro-deposition process are used in certain applications where additional protection against rusting is required. As will be noted from the tables of wire-rope sizes and strengths, the breaking strength of galvanized wire rope is 10 per cent less than that of ungalvanized (bright) wire rope. Bethanized (zinc-coated) wire rope can be furnished to bright wire rope strength when so specified.

Galvanized carbon steel, tinned carbon steel, and stainless steel are used for small cords and strands ranging in diameter from  $\frac{1}{64}$  to  $\frac{3}{8}$  inch and larger.

Marline clad wire rope has each strand wrapped with a layer of tarred marline. The cladding provides hand protection for workers and wear protection for the rope.

*Rope Cores:* Wire-rope cores are made of fiber, cotton, asbestos, polyvinyl plastic, a small wire rope (independent wire-rope core), a multiple-wire strand (wire-strand core) or a cold-drawn wire-wound spring.

*Fiber* (manila or sisal) is the type of core most widely used when loads are not too great. It supports the strands in their relative positions and acts as a cushion to prevent nicking of the wires lying next to the core.

*Cotton* is used for small ropes such as sash cord and aircraft cord.

*Asbestos cores* can be furnished for certain special operations where the rope is used in oven operations.

*Polyvinyl plastics cores* are offered for use where exposure to moisture, acids, or caustics is excessive.

A *wire-strand core* often referred to as WSC, consists of a multiple-wire strand that may be the same as one of the strands of the rope. It is smoother and more solid than the independent wire rope core and provides a better support for the rope strands.

The *independent wire rope core*, often referred to as IWRC, is a small  $6 \times 7$  wire rope with a wire-strand core and is used to provide greater resistance to crushing and distortion of the wire rope. For certain applications it has the advantage over a wire-strand core in that it stretches at a rate closer to that of the rope itself.

Wire ropes with wire-strand cores are, in general, less flexible than wire ropes with independent wire-rope or non-metallic cores.

Ropes with metallic cores are rated  $7\frac{1}{2}$  per cent stronger than those with non-metallic cores.

*Wire-Rope Lay:* The lay of a wire rope is the direction of the helical path in which the strands are laid and, similarly, the lay of a strand is the direction of the helical path in which the wires are laid. If the wires in the strand or the strands in the rope form a helix similar to the threads of a right-hand screw, i.e., they wind around to the right, the lay is called right hand and, conversely, if they wind around to the left, the lay is called left hand. In the *regular lay*, the wires in the strands are laid in the opposite direction to the lay of the strands in the rope. In right-regular lay, the strands are laid to the right and the wires to the left. In left-regular lay, the strands are laid to the left, the wires to the right. In *Lang lay*, the wires and strands are laid in the same direction, i.e., in right Lang lay, both the wires and strands are laid to the right and in left Lang they are laid to the left.

Alternate lay ropes having alternate right and left laid strands are used to resist distortion and prevent clamp slippage, but because other advantages are missing, have limited use.

The regular lay wire rope is most widely used and right regular lay rope is customarily furnished. Regular lay rope has less tendency to spin or untwist when placed under load and is generally selected where long ropes are employed and the loads handled are frequently removed. Lang lay ropes have greater flexibility than regular lay ropes and are more resistant to abrasion and fatigue.

In preformed wire ropes the wires and strands are preshaped into a helical form so that when laid to form the rope they tend to remain in place. In a non-preformed rope, broken wires tend to "wicker out" or protrude from the rope and strands that are not seized tend to spring apart. Preforming also tends to remove locked-in stresses, lengthen service life, and make the rope easier to handle and to spool.

*Strand Construction:* Various arrangements of wire are used in the construction of wire rope strands. In the simplest arrangement six wires are grouped around a central wire thus making seven wires, all of the same size. Other types of construction known as "filler-wire," Warrington, Seale, etc. make use of wires of different sizes. Their respective patterns of arrangement are shown diagrammatically in the table of wire weights and strengths.

**Specifying Wire Rope.**—In specifying wire rope the following information will be required: length, diameter, number of strands, number of wires in each strand, type of rope construction, grade of steel used in rope, whether preformed or not preformed, type of center, and type of lay. The manufacturer should be consulted in selecting the best type of wire rope for a new application.

**Properties of Wire Rope.**—Important properties of wire rope are strength, wear resistance, flexibility, and resistance to crushing and distortion.

*Strength:* The strength of wire rope depends upon its size, kind of material of which the wires are made and their number, the type of core, and whether the wire is galvanized or not. Strengths of various types and sizes of wire ropes are given in the accompanying tables together with appropriate factors to apply for ropes with steel cores and for galvanized wire ropes.

*Wear Resistance:* When wire rope must pass back and forth over surfaces that subject it to unusual wear or abrasion, it must be specially constructed to give satisfactory service.

Such construction may make use of 1) relatively large outer wires; 2) Lang lay in which wires in each strand are laid in the same direction as the strand; and 3) flattened strands.

The object in each type is to provide a greater outside surface area to take the wear or abrasion. From the standpoint of material, improved plow steel has not only the highest tensile strength but also the greatest resistance to abrasion in regularly stocked wire rope.

**Flexibility:** Wire rope that undergoes repeated and severe bending, such as in passing around small sheaves and drums, must have a high degree of flexibility to prevent premature breakage and failure due to fatigue. Greater flexibility in wire rope is obtained by

1) using small wires in larger numbers; 2) using Lang lay; and 3) preforming, that is, the wires and strands of the rope are shaped during manufacture to fit the position they will assume in the finished rope.

**Resistance to Crushing and Distortion:** Where wire rope is to be subjected to transverse loads that may crush or distort it, care should be taken to select a type of construction that will stand up under such treatment.

Wire rope designed for such conditions may have 1) large outer wires to spread the load per wire over a greater area; and 2) an independent wire core or a high-carbon cold-drawn wound spring core.

**Standard Classes of Wire Rope.**—Wire rope is commonly designated by two figures, the first indicating the number of strands and the second, the number of wires per strand, as:  $6 \times 7$ , a six-strand rope having seven wires per strand, or  $8 \times 19$ , an eight-strand rope having 19 wires per strand. When such numbers are used as designations of standard wire rope classes, the second figure in the designation may be purely nominal in that the number of wires per strand for various ropes in the class may be slightly less or slightly more than the nominal as will be seen from the following brief descriptions. (For ropes with a wire strand core, a second group of two numbers may be used to indicate the construction of the wire core, as  $1 \times 21$ ,  $1 \times 43$ , and so on.)

**$6 \times 7$  Class (Standard Coarse Laid Rope):** Wire ropes in this class are for use where resistance to wear, as in dragging over the ground or across rollers, is an important requirement. Heavy hauling, rope transmissions, and well drilling are common applications. These wire ropes are furnished in right regular lay and occasionally in Lang lay. The cores may be of fiber, independent wire rope, or wire strand. Since this class is a relatively stiff type of construction, these ropes should be used with large sheaves and drums. Because of the small number of wires, a larger factor of safety may be called for.

Fig. 1a.  
 $6 \times 7$  with fiber core

Fig. 1b.  
 $6 \times 7$  with  $1 \times 7$  WSC

Fig. 1c.  
 $6 \times 7$  with  $1 \times 19$  WSC

Fig. 1d.  
 $6 \times 7$  with IWRC

As shown in Figs. 1a through Figs. 1d, this class includes a  $6 \times 7$  construction with fiber core; a  $6 \times 7$  construction with  $1 \times 7$  wire strand core (sometimes called  $7 \times 7$ ); a  $6 \times 7$  construction with  $1 \times 19$  wire strand core; and a  $6 \times 7$  construction with independent wire rope core. Table 1 provides strength and weight data for this class.

Two special types of wire rope in this class are: aircraft cord, a  $6 \times 6$  or  $7 \times 7$  Bethanized wire rope of high tensile strength and sash cord, a  $6 \times 7$  iron rope used for a variety of purposes where strength is not an important factor.

**Table 1. Weights and Strengths of 6 × 7 (Standard Coarse Laid) Wire Ropes, Preformed and Not Preformed**

| Dia., Inches | Approx. Weight per Ft., Pounds | Breaking Strength, Tons of 2000 Lbs. |            |                 | Dia., Inches | Approx. Weight per Ft., Pounds | Breaking Strength, Tons of 2000 Lbs. |            |                 |
|--------------|--------------------------------|--------------------------------------|------------|-----------------|--------------|--------------------------------|--------------------------------------|------------|-----------------|

**6 × 19 Class (Standard Hoisting Rope):** This rope is the most popular and widely used class. Ropes in this class are furnished in regular or Lang lay and may be obtained preformed or not preformed. Cores may be of fiber, independent wire rope, or wire strand. As can be seen from Table 2 and Figs. 2a through 2h, there are four common types: 6 × 25 filler wire construction with fiber core (not illustrated), independent wire core, or wire strand core (1 × 25 or 1 × 43); 6 × 19 Warrington construction with fiber core; 6 × 21 filler wire construction with fiber core; and 6 × 19, 6 × 21, and 6 × 17 Seale construction with fiber core.

**6 × 37 Class (Extra Flexible Hoisting Rope):** For a given size of rope, the component wires are of smaller diameter than those in the two classes previously described and hence have less resistance to abrasion. Ropes in this class are furnished in regular and Lang lay with fiber core or independent wire rope core, preformed or not preformed.

As shown in Table 3 and Figs. 3a through 3h, there are four common types: 6 x 29 filler wire construction with fiber core and 6 x 36 filler wire construction with independent wire rope core, a special rope for construction equipment; 6 x 35 (two operations) construction with fiber core and 6 x 41 Warrington Seale construction with fiber core, a standard crane rope in this class of rope construction; 6 x 41 filler wire construction with fiber core or independent wire core, a special large shovel rope usually furnished in Lang lay; and 6 x 46

filler wire construction with fiber core or independent wire rope core, a special large shovel and dredge rope.

*8 x 19 Class (Special Flexible Hoisting Rope):* This rope is stable and smooth-running, and is especially suitable, because of its flexibility, for high speed operation with reverse bends. Ropes in this class are available in regular lay with fiber core.

As shown in Table 4 and Figs. 4a through 4d, there are four common types: 8 x 25 filler wire construction, the most flexible but the least wear resistant rope of the four types; Warrington type in 8 x 19 construction, less flexible than the 8 x 25; 8 x 21 filler wire construction, less flexible than the Warrington; and Seale type in 8 x 19 construction, which has the greatest wear resistance of the four types but is also the least flexible.

Also in this class, but not shown in [Table 4](#) are elevator ropes made of traction steel and iron.

**18 x 7 Non-rotating Wire Rope:** This rope is specially designed for use where a minimum of rotating or spinning is called for, especially in the lifting or lowering of free loads with a single-part line. It has an inner layer composed of 6 strands of 7 wires each laid in left Lang lay over a fiber core and an outer layer of 12 strands of 7 wires each laid in right regular lay. The combination of opposing lays tends to prevent rotation when the rope is stretched. However, to avoid any tendency to rotate or spin, loads should be kept to at least one-eighth and preferably one-tenth of the breaking strength of the rope. Weights and strengths are shown in [Table 5](#).

**Flattened Strand Wire Rope:** The wires forming the strands of this type of rope are wound around triangular centers so that a flattened outer surface is provided with a greater area than in the regular round rope to withstand severe conditions of abrasion. The triangu-

lar shape of the strands also provides superior resistance to crushing. Flattened strand wire rope is usually furnished in Lang lay and may be obtained with fiber core or independent wire rope core. The three types shown in Table 6 and Figs. 6a through 6c are flexible and are designed for hoisting work.

<sup>a</sup>These sizes in Type B only.

Type H is not in U.S. Simplified Practice Recommendation.

Source: Rope diagrams, Bethlehem Steel Co. All other data, U.S. Simplified Practice Recommendation 198-50.

*Flat Wire Rope:* This type of wire rope is made up of a number of four-strand rope units placed side by side and stitched together with soft steel sewing wire. These four-strand units are alternately right and left lay to resist warping, curling, or rotating in service. Weights and strengths are shown in Table 7.

**Simplified Practice Recommendations.**—Because the total number of wire rope types is large, manufacturers and users have agreed upon and adopted a U.S. Simplified Practice Recommendation to provide a simplified listing of those kinds and sizes of wire rope which are most commonly used and stocked. These, then, are the types and sizes which are most generally available. Other types and sizes for special or limited uses also may be found in individual manufacturer's catalogs.

**Sizes and Strengths of Wire Rope.**—The data shown in Tables 1 through 7 have been taken from U.S. Simplified Practice Recommendation 198-50 but do not include those wire ropes shown in that Simplified Practice Recommendation which are intended primarily for marine use.

*Wire Rope Diameter:* The diameter of a wire rope is the diameter of the circle that will just enclose it, hence when measuring the diameter with calipers, care must be taken to obtain the largest outside dimension, taken across the opposite strands, rather than the smallest dimension across opposite "valleys" or "flats." It is standard practice for the nominal diameter to be the minimum with all tolerances taken on the plus side. Limits for diam-

eter as well as for minimum breaking strength and maximum pitch are given in Federal Specification for Wire Rope, RR-R—571a.

*Wire Rope Strengths:* The strength figures shown in the accompanying tables have been obtained by a mathematical derivation based on actual breakage tests of wire rope and represent from 80 to 95 per cent of the total strengths of the individual wires, depending upon the type of rope construction.

**Table 7. Weights and Strengths of Standard Flat Wire Rope, Not Preformed**

**Safe Working Loads and Factors of Safety.**—The maximum load for which a wire rope is to be used should take into account such associated factors as friction, load caused by bending around each sheave, acceleration and deceleration, and, if a long length of rope is to be used for hoisting, the weight of the rope at its maximum extension. The condition of the rope — whether new or old, worn or corroded — and type of attachments should also be considered.

Factors of safety for standing rope usually range from 3 to 4; for operating rope, from 5 to 12. Where there is the element of hazard to life or property, higher values are used.

**Installing Wire Rope.**—The main precaution to be taken in removing and installing wire rope is to avoid kinking which greatly lessens the strength and useful life. Thus, it is preferable when removing wire rope from the reel to have the reel with its axis in a horizontal position and, if possible, mounted so that it will revolve and the wire rope can be taken off straight. If the rope is in a coil, it should be unwound with the coil in a vertical position as by rolling the coil along the ground. Where a drum is to be used, the rope should be run directly onto it from the reel, taking care to see that it is not bent around the drum in a direction opposite to that on the reel, thus causing it to be subject to reverse bending. On flat or smooth-faced drums it is important that the rope be started from the proper end of the drum. A right lay rope that is being overwound on the drum, that is, it passes over the top of the drum as it is wound on, should be started from the right flange of the drum (looking at the drum from the side that the rope is to come) and a left lay rope from the left flange.

When the rope is under wound on the drum, a right lay rope should be started from the left flange and a left lay rope from the right flange, so that the rope will spool evenly and the turns will lie snugly together.

Sheaves and drums should be properly aligned to prevent undue wear. The proper position of the main or lead sheave for the rope as it comes off the drum is governed by what is called the fleet angle or angle between the rope as it stretches from drum to sheave and an imaginary center-line passing through the center of the sheave groove and a point halfway between the ends of the drum. When the rope is at one end of the drum, this angle should not exceed one and a half to two degrees. With the lead sheave mounted with its groove on this center-line, a safe fleet angle is obtained by allowing 30 feet of lead for each two feet of drum width.

*Sheave and Drum Dimensions:* Sheaves and drums should be as large as possible to obtain maximum rope life. However, factors such as the need for lightweight equipment for easy transport and use at high speeds, may call for relatively small sheaves with consequent sacrifice in rope life in the interest of overall economy. No hard and fast rules can be laid down for any particular rope if the utmost in economical performance is to be obtained. Where maximum rope life is of prime importance, the following recommendations of Federal Specification RR-R-571a for minimum sheave or drum diameters  $D$  in terms of rope diameter  $d$  will be of interest. For  $6 \times 7$  rope (six strands of 7 wires each)  $D = 72d$ ; for  $6 \times 19$  rope,  $D = 45d$ ; for  $6 \times 25$  rope,  $D = 45d$ ; for  $6 \times 29$  rope,  $D = 30d$ ; for  $6 \times 37$  rope,  $D = 27d$ ; and for  $8 \times 19$  rope,  $D = 31d$ .

Too small a groove for the rope it is to carry will prevent proper seating of the rope in the bottom of the groove and result in uneven distribution of load on the rope. Too large a groove will not give the rope sufficient side support. Federal Specification RR-R-571a recommends that sheave groove diameters be larger than the nominal rope diameters by the following minimum amounts: For ropes of  $\frac{1}{4}$ - to  $\frac{5}{16}$ -inch diameters,  $\frac{1}{64}$  inch larger; for  $\frac{3}{8}$ - to  $\frac{3}{4}$ -inch diameter ropes,  $\frac{1}{32}$  inch larger; for  $\frac{13}{16}$ - to  $1\frac{1}{8}$ -inch diameter ropes,  $\frac{3}{64}$  inch larger; for  $1\frac{3}{16}$ - to  $1\frac{1}{2}$ -inch ropes,  $\frac{1}{16}$  inch larger; for  $1\frac{9}{16}$ - to  $2\frac{1}{4}$ -inch ropes,  $\frac{3}{32}$  inch larger; and for  $2\frac{5}{16}$  and larger diameter ropes,  $\frac{1}{8}$  inch larger. For new or regrooved sheaves these values should be doubled; in other words for  $\frac{1}{4}$ - to  $\frac{5}{16}$ -inch diameter ropes, the groove diameter should be  $\frac{1}{32}$  inch larger, and so on.

*Drum or Reel Capacity:* The length of wire rope, in feet, that can be spooled onto a drum or reel, is computed by the following formula, where

$$A = \text{depth of rope space on drum, inches: } A = (H - D - 2Y) \div 2$$

$$B = \text{width between drum flanges, inches}$$

$$D = \text{diameter of drum barrel, inches}$$

$$H = \text{diameter of drum flanges, inches}$$

$$K = \text{factor from Table 8 for size of line selected}$$

$$Y = \text{depth not filled on drum or reel where winding is to be less than full capacity}$$

$$L = \text{length of wire rope on drum or reel, feet: } L = (A + D) \times A \times B \times K$$

**Table 8. Factors  $K$  Used in Calculating Wire Rope Drum and Reel Capacities**

| Rope Dia., In. | Factor $K$ | Rope Dia., In.  | Factor $K$ | Rope Dia., In. | Factor $K$ |
|----------------|------------|-----------------|------------|----------------|------------|
| $\frac{3}{32}$ | 23.4       | $\frac{1}{2}$   | 0.925      | $1\frac{3}{8}$ | 0.127      |
| $\frac{1}{8}$  | 13.6       | $\frac{9}{16}$  | 0.741      | $1\frac{1}{2}$ | 0.107      |
| $\frac{3}{64}$ | 10.8       | $\frac{5}{8}$   | 0.607      | $1\frac{5}{8}$ | 0.0886     |
| $\frac{5}{32}$ | 8.72       | $1\frac{1}{16}$ | 0.506      | $1\frac{3}{4}$ | 0.0770     |
| $\frac{3}{16}$ | 6.14       | $\frac{3}{4}$   | 0.428      | $1\frac{7}{8}$ | 0.0675     |
| $\frac{7}{32}$ | 4.59       | $1\frac{3}{16}$ | 0.354      | 2              | 0.0597     |
| $\frac{1}{4}$  | 3.29       | $\frac{7}{8}$   | 0.308      | $2\frac{1}{8}$ | 0.0532     |
| $\frac{5}{16}$ | 2.21       | 1               | 0.239      | $2\frac{1}{4}$ | 0.0476     |
| $\frac{3}{8}$  | 1.58       | $1\frac{1}{8}$  | 0.191      | $2\frac{3}{8}$ | 0.0419     |
| $\frac{7}{16}$ | 1.19       | $1\frac{1}{4}$  | 0.152      | $2\frac{1}{2}$ | 0.0380     |

*Note:* The values of “ $K$ ” allow for normal oversize of ropes, and the fact that it is practically impossible to “thread-wind” ropes of small diameter. However, the formula is based on uniform rope winding and will not give correct figures if rope is wound non-uniformly on the reel. The amount of tension applied when spooling the rope will also affect the length. The formula is based on the same number of wraps of rope in each layer, which is not strictly correct, but does not result in appreciable error unless the width ( $B$ ) of the reel is quite small compared with the flange diameter ( $H$ ).

*Example:* Find the length in feet of  $\frac{9}{16}$ -inch diameter rope required to fill a drum having the following dimensions:  $B = 24$  inches,  $D = 18$  inches,  $H = 30$  inches,

$$A = (30 - 18 - 0) \div 2 = 6 \text{ inches}$$

$$L = (6 + 18) \times 6 \times 24 \times 0.741 = 2560.0 \text{ or } 2560 \text{ feet}$$

The above formula and factors  $K$  allow for normal oversize of ropes but will not give correct figures if rope is wound non-uniformly on the reel.

*Load Capacity of Sheave or Drum:* To avoid excessive wear and groove corrugation, the radial pressure exerted by the wire rope on the sheave or drum must be kept within certain maximum limits. The radial pressure of the rope is a function of rope tension, rope diameter, and tread diameter of the sheave and can be determined by the following equation:

$$P = \frac{2T}{D \times d}$$

where  $P$  = Radial pressure in pounds per square inch (see Table 9)

$T$  = Rope tension in pounds

$D$  = Tread diameter of sheave or drum in inches

$d$  = Rope diameter in inches

According to the Bethlehem Steel Co. the radial pressures shown in Table 9 are recommended as maximums according to the material of which the sheave or drum is made.

**Table 9. Maximum Radial Pressures for Drums and Sheaves**

| Type of Wire Rope | Drum or Sheave Material                   |                  |                              | Type of Wire Rope       | Drum or Sheave Material                   |            |                              |
|-------------------|---|------------------|------------------------------|-------------------------|---|------------|------------------------------|

| 1 1/4                 | 0.669         | 0.639 | 3                     | 1.607         | 1.538 | 6                     | 3.198         | 3.075 |
| 1 3/8                 | 0.736         | 0.699 | 3 1/8                 | 1.664         | 1.598 |                       |               |       |
| 1 1/2                 | 0.803         | 0.759 | 3 1/4                 | 1.731         | 1.658 |                       |               |       |

All dimensions in inches. Data taken from *Wire Rope Users Manual*, 2nd ed., American Iron and Steel Institute, Washington, D. C. The values given in this table are applicable to grooves in sheaves and drums but are not generally suitable for pitch design, since other factors may be involved.

**Rope Loads due to Bending:** When a wire rope is bent around a sheave, the resulting bending stress  $s_b$  in the outer wire, and equivalent bending load  $P_b$  (amount that direct tension load on rope is increased by bending) may be computed by the following formulas:

$s_b = Ed_w \div D$ ;  $P_b = s_b A$ , where  $A = d^2 Q$ .  $E$  is the modulus of elasticity of the wire rope (varies with the type and condition of rope from 10,000,000 to 14,000,000. An average value of 12,000,000 is frequently used),  $d$  is the diameter of the wire rope,  $d_w$  is the diameter of the component wire (for 6 × 7 rope,  $d_w = 0.106d$ ; for 6 × 19 rope,  $0.063d$ ; for 6 × 37 rope,  $0.045d$ ; and for 8 × 19 rope,  $d_w = 0.050d$ ).  $D$  is the pitch diameter of the sheave in inches,  $A$  is the metal cross-sectional area of the rope, and  $Q$  is a constant, values for which are: 6 × 7 (Fiber Core) rope, 0.380; 6 × 7 (IWRC or WSC), 0.437; 6 × 19 (Fiber Core), 0.405; 6 × 19 (IWRC or WSC), 0.475; 6 × 37 (Fiber Core), 0.400; 6 × 37 (IWRC), 0.470; 8 × 19 (Fiber Core), 0.370; and Flattened Strand Rope, 0.440.

**Example:** Find the bending stress and equivalent bending load due to the bending of a 6 × 19 (Fiber Core) wire rope of 1/2-inch diameter around a 24-inch pitch diameter sheave.

$$d_w = 0.063 \times 0.5 = 0.0315 \text{ in.} \quad A = 0.5^2 \times 0.405 = 0.101 \text{ sq. in.}$$

$$s_b = 12,000,000 \times 0.0315 \div 24 = 15,750 \text{ lbs. per sq. in.}$$

$$P_b = 15,750 \times 0.101 = 1590 \text{ lbs.}$$

**Cutting and Seizing of Wire Rope.**—Wire rope can be cut with mechanical wire rope shears, an abrasive wheel, an electric resistance cutter (used for ropes of smaller diameter only), or an acetylene torch. This last method fuses the ends of the wires in the strands. It is important that the rope be seized on either side of where the cut is to be made. Any annealed low carbon steel wire may be used for seizing, the recommended sizes being as follows: For a wire rope of  $\frac{1}{4}$ - to  $\frac{15}{16}$ -inch diameter, use a seizing wire of 0.054-inch (No. 17 Steel Wire Gage); for a rope of 1- to  $1\frac{1}{8}$ -inch diameter, use a 0.105-inch wire (No. 12); and for rope of  $1\frac{3}{4}$ - to  $3\frac{1}{2}$ -inch diameter, use a 0.135-inch wire (No. 10). Except for preformed wire ropes, a minimum of two seizings on either side of a cut is recommended. Four seizings should be used on either side of a cut for Lang lay rope, a rope with a steel core, or a non-spinning type of rope.

The following method of seizing is given in Federal Specification for wire rope, RR-R-571a. Lay one end of the seizing wire in the groove between two strands of wire rope and wrap the other end tightly in a close helix over the portion in the groove. A seizing iron (round bar  $\frac{1}{2}$  to  $\frac{5}{8}$  inch diameter by 18 inches long) should be used to wrap the seizing tightly. This bar is placed at right angles to the rope next to the first turn or two of the seizing wire. The seizing wire is brought around the back of the seizing iron and wrapped loosely around the wire rope in the opposite direction to that of the seizing coil. As the seizing iron is now rotated around the rope it will carry the seizing wire snugly and tightly into place. When completed, both ends of the seizing should be twisted together tightly.

**Maintenance of Wire Rope.**—Heavy abrasion, overloading, and bending around sheaves or drums that are too small in diameter are the principal reasons for the rapid deterioration of wire rope. Wire rope in use should be inspected periodically for evidence of wear and damage by corrosion. Such inspections should take place at progressively shorter intervals over the useful life of the rope as wear tends to accelerate with use. Where wear is rapid, the outside of a wire rope will show flattened surfaces in a short time.

If there is any hazard involved in the use of the rope, it may be prudent to estimate the remaining strength and service life. This assessment should be done for the weakest point where the most wear or largest number of broken wires are in evidence. One way to arrive at a conclusion is to set an arbitrary number of broken wires in a given strand as an indication that the rope should be removed from service and an ultimate strength test run on the worn sample. The arbitrary figure can then be revised and rechecked until a practical working formula is arrived at. A piece of waste rubbed along the wire rope will help to reveal broken wires. The effects of corrosion are not easy to detect because the exterior wires may appear to be only slightly rusty, and the damaging effects of corrosion may be confined to the hidden inner wires where it cannot be seen. To prevent damage by corrosion, the rope should be kept well lubricated. Use of zinc coated wire rope may be indicated for some applications.

Periodic cleaning of wire rope by using a stiff brush and kerosene or with compressed air or live steam and relubricating will help to lengthen rope life and reduce abrasion and wear on sheaves and drums. Before storing after use, wire rope should be cleaned and lubricated.

**Lubrication of Wire Rope.**—Although wire rope is thoroughly lubricated during manufacture to protect it against corrosion and to reduce friction and wear, this lubrication should be supplemented from time to time. Special lubricants are supplied by wire rope manufacturers. These lubricants vary somewhat with the type of rope application and operating condition. Where the preferred lubricant can not be obtained from the wire rope manufacturer, an adhesive type of lubricant similar to that used for open gearing will often be found suitable. At normal temperatures, some wire rope lubricants may be practically solid and will require thinning before application. Thinning may be done by heating to 160 to 200 degrees F. or by diluting with gasoline or some other fluid that will allow the lubricant to penetrate the rope. The lubricant may be painted on the rope or the rope may be passed through a box or tank filled with the lubricant.

**Replacement of Wire Rope.**—When an old wire rope is to be replaced, all drums and sheaves should be examined for wear. All evidence of scoring or imprinting of grooves from previous use should be removed and sheaves with flat spots, defective bearings, and broken flanges, should be repaired or replaced. It will frequently be found that the area of maximum wear is located relatively near one end of the rope. By cutting off that portion, the remainder of the rope may be salvaged for continued use. Sometimes the life of a rope can be increased by simply changing it end for end at about one-half the estimated normal life. The worn sections will then no longer come at the points that cause the greatest wear.

### Wire Rope Slings and Fittings

**Slings.**—A few of the simpler sling arrangements or hitches as they are called, are shown in the accompanying illustration. Normally  $6 \times 19$  Class wire rope is recommended where a diameter in the  $\frac{1}{4}$ -inch to  $1\frac{1}{8}$ -inch range is to be used and  $6 \times 37$  Class wire rope where a diameter in the  $1\frac{1}{4}$ -inch and larger range is to be used. However, the  $6 \times 19$  Class may be used even in the larger sizes if resistance to abrasion is of primary importance and the  $6 \times 37$  Class in the smaller sizes if greater flexibility is desired.

The *straight lift hitch*, Fig. 7a, is a straight connector between crane hook and load.

The *basket hitch* may be used with two hooks so that the sides are vertical as shown at Fig. 7b or with a single hook with sides at various angles with the vertical as shown at Fig. 7c, Fig. 7d, and Fig. 7e. As the angle with the vertical increases, a greater tension is placed on the rope so that for any given load, a sling of greater lifting capacity must be used.

The *choker hitch*, shown at Fig. 7f, is widely used for lifting bundles of items such as bars, poles, pipe, and similar objects. The choker hitch holds these items firmly, but the load must be balanced so that it rides safely. Since additional stress is imposed on the rope due to the choking action, the capacity of this type of hitch is 25 per cent less than that of the comparable straight lift. If two choker hitches are used at an angle, these angles must also be taken into consideration as with the basket hitches.

**Wire Rope Fittings.**—Many varieties of swaged fittings are available for use with wire rope and several industrial and aircraft types are shown in the accompanying illustration. Swaged fittings on wire rope have an efficiency (ability to hold the wire rope) of approximately 100 per cent of the catalogue rope strength. These fittings are attached to the end or body of the wire rope by the application of high pressure through special dies that cause the material of the fitting to “flow” around the wires and strands of the rope to form a union that is as strong as the rope itself. The more commonly used types, of swaged fittings range from  $\frac{1}{8}$ - to  $\frac{5}{8}$ -inch diameter sizes in industrial types and from the  $\frac{1}{16}$ - to  $\frac{5}{8}$ -inch sizes in aircraft types. These fittings are furnished attached to the wire strand, rope, or cable.

**Applying Clips and Attaching Sockets.**—In attaching U-bolt clips for fastening the end of a wire rope to form a loop, it is essential that the saddle or base of the clip bears against the longer or “live” end of the rope loop and the U-bolt against the shorter or “dead” end. The “U” of the clips should never bear against the live end of the rope because the rope may be cut or kinked. A wire-rope thimble should be used in the loop eye of the rope to prevent kinking when rope clips are used. The strength of a clip fastening is usually less than 80 per cent of the strength of the rope. Table 10 gives the proper size, number, and spacing for each size of wire rope.

In attaching commercial sockets of forged steel to wire rope ends, the following procedure is recommended. The wire rope is seized at the end and another seizing is applied at a distance from the end equal to the length of the basket of the socket. As explained in a previous section, soft iron wire is used and particularly for the larger sizes of wire rope, it is important to use a seizing iron to secure a tight winding. For large ropes, the seizing should be several inches long.

Wire Rope Slings and Fittings

Fig. 7a. Straight Lift  
One leg vertical  
Load capacity is 100% of a single rope.

Fig. 7b. Basket Hitch  
Two legs vertical  
Load capacity is 200% of the single rope in Fig. 7a.

Fig. 7c. Basket Hitch  
Two legs at 30° with the vertical  
Load capacity is 174% of the single rope in Fig. 7a.

Fig. 7d. Basket Hitch  
Two legs at 45° with the vertical  
Load capacity is 141% of the single rope in Fig. 7a.

Fig. 7e. Basket Hitch  
Two legs at 60° with the vertical  
Load capacity is 100% of the single rope in Fig. 7a.

Fig. 7f. Choker Hitch  
One leg vertical, with slip-through loop  
Rated capacity is 75% of the single rope in Fig. 7a.

The end seizing is now removed and the strands are separated so that the fiber core can be cut back to the next seizing. The individual wires are then untwisted and "broomed out" and for the distance they are to be inserted in the socket are carefully cleaned with benzine, naphtha, or unleaded gasoline. The wires are then dipped into commercial muriatic (hydrochloric) acid and left (usually one to three minutes) until the wires are bright and clean or, if zinc coated, until the zinc is removed. After cleaning, the wires are dipped into a hot soda solution (1 pound of soda to 4 gallons of water at 175 degrees F. minimum) to neutralize the acid. The rope is now placed in a vise. A temporary seizing is used to hold the wire ends

## Rated Capacities for Improved Plow Steel Wire Rope and Wire Rope Slings (in tons of 2,000 lbs)

| Dia.<br>(in.)  | Independent Wire Rope Core |      |      |        |      |      |            |      |      |            |      |      | Fiber Core |      |      |          |      |      |        |      |      |            |      |      |            |      |      |            |      |      |     |     |     |     |

Wire Rope Fittings

together until the socket is placed over the rope end. The temporary seizing is then removed and the socket located so that the ends of the wires are about even with the upper end of the basket. The opening around the rope at the bottom of the socket is now sealed with putty.

A special high grade pure zinc is used to fill the socket. Babbit metal should not be used as it will not hold properly. For proper fluidity and penetration, the zinc is heated to a tem-

perature in the 830- to 900-degree F. range. If a pyrometer is not available to measure the temperature of the molten zinc, a dry soft pine stick dipped into the zinc and quickly withdrawn will show only a slight discoloration and no zinc will adhere to it. If the wood chars, the zinc is too hot. The socket is now permitted to cool and the resulting joint is ready for use. When properly prepared, the strength of the joint should be approximately equal to that of the rope itself.

### Crane Chain and Hooks

**Material for Crane Chains.**—The best material for crane and hoisting chains is a good grade of wrought iron, in which the percentage of phosphorus, sulfur, silicon, and other impurities is comparatively low. The tensile strength of the best grades of wrought iron does not exceed 46,000 pounds per square inch, whereas mild steel with about 0.15 per cent carbon has a tensile strength nearly double this amount. The ductility and toughness of wrought iron, however, is greater than that of ordinary commercial steel, and for this reason it is preferable for chains subjected to heavy intermittent strains, because wrought iron will always give warning by bending or stretching, before breaking. Another important reason for using wrought iron in preference to steel is that a perfect weld can be effected more easily. Heat-treated alloy steel is also widely used for chains. This steel contains carbon, 0.30 per cent, max; phosphorus, 0.045 per cent, max; and sulfur, 0.045 per cent, max. The selection and amounts of alloying elements are left to the individual manufacturers.

**Strength of Chains.**—When calculating the strength of chains it should be observed that the strength of a link subjected to tensile stresses is not equal to twice the strength of an iron bar of the same diameter as the link stock, but is a certain amount less, owing to the bending action caused by the manner in which the load is applied to the link. The strength is also reduced somewhat by the weld. The following empirical formula is commonly used for calculating the breaking load, in pounds, of wrought-iron crane chains:  $W = 54,000D^2$  in which  $W$  = breaking load in pounds and  $D$  = diameter of bar (in inches) from which links are made. The working load for chains should not exceed one-third the value of  $W$ , and, it is often one-fourth or one-fifth of the breaking load. When a chain is wound around a casting and severe bending stresses are introduced, a greater factor of safety should be used.

**Care of Hoisting and Crane Chains.**—Chains used for hoisting heavy loads are subject to deterioration, both apparent and invisible. The links wear, and repeated loading causes localized deformations to form cracks that spread until the links fail. Chain wear can be reduced by occasional lubrication. The life of a wrought-iron chain can be prolonged by frequent annealing or normalizing unless it has been so highly or frequently stressed that small cracks have formed. If this condition is present, annealing or normalizing will not "heal" the material, and the links will eventually fracture. To anneal a wrought-iron chain, heat it to cherry-red and allow it to cool slowly. Annealing should be done every six months, and oftener if the chain is subjected to unusually severe service.

**Maximum Allowable Wear at Any Point of Link**

| Chain Size (in.)                 | Maximum Allowable Wear (in.) | Chain Size (in.) | Maximum Allowable Wear (in.) | Chain Size (in.) | Maximum Allowable Wear (in.) |
|----------------------------------|------------------------------|------------------|------------------------------|------------------|------------------------------|
| $\frac{1}{4}$ ( $\frac{9}{32}$ ) | $\frac{3}{64}$               | $\frac{3}{4}$    | $\frac{5}{32}$               | $1\frac{1}{4}$   | $\frac{1}{4}$                |
| $\frac{3}{8}$                    | $\frac{5}{64}$               | $\frac{7}{8}$    | $\frac{11}{64}$              | $1\frac{3}{8}$   | $\frac{3}{32}$               |
| $\frac{1}{2}$                    | $\frac{7}{64}$               | 1                | $\frac{3}{16}$               | $1\frac{1}{2}$   | $\frac{5}{16}$               |
| $\frac{5}{8}$                    | $\frac{9}{64}$               | $1\frac{1}{8}$   | $\frac{7}{32}$               | $1\frac{3}{4}$   | $\frac{11}{32}$              |

Chains should be examined periodically for twists, as a twisted chain will wear rapidly. Any links that have worn excessively should be replaced with new ones, so that every link will do its full share of work during the life of the chain, without exceeding the limit of

safety. Chains for hoisting purposes should be made with short links, so that they will wrap closely around the sheaves or drums without bending. The diameter of the winding drums should be not less than 25 or 30 times the diameter of the iron used for the links. The accompanying table lists the maximum allowable wear for various sizes of chains.

**Safe Loads for Ropes and Chains.**—Safe loads recommended for wire rope or chain slings depend not only upon the strength of the sling but also upon the method of applying it to the load, as shown by the accompanying table giving safe loads as prepared by OSHA. The loads recommended in this table are more conservative than those usually specified, in order to provide ample allowance for some unobserved weakness in the sling, or the possibility of excessive strains due to misjudgment or accident.

**Safe Working Loads in Pounds for Manila Rope and Chains**

<sup>a</sup> These sizes of wrought chain are no longer manufactured in the United States.

Data from *Longshoring Industry*, OSHA Safety and Health Standards Digest, OSHA 2232, 1985.

The working load limit is defined as the maximum load in pounds that should ever be applied to chain, when the chain is new or in "as new" condition, and when the load is uniformly applied in direct tension to a straight length of chain. This limit is also affected by the number of chains used and their configuration. The accompanying table shows the working load limit for various configurations of heat-treated alloy steel chain using a 4 to 1 design factor, which conforms to ISO practice.

**Working Load Limit for Heat-Treated Alloy Steel Chain, pounds**

| Chain Size (in.) | Single Leg   | Double Leg   |  |  |  | Triple and Quad Leg  |  |  |
|------------------|--|--|--|--|--|--|--|--|

**Protection from Sharp Corners:** When the load to be lifted has sharp corners or edges, as are often encountered with castings, and with structural steel and other similar objects, pads or wooden protective pieces should be applied at the corners, to prevent the slings from being abraded or otherwise damaged where they come in contact with the load. These precautions are especially important when the slings consist of wire cable or fiber rope, although they should also be used even when slings are made of chain. Wooden corner-pieces are often provided for use in hoisting loads with sharp angles. If pads of burlap or other soft material are used, they should be thick and heavy enough to sustain the pressure, and distribute it over a considerable area, instead of allowing it to be concentrated directly at the edges of the part to be lifted.

**Strength of Manila Rope**

<sup>a</sup> Average value is shown; maximum is 5 per cent higher.

<sup>b</sup> Based on tests of new and unused rope of standard construction in accordance with Cordage Institute Standard Test Methods.

<sup>c</sup> These values are for rope in good condition with appropriate splices, in noncritical applications, and under normal service conditions. These values should be reduced where life, limb, or valuable property are involved, or for exceptional service conditions such as shock loads or sustained loads.

Data from Cordage Institute Rope Specifications for three-strand laid and eight-strand plaited manila rope (standard construction).

<sup>a</sup> Average value is shown. Maximum for nylon rope is 5 per cent higher; tolerance for double braided nylon rope is  $\pm 5$  per cent.

<sup>b</sup> Based on tests of new and unused rope of standard construction in accordance with Cordage Institute Standard Test Methods. For double braided nylon rope these values are minimums and are based on a large number of tests by various manufacturers; these values represent results two standard deviations below the mean. The minimum tensile strength is determined by the formula  $1057 \times (\text{linear density})^{0.995}$ .

<sup>c</sup> These values are for rope in good condition with appropriate splices, in noncritical applications, and under normal service conditions. These values should be reduced where life, limb, or valuable property are involved, or for exceptional service conditions such as shock loads or sustained loads.

Data from Cordage Institute Specifications for nylon rope (three-strand laid and eight-strand plaited, standard construction) and double braided nylon rope.

**Loads Lifted by Crane Chains.**—To find the approximate weight a chain will lift when rove as a tackle, multiply the safe load given in the table *Close-link Hoisting, Sling and Crane Chain* by the number of parts or chains at the movable block, and subtract one-quarter for frictional resistance.

To find the size of chain required for lifting a given weight, divide the weight by the number of chains at the movable block, and add one-third for friction; next find in the column headed "Average Safe Working Load" the corresponding load, and then the corresponding size of chain in the column headed "Size." With the heavy chain or where the chain is unusually long, the weight of the chain itself should also be considered.

**Close-link Hoisting, Sling and Crane Chain**

Source: The Crosby Group. All dimensions are in inches. Hooks are made of alloy steel, quenched and tempered. For swivel hooks, the data are for a bail of carbon steel. The ultimate load is four times the working load limit (capacity). The swivel hook is a positioning device and is not intended to rotate under load; special load swiveling hooks must be used in such applications.

**Method of Making an Eye-splice.**—When a loop is formed at the end of a rope by splicing the free end to the main or standing part of the rope, this is known as an *eye-splice*. The end of the rope is first unlaidd about as far as it would be for making a short splice. After bending the end around to form a loop of the required size, the middle strand *a*, Fig. 8a, is tucked under a strand on the main part of the rope. The strand *b* is next inserted from the rear side under the strand on the main part which is just above the strand under which *a* was inserted. Since strand *b* is pushed under the strand on the main part from the rear side, it will come out at the point where strand *a* went in, as Fig. 8b. The third strand *c* is now passed over the strand under which strand *a* was inserted, and then under the next successive one, as Fig. 8c. These three strands are next pulled taut and then about one-third of the fiber should be cut from them; they are next tucked away by passing a strand over its adjoining one and under the next successive strand. The reason for cutting away part of the fiber or yarns is to reduce the size of the splice and give it a neater appearance. By gradually thinning out the fiber, the over-lapping strands may be given a gradual taper, as Fig. 8d which shows the completed eye-splice.

Eye Nuts and Lift Eyes

Eye Nuts

The general function of eye nuts is similar to that of eye-bolts. Eye nuts are utilized for a variety of applications in either the swivel or tapped design.

<sup>a</sup> At 28 atm.<sup>b</sup> Approximate.<sup>c</sup> Sublimates.<sup>d</sup> At 26 atm.

Notes: Values in parentheses are atomic weights of the most stable known isotopes. Melting points at standard pressure except as noted.

### Heat and Combustion Related Properties

**Latent Heat.**—When a body changes from the solid to the liquid state or from the liquid to the gaseous state, a certain amount of heat is used to accomplish this change. This heat does not raise the temperature of the body and is called latent heat. When the body changes again from the gaseous to the liquid, or from the liquid to the solid state, it gives out this quantity of heat. The *latent heat of fusion* is the heat supplied to a solid body at the melting point; this heat is absorbed by the body although its temperature remains nearly stationary during the whole operation of melting. The *latent heat of evaporation* is the heat that must be supplied to a liquid at the boiling point to transform the liquid into a vapor. The latent heat is generally given in British thermal units per pound. When it is said that the latent heat of evaporation of water is 966.6, this means that it takes 966.6 heat units to evaporate 1 pound of water after it has been raised to the boiling point, 212°F.

When a body changes from the solid to the gaseous state without passing through the liquid stage, as solid carbon dioxide does, the process is called *sublimation*.

**Table 2. Latent Heat of Fusion**

| Substance        | Btu per Pound | Substance  | Btu per Pound | Substance | Btu per Pound |
|------------------|---------------|------------|---------------|-----------|---------------|
| Bismuth          | 22.75         | Paraffine  | 63.27         | Sulfur    | 16.86         |

**Specific Heat.**—The specific heat of a substance is the ratio of the heat required to raise the temperature of a certain weight of the given substance 1°F, to the heat required to raise the temperature of the same weight of water 1°F. As the specific heat is not constant at all temperatures, it is generally assumed that it is determined by raising the temperature from 62 to 63°F. For most substances, however, specific heat is practically constant for temperatures up to 212°F.

In metric units, specific heat is defined as the ratio of the heat needed to raise the temperature of a mass by 1°C, to the heat needed to raise the temperature of the same mass of water by 1°C. In the metric system, heat is measured in calories (cal), mass is in grams (g), and measurements usually taken at 15°C.

Because specific heat is a dimensionless ratio, the values given in the table that follows are valid in both the US system and the metric system.

**Table 5. Average Specific Heats (Btu/lb-°F) of Various Substances**

| Substance                    | Specific Heat | Substance          | Specific Heat |
|------------------------------|---------------|--------------------|---------------|
| Alcohol (absolute)           | 0.700         | Lead               | 0.031         |
| Alcohol (density 0.8)        | 0.622         | Lead (fluid)       | 0.037         |
| Aluminum                     | 0.214         | Limestone          | 0.217         |
| Antimony                     | 0.051         | Magnesia           | 0.222         |
| Benzine                      | 0.450         | Marble             | 0.210         |

**Table 6. Specific Heat of Gases (Btu/lb-°F)**

| Gas            | Constant Pressure | Constant Volume | Gas        | Constant Pressure | Constant Volume |
|----------------|-------------------|-----------------|------------|-------------------|-----------------|
| Acetic acid    | 0.412             | ...             | Chloroform | 0.157             | ...             |
| Air            | 0.238             | 0.168           | Ethylene   | 0.404             | 0.332           |
| Alcohol        | 0.453             | 0.399           | Hydrogen   | 3.409             | 2.412           |
| Ammonia        | 0.508             | 0.399           | Nitrogen   | 0.244             | 0.173           |
| Carbonic acid  | 0.217             | 0.171           | Oxygen     | 0.217             | 0.155           |
| Carbonic oxide | 0.245             | 0.176           | Steam      | 0.480             | 0.346           |
| Chlorine       | 0.121             | ...             |            |                   |                 |

**Heat Loss from Uncovered Steam Pipes.**—The loss of heat from a bare steam or hot-water pipe varies with the temperature difference of the inside the pipe and that of the surrounding air. The loss is 2.15 Btu per hour, per square foot of pipe surface, per degree F of temperature difference when the latter is 100 degrees; for a difference of 200 degrees, the loss is 2.66 Btu; for 300 degrees, 3.26 Btu; for 400 degrees, 4.03 Btu; for 500 degrees, 5.18 Btu. Thus, if the pipe area is 1.18 square feet per foot of length, and the temperature difference 300°F, the loss per hour per foot of length =  $1.18 \times 300 \times 3.26 = 1154$  Btu.

**Table 7. Values of Thermal Conductivity ( $k$ ) and of Conductance ( $C$ ) of Common Building and Insulating Materials**

| Type of Material   | Thick-ness, in.                  | $k$ or $C^a$ | Type of Material            | Thick-ness, in. | $k$ or $C^a$ | Max. Temp., °F | Density, lb per cu. ft. | $k^a$             |

<sup>a</sup> Units are in Btu/hr-ft<sup>2</sup>-°F. Where thickness is given as 1 inch, the value given is thermal conductivity ( $k$ ); for other thicknesses the value given is thermal conductance ( $C$ ). All values are for a test mean temperature of 75°F, except those designated with <sup>c</sup>, which are for 100°F.

<sup>b</sup> Over hollowback sheathing.

<sup>c</sup> Test mean temperature 100°F, see footnote <sup>a</sup>.

<sup>a</sup> Alloy designations correspond to the Aluminum Association numbers for aluminum alloys and to the unified numbering system (UNS) for copper and stainless steel alloys. A220 and A536 are ASTM specified irons.

**Adjusting Lengths for Reference Temperature.**—The standard reference temperature for industrial length measurements is 20 degrees Celsius (68 degrees Fahrenheit). For other temperatures, corrections should be made in accordance with the difference in thermal expansion for the two parts, especially when the gage is made of a different material than the part to be inspected.

*Example:* An aluminum part is to be measured with a steel gage when the room temperature is 30 °C. The aluminum part has a coefficient of linear thermal expansion,  $\alpha_{part} = 24.7 \times 10^{-6}$  mm/mm-°C, and for the steel gage,  $\alpha_{Gage} = 10.8 \times 10^{-6}$  mm/mm-°C.

At the reference temperature, the specified length of the aluminum part is 20.021 mm. What is the length of the part at the measuring (room) temperature?

$\Delta L$ , the change in the measured length due to temperature, is given by:

$$\begin{aligned}\Delta L &= L(T_R - T_0)(\alpha_{part} - \alpha_{Gage}) \\ &= 20.021(30 - 20)(24.7 - 10.8) \times 10^{-6} \text{ mm} \\ &= 2782.919 \times 10^{-6} \approx 0.003 \text{ mm}\end{aligned}$$

where  $L$  = length of part at reference temperature;  $T_R$  = room temperature (temperature of part and gage); and,  $T_0$  = reference temperature.

Thus, the temperature corrected length at 30°C is  $L + \Delta L = 20.021 + 0.003 = 20.024$  mm.

**Length Change Due to Temperature.**—Table 14 gives changes in length for variations from the standard reference temperature of 68°F (20°C) for materials of known coefficients of expansion,  $\alpha$ . Coefficients of expansion are given in tables on pages 402, 403, 415, 416, 427, and elsewhere.

*Example:* In Table 14, for coefficients between those listed, add appropriate listed values. For example, a length change for a coefficient of 7 is the sum of values in the 5 and 2 columns. Fractional interpolation also is possible. Thus, in a steel bar with a coefficient of thermal expansion of  $6.3 \times 10^{-6} = 0.0000063$  in/in = 6.3  $\mu\text{m/in}$  of length/°F, the increase in length at 73°F is  $25 + 5 + 1.5 = 31.5$   $\mu\text{m/in}$  of length. For a steel with the same coefficient of expansion, the change in length, measured in degrees C, is expressed in microns (micrometers)/meter ( $\mu\text{m/m}$ ) of length.

Alternatively, and for temperatures beyond the scope of the table, the length difference due to a temperature change is equal to the coefficient of expansion multiplied by the change in temperature, i.e.,  $\Delta L = \alpha \Delta T$ . Thus, for the previous example,  $\Delta L = 6.3 \times (73 - 68) = 6.3 \times 5 = 31.5$   $\mu\text{m/in}$ .

**Change in Radius of Thin Circular Ring with Temperature.**—Consider a circular ring of initial radius  $r$ , that undergoes a temperature change  $\Delta T$ . Initially, the circumference of the ring is  $c = 2\pi r$ . If the coefficient of expansion of the ring material is  $\alpha$ , the change in circumference due to the temperature change is  $\Delta c = 2\pi r \alpha \Delta T$

The new circumference of the ring will be:  $c_n = c + \Delta c = 2\pi r + 2\pi r \alpha \Delta T = 2\pi r(1 + \alpha \Delta T)$

*Note:* An increase in temperature causes  $\Delta c$  to be positive, and a decrease in temperature causes  $\Delta c$  to be negative.

As the circumference increases, the radius of the circle also increases. If the new radius is  $R$ , the new circumference  $2\pi R$ . For a given change in temperature,  $\Delta T$ , the change in radius of the ring is found as follows:

$$c_n = 2\pi R = 2\pi r(1 + \alpha \Delta T) \quad R = r + r\alpha \Delta T \quad \Delta r = R - r = r\alpha \Delta T$$

LENGTH/TEMPERATURE CHANGES

**Table 14. Differences in Length in Inches/Inch (Microns/Meter) for Changes from the Standard Temperature of 68°F (20°C)**

## Properties of Mass and Weight

**Specific Gravity.**—Specific gravity is a number indicating how many times a certain volume of a material is heavier than an equal volume of water. The density of water differs slightly at different temperatures, so the usual custom is to make comparisons on the basis that the water has a temperature of 62°F. The weight of 1 cubic inch of pure water at 62°F is 0.0361 pound. If the specific gravity of any material is known, the weight of a cubic inch of the material, therefore, can be found by multiplying its specific gravity by 0.0361. To find the weight per cubic foot of a material, multiply the specific gravity by 62.355. If the weight of a cubic inch of a material is known, the specific gravity is found by dividing the weight per cubic inch by 0.0361.

*Example:* Given the specific gravity of cast iron is 7.2. Then, the weight of 5 cubic inches of cast iron =  $7.2 \times 0.0361 \times 5 = 1.2996$  pounds.

*Example:* Given the weight of a cubic inch of gold is 0.697 pound. Then, the specific gravity of gold =  $0.697 \div 0.0361 = 19.31$

If the weight per cubic foot of a material is known, the specific gravity is found by multiplying this weight by 0.01604.

Table 15. Average Specific Gravity of Various Substances

| Substance              | Specific Gravity | <sup>a</sup> Weight lb/ft <sup>3</sup> | Substance           | Specific Gravity | <sup>a</sup> Weight lb/ft <sup>3</sup> | Substance       | Specific Gravity | <sup>a</sup> Weight lb/ft <sup>3</sup> |
|------------------------|------------------|--|---------------------|------------------|--|-----------------|------------------|--|
| ABS                    | 1.05             | 66                                     | Glass               | 2.6              | 162                                    | Platinum        | 21.5             | 1342                                   |
| Acrylic                | 1.19             | 74                                     | Glass, crushed      | ...              | 74                                     | Polycarbonate   | 1.19             | 74                                     |

<sup>a</sup> The weight per cubic foot is calculated on the basis of the specific gravity except for those substances that occur in bulk, heaped, or loose form. In these instances, only the weights per cubic foot are given because the voids present in representative samples make the values of the specific gravities inaccurate.

**Specific Gravity of Gases.**—The specific gravity of gases is the number that indicates their weight in comparison with that of an equal volume of air. The specific gravity of air is 1, and the comparison is made at 32°F. Values are given in Table 16.

**Specific Gravity of Liquids.**—The specific gravity of liquids is the number that indicates how much a certain volume of the liquid weighs compared with an equal volume of water, the same as with solid bodies. Specific gravity of various liquids is given in Table 17.

The density of liquid is often expressed in degrees on the hydrometer, an instrument for determining the density of liquids, provided with graduations made to an arbitrary scale. The hydrometer consists of a glass tube with a bulb at one end containing air, and arranged with a weight at the bottom so as to float in an upright position in the liquid, the density of

**Table 16. Specific Gravity of Gases At 32°F**

| Gas              | Sp. Gr. | Gas               | Sp. Gr. | Gas            | Sp. Gr. |
|------------------|---------|-------------------|---------|----------------|---------|

| Carbon monoxide  | 0.967   | Illuminating gas  | 0.400   | Sulfur dioxide | 2.250   |
| Chlorine         | 2.423   | Mercury vapor     | 6.940   | Water vapor    | 0.623   |

<sup>a</sup> 1 cubic foot of air at 32°F and atmospheric pressure weighs 0.0807 pound.

which is to be measured. The depth to which the hydrometer sinks in the liquid is read off on the graduated scale. The most commonly used hydrometer is the Baumé, see [Table 18](#). The value of the degrees of the Baumé scale differs according to whether the liquid is heavier or lighter than water. The specific gravity for liquids heavier than water equals  $145 \div (145 - \text{degrees Baumé})$ . For liquids lighter than water, the specific gravity equals  $140 \div (130 + \text{degrees Baumé})$ .

**Table 17. Specific Gravity of Liquids**

| Liquid              | Sp. Gr. | Liquid        | Sp. Gr. | Liquid          | Sp. Gr. |
|---------------------|---------|---------------|---------|-----------------|---------|
| Acetic acid         | 1.06    | Fluoric acid  | 1.50    | Petroleum oil   | 0.82    |

**Average Weights and Volumes of Solid Fuels.**—Anthracite coal, 55–65 lb/ft<sup>3</sup>; 34–41 ft<sup>3</sup>/ton (2240 lb); 67 lb/bushel. Bituminous coal, 50–55 lb/ft<sup>3</sup>; 41–45 ft<sup>3</sup>/ton (2240 lb); 60 lb/bushel. Charcoal, 8–18.5 lb/ft<sup>3</sup>; 120–124 ft<sup>3</sup>/ton (2240 lb); 20 lb/bushel. Coke, 28 lb/ft<sup>3</sup>; 80 ft<sup>3</sup>/ton (2240 lb); 40 lb/bushel.

**How to Estimate the Weight of Natural Piles.**—To calculate the upper and lower limits of the weight of a substance piled naturally on a circular plate, so as to form a cone of material, use the equation:

$$W = MD^3 \tag{1}$$

where  $W$  = weight, lb;  $D$  = diameter of plate, ft. (Fig. 1a); and,  $M$  = materials factor, whose upper and lower limits are given in Table 19b.

For a rectangular plate, calculate the weight of material piled naturally by means of the following equation:

$$W = MRA^3 \tag{2}$$

where  $A$  and  $B$  = the length and width in ft., respectively, of the rectangular plate in Fig. 1b, with  $B \leq A$ ; and,  $R$  = is a factor given in Table 19a as a function of the ratio  $B/A$ .

*Example:* Find the upper and lower limits of the weight of dry ashes piled naturally on a plate 10 ft. in diameter.

Using Equation (1),  $M = 4.58$  from Table 19b, the lower limit  $W = 4.58 \times 10^3 = 4,580$  lb. For  $M = 5.89$ , the upper limit  $W = 5.89 \times 10^3 = 5,890$  lb.

*Example:* What weight of dry ashes rests on a rectangular plate 10 ft. by 5 ft.?

For  $B/A = 5/10 = 0.5$ ,  $R = 0.39789$  from Table 19a. Using Equation (2), for  $M = 4.58$ , the lower limit  $W = 4.58 \times 0.39789 \times 10^3 = 1,822$  lb. For  $M = 5.89$ , the upper limit  $W = 5.89 \times 0.39789 \times 10^3 = 2,344$  lb.

| Coffee beans               | 2.42-5.89       | Orange peel, dry           | 1.96            | ...                     | ...             |

**Earth or Soil Weight.**—Loose earth has a weight of approximately 75 pounds per cubic foot and rammed earth, 100 pounds per cubic foot. The solid crust of the earth, according to an estimate, is composed approximately of the following elements:

Oxygen, 44.0 to 48.7 per cent; silicon, 22.8 to 36.2 per cent; aluminum, 6.1 to 9.9 per cent; iron, 2.4 to 9.9 per cent; calcium, 0.9 to 6.6 per cent; magnesium, 0.1 to 2.7 per cent; sodium, 2.4 to 2.5 per cent; potassium, 1.7 to 3.1 per cent.

**Molecular Weight.**—The smallest mass of a chemical combination which can be conceived of as existing and yet preserving its chemical properties is known as a *molecule*. The molecular weight of a chemical compound is equal to the sum of the atomic weights of the atoms contained in the molecule, and are calculated from the atomic weights, when the symbol of the compound is known. The atomic weight of silver is 107.88; of nitrogen, 14.01; and of oxygen, 16; hence, the molecular weight of silver-nitrate, the chemical formula of which is  $\text{AgNO}_3$  equals  $107.88 + 14.01 + (3 \times 16) = 169.89$ .

**Mol.**—The term “mol” is used as a designation of quantity in electro-chemistry, and indicates the number of grams of a substance equal to its molecular weight. For example, one mol of silver-nitrate equals 169.89 grams, the molecular weight of silver-nitrate being 169.89.

## PROPERTIES OF WOOD, CERAMICS, PLASTICS, METALS, WATER, AND AIR

### Properties of Wood

**Mechanical Properties of Wood.**—Wood is composed of cellulose, lignin, ash-forming minerals, and extractives formed into a cellular structure. (Extractives are substances that can be removed from wood by extraction with such solvents as water, alcohol, acetone, benzene, and ether.) Variations in the characteristics and volumes of the four components and differences in the cellular structure result in some woods being heavy and some light, some stiff and some flexible, and some hard and some soft. For a single species, the properties are relatively constant within limits; therefore, selection of wood by species alone may sometimes be adequate. However, to use wood most effectively in engineering applications, the effects of physical properties or specific characteristics must be considered.

The mechanical properties listed in the accompanying [Table 1](#) were obtained from tests on small pieces of wood termed “clear” and “straight grained” because they did not contain such characteristics as knots, cross grain, checks, and splits. However, these test pieces did contain such characteristics as growth rings that occur in consistent patterns within the piece. Since wood products may contain knots, cross grain, etc., these characteristics must be taken into account when assessing actual properties or when estimating actual performance. In addition, the methods of data collection and analysis have changed over the years during which the data in [Table 1](#) have been collected; therefore, the appropriateness of the data should be reviewed when used for critical applications such as stress grades of lumber.

Wood is an orthotropic material; that is, its mechanical properties are unique and independent in three mutually perpendicular directions—longitudinal, radial, and tangential. These directions are illustrated in the following figure.

**Modulus of Rupture:** The modulus of rupture in bending reflects the maximum load-carrying capacity of a member and is proportional to the maximum moment borne by the member. The modulus is an accepted criterion of strength, although it is not a true stress because the formula used to calculate it is valid only to the proportional limit.

**Work to Maximum Load in Bending:** The work to maximum load in bending represents the ability to absorb shock with some permanent deformation and more or less injury to a specimen; it is a measure of the combined strength and toughness of the wood under bending stress.

**Maximum Crushing Strength:** The maximum crushing strength is the maximum stress sustained by a compression parallel-to-grain specimen having a ratio of length to least diameter of less than 11.

**Compression Perpendicular to Grain:** Strength in compression perpendicular to grain is reported as the stress at the proportional limit because there is no clearly defined ultimate stress for this property.

**Shear Strength Parallel to Grain:** Shear strength is a measure of the ability to resist internal slipping of one part upon another along the grain. The values listed in the table are averages of the radial and tangential shears.

**Tensile Strength Perpendicular to Grain:** The tensile strength perpendicular to the grain is a measure of the resistance of wood to forces acting across the grain that tend to split the material. Averages of radial and tangential measurements are listed.

**Table 1. Mechanical Properties of Commercially Important U.S. Grown Woods**

| Use the first number in each column for GREEN wood; use the second number for DRY wood. | Static Bending                           |   |      |      | Maximum Crushing Strength (10 <sup>3</sup> psi) | Compression Strength Perpendicular to Grain (psi) | Shear Strength Parallel to Grain (psi) | Tensile Strength Perp. to Grain (psi) |     |       |     |     |
|---|--|---|------|------|---|---|--|---------------------------------------|-----|-------|-----|-----|
|   | Modulus of Rupture (10 <sup>3</sup> psi) | Work to Max Load (in.-lb/in. <sup>3</sup> ) |      |      |   |   |  |                                       |     |       |     |     |

<sup>a</sup> Coast: grows west of the summit of the Cascade Mountains in OR and WA. Interior west: grows in CA and all counties in OR and WA east of but adjacent to the Cascade summit. Interior north: grows in remainder of OR and WA and ID, MT, and WY. Interior south: grows in UT, CO, AZ, and NM.

Results of tests on small, clear, straight-grained specimens. Data for dry specimens are from tests of seasoned material adjusted to a moisture content of 12%.

Source: U.S. Department of Agriculture: *Wood Handbook*.

**Weight of Wood.**—The weight of seasoned wood per cord is approximately as follows, assuming about 70 cubic feet of *solid wood* per cord: beech, 3300 pounds; chestnut, 2600 pounds; elm, 2900 pounds; maple, 3100 pounds; poplar, 2200 pounds; white pine, 2200 pounds; red oak, 3300 pounds; white oak, 3500 pounds. For additional weights of green and dry woods, see [Table 2](#).

**Weight per Foot of Wood, Board Measure.**—The following is the weight in pounds of various kinds of woods, commercially known as dry timber, per foot board measure: white oak, 4.16; white pine, 1.98; Douglas fir, 2.65; short leaf yellow pine, 2.65; red pine, 2.60; hemlock, 2.08; spruce, 2.08; cypress, 2.39; cedar, 1.93; chestnut, 3.43; Georgia yellow pine, 3.17; California spruce, 2.08. For other woods, divide the weight/ft<sup>3</sup> from [Table 2](#) by 12 to obtain the approximate weight per board foot.

**Effect of Pressure Treatment on Mechanical Properties of Wood.**—The strength of wood preserved with creosote, coal-tar, creosote-coal-tar mixtures, creosote-petroleum mixtures, or pentachlorophenol dissolved in petroleum oil is not reduced. However, water-borne salt preservatives contain chemicals such as copper, arsenic, chromium, and ammonia, which have the potential of affecting mechanical properties of treated wood and

causing mechanical fasteners to corrode. Preservative salt-retention levels required for marine protection may reduce bending strength by 10 per cent or more.

**Density of Wood.**—The following formula can be used to find the density of wood in lb/ft<sup>3</sup> as a function of its moisture content. 

$$\rho = 62.4 \left( \frac{G}{1 + G \times 0.009 \times M} \right) \left( 1 + \frac{M}{100} \right)$$

where  $\rho$  is the density,  $G$  is the specific gravity of wood, and  $M$  is the moisture content expressed in per cent.

**Table 2. Weights of American Woods, in Pounds per Cubic Foot**

| Species                    | Green | Airdry | Species                       | Green | Airdry | Species                 | Green | Airdry |
|----------------------------|-------|--------|-------------------------------|-------|--------|-------------------------|-------|--------|
|                            |       |        |                               |       |        |                         |       |        |

**Machinability of Wood.**—The ease of working wood with hand tools generally varies directly with the specific gravity of the wood; the lower the specific gravity, the easier the wood is to cut with a sharp tool. A rough idea of the specific gravity of various woods can be obtained from the preceding table by dividing the weight of wood in lb/ft<sup>3</sup> by 62.355.

A wood species that is easy to cut does not necessarily develop a smooth surface when it is machined. Three major factors, other than specific gravity, influence the smoothness of the surface obtained by machining: interlocked and variable grain, hard deposits in the grain, and reaction wood. Interlocked and variable grain is a characteristic of many tropical and some domestic species; this type of grain structure causes difficulty in planing quarter sawn boards unless careful attention is paid to feed rates, cutting angles, and sharpness of the knives. Hard deposits of calcium carbonate, silica, and other minerals in the grain tend to dull cutting edges quickly, especially in wood that has been dried to the usual in service moisture content. Reaction wood results from growth under some physical stress such as occurs in leaning trunks and crooked branches. Generally, reaction wood occurs as tension wood in hardwoods and as compression wood in softwoods. Tension wood is particularly troublesome, often resulting in fibrous and fuzzy surfaces, especially in woods of lower density. Reaction wood may also be responsible for pinching saw blades, resulting in burning and dulling of teeth.

The Table 3 rates the suitability of various domestic hardwoods for machining. The data for each species represent the percentage of pieces machined that successfully met the listed quality requirement for the processes. For example, 62 per cent of the black walnut

pieces planed came out perfect, but only 34 per cent of the pieces run on the shaper achieved good to excellent results.

**Table 3. Machinability and Related Properties of Various Domestic Hardwoods**

| Type of Wood   | Planing          | Shaping           | Turning           | Boring            | Mortising         | Sanding           |

|                  | 4                  | $3\frac{1}{2}$ | $3\frac{9}{16}$     | ...                  | ...                 | ...                  |
| Timbers          | $4\frac{1}{2}$     | 4              | $4\frac{1}{16}$     | ...                  | ...                 | ...                  |
|                  | 5 and up           | ...            | $T_n - \frac{1}{2}$ | 5 and up             | ...                 | $W_n - \frac{1}{2}$  |

Source: National Forest Products Association: *Design Values for Wood Construction*. Moisture content: dry lumber  $\leq 19\%$ ; green lumber  $> 19\%$ . Dimension lumber refers to lumber 2 to 4 inches thick (nominal) and 2 inches or greater in width. Timbers refers to lumber of approximately square cross-section,  $5 \times 5$  inches or larger, and a width no more than 2 inches greater than the thickness.

## Tabulated Properties of Ceramics, Plastics, and Metals

## Typical Properties of Ceramics Materials

<sup>a</sup>Obtain specific gravity by dividing density in lb/in.<sup>3</sup> by 0.0361; for density in lb/ft<sup>3</sup>, multiply lb/in.<sup>3</sup> by 1728; for g/cm<sup>3</sup>, multiply density in lb/in.<sup>3</sup> by 27.68; for kg/m<sup>3</sup>, multiply density in lb/in.<sup>3</sup> by 27,679.9.

<sup>b</sup>To convert coefficient of expansion to 10<sup>-6</sup> in./in.-°C, multiply table value by 1.8.

<sup>c</sup>Mohs's Hardness scale is used unless otherwise indicated as follows: Ra and Rh for Rockwell A and H scales, respectively; V for Vickers hardness.

<sup>d</sup>To convert conductivity from Btu-ft/hr-ft<sup>2</sup>-°F to cal-cm/sec-cm<sup>2</sup>-°C, divide by 241.9.

## Typical Properties of Plastics Materials

<sup>a</sup> To obtain specific gravity, divide density in lb/in<sup>3</sup> by 0.0361; for density in lb/ft<sup>3</sup>, multiply lb/in<sup>3</sup> by 1728; for g/cm<sup>3</sup>, multiply density in lb/in<sup>3</sup> by 27.68; for kg/m<sup>3</sup>, multiply density in lb/in<sup>3</sup> by 27,679.9.

<sup>b</sup> To convert coefficient of expansion to 10<sup>-6</sup> in/in-°C, multiply table value by 1.8.

<sup>c</sup> Hardness value scales are as follows: Rm for Rockwell M scale; Rr for Rockwell R scale.

## Mechanical Properties of Various Investment Casting Alloys

| Alloy Designation                    | Material Condition | Tensile Strength (10 <sup>3</sup> psi) | 0.2% Yield Strength <sup>a</sup> (10 <sup>3</sup> psi) | % Elongation | Hardness    |
|--------------------------------------|--------------------|--|--|--------------|-------------|

<sup>a</sup> For copper alloys, yield strength is determined by 0.5% extension under load or 0.2% offset method. A number in parentheses following a copper alloy indicates the UNS designation of that alloy (for example, Al Bronze C (954) identifies the alloy as UNS C95400).

<sup>b</sup> AC = air cooled to temperature indicated.

Source: Investment Casting Institute. Mechanical properties are average values of separately cast test bars, and are for reference only. Items marked ... indicates data are not available. Alloys identified by IC followed by an SAE designation number (IC 1010 steel, for example) are generally similar to the SAE material although properties and chemical composition may be different.

## Typical Properties of Compressed and Sintered Powdered Metal Alloys

| Alloy Number <sup>a</sup> and Nominal Composition (%) |                                   | Density (g/cc) | Hardness | Strength (10 <sup>3</sup> psi) |                  |       | % Elongation |
|---|-----------------------------------|----------------|----------|--------------------------------|------------------|-------|--------------|
|   |                                   |                |          | Transverse Rupture             | Ultimate Tensile | Yield |              |

For allowable working stresses and recommended design stresses in bending, related to severity of service, refer to Fig. 1 through Fig. 10 on pages 314 through 317, and for endurance limits for compression springs made from these materials refer to Fig. 11 on page 319 in the section on spring stresses.

**Effect of Temperature on Strength and Elasticity of Metals.**—Most ferrous metals have a maximum strength at approximately 400 degrees F, whereas the strength of nonferrous alloys is a maximum at about room temperature. The table on page 421 gives general data for variation in metal strength with temperature.

The modulus of elasticity of metals decreases regularly with increasing temperatures above room temperature until at some elevated temperature it falls off rapidly and reaches zero at the melting point.

## Influence of Temperature on the Strength of Metals

| Material         | Degrees Fahrenheit                               |     |     |     |     |      |      |      |
|------------------|--|-----|-----|-----|-----|------|------|------|

**Pressure and Flow of Water**

**Water Pressure.**—Water is composed of two elements, hydrogen and oxygen, in the ratio of two volumes of hydrogen to one of oxygen. In the common system of measure, water boils under atmospheric pressure at 212 degrees F and freezes at 32 degrees F. Water's greatest density is 62.425 pounds per cubic foot, at 39.1 degrees F. In metric (SI) measure, water boils under atmospheric pressure at 100°C (Celsius) and freezes at 0°C. Its density is equal to 1 kilogram per liter, where 1 liter is 1 cubic decimeter. Also in metric SI, pressure is given in pascals (Pa) or the equivalent newtons per square meter. See page 2544 for additional information on the metric (SI) system of units.

For higher temperatures, the pressure slightly decreases in the proportion indicated by the table *Density of Water at Different Temperatures*. The pressure per square inch is equal in all directions, downwards, upwards, and sideways. Water can be compressed only to a very slight degree, the compressibility being so slight that even at the depth of a mile, a cubic foot of water weighs only about one-half pound more than at the surface.

**Pressure in Pounds per Square Inch for Different Heads of Water**

| Head, ft | 0     | 1     | 2     | 3     | 4     | 5     | 6     | 7     | 8     | 9     |

The table gives the horsepower of 1 cubic foot of water per minute, and is based on an efficiency of 85 per cent.

**Flow of Water in Pipes.**—The quantity of water that will flow through a pipe depends primarily on the head but also on the diameter of the pipe, the character of the interior surface, and the number and shape of the bends. The head may be either the distance between the levels of the surface of water in a reservoir and the point of discharge, or it may be caused by mechanically applied pressure, as by pumping, when the head is calculated as the vertical distance corresponding to the pressure.

One pound per square inch is equal to 2.309 feet head, and a 1-foot head is equal to a pressure of 0.433 pound per square inch.

All formulas for finding the amount of water that will flow through a pipe in a given time are approximate. The formula that follows will give results within 5 or 10 per cent of actual flows, if applied to pipe lines carefully laid and in fair condition.

## FLOW OF WATER

$$V = C \sqrt{\frac{hD}{L + 54D}}$$

where  $V$  = approximate mean velocity in feet per second;  $C$  = coefficient from the accompanying table;  $D$  = diameter of pipe in feet;  $h$  = total head in feet; and,  $L$  = total length of pipe line in feet.

Values of Coefficient  $C$ 

| Dia. of Pipe |        | C  | Dia. of Pipe |        | C  | Dia. of Pipe |        | C  |
|--------------|--------|----|--------------|--------|----|--------------|--------|----|
| Feet         | Inches |    | Feet         | Inches |    | Feet         | Inches |    |
| 0.1          | 1.2    | 23 | 0.8          | 9.6    | 46 | 3.5          | 42     | 64 |
| 0.2          | 2.4    | 30 | 0.9          | 10.8   | 47 | 4.0          | 48     | 66 |
| 0.3          | 3.6    | 34 | 1.0          | 12.0   | 48 | 5.0          | 60     | 68 |
| 0.4          | 4.8    | 37 | 1.5          | 18.0   | 53 | 6.0          | 72     | 70 |
| 0.5          | 6.0    | 39 | 2.0          | 24.0   | 57 | 7.0          | 84     | 72 |
| 0.6          | 7.2    | 42 | 2.5          | 30.0   | 60 | 8.0          | 96     | 74 |
| 0.7          | 8.4    | 44 | 3.0          | 36.0   | 62 | 10.0         | 120    | 77 |

*Example:* A pipe line, 1 mile long, 12 inches in diameter, discharges water under a head of 100 feet. Find the velocity and quantity of discharge.

From the table, the coefficient  $C$  is found to be 48 for a pipe 1 foot in diameter, hence:

$$V = 48 \sqrt{\frac{100 \times 1}{5280 + 54 \times 1}} = 6.57 \text{ feet per second}$$

To find the discharge in cubic feet per second, multiply the velocity found by the area of cross-section of the pipe in square feet:

$$6.57 \times 0.7854 = 5.16 \text{ cubic feet per second}$$

The loss of head due to a bend in the pipe is most frequently given as the equivalent length of straight pipe, which would cause the same loss in head as the bend. Experiments show that a right-angle bend should have a radius of about three times the diameter of the pipe. Assuming this curvature, then, if  $d$  is the diameter of the pipe in inches and  $L$  is the length of straight pipe in feet that causes the same loss of head as the bend in the pipe, the following formula gives the equivalent length of straight pipe that should be added to simulate a right-angle bend:

$$L = 4d \div 3$$

Thus, the loss of head due to a right-angle bend in a 6-inch pipe would be equal to that in 8 feet of straight pipe. Experiments undertaken to determine the losses due to valves in pipe lines indicate that a fully open gate valve in a pipe causes a loss of head corresponding to the loss in a length of pipe equal to six diameters.

**Buoyancy.**—A body submerged in water or other fluid will lose in weight an amount equal to the weight of the fluid displaced by the body. This is known as the principle of Archimedes.

*Example, Weight of a Submerged Body:* To illustrate, suppose the upper surface of a 10-inch cube is 20 inches below the surface of the water. The total downward pressure on the upper side of this cube will equal the area of the top surface of the cube, in square inches, multiplied by the product of the depth, in inches, to which the surface is submerged and the weight of 1 cubic inch of water.

Thus, the

weight of 1 cubic inch of water: 0.03617 pounds

downward pressure:  $10 \times 10 \times 20 \times 0.03617 = 72.34$  pounds

upward pressure on the under side:  $10 \times 10 \times 30 \times 0.03617 = 108.51$  pounds

weight of the water displaced by the body:  $10 \times 10 \times 10 \times 0.03617 = 36.17$  pounds

upward pressure – downward pressure:  $108.51 - 72.34 = 36.17$  pounds

This excess of upward pressure explains why it is comparatively easy to lift a submerged stone or other body.

## Flow of Water Through Nozzles in Cubic Feet per Second

| Head in Feet, at Nozzle | Pressure, lb/in <sup>2</sup> | Theoretical Velocity, ft/s | Diameter of Nozzle, Inches |      |      |      |      |       |       |       |
|-------------------------|------------------------------|----------------------------|----------------------------|------|------|------|------|-------|-------|-------|
|                         |                              |                            | 1                          | 1.5  | 2    | 2.5  | 3    | 3.5   | 4     | 4.5   |

| 12                      | 29.8     | 15.9     | 24.7            | 49.7       | 25.9       | 56.7          | 24.7          | 59.7             |

**Pipe Expansion Due to Temperature Changes.**—The expansion for any length of pipe caused by a given temperature change can be determined from the following table. Find the expansion factor corresponding to the expected difference in the minimum and maximum pipe temperatures and divide by 100 to obtain the increase in length per foot of pipe. Multiply the increase per foot result by the length of the pipe run to get the total change in pipe length.

## Linear Expansion and Contraction Factors per 100 Feet of Pipe

| Temperature Change, °F | Pipe Material |        |      |      |           |
|------------------------|---------------|--------|------|------|-----------|
|                        | Steel         | Copper | PVC  | FRP  | PP & PVDF |
| 0                      | 0             | 0      | 0    | 0    | 0         |
| 20                     | 0.15          | 0.25   | 0.62 | 0.26 | 2.00      |
| 40                     | 0.30          | 0.45   | 1.30 | 0.52 | 4.00      |
| 60                     | 0.46          | 0.65   | 2.20 | 0.78 | 6.00      |
| 80                     | 0.61          | 0.87   | 2.80 | 1.05 | 8.00      |
| 100                    | 0.77          | 1.10   | 3.50 | 1.31 | 10.00     |
| 120                    | 0.92          | 1.35   | 4.25 | 1.57 | 12.00     |
| 140                    | 1.08          | 1.57   | 4.80 | 1.83 | 14.00     |
| 160                    | 1.24          | 1.77   | 5.50 | 2.09 | 16.00     |
| 180                    | 1.40          | 2.00   | 6.30 | 2.35 | 18.00     |
| 200                    | 1.57          | 2.25   | 7.12 | 2.62 | 20.00     |

Multiply the length of pipe by the table factor and divide by 100 for the increase or decrease in length.

## Properties, Compression, and Flow of Air

**Properties of Air.**—Air is a mechanical mixture composed of 78 per cent of nitrogen, 21 per cent of oxygen, and 1 per cent of argon, by volume. The density of dry air at 32 degrees F and atmospheric pressure (29.92 inches of mercury or 14.70 pounds per square inch) is 0.08073 pound per cubic foot. The density of air at any other temperature or pressure is

$$\rho = \frac{1.325 \times B}{T}$$

in which  $\rho$  = density in pounds per cubic foot;  $B$  = height of barometric pressure in inches of mercury;  $T$  = absolute temperature in degrees Rankine. (When using pounds as a unit, here and elsewhere, care must be exercised to differentiate between pounds mass and pounds force. See *Acceleration of Gravity  $g$  Used in Mechanics Formulas* on page 142 and *The Use of the Metric SI System in Mechanics Calculations* on page 142.)

## Volumes and Weights of Air at Different Temperatures, at Atmospheric Pressure

| Temperature, °F | Volume of 1 lb of Air in Cubic Feet | Density, Pounds per Cubic Foot | Temperature, °F | Volume of 1 lb of Air in Cubic Feet | Density, Pounds per Cubic Foot | Temperature, °F | Volume of 1 lb of Air in Cubic Feet | Density, Pounds per Cubic Foot |
|-----------------|-------------------------------------|--------------------------------|-----------------|-------------------------------------|--------------------------------|-----------------|-------------------------------------|--------------------------------|
| 0               | 11.57                               | 0.0864                         | 172             | 15.92                               | 0.0628                         | 800             | 31.75                               | 0.0315                         |

The absolute zero from which all temperatures must be counted when dealing with the weight and volume of gases is assumed to be  $-459.7$  degrees F. Hence, to obtain the absolute temperature  $T$  used in preceding formula, add the value 459.7 to the temperature observed on a regular Fahrenheit thermometer.

In obtaining the value of  $B$ , 1 inch of mercury at 32 degrees F may be taken as equal to a pressure of 0.491 pound per square inch.

*Example 1:* What would be the weight of a cubic foot of air at atmospheric pressure (29.92 inches of mercury) at 100 degrees F? The weight,  $W$ , is given by  $W = \rho V$ .

$$W = \rho V = \frac{1.325 \times 29.92}{100 + 459.7} \times 1 = 0.0708 \text{ pound}$$

**Relation Between Pressure, Temperature, and Volume of Air.**—This relationship is expressed by the following formulas:

$$PV = 53.3mT \quad \text{For fps units}$$

$$PV = 1545.3nT \quad \text{For fps units}$$

$$PV = 8314nT \quad \text{For SI units}$$

in which  $P$  = absolute pressure in pounds per square foot or Pa ( $N/m^2$ );  $V$  = volume in cubic feet or cubic meter;  $T$  = absolute temperature in degrees R or degrees K;  $m$  = the mass of substance; and  $n$  = number of pound moles or kg moles. A mole is the mass of substance, in appropriate units, divided by its molecular weight. The first equation above is for air only; the second and third are general formulas that apply to any gas that behaves the ideal gas law.

*Example 2:* What is the volume of one pound of air at a pressure of 24.7 pounds per square inch and at a temperature of 210 degrees F?

$$PV = 53.3mT \quad V = \frac{53.3mT}{P} \quad V = \frac{53.3 \times 1 \times (210 + 459.6)}{24.7 \times 144}$$

$$= 10.04 \text{ cubic ft}$$

<sup>a</sup> Psi is pounds per square inch; Psf is pounds per square foot

**Expansion and Compression of Air.**—The formula for the relationship between pressure, temperature, and volume of air just given indicates that when the pressure remains constant the volume is directly proportional to the absolute temperature. If the temperature remains constant, the volume is inversely proportional to the absolute pressure. Theoretically, air (as well as other gases) can be expanded or compressed according to different laws.

*Adiabatic Expansion or Compression* takes place when the air is expanded or compressed without transmission of heat to or from it, as, for example, if the air could be expanded or compressed in a cylinder of an absolutely nonconducting material.

- Let:  $P_1$  = initial absolute pressure in pounds per square foot  
 $V_1$  = initial volume in cubic feet  
 $T_1$  = initial absolute temperature in degrees R  
 $P_2$  = absolute pressure in pounds per square foot, after compression  
 $V_2$  = volume in cubic feet, after compression  
 $T_2$  = absolute temperature in degrees R, after compression

Then:

$$\frac{V_2}{V_1} = \left(\frac{P_1}{P_2}\right)^{0.71} \quad \frac{P_2}{P_1} = \left(\frac{V_1}{V_2}\right)^{1.41} \quad \frac{T_2}{T_1} = \left(\frac{V_1}{V_2}\right)^{0.41}$$

$$\frac{V_2}{V_1} = \left(\frac{T_1}{T_2}\right)^{2.46} \quad \frac{P_2}{P_1} = \left(\frac{T_2}{T_1}\right)^{3.46} \quad \frac{T_2}{T_1} = \left(\frac{P_2}{P_1}\right)^{0.29}$$

These formulas are also applicable if all pressures are in pounds per square inch; if all volumes are in cubic inches; or if any other consistent set of units is used for pressure or volume.

*Example 3:* A volume of 165 cubic feet of air, at a pressure of 15 pounds per square inch, is compressed adiabatically to a pressure of 80 pounds per square inch. What will be the volume at this pressure?

$$V_2 = V_1 \left( \frac{P_1}{P_2} \right)^{0.71} = 165 \left( \frac{15}{80} \right)^{0.71} = 50 \text{ cubic feet, approx.}$$

*Isothermal Expansion or Compression* takes place when a gas is expanded or compressed with an addition or transmission of sufficient heat to maintain a constant temperature.

Let:  $P_1$  = initial absolute pressure in pounds per square foot

$V_1$  = initial volume in cubic feet

$P_2$  = absolute pressure in pounds per square foot, after compression

$V_2$  = volume in cubic feet, after compression

$R = 53.3$

$T$  = temperature in degrees Rankine maintained during isothermal expansion or contraction

Then:

$$P_1 \times V_1 = P_2 \times V_2 = RT$$

*Example 4:* The same volume of air as in [Example 3](#) is compressed isothermally from 15 to 80 pounds per square inch. What will be the volume after compression?

$$V_2 = \frac{P_1 \times V_1}{P_2} = \frac{15 \times 165}{80} = 31 \text{ cubic feet}$$

### Foot-pounds of Work Required in Compression of Air Initial Pressure = 1 atmosphere = 14.7 pounds per square inch

| Gage Pressure in Pounds per Square Inch | Isothermal Compression   | Adiabatic Compression | Actual Compression | Gage Pressure in Pounds per Square Inch | Isothermal Compression   | Adiabatic Compression | Actual Compression |

**Work Required in Compression of Air.**—The total work required for compression and expulsion of air, adiabatically compressed, is:

$$\text{Total work in foot-pounds} = 3.46 P_1 V_1 \left[ \left( \frac{P_2}{P_1} \right)^{0.29} - 1 \right]$$

where  $P_1$  = initial absolute pressure in pounds per square foot;  $P_2$  = absolute pressure in pounds per square foot, after compression; and,  $V_1$  = initial volume in cubic feet.

The total work required for isothermal compression is:

$$\text{Total work in foot-pounds} = P_1 V_1 \log_e \frac{V_1}{V_2}$$

in which  $P_1$ ,  $P_2$ , and  $V_1$  denote the same quantities as in the previous equation, and  $V_2$  = volume of air in cubic feet, after compression.

The work required to compress air isothermally, that is, when the heat of compression is removed as rapidly as produced, is considerably less than the work required for compressing air adiabatically, or when all the heat is retained. In practice, neither of these two theoretical extremes is obtainable, but the power required for air compression is about the median between the powers that would be required for each. The accompanying table gives the average number of foot-pounds of work required to compress air.

**Horsepower Required to Compress Air.**—In the accompanying tables is given the horsepower required to compress one cubic foot of free air per minute (isothermally and adiabatically) from atmospheric pressure (14.7 pounds per square inch) to various gage pressures, for one-, two-, and three-stage compression. The formula for calculating the horsepower required to compress, adiabatically, a given volume of free air to a given pressure is:

$$\text{HP} = \frac{144NPVn}{33,000(n-1)} \left[ \left( \frac{P_2}{P} \right)^{\frac{n-1}{n}} - 1 \right]$$

where  $N$  = number of stages in which compression is accomplished

$P$  = atmospheric pressure in pounds per square inch

$P_2$  = absolute terminal pressure in pounds per square inch

$V$  = volume of air, in cubic feet, compressed per minute, at atmospheric pressure

$n$  = exponent of the compression curve = 1.41 for adiabatic compression

For different methods of compression and for one cubic foot of air per minute, this formula may be simplified as follows:

For one-stage compression:  $\text{HP} = 0.015P(R^{0.29} - 1)$

For two-stage compression:  $\text{HP} = 0.030P(R^{0.145} - 1)$

For three-stage compression:  $\text{HP} = 0.045P(R^{0.0975} - 1)$

For four-stage compression:  $\text{HP} = 0.060P(R^{0.0725} - 1)$

In these latter formulas  $R = \frac{P_2}{P}$  = number of atmospheres to be compressed

The formula for calculating the horsepower required to compress isothermally a given volume of free air to a given pressure is:

$$\text{HP} = \frac{144PV}{33000} \left( \log_e \frac{P_2}{P} \right)$$

Natural logarithms are obtained by multiplying common logarithms by 2.30259 or by using a handheld calculator.

**Continuity Equation.**—The net rate of mass inflow to the control volume is equal to the rate of increase of mass within the control volume.

For steady flow,  $\rho_1 A_1 V_1 = \rho_2 A_2 V_2 = M$  where  $\rho$  = density,  $A$  = area,  $V$  = velocity, and  $M$  = mass flow rate.

If the flow is steady and incompressible, then  $A_1 V_1 = A_2 V_2 = Q$  where  $Q$  is flow.

**Horsepower Required to Compress Air, Single-Stage Compression**

Horsepower required to compress one cubic foot of free air per minute (isothermally and adiabatically) from atmospheric pressure (14.7 pounds per square inch) to various gage pressures.

Single-Stage Compression, initial temperature of air, 60°F, jacket cooling not considered.

<sup>a</sup> Mean Effective Pressure (MEP) is defined as that single pressure rise, above atmospheric, which would require the same horsepower as the actual varying pressures during compression.

## Horsepower Required to Compress Air, Two-Stage Compression

Horsepower required to compress one cubic foot of free air per minute (isothermally and adiabatically) from atmospheric pressure (14.7 pounds per square inch) to various gage pressures.  
Two-Stage Compression, initial temperature of air, 60°F, jacket cooling not considered.

<sup>a</sup> Mean Effective Pressure (MEP) is defined as that single pressure rise, above atmospheric, which would require the same horsepower as the actual varying pressures during compression.

**Horsepower Required to Compress Air, Three-stage Compression**

Horsepower required for compressing one cubic foot of free air per minute (isothermally and adiabatically) from atmospheric pressure (14.7 pounds per square inch) to various gage pressures.

Three-stage Compression, initial temperature of air, 60°F, jacket-cooling not considered.

<sup>a</sup> Mean Effective Pressure (MEP) is defined as that single pressure rise, above atmospheric, which would require the same horsepower as the actual varying pressures during compression.

**Flow of Air in Pipes.**—The following formulas are used:

$$v = \sqrt{\frac{25,000 dp}{L}} \quad p = \frac{Lv^2}{25,000 d}$$

where  $v$  = velocity of air in feet per second

$p$  = loss of pressure due to flow through the pipes in ounces per square inch

$d$  = inside diameter of pipe in inches

$L$  = length of pipe in feet

The quantity of air discharged in cubic feet per second is the product of the velocity as obtained from the preceding formula and the area of the pipe in square feet. The horsepower required to drive air through a pipe equals the volume of air in cubic feet per second multiplied by the pressure in pounds per square foot, and this product divided by 550.

### Volume of Air Transmitted Through Pipes, in Cubic Feet per Minute

| Velocity of Air in Feet per Second | Actual Inside Diameter of Pipe, Inches |       |       |       |       |       |       |        |        |      |
|------------------------------------|--|-------|-------|-------|-------|-------|-------|--------|--------|------|
|                                    | 1                                      | 2     | 3     | 4     | 6     | 8     | 10    | 12     | 16     | 24   |
| 1                                  | 0.33                                   | 1.31  | 2.95  | 5.2   | 11.8  | 20.9  | 32.7  | 47.1   | 83.8   | 188  |
| 2                                  | 0.65                                   | 2.62  | 5.89  | 10.5  | 23.6  | 41.9  | 65.4  | 94.2   | 167.5  | 377  |
| 3                                  | 0.98                                   | 3.93  | 8.84  | 15.7  | 35.3  | 62.8  | 98.2  | 141.4  | 251.3  | 565  |

**Flow of Compressed Air in Pipes.**—When there is a comparatively small difference of pressure at the two ends of the pipe, the volume of flow in cubic feet per minute is found by the formula:

$$V = 58 \sqrt{\frac{pd^5}{WL}}$$

where  $V$  = volume of air in cubic feet per minute

$p$  = difference in pressure at the two ends of the pipe in pounds per square inch

$d$  = inside diameter of pipe in inches

$W$  = weight in pounds of one cubic foot of entering air

$L$  = length of pipe in feet

**Velocity of Escaping Compressed Air.**—If air, or gas, flows from one chamber to another, as from a chamber or tank through an orifice or nozzle into the open air, large changes in velocity may take place owing to the difference in pressures. Since the change takes place almost instantly, little heat can escape from the fluid and the flow may be assumed to be adiabatic.

For a large container with a small orifice or hole from which the air escapes, the velocity of escape (theoretical) may be calculated from the formula:

$$v_2 = \sqrt{2g \cdot \frac{k}{k-1} \cdot 53.3(459.7 + F) \left[ 1 - \left( \frac{p_2}{p_1} \right)^{\frac{k-1}{k}} \right]}$$

In this formula,  $v_2$  = velocity of escaping air in feet per second;  $g$  = acceleration due to gravity, 32.16 feet per second squared;  $k = 1.41$  for adiabatic expansion or compression of air;  $F$  = temperature, degrees F;  $p_2$  = atmospheric pressure = 14.7 pounds per square inch; and  $p_1$  = pressure of air in container, pounds per square inch. In applying the preceding formula, when the ratio  $p_2/p_1$  approximately equals 0.53, under normal temperature conditions at sea level, the escape velocity  $v_2$  will be equal to the velocity of sound. Increasing the pressure  $p_1$  will not increase the velocity of escaping air beyond this limiting velocity unless a special converging diverging nozzle design is used rather than an orifice.

The accompanying table provides velocity of escaping air for various values of  $p_1$ . These values were calculated from the preceding formula simplified by substituting the appropriate constants:

$$v_2 = 108.58 \sqrt{(459.7 + F) \left[ 1 - \left( \frac{14.7}{p_1} \right)^{0.29} \right]}$$

### Velocity of Escaping Air at 70-Degrees F

| Pressure Above Atmospheric Pressure |                   |                    | Theoretical Velocity, Feet per Second | Pressure Above Atmospheric Pressure |                   |                    | Theoretical Velocity, Feet per Second |
|-------------------------------------|-------------------|--------------------|---------------------------------------|-------------------------------------|-------------------|--------------------|---------------------------------------|

| 0.272                               | 8.16              | 4.00               | 650                                   | 0.816                               | 24.49             | 12.0               | 997                                   |
| 0.340                               | 10.20             | 5.00               | 714                                   | 0.884                               | 26.53             | 13.0               | 1025                                  |

The theoretical velocities in the preceding table must be reduced by multiplying by a "coefficient of discharge," which varies with the orifice and the pressure. The following coefficients are used for orifices in thin plates and short tubes.

| Type of Orifice       | Pressures in Atmospheres Above Atmospheric Pressure |      |      |      |
|-----------------------|---|------|------|------|
|                       | 0.01  | 0.1  | 0.5  | 1    |
| Orifice in thin plate | 0.65  | 0.64 | 0.57 | 0.54 |
| Orifice in short tube | 0.83  | 0.82 | 0.71 | 0.67 |

## STANDARD STEELS

### Properties, Compositions, and Applications

Steel is the generic term for a large family of iron-carbon alloys, which are malleable, within some temperature range, immediately after solidification from the molten state. The principal raw materials used in steelmaking are iron ore, coal, and limestone. These materials are converted in a blast furnace into a product known as "pig iron," which contains considerable amounts of carbon, manganese, sulfur, phosphorus, and silicon. Pig iron is hard, brittle, and unsuitable for direct processing into wrought forms. Steelmaking is the process of refining pig iron as well as iron and steel scrap by removing undesirable elements from the melt and then adding desirable elements in predetermined amounts. A primary reaction in most steelmaking is the combination of carbon with oxygen to form a gas. If dissolved oxygen is not removed from the melt prior to or during pouring, the gaseous products continue to evolve during solidification. If the steel is strongly deoxidized by the addition of deoxidizing elements, no gas is evolved, and the steel is called "killed" because it lies quietly in the molds. Increasing degrees of gas evolution (decreased deoxidation) characterize steels called "semikilled," "capped," or "rimmed." The degree of deoxidation affects some of the properties of the steel. In addition to oxygen, liquid steel contains measurable amounts of dissolved hydrogen and nitrogen. For some critical steel applications, special deoxidation practices as well as vacuum treatments may be used to reduce and control dissolved gases.

The carbon content of common steel grades ranges from a few hundredths of a per cent to about 1 per cent. All steels also contain varying amounts of other elements, principally manganese, which acts as a deoxidizer and facilitates hot working. Silicon, phosphorus, and sulfur are also always present, if only in trace amounts. Other elements may be present, either as residuals that are not intentionally added, but result from the raw materials or steelmaking practice, or as alloying elements added to effect changes in the properties of the steel.

Steels can be cast to shape, or the cast ingot or strand can be reheated and hot worked by rolling, forging, extrusion, or other processes into a wrought mill shape. Wrought steels are the most widely used of engineering materials, offering a multitude of forms, finishes, strengths, and usable temperature ranges. No other material offers comparable versatility for product design.

**Standard Steel Classification.**—Wrought steels may be classified systematically into groups based on some common characteristic, such as chemical composition, deoxidation practice, finishing method, or product form. Chemical composition is the most often used basis for identifying and assigning standard designations to wrought steels. Although carbon is the principal hardening and strengthening element in steel, no single element controls the steel's characteristics. The combined effect of several elements influences response to heat treatment, hardness, strength, microstructure, corrosion resistance, and formability. The standard steels can be divided broadly into three main groups: carbon steels, alloy steels, and stainless steels.

*Carbon Steels:* A steel qualifies as a carbon steel when its manganese content is limited to 1.65 per cent (max), silicon to 0.60 per cent (max), and copper to 0.60 per cent (max). With the exception of deoxidizers and boron when specified, no other alloying elements are added intentionally, but they may be present as residuals. If any of these incidental elements are considered detrimental for special applications, maximum acceptable limits may be specified. In contrast to most alloy steels, carbon steels are most often used without a final heat treatment; however, they may be annealed, normalized, case hardened, or quenched and tempered to enhance fabrication or mechanical properties. Carbon steels may be killed, semikilled, capped, or rimmed, and, when necessary, the method of deoxidation may be specified.

*Alloy Steels:* Alloy steels comprise not only those grades that exceed the element content limits for carbon steel, but also any grade to which different elements than used for carbon steel are added, within specific ranges or specific minimums, to enhance mechanical properties, fabricating characteristics, or any other attribute of the steel. By this definition, alloy steels encompass all steels other than carbon steels; however, by convention, steels containing over 3.99 per cent chromium are considered "special types" of alloy steel, which include the stainless steels and many of the tool steels.

In a technical sense, the term alloy steel is reserved for those steels that contain a modest amount of alloying elements (about 1–4 per cent) and generally depend on thermal treatments to develop specific mechanical properties. Alloy steels are always killed, but special deoxidation or melting practices, including vacuum, may be specified for special critical applications. Alloy steels generally require additional care throughout their manufacture, because they are more sensitive to thermal and mechanical operations.

*Stainless Steels:* Stainless steels are high-alloy steels and have superior corrosion resistance to the carbon and conventional low-alloy steels because they contain relatively large amounts of chromium. Although other elements may also increase corrosion resistance, their usefulness in this respect is limited.

Stainless steels generally contain at least 10 per cent chromium, with or without other elements. It has been customary in the United States, however, to include in the stainless steel classification those steels that contain as little as 4 per cent chromium. Together, these steels form a family known as the stainless and heat-resisting steels, some of which possess very high strength and oxidation resistance. Few, however, contain more than 30 per cent chromium or less than 50 per cent iron.

In the broadest sense, the standard stainless steels can be divided into three groups based on their structures: austenitic, ferritic, and martensitic. In each of the three groups, there is one composition that represents the basic, general-purpose alloy. All other compositions are derived from the basic alloy, with specific variations in composition being made to obtain very specific properties.

The *austenitic grades* are nonmagnetic in the annealed condition, although some may become slightly magnetic after cold working. They can be hardened only by cold working, and not by heat treatment, and combine outstanding corrosion and heat resistance with good mechanical properties over a wide temperature range. The austenitic grades are further classified into two subgroups: the chromium–nickel types and the less frequently used chromium–manganese–low–nickel types. The basic composition in the chromium–nickel group is widely known as 18–8 (Cr–Ni) and is the general-purpose austenitic grade. This grade is the basis for over 20 modifications that can be characterized as follows: the chromium–nickel ratio has been modified to change the forming characteristics; the carbon content has been decreased to prevent intergranular corrosion; the elements niobium or titanium have been added to stabilize the structure; or molybdenum has been added or the chromium and nickel contents have been increased to improve corrosion or oxidation resistance.

The standard *ferritic grades* are always magnetic and contain chromium but no nickel. They can be hardened to some extent by cold working, but not by heat treatment, and they combine corrosion and heat resistance with moderate mechanical properties and decorative appeal. The ferritic grades generally are restricted to a narrower range of corrosive conditions than the austenitic grades. The basic ferritic grade contains 17 per cent chromium. In this series, there are free-machining modifications and grades with increased chromium content to improve scaling resistance. Also in this ferritic group is a 12 per cent chromium steel (the basic composition of the martensitic group) with other elements, such as aluminum or titanium, added to prevent hardening.

The standard *martensitic grades* are magnetic and can be hardened by quenching and tempering. They contain chromium and, with two exceptions, no nickel. The basic martensitic grade normally contains 12 per cent chromium. There are more than 10 standard com-

positions in the martensitic series; some are modified to improve machinability and others have small additions of nickel or other elements to improve the mechanical properties or their response to heat treatment. Still others have greatly increased carbon content, in the tool steel range, and are hardenable to the highest levels of all the stainless steels. The martensitic grades are excellent for service in mild environments such as the atmosphere, freshwater, steam, and weak acids, but are not resistant to severely corrosive solutions.

**Numbering Systems for Metals and Alloys.**—Several different numbering systems have been developed for metals and alloys by various trade associations, professional engineering societies, standards organizations, and by private industries for their own use. The numerical code used to identify the metal or alloy may or may not be related to a specification, which is a statement of the technical and commercial requirements that the product must meet. Numbering systems in use include those developed by the American Iron and Steel Institute (AISI), Society of Automotive Engineers (SAE), American Society for Testing and Materials (ASTM), American National Standards Institute (ANSI), Steel Founders Society of America, American Society of Mechanical Engineers (ASME), American Welding Society (AWS), Aluminum Association, Copper Development Association, U.S. Department of Defense (Military Specifications), and the General Accounting Office (Federal Specifications).

The Unified Numbering System (UNS) was developed through a joint effort of the ASTM and the SAE to provide a means of correlating the different numbering systems for metals and alloys that have a commercial standing. This system avoids the confusion caused when more than one identification number is used to specify the same material, or when the same number is assigned to two entirely different materials. It is important to understand that a UNS number is not a specification; it is an identification number for metals and alloys for which detailed specifications are provided elsewhere. UNS numbers are shown in [Table 1](#); each number consists of a letter prefix followed by five digits. In some, the letter is suggestive of the family of metals identified by the series, such as A for aluminum and C for copper. Whenever possible, the numbers in the UNS groups contain numbering sequences taken directly from other systems to facilitate identification of the material; e.g., the corresponding UNS number for AISI 1020 steel is G10200. The UNS numbers corresponding to the commonly used AISI-SAE numbers that are used to identify plain carbon, alloy, and tool steels are given in [Table 2](#).

**Table 1. Unified Numbering System (UNS) for Metals and Alloys**

| UNS Series       | Metal   |
|------------------|---|
| A00001 to A99999 | Aluminum and aluminum alloys                              |
| C00001 to C99999 | Copper and copper alloys                                  |
| D00001 to D99999 | Specified mechanical property steels                      |
| E00001 to E99999 | Rare earth and rare earthlike metals and alloys           |
| F00001 to F99999 | Cast irons  |
| G00001 to G99999 | AISI and SAE carbon and alloy steels (except tool steels) |
| H00001 to H99999 | AISI and SAE H-steels                                     |
| J00001 to J99999 | Cast steels (except tool steels)                          |
| K00001 to K99999 | Miscellaneous steels and ferrous alloys                   |
| L00001 to L99999 | Low-melting metals and alloys                             |
| M00001 to M99999 | Miscellaneous nonferrous metals and alloys                |
| N00001 to N99999 | Nickel and nickel alloys                                  |
| P00001 to P99999 | Precious metals and alloys                                |
| R00001 to R99999 | Reactive and refractory metals and alloys                 |
| S00001 to S99999 | Heat and corrosion resistant (stainless) steels           |
| T00001 to T99999 | Tool steels, wrought and cast                             |
| W00001 to W99999 | Welding filler metals                                     |
| Z00001 to Z99999 | Zinc and zinc alloys                                      |

**Identifying Metals.**—When it is necessary to sort materials, several rough methods may be used without elaborate chemical analysis. The most obvious of these is by using a magnet to pick out those materials that contain magnetic elements. To differentiate various levels of carbon and other elements in a steel bar, hold the bar in contact with a grinding wheel and observe the sparks. With high levels of carbon, for instance, sparks are produced that appear to split into several bright tracers. Patterns produced by several other elements, including small amounts of aluminum and titanium, for instance, can be identified with the aid of Data Sheet 13, issued by the American Society for Metals (ASM), Metals Park, OH.

**Standard Steel Numbering System.**—The most widely used systems for identifying wrought carbon, low-alloy, and stainless steels are based on chemical composition, and are those of the American Iron and Steel Institute (AISI) and the Society of Automotive Engineers (SAE). These systems are almost identical, but they are carefully coordinated. The standard steels so designated have been developed cooperatively by producers and users and have been found through long experience to cover most of the wrought ferrous metals used in automotive vehicles and related equipment. These designations, however, are not specifications, and should not be used for purchasing unless accompanied by supplementary information necessary to describe commercially the product desired. Engineering societies, associations, and institutes whose members make, specify, or purchase steel products publish standard specifications, many of which have become well known and respected. The most comprehensive and widely used specifications are those published by the American Society for Testing and Materials (ASTM). The U.S. government and various companies also publish their own specification for steel products to serve their own special procurement needs. The Unified Numbering System (UNS) for metals and alloys is also used to designate steels (see pages 440 and 442).

The numerical designation system used by both AISI and SAE for wrought carbon, alloy, and stainless steels is summarized in Table 3. In Table 4 is given the compositions of the standard carbon steels; Table 5 lists the standard low-alloy steel compositions; and Table 6 includes the typical compositions of the standard stainless steels.

**Binary Alloy.**—An alloy containing two elements. When the term is used in regard to iron or steel, it refers to a material that has one alloying element in addition to iron. Since carbon is always present in steel, plain carbon steel is the typical binary iron alloy.

**Ternary Alloy.**—This is an alloy consisting of three elements. When the term refers to steel, it denotes a steel which contains two alloying elements in addition to iron; since carbon is always present, it is one of these elements. The third element may be nickel, chromium, manganese, tungsten, molybdenum, titanium, or any other element that is alloyed to give the steel some special property.

**Quarternary Alloy.**—A quarternary alloy is an alloy consisting of four elements. When applied to steel, such an alloy contains, in addition to iron, three alloying elements. Carbon is one of these, and the other two may be chromium and nickel, silicon and manganese, etc.

**Damascus Steel.**—A characteristic feature of Damascus steel is its surface patterns which vary with the carbon content and are either in the form of wavy parallel stripes or mottled patterns. This steel represents an early development in steel making, as it was imported during the Middle Ages to Western Europe through Syria and Palestine, and is known also as Indian steel and bulat. The old Indian method of producing real damascene steel consists in using a pure ore and the best grade of charcoal. The Persian practice is to use soft iron bars and charcoal and plumbago (black lead or graphite) to supply the carbon; and a third method consists of a certain heat-treatment which resembles a prolonged tempering. One investigator has concluded that the carbon, irregularly dispersed in the metal and forming two distinct combinations, is what causes the damask or characteristic pattern and that the slower the cooling the larger the veins will be.

An imitation of Damascus steel can be obtained by etching the surface of the steel blade with acids, the parts which are not to be attacked by the acid being protected by a "resist."

## NUMBERING SYSTEMS

**Table 2. AISI and SAE Numbers and Their Corresponding UNS Numbers for Plain Carbon, Alloy, and Tool Steels**

| AISI-SAE Numbers                | UNS Numbers | AISI-SAE Numbers | UNS Numbers | AISI-SAE Numbers | UNS Numbers | AISI-SAE Numbers | UNS Numbers |
|---------------------------------|-------------|------------------|-------------|------------------|-------------|------------------|-------------|
| Plain Carbon Steels             |             |                  |             |                  |             |                  |             |
| 1005                            | G10050      | 1030             | G10300      | 1070             | G10700      | 1566             | G15660      |
| 1006                            | G10060      | 1035             | G10350      | 1078             | G10780      | 1110             | G11100      |
| 1008                            | G10080      | 1037             | G10370      | 1080             | G10800      | 1117             | G11170      |
| 1010                            | G10100      | 1038             | G10380      | 1084             | G10840      | 1118             | G11180      |
| 1012                            | G10120      | 1039             | G10390      | 1086             | G10860      | 1137             | G11370      |
| 1015                            | G10150      | 1040             | G10400      | 1090             | G10900      | 1139             | G11390      |
| 1016                            | G10160      | 1042             | G10420      | 1095             | G10950      | 1140             | G11400      |
| 1017                            | G10170      | 1043             | G10430      | 1513             | G15130      | 1141             | G11410      |
| 1018                            | G10180      | 1044             | G10440      | 1522             | G15220      | 1144             | G11440      |
| 1019                            | G10190      | 1045             | G10450      | 1524             | G15240      | 1146             | G11460      |
| 1020                            | G10200      | 1046             | G10460      | 1526             | G15260      | 1151             | G11510      |
| 1021                            | G10210      | 1049             | G10490      | 1527             | G15270      | 1211             | G12110      |
| 1022                            | G10220      | 1050             | G10500      | 1541             | G15410      | 1212             | G12120      |
| 1023                            | G10230      | 1053             | G10530      | 1548             | G15480      | 1213             | G12130      |

<sup>a</sup>The following notes refer to boron, copper, lead, and silicon additions: Boron: Standard killed carbon steels, which are generally fine grain, may be produced with a boron treatment addition to improve hardenability. Such steels are produced to a range of 0.0005–0.003 per cent B. These steels are identified by inserting the letter "B" between the second and third numerals of the AISI or SAE number, e.g., 10B46. Copper: When copper is required, 0.20 per cent (min) is generally specified. Lead: Standard carbon steels can be produced with a lead range of 0.15–0.35 per cent to improve machinability. Such steels are identified by inserting the letter "L" between the second and third numerals of the AISI or SAE number, e.g., 12L15 and 10L45. Silicon: It is not common practice to produce the 12XX series of resulfurized and rephosphorized steels to specified limits for silicon because of its adverse effect on machinability. When silicon ranges or limits are required for resulfurized or nonresulfurized steels, however, these values apply: a range of 0.08 per cent Si for Si max up to 0.15 per cent inclusive, a range of 0.10 per cent Si for Si max over 0.15 to 0.20 per cent inclusive, a range of 0.15 per cent Si for Si max over 0.20 to 0.30 per cent inclusive, and a range of 0.20 per cent Si for Si max over 0.30 to 0.60 per cent inclusive. Example: Si max is 0.25 per cent, range is 0.10–0.25 per cent.

<sup>b</sup> Values given are maximum percentages, except where a range of values is given.

<sup>c</sup> Standard grades for wire rods and wire only.

<sup>d</sup> 0.15–0.35 per cent Pb.

Table 5. Compositions of AISI-SAE Standard Alloy Steels

| AISI-SAE No.       | UNS No. | Composition (%) <sup>a,b</sup> |           |         |             |           |           |           |           |
|--------------------|---------|--------------------------------|-----------|---------|-------------|-----------|-----------|-----------|-----------|

<sup>a</sup> Small quantities of certain elements are present that are not specified or required. These incidental elements may be present to the following maximum amounts: Cu, 0.35 per cent; Ni, 0.25 per cent; Cr, 0.20 per cent; and Mo, 0.06 per cent.

<sup>b</sup> Standard alloy steels can also be produced with a lead range of 0.15-0.35 per cent. Such steels are identified by inserting the letter "L" between the second and third numerals of the AISI or SAE number, e.g., 41L40.

<sup>c</sup> Electric furnace steel.

<sup>d</sup> 0.0005-0.003 per cent B.

**Thermal Treatments of Steel.**—Steel's versatility is due to its response to thermal treatment. Although most steel products are used in the as-rolled or un-heat-treated condition, thermal treatment greatly increases the number of properties that can be obtained, because at certain "critical temperatures" iron changes from one type of crystal structure to another. This structural change, known as an allotropic transformation, is spontaneous and reversible and can be made to occur by simply changing the temperature of the metal.

In steel, the transformation in crystal structure occurs over a range of temperatures, bounded by lower and upper critical points. When heated, most carbon and low-alloy steels have a critical temperature range between 1300 and 1600 degrees F. Steel above this temperature, but below the melting range, has a crystalline structure known as austenite, in which the carbon and alloying elements are dissolved in a solid solution. Below this critical range, the crystal structure changes to a phase known as ferrite, which is capable of maintaining only a very small percentage of carbon in solid solution. The remaining carbon exists in the form of carbides, which are compounds of carbon and iron and certain of the other alloying elements. Depending primarily on cooling rate, the carbides may be present as thin plates alternating with the ferrite (pearlite); as spheroidal globular particles at ferrite grain boundaries or dispersed throughout the ferrite; or as a uniform distribution of extremely fine particles throughout a "ferritelike" phase, which has an acicular (needle-like) appearance, named martensite. In some of the highly alloyed stainless steels the addition of certain elements stabilizes the austenite structure so that it persists even at very low temperatures (austenitic grades). Other alloying elements can prevent the formation of austenite entirely up to the melting point (ferritic grades).

Fundamentally, all steel heat treatments are intended to either harden or soften the metal. They involve one or a series of operations in which the solid metal is heated and cooled under specified conditions to develop a required structure and properties. In general, there are five major forms of heat treatment for the standard steels that modify properties to suit either fabrication or end use.

*Quenching and Tempering:* The primary hardening treatment for steel, quenching and tempering, usually consists of three successive operations: heating the steel above the critical range and holding it at these temperatures for a sufficient time to approach a uniform

solid solution (austenitizing); cooling the steel rapidly by quenching in oil, water, brine, salt or air to form a hard, usually brittle, metastable structure known as untempered or white martensite; tempering the steel by reheating it to a temperature below the critical range in order to obtain the required combination of hardness, strength, ductility, toughness, and structural stability (tempered martensite).

Two well-known modifications of conventional quenching and tempering are "austempering" and "martempering." They involve interrupted quenching techniques (two or more quenching media) that can be utilized for some steels to obtain desired structures and properties while minimizing distortion and cracking problems that may occur in conventional hardening.

*Normalizing:* The steel is heated to a temperature above the critical range, after which it is cooled in still air to produce a generally fine pearlite structure. The purpose is to promote uniformity of structure and properties after a hot-working operation such as forging or extrusion. Steels may be placed in service in the normalized condition, or they may be subjected to additional thermal treatment after subsequent machining or other operations.

*Annealing:* The steel is heated to a temperature above or within the critical range, then cooled at a predetermined slow rate (usually in a furnace) to produce a coarse pearlite structure. This treatment is used to soften the steel for improved machinability; to improve or restore ductility for subsequent forming operations; or to eliminate the residual stresses and microstructural effects of cold working.

*Spheroidize Annealing:* This is a special form of annealing that requires prolonged heating at an appropriate temperature followed by slow cooling in order to produce globular carbides, a structure desirable for machining, cold forming, or cold drawing, or for the effect it will have on subsequent heat treatment.

*Stress Relieving:* This process reduces internal stresses, caused by machining, cold working, or welding, by heating the steel to a temperature below the critical range and holding it there long enough to equalize the temperature throughout the piece.

See the sections *HARDENING, TEMPERING, AND ANNEALING* on page 503 and *Heat Treating High-Speed Steels* on page 538 for more information about the heat treatment of steels.

**Applications.**—Many factors enter into the selection of a steel for a particular application. These factors include the mechanical and physical properties needed to satisfy the design requirements and service environment; the cost and availability of the material; the cost of processing (machining, heat treatment, welding, etc.); and the suitability of available processing equipment or the cost of any new equipment required.

These steel selection considerations require input from designers, metallurgists, manufacturing engineers, service engineers, and procurement specialists, and can be considered proper or optimum when the part is made from the lowest cost material consistent with satisfying engineering and service requirements. The factors in selection can vary widely among different organizations, so that several different steels may be used successfully for similar applications. The best choice of a steel for any application most often results from a balance or trade-offs among the various selection considerations.

The AISI/SAE designated "standard steels" provide a convenient way for engineers and metallurgists to state briefly but clearly the chemical composition and, in some instances, some of the properties desired, and they are widely recognized and used in the United States and in many other countries. There are, however, numerous nonstandard carbon, alloy, and stainless steel grades that are widely used for special applications.

The following sections and tables illustrate the general characteristics and typical applications of most of the standard carbon, alloy, and stainless steel grades.

*General Application of SAE Steels:* These applications are intended as a general guide only since the selection may depend on the exact character of the service, cost of material,

machinability when machining is required, or other factors. When more than one steel is recommended for a given application, information on the characteristics of each steel listed will be found in the section beginning on page 452.

**Carbon Steels.**—*SAE Steels 1006, 1008, 1010, 1015*: These steels are the lowest carbon steels of the plain carbon type, and are selected where cold formability is the primary requisite of the user. They are produced both as rimmed and killed steels. Rimmed steel is used for sheet, strip, rod, and wire where excellent surface finish or good drawing qualities are required, such as body and fender stock, hoods, lamps, oil pans, and other deep-drawn and -formed products. This steel is also used for cold-heading wire for tacks, and rivets and low carbon wire products. Killed steel (usually aluminum killed or special killed) is used for difficult stampings, or where nonaging properties are needed. Killed steels (usually silicon killed) should be used in preference to rimmed steel for forging or heat-treating applications.

These steels have relatively low tensile values and should not be selected where much strength is desired. Within the carbon range of the group, strength and hardness will rise with increases in carbon and/or with cold work, but such increases in strength are at the sacrifice of ductility or the ability to withstand cold deformation. Where cold rolled strip is used, the proper temper designation should be specified to obtain the desired properties.

With less than 0.15 carbon, the steels are susceptible to serious grain growth, causing brittleness, which may occur as the result of a combination of critical strain (from cold work) followed by heating to certain elevated temperatures. If cold-worked parts formed from these steels are to be later heated to temperatures in excess of 1100 degrees F, the user should exercise care to avoid or reduce cold working. When this condition develops, it can be overcome by heating the parts to a temperature well in excess of the upper critical point, or at least 1750 degrees F.

Steels in this group, being nearly pure iron or ferritic in structure, do not machine freely and should be avoided for cut screws and operations requiring broaching or smooth finish on turning. The machinability of bar, rod, and wire products is improved by cold drawing. Steels in this group are readily welded.

*SAE 1016, 1017, 1018, 1019, 1020, 1021, 1022, 1023, 1024, 1025, 1026, 1027, 1030:*

Steels in this group, due to the carbon range covered, have increased strength and hardness, and reduced cold formability compared to the lowest carbon group. For heat-treating purposes, they are known as carburizing or case hardening grades. When uniform response to heat treatment is required, or for forgings, killed steel is preferred; for other uses, semi-killed or rimmed steel may be indicated, depending on the combination of properties desired. Rimmed steels can ordinarily be supplied up to 0.25 carbon.

Selection of one of these steels for carburizing applications depends on the nature of the part, the properties desired, and the processing practice preferred. Increases in carbon give greater core hardness with a given quench, or permit the use of thicker sections. Increases in manganese improve the hardenability of both the core and case; in carbon steels this is the only change in composition that will increase case hardenability. The higher manganese variants also machine much better. For carburizing applications, SAE 1016, 1018, and 1019 are widely used for thin sections or water-quenched parts. SAE 1022 and 1024 are used for heavier sections or where oil quenching is desired, and SAE 1024 is sometimes used for such parts as transmission and rear axle gears. SAE 1027 is used for parts given a light case to obtain satisfactory core properties without drastic quenching. SAE 1025 and 1030, although not usually regarded as carburizing types, are sometimes used in this manner for larger sections or where greater core hardness is needed.

For cold-formed or -headed parts, the lowest manganese grades (SAE 1017, 1020, and 1025) offer the best formability at their carbon level. SAE 1020 is used for fan blades and some frame members, and SAE 1020 and 1025 are widely used for low-strength bolts. The next higher manganese types (SAE 1018, 1021, and 1026) provide increased strength.

All steels listed may be readily welded or brazed by the common commercial methods. SAE 1020 is frequently used for welded tubing. These steels are used for numerous forged parts, the lower-carbon grades where high strength is not essential. Forgings from the lower-carbon steels usually machine better in the as-forged condition without annealing, or after normalizing.

*SAE 1030, 1033, 1034, 1035, 1036, 1038, 1039, 1040, 1041, 1042, 1043, 1045, 1046, 1049, 1050, 1052:* These steels, of the medium-carbon type, are selected for uses where higher mechanical properties are needed and are frequently further hardened and strengthened by heat treatment or by cold work. These grades are ordinarily produced as killed steels.

Steels in this group are suitable for a wide variety of automotive-type applications. The particular carbon and manganese level selected is affected by a number of factors. Increases in the mechanical properties required in section thickness, or in depth of hardening, ordinarily indicate either higher carbon or manganese or both. The heat-treating practice preferred, particularly the quenching medium, has a great effect on the steel selected. In general, any of the grades over 0.30 carbon may be selectively hardened by induction or flame methods.

The lower-carbon and manganese steels in this group find usage for certain types of cold-formed parts. SAE 1030 is used for shift and brake levers. SAE 1034 and 1035 are used in the form of wire and rod for cold upsetting such as bolts, and SAE 1038 for bolts and studs. The parts cold-formed from these steels are usually heat-treated prior to use. Stampings are generally limited to flat parts or simple bends. The higher-carbon SAE 1038, 1040, and 1042 are frequently cold drawn to specified physical properties for use without heat treatment for some applications such as cylinder head studs.

Any of this group of steels may be used for forgings, the selection being governed by the section size and the physical properties desired after heat treatment. Thus, SAE 1030 and 1035 are used for shifter forks and many small forgings where moderate properties are desired, but the deeper-hardening SAE 1036 is used for more critical parts where a higher strength level and more uniformity are essential, such as some front suspension parts. Forgings such as connecting rods, steering arms, truck front axles, axle shafts, and tractor wheels are commonly made from the SAE 1038 to 1045 group. Larger forgings at similar strength levels need more carbon and perhaps more manganese. Examples are crankshafts made from SAE 1046 and 1052. These steels are also used for small forgings where high hardness after oil quenching is desired. Suitable heat treatment is necessary on forgings from this group to provide machinability. These steels are also widely used for parts machined from bar stock, the selection following an identical pattern to that described for forgings. They are used both with and without heat treatment, depending on the application and the level of properties needed. As a class, they are considered good for normal machining operations. It is also possible to weld these steels by most commercial methods, but precautions should be taken to avoid cracking from too rapid cooling.

*SAE 1055, 1060, 1062, 1064, 1065, 1066, 1070, 1074, 1078, 1080, 1085, 1086, 1090, 1095:* Steels in this group are of the high-carbon type, having more carbon than is required to achieve maximum as quenched hardness. They are used for applications where the higher carbon is needed to improve wear characteristics for cutting edges, to make springs, and for special purposes. Selection of a particular grade is affected by the nature of the part, its end use, and the manufacturing methods available.

In general, cold-forming methods are not practical on this group of steels, being limited to flat stampings and springs coiled from small-diameter wire. Practically all parts from these steels are heat treated before use, with some variations in heat-treating methods to obtain optimum properties for the particular use to which the steel is to be put.

Uses in the spring industry include SAE 1065 for pretempered wire and SAE 1066 for cushion springs of hard-drawn wire, SAE 1064 may be used for small washers and thin stamped parts, SAE 1074 for light flat springs formed from annealed stock, and SAE 1080 and 1085 for thicker flat springs. SAE 1085 is also used for heavier coil springs. Valve spring wire and music wire are special products.

Due to good wear properties when properly heat-treated, the high-carbon steels find wide usage in the farm implement industry. SAE 1070 has been used for plow beams, SAE 1074 for plow shares, and SAE 1078 for such parts as rake teeth, scrapers, cultivator shovels, and plow shares. SAE 1085 has been used for scraper blades, disks, and for spring tooth harrows. SAE 1086 and 1090 find use as mower and binder sections, twine holders, and knottor disks.

*SAE 1111, 1112, 1113:* This class of steels is intended for those uses where easy machining is the primary requirement. They are characterized by a higher sulfur content than comparable carbon steels. This composition results in some sacrifice of cold-forming properties, weldability, and forging characteristics. In general, the uses are similar to those for carbon steels of similar carbon and manganese content.

These steels are commonly known as Bessemer screw stock, and are considered the best machining steels available, machinability improving within the group as sulfur increases. They are used for a wide variety of machined parts. Although of excellent strength in the

cold-drawn condition, they have an unfavorable property of cold shortness and are not commonly used for vital parts. These steels may be cyanided or carburized, but when uniform response to heat-treating is necessary, open-hearth steels are recommended.

*SAE 1109, 1114, 1115, 1116, 1117, 1118, 1119, 1120, 1126:* Steels in this group are used where a combination of good machinability and more uniform response to heat treatment is needed. The lower-carbon varieties are used for small parts that are to be cyanided or carbonitrided. SAE 1116, 1117, 1118, and 1119 carry more manganese for better hardenability, permitting oil quenching after case-hardening heat treatments in many instances. The higher-carbon SAE 1120 and 1126 provide more core hardness when this is needed.

*SAE 1132, 1137, 1138, 1140, 1141, 1144, 1145, 1146, 1151:* This group of steels has characteristics comparable to carbon steels of the same carbon level, except for changes due to higher sulfur as noted previously. They are widely used for parts where large amounts of machining are necessary, or where threads, splines, or other contours present special problems with tooling. SAE 1137, for example, is widely used for nuts and bolts and studs with machined threads. The higher-manganese SAE 1132, 1137, 1141, and 1144 offer greater hardenability, the higher-carbon types being suitable for oil quenching for many parts. All these steels may be selectively hardened by induction or flame heating if desired.

**Carburizing Grades of Alloy Steels.**—*Properties of the Case:* The properties of carburized and hardened cases (surface layers) depend on the carbon and alloy content, the structure of the case, and the degree and distribution of residual stresses. The carbon content of the case depends on the details of the carburizing process, and the response of iron and the alloying elements present, to carburization. The original carbon content of the steel has little or no effect on the carbon content produced in the case. The hardenability of the case, therefore, depends on the alloy content of the steel and the final carbon content produced by carburizing, but not on the initial carbon content of the steel.

With complete carbide solution, the effect of alloying elements on the hardenability of the case is about the same as the effect of these elements on the hardenability of the core. As an exception to this statement, any element that inhibits carburizing may reduce the hardenability of the case. Some elements that raise the hardenability of the core may tend to produce more retained austenite and consequently somewhat lower hardness in the case.

Alloy steels are frequently used for case hardening because the required surface hardness can be obtained by moderate speeds of quenching. Slower quenching may mean less distortion than would be encountered with water quenching. It is usually desirable to select a steel that will attain a minimum surface hardness of 58 or 60 Rockwell C after carburizing and oil quenching. Where section sizes are large, a high-hardenability alloy steel may be necessary, whereas for medium and light sections, low-hardenability steels will suffice.

In general, the case-hardening alloy steels may be divided into two classes as far as the hardenability of the case is concerned. Only the general type of steel (SAE 3300–4100, etc.) is discussed. The original carbon content of the steel has no effect on the carbon content of the case, so the last two digits in the specification numbers are not meaningful as far as the case is concerned.

a) High-Hardenability Case: SAE 2500, 3300, 4300, 4800, 9300

As these are high-alloy steels, both the case and the core have high hardenability. They are used particularly for carburized parts having thick sections, such as bevel drive pinions and heavy gears. Good case properties can be obtained by oil quenching. These steels are likely to have retained austenite in the case after carburizing and quenching; consequently, special precautions or treatments, such as refrigeration, may be required.

b) Medium-Hardenability Case: SAE 1300, 2300, 4000, 4100, 4600, 5100, 8600, 8700

Carburized cases of these steels have medium hardenability, which means that their hardenability is intermediate between that of plain carbon steel and the higher-alloy car-

burizing steels discussed earlier. In general, these steels can be used for average-size case-hardened automotive parts such as gears, pinions, piston pins, ball studs, universal joint crosses, crankshafts, etc. Satisfactory case hardness is usually produced by oil quenching.

**Core Properties:** The core properties of case-hardened steels depend on both carbon and alloy content of the steel. Each of the general types of alloy case-hardening steel is usually made with two or more carbon contents to permit different hardenability in the core.

The most desirable hardness for the core depends on the design and functioning of the individual part. In general, where high compressive loads are encountered, relatively high core hardness is beneficial in supporting the case. Low core hardnesses may be desirable where great toughness is essential.

The case-hardening steels may be divided into three general classes, depending on hardenability of the core.

a) Low-Hardenability Core: SAE 4017, 4023, 4024, 4027,\* 4028,\* 4608, 4615, 4617,\* 8615,\* 8617\*

b) Medium-Hardenability Core: SAE 1320, 2317, 2512, 2515,\* 3115, 3120, 4032, 4119, 4317, 4620, 4621, 4812, 4815,\* 5115, 5120, 8620, 8622, 8720, 9420

c) High-Hardenability Core: SAE 2517, 3310, 3316, 4320, 4817, 4820, 9310, 9315, 9317

**Heat Treatments:** In general, all the alloy carburizing steels are made with fine grain and most are suitable for direct quenching from the carburizing temperature. Several other types of heat treatment involving single and double quenching are also used for most of these steels. (See on page 532 and on page 533)

**Directly Hardenable Grades of Alloy Steels.**—These steels may be considered in five groups on the basis of approximate mean carbon content of the SAE specification. In general, the last two figures of the specification agree with the mean carbon content. Consequently the heading “0.30–0.37 Mean Carbon Content of SAE Specification” includes steels such as SAE 1330, 3135, and 4137.

It is necessary to deviate from the above plan in the classification of the carbon molybdenum steels. When carbon molybdenum steels are used, it is customary to specify higher carbon content for any given application than would be specified for other alloy steels, due to the low alloy content of these steels. For example, SAE 4063 is used for the same applications as SAE 4140, 4145, and 5150. Consequently, in the following discussion, the carbon molybdenum steels have been shown in the groups where they belong on the basis of applications rather than carbon content.

| Mean Carbon Content<br>of SAE Specification | Common Applications   |
|---|---|
| (a) 0.30–0.37 per cent                      | Heat-treated parts requiring moderate strength and great toughness.                     |
| (b) 0.40–0.42 per cent                      | Heat-treated parts requiring higher strength and good toughness.                        |
| (c) 0.45–0.50 per cent                      | Heat-treated parts requiring fairly high hardness and strength with moderate toughness. |
| (d) 0.50–0.62 per cent                      | Springs and hand tools.   |
| (e) 1.02 per cent                           | Ball and roller bearings.   |

For the present discussion, steels of each carbon content are divided into two or three groups on the basis of hardenability. Transformation ranges and consequently heat-treating practices vary somewhat with different alloying elements even though the hardenability is not changed.

**0.30–0.37 Mean Carbon Content of SAE Specification:** These steels are frequently used for water-quenched parts of moderate section size and for oil-quenched parts of small section size. Typical applications of these steels are connecting rods, steering arms and steering knuckles, axle shafts, bolts, studs, screws, and other parts requiring strength and

\* Borderline classifications might be considered in the next higher hardenability group.

toughness where section size is small enough to permit the desired physical properties to be obtained with the customary heat treatment.

Steels falling in this classification may be subdivided into two groups on the basis of hardenability:

- a) Low Hardenability: SAE 1330, 1335, 4037, 4042, 4130, 5130, 5132, 8630
- b) Medium Hardenability: SAE 2330, 3130, 3135, 4137, 5135, 8632, 8635, 8637, 8735, 9437

*0.40–0.42 Mean Carbon Content of SAE Specification:* In general, these steels are used for medium and large size parts requiring high degree of strength and toughness. The choice of the proper steel depends on the section size and the mechanical properties that must be produced. The low and medium hardenability steels are used for average size automotive parts such as steering knuckles, axle shafts, propeller shafts, etc. The high hardenability steels are used particularly for large axles and shafts for large aircraft parts.

These steels are usually considered as oil quenching steels, although some large parts made of the low and medium hardenability classifications may be quenched in water under properly controlled conditions.

These steels may be divided into three groups on the basis of hardenability:

- a) Low Hardenability: SAE 1340, 4047, 5140, 9440
- b) Medium Hardenability: SAE 2340, 3140, 3141, 4053, 4063, 4140, 4640, 8640, 8641, 8642, 8740, 8742, 9442
- c) High Hardenability: SAE 4340, 9840

*0.45–0.50 Mean Carbon Content of SAE Specification:* These steels are used primarily for gears and other parts requiring fairly high hardness as well as strength and toughness. Such parts are usually oil-quenched and a minimum of 90 per cent martensite in the as-quenched condition is desirable.

- a) Low Hardenability: SAE 5045, 5046, 5145, 9747, 9763
- b) Medium Hardenability: SAE 2345, 3145, 3150, 4145, 5147, 5150, 8645, 8647, 8650, 8745, 8747, 8750, 9445, 9845
- c) High Hardenability: SAE 4150, 9850

*0.50–0.63 Mean Carbon Content of SAE Specification:* These steels are used primarily for springs and hand tools. The hardenability necessary depends on the thickness of the material and the quenching practice.

- a) Medium hardenability: SAE 4068, 5150, 5152, 6150, 8650, 9254, 9255, 9260, 9261
- b) High Hardenability: SAE 8653, 8655, 8660, 9262

*1.02 Mean Carbon Content of SAE Specification—SAE 50100, 51100, 52100:* These straight chromium electric furnace steels are used primarily for the races and balls or rollers of antifriction bearings. They are also used for other parts requiring high hardness and wear resistance. The compositions of the three steels are identical, except for a variation in chromium, with a corresponding variation in hardenability.

- a) Low Hardenability: SAE 50100
- b) Medium Hardenability: SAE 51100, 52100

*Resulfurized Steel:* Some of the alloy steels, SAE 4024, 4028, and 8641, are made resulfurized so as to give better machinability at a relatively high hardness. In general, increased sulfur results in decreased transverse ductility, notched impact toughness, and weldability.

**Characteristics and Typical Applications of Standard Stainless Steels.**—Typical applications of various stainless steel alloys are given in the following. The first number given is the AISI designation followed by the UNS number in parenthesis. (See also *Numbering Systems for Metals and Alloys* on page 440)

*201 (S20100):* High work-hardening rate; low-nickel equivalent of type 301. Flatware; automobile wheel covers, trim.

*202 (S20200)*: General-purpose low-nickel equivalent of type 302. Kitchen equipment; hub caps; milk handling.

*205 (S20500)*: Lower work-hardening rate than type 202; used for spinning and special drawing operations. Nonmagnetic and cryogenic parts.

*301 (S30100)*: High work-hardening rate; used for structural applications where high strength plus high ductility are required. Railroad cars; trailer bodies; aircraft structurals; fasteners; automobile wheel covers, trim; pole line hardware.

*302 (S30200)*: General-purpose austenitic stainless steel. Trim; food-handling equipment; aircraft cowlings; antennas; springs; cookware; building exteriors; tanks; hospital, household appliances; jewelry; oil refining equipment; signs.

*302B (S30215)*: More resistant to scale than type 302. Furnace parts; still liners; heating elements; annealing covers; burner sections.

*303 (S30300)*: Free-machining modification of type 302, for heavier cuts. Screw machine products; shafts; valves; bolts; bushings; nuts.

*303Se (S30323)*: Free-machining modification of type 302, for lighter cuts; used where hot working or cold heading may be involved. Aircraft fittings; bolts; nuts; rivets; screws; studs.

*304 (S30400)*: Low-carbon modification of type 302 for restriction of carbide precipitation during welding. Chemical and food processing equipment; brewing equipment; cryogenic vessels; gutters; downspouts; flashings.

*304L (S30403)*: Extra-low-carbon modification of type 304 for further restriction of carbide precipitation during welding. Coal hopper linings; tanks for liquid fertilizer and tomato paste.

*304Cu (S30430)*: Lower work-hardening rate than type 304. Severe cold-heading applications.

*304N (S30451)*: Higher nitrogen than type 304 to increase strength with minimum effect on ductility and corrosion resistance, more resistant to increased magnetic permeability. Type 304 applications requiring higher strength.

*305 (S30500)*: Low work-hardening rate; used for spin forming, severe drawing, cold heading, and forming. Coffee urn tops; mixing bowls; reflectors.

*308 (S30800)*: Higher-alloy steel having high corrosion and heat resistance. Welding filler metals to compensate for alloy loss in welding; industrial furnaces.

*309 (S30900)*: High-temperature strength and scale resistance. Aircraft heaters; heat-treating equipment; annealing covers; furnace parts; heat exchangers; heat-treating trays; oven linings; pump parts.

*309S (S30908)*: Low-carbon modification of type 309. Welded constructions; assemblies subject to moist corrosion conditions.

*310 (S31000)*: Higher elevated temperature strength and scale resistance than type 309. Heat exchangers; furnace parts; combustion chambers; welding filler metals; gas-turbine parts; incinerators; recuperators; rolls for roller hearth furnaces.

*310S (S31008)*: Low-carbon modification of type 310. Welded constructions; jet engine rings.

*314 (S31400)*: More resistant to scale than type 310. Severe cold-heading or -forming applications. Annealing and carburizing boxes; heat-treating fixtures; radiant tubes.

*316 (S31600)*: Higher corrosion resistance than types 302 and 304; high creep strength. Chemical and pulp handling equipment; photographic equipment; brandy vats; fertilizer parts; ketchup cooking kettles; yeast tubs.

*316L (S31603)*: Extra-low-carbon modification of type 316. Welded construction where intergranular carbide precipitation must be avoided. Type 316 applications requiring extensive welding.

*316F (S31620)*: Higher phosphorus and sulfur than type 316 to improve machining and nonseizing characteristics. Automatic screw machine parts.

*316N (S31651)*: Higher nitrogen than type 316 to increase strength with minimum effect on ductility and corrosion resistance. Type 316 applications requiring extra strength.

317 (S31700): Higher corrosion and creep resistance than type 316. Dyeing and ink manufacturing equipment.

317L (S31703): Extra-low-carbon modification of type 317 for restriction of carbide precipitation during welding. Welded assemblies.

321 (S32100): Stabilized for weldments subject to severe corrosive conditions, and for service from 800 to 1650°F Aircraft exhaust manifolds; boiler shells; process equipment; expansion joints; cabin heaters; fire walls; flexible couplings; pressure vessels.

329 (S32900): Austenitic-ferritic type with general corrosion resistance similar to type 316 but with better resistance to stress-corrosion cracking; capable of age hardening. Valves; valve fittings; piping; pump parts.

330 (N08330): Good resistance to carburization and oxidation and to thermal shock. Heat-treating fixtures.

347 (S34700): Similar to type 321 with higher creep strength. Airplane exhaust stacks; welded tank cars for chemicals; jet engine parts.

348 (S34800): Similar to type 321; low retentivity. Tubes and pipes for radioactive systems; nuclear energy uses.

384 (S38400): Suitable for severe cold heading or cold forming; lower cold-work-hardening rate than type 305. Bolts; rivets; screws; instrument parts.

403 (S40300): "Turbine quality" grade. Steam turbine blading and other highly stressed parts including jet engine rings.

405 (S40500): Nonhardenable grade for assemblies where air-hardening types such as 410 or 403 are objectionable. Annealing boxes; quenching racks; oxidation-resistant partitions.

409 (S40900): General-purpose construction stainless. Automotive exhaust systems; transformer and capacitor cases; dry fertilizer spreaders; tanks for agricultural sprays.

410 (S41000): General-purpose heat-treatable type. Machine parts; pump shafts; bolts; bushings; coal chutes; cutlery; hardware; jet engine parts; mining machinery; rifle barrels; screws; valves.

414 (41400): High hardenability steel. Springs; tempered rules; machine parts, bolts; mining machinery; scissors; ships' bells; spindles; valve seats.

416 (S41600): Free-machining modification of type 410, for heavier cuts. Aircraft fittings; bolts; nuts; fire extinguisher inserts; rivets; screws.

416Se (S41623): Free-machining modification of type 410, for lighter cuts. Machined parts requiring hot working or cold heading.

420 (S42000): Higher carbon modification of type 410. Cutlery; surgical instruments; valves; wear-resisting parts; glass molds; hand tools; vegetable choppers.

420F (S42020): Free-machining modification of type 420. Applications similar to those for type 420 requiring better machinability.

422 (S42200): High strength and toughness at service temperatures up to 1200 degrees F. Steam turbine blades; fasteners.

429 (S42900): Improved weldability as compared to type 430. Nitric acid and nitrogen-fixation equipment.

430 (S43000): General-purpose nonhardenable chromium type. Decorative trim; nitric acid tanks; annealing baskets; combustion chambers; dishwashers; heaters; mufflers; range hoods; recuperators; restaurant equipment.

430F (S43020): Free-machining modification of type 430, for heavier cuts. Screw machine parts.

430FSe (S43023): Free-machining modification of type 430, for lighter cuts. Machined parts requiring light cold heading or forming.

431 (S43100): Special-purpose hardenable steel used where particularly high mechanical properties are required. Aircraft fittings; beater bars; paper machinery; bolts.

434 (S43400): Modification of type 430 designed to resist atmospheric corrosion in the presence of winter road conditioning and dust-laying compounds. Automotive trim and fasteners.

*436 (S43600)*: Similar to types 430 and 434. Used where low "roping" or "ridging" required. General corrosion and heat-resistant applications such as automobile trim.

*440A (S44002)*: Hardenable to higher hardness than type 420 with good corrosion resistance. Cutlery; bearings; surgical tools.

*440B (S44003)*: Cutlery grade. Cutlery, valve parts; instrument bearings.

*440C (S44004)*: Yields highest hardnesses of hardenable stainless steels. Balls; bearings; races; nozzles; balls and seats for oil well pumps; valve parts.

*442 (S44200)*: High-chromium steel, principally for parts that must resist high service temperatures without scaling. Furnace parts; nozzles; combustion chambers.

*446 (S44600)*: High-resistance to corrosion and scaling at high temperatures, especially for intermittent service; often used in sulfur-bearing atmosphere. Annealing boxes; combustion chambers; glass molds; heaters; pyrometer tubes; recuperators; stirring rods; valves.

*501 (S50100)*: Heat resistance; good mechanical properties at moderately elevated temperatures. Heat exchangers; petroleum refining equipment.

*502 (S50200)*: More ductility and less strength than type 501. Heat exchangers; petroleum refining equipment; gaskets.

**Chromium-Nickel Austenitic Steels** (Not capable of heat treatment).—*SAE 30201*:

This steel is an austenitic chromium–nickel–manganese stainless steel usually required in flat products. In the annealed condition, it exhibits higher strength values than the corresponding chromium–nickel stainless steel (SAE 30301). It is nonmagnetic in the annealed condition, but may be magnetic when cold-worked. SAE 30201 is used to obtain high strength by work-hardening and is well suited for corrosion-resistant structural members requiring high strength with low weight. It has excellent resistance to a wide variety of corrosive media, showing behavior comparable to stainless grade SAE 30301. It has high ductility and excellent forming properties. Owing to this steel's work-hardening rate and yield strength, tools for forming must be designed to allow for a higher springback or recovery rate. It is used for automotive trim, automotive wheel covers, railroad passenger car bodies and structural members, and truck trailer bodies.

*SAE 30202*: Like chromium–nickel stainless steel SAE 30302, this is a general-purpose stainless steel. It has excellent corrosion resistance and deep drawing qualities. It is nonhardenable by thermal treatments, but may be cold worked to high tensile strengths. In the annealed condition, it is nonmagnetic but slightly magnetic when cold-worked. Applications for this stainless steel are hub cap, railcar and truck trailer bodies, and spring wire.

*SAE 30301*: Capable of attaining high tensile strength and ductility by moderate or severe cold working. It is used largely in the cold-rolled or cold-drawn condition in the form of sheet, strip, and wire. Its corrosion resistance is good but not equal to SAE 30302.

*SAE 30302*: The most widely used of the general-purpose austenitic chromium–nickel stainless steels. It is used for deep drawing largely in the annealed condition. It can be worked to high tensile strengths but with slightly lower ductility than SAE 30301.

*SAE 30303F*: A free-machining steel recommended for the manufacture of parts produced on automatic screw machines. Caution must be used in forging this steel.

*SAE 30304*: Similar to SAE 30302 but somewhat superior in corrosion resistance and having superior welding properties for certain types of equipment.

*SAE 30305*: Similar to SAE 30304 but capable of lower hardness. Has greater ductility with slower work-hardening tendency.

*SAE 30309*: A steel with high heat-resisting qualities which is resistant to oxidation at temperatures up to about 1800 degrees F.

*SAE 30310*: This steel has the highest heat-resisting properties of the chromium nickel steels listed here and will resist oxidation at temperatures up to about 1900 degrees F.

*SAE 30316*: Recommended for use in parts where unusual resistance to chemical or salt water corrosion is necessary. It has superior creep strength at elevated temperatures.

*SAE 30317*: Similar to SAE 30316 but has the highest corrosion resistance of all these alloys in many environments.

*SAE 30321*: Recommended for use in the manufacture of welded structures where heat treatment after welding is not feasible. It is also recommended for use where temperatures up to 1600 degrees F are encountered in service.

*SAE 30325*: Used for such parts as heat control shafts.

*SAE 30347*: This steel is similar to SAE 30321. This niobium alloy is sometimes preferred to titanium because niobium is less likely to be lost in welding operations.

**Stainless Chromium Irons and Steels.**—*SAE 51409*: An 11 per cent chromium alloy developed, especially for automotive mufflers and tailpipes. Resistance to corrosion and oxidation is very similar to SAE 51410. It is nonhardenable and has good forming and welding characteristics. This alloy is recommended for mildly corrosive applications where surface appearance is not critical.

*SAE 51410*: A general-purpose stainless steel capable of heat treatment to show good physical properties. It is used for general stainless applications, both in the heat-treated and annealed condition but is not as resistant to corrosion as SAE 51430 in either the annealed or heat-treated condition.

*SAE 51414*: A corrosion and heat-resisting nickel-bearing chromium steel with somewhat better corrosion resistance than SAE 51410. It will attain slightly higher mechanical properties when heat-treated than SAE 51410. It is used in the form of tempered strip or wire, and in bars and forgings for heat-treated parts.

*SAE 51416F*: A free-machining grade for the manufacture of parts produced in automatic screw machines.

*SAE 51420*: This steel heat-treatable to a relatively high hardness. It will harden to a maximum of approximately 500 Brinell. Maximum corrosion resisting qualities exist only in the fully hardened condition. It is used for cutlery, hardened pump shafts, etc.

*SAE 51420F*: This is similar to SAE 51420 except for its free-machining properties.

*SAE 51430*: This high-chromium steel is not capable of heat treatment and is recommended for use in shallow parts requiring moderate draw. Corrosion and heat resistance are superior to SAE 51410.

*SAE 51430F*: This steel is similar to SAE 51430 except for its free-machining properties.

*SAE 51431*: This nickel-bearing chromium steel is designed for heat treatment to high mechanical properties. Its corrosion resistance is superior to other hardenable steels.

*SAE 51440A*: A hardenable chromium steel with greater quenched hardness than SAE 51420 and greater toughness than SAE 51440B and 51440C. Maximum corrosion resistance is obtained in the fully hardened and polished condition.

*SAE 51440B*: A hardenable chromium steel with greater quenched hardness than SAE 51440A. Maximum corrosion resistance is obtained in the fully hardened and polished condition. Capable of hardening to 50–60 Rockwell C depending on carbon content.

*SAE 51440C*: This steel has the greatest quenched hardness and wear resistance on heat treatment of any corrosion- or heat-resistant steel.

*SAE 51440F*: The same as SAE 51440C, except for its free-machining characteristics.

*SAE 51442*: A corrosion- and heat-resisting chromium steel with corrosion-resisting properties slightly better than SAE 51430 and with good scale resistance up to 1600 degrees F.

*SAE 51446*: A corrosion- and heat-resisting steel with maximum amount of chromium consistent with commercial malleability. Used principally for parts that must resist high temperatures in service without scaling. Resists oxidation up to 2000 degrees F.

*SAE 51501*: Used for its heat and corrosion resistance and good mechanical properties at temperatures up to approximately 1000 degrees F.

**High-Strength, Low-Alloy Steels.**—High-strength, low-alloy (HSLA) steel represents a specific group of steels in which enhanced mechanical properties and, sometimes, resistance to atmospheric corrosion are obtained by the addition of moderate amounts of one or more alloying elements other than carbon. Different types are available, some of which are carbon–manganese steels and others contain further alloy additions, governed by special requirements for weldability, formability, toughness, strength, and economics. These steels may be obtained in the form of sheet, strip, plates, structural shapes, bars, and bar size sections.

HSLA steels are especially characterized by their mechanical properties, obtained in the as-rolled condition. They are not intended for quenching and tempering. For certain applications, they are sometimes annealed, normalized, or stress relieved with some influence on mechanical properties.

Where these steels are used for fabrication by welding, care must be exercised in selection of grade and in the details of the welding process. Certain grades may be welded without preheat or postheat.

Because of their high strength-to-weight ratio, abrasion resistance, and, in certain compositions, improved atmospheric corrosion resistance, these steels are adapted particularly for use in mobile equipment and other structures where substantial weight savings are generally desirable. Typical applications are truck bodies, frames, structural members, scrapers, truck wheels, cranes, shovels, booms, chutes, and conveyors.

*Grade 942X:* A niobium- or vanadium-treated carbon–manganese high-strength steel similar to 945X and 945C except for somewhat improved welding and forming properties.

*Grade 945A:* A HSLA steel with excellent welding characteristics, both arc and resistance, and the best formability, weldability, and low-temperature notch toughness of the high-strength steels. It is generally used in sheets, strip, and light plate thicknesses.

*Grade 945C:* A carbon–manganese high-strength steel with satisfactory arc welding properties if adequate precautions are observed. It is similar to grade 950C, except that lower carbon and manganese improve arc welding characteristics, formability, and low-temperature notch toughness at some sacrifice in strength.

*Grade 945X:* A niobium- or vanadium-treated carbon–manganese high-strength steel similar to 945C, except for somewhat improved welding and forming properties.

*Grade 950A:* A HSLA steel with good weldability, both arc and resistance, with good low-temperature notch toughness, and good formability. It is generally used in sheet, strip, and light plate thicknesses.

*Grade 950B:* A HSLA steel with satisfactory arc welding properties and fairly good low-temperature notch toughness and formability.

*Grade 950C:* A carbon–manganese high-strength steel that can be arc welded with special precautions, but is unsuitable for resistance welding. The formability and toughness are fair.

*Grade 950D:* A HSLA steel with good weldability, both arc and resistance, and fairly good formability. Where low-temperature properties are important, the effect of phosphorus in conjunction with other elements present should be considered.

*Grade 950X:* A niobium- or vanadium-treated carbon–manganese high-strength steel similar to 950C, except for somewhat improved welding and forming properties.

*Grades 955X, 960X, 965X, 970X, 980X:* These are steels similar to 945X and 950X with higher strength obtained by increased amounts of strengthening elements, such as carbon or manganese, or by the addition of nitrogen up to about 0.015 per cent. This increased strength involves reduced formability and usually decreased weldability. Toughness will vary considerably with composition and mill practice.

The formability, composition, and minimum mechanical properties of the HSLA steel grades are shown in [Tables 7](#) through [Table 9](#) on page [463](#).

**Table 7. HSLA Steel Grades in Approximate Order of Increasing Excellence**

| Weldability      | Formability      | Toughness        |
|------------------|------------------|------------------|
| 980X             | 980X             | 980X             |

<sup>a</sup> All grades are fine-grained except those in the 1100 series that are coarse-grained. Austenitizing temperatures are given in parentheses. Heat-treated specimens were oil-quenched unless otherwise indicated.

<sup>b</sup> Water quenched.

<sup>a</sup> Synonymous in other literature to the modulus of elasticity in torsion and the modulus of rigidity, *G*.

<sup>b</sup> Minimum specified value of the American Society for Testing and Materials. The specifications for the various materials are as follows: Cast iron, ASTM A48; structural steel for bridges and structures, ASTM A7; structural rivet steel, ASTM A141; high-strength structural rivet steel, ASTM A195.

<sup>c</sup> Range of minimum specified values of the ASTM (ASTM A47, A197, and A220).

<sup>d</sup> Range of minimum specified values of the ASTM (ASTM A339) and the Munitions Board Standards Agency (MIL-I-17166A and MIL-I-11466).

<sup>e</sup> Carburizing grades of steel.

<sup>f</sup> Nonhardenable nickel-chromium and Chromium-nickel-manganese steel (austenitic).

<sup>g</sup> Hardenable chromium steel (martensitic).

<sup>h</sup> Nonhardenable chromium steel (ferritic).

**TOOL STEELS****Overview**

As the designation implies, tool steels serve primarily for making tools used in manufacturing and in the trades for the working and forming of metals, wood, plastics, and other industrial materials. Tools must withstand high specific loads, often concentrated at exposed areas, may have to operate at elevated or rapidly changing temperatures and in continual contact with abrasive types of work materials, and are often subjected to shocks, or may have to perform under other varieties of adverse conditions. Nevertheless, when employed under circumstances that are regarded as normal operating conditions, the tool should not suffer major damage, untimely wear resulting in the dulling of the edges, or be susceptible to detrimental metallurgical changes.

Tools for less demanding uses, such as ordinary handtools, including hammers, chisels, files, mining bits, etc., are often made of standard AISI steels that are not considered as belonging to any of the tool steel categories.

The steel for most types of tools must be used in a heat-treated state, generally hardened and tempered, to provide the properties needed for the particular application. The adaptability to heat treatment with a minimum of harmful effects, which dependably results in the intended beneficial changes in material properties, is still another requirement that tool steels must satisfy.

To meet such varied requirements, steel types of different chemical composition, often produced by special metallurgical processes, have been developed. Due to the large number of tool steel types produced by the steel mills, which generally are made available with proprietary designations, it is rather difficult for the user to select those types that are most suitable for any specific application, unless the recommendations of a particular steel producer or producers are obtained.

Substantial clarification has resulted from the development of a classification system that is now widely accepted throughout the industry, on the part of both the producers and the users of tool steels. That system is used in the following as a base for providing concise information on tool steel types, their properties, and methods of tool steel selection.

The tool steel classification system establishes seven basic categories of tool and die steels. These categories are associated with the predominant applicational characteristics of the tool steel types they comprise. A few of these categories are composed of several groups to distinguish between families of steel types that, while serving the same general purpose, differ with regard to one or more dominant characteristics.

To provide an easily applicable guide for the selection of tool steel types best suited for a particular application, the subsequent discussions and tables are based on the previously mentioned application-related categories. As an introduction to the detailed surveys, a concise discussion is presented of the principal tool steel characteristics that govern the suitability for varying service purposes and operational conditions. A brief review of the major steel alloying elements and of the effect of these constituents on the significant characteristics of tool steels is also given in the following sections.

**The Properties of Tool Steels.**—Tool steels must possess certain properties to a higher than ordinary degree to make them adaptable for uses that require the ability to sustain heavy loads and perform dependably even under adverse conditions.

The extent and the types of loads, the characteristics of the operating conditions, and the expected performance with regard to both the duration and the level of consistency are the principal considerations, in combination with the aspects of cost, that govern the selection of tool steels for specific applications.

Although it is not possible to define and apply exact parameters for measuring significant tool steel characteristics, certain properties can be determined that may greatly assist in appraising the suitability of various types of tool steels for specific uses.

Because tool steels are generally heat-treated to make them adaptable to the intended use by enhancing the desirable properties, *the behavior of the steel during heat treatment* is of prime importance. The behavior of the steel comprises, in this respect, both the resistance to harmful effects and the attainment of the desirable properties. The following are considered the major properties related to heat treatment:

**Safety in Hardening:** This designation expresses the ability of the steel to withstand the harmful effects of exposure to very high heat and particularly to the sudden temperature changes during quenching, without harmful effects. One way of obtaining this property is by adding alloying elements to reduce the critical speed at which quenching must be carried out, thus permitting the use of milder quenching media such as oil, salt, or just still air.

Fig. 1. Tool and die design tips to reduce breakage in heat treatment.

*Courtesy of Society of Automotive Engineers, Inc.*

The most common harm parts made of tool steel suffer from during heat treatment is the development of cracks. In addition to the composition of the steel and the applied heat-treating process, the configuration of the part can also affect the sensitivity to cracking. The preceding figure illustrates a few design characteristics related to cracking and warpage in heat treatment; the observation of these design tips, which call for generous filleting, avoidance of sharp angles, and major changes without transition in the cross-section, is particularly advisable when using tool steel types with a low index value for safety in hardening.

In current practice, the previously mentioned property of tool steels is rated in the order of decreasing safety (i.e., increasing sensitivity) as Highest, Very High, High, Medium, and Low safety, expressed in Tables 6 through 11 by the letters A, B, C, D, and E.

**Distortions in Heat Treating:** In parts made from tool steels, distortions are often a consequence of inadequate design (See Fig. 1.) or improper heat treatment (e.g., lack of stress relieving). However, certain types of tool steels display different degrees of sensitivity to

distortion. Steels that are less stable require safer design of the parts for which they are used, more careful heat treatment, including the proper support for long and slender parts, or thin sections, and possibly greater grinding allowance to permit subsequent correction of the distorted shape. Some parts made of a type of steel generally sensitive to distortions can be heat-treated with very little damage when the requirements of the part call for a relatively shallow hardened layer over a soft core. However, for intricate shapes and large tools, steel types should be selected that possess superior nondeforming properties. The ratings used in Tables 6 through 11 express the nondeforming properties (stability of shape in heat treatment) of the steel types and start with the lowest distortion (the best stability) designated as A; the greatest susceptibility to distortion is designated as E.

*Depth of Hardening:* Hardening depth is indicated by a relative rating based on how deep the phase transformation penetrates from the surface and thus produces a hardened layer. Because of the effect of the heat-treating process, and particularly of the applied quenching medium, on the depth of hardness, reference is made in Tables 6 through 11 to the quench that results in the listed relative hardenability values. These values are designated by letters A, B, and C, expressing deep, medium, and shallow depth, respectively.

*Resistance to Decarburization:* Higher or lower sensitivity to losing a part of the carbon content of the surface exposed to heat depends on the chemistry of the steel. The sensitivity can be balanced partially by appropriate heat-treating equipment and processes. Also, the amount of material to be removed from the surface after heat treatment, usually by grinding, should be specified in such a manner as to avoid the retention of a decarburized layer on functional surfaces. The relative resistance of individual tool steel types to decarburization during heat treatment is rated in Tables 6 through 11 from High to Low, expressed by the letters A, B, and C.

Tool steels must be workable with generally available means, without requiring highly specialized processes. The tools made from these steels must, of course, perform adequately, often under adverse environmental and burdensome operational conditions. The ability of the individual types of tool steels to satisfy, to different degrees, such application requirements can also be appraised on the basis of significant properties, such as the following.

*Machinability:* Tools are precision products whose final shape and dimensions must be produced by machining, a process to which not all tool steel types lend themselves equally well. The difference in machinability is particularly evident in tool steels that, depending on their chemical composition, may contain substantial amounts of metallic carbides, beneficial to increased wear resistance, yet detrimental to the service life of tools with which the steel has to be worked. The microstructure of the steel type can also affect the ease of machining and, in some types, certain phase conditions, such as those due to low carbon content, may cause difficulties in achieving a fine surface finish. Certain types of tool steels have their machinability improved by the addition of small amounts of sulfur or lead.

Machinability affects the cost of making the tool, particularly for intricate tool shapes, and must be considered in selection of the steel to be used. The ratings in Tables 6 through 11, starting with A for the greatest ease of machining to E for the lowest machinability, refer to working of the steel in an unhardened condition. Machinability is not necessarily identical with grindability, which expresses how well the steel is adapted to grinding after heat treating. The ease of grinding, however, may become an important consideration in tool steel selection, particularly for cutting tools and dies, which require regular sharpening involving extensive grinding. AVCO Bay State Abrasives Company compiled information on the relative grindability of frequently used types of tool steels. A simplified version of that information is presented in Table 1, which assigns the listed tool steel types to one of the following grindability grades: High (A), Medium (B), Low (C), and Very Low (D), expressing decreasing ratios of volume of metal removed to wheel wear.

**Table 1. Relative Grindability of Selected Types of Frequently Used Tool Steels**

| AISI Tool Steel Type        | H41 |    |        | H42    |    | H43 |    | Other H |     | D2  |     | D3 |    | D5 |    | D7 |     | A Types |  | O Types |  | L Types |  | F Types |  |
|-----------------------------|-----|----|--------|--------|----|-----|----|---------|-----|-----|-----|----|----|----|----|----|-----|---------|--|---------|--|---------|--|---------|--|
| Relative Grindability Index | B   |    |        | B      |    | B   |    | A       |     | B   |     | B  |    | B  |    | C  |     | A       |  | A       |  | A       |  | B       |  |
| High-Speed Tool Steel Type  | M1  | M2 | M3 (1) | M3 (2) | M4 | M7  | M8 | M10     | M15 | M36 | M43 | T1 | T2 | T3 | T5 | T6 | T15 |         |  |         |  |         |  |         |  |
| Relative Grindability Index | A   | B  | C      | C      | D  | B   | A  | B       | D   | B   | B   | A  | B  | C  | B  | B  | D   |         |  |         |  |         |  |         |  |

**Hot Hardness:** This property designates the steel's resistance to the softening effect of elevated temperature. This characteristic is related to the tempering temperature of the type of steel, which is controlled by various alloying elements such as tungsten, molybdenum, vanadium, cobalt, and chromium.

Hot hardness is a necessary property of tools used for hot work, like forging, casting, and hot extrusion. Hot hardness is also important in cutting tools operated at high-speed, which generate sufficient heat to raise their temperature well above the level where ordinary steels lose their hardness; hence the designation *high-speed steels*, which refers to a family of tool steels developed for use at high cutting speeds. Frequently it is the degree of the tool steel's resistance to softening at elevated temperature that governs important process data, such as the applicable cutting speed. In the ratings of Tables 6 through 11, tool steel types having the highest hot hardness are marked with A, subsequent letters expressing gradually decreasing capacity to endure elevated temperature without losing hardness.

**Wear Resistance:** The gradual erosion of the tool's operating surface, most conspicuously occurring at the exposed edges, is known as wear. Resistance to wear prolongs the useful life of the tool by delaying the degradation of its surface through abrasive contact with the work at regular operating temperatures; these temperatures vary according to the type of process. Wear resistance is observable experimentally and measurable by comparison. Certain types of metallic carbides embedded into the steel matrix are considered to be the prime contributing factors to wear resistance, besides the hardness of the heat-treated steel material. The ratings of Tables 6 through 11, starting with A for the best to E for poor, are based on conditions thought to be normal in operations for which various types of tool materials are primarily used.

**Toughness:** In tool steels, this property expresses ability to sustain shocks, suddenly applied and relieved loads, or major impacts, without breaking. Steels used for making tools must also be able to absorb such forces with only a minimum of elastic deformation and without permanent deformation to any extent that would interfere with the proper functioning of the tool. Certain types of tool steels, particularly those with high carbon content and without the presence of beneficial alloying constituents, tend to be the most sensitive to shocks, although they can also be made to act tougher when used for tools that permit a hardened case to be supported by a soft core. Tempering improves toughness, while generally reducing hardness. The rating indexes in Tables 6 through 11, A for the highest toughness through E for the types most sensitive to shocks, apply to tools heat treated to hardness values normally used for the particular type of tool steel.

**Common Tool Faults and Failures.**—The proper selection of the steel grade used for any particular type of tool is of great importance, but it should be recognized that many of the failures experienced in common practice originate from causes other than those related to the tool material.

To permit a better appraisal of the actual causes of failure and possible corrective action, a general, although not complete, list of common tool faults, resulting failures, and corrective actions is shown in Tables 2a through 2d. In this list, the potential failure causes are grouped into four categories. The possibility of more than a single cause being responsible for the experienced failure should not be excluded.

*Note:* Examples of tool failures from causes such as listed above may be found in “The Tool Steel Trouble Shooter” handbook, published by Bethlehem Steel Corporation.

Finally, it must be remembered that the proper usage of tools is indispensable for obtaining satisfactory performance and tool life. Using the tools properly involves, for example, the avoidance of damage to the tool; overloading; excessive speeds and feeds; the application of adequate coolant when called for; a rigid setup; proper alignment; and firm tool and work holding.

**Table 2a. Common Tool Faults, Failures, and Cures**  
Improper Tool Design

| Fault Description   | Probable Failure   | Possible Cure   |
|---|--|---|
| Drastic section changes—widely different thicknesses of adjacent wall sections or protruding elements | In liquid quenching, the thin section will cool and then harden more rapidly than the adjacent thicker section, setting up stresses that may exceed the strength of the steel. | Make such parts of two pieces or use an air-hardening tool steel that avoids the harsh action of a liquid quench.   |
| Sharp corners on shoulders or in square holes   | Cracking can occur, particularly in liquid quenching, due to stress concentrations.  | Apply fillets to the corners and/or use an air-hardening tool steel.  |
| Sharp cornered keyways  | Failure may arise during service, and is usually considered to be caused by fatigue.   | The use of round keyways should be preferred when the general configuration of the part makes it prone to failure due to square keyways.                                  |
| Abrupt section changes in battering tools   | Due to impact in service, pneumatic tools are particularly sensitive to stress concentrations that lead to fatigue failures.   | Use taper transitions, which are better than even generous fillets.   |
| Functional inadequacy of tool design—e.g., insufficient guidance for a punch                          | Excessive wear or breakage in service may occur.   | Assure solid support, avoid unnecessary play, adapt travel length to operational conditions (e.g., punch to penetrate to four-fifths of thickness in hard work material). |
| Improper tool clearance, such as in blanking and punching tools                                       | Deformed and burred parts may be produced, excessive tool wear or breakage can result.   | Adapt clearances to material conditions and dimensions to reduce tool load and to obtain clean sheared surfaces.  |

**The Effect of Alloying Elements on Tool Steel Properties.**—*Carbon (C):* The presence of carbon, usually in excess of 0.60 per cent for nonalloyed types, is essential for raising the hardenability of steels to the levels needed for tools. Raising the carbon content by different amounts up to a maximum of about 1.3 per cent increases the hardness slightly and the wear resistance considerably. The amount of carbon in tool steels is designed to attain certain properties (such as in the water-hardening category where higher carbon content may be chosen to improve wear resistance, although to the detriment of toughness) or, in the alloyed types of tool steels, in conformance with the other constituents to produce well-balanced metallurgical and performance properties.

*Manganese (Mn):* In small amounts, to about 0.60 per cent, manganese is added to reduce brittleness and to improve forgeability. Larger amounts of manganese improve hardenability, permitting oil quenching for nonalloyed carbon steels, thus reducing deformation, although with regard to several other properties, manganese is not an equivalent replacement for the regular alloying elements.

*Silicon (Si):* In itself, silicon may not be considered an alloying element of tool steels, but it is needed as a deoxidizer and improves the hot-forming properties of the steel. In combination with certain alloying elements, the silicon content is sometimes raised to about 2 per cent to increase the strength and toughness of steels used for tools that have to sustain shock loads.

**Table 2b. Common Tool Faults, Failures, and Cures**  
Faulty Condition or Inadequate Grade of Tool Steel

| Fault Description  | Probable Failure  | Possible Cure  |
|--|---|--|
| Improper tool steel grade selection  | Typical failures:<br>Chipping—insufficient toughness.<br>Wear—poor abrasion resistance.<br>Softening—inadequate “red hardness.” | Choose the tool steel grade by following recommendations and improve selection when needed, guided by property ratings.  |
| Material defects—voids, streaks, tears, flakes, surface cooling cracks, etc. | When not recognized during material inspection, tools made of defective steel often prove to be useless.                        | Obtain tool steels from reliable sources and inspect tool material for detectable defects.   |
| Decarburized surface layer (“bark”) in rolled tool steel bars                | Cracking may originate from the decarburized layer or it will not harden (“soft skin”).   | Provide allowance for stock to be removed from all surfaces of hot-rolled tool steel. Recommended amounts are listed in tool steel catalogs and vary according to section size, generally about 10 per cent for smaller and 5 per cent for larger diameters. |
| Brittleness caused by poor carbide distribution in high-alloy tool steels    | Excessive brittleness can cause chipping or breakage during service.  | Bars with large diameter (above about 4 inches) tend to be prone to nonuniform carbide distribution. Choose upset forged discs instead of large-diameter bars.   |
| Unfavorable grain flow   | Improper grain flow of the steel used for milling cutters and similar tools can cause teeth to break out.                       | Upset forged discs made with an upset ratio of about 2 to 1 (starting to upset thickness) display radial grain flow. Highly stressed tools, such as gear-shaper cutters, may require the cross forging of blanks.  |

**Tungsten (W):** Tungsten is one of the important alloying elements of tool steels, particularly because of two valuable properties: it improves “hot hardness,” that is, the resistance of the steel to the softening effect of elevated temperature, and it forms hard, abrasion-resistant carbides, thus improving the wear properties of tool steels.

**Vanadium (V):** Vanadium contributes to the refinement of the carbide structure and thus improves the forgeability of alloy tool steels. Vanadium has a very strong tendency to form a hard carbide, which improves both the hardness and the wear properties of tool steels. However, a large amount of vanadium carbide makes the grinding of the tool very difficult (causing low grindability).

**Molybdenum (Mo):** In small amounts, molybdenum improves certain metallurgical properties of alloy steels such as deep hardening and toughness. It is used often in larger amounts in certain high-speed tool steels to replace tungsten, primarily for economic reasons, often with nearly equivalent results.

**Cobalt (Co):** As an alloying element of tool steels, cobalt increases hot hardness and is used in applications where that property is needed. Substantial addition of cobalt, however, raises the critical quenching temperature of the steel with a tendency to increase the decarburization of the surface, and reduces toughness.

**Chromium (Cr):** This element is added in amounts of several per cent to high-alloy tool steels, and up to 12 per cent to types in which chromium is the major alloying element. Chromium improves hardenability and, together with high carbon, provides both wear resistance and toughness, a combination valuable in certain tool applications. However, high chromium raises the hardening temperature of the tool steel, and thus can make it prone to hardening deformations. A high percentage of chromium also affects the grindability of the tool steel.

**Nickel (Ni):** Generally in combination with other alloying elements, particularly chromium, nickel is used to improve the toughness and, to some extent, the wear resistance of tool steels.

**Table 2c. Common Tool Faults, Failures, and Cures**  
Heat-Treatment Faults

| Fault Description   | Probable Failure  | Possible Cure  |
|---|---|--|
| Improper preparation for heat treatment. Certain tools may require stress relieving or annealing, and often preheating, too | Tools highly stressed during machining or forming, unless stress relieved, may aggravate the thermal stresses of heat treatment, thus causing cracks. Excessive temperature gradients developed in nonpreheated tools with different section thicknesses can cause warpage. | Stress relieve, when needed, before hardening. Anneal prior to heavy machining or cold forming (e.g., hobbing). Preheat tools (a) having substantial section thickness variations or (b) requiring high quenching temperatures, as those made of high-speed tool steels.       |
| Overheating during hardening; quenching from too high a temperature   | Causes grain coarsening and a sensitivity to cracking that is more pronounced in tools with drastic section changes.  | Overheated tools have a characteristic microstructure that aids recognition of the cause of failure and indicates the need for improved temperature control.   |
| Low hardening temperature   | The tool may not harden at all, or in its outer portion only, thereby setting up stresses that can lead to cracks.  | Controlling both the temperature of the furnace and the time of holding the tool at quenching temperature will prevent this not too frequent deficiency.   |
| Inadequate composition or condition of the quenching media  | Water-hardening tool steels are particularly sensitive to inadequate quenching media, which can cause soft spots or even violent cracking.  | For water-hardening tool steels, use water free of dissolved air and contaminants, also assure sufficient quantity and proper agitation of the quench.   |
| Improper handling during and after quenching  | Cracking, particularly of tools with sharp corners, during the heat treatment can result from holding the part too long in the quench or incorrectly applied tempering.   | Following the steel producer's specifications is a safe way to assure proper heat-treatment handling. In general, the tool should be left in the quench until it reaches a temperature of 150 to 200°F, and should then be transferred promptly into a warm tempering furnace. |
| Insufficient tempering  | Omission of double tempering for steel types that require it may cause early failure by heat checking in hot-work steels or make the tool abnormally sensitive to grinding checks.  | Double temper highly alloyed tool steel of the high-speed, hot-work, and high-chromium categories, to remove stresses caused by martensite formed during the first tempering phase. Second temper also increases hardness of most high-speed steels.                           |
| Decarburization and carburization   | Unless hardened in a neutral atmosphere the original carbon content of the tool surface may be changed: Reduced carbon (decarburization) causes a soft layer that wears rapidly. Increased carbon (carburization) when excessive may cause brittleness.                     | Heating in neutral atmosphere or well-maintained salt bath and controlling the furnace temperature and the time during which the tool is subjected to heating can usually keep the carbon imbalance within acceptable limits.  |

The addition of more than one element to a steel often produces what is called a synergistic effect. Thus, the combined effects of two or more alloy elements may be greater than the sum of the individual effects of each element.

**Classification of Tool Steels.**—Steels for tools must satisfy a number of different, often conflicting requirements. The need for specific steel properties arising from widely varying applications has led to the development of many compositions of tool steels, each intended to meet a particular combination of applicational requirements. The diversity of tool steels, their number being continually expanded by the addition of new developments, makes it extremely difficult for the user to select the type best suited to his needs, or to find equivalent alternatives for specific types available from particular sources.

As a cooperative industrial effort under the sponsorship of AISI and SAE, a tool classification system has been developed in which the commonly used tool steels are grouped into seven major categories. These categories, several of which contain more than a single group, are listed in [Table 3](#) with the letter symbols used for their identification. The individual types of tool steels within each category are identified by suffix numbers following the letter symbols.

**Table 2d. Common Tool Faults, Failures, and Cures**  
Grinding Damages

| Fault Description   | Probable Failure   | Possible Cure   |
|---|--|---|
| Grinding Damages  |  |   |
| Excessive stock removal rate causing heating of the part surface beyond the applied tempering temperature | Scorched tool surface displaying temper colors varying from yellow to purple, depending on the degree of heat, causes softening of the ground surface. When coolant is used, a local rehardening can take place, often resulting in cracks.  | Prevention: by reducing speed and feed, or using coarser, softer, more open-structured grinding wheel, with ample coolant. Correction: eliminate the discolored layer by subsequent light stock removal. Not always a cure, because the effects of abusive grinding may not be corrected.                     |
| Improper grinding wheel specifications; grain too fine or bond too hard                                   | Intense localized heating during grinding may set up surface stresses causing grinding cracks. These cracks are either parallel but at right angles to the direction of grinding or, when more advanced, form a network. May need cold etch or magnetic particle testing to become recognizable. | Prevention: by correcting the grinding wheel specifications. Correction: in shallow (0.002- to 0.004-inch) cracks, by removing the damaged layer, when permitted by the design of the tool, using very light grinding passes.   |
| Incorrectly dressed or loaded grinding wheel  | Heating of the work surface can cause scorching or cracking. Incorrect dressing can also cause a poor finish of the ground work surface.   | Dress wheel with sharper diamond and faster diamond advance to produce coarser wheel surface. Alternate dressing methods, like crush-dressing, can improve wheel surface conditions. Dress wheel regularly to avoid loading or glazing of the wheel surface.  |
| Inadequate coolant, with regard to composition, amount, distribution, and cleanliness                     | Introducing into the tool surface heat that is not adequately dissipated or absorbed by the coolant can cause softening, or even the development of cracks.  | Improve coolant supply and quality, or reduce stock removal rate to reduce generation of heat in grinding.  |
| Damage caused by abusive abrasive cutoff  | The intensive heat developed during this process can cause a hardening of the steel surface, or may even result in cracks.   | Reduce rate of advance; adopt wheel specifications better suited for the job. Use ample coolant or, when harmful effect not eliminated, replace abrasive cutoff by some cooler-acting stock separation method (e.g., sawing or lathe cutoff) unless damaged surface is being removed by subsequent machining. |

**Table 3. Classification of Tool Steels**

| Category Designation        | Letter Symbol | Group Designation                 |
|-----------------------------|---------------|-----------------------------------|
| High-Speed Tool Steels      | M             | Molybdenum types                  |
|                             | T             | Tungsten types                    |
| Hot-Work Tool Steels        | H1-H19        | Chromium types                    |
|                             | H20-H39       | Tungsten types                    |
|                             | H40-H59       | Molybdenum types                  |
| Cold-Work Tool Steels       | D             | High-carbon, high-chromium types  |
|                             | A             | Medium-alloy, air-hardening types |
|                             | O             | Oil-hardening types               |
| Shock-Resisting Tool Steels | S             | ...                               |
| Mold Steels                 | P             | ...                               |
| Special-Purpose Tool Steels | L             | Low-alloy types                   |
|                             | F             | Carbon-tungsten types             |
| Water-Hardening Tool Steels | W             | ...                               |

The following detailed discussion of tool steels will be in agreement with these categories, showing for each type the percentages of the major alloying elements. However, these values are for identification only; elements in tool steels of different producers in the mean analysis of the individual types may deviate from the listed percentages.

**Table 4. Classification, Approximate Compositions, and Properties Affecting Selection of Tool and Die Steels**  
(From SAE Recommended Practice)

| Type of Tool Steel                      | Chemical Composition <sup>a</sup> |      |      |                   |                   |      |                   |                   | Non-warping Prop. | Safety in Hardening | Toughness         | Depth of Hardening | Wear Resistance |
|---|-----------------------------------|------|------|-------------------|-------------------|------|-------------------|-------------------|-------------------|---------------------|-------------------|--------------------|-----------------|
|   | C                                 | Mn   | Si   | Cr                | V                 | W    | Mo                | Co                |                   |                     |                   |                    |                 |
| <b>Water Hardening</b>                  |                                   |      |      |                   |                   |      |                   |                   |                   |                     |                   |                    |                 |
| 0.80 Carbon                             | 70–85                             | b    | b    | b                 | ...               | ...  | ...               | ...               | Poor              | Fair                | Good <sup>c</sup> | Shallow            | Fair            |
| 0.90 Carbon                             | 85–95                             | b    | b    | b                 | ...               | ...  | ...               | ...               | Poor              | Fair                | Good <sup>c</sup> | Shallow            | Fair            |
| 1.00 Carbon                             | 95–1.10                           | b    | b    | b                 | ...               | ...  | ...               | ...               | Poor              | Fair                | Good <sup>c</sup> | Shallow            | Good            |
| 1.20 Carbon                             | 1.10–1.30                         | b    | b    | b                 | ...               | ...  | ...               | ...               | Poor              | Fair                | Good <sup>c</sup> | Shallow            | Good            |

<sup>a</sup> C = carbon; Mn = manganese; Si = silicon; Cr = chromium; V = vanadium; W = tungsten; Mo = molybdenum; Co = cobalt.

<sup>b</sup> Carbon tool steels are usually available in four grades or qualities: *Special (Grade 1)*—The highest quality water-hardening carbon tool steel, controlled for hardenability, chemistry held to closest limits, and subject to rigid tests to ensure maximum uniformity in performance; *Extra (Grade 2)*—A high-quality water-hardening carbon tool steel, controlled for hardenability, subject to tests to ensure good service; *Standard (Grade 3)*—A good-quality water-hardening carbon tool steel, not controlled for hardenability, recommended for application where some latitude with respect to uniformity is permissible; *Commercial (Grade 4)*—A commercial-quality water-hardening carbon tool steel, not controlled for hardenability, not subject to special tests. On *special* and *extra* grades, limits on manganese, silicon, and chromium are not generally required if Shepherd hardenability limits are specified. For *standard* and *commercial* grades, limits are 0.35 max. each for Mn and Si; 0.15 max. Cr for standard; 0.20 max. Cr for commercial.

<sup>c</sup> Toughness decreases somewhat when increasing depth of hardening.

<sup>d</sup> Optional element. Steels have found satisfactory application either with or without the element present. In silicon-manganese steel listed under Shock-Resisting Steels, if chromium, vanadium, and molybdenum are not present, then hardenability will be affected.

<sup>e</sup> This steel may have 0.50 per cent nickel as an optional element. The steel has been found to give satisfactory application either with or without the element present.

<sup>f</sup> Approximate nickel content of this steel is 1.50 per cent.

<sup>g</sup> Poor when water quenched, fair when oil quenched.

<sup>h</sup> Poor when water quenched, good when oil quenched.

**The Selection of Tool Steels for Particular Applications.**—Although the advice of the specialized steel producer is often sought as a reliable source of information, the engineer is still faced with the task of selecting the tool steel. It must be realized that frequently the designation of the tool or of the process will not define the particular tool steel type best suited for the job. For that reason, tool steel selection tables naming a single type for each listed application cannot take into consideration such often conflicting work factors as ease of tool fabrication and maintenance (resharpening), productivity, product quality, and tooling cost.

When data related to past experience with tool steels for identical or similar applications are not available, a tool steel selection procedure may be followed, based on information in this Handbook section as follows:

1) Identify the AISI category that contains the sought type of steel by consulting the Quick Reference Table, [Table 5](#), starting on page [485](#).

Within the defined category

- a) find from the listed applications of the most frequently used types of tool steels the particular type that corresponds to the job on hand; or
- b) evaluate from the table of property ratings the best compromise between any conflicting properties (e.g., compromising on wear resistance to obtain better toughness).

For those willing to refine even further the first choice or to improve on it when there is not entirely satisfactory experience in one or more meaningful respects, the identifying analyses of the different types of tool steels within each general category may provide additional guidance. In this procedure, the general discussion of the effects of different alloying elements on the properties of tool steels, in a previous section, will probably be found useful.

The following two examples illustrate the procedure for refining an original choice with the purpose of adopting a tool steel grade best suited to a particular set of conditions:

*Example 1, Workpiece—Trimming Dies:* For the manufacture of a type of trimming die, the first choice was grade A2, because for the planned medium rate of production, the lower material cost was considered an advantage.

A subsequent rise in the production rate indicated the use of a higher-alloy tool steel, such as D2, whose increased abrasion resistance would permit longer runs between regrinds.

A still further increase in the abrasion-resistant properties was then sought, which led to the use of D7, the high carbon and high chromium content of which provided excellent edge retainment, although at the cost of greatly reduced grindability. Finally, it became a matter of economic appraisal, whether the somewhat shorter tool regrind intervals (for D2) or the more expensive tool sharpening (for D7) constituted the lesser burden.

*Example 2, Workpiece—Circular form cutter made of high-speed tool steel for use on multiple-spindle automatic turning machines:* The first choice from the [Table 5](#) may be the classical tungsten-base high-speed tool steel T1, because of its good performance and ease of heat treatment, or its alternate in the molybdenum high-speed tool steel category, the type M2.

In practice, neither of these grades provided a tool that could hold its edge and profile over the economical tool change time, because of the abrasive properties of the work material and the high cutting speeds applied in the cycle. An overrating of the problem resulted in reaching for the top of the scale, making the tool from T15, a high-alloy high-speed tool steel (high vanadium and high cobalt).

Although the performance of the tools made of T15 was excellent, the cost of this steel type was rather high, and the grinding of the tool, both for making it and in the regularly needed resharpening, proved to be very time-consuming and expensive. Therefore, an intermediate tool steel type was tried, the M3 that provided added abrasion resistance (due to increased carbon and vanadium content), and was less expensive and much easier to grind than the T15.

### High-Speed Tool Steels

The primary application of high-speed steels is to tools used for the working of metals at high cutting speeds. Cutting metal at high speed generates heat, the penetration of the cutting tool edge into the work material requires great hardness and strength, and the continued frictional contact of the tool with both the parent material and the detached chips can only be sustained by an abrasion-resistant tool edge.

Accordingly, the dominant properties of high-speed steel are a) resistance to the softening effect of elevated temperature; b) great hardness penetrating to substantial depth from the surface; and c) excellent abrasion resistance.

High-speed tool steels are listed in the AISI specifications in two groups: molybdenum types and tungsten types, these designations expressing the dominant alloying element of the respective group.

**Molybdenum-Type High-Speed Tool Steels.**—Unlike the traditional tungsten-base high-speed steels, the tool steels listed in this category are considered to have molybdenum as the principal alloying constituent, this element also being used in the designation of the group. Other significant elements like tungsten and cobalt might be present in equal, or even greater amounts in several types listed in this category. The available range of types also includes high-speed tool steels with higher than usual carbon and vanadium content. Amounts of these alloying elements have been increased to obtain better abrasion resistance although such a change in composition may adversely affect the machinability and the grindability of the steel. The series in whose AISI identification numbers the number 4 is the first digit was developed to attain exceptionally high hardness in heat treatment that, for these types, usually requires triple tempering rather than the double tempering generally applied for high-speed tool steels.

*Frequently Used Molybdenum Types: AISI M1:* This alloy was developed as a substitute for the classical T1 to save on the alloying element tungsten by replacing most of it with molybdenum. In most uses, this steel is an acceptable substitute, although it requires greater care or more advanced equipment for its heat treatment than the tungsten alloyed type it replaces. The steel is often selected for cutting tools like drills, taps, milling cutters, reamers, lathe tools used for lighter cuts, and for shearing dies.

*AISI M2:* Similar to M1, yet with substantial tungsten content replacing a part of the molybdenum. This is one of the general-purpose high-speed tool steels, combining the economic advantages of the molybdenum-type steels with greater ease of hardening, excellent wear resistance, and improved toughness. It is a preferred steel type for the manufacture of general-purpose lathe tools; of most categories of multiple-edge cutting tools, like milling cutters, taps, dies, reamers, and for form tools in lathe operations.

*AISI M3:* A high-speed tool steel with increased vanadium content for improved wear resistance, yet still below the level where vanadium would interfere with the ease of grinding. This steel is preferred for cutting tools requiring improved wear resistance, like broaches, form tools, milling cutters, chasers, and reamers.

*AISI M7:* The chemical composition of this type is similar to that of M1, except for the higher carbon and vanadium content that raises the cutting efficiency without materially reducing the toughness. Because of sensitivity to decarburization, heat treatment in a salt bath or a controlled atmosphere is advisable. Used for blanking and trimming dies, shear blades, lathe tools, and thread rolling dies.

*AISI M10:* Although the relatively high vanadium content assures excellent wear and cutting properties, the only slightly increased carbon does not cause brittleness to an extent that is harmful in many applications. Form cutters and single-point lathe tools, broaches, planer tools, punches, blanking dies, and shear blades are examples of typical uses.

*AISI M42:* In applications where high hardness both at regular and at elevated temperatures is needed, this type of high-speed steel with high cobalt content can provide excellent service. Typical applications are tool bits, form tools, shaving tools, fly cutters, roll turning

tools, and thread rolling dies. Important uses are found for M42, and for other types of the "M40" group in the working of "difficult-to-machine" alloys.

**Tungsten-Type High-Speed Tool Steels.**—For several decades following their introduction, the tungsten-base high-speed steels were the only types available for cutting operations involving the generation of substantial heat, and are still preferred by users who do not have the kind of advanced heat-treating equipment that efficient hardening of the molybdenum-type high-speed tool steels requires. Most tungsten high-speed steels display excellent resistance to decarburization and can be brought to good hardness by simple heat treatment. However, even with tungsten-type high-speed steels, heat treatment using modern methods and furnaces can appreciably improve the metallurgical qualities of the hardened material and the performance of the cutting tools made from these steels.

<sup>a</sup>Relative Ratings of Properties (A = greatest to E = least)

*Frequently Used Tungsten Types: AISI T1:* Also mentioned as the 18–4–1 type with reference to the nominal percentage of its principal alloying elements (W–Cr–V), it is considered to be the classical type of high-speed tool steel. The chemical composition of T1 was developed in the early 1900s, and has changed very little since. T1 is still considered to be perhaps the best general-purpose high-speed tool steel because of the comparative ease of its machining and heat treatment. It combines a high degree of cutting ability with relative toughness. T1 steel is used for all types of multiple-edge cutting tools like drills, reamers, milling cutters, threading taps and dies, light- and medium-duty lathe tools, and is also used for punches, dies, and machine knives, as well as for structural parts that are subjected to elevated temperatures, like lathe centers, and certain types of antifriction bearings.

*AISI T2:* Similar to T1 except for somewhat higher carbon content and twice the vanadium contained in the former grade. Its handling ease, both in machining and heat treating, is comparable to that of T1, although it should be held at the quenching temperature slightly longer, particularly when the heating is carried out in a controlled atmosphere furnace. The applications are similar to that of T1, however, because of its increased wear

resistance T2 is preferred for tools required for finer cuts, and where the form or size retention of the tool is particularly important, such as for form and finishing tools.

**AISI T5:** The essential characteristic of this type of high-speed steel, its superior red hardness, stems from its substantial cobalt content that, combined with the relatively high amount of vanadium, provides this steel with excellent wear resistance. In heat treatment, the tendency for decarburization must be considered, and heating in a controlled, slightly reducing atmosphere is recommended. This type of high-speed tool steel is mainly used for single-point tools and inserts; it is well adapted for working at high-speeds and feeds, for cutting hard materials and those that produce discontinuous chips, also for nonferrous metals and, for all kinds of tools needed for hogging (removing great bulks of material).

**AISI T15:** The performance qualities of this high-alloy tool steel surpass most of those found in other grades of high-speed tool steels. The high vanadium content, supported by uncommonly high carbon assures superior cutting ability and wear resistance. The addition of high cobalt increases the "hot hardness," and therefore tools made of T15 can sustain cutting speeds in excess of those commonly applicable to tools made of steel. The machining and heat treatment of T15 does not cause extraordinary problems, although for best results, heating to high temperature is often applied in its heat treatment, and double or even triple tempering is recommended. On the other hand, T15 is rather difficult to grind because of the presence of large amounts of very hard metallic carbides; therefore, it is considered to have a very low "grindability" index. The main uses are in the field of high-speed cutting and the working of hard metallic materials, T15 being often considered to represent in its application a transition from the regular high-speed tool steels to cemented carbides. Lathe tool bits, form cutters, and solid and inserted blade milling cutters are examples of uses of this steel type for cutting tools; excellent results may also be obtained with such tools as cold-work dies, punches, blanking, and forming dies, etc. The low toughness rating of the T15 steel excludes its application for operations that involve shock or sudden variations in load.

### Hot-Work Tool Steels

A family of special tool steels has been developed for tools that in their regular service are in contact with hot metals over a shorter or longer period of time, with or without cooling being applied, and are known as hot-work steels. The essential property of these steels is their capability to sustain elevated temperature without seriously affecting the usefulness of the tools made from them. Depending on the purpose of the tools for which they were developed, the particular types of hot-work tool steels have different dominant properties and are assigned to one of three groups, based primarily on their principal alloying elements.

**Hot-Work Tool Steels, Chromium Types.**—As referred to in the group designation, the chromium content is considered the characteristic element of these tool steels. Their predominant properties are high hardenability, excellent toughness, and great ductility, even at the cost of wear resistance. Some members of this family are made with the addition of tungsten, and in one type, cobalt as well. These alloying elements improve the resistance to the softening effect of elevated temperatures, but reduce ductility.

**Frequently Used Chromium Types:** *AISI H11:* This hot-work tool steel of the Chromium-molybdenum-vanadium type has excellent ductility, can be machined easily, and retains its strength at temperatures up to 1000 degrees F.

These properties, combined with relatively good abrasion and shock resistance, account for the varied fields of application of H11, which include the following typical uses: a) structural applications where high strength is needed at elevated operating temperatures, as for gas turbine engine components; and b) hot-work tools, particularly of the kind whose service involves shocks and drastic cooling of the tool, such as in extrusion tools, pierce and draw punches, bolt header dies, etc.

**Table 8. Hot-Work Tool Steels**

*AISI H12:* The properties of this type of steel are comparable to those of H11, with increased abrasion resistance and hot hardness, resulting from the addition of tungsten, yet in an amount that does not affect the good toughness of this steel type. The applications, based on these properties, are hot-work tools that often have to withstand severe impact, such as various punches, bolt header dies, trimmer dies, and hot shear blades. H12 is also used to make aluminum extrusion dies and die-casting dies.

*AISI H13:* This type of tool steel differs from the preceding ones particularly in properties related to the addition of about 1 per cent vanadium, which contributes to increased hot hardness, abrasion resistance, and reduced sensitivity to heat checking. Such properties are needed in die casting, particularly of aluminum, where the tools are subjected to drastic heating and cooling at high operating temperatures. Besides die-casting dies, H13 is also widely used for extrusion dies, trimmer dies, hot gripper and header dies, and hot shear blades.

*AISI H19:* This high-alloyed hot-work tool steel, containing chromium, tungsten, cobalt, and vanadium, has excellent resistance to abrasion and shocks at elevated temperatures. It is particularly well adapted to severe hot-work uses where the tool, to retain its size and shape, must withstand wear and the washing-out effect of molten work material. Typical applications include brass extrusion dies and dummy blocks, inserts for forging and valve extrusion dies, press forging dies, and hot punches.

**Hot-Work Tool Steels, Tungsten Types.**—Substantial amounts of tungsten, yet very low-carbon content characterize the hot-work tool steels of this group. These tool steels have been developed for applications where the tool is in contact with the hot-work material over extended periods of time; therefore, the resistance of the steel to the softening effect of elevated temperatures is of prime importance, even to the extent of accepting a lower degree of toughness.

*Frequently Used Tungsten Types:* *AISI H21:* This medium-tungsten alloyed hot-work tool steel has substantially increased abrasion resistance over the chromium alloyed types, yet possesses a degree of toughness that represents a transition between the chromium and the higher-alloyed tungsten-steel types. The principal applications are for tools subjected to continued abrasion, yet to only a limited amount of shock loads, like tools for the extrusion of brass, both dies and dummy blocks, pierces for forging machines, inserts for forging tools, and hot nut tools. Another typical application is dies for the hot extrusion of automobile valves.

*AISI H24:* The comparatively high tungsten content (about 14 per cent) of this steel results in good hardness, great compression strength, and excellent abrasion resistance, but makes it sensitive to shock loads. By taking these properties into account, the principal applications include extrusion dies for brass in long-run operations, hot-forming and gripper dies with shallow impressions, punches that are subjected to great wear yet only to moderate shocks, and hot shear blades.

*AISI H20:* The composition of this high-alloyed tungsten-type hot-work steel resembles the tungsten-type high-speed steel AISI T1, except for the somewhat lower carbon content for improved toughness. The high amount of tungsten provides the maximum resistance to the softening effect of elevated temperature and assures excellent wear-resistant properties, including withstanding the washing-out effect of certain processes. However, this steel is less resistant to thermal shocks than the chromium hot-work steels. Typical applications comprise extrusion dies for long production runs, extrusion mandrels operated without cooling, hot piercing punches, hot forging dies and inserts. It is also used as special structural steel for springs operating at elevated temperatures.

**Hot-Work Tool Steels, Molybdenum Types.**—These steels are closely related to certain types of molybdenum high-speed steels and possess excellent resistance to the softening effect of elevated temperature but their ductility is rather low. These steel types are generally available on special orders only.

*Frequently Used Molybdenum Types: AISI H43:* The principal constituents of this hot-work steel, chromium, molybdenum, and vanadium, provide excellent abrasion- and wear-resistant properties at elevated temperatures. H43 has a good resistance to the development of heat checks and a toughness adequate for many different purposes. Applications include tools and operations that tend to cause surface wear in high-temperature work, like hot headers, punch and die inserts, hot heading and hot nut dies, as well as different kinds of punches operating at high temperature in service involving considerable wear.

### Cold-Work Tool Steels

Tool steels of the cold-working category are primarily intended for die work, although their use is by no means restricted to that general field. Cold-work tool steels are extensively used for tools whose regular service does not involve elevated temperatures. They are available in chemical compositions adjusted to the varying requirements of a wide range of different applications. According to their predominant properties, characterized either by the chemical composition or by the quenching medium in heat treatment, the cold-work tool steels are assigned to three different groups, as discussed in what follows.

**Cold-Work Tool Steels, High-Carbon, High-Chromium Types.**—The chemical composition of tool steels of this family is characterized by the very high chromium content, to the order of 12 to 13 per cent, and the uncommonly high carbon content, in the range of about 1.50 to 2.30 per cent. Additional alloying elements that are present in different amounts in some of the steel types of this group are vanadium, molybdenum, and cobalt, each of which contributes desirable properties.

The predominant properties of the whole group are: 1) excellent dimensional stability in heat treatment, where, with one exception, air quench is used; 2) great wear resistance, particularly in the types with the highest carbon content; and 3) rather good machinability.

*Frequently Used High-Carbon, High-Chromium Types: AISI D2:* An air-hardening die steel with high-carbon, high-chromium content having several desirable tool steel properties, such as abrasion resistance, high hardness, and nondeforming characteristics. The carbon content of this type, although relatively high, is not particularly detrimental to its machining. The ease of working can be further improved by selecting the same basic type with the addition of sulfur. Several steel producers supply the sulfurized version of D2, in which the uniformly distributed sulfide particles substantially improve the machinability and the resulting surface finish. The applications comprise primarily cold-working press tools for shearing (blanking and stamping dies, punches, shear blades), for forming (bending, seaming), also for thread rolling dies, solid gages, and wear-resistant structural parts. Dies for hot trimming of forgings are also made of D2 which is then heated treated to a lower hardness for the purpose of increasing toughness.

*AISI D3:* The high carbon content of this high-chromium tool steel type results in excellent resistance to wear and abrasion and provides superior compressive strength as long as the pressure is applied gradually, without exerting sudden shocks. In hardening, an oil quench is used, without affecting the excellent nondeforming properties of this type. Its deep-hardening properties make it particularly suitable for tools that require repeated regrinding during their service life, such as different types of dies and punches. The more important applications comprise blanking, stamping, and trimming dies and punches for long production runs; forming, bending and drawing tools; and structural elements like plug and ring gages, and lathe centers, in applications where high wear resistance is important.

**Cold-Work Tool Steels, Oil-Hardening Types.**—With a relatively low percentage of alloying elements, yet with a substantial amount of manganese, these less expensive types of tool steels attain good depth of hardness in an oil quench, although at the cost of reduced resistance to deformation. Their good machinability supports general-purpose applica-

tions, yet because of relatively low wear resistance, they are mostly selected for comparatively short-run work.

*Frequently Used Oil-Hardening Types: AISI O1:* A low-alloy tool steel that is hardened in oil and exhibits only a low tendency to shrinking or warping. It is used for cutting tools, the operation of which does not generate high heat, such as taps and threading dies, reamers, and broaches, and for press tools like blanking, trimming, and forming dies in short- or medium-run operations.

*AISI O2:* Manganese is the dominant alloying element in this type of oil-hardening tool steel that has good nondeforming properties, can be machined easily, and performs satisfactorily in low-volume production. The low hardening temperature results in good safety in hardening, both with regard to form stability and freedom from cracking. The combination of handling ease, including free-machining properties, with good wear resistance, makes this type of tool steel adaptable to a wide range of common applications such as cutting tools for low- and medium-speed operations; forming tools including thread rolling dies; structural parts such as bushings and fixed gages, and for plastics molds.

*AISI O6:* This oil-hardening type of tool steel belongs to a group often designated as graphitic because of the presence of small particles of graphitic carbon that are uniformly dispersed throughout the steel. Usually, about one-third of the total carbon is present as free graphite in nodular form, which contributes to the uncommon ease of machining. In the service of parts made of this type of steel, the free graphite acts like a lubricant, reducing wear and galling. The ease of hardening is also excellent, requiring only a comparatively low quenching temperature. Deep hardness penetration is produced and the oil quench causes very little dimensional change. The principal applications of the O6 tool steel are in the field of structural parts, like arbors, bushings, bodies for inserted tool cutters, and shanks for cutting tools, jigs, and machine parts, and fixed gages like plugs, rings, and snap gages. It is also used for blanking, forming, and trimming dies and punches, in applications where the stability of the tool material is more important than high wear resistance.

**Cold-Work Tool Steels, Medium-Alloy, Air-Hardening Types.**—The desirable nondeforming properties of the high-chromium types are approached by the members of this family, with substantially lower alloy content that, however, is sufficient to permit hardening by air quenching. The machinability is good, and the comparatively low wear resistance is balanced by relatively high toughness, a property that, in certain applications, may be considered of prime importance.

*Frequently Used Medium-Alloy, Air-Hardening Types: AISI A2:* The lower chromium content, about 5 per cent, makes this air-hardening tool steel less expensive than the high-chromium types, without affecting its nondeforming properties. The somewhat reduced wear resistance is balanced by greater toughness, making this type suitable for press work where the process calls for tough tool materials. The machinability is improved by the addition of about 0.12 percent sulfur, offered as a variety of the basic composition by several steel producers. The prime uses of this tool steel type are punches for blanking and forming, cold and hot trimming dies (the latter heat treated to a lower hardness), thread rolling dies, and plastics molds.

*AISI A6:* The composition of this type of tool steel makes it adaptable to air hardening from a relatively low temperature, comparable to that of oil-hardening types, yet offering improved stability in heat treating. Its reduced tendency to heat-treatment distortions makes this tool steel type well adapted for die work, forming tools, and gages, which do not require the highest degree of wear resistance.

### **Shock-Resisting, Mold, and Special-Purpose Tool Steels**

There are fields of tool application in which specific properties of the tool steels have dominant significance, determining to a great extent the performance and the service life of tools made of these materials. To meet these requirements, special types of tool steels

have been developed. These individual types grew into families with members that, while similar in their major characteristics, provide related properties to different degrees. Originally developed for a specific use, the resulting particular properties of some of these tool steels made them desirable for other uses as well. In the tool steel classification system, they are shown in three groups, as discussed in what follows.

**Shock-Resisting Tool Steels.**—These steels are made with low-carbon content for increased toughness, even at the expense of wear resistance, which is generally low. Each member of this group also contains alloying elements, different in composition and amount, selected to provide properties particularly adjusted to specific applications. Such varying properties are the degree of toughness (generally, high in all members), hot hardness, abrasion resistance, and machinability.

*Properties and Applications of Frequently Used Shock-Resisting Types: AISI S1:* This Chromium–tungsten alloyed tool steel combines, in its hardened state, great toughness with high hardness and strength. Although it has a low-carbon content for reasons of good toughness, the carbon-forming alloys contribute to deep hardenability and abrasion resistance. When high wear resistance is also required, this property can be improved by carburizing the surface of the tool while still retaining its shock-resistant characteristics. Primary uses are for battering tools, including hand and pneumatic chisels. The chemical composition, particularly the silicon and tungsten content, provides good hot hardness, too, up to operating temperatures of about 1050 °F, making this tool steel type also adaptable for such hot-work tool applications involving shock loads, as headers, pierces, forming tools, drop forge die inserts, and heavy shear blades.

*AISI S2:* This steel type serves primarily for hand chisels and pneumatic tools, although it also has limited applications for hot work. Although its wear-resistance properties are only moderate, S2 is sometimes used for forming and thread rolling applications, when the resistance to rupturing is more important than extended service life. For hot-work applications, this steel requires heat treatment in a neutral atmosphere to avoid either carburization or decarburization of the surface. Such conditions make this tool steel type particularly susceptible to failure in hot-work uses.

*AISI S5:* This composition is essentially a Silicon–manganese type tool steel with small additions of chromium, molybdenum, and vanadium for the purpose of improved deep hardening and refinement of the grain structure. The most important properties of this steel are its high elastic limit and good ductility, resulting in excellent shock-resisting characteristics, when used at atmospheric temperatures. Its recommended quenching medium is oil, although a water quench may also be applied as long as the design of the tools avoids sharp corners or drastic sectional changes. Typical applications include pneumatic tools in severe service, like chipping chisels, also shear blades, heavy-duty punches, and bending rolls. Occasionally, this steel is also used for structural applications, like shanks for carbide tools and machine parts subject to shocks.

**Mold Steels.**—These materials differ from all other types of tool steels by their very low-carbon content, generally requiring carburizing to obtain a hard operating surface. A special property of most steel types in this group is the adaptability to shaping by impression (hobbing) instead of by conventional machining. They also have high resistance to decarburization in heat treatment and dimensional stability, characteristics that obviate the need for grinding following heat treatment. Molding dies for plastics materials require an excellent surface finish, even to the degree of high luster; the generally high-chromium content of these types of tool steels greatly aids in meeting this requirement.

*Properties and Applications of Frequently Used Mold Steel Types: AISI P3 and P4:*

Essentially, both types of tool steels were developed for the same special purpose, that is, the making of plastics molds. The application conditions of plastics molds require high core strength, good wear resistance at elevated temperature, and excellent surface finish. Both types are carburizing steels that possess good dimensional stability. Because hob-

<sup>a</sup> Contains also about 1.20 per cent Al. Solution treated in hardening.<sup>b</sup> Quenched in oil.<sup>c</sup> After carburizing.<sup>d</sup> Carburized case.<sup>e</sup> Core hardenability.<sup>f</sup> Sometimes brine is used.

bing, that is, sinking the cavity by pressing a punch representing the inverse replica of the cavity into the tool material, is the process by which many plastics mold cavities are produced, good "hobbability" of the tool steels used for this purpose is an important requirement. The different chemistry of these two types of mold steels is responsible for the high core hardness of the P4, which makes it better suited for applications requiring high strength at elevated temperature.

*AISI P6:* This nickel–chromium-type plastics mold steel has exceptional core strength and develops a deep carburized case. Due to the high nickel–chromium content, the cavities of molds made of this steel type are produced by machining rather than by hobbing. An outstanding characteristic of this steel type is the high luster that is produced by polishing of the hard case surface.

*AISI P20:* This general-type mold steel is adaptable to both through hardening and carburized case hardening. In through hardening, an oil quench is used and a relatively lower, yet deeply penetrating hardness is obtained, such as is needed for zinc die-casting dies and injection molds for plastics. After the direct quenching and tempering, carburizing produces a very hard case and comparatively high core hardness. When thus heat treated, this steel is particularly well adapted for making compression, transfer, and plunger-type plastics molds.

**Special-Purpose Tool Steels.**—These steels include several low-alloy types of tool steels that were developed to provide transitional types between the more commonly used basic types of tool steels, and thereby contribute to the balancing of certain conflicting properties such as wear resistance and toughness; to offer intermediate depth of hardening; and to be less expensive than the higher-alloyed types of tool steels.

*Properties and Applications of Frequently Used Special-Purpose Types:* *AISI L6:* This material is a low-alloy-type special-purpose tool steel. The comparatively safe hardening and the fair nondeforming properties, combined with the service advantage of good toughness in comparison to most other oil-hardening types, explains the acceptance of this steel with a rather special chemical composition. The uses of L6 are for tools whose toughness requirements prevail over abrasion-resistant properties, such as forming rolls and forming and trimmer dies in applications where combinations of moderate shock- and wear-resistant properties are sought. The areas of use also include structural parts, like clutch members, pawls, and knuckle pins, that must withstand shock loads and still display good wear properties.

*AISI F2:* This carbon–tungsten type is one of the most abrasion-resistant of all water-hardening tool steels. However, it is sensitive to thermal changes, such as are involved in heat treatment and it is also susceptible to distortions. Consequently, its use is limited to tools of simple shape in order to avoid cracking in hardening. The shallow hardening characteristics of F2 result in a tough core and are desirable properties for certain tool types that, at the same time, require excellent wear-resistant properties.

**Water-Hardening Tool Steels.**—Steel types in this category are made without, or with only a minimum amount of alloying elements and, their heat treatment needs the harsh quenching action of water or brine, hence the general designation of the category.

Water-hardening steels are usually available with different percentages of carbon, to provide properties required for different applications; the classification system lists a carbon range of 0.60 to 1.40 per cent. In practice, however, the steel mills produce these steels in a few varieties of differing carbon content, often giving proprietary designations to each particular group. Typical carbon content limits of frequently used water-hardening tool steels are 0.70–0.90, 0.90–1.10, 1.05–1.20, and 1.20–1.30 per cent. The appropriate group should be chosen according to the intended use, as indicated in the steel selection guide for this category, keeping in mind that whereas higher carbon content results in deeper hardness penetration, it also reduces toughness.

The general system distinguishes the following four grades, listed in the order of decreasing quality: 1) special; 2) extra; 3) standard; and 4) commercial.

The differences between these grades, which are not offered by all steel mills, are defined in principle only. The distinguishing characteristics are purity and consistency, resulting from different degrees of process refinement and inspection steps applied in making the steel. Higher qualities are selected for assuring dependable uniformity and performance of the tools made from the steel.

The groups with higher carbon content are more sensitive to heat-treatment defects and are generally used for the more demanding applications, so the better grades are usually chosen for the high-carbon types and the lower grades for applications where steels with lower carbon content only are needed.

Water-hardening tool steels, although the least expensive, have several drawbacks, but these are quite acceptable in many types of applications. Some limiting properties are the tendency to deformation in heat treatment due to harsh effects of the applied quenching medium, the sensitivity to heat during the use of the tools made of these steels, the only fair degree of toughness, and the shallow penetration of hardness. However, this last-mentioned property may prove a desirable characteristic in certain applications, such as cold-heading dies, because the relatively shallow hard case is supported by the tough, although softer core.

The AISI designation for water-hardening tool steels is W, followed by a numeral indicating the type, primarily defined by the chemical composition, as shown in Table 11.

**Table 11. Water-Hardening Tool Steels—Identifying Chemical Composition and Heat-Treatment Data**

| Chemical Composition in Per Cent                                |   | AISI Types                    |                                      |                    |              |                 |           |
|---|---|-------------------------------|--------------------------------------|--------------------|--------------|-----------------|-----------|
|   |   | W1                            | W2                                   | W5                 |              |                 |           |
| C   | 0.60–1.40   | 0.60–1.40                     | 1.10                                 |                    |              |                 |           |
| V   | Varying carbon content may be available                           |                               |                                      |                    |              |                 |           |
| Cr  | ...   | 0.25                          | ...                                  |                    |              |                 |           |
| Mn  | These elements are adjusted to satisfy the hardening requirements |                               |                                      |                    |              |                 |           |

| D   | C   | A                             | E                                    | A                  | E            | D/E             | C/D       |

*Water-Hardening Type W1 (Plain Carbon) Tool Steels, Recommended Applications:*

*Group I (C-0.70 to 0.90%):* This group is relatively tough and therefore preferred for tools that are subjected to shocks or abusive treatment. Used for such applications as: hand tools, chisels, screwdriver blades, cold punches, and nail sets, and fixture elements, vise jaws, anvil faces, and chuck jaws.

*Group II (C-0.90 to 1.10%):* This group combines greater hardness with fair toughness, resulting in improved cutting capacity and moderate ability to sustain shock loads. Used for such applications as: hand tools, knives, center punches, pneumatic chisels, cutting tools, reamers, hand taps, and threading dies, wood augers; die parts, drawing and heading dies, shear knives, cutting and forming dies; and fixture elements, drill bushings, lathe centers, collets, and fixed gages.

*Group III (C-1.05 to 1.20%):* The higher carbon content of this group increases the depth of hardness penetrations, yet reduces toughness, thus the resistance to shock loads. Preferred for applications where wear resistance and cutting ability are the prime considerations. Used for such applications as: hand tools, woodworking chisels, paper knives, cutting tools (for low-speed applications), milling cutters, reamers, planer tools, thread chasers, center drills, die parts, cold blanking, coining, bending dies.

*Group IV (C-1.20 to 1–30%):* The high carbon content of this group produces a hard case of considerable depth with improved wear resistance yet sensitive to shock and concentrated stresses. Selected for applications where the capacity to withstand abrasive wear is needed, and where the retention of a keen edge or the original shape of the tool is important. Used for such applications as: cutting tools for finishing work, like cutters and reamers, and for cutting chilled cast iron and forming tools, for ferrous and nonferrous metals, and burnishing tools.

By adding small amounts of alloying elements to W-steel types 2 and 5, certain characteristics that are desirable for specific applications are improved. The vanadium in type 2 contributes to retaining a greater degree of fine-grain structure after heat treating. Chromium in type 5 improves the deep-hardening characteristics of the steel, a property needed for large sections, and assists in maintaining the keen cutting edge that is desirable in cutting tools like broaches, reamers, threading taps, and dies.

### Mill Production Forms of Tool Steels

Tool steels are produced in many different forms, but not all those listed in the following are always readily available; certain forms and shapes are made for special orders only.

*Hot-Finished Bars and Cold-Finished Bars:* These bars are the most commonly produced forms of tool steels. Bars can be furnished in many different cross-sections, the round shape being the most common. Sizes can vary over a wide range, with a more limited number of standard stock sizes. Various conditions may also be available, however, technological limitations prevent all conditions applying to every size, shape, or type of steel. Tool steel bars may be supplied in one of the following conditions and surface finishes:

*Conditions:* Hot-rolled or forged (natural); hot-rolled or forged and annealed; hot-rolled or forged and heat-treated; cold- or hot-drawn (as drawn); and cold- or hot-drawn and annealed.

*Finishes:* Hot-rolled finish (scale not removed); pickled or blast-cleaned; cold-drawn; turned or machined; rough ground; centerless ground or precision flat ground; and polished (rounds only).

Other forms in which tool steels are supplied are the following:

*Rolled or Forged Special Shapes:* These shapes are usually produced on special orders only, for the purpose of reducing material loss and machining time in the large-volume manufacture of certain frequently used types of tools.

*Forgings:* All types of tool steels may be supplied in the form of forgings, that are usually specified for special shapes and for dimensions that are beyond the range covered by bars.

*Wires:* Tool steel wires are produced either by hot or cold drawing and are specified when special shapes, controlled dimensional accuracy, improved surface finish, or special mechanical properties are required. Round wire is commonly produced within an approximate size range of 0.015 to 0.500 inch, and these dimensions also indicate the limits within which other shapes of tool steel wires, like oval, square, or rectangular, may be produced.

*Drill Rods:* Rods are produced in round, rectangular, square, hexagonal, and octagonal shapes, usually with tight dimensional tolerances to eliminate subsequent machining, thereby offering manufacturing economies for the users.

*Hot-Rolled Plates and Sheets, and Cold-Rolled Strips:* Such forms of tool steel are generally specified for the high-volume production of specific tool types.

**Tool Bits:** These pieces are semifinished tools and are used by clamping in a tool holder or shank in a manner permitting ready replacement. Tool bits are commonly made of high-speed types of tool steels, mostly in square, but also in round, rectangular, and other shapes. Tool bits are made of hot rolled bars and are commonly, yet not exclusively, supplied in hardened and ground form, ready for use after the appropriate cutting edges are ground, usually in the user's plant.

**Hollow Bars:** These bars are generally produced by trepanning, boring, or drilling of solid round rods and are used for making tools or structural parts of annular shapes, like rolls, ring gages, bushings, etc.

**Tolerances of Dimensions.**—Such tolerances have been developed and published by the American Iron and Steel Institute (AISI) as a compilation of available industry experience that, however, does not exclude the establishment of closer tolerances, particularly for hot rolled products manufactured in large quantities. The tolerances differ for various categories of production processes (e.g., forged, hot-rolled, cold-drawn, centerless ground) and of general shapes.

**Allowances for Machining.**—These allowances provide freedom from soft spots and defects of the tool surface, thereby preventing failures in heat treatment or in service. After a layer of specific thickness, known as the allowance, has been removed, the bar or other form of tool steel material should have a surface without decarburization and other surface defects, such as scale marks or seams. The industry wide accepted machining allowance values for tool steels in different conditions, shapes, and size ranges are spelled out in AISI specifications and are generally also listed in the tool steel catalogs of the producer companies.

**Decarburization Limits.**—Heating of steel for production operation causes the oxidation of the exposed surfaces resulting in the loss of carbon. That condition, called decarburization, penetrates to a certain depth from the surface, depending on the applied process, the shape and the dimensions of the product. Values of tolerance for decarburization must be considered as one of the factors for defining the machining allowances, which must also compensate for expected variations of size and shape, the dimensional effects of heat treatment, and so forth. Decarburization can be present not only in hot-rolled and forged, but also in rough turned and cold-drawn conditions.

**Advances in Tool Steel Making Technology.**—Significant advances in processes for tool steel production have been made that offer more homogeneous materials of greater density and higher purity for applications where such extremely high quality is required. Two of these methods of tool steel production are of particular interest.

**Vacuum-melted tool steels:** These steels are produced by the consumable electrode method, which involves remelting of the steel originally produced by conventional processes. Inside a vacuum-tight shell that has been evacuated, the electrode cast of tool steel of the desired chemical analysis is lowered into a water-cooled copper mold where it strikes a low-voltage, high-amperage arc causing the electrode to be consumed by gradual melting. The undesirable gases and volatiles are drawn off by the vacuum, and the inclusions float on the surface of the pool, accumulating on the top of the produced ingot, to be removed later by cropping. In the field of tool steels, the consumable-electrode vacuum-melting (CVM) process is applied primarily to the production of special grades of hot-work and high-speed tool steels.

**High-speed tool steels produced by powder metallurgy:** The steel produced by conventional methods is reduced to a fine powder by a gas atomization process. The powder is compacted by a hot isostatic method with pressures in the range of 15,000 to 17,000 psi. The compacted billets are hot-rolled to the final bar size, yielding a tool-steel material which has 100 per cent theoretical density. High-speed tool steels produced by the P/M method offer a tool material providing increased tool wear life and high impact strength, of particular advantage in interrupted cuts.

## HARDENING, TEMPERING, AND ANNEALING

### Heat Treatment Of Standard Steels

**Heat-Treating Definitions.**—This glossary of heat-treating terms has been adopted by the American Foundrymen's Association, the American Society for Metals, the American Society for Testing and Materials, and the Society of Automotive Engineers. Since it is not intended to be a specification but is strictly a set of definitions, temperatures have purposely been omitted.

**Aging:** Describes a time–temperature-dependent change in the properties of certain alloys. Except for strain aging and age softening, it is the result of precipitation from a solid solution of one or more compounds whose solubility decreases with decreasing temperature. For each alloy susceptible to aging, there is a unique range of time–temperature combinations to which it will respond.

**Annealing:** A term denoting a treatment, consisting of heating to and holding at a suitable temperature followed by cooling at a suitable rate, used primarily to soften but also to simultaneously produce desired changes in other properties or in microstructure. The purpose of such changes may be, but is not confined to, improvement of machinability; facilitation of cold working; improvement of mechanical or electrical properties; or increase in stability of dimensions. The time–temperature cycles used vary widely both in maximum temperature attained and in cooling rate employed, depending on the composition of the material, its condition, and the results desired. When applicable, the following more specific process names should be used: Black Annealing, Blue Annealing, Box Annealing, Bright Annealing, Cycle Annealing, Flame Annealing, Full Annealing, Graphitizing, Intermediate Annealing, Isothermal Annealing, Process Annealing, Quench Annealing, and Spheroidizing. When the term is used without qualification, full annealing is implied. When applied only for the relief of stress, the process is properly called stress relieving.

**Black Annealing:** Box annealing or pot annealing, used mainly for sheet, strip, or wire.

**Blue Annealing:** Heating hot-rolled sheet in an open furnace to a temperature within the transformation range and then cooling in air, to soften the metal. The formation of a bluish oxide on the surface is incidental.

**Box Annealing:** Annealing in a sealed container under conditions that minimize oxidation. In box annealing, the charge is usually heated slowly to a temperature below the transformation range, but sometimes above or within it, and is then cooled slowly; this process is also called “close annealing” or “pot annealing.”

**Bright Annealing:** Annealing in a protective medium to prevent discoloration of the bright surface.

**Cycle Annealing:** An annealing process employing a predetermined and closely controlled time–temperature cycle to produce specific properties or microstructure.

**Flame Annealing:** Annealing in which the heat is applied directly by a flame.

**Full Annealing:** Austenitizing and then cooling at a rate such that the hardness of the product approaches a minimum.

**Graphitizing:** Annealing in such a way that some or all of the carbon is precipitated as graphite.

**Intermediate Annealing:** Annealing at one or more stages during manufacture and before final thermal treatment.

**Isothermal Annealing:** Austenitizing and then cooling to and holding at a temperature at which austenite transforms to a relatively soft ferrite-carbide aggregate.

**Process Annealing:** An imprecise term used to denote various treatments that improve workability. For the term to be meaningful, the condition of the material and the time–temperature cycle used must be stated.

**Quench Annealing:** Annealing an austenitic alloy by *Solution Heat Treatment*.

**Spheroidizing:** Heating and cooling in a cycle designed to produce a spheroidal or globular form of carbide.

*Austempering:* Quenching from a temperature above the transformation range, in a medium having a rate of heat abstraction high enough to prevent the formation of high-temperature transformation products, and then holding the alloy, until transformation is complete, at a temperature below that of pearlite formation and above that of martensite formation.

*Austenitizing:* Forming austenite by heating into the transformation range (partial austenitizing) or above the transformation range (complete austenitizing). When used without qualification, the term implies complete austenitizing.

*Baking:* Heating to a low temperature in order to remove entrained gases.

*Bluing:* A treatment of the surface of iron-base alloys, usually in the form of sheet or strip, on which, by the action of air or steam at a suitable temperature, a thin blue oxide film is formed on the initially scale-free surface, as a means of improving appearance and resistance to corrosion. This term is also used to denote a heat treatment of springs after fabrication, to reduce the internal stress created by coiling and forming.

*Carbon Potential:* A measure of the ability of an environment containing active carbon to alter or maintain, under prescribed conditions, the carbon content of the steel exposed to it. In any particular environment, the carbon level attained will depend on such factors as temperature, time, and steel composition.

*Carbon Restoration:* Replacing the carbon lost in the surface layer from previous processing by carburizing this layer to substantially the original carbon level.

*Carbonitriding:* A case-hardening process in which a suitable ferrous material is heated above the lower transformation temperature in a gaseous atmosphere of such composition as to cause simultaneous absorption of carbon and nitrogen by the surface and, by diffusion, create a concentration gradient. The process is completed by cooling at a rate that produces the desired properties in the workpiece.

*Carburizing:* A process in which carbon is introduced into a solid iron-base alloy by heating above the transformation temperature range while in contact with a carbonaceous material that may be a solid, liquid, or gas. Carburizing is frequently followed by quenching to produce a hardened case.

*Case:* 1) The surface layer of an iron-base alloy that has been suitably altered in composition and can be made substantially harder than the interior or core by a process of case hardening; and 2) the term case is also used to designate the hardened surface layer of a piece of steel that is large enough to have a distinctly softer core or center.

*Cementation:* The process of introducing elements into the outer layer of metal objects by means of high-temperature diffusion.

*Cold Treatment:* Exposing to suitable subzero temperatures for the purpose of obtaining desired conditions or properties, such as dimensional or microstructural stability. When the treatment involves the transformation of retained austenite, it is usually followed by a tempering treatment.

*Conditioning Heat Treatment:* A preliminary heat treatment used to prepare a material for a desired reaction to a subsequent heat treatment. For the term to be meaningful, the treatment used must be specified.

*Controlled Cooling:* A term used to describe a process by which a steel object is cooled from an elevated temperature, usually from the final hot-forming operation in a predetermined manner of cooling to avoid hardening, cracking, or internal damage.

*Core:* 1) The interior portion of an iron-base alloy that after case hardening is substantially softer than the surface layer or case; and 2) the term core is also used to designate the relatively soft central portion of certain hardened tool steels.

*Critical Range or Critical Temperature Range:* Synonymous with *Transformation Range*, which is preferred.

*Cyaniding:* A process of case hardening an iron-base alloy by the simultaneous absorption of carbon and nitrogen by heating in a cyanide salt. Cyaniding is usually followed by quenching to produce a hard case.

*Decarburization:* The loss of carbon from the surface of an iron-base alloy as the result of heating in a medium that reacts with the carbon.

*Drawing:* Drawing, or drawing the temper, is synonymous with *Tempering*, which is preferable.

*Eutectic Alloy:* The alloy composition that freezes at constant temperature similar to a pure metal. The lowest melting (or freezing) combination of two or more metals. The alloy structure (homogeneous) of two or more solid phases formed from the liquid eutectically.

*Hardenability:* In a ferrous alloy, the property that determines the depth and distribution of hardness induced by quenching.

*Hardening:* Any process of increasing hardness of metal by suitable treatment, usually involving heating and cooling. See also *Aging*.

*Hardening, Case:* A process of surface hardening involving a change in the composition of the outer layer of an iron-base alloy followed by appropriate thermal treatment. Typical case-hardening processes are *Carburizing*, *Cyaniding*, *Carbonitriding*, and *Nitriding*.

*Hardening, Flame:* A process of heating the surface layer of an iron-base alloy above the transformation temperature range by means of a high-temperature flame, followed by quenching.

*Hardening, Precipitation:* A process of hardening an alloy in which a constituent precipitates from a supersaturated solid solution. See also *Aging*.

*Hardening, Secondary:* An increase in hardness following the normal softening that occurs during the tempering of certain alloy steels.

*Heating, Differential:* A heating process by which the temperature is made to vary throughout the object being heated so that on cooling, different portions may have such different physical properties as may be desired.

*Heating, Induction:* A process of local heating by electrical induction.

*Heat Treatment:* A combination of heating and cooling operations applied to a metal or alloy in the solid state to obtain desired conditions or properties. Heating for the sole purpose of hot working is excluded from the meaning of this definition.

*Heat Treatment, Solution:* A treatment in which an alloy is heated to a suitable temperature and held at this temperature for a sufficient length of time to allow a desired constituent to enter into solid solution, followed by rapid cooling to hold the constituent in solution. The material is then in a supersaturated, unstable state, and may subsequently exhibit *Age Hardening*.

*Homogenizing:* A high-temperature heat-treatment process intended to eliminate or to decrease chemical segregation by diffusion.

*Isothermal Transformation:* A change in phase at constant temperature.

*Malleablizing:* A process of annealing white cast iron in which the combined carbon is wholly or in part transformed to graphitic or free carbon and, in some cases, part of the carbon is removed completely. See *Temper Carbon*.

*Maraging:* A precipitation hardening treatment applied to a special group of iron-base alloys to precipitate one or more intermetallic compounds in a matrix of essentially carbon-free martensite.

*Martempering:* A hardening procedure in which an austenitized ferrous workpiece is quenched into an appropriate medium whose temperature is maintained substantially at the  $M_s$  of the workpiece, held in the medium until its temperature is uniform throughout but not long enough to permit bainite to form, and then cooled in air. The treatment is followed by tempering.

*Nitriding:* A process of case hardening in which an iron-base alloy of special composition is heated in an atmosphere of ammonia or in contact with nitrogenous material. Surface hardening is produced by the absorption of nitrogen without quenching.

*Normalizing:* A process in which an iron-base alloy is heated to a temperature above the transformation range and subsequently cooled in still air at room temperature.

*Overheated:* A metal is said to have been overheated if, after exposure to an unduly high temperature, it develops an undesirably coarse grain structure but is not permanently damaged. The structure damaged by overheating can be corrected by suitable heat treatment or by mechanical work or by a combination of the two. In this respect it differs from a Burnt structure.

*Patenting:* A process of heat treatment applied to medium- or high-carbon steel in wire making prior to the wire drawing or between drafts. It consists in heating to a temperature above the transformation range, followed by cooling to a temperature below that range in air or in a bath of molten lead or salt maintained at a temperature appropriate to the carbon content of the steel and the properties required of the finished product.

*Preheating:* Heating to an appropriate temperature immediately prior to austenitizing when hardening high-hardenability constructional steels, many of the tool steels, and heavy sections.

*Quenching:* Rapid cooling. When applicable, the following more specific terms should be used: Direct Quenching, Fog Quenching, Hot Quenching, Interrupted Quenching, Selective Quenching, Slack Quenching, Spray Quenching, and Time Quenching.

*Direct Quenching:* Quenching carburized parts directly from the carburizing operation.

*Fog Quenching:* Quenching in a mist.

*Hot Quenching:* An imprecise term used to cover a variety of quenching procedures in which a quenching medium is maintained at a prescribed temperature above 160 degrees F (71 degrees C).

*Interrupted Quenching:* A quenching procedure in which the workpiece is removed from the first quench at a temperature substantially higher than that of the quenchant and is then subjected to a second quenching system having a different cooling rate than the first.

*Selective Quenching:* Quenching only certain portions of a workpiece.

*Slack Quenching:* The incomplete hardening of steel due to quenching from the austenitizing temperature at a rate slower than the critical cooling rate for the particular steel, resulting in the formation of one or more transformation products in addition to martensite.

*Spray Quenching:* Quenching in a spray of liquid.

*Time Quenching:* Interrupted quenching in which the duration of holding in the quenching medium is controlled.

*Soaking:* Prolonged heating of a metal at a selected temperature.

*Stabilizing Treatment:* A treatment applied to stabilize the dimensions of a workpiece or the structure of a material such as 1) before finishing to final dimensions, heating a workpiece to or somewhat beyond its operating temperature and then cooling to room temperature a sufficient number of times to ensure stability of dimensions in service; 2) transforming retained austenite in those materials that retain substantial amounts when quench hardened (see cold treatment); and 3) heating a solution-treated austenitic stainless steel that contains controlled amounts of titanium or niobium plus tantalum to a temperature below the solution heat-treating temperature to cause precipitation of finely divided, uniformly distributed carbides of those elements, thereby substantially reducing the amount of carbon available for the formation of chromium carbides in the grain boundaries on subsequent exposure to temperatures in the sensitizing range.

*Stress Relieving:* A process to reduce internal residual stresses in a metal object by heating the object to a suitable temperature and holding for a proper time at that temperature. This treatment may be applied to relieve stresses induced by casting, quenching, normalizing, machining, cold working, or welding.

*Temper Carbon:* The free or graphitic carbon that comes out of solution usually in the form of rounded nodules in the structure during *Graphitizing* or *Malleablizing*.

*Tempering:* Heating a quench-hardened or normalized ferrous alloy to a temperature below the transformation range to produce desired changes in properties.

*Double Tempering:* A treatment in which quench hardened steel is given two complete tempering cycles at substantially the same temperature for the purpose of ensuring completion of the tempering reaction and promoting stability of the resulting microstructure.

*Snap Temper:* A precautionary interim stress-relieving treatment applied to high hardenability steels immediately after quenching to prevent cracking because of delay in tempering them at the prescribed higher temperature.

*Temper Brittleness:* Brittleness that results when certain steels are held within, or are cooled slowly through, a certain range of temperatures below the transformation range. The brittleness is revealed by notched-bar impact tests at or below room temperature.

*Transformation Ranges or Transformation Temperature Ranges:* Those ranges of temperature within which austenite forms during heating and transforms during cooling. The two ranges are distinct, sometimes overlapping but never coinciding. The limiting temperatures of the ranges depend on the composition of the alloy and on the rate of change of temperature, particularly during cooling.

*Transformation Temperature:* The temperature at which a change in phase occurs. The term is sometimes used to denote the limiting temperature of a transformation range. The following symbols are used for iron and steels:

$Ac_{cm}$  = In hypereutectoid steel, the temperature at which the solution of cementite in austenite is completed during heating

$Ac_1$  = The temperature at which austenite begins to form during heating

$Ac_3$  = The temperature at which transformation of ferrite to austenite is completed during heating

$Ac_4$  = The temperature at which austenite transforms to delta ferrite during heating

$Ae_1, Ae_3, Ae_{cm}, Ae_4$  = The temperatures of phase changes at equilibrium

$Ar_{cm}$  = In hypereutectoid steel, the temperature at which precipitation of cementite starts during cooling

$Ar_1$  = The temperature at which transformation of austenite to ferrite or to ferrite plus cementite is completed during cooling

$Ar_3$  = The temperature at which austenite begins to transform to ferrite during cooling

$Ar_4$  = The temperature at which delta ferrite transforms to austenite during cooling

$M_s$  = The temperature at which transformation of austenite to martensite starts during cooling

$M_f$  = The temperature, during cooling, at which transformation of austenite to martensite is substantially completed

All these changes except the formation of martensite occur at lower temperatures during cooling than during heating, and depend on the rate of change of temperature.

**Hardness and Hardenability.**—Hardenability is the property of steel that determines the *depth and distribution of hardness* induced by quenching from the austenitizing temperature. Hardenability should not be confused with hardness as such or with maximum hardness. Hardness is a measure of the ability of a metal to resist penetration as determined by any one of a number of standard tests (Brinell, Rockwell, Vickers, etc). The maximum attainable hardness of any steel depends solely on carbon content and is not significantly affected by alloy content. Maximum hardness is realized only when the cooling rate in quenching is rapid enough to ensure full transformation to martensite.

The as-quenched surface hardness of a steel part is dependent on carbon content and cooling rate, but the *depth* to which a certain hardness level is maintained with given quenching conditions is a function of its hardenability. Hardenability is largely determined by the percentage of alloying elements in the steel; however, austenite grain size, time and temperature during austenitizing, and prior microstructure also significantly affect the hardness depth. The hardenability required for a particular part depends on size, design, and service stresses. For highly stressed parts, the best combination of strength and toughness is obtained by through hardening to a martensitic structure followed by adequate tempering. There are applications, however, where through hardening is not necessary or even

desirable. For parts that are stressed principally at or near the surface, or in which wear resistance or resistance to shock loading is anticipated, a shallow hardening steel with a moderately soft core may be appropriate.

For through hardening of thin sections, carbon steels may be adequate; but as section size increases, alloy steels of increasing hardenability are required. The usual practice is to select the most economical grade that can meet the desired properties consistently. It is not good practice to utilize a higher alloy grade than necessary, because excessive use of alloying elements adds little to the properties and can sometimes induce susceptibility to quenching cracks.

*Quenching Media:* The choice of quenching media is often a critical factor in the selection of steel of the proper hardenability for a particular application. Quenching severity can be varied by selection of quenching medium, agitation control, and additives that improve the cooling capability of the quenchant. Increasing the quenching severity permits the use of less expensive steels of lower hardenability; however, consideration must also be given to the amount of distortion that can be tolerated and the susceptibility to quench cracking. In general, the more severe the quenchant and the less symmetrical the part being quenched, the greater are the size and shape changes that result from quenching and the greater is the risk of quench cracking. Consequently, although water quenching is less costly than oil quenching, and water quenching steels are less expensive than those requiring oil quenching, it is important to know that the parts being hardened can withstand the resulting distortion and the possibility of cracking.

Oil, salt, and synthetic water-polymer quenchant are also used, but they often require steels of higher alloy content and hardenability. A general rule for the selection of steel and quenchant for a particular part is that the steel should have a hardenability not exceeding that required by the severity of the quenchant selected. The carbon content of the steel should also not exceed that required to meet specified hardness and strength, because quench cracking susceptibility increases with carbon content.

The choice of quenching media is important in hardening, but another factor is agitation of the quenching bath. The more rapidly the bath is agitated, the more rapidly heat is removed from the steel and the more effective is the quench.

*Hardenability Test Methods:* The most commonly used method for determining hardenability is the end-quench test developed by Jominy and Boegehold, and described in detail in both SAE J406 and ASTM A255. In this test a normalized 1-inch-round, approximately 4-inch-long specimen of the steel to be evaluated is heated uniformly to its austenitizing temperature. The specimen is then removed from the furnace, placed in a jig, and immediately end quenched by a jet of room-temperature water. The water is played on the end face of the specimen, without touching the sides, until the entire specimen has cooled. Longitudinal flat surfaces are ground on opposite sides of the piece and Rockwell C scale hardness readings are taken at  $\frac{1}{16}$ -inch intervals from the quenched end. The resulting data are plotted on graph paper with the hardness values as ordinates ( $y$ -axis) and distances from the quenched end as abscissas ( $x$ -axis). Representative data have been accumulated for a variety of standard steel grades and are published by SAE and AISI as "H-bands." These data show graphically and in tabular form the high and low limits applicable to each grade. The suffix H following the standard AISI/SAE numerical designation indicates that the steel has been produced to specific hardenability limits.

Experiments have confirmed that the cooling rate at a given point along the Jominy bar corresponds closely to the cooling rate at various locations in round bars of various sizes. In general, when end-quench curves for different steels coincide approximately, similar treatments will produce similar properties in sections of the same size. On occasion it is necessary to predict the end-quench hardenability of a steel not available for testing, and reasonably accurate means of calculating hardness for any Jominy location on a section of steel of known analysis and grain size have been developed.

**Tempering:** As-quenched steels are in a highly stressed condition and are seldom used without tempering. Tempering imparts plasticity or toughness to the steel, and is inevitably accompanied by a loss in hardness and strength. The loss in strength, however, is only incidental to the very important increase in toughness, which is due to the relief of residual stresses induced during quenching and to precipitation, coalescence, and spheroidization of iron and alloy carbides resulting in a microstructure of greater plasticity.

Alloying slows the tempering rate, so that alloy steel requires a higher tempering temperature to obtain a given hardness than carbon steel of the same carbon content. The higher tempering temperature for a given hardness permits a greater relaxation of residual stress and thereby improves the steel's mechanical properties. Tempering is done in furnaces or in oil or salt baths at temperatures varying from 300 to 1200 degrees F. With most grades of alloy steel, the range between 500 and 700 degrees F is avoided because of a phenomenon known as "blue brittleness," which reduces impact properties. Tempering the martensitic stainless steels in the range of 800-1100 degrees F is not recommended because of the low and erratic impact properties and reduced corrosion resistance that result. Maximum toughness is achieved at higher temperatures. It is important to temper parts as soon as possible after quenching, because any delay greatly increases the risk of cracking resulting from the high-stress condition in the as-quenched part.

**Surface Hardening Treatment (Case Hardening).**—Many applications require high hardness or strength primarily at the surface, and complex service stresses frequently require not only a hard, wear-resistant surface, but also core strength and toughness to withstand impact stress.

To achieve these different properties, two general processes are used: 1) The chemical composition of the surface is altered, prior to or after quenching and tempering; the processes used include carburizing, nitriding, cyaniding, and carbonitriding; and 2) Only the surface layer is hardened by the heating and quenching process; the most common processes used for surface hardening are flame hardening and induction hardening.

**Carburizing:** Carbon is diffused into the part's surface to a controlled depth by heating the part in a carbonaceous medium. The resulting depth of carburization, commonly referred to as case depth, depends on the carbon potential of the medium used and the time and temperature of the carburizing treatment. The steels most suitable for carburizing to enhance toughness are those with sufficiently low carbon contents, usually below 0.03 per cent. Carburizing temperatures range from 1550 to 1750 degrees F, with the temperature and time at temperature adjusted to obtain various case depths. Steel selection, hardenability, and type of quench are determined by section size, desired core hardness, and service requirements.

Three types of carburizing are most often used: 1) *Liquid carburizing* involves heating the steel in molten barium cyanide or sodium cyanide. The case absorbs some nitrogen in addition to carbon, thus enhancing surface hardness; 2) *Gas carburizing* involves heating the steel in a gas of controlled carbon content. When used, the carbon level in the case can be closely controlled; and 3) *Pack carburizing*, which involves sealing both the steel and solid carbonaceous material in a gas-tight container, then heating this combination.

With any of these methods, the part may be either quenched after the carburizing cycle without reheating or air cooled followed by reheating to the austenitizing temperature prior to quenching. The case depth may be varied to suit the conditions of loading in service. However, service characteristics frequently require that only selective areas of a part have to be case hardened. Covering the areas not to be cased, with copper plating or a layer of commercial paste, allows the carbon to penetrate only the exposed areas. Another method involves carburizing the entire part, then removing the case in selected areas by machining, prior to quench hardening.

**Nitriding:** The steel part is heated to a temperature of 900-1150 degrees F in an atmosphere of ammonia gas and dissociated ammonia for an extended period of time that

depends on the case depth desired. A thin, very hard case results from the formation of nitrides. Strong nitride-forming elements (chromium and molybdenum) are required to be present in the steel, and often special nonstandard grades containing aluminum (a strong nitride former) are used. The major advantage of this process is that parts can be quenched and tempered, then machined, prior to nitriding, because only a little distortion occurs during nitriding.

**Cyaniding:** This process involves heating the part in a bath of sodium cyanide to a temperature slightly above the transformation range, followed by quenching, to obtain a thin case of high hardness.

**Carbonitriding:** This process is similar to cyaniding except that the absorption of carbon and nitrogen is accomplished by heating the part in a gaseous atmosphere containing hydrocarbons and ammonia. Temperatures of 1425–1625 degrees F are used for parts to be quenched, and lower temperatures, 1200–1450 degrees F, may be used where a liquid quench is not required.

**Flame Hardening:** This process involves rapid heating with a direct high-temperature gas flame, such that the surface layer of the part is heated above the transformation range, followed by cooling at a rate that causes the desired hardening. Steels for flame hardening are usually in the range of 0.30–0.60 per cent carbon, with hardenability appropriate for the case depth desired and the quenchant used. The quenchant is usually sprayed on the surface a short distance behind the heating flame. Immediate tempering is required and may be done in a conventional furnace or by a flame-tempering process, depending on part size and costs.

**Induction Hardening:** This process is similar in many respects to flame hardening except that the heating is caused by a high-frequency electric current sent through a coil or inductor surrounding the part. The depth of heating depends on the frequency, the rate of heat conduction from the surface, and the length of the heating cycle. Quenching is usually accomplished with a water spray introduced at the proper time through jets in or near the inductor block or coil. In some instances, however, parts are oil-quenched by immersing them in a bath of oil after they reach the hardening temperature.

**Structure of Fully Annealed Carbon Steel.**—In carbon steel that has been fully annealed, there are normally present, apart from such impurities as phosphorus and sulfur, two constituents: the element iron in a form metallurgically known as *ferrite* and the chemical compound iron carbide in the form metallurgically known as *cementite*. This latter constituent consists of 6.67 per cent carbon and 93.33 per cent iron. A certain proportion of these two constituents will be present as a mechanical mixture. This mechanical mixture, the amount of which depends on the carbon content of the steel, consists of alternate bands or layers of ferrite and cementite. Under the microscope, the matrix frequently has the appearance of mother-of-pearl and hence has been named *pearlite*. Pearlite contains about 0.85 per cent carbon and 99.15 per cent iron, neglecting impurities. A fully annealed steel containing 0.85 per cent carbon would consist entirely of pearlite. Such a steel is known as *eutectoid* steel and has a laminated structure characteristic of a eutectic alloy. Steel that has less than 0.85 per cent carbon (*hypoeutectoid* steel) has an excess of ferrite above that required to mix with the cementite present to form pearlite; hence, both ferrite and pearlite are present in the fully annealed state. Steel having a carbon content greater than 0.85 per cent (*hypereutectoid* steel) has an excess of cementite over that required to mix with the ferrite to form pearlite; hence, both cementite and pearlite are present in the fully annealed state. The structural constitution of carbon steel in terms of ferrite, cementite, pearlite and austenite for different carbon contents and at different temperatures is shown by the accompanying figure, *Phase Diagram of Carbon Steel*.

**Effect of Heating Fully Annealed Carbon Steel.**—When carbon steel in the fully annealed state is heated above the lower critical point, which is some temperature in the range of 1335 to 1355 degrees F (depending on the carbon content), the alternate bands or

layers of ferrite and cementite that make up the pearlite begin to merge into each other. This process continues until the pearlite is thoroughly "dissolved," forming what is known as *austenite*. If the temperature of the steel continues to rise and there is present, in addition to the pearlite, any excess ferrite or cementite, this also will begin to dissolve into the austenite until finally only austenite will be present. The temperature at which the excess ferrite or cementite is completely dissolved in the austenite is called the *upper critical point*. This temperature varies with the carbon content of the steel much more widely than the lower critical point (see Fig. 1).  [LIVE GRAPH](#)  
[Click here to view](#)

Fig. 1. Phase Diagram of Carbon Steel

**Effect of Slow Cooling on Carbon Steel.**—If carbon steel that has been heated to the point where it consists entirely of austenite is slowly cooled, the process of transformation that took place during the heating will be reversed, but the upper and lower critical points will occur at somewhat lower temperatures than they do on heating. Assuming that the steel was originally fully annealed, its structure on returning to atmospheric temperature after slow cooling will be the same as before in terms of the proportions of ferrite or cementite and pearlite present. The austenite will have entirely disappeared.

**Effect of Rapid Cooling or Quenching on Carbon Steel.**—Observations have shown that as the rate at which carbon steel is cooled from an austenitic state is increased, the temperature at which the austenite begins to change into pearlite drops more and more below the slow cooling transformation temperature of about 1300 degrees F. (For example, a 0.80 per cent carbon steel that is cooled at such a rate that the temperature drops 500 degrees in one second will show transformation of austenite beginning at 930 degrees F.) As the cooling rate is increased, the laminations of the pearlite formed by the transformation of the austenite become finer and finer up to the point where they cannot be detected under a high-power microscope, while the steel itself increases in hardness and tensile strength. As the rate of cooling is still further increased, this transformation temperature suddenly drops to around 500 degrees F or lower, depending on the carbon content of the steel. The cooling rate at which this sudden drop in transformation temperature takes place is called the *critical cooling rate*. When a piece of carbon steel is quenched at this rate or faster, a new struc-

ture is formed. The austenite is transformed into *martensite*, which is characterized by an angular needlelike structure and a very high hardness.

If carbon steel is subjected to a severe quench or to extremely rapid cooling, a small percentage of the austenite, instead of being transformed into martensite during the quenching operation, may be retained. Over a period of time, however, this remaining austenite tends to be gradually transformed into martensite even though the steel is not subjected to further heating or cooling. Martensite has a lower density than austenite, and such a change, or "aging" as it is called, often results in an appreciable increase in volume or "growth" and the setting up of new internal stresses in the steel.

**Steel Heat-Treating Furnaces.**—Various types of furnaces heated by gas, oil, or electricity are used for the heat treatment of steel. These furnaces include the oven or box type in various modifications for "in-and-out" or for continuous loading and unloading; the retort type; the pit type; the pot type; and the salt-bath electrode type.

*Oven or Box Furnaces:* This type of furnace has a box or oven-shaped heating chamber. The "in-and-out" oven furnaces are loaded by hand or by a track-mounted car that, when rolled into the furnace, forms the bottom of the heating chamber. The car type is used where heavy or bulky pieces must be handled. Some oven-type furnaces are provided with a full muffle or a semimuffle, which is an enclosed refractory chamber into which the parts to be heated are placed. The full-muffle, being fully enclosed, prevents any flames or burning gases from coming in contact with the work and permits a special atmosphere to be used to protect or condition the work. The semimuffle, which is open at the top, protects the work from direct impingement of the flame although it does not shut off the work from the hot gases. In the direct-heat-type oven furnace, the work is open to the flame. In the electric oven furnace, a retort is provided when gas atmospheres are to be employed to confine the gas and prevent it from attacking the heating elements. Where muffles are used, they must be replaced periodically, and a greater amount of fuel is required than in a direct-heat type of oven furnace.

For continuous loading and unloading, there are several types of furnaces such as rotary hearth car; roller-, furnace belt-, walking-beam, or pusher-conveyor; and a continuous-kiln-type through which track-mounted cars are run. In the continuous type of furnace, the work may pass through several zones that are maintained at different temperatures for preheating, heating, soaking, and cooling.

*Retort Furnace:* This is a vertical type of furnace provided with a cylindrical metal retort into which the parts to be heat-treated are suspended either individually, if large enough, or in a container of some sort. The use of a retort permits special gas atmospheres to be employed for carburizing, nitriding, etc.

*Pit-Type Furnace:* This is a vertical furnace arranged for the loading of parts in a metal basket. The parts within the basket are heated by convection, and when the basket is lowered into place, it fits into the furnace chamber in such a way as to provide a dead-air space to prevent direct heating.

*Pot-Type Furnace:* This furnace is used for the immersion method of heat treating small parts. A cast-alloy pot is employed to hold a bath of molten lead or salt in which the parts are placed for heating.

*Salt Bath Electrode Furnace:* In this type of electric furnace, heating is accomplished by means of electrodes suspended directly in the salt bath. The patented grouping and design of electrodes provide an electromagnetic action that results in an automatic stirring action. This stirring tends to produce an even temperature throughout the bath.

*Vacuum Furnace:* Vacuum heat treatment is a relatively new development in metallurgical processing, with a vacuum substituting for the more commonly used protective gas atmospheres. The most often used furnace is the "cold wall" type, consisting of a water-cooled vessel that is maintained near ambient temperature during operation. During quenching, the chamber is backfilled up to or above atmospheric pressure with an inert gas,

which is circulated by an internal fan. When even faster cooling rates are needed, furnaces are available with capability for liquid quenching, performed in an isolated chamber.

**Fluidized-Bed Furnace:** Fluidized-bed techniques are not new; however, new furnace designs have extended the technology into the temperature ranges required for most common heat treatments. In fluidization, a bed of dry, finely divided particles, typically aluminum oxide, is made to behave like a liquid by feeding gas upward through the bed. An important characteristic of the bed is high-efficiency heat transfer. Applications include continuous or batch-type units for all general heat treatments.

**Physical Properties of Heat-Treated Steels.**—Steels that have been “fully hardened” to the same hardness when quenched will have about the same tensile and yield strengths regardless of composition and alloying elements. When the hardness of such a steel is known, it is also possible to predict its reduction of area and tempering temperature. The accompanying figures illustrating these relationships have been prepared by the Society of Automotive Engineers.

Fig. 1 gives the range of Brinell hardnesses that could be expected for any particular tensile strength or it may be used to determine the range of tensile strengths that would correspond to any particular hardness. Fig. 2 shows the relationship between the tensile strength or hardness and the yield point. The solid line is the normal-expectancy curve. The dotted-line curves give the range of the variation of scatter of the plotted data. Fig. 3 shows the relationship that exists between the tensile strength (or hardness) and the reduction of area. The curve to the left represents the alloy steels and that on the right the carbon steels. Both are normal-expectancy curves and the extremities of the perpendicular lines that intersect them represent the variations from the normal-expectancy curves that may be caused by quality differences and by the magnitude of parasitic stresses induced by quenching. Fig. 4 shows the relationship between the hardness (or approximately equivalent tensile strength) and the tempering temperature. Three curves are given, one for fully hardened steels with a carbon content between 0.40 and 0.55 per cent, one for fully hardened steels with a carbon content between 0.30 and 0.40 per cent, and one for steels that are not fully hardened.

From Fig. 1, it can be seen that for a tensile strength of, say, 200,000 pounds per square inch, the Brinell hardness could range between 375 and 425. By taking 400 as the mean hardness value and using Fig. 4, it can be seen that the tempering temperature of fully hardened steels of 0.40 to 0.55 per cent carbon content would be 990 degrees F and that of fully hardened steels of 0.30 to 0.40 per cent carbon would be 870 degrees F. This chart also shows that the tempering temperature for a steel not fully hardened would approach 520 degrees F. A yield point of  $0.9 \times 200,000$ , or 180,000, pounds per square inch is indicated (Fig. 2) for the fully hardened steel with a tensile strength of 200,000 pounds per square inch. Most alloy steels of 200,000 pounds per square inch tensile strength would probably have a reduction in area of close to 44 per cent (Fig. 3) but some would have values in the range of 35 to 53 per cent. Carbon steels of the same tensile strength would probably have a reduction in area of close to 24 per cent but could possibly range from 17 to 31 per cent.

Figs. 2 and 3 represent steel in the quenched and tempered condition and Fig. 1 represents steel in the hardened and tempered, as-rolled, annealed, and normalized conditions. These charts give a good general indication of mechanical properties; however, more exact information when required should be obtained from tests on samples of the individual heats of steel under consideration.

### Hardening

**Basic Steps in Hardening.**—The operation of hardening steel consists fundamentally of two steps. The first step is to heat the steel to some temperature above (usually at least 100 degrees F above) its transformation point so that it becomes entirely austenitic in structure. The second step is to quench the steel at some rate faster than the critical rate (which

Fig. 1.

Fig. 2.

Fig. 3.

Fig. 4.

depends on the carbon content, the amounts of alloying elements present other than carbon, and the grain size of the austenite) to produce a martensitic structure. The hardness of a martensitic steel depends on its carbon content and ranges from about 460 Brinell at 0.20 per cent carbon to about 710 Brinell above 0.50 carbon. In comparison, ferrite has a hardness of about 90 Brinell, pearlite about 240 Brinell, and cementite around 550 Brinell.

**Critical Points of Decalescence and Recalescence.**—The critical or transformation point at which pearlite is transformed into austenite as it is being heated is also called the *decalescence point*. If the temperature of the steel was observed as it passed through the

decalescence point, it would be noted that it would continue to absorb heat without appreciably rising in temperature, although the immediate surroundings were hotter than the steel. Similarly, the critical or transformation point at which austenite is transformed back into pearlite on cooling is called the *recalescence point*. When this point is reached, the steel will give out heat so that its temperature instead of continuing to fall, will momentarily increase.

The recalescence point is lower than the decalescence point by anywhere from 85 to 215 degrees F, and the lower of these points does not manifest itself unless the higher one has first been fully passed. These critical points have a direct relation to the hardening of steel. Unless a temperature sufficient to reach the decalescence point is obtained, so that the pearlite is changed into austenite, no hardening action can take place; and unless the steel is cooled suddenly before it reaches the recalescence point, thus preventing the changing back again from austenite to pearlite, no hardening can take place. The critical points vary for different kinds of steel and must be determined by tests. The variation in the critical points makes it necessary to heat different steels to different temperatures when hardening.

**Hardening Temperatures.**—The maximum temperature to which a steel is heated before quenching to harden it is called the hardening temperature. Hardening temperatures vary for different steels and different classes of service, although, in general, it may be said that the hardening temperature for any given steel is above the lower critical point of that steel.

Just how far above this point the hardening temperature lies for any particular steel depends on three factors: 1) the chemical composition of the steel; 2) the amount of excess ferrite (if the steel has less than 0.85 per cent carbon content) or the amount of excess cementite (if the steel has more than 0.85 per cent carbon content) that is to be dissolved in the austenite; and 3) the maximum grain size permitted, if desired.

The general range of full-hardening temperatures for carbon steels is shown by the diagram. This range is merely indicative of general practice and is not intended to represent absolute hardening temperature limits. It can be seen that for steels of less than 0.85 per cent carbon content, the hardening range is above the upper critical point — that is, above the temperature at which all the excess ferrite has been dissolved in the austenite. On the other hand, for steels of more than 0.85 per cent carbon content, the hardening range lies somewhat below the upper critical point. This indicates that in this hardening range, some of the excess cementite still remains undissolved in the austenite. If steel of more than 0.85 per cent carbon content were heated above the upper critical point and then quenched, the resulting grain size would be excessively large.

At one time, it was considered desirable to heat steel only to the minimum temperature at which it would fully harden, one of the reasons being to avoid grain growth that takes place at higher temperature. It is now realized that no such rule as this can be applied generally since there are factors other than hardness that must be taken into consideration. For example, in many cases, toughness can be impaired by too low a temperature just as much as by too high a temperature. It is true, however, that too high hardening temperatures result in warpage, distortion, increased scale, and decarburization.

**Hardening Temperatures for Carbon Tool Steels.**—The best hardening temperatures for any given tool steel are dependent on the type of tool and the intended class of service. Wherever possible, the specific recommendations of the tool steel manufacturer should be followed. General recommendations for hardening temperatures of carbon tool steels based on carbon content are as follows: For steel of 0.65 to 0.80 per cent carbon content, 1450 to 1550 degrees F; for steel of 0.80 to 0.95 per cent carbon content, 1410 to 1460 degrees F; for steel of 0.95 to 1.10 per cent carbon content, 1390 to 1430 degrees F; and for steels of 1.10 per cent and over carbon content, 1380 to 1420 degrees F. For a given hardening temperature range, the higher temperatures tend to produce deeper hardness penetration and increased compressional strength, whereas the lower temperatures tend to result in shallower hardness penetration but increased resistance to splitting or bursting stresses.

**Determining Hardening Temperatures.**—A hardening temperature can be specified directly or it may be specified indirectly as a certain temperature rise above the lower critical point of the steel. Where the temperature is specified directly, a pyrometer of the type that indicates the furnace temperature or a pyrometer of the type that indicates the work temperature may be employed. If the pyrometer shows furnace temperature, care must be taken to allow sufficient time for the work to reach the furnace temperature after the pyrometer indicates that the required hardening temperature has been attained. If the pyrometer indicates work temperature, then, where the workpiece is large, time must be allowed for the interior of the work to reach the temperature of the surface, which is the temperature indicated by the pyrometer.

Where the hardening temperature is specified as a given temperature rise above the critical point of the steel, a pyrometer that indicates the temperature of the work should be used. The critical point, as well as the given temperature rise, can be more accurately determined with this type of pyrometer. As the work is heated, its temperature, as indicated by the pyrometer, rises steadily until the lower critical or decalescence point of the steel is reached. At this point, the temperature of the work ceases to rise and the pyrometer indicating or recording pointer remains stationary or fluctuates slightly. After a certain elapsed period, depending on the heat input rate, the internal changes in structure of the steel that take place at the lower critical point are completed and the temperature of the work again begins to rise. A small fluctuations in temperature may occur in the interval during which structural changes are taking place, so for uniform practice, the critical point may be considered as the temperature at which the pointer first becomes stationary.

**Heating Steel in Liquid Baths.**—The liquid bath commonly used for heating steel tools preparatory to hardening are molten lead, sodium cyanide, barium chloride, a mixture of barium and potassium chloride, and other metallic salts. The molten substance is retained in a crucible or pot and the heat required may be obtained from gas, oil, or electricity. The principal advantages of heating baths are as follows: No part of the work can be heated to a temperature above that of the bath; the temperature can be easily maintained at whatever degree has proved, in practice, to give the best results; the submerged steel can be heated uniformly, and the finished surfaces are protected against oxidation.

**Salt Baths.**—Molten baths of various salt mixtures or compounds are used extensively for heat-treating operations such as hardening and tempering; they are also utilized for annealing ferrous and nonferrous metals. Commercial salt-bath mixtures are available that meet a wide range of temperature and other metallurgical requirements. For example, there are neutral baths for heating tool and die steels without carburizing the surfaces; baths for carburizing the surfaces of low-carbon steel parts; baths adapted for the usual tempering temperatures of, say, 300 to 1100 degrees F; and baths that may be heated to temperatures up to approximately 2400 degrees F for hardening high-speed steels. Salt baths are also adapted for local or selective hardening, the type of bath being selected to suit the requirements. For example, a neutral bath may be used for annealing the ends of tubing or other parts, or an activated cyanide bath for carburizing the ends of shafts or other parts. Surfaces that are not to be carburized are protected by copper plating. When the work is immersed, the unplated surfaces are subjected to the carburizing action.

Baths may consist of a mixture of sodium, potassium, barium, and calcium chlorides or nitrates of sodium, potassium, barium, and calcium in varying proportions, to which sodium carbonate and sodium cyanide are sometimes added to prevent decarburization. Various proportions of these salts provide baths of different properties. Potassium cyanide is seldom used as sodium cyanide costs less. The specific gravity of a salt bath is not as high as that of a lead bath; consequently, the work may be suspended in a salt bath and does not have to be held below the surface as in a lead bath.

**The Lead Bath.**—The lead bath is extensively used, but is not adapted to the high temperatures required for hardening high-speed steel, as it begins to vaporize at about 1190 degrees F. As the temperature increases, the lead volatilizes and gives off poisonous

vapors; hence, lead furnaces should be equipped with hoods to carry away the fumes. Lead baths are generally used for temperatures below 1500 or 1600 degrees F. They are often employed for heating small pieces that must be hardened in quantities. It is important to use pure lead that is free from sulfur. The work should be preheated before plunging it into the molten lead.

**Defects in Hardening.**—Uneven heating is the cause of most of the defects in hardening. Cracks of a circular form, from the corners or edges of a tool, indicate uneven heating in hardening. Cracks of a vertical nature and dark-colored fissures indicate that the steel has been burned and should be put on the scrap heap. Tools that have hard and soft places have been either unevenly heated, unevenly cooled, or “soaked,” a term used to indicate prolonged heating. A tool not thoroughly moved about in the hardening fluid will show hard and soft places, and have a tendency to crack. Tools that are hardened by dropping them to the bottom of the tank sometimes have soft places, owing to contact with the floor or sides.

**Scale on Hardened Steel.**—The formation of scale on the surface of hardened steel is due to the contact of oxygen with the heated steel; hence, to prevent scale, the heated steel must not be exposed to the action of the air. When using an oven heating furnace, the flame should be so regulated that it is not visible in the heating chamber. The heated steel should be exposed to the air as little as possible, when transferring it from the furnace to the quenching bath. An old method of preventing scale and retaining a fine finish on dies used in jewelry manufacture, small taps, etc., is as follows: Fill the die impression with powdered boracic acid and place near the fire until the acid melts; then add a little more acid to ensure covering all the surfaces. The die is then hardened in the usual way. If the boracic acid does not come off entirely in the quenching bath, immerse the work in boiling water. Dies hardened by this method are said to be as durable as those heated without the acid.

**Hardening or Quenching Baths.**—The purpose of a quenching bath is to remove heat from the steel being hardened at a rate that is faster than the critical cooling rate. Generally speaking, the more rapid the rate of heat extraction above the cooling rate, the higher will be the resulting hardness. To obtain the different rates of cooling required by different classes of work, baths of various kinds are used. These include plain or fresh water, brine, caustic soda solutions, oils of various classes, oil-water emulsions, baths of molten salt or lead for high-speed steels, and air cooling for some high-speed steel tools when a slow rate of cooling is required. To minimize distortion and cracking where such tendencies are present, without sacrificing depth-of-hardness penetration, a quenching medium should be selected that will cool rapidly at the higher temperatures and more slowly at the lower temperatures, that is below 750 degrees F. Oil quenches in general meet this requirement.

*Oil Quenching Baths:* Oil is used very extensively as a quenching medium as it results in a good proportion of hardness, toughness, and freedom from warpage when used with standard steels. Oil baths are used extensively for alloy steels. Various kinds of oils are employed, such as prepared mineral oils and vegetable, animal, and fish oils, either singly or in combination. Prepared mineral quenching oils are widely used because they have good quenching characteristics, are chemically stable, do not have an objectionable odor, and are relatively inexpensive. Special compounded oils of the soluble type are used in many plants instead of such oils as fish oil, linseed oil, cottonseed oil, etc. The soluble properties enable the oil to form an emulsion with water.

Oil cools steel at a slower rate than water, but the rate is fast enough for alloy steel. Oils have different cooling rates, however, and this rate may vary through the initial and final stages of the quenching operation. Faster cooling in the initial stage and slower cooling at lower temperatures are preferable because there is less danger of cracking the steel. The temperature of quenching oil baths should range ordinarily between 90 and 130 degrees F. A fairly constant temperature may be maintained either by circulating the oil through cooling coils or by using a tank provided with a cold-water jacket.

A good quenching oil should possess a flash and fire point sufficiently high to be safe under the conditions used and 350 degrees F should be about the minimum point. The specific heat of the oil regulates the hardness and toughness of the quenched steel; and the greater the specific heat, the higher will be the hardness produced. Specific heats of quenching oils vary from 0.20 to 0.75, the specific heats of fish, animal, and vegetable oils usually being from 0.2 to 0.4, and of soluble and mineral oils from 0.5 to 0.7. The efficient temperature range for quenching oil is from 90 to 140 degrees F.

**Quenching in Water.**—Many carbon tool steels are hardened by immersing them in a bath of fresh water, but water is not an ideal quenching medium. Contact between the water and work and the cooling of the hot steel are impaired by the formation of gas bubbles or an insulating vapor film especially in holes, cavities, or pockets. The result is uneven cooling and sometimes excessive strains which may cause the tool to crack; in fact, there is greater danger of cracking in a fresh-water bath than in one containing salt water or brine.

In order to secure more even cooling and reduce danger of cracking, either rock salt (8 or 9 per cent) or caustic soda (3 to 5 per cent) may be added to the bath to eliminate or prevent the formation of a vapor film or gas pockets, thus promoting rapid early cooling. Brine is commonly used and  $\frac{3}{4}$  pound of rock salt per gallon of water is equivalent to about 8 per cent of salt. Brine is not inherently a more severe or drastic quenching medium than plain water, although it may seem to be because the brine makes better contact with the heated steel and, consequently, cooling is more effective. In still-bath quenching, a slow up-and-down movement of the tool is preferable to a violent swishing around.

The temperature of water-base quenching baths should preferably be kept around 70 degrees F, but 70 to 90 or 100 degrees F is a safe range. The temperature of the hardening bath has a great deal to do with the hardness obtained. The higher the temperature of the quenching water, the more nearly does its effect approach that of oil; and if boiling water is used for quenching, it will have an effect even more gentle than that of oil — in fact, it would leave the steel nearly soft. Parts of irregular shape are sometimes quenched in a water bath that has been warmed somewhat to prevent sudden cooling and cracking.

When water is used, it should be “soft” because unsatisfactory results will be obtained with “hard” water. Any contamination of water-base quenching liquids by soap tends to decrease their rate of cooling. A water bath having 1 or 2 inches of oil on the top is sometimes employed to advantage for quenching tools made of high-carbon steel as the oil through which the work first passes reduces the sudden quenching action of the water.

The bath should be amply large to dissipate the heat rapidly and the temperature should be kept about constant so that successive pieces will be cooled at the same rate. Irregularly shaped parts should be immersed so that the heaviest or thickest section enters the bath first. After immersion, the part to be hardened should be agitated in the bath; the agitation reduces the tendency of the formation of a vapor coating on certain surfaces, and a more uniform rate of cooling is obtained. The work should never be dropped to the bottom of the bath until quite cool.

*Flush or Local Quenching by Pressure-Spraying:* When dies for cold heading, drawing, extruding, etc., or other tools, require a hard working surface and a relatively soft but tough body, the quenching may be done by spraying water under pressure against the interior or other surfaces to be hardened. Special spraying fixtures are used to hold the tool and apply the spray where the hardening is required. The pressure spray prevents the formation of gas pockets previously referred to in connection with the fresh-water quenching bath; hence, fresh water is effective for flush quenching and there is no advantage in using brine.

**Quenching in Molten Salt Bath.**—A molten salt bath may be used in preference to oil for quenching high-speed steel. The object in using a liquid salt bath for quenching (instead of an oil bath) is to obtain maximum hardness with minimum cooling stresses and distortion that might result in cracking expensive tools, especially if there are irregular sections. The temperature of the quenching bath may be around 1100 or 1200 degrees F. Quenching is

followed by cooling to room temperature and then the tool is tempered or drawn in a bath having a temperature range of 950 to 1100 degrees F. In many cases, the tempering temperature is about 1050 degrees F.

**Tanks for Quenching Baths.**—The main point to be considered in a quenching bath is to keep it at a uniform temperature, so that successive pieces quenched will be subjected to the same heat treatment. The next consideration is to keep the bath agitated, so that it will not be of different temperatures in different places; if thoroughly agitated and kept in motion, as the case with the bath shown in Fig. 1, it is not even necessary to keep the pieces in motion in the bath, as steam will not be likely to form around the pieces quenched. Experience has proved that if a piece is held still in a thoroughly agitated bath, it will come out much straighter than if it has been moved around in an unagitated bath, an important consideration, especially when hardening long pieces. It is, besides, no easy matter to keep heavy and long pieces in motion unless it be done by mechanical means.

In Fig. 1 is shown a water or brine tank for quenching baths. Water is forced by a pump or other means through the supply pipe into the intermediate space between the outer and inner tank. From the intermediate space, it is forced into the inner tank through holes as indicated. The water returns to the storage tank by overflowing from the inner tank into the outer one and then through the overflow pipe as indicated. In Fig. 3 is shown another water or brine tank of a more common type. In this case, the water or brine is pumped from the storage tank and continuously returned to it. If the storage tank contains a large volume of water, there is no need for a special means for cooling. Otherwise, arrangements must be made for cooling the water after it has passed through the tank. The bath is agitated by the force with which the water is pumped into it. The holes at A are drilled at an angle, so as to throw the water toward the center of the tank. In Fig. 2 is shown an oil-quenching tank in which water is circulated in an outer surrounding tank to keep the oil bath cool. Air is forced into the oil bath to keep it agitated. Fig. 4 shows the ordinary type of quenching tank cooled by water forced through a coil of pipe. This arrangement can be used for oil, water, or brine. Fig. 5 shows a similar type of quenching tank, but with two coils of pipe. Water flows through one of these and steam through the other. By these means, it is possible to keep the bath at a constant temperature.

Fig. 2.

**Interrupted Quenching.**—*Austempering, martempering, and isothermal quenching* are three methods of interrupted quenching that have been developed to obtain greater toughness and ductility for given hardnesses and to avoid the difficulties of quench cracks, internal stresses, and warpage, frequently experienced when the conventional method of

Fig. 3.

Fig. 4.

Fig. 5.

quenching steel directly and rapidly from above the transformation point to atmospheric temperature is employed. In each of these three methods, quenching is begun when the work has reached some temperature above the transformation point and is conducted at a rate faster than the critical rate. The rapid cooling of the steel is interrupted, however, at some temperature above that at which martensite begins to form. The three methods differ in the temperature range at which interruption of the rapid quench takes place, the length of time that the steel is held at this temperature, and whether the subsequent cooling to atmospheric temperature is rapid or slow, and is or is not preceded by a tempering operation.

One of the reasons for maintaining the steel at a constant temperature for a definite period of time is to permit the inside sections of the piece to reach the same temperature as the outer sections so that when transformation of the structure does take place, it will occur at about the same rate and period of time throughout the piece. In order to maintain the constant temperature required in interrupted quenching, a quenching arrangement for absorbing and dissipating a large quantity of heat without increase in temperature is needed. Molten salt baths equipped for water spray or air cooling around the exterior of the bath container have been used for this purpose.

*Austempering:* This is a heat-treating process in which steels are quenched in a bath maintained at some constant temperature in the range of 350 to 800 degrees F, depending on the analysis of the steel and the characteristics to be obtained. On immersion in the quenching bath, the steel is cooled more rapidly than the critical quenching rate. When the temperature of the steel reaches that of the bath, however, the quenching action is interrupted. If the steel is now held at this temperature for a predetermined length of time, say, from 10 to 60 minutes, the austenitic structure of the steel is gradually changed into a new structure, called *bainite*. The structure of bainite is acicular (needlelike) and resembles that of tempered martensite such as is usually obtained by quenching in the usual manner to atmospheric temperature and tempering at 400 degrees F or higher.

Hardnesses ranging up to 60 Rockwell C, depending on the carbon and alloy content of the steel, are obtainable and compare favorably with those obtained for the respective steels by a conventional quench and tempering to above 400 degrees F. Much greater

toughness and ductility are obtained in an austempered piece, however, as compared with a similar piece quenched and tempered in the usual manner.

Two factors are important in austempering. First, the steel must be quenched rapidly enough to the specified subtransformation temperature to avoid any formation of pearlite, and, second, it must be held at this temperature until the transformation from austenite to bainite is completed. Time and temperature transformation curves (called S-curves because of their shape) have been developed for different steels and these curves provide important data governing the conduct of austempering, as well as the other interrupted quenching methods.

Austempering has been applied chiefly to steels having 0.60 per cent or more carbon content with or without additional low-alloy content, and to pieces of small diameter or section, usually under 1 inch, but varying with the composition of the steel. Case-hardened parts may also be austempered.

*Martempering:* In this process the steel is first rapidly quenched from some temperature above the transformation point down to some temperature (usually about 400 degrees F) just above that at which martensite begins to form. It is then held at this temperature for a length of time sufficient to equalize the temperature throughout the part, after which it is removed and cooled in air. As the temperature of the steel drops below the transformation point, martensite begins to form in a matrix of austenite at a fairly uniform rate throughout the piece. The soft austenite acts as a cushion to absorb some of the stresses which develop as the martensite is formed. The difficulties presented by quench cracks, internal stresses, and dimensional changes are largely avoided, thus a structure of high hardness can be obtained. If greater toughness and ductility are required, conventional tempering may follow. In general, heavier sections can be hardened more easily by the martempering process than by the austempering process. The martempering process is especially suited to the higher-alloyed steels.

*Isothermal Quenching:* This process resembles austempering in that the steel is first rapidly quenched from above the transformation point down to a temperature that is above that at which martensite begins to form and is held at this temperature until the austenite is completely transformed into bainite. The constant temperature to which the piece is quenched and then maintained is usually 450 degrees F or above. The process differs from austempering in that after transformation to a bainite structure has been completed, the steel is immersed in another bath and is brought up to some higher temperature, depending on the characteristics desired, and is maintained at this temperature for a definite period of time, followed by cooling in air. Thus, tempering to obtain the desired toughness or ductility takes place immediately after the structure of the steel has changed to bainite and before it is cooled to atmospheric temperature.

**Laser and Electron-Beam Surface Hardening.**—Industrial lasers and electron-beam equipment are now available for surface hardening of steels. The laser and electron beams can generate very intense energy fluxes and steep temperature profiles in the workpiece, so that external quench media are not needed. This self-quenching is due to a cold interior with sufficient mass acting as a large heat sink to rapidly cool the hot surface by conducting heat to the interior of a part. The laser beam is a beam of light and does not require a vacuum for operation. The electron beam is a stream of electrons and processing usually takes place in a vacuum chamber or envelope. Both processes may normally be applied to finished machined or ground surfaces, because little distortion results.

### Tempering

The object of *tempering* or *drawing* is to reduce the brittleness in hardened steel and to remove the internal strains caused by the sudden cooling in the quenching bath. The tempering process consists in heating the steel by various means to a certain temperature and then cooling it. When steel is in a fully hardened condition, its structure consists largely of

*martensite*. On reheating to a temperature of from about 300 to 750 degrees F, a softer and tougher structure known as *troostite* is formed. If the steel is reheated to a temperature of from 750 to 1290 degrees F, a structure known as *sorbite* is formed that has somewhat less strength than troostite but much greater ductility.

**Tempering Temperatures.**—If steel is heated in an oxidizing atmosphere, a film of oxide forms on the surface that changes color as the temperature increases. These oxide colors (see [Table 1](#)) have been used extensively in the past as a means of gaging the correct amount of temper; but since these colors are affected to some extent by the composition of the metal, the method is not dependable.

**Table 1. Temperatures as Indicated by the Color of Plain Carbon Steel**

| Degrees Centigrade | Degrees Fahrenheit | Color of Steel    | Degrees Centigrade | Degrees Fahrenheit | Color of Steel    |
|--------------------|--------------------|-------------------|--------------------|--------------------|-------------------|
| 221.1              | 430                | Very pale yellow  | 265.6              | 510                | Spotted red-brown |
| 226.7              | 440                | Light yellow      | 271.1              | 520                | Brown-purple      |
| 232.2              | 450                | Pale straw-yellow | 276.7              | 530                | Light purple      |
| 237.8              | 460                | Straw-yellow      | 282.2              | 540                | Full purple       |
| 243.3              | 470                | Deep straw-yellow | 287.8              | 550                | Dark purple       |
| 248.9              | 480                | Dark yellow       | 293.3              | 560                | Full blue         |
| 254.4              | 490                | Yellow-brown      | 298.9              | 570                | Dark blue         |
| 260.0              | 500                | Brown-yellow      | 337.8              | 640                | Light blue        |

The availability of reliable pyrometers in combination with tempering baths of oil, salt, or lead make it possible to heat the work uniformly and to a given temperature within close limits.

Suggested temperatures for tempering various tools are given in [Table 2](#).

**Tempering in Oil.**—Oil baths are extensively used for tempering tools (especially in quantity), the work being immersed in oil heated to the required temperature, which is indicated by a thermometer. It is important that the oil have a uniform temperature throughout and that the work be immersed long enough to acquire this temperature. Cold steel should not be plunged into a bath heated for tempering, owing to the danger of cracking. The steel should either be preheated to about 300 degrees F, before placing it in the bath, or the latter should be at a comparatively low temperature before immersing the steel, and then be heated to the required degree. A temperature of from 650 to 700 degrees F can be obtained with heavy tempering oils; for higher temperatures, either a bath of nitrate salts or a lead bath may be used.

In tempering, the best method is to immerse the pieces to be tempered before starting to heat the oil, so that they are heated with the oil. After the pieces tempered are taken out of the oil bath, they should be immediately dipped in a tank of caustic soda, and after that in a tank of hot water. This will remove all oil that might adhere to the tools. The following tempering oil has given satisfactory results: mineral oil, 94 per cent; saponifiable oil, 6 per cent; specific gravity, 0.920; flash point, 550 degrees F; fire test, 625 degrees F.

**Tempering in Salt Baths.**—Molten salt baths may be used for tempering or drawing operations. Nitrate baths are particularly adapted for the usual drawing temperature range of, say, 300 to 1100 degrees F. Tempering in an oil bath usually is limited to temperatures of 500 to 600 degrees F, and some heat-treating specialists recommend the use of a salt bath for temperatures above 350 or 400 degrees F, as it is considered more efficient and economical. Tempering in a bath (salt or oil) has several advantages, such as ease in controlling the temperature range and maintenance of a uniform temperature. The work is also heated much more rapidly in a molten bath. A gas- or oil-fired muffle or semimuffle furnace may be used for tempering, but a salt bath or oil bath is preferable. A salt bath is rec-

**Table 2. Tempering Temperatures for Various Plain Carbon Steel Tools**

| Degrees F  | Class of Tool  |
|------------|--|
| 495 to 500 | Taps $\frac{1}{2}$ inch or over, for use on automatic screw machines                                     |
| 495 to 500 | Nut taps $\frac{1}{2}$ inch and under  |
| 515 to 520 | Taps $\frac{1}{4}$ inch and under, for use on automatic screw machines                                   |
| 525 to 530 | Thread dies to cut thread close to shoulder  |
| 500 to 510 | Thread dies for general work   |
| 495        | Thread dies for tool steel or steel tube   |
| 525 to 540 | Dies for bolt threader threading to shoulder   |
| 460 to 470 | Thread rolling dies  |
| 430 to 435 | Hollow mills (solid type) for roughing on automatic screw machines                                       |
| 485        | Knurls   |
| 450        | Twist drills for hard service  |
| 450        | Centering tools for automatic screw machines   |
| 430        | Forming tools for automatic screw machines   |
| 430 to 435 | Cut-off tools for automatic screw machines   |
| 440 to 450 | Profile cutters for milling machines   |
| 430        | Formed milling cutters   |
| 435 to 440 | Milling cutters  |
| 430 to 440 | Reamers  |
| 460        | Counterbores and countersinks  |
| 480        | Cutters for tube- or pipe-cutting machines   |
| 460 to 520 | Snaps for pneumatic hammers — harden full length, temper to 460 degrees, then bring point to 520 degrees |

ommended for tempering high-speed steel, although furnaces may also be used. The bath or furnace temperature should be increased gradually, say, from 300 to 400 degrees F up to the tempering temperature, which may range from 1050 to 1150 degrees F for high-speed steel.

**Tempering in a Lead Bath.**—The lead bath is commonly used for heating steel in connection with tempering, as well as for hardening. The bath is first heated to the temperature at which the steel should be tempered; the preheated work is then placed in the bath long enough to acquire this temperature, after which it is removed and cooled. As the melting temperature of pure lead is about 620 degrees F, tin is commonly added to it to lower the temperature sufficiently for tempering. Reductions in temperature can be obtained by varying the proportions of lead and tin, as shown in [Table 3](#).

**Table 3. Temperatures of Lead Bath Alloys**

| Parts Lead | Parts Tin | Melting Temp., Deg. F | Parts Lead | Parts Tin | Melting Temp., Deg. F | Parts Lead | Parts Tin | Melting Temp., Deg. F |
|------------|-----------|-----------------------|------------|-----------|-----------------------|------------|-----------|-----------------------|
| 200        | 8         | 560                   | 39         | 8         | 510                   | 19         | 8         | 460                   |
| 100        | 8         | 550                   | 33         | 8         | 500                   | 17         | 8         | 450                   |

**To Prevent Lead from Sticking to Steel.**—To prevent hot lead from sticking to parts heated in it, mix common whiting with wood alcohol, and paint the part that is to be heated. Water can be used instead of alcohol, but in that case, the paint must be thoroughly dry, as

otherwise the moisture will cause the lead to "fly." Another method is to make a thick paste according to the following formula: Pulverized charred leather, 1 pound; fine wheat flour, 1½ pounds; fine table salt, 2 pounds. Coat the tool with this paste and heat slowly until dry, then proceed to harden. Still another method is to heat the work to a blue color, or about 600 degrees F, and then dip it in a strong solution of salt water, prior to heating in the lead bath. The lead is sometimes removed from parts having fine projections or teeth, by using a stiff brush just before immersing in the cooling bath. Removal of lead is necessary to prevent the formation of soft spots.

**Tempering in Sand.**—The sand bath is used for tempering certain classes of work. One method is to deposit the sand on an iron plate or in a shallow box that has burners beneath it. With this method of tempering, tools such as boiler punches, etc., can be given a varying temper by placing them endwise in the sand. As the temperature of the sand bath is higher toward the bottom, a tool can be so placed that the color of the lower end will become a deep dark blue when the middle portion is a very dark straw, and the working end or top a light straw color, the hardness gradually increasing from the bottom up.

**Double Tempering.**—In tempering high-speed steel tools, it is common practice to repeat the tempering operation or "double temper" the steel. Double tempering is done by heating the steel to the tempering temperature (say, 1050 degrees F) and holding it at that temperature for two hours. It is then cooled to room temperature, reheated to 1050 degrees F for another two-hour period, and again cooled to room temperature. After the first tempering operation, some untempered martensite remains in the steel. This martensite is not only tempered by a second tempering operation but is relieved of internal stresses, thus improving the steel for service conditions. The hardening temperature for the higher-alloy steels may affect the hardness after tempering. For example, molybdenum high-speed steel when heated to 2100 degrees F had a hardness of 61 Rockwell C after tempering, whereas a temperature of 2250 degrees F resulted in a hardness of 64.5 Rockwell C after tempering.

### Annealing, Spheroidizing, and Normalizing

Annealing of steel is a heat-treating process in which the steel is heated to some elevated temperature, usually in or near the critical range, is held at this temperature for some period of time, and is then cooled, usually at a slow rate. Spheroidizing and normalizing may be considered as special cases of annealing.

The *full annealing* of carbon steel consists in heating it slightly above the *upper* critical point for hypoeutectoid steels (steels of less than 0.85 per cent carbon content) and slightly above the *lower* critical point for hypereutectoid steels (steels of more than 0.85 per cent carbon content), holding it at this temperature until it is uniformly heated and then slowly cooling it to 1000 degrees F or below. The resulting structure is layerlike, or lamellar, in character due to the pearlite that is formed during the slow cooling.

Annealing is employed 1) to soften steel for machining, cutting, stamping, etc., or for some particular service; 2) to alter ductility, toughness, electrical or magnetic characteristics or other physical properties; 3) to refine the crystal structure; 4) to produce grain reorientation; and 5) to relieve stresses and hardness resulting from cold working.

The *spheroidizing* of steel, according to the American Society of Metals, is "any process of heating and cooling that produces a rounded or globular form of carbide." High-carbon steels are spheroidized to improve their machinability especially in continuous cutting operations such as are performed by lathes and screw machines. In low-carbon steels, spheroidizing may be employed to meet certain strength requirements before subsequent heat treatment. Spheroidizing also tends to increase resistance to abrasion.

The *normalizing* of steel consists in heating it to some temperature above that used for annealing, usually about 100 degrees F above the upper critical range, and then cooling it in still air at room temperature. Normalizing is intended to put the steel into a uniform, unstressed condition of proper grain size and refinement so that it will properly respond to

further heat treatments. It is particularly important in the case of forgings that are to be later heat treated. Normalizing may or may not (depending on the composition) leave steel in a sufficiently soft state for machining with available tools. Annealing for machinability is often preceded by normalizing and the combined treatment — frequently called a *double anneal* — produces a better result than a simple anneal.

**Annealing Practice.**—For carbon steels, the following annealing temperatures are recommended by the American Society for Testing and Materials: Steels of less than 0.12 per cent carbon content, 1600 to 1700 degrees F; steels of 0.12 to 0.29 per cent carbon content, 1550 to 1600 degrees F, steels of 0.30 to 0.49 per cent carbon content, 1500 to 1550 degrees F; and for 0.50 to 1.00 per cent carbon steels, from 1450 to 1500 degrees F. Slightly lower temperatures are satisfactory for steels having more than 0.75 per cent manganese content. Heating should be uniform to avoid the formation of additional stresses. In the case of large workpieces, the heating should be slow enough so that the temperature of the interior does not lag too far behind that of the surface.

It has been found that in annealing steel, the higher the temperature to which it is heated to produce an austenitic structure, the greater the tendency of the structure to become lamellar (pearlitic) in cooling. On the other hand, the closer the austenitizing temperature to the critical temperature, the greater is the tendency of the annealed steel to become spheroidal.

*Rate of Cooling:* After heating the steel to some temperature within the annealing range, it should be cooled slowly enough to permit the development of the desired softness and ductility. In general, the slower the cooling rate, the greater the resulting softness and ductility. Steel of a high-carbon content should be cooled more slowly than steel of a low-carbon content; and the higher the alloy content, the slower is the cooling rate usually required. Where extreme softness and ductility are not required, the steel may be cooled in the annealing furnace to some temperature well below the critical point, say, to about 1000 degrees F and then removed and cooled in air.

**Annealing by Constant-Temperature Transformation.**—It has been found that steel that has been heated above the critical point so that it has an austenitic structure can be transformed into a lamellar (pearlitic) or a spheroidal structure by holding it for a definite period of time at some constant subcritical temperature. In other words, it is feasible to anneal steel by means of a constant-temperature transformation as well as by the conventional continuous cooling method. When the constant-temperature transformation method is employed, the steel, after being heated to some temperature above the critical and held at this temperature until it is austenitized, is cooled as rapidly as feasible to some relatively high subcritical transformation temperature. The selection of this temperature is governed by the desired microstructure and hardness required and is taken from a transformation time and temperature curve (often called a TTT curve). As drawn for a particular steel, such a curve shows the length of time required to transform that steel from an austenitic state at various subcritical temperatures. After being held at the selected sub-critical temperature for the required length of time, the steel is cooled to room temperature — again, as rapidly as feasible. This rapid cooling down to the selected transformation temperature and then down to room temperature has a negligible effect on the structure of the steel and often produces a considerable saving in time over the conventional slow cooling method of annealing.

The softest condition in steel can be developed by heating it to a temperature usually less than 100 degrees F above the lower critical point and then cooling it to some temperature, usually less than 100 degrees, below the critical point, where it is held until the transformation is completed. Certain steels require a very lengthy period of time for transformation of the austenite when held at a constant temperature within this range. For such steels, a practical procedure is to allow most of the transformation to take place in this temperature range where a soft product is formed and then to finish the transformation at a lower temperature where the time for the completion of the transformation is short.

**Spheroidizing Practice.**—A common method of spheroidizing steel consists in heating it to or slightly below the lower critical point, holding it at this temperature for a period of time, and then cooling it slowly to about 1000 degrees F or below. The length of time for which the steel is held at the spheroidizing temperature largely governs the degree of spheroidization. High-carbon steel may be spheroidized by subjecting it to a temperature that alternately rises and falls between a point within and a point without the critical range. Tool steel may be spheroidized by heating to a temperature slightly above the critical range and then, after being held at this temperature for a period of time, cooling without removal from the furnace.

**Normalizing Practice.**—When using the lower-carbon steels, simple normalizing is often sufficient to place the steel in its best condition for machining and will lessen distortion in carburizing or hardening. In the medium- and higher-carbon steels, combined normalizing and annealing constitutes the best practice. For unimportant parts, the normalizing may be omitted entirely or annealing may be practiced only when the steel is otherwise difficult to machine. Both processes are recommended in the following heat treatments (for SAE steels) as representing the best metallurgical practice. The temperatures recommended for normalizing and annealing have been made indefinite in many instances because of the many different types of furnaces used in various plants and the difference in results desired.

### Case Hardening

In order to harden low-carbon steel, it is necessary to increase the carbon content of the surface of the steel so that a thin outer "case" can be hardened by heating the steel to the hardening temperature and then quenching it. The process, therefore, involves two separate operations. The first is the *carburizing* operation for impregnating the outer surface with sufficient carbon, and the second operation is that of heat treating the carburized parts so as to obtain a hard outer case and, at the same time, give the "core" the required physical properties. The term "case hardening" is ordinarily used to indicate the complete process of carburizing and hardening.

**Carburization.**—Carburization is the result of heating iron or steel to a temperature below its melting point in the presence of a solid, liquid, or gaseous material that decomposes so as to liberate carbon when heated to the temperature used. In this way, it is possible to obtain by the gradual penetration, diffusion, or absorption of the carbon by the steel, a "zone" or "case" of higher-carbon content at the outer surfaces than that of the original object. When a carburized object is rapidly cooled or quenched in water, oil, brine, etc., from the proper temperature, this case becomes hard, leaving the inside of the piece soft, but of great toughness.

**Use of Carbonaceous Mixtures.**—When carburizing materials of the solid class are used, the case-hardening process consists in packing steel articles in metal boxes or pots, with a carbonaceous compound surrounding the steel objects. The boxes or pots are sealed and placed in a carburizing oven or furnace maintained usually at a temperature of from about 1650 to 1700 degrees F for a length of time depending on the extent of the carburizing action desired. The carbon from the carburizing compound will then be absorbed by the steel on the surfaces desired, and the low-carbon steel is converted into high-carbon steel at these portions. The internal sections and the insulated parts of the object retain practically their original low-carbon content. The result is a steel of a dual structure, a high-carbon and a low-carbon steel in the same piece. The carburized steel may now be heat treated by heating and quenching, in much the same way as high-carbon steel is hardened, in order to develop the properties of hardness and toughness; but as the steel is, in reality, two steels in one, one high-carbon and one low-carbon, the correct heat treatment after carburizing includes two distinct processes, one suitable for the high-carbon portion or the "case," as it is generally called, and one suitable for the low-carbon portion or core. The method of heat treatment varies according to the kind of steel used. Usually, an initial heating and slow

cooling is followed by reheating to 1400–1450 degrees F, quenching in oil or water, and a final tempering. More definite information is given in the following section on S.A.E. steels.

**Carburizers:** There are many commercial carburizers on the market in which the materials used as the generator may be hard and soft wood charcoal, animal charcoal, coke, coal, beans and nuts, bone and leather, or various combinations of these. The energizers may be barium, cyanogen, and ammonium compounds, various salts, soda ash, or lime and oil hydrocarbons.

**Pack-Hardening.**—When cutting tools, gages, and other parts made from high-carbon steels are heated for hardening while packed in some carbonaceous material in order to protect delicate edges, corners, or finished surfaces, the process usually is known as pack-hardening. Thus, the purpose is to protect the work, prevent scale formation, ensure uniform heating, and minimize the danger of cracking and warpage. The work is packed, as in carburizing, and in the same type of receptacle. Common hardwood charcoal often is used, especially if it has had an initial heating to eliminate shrinkage and discharge its more impure gases. The lowest temperature required for hardening should be employed for pack-hardening — usually 1400 to 1450 degrees F for carbon steels. Pack-hardening has also been applied to high-speed steels, but modern developments in heat-treating salts have made it possible to harden high-speed steel without decarburization, injury to sharp edges, or marring the finished surfaces. See *Salt Baths* on page 516.

**Cyanide Hardening.**—When low-carbon steel requires a very hard outer surface but does not need high shock-resisting qualities, the cyanide-hardening process may be employed to produce what is known as superficial hardness. This superficial hardening is the result of carburizing a very thin outer skin (which may be only a few thousandths inch thick) by immersing the steel in a bath containing sodium cyanide. The temperatures usually vary from 1450 to 1650 degrees F and the percentage of sodium cyanide in the bath extends over a wide range, depending on the steel used and properties required.

**Nitriding Process.**—Nitriding is a process for surface hardening certain alloy steels by heating the steel in an atmosphere of nitrogen (ammonia gas) at approximately 950 degrees F. The steel is then cooled slowly. Finish machined surfaces hardened by nitriding are subject to minimum distortion. The physical properties, such as toughness, high impact strength, etc., can be imparted to the core by previous heat treatments and are unaffected by drawing temperatures up to 950 degrees F. The “Nitralloy” steels suitable for this process may be readily machined in the heat-treated as well as in the annealed state, and they forge as easily as alloy steels of the same carbon content. Certain heat treatments must be applied prior to nitriding, the first being annealing to relieve rolling, forging, or machining strains. Parts or sections not requiring heat treating should be machined or ground to the exact dimensions required. Close tolerances must be maintained in finish machining, but allowances for growth due to adsorption of nitrogen should be made, and this usually amounts to about 0.0005 inch for a case depth of 0.02 inch. Parts requiring heat treatment for definite physical properties are forged or cut from annealed stock, heat treated for the desired physical properties, rough machined, normalized, and finish machined. If quenched and drawn parts are normalized afterwards, the drawing and normalizing temperatures should be alike. The normalizing temperature may be below but should never be above the drawing temperature.

**Ion Nitriding.**—Ion nitriding, also referred to as glow discharge nitriding, is a process for case hardening of steel parts such as tool spindles, cutting tools, extrusion equipment, forging dies, gears, and crankshafts. An electrical potential ionizes low-pressure nitrogen gas, and the ions produced are accelerated to and impinge on the workpiece, heating it to the appropriate temperature for diffusion to take place. Therefore, there is no requirement for a supplemental heat source. The inward diffusion of the nitrogen ions forms the iron and

alloy nitrides in the case. White layer formation, familiar in conventional gas nitriding, is readily controlled by this process.

**Liquid Carburizing.**—Activated liquid salt baths are now used extensively for carburizing. Sodium cyanide and other salt baths are used. The salt bath is heated by electrodes immersed in it, the bath itself acting as the conductor and resistor. One or more groups of electrodes, with two or more electrodes per group, may be used. The heating is accompanied by a stirring action to ensure uniform temperature and carburizing activity throughout the bath. The temperature may be controlled by a thermocouple immersed in the bath and connecting with a pyrometer designed to provide automatic regulation. The advantages of liquid baths include rapid action; uniform carburization; minimum distortion; and elimination of the packing and unpacking required when carbonaceous mixtures are used. In selective carburizing, the portions of the work that are not to be carburized are copper-plated and the entire piece is then immersed in an activated cyanide bath. The copper inhibits any carburizing action on the plated parts, and this method offers a practical solution for selectively carburizing any portion of a steel part.

**Gas Carburizing.**—When carburizing gases are used, the mixture varies with the type of case and quality of product desired. The gaseous hydrocarbons most widely used are methane (natural gas), propane, and butane. These carbon-bearing gases are mixed with air, with manufactured gases of several types, with flue gas, or with other specially prepared “diluent” gases. It is necessary to maintain a continuous fresh stream of carburizing gases to the carburizing retort or muffle, as well as to remove the spent gases from the muffle continuously, in order to obtain the correct mixture of gases inside the muffle. A slight pressure is maintained on the muffle to exclude unwanted gases.

The horizontal rotary type of gas carburizing furnace has a retort or muffle that revolves slowly. This type of furnace is adapted to small parts such as ball and roller bearings, chain links, small axles, bolts, etc. With this type of furnace, very large pieces such as gears, for example, may be injured by successive shocks due to tumbling within the rotor.

The vertical pit type of gas carburizer has a stationary workholder that is placed vertically in a pit. The work, instead of circulating in the gases as with the rotary type, is stationary and the gases circulate around it. This type is applicable to long large shafts or other parts or shapes that cannot be rolled in a rotary type of furnace.

There are three types of continuous gas furnaces that may be designated as

- 1) direct quench and manually operated
- 2) direct quench and mechanically operated
- 3) cooling-zone type

Where production does not warrant using a large continuous-type furnace, a horizontal muffle furnace of the batch type may be used, especially if the quantities of work are varied and the production not continuous.

**Vacuum Carburizing.**—Vacuum carburizing is a high-temperature gas carburizing process that is performed at pressures below atmospheric. The furnace atmosphere usually consists solely of an enriching gas, such as natural gas, pure methane, or propane; nitrogen is sometimes used as a carrier gas. Vacuum carburizing offers several advantages such as combining of processing operations and reduced total processing time.

**Carburizing Steels.**—A low-carbon steel containing, say, from 0.10 to 0.20 per cent of carbon is suitable for carburized case hardening. In addition to straight-carbon steels, the low-carbon alloy steels are employed. The alloys add to case-hardened parts the same advantageous properties that they give to other classes of steel. Various steels suitable for case hardening will be found in the section on SAE steels.

**To Clean Work after Case Hardening.**—To clean work, especially if knurled, or if dirt is likely to stick into crevices after case hardening, wash it in caustic soda (1 part soda to 10 parts water). In making the solution, the soda should be put into hot water gradually, and the mixture stirred until the soda is thoroughly dissolved. A still more effective method of

cleaning is to dip the work into a mixture of 1 part sulfuric acid and 2 parts water. Leave the pieces in this mixture about three minutes; then wash them immediately in a soda solution.

**Flame Hardening.**—This method of hardening is especially applicable to the selective hardening of large steel forgings or castings that must be finish-machined prior to heat-treatment, or that because of size or shape cannot be heat treated by using a furnace or bath. An oxyacetylene torch is used to heat quickly the surface to be hardened; this surface is then quenched to secure a hardened layer that may vary in depth from a mere skin to  $\frac{1}{4}$  inch and with hardness ranging from 400 to 700 Brinell. A multiflame torchhead may be equipped with quenching holes or a spray nozzle back of the flame. This is not a carburizing or a case-hardening process as the torch is only a heating medium. Most authorities recommend tempering or drawing of the hardened surface at temperatures between 200 and 350 degrees F. This treatment may be done in a standard furnace, an oil bath, or with a gas flame. It should follow the hardening process as closely as possible. Medium-carbon and many low-alloy steels are suitable for flame hardening. Plain carbon steels ranging from 0.35 to 0.60 per cent carbon will give hardnesses of from 400 to 700 Brinell. Steels in the 0.40 to 0.45 per cent carbon range are preferred, as they have excellent core properties and produce hardnesses of from 400 to 500 Brinell without checking or cracking. Higher-carbon steels will give greater hardnesses, but extreme care must be taken to prevent cracking. Careful control of the quenching operation is required.

*Spinning Method of Flame Hardening:* This method is employed on circular objects that can be rotated or spun past a stationary flame. It may be subdivided according to the speed of rotation, as where the part is rotated slowly in front of a stationary flame and the quench is applied immediately after the flame. This method is used on large circular pieces such as track wheels and bearing surfaces. There will be a narrow band of material with lower hardness between adjacent torches if more than one path of the flame is required to harden the surface. There will also be an area of lower hardness where the flame is extinguished. A second method is applicable to small rollers or pinions. The work is spun at a speed of 50 to 150 rpm in front of the flame until the entire piece has reached the proper temperature; then it is quenched as a unit by a cooling spray or by ejecting it into a cooling bath.

*The Progressive Method:* In this method the torch travels along the face of the work and the work remains stationary. It is used to harden lathe ways, gear teeth, and track rails.

*The Stationary or Spot-hardening Method:* When this method is employed, the work and torch are both stationary. When the spot to be hardened reaches the quenching temperature, the flame is removed and the quench applied.

*The Combination Method:* This approach is a combination of the spinning and progressive methods, and is used for long bearing surfaces. The work rotates slowly past the torch as the torch travels longitudinally across the face of the work at the rate of the torch width per revolution of the work.

Equipment for the stationary method of flame hardening consists merely of an acetylene torch, an oxyacetylene supply, and a suitable means of quenching; but when the other methods are employed, work-handling tools are essential and specialty designed torches are desirable. A lathe is ideally suited for the spinning or combination hardening method, whereas a planer is easily adapted for progressive hardening. Production jobs, such as the hardening of gears, require specially designed machines. These machines reduce handling and hardening time, as well as assuring consistent results.

**Induction Hardening.**—The hardening of steel by means of induction heating and subsequent quenching in either liquid or air is particularly applicable to parts that require localized hardening or controlled depth of hardening and to irregularly shaped parts, such as cams that require uniform surface hardening around their contour.

Advantages offered by induction hardening are: 1) a short heating cycle that may range from a fraction of a second to several seconds (heat energy can be induced in a piece of steel at the rate of 100 to 250 Btu per square inch per minute by induction heating, as com-

pared with a rate of 3 Btu per square inch per minute for the same material at room temperature when placed in a furnace with a wall temperature of 2000 degrees F); 2) absence of tendency to produce oxidation or decarburization; 3) exact control of depth and area of hardening; 4) close regulation of degree of hardness obtained by automatic timing of heating and quenching cycles; 5) minimum amount of warpage or distortion; and 6) possibility of substituting carbon steels for higher-cost alloy steels.

The principal advantage of induction hardening to the designer lies in its application to localized zones. Thus, specific areas in a given part can be heat treated separately to the respective hardnesses required. Parts can be designed so that the stresses at any given point in the finished piece can be relieved by local heating. Parts can be designed in which welded or brazed assemblies are built up prior to heat treating with only internal surfaces or projections requiring hardening.

**Types of Induction Heating Equipment.**—Induction heating is secured by placing the metal part inside or close to an “applicator” coil of one or more turns, through which alternating current is passed. The coil, formed to suit the general class of work to be heated, is usually made of copper tubing through which water is passed to prevent overheating of the coil itself. The workpiece is held either in a fixed position or is rotated slowly within or close to the applicator coil. Where the length of work is too great to permit heating in a fixed position, progressive heating may be employed. Thus, a rod or tube of steel may be fed through an applicator coil of one or more turns so that the heating zone travels progressively along the entire length of the workpiece.

The frequency of the alternating current used and the type of generator employed to supply this current to the applicator coil depend on the character of the work to be done.

There are three types of commercial equipment used to produce high-frequency current for induction heating: 1) motor generator sets that deliver current at frequencies of approximately 1000, 2000, 3000, and 10,000 cycles; 2) spark gap oscillator units that produce frequencies ranging from 80,000 to 300,000 cycles; and 3) vacuum tube oscillator sets, which produce currents at frequencies ranging from 350,000 to 15,000,000 cycles or more.

**Depth of Heat Penetration.**—Generally speaking, the higher the frequency used, the shallower the depth of heat penetration. For heating clear through, for deep hardening, and for large workpieces, low power concentrations and low frequencies are usually used. For very shallow and closely controlled depths of heating, as in surface hardening, and in localized heat treating of small workpieces, currents at high frequencies are used.

For example, a  $\frac{1}{2}$ -inch round bar of hardenable steel will be heated through its entire structure quite rapidly by an induced current of 2000 cycles. After quenching, the bar would show through hardness with a decrease in hardness from surface to center. The same piece of steel could be readily heated and surface hardened to a depth of 0.100 inch with current at 9600 cycles, and to an even shallower depth with current at 100,000 cycles. A  $\frac{1}{4}$ -inch bar, however, would not reach a sufficiently high temperature at 2000 cycles to permit hardening, but at 9600 cycles through hardening would be accomplished. Current at over 100,000 cycles would be needed for surface hardening such a bar.

**Types of Steel for Induction Hardening.**—Most of the standard types of steels can be hardened by induction heating, providing the carbon content is sufficient to produce the desired degree of hardness by quenching. Thus, low-carbon steels with a carburized case, medium- and high-carbon steels (both plain and alloy), and cast iron with a portion of the carbon in combined form, may be used for this purpose. Induction heating of alloy steels should be limited primarily to the shallow hardening type, that is those of low alloy content, otherwise the severe quench usually required may result in a highly stressed surface with consequent reduced load-carrying capacity and danger of cracking.

**Through Hardening, Annealing, and Normalizing by Induction.**—For through hardening, annealing, and normalizing by induction, low power concentrations are desirable to prevent too great a temperature differential between the surface and the interior of the

work. A satisfactory rate of heating is obtained when the total power input to the work is slightly greater than the radiation losses at the desired temperature. If possible, as low a frequency should be used as is consistent with good electrical coupling. A number of applicator coils may be connected in a series so that several workpieces can be heated simultaneously, thus reducing the power input to each. Widening the spacing between work and applicator coil also will reduce the amount of power delivered to the work.

**Induction Surface Hardening.**—As indicated earlier in “Depth of Heat Penetration,” currents at much higher frequencies are required in induction surface hardening than in through hardening by induction. In general, the smaller the workpiece, the thinner the section, or the shallower the depth to be hardened, the higher will be the frequency required. High power concentrations are also needed to make possible a short heating period so that an undue amount of heat will not be conducted to adjacent or interior areas, where a change in hardness is not desired. Generators of large capacity and applicator coils of but a few turns, or even a single turn, provide the necessary concentration of power in the localized area to be hardened.

Induction heating of internal surfaces, such as the interior of a hollow cylindrical part or the inside of a hole, can be accomplished readily with applicator coils shaped to match the cross-section of the opening, which may be round, square, elliptical or other form. If the internal surface is of short length, a multiturn applicator coil extending along its entire length may be employed. Where the power available is insufficient to heat the entire internal surface at once, progressive heating is used. For this purpose, an applicator coil of few turns — often but a single turn — is employed, and either coil or work is moved so that the heated zone passes progressively from one end of the hole or opening to the other. For bores of small diameter, a hairpin-shaped applicator, extending the entire length of the hole, may be used and the work rotated about the axis of the hole to ensure even heating.

**Quenching After Induction Heating.**—After induction heating, quenching may be by immersion in a liquid bath (usually oil), by liquid spray (usually water), or by self-quenching. (The term “self-quenching” is used when there is no quenching medium and hardening of the heated section is due chiefly to rapid absorption of heat by the mass of cool metal adjacent to it.) Quenching by immersion offers the advantage of even cooling and is particularly satisfactory for through heated parts. Spray quenching may be arranged so that the quenching ring and applicator coil are in the same or adjacent units, permitting the quenching cycle to follow the heating cycle immediately without removal of the work from the holding fixture. Automatic timing to a fraction of a second may also be employed for both heating and quenching with this arrangement to secure the exact degree of hardness desired. Self-quenching is applicable only in thin-surface hardening where the mass of adjacent cool metal in the part is great enough to conduct the heat rapidly out of the surface layer that is being hardened. It has been recommended that for adequate self-quenching, the mass of the unheated section should be at least ten times that of the heated shell. It has been found difficult to use the self-quenching technique to produce hardened shells of much more than about 0.060 inch thickness. Close to this limit, self-quenching can only be accomplished with the easily hardenable steels. By using a combination of self-quench and liquid quench, however, it is possible to produce hardened shells on work too thin to self-quench completely. In general, self-quenching is confined chiefly to relatively small parts and simple shapes.

**Induction Hardening of Gear Teeth.**—Several advantages are claimed for the induction hardening of gear teeth. One advantage is that the gear teeth can be completely machined, including shaving, when in the soft-annealed or normalized condition, and then hardened, because when induction heating is used, distortion is held to a minimum. Another advantage claimed is that bushings and inserts can be assembled in the gears before hardening. A wide latitude in choice of built-up webs and easily machined hubs is afforded because the hardness of neither web nor hub is affected by the induction-hardening operation although slight dimensional changes may occur in certain designs. Regular carbon steels can be

used in place of alloy steels for a wide variety of gears, and a steel with a higher carbon content can frequently be substituted for a carburizing steel so that the carburizing operation can be eliminated. Another saving in time is the elimination of cleaning after hardening.

In heating spur gear teeth by induction, the gear is usually placed inside a circular unit that combines the applicator coil and quenching ring. An automatic timing device controls both the heating and quenching cycles. During the heating cycle, the gear is rotated at 25 to 35 rpm to ensure uniform heating.

In hardening bevel gears, the applicator coil is wound to conform to the face angle of the gear. In some spiral-bevel gears, there is a tendency to obtain more heat on one side of the tooth than on the other. In some sizes of spiral-bevel gears, this tendency can be overcome by applying slightly more heat to ensure hardening of the concave side. In some forms of spiral-bevel gears, it has been the practice to carburize that part of the gear surface which is to be hardened, after the teeth have been rough-cut. Carburizing is followed by the finish-cutting operation, after which the teeth can be induction heated, using a long enough period to heat the entire tooth. When the gear is quenched, only the carburized surface will become hardened.

<sup>a</sup> Symbols: A = water or brine; B = water or oil; C = cool slowly; D = air or oil; E = oil; F = water, brine, or oil.

<sup>b</sup> Even where tempering temperatures are shown, tempering is not mandatory in many applications. Tempering is usually employed for partial stress relief and improves resistance to grinding cracks.

<sup>c</sup> Activated or cyanide baths.

<sup>d</sup> May be given refining heat as in other processes.

<sup>e</sup> Carbonitriding atmospheres

<sup>f</sup> Normalizing temperatures at least 50 deg. F above the carburizing temperature are sometimes recommended where minimum heat-treatment distortion is of vital importance.

<sup>a</sup> Normalizing temperatures should be not less than 50 deg. F higher than the carburizing temperature. Follow by air cooling.

<sup>b</sup> For cycle annealing, heat to normalizing temperature—hold for uniformity—cool rapidly to 1000-1250 deg. F; hold 1 to 3 hours, then air or furnace cool to obtain a structure suitable for machining and finishing.

<sup>c</sup> Symbols: C = cool slowly; E = oil.

<sup>d</sup> Tempering treatment is optional and is generally employed for partial stress relief and improved resistance to cracking from grinding operations.

<sup>e</sup> For use when case hardness only is paramount.

<sup>f</sup> For use when higher core hardness is desired.

<sup>g</sup> Treatment is for fine-grained steels only, when a second reheat is often unnecessary.

<sup>h</sup> Treatment is for activated or cyanide baths. Parts may be given refining heats as indicated for other heat-treating processes.

<sup>i</sup> After normalizing, reheat to temperatures of 1000-1200 deg. F and hold approximately 4 hours.

**Metallography.**—The science or study of the microstructure of metal is known by most metallurgists as “metallography” or sometimes “crystallography”. The examination of metals and metal alloys by the aid of the microscope is one of the most effective methods of studying their properties, and is also a valuable means of controlling the quality of manufactured metallic articles and of testing the finished product. In preparing the specimen, a flat surface is first formed by filing or grinding, and then given a high polish, which is later etched in order to reveal clearly the internal structure under the microscope. This process shows clearly to an experienced observer the effect of variation in composition, heat-treatment, etc., and in many cases it has proved a correct means of determining certain properties of industrial products that a chemical analysis has failed to reveal.

### Heat Treating High-Speed Steels

**Cobaltcrom Steel.**—A tungstenless alloy steel or high-speed steel that contains approximately 1.5 per cent carbon, 12.5 per cent chromium, and 3.5 per cent cobalt. Tools such as dies and milling cutters, made from cobaltcrom steel can be cast to shape in suitable molds, the teeth of cutters being formed so that it is necessary only to grind them.

Before the blanks can be machined, they must be annealed; this operation is performed by pack annealing at the temperature of 1800 degrees F, for a period of from three to six hours, according to the size of the castings being annealed. The following directions are given for the hardening of blanking and trimming dies, milling cutters, and similar tools made from cobaltcrom steel: Heat slowly in a hardening furnace to about 1830 degrees F, and hold at this temperature until the tools are thoroughly soaked. Reduce the temperature about 50 degrees, withdraw the tools from the furnace, and allow them to cool in the atmosphere. As soon as the red color disappears from the cooling tool, place it in quenching oil until cold. The slight drop of 50 degrees in temperature while the tool is still in the hardening furnace is highly important to obtain proper results. The steel will be injured if the tool is heated above 1860 degrees F. In cooling milling cutters or other rotary tools, it is suggested that they be suspended on a wire to ensure a uniform rate of cooling.

Tools that are to be subjected to shocks or vibration, such as pneumatic rivet sets, shear blades, etc., should be heated slowly to 1650 degrees F, after which the temperature should be reduced to about 1610 degrees F, at which point the tool should be removed from the furnace and permitted to cool in the atmosphere. No appreciable scaling occurs in the hardening of cobaltcrom steel tools.

**Preheating Tungsten High-Speed Steel.**—Tungsten high-speed steel must be hardened at a very high temperature; consequently, tools made from such steel are seldom hardened without at least one preheating stage to avoid internal strain. This requirement applies especially to milling cutters, taps, and other tools having thin teeth and thick bodies and to forming tools of irregular shape and section. The tools should be heated slowly and carefully to a temperature somewhat below the critical point of the steel, usually in the range of 1500 to 1600 degrees F. Limiting the preheating temperature prevents the operation from being unduly sensitive, and the tool may be safely left in the furnace until it reaches a uniform temperature throughout its length and cross-section.

A single stage of preheating is customary for tools of simple form that are not more than from 1 to 1½ inches in thickness. For large, intricate tools, two stages of preheating are frequently used. The first brings the tool up to a temperature of about 1100 to 1200 degrees F, and the second raises its temperature to 1550 to 1600 degrees F. A preheating time of 5 minutes for each ¼ inch in tool thickness has been recommended for a furnace temperature of 1600 degrees F. This is where a single stage of preheating is used and the furnace capacity should be sufficient to maintain practically constant temperature when the tools are changed. To prevent undue chilling, it is common practice to insert a single tool or a small lot in the hardening furnace whenever a tool or lot is removed, rather than to insert a full charge of cold metal at one time.

Preheating is usually done in a simple type of oven furnace heated by gas, electricity, or oil. Atmospheric control is seldom used, although for 18–4–1 steel a slightly reducing atmosphere (2 to 6 per cent carbon monoxide) has been found to produce the least amount of scale and will result in a better surface after final hardening.

**Hardening of Tungsten High-Speed Steel.**—All tungsten high-speed steels must be heated to a temperature close to their fusion point to develop their maximum efficiency as metal-cutting tools. Hardening temperatures ranging from 2200 to 2500 deg. F may be needed. The effects of changes in the hardening temperature on the cutting efficiency of several of the more common high-speed steels are shown in [Table 1](#). The figures given are ratios, the value 1.00 for each steel being assigned to the highest observed cutting speed for

that steel. The figures for different steels, therefore, cannot be directly compared with each other, except to note changes in the point of maximum cutting efficiency.

**Table 1. Relation of Hardening Temperature to Cutting Efficiency**

| Hardening Temperature, Deg. F | Typical Analyses of High-Speed Steels |            |                   |                   |
|-------------------------------|---------------------------------------|------------|-------------------|-------------------|
|                               | 18 - 4 - 1                            | 14 - 4 - 2 | 18 - 4 - 1 Cobalt | 14 - 4 - 2 Cobalt |
| 2200                          | 0.86                                  | 0.83       | 0.84              | 0.85              |
| 2250                          | 0.88                                  | 0.88       | 0.86              | 0.88              |
| 2300                          | 0.90                                  | 0.93       | 0.90              | 0.91              |
| 2350                          | 0.95                                  | 0.98       | 0.94              | 0.94              |
| 2400                          | 0.99                                  | 0.98       | 0.98              | 0.98              |
| 2450                          | 1.00                                  | ...        | 0.99              | 1.00              |
| 2500                          | 0.98                                  | ...        | 1.00              | 0.97              |

The figures in the table refer to tools heated in an oven-type furnace in which a neutral atmosphere is maintained. The available data indicate that a steel reaches its best cutting qualities at a temperature approximately 50 deg. F lower than the figures in the table if it is hardened in a bath-type furnace. It is, however, desirable to use a hardening temperature approximately 50 deg. F lower than that giving maximum cutting qualities, to avoid the possibility of overheating the tool.

*Length of Time for Heating:* The cutting efficiency of a tool is affected by the time that it is kept at the hardening temperature, almost as much as by the hardening temperature itself. It has been common practice to heat a tool for hardening until a "sweat" appeared on its surface. This sweat is presumably a melting of the oxide film on the surface of a tool heated in an oxidizing atmosphere. It does not appear when the tool is heated in an inert atmosphere. This method of determining the proper heating time is at best an approximation and indicates only the temperature on the outside of the tool rather than the condition of the interior. As such, it cannot be relied upon to give consistent results.

The only safe method is to heat the tool for a definite predetermined time, based on the size and the thickness of metal that the heat must penetrate to reach the interior. The values given in [Table 2](#) are based on a series of experiments to determine the relative cutting efficiency of a group of tools hardened in an identical manner, except for variations in the time the tools were kept at the hardening temperature. The time given is based on that required to harden throughout a tool resting on a conducting hearth; the tool receives heat freely from three sides, on its large top surface and its smaller side surfaces. (The table does not apply to a disk lying flat on the hearth.) For a tool having a projecting cutting edge, such as a tap, the thickness or depth of the projecting portion on which the cutting edge is formed should be used when referring to the table.

**Table 2. Length of Heating Time for Through Hardening**

| High-Speed Steel Tool Thickness, in Inches | Time in Furnace at High Heat, in Minutes | High-Speed Steel Tool Thickness, in Inches | Time in Furnace at High Heat, in Minutes | High-Speed Steel Tool Thickness, in Inches | Time in Furnace at High Heat, in Minutes |
|--|--|--|--|--|--|
| 1/4  | 2  | 1 1/2                                      | 7  | 5  | 18                                       |
| 1/2  | 3  | 2  | 8  | 6  | 20                                       |
| 3/4  | 4  | 3  | 12                                       | 8  | 25                                       |
| 1  | 5  | 4  | 15                                       | 10   | 30                                       |

The time periods given in [Table 2](#) are based on complete penetration of the hardening effect. For very thick tools, the practical procedure is to harden to a depth sufficient to produce an adequate cutting edge, leaving the interior of the tool relatively soft.

Where atmosphere control is not provided, it often will be found impracticable to use both the temperature for maximum cutting efficiency, given in [Table 1](#), and the heating time, given in [Table 2](#), because abnormal scaling, grain growth, and surface decarburization of the tool will result. The principal value of an accurate control of the furnace atmosphere appears to lie in the fact that its use makes possible the particular heat treatment that produces the best structure in the tool without destruction of the tool surface or grain.

**Quenching Tungsten High-Speed Steel.**—High-speed steel is usually quenched in oil. The oil bath offers a convenient quench; it calls for no unusual care in handling and brings about a uniform and satisfactory rate of cooling, which does not vary appreciably with the temperature of the oil. Some authorities believe it desirable to withdraw the tool from the oil bath for a few seconds after it has reached a dull red. It is also believed desirable to move the tool around in the quenching oil, particularly immediately after it has been placed in it, to prevent the formation of a gas film on the tool. Such a film is usually a poor conductor of heat and slows the rate of cooling.

*Salt Bath:* Quenching in a lead or salt bath at from 1000 to 1200 deg. F has the advantage that cooling of the tool from hardening to room temperature is accomplished in two stages, thus reducing the possibility of setting up internal strains that may tend to crack the tool. The quenching temperature is sufficiently below the lower critical point for a tool so quenched to be allowed to cool to room temperature in still air. This type of quench is particularly advantageous for tools of complicated section that would easily develop hardening cracks. The salt quench has the advantage that the tool sinks and requires only a support, whereas the same tool will float in the lead bath and must be held under the surface. It is believed that the lead quench gives a somewhat higher matrix hardness, and is of advantage for tools that tend to fail by nose abrasion. Tools treated as described are brittle unless given a regular tempering treatment, because the 1000-deg. F quenching temperature is not a substitute for later tempering at the same temperature, after the tool has cooled to room temperature.

*Air Cooling:* Many high-speed steel tools are quenched in air, either in a stream of dry compressed air or in still air. Small sections harden satisfactorily in still air, but heavier sections should be subjected to air under pressure. One advantage of air cooling is that the tool can be kept straight and free from distortion, although it is likely that there will be more scale on a tool thus quenched than when oil, lead, or salt is used. Cooling between steel plates may help to keep thin flat tools straight and flat.

**Straightening High-Speed Tools when Quenching.**—The final straightness required in a tool must be considered when it is quenched. When several similar tools are to be hardened, a jig can be used to advantage for holding the tools while quenching. When long slender tools are quenched without holders, they frequently warp and must be straightened later. The best time for this straightening is during the first few minutes after the tools have been quenched, as the steel is then quite pliable and may be straightened without difficulty. The straightening must be done at once, as the tools become hard in a few minutes.

**Anneal Before Rehardening.**—Tools that are too soft after hardening must be annealed before rehardening. A quick anneal, such as previously described, is all that is required to put such a tool into the proper condition for rehardening. This treatment is absolutely essential. For milling cutters and forming tools of irregular section, a full anneal should be used.

**Tempering or Drawing Tungsten High-Speed Steel.**—The tempering or drawing temperature for high-speed steel tools usually varies from 900 to 1200 deg. F. This temperature is higher for turning and planing tools than for such tools as milling cutters, forming tools, etc. If the temperature is below 800 deg. F, the tool is likely to be too brittle. The general idea is to temper tools at the highest temperature likely to occur in service. Because this temperature ordinarily would not be known, the general practice is to temper at whatever temperature experience with that particular steel and tool has proved to be the best.

The furnace used for tempering usually is kept at a temperature of from 1000 to 1100 deg. F for ordinary high-speed steels and from 1200 to 1300 deg. F for steels of the cobalt type. These furnace temperatures apply to tools of the class used on lathes and planers. Such tools, in service, frequently heat to the point of visible redness. Milling cutters, forming tools, or any other tools for lighter duty may be tempered as low as 850 or 900 deg. F. When the tool has reached the temperature of the furnace, it should be held at this temperature for from one to several hours until it has been heated evenly throughout. It should then be allowed to cool gradually in the air and in a place that is dry and free from air drafts. In tempering, the tool should not be quenched, because quenching tends to produce strains that may result later in cracks.

**Annealing Tungsten High-Speed Steel.**—The following method of annealing high-speed steel has been used extensively. Use an iron box or pipe of sufficient size to allow at least  $\frac{1}{2}$  inch of packing between the pieces of steel to be annealed and the sides of the box or pipe. It is not necessary that each piece of steel be kept separate from every other piece, but only that the steel be prevented from touching the sides of the annealing pipe or box. Pack carefully with powdered charcoal, fine dry lime, or mica (preferably charcoal), and cover with an airtight cap or lute with fire clay; heat slowly to 1600 to 1650 deg. F and keep at this heat from 2 to 8 hours, depending on the size of the pieces to be annealed. A piece measuring 2 by 1 by 8 inches requires about 3 hours. Cool as slowly as possible, and do not expose to the air until cold, because cooling in air is likely to cause partial hardening. A good method is to allow the box or pipe to remain in the furnace until cold.

**Hardening Molybdenum High-Speed Steels.**—Table 3 gives the compositions of several molybdenum high-speed steels that are widely used for general commercial tool applications. The general method of hardening molybdenum high-speed steels resembles that used for 18–4–1 tungsten high-speed steel except that the hardening temperatures are lower and more precautions must be taken to avoid decarburization, especially on tools made from Type I or Type II steels, when the surface is not ground after hardening. Either salt baths or atmosphere-controlled furnaces are recommended for hardening molybdenum high-speed steels.

**Table 3. Compositions of Molybdenum High-Speed Steels**

| Element    | Molybdenum–Tungsten   |                                    | Molybdenum–Vanadium   | Tungsten–Molybdenum    |
|------------|-----------------------|------------------------------------|-----------------------|------------------------|
|            | Type Ia<br>(Per Cent) | Type Ib <sup>a</sup><br>(Per Cent) | Type II<br>(Per Cent) | Type III<br>(Per Cent) |
| Carbon     | 0.70–0.85             | 0.76–0.82                          | 0.70–0.90             | 0.75–0.90              |
| Tungsten   | 1.25–2.00             | 1.60–2.30                          | ...                   | 5.00–6.00              |
| Chromium   | 3.00–5.00             | 3.70–4.20                          | 3.00–5.00             | 3.50–5.00              |
| Vanadium   | 0.90–1.50             | 1.05–1.35                          | 1.50–2.25             | 1.25–1.75              |
| Molybdenum | 8.00–9.50             | 8.00–9.00                          | 7.50–9.50             | 3.50–5.50              |
| Cobalt     | See footnote          | 4.50–5.50                          | See footnote          | See footnote           |

<sup>a</sup> Cobalt may be used in any of these steels in varying amounts up to 9 per cent, and the vanadium content may be as high as 2.25 percent. When cobalt is used in Type III steel, the vanadium content may be as high as 2.25 per cent. When cobalt is used in Type III steel, this steel becomes susceptible to decarburization. As an illustration of the use of cobalt, Type Ib steel is included. This is steel T10 in the U.S. Navy Specification 46S37, dated November 1, 1939.

The usual method is to preheat uniformly in a separate furnace to 1250 to 1550 deg. F then transfer to a high-heat furnace maintained within the hardening temperature range given in Table 4. Single-point cutting tools, in general, should be hardened at the upper end of the temperature range indicated by Table 4. Slight grain coarsening is not objectionable in such tools when they are properly supported in service and are not subjected to chattering; however, when these tools are used for intermittent cuts, it is better to use the middle of the temperature range. All other cutting tools, such as drills, countersinks, taps, milling

cutters, reamers, broaches, and form tools, should be hardened in the middle of the range shown. For certain tools, such as slender taps, cold punches, and blanking and trimming dies, where greater toughness to resist shocks is required, the lower end of the hardening temperature range should be used.

**Table 4. Heat Treatment of Molybdenum High-Speed Steels**

| Heat-Treating Operation | Molybdenum–Tungsten                                | Molybdenum–Vanadium           | Tungsten–Molybdenum            |
|-------------------------|--|-------------------------------|--------------------------------|
|                         | Types Ia and Ib <sup>a</sup><br>(Temp., in Deg. F) | Type II<br>(Temp., in Deg. F) | Type III<br>(Temp., in Deg. F) |
| Forging                 | 1850–2000  | 1850–2000                     | 1900–2050                      |
| Not below               | 1600   | 1600                          | 1600                           |
| Annealing               | 1450–1550  | 1450–1550                     | 1450–1550                      |
| Strain relief           | 1150–1350  | 1150–1350                     | 1150–1350                      |
| Preheating              | 1250–1500  | 1250–1500                     | 1250–1550                      |
| Hardening <sup>b</sup>  | 2150–2250 <sup>a</sup>                             | 2150–2250                     | 2175–2275                      |
| Salt                    | 2150–2225  | 2150–2225                     | 2150–2250                      |
| Tempering               | 950–1100   | 950–1100                      | 950–1100                       |

<sup>a</sup> For similar working conditions, Type Ib steel requires a slightly higher hardening heat than Type Ia.

<sup>b</sup> The higher side of the hardening range should be used for large sections, and the lower side for small sections.

Molybdenum high-speed steels can be pack-hardened following the same practice as is used for tungsten high-speed steels, but keeping on the lower side of the hardening range (approximately 1850 degrees F). Special surface treatments such as nitriding by immersion in molten cyanide that are used for tungsten high-speed steels are also applicable to molybdenum high-speed tools.

When heated in an open fire or in furnaces without atmosphere control, these steels do not sweat like 18–4–1 steels; consequently, determining the proper time in the high-heat chamber is a matter of experience. This time approximates that used with 18–4–1 steels, although it may be slightly longer when the lower part of the hardening range is used. Much can be learned by preliminary hardening of test pieces and checking on the hardness fracture and structure. It is difficult to give the exact heating time, because it is affected by temperature, type of furnace, size and shape, and furnace atmosphere. Rate of heat transfer is most rapid in salt baths, and slowest in controlled-atmosphere furnaces with high carbon monoxide content.

**Quenching and Tempering of Molybdenum High-Speed Tools.**—Quenching may be done in oil, air, or molten bath. To reduce the possibility of breakage and undue distortion of intricately shaped tools, it is advisable to quench in a molten bath at approximately 1100 degrees F. The tool also may be quenched in oil and removed while still red, or at approximately 1100 degrees F. The tool is then cooled in air to room temperature, and tempered immediately to avoid cracking.

When straightening is necessary, it should be done after quenching and before cooling to room temperature prior to tempering.

To temper, the tools should be reheated slowly and uniformly to 950 to 1100 degrees F. For general work, 1050 degrees F is most common. The tools should be held at this temperature at least 1 hour. Two hours is a safer minimum, and 4 hours is maximum. The time and temperature depend on the hardness and toughness required. Where tools are subjected to more or less shock, multiple temperings are suggested.

**Protective Coatings for Molybdenum Steels.**—To protect the surface from oxidation during heat treatment, borax may be applied by sprinkling it lightly over the steel when the latter is heated in a furnace to a low temperature (1200 to 1400 deg. F). Small tools may be rolled in a box of borax before heating. Another method more suitable for finished tools is

to apply the borax or boric acid in the form of a supersaturated water solution. The tools are then immersed in the solution at 180 to 212 deg. F, or the solution may be applied with a brush or spray. Pieces so treated are heated as usual, taking care in handling to ensure good adherence of the coating. Special protective coatings or paints, when properly applied, have been found extremely useful. These materials do not fuse or run at the temperatures used, and therefore do not affect the furnace hearth. When applying these coatings, it is necessary to have a surface free from scale or grease to ensure good adherence. Coatings may be sprayed or brushed on, and usually one thin coat is sufficient. Heavy coats tend to pit the surface of the tool and are difficult to remove. Tools covered with these coatings should be allowed to dry before they are charged into the preheat furnace. After hardening and tempering, the coating can be easily removed by light blasting with sand or steel shot. When tools are lightly ground, these coatings come off immediately. Protection may also be obtained by wrapping pieces in stainless steel foil.
