<sup>a</sup> Use UNR designation instead of UN wherever UNR thread form is desired for external use.

<sup>b</sup> Regarding combinations of thread classes, see text on page 1773.

<sup>c</sup> UN series external thread maximum minor diameter is basic for Class 3A and basic minus allowance for Classes 1A and 2A.

<sup>d</sup> For Class 2A threads having an additive finish the maximum is increased, by the allowance, to the basic size, the value being the same as for Class 3A.

<sup>e</sup> For unfinished hot-rolled material not including standard fasteners with rolled threads.

<sup>f</sup> Formerly NF, tolerances and allowances are based on one diameter length of engagement.

All dimensions in inches.

Use UNS threads only if Standard Series do not meet requirements (see pages 1733, 1765, and 1776). For additional sizes above 4 inches see ASME/ANSI B1.1-1989 (R2001).

*Coarse-Thread Series:* This series, UNC/UNRC, is the one most commonly used in the bulk production of bolts, screws, nuts and other general engineering applications. It is also used for threading into lower tensile strength materials such as cast iron, mild steel and softer materials (bronze, brass, aluminum, magnesium and plastics) to obtain the optimum resistance to stripping of the internal thread. It is applicable for rapid assembly or disassembly, or if corrosion or slight damage is possible.

*Fine-Thread Series:* This series, UNF/UNRF, is suitable for the production of bolts, screws, and nuts and for other applications where the Coarse series is not applicable. External threads of this series have greater tensile stress area than comparable sizes of the Coarse series. The Fine series is suitable when the resistance to stripping of both external

and mating internal threads equals or exceeds the tensile load carrying capacity of the externally threaded member (see page 1510). It is also used where the length of engagement is short, where a smaller lead angle is desired, where the wall thickness demands a fine pitch, or where finer adjustment is needed.

<sup>a</sup> British: Effective Diameter.

<sup>b</sup> See formula, pages 1502 and 1510.

<sup>c</sup> Design form for UNR threads. (See figure on page 1733.)

<sup>d</sup> Basic minor diameter.

<sup>e</sup> Secondary sizes.

*Extra-Fine-Thread Series:* This series, UNEF/UNREF, is applicable where even finer pitches of threads are desirable, as for short lengths of engagement and for thin-walled tubes, nuts, ferrules, or couplings. It is also generally applicable under the conditions stated above for the fine threads. See Table 4c.

*Fine Threads for Thin-Wall Tubing:* Dimensions for a 27-thread series, ranging from 1/4- to 1-inch nominal size, also are included in Table 3. These threads are recommended for general use on thin-wall tubing. The minimum length of complete thread is one-third of the basic major diameter plus 5 threads (+ 0.185 in.).

*Selected Combinations:* Thread data are tabulated in Table 3 for certain additional selected special combinations of diameter and pitch, with pitch diameter tolerances based on a length of thread engagement of 9 times the pitch. The pitch diameter limits are applicable to a length of engagement of from 5 to 15 times the pitch. (This provision should not be confused with the lengths of thread on mating parts, as they may exceed the length of engagement by a considerable amount.) Thread symbols are UNS and UNRS.

<sup>a</sup> British: Effective Diameter.<sup>b</sup> See formula, pages 1502 and 1510.<sup>c</sup> Design form for UNR threads. (See figure on page 1733.)<sup>d</sup> Basic minor diameter.<sup>e</sup> Secondary sizes.

*Other Threads of Special Diameters, Pitches, and Lengths of Engagement:* Thread data for special combinations of diameter, pitch, and length of engagement not included in selected combinations are also given in the Standard but are not given here. Also, when design considerations require non-standard pitches or extreme conditions of engagement not covered by the tables, the allowance and tolerances should be derived from the formulas in the Standard. The thread symbol for such special threads is UNS.

**Constant Pitch Series.**—The various constant-pitch series, UN, with 4, 6, 8, 12, 16, 20, 28 and 32 threads per inch, given in Table 3, offer a comprehensive range of diameter-pitch combinations for those purposes where the threads in the Coarse, Fine, and Extra-Fine series do not meet the particular requirements of the design.

When selecting threads from these constant-pitch series, preference should be given wherever possible to those tabulated in the 8-, 12-, or 16-thread series.

*8-Thread Series:* The 8-thread series (8-UN) is a uniform-pitch series for large diameters. Although originally intended for high-pressure-joint bolts and nuts, it is now widely used as a substitute for the Coarse-Thread Series for diameters larger than 1 inch.

**12-Thread Series:** The 12-thread series (12-UN) is a uniform pitch series for large diameters requiring threads of medium-fine pitch. Although originally intended for boiler practice, it is now used as a continuation of the Fine-Thread Series for diameters larger than  $1\frac{1}{2}$  inches.

**16-Thread Series:** The 16-thread series (16-UN) is a uniform pitch series for large diameters requiring fine-pitch threads. It is suitable for adjusting collars and retaining nuts, and also serves as a continuation of the Extra-fine Thread Series for diameters larger than  $1\frac{11}{16}$  inches.

**4-, 6-, 20-, 28-, and 32-Thread Series:** These thread series have been used more or less widely in industry for various applications where the Standard Coarse, Fine or Extra-fine Series were not as applicable. They are now recognized as Standard Unified Thread Series in a specified selection of diameters for each pitch (see Table 2).

Whenever a thread in a constant-pitch series also appears in the UNC, UNF, or UNEF series, the symbols and tolerances for limits of size of UNC, UNF, or UNEF series are applicable, as will be seen in Tables 2 and 3.

**Table 5a. 4-Thread Series, 4-UN and 4-UNR — Basic Dimensions**

<sup>a</sup> British: Effective Diameter.

<sup>b</sup> See formula, pages 1502 and 1510.

<sup>c</sup> Design form for UNR threads. (See figure on page 1733).

<sup>d</sup> Basic minor diameter.

<sup>e</sup> These are standard sizes of the UNC series.

Table 5b. 6-Thread Series, 6-UN and 6-UNR—Basic Dimensions

<sup>a</sup> British: Effective Diameter.

<sup>b</sup> See formula, pages 1502 and 1510.

<sup>c</sup> Design form for UNR threads. (See figure on page 1733.)

<sup>d</sup> Basic minor diameter.

<sup>e</sup> These are standard sizes of the UNC or UNF Series.

**Table 5f. 20-Thread Series, 20-UN and 20-UNR—Basic Dimensions**

<sup>a</sup> British: Effective Diameter.

<sup>b</sup> See formula, pages 1502 and 1510.

<sup>c</sup> Design form for UNR threads. (See figure on page 1733.)

<sup>d</sup> Basic minor diameter.

<sup>e</sup> These are standard sizes of the UNC, UNF, or UNEF Series.

UNIFIED SCREW THREADS

**Thread Classes.**—Thread classes are distinguished from each other by the amounts of tolerance and allowance. Classes identified by a numeral followed by the letters A and B are derived from certain Unified formulas (not shown here) in which the pitch diameter tolerances are based on increments of the basic major (nominal) diameter, the pitch, and the length of engagement. These formulas and the class identification or symbols apply to all of the Unified threads.

Classes 1A, 2A, and 3A apply to external threads only, and Classes 1B, 2B, and 3B apply to internal threads only. The disposition of the tolerances, allowances, and crest clearances for the various classes is illustrated on pages 1774 and 1774.

*Classes 2A and 2B:* Classes 2A and 2B are the most commonly used for general applications, including production of bolts, screws, nuts, and similar fasteners.

The maximum diameters of Class 2A (external) uncoated threads are less than basic by the amount of the allowance. The allowance minimizes galling and seizing in high-cycle wrench assembly, or it can be used to accommodate plated finishes or other coating. However, for threads with additive finish, the maximum diameters of Class 2A may be exceeded by the amount of the allowance, for example, the 2A maximum diameters apply to an unplated part or to a part before plating whereas the basic diameters (the 2A maximum diameter plus allowance) apply to a part after plating. The minimum diameters of Class 2B (internal) threads, whether or not plated or coated, are basic, affording no allowance or clearance in assembly at maximum metal limits.

*Class 2AG:* Certain applications require an allowance for rapid assembly to permit application of the proper lubricant or for residual growth due to high-temperature expansion. In these applications, when the thread is coated and the 2A allowance is not permitted to be consumed by such coating, the thread class symbol is qualified by G following the class symbol.

*Classes 3A and 3B:* Classes 3A and 3B may be used if closer tolerances are desired than those provided by Classes 2A and 2B. The maximum diameters of Class 3A (external) threads and the minimum diameters of Class 3B (internal) threads, whether or not plated or coated, are basic, affording no allowance or clearance for assembly of maximum metal components.

*Classes 1A and 1B:* Classes 1A and 1B threads replaced American National Class 1. These classes are intended for ordnance and other special uses. They are used on threaded components where quick and easy assembly is necessary and where a liberal allowance is required to permit ready assembly, even with slightly bruised or dirty threads.

Maximum diameters of Class 1A (external) threads are less than basic by the amount of the same allowance as applied to Class 2A. For the intended applications in American practice the allowance is not available for plating or coating. Where the thread is plated or coated, special provisions are necessary. The minimum diameters of Class 1B (internal) threads, whether or not plated or coated, are basic, affording no allowance or clearance for assembly with maximum metal external thread components having maximum diameters which are basic.

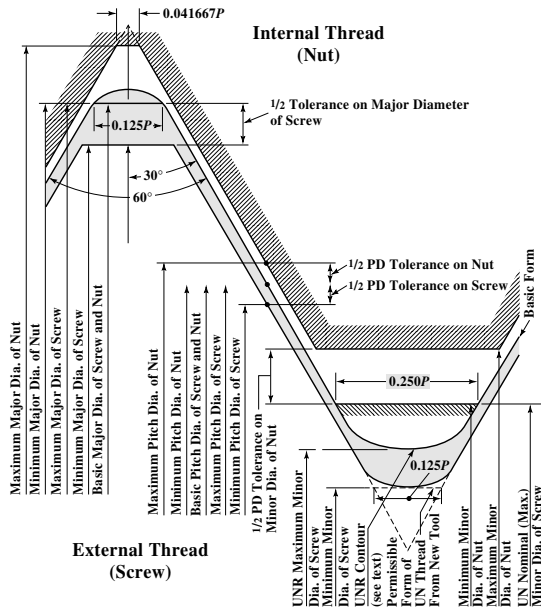

**Coated 60-deg. Threads.**—Although the Standard does not make recommendations for thicknesses of, or specify limits for coatings, it does outline certain principles that will aid mechanical interchangeability if followed whenever conditions permit.

To keep finished threads within the limits of size established in the Standard, external threads should not exceed basic size after plating and internal threads should not be below basic size after plating. This recommendation does not apply to threads coated by certain commonly used processes such as hot-dip galvanizing where it may not be required to maintain these limits.

Class 2A provides both a tolerance and an allowance. Many thread requirements call for coatings such as those deposited by electro-plating processes and, in general, the 2A allow-

Limits of Size Showing Tolerances, Allowances (Neutral Space), and Crest Clearances for Unified Classes 1A, 2A, 1B, and 2B

Limits of Size Showing Tolerances and Crest Clearances for Unified Classes 3A and 3B and American National Classes 2 and 3

ance provides adequate undercut for such coatings. There may be variations in thickness and symmetry of coating resulting from commercial processes but after plating the threads should be accepted by a basic Class 3A size GO gage and a Class 2A gage as a NOT-GO gage. Class 1A provides an allowance which is maintained for both coated and uncoated product, i.e., it is not available for coating.

Class 3A does not include an allowance so it is suggested that the limits of size before plating be reduced by the amount of the 2A allowance whenever that allowance is adequate.

No provision is made for overcutting internal threads as coatings on such threads are not generally required. Further, it is very difficult to deposit a significant thickness of coating on the flanks of internal threads. Where a specific thickness of coating is required on an internal thread, it is suggested that the thread be overcut so that the thread as coated will be accepted by a GO thread plug gage of basic size.

This Standard ASME/ANSI B1.1-1989 (R2001) specifies limits of size that pertain whether threads are coated or uncoated. Only in Class 2A threads is an allowance available to accommodate coatings. Thus, in all classes of internal threads and in all Class 1A, 2AG, and 3A external threads, limits of size must be adjusted to provide suitable provision for the desired coating.

For further information concerning dimensional accommodation of coating or plating for 60-degree threads, see Section 7, ASME/ANSI B1.1-1989 (R2001).

**Screw Thread Selection — Combination of Classes.**—Whenever possible, selection should be made from [Table 2](#), Standard Series Unified Screw Threads, preference being given to the Coarse- and Fine- thread Series. If threads in the standard series do not meet the requirements of design, reference should be made to the selected combinations in [Table 3](#). The third expedient is to compute the limits of size from the tolerance tables or tolerance increment tables given in the Standard. The fourth and last resort is calculation by the formulas given in the Standard.

The requirements for screw thread fits for specific applications depend on end use and can be met by specifying the proper combinations of thread classes for the components. For example, a Class 2A external thread may be used with a Class 1B, 2B, or 3B internal thread.

**Pitch Diameter Tolerances, All Classes.**—The pitch diameter tolerances in [Table 3](#) for all classes of the UNC, UNF, 4-UN, 6-UN, and 8-UN series are based on a length of engagement equal to the basic major (nominal) diameter and are applicable for lengths of engagement up to  $1\frac{1}{2}$  diameters.

The pitch diameter tolerances used in [Table 3](#) for all classes of the UNEF, 12-UN, 16-UN, 20-UN, 28-UN, and 32-UN series and the UNS series, are based on a length of engagement of 9 pitches and are applicable for lengths of engagement of from 5 to 15 pitches.

**Screw Thread Designation.**—The basic method of designating a screw thread is used where the standard tolerances or limits of size based on the standard length of engagement are applicable. The designation specifies in sequence the nominal size, number of threads per inch, thread series symbol, thread class symbol, and the gaging system number per ASME/ANSI B1.3M. The nominal size is the basic major diameter and is specified as the fractional diameter, screw number, or their decimal equivalent. Where decimal equivalents are used for size callout, they shall be interpreted as being nominal size designations only and shall have no dimensional significance beyond the fractional size or number designation. The symbol LH is placed after the thread class symbol to indicate a left-hand thread:

*Examples:*

$\frac{1}{4}$ -20 UNC-2A (21) or 0.250-20 UNC-2A (21)

10–32 UNF-2A (22) or 0.190–32 UNF-2A (22)

$\frac{7}{16}$ –20 UNRF-2A (23) or 0.4375–20 UNRF-2A (23)

2–12 UN-2A (21) or 2.000–12 UN-2A (21)

$\frac{1}{4}$ –20 UNC-3A-LH (21) or 0.250–20 UNC-3A-LH (21)

For uncoated standard series threads these designations may optionally be supplemented by the addition of the pitch diameter limits of size.

*Example:*

$\frac{1}{4}$ –20 UNC-2A (21)

PD 0.2164–0.2127 (Optional for uncoated threads)

**Designating Coated Threads.**—For coated (or plated) Class 2A external threads, the basic (max) major and basic (max) pitch diameters are given followed by the words AFTER COATING. The major and pitch diameter limits of size before coating are also given followed by the words BEFORE COATING.

*Example:*

$\frac{3}{4}$ –10 UNC-2A (21)

<sup>a</sup>Major dia 0.7500 max  
PD 0.6850 max

} AFTER COATING

<sup>b</sup>Major dia 0.7482–0.7353  
PD 0.6832–0.6773

} BEFORE COATING

<sup>a</sup> Major and PD values are equal to basic and correspond to those in Table 3 for Class 3A.

<sup>b</sup> Major and PD limits are those in Table 3 for Class 2A.

Certain applications require an allowance for rapid assembly, to permit application of a proper lubricant, or for residual growth due to high-temperature expansion. In such applications where the thread is to be coated and the 2A allowance is not permitted to be consumed by such coating, the thread class symbol is qualified by the addition of the letter G (symbol for allowance) following the class symbol, and the maximum major and maximum pitch diameters are reduced below basic size by the amount of the 2A allowance and followed by the words AFTER COATING. This arrangement ensures that the allowance is maintained. The major and pitch diameter limits of size before coating are also given followed by SPL and BEFORE COATING. For information concerning the designating of this and other special coating conditions reference should be made to American National Standard ASME/ANSI B1.1-1989 (R2001).

**Designating UNS Threads.**—UNS screw threads that have special combinations of diameter and pitch with tolerance to Unified formulation have the basic form designation set out first followed always by the limits of size.

**Designating Multiple Start Threads.**—If a screw thread is of multiple start, it is designated by specifying in sequence the nominal size, pitch (in decimals or threads per inch) and lead (in decimals or fractions).

**Other Special Designations.**—For other special designations including threads with modified limits of size or with special lengths of engagement, reference should be made to American National Standard ASME/ANSI B1.1-1989 (R2001).

**Hole Sizes for Tapping.**—Hole size limits for tapping Classes 1B, 2B, and 3B threads of various lengths of engagement are given in Table 2 on page 1925.

**Internal Thread Minor Diameter Tolerances.**—Internal thread minor diameter tolerances in Table 3 are based on a length of engagement equal to the nominal diameter. For general applications these tolerances are suitable for lengths of engagement up to  $1\frac{1}{2}$  diameters. However, some thread applications have lengths of engagement which are greater than  $1\frac{1}{2}$  diameters or less than the nominal diameter. For such applications it may be advantageous to increase or decrease the tolerance, respectively, as explained in the Tapping Section.

### American Standard for Unified Miniature Screw Threads

This American Standard (B1.10-1958, R1988) introduces a new series to be known as Unified Miniature Screw Threads and intended for general purpose fastening screws and similar uses in watches, instruments, and miniature mechanisms. Use of this series is recommended on all new products in place of the many improvised and unsystematized sizes now in existence which have never achieved broad acceptance nor recognition by standardization bodies. The series covers a diameter range from 0.30 to 1.40 millimeters (0.0118 to 0.0551 inch) and thus supplements the Unified and American thread series which begins at 0.060 inch (number 0 of the machine screw series). It comprises a total of fourteen sizes which, together with their respective pitches, are those endorsed by the American-British-Canadian Conference of April 1955 as the basis for a Unified standard among the inch-using countries, and coincide with the corresponding range of sizes in ISO (International Organization for Standardization) Recommendation No. 68. Additionally, it utilizes thread forms which are compatible in all significant respects with both the Unified and ISO basic thread profiles. Thus, threads in this series are interchangeable with the corresponding sizes in both the American-British-Canadian and ISO standardization programs.

**Basic Form of Thread.**—The basic profile by which the design forms of the threads covered by this standard are governed is shown in Table 1. The thread angle is 60 degrees and except for basic height and depth of engagement which are  $0.52p$ , instead of  $0.54127p$ , the basic profile for this thread standard is identical with the Unified and American basic thread form. The selection of 0.52 as the exact value of the coefficient for the height of this basic form is based on practical manufacturing considerations and a plan evolved to simplify calculations and achieve more precise agreement between the metric and inch dimensional tables.

Products made to this standard will be interchangeable with products made to other standards which allow a maximum depth of engagement (or combined addendum height) of  $0.54127p$ . The resulting difference is negligible (only 0.00025 inch for the coarsest pitch) and is completely offset by practical considerations in tapping, since internal thread heights exceeding  $0.52p$  are avoided in these (Unified Miniature) small thread sizes in order to reduce excessive tap breakage.

**Design Forms of Threads.**—The design (maximum material) forms of the external and internal threads are shown in Table 2. These forms are derived from the basic profile shown in Table 1 by the application of clearances for the crests of the addenda at the roots of the mating dedendum forms. Basic and design form dimensions are given in Table 3.

**Nominal Sizes:** The thread sizes comprising this series and their respective pitches are shown in the first two columns of Table 5. The fourteen sizes shown in Table 5 have been systematically distributed to provide a uniformly proportioned selection over the entire range. They are separated alternately into two categories: The sizes shown in bold type are selections made in the interest of simplification and are those to which it is recommended that usage be confined wherever the circumstances of design permit. Where these sizes do not meet requirements the intermediate sizes shown in light type are available.

**Table 1. Unified Miniature Screw Threads — Basic Thread Form**

| Formulas for Basic Thread Form                      |           |            |  |
|---|-----------|------------|--|
| Metric units (millimeters) are used in all formulas |           |            |  |
| Thread Element                                      | Symbol    | Formula    |  |
| Angle of thread                                     | $2\alpha$ | 60°        |  |
| Half angle of thread                                | $\alpha$  | 30°        |  |
| Pitch of thread                                     | $p$       |            |  |
| No. of threads per inch                             | $n$       | $25.4/p$   |  |
| Height of sharp V thread                            | $H$       | $0.86603p$ |  |
| Addendum of basic thread                            | $h_{db}$  | $0.32476p$ |  |
| Height of basic thread                              | $h_b$     | $0.52p$    |  |

<sup>a</sup>In Tables 5 and 6 these values are shown rounded to the nearest whole number.

**Table 4. Unified Miniature Screw Threads — Formulas for Basic and Design Dimensions and Tolerances**

| Formulas for Basic Dimensions  |  |
|--|--|
| D = Basic Major Diameter and Nominal Size in millimeters; $p$ = Pitch in millimeters; $E$ = Basic Pitch Diameter in millimeters = $D - 0.64952p$ ; and $K$ = Basic Minor Diameter in millimeters = $D - 1.04p$ |  |
| Formulas for Design Dimensions (Maximum Material)  |  |
| External Thread  | Internal Thread                                    |
| $D_s$ = Major Diameter = $D$   | $D_n$ = Major Diameter = $D + 0.072p$              |
| $E_s$ = Pitch Diameter = $E$   | $E_n$ = Pitch Diameter = $E$                       |
| $K_s$ = Minor Diameter = $D - 1.20p$   | $K_n$ = Minor Diameter = $K$                       |
| Formulas for Tolerances on Design Dimensions <sup>a</sup>  |  |
| External Thread (-)  | Internal Thread (+)                                |
| Major Diameter Tol., $0.12p + 0.006$   | <sup>b</sup> Major Diameter Tol., $0.168p + 0.008$ |
| Pitch Diameter Tol., $0.08p + 0.008$   | Pitch Diameter Tol., $0.08p + 0.008$               |
| <sup>c</sup> Minor Diameter Tol., $0.16p + 0.008$  | Minor Diameter Tol., $0.32p + 0.012$               |

<sup>a</sup>These tolerances are based on lengths of engagement of  $\frac{2}{3}D$  to  $1\frac{1}{2}D$ .

<sup>b</sup>This tolerance establishes the maximum limit of the major diameter of the internal thread. In practice, this limit is applied to the threading tool (tap) and not gaged on the product. Values for this tolerance are, therefore, not given in Table 5.

<sup>c</sup>This tolerance establishes the minimum limit of the minor diameter of the external thread. In practice, this limit is applied to the threading tool and only gaged on the product in confirming new tools. Values for this tolerance are, therefore, not given in Table 5.

Metric units (millimeters) apply in all formulas. Inch tolerances are not derived by direct conversion of the metric values. They are the differences between the rounded off limits of size in inch units.

Table 5. Unified Miniature Screw Threads — Limits of Size and Tolerances

| Size Designation <sup>a</sup> | External Threads |                        |               |                        |               |                        |                        |                        | Internal Threads |                        |               |                        | Lead Angle at Basic Pitch Diam. |          | Sectional Area at Minor Diam. at D — 1.28p |                  |

<sup>a</sup> Sizes shown in bold type are preferred.

<sup>b</sup> This is also the basic dimension.

<sup>c</sup> This limit, in conjunction with root form shown in Table 2, is advocated for use when optical projection methods of gaging are employed. For mechanical gaging the minimum minor diameter of the internal thread is applied.

<sup>d</sup> This limit is provided for reference only. In practice, the form of the threading tool is relied upon for this limit.

<sup>e</sup> This limit is provided for reference only, and is not gaged. For gaging, the maximum major diameter of the external thread is applied.

Limits of Size Showing Tolerances and Crest Clearances for UNM Threads

*Limits of Size:* Formulas used to determine limits of size are given in [Table 4](#); the limits of size are given in [Table 5](#). The diagram on page [1781](#) illustrates the limits of size and [Table 6](#) gives values for the minimum flat at the root of the external thread shown on the diagram.

*Classes of Threads:* The standard establishes one class of thread with zero allowance on all diameters. When coatings of a measurable thickness are required, they should be included within the maximum material limits of the threads since these limits apply to both coated and uncoated threads.

*Hole Sizes for Tapping:* Suggested hole sizes are given in the Tapping Section.

#### **British Standard Unified Screw Threads of UNJ Basic Profile**

This British Standard B.S. 4084: 1978 arises from a request originating from within the British aircraft industry and is based upon specifications for Unified screw threads and American military standard MIL-S-8879.

These UNJ threads, having an enlarged root radius, were introduced for applications requiring high fatigue strength where working stress levels are high, in order to minimize size and weight, as in aircraft engines, airframes, missiles, space vehicles and similar designs where size and weight are critical. To meet these requirements the root radius of external Unified threads is controlled between appreciably enlarged limits, the minor diameter of the mating internal threads being appropriately increased to insure the necessary clearance. The requirement for high strength is further met by restricting the tolerances for UNJ threads to the highest classes, Classes 3A and 3B, of Unified screw threads.

The standard, not described further here, contains both a coarse and a fine pitch series of threads.

## METRIC SCREW THREADS

### American National Standard Metric Screw Threads M Profile

American National Standard ANSI/ASME B1.13M-1983 (R1995) describes a system of metric threads for general fastening purposes in mechanisms and structures. The standard is in basic agreement with ISO screw standards and resolutions, as of the date of publication, and features detailed information for diameter-pitch combinations selected as to preferred standard sizes. This Standard contains general metric standards for a 60-degree symmetrical screw thread with a basic ISO 68 designated profile.

**Application Comparison with Inch Threads.**—The metric M profile threads of tolerance class 6H/6g (see page 1790) are intended for metric applications where the inch class 2A/2B have been used. At the minimum material limits, the 6H/6g results in a looser fit than the 2A/2B. Tabular data are also provided for a tighter tolerance fit external thread of class 4g6g which is approximately equivalent to the inch class 3A but with an allowance applied. It may be noted that a 4H5H/4h6h fit is approximately equivalent to class 3A/3B fit in the inch system.

**Interchangeability with Other System Threads.**—Threads produced to this Standard ANSI/ASME B1.13M are fully interchangeable with threads conforming to other National Standards that are based on ISO 68 basic profile and ISO 965/1 tolerance practices.

Threads produced to this Standard should be mechanically interchangeable with those produced to ANSI B1.18M-1982 (R1987) "Metric Screw Threads for Commercial Mechanical Fasteners—Boundary Profile Defined," of the same size and tolerance class. However, there is a possibility that some parts may be accepted by conventional gages used for threads made to ANSI/ASME B1.13M and rejected by the Double-NOT-GO gages required for threads made to ANSI B1.18M.

Threads produced in accordance with M profile and MJ profile ANSI/ASME B1.21M design data will assemble with each other. However, external MJ threads will encounter interference on the root radii with internal M thread crests when both threads are at maximum material condition.

**Definitions.**—The following definitions apply to metric screw threads — M profile.

*Allowance:* The minimum nominal clearance between a prescribed dimension and its basic dimension. Allowance is not an ISO metric screw thread term but it is numerically equal to the absolute value of the ISO term *fundamental deviation*.

*Basic Thread Profile:* The cyclical outline in an axial plane of the permanently established boundary between the provinces of the external and internal threads. All deviations are with respect to this boundary. (See Figs. 1 and 5.)

*Bolt Thread (External Thread):* The term used in ISO metric thread standards to describe all external threads. All symbols associated with external threads are designated with lower case letters. This Standard uses the term external threads in accordance with United States practice.

*Clearance:* The difference between the size of the internal thread and the size of the external thread when the latter is smaller.

*Crest Diameter:* The major diameter of an external thread and the minor diameter of an internal thread.

*Design Profiles:* The maximum material profiles permitted for external and internal threads for a specified tolerance class. (See Figs. 2 and 3.)

*Deviation:* An ISO term for the algebraic difference between a given size (actual, measured, maximum, minimum, etc.) and the corresponding basic size. The term deviation does not necessarily indicate an error.

**Fit:** The relationship existing between two corresponding external and internal threads with respect to the amount of clearance or interference which is present when they are assembled.

**Fundamental Deviation:** For Standard threads, the deviation (upper or lower) closer to the basic size. It is the upper deviation,  $es$ , for an external thread and the lower deviation,  $ei$ , for an internal thread. (See Fig. 5.)

**Limiting Profiles:** The limiting M profile for internal threads is shown in Fig. 6. The limiting M profile for external threads is shown in Fig. 7.

**Lower Deviation:** The algebraic difference between the minimum limit of size and the corresponding basic size.

**Nut Thread (Internal Thread):** A term used in ISO metric thread standards to describe all internal threads. All symbols associated with internal threads are designated with upper case letters. This Standard uses the term *internal thread* in accordance with United States practice.

**Tolerance:** The total amount of variation permitted for the size of a dimension. It is the difference between the maximum limit of size and the minimum limit of size (i.e., the algebraic difference between the upper deviation and the lower deviation). The tolerance is an absolute value without sign. Tolerance for threads is applied to the design size in the direction of the minimum material. On external threads the tolerance is applied negatively. On internal threads the tolerance is applied positively.

**Tolerance Class:** The combination of a tolerance position with a tolerance grade. It specifies the allowance (fundamental deviation) and tolerance for the pitch and major diameters of external threads and pitch and minor diameters of internal threads.

**Tolerance Grade:** A numerical symbol that designates the tolerances of crest diameters and pitch diameters applied to the design profiles.

**Tolerance Position:** A letter symbol that designates the position of the tolerance zone in relation to the basic size. This position provides the allowance (fundamental deviation).

**Upper Deviation:** The algebraic difference between the maximum limit of size and the corresponding basic size.

**Basic M Profile.**—The basic M thread profile also known as ISO 68 basic profile for metric screw threads is shown in Fig. 1 with associated dimensions listed in Table 3.

**Design M Profile for Internal Thread.**—The design M profile for the internal thread at maximum material condition is the basic ISO 68 profile. It is shown in Fig. 2 with associated thread data listed in Table 3.

**Design M Profile for External Thread.**—The design M profile for the external thread at the no allowance maximum material condition is the basic ISO 68 profile except where a rounded root is required. For the standard  $0.125P$  minimum radius, the ISO 68 profile is modified at the root with a  $0.17783H$  truncation blending into two arcs with radii of  $0.125P$  tangent to the thread flanks as shown in Fig. 3 with associated thread data in Table 3.

**M Crest and Root Form.**—The form of crest at the major diameter of the external thread is flat, permitting corner rounding. The external thread is truncated  $0.125H$  from a sharp crest. The form of the crest at the minor diameter of the internal thread is flat. It is truncated  $0.25H$  from a sharp crest.

The crest and root tolerance zones at the major and minor diameters will permit rounded crest and root forms in both external and internal threads.

The root profile of the external thread must lie within the "section lined" tolerance zone shown in Fig. 4. For the rounded root thread, the root profile must lie within the "section lined" rounded root tolerance zone shown in Fig. 4. The profile must be a continuous, smoothly blended non-reversing curve, no part of which has a radius of less than  $0.125P$ , and which is tangential to the thread flank. The profile may comprise tangent flank arcs that are joined by a tangential flat at the root.

The root profile of the internal thread must not be smaller than the basic profile. The maximum major diameter must not be sharp.

**General Symbols.**—The general symbols used to describe the metric screw thread forms are shown in Table 1.

**Table 1. American National Standard Symbols for Metric Threads  
ANSI/ASME B1.13M-1983 (R1995)**

| Symbol           | Explanation   |
|------------------|---|
| $D$              | Major Diameter Internal Thread  |
| $D_1$            | Minor Diameter Internal Thread  |
| $D_2$            | Pitch Diameter Internal Thread  |
| $d$              | Major Diameter External Thread  |
| $d_1$            | Minor Diameter External Thread  |
| $d_2$            | Pitch Diameter External Thread  |
| $d_3$            | Rounded Form Minor Diameter External Thread   |
| $P$              | Pitch   |
| $r$              | External Thread Root Radius   |
| $T$              | Tolerance   |
| $T_{D1}, T_{D2}$ | Tolerances for $D_1, D_2$   |
| $T_d, T_{d2}$    | Tolerances for $d, d_2$   |
| $ES$             | Upper Deviation, Internal Thread [Equals the Allowance (Fundamental Deviation) Plus the Tolerance]. See Fig. 5.   |
| $EI$             | Lower Deviation, Internal Thread Allowance (Fundamental Deviation). See Fig. 5.   |
| $G, H$           | Letter Designations for Tolerance Positions for Lower Deviation, Internal Thread  |
| $g, h$           | Letter Designations for Tolerance Positions for Upper Deviation, External Thread  |
| $es$             | Upper Deviation, External Thread Allowance (Fundamental Deviation). See Fig. 5. In the ISO system $es$ is always negative for an allowance fit or zero for no allowance.        |
| $ei$             | Lower Deviation, External Thread [Equals the Allowance (Fundamental Deviation) Plus the Tolerance]. See Fig. 5. In the ISO system $ei$ is always negative for an allowance fit. |
| $H$              | Height of Fundamental Triangle  |
| $LE$             | Length of Engagement  |
| $LH$             | Left Hand Thread  |

**Standard M Profile Screw Thread Series.**—The standard metric screw thread series for general purpose equipment's threaded components design and mechanical fasteners is a *coarse thread* series. Their diameter/pitch combinations are shown in Table 4. These diameter/pitch combinations are the preferred sizes and should be the first choice as applicable. Additional *fine pitch* diameter/pitch combinations are shown in Table 5.

**Table 2. American National Standard General Purpose and Mechanical Fastener  
Coarse Pitch Metric Thread—M Profile Series ANSI/ASME B1.13M-1983 (R1995)**

| Nom.Size | Pitch | Nom.Size | Pitch | Nom.Size | Pitch            | Nom.Size | Pitch |
|----------|-------|----------|-------|----------|------------------|----------|-------|
| 1.6      | 0.35  | 6        | 1     | 22       | 2.5 <sup>a</sup> | 56       | 5.5   |
| 2        | 0.4   | 8        | 1.25  | 24       | 3                | 64       | 6     |
| 2.5      | 0.45  | 10       | 1.5   | 27       | 3 <sup>a</sup>   | 72       | 6     |
| 3        | 0.5   | 12       | 1.75  | 30       | 3.5              | 80       | 6     |

<sup>a</sup> Difference between max theoretical pitch diameter and max minor diameter of external thread and between min theoretical pitch diameter and min minor diameter of internal thread.

<sup>b</sup> Difference between min theoretical pitch diameter and min design minor diameter of external thread for 0.125P root radius.

<sup>c</sup> Difference between max major diameter and max theoretical pitch diameter of internal thread.

All dimensions are in millimeters.

<sup>a</sup> Only for wheel studs and nuts.

All dimensions are in millimeters.

**Limits and Fits for Metric Screw Threads — M Profile.**—The International (ISO) metric tolerance system is based on a system of limits and fits. The limits of the tolerances on the mating parts together with their allowances (fundamental deviations) determine the fit of the assembly. For simplicity the system is described for cylindrical parts (see *British Standard for Metric ISO Limits and Fits* starting on page 679) but in this Standard it is applied to screw threads. Holes are equivalent to internal threads and shafts to external threads.

**Basic Size:** This is the zero line or surface at assembly where the interface of the two mating parts have a common reference.\*

**Upper Deviation:** This is the algebraic difference between the maximum limit of size and the basic size. It is designated by the French term “écart supérieur” (ES for internal and es for external threads).

**Lower Deviation:** This is the algebraic difference between the minimum limit of size and the basic size. It is designated by the French term “écart inférieur” (EI for internal and ei for external threads).

\* Basic,” when used to identify a particular dimension in this Standard, such as basic major diameter, refers to the h/H tolerance position (zero fundamental deviation) value.

*Fundamental Deviations (Allowances):* These are the deviations which are closest to the basic size. In the accompanying figure they would be *EI* and *es*.

*Fits:* Fits are determined by the fundamental deviations assigned to the mating parts and may be positive or negative. The selected fits can be clearance, transition, or interference. To illustrate the fits schematically, a zero line is drawn to represent the basic size as shown in Fig. 5. By convention, the external thread lies below the zero line and the internal thread lies above it (except for interference fits). This makes the fundamental deviation negative for the external thread and equal to its upper deviation (*es*). The fundamental deviation is positive for the internal thread and equal to its lower deviation (*EI*).

$$H = \frac{\sqrt{3}}{2} \times P = 0.866025P$$

$$0.125H = 0.108253P \quad 0.250H = 0.216506P \quad 0.375H = 0.324760P \quad 0.625H = 0.541266P$$

Fig. 1. Basic M Thread Profile (ISO 68 Basic Profile)

Fig. 2. Internal Thread Design M Profile with No Allowance (Fundamental Deviation) (Maximum Material Condition). For Dimensions see Table 3

Fig. 3. External Thread Design M Profile with No Allowance (Fundamental Deviation) (Flanks at Maximum Material Condition). For Dimensions see Table 3

Fig. 4. M Profile, External Thread Root, Upper and Lower Limiting Profiles for  $r_{min} = 0.125P$  and for Flat Root (Shown for Tolerance Position g)

Notes:

- 1) "Section lined" portions identify tolerance zone and unshaded portions identify allowance (fundamental deviation).
- 2) The upper limiting profile for rounded root is not a design profile; rather it indicates the limiting acceptable condition for the rounded root which will pass a GO thread gage.
- 3) Max truncation =  $\frac{H}{4} - r_{min} \left( 1 - \cos \left[ 60^\circ - \arccos \left( 1 - \frac{T_{d2}}{4r_{min}} \right) \right] \right)$

where

$H$  = Height of fundamental triangle  
 $r_{min}$  = Minimum external thread root radius  
 $T_{d2}$  = Tolerance on pitch diameter of external thread

Fig. 5. Metric Tolerance System for Screw Threads

**Tolerance:** The tolerance is defined by a series of numerical grades. Each grade provides numerical values for the various nominal sizes corresponding to the standard tolerance for that grade.

In the schematic diagram the tolerance for the external thread is shown as negative. Thus the tolerance plus the fit define the lower deviation ( $ei$ ). The tolerance for the mating internal thread is shown as positive. Thus the tolerance plus the fit defines the upper deviation ( $ES$ ).

**Tolerance Grade:** This is indicated by a number. The system provides for a series of tolerance grades for each of the four screw thread parameters: minor diameter, internal thread,  $D_1$ ; major diameter, external thread,  $d$ ; pitch diameter, internal thread,  $D_2$ ; and pitch diameter, external thread,  $d_2$ . The tolerance grades for this Standard ANSI B1.13M were selected from those given in ISO 965/1.

| Dimension | Tolerance Grades                    | Table                    |
|-----------|-------------------------------------|--------------------------|
| $D_1$     | 4, 5, <u>6</u> , 7, 8               | <a href="#">Table 8</a>  |
| $d$       | 4, <u>6</u> , 8                     | <a href="#">Table 9</a>  |
| $D_2$     | 4, 5, <u>6</u> , 7, 8               | <a href="#">Table 10</a> |
| $d_2$     | 3, <u>4</u> , 5, <u>6</u> , 7, 8, 9 | <a href="#">Table 11</a> |

*Note:* The underlined tolerance grades are used with normal length of thread engagement.

**Tolerance Position:** This position is the allowance (fundamental deviation) and is indicated by a letter. A capital letter is used for internal threads and a lower case letter for external threads. The system provides a series of tolerance positions for internal and external threads. The underlined letters are used in this Standard:

|                  |                    |                         |
|------------------|--------------------|-------------------------|
| Internal threads | G, <u>H</u>        | <a href="#">Table 6</a> |
| External threads | e, f, <u>g</u> , h | <a href="#">Table 6</a> |

**Designations of Tolerance Grade, Tolerance Position, and Tolerance Class:** The tolerance grade is given first followed by the tolerance position, thus: 4g or 5H. To designate the tolerance class the grade and position of the pitch diameter is shown first followed by that for the major diameter in the case of the external thread or that for the minor diameter in the case of the internal thread, thus 4g6g for an external thread and 5H6H for an internal thread. If the two grades and positions are identical, it is not necessary to repeat the symbols, thus 4g, alone, stands for 4g4g and 5H, alone, stands for 5H5H.

**Table 6. American National Standard Allowance (Fundamental Deviation) for Internal and External Metric Threads**  
*ISO 965/1 ANSI/ASME B1.13M-1983 (R1995)*

| Pitch<br><i>P</i> | Allowance (Fundamental Deviation) <sup>a</sup>                   |           |   |           |           |           |

| 5.5               | +0.075   | 0         | -0.112  | -0.090    | -0.075    | 0         |
| 6                 | +0.080   | 0         | -0.118  | -0.095    | -0.080    | 0         |

All dimensions are in millimeters.

<sup>a</sup> Allowance is the absolute value of fundamental deviation.

**Lead and Flank Angle Tolerances:** For acceptance of lead and flank angles of product screw threads, see Section 10 of ANSI/ASME B1.13M-1983 (R1995).

**Short and Long Lengths of Thread Engagement when Gaged with Normal Length Contacts:** For short lengths of thread engagement, LE, reduce the pitch diameter tolerance of the external thread by one tolerance grade number. For long lengths of thread engagement, LE, increase the allowance (fundamental deviation) at the pitch diameter of the external thread. Examples of tolerance classes required for normal, short, and long gage length contacts are given in the following table.

| Normal LE         | Short LE | Long LE |
|-------------------|----------|---------|
| 6g                | 5g6g     | 6e6g    |
| 4g6g              | 3g6g     | 4e6g    |
| 6h <sup>a</sup>   | 5h6h     | 6g6h    |
| 4h6h <sup>a</sup> | 3h6h     | 4g6h    |

<sup>a</sup> Applies to maximum material functional size (GO thread gage) for plated 6g and 4g6g class threads, respectively.

For lengths of thread engagement classified as normal, short, and long, see [Table 7](#).

**Coated or Plated Threads:** Coating is one or more applications of additive material to the threads, including dry-film lubricants, but excluding soft or liquid lubricants that are readily displaced in assembly or gaging. Plating is included as coating in the Standard.

**Table 7. American National Standard Length of Metric Thread Engagement**  
*ISO 965/1 and ANSI/ASME B1.13M-1983 (R1995)*

| Basic Major Diameter $d_{\text{bsc}}$ |                 | Pitch<br>$P$ | Length of Thread Engagement |           |                 |         |
|---------------------------------------|-----------------|--------------|-----------------------------|-----------|-----------------|---------|
|                                       |                 |              | Short LE                    | Normal LE |                 | Long LE |
| Over                                  | Up to and incl. |              | Up to and incl.             | Over      | Up to and incl. | Over    |
| 1.5                                   | 2.8             | 0.2          | 0.5                         | 0.5       | 1.5             | 1.5     |

|                                       |                 | 6            | 40                          | 40        | 118             | 118     |

All dimensions are in millimeters.

Unless otherwise specified, size limits for standard external tolerance classes 6g and 4g6g apply prior to coating. The external thread allowance may thus be used to accommodate the coating thickness on coated parts, provided that the maximum coating thickness is no more than one-quarter of the allowance. Thus, the thread after coating is subject to acceptance using a basic (tolerance position h) size GO thread gage and tolerance position g thread gage for either minimum material, LO, or NOT-GO. Where the external thread has no allowance or the allowance must be maintained after coating, and for standard internal

threads, sufficient allowance must be provided prior to coating to ensure that finished product threads do not exceed the maximum material limits specified. For thread classes with tolerance position H or h, coating allowances in accordance with Table 6 for position G or g, respectively, should be applied wherever possible.

**Dimensional Effect of Coating.**—On a cylindrical surface, the effect of coating is to change the diameter by twice the coating thickness. On a 60-degree thread, however, since the coating thickness is measured perpendicular to the thread surface while the pitch diameter is measured perpendicular to the thread axis, the effect of a uniformly coated flank on the pitch diameter is to change it by four times the thickness of the coating on the flank.

*External Thread with No Allowance for Coating:* To determine gaging limits before coating for a uniformly coated thread, decrease: 1) maximum pitch diameter by four times maximum coating thickness; 2) minimum pitch diameter by four times minimum coating thickness; 3) maximum major diameter by two times maximum coating thickness; and

4) minimum major diameter by two times minimum coating thickness.

*External Thread with Only Nominal or Minimum Thickness Coating:* If no coating thickness tolerance is given, it is recommended that a tolerance of plus 50 per cent of the nominal or minimum thickness be assumed.

Then, to determine before coating gaging limits for a uniformly coated thread, decrease:

1) maximum pitch diameter by six times coating thickness; 2) minimum pitch diameter by four times coating thickness; 3) maximum major diameter by three times coating thickness; and 4) minimum major diameter by two times coating thickness.

*Adjusted Size Limits:* It should be noted that the before coating material limit tolerances are less than the tolerance after coating. This is because the coating tolerance consumes some of the product tolerance. In cases there may be insufficient pitch diameter tolerance available in the before coating condition so that additional adjustments and controls will be necessary.

*Strength:* On small threads (5 mm and smaller) there is a possibility that coating thickness adjustments will cause base material minimum material conditions which may significantly affect strength of externally threaded parts. Limitations on coating thickness or part redesign may then be necessary.

*Internal Threads:* Standard internal threads provide no allowance for coating thickness.

To determine before coating, gaging limits for a uniformly coated thread, increase:

1) minimum pitch diameter by four times maximum coating thickness, if specified, or by six times minimum or nominal coating thickness when a tolerance is not specified; 2) maximum pitch diameter by four times minimum or nominal coating thickness; 3) minimum minor diameter by two times maximum coating thickness, if specified, or by three times minimum or nominal coating thickness; and 4) maximum minor diameter by two times minimum or nominal coating thickness.

**Other Considerations.**—It is essential to review all possibilities adequately and consider limitations in the threading and coating production processes before finally deciding on the coating process and the allowance required to accommodate the coating. A no-allowance thread after coating must not transgress the basic profile and is, therefore, subject to acceptance using a basic (tolerance position H/h) size GO thread gage.

**Formulas for M Profile Screw Thread Limiting Dimensions.**—The limiting dimensions for M profile screw threads are calculated from the following formulas.

**Internal Threads:**

*Min major dia.* = basic major dia. +  $EI$  (Table 6)

*Min pitch dia.* = basic major dia. -  $0.649519P$  (Table 3) +  $EI$  for  $D_2$  (Table 6)

*Max pitch dia.* = min pitch dia. +  $T_{D_2}$  (Table 10)

*Max major dia.* = max pitch dia. +  $0.793857P$  (Table 3)

*Min minor dia.* = min major dia. -  $1.082532P$  (Table 3)

*Max minor dia.* = min minor dia. +  $T_{D_1}$  (Table 8)

**External Threads:**

*Max major dia.* = basic major dia. -  $es$  (Table 6) (Note that  $es$  is an absolute value.)

*Min major dia.* = max major dia. -  $T_d$  (Table 9)

*Max pitch dia.* = basic major dia. -  $0.649519P$  (Table 3) -  $es$  for  $d_2$  (Table 6)

*Min pitch dia.* = max pitch dia. -  $T_{d_2}$  (Table 11)

*Max flat form minor dia.* = max pitch dia. -  $0.433013P$  (Table 3)

*Max rounded root minor dia.* = max pitch dia. -  $2 \times$  max trunc. (See Fig. 4)

*Min rounded root minor dia.* = min pitch dia. -  $0.616025P$  (Table 3)

*Min root radius* =  $0.125P$

All dimensions are in millimeters.

**Tolerance Grade Comparisons.**—The approximate ratios of the tolerance grades shown in Tables 8, 9, 10, and 11 in terms of Grade 6 are as follows:

*Minor Diameter Tolerance of Internal Thread:*  $T_{D_1}$  (Table 8): Grade 4 is  $0.63 T_{D_1}$  (6); Grade 5 is  $0.8 T_{D_1}$  (6); Grade 7 is  $1.25 T_{D_1}$  (6); and Grade 8 is  $1.6 T_{D_1}$  (6).

*Pitch Diameter Tolerance of Internal Thread:*  $T_{D_2}$  (Table 10): Grade 4 is  $0.85 T_{D_2}$  (6); Grade 5 is  $1.06 T_{D_2}$  (6); Grade 6 is  $1.32 T_{D_2}$  (6); Grade 7 is  $1.7 T_{D_2}$  (6); and Grade 8 is  $2.12 T_{D_2}$  (6). It should be noted that these ratios are in terms of the Grade 6 pitch diameter tolerance for the external thread.

*Major Diameter Tolerance of External Thread:*  $T_d$  (Table 9): Grade 4 is  $0.63 T_d$  (6); and Grade 8 is  $1.6 T_d$  (6).

*Pitch Diameter Tolerance of External Thread:*  $T_{d_2}$  (Table 11): Grade 3 is  $0.5 T_{d_2}$  (6); Grade 4 is  $0.63 T_{d_2}$  (6); Grade 5 is  $0.8 T_{d_2}$  (6); Grade 7 is  $1.25 T_{d_2}$  (6); Grade 8 is  $1.6 T_{d_2}$  (6); and Grade 9 is  $2 T_{d_2}$  (6).

**Standard M Profile Screw Threads, Limits of Size.**—The limiting M profile for internal threads is shown in Fig. 6 with associated dimensions for standard sizes in Table 12. The limiting M profiles for external threads are shown in Fig. 7 with associated dimensions for standard sizes in Table 13.

If the required values are not listed in these tables, they may be calculated using the data in Tables 3, 6, 7, 8, 9, 10, and 11 together with the preceding formulas. If the required data are not included in any of the tables listed above, reference should be made to Sections 6 and 9.3 of ANSI/ASME B1.13M, which gives design formulas.

Fig. 6. Internal Thread—Limiting M Profile. Tolerance Position H

\*This dimension is used in the design of tools, etc. For internal threads it is not normally specified. Generally, major diameter acceptance is based on maximum material condition gaging.

METRIC SCREW THREADS M PROFILE

NOTE: "SECTION LINED" PORTIONS IDENTIFY TOLERANCE ZONE AND UNSHADED PORTIONS IDENTIFY ALLOWANCE (FUNDAMENTAL DEVIATION)

<sup>a</sup> This reference dimension is used in design of tools, etc., and is not normally specified. Generally, major diameter acceptance is based upon maximum material condition gaging.

All dimensions are in millimeters.

<sup>a</sup>  $e_s$  is an absolute value.<sup>b</sup> (Flat form) For screw threads at maximum limits of tolerance position  $h$ , add the absolute value  $e_s$  to the maximum diameters required. For maximum major diameter this value is the basic thread size listed in Table 12 as Minimum Major Diameter ( $D_{1min}$ ); for maximum pitch diameter this value is the same as listed in Table 12 as Minimum Pitch Diameter ( $D_{2min}$ ); and for maximum minor diameter this value is the same as listed in Table 12 as Minimum Minor Diameter ( $D_{1min}$ ).<sup>c</sup> (Rounded form) This reference dimension is used in the design of tools, etc. In dimensioning external threads it is not normally specified. Generally minor diameter acceptance is based upon maximum material condition gaging.

All dimensions are in millimeters.

**Metric Screw Thread Designations.**—Metric screw threads are identified by the letter (M) for the thread form profile, followed by the nominal diameter size and the pitch expressed in millimeters, separated by the sign (×) and followed by the tolerance class separated by a dash (–) from the pitch.

The simplified international practice for designating coarse pitch M profile metric screw threads is to leave off the pitch. Thus a M14 × 2 thread is designated just M14. However, to prevent misunderstanding, it is mandatory to use the value for pitch in all designations.

Thread acceptability gaging system requirements of ANSI B1.3M may be added to the thread size designation as noted in the examples (numbers in parentheses) or as specified in pertinent documentation, such as the drawing or procurement document.

Unless otherwise specified in the designation, the screw thread is right hand.

*Examples:* External thread of M profile, right hand: M6 × 1 – 4g6g (22)  
Internal thread of M profile, right hand: M6 × 1 – 5H6H (21)

*Designation of Left Hand Thread:* When a left hand thread is specified, the tolerance class designation is followed by a dash and LH.

*Example:* M6 × 1 – 5H6H – LH (23)

*Designation for Identical Tolerance Classes:* If the two tolerance class designations for a thread are identical, it is not necessary to repeat the symbols.

*Example:* M6 × 1 – 6H (21)

*Designation Using All Capital Letters:* When computer and teletype thread designations use all capital letters, the external or internal thread may need further identification. Thus the tolerance class is followed by the abbreviations EXT or INT in capital letters.

*Examples:* M6 × 1 – 4G6G EXT; M6 × 1 – 6H INT

*Designation for Thread Fit:* A fit between mating threads is indicated by the internal thread tolerance class followed by the external thread tolerance class and separated by a slash.

*Examples:* M6 × 1 – 6H/6g; M6 × 1 – 6H/4g6g

*Designation for Rounded Root External Thread:* The M profile with a minimum root radius of 0.125P on the external thread is desirable for all threads but is mandatory for threaded mechanical fasteners of ISO 898/I property class 8.8 (minimum tensile strength 800 MPa) and stronger. No special designation is required for these threads. Other parts requiring a 0.125P root radius must have that radius specified.

When a special rounded root is required, its external thread designation is suffixed by the minimum root radius value in millimeters and the letter R.

*Example:* M42 × 4.5 – 6g – 0.63R

*Designation of Threads Having Modified Crests:* Where the limits of size of the major diameter of an external thread or the minor diameter of an internal thread are modified, the thread designation is suffixed by the letters MOD followed by the modified diameter limits.

*Examples:*

|   |   |
|---|---|
| External thread M profile, major diameter reduced 0.075 mm.<br>M6 × 1 – 4h6h MOD<br>Major dia = 5.745 – 5.925 MOD | Internal thread M profile, minor diameter increased 0.075 mm.<br>M6 × 1 – 4H5H MOD<br>Minor dia = 5.101 – 5.291 MOD |
|---|---|

*Designation of Special Threads:* Special diameter-pitch threads developed in accordance with this Standard ANSI/ASME B1.13M are identified by the letters SPL following the tolerance class. The limits of size for the major diameter, pitch diameter, and minor diameter are specified below this designation.

*Examples:*

| External thread            | Internal thread            |
|----------------------------|----------------------------|
| M6.5 × 1 – 4h6h – SPL (22) | M6.5 × 1 – 4H5H – SPL (23) |
| Major dia = 6.320 – 6.500  | Major dia = 6.500 min      |
| Pitch dia = 5.779 – 5.850  | Pitch dia = 5.850 – 5.945  |
| Minor dia = 5.163 – 5.386  | Minor dia = 5.417 – 5.607  |

*Designation of Multiple Start Threads:* When a thread is required with a multiple start, it is designated by specifying sequentially: M for metric thread, nominal diameter size, × L for lead, lead value, dash, P for pitch, pitch value, dash, tolerance class, parenthesis, script number of starts, and the word starts, close parenthesis.

*Examples:* M16 × L4 – P2 – 4h6h (TWO STARTS)  
M14 × L6 – P2 – 6H (THREE STARTS)

*Designation of Coated or Plated Threads:* In designating coated or plated M threads the tolerance class should be specified as after coating or after plating. If no designation of after coating or after plating is specified, the tolerance class applies before coating or plating in accordance with ISO practice. After plating, the thread must not transgress the maximum material limits for the tolerance position H/h.

*Examples:* M6 × 1 – 6h AFTER COATING or AFTER PLATING  
M6 × 1 – 6g AFTER COATING or AFTER PLATING

Where the tolerance position G/g is insufficient relief for the application to hold the threads within product limits, the coating or plating allowance may be specified as the maximum and minimum limits of size for minor and pitch diameters of internal threads or major and pitch diameters for external threads before coating or plating.

*Example:* Allowance on external thread M profile based on 0.010 mm minimum coating thickness.

M6 × 1 – 4h6h – AFTER COATING  
BEFORE COATING  
Major dia = 5.780 – 5.940  
Pitch dia = 5.239 – 5.290

**Metric Screw Threads—MJ Profile**

The MJ screw thread is intended for aerospace metric threaded parts and for other highly stressed applications requiring high temperature or high fatigue strength, or for “no allowance” applications. The MJ profile thread is a hard metric version similar to the UNJ inch standards, ANSI/ASME B1.15 and MIL-S-8879. The MJ profile thread has a 0.15011P to 0.180424P controlled root radius in the external thread and the internal thread minor diameter truncated to accommodate the external thread maximum root radius.

First issued in 1978, the American National Standard ANSI/ASME B1.21M-1997 establishes the basic triangular profile for the MJ form of thread; gives a system of designations; lists the standard series of diameter-pitch combinations for diameters from 1.6 to 200 mm; and specifies limiting dimensions and tolerances. Changes included in the 1997 revision are the addition of tolerance class 4G6G and 4G5G/4g6g comparable to ANSI/ASME B1.15 (UNJ thread); the addition of tolerance class 6H/6g comparable to ANSI/ASME B1.13M; and changes in the rounding procedure as set forth in ANSI/ASME B1.30M.

**Diameter-Pitch Combinations.**—This Standard includes a selected series of diameter-pitch combinations of threads taken from International Standard ISO 261 plus some additional sizes in the constant pitch series. These are given in [Table 1](#). It also includes the standard series of diameter-pitch combinations for aerospace screws, bolts, nuts, and fluid system fittings as shown in [Table 2](#).

**Table 1. ANSI Standard Metric Screw Threads MJ Profile Diameter-Pitch Combinations ANSI/ASME B1.21M-1997**

| Nominal Diameter |     | Pitches |                             | Nominal Diameter |     | Pitches |                                      |
|------------------|-----|---------|-----------------------------|------------------|-----|---------|--------------------------------------|

All dimensions are in millimeters.

<sup>a</sup>For threads smaller than 1.6 mm nominal size, use miniature screw threads (ANSI B1.10M).

Fig. 1. Internal MJ Thread Basic and Design Profiles (Top) and External MJ Thread Basic and Design Profiles (Bottom) Showing Tolerance Zones

*Tolerances:* The thread tolerance system is based on ISO 965/1, *Metric Screw thread System of Tolerance Positions and Grades*. Tolerances are positive for internal threads and negative for external threads, that is, in the direction of minimum material.

For aerospace applications, except for fluid fittings, tolerance classes 4H5H or 4G6G and 4g6g should be used. These classes approximate classes 3B/3A in the inch system. Aerospace fluid fittings use classes 4H5H or 4H6H and 4g6g.

Tolerance classes 4G5G or 4G6G and 4g6g are provided for use when thread allowances are required. These classes provide a slightly tighter fit than the inch classes 2B/2A at minimum material condition.

Additional tolerance classes 6H/6g are included in this Standard to provide appropriate product selection based on general applications. These classes and the selection of standard diameter/pitch combinations are the same as those provided for the M profile metric screw threads in ANSI/ASME B1.13M. Classes 6H/6g result in a slightly looser fit than inch classes 2B/2A at minimum material condition.

*Symbols:* Standard symbols appearing in Fig. 1 are:

$D$  = Basic major diameter of internal thread

$D_2$  = Basic pitch diameter of internal thread

$D_1$  = Basic minor diameter of internal thread

$d$  = Basic major diameter of external thread

$d_2$  = Basic pitch diameter of external thread

$d_1$  = Basic minor diameter of internal thread

$d_3$  = Diameter to bottom of external thread root radius

$H$  = Height of fundamental triangle

$P$  = Pitch

*Basic Designations:* The aerospace metric screw thread is designated by the letters "MJ" to identify the metric J thread form, followed by the nominal size and pitch in millimeters (separated by the sign "×") and followed by the tolerance class (separated by a dash from the pitch). Unless otherwise specified in the designation, the thread helix is right hand.

*Example:* MJ6 × 1 – 4h6h

For further details concerning limiting dimensions, allowances for coating and plating, modified and special threads, etc., reference should be made to the Standard.

### Trapezoidal Metric Thread

**Comparison of ISO and DIN Standards.**—ISO metric trapezoidal screw threads standard, ISO 2904-1977, describes the system of general purpose metric threads for use in mechanisms and structures. The standard is in basic agreement with trapezoidal metric thread DIN 103. The DIN 103 standard applies a particular pitch for a particular diameter of thread, but the ISO standard applies a variety of pitches for a particular diameter. In ISO 2904-1977, the same clearance is applied to both the major diameter and minor diameter, but in DIN 103 the clearance in the minor diameter is two or three times greater than clearance in the major diameter. A comparison of ISO 2904 and DIN 103 is given in Table 1.

Metric Trapezoidal Thread, ISO 2904

**Terminology:** The term "bolt threads" is used for external screw threads, the term "nut threads" for internal screw threads.

**Calculation:** The value given in the International standards have been calculated by using the following formulas:

$$\begin{aligned}
 H_1 &= 0.5P & H_4 &= H_1 + a_c = 0.5P + a_c & H_3 &= H_1 + a_c = 0.5P + a_c \\
 D_4 &= d + 2a_c & Z &= 0.25P = H_1/2 & D_1 &= d - 2H_1 = d - p \\
 D_3 &= D - 2h_3 & d_2 &= D_2 = d - 2Z = d - 0.5P & R_{1max.} &= 0.5a_c & R_{2max.} &= a_c
 \end{aligned}$$

where  $a_c$  = clearance on the crest;  $D$  = major diameter for nut threads;  $D_2$  = pitch diameter for nut threads;  $D_1$  = minor diameter for nut threads;  $d$  = major diameter for bolt threads = nominal diameter;  $d_2$  = pitch diameter for bolt threads;  $d_3$  = minor diameter for bolt threads;  $h_1$  = Height of overlapping;  $h_4$  = height of nut threads;  $h_3$  = height of bolt threads; and,  $P$  = pitch.

**Table 1. Comparison of ISO Metric Trapezoidal Screw Thread ISO 2904-1977 and Trapezoidal Metric Screw Thread DIN 103**

|                                     | ISO 2904            | DIN 103            | Comment  |
|-------------------------------------|---------------------|--------------------|----------|
| Nominal Diameter                    | $D$                 | $D_S$              |          |

All dimensions are in millimeters.

\*Roots are rounded to a radius,  $r$ , equal to 0.25 mm for pitches of from 3 to 12 mm inclusive and 0.5 mm for pitches of from 14 to 26 mm inclusive for power transmission.

$D$  and  $d$  dimensions refer to the nut (internal) and screw (external) threads, respectively.

## British Standard ISO Metric Screw Threads

BS 3643:Part 1:1981 (1998) provides principles and basic data for ISO metric screw threads. It covers single-start, parallel screw threads of from 1 to 300 millimeters in diameter. Part 2 of the Standard gives the specifications for selected limits of size.

**Basic Profile.**—The ISO basic profile for triangular screw threads is shown in Fig. 1, and basic dimensions of this profile are given in Table 1.

**Table 1. British Standard ISO Metric Screw Threads  
Basic Profile Dimensions BS 3643:1981 (1998)**

<sup>a</sup>This pitch is not used in any of the ISO metric standard series.  
All dimensions are given in millimeters.

**Tolerance System.**—The tolerance system defines *tolerance classes* in terms of a combination of a *tolerance grade* (figure) and a *tolerance position* (letter). The tolerance position is defined by the distance between the basic size and the nearest end of the tolerance zone, this distance being known as the *fundamental deviation*, EI, in the case of internal threads, and es in the case of external threads. These tolerance positions with respect to the basic size (zero line) are shown in Fig. 2 and fundamental deviations for nut and bolt threads are given in Table 2.

**Table 2. Fundamental Deviations for Nut Threads and Bolt Threads**

| Pitch<br><i>P</i><br>mm | Nut Thread<br><i>D</i> <sub>2</sub> , <i>D</i> <sub>1</sub> |    | Bolt Thread<br><i>d</i> , <i>d</i> <sub>2</sub> |     |     |    | Pitch<br><i>P</i><br>mm | Nut Thread<br><i>D</i> <sub>2</sub> , <i>D</i> <sub>1</sub> |    | Bolt Thread<br><i>d</i> , <i>d</i> <sub>2</sub> |     |     |    |

See Figs. 1 and 2 for meaning of symbols.

**Tolerance Grades.**—Tolerance grades specified in the Standard for each of the four main screw thread diameters are as follows:

Minor diameter of nut threads ( $D_1$ ): tolerance grades 4, 5, 6, 7, and 8.

Major diameter of bolt threads ( $d$ ): tolerance grades 4, 6, and 8.

Pitch diameter of nut threads ( $D_2$ ): tolerance grades 4, 5, 6, 7, and 8.

Pitch diameter of bolt threads ( $d_2$ ): tolerance grades 3, 4, 5, 6, 7, 8, and 9.

**Tolerance Positions.**—Tolerance positions are G and H for nut threads and e, f, g, and h for bolt threads. The relationship of these tolerance position identifying letters to the amount of fundamental deviation is shown in Table 2.

- $D$  = maj. diam. of internal thread;
- $d$  = maj. diam. of external th
- $D_2$  = pitch diam. of internal thread;
- $d_2$  = pitch diam. of internal thread;
- $D_1$  = minor diam. of internal thread;
- $d_1$  = minor diam. of external thread;
- $P$  = Pitch;
- $H$  = height of fundamental angle;

Fig. 1. Basic Profile of ISO Metric Thread

**Tolerance Classes.**—To reduce the number of gages and tools, the Standard specifies that the tolerance positions and classes shall be chosen from those listed in Table 3 for short, normal, and long lengths of thread engagement. The following rules apply for the choice of tolerance quality: *Fine*: for precision threads when little variation of fit character is needed; *Medium*: for general use; and *Coarse*: for cases where manufacturing difficulties can arise as, for example, when threading hot-rolled bars and long blind holes. If the actual length of thread engagement is unknown, as in the manufacturing of standard bolts, normal is recommended.

Table 3. Tolerance Classes<sup>a,b,c</sup> for Nuts and Bolts

| Tolerance Classes for Nuts  |                      |                 |                   |                      |                   |                 |                      |                   |                   |                      |                 |                   |

<sup>a</sup> First choice.

<sup>b</sup> Second choice.

<sup>c</sup> Third choice; these are to be avoided.

<sup>d</sup> For commercial nut and bolt threads.

*Note:* See Table 4 for short, normal, and long categories. Any of the recommended tolerance classes for nuts can be combined with any of the recommended tolerance classes for bolts with the exception of sizes M1.4 and smaller for which the combination 5H/6h or finer shall be chosen. However, to guarantee a sufficient overlap, the finished components should preferably be made to form the fits H/g, H/h, or G/h.

All dimensions are given in millimeters

Fig. 2. Tolerance Positions with Respect to Zero Line (Basic Size)

**Design Profiles.**—The design profiles for ISO metric internal and external screw threads are shown in Fig. 3. These represent the profiles of the threads at their maximum metal condition. It may be noted that the root of each thread is deepened so as to clear the basic flat crest of the other thread. The contact between the thread is thus confined to their sloping flanks. However, for nut threads as well as bolt threads, the actual root contours shall not at any point violate the basic profile.

**Designation.**—Screw threads complying with the requirements of the Standard shall be designated by the letter M followed by values of the nominal diameter and of the pitch, expressed in millimeters, and separated by the sign  $\times$ . *Example:* M6  $\times$  0.75. The absence of the indication of pitch means that a coarse pitch is specified.

The complete designation of a screw thread consists of a designation for the thread system and size, and a designation for the crest diameter tolerance. Each class designation consists of: a figure indicating the tolerance grade; and a letter indicating the tolerance

position, capital for nuts, lower case for bolts. If the two class designations for a thread are the same (one for the pitch diameter and one for the crest diameter), it is not necessary to repeat the symbols. As examples, a bolt thread designated M10-6g signifies a thread of 10 mm nominal diameter in the Coarse Thread Series having a tolerance class 6g for both pitch and major diameters. A designation M10 × 1-5g6g signifies a bolt thread of 10 mm nominal diameter having a pitch of 1 mm, a tolerance class 5g for pitch diameter, and a tolerance class 6g for major diameter. A designation M10-6H signifies a nut thread of 10 mm diameter in the Coarse Thread Series having a tolerance class 6H for both pitch and minor diameters.

## Nut (Internal Thread)

## Bolt (External Thread)

Fig. 3. Maximum Material Profiles for Internal and External Threads

A fit between mating parts is indicated by the nut thread tolerance class followed by the bolt thread tolerance class separated by an oblique stroke. *Examples:* M6-6H/6g and M20 × 2-6H/5g6g. For coated threads, the tolerances apply to the parts before coating, unless otherwise specified. After coating, the actual thread profile shall not at any point exceed the maximum material limits for either tolerance position H or h.

**Fundamental Deviation Formulas.**—The formulas used to calculate the fundamental deviations in Table 2 are:

$$EI_G = + (15 + 11P)$$

$$EI_H = 0$$

$$es_e = -(50 + 11P) \text{ except for threads with } P \leq 0.45 \text{ mm}$$

$$es_f = -(30 + 11P)$$

$$es_g = -(15 + 11P)$$

$$es_h = 0$$

In these formulas, EI and es are expressed in micrometers and P is in millimeters.

**Crest Diameter Tolerance Formulas.**—The tolerances for the major diameter of bolt threads ( $T_d$ ), grade 6, in Table 5, were calculated from the formula:

$$T_d(6) = 180 \sqrt[3]{P^2} - \frac{3.15}{\sqrt{P}}$$

In this formula,  $T_d(6)$  is in micrometers and  $P$  is in millimeters. For tolerance grades 4 and 8:  $T_d(4) = 0.63 T_d(6)$  and  $T_d(8) = 1.6 T_d(6)$ , respectively.

The tolerances for the minor diameter of nut threads ( $T_{D1}$ ), grade 6, in Table 5, were calculated as follows:

For pitches 0.2 to 0.8 mm,  $T_{D1}(6) = 433P - 190P^{1.22}$ .

For pitches 1 mm and coarser,  $T_{D1}(6) = 230P^{0.7}$ .

In these formulas,  $T_{D1}(6)$  is in micrometers and  $P$  is in millimeters. For tolerance grades 4, 5, 7, and 8:  $T_{D1}(4) = 0.63 T_{D1}(6)$ ;  $T_{D1}(5) = 0.8 T_{D1}(6)$ ;  $T_{D1}(7) = 1.25 T_{D1}(6)$ ; and  $T_{D1}(8) = 1.6 T_{D1}(6)$ , respectively.

**Table 5. British Standard ISO Metric Screw Threads: Limits and Tolerances for Finished Uncoated Threads for Normal Lengths of Engagement BS 3643: Part 2: 1981**

| Nominal Diameter <sup>a</sup> | Pitch  |      | External Threads (Bolts) |            |            |        |            |        | Internal Threads (Nuts) <sup>b</sup> |            |            |       |            |       |           |       |
|-------------------------------|--------|------|--------------------------|------------|------------|--------|------------|--------|--------------------------------------|------------|------------|-------|------------|-------|-----------|-------|

<sup>a</sup> This table provides coarse- and fine-pitch series data for threads listed in Table 6 for first, second, and third choices. For constant-pitch series and for larger sizes than are shown, refer to the Standard.

<sup>b</sup> The fundamental deviation for internal threads (nuts) is zero for threads in this table.

All dimensions are in millimeters.

**Diameter/Pitch Combinations.**—Part 1 of BS 3643 provides a choice of diameter/pitch combinations shown here in Table 6. The use of first-choice items is preferred but if necessary, second, then third choice combinations may be selected. If pitches finer than those given in Table 6 are necessary, only the following pitches should be used: 3, 2, 1.5, 1, 0.75, 0.5, 0.35, 0.25, and 0.2 mm. When selecting such pitches it should be noted that there is increasing difficulty in meeting tolerance requirements as the diameter is increased for a given pitch. It is suggested that diameters greater than the following should not be used with the pitches indicated:

|                      |     |      |    |     |     |     |
|----------------------|-----|------|----|-----|-----|-----|
| Pitch, mm            | 0.5 | 0.75 | 1  | 1.5 | 2   | 3   |
| Maximum Diameter, mm | 22  | 33   | 80 | 150 | 200 | 300 |

In cases where it is necessary to use a thread with a pitch larger than 6 mm, in the diameter range of 150 to 300 mm, the 8 mm pitch should be used.

**Limits and Tolerances for Finished Uncoated Threads.**—Part 2 of BS 3643 specifies the fundamental deviations, tolerances, and limits of size for the tolerance classes 4H, 5H, 6H, and 7H for internal threads (nuts) and 4h, 6g, and 8g for external threads (bolts) for coarse-pitch series within the range of 1 to 68 mm; fine-pitch series within the range of 1 to 33 mm; and constant pitch series within the range of 8 to 300 mm diameter.

The data in Table 5 provide the first, second, and third choice combinations shown in Table 6 except that constant-pitch series threads are omitted. For diameters larger than shown in Table 5, and for constant-pitch series data, refer to the Standard.

**Table 6. British Standard ISO Metric Screw Threads — Diameter/Pitch Combinations BS 3643:Part 1:1981 (1998)**

| Nominal Diameter |     |                 | Coarse Pitch | Fine Pitch | Constant Pitch        | Nominal Diameter |     |                 | Constant Pitch |

<sup>a</sup>Only for spark plugs for engines.<sup>b</sup>Only for locking nuts for bearings.

All dimensions are in millimeters. Pitches in parentheses ( ) are to be avoided as far as possible.

## Comparison of Various Metric Thread Systems

**Metric Series Threads — A comparison of Maximum Metal Dimensions of British (BS 1095), French (NF E03-104), German (DIN 13), and Swiss (VSM 12003) Systems**

| Nominal Size and Major Bolt Diam. | Pitch | Pitch Diam. | Bolt           |        |        |       | Nut              |        |        |                        |         |
|-----------------------------------|-------|-------------|----------------|--------|--------|-------|------------------|--------|--------|------------------------|---------|

<sup>a</sup>The value shown is given in the German Standard; the value in the French Standard is 20.002; and in the Swiss Standard, 20.104.

<sup>b</sup>The value shown is given in the German Standard; the value in the French Standard is 23.002; and in the Swiss Standard, 23.104.

All dimensions are in mm.

## ACME SCREW THREADS

### American National Standard Acme Screw Threads

This American National Standard ASME/ANSI B1.5-1997 is a revision of American Standard ANSI B1.5-1988 and provides for two general applications of Acme threads, namely, General Purpose and Centralizing.

The limits and tolerances in this standard relate to single-start Acme threads, and may be used, if considered suitable, for multi-start Acme threads, which provide fast relative traversing motion when this is necessary. For information on additional allowances for multi-start Acme threads, see later section on page 1827.

**General Purpose Acme Threads.**—Three classes of General Purpose threads, 2G, 3G, and 4G, are provided in the standard, each having clearance on all diameters for free movement, and may be used in assemblies with the internal thread rigidly fixed and movement of the external thread in a direction perpendicular to its axis limited by its bearing or bearings. It is suggested that external and internal threads of the same class be used together for general purpose assemblies, Class 2G being the preferred choice. If less backlash or end play is desired, Classes 3G and 4G are provided. Class 5G is not recommended for new designs.

**Thread Form:** The accompanying Fig. 1 shows the thread form of these General Purpose threads, and the formulas accompanying the figure determine their basic dimensions. Table 1 gives the basic dimensions for the most generally used pitches.

**Angle of Thread:** The angle between the sides of the thread, measured in an axial plane, is 29 degrees. The line bisecting this 29-degree angle shall be perpendicular to the axis of the screw thread.

**Thread Series:** A series of diameters and associated pitches is recommended in the Standard as preferred. These diameters and pitches have been chosen to meet present needs with the fewest number of items in order to reduce to a minimum the inventory of both tools and gages. This series of diameters and associated pitches is given in Table 3.

**Chamfers and Fillets:** General Purpose external threads may have the crest corner chamfered to an angle of 45 degrees with the axis to a maximum width of  $P/15$ , where  $P$  is the pitch. This corresponds to a maximum depth of chamfer flat of  $0.0945P$ .

**Basic Diameters:** The max major diameter of the external thread is basic and is the nominal major diameter for all classes. The min pitch diameter of the internal thread is basic and is equal to the basic major diameter minus the basic height of the thread,  $h$ . The basic minor diameter is the min minor diameter of the internal thread. It is equal to the basic major diameter minus twice the basic thread height,  $2h$ .

**Length of Engagement:** The tolerances specified in this standard are applicable to lengths of engagement not exceeding twice the nominal major diameter.

**Major and Minor Diameter Allowances:** A minimum diametral clearance is provided at the minor diameter of all external threads by establishing the maximum minor diameter 0.020 inch below the basic minor diameter of the nut for pitches of 10 threads per inch and coarser, and 0.10 inch for finer pitches. A minimum diametral clearance at the major diameter is obtained by establishing the minimum major diameter of the internal thread 0.020 inch above the basic major diameter of the screw for pitches of 10 threads per inch and coarser, and 0.010 inch for finer pitches.

**Major and Minor Diameter Tolerances:** The tolerance on the external thread major diameter is  $0.05P$ , where  $P$  is the pitch, with a minimum of 0.005 inch. The tolerance on the internal thread major diameter is 0.020 inch for 10 threads per inch and coarser and 0.010 for finer pitches. The tolerance on the external thread minor diameter is  $1.5 \times$  pitch diameter tolerance. The tolerance on the internal thread minor diameter is  $0.05P$  with a minimum of 0.005 inch.

**ANSI General Purpose Acme Thread Form ASME/ANSI B1.5-1997,  
and Stub Acme Screw Thread Form ASME/ANSI B1.8-1988 (R2001)**

Fig. 1. General Purpose and Stub Acme Thread Forms

**Formulas for Basic Dimensions of General Purpose and Stub Acme Screw Threads**

| General Purpose   | Stub Acme Threads   |
|---|---|
| Pitch = $P = 1 \div$ No. threads per inch, $n$  | Pitch = $P = 1 \div$ No. threads per inch, $n$  |
| Basic thread height $h = 0.5P$  | Basic thread height $h = 0.3P$  |
| Basic thread thickness $t = 0.5P$   | Basic thread thickness $t = 0.5P$   |
| Basic flat at crest $F_{cn} = 0.3707P$ (internal thread)  | Basic flat at crest $F_{cn} = 0.4224P$ (internal thread)  |
| Basic flat at crest $F_{cs} = 0.3707P - 0.259 \times$<br>(pitch dia. allowance on ext. thd.)                        | Basic flat at crest $F_{cs} = 0.4224P - 0.259 \times$<br>(pitch dia. allowance on ext. thread)                      |
| $F_{rn} = 0.3707P - 0.259 \times$ (major dia. allowance<br>on internal thread)                                      | $F_{rn} = 0.4224P - 0.259 \times$ (major dia. allowance<br>on internal thread)                                      |
| $F_{rs} = 0.3707P - 0.259 \times$ (minor dia. allowance<br>on ext. thread - pitch dia.<br>allowance on ext. thread) | $F_{rs} = 0.4224P - 0.259 \times$ (minor dia. allowance<br>on ext. thread - pitch dia. allowance<br>on ext. thread) |

**Pitch Diameter Allowances and Tolerances:** Allowances on the pitch diameter of General Purpose Acme threads are given in Table 4. Pitch diameter tolerances are given in Table 5. The ratios of the pitch diameter tolerances of Classes 2G, 3G, and 4G, General Purpose threads are 3.0, 1.4, and 1, respectively.

An increase of 10 per cent in the allowance is recommended for each inch, or fraction thereof, that the length of engagement exceeds two diameters.

**Application of Tolerances:** The tolerances specified are designed to ensure interchangeability and maintain a high grade of product. The tolerances on diameters of the internal thread are plus, being applied from minimum sizes to above the minimum sizes. The tolerances on diameters of the external thread are minus, being applied from the maximum sizes to below the maximum sizes. The pitch diameter (or thread thickness) tolerances for an external or internal thread of a given class are the same. The thread thickness tolerance is 0.259 times the pitch diameter tolerance.

*Limiting Dimensions:* Limiting dimensions of General Purpose Acme screw threads in the recommended series are given in Table 2b. These limits are based on the formulas in Table 2a.

For combinations of pitch and diameter other than those in the recommended series, the formulas in Table 2a and the data in Tables 4 and 5 make it possible to readily determine the limiting dimensions required.

A diagram showing the disposition of allowances, tolerances, and crest clearances for General Purpose Acme threads appears on page 1826.

*Stress Area of General Purpose Acme Threads:* For computing the tensile strength of the thread section, the minimum stress area based on the mean of the minimum pitch diameter  $d_2$  min. and the minimum minor diameter  $d_1$  max. of the external thread is used:

$$\text{Stress Area} = 3.1416 \left( \frac{d_2 \text{ min.} + d_1 \text{ max.}}{4} \right)^2$$

where  $d_2$  min. and  $d_1$  max. may be computed by Formulas 4 and 6, Table 2a or taken from Table 2b.

*Shear Area of General Purpose Acme Threads:* For computing the shear area per inch length of engagement of the external thread, the maximum minor diameter of the internal thread  $D_1$  max., and the minimum pitch diameter of the external thread  $D_2$  min., Table 2b or Formulas 12 and 4, Table 2a, are used:

$$\text{Shear Area} = 3.1416 D_1 \text{ max.} [0.5 + n \tan 14\frac{1}{2}^\circ (D_2 \text{ min.} - D_1 \text{ max.})]$$

**Acme Thread Abbreviations.**—The following abbreviations are recommended for use on drawings and in specifications, and on tools and gages:

ACME = Acme threads  
 G = General Purpose  
 C = Centralizing  
 P = pitch  
 L = lead  
 LH = left hand

**Designation of General Purpose Acme Threads.**—The examples listed below are given here to show how General Purpose Acme threads are designated on drawings and tools:

1.750-4 ACME-2G indicates a General Purpose Class 2G Acme thread of 1.750-inch major diameter, 4 threads per inch, single thread, right hand. The same thread, but left hand, is designated 1.750-4 ACME-2G-LH.

2.875-0.4P-0.8L-ACME-3G indicates a General Purpose Class 3G Acme thread of 2.875-inch major diameter, pitch 0.4 inch, lead 0.8 inch, double thread, right hand.

**Multiple Start Acme Threads.**—The tabulated diameter-pitch data with allowances and tolerances relate to single-start threads. These data, as tabulated, may be and often are used for two-start Class 2G threads but this usage generally requires reduction of the full working tolerances to provide a greater allowance or clearance zone between the mating threads to assure satisfactory assembly.

When the class of thread requires smaller working tolerances than the 2G class or when threads with 3, 4, or more starts are required, some additional allowances or increased tolerances or both may be needed to ensure adequate working tolerances and satisfactory assembly of mating parts.

It is suggested that the allowances shown in Table 4 be used for all external threads and that allowances be applied to internal threads in the following ratios: for two-start threads, 50 per cent of the allowances shown in the Class 2G, 3G and 4G columns of Table 4; for

| 1                          | 1.00000             | 0.50000                                | 0.5100  | 0.50000                                | 0.3707  | 0.3655  |

All dimensions are in inches.

<sup>a</sup> Allowance is 0.020 inch for 10 threads per inch and coarser, and 0.010 inch for finer threads.

**Table 2a. American National Standard General Purpose Acme Single-Start Screw Threads — Formulas for Determining Diameters ASME/ANSI B1.5-1997**

| <p><math>D</math> = Basic Major Diameter and Nominal Size, in Inches.<br/> <math>P</math> = Pitch = <math>1 \div</math> Number of Threads per Inch.<br/> <math>E</math> = Basic Pitch Diameter = <math>D - 0.5P</math><br/> <math>K</math> = Basic Minor Diameter = <math>D - P</math></p> |   |
|--|---|
| No.  | External Threads (Screws)   |
| 1  | Major Dia., Max. = $D$  |
| 2  | Major Dia., Min. = $D$ minus $0.05P^a$ but not less than 0.005.   |
| 3  | Pitch Dia., Max. = $E$ minus allowance from Table 4.  |
| 4  | Pitch Dia., Min. = Pitch Dia., Max. (Formula 3) minus tolerance from Table 5.   |
| 5  | Minor Dia., Max. = $K$ minus 0.020 for 10 threads per inch and coarser and 0.010 for finer-pitches.                         |
| 6  | Minor Dia., Min. = Minor Dia., Max. (Formula 5) minus $1.5 \times$ pitch diameter tolerance from Table 5.                   |
| Internal Threads (Nuts)  |   |
| 7  | Major Dia., Min. = $D$ plus 0.020 for 10 threads per inch and coarser and 0.010 for finer pitches.                          |
| 8  | Major Dia., Max. = Major Dia., Min. (Formula 7) plus 0.020 for 10 threads per inch and coarser and 0.010 for finer pitches. |
| 9  | Pitch Dia., Min. = $E$  |
| 10   | Pitch Dia., Max. = Pitch Dia., Min. (Formula 9) plus tolerance from Table 5.  |
| 11   | Minor Dia., Min. = $K$  |
| 12   | Minor Dia., Max. = Minor Dia., Min. (Formula 11) plus $0.05P^a$ but not less than 0.005.                                    |

<sup>a</sup> If  $P$  is between two recommended pitches listed in Table 3, use the coarser of the two pitches in this formula instead of the actual value of  $P$ .

<sup>a</sup> All other dimensions are given in inches.<sup>b</sup> Per inch length of engagement of the external thread in line with the minor diameter crests of the internal thread. Figures given are the minimum shear area based on max  $D_1$  and min  $d_2$ .<sup>c</sup> Figures given are the minimum stress area based on the mean of the minimum minor and pitch diameters of the external thread. See formulas for shear area and stress area on page 1827.

**Table 4. American National Standard General Purpose Acme Single-Start Screw Threads — Pitch Diameter Allowances ASME/ANSI B1.5-1988**

| Nominal Size Range <sup>a</sup> |                  | Allowances on External Threads <sup>b</sup> |                               |                               | Nominal Size Range <sup>a</sup> |                  | Allowances on External Threads <sup>b</sup> |                               |                               |

All dimensions in inches. It is recommended that the sizes given in Table 3 be used whenever possible.

<sup>a</sup> The values in columns for Classes 2G, 3G, and 4G are to be used for any size within the nominal size range shown. These values are calculated from the mean of the range.

<sup>b</sup> An increase of 10 per cent in the allowance is recommended for each inch, or fraction thereof, that the length of engagement exceeds two diameters.

<sup>c</sup> Allowances for the 2G Class of thread in this table also apply to American National Standard Stub Acme threads ASME/ANSI B 1.8-1988.

three-start threads, 75 per cent of these allowances; and for four-start threads, 100 per cent of these same values.

These values will provide for a 0.25-16 ACME-2G thread size, 0.002, 0.003, and 0.004 inch additional clearance for 2-, 3-, and 4-start threads, respectively. For a 5-2 ACME-3G thread size the additional clearances would be 0.0091, 0.0136, and 0.0181 inch, respectively. GO thread plug gages and taps would be increased by these same values. To maintain the same working tolerances on multi-start threads, the pitch diameter of the NOT GO thread plug gage would also be increased by these same values.

For multi-start threads with more than four starts, it is believed that the 100 per cent allowance provided by the above procedures would be adequate as index spacing variables would generally be no greater than on a four-start thread.

In general, for multi-start threads of Classes 2G, 3G, and 4G the percentages would be applied, usually, to allowances for the same class, respectively. However, where exceptionally good control over lead, angle, and spacing variables would produce close to theoretical values in the product, it is conceivable that these percentages could be applied to Class 3G or Class 4G allowances used on Class 2G internally threaded product. Also, these percentages could be applied to Class 4G allowances used on Class 3G internally threaded product. It is not advocated that any change be made in externally threaded products.

Designations for gages or tools for internal threads could cover allowance requirements as follows:

GO and NOT GO thread plug gages for: 2.875-0.4P-0.8L-ACME-2G with 50 per cent of the 4G internal thread allowance.

**Centralizing Acme Threads.**—The three classes of Centralizing Acme threads in American National Standard ASME/ANSI B1.5-1988, designated as 2C, 3C, and 4C, have limited clearance at the major diameters of internal and external threads so that a bearing at the major diameters maintains approximate alignment of the thread axis and prevents wedging

| 5   | .01342             | .00626            | .00447            | 1   | .03000             | .01400            | .01000            |

For any particular size of thread, the pitch diameter tolerance is obtained by adding the *diameter increment* from the upper half of the table to the *pitch increment* from the lower half of the table. *Example:* A ¼-16 Acme-2G thread has a pitch diameter tolerance of  $0.00300 + 0.00750 = 0.0105$  inch.

The equivalent tolerance on thread thickness is 0.259 times the pitch diameter tolerance.

<sup>a</sup> For a nominal diameter between any two tabulated nominal diameters, use the diameter increment for the larger of the two tabulated nominal diameters.

<sup>b</sup> Columns for the 2G Class of thread in this table also apply to American National Standard Stub Acme threads, ASME/ANSI B1.8-1988 (R2001).

<sup>c</sup> All other dimensions are given in inches.

on the flanks of the thread. An alternative series having centralizing control on the *minor* diameter is described on page 1843. For any combination of the three classes of threads covered in this standard some end play or backlash will result. Classes 5C and 6C are not recommended for new designs.

*Application:* These three classes together with the accompanying specifications are for the purpose of ensuring the interchangeable manufacture of Centralizing Acme threaded parts. Each user is free to select the classes best adapted to his particular needs. It is suggested that external and internal threads of the same class be used together for centralizing assemblies, Class 2C providing the maximum end play or backlash. If less backlash or end play is desired, Classes 3C and 4C are provided. The requirement for a centralizing fit is that the sum of the major diameter tolerance plus the major diameter allowance on the internal thread, and the major diameter tolerance on the external thread shall equal or be less than the pitch diameter allowance on the external thread. A Class 2C external thread, which has a larger pitch diameter allowance than either a Class 3C or 4C, can be used inter-

Fig. 2. Disposition of Allowances, Tolerances, and Crest Clearances for General Purpose Single-start Acme Threads (All Classes)

changeably with a Class 2C, 3C, or 4C internal thread and fulfill this requirement. Similarly, a Class 3C external thread can be used interchangeably with a Class 3C or 4C internal thread, but only a Class 4C internal thread can be used with a Class 4C external thread.

**Thread Form:** The thread form is the same as the General Purpose Acme Thread and is shown in Fig. 3. The formulas in Table 7 determine the basic dimensions, which are given in Table 6 for the most generally used pitches.

**Angle of Thread:** The angle between the sides of the thread measured in an axial plane is 29 degrees. The line bisecting this 29-degree angle shall be perpendicular to the axis of the thread.

**Chamfers and Fillets:** External threads have the crest corners chamfered at an angle of 45 degrees with the axis to a minimum depth of  $P/20$  and a maximum depth of  $P/15$ . These modifications correspond to a minimum width of chamfer flat of  $0.0707P$  and a maximum width of  $0.0945P$  (see Table 6, columns 6 and 7).

External threads for Classes 2C, 3C, and 4C may have a fillet at the minor diameter not greater than  $0.1P$

**Thread Series:** A series of diameters and pitches is recommended in the Standard as preferred. These diameters and pitches have been chosen to meet present needs with the few-

All dimensions in inches. See Fig. 3.

<sup>a</sup> Allowance is 0.020 inch for 10 or less threads per inch and 0.010 inch for more than 10 threads per inch.

Fig. 3. Centralizing Acme Screw Thread Form

**Table 7. Formulas for Finding Basic Dimensions of Centralizing Acme Screw Threads**

|   |                                |
|---|--------------------------------|
| Pitch = $P = 1 \div \text{No. threads per inch, } n$ :  | Basic thread height $h = 0.5P$ |
| Basic thread thickness $t = 0.5P$   |                                |
| Basic flat at crest $F_{cn} = 0.3707P + 0.259 \times (\text{minor diameter allowance on internal threads})$ (internal thread)       |                                |
| Basic flat at crest $F_{cs} = 0.3707P - 0.259 \times (\text{pitch diameter allowance on external thread})$ (external thread)        |                                |
| $F_m = 0.3707P - 0.259 \times (\text{major dia. allowance on internal thread})$   |                                |
| $F_{rs} = 0.3707P - 0.259 \times (\text{minor dia. allowance on external thread} - \text{pitch dia. allowance on external thread})$ |                                |

Fig. 4. Disposition of Allowances, Tolerances, and Crest Clearances for Centralizing Single-Start Acme Threads—Classes 2C, 3C, and 4C

est number of items in order to reduce to a minimum the inventory of both tools and gages. This series of diameters and associated pitches is given in [Table 9](#).

**Basic Diameters:** The maximum major diameter of the external thread is basic and is the nominal major diameter for all classes.

The minimum pitch diameter of the internal thread is basic for all classes and is equal to the basic major diameter  $D$  minus the basic height of thread,  $h$ . The minimum minor diameter of the internal thread for all classes is  $0.1P$  above basic.

**Length of Engagement:** The tolerances specified in this Standard are applicable to lengths of engagement not exceeding twice the nominal major diameter.

**Pitch Diameter Allowances:** Allowances applied to the pitch diameter of the external thread for all classes are given in [Table 10](#).

**Major and Minor Diameter Allowances:** A minimum diametral clearance is provided at the minor diameter of all external threads by establishing the maximum minor diameter  $0.020$  inch below the basic minor diameter for 10 threads per inch and coarser, and  $0.010$  inch for finer pitches and by establishing the minimum minor diameter of the internal thread  $0.1P$  greater than the basic minor diameter.

**Table 8a. American National Standard Centralizing Acme Single-Start Screw Threads — Formulas for Determining Diameters ASME/ANSI B1.5-1988**

| $D$ = Nominal Size or Diameter in Inches<br>$P$ = Pitch = $1 \div$ Number of Threads per Inch |   |
|---|---|
| No.   | Classes 2C, 3C, and 4C External Threads (Screws)  |
| 1   | Major Dia., Max = $D$ (Basic).  |
| 2   | Major Dia., Min = $D$ minus tolerance from Table 12, columns 7, 8, or 10.   |
| 3   | Pitch Dia., Max = Int. Pitch Dia., Min (Formula 9) minus allowance from the appropriate Class 2C, 3C, or 4C column of Table 10. |
| 4   | Pitch Dia., Min = Ext. Pitch Dia., Max (Formula 3) minus tolerance from Table 11.   |
| 5   | Minor Dia., Max = $D$ minus $P$ minus allowance from Table 12, column 3.  |
| 6   | Minor Dia., Min = Ext. Minor Dia., Max (Formula 5) minus $1.5 \times$ Pitch Dia. tolerance from Table 11.                       |
| Classes 2C, 3C, and 4C Internal Threads (Nuts)  |   |
| 7   | Major Dia., Min = $D$ plus allowance from Table 12, column 4.   |
| 8   | Major Dia., Max = Int. Major Dia., Min (Formula 7) plus tolerance from Table 12, columns 7, 9, or 11.                           |
| 9   | Pitch Dia., Min = $D$ minus $P/2$ (Basic).  |
| 10  | Pitch Dia., Max = Int. Pitch Dia., Min (Formula 9) plus tolerance from Table 11.  |
| 11  | Minor Dia., Min = $D$ minus $0.9P$ .  |
| 12  | Minor Dia., Max = Int. Minor Dia., Min (Formula 11) plus tolerance from Table 12, column 6.                                     |

A minimum diametral clearance at the major diameter is obtained by establishing the minimum major diameter of the internal thread  $0.001\sqrt{D}$  above the basic major diameter. These allowances are shown in Table 12.

**Major and Minor Diameter Tolerances:** The tolerances on the major and minor diameters of the external and internal threads are listed in Table 12 and are based upon the formulas given in the column headings.

An increase of 10 per cent in the allowance is recommended for each inch or fraction thereof that the length of engagement exceeds two diameters.

For information on gages for Centralizing Acme threads the Standard ASME/ANSI B1.5 should be consulted.

**Pitch Diameter Tolerances:** Pitch diameter tolerances for Classes 2C, 3C and 4C for various practicable combinations of diameter and pitch are given in Table 11. The ratios of the pitch diameter tolerances of Classes 2C, 3C, and 4C are 3.0, 1.4, and 1, respectively.

**Application of Tolerances:** The tolerances specified are such as to insure interchangeability and maintain a high grade of product. The tolerances on the diameters of internal threads are plus, being applied from the minimum sizes to above the minimum sizes. The tolerances on the diameters of external threads are minus, being applied from the maximum sizes to below the maximum sizes. The pitch diameter tolerances for an external or internal thread of a given class are the same.

**Limiting Dimensions:** Limiting dimensions for Centralizing Acme threads in the preferred series of diameters and pitches are given in Tables 8b and 8c. These limits are based on the formulas in Table 8a.

For combinations of pitch and diameter other than those in the preferred series the formulas in Tables 8b and 8c and the data in the tables referred to therein make it possible to readily determine the limiting dimension required.

**Table 8b. Limiting Dimensions of American National Standard Centralizing Acme Single-Start Screw Threads, Classes 2C, 3C, and 4C ASME/ANSI B1.5-1988**

| Nominal Diameter, $D$<br>Threads per Inch <sup>a</sup> |     | $\frac{1}{2}$           | $\frac{5}{8}$ | $\frac{3}{4}$ | $\frac{7}{8}$ | 1      | $1\frac{1}{8}$ | $1\frac{1}{4}$ | $1\frac{3}{8}$ | $1\frac{1}{2}$ |
|--|-----|-------------------------|---------------|---------------|---------------|--------|----------------|----------------|----------------|----------------|
|  |     | 10                      | 8             | 6             | 6             | 5      | 5              | 5              | 4              | 4              |
| Limiting Dimensions                                    |     | <b>External Threads</b> |               |               |               |        |                |                |                |                |

All dimensions are given in inches.

It is recommended that the sizes given in Table 9 be used whenever possible.

<sup>a</sup>The values in columns for Classes 2C, 3C, and 4C are to be used for any size within the nominal size range columns. These values are calculated from the mean of the range.

<sup>b</sup>An increase of 10 per cent in the allowance is recommended for each inch, or fraction thereof, that the length of engagement exceeds two diameters.

All dimensions are given in inches.

For any particular size of thread, the pitch diameter tolerance is obtained by adding the diameter increment from the upper half of the table to the pitch increment from the lower half of the table. Example: A 0.250-16-ACME-2C thread has a pitch diameter tolerance of 0.00300 + 0.00750 = 0.0105 inch.

The equivalent tolerance on thread thickness is 0.259 times the pitch diameter tolerance.

<sup>a</sup>For a nominal diameter between any two tabulated nominal diameters, use the diameter increment for the larger of the two tabulated nominal diameters.

<sup>a</sup> All other dimensions are given in inches. Intermediate pitches take the values of the next coarser pitch listed. Values for intermediate diameters should be calculated from the formulas in column headings, but ordinarily may be interpolated.

<sup>b</sup> To avoid a complicated formula and still provide an adequate tolerance, the pitch factor is used as a basis, with the minimum tolerance set at 0.005 in.

<sup>c</sup> Tolerance on minor diameter of all external threads is  $1.5 \times$  pitch diameter tolerance.

<sup>d</sup> The minimum clearance at the minor diameter between the internal and external thread is the sum of the values in columns 3 and 5.

<sup>e</sup> The minimum clearance at the major diameter between the internal and external thread is equal to column 4.

**Designation of Centralizing Acme Threads.**—The following examples are given to show how these Acme threads are designated on drawings, in specifications, and on tools and gages:

*Example, 1.750-6-ACME-4C:* Indicates a Centralizing Class 4C Acme thread of 1.750-inch major diameter, 0.1667-inch pitch, single thread, right-hand.

*Example, 1.750-6-ACME-4C-LH:* Indicates the same thread left-hand.

*Example, 2.875-0.4P-0.8L-ACME-3C (Two Start):* Indicates a Centralizing Class 3C Acme thread with 2.875-inch major diameter, 0.4-inch pitch, 0.8-inch lead, double thread, right-hand.

*Example, 2.500-0.3333P-0.6667L-ACME-4C (Two Start):* Indicates a Centralizing Class 4C Acme thread with 2.500-inch nominal major diameter (basic major diameter 2.500 inches), 0.3333-inch pitch, 0.6667-inch lead, double thread, right-hand. The same thread left-hand would have LH at the end of the designation.

**Acme Centralizing Threads—Alternative Series with Minor Diameter Centralizing Control.**—When Acme centralizing threads are produced in single units or in very small quantities (and principally in sizes larger than the range of commercial taps and dies) where the manufacturing process employs cutting tools (such as lathe cutting), it may be economically advantageous and therefore desirable to have the centralizing control of the mating threads located at the *minor diameters*.

Particularly under the above-mentioned type of manufacturing, the two advantages cited for minor diameter centralizing control over centralizing control at the major diameters of the mating threads are: 1) Greater ease and faster checking of machined thread dimensions. It is much easier to measure the minor diameter (root) of the external thread and the mating minor diameter (crest or bore) of the internal thread than it is to determine the major diameter (root) of the internal thread and the major diameter (crest or turn) of the external thread; and 2) better manufacturing control of the machined size due to greater ease of checking.

In the event that minor diameter centralizing is necessary, recalculate all thread dimensions, reversing major and minor diameter allowances, tolerances, radii, and chamfer.

**American National Standard Stub Acme Threads.**—This American National Standard ASME/ANSI B1.8-1988 (R2001) provides a Stub Acme screw thread for those unusual applications where, due to mechanical or metallurgical considerations, a coarse-pitch thread of shallow depth is required. The fit of Stub Acme threads corresponds to the Class 2G General Purpose Acme thread in American National Standard ANSI B1.5-1988. For a fit having less backlash, the tolerances and allowances for Classes 3G or 4G General Purpose Acme threads may be used.

*Thread Form:* The thread form and basic formulas for Stub Acme threads are given on page 1826 and the basic dimensions in Table 13.

*Allowances and Tolerances:* The major and minor diameter allowances for Stub Acme threads are the same as those given for General Purpose Acme threads on page 1825.

Pitch diameter allowances for Stub Acme threads are the same as for Class 2G General Purpose Acme threads and are given in Table 4. Pitch diameter tolerances for Stub Acme threads are the same as for Class 2G General Purpose Acme threads given in Table 5.

*Limiting Dimensions:* Limiting dimensions of American Standard Stub Acme threads may be determined by using the formulas given in Table 14a, or directly from Table 14b. The diagram below shows the limits of size for Stub Acme threads.

*Thread Series:* A preferred series of diameters and pitches for General Purpose Acme threads (Table 15) is recommended for Stub Acme threads.

**Table 13. American National Standard Stub Acme Screw Thread Form — Basic Dimensions ASME/ANSI B1.8-1988 (R2001)**

| Thds. per Inch <sup>a</sup><br><i>n</i> | Pitch,<br>$P = 1/n$ | Height of Thread (Basic),<br>$0.3P$ | Total Height of Thread,<br>$0.3P + \frac{1}{2}$ allowance <sup>b</sup> | Thread Thickness (Basic),<br>$P/2$ | Width of Flat                                  |   |

<sup>a</sup> All other dimensions are given in inches.

Limits of Size, Allowances, Tolerances, and Crest Clearances for American National Standard Stub Acme Threads

**Stub Acme Thread Designations.**—The method of designation for Standard Stub Acme threads is illustrated in the following examples: 0.500-20 Stub Acme indicates a  $\frac{1}{2}$ -inch major diameter, 20 threads per inch, right hand, single thread, Standard Stub Acme thread. The designation 0.500-20 Stub Acme-LH indicates the same thread except that it is left hand.

**Alternative Stub Acme Threads.**—Since one Stub Acme thread form may not meet the requirements of all applications, basic data for two of the other commonly used forms are included in the appendix of the American Standard for Stub Acme Threads. These so-called Modified Form 1 and Modified Form 2 threads utilize the same tolerances and allowances as Standard Stub Acme threads and have the same major diameter and basic thread thickness at the pitchline ( $0.5P$ ). The basic height of Form 1 threads,  $h$ , is  $0.375P$ ; for Form 2 it is  $0.250P$ . The basic width of flat at the crest of the internal thread is  $0.4030P$  for Form 1 and  $0.4353P$  for Form 2.

The pitch diameter and minor diameter for Form 1 threads will be smaller than similar values for the Standard Stub Acme Form and for Form 2 they will be larger owing to the differences in basic thread height  $h$ . Therefore, in calculating the dimensions of Form 1 and Form 2 threads using Formulas 1 through 12 in Table 14a, it is only necessary to substitute the following values in applying the formulas: For Form 1,  $D_2 = D - 0.375P$ ,  $D_1 = D - 0.75P$ ; for Form 2,  $D_2 = D - 0.25P$ ,  $D_1 = D - 0.5P$ .

**Thread Designation:** These threads are designated in the same manner as Standard Stub Acme threads except for the insertion of either M1 or M2 after "Acme." Thus, 0.500-20 Stub Acme M1 for a Form 1 thread; and 0.500-20 Stub Acme M2 for a Form 2 thread.

**Former 60-Degree Stub Thread.**—Former American Standard B1.3-1941 included a 60-degree stub thread for use where design or operating conditions could be better satisfied by the use of this thread, or other modified threads, than by Acme threads. Data for 60-Degree Stub thread form are given in the accompanying diagram.

Table 15. Stub Acme Screw Thread Data ASME/ANSI B1.8-1988 (R2001)

<sup>a</sup> All other dimensions are given in inches.

60-Degree Stub Thread

A clearance of at least  $0.02 \times$  pitch is added to depth  $h$  to produce extra depth, thus avoiding interference with threads of mating part at minor or major diameters.

Basic thread thickness at pitch line =  $0.5 \times$  pitch  $p$ ; basic depth  $h = 0.433 \times$  pitch; basic width of flat at crest =  $0.25 \times$  pitch; width of flat at root of screw thread =  $0.227 \times$  pitch; basic pitch diameter = basic major diameter -  $0.433 \times$  pitch; basic minor diameter = basic major diameter -  $0.866 \times$  pitch.

**Square Thread.**—The square thread is so named because the section is square, the depth, in the case of a screw, being equal to the width or one-half the pitch. The thread groove in a square-threaded nut is made a little greater than one-half the pitch in order to provide a slight clearance for the screw; hence, the tools used for threading square-threaded taps are a little less in width at the point than one-half the pitch. The pitch of a square thread is usually twice the pitch of an American Standard thread of corresponding diameter. The square thread has been superseded quite largely by the Acme form which has several advantages. See *ACME SCREW THREADS*.

**10-Degree Modified Square Thread:** The included angle between the sides of the thread is 10 degrees (see accompanying diagram). The angle of 10 degrees results in a thread which is the practical equivalent of a "square thread," and yet is capable of economical production. Multiple thread milling cutters and ground thread taps should not be specified for modified square threads of the larger lead angles without consulting the cutting tool manufacturer.

In the following formulas,  $D$  = basic major diameter;  $E$  = basic pitch diameter;  $K$  = basic minor diameter;  $p$  = pitch;  $h$  = basic depth of thread on screw depth when there is no clearance between root of screw and crest of thread on nut;  $t$  = basic thickness of thread at pitch line;  $F$  = basic width of flat at crest of screw thread;  $G$  = basic width of flat at root of screw thread;  $C$  = clearance between root of screw and crest of thread on nut:  $E = D - 0.5p$ ;  $K = D - p$ ;  $h = 0.5p$  (see Note);  $t = 0.5p$ ;  $F = 0.4563p$ ;  $G = 0.4563p - (0.17 \times C)$ .

*Note:* A clearance should be added to depth  $h$  to avoid interference with threads of mating parts at minor or major diameters.

## BUTTRESS THREADS

## Threads of Buttress Form

The buttress form of thread has certain advantages in applications involving exceptionally high stresses along the thread axis in one direction only. The contacting flank of the thread, which takes the thrust, is referred to as the *pressure flank* and is so nearly perpendicular to the thread axis that the radial component of the thrust is reduced to a minimum. Because of the small radial thrust, this form of thread is particularly applicable where tubular members are screwed together, as in the case of breech mechanisms of large guns and airplane propeller hubs.

Fig. 1a shows a common form. The front or load-resisting face is perpendicular to the axis of the screw and the thread angle is 45 degrees. According to one rule, the pitch  $P = 2 \times$  screw diameter  $\div 15$ . The thread depth  $d$  may equal  $\frac{3}{4} \times$  pitch, making the flat  $f = \frac{1}{8} \times$  pitch. Sometimes depth  $d$  is reduced to  $\frac{2}{3} \times$  pitch, making  $f = \frac{1}{6} \times$  pitch.

Fig. 1a.

Fig. 1b.

Fig. 1c.

The load-resisting side or flank may be inclined an amount (Fig. 1b) ranging usually from 1 to 5 degrees to avoid cutter interference in milling the thread. With an angle of 5 degrees and an included thread angle of 50 degrees, if the width of the flat  $f$  at both crest and root equals  $\frac{1}{8} \times$  pitch, then the thread depth equals  $0.69 \times$  pitch or  $\frac{3}{4} d_1$ .

The saw-tooth form of thread illustrated by Fig. 1c is known in Germany as the "Sägewinde" and in Italy as the "Filettatura a dente di Sega." Pitches are standardized from 2 millimeters up to 48 millimeters in the German and Italian specifications. The front face inclines 3 degrees from the perpendicular and the included angle is 33 degrees.

The thread depth  $d$  for the screw =  $0.86777 \times$  pitch  $P$ . The thread depth  $g$  for the nut =  $0.75 \times$  pitch. Dimension  $h = 0.341 \times P$ . The width  $f$  of flat at the crest of the thread on the screw =  $0.26384 \times$  pitch. Radius  $r$  at the root =  $0.12427 \times$  pitch. The clearance space  $e = 0.11777 \times$  pitch.

**British Standard Buttress Threads BS 1657: 1950.**—Specifications for buttress threads in this standard are similar to those in the American Standard (see page 1850) except: 1) A basic depth of thread of  $0.4p$  is used instead of  $0.6p$ ; 2) Sizes below 1 inch are not included; 3) Tolerances on major and minor diameters are the same as the pitch diameter tolerances, whereas in the American Standard separate tolerances are provided; however, provision is made for smaller major and minor diameter tolerances when crest surfaces of screws or nuts are used as datum surfaces, or when the resulting reduction in depth of engagement must be limited; and 4) Certain combinations of large diameters with fine pitches are provided that are not encouraged in the American Standard.

**Lowenherz or Löwenherz Thread.**—The Lowenherz thread is intended for the fine screws of instruments and is based on the metric system. The Löwenherz thread has flats at the top and bottom the same as the U.S. standard buttress form, but the angle is 53 degrees 8 minutes. The depth equals  $0.75 \times$  the pitch, and the width of the flats at the top and bottom is equal to  $0.125 \times$  the pitch. This screw thread used for measuring instruments, optical apparatus, etc., especially in Germany.

## Löwenherz Thread

## American National Standard Buttress Inch Screw Threads

The buttress form of thread has certain advantages in applications involving exceptionally high stresses along the thread axis in one direction only. As the thrust side (load flank) of the standard buttress thread is made very nearly perpendicular to the thread axis, the radial component of the thrust is reduced to a minimum. On account of the small radial thrust, the buttress form of thread is particularly applicable when tubular members are screwed together. Examples of actual applications are the breech assemblies of large guns, airplane propeller hubs, and columns for hydraulic presses.

**7°/45° Buttress Thread Form.**—In selecting the form of thread recommended as standard, ANSI B1.9-1973 (R1992), manufacture by milling, grinding, rolling, or other suitable means, has been taken into consideration. All dimensions are in inches.

*Form of Thread:* The form of the buttress thread is shown in the accompanying Figs. 2a and 2b, and has the following characteristics:

- A load flank angle, measured in an axial plane, of 7 degrees from the normal to the axis.
- A clearance flank angle, measured in an axial plane, of 45 degrees from the normal to the axis.
- Equal truncations at the crests of the external and internal threads such that the basic height of thread engagement (assuming no allowance) is equal to 0.6 of the pitch
- Equal radii, at the roots of the external and internal basic thread forms tangential to the load flank and the clearance flank. (There is, in practice, almost no chance that the thread forms will be achieved strictly as basically specified, that is, as true radii.) When specified, equal flat roots of the external and internal thread may be supplied.

<sup>a</sup> All other dimensions are in inches.

<sup>b</sup> Minimum root truncation is one-half of maximum.

<sup>c</sup> Minimum root radius is one-half of maximum.

**Buttress Thread Tolerances.**—Tolerances from basic size on external threads are applied in a minus direction and on internal threads in a plus direction.

**Pitch Diameter Tolerances:** The following formula is used for determining the pitch diameter product tolerance for Class 2 (standard grade) external or internal threads:

$$\text{PD tolerance} = 0.002 \sqrt[3]{D} + 0.00278 \sqrt{L_e} + 0.00854 \sqrt{p}$$

where  $D$  = basic major diameter of external thread (assuming no allowance)

$L_e$  = length of engagement

$p$  = pitch of thread

When the length of engagement is taken as  $10p$ , the formula reduces to

$$0.002 \sqrt[3]{D} + 0.0173 \sqrt{p}$$

It is to be noted that this formula relates specifically to Class 2 (standard grade) PD tolerances. Class 3 (precision grade) PD tolerances are two-thirds of Class 2 PD tolerances. Pitch diameter tolerances based on this latter formula, for various diameter pitch combinations, are given in [Table 4](#).

**Functional Size:** Deviations in lead and flank angle of product threads increase the functional size of an external thread and decrease the functional size of an internal thread by the cumulative effect of the diameter equivalents of these deviations. The functional size of all buttress product threads shall not exceed the maximum-material limit.

**Tolerances on Major Diameter of External Thread and Minor Diameter of Internal Thread:** Unless otherwise specified, these tolerances should be the same as the pitch diameter tolerance for the class used.

**Tolerances on Minor Diameter of External Thread and Major Diameter of Internal Thread:** It will be sufficient in most instances to state only the maximum minor diameter of the external thread and the minimum major diameter of the internal thread without any tol-

Form of American National Standard 7°/45° Buttress Thread with 0.6p Basic Height of Thread Engagement

<sup>a</sup> For threads with pitches not shown in this table, pitch increment to be used in tolerance formula is to be determined by use of formula  $PD \text{ Tolerance} = 0.002\sqrt[3]{D} + 0.00278\sqrt{L_e} + 0.00854\sqrt{p}$ , where:  $D$  = basic major diameter of external thread (assuming no allowance),  $L_e$  = length of engagement, and  $p$  = pitch of thread. This formula relates specifically to Class 2 (standard grade) PD tolerances. Class 3 (precision grade) PD tolerances are two-thirds of Class 2 PD tolerances. See text

<sup>b</sup> When the length of engagement is taken as  $10p$ , the formula reduces to:  $0.002\sqrt[3]{D} + 0.0173\sqrt{p}$

<sup>c</sup> Diameter  $D$ , used in diameter increment formula, is based on the average of the range.

angle for Class 3, shall not exceed 50 percent of the Class 2 pitch diameter tolerances given in Table 4.

*Tolerances on Taper and Roundness:* There are no requirements for taper and roundness for Class 2 buttress screw threads.

The major and minor diameters of Class 3 buttress threads shall not taper nor be out of round to the extent that specified limits for major and minor diameter are exceeded. The taper and out-of-roundness of the pitch diameter for Class 3 buttress threads shall not exceed 50 per cent of the pitch-diameter tolerances.

**Allowances for Easy Assembly.**—An allowance (clearance) should be provided on all external threads to secure easy assembly of parts. The amount of the allowance is deducted from the nominal major, pitch, and minor diameters of the external thread when the maximum material condition of the external thread is to be determined.

The minimum internal thread is basic.

The amount of the allowance is the same for both classes and is equal to the Class 3 pitch-diameter tolerance as calculated by the formulas previously given. The allowances for various diameter-pitch combinations are given in [Table 5](#).

**Table 5. American National Standard External Thread Allowances for Classes 2 and 3 Buttress Inch Screw Threads ANSI B1.9-1973 (R1992)**

| Threads per Inch | Pitch, <i>p</i> Inch | Basic Major Diameter, Inch   |                   |                   |                   |                 |               |                |                 |                 |

**Example Showing Dimensions for a Typical Buttress Thread.**—The dimensions for a 2-inch diameter, 4 threads per inch, Class 2 buttress thread with flank angles of 7 degrees and 45 degrees are

$$h = \text{basic thread height} = 0.1500 \text{ (Table 2)}$$

$$h_s = h_n = \text{height of thread in external and internal threads} = 0.1657 \text{ (Table 2)}$$

$$G = \text{pitch-diameter allowance on external thread} = 0.0074 \text{ (Table 5)}$$

Tolerance on PD of external and internal threads = 0.0112 (Table 4)

Tolerance on major diameter of external thread and minor diameter of internal thread = 0.0112 (Table 4)

**Internal Thread:**

Basic Major Diameter:  $D = 2.0000$

Min. Major Diameter:  $D - 2h + 2h_n = 2.0314$  (see [Table 2](#))

Min. Pitch Diameter:  $D - h = 1.8500$  (see [Table 2](#))

Max. Pitch Diameter:  $D - h + PD \text{ Tolerance} = 1.8612$  (see [Table 4](#))

Min. Minor Diameter:  $D - 2h = 1.7000$  (see [Table 2](#))

Max. Minor Diameter:  $D - 2h + \text{Minor Diameter Tolerance} = 1.7112$  (see [Table 4](#))

**External Thread:**

*Max. Major Diameter:*  $D - G = 1.9926$  (see Table 5)

*Min. Major Diameter:*  $D - G - \text{Major Diameter Tolerance} = 1.9814$  (see Tables 4 and 5)

*Max. Pitch Diameter:*  $D - h - G = 1.8426$  (see Tables 2 and 5)

*Min. Pitch Diameter:*  $D - h - G - PD \text{ Tolerance} = 1.8314$  (see Table 4)

*Max. Minor Diameter:*  $D - G - 2h_s = 1.6612$  (see Tables 2 and 5)

**Buttress Thread Designations.**—When only the designation, BUTT is used, the thread is “pull” type buttress (external thread pulls) with the clearance flank leading and the 7-degree pressure flank following. When the designation, PUSH-BUTT is used, the thread is a push type buttress (external thread pushes) with the 7-degree load flank leading and the 45-degree clearance flank following. Whenever possible this description should be confirmed by a simplified view showing thread angles on the drawing of the product that has the buttress thread.

*Standard Buttress Threads:* A buttress thread is considered to be standard when: 1) opposite flank angles are 7-degrees and 45-degrees; 2) basic thread height is  $0.6p$ ; 3) tolerances and allowances are as shown in Tables 4 and 5; and 4) length of engagement is  $10p$  or less.

*Thread Designation Abbreviations:* In thread designations on drawings, tools, gages, and in specifications, the following abbreviations and letters are to be used:

|           |  |   |
|-----------|--|---|
| BUTT      | for buttress thread, pull type   |   |
| PUSH-BUTT | for buttress thread, push type   |   |
| LH        | for left-hand thread (Absence of LH indicates that the thread is a right-hand thread.) |   |
| P         | for pitch  |   |
| L         | for lead   |   |
| A         | for external thread  | <i>Note:</i> Absence of A or B after thread class indicates that designation covers both the external and internal threads. |
| B         | for internal thread  |   |
| Le        | for length of thread engagement  |   |
| SPL       | for special  |   |
| FL        | for flat root thread   |   |
| E         | for pitch diameter   |   |
| TPI       | for threads per inch   |   |
| THD       | for thread   |   |

**Designation Sequence for Buttress Inch Screw Threads.**—When designating single-start standard buttress threads the nominal size is given first, the threads per inch next, then PUSH if the internal member is to push, but nothing if it is to pull, then the class of thread (2 or 3), then whether external (A) or internal (B), then LH if left-hand, but nothing if right-hand, and finally FL if a flat root thread, but nothing if a radiused root thread; thus, 2.5-8 BUTT-2A indicates a 2.5 inch, 8 threads per inch buttress thread, Class 2 external, right-hand, internal member to pull, with radiused root of thread. The designation 2.5-8 PUSH-BUTT-2A-LH-FL signifies a 2.5 inch size, 8 threads per inch buttress thread with internal member to push, Class 2 external, left-hand, and flat root.

A multiple-start standard buttress thread is similarly designated but the pitch is given instead of the threads per inch, followed by the lead and the number of starts is indicated in parentheses after the class of thread. Thus, 10-0.25P-0.5L - BUTT-3B (2 start) indicates a 10-inch thread with 4 threads per inch, 0.5 inch lead, buttress form with internal member to pull, Class 3 internal, 2 starts, with radiused root of thread.

## WHITWORTH THREADS

**British Standard Whitworth (BSW) and British Standard Fine (BSF) Threads**

The BSW is the Coarse Thread series and the BSF is the Fine Thread series of British Standard 84:1956—Parallel Screw Threads of Whitworth Form. The dimensions given in the tables on the following pages for the major, effective, and minor diameters are, respectively, the maximum limits of these diameters for bolts and the minimum limits for nuts. Formulas for the tolerances on these diameters are given in the table below.

**Whitworth Standard Thread Form.**—This thread form is used for the British Standard Whitworth (BSW) and British Standard Fine (BSF) screw threads. More recently, both threads have been known as parallel screw threads of Whitworth form.

With standardization of the Unified thread, the Whitworth thread form is expected to be used only for replacements or spare parts. Tables of British Standard Parallel Screw Threads of Whitworth Form will be found on the following pages; tolerance formulas are given in the table below. The form of the thread is shown by the diagram. If  $p$  = pitch,  $d$  = depth of thread,  $r$  = radius at crest and root, and  $n$  = number of threads per inch, then

$$d = \frac{1}{2}p \times \cot 27^{\circ}30' = 0.640327p = 0.640327 \div n$$

$$r = 0.137329p = 0.137329 \div n$$

It is recommended that stainless steel bolts of nominal size  $\frac{3}{4}$  inch and below should not be made to Close Class limits but rather to Medium or Free Class limits. Nominal sizes above  $\frac{3}{4}$  inch should have maximum and minimum limits 0.001 inch smaller than the values obtained from the table.

**Tolerance Classes :** *Close Class bolts.* Applies to screw threads requiring a fine snug fit, and should be used only for special work where refined accuracy of pitch and thread form are particularly required. *Medium Class bolts and nuts.* Applies to the better class of ordinary interchangeable screw threads. *Free Class bolts.* Applies to the majority of bolts of ordinary commercial quality. *Normal Class nuts.* Applies to ordinary commercial quality nuts; this class is intended for use with Medium or Free Class bolts.

**Table 1. Tolerance Formulas for BSW and BSF Threads**

|       | Class or Fit | Tolerance in inches <sup>a</sup> (+ for nuts, - for bolts) |                |  |
|-------|--------------|--|----------------|--|
|       |              | Major Dia.   | Effective Dia. | Minor Dia.   |
| Bolts | Close        | $\frac{2}{3}T + 0.01\sqrt{p}$                              | $\frac{2}{3}T$ | $\frac{2}{3}T + 0.013\sqrt{p}$   |
|       | Medium       | $T + 0.01\sqrt{p}$   | $T$            | $T + 0.02\sqrt{p}$   |
|       | Free         | $\frac{3}{2}T + 0.01\sqrt{p}$                              | $\frac{3}{2}T$ | $\frac{3}{2}T + 0.02\sqrt{p}$  |
| Nuts  | Close        | ...  | $\frac{2}{3}T$ | } {<br>0.2p + 0.004 <sup>b</sup><br>0.2p + 0.005 <sup>c</sup><br>0.2p + 0.007 <sup>d</sup> |
|       | Medium       | ...  | $T$            |  |
|       | Normal       | ...  | $\frac{3}{2}T$ |  |

<sup>a</sup> The symbol  $T = 0.002\sqrt[3]{D} + 0.003\sqrt{L} + 0.005\sqrt{p}$ , where  $D$  = major diameter of thread in inches;  $L$  = length of engagement in inches;  $p$  = pitch in inches. The symbol  $p$  signifies pitch.

<sup>b</sup> For 26 threads per inch and finer.

<sup>c</sup> For 24 and 22 threads per inch.

<sup>d</sup> For 20 threads per inch and coarser.

WHITWORTH THREADS

Table 2. Threads of Whitworth Form—Basic Dimensions

$p = 1 \div n$   
 $H = 0.960491p$   
 $H/6 = 0.160082p$   
 $h = 0.640327p$   
 $e = 0.0739176p$   
 $r = 0.137329p$

| Threads per Inch | Pitch    | Triangular Height | Shortening | Depth of Thread | Depth of Rounding | Radius   |
|------------------|----------|-------------------|------------|-----------------|-------------------|----------|
| <i>n</i>         | <i>p</i> | <i>H</i>          | <i>H/6</i> | <i>h</i>        | <i>e</i>          | <i>r</i> |

Dimensions are in inches.

*Allowances:* Only Free Class and Medium Class bolts have an allowance. For nominal sizes of 3/4 inch down to 1/4 inch, the allowance is 30 per cent of the Medium Class bolt effective-diameter tolerance (0.3T); for sizes less than 1/4 inch, the allowance for the 1/4-inch size applies. Allowances are applied minus from the basic bolt dimensions; the tolerances are then applied to the reduced dimensions.

**Table 3. British Standard Whitworth (BSW) and British Standard Fine (BSF) Screw Thread Series—Basic Dimensions BS 84:1956 (obsolescent)**

| Nominal Size, Inches              | Threads per Inch | Pitch, Inches | Depth of Thread, Inches | Major Diameter, Inches | Effective Diameter, Inches | Minor Diameter, Inches | Area at Bottom of Thread, Sq. in. | Tap Drill Dia.   |
|-----------------------------------|------------------|---------------|-------------------------|------------------------|----------------------------|------------------------|-----------------------------------|--|
| <b>Coarse Thread Series (BSW)</b> |                  |               |                         |                        |                            |                        |                                   |  |

<sup>a</sup>To be dispensed with wherever possible.<sup>b</sup>The use of number 2 BA threads is recommended in place of 3/16-inch BSF thread, see page 1885.

## PIPE AND HOSE THREADS

The types of threads used on pipe and pipe fittings may be classed according to their intended use: 1) threads that when assembled with a sealer will produce a pressure-tight joint; 2) threads that when assembled without a sealer will produce a pressure-tight joint; 3) threads that provide free- and loose-fitting mechanical joints without pressure tightness; and 4) threads that produce rigid mechanical joints without pressure tightness.

## American National Standard Pipe Threads

American National Standard pipe threads described in the following paragraphs provide taper and straight pipe threads for use in various combinations and with certain modifications to meet these specific needs.

**Thread Designation and Notation.**—American National Standard Pipe Threads are designated by specifying in sequence the nominal size, number of threads per inch, and the symbols for the thread series and form, as:  $\frac{3}{8}$ —18 NPT. The symbol designations are as follows: NPT—American National Standard Taper Pipe Thread; NPTR—American National Standard Taper Pipe Thread for Railing Joints; NPSC—American National Standard Straight Pipe Thread for Couplings; NPSM—American National Standard Straight Pipe Thread for Free-fitting Mechanical Joints; NPSL—American National Standard Straight Pipe Thread for Loose-fitting Mechanical Joints with Locknuts; and NPSH—American National Standard Straight Pipe Thread for Hose Couplings.

**American National Standard Taper Pipe Threads.**—The basic dimensions of the ANSI Standard taper pipe thread are given in [Table 1a](#).

*Form of Thread:* The angle between the sides of the thread is 60 degrees when measured in an axial plane, and the line bisecting this angle is perpendicular to the axis. The depth of the truncated thread is based on factors entering into the manufacture of cutting tools and the making of tight joints and is given by the formulas in [Table 1a](#) or the data in [Table 2](#) obtained from these formulas. Although the standard shows flat surfaces at the crest and root of the thread, some rounding may occur in commercial practice, and it is intended that the pipe threads of product shall be acceptable when crest and root of the tools or chasers lie within the limits shown in [Table 2](#).

*Pitch Diameter Formulas:* In the following formulas, which apply to the ANSI Standard taper pipe thread,  $E_0$  = pitch diameter at end of pipe;  $E_1$  = pitch diameter at the large end of the internal thread and at the gaging notch;  $D$  = outside diameter of pipe;  $L_1$  = length of hand-tight or normal engagement between external and internal threads;  $L_2$  = basic length of effective external taper thread; and  $p$  = pitch =  $1 \div$  number of threads per inch.

$$E_0 = D - (0.05D + 1.1)p$$

$$E_1 = E_0 + 0.0625L_1$$

*Thread Length:* The formula for  $L_2$  determines the length of the effective thread and includes approximately two usable threads that are slightly imperfect at the crest. The normal length of engagement,  $L_1$ , between external and internal taper threads, when assembled by hand, is controlled by the use of the gages.

$$L_2 = (0.80D + 6.8)p$$

*Taper:* The taper of the thread is 1 in 16, or 0.75 inch per foot, measured on the diameter and along the axis. The corresponding half-angle of taper or angle with the center line is 1 degree, 47 minutes.

**Table 1a. Basic Dimensions, American National Standard Taper Pipe Threads, NPT  
ANSI/ASME B1.20.1-1983 (R2001)**

For all dimensions, see corresponding reference letter in table.

Angle between sides of thread is 60 degrees. Taper of thread, on diameter, is  $\frac{3}{4}$  inch per foot. Angle of taper with center line is  $1^{\circ}47'$ .

The basic maximum thread height,  $h$ , of the truncated thread is  $0.8 \times$  pitch of thread. The crest and root are truncated a minimum of  $0.033 \times$  pitch for all pitches. For maximum depth of truncation, see Table 2.

| Nominal Pipe Size | Outside Dia. of Pipe, $D$ | Threads per Inch, $n$ | Pitch of Thread, $p$ | Pitch Diameter at Beginning of External Thread, $E_0$ | Handtight Engagement       |                          | Effective Thread, External |             |

<sup>a</sup> Also length of thin ring gage and length from gaging notch to small end of plug gage.

<sup>b</sup> Also pitch diameter at gaging notch (handtight plane).

<sup>c</sup> Also length of plug gage.

<sup>a</sup>The length  $L_5$  from the end of the pipe determines the plane beyond which the thread form is imperfect at the crest. The next two threads are perfect at the root. At this plane the cone formed by the crests of the thread intersects the cylinder forming the external surface of the pipe.  $L_5 = L_2 - 2p$ .

<sup>b</sup>Given as information for use in selecting tap drills.

<sup>c</sup>Three threads for 2-inch size and smaller; two threads for larger sizes.

<sup>d</sup>Military Specification MIL—P—7105 gives the wrench makeup as three threads for 3 in. and smaller. The  $E_3$  dimensions are then as follows: Size 2 1/2 in., 2.69609 and size 3 in., 3.31719.

All dimensions given in inches.

Increase in diameter per thread is equal to  $0.0625/n$ .

The basic dimensions of the ANSI Standard Taper Pipe Thread are given in inches to four or five decimal places. While this implies a greater degree of precision than is ordinarily attained, these dimensions are the basis of gage dimensions and are so expressed for the purpose of eliminating errors in computations.

**Engagement Between External and Internal Taper Threads.**—The normal length of engagement between external and internal taper threads when screwed together handtight is shown as  $L_1$  in Table 1a. This length is controlled by the construction and use of the pipe thread gages. It is recognized that in special applications, such as flanges for high-pressure work, longer thread engagement is used, in which case the pitch diameter  $E_1$  (Table 1a) is maintained and the pitch diameter  $E_0$  at the end of the pipe is proportionately smaller.

**Tolerances on Thread Elements.**—The maximum allowable variation in the commercial product (manufacturing tolerance) is one turn large or small from the basic dimensions.

The permissible variations in thread elements on steel products and all pipe made of steel, wrought iron, or brass, exclusive of butt-weld pipe, are given in Table 3. This table is a

guide for establishing the limits of the thread elements of taps, dies, and thread chasers. These limits may be required on product threads.

On pipe fittings and valves (not steel) for steam pressures 300 pounds and below, it is intended that plug and ring gage practice as set up in the Standard ANSI/ASME B1.20.1 will provide for a satisfactory check of accumulated variations of taper, lead, and angle in such product. Therefore, no tolerances on thread elements have been established for this class.

For service conditions where a more exact check is required, procedures have been developed by industry to supplement the regulation plug and ring method of gaging.

**Table 2. Limits on Crest and Root of American National Standard External and Internal Taper Pipe Threads, NPT ANSI/ASME B1.20.1-1983 (R2001)**

| INTERNAL THREAD  |                               |                            |         |                 |        |   |        |
|------------------|-------------------------------|----------------------------|---------|-----------------|--------|---|--------|
|                  |                               |                            |         |                 |        |   |        |
| EXTERNAL THREAD  |                               |                            |         |                 |        |   |        |
| Threads per Inch | Height of Sharp V Thread, $H$ | Height of Pipe Thread, $h$ |         | Truncation, $f$ |        | Width of Flat, $F$ , Equivalent to Truncation |        |
|                  |                               | Max.                       | Min.    | Min.            | Max.   | Min.  | Max.   |
| 27               | 0.03208                       | 0.02963                    | 0.02496 | 0.0012          | 0.0036 | 0.0014  | 0.0041 |
| 18               | 0.04811                       | 0.04444                    | 0.03833 | 0.0018          | 0.0049 | 0.0021  | 0.0057 |
| 14               | 0.06186                       | 0.05714                    | 0.05071 | 0.0024          | 0.0056 | 0.0027  | 0.0064 |
| 11½              | 0.07531                       | 0.06957                    | 0.06261 | 0.0029          | 0.0063 | 0.0033  | 0.0073 |
| 8                | 0.10825                       | 0.10000                    | 0.09275 | 0.0041          | 0.0078 | 0.0048  | 0.0090 |

All dimensions are in inches and are given to four or five decimal places only to avoid errors in computations, not to indicate required precision.

**Table 3. Tolerances on Taper, Lead, and Angle of Pipe Threads of Steel Products and All Pipe of Steel, Wrought Iron, or Brass ANSI/ASME B1.20.1-1983 (R2001) (Exclusive of Butt-Weld Pipe)**

| Nominal Pipe Size            | Threads per Inch | Taper on Pitch Line ( $\frac{1}{4}$ in./ft) |                 | Lead in Length of Effective Threads | 60 Degree Angle of Threads, Degrees |
|------------------------------|------------------|---|-----------------|-------------------------------------|-------------------------------------|
|                              |                  | Max.  | Min.            |                                     |                                     |
| $\frac{1}{16}$ $\frac{1}{8}$ | 27               | $+\frac{1}{8}$                              | $-\frac{1}{16}$ | $\pm 0.003$                         | $\pm 2\frac{1}{2}$                  |
| $\frac{1}{4}$ $\frac{3}{8}$  | 18               | $+\frac{1}{8}$                              | $-\frac{1}{16}$ | $\pm 0.003$                         | $\pm 2$                             |
| $\frac{1}{2}$ $\frac{3}{4}$  | 14               | $+\frac{1}{8}$                              | $-\frac{1}{16}$ | $\pm 0.003^a$                       | $\pm 2$                             |
| 1, 1¼, 1½, 2                 | 11½              | $+\frac{1}{8}$                              | $-\frac{1}{16}$ | $\pm 0.003^a$                       | $\pm 1\frac{1}{2}$                  |
| 2½ and larger                | 8                | $+\frac{1}{8}$                              | $-\frac{1}{16}$ | $\pm 0.003^a$                       | $\pm 1\frac{1}{2}$                  |

<sup>a</sup>The tolerance on lead shall be  $\pm 0.003$  in. per inch on any size threaded to an effective thread length greater than 1 in.

For tolerances on height of thread, see Table 2.

The limits specified in this table are intended to serve as a guide for establishing limits of the thread elements of taps, dies, and thread chasers. These limits may be required on product threads.

**Table 4. Internal Threads in Pipe Couplings, NPSC for Pressure-tight Joints with Lubricant or Sealer ANSI/ASME B1.20.1-1983 (R2001)**

| Nom. Pipe-Size | Thds. per Inch | Minor <sup>a</sup> Dia. | Pitch Diameter <sup>b</sup> |        | Nom. Pipe | Thds. per Inch | Minor <sup>a</sup> Dia. | Pitch Diameter <sup>b</sup> |        |

<sup>a</sup> As the ANSI Standard Pipe Thread form is maintained, the major and minor diameters of the internal thread vary with the pitch diameter. All dimensions are given in inches.

<sup>b</sup> The actual pitch diameter of the straight tapped hole will be slightly smaller than the value given when gaged with a taper plug gage as called for in ANSI/ASME B1.20.1.

**Railing Joint Taper Pipe Threads, NPTR.**—Railing joints require a rigid mechanical thread joint with external and internal taper threads. The external thread is basically the same as the ANSI Standard Taper Pipe Thread, except that sizes 1/2 through 2 inches are shortened by 3 threads and sizes 2 1/2 through 4 inches are shortened by 4 threads to permit the use of the larger end of the pipe thread. A recess in the fitting covers the last scratch or imperfect threads on the pipe.

**Straight Pipe Threads in Pipe Couplings, NPSC.**—Threads in pipe couplings made in accordance with the ANSI/ASME B1.20.1 specifications are straight (parallel) threads of the same thread form as the ANSI Standard Taper Pipe Thread. They are used to form pressure-tight joints when assembled with an ANSI Standard external taper pipe thread and made up with lubricant or sealant. These joints are recommended for comparatively low pressures only.

**Straight Pipe Threads for Mechanical Joints, NPSM, NPSL, and NPSH.**—While external and internal taper pipe threads are recommended for pipe joints in practically every service, there are mechanical joints where straight pipe threads are used to advantage. Three types covered by ANSI/ASME B1.20.1 are:

*Loose-fitting Mechanical Joints With Locknuts (External and Internal), NPSL:* This thread is designed to produce a pipe thread having the largest diameter that it is possible to cut on standard pipe. The dimensions of these threads are given in Table 5. It will be noted that the maximum major diameter of the external thread is slightly greater than the nominal outside diameter of the pipe. The normal manufacturer's variation in pipe diameter provides for this increase.

*Loose-fitting Mechanical Joints for Hose Couplings (External and Internal), NPSH:*

Hose coupling joints are ordinarily made with straight internal and external loose-fitting threads. There are several standards of hose threads having various diameters and pitches. One of these is based on the ANSI Standard pipe thread and by the use of this thread series, it is possible to join small hose couplings in sizes 1/2 to 4 inches, inclusive, to ends of standard pipe having ANSI Standard External Pipe Threads, using a gasket to seal the joints. For the hose coupling thread dimensions see *ANSI Standard Hose Coupling Screw Threads* starting on page 1872.

*Free-fitting Mechanical Joints for Fixtures (External and Internal), NPSM:* Standard iron, steel, and brass pipe are often used for special applications where there are no internal pressures. Where straight thread joints are required for mechanical assemblies, straight pipe threads are often found more suitable or convenient. Dimensions of these threads are given in Table 5.

**Table 5. American National Standard Straight Pipe Threads for Mechanical Joints, NPSM and NPSL ANSI/ASME B1.20.1-1983 (R2001)**

| Nominal Pipe Size  | Threads per Inch | Allowance | External Thread   |       |                |         | Internal Thread   |       |                   |         |
|--|------------------|-----------|-------------------|-------|----------------|---------|-------------------|-------|-------------------|---------|
|  |                  |           | Major Diameter    |       | Pitch Diameter |         | Minor Diameter    |       | Pitch Diameter    |         |
|  |                  |           | Max. <sup>a</sup> | Min.  | Max.           | Min.    | Min. <sup>a</sup> | Max.  | Min. <sup>b</sup> | Max.    |
| Free-fitting Mechanical Joints for Fittings—NPSM             |                  |           |                   |       |                |         |                   |       |                   |         |

<sup>a</sup> As the ANSI Standard Straight Pipe Thread form of thread is maintained, the major and the minor diameters of the internal thread and the minor diameter of the external thread vary with the pitch diameter. The major diameter of the external thread is usually determined by the diameter of the pipe. These theoretical diameters result from adding the depth of the truncated thread ( $0.666025 \times p$ ) to the maximum pitch diameters, and it should be understood that commercial pipe will not always have these maximum major diameters.

<sup>b</sup> This is the same as the pitch diameter at end of internal thread,  $E_1$  Basic. (See Table 1a.)

All dimensions are given in inches.

*Notes for Free-fitting Fixture Threads:* The minor diameters of external threads and major diameters of internal threads are those as produced by commercial straight pipe dies and commercial ground straight pipe taps.

The major diameter of the external thread has been calculated on the basis of a truncation of  $0.10825p$ , and the minor diameter of the internal thread has been calculated on the basis of a truncation of  $0.21651p$ , to provide no interference at crest and root when product is gaged with gages made in accordance with the Standard.

*Notes for Loose-fitting Locknut Threads:* The locknut thread is established on the basis of retaining the greatest possible amount of metal thickness between the bottom of the thread and the inside of the pipe. In order that a locknut may fit loosely on the externally threaded part, an allowance equal to the "increase in pitch diameter per turn" is provided, with a tolerance of  $1\frac{1}{2}$  turns for both external and internal threads.

**American National Standard Dryseal Pipe Threads for Pressure-Tight Joints.—**

Dryseal pipe threads are based on the USA (American) pipe thread; however, they differ in that they are designed to seal pressure-tight joints without the necessity of using sealing compounds. To accomplish this, some modification of thread form and greater accuracy in manufacture is required. The roots of both the external and internal threads are truncated slightly more than the crests, i.e., roots have wider flats than crests so that metal-to-metal contact occurs at the crests and roots coincident with, or prior to, flank contact. Thus, as the threads are assembled by wrenching, the roots of the threads crush the sharper crests of the mating threads. This sealing action at both major and minor diameters tends to prevent spiral leakage and makes the joints pressure-tight without the necessity of using sealing compounds, provided that the threads are in accordance with standard specifications and tolerances and are not damaged by galling in assembly. The control of crest and root truncation is simplified by the use of properly designed threading tools. Also, it is desirable that both external and internal threads have full thread height for the length of hand engagement. Where not functionally objectionable, the use of a compatible lubricant or sealant is permissible to minimize the possibility of galling. This is desirable in assembling Dryseal pipe threads in refrigeration and other systems to effect a pressure-tight seal. The crest and root of Dryseal pipe threads may be slightly rounded, but are acceptable if they lie within the truncation limits given in Table 6.

**Table 6. American National Standard Dryseal Pipe Threads—Limits on Crest and Root Truncation ANSI B1.20.3-1976 (R1998)**

| Threads Per Inch | Height of Sharp V Thread ( $H$ ) | Truncation |        |           |        |           |        |           |        |
|------------------|----------------------------------|------------|--------|-----------|--------|-----------|--------|-----------|--------|
|                  |                                  | Minimum    |        |           |        | Maximum   |        |           |        |

| 11½              | 0.07531                          | 0.040 $p$  | 0.0035 | 0.060 $p$ | 0.0052 | 0.060 $p$ | 0.0052 | 0.090 $p$ | 0.0078 |
| 8                | 0.10825                          | 0.042 $p$  | 0.0052 | 0.055 $p$ | 0.0069 | 0.055 $p$ | 0.0069 | 0.076 $p$ | 0.0095 |

All dimensions are given in inches. In the formulas,  $p$  = pitch.

**Types of Dryseal Pipe Thread.—**American National Standard ANSI B1.20.3-1976 (R1998) covers four types of standard Dryseal pipe threads:

NPTF, Dryseal USA (American) Standard Taper Pipe Thread

PTF-SAE SHORT, Dryseal SAE Short Taper Pipe Thread

NPSF, Dryseal USA (American) Standard Fuel Internal Straight Pipe Thread

NPSI, Dryseal USA (American) Standard Intermediate Internal Straight Pipe Thread

**Table 7. Recommended Limitation of Assembly among the Various Types of Dryseal Threads**

| External Dryseal Thread |                                 | For Assembly with Internal Dryseal Thread |                                  |
|-------------------------|---------------------------------|---|----------------------------------|
| Type                    | Description                     | Type                                      | Description                      |

|                         |                                 | 2 <sup>a,b</sup>                          | PTF-SAE SHORT (tapered), int thd |
|                         |                                 | 3 <sup>a,c</sup>                          | NPSF (straight), int thd         |
|                         |                                 | 4 <sup>a,c,d</sup>                        | NPSI (straight), int thd         |
| 2 <sup>a,c</sup>        | PTF-SAE SHORT (tapered) ext thd | 4   | NPSI (straight), int thd         |
|                         |                                 | 1   | NPTF (tapered), int thd          |

<sup>a</sup> Pressure-tight joints without the use of a sealant can best be ensured where both components are threaded with NPTF (full length threads), since theoretically interference (sealing) occurs at all threads, but there are two less threads engaged than for NPTF assemblies. When straight internal threads are used, there is interference only at one thread depending on ductility of materials.

<sup>b</sup>PTF-SAE SHORT internal threads are primarily intended for assembly with type 1-NPTF external threads. They are not designed for, and at extreme tolerance limits may not assemble with, type 2-PTF-SAE SHORT external threads.

<sup>c</sup>There is no external straight Dryseal thread.

<sup>d</sup>NPSI internal threads are primarily intended for assembly with type 2-PTF-SAE SHORT external threads but will also assemble with full length type 1 NPTF external threads.

<sup>e</sup>PTF-SAE SHORT external threads are primarily intended for assembly with type 4-NPSI internal threads but can also be used with type 1-NPTF internal threads. They are not designed for, and at extreme tolerance limits may not assemble with, type 2-PTF-SAE SHORT internal threads or type 3-NPSF internal threads.

An assembly with straight internal pipe threads and taper external pipe threads is frequently more advantageous than an all taper thread assembly, particularly in automotive and other allied industries where economy and rapid production are major considerations. Dryseal threads are not used in assemblies in which both components have straight pipe threads.

*NPTF Threads:* This type applies to both external and internal threads and is suitable for pipe joints in practically every type of service. Of all Dryseal pipe threads, NPTF external and internal threads mated are generally conceded to be superior for strength and seal since they have the longest length of thread and, theoretically, interference (sealing) occurs at every engaged thread root and crest. Use of tapered internal threads, such as NPTF or PTF-SAE SHORT in hard or brittle materials having thin sections will minimize the possibility of fracture.

There are two classes of NPTF threads. Class 1 threads are made to interfere (seal) at root and crest when mated, but inspection of crest and root truncation is not required. Consequently, Class 1 threads are intended for applications where close control of tooling is required for conformance of truncation or where sealing is accomplished by means of a sealant applied to the threads.

Class 2 threads are theoretically identical to those made to Class 1, however, inspection of root and crest truncation is required. Consequently, where a sealant is not used, there is more assurance of a pressure-tight seal for Class 2 threads than for Class 1 threads.

*PTF-SAE SHORT Threads:* External threads of this type conform in all respects with NPTF threads except that the thread length has been shortened by eliminating one thread from the small (entering) end. These threads are designed for applications where clearance is not sufficient for the full length of the NPTF threads or for economy of material where the full thread length is not necessary.

Internal threads of this type conform in all respects with NPTF threads, except that the thread length has been shortened by eliminating one thread from the large (entry) end. These threads are designed for thin materials where thickness is not sufficient for the full thread length of the NPTF threads or for economy in tapping where the full thread length is not necessary.

Pressure-tight joints without the use of lubricant or sealer can best be ensured where mating components are both threaded with NPTF threads. This should be considered before specifying PTF-SAE SHORT external or internal threads.

*NPSF Threads:* Threads of this type are straight (cylindrical) instead of tapered and are internal only. They are more economical to produce than tapered internal threads, but when assembled do not offer as strong a guarantee of sealing since root and crest interference will not occur for all threads. NPSF threads are generally used with soft or ductile materials which will tend to adjust at assembly to the taper of external threads, but may be used in hard or brittle materials where the section is thick.

*NPSI Threads:* Threads of this type are straight (cylindrical) instead of tapered, are internal only and are slightly larger in diameter than NPSF threads but have the same tolerance and thread length. They are more economical to produce than tapered threads and may be used in hard or brittle materials where the section is thick or where there is little expansion at assembly with external taper threads. As with NPSF threads, NPSI threads when assembled do not offer as strong a guarantee of sealing as do tapered internal threads.

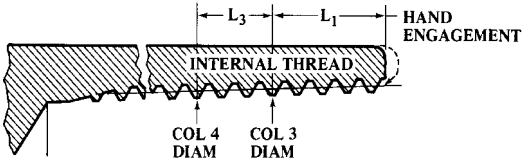

DRYSEAL PIPE THREADS

For more complete specifications for production and acceptance of Dryseal pipe threads, see ANSI B1.20.3 (Inch) and ANSI B1.20.4 (Metric Translation), and for gaging and inspection, see ANSI B1.20.5 (Inch) and ANSI B1.20.6M (Metric Translation).

*Designation of Dryseal Pipe Threads:* The standard Dryseal pipe threads are designated by specifying in sequence nominal size, thread series symbol, and class:

*Examples:* 1/8-27 NPTF-1; 1/8-27 PTF-SAE SHORT; and 3/8-18 NPTF-1 AFTER PLATING.

**Table 8. Suggested Tap Drill Sizes for Internal Dryseal Pipe Threads**

| Size         | Probable Drill Oversize Cut (Mean) | Taper Pipe Thread             |  |                         |                 | Straight Pipe Thread |        |                         |
|--------------|------------------------------------|-------------------------------|--|-------------------------|-----------------|----------------------|--------|-------------------------|
|              |                                    | Minor Diameter At Distance    |  | Drill Size <sup>a</sup> |                 | Minor Diameter       |        | Drill Size <sup>a</sup> |
|              |                                    | L <sub>1</sub> From Large End | L <sub>1</sub> + L <sub>3</sub> From Large End | Without Reamer          | With Reamer     | NPSF                 | NPSI   |                         |

<sup>a</sup> Some drill sizes listed may not be standard drills.

All dimensions are given in inches.

**Special Dryseal Threads.**—Where design limitations, economy of material, permanent installation, or other limiting conditions prevail, consideration may be given to using a special Dryseal thread series.

*Dryseal Special Short Taper Pipe Thread, PTF-SPL SHORT:* Threads of this series conform in all respects to PTF-SAE SHORT threads except that the full thread length has been further shortened by eliminating one thread at the small end of internal threads or one thread at the large end of external threads.

*Dryseal Special Extra Short Taper Pipe Thread, PTF-SPL EXTRA SHORT:* Threads of this series conform in all respects to PTF-SAE SHORT threads except that the full thread length has been further shortened by eliminating two threads at the small end of internal threads or two threads at the large end of external threads.

*Limitations of Assembly:* Table 9 applies where Dryseal Special Short or Extra Short Taper Pipe Threads are to be assembled as special combinations.

**Table 9. Assembly Limitations for Special Combinations of Dryseal Threads**

| Thread   | May Assemble with <sup>a</sup>  | May Assemble with <sup>b</sup> |
|--|---|--------------------------------|
| PTF SPL SHORT EXTERNAL<br>PTF SPL EXTRA SHORT EXTERNAL | PTF-SAE SHORT INTERNAL<br>NPSF INTERNAL<br>PTF SPL SHORT INTERNAL<br>PTF SPL EXTRA SHORT INTERNAL | NPTF or NPSI INTERNAL          |
| PTF SPL SHORT INTERNAL<br>PTF SPL EXTRA SHORT INTERNAL | PTF-SAE SHORT EXTERNAL  | NPTF EXTERNAL                  |

<sup>a</sup> Only when the external thread or the internal thread or both are held closer than the standard tolerance, the external thread toward the minimum and the internal thread toward the maximum pitch diameter to provide a minimum of one turn hand engagement. At extreme tolerance limits the shortened full-thread lengths reduce hand engagement and the threads may not start to assemble.

<sup>b</sup> Only when the internal thread or the external thread or both are held closer than the standard tolerance, the internal thread toward the minimum and the external thread toward the maximum pitch diameter to provide a minimum of two turns for wrench make-up and sealing. At extreme tolerance limits the shortened full-thread lengths reduce wrench make-up and the threads may not seal.

*Dryseal Fine Taper Thread Series, F-PTF:* The need for finer pitches for nominal pipe sizes has brought into use applications of 27 threads per inch to  $\frac{1}{4}$ - and  $\frac{3}{8}$ -inch pipe sizes. There may be other needs that require finer pitches for larger pipe sizes. It is recommended that the existing threads per inch be applied to the next larger pipe size for a fine thread series, thus:  $\frac{1}{4}$ -27,  $\frac{3}{8}$ -27,  $\frac{1}{2}$ -18,  $\frac{3}{4}$ -18, 1-14,  $1\frac{1}{4}$ -14,  $1\frac{1}{2}$ -14, and 2-14. This series applies to external and internal threads of full length and is suitable for applications where threads finer than NPTF are required.

*Dryseal Special Diameter-Pitch Combination Series, SPL-PTF:* Other applications of diameter-pitch combinations have come into use where taper pipe threads are applied to nominal size thin wall tubing. These combinations are:  $\frac{1}{2}$ -27,  $\frac{5}{8}$ -27,  $\frac{3}{4}$ -27,  $\frac{7}{8}$ -27, and 1-27. This series applies to external and internal threads of full length and is applicable to thin wall nominal diameter outside tubing.

*Designation of Special Dryseal Pipe Threads:* The designations used for these special dryseal pipe threads are as follows:

$\frac{1}{8}$ -27 PTF-SPL SHORT

$\frac{1}{8}$ -27 PTF-SPL EXTRA SHORT

$\frac{1}{2}$ -27 SPL PTF, OD 0.500

Note that in the last designation the OD of tubing is given.

### British Standard Pipe Threads

**British Standard Pipe Threads for Non-pressure-tight Joints.**—The threads in BS 2779:1973, “Specifications for Pipe Threads where Pressure-tight Joints are not Made on the Threads”, are Whitworth form parallel fastening threads that are generally used for fastening purposes such as the mechanical assembly of component parts of fittings, cocks and valves. They are not suitable where pressure-tight joints are made on the threads.

The crests of the basic Whitworth thread form may be truncated to certain limits of size given in the Standard except on internal threads, when they are likely to be assembled with external threads conforming to the requirements of BS 21 “British Standard Pipe Threads for Pressure-tight Joints” (see page 1870).

For external threads two classes of tolerance are provided and for internal, one class. The two classes of tolerance for external threads are Class A and Class B. For economy of manufacture the class B fit should be chosen whenever possible. The class A is reserved for those applications where the closer tolerance is essential. Class A tolerance is an entirely negative value, equivalent to the internal thread tolerance. Class B tolerance is an entirely negative value twice that of class A tolerance. Tables showing limits and dimensions are given in the Standard.

The thread series specified in this Standard shall be designated by the letter "G". A typical reference on a drawing might be "G $\frac{1}{2}$ ", for internal thread; "G $\frac{1}{2}$ A", for external thread, class A; and "G  $\frac{1}{2}$  B", for external thread, class B. Where no class reference is stated for external threads, that of class B will be assumed. The designation of truncated threads shall have the addition of the letter "T" to the designation, i.e., G  $\frac{1}{2}$ T and G  $\frac{1}{2}$ BT.

**British Standard Pipe Threads (Non-pressure-tight Joints)  
Metric and Inch Basic Sizes BS 2779:1973**

| Nominal Size, Inches | Threads per Inch <sup>a</sup> | Depth of Thread | Major Diameter | Pitch Diameter | Minor Diameter | Nominal Size, Inches | Threads per Inch <sup>a</sup> | Depth of Thread | Major Diameter | Pitch Diameter | Minor Diameter |
|----------------------|-------------------------------|-----------------|----------------|----------------|----------------|----------------------|-------------------------------|-----------------|----------------|----------------|----------------|

<sup>a</sup>The thread pitches in millimeters are as follows: 0.907 for 28 threads per inch. 1.337 for 19 threads per inch, 1.814 for 14 threads per inch, and 2.309 for 11 threads per inch.

Each basic metric dimension is given in roman figures (nominal sizes excepted) and each basic inch dimension is shown in italics directly beneath it.

**British Standard Pipe Threads for Pressure-tight Joints.**—The threads in BS 21:1973, "Specification for Pipe Threads where Pressure-tight Joints are Made on the Threads", are based on the Whitworth thread form and are specified as:

1) *Jointing threads:* These relate to pipe threads for joints made pressure-tight by the mating of the threads; they include taper external threads for assembly with either taper or parallel internal threads (parallel external pipe threads are not suitable as jointing threads)

2) *Longscrew threads:* These relate to parallel external pipe threads used for longscrews (connectors) specified in BS 1387 where a pressure-tight joint is achieved by the compression of a soft material onto the surface of the external thread by tightening a back nut against a socket

**British Standard External and Internal Pipe Threads (Pressure-tight Joints)

<sup>a</sup>In the Standard BS 21:1973 the thread pitches in millimeters are as follows: 0.907 for 28 threads per inch, 1.337 for 19 threads per inch, 1.814 for 14 threads per inch, and 2.309 for 11 threads per inch.

<sup>b</sup>This is the minimum number of useful threads on the pipe for the basic gage length; for the maximum and minimum gage lengths, the minimum numbers of useful threads are, respectively, greater and less by the amount of tolerance in the column to the left. The design of internally threaded parts shall make allowance for receiving pipe ends of up to the minimum number of useful threads corresponding to the maximum gage length; the minimum number of useful *internal* threads shall be no less than 80 per cent of the minimum number of useful external threads for the minimum gage length.

Each basic metric dimension is given in roman figures (nominal sizes excepted) and each basic inch dimension is shown in italics directly beneath it. Figures in ( ) are numbers of turns of thread with metric linear equivalents given beneath. Taper of taper thread is 1 in 16 on diameter.

## Hose Coupling Screw Threads

**ANSI Standard Hose Coupling Screw Threads.**—Threads for hose couplings, valves, and all other fittings used in direct connection with hose intended for domestic, industrial, and general service in sizes  $\frac{1}{2}$ ,  $\frac{5}{8}$ ,  $\frac{3}{4}$ , 1,  $1\frac{1}{4}$ ,  $1\frac{1}{2}$ , 2,  $2\frac{1}{2}$ , 3,  $3\frac{1}{2}$ , and 4 inches are covered by American National Standard ANSI/ASME B1.20.7-1991. These threads are designated as follows:

NH — Standard hose coupling threads of full form as produced by cutting or rolling.

NHR — Standard hose coupling threads for garden hose applications where the design utilizes thin walled material which is formed to the desired thread.

NPSH — Standard straight hose coupling thread series in sizes  $\frac{1}{2}$  to 4 inches for joining to American National Standard taper pipe threads using a gasket to seal the joint.

Thread dimensions are given in [Table 1](#) and thread lengths in [Table 2](#).

Fig. 1. Thread Form for ANSI Standard Hose Coupling Threads, NPSH, NH, and NHR. Heavy Line Shows Basic Size.

All dimensions are given in inches.

Dimensions given for the maximum minor diameter of the nipple are figured to the intersection of the worn tool arc with a centerline through crest and root. The minimum minor diameter of the nipple shall be that corresponding to a flat at the minor diameter of the minimum nipple equal to  $\frac{1}{2}p$ , and may be determined by subtracting  $0.7939p$  from the minimum pitch diameter of the nipple. (See Fig. 1)

Dimensions given for the minimum major diameter of the coupling correspond to the basic flat,  $\frac{1}{2}p$ , and the profile at the major diameter produced by a worn tool must not fall below the basic outline. The maximum major diameter of the coupling shall be that corresponding to a flat at the major diameter of the maximum coupling equal to  $\frac{1}{2}p$  and may be determined by adding  $0.7939p$  to the maximum pitch diameter of the coupling. (See Fig. 1)

NH and NHR threads are used for garden hose applications. NPSH threads are used for steam, air and all other hose connections to be made up with standard pipe threads. NH (SPL) threads are used for marine applications.

All dimensions are given in inches. For thread designation see Table 1.

**American National Fire Hose Connection Screw Thread.**—This thread is specified in the National Fire Protection Association's Standard NFPA No. 194-1974. It covers the dimensions for screw thread connections for fire hose couplings, suction hose couplings, relay supply hose couplings, fire pump suction, discharge valves, fire hydrants, nozzles, adaptors, reducers, caps, plugs, wyes, siamese connections, standpipe connections, and sprinkler connections.

**Form of Thread:** The basic form of thread is as shown in Fig. 1. It has an included angle of 60 degrees and is truncated top and bottom. The flat at the root and crest of the basic thread form is equal to  $\frac{1}{8}$  (0.125) times the pitch in inches. The height of the thread is equal to 0.649519 times the pitch. The outer ends of both external and internal threads are terminated by the blunt start or "Higbee Cut" on full thread to avoid crossing and mutilation of thread.

**Thread Designation:** The thread is designated by specifying in sequence the nominal size of the connection, number of threads per inch followed by the thread symbol NH.

Thus, .75-8NH indicates a nominal size connection of 0.75 inch diameter with 8 threads per inch.

*Basic Dimensions:* The basic dimensions of the thread are as given in [Table 1](#).

**Table 1. Basic Dimensions of NH Threads NFPA 1963–1993 Edition**

| Nom. Size      | Threads per Inch (tpi) | Thread Designation | Pitch, $p$ | Basic Thread Height, $h$            | Minimum Internal Thread Dimensions |                  |                  |
|----------------|------------------------|--------------------|------------|-------------------------------------|------------------------------------|------------------|------------------|

| 6              | 4                      | 6-4 NH             | 0.25000    | 0.0250                              | 7.0250                             | 6.8626           | 6.7002           |

All dimensions are in inches.

*Thread Limits of Size:* Limits of size for NH external threads are given in [Table 2](#). Limits of size for NH internal threads are given in [Table 3](#).

*Tolerances:* The pitch-diameter tolerances for mating external and internal threads are the same. Pitch-diameter tolerances include lead and half-angle deviations. Lead deviations consuming one-half of the pitch-diameter tolerance are 0.0032 inch for  $\frac{3}{4}$ -, 1-, and  $1\frac{1}{2}$ -inch sizes; 0.0046 inch for  $2\frac{1}{2}$ -inch size; 0.0052 inch for 3-, and  $3\frac{1}{2}$ -inch sizes; and 0.0072 inch for 4-,  $4\frac{1}{2}$ -, 5-, and 6-inch sizes. Half-angle deviations consuming one-half of the pitch-diameter tolerance are 1 degree, 42 minutes for  $\frac{3}{4}$ - and 1-inch sizes; 1 degree, 54 minutes for  $1\frac{1}{2}$ -inch size; 2 degrees, 17 minutes for  $2\frac{1}{2}$ -inch size; 2 degrees, 4 minutes for 3- and  $3\frac{1}{2}$ -inch size; and 1 degree, 55 minutes for 4-,  $4\frac{1}{2}$ -, 5-, and 6-inch sizes.

Tolerances for the external threads are:

Major diameter tolerance =  $2 \times$  pitch-diameter tolerance

Minor diameter tolerance = pitch-diameter tolerance +  $2h/9$

The minimum minor diameter of the external thread is such as to result in a flat equal to one-third of the  $p/8$  basic flat, or  $p/24$ , at the root when the pitch diameter of the external thread is at its minimum value. The maximum minor diameter is basic, but may be such as results from the use of a worn or rounded threading tool. The maximum minor diameter is shown in [Fig. 1](#) and is the diameter upon which the minor diameter tolerance formula shown above is based.

Tolerances for the internal threads are:

Minor diameter tolerance =  $2 \times$  pitch-diameter tolerance

The minimum minor diameter of the internal thread is such as to result in a basic flat,  $p/8$ , at the crest when the pitch diameter of the thread is at its minimum value.

Major diameter tolerance = pitch-diameter tolerance -  $2h/9$

<sup>a</sup>Dimensions given for the maximum minor diameter of the nipple are figured to the intersection of the worn tool arc with a center line through crest and root. The minimum minor diameter of the nipple shall be that corresponding to a flat at the minor diameter of the minimum nipple equal to  $p/24$  and may be determined by subtracting  $11h/9$  (or  $0.7939p$ ) from the minimum pitch diameter of the nipple.

All dimensions are in inches.

<sup>a</sup>Dimensions for the minimum major diameter of the coupling correspond to the basic flat ( $p/8$ ), and the profile at the major diameter produced by a worn tool must not fall below the basic outline. The maximum major diameter of the coupling shall be that corresponding to a flat at the major diameter of the maximum coupling equal to  $p/24$  and may be determined by adding  $11h/9$  (or  $0.7939p$ ) to the maximum pitch diameter of the coupling.

All dimensions are in inches.

**Gages and Gaging:** Full information on gage dimensions and the use of gages in checking the NH thread are given in NFPA Standard No. 1963, 1993 Edition, published by the National Fire Protection Association, Batterymarch Park, Quincy, MA 02269.

The information and data taken from this standard are reproduced with the permission of the NFPA.

## OTHER THREADS

### Interference-Fit Threads

**Interference-Fit Threads.**—Interference-fit threads are threads in which the externally threaded member is larger than the internally threaded member when both members are in the free state and that, when assembled, become the same size and develop a holding torque through elastic compression, plastic movement of material, or both. By custom, these threads are designated Class 5.

The data in [Tables 1, 2, and 3](#), which are based on years of research, testing and field study, represent an American standard for interference-fit threads that overcomes the difficulties experienced with previous interference-fit recommendations such as are given in Federal Screw Thread Handbook H28. These data were adopted as American Standard ASA B1.12-1963. Subsequently, the standard was revised and issued as American National Standard ANSI B1.12-1972. More recent research conducted by the Portsmouth Naval Shipyard has led to the current revision ASME/ANSI B1.12-1987 (R1998).

The data in [Tables 1, 2, and 3](#) provide dimensions for external and internal interference-fit (Class 5) threads of modified American National form in the Coarse Thread series, sizes  $\frac{1}{4}$  inch to  $1\frac{1}{2}$  inches. It is intended that interference-fit threads conforming with this standard will provide adequate torque conditions which fall within the limits shown in [Table 3](#). The minimum torques are intended to be sufficient to ensure that externally threaded members will not loosen in service; the maximum torques establish a ceiling below which seizing, galling, or torsional failure of the externally threaded components is reduced.

[Tables 1 and 2](#) give external and internal thread dimensions and are based on engagement lengths, external thread lengths, and tapping hole depths specified in [Table 3](#) and in compliance with the design and application data given in the following paragraphs. [Table 4](#) gives the allowances and [Table 5](#) gives the tolerances for pitch, major, and minor diameters for the Coarse Thread Series.

Basic Profile of American National Standard Class 5 Interference Fit Thread

## INTERFERENCE FIT THREADS

Note: Plastic flow of interference metal into cavities at major and minor diameters is not illustrated.

Maximum and Minimum Material Limits for Class 5 Interference-Fit Thread

**Design and Application Data for Class 5 Interference-Fit Threads.**—Following are conditions of usage and inspection on which satisfactory application of products made to dimensions in [Tables 1, 2, and 3](#) are based.

*Thread Designations:* The following thread designations provide a means of distinguishing the American Standard Class 5 Threads from the tentative Class 5 and alternate Class 5 threads, specified in Handbook H28. They also distinguish between external and internal American Standard Class 5 Threads.

Class 5 External Threads are designated as follows:

NC-5 HF—For driving in hard ferrous material of hardness over 160 BHN.

NC-5 CSF—For driving in copper alloy and soft ferrous material of 160 BHN or less.

NC-5 ONF—For driving in other nonferrous material (nonferrous materials other than copper alloys), any hardness.

Class 5 Internal Threads are designated as follows:

NC-5 IF—Entire ferrous material range.

NC-5 INF—Entire nonferrous material range.

<sup>a</sup> Fourth decimal place is 0 for all sizes.

All dimensions are in inches, unless otherwise specified.

*Externally Threaded Products:* Points of externally threaded components should be chamfered or otherwise reduced to a diameter below the minimum minor diameter of the thread. The limits apply to bare or metallic coated parts. The threads should be free from excessive nicks, burrs, chips, grit or other extraneous material before driving.

**Table 3. Torques, Interferences, and Engagement Lengths for Class 5 Interference-Fit Threads ANSI/ASME B1.12-1987 (R1998)**

| Nominal Size | Interference on Pitch Diameter |       | Engagement Lengths, External Thread Lengths and Tapped Hole Depths <sup>a</sup> |                  |           |                            |                  |           | Torque at $1\frac{1}{2}D$ Engagement in Ferrous Material |            |

<sup>a</sup> $L_e$  = Length of engagement.  $T_s$  = External thread length of full form thread.  $T_h$  = Minimum depth of full form thread in hole.

All dimensions are inches.

**Materials for Externally Threaded Products:** The length of engagement, depth of thread engagement and pitch diameter in Tables 1, 2, and 3 are designed to produce adequate torque conditions when heat-treated medium-carbon steel products, ASTM A-325 (SAE Grade 5) or better, are used. In many applications, case-carburized and nonheat-treated medium-carbon steel products of SAE Grade 4 are satisfactory. SAE Grades 1 and 2, may be usable under certain conditions. This standard is not intended to cover the use of products made of stainless steel, silicon bronze, brass or similar materials. When such materials are used, the tabulated dimensions will probably require adjustment based on pilot experimental work with the materials involved.

**Lubrication:** For driving in ferrous material, a good lubricant sealer should be used, particularly in the hole. A non-carbonizing type of lubricant (such as a rubber-in-water dispersion) is suggested. The lubricant must be applied to the hole and it may be applied to the male member. In applying it to the hole, care must be taken so that an excess amount of lubricant will not cause the male member to be impeded by hydraulic pressure in a blind hole. Where sealing is involved, the lubricant selected should be insoluble in the medium being sealed.

For driving, in nonferrous material, lubrication may not be needed. The use of medium gear oil for driving in aluminum is recommended. American research has observed that the minor diameter of lubricated tapped holes in non-ferrous materials may tend to close in, that is, be reduced in driving; whereas with an unlubricated hole the minor diameter may tend to open up.

**Driving Speed:** This standard makes no recommendation for driving speed. Some opinion has been advanced that careful selection and control of driving speed is desirable to obtain optimum results with various combinations of surface hardness and roughness. Experience with threads made to this standard may indicate what limitations should be placed on driving speeds.

<sup>a</sup>The allowances in these columns were obtained from industrial research data.

<sup>b</sup>Negative allowance is the difference between the basic pitch diameter and pitch diameter value at maximum material condition.

All dimensions are in inches.

The difference between basic major diameter and internal thread minimum major diameter is  $0.075H$  and is tabulated in Table 5.

<sup>a</sup>National Class 3 pitch diameter tolerance from ASA B1.1-1960.

<sup>b</sup>Twice the NC-3 pitch diameter tolerance.

<sup>c</sup>National Class 3 minor diameter tolerance from ASA B1.1-1960.

All dimensions are in inches.

**Relation of Driving Torque to Length of Engagement:** Torques increase directly as the length of engagement and this increase is proportionately more rapid as size increases. The standard does not establish recommended breakloose torques.

**Surface Roughness:** Surface roughness is not a required measurement. Roughness between 63 and 125  $\mu\text{in}$ . Ra is recommended. Surface roughness greater than 125  $\mu\text{in}$ . Ra may encourage galling and tearing of threads. Surfaces with roughness less than 63  $\mu\text{in}$ . Ra may hold insufficient lubricant and wring or weld together.

**Lead and Angle Variations:** The lead variation values tabulated in Table 6 are the maximum variations from specified lead between any two points not farther apart than the length of the standard GO thread gage. Flank angle variation values tabulated in Table 7 are maximum variations from the basic 30° angle between thread flanks and perpendiculars to the thread axis. The application of these data in accordance with ANSI/ASME B1.3M, the screw thread gaging system for dimensional acceptability, is given in the Standard. Lead variation does not change the volume of displaced metal, but it exerts a cumulative unilateral stress on the pressure side of the thread flank. Control of the difference between pitch diameter size and functional diameter size to within one-half the pitch diameter tolerance will hold lead and angle variables to within satisfactory limits. Both the variations may produce unacceptable torque and faulty assemblies.

**Table 6. Maximum Allowable Variations in Lead and Maximum Equivalent Change in Functional Diameter ANSI/ASME B1.12-1987 (R1998)**

| Nominal Size | External and Internal Threads                     |   |
|--------------|---|---|
|              | Allowable Variation in Axial Lead (Plus or Minus) | Max Equivalent Change in Functional Diam. (Plus for Ext, Minus for Int) |
| 0.2500–20    | 0.0008  | 0.0013  |
| 0.3125–18    | 0.0009  | 0.0015  |
| 0.3750–16    | 0.0009  | 0.0016  |
| 0.4375–14    | 0.0010  | 0.0018  |
| 0.5000–13    | 0.0011  | 0.0018  |
| 0.5625–12    | 0.0012  | 0.0020  |
| 0.6250–11    | 0.0012  | 0.0021  |
| 0.7500–10    | 0.0013  | 0.0022  |
| 0.8750– 9    | 0.0014  | 0.0024  |
| 1.0000– 8    | 0.0016  | 0.0027  |
| 1.1250– 7    | 0.0017  | 0.0030  |
| 1.2500– 7    | 0.0017  | 0.0030  |
| 1.3750– 6    | 0.0020  | 0.0036  |
| 1.5000– 6    | 0.0020  | 0.0036  |

All dimensions are in inches.

Note: The equivalent change in functional diameter applies to total effect of form errors.

Maximum allowable variation in lead is permitted only when all other form variations are zero.

For sizes not tabulated, maximum allowable variation in lead is equal to 0.57735 times one-half the pitch diameter tolerance.

## Spark Plug Threads

**British Standard for Spark Plugs BS 45:1972 (withdrawn).**—This revised British Standard refers solely to spark plugs used in automobiles and industrial spark ignition internal combustion engines. The basic thread form is that of the ISO metric (see page 1816). In assigning tolerances to the threads of the spark plug and the tapped holes, full consideration has been given to the desirability of achieving the closest possible measure of interchangeability between British spark plugs and engines, and those made to the standards of other ISO Member Bodies.

## Basic Thread Dimensions for Spark Plug and Tapped Hole in Cylinder Head

| Nom. Size | Pitch | Thread | Major Dia.          |        | Pitch Dia. |        | Minor Dia. |        |
|-----------|-------|--------|---------------------|--------|------------|--------|------------|--------|
|           |       |        | Max.                | Min.   | Max.       | Min.   | Max.       | Min.   |
| 14        | 1.25  | Plug   | 13.937 <sup>a</sup> | 13.725 | 13.125     | 12.993 | 12.402     | 12.181 |
| 14        | 1.25  | Hole   |                     | 14.00  | 13.368     | 13.188 | 12.912     | 12.647 |
| 18        | 1.5   | Plug   | 17.933 <sup>a</sup> | 17.697 | 16.959     | 16.819 | 16.092     | 15.845 |
| 18        | 1.5   | Hole   |                     | 18.00  | 17.216     | 17.026 | 16.676     | 16.376 |

<sup>a</sup> Not specified

All dimensions are given in millimeters.

The tolerance grades for finished spark plugs and corresponding tapped holes in the cylinder head are: for 14 mm size, 6e for spark plugs and 6H for tapped holes which gives a minimum clearance of 0.063 mm; and for 18 mm size, 6e for spark plugs and 6H for tapped holes which gives a minimum clearance of 0.067 mm.

These minimum clearances are intended to prevent the possibility of seizure, as a result of combustion deposits on the bare threads, when removing the spark plugs and applies to both ferrous and non-ferrous materials. These clearances are also intended to enable spark plugs with threads in accordance with this standard to be fitted into existing holes.

**SAE Spark-Plug Screw Threads.**—The SAE Standard includes the following sizes:  $\frac{7}{8}$ -inch nominal diameter with 18 threads per inch; 18-millimeter nominal diameter with a 18-millimeter nominal diameter with a 1.5-millimeter pitch; 14-millimeter nominal diameter with a 1.25-millimeter pitch; 10-millimeter nominal diameter with a 1.0 millimeter pitch;  $\frac{3}{8}$ -inch nominal diameter with 24 threads per inch; and  $\frac{1}{4}$ -inch nominal diameter with 32 threads per inch. During manufacture, in order to keep the wear on the threading tools within permissible limits, the threads in the spark plug GO (ring) gage should be truncated to the maximum minor diameter of the spark plug; and in the tapped hole GO (plug) gage to the minimum major diameter of the tapped hole.

<sup>a</sup> M14 and M18 are preferred for new applications.

In order to keep the wear on the threading tools within permissible limits, the threads in the spark plug GO (ring) gage shall be truncated to the maximum minor diameter of the spark plug, and in the tapped hole GO (plug) gage to the minimum major diameter of the tapped hole. The plain plug gage for checking the minor diameter of the tapped hole shall be the minimum specified. The thread form is that of the ISO metric (see page 1816).

**Lamp Base and Electrical Fixture Threads**

**Lamp Base and Socket Shell Threads.**—The “American Standard” threads for lamp base and socket shells are sponsored by the American Society of Mechanical Engineers, the National Electrical Manufacturers’ Association and by most of the large manufacturers of products requiring rolled threads on sheet metal shells or parts, such as lamp bases, fuse plugs, attachment plugs, etc. There are five sizes, designated as the “miniature size,” the “candelabra size,” the “intermediate size,” the “medium size” and the “mogul size.”

All dimensions are in inches.

*Base Screw Shell Gage Tolerances:* Threaded ring gages—"Go," Max. thread size to minus 0.0003 inch; "Not Go," Min. thread size to plus 0.0003 inch. Plain ring gages—"Go," Max. thread O.D. to minus 0.0002 inch; "Not Go," Min. thread O.D. to plus 0.0002 inch.

*Socket Screw Shell Gages:* Threaded plug gages—"Go," Min. thread size to plus 0.0003 inch; "Not Go," Max. thread size to minus 0.0003 inch. Plain plug gages—"Go," Min. minor dia. to plus 0.0002 inch; "Not Go," Max. minor dia. to minus 0.0002 inch.

*Check Gages for Base Screw Shell Gages:* Threaded plugs for checking threaded ring gages—"Go," Max. thread size to minus 0.0003 inch; "Not Go," Min. thread size to plus 0.0003 inch.

**Electric Fixture Thread.**—The special straight electric fixture thread consists of a straight thread of the same pitches as the American standard pipe thread, and having the regular American or U. S. standard form; it is used for caps, etc. The male thread is smaller, and the female thread larger than those of the special straight-fixture pipe threads. The male thread assembles with a standard taper female thread, while the female thread assembles with a standard taper male thread. This thread is used when it is desired to have the joint "make up" on a shoulder. The gages used are straight-threaded limit gages.

### Instrument and Microscope Threads

**British Association Standard Thread (BA).**—This form of thread is similar to the Whitworth thread in that the root and crest are rounded (see illustration). The angle, however, is only 47 degrees 30 minutes and the radius of the root and crest are proportionately larger. This thread is used in Great Britain and, to some extent, in other European countries for very small screws. Its use in the United States is practically confined to the manufacture of tools for export. This thread system was originated in Switzerland as a standard for watch and clock screws, and it is sometimes referred to as the "Swiss small screw thread standard." See also *Swiss Screw Thread*.

This screw thread system is recommended by the British Standards Institution for use in preference to the BSW and BSF systems for all screws smaller than  $\frac{1}{4}$  inch except that the use of the "0" BA thread be discontinued in favor of the  $\frac{1}{4}$ -in. BSF. It is further recommended that in the selection of sizes, preference be given to even numbered BA sizes. The thread form is shown by the diagram.

British Association Thread

$$H = 1.13634 \times p$$

$$h = 0.60000 \times p$$

$$r = 0.18083 \times p$$

$$s = 0.26817 \times p$$

It is a symmetrical V-thread, of  $47\frac{1}{2}$  degree included angle, having its crests and roots rounded with equal radii, such that the basic depth of the thread is 0.6000 of the pitch. Where  $p$  = pitch of thread,  $H$  = depth of V-thread,  $h$  = depth of BA thread,  $r$  = radius at root and crest of thread, and  $s$  = root and crest truncation.

| 15                 | 0.2100    | 0.125               | 0.90               | 0.775                  | 0.65               | 0.0380     | 121                        |
| 16                 | 0.1900    | 0.115               | 0.79               | 0.675                  | 0.56               | 0.0344     | 134                        |

**Tolerances and Allowances:** Two classes of bolts and one for nuts are provided: *Close Class bolts* are intended for precision parts subject to stress, no allowance being provided between maximum bolt and minimum nut sizes. *Normal Class bolts* are intended for general commercial production and general engineering use; for sizes 0 to 10 BA, an allowance of 0.025 mm is provided.

**Tolerance Formulas for British Association (BA) Screw Threads**

|       | Class or Fit                   | Tolerance (+ for nuts, - for bolts) |                          |                         |
|-------|--------------------------------|-------------------------------------|--------------------------|-------------------------|
|       |                                | Major Dia.                          | Effective Dia.           | Minor Dia.              |
| Bolts | Close Class 0 to 10 BA incl.   | 0.15 <i>p</i> mm                    | 0.08 <i>p</i> + 0.02 mm  | 0.16 <i>p</i> + 0.04 mm |
|       | Normal Class 0 to 10 BA incl.  | 0.20 <i>p</i> mm                    | 0.10 <i>p</i> + 0.025 mm | 0.20 <i>p</i> + 0.05 mm |
|       | Normal Class 11 to 16 BA incl. | 0.25 <i>p</i> mm                    | 0.10 <i>p</i> + 0.025 mm | 0.20 <i>p</i> + 0.05 mm |
| Nuts  | All Classes                    |                                     | 0.12 <i>p</i> + 0.03 mm  | 0.375 <i>p</i> mm       |

In these formulas, *p* = pitch in millimeters.

**Instrument Makers' Screw Thread System.**—The standard screw system of the Royal Microscopical Society of London, also known as the "Society Thread," is employed for microscope objectives and the nose pieces of the microscope into which these objectives screw. The form of the thread is the standard Whitworth form. The number of threads per inch is 36. There is one size only. The maximum pitch diameter of the objective is 0.7804 inch and the minimum pitch diameter of the nose-piece is 0.7822 inch. The dimensions are as follows:

|               |                |                   |                   |
|---------------|----------------|-------------------|-------------------|
| Male thread   | outside dia.   | max., 0.7982 inch | min., 0.7952 inch |
|               | root dia.      | max., 0.7626 inch | min., 0.7596 inch |
| Female thread | root of thread | max., 0.7674 inch | min., 0.7644 inch |
|               | top of thread  | max., 0.8030 inch | min., 0.8000 inch |

The Royal Photographic Society Standard Screw Thread ranges from 1-inch diameter upward. For screws less than 1 inch, the Microscopical Society Standard is used. The British Association thread is another thread system employed on instruments abroad.

**American Microscope Objective Thread (AMO).**—The standard, ANSI B1.11-1958 (R2001), describes the American microscope objective thread, AMO, the screw thread form used for mounting a microscope objective assembly to the body or lens turret of a microscope. This screw thread is also recommended for other microscope optical assem-

bles as well as related applications such as photomicrographic equipment. It is based on, and intended to be interchangeable with, the screw thread produced and adopted many years ago by the Royal Microscopical Society of Great Britain, generally known as the RMS thread. While the standard is almost universally accepted as the basic standard for microscope objective mountings, formal recognition has been extremely limited.

The basic thread possesses the overall British Standard Whitworth form. (See *Whitworth Standard Thread Form* starting on page 1857). However, the actual design thread form implementation is based on the WWII era ASA B1.6-1944 "Truncated Whitworth Form" in which the rounded crests and roots are removed. ASA B1.6-1944 was withdrawn in 1951, however, ANSI B1.11-1958 (R2001) is still active for new design.

*Design Requirements of Microscope Objective Threads:* Due to the inherent longevity of optical equipment and the repeated use to which the objective threads are subjected, the following factors should be considered when designing microscope objective threads:

Adequate clearance to afford protection against binding due to the presence of foreign particles or minor crest damage.

Sufficient depth of thread engagement to assure security in the short lengths of engagement commonly encountered.

Allowances for limited eccentricities so that centralization and squareness of the objective are not influenced by such errors in manufacture.

*Deviation from the Truncated Whitworth Thread Form:* Although ANSI B1.11-1958 (R2001) is based on the withdrawn ASA B1.6-1944 truncated Whitworth standard, the previously described design requirements necessitate a deviation from the truncated Whitworth thread form. Some of the more significant modifications are:

A larger allowance on the pitch diameter of the external thread.

Smaller tolerances on the major diameter of the external thread and minor diameter of the internal thread.

The provision of allowances on the major and minor diameters of the external thread.

*Thread Overview:* The thread is a single start type. There is only one class of thread based on a basic major diameter of 0.800 in. and a pitch,  $p$ , of 0.027778 inch (36 threads per inch). The AMO thread shall be designated on drawings, tools and gages as "0.800–36 AMO." Thread nomenclature, definitions and terminology are based on ANSI B1.7-1965 (R1972), "Nomenclature, Threads, and Letter Symbols for Screw Threads."

It should also be noted that ISO 8038-1:1997 "Screw threads for objectives and related nosepieces" is also based on the 0.800 inch, 36 tpi RMS thread form.

*Tolerances and Allowances:* Tolerances are given in Table 2. A positive allowance (minimum clearance) of 0.0018 in. is provided for the pitch diameter  $E$ , major diameter  $D$ , and minor diameter,  $K$

If interchangeability with full-form Whitworth threads is not required, the allowances for the major and minor diameters are not necessary, because the forms at the root and crest are truncated. In these cases, either both limits or only the maximum limit of the major and minor diameters may be increased by the amount of the allowance, 0.0018 inch.

*Lengths of Engagement:* The tolerances specified in Table 2 are applicable to lengths of engagement ranging from  $\frac{1}{8}$  in. to  $\frac{3}{8}$  inch, approximately 15% to 50% of the basic diameter. Microscope objective assemblies generally have a length of engagement of  $\frac{1}{8}$  inch. Lengths exceeding these limits are seldom employed and not covered in this standard.

*Gage testing:* Recommended ring and plug testing gage dimensions for the 0.800–36 AMO thread size can be found in ANSI B1.11–1958 (R2001), Appendix.

*Dimensional Terminology:* Because the active standard ANSI B1.11–1958 (R2001) is based on the withdrawn ASA Truncated Whitworth standard, dimensional nomenclature is described below.

MICROSCOPE OBJECTIVE THREAD

Tolerances, Allowances and Crest Clearances for Microscope Objective Thread (AMO) ANSI B1.11-1958 (R2001)

**Table 1. Definitions, Formulas, Basic and Design Dimensions**  
ANSI B1.11-1958 (R1994)

| Symbol            | Property   | Formula     | Dimension |
|-------------------|--|-------------|-----------|
| Basic Thread Form |  |             |           |
| $\alpha$          | Half angle of thread   | ...         | 27°30'    |
| $2\alpha$         | Included angle of thread   | ...         | 55°00'    |
| $n$               | Number of threads per inch   | ...         | 36        |
| $p$               | Pitch  | $1/n$       | 0.027778  |
| $H$               | Height of fundamental triangle   | $0.960491p$ | 0.026680  |
| $h_b$             | Height of basic thread   | $0.640327p$ | 0.0178    |
| $r$               | Radius at crest and root of British Standard Whitworth basic thread (not used) | $0.137329p$ | 0.0038    |

**Table 1. (Continued) Definitions, Formulas, Basic and Design Dimensions**  
*ANSI B1.11-1958 (R1994)*

| Symbol                 | Property   | Formula               | Dimension |
|------------------------|--|-----------------------|-----------|
| Design Thread Form     |  |                       |           |
| $k$                    | Height of truncated Whitworth thread                       | $h_b - U = 0.566410p$ | 0.0157    |
| $F_c$                  | Width of flat at crest                                     | $0.243624p$           | 0.0068    |
| $F_r$                  | Width of flat at root                                      | $0.166667p$           | 0.0046    |
| $U$                    | Basic truncation of crest from basic Whitworth form        | $0.073917p$           | 0.00205   |
| Basic and Design Sizes |  |                       |           |
| $D$                    | Major diameter, nominal and basic                          | ...                   | 0.800     |
| $D_n$                  | Major diameter of internal thread                          | $D$                   | 0.800     |
| $D_s$                  | Major diameter of external thread <sup>a</sup>             | $D - 2U - G$          | 0.7941    |
| $E$                    | Pitch (effective) diameter, basic                          | $D - h_b$             | 0.7822    |
| $E_n$                  | Pitch (effective) diameter of internal thread              | $D - h_b$             | 0.7822    |
| $E_s$                  | Pitch (effective) diameter of external thread <sup>b</sup> | $D - h_b - G$         | 0.7804    |
| $K$                    | Minor diameter, basic                                      | $D - 2h_b$            | 0.7644    |
| $K_n$                  | Minor diameter of internal thread                          | $D - 2k$              | 0.7685    |
| $K_s$                  | Minor diameter of external thread <sup>a</sup>             | $D - 2h_b - G$        | 0.7626    |
| $G$                    | Allowance at pitch (effective) diameter <sup>a, b</sup>    | ...                   | 0.0018    |

<sup>a</sup> An allowance equal to that on the pitch diameter is also provided on the major and minor diameters of the external thread for additional clearance and centralizing.

<sup>b</sup> Allowance (minimum clearance) on pitch (effective) diameter is the same as the British RMS thread.

All dimensions are in inches.

**Table 2. Limits of Size and Tolerances — 0.800–36 AMO Thread**  
*ANSI B1.11-1958 (R2001)*

| Element         | Major Diameter, $D$ |        |        | Pitch Diameter, $E$ |        |        | Minor Diameter, $K$ |                     |        |
|-----------------|---------------------|--------|--------|---------------------|--------|--------|---------------------|---------------------|--------|
|                 | Max.                | Min.   | Tol.   | Max.                | Min.   | Tol.   | Max.                | Min.                | Tol.   |
| External thread | 0.7941              | 0.7911 | 0.0030 | 0.7804              | 0.7774 | 0.0030 | 0.7626              | 0.7552 <sup>a</sup> | ...    |
| Internal thread | 0.8092 <sup>b</sup> | 0.8000 | ...    | 0.7852              | 0.7822 | 0.0030 | 0.7715              | 0.7865              | 0.0030 |

<sup>a</sup> Extreme minimum minor diameter produced by a new threading tool having a minimum flat of  $p/12 = 0.0023$  inch. This minimum diameter is not controlled by gages but by the form of the threading tool.

<sup>b</sup> Extreme maximum major diameter produced by a new threading tool having a minimum flat of  $p/20 = 0.0014$  inch. This maximum diameter is not controlled by gages but by the form of the threading tool.

Tolerances on the internal thread are applied in a plus direction from the basic and design size and tolerances on the external thread are applied in a minus direction from its design (maximum material) size.

All dimensions are in inches.

**Swiss Screw Thread.**—This is a thread system originated in Switzerland as a standard for screws used in watch and clock making. The angle between the two sides of the thread is 47 degrees 30 minutes, and the top and bottom of the thread are rounded. This system has been adopted by the British Association as a standard for small screws, and is known as the British Association thread. See *British Association Standard Thread (BA)* on page 1885.

### Historical and Miscellaneous Threads

**Aero-Thread.**—The name “Aero-thread” has been applied to a patented screw thread system that is specially applicable in cases where the nut or internally threaded part is made from a soft material, such as aluminum or magnesium alloy, for the sake of obtaining lightness, as in aircraft construction, and where the screw is made from a high-strength steel to provide strength and good wearing qualities. The nut or part containing the internal thread has a 60-degree truncated form of thread. See Fig. 1. The screw, or stud, is provided with a semi-circular thread form, as shown. Between the screw and the nut there is an intermediary part known as a thread lining or insert, which is made in the form of a helical spring, so that it can be screwed into the nut. The stud, in turn, is then screwed into the thread formed by the semicircular part of the thread insert. When the screw is provided with a V-form of thread, like the American Standard, frequent loosening and tightening of the screw would cause rapid wear of the softer metal from which the nut is made; furthermore, all the threads might not have an even bearing on the mating threads. By using a thread insert which is screwed into the nut permanently, and which is made from a reasonably hard material like phosphor bronze, good wearing qualities are obtained. Also, the bearing or load is evenly distributed over all the threads of the nut since the insert, being in the form of a spring, can adjust itself to bear on all of the thread surfaces.

Fig. 1. The Basic Thread Form Used in the Aero-Thread System

**Briggs Pipe Thread.**—The Briggs pipe thread (now known as the American Standard) is used for threaded pipe joints and is the standard for this purpose in the United States. It derives its name from Robert Briggs.

**Casing Thread.**—The standard casing thread of the American Petroleum Institute has an included angle of 60 degrees and a taper of  $\frac{3}{4}$  inch per foot.

The fourteen casing sizes listed in the 1942 revision have outside diameters ranging from  $4\frac{1}{2}$  to 20 inches. All sizes have 8 threads per inch.

**Rounded Thread Form:** Threads for casing sizes up to  $13\frac{3}{8}$  inches, inclusive, have rounded crests and roots, and the depth, measured perpendicular to the axis of the pipe, equals  $0.626 \times \text{pitch} - 0.007 = 0.07125$  inch.

**Truncated Form:** Threads for the 16- and 20-inch casing sizes have flat crests and roots. The depth equals  $0.760 \times \text{pitch} = 0.0950$  inch. This truncated form is designated in the A.P.I. Standard as a “sharp thread.”

**Cordeaux Thread.**—The Cordeaux screw thread derives its name from John Henry Cordeaux, an English telegraph inspector who obtained a patent for this thread in 1877. This thread is used for connecting porcelain insulators with their stalks by means of a screw thread on the stalk and a corresponding thread in the insulator. The thread is approximately a Whitworth thread, 6 threads per inch, the diameters most commonly used being  $\frac{5}{8}$  or  $\frac{3}{4}$  inch outside diameter of thread;  $\frac{5}{8}$  inch is almost universally used for telegraph purposes, while a limited number of  $\frac{3}{4}$ -inch sizes are used for large insulators.

**Dardelet Thread.**—The Dardelet patented self-locking thread is designed to resist vibrations and remain tight without auxiliary locking devices. The locking surfaces are the tapered root of the bolt thread and the tapered crest of the nut thread. The nut is free to turn until seated tightly against a resisting surface, thus causing it to shift from the free position (indicated by dotted lines) to the locking position. The locking is due to a wedging action between the tapered crest of the nut thread and the tapered root or binding surface of the bolt thread. This self-locking thread is also applied to set-screws and cap-screws. The holes must, of course, be threaded with Dardelet taps. The abutment sides of the Dardelet thread carry the major part of the tensile load. The nut is unlocked simply by turning it backward with a wrench. The Dardelet thread can either be cut or rolled, using standard equipment provided with tools, taps, dies, or rolls made to suit the Dardelet thread profile. The included thread angle is 29 degrees; depth  $E = 0.3P$ ; maximum axial movement =  $0.28P$ . The major internal thread diameter (standard series) equals major external thread diameter plus 0.003 inch except for  $\frac{1}{4}$ -inch size which is plus 0.002 inch. The width of both external and internal threads at pitch line equals  $0.36P$ .

**"Drunken" Thread.**—A "drunken" thread, according to prevalent usage of this expression by machinists, etc., is a thread that does not coincide with a true helix or advance uniformly. This irregularity in a taper thread may be due to the fact that in taper turning with the tailstock set over, the work does not turn with a uniform angular velocity, while the cutting tool is advancing along the work longitudinally with a uniform linear velocity. The change in the pitch and the irregularity of the thread is so small as to be imperceptible to the eye, if the taper is slight, but as the tapers increase to, say,  $\frac{3}{4}$  inch per foot or more, the errors become more pronounced. To avoid this defect, a taper attachment should be used for taper thread cutting.

**Echols Thread.**—Chip room is of great importance in machine taps and taper taps where the cutting speed is high and always in one direction. The tap as well as the nut to be threaded is liable to be injured, if ample space for the chips to pass away from the cutting edges is not provided. A method of decreasing the number of cutting edges, as well as increasing the amount of chip room, is embodied in the "Echols thread," where every alternate tooth is removed. If a tap has an even number of flutes, the removal of every other tooth in the lands will be equivalent to the removal of the teeth of a continuous thread. It is, therefore, necessary that taps provided with this thread be made with an odd number of lands, so that removing the tooth in alternate lands may result in removing every other tooth in each individual land. Machine taps are often provided with the Echols thread.

**French Thread (S.F.).**—The French thread has the same form and proportions as the American Standard (formerly U. S. Standard). This French thread is being displaced gradually by the International Metric Thread System.

**Harvey Grip Thread.**—The characteristic feature of this thread is that one side inclines 44 degrees from a line at right angles to the axis, whereas the other side has an inclination of only 1 degree. This form of thread is sometimes used when there is considerable resistance or pressure in an axial direction and when it is desirable to reduce the radial or bursting pressure on the nut as much as possible. See *BUTTRESS THREADS*.

**Lloyd & Lloyd Thread.**—The Lloyd & Lloyd screw thread is the same as the regular Whitworth screw thread in which the sides of the thread form an angle of 55 degrees with one another. The top and bottom of the thread are rounded.

**Lock-Nut Pipe Thread.**—The lock-nut pipe thread is a straight thread of the largest diameter which can be cut on a pipe. Its form is identical with that of the American or Briggs standard taper pipe thread. In general, “Go” gages only are required. These consist of a straight-threaded plug representing the minimum female lock-nut thread, and a straight-threaded ring representing the maximum male lock-nut thread. This thread is used only to hold parts together, or to retain a collar on the pipe. It is never used where a tight threaded joint is required.

**Philadelphia Carriage Bolt Thread.**—This is a screw thread for carriage bolts which is somewhat similar to a square thread, but having rounded corners at the top and bottom. The sides of the thread are inclined to an inclusive angle of  $3\frac{1}{2}$  degrees. The width of the thread at the top is 0.53 times the pitch.

**SAE Standard Screw Thread.**—The screw thread standard of the Society of Automotive Engineers (SAE) is intended for use in the automotive industries of the United States. The SAE Standard includes a Coarse series, a Fine series, an 8-thread series, a 12-thread series, a 16-thread series, an Extra-fine series, and a Special-pitch series. The Coarse and Fine series, and also the 8-, 12- and 16-thread series, are exactly the same as corresponding series in the American Standard. The Extra-fine and Special-pitch series are SAE Standards only.

The American Standard thread *form* (or the form previously known as the U. S. Standard) is applied to all SAE Standard screw threads. The Extra-fine series has a total of six pitches ranging from 32 down to 16 threads per inch. The 16 threads per inch in the Extra-fine series, applies to all diameters from  $1\frac{3}{4}$  up to 6 inches. This Extra-fine series is intended for use on relatively light sections; on parts requiring fine adjustment; where jar and vibration are important factors; when the thickness of a threaded section is relatively small as in tubing, and where assembly is made without the use of wrenches.

The SAE Special pitches include some which are finer than any in the Extra-fine series. The special pitches apply to a range of diameters extending from No. 10 (0.1900 inch) up to 6 inches. Each diameter has a range of pitches varying from five to eight. For example, a  $\frac{1}{4}$ -inch diameter has six pitches ranging from 24 to 56 threads per inch, whereas a 6-inch diameter has eight pitches ranging from 4 to 16 threads per inch. These various SAE Standard series are intended to provide adequate screw thread specifications for all uses in the automotive industries.

**Sellers Screw Thread.**—The Sellers screw thread, later known as the “United States standard thread,” and now as the “American Standard,” is the most commonly used screw thread in the United States. It was originated by William Sellers, of Philadelphia, and first proposed by him in a paper read before the Franklin Institute, in April, 1864. In 1868, it was adopted by the United States Navy and has since become the generally accepted standard screw thread in the United States.

## MEASURING SCREW THREADS

### Measuring Screw Threads

**Pitch and Lead of Screw Threads.**—The *pitch* of a screw thread is the distance from the center of one thread to the center of the next thread. This applies no matter whether the screw has a single, double, triple or quadruple thread. The *lead* of a screw thread is the distance the nut will move forward on the screw if it is turned around one full revolution. In a single-threaded screw, the pitch and lead are equal, because the nut would move forward the distance from one thread to the next, if turned around once. In a double-threaded screw, the nut will move forward two threads, or twice the pitch, so that in this case the lead equals twice the pitch. In a triple-threaded screw, the lead equals three times the pitch, and so on.

The word “pitch” is often, although improperly, used to denote the *number of threads per inch*. Screws are spoken of as having a 12-pitch thread, when twelve threads per inch is what is really meant. The number of threads per inch equals 1 divided by the pitch, or expressed as a formula:

$$\text{Number of threads per inch} = \frac{1}{\text{pitch}}$$

The pitch of a screw equals 1 divided by the number of threads per inch, or:

$$\text{Pitch} = \frac{1}{\text{number of threads per inch}}$$

If the number of threads per inch equals 16, the pitch =  $\frac{1}{16}$ . If the pitch equals 0.05, the number of threads equals  $1 \div 0.05 = 20$ . If the pitch is  $\frac{2}{5}$  inch, the number of threads per inch equals  $1 \div \frac{2}{5} = 2\frac{1}{2}$ .

Confusion is often caused by the indefinite designation of multiple-thread screws (double, triple, quadruple, etc.). The expression, “four threads per inch, triple,” for example, is not to be recommended. It means that the screw is cut with four triple threads or with twelve threads per inch, if the threads are counted by placing a scale alongside the screw. To cut this screw, the lathe would be geared to cut four threads per inch, but they would be cut only to the depth required for twelve threads per inch. The best expression, when a multiple-thread is to be cut, is to say, in this case, “ $\frac{1}{4}$  inch lead,  $\frac{1}{12}$  inch pitch, triple thread.” For single-threaded screws, only the number of threads per inch and the form of the thread are specified. The word “single” is not required.

**Measuring Screw Thread Pitch Diameters by Thread Micrometers.**—As the pitch or angle diameter of a tap or screw is the most important dimension, it is necessary that the pitch diameter of screw threads be measured, in addition to the outside diameter.

Fig. 1.

One method of measuring in the angle of a thread is by means of a special screw thread micrometer, as shown in the accompanying engraving, Fig. 1. The fixed anvil is W-shaped to engage two thread flanks, and the movable point is cone-shaped so as to enable it to enter the space between two threads, and at the same time be at liberty to revolve. The contact points are on the sides of the thread, as they necessarily must be in order that the pitch diam-

eter may be determined. The cone-shaped point of the measuring screw is slightly rounded so that it will not bear in the bottom of the thread. There is also sufficient clearance at the bottom of the V-shaped anvil to prevent it from bearing on the top of the thread. The movable point is adapted to measuring all pitches, but the fixed anvil is limited in its capacity. To cover the whole range of pitches, from the finest to the coarsest, a number of fixed anvils are therefore required.

To find the theoretical pitch diameter, which is measured by the micrometer, subtract twice the addendum of the thread from the standard outside diameter. The addendum of the thread for the American and other standard threads is given in the section on screw thread systems.

**Ball-point Micrometers.**—If standard plug gages are available, it is not necessary to actually measure the pitch diameter, but merely to compare it with the standard gage. In this case, a ball-point micrometer, as shown in Fig. 2, may be employed. Two types of ball-point micrometers are ordinarily used. One is simply a regular plain micrometer with ball points made to slip over both measuring points. (See B, Fig. 2.) This makes a kind of combination plain and ball-point micrometer, the ball points being easily removed. These ball points, however, do not fit solidly on their seats, even if they are split, as shown, and are apt to cause errors in measurements. The best, and, in the long run, the cheapest, method is to use a regular micrometer arranged as shown at A. Drill and ream out both the end of the measuring screw or spindle and the anvil, and fit ball points into them as shown. Care should be taken to have the ball point in the spindle run true. The holes in the micrometer spindle and anvil and the shanks on the points are tapered to insure a good fit. The hole *H* in spindle *G* is provided so that the ball point can be easily driven out when a change for a larger or smaller size of ball point is required.

Fig. 2.

A ball-point micrometer may be used for comparing the *angle* of a screw thread, with that of a gage. This can be done by using different sizes of ball points, comparing the size first near the root of the thread, then (using a larger ball point) at about the point of the pitch diameter, and finally near the top of the thread (using in the latter case, of course, a much larger ball point). If the gage and thread measurements are the same at each of the three points referred to, this indicates that the thread angle is correct.

**Measuring Screw Threads by Three-wire Method.**—The *effective* or *pitch diameter* of a screw thread may be measured very accurately by means of some form of micrometer and three wires of equal diameter. This method is extensively used in checking the accuracy of threaded plug gages and other precision screw threads. Two of the wires are placed in contact with the thread on one side and the third wire in a position diametrically opposite as illustrated by the diagram, (see table "Formulas for Checking Pitch Diameters of Screw Threads") and the dimension over the wires is determined by means of a micrometer. An ordinary micrometer is commonly used but some form of "floating micrometer" is preferable, especially for measuring thread gages and other precision work. The floating micrometer is mounted upon a compound slide so that it can move freely in directions parallel or at right angles to the axis of the screw, which is held in a horizontal position between adjustable centers. With this arrangement the micrometer is held constantly at

right angles to the axis of the screw so that only one wire on each side may be used instead of having two on one side and one on the other, as is necessary when using an ordinary micrometer. The pitch diameter may be determined accurately if the correct micrometer reading for wires of a given size is known.

**Classes of Formulas for Three-Wire Measurement.**—Various formulas have been established for checking the pitch diameters of screw threads by measurement over wires of known size. These formulas differ with regard to their simplicity or complexity and resulting accuracy. They also differ in that some show what measurement  $M$  over the wires should be to obtain a given pitch diameter  $E$ , whereas others show the value of the pitch diameter  $E$  for a given measurement  $M$ .

*Formulas for Finding Measurement  $M$ :* In using a formula for finding the value of measurement  $M$ , the required pitch diameter  $E$  is inserted in the formula. Then, in cutting or grinding a screw thread, the actual measurement  $M$  is made to conform to the calculated value of  $M$ . Formulas for finding measurement  $M$  may be modified so that the basic major or outside diameter is inserted in the formula instead of the pitch diameter; however, the pitch-diameter type of formula is preferable because the pitch diameter is a more important dimension than the major diameter.

*Formulas for Finding Pitch Diameters  $E$ :* Some formulas are arranged to show the value of the pitch diameter  $E$  when measurement  $M$  is known. Thus, the value of  $M$  is first determined by measurement and then is inserted in the formula for finding the corresponding pitch diameter  $E$ . This type of formula is useful for determining the pitch diameter of an existing thread gage or other screw thread in connection with inspection work. The formula for finding measurement  $M$  is more convenient to use in the shop or tool room in cutting or grinding new threads, because the pitch diameter is specified on the drawing and the problem is to find the value of measurement  $M$  for obtaining that pitch diameter.

**General Classes of Screw Thread Profiles.**—Thread profiles may be divided into three general classes or types as follows:

*Screw Helicoid:* Represented by a screw thread having a straight-line profile in the axial plane. Such a screw thread may be cut in a lathe by using a straight-sided single-point tool, provided the top surface lies in the axial plane.

*Involute Helicoid:* Represented either by a screw thread or a helical gear tooth having an involute profile in a plane perpendicular to the axis. A rolled screw thread, theoretically at least, is an exact involute helicoid.

*Intermediate Profiles:* An intermediate profile that lies somewhere between the screw helicoid and the involute helicoid will be formed on a screw thread either by milling or grinding with a straight-sided wheel set in alignment with the thread groove. The resulting form will approach closely the involute helicoid form. In milling or grinding a thread, the included cutter or wheel angle may either equal the standard thread angle (which is always measured in the axial plane) or the cutter or wheel angle may be reduced to approximate, at least, the thread angle in the normal plane. In practice, all these variations affect the three-wire measurement.

**Accuracy of Formulas for Checking Pitch Diameters by Three-Wire Method.**—The exact measurement  $M$  for a given pitch diameter depends upon the lead angle, the thread angle, and the profile or cross-sectional shape of the thread. As pointed out in the preceding paragraph, the profile depends upon the method of cutting or forming the thread. In a milled or ground thread, the profile is affected not only by the cutter or wheel angle, but also by the diameter of the cutter or wheel; hence, because of these variations, an absolutely exact and reasonably simple general formula for measurement  $M$  cannot be established; however, if the lead angle is low, as with a standard single-thread screw, and especially if the thread angle is high like a 60-degree thread, simple formulas that are not arranged to compensate for the lead angle are used ordinarily and meet most practical requirements, particularly in measuring 60-degree threads. If lead angles are large enough

to greatly affect the result, as with most multiple threads (especially Acme or 29-degree worm threads), a formula should be used that compensates for the lead angle sufficiently to obtain the necessary accuracy.

The formulas that follow include 1) a very simple type in which the effect of the lead angle on measurement  $M$  is entirely ignored. This simple formula usually is applicable to the measurement of 60-degree single-thread screws, except possibly when gage-making accuracy is required; 2) formulas that do include the effect of the lead angle but, nevertheless, are approximations and not always suitable for the higher lead angles when extreme accuracy is required; and 3) formulas for the higher lead angles and the most precise classes of work.

Where approximate formulas are applied consistently in the measurement of both thread plug gages and the thread "setting plugs" for ring gages, interchangeability might be secured, assuming that such approximate formulas were universally employed.

**Wire Sizes for Checking Pitch Diameters of Screw Threads.**—In checking screw threads by the 3-wire method, the general practice is to use measuring wires of the so-called "best size." The "best-size" wire is one that contacts at the pitch line or midslope of the thread because then the measurement of the pitch diameter is least affected by an error in the thread angle. In the following formula for determining approximately the "best-size" wire or the diameter for pitch-line contact,  $A$  = one-half included angle of thread in the axial plane.

$$\text{Best-size wire} = \frac{0.5 \text{ pitch}}{\cos A} = 0.5 \text{ pitch} \times \sec A$$

For 60-degree threads, this formula reduces to

$$\text{Best-size wire} = 0.57735 \times \text{pitch}$$

### Diameters of Wires for Measuring American Standard and British Standard Whitworth Screw Threads

| Threads per Inch | Pitch, Inch | Wire Diameters for American Standard Threads |        |                    | Wire Diameters for Whitworth Standard Threads |        |                    |
|------------------|-------------|--|--------|--------------------|---|--------|--------------------|
|                  |             | Max.   | Min.   | Pitch-Line Contact | Max.  | Min.   | Pitch-Line Contact |
| 4                | 0.2500      | 0.2250                                       | 0.1400 | 0.1443             | 0.1900  | 0.1350 | 0.1409             |

These formulas are based upon a thread groove of zero lead angle because ordinary variations in the lead angle have little effect on the wire diameter and it is desirable to use one wire size for a given pitch regardless of the lead angle. A theoretically correct solution for finding the *exact* size for pitch-line contact involves the use of cumbersome indeterminate equations with solution by successive trials. The accompanying table gives the wire sizes for both American Standard (formerly, U.S. Standard) and the Whitworth Standard Threads. The following formulas for determining wire diameters do not give the extreme theoretical limits, but the smallest and largest practicable sizes. The diameters in the table are based upon these approximate formulas.

|                   |   |
|-------------------|---|
|                   | Smallest wire diameter = $0.56 \times \text{pitch}$             |
| American Standard | Largest wire diameter = $0.90 \times \text{pitch}$              |
|                   | Diameter for pitch-line contact = $0.57735 \times \text{pitch}$ |
|                   | Smallest wire diameter = $0.54 \times \text{pitch}$             |
| Whitworth         | Largest wire diameter = $0.76 \times \text{pitch}$              |
|                   | Diameter for pitch-line contact = $0.56369 \times \text{pitch}$ |

**Measuring Wire Accuracy.**—A set of three measuring wires should have the same diameter within 0.0002 inch. To measure the pitch diameter of a screw-thread gage to an accuracy of 0.0001 inch by means of wires, it is necessary to know the wire diameters to 0.00002 inch. If the diameters of the wires are known only to an accuracy of 0.0001 inch, an accuracy better than 0.0003 inch in the measurement of pitch diameter cannot be expected. The wires should be accurately finished hardened steel cylinders of the maximum possible hardness without being brittle. The hardness should not be less than that corresponding to a Knoop indentation number of 630. A wire of this hardness can be cut with a file only with difficulty. The surface should not be rougher than the equivalent of a deviation of 3 microinches from a true cylindrical surface.

**Measuring or Contact Pressure.**—In measuring screw threads or screw-thread gages by the 3-wire method, variations in contact pressure will result in different readings. The effect of a variation in contact pressure in measuring threads of fine pitches is indicated by the difference in readings obtained with pressures of 2 and 5 pounds in checking a thread plug gage having 24 threads per inch. The reading over the wires with 5 pounds pressure was 0.00013 inch less than with 2 pounds pressure. For pitches finer than 20 threads per inch, a pressure of 16 ounces is recommended by the National Bureau of Standards, now National Institute of Standards and Technology (NIST). For pitches of 20 threads per inch and coarser, a pressure of  $2 \frac{1}{2}$  pounds is recommended.

For Acme threads, the wire presses against the sides of the thread with a pressure of approximately twice that of the measuring instrument. To limit the tendency of the wires to wedge in between the sides of an Acme thread, it is recommended that pitch-diameter measurements be made at 1 pound on 8 threads per inch and finer, and at  $2 \frac{1}{2}$  pounds for pitches coarser than 8 threads per inch.

**Approximate Three-Wire Formulas That Do Not Compensate for Lead Angle.**—A general formula in which the effect of lead angle is ignored is as follows (see accompanying notation used in formulas):

$$M = E - T \cot A + W(1 + \csc A) \quad (1)$$

This formula can be simplified for any given thread angle and pitch. To illustrate, because  $T = 0.5P$ ,  $M = E - 0.5P \cot 30^\circ + W(1 + 2)$ , for a 60-degree thread, such as the American Standard,

$$M = E - 0.866025P + 3W$$

The accompanying table contains these simplified formulas for different standard threads. Two formulas are given for each. The upper one is used when the measurement over wires,  $M$ , is known and the corresponding pitch diameter,  $E$ , is required; the lower formula gives the measurement  $M$  for a specified value of pitch diameter. These formulas are sufficiently accurate for checking practically all standard 60-degree single-thread screws because of the low lead angles, which vary from  $1^\circ 11'$  to  $4^\circ 31'$  in the American Standard Coarse-Thread Series.

**Bureau of Standards (now NIST) General Formula.**—**Formula (2)**, which follows, compensates quite largely for the effect of the lead angle. It is from the National Bureau of Standards Handbook H 28 (1944), now FED-STD-H28. The formula, however, as here given has been arranged for finding the value of  $M$  (instead of  $E$ ).

$$M = E - T \cot A + W(1 + \csc A + 0.5 \tan^2 B \cos A \cot A) \quad (2)$$

This expression is also found in ANSI/ASME B1.2-1983 (R2001). The Bureau of Standards uses **Formula (2)** in preference to **Formula (1)** when the value of  $0.5W \tan^2 B \cos A \cot A$  exceeds 0.00015, with the larger lead angles. If this test is applied to American Standard 60-degree threads, it will show that **Formula (1)** is generally applicable; but for 29-degree Acme or worm threads, **Formula (2)** (or some other that includes the effect of lead angle) should be employed.

#### Notation Used in Formulas for Checking Pitch Diameters by Three-Wire Method

$A$  = one-half included thread angle in the axial plane

$A_n$  = one-half included thread angle in the normal plane or in plane perpendicular to sides of thread = one-half included angle of cutter when thread is milled ( $\tan A_n = \tan A \times \cos B$ ). (Note: Included angle of milling cutter or grinding wheel may equal the nominal included angle of thread, or may be reduced to whatever normal angle is required to make the thread angle standard in the axial plane. In either case,  $A_n$  = one-half cutter angle.)

$B$  = lead angle at pitch diameter = helix angle of thread as measured from a plane perpendicular to the axis,  $\tan B = L \div 3.1416E$

$D$  = basic major or outside diameter

$E$  = pitch diameter (basic, maximum, or minimum) for which  $M$  is required, or pitch diameter corresponding to measurement  $M$

$F$  = angle required in **Formulas (4b)**, **(4d)**, and **(4e)**

$G$  = angle required in **Formula (4)**

$H$  = helix angle at pitch diameter and measured from axis =  $90^\circ - B$  or  $\tan H = \cot B$

$H_b$  = helix angle at  $R_b$  measured from axis

$L$  = lead of thread = pitch  $P \times$  number of threads  $S$

$M$  = dimension over wires

$P$  = pitch =  $1 \div$  number of threads per inch

$R_b$  = radius required in **Formulas (4)** and **(4e)**

$S$  = number of "starts" or threads on a multiple-threaded worm or screw

$T = 0.5 P$  = width of thread in axial plane at diameter  $E$

$T_a$  = arc thickness on pitch cylinder in plane perpendicular to axis

$W$  = wire or pin diameter

## Formulas for Checking Pitch Diameters of Screw Threads

The formulas below do not compensate for the effect of the lead angle upon measurement  $M$ , but they are sufficiently accurate for checking standard single-thread screws unless exceptional accuracy is required. See accompanying information on effect of lead angle; also matter relating to measuring wire sizes, accuracy required for such wires, and contact or measuring pressure.

The approximate best wire size for pitch-line contact may be obtained by the formula

$$W = 0.5 \times \text{pitch} \times \sec \frac{1}{2} \text{ included thread angle}$$

For 60-degree threads,  $W = 0.57735 \times \text{pitch}$ .

| International Standard             | Use the formula above for the American National Standard Unified Thread.  |
| Pipe Thread                        | See accompanying paragraph on <i>Buckingham Exact Involute Helicoid Formula Applied to Screw Threads</i> .  |
| Acme and Worm Threads              | See Buckingham Formulas page 1903; also <i>Three-wire Measurement of Acme and Stub Acme Thread Pitch Diameter</i> .   |
| Buttress Form of Thread            | Different forms of buttress threads are used. See paragraph on <i>Three-Wire Method Applied to Buttress Threads</i> .   |

<sup>a</sup>The wires must be lapped to a uniform diameter and it is very important to insert in the rule or formula the wire diameter as determined by precise means of measurement. Any error will be multiplied. See paragraph on *Wire Sizes for Checking Pitch Diameters of Screw Threads* on page 1896.

**Why Small Thread Angle Affects Accuracy of Three-Wire Measurement.**—In measuring or checking Acme threads, or any others having a comparatively small thread angle  $A$ , it is particularly important to use a formula that compensates largely, if not entirely, for the effect of the lead angle, especially in all gage and precision work. The effect of the lead angle on the position of the wires and upon the resulting measurement  $M$  is much greater in a 29-degree thread than in a higher thread angle such, for example, as a 60-degree thread. This effect results from an increase in the cotangent of the thread angle as this angle becomes smaller. The reduction in the width of the thread groove in the normal plane due

to the lead angle causes a wire of given size to rest higher in the groove of a thread having a small thread angle  $A$  (like a 29-degree thread) than in the groove of a thread with a larger angle (like a 60-degree American Standard).

*Acme Threads:* Three-wire measurements of high accuracy require the use of [Formula \(4\)](#). For most measurements, however, [Formula \(2\)](#) or [\(3\)](#) gives satisfactory results. The table on page [1906](#) lists suitable wire sizes for use in [Formulas \(2\)](#) and [\(4\)](#).

This table may be used for American National Standard Metric Threads. The formulas for American Standard Unified Threads on page [1899](#) are used. In the table above, the values of  $0.866025P$  and  $W$  are in inches so that the values for  $E$  and  $M$  calculated from the formulas on page [1899](#) are also in inches.

**Dimensions Over Wires of Given Diameter for Checking Screw Threads  
of American National Form (U.S. Standard) and the V-Form**

| Dia. of Thread | No. of Threads per Inch | Wire Dia. Used | Dimension over Wires |             | Dia. of Thread | No. of Threads per Inch | Wire Dia. Used | Dimension over Wires |             |
|----------------|-------------------------|----------------|----------------------|-------------|----------------|-------------------------|----------------|----------------------|-------------|
|                |                         |                | V-Thread             | U.S. Thread |                |                         |                | V-Thread             | U.S. Thread |

**Buckingham Simplified Formula which Includes Effect of Lead Angle.**—The **Formula (3)** which follows gives very accurate results for the lower lead angles in determining measurement  $M$ . However, if extreme accuracy is essential, it may be advisable to use the involute helicoid formulas as explained later.

$$M = E + W(1 + \sin A_n) \quad (3) \quad \text{where} \quad W = \frac{T \times \cos B}{\cos A_n} \quad (3a)$$

Theoretically correct equations for determining measurement  $M$  are complex and cumbersome to apply. **Formula (3)** combines simplicity with a degree of accuracy which meets all but the most exacting requirements, particularly for lead angles below 8 or 10 degrees and the higher thread angles. However, the wire diameter used in **Formula (3)** must conform to that obtained by **Formula (3a)** to permit a direct solution or one not involving indeterminate equations and successive trials.

**Application of Buckingham Formula:** In the application of **Formula (3)** to screw or worm threads, two general cases are to be considered.

**Case 1:** The screw thread or worm is to be milled with a cutter having an included angle equal to the nominal or standard thread angle that is assumed to be the angle in the axial plane. For example, a 60-degree cutter is to be used for milling a thread. In this case, the

**Table for Measuring Whitworth Standard Threads by the Three-wire Method**

| Dia. of Thread   | No. of Threads per Inch | Dia. of Wire Used | Dia. Measured over Wires | Dia. of Thread | No. of Threads per Inch | Dia. of Wire Used | Dia. Measured over Wires |
|------------------|-------------------------|-------------------|--------------------------|----------------|-------------------------|-------------------|--------------------------|

All dimensions are given in inches.

thread angle in the plane of the axis will exceed 60 degrees by an amount increasing with the lead angle. This variation from the standard angle may be of little or no practical importance if the lead angle is small or if the mating nut (or teeth in worm gearing) is formed to suit the thread as milled.

*Case 2:* The screw thread or worm is to be milled with a cutter reduced to whatever normal angle is equivalent to the standard thread angle in the axial plane. For example, a 29-degree Acme thread is to be milled with a cutter having some angle smaller than 29 degrees (the reduction increasing with the lead angle) to make the thread angle standard in the plane of the axis. Theoretically, the milling cutter angle should always be corrected to suit the normal angle; but if the lead angle is small, such correction may be unnecessary.

If the thread is cut in a lathe to the standard angle as measured in the axial plane, Case 2 applies in determining the pin size  $W$  and the overall measurement  $M$ .

In solving all problems under Case 1, angle  $A_n$  used in Formulas (3) and (3a) equals one-half the included angle of the milling cutter.

When Case 2 applies, angle  $A_n$  for milled threads also equals one-half the included angle of the cutter, but the cutter angle is reduced and is determined as follows:

$$\tan A_n = \tan A \times \cos B$$

The included angle of the cutter or the normal included angle of the thread groove =  $2A_n$ . Examples 1 and 2, which follow, illustrate Cases 1 and 2.

*Example 1 (Case 1):* Take, for example, an Acme screw thread that is milled with a cutter having an included angle of 29 degrees; consequently, the angle of the thread exceeds 29 degrees in the axial section.

The outside or major diameter is 3 inches; the pitch,  $\frac{1}{2}$  inch; the lead, 1 inch; the number of threads or "starts," 2. Find pin size  $W$  and measurement  $M$ .

Pitch diameter  $E = 2.75$ ;  $T = 0.25$ ;  $L = 1.0$ ;  $A_n = 14.50^\circ$   $\tan A_n = 0.258618$ ;  $\sin A_n = 0.25038$ ; and  $\cos A_n = 0.968148$ .

$$\tan B = \frac{1.0}{3.1416 \times 2.75} = 0.115749 \quad B = 6.6025^\circ$$

$$W = \frac{0.25 \times 0.993368}{0.968148} = 0.25651 \text{ inch}$$

$$M = 2.75 + 0.25651 \times (1 + 0.25038) = 3.0707 \text{ inches}$$

*Note:* This value of  $M$  is only 0.0001 inch larger than that obtained by using the very accurate involute helicoid Formula (4) discussed on the following page.

*Example 2 (Case 2):* A triple-threaded worm has a pitch diameter of 2.481 inches, pitch of 1.5 inches, lead of 4.5 inches, lead angle of 30 degrees, and nominal thread angle of 60 degrees in the axial plane. Milling cutter angle is to be reduced.  $T = 0.75$  inch;  $\cos B = 0.866025$ ; and  $\tan A = 0.57735$ . Again use Formula (3) to see if it is applicable.

$\tan A_n = \tan A \times \cos B = 0.57735 \times 0.866025 = 0.5000$ ; hence  $A_n = 26.565^\circ$ , making the included cutter angle  $53.13^\circ$ , thus  $\cos A_n = 0.89443$  and  $\sin A_n = 0.44721$ .

$$W = \frac{0.75 \times 0.866025}{0.89443} = 0.72618 \text{ inch}$$

$$M = 2.481 + 0.72618 \times (1 + 0.44721) = 3.532 \text{ inches}$$

*Note:* If the value of measurement  $M$  is determined by using the following Formula (4) it will be found that  $M = 3.515$  inches; hence the error equals  $3.532 - 3.515 = 0.017$  inch approximately, which indicates that Formula (3) is not accurate enough here. The application of this simpler Formula (3) will depend upon the lead angle and thread angle (as previously explained) and upon the class of work.

**Buckingham Exact Involute Helicoid Formula Applied to Screw Threads.**—When extreme accuracy is required in finding measurement  $M$  for obtaining a given pitch diameter, the equations that follow, although somewhat cumbersome to apply, have the merit of providing a direct and very accurate solution; consequently, they are preferable to the indeterminate equations and successive trial solutions heretofore employed when extreme precision is required. These equations are exact for involute helical gears and, consequently, give theoretically correct results when applied to a screw thread of the involute helicoidal form; they also give very close approximations for threads having intermediate profiles.

*Helical Gear Equation Applied to Screw Thread Measurement:* In applying the helical gear equations to a screw thread, use either the axial or normal thread angle and the lead

angle of the helix. To keep the solution on a practical basis, either thread angle  $A$  or  $A_n$ , as the case may be, is assumed to equal the cutter angle of a milled thread. Actually, the profile of a milled thread will have some curvature in both axial and normal sections; hence angles  $A$  and  $A_n$  represent the angular approximations of these slightly curved profiles. The equations that follow give the values needed to solve the screw thread problem as a helical gear problem.

$$M = \frac{2R_b}{\cos G} + W \quad (4)$$

$$\tan F = \frac{\tan A}{\tan B} = \frac{\tan A_n}{\sin B} \quad (4a) \quad R_b = \frac{E}{2} \cos F \quad (4b)$$

$$T_a = \frac{T}{\tan B} \quad (4c) \quad \tan H_b = \cos F \times \tan H \quad (4d)$$

$$\text{inv } G = \frac{T_a}{E} + \text{inv } F + \frac{W}{2R_b \cos H_b} - \frac{\pi}{S} \quad (4e)$$

The tables of involute functions starting on page 104 provide values for angles from 14 to 51 degrees, used for gear calculations. The formula for involute functions on page 103 may be used to extend this table as required.

*Example 3:* To illustrate the application of [Formula \(4\)](#) and the supplementary formulas, assume that the number of starts  $S = 6$ ; pitch diameter  $E = 0.6250$ ; normal thread angle  $A_n = 20^\circ$ ; lead of thread  $L = 0.864$  inch;  $T = 0.072$ ;  $W = 0.07013$  inch.

$$\tan B = \frac{L}{\pi E} = \frac{0.864}{1.9635} = 0.44003 \quad B = 23.751^\circ$$

$$\text{Helix angle } H = 90^\circ - 23.751^\circ = 66.249^\circ$$

$$\tan F = \frac{\tan A_n}{\sin B} = \frac{0.36397}{0.40276} = 0.90369 \quad F = 42.104^\circ$$

$$R_b = \frac{E}{2} \cos F = \frac{0.6250}{2} \times 0.74193 = 0.23185$$

$$T_a = \frac{T}{\tan B} = \frac{0.072}{0.44003} = 0.16362$$

$$\tan H_b = \cos F \tan H = 0.74193 \times 2.27257 = 1.68609 \quad H_b = 59.328^\circ$$

The involute function of  $G$  is found next by [Formula \(4e\)](#).

$$\text{inv } G = \frac{0.16362}{0.625} + 0.16884 + \frac{0.07013}{2 \times 0.23185 \times 0.51012} - \frac{3.1416}{6} = 0.20351$$

Since 0.20351 is outside the values for involute functions given in the tables on pages 104 through 107 use the formula for involute functions on page 103 to extend these tables as required. It will be found that 44 deg. 21 min. or 44.350 degrees is the angular equivalent of 0.20351; hence,  $G = 44.350$  degrees.

$$M = \frac{2R_b}{\cos G} + W = \frac{2 \times 0.23185}{0.71508} + 0.07013 = 0.71859 \text{ inch}$$

**Accuracy of Formulas (3) and (4) Compared.**—With the involute helicoid [Formula \(4\)](#) any wire size that makes contact with the flanks of the thread may be used; however, in the preceding example, the wire diameter  $W$  was obtained by [Formula \(3a\)](#) in order to compare [Formula \(4\)](#) with (3). If [Example \(3\)](#) is solved by [Formula \(3\)](#),  $M = 0.71912$ ; hence

the difference between the values of  $M$  obtained with Formulas (3) and (4) equals  $0.71912 - 0.71859 = 0.00053$  inch. The included thread angle in this case is 40 degrees. If Formulas (3) and (4) are applied to a 29-degree thread, the difference in measurements  $M$  or the error resulting from the use of Formula (3) will be larger. For example, with an Acme thread having a lead angle of about 34 degrees, the difference in values of  $M$  obtained by the two formulas equals 0.0008 inch.

**Three-wire Measurement of Acme and Stub Acme Thread Pitch Diameter.**—For single- and multiple-start Acme and Stub Acme threads having lead angles of less than 5 degrees, the approximate three-wire formula given on page 1897 and the best wire size taken from the table on page 1906 may be used.

Multiple-start Acme and Stub Acme threads commonly have a lead angle of greater than 5 degrees. For these, a direct determination of the actual pitch diameter is obtained by using the formula:  $E = M - (C + c)$  in conjunction with the table on page 1907. To enter the table, the lead angle  $B$  of the thread to be measured must be known. It is found by the formula:  $\tan B = L \div 3.1416E_1$  where  $L$  is the lead of the thread and  $E_1$  is the nominal pitch diameter. The best wire size is now found by taking the value of  $w_1$  as given in the table for lead angle  $B$ , with interpolation, and dividing it by the number of threads per inch. The value of  $(C + c)_1$  given in the table for lead angle  $B$  is also divided by the number of threads per inch to get  $(C + c)$ . Using the best size wires, the actual measurement over wires  $M$  is made and the actual pitch diameter  $E$  found by using the formula:  $E = M - (C + c)$ .

*Example:* For a 5 tpi, 4-start Acme thread with a  $13.952^\circ$  lead angle, using three 0.10024-inch wires,  $M = 1.1498$  inches, hence  $E = 1.1498 - 0.1248 = 1.0250$  inches.

Under certain conditions, a wire may contact one thread flank at two points, and it is then advisable to substitute balls of the same diameter as the wires.

**Checking Thickness of Acme Screw Threads.**—In some instances it may be preferable to check the thread thickness instead of the pitch diameter, especially if there is a thread thickness tolerance.

A direct method, applicable to the larger pitches, is to use a vernier gear-tooth caliper for measuring the thickness in the normal plane of the thread. This measurement, for an American Standard General Purpose Acme thread, should be made at a distance below the basic outside diameter equal to  $p/4$ . The thickness at this basic pitch-line depth and in the axial plane should be  $p/2 - 0.259 \times$  the pitch diameter allowance from the table on page 1827 with a tolerance of *minus*  $0.259 \times$  the pitch diameter tolerance from the table on page 1832. The thickness in the normal plane or plane of measurement is equal to the thickness in the axial plane multiplied by the cosine of the helix angle. The helix angle may be determined from the formula:

$$\text{tangent of helix angle} = \text{lead of thread} \div (3.1416 \times \text{pitch diameter})$$

**Three-Wire Method for Checking Thickness of Acme Threads.**—The application of the 3-wire method of checking the thickness of an Acme screw thread is included in the Report of the National Screw Thread Commission. In applying the 3-wire method for checking thread thickness, the procedure is the same as in checking pitch diameter (see *Three-wire Measurement of Acme and Stub Acme Thread Pitch Diameter*), although a different formula is required. Assume that  $D$  = basic major diameter of screw;  $M$  = measurement over wires;  $W$  = diameter of wires;  $S$  = tangent of helix angle at pitch line;  $P$  = pitch;  $T$  = thread thickness at depth equal to  $0.25P$ .

$$T = 1.12931 \times P + 0.25862 \times (M - D) - W \times (1.29152 + 0.48407S^2)$$

This formula transposed to show the correct measurement  $M$  equivalent to a given required thread thickness is as follows:

$$M = D + \frac{W \times (1.29152 + 0.48407S^2) + T - 1.12931 \times P}{0.25862}$$

**Wire Sizes for Three-Wire Measurement of Acme Threads  
with Lead Angles of Less than 5 Degrees**

| Threads per Inch | Best Size | Max.    | Min.    | Threads per Inch | Best Size | Max.    | Min.    |
|------------------|-----------|---------|---------|------------------|-----------|---------|---------|
| 1                | 0.51645   | 0.65001 | 0.48726 | 5                | 0.10329   | 0.13000 | 0.09745 |
| 1½               | 0.38734   | 0.48751 | 0.36545 | 6                | 0.08608   | 0.10834 | 0.08121 |
| 1½               | 0.34430   | 0.43334 | 0.32484 | 8                | 0.06456   | 0.08125 | 0.06091 |
| 2                | 0.25822   | 0.32501 | 0.24363 | 10               | 0.05164   | 0.06500 | 0.04873 |
| 2½               | 0.20658   | 0.26001 | 0.19491 | 12               | 0.04304   | 0.05417 | 0.04061 |
| 3                | 0.17215   | 0.21667 | 0.16242 | 14               | 0.03689   | 0.04643 | 0.03480 |
| 4                | 0.12911   | 0.16250 | 0.12182 | 16               | 0.03228   | 0.04063 | 0.03045 |

Wire sizes are based upon zero helix angle. Best size =  $0.51645 \times \text{pitch}$ ; maximum size =  $0.650013 \times \text{pitch}$ ; minimum size =  $0.487263 \times \text{pitch}$ .

*Example:* An Acme General Purpose thread, Class 2G, has a 5-inch basic major diameter, 0.5-inch pitch, and 1-inch lead (double thread). Assume the wire size is 0.258 inch. Determine measurement  $M$  for a thread thickness  $T$  at the basic pitch line of 0.2454 inch. ( $T$  is the maximum thickness at the basic pitch line and equals  $0.5P$ , the basic thickness,  $-0.259 \times$  allowance from Table 4, page 1832.)

$$M = 5 + \frac{0.258 \times [1.29152 + 0.48407 \times (0.06701)^2] + 0.2454 - 1.12931 \times 0.5}{0.25862}$$

$$= 5.056 \text{ inches}$$

**Testing Angle of Thread by Three-Wire Method.**—The error in the angle of a thread may be determined by using sets of wires of two diameters, the measurement over the two sets of wires being followed by calculations to determine the amount of error, assuming that the angle cannot be tested by comparison with a standard plug gage, known to be correct. The diameter of the small wires for the American Standard thread is usually about 0.6 times the pitch and the diameter of the large wires, about 0.9 times the pitch. The total difference between the measurements over the large and small sets of wires is first determined. If the thread is an American Standard or any other form having an included angle of 60 degrees, the difference between the two measurements should equal three times the difference between the diameters of the wires used. Thus, if the wires are 0.116 and 0.076 inch in diameter, respectively, the difference equals  $0.116 - 0.076 = 0.040$  inch. Therefore, the difference between the micrometer readings for a standard angle of 60 degrees equals  $3 \times 0.040 = 0.120$  inch for this example. If the angle is incorrect, the amount of error may be determined by the following formula, which applies to any thread regardless of angle:

$$\sin a = \frac{A}{B - A}$$

where  $A$  = difference in diameters of the large and small wires used

$B$  = total difference between the measurements over the large and small wires

$a$  = one-half the included thread angle

*Example:* The diameter of the large wires used for testing the angle of a thread is 0.116 inch and of the small wires 0.076 inch. The measurement over the two sets of wires shows a total difference of 0.122 inch instead of the correct difference, 0.120 inch, for a standard angle of 60 degrees when using the sizes of wires mentioned. The amount of error is determined as follows:

$$\sin a = \frac{0.040}{0.122 - 0.040} = \frac{0.040}{0.082} = 0.4878$$

A table of sines shows that this value (0.4878) is the sine of 29 degrees 12 minutes, approximately. Therefore, the angle of the thread is 58 degrees 24 minutes or 1 degree 36 minutes less than the standard angle.

**Best Wire Diameters and Constants for Three-wire Measurement of Acme and Stub  
Acme Threads with Large Lead Angles, 1-inch Axial Pitch**

| Lead angle, $B$ , deg. | 1-start threads |             | 2-start threads |             | Lead angle, $B$ , deg. | 2-start threads |             | 3-start threads |             |
|------------------------|-----------------|-------------|-----------------|-------------|------------------------|-----------------|-------------|-----------------|-------------|
|                        | $w_1$           | $(C + c)_1$ | $w_1$           | $(C + c)_1$ |                        | $w_1$           | $(C + c)_1$ | $w_1$           | $(C + c)_1$ |
| 5.0                    | 0.51450         | 0.64311     | 0.51443         | 0.64290     | 10.0                   | 0.50864         | 0.63518     | 0.50847         | 0.63463     |

All dimensions are in inches.

Values given for  $w_1$  and  $(C + c)_1$  in table are for 1-inch pitch axial threads. For other pitches, divide table values by number of threads per inch.

All dimensions are in inches.

Values given for  $w_1$  and  $(C + c)_1$  in table are for 1-inch pitch axial threads. For other pitches divide table values by number of threads per inch.

**Measuring Taper Screw Threads by Three-Wire Method.**—When the 3-wire method is used in measuring a taper screw thread, the measurement is along a line that is not perpendicular to the axis of the screw thread, the inclination from the perpendicular equaling one-half the included angle of the taper. The formula that follows compensates for this inclination resulting from contact of the measuring instrument surfaces, with two wires on one side and one on the other. The taper thread is measured over the wires in the usual manner except that the single wire must be located in the thread at a point where the effective diameter is to be checked (as described more fully later). The formula shows the dimension equivalent to the correct pitch diameter at this given point. The general formula for taper screw threads follows:

$$M = \frac{E - (\cot a)/2N + W(1 + \csc a)}{\sec b}$$

where  $M$  = measurement over the 3 wires

$E$  = pitch diameter

$a$  = one-half the angle of the thread

$N$  = number of threads per inch

$W$  = diameter of wires; and

$b$  = one-half the angle of taper.

This formula is not theoretically correct but it is accurate for screw threads having tapers of  $\frac{3}{4}$  inch per foot or less. This general formula can be simplified for a given thread angle and taper. The simplified formula following (in which  $P$  = pitch) is for an American National Standard pipe thread:

$$M = \frac{E - (0.866025 \times P) + 3 \times W}{1.00049}$$

Standard pitch diameters for pipe threads will be found in the section "American Pipe Threads," which also shows the location, or distance, of this pitch diameter from the end of the pipe. In using the formula for finding dimension  $M$  over the wires, the single wire is placed in whatever part of the thread groove locates it at the point where the pitch diameter is to be checked. The wire must be accurately located at this point. The other wires are then placed on each side of the thread that is diametrically opposite the single wire. If the pipe thread is straight or without taper,

$$M = E - (0.866025 \times P) + 3 \times W$$

*Application of Formula to Taper Pipe Threads:* To illustrate the use of the formula for taper threads, assume that dimension  $M$  is required for an American Standard 3-inch pipe thread gage. Table 1a starting on page 1861 shows that the 3-inch size has 8 threads per inch, or a pitch of 0.125 inch, and a pitch diameter at the gaging notch of 3.3885 inches. Assume that the wire diameter is 0.07217 inch: Then when the pitch diameter is correct

$$M = \frac{3.3885 - (0.866025 \times 0.125) + 3 \times 0.07217}{1.00049} = 3.495 \text{ inches}$$

*Pitch Diameter Equivalent to a Given Measurement Over the Wires:* The formula following may be used to check the pitch diameter at any point along a tapering thread when measurement  $M$  over wires of a given diameter is known. In this formula,  $E$  = the effective or pitch diameter at the position occupied by the single wire. The formula is not theoretically correct but gives very accurate results when applied to tapers of  $\frac{3}{4}$  inch per foot or less.

$$E = 1.00049 \times M + (0.866025 \times P) - 3 \times W$$

*Example:* Measurement  $M$  = 3.495 inches at the gaging notch of a 3-inch pipe thread and the wire diameter = 0.07217 inch. Then

$$E = 1.00049 \times 3.495 + (0.866025 \times 0.125) - 3 \times 0.07217 = 3.3885 \text{ inches}$$

**Pitch Diameter at Any Point Along Taper Screw Thread:** When the pitch diameter in any position along a tapering thread is known, the pitch diameter at any other position may be determined as follows:

Multiply the distance (measured along the axis) between the location of the known pitch diameter and the location of the required pitch diameter, by the taper per inch or by 0.0625 for American National Standard pipe threads. Add this product to the known diameter, if the required diameter is at a large part of the taper, or subtract if the required diameter is smaller.

**Example:** The pitch diameter of a 3-inch American National Standard pipe thread is 3.3885 at the gaging notch. Determine the pitch diameter at the small end. The table starting on page 1861 shows that the distance between the gaging notch and the small end of a 3-inch pipe is 0.77 inch. Hence the pitch diameter at the small end =  $3.3885 - (0.77 \times 0.0625) = 3.3404$  inches.

#### Three-Wire Method Applied to Buttress Threads

The angles of buttress threads vary somewhat, especially on the front or load-resisting side. **Formula (1)**, which follows, may be applied to any angles required. In this formula,  $M$  = measurement over wires when *pitch diameter*  $E$  is correct;  $A$  = included angle of thread and thread groove;  $a$  = angle of front face or load-resisting side, measured from a line perpendicular to screw thread axis;  $P$  = pitch of thread; and  $W$  = wire diameter.

$$M = E - \left[ \frac{P}{\tan a + \tan(A - a)} \right] + W \left[ 1 + \cos\left(\frac{A}{2} - a\right) \times \csc\frac{A}{2} \right] \quad (1)$$

For given angles  $A$  and  $a$ , this general formula may be simplified as shown by **Formulas (3)** and **(4)**. These simplified formulas contain constants with values depending upon angles  $A$  and  $a$ .

**Wire Diameter:** The wire diameter for obtaining pitch-line contact at the back of a buttress thread may be determined by the following general **Formula (2)**:

$$W = P \left( \frac{\cos a}{1 + \cos A} \right) \quad (2)$$

**45-Degree Buttress Thread:** The buttress thread shown by the diagram at the left, has a front or load-resisting side that is perpendicular to the axis of the screw. Measurement  $M$  equivalent to a correct pitch diameter  $E$  may be determined by **Formula (3)**:

$$M = E - P + (W \times 3.4142) \quad (3)$$

Wire diameter  $W$  for pitch-line contact at back of thread =  $0.586 \times$  pitch.

*50-Degree Buttress Thread with Front-face Inclination of 5 Degrees:* This buttress thread form is illustrated by the diagram at the right. Measurement  $M$  equivalent to the correct pitch diameter  $E$  may be determined by [Formula \(4\)](#):

$$M = E - (P \times 0.91955) + (W \times 3.2235) \quad (4)$$

Wire diameter  $W$  for pitch-line contact at back of thread =  $0.606 \times$  pitch. If the width of flat at crest and root =  $\frac{1}{8} \times$  pitch, depth =  $0.69 \times$  pitch.

*American National Standard Buttress Threads ANSI B1.9-1973:* This buttress screw thread has an included thread angle of 52 degrees and a front face inclination of 7 degrees. Measurements  $M$  equivalent to a pitch diameter  $E$  may be determined by [Formula \(5\)](#):

$$M = E - 0.89064P + 3.15689W + c \quad (5)$$

The wire angle correction factor  $c$  is less than 0.0004 inch for recommended combinations of thread diameters and pitches and may be neglected. Use of wire diameter  $W = 0.54147P$  is recommended.

**Measurement of Pitch Diameter of Thread Ring Gages.**—The application of direct methods of measurement to determine the pitch diameter of thread ring gages presents serious difficulties, particularly in securing proper contact pressure when a high degree of precision is required. The usual practice is to fit the ring gage to a master setting plug. When the thread ring gage is of correct lead, angle, and thread form, within close limits, this method is quite satisfactory and represents standard American practice. It is the only method available for small sizes of threads. For the larger sizes, various more or less satisfactory methods have been devised, but none of these have found wide application.

**Screw Thread Gage Classification.**—Screw thread gages are classified by their degree of accuracy, that is, by the amount of tolerance afforded the gage manufacturer and the wear allowance, if any.

There are also three classifications according to use: 1) Working gages for controlling production; 2) inspection gages for rejection or acceptance of the finished product; and 3) reference gages for determining the accuracy of the working and inspection gages.

**American National Standard for Gages and Gaging for Unified Inch Screw Threads ANSI/ASME B1.2-1983 (R2001).**—This standard covers gaging methods for conformance of Unified Screw threads and provides the essential specifications for applicable gages required for unified inch screw threads.

The standard includes the following gages for *Product Internal Thread*:

*GO Working Thread Plug Gage* for inspecting the maximum-material GO functional limit.

*NOT GO (HI) Thread Plug Gage* for inspecting the NOT GO (HI) functional diameter limit.

*Thread Snap Gage—GO Segments or Rolls* for inspecting the maximum-material GO functional limit.

*Thread Snap Gage—NOT GO (HI) Segments or Rolls* for inspecting the NOT GO (HI) functional diameter limit.

*Thread Snap Gages—Minimum Material: Pitch Diameter Cone Type and Vee and Thread Groove Diameter Type* for inspecting the minimum-material limit pitch diameter.

*Thread-Setting Solid Ring Gage* for setting internal thread indicating and snap gages.

*Plain Plug, Snap, and Indicating Gages* for checking the minor diameter of internal threads.

*Snap and Indicating Gages* for checking the major diameter of internal threads.

*Functional Indicating Thread Gage* for inspecting the maximum-material GO functional limit and size and the NOT GO (HI) functional diameter limit and size.

*Minimum-Material Indicating Thread Gage* for inspecting the minimum-material limit and size.

*Indicating Runout Thread Gage* for inspecting runout of the minor diameter to pitch diameter.

In addition to these gages for product internal threads, the Standard also covers differential gaging and such instruments as pitch micrometers, thread-measuring balls, optical comparator and toolmaker's microscope, profile tracing instrument, surface roughness measuring instrument, and roundness measuring equipment.

The Standard includes the following gages for *Product External Thread*:

*GO Working Thread Ring Gage* for inspecting the maximum-material GO functional limit.

*NOT GO (LO) Thread Ring Gage* for inspecting the NOT GO (LO) functional diameter limit.

*Thread Snap Gage—GO Segments or Rolls* for inspecting the maximum-material GO functional limit.

*Thread Snap Gage—NOT GO (LO) Segments or Rolls* for inspecting the NOT GO (LO) functional diameter limit.

*Thread Snap Gages—Cone and Vee Type and Minimum Material Thread Groove Diameter Type* for inspecting the minimum-material pitch diameter limit.

*Plain Ring and Snap Gages* for checking the major diameter.

*Snap Gage* for checking the minor diameter.

*Functional Indicating Thread Gage* for inspecting the maximum-material GO functional limit and size and the NOT GO (LO) functional diameter limit and size.

*Minimum-Material Indicating Thread Gage* for inspecting the minimum-material limit and size.

*Indicating Runout Gage* for inspecting the runout of the major diameter to the pitch diameter.

*WTolerance Thread-Setting Plug Gage* for setting adjustable thread ring gages, checking solid thread ring gages, setting thread snap limit gages, and setting indicating thread gages.

*Plain Check Plug Gage for Thread Ring Gage* for verifying the minor diameter limits of thread ring gages after the thread rings have been properly set with the applicable thread-setting plug gages.

*Indicating Plain Diameter Gage* for checking the major diameter.

*Indicating Gage* for checking the minor diameter.

In addition to these gages for product external threads, the Standard also covers differential gaging and such instruments as thread micrometers, thread-measuring wires, optical comparator and toolmaker's microscope, profile tracing instrument, electromechanical lead tester, helical path attachment used with GO type thread indicating gage, helical path analyzer, surface roughness measuring equipment, and roundness measuring equipment.

The standard lists the following for use of Threaded and Plain Gages for verification of product internal threads:

*Tolerance:* Unless otherwise specified all thread gages which directly check the product thread shall be X tolerance for all classes.

*GO Thread Plug Gages:* GO thread plug gages must enter and pass through the full threaded length of the product freely. The GO thread plug gage is a cumulative check of all thread elements except the minor diameter.

*NOT GO (HI) Thread Plug Gages:* NOT GO (HI) thread plug gages when applied to the product internal thread may engage only the end threads (which may not be representative of the complete thread). Entering threads on product are incomplete and permit gage to start. Starting threads on NOT GO (HI) plugs are subject to greater wear than the remaining threads. Such wear in combination with the incomplete product threads permits further entry of the gage. NOT GO (HI) functional diameter is acceptable when the NOT GO (HI) thread plug gage applied to the product internal thread does not enter more than three complete turns. The gage should not be forced. Special requirements such as exceptionally thin or ductile material, small number of threads, etc., may necessitate modification of this practice.

*GO and NOT GO Plain Plug Gages for Minor Diameter of Product Internal Thread:* (Recommended in Class Z tolerance.) GO plain plug gages must completely enter and pass through the length of the product without force. NOT GO cylindrical plug gage must not enter.

The standard lists the following for use of Thread Gages for verification of product external threads:

*GO Thread Ring Gages:* Adjustable GO thread ring gages must be set to the applicable W tolerance setting plugs to assure they are within specified limits. The product thread must freely enter the GO thread ring gage for the entire length of the threaded portion. The GO thread ring gage is a cumulative check of all thread elements except the major diameter.

*NOT GO (LO) Thread Ring Gages:* NOT GO (LO) thread ring gages must be set to the applicable W tolerance setting plugs to assure that they are within specified limits. NOT GO (LO) thread ring gages when applied to the product external thread may engage only the end threads (which may not be representative of the complete product thread)

Starting threads on NOT GO (LO) rings are subject to greater wear than the remaining threads. Such wear in combination with the incomplete threads at the end of the product thread permit further entry in the gage. NOT GO (LO) functional diameter is acceptable when the NOT GO (LO) thread ring gage applied to the product external thread does not pass over the thread more than three complete turns. The gage should not be forced. Special requirements such as exceptionally thin or ductile material, small number of threads, etc., may necessitate modification of this practice.

*GO and NOT GO Plain Ring and Snap Gages for Checking Major Diameter of Product External Thread:* The GO gage must completely receive or pass over the major diameter of the product external thread to ensure that the major diameter does not exceed the maximum-material-limit. The NOT GO gage must not pass over the major diameter of the product external thread to ensure that the major diameter is not less than the minimum-material-limit.

Limitations concerning the use of gages are given in the standard as follows:

*Product threads* accepted by a gage of one type may be verified by other types. It is possible, however, that parts which are near either rejection limit may be accepted by one type and rejected by another. Also, it is possible for two individual limit gages of the same type to be at the opposite extremes of the gage tolerances permitted, and borderline product threads accepted by one gage could be rejected by another. For these reasons, a product screw thread is considered acceptable when it passes a test by any of the permissible gages in ANSI B1.3 for the gaging system that are within the tolerances.

*Gaging large product external and internal threads* equal to above 6.25-inch nominal size with plain and threaded plug and ring gages presents problems for technical and economic reasons. In these instances, verification may be based on use of modified snap or indicating gages or measurement of thread elements. Various types of gages or measuring

devices in addition to those defined in the Standard are available and acceptable when properly correlated to this Standard. Producer and user should agree on the method and equipment used.

**Thread Forms of Gages.**—Thread forms of gages for product internal and external threads are given in [Table 1](#). The Standard ANSI/ASME B1.2-1983 (R2001) also gives illustrations of the thread forms of truncated thread setting plug gages, the thread forms of full-form thread setting plug gages, the thread forms of solid thread setting ring gages, and an illustration that shows the chip groove and removal of partial thread.

**Thread Gage Tolerances.**—Gage tolerances of thread plug and ring gages, thread setting plugs, and setting rings for Unified screw threads, designated as W and X tolerances, are given in [Table 4](#). W tolerances represent the highest commercial grade of accuracy and workmanship, and are specified for thread setting gages; X tolerances are larger than W tolerances and are used for product inspection gages. Tolerances for plain gages are given in [Table 2](#).

*Determining Size of Gages:* The three-wire method of determining pitch diameter size of plug gages is recommended for gages covered by American National Standard B1.2, described in Appendix B of the 1983 issue of that Standard.

Size limit adjustments of thread ring and external thread snap gages are determined by their fit on their respective calibrated setting plugs. Indicating gages and thread gages for product external threads are controlled by reference to appropriate calibrated setting plugs.

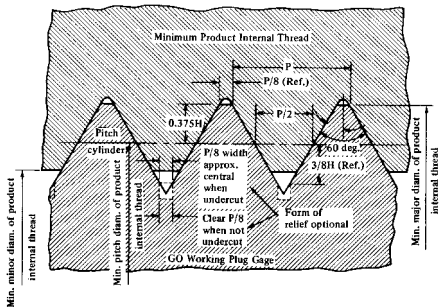

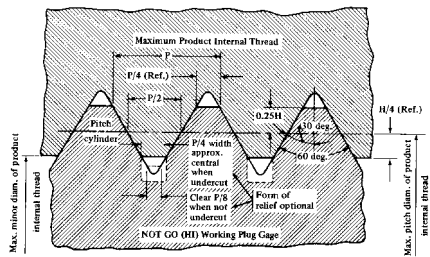

Size limit adjustments of internal thread snap gages are determined by their fit on their respective calibrated setting rings. Indicating gages and other adjustable thread gages for product internal threads are controlled by reference to appropriate calibrated setting rings or by direct measuring methods.

*Interpretation of Tolerances:* Tolerances on lead, half-angle, and pitch diameter are variations which may be taken independently for each of these elements and may be taken to the extent allowed by respective tabulated dimensional limits. The tabulated tolerance on any one element must not be exceeded, even though variations in the other two elements are smaller than the respective tabulated tolerances.

*Direction of Tolerance on Gages:* At the maximum-material limit (GO), the dimensions of all gages used for final conformance gaging are to be within limits of size of the product thread. At the functional diameter limit, using NOT GO (HI and LO) thread gages, the standard practice is to have the gage tolerance within the limits of size of the product thread.

*Formulas for Limits of Gages:* Formulas for limits of American National Standard Gages for Unified screw threads are given in [Table 5](#). Some constants which are required to determine gage dimensions are tabulated in [Table 3](#).

Table 1. Thread Forms of Gages for Product Internal and External Threads

**Table 2. American National Standard Tolerances for Plain Cylindrical Gages  
ANSI/ASME B1.2-1983 (R2001)**

| Size Range |                  | Tolerance Class <sup>a</sup> |        |        |        |        |
|------------|------------------|------------------------------|--------|--------|--------|--------|
| Above      | To and Including | XX                           | X      | Y      | Z      | ZZ     |
|            |                  | Tolerance                    |        |        |        |        |
| 0.020      | 0.825            | .00002                       | .00004 | .00007 | .00010 | .00020 |
| 0.825      | 1.510            | .00003                       | .00006 | .00009 | .00012 | .00024 |
| 1.510      | 2.510            | .00004                       | .00008 | .00012 | .00016 | .00032 |
| 2.510      | 4.510            | .00005                       | .00010 | .00015 | .00020 | .00040 |
| 4.510      | 6.510            | .000065                      | .00013 | .00019 | .00025 | .00050 |
| 6.510      | 9.010            | .00008                       | .00016 | .00024 | .00032 | .00064 |
| 9.010      | 12.010           | .00010                       | .00020 | .00030 | .00040 | .00080 |

<sup>a</sup> Tolerances apply to actual diameter of plug or ring. Apply tolerances as specified in the Standard. Symbols XX, X, Y, Z, and ZZ are standard gage tolerance classes.

All dimensions are given in inches.

**Table 3. Constants for Computing Thread Gage Dimensions  
ANSI/ASME B1.2-1983 (R2001)**

| Threads per Inch | Pitch, $p$ | $0.060\sqrt[3]{p^2} + 0.017p$ | $.05p$ | $.087p$ | Height of Sharp V-Thread, $H = .866025p$ | $H/2 = .43301p$ | $H/4 = .216506p$ |
|------------------|------------|-------------------------------|--------|---------|--|-----------------|------------------|
| 80               | .012500    | .0034                         | .00063 | .00109  | .010825                                  | .00541          | .00271           |
| 72               | .013889    | .0037                         | .00069 | .00122  | .012028                                  | .00601          | .00301           |
| 64               | .015625    | .0040                         | .00078 | .00136  | .013532                                  | .00677          | .00338           |
| 56               | .017857    | .0044                         | .00089 | .00155  | .015465                                  | .00773          | .00387           |
| 48               | .020833    | .0049                         | .00104 | .00181  | .018042                                  | .00902          | .00451           |
| 44               | .022727    | .0052                         | .00114 | .00198  | .019682                                  | .00984          | .00492           |
| 40               | .025000    | .0056                         | .00125 | .00218  | .021651                                  | .01083          | .00541           |
| 36               | .027778    | .0060                         | .00139 | .00242  | .024056                                  | .01203          | .00601           |
| 32               | .031250    | .0065                         | .00156 | .00272  | .027063                                  | .01353          | .00677           |
| 28               | .035714    | .0071                         | .00179 | .00311  | .030929                                  | .01546          | .00773           |
| 27               | .037037    | .0073                         | .00185 | .00322  | .032075                                  | .01604          | .00802           |
| 24               | .041667    | .0079                         | .00208 | .00361  | .036084                                  | .01804          | .00902           |
| 20               | .050000    | .0090                         | .00250 | .00435  | .043301                                  | .02165          | .01083           |
| 18               | .055556    | .0097                         | .00278 | .00483  | .048113                                  | .02406          | .01203           |
| 16               | .062500    | .0105                         | .00313 | .00544  | .054127                                  | .02706          | .01353           |
| 14               | .071429    | .0115                         | .00357 | .00621  | .061859                                  | .03093          | .01546           |
| 13               | .076923    | .0122                         | .00385 | .00669  | .066617                                  | .03331          | .01665           |
| 12               | .083333    | .0129                         | .00417 | .00725  | .072169                                  | .03608          | .01804           |
| 11½              | .086957    | .0133                         | .00435 | .00757  | .075307                                  | .03765          | .01883           |
| 11               | .090909    | .0137                         | .00451 | .00791  | .078730                                  | .03936          | .01968           |

<sup>a</sup> Allowable variation in lead between any two threads not farther apart than the length of the standard gage as shown in ANSI B47.1. The tolerance on lead establishes the width of a zone, measured parallel to the axis of the thread, within which the actual helical path must lie for the specified length of the thread. Measurements are taken from a fixed reference point, located at the start of the first full thread, to a sufficient number of positions along the entire helix to detect all types of lead variations. The amounts that these positions vary from their basic (theoretical) positions are recorded with due respect to sign. The greatest variation in each direction (±) is selected, and the sum of their values, disregarding sign, must not exceed the tolerance limits specified for W gages.

<sup>b</sup> Tolerances apply to designated size of thread. The application of the tolerances is specified in the Standard.

<sup>c</sup> Above 12 in. the tolerance is directly proportional to the tolerance given in this column below, in the ratio of the diameter to 12 in.

All dimensions are given in inches unless otherwise specified.

**Table 5. Formulas for Limits of American National Standard Gages for Unified Inch Screw Threads ANSI/ASME B1.2-1983 (R2001)**

| No.  | Thread Gages for External Threads   |
|--|---|
| 1  | GO Pitch Diameter = Maximum pitch diameter of external thread. Gage tolerance is <i>minus</i> .   |
| 2  | GO Minor Diameter = Maximum pitch diameter of external thread minus $H/2$ . Gage tolerance is <i>minus</i> .  |
| 3  | NOT GO (LO) Pitch Diameter (for plus tolerance gage) = Minimum pitch diameter of external thread. Gage tolerance is <i>plus</i> .   |
| 4  | NOT GO (LO) Minor Diameter = Minimum pitch diameter of external thread minus $H/4$ . Gage tolerance is <i>plus</i> .  |
| Plain Gages for Major Diameter of External Threads       |   |
| 5  | GO = Maximum major diameter of external thread. Gage tolerance is <i>minus</i> .  |
| 6  | NOT GO = Minimum major diameter of external thread. Gage tolerance is <i>plus</i> .   |
| Thread Gages for Internal Threads                        |   |
| 7  | GO Major Diameter = Minimum major diameter of internal thread. Gage tolerance is <i>plus</i> .  |
| 8  | GO Pitch Diameter = Minimum pitch diameter of internal thread. Gage tolerance is <i>plus</i> .  |
| 9  | NOT GO (HI) Major Diameter = Maximum pitch diameter of internal thread plus $H/2$ . Gage tolerance is <i>minus</i> .  |
| 10   | NOT GO (HI) Pitch Diameter = Maximum pitch diameter of internal thread. Gage tolerance is <i>minus</i> .  |
| Plain Gages for Minor Diameter of Internal Threads       |   |
| 11   | GO = Minimum minor diameter of internal thread. Gage tolerance is <i>plus</i> .   |
| 12   | NOT GO = Maximum minor diameter of internal thread. Gage tolerance is <i>minus</i> .  |
| Full Form and Truncated Setting Plugs                    |   |
| 13   | GO Major Diameter (Truncated Portion) = Maximum major diameter of external thread (= minimum major diameter of full portion of GO setting plug) minus $(0.060\sqrt[3]{p^2} + 0.017p)$ . Gage tolerance is <i>minus</i> .  |
| 14   | GO Major Diameter (Full Portion) = Maximum major diameter of external thread. Gage tolerance is <i>plus</i> .   |
| 15   | GO Pitch Diameter = Maximum pitch diameter of external thread. Gage tolerance is <i>minus</i> .   |
| 16   | <sup>a</sup> NOT GO (LO) Major Diameter (Truncated Portion) = Minimum pitch diameter of external thread plus $H/2$ . Gage tolerance is <i>minus</i> .   |
| 17   | NOT GO (LO) Major Diameter (Full Portion) = Maximum major diameter of external thread provided major diameter crest width shall not be less than 0.001 in. (0.0009 in. truncation). Apply $W$ tolerance <i>plus</i> for maximum size except that for 0.001 in. crest width apply tolerance <i>minus</i> . For the 0.001 in. crest width, major diameter is equal to maximum major diameter of external thread plus $0.216506p$ minus the sum of external thread pitch diameter tolerance and 0.0017 in. |
| 18   | NOT GO (LO) Pitch Diameter = Minimum pitch diameter of external thread. Gage tolerance is <i>plus</i> .   |
| Solid Thread-setting Rings for Snap and Indicating Gages |   |
| 19   | <sup>b</sup> GO Pitch Diameter = Minimum pitch diameter of internal thread. $W$ gage tolerance is <i>plus</i> .   |
| 20   | GO Minor Diameter = Minimum minor diameter of internal thread. $W$ gage tolerance is <i>minus</i> .   |
| 21   | <sup>b</sup> NOT GO (HI) Pitch Diameter = Maximum pitch diameter of internal thread. $W$ gage tolerance is <i>minus</i> .   |
| 22   | NOT GO (HI) Minor Diameter = Maximum minor diameter of internal thread. $W$ gage tolerance is <i>minus</i> .  |

<sup>a</sup>Truncated portion is required when optional sharp root profile is used.

<sup>b</sup>Tolerances greater than  $W$  tolerance for pitch diameter are acceptable when internal indicating or snap gage can accommodate a greater tolerance and when agreed upon by supplier and user.

See data in Screw Thread Systems section for symbols and dimensions of Unified Screw Threads.

## TAPPING AND THREAD CUTTING

**Selection of Taps.**—For most applications, a standard tap supplied by the manufacturer can be used, but some jobs may require special taps. A variety of standard taps can be obtained. In addition to specifying the size of the tap it is necessary to be able to select the one most suitable for the application at hand.

The elements of standard taps that are varied are: the number of flutes; the type of flute, whether straight, spiral pointed, or spiral fluted; the chamfer length; the relief of the land, if any; the tool steel used to make the tap; and the surface treatment of the tap.

Details regarding the nomenclature of tap elements are given in the section *TAPS AND THREADING DIES* starting on page 892, along with a listing of the standard sizes available.

Factors to consider in selecting a tap include: the method of tapping, by hand or by machine; the material to be tapped and its heat treatment; the length of thread, or depth of the tapped hole; the required tolerance or class of fit; and the production requirement and the type of machine to be used.

The diameter of the hole must also be considered, although this action is usually only a matter of design and the specification of the tap drill size.

*Method of Tapping:* The term *hand tap* is used for both hand and machine taps, and almost all taps can be applied by the hand or machine method. While any tap can be used for hand tapping, those having a concentric land without the relief are preferable. In hand tapping the tool is reversed periodically to break the chip, and the heel of the land of a tap with a concentric land (without relief) will cut the chip off cleanly or any portion of it that is attached to the work, whereas a tap with an eccentric or con-eccentric relief may leave a small burr that becomes wedged between the relieved portion of the land and the work. This wedging creates a pressure towards the cutting face of the tap that may cause it to chip; it tends to roughen the threads in the hole, and it increases the overall torque required to turn the tool. When tapping by machine, however, the tap is usually turned only in one direction until the operation is complete, and an eccentric or con-eccentric relief is often an advantage.

*Chamfer Length:* Three types of hand taps, used both for hand and machine tapping, are available, and they are distinguished from each other by the length of chamfer. *Taper taps* have a chamfer angle that reduces the height about 8–10 teeth; *plug taps* have a chamfer angle with 3–5 threads reduced in height; and *bottoming taps* have a chamfer angle with  $1\frac{1}{2}$  threads reduced in height. Since the teeth that are reduced in height do practically all the cutting, the chip load or chip thickness per tooth will be least for a taper tap, greater for a plug tap, and greatest for a bottoming tap.

For most through hole tapping applications it is necessary to use only a plug type tap, which is also most suitable for blind holes where the tap drill hole is deeper than the required thread. If the tap must bottom in a blind hole, the hole is usually threaded first with a plug tap and then finished with a bottoming tap to catch the last threads in the bottom of the hole. Taper taps are used on materials where the chip load per tooth must be kept to a minimum. However, taper taps should not be used on materials that have a strong tendency to work harden, such as the austenitic stainless steels.

*Spiral Point Taps:* Spiral point taps offer a special advantage when machine tapping through holes in ductile materials because they are designed to handle the long continuous chips that form and would otherwise cause a disposal problem. An angular gash is ground at the point or end of the tap along the face of the chamfered threads or lead teeth of the tap. This gash forms a left-hand helix in the flutes adjacent to the lead teeth which causes the chips to flow ahead of the tap and through the hole. The gash is usually formed to produce a rake angle on the cutting face that increases progressively toward the end of the tool. Since the flutes are used primarily to provide a passage for the cutting fluid, they are usu-

ally made narrower and shallower thereby strengthening the tool. For tapping thin workpieces short fluted spiral point taps are recommended. They have a spiral point gash along the cutting teeth; the remainder of the threaded portion of the tap has no flute. Most spiral pointed taps are of plug type; however, spiral point bottoming taps are also made.

*Spiral Fluted Taps:* Spiral fluted taps have a helical flute; the helix angle of the flute may be between 15 and 52 degrees and the hand of the helix is the same as that of the threads on the tap. The spiral flute and the rake that it forms on the cutting face of the tap combine to induce the chips to flow backward along the helix and out of the hole. Thus, they are ideally suited for tapping blind holes and they are available as plug and bottoming types. A higher spiral angle should be specified for tapping very ductile materials; when tapping harder materials, chipping at the cutting edge may result and the spiral angle must be reduced.

Holes having a pronounced interruption such as a groove or a keyway can be tapped with spiral fluted taps. The land bridges the interruption and allows the tap to cut relatively smoothly.

*Serial Taps and Close Tolerance Threads:* For tapping holes to close tolerances a set of serial taps is used.

They are usually available in sets of three: the No. 1 tap is undersize and is the first rougher; the No. 2 tap is of intermediate size and is the second rougher; and the No. 3 tap is used for finishing.

The different taps are identified by one, two, and three annular grooves in the shank adjacent to the square. For some applications involving finer pitches only two serial taps are required. Sets are also used to tap hard or tough materials having a high tensile strength, deep blind holes in normal materials, and large coarse threads. A set of more than three taps is sometimes required to produce threads of coarse pitch. Threads to some commercial tolerances, such as American Standard Unified 2B, or ISO Metric 6H, can be produced in one cut using a ground tap; sometimes even closer tolerances can be produced with a single tap. Ground taps are recommended for all close tolerance tapping operations. For much ordinary work, cut taps are satisfactory and more economical than ground taps.

*Tap Steels:* Most taps are made from high speed steel. The type of tool steel used is determined by the tap manufacturer and is usually satisfactory when correctly applied except in a few exceptional cases. Typical grades of high speed steel used to make taps are M-1, M-2, M-3, M-42, etc. Carbon tool steel taps are satisfactory where the operating temperature of the tap is low and where a high resistance to abrasion is not required as in some types of hand tapping.

*Surface Treatment:* The life of high speed steel taps can sometimes be increased significantly by treating the surface of the tap. A very common treatment is oxide coating, which forms a thin metallic oxide coating on the tap that has lubricity and is somewhat porous to absorb and retain oil. This coating reduces the friction between the tap and the work and it makes the surface virtually impervious to rust. It does not increase the hardness of the surface but it significantly reduces or prevents entirely galling, or the tendency of the work material to weld or stick to the cutting edge and to other areas on the tap with which it is in contact. For this reason oxide coated taps are recommended for metals that tend to gall and stick such as non-free cutting low carbon steels and soft copper. It is also useful for tapping other steels having higher strength properties.

Nitriding provides a very hard and wear resistant case on high speed steel. Nitrided taps are especially recommended for tapping plastics; they have also been used successfully on a variety of other materials including high strength high alloy steels. However, some caution must be used in specifying nitrided taps because the nitride case is very brittle and may have a tendency to chip.

Chrome plating has been used to increase the wear resistance of taps but its application has been limited because of the high cost and the danger of hydrogen embrittlement which can cause cracks to form in the tool. A flash plate of about .0001 in. or less in thickness is

applied to the tap. Chrome-plated taps have been used successfully to tap a variety of ferrous and nonferrous materials including plastics, hard rubber, mild steel, and tool steel. Other surface treatments that have been used successfully to a limited extent are vapor blasting and liquid honing.

**Rake Angle:** For the majority of applications in both ferrous and nonferrous materials the rake angle machined on the tap by the manufacturer is satisfactory. This angle is approximately 5 to 7 degrees. In some instances it may be desirable to alter the rake angle of the tap to obtain beneficial results and Table 1 provides a guide that can be used. In selecting a rake angle from this table, consideration must be given to the size of the tap and the strength of the land. Most standard taps are made with a curved face with the rake angle measured as a chord between the crest and root of the thread. The resulting shape is called a hook angle.

**Table 1. Tap Rake Angles for Tapping Different Materials**

| Material  | Rake Angle, Degrees | Material          | Rake Angle, Degrees |
|---|---------------------|-------------------|---------------------|
| Cast Iron   | 0-3                 | Aluminum          | 8-20                |
| Malleable Iron                                      | 5-8                 | Brass             | 2-7                 |
| Steel   |                     | Naval Brass       | 5-8                 |
| AISI 1100 Series                                    | 5-12                | Phosphor Bronze   | 5-12                |
| Low Carbon (up to .25 per cent)                     | 5-12                | Tobin Bronze      | 5-8                 |
| Medium Carbon, Annealed (.30 to .60 per cent)       | 5-10                | Manganese Bronze  | 5-12                |
| Heat Treated, 225-283 Brinell (.30 to .60 per cent) | 0-8                 | Magnesium         | 10-20               |
| High Carbon and High Speed                          | 0-5                 | Monel             | 9-12                |
| Stainless   | 8-15                | Copper            | 10-18               |
| Titanium  | 5-10                | Zinc Die Castings | 10-15               |
|   |                     | Plastic           |                     |
|   |                     | Thermoplastic     | 5-8                 |
|   |                     | Thermosetting     | 0-3                 |
|   |                     | Hard Rubber       | 0-3                 |

**Cutting Speed.**—The cutting speed for machine tapping is treated in detail on page 1072. It suffices to say here that many variables must be considered in selecting this cutting speed and any tabulation may have to be modified greatly. Where cutting speeds are mentioned in the following section, they are intended only to provide a guideline to show the possible range of speeds that could be used.

**Tapping Specific Materials.**—The work material has a great influence on the ease with which a hole can be tapped. For production work, in many instances, modified taps are recommended; however, for toolroom or short batch work, standard hand taps can be used on most jobs, providing reasonable care is taken when tapping. The following concerns the tapping of metallic materials; information on the tapping of plastics is given on page 623.

**Low Carbon Steel (Less than 0.15% C):** These steels are very soft and ductile resulting in a tendency for the work material to tear and to weld to the tap. They produce a continuous chip that is difficult to break and spiral pointed taps are recommended for tapping through holes; for blind holes a spiral fluted tap is recommended. To prevent galling and welding, a liberal application of a sulfur base or other suitable cutting fluid is essential and the selection of an oxide coated tap is very helpful.

**Low Carbon Steels (0.15 to 0.30% C):** The additional carbon in these steels is beneficial as it reduces the tendency to tear and to weld; their machinability is further improved by cold drawing. These steels present no serious problems in tapping provided a suitable cut-

ting fluid is used. An oxide coated tap is recommended, particularly in the lower carbon range.

*Medium Carbon Steels (0.30 to 0.60% C):* These steels can be tapped without too much difficulty, although a lower cutting speed must be used in machine tapping. The cutting speed is dependent on the carbon content and the heat treatment. Steels that have a higher carbon content must be tapped more slowly, especially if the heat treatment has produced a pearlitic microstructure. The cutting speed and ease of tapping is significantly improved by heat treating to produce a spheroidized microstructure. A suitable cutting fluid must be used.

*High Carbon Steels (More than 0.6% C):* Usually these materials are tapped in the annealed or normalized condition although sometimes tapping is done after hardening and tempering to a hardness below 55 Rc. Recommendations for tapping after hardening and tempering are given under High Tensile Strength Steels. In the annealed and normalized condition these steels have a higher strength and are more abrasive than steels with a lower carbon content; thus, they are more difficult to tap. The microstructure resulting from the heat treatment has a significant effect on the ease of tapping and the tap life, a spheroidite structure being better in this respect than a pearlitic structure. The rake angle of the tap should not exceed 5 degrees and for the harder materials a concentric tap is recommended. The cutting speed is considerably lower for these steels and an activated sulfur-chlorinated cutting fluid is recommended.

*Alloy Steels:* This classification includes a wide variety of steels, each of which may be heat treated to have a wide range of properties. When annealed and normalized they are similar to medium to high carbon steels and usually can be tapped without difficulty, although for some alloy steels a lower tapping speed may be required. Standard taps can be used and for machine tapping a con-eccentric relief may be helpful. A suitable cutting fluid must be used.

*High-Tensile Strength Steels:* Any steel that must be tapped after being heat treated to a hardness range of 40–55 Rc is included in this classification. Low tap life and excessive tap breakage are characteristics of tapping these materials; those that have a high chromium content are particularly troublesome. Best results are obtained with taps that have concentric lands, a rake angle that is at or near zero degrees, and 6 to 8 chamfered threads on the end to reduce the chip load per tooth. The chamfer relief should be kept to a minimum. The load on the tap should be kept to a minimum by every possible means, including using the largest possible tap drill size; keeping the hole depth to a minimum; avoidance of bottoming holes; and, in the larger sizes, using fine instead of coarse pitches. Oxide coated taps are recommended although a nitrided tap can sometimes be used to reduce tap wear. An active sulfur-chlorinated oil is recommended as a cutting fluid and the tapping speed should not exceed about 10 feet per minute.

*Stainless Steels:* Ferritic and martensitic type stainless steels are somewhat like alloy steels that have a high chromium content, and they can be tapped in a similar manner, although a slightly slower cutting speed may have to be used. Standard rake angle oxide coated taps are recommended and a cutting fluid containing molybdenum disulphide is helpful to reduce the friction in tapping. Austenitic stainless steels are very difficult to tap because of their high resistance to cutting and their great tendency to work harden. A work-hardened layer is formed by a cutting edge of the tap and the depth of this layer depends on the severity of the cut and the sharpness of the tool. The next cutting edge must penetrate below the work-hardened layer, if it is to be able to cut. Therefore, the tap must be kept sharp and each succeeding cutting edge on the tool must penetrate below the work-hardened layer formed by the preceding cutting edge. For this reason, a taper tap should not be used, but rather a plug tap having 3–5 chamfered threads. To reduce the rubbing of the lands, an eccentric or con-eccentric relieved land should be used and a 10–15 degree rake angle is recommended. A tough continuous chip is formed that is difficult to break. To con-

trol this chip, spiral pointed taps are recommended for through holes and low-helix angle spiral fluted taps for blind holes. An oxide coating on the tap is very helpful and a sulfur-chlorinated mineral lard oil is recommended, although heavy duty soluble oils have also been used successfully.

*Free Cutting Steels:* There are large numbers of free cutting steels, including free cutting stainless steels, which are also called free machining steels. Sulfur, lead, or phosphorus are added to these steels to improve their machinability. Free machining steels are always easier to tap than their counterparts that do not have the free machining additives. Tool life is usually increased and a somewhat higher cutting speed can be used. The type of tap recommended depends on the particular type of free machining steel and the nature of the tapping operation; usually a standard tap can be used.

*High Temperature Alloys:* These are cobalt or nickel base nonferrous alloys that cut like austenitic stainless steel, but are often even more difficult to machine. The recommendations given for austenitic stainless steel also apply to tapping these alloys but the rake angle should be 0 to 10 degrees to strengthen the cutting edge. For most applications a nitrided tap or one made from M41, M42, M43, or M44 steel is recommended. The tapping speed is usually in the range of 5 to 10 feet per minute.

*Titanium and Titanium Alloys:* Titanium and its alloys have a low specific heat and a pronounced tendency to weld on to the tool material; therefore, oxide coated taps are recommended to minimize galling and welding. The rake angle of the tap should be from 6 to 10 degrees. To minimize the contact between the work and the tap an eccentric or con-eccentric relief land should be used. Taps having interrupted threads are sometimes helpful. Pure titanium is comparatively easy to tap but the alloys are very difficult. The cutting speed depends on the composition of the alloy and may vary from 40 to 10 feet per minute. Special cutting oils are recommended for tapping titanium.

*Gray Cast Iron:* The microstructure of gray cast iron can vary, even within a single casting, and compositions are used that vary in tensile strength from about 20,000 to 60,000 psi (160 to 250 Bhn). Thus, cast iron is not a single material, although in general it is not difficult to tap. The cutting speed may vary from 90 feet per minute for the softer grades to 30 feet per minute for the harder grades. The chip is discontinuous and straight fluted taps should be used for all applications. Oxide coated taps are helpful and gray cast iron can usually be tapped dry, although water soluble oils and chemical emulsions are sometimes used.

*Malleable Cast Iron:* Commercial malleable cast irons are also available having a rather wide range of properties, although within a single casting they tend to be quite uniform. They are relatively easy to tap and standard taps can be used. The cutting speed for ferritic cast irons is 60–90 feet per minute, for pearlitic malleable irons 40–50 feet per minute, and for martensitic malleable irons 30–35 feet per minute. A soluble oil cutting fluid is recommended except for martensitic malleable iron where a sulfur base oil may work better.

*Ductile or Nodular Cast Iron:* Several classes of nodular iron are used having a tensile strength varying from 60,000 to 120,000 psi. Moreover, the microstructure in a single casting and in castings produced at different times vary rather widely. The chips are easily controlled but have some tendency to weld to the faces and flanks of cutting tools. For this reason oxide coated taps are recommended. The cutting speed may vary from 15 fpm for the harder martensitic ductile irons to 60 fpm for the softer ferritic grades. A suitable cutting fluid should be used.

*Aluminum:* Aluminum and aluminum alloys are relatively soft materials that have little resistance to cutting. The danger in tapping these alloys is that the tap will ream the hole instead of cutting threads, or that it will cut a thread eccentric to the hole. For these reasons, extra care must be taken when aligning the tap and starting the thread. For production tapping a spiral pointed tap is recommended for through holes and a spiral fluted tap for blind holes; preferably these taps should have a 10 to 15 degree rake angle. A lead screw tapping

machine is helpful in cutting accurate threads. A heavy duty soluble oil or a light base mineral oil should be used as a cutting fluid.

**Copper Alloys:** Most copper alloys are not difficult to tap, except beryllium copper and a few other hard alloys. Pure copper offers some difficulty because of its ductility and the ductile continuous chip formed, which can be difficult to control. However, with reasonable care and the use of medium heavy duty mineral lard oil it can be tapped successfully. Red brass, yellow brass, and similar alloys containing not more than 35 per cent zinc produce a continuous chip. While straight fluted taps can be used for hand tapping these alloys, machine tapping should be done with spiral pointed or spiral fluted taps for through and blind holes respectively. Naval brass, leaded brass, and cast brasses produce a discontinuous chip and a straight fluted tap can be used for machine tapping. These alloys exhibit a tendency to close in on the tap and sometimes an interrupted thread tap is used to reduce the resulting jamming effect. Beryllium copper and the silicon bronzes are the strongest of the copper alloys. Their strength combined with their ability to work harden can cause difficulties in tapping. For these alloys plug type taps should be used and the taps should be kept as sharp as possible. A medium or heavy duty water soluble oil is recommended as a cutting fluid.

**Diameter of Tap Drill.**—Tapping troubles are sometimes caused by tap drills that are too small in diameter. The tap drill should not be smaller than is necessary to give the required strength to the thread as even a very small decrease in the diameter of the drill will increase the torque required and the possibility of broken taps. Tests have shown that any increase in the percentage of full thread over 60 per cent does not significantly increase the strength of the thread. Often, a 55 to 60 per cent thread is satisfactory, although 75 per cent threads are commonly used to provide an extra measure of safety. The present thread specifications do not always allow the use of the smaller thread depths. However, the specification given on a part drawing must be adhered to and may require smaller minor diameters than might otherwise be recommended.

The depth of the thread in the tapped hole is dependent on the length of thread engagement and on the material. In general, when the engagement length is more than one and one-half times the nominal diameter a 50 or 55 per cent thread is satisfactory. Soft ductile materials may permit use of a slightly larger tapping hole than brittle materials such as gray cast iron.

It must be remembered that a twist drill is a roughing tool that may be expected to drill slightly oversize and that some variations in the size of the tapping holes are almost inevitable. When a closer control of the hole size is required it must be reamed. Reaming is recommended for the larger thread diameters and for some fine pitch threads.

For threads of Unified form (see *American National and Unified Screw Thread Forms* on page 1725) the selection of tap drills is covered in the following section, Factors Influencing Minor Diameter Tolerances of Tapped Holes and the hole size limits are given in [Table 2](#). [Tables 3](#) and [4](#) give tap drill sizes for American National Form threads based on 75 per cent of full thread depth. For smaller-size threads the use of slightly larger drills, if permissible, will reduce tap breakage. The selection of tap drills for these threads also may be based on the hole size limits given in [Table 2](#) for Unified threads that take lengths of engagement into account.

**Table 2. Recommended Hole Size Limits Before Tapping Unified Threads**

| Thread Size                     | Classes 1B and 2B                                    |         |  |                      |   |         |                               |                      | Class 3B                        |         |  |                      |   |         |                               |        |
|---------------------------------|--|---------|--|----------------------|---|---------|-------------------------------|----------------------|---------------------------------|---------|--|----------------------|---|---------|-------------------------------|--------|
|                                 | Length of Engagement ( $D =$ Nominal Size of Thread) |         |  |                      |   |         |                               |                      |                                 |         |  |                      |   |         |                               |        |
|                                 | To and Including $\frac{1}{2}D$                      |         | Above $\frac{1}{2}D$ to $\frac{3}{4}D$ |                      | Above $\frac{3}{4}D$ to $1\frac{1}{2}D$ |         | Above $1\frac{1}{2}D$ to $3D$ |                      | To and Including $\frac{1}{2}D$ |         | Above $\frac{1}{2}D$ to $\frac{3}{4}D$ |                      | Above $\frac{3}{4}D$ to $1\frac{1}{2}D$ |         | Above $1\frac{1}{2}D$ to $3D$ |        |

<sup>a</sup> This is the minimum minor diameter specified in the thread tables, page 1736.

<sup>b</sup> This is the maximum minor diameter specified in the thread tables, page 1736.

All dimensions are in inches.

For basis of recommended hole size limits see accompanying text.

As an aid in selecting suitable drills, see the listing of American Standard drill sizes in the twist drill section. For amount of expected drill oversize, see page 885.

Table 3. Tap Drill Sizes for Threads of American National Form

| Screw Thread        |            | Commercial Tap Drills <sup>a</sup> |                | Screw Thread                    |            | Commercial Tap Drills <sup>a</sup> |                |

<sup>a</sup>These tap drill diameters allow approximately 75 per cent of a full thread to be produced. For small thread sizes in the first column, the use of drills to produce the larger hole sizes shown in Table 2 will reduce defects caused by tap problems and breakage.

**Table 4. Tap Drills and Clearance Drills for Machine Screws with American National Thread Form**

| Size of Screw  |                | No. of Threads per Inch            | Tap Drills                         |                         | Clearance Hole Drills |                |                 |                |

<sup>a</sup>These screws are not in the American Standard but are from the former A.S.M.E. Standard.

The size of the tap drill hole for any desired percentage of full thread depth can be calculated by the formulas below. In these formulas the Per Cent Full Thread is expressed as a decimal; e.g., 75 per cent is expressed as .75. The tap drill size is the size nearest to the calculated hole size.

For American Unified Thread form:

$$\text{Hole Size} = \text{Basic Major Diameter} - \frac{1.08253 \times \text{Per Cent Full Thread}}{\text{Number of Threads per Inch}}$$

For ISO Metric threads (all dimensions in millimeters):

$$\text{Hole Size} = \text{Basic Major Diameter} - (1.08253 \times \text{Pitch} \times \text{Per Cent Full Thread})$$

The constant 1.08253 in the above equation represents  $5H/8$  where  $H$  is the height of a sharp V-thread (see page 1725). (The pitch is taken to be 1.)

**Factors Influencing Minor Diameter Tolerances of Tapped Holes.**—As stated in the Unified screw thread standard, the principle practical factors that govern minor diameter tolerances of internal threads are tapping difficulties, particularly tap breakage in the small sizes, availability of standard drill sizes in the medium and large sizes, and depth (radial) of engagement. Depth of engagement is related to the stripping strength of the thread assembly, and thus also, to the length of engagement. It also has an influence on the tendency toward disengagement of the threads on one side when assembly is eccentric. The amount of possible eccentricity is one-half of the sum of the pitch diameter allowance and toler-

ances on both mating threads. For a given pitch, or height of thread, this sum increases with the diameter, and accordingly this factor would require a decrease in minor diameter tolerance with increase in diameter. However, such decrease in tolerance would often require the use of special drill sizes; therefore, to facilitate the use of standard drill sizes, for any given pitch the minor diameter tolerance for Unified thread classes 1B and 2B threads of  $\frac{1}{4}$  inch diameter and larger is constant, in accordance with a formula given in the American Standard for Unified Screw Threads.

*Effect of Length of Engagement of Minor Diameter Tolerances:* There may be applications where the lengths of engagement of mating threads is relatively short or the combination of materials used for mating threads is such that the maximum minor diameter tolerance given in the Standard (based on a length of engagement equal to the nominal diameter) may not provide the desired strength of the fastening. Experience has shown that for lengths of engagement less than  $\frac{2}{3}D$  (the minimum thickness of standard nuts) the minor diameter tolerance may be reduced without causing tapping difficulties. In other applications the length of engagement of mating threads may be long because of design considerations or the combination of materials used for mating threads. As the threads engaged increase in number, a shallower depth of engagement may be permitted and still develop stripping strength greater than the external thread breaking strength. Under these conditions the maximum tolerance given in the Standard should be increased to reduce the possibility of tapping difficulties. The following paragraphs indicate how the aforementioned considerations were taken into account in determining the minor diameter limits for various lengths of engagement given in [Table 2](#).

**Recommended Hole Sizes before Tapping.**—Recommended hole size limits before threading to provide for optimum strength of fastenings and tapping conditions are shown in [Table 2](#) for classes 1B, 2B, and 3B. The hole size limit before threading, and the tolerances between them, are derived from the minimum and maximum minor diameters of the internal thread given in the dimensional tables for Unified threads in the screw thread section using the following rules:

- 1) For lengths of engagement in the range to and including  $\frac{1}{3}D$ , where  $D$  equals nominal diameter, the minimum hole size will be equal to the minimum minor diameter of the internal thread and the maximum hole size will be larger by one-half the minor diameter tolerance.
- 2) For the range from  $\frac{1}{3}D$  to  $\frac{2}{3}D$ , the minimum and maximum hole sizes will each be one quarter of the minor diameter tolerance larger than the corresponding limits for the length of engagement to and including  $\frac{1}{3}D$ .
- 3) For the range from  $\frac{2}{3}D$  to  $1\frac{1}{2}D$  the minimum hole size will be larger than the minimum minor diameter of the internal thread by one-half the minor diameter tolerance and the maximum hole size will be equal to the maximum minor diameter.
- 4) For the range from  $1\frac{1}{2}D$  to  $3D$  the minimum and maximum hole sizes will each be one-quarter of the minor diameter tolerance of the internal thread larger than the corresponding limits for the  $\frac{2}{3}D$  to  $1\frac{1}{2}D$  length of engagement.

From the foregoing it will be seen that the difference between limits in each range is the same and equal to one-half of the minor diameter tolerance given in the Unified screw thread dimensional tables. This is a general rule, except that the minimum differences for sizes below  $\frac{1}{4}$  inch are equal to the minor diameter tolerances calculated on the basis of lengths of engagement to and including  $\frac{1}{3}D$ . Also, for lengths of engagement greater than  $\frac{1}{3}D$  and for sizes  $\frac{1}{4}$  inch and larger the values are adjusted so that the difference between limits is never less than 0.004 inch.

For diameter-pitch combinations other than those given in [Table 2](#), the foregoing rules should be applied to the tolerances given in the dimensional tables in the screw thread sec-

tion or the tolerances derived from the formulas given in the Standard to determine the hole size limits.

*Selection of Tap Drills:* In selecting standard drills to produce holes within the limits given in Table 2 it should be recognized that drills have a tendency to cut oversize. The material on page 885 may be used as a guide to the expected amount of oversize.

**Table 5. Unified Miniature Screw Threads—Recommended Hole Size Limits Before Tapping**

As an aid in selecting suitable drills, see the listing of American Standard drill sizes in the twist drill section. Thread sizes in heavy type are preferred sizes.

**Hole Sizes for Tapping Unified Miniature Screw Threads.**—Table 5 indicates the hole size limits recommended for tapping. These limits are derived from the internal thread minor diameter limits given in the American Standard for Unified Miniature Screw Threads ASA B1.10-1958 and are disposed so as to provide the optimum conditions for tapping. The maximum limits are based on providing a functionally adequate fastening for the most common applications, where the material of the externally threaded member is of a strength essentially equal to or greater than that of its mating part. In applications where, because of considerations other than the fastening, the screw is made of an appreciably

weaker material, the use of smaller hole sizes is usually necessary to extend thread engagement to a greater depth on the external thread. Recommended minimum hole sizes are greater than the minimum limits of the minor diameters to allow for the spin-up developed in tapping.

In selecting drills to produce holes within the limits given in [Table 5](#) it should be recognized that drills have a tendency to cut oversize. The material on [page 885](#) may be used as a guide to the expected amount of oversize.

**British Standard Tapping Drill Sizes for Screw and Pipe Threads.**—British Standard BS 1157:1975 (1998) provides recommendations for tapping drill sizes for use with fluted taps for various ISO metric, Unified, British Standard fine, British Association, and British Standard Whitworth screw threads as well as British Standard parallel and taper pipe threads.

<sup>a</sup> These tapping drill sizes are for fluted taps only.

<sup>b</sup> For tolerance class 6H and 7H threads only.

<sup>c</sup> For tolerance class 7H threads only.

Drill sizes are given in millimeters.

In the accompanying [Table 6](#), recommended and alternative drill sizes are given for producing holes for ISO metric coarse pitch series threads. These coarse pitch threads are suitable for the large majority of general-purpose applications, and the limits and tolerances for internal coarse threads are given in the table starting on [page 1823](#). It should be noted that [Table 6](#) is for fluted taps only since a fluteless tap will require for the same screw thread a different size of twist drill than will a fluted tap. When tapped, holes produced with drills of the recommended sizes provide for a theoretical radial engagement with the external thread of about 81 per cent in most cases. Holes produced with drills of the alternative sizes provide for a theoretical radial engagement with the external thread of about 70 to 75

per cent. In some cases, as indicated in Table 6, the alternative drill sizes are suitable only for medium (6H) or for free (7H) thread tolerance classes.

When relatively soft material is being tapped, there is a tendency for the metal to be squeezed down towards the root of the tap thread, and in such instances, the minor diameter of the tapped hole may become smaller than the diameter of the drill employed. Users may wish to choose different tapping drill sizes to overcome this problem or for special purposes, and reference can be made to the pages mentioned above to obtain the minor diameter limits for internal pitch series threads.

Reference should be made to this standard BS 1157:1975 (1998) for recommended tapping hole sizes for other types of British Standard screw threads and pipe threads.

**Table 7. British Standard Metric Bolt and Screw Clearance Holes BS 4186: 1967**

All dimensions are given in millimeters.

**British Standard Clearance Holes for Metric Bolts and Screws.**—The dimensions of the clearance holes specified in this British Standard BS 4186:1967 have been chosen in such a way as to require the use of the minimum number of drills. The recommendations cover three series of clearance holes, namely close fit (H 12), medium fit (H 13), and free fit (H 14) and are suitable for use with bolts and screws specified in the following metric British Standards: BS 3692, ISO metric precision hexagon bolts, screws, and nuts; BS 4168, Hexagon socket screws and wrench keys; BS 4183, Machine screws and machine screw nuts; and BS 4190, ISO metric black hexagon bolts, screws, and nuts. The sizes are in accordance with those given in ISO Recommendation R273, and the range has been extended up to 150 millimeters diameter in accordance with an addendum to that recommendation. The selection of clearance holes sizes to suit particular design requirements

can of course be dependent upon many variable factors. It is however felt that the medium fit series should suit the majority of general purpose applications. In the Standard, limiting dimensions are given in a table which is included for reference purposes only, for use in instances where it may be desirable to specify tolerances.

To avoid any risk of interference with the radius under the head of bolts and screws, it is necessary to countersink slightly all recommended clearance holes in the close and medium fit series. Dimensional details for the radius under the head of fasteners made according to BS 3692 are given on page 1575; those for fasteners to BS 4168 are given on page 1633; those to BS 4183 are given on pages 1607 through 1611.

**Cold Form Tapping.**—Cold form taps do not have cutting edges or conventional flutes; the threads on the tap form the threads in the hole by displacing the metal in an extrusion or swaging process. The threads thus produced are stronger than conventionally cut threads because the grains in the metal are unbroken and the displaced metal is work hardened. The surface of the thread is burnished and has an excellent finish. Although chip problems are eliminated, cold form tapping does displace the metal surrounding the hole and countersinking or chamfering before tapping is recommended. Cold form tapping is not recommended if the wall thickness of the hole is less than two-thirds of the nominal diameter of the thread. If possible, blind holes should be drilled deep enough to permit a cold form tap having a four thread lead to be used as this will require less torque, produce less burr surrounding the hole, and give a greater tool life.

The operation requires 0 to 50 per cent more torque than conventional tapping, and the cold form tap will pick up its own lead when entering the hole; thus, conventional tapping machines and tapping heads can be used. Another advantage is the better tool life obtained. The best results are obtained by using a good lubricating oil instead of a conventional cutting oil.

The method can be applied only to relatively ductile metals, such as low-carbon steel, leaded steels, austenitic stainless steels, wrought aluminum, low-silicon aluminum die casting alloys, zinc die casting alloys, magnesium, copper, and ductile copper alloys. A higher than normal tapping speed can be used, sometimes by as much as 100 per cent.

Conventional tap drill sizes should not be used for cold form tapping because the metal is displaced to form the thread. The cold formed thread is stronger than the conventionally tapped thread, so the thread height can be reduced to 60 per cent without much loss of strength; however, the use of a 65 per cent thread is strongly recommended. The following formula is used to calculate the theoretical hole size for cold form tapping:

$$\text{Theoretical hole size} = \text{basic tap O.D.} - \frac{0.0068 \times \text{per cent of full thread}}{\text{threads per inch}}$$

The theoretical hole size and the tap drill sizes for American Unified threads are given in Table 8, and Table 9 lists drills for ISO metric threads. Sharp drills should be used to prevent cold working the walls of the hole, especially on metals that are prone to work hardening. Such damage may cause the torque to increase, possibly stopping the machine or breaking the tap. On materials that can be die cast, cold form tapping can be done in cored holes provided the correct core pin size is used. The core pins are slightly tapered, so the theoretical hole size should be at the position on the pin that corresponds to one-half of the required engagement length of the thread in the hole. The core pins should be designed to form a chamfer on the hole to accept the vertical extrusion.

**Table 8. Theoretical and Tap Drill or Core Hole Sizes for Cold Form Tapping Unified Threads**

| Tap Size       | Threads Per Inch | Percentage of Full Thread |                    |             |                  |                    |             |                  |                    |             |

**Table 9. Tap Drill or Core Hole Sizes for Cold Form Tapping ISO Metric Threads**

| Nominal Size of Tap | Pitch   | Recommended Tap Drill Size |
|---------------------|---------|----------------------------|
| 1.6 mm              | 0.35 mm | 1.45 mm                    |
| 1.8 mm              | 0.35 mm | 1.65 mm                    |
| 2.0 mm              | 0.40 mm | 1.8 mm                     |
| 2.2 mm.             | 0.45 mm | 2.0 mm                     |
| 2.5 mm              | 0.45 mm | 2.3 mm                     |
| 3.0 mm              | 0.50 mm | 2.8 mm <sup>a</sup>        |
| 3.5 mm              | 0.60 mm | 3.2 mm                     |
| 4.0 mm              | 0.70 mm | 3.7 mm                     |
| 4.5 mm              | 0.75 mm | 4.2 mm <sup>a</sup>        |
| 5.0 mm              | 0.80 mm | 4.6 mm                     |
| 6.0 mm              | 1.00 mm | 5.6 mm <sup>a</sup>        |
| 7.0 mm              | 1.00 mm | 6.5 mm                     |
| 8.0 mm              | 1.25 mm | 7.4 mm                     |
| 10.0 mm             | 1.50 mm | 9.3 mm                     |

<sup>a</sup>These diameters are the nearest stocked drill sizes and not the theoretical hole size, and may not produce 60 to 75 per cent full thread.

The sizes are calculated to provide 60 to 75 per cent of full thread.

**Removing a Broken Tap.**—Broken taps can be removed by electrodischarge machining (EDM), and this method is recommended when available. When an EDM machine is not available, broken taps may be removed by using a tap extractor, which has fingers that enter the flutes of the tap; the tap is backed out of the hole by turning the extractor with a wrench. Sometimes the injection of a small amount of a proprietary solvent into the hole will be helpful. A solvent can be made by diluting about one part nitric acid with five parts water. The action of the proprietary solvent or the diluted nitric acid on the steel loosens the tap so that it can be removed with pliers or with a tap extractor. The hole should be washed out afterwards so that the acid will not continue to work on the part. Another method is to add, by electric arc welding, additional metal to the shank of the broken tap, above the level of the hole. Care must be taken to prevent depositing metal on the threads in the tapped hole. After the shank has been built up, the head of a bolt or a nut is welded to it and then the tap may be backed out.

### Tap Drills for Pipe Taps

| Size of Tap | Drills for Briggs Pipe Taps | Drills for Whitworth Pipe Taps | Size of Tap | Drills for Briggs Pipe Taps | Drills for Whitworth Pipe Taps | Size of Tap | Drills for Briggs Pipe Taps | Drills for Whitworth Pipe Taps |

| 1           | 1 5/32                      | 1 1/8                          | 3           | 3 1/4                       | 3 9/32                         | 6           | 6 3/8                       | 6 1/4                          |

All dimensions are in inches.

To secure the best results, the hole should be reamed before tapping with a reamer having a taper of 3/4 inch per foot.

**Power for Pipe Taps.**—The power required for driving pipe taps is given in the following table, which includes nominal pipe tap sizes from 2 to 8 inches.

The holes to be tapped were reamed with standard pipe tap reamers before tapping. The horsepower recorded was read off just before the tap was reversed. The table gives the net horsepower, deductions being made for the power required to run the machine without a load. The material tapped was cast iron, except in two instances, where cast steel was tapped. It will be seen that nearly double the power is required for tapping cast steel. The

power varies, of course, with the conditions. More power than that indicated in the table will be required if the cast iron is of a harder quality or if the taps are not properly relieved. The taps used in these experiments were of the inserted-blade type, the blades being made of high-speed steel.

### Power Required for Pipe Taps

| Nominal Tap Size | Rev. per Min. | Net H.P. | Thickness of Metal | Nominal Tap Size | Rev. per Min. | Net H.P. | Thickness of Metal |
|------------------|---------------|----------|--------------------|------------------|---------------|----------|--------------------|
| 2                | 40            | 4.24     | 1 $\frac{1}{8}$    | 3 $\frac{1}{2}$  | 25.6          | 7.20     | 1 $\frac{3}{4}$    |
| 2 $\frac{1}{2}$  | 40            | 5.15     | 1 $\frac{1}{8}$    | 4                | 18            | 6.60     | 2                  |

<sup>a</sup>Tapping cast steel; other tests in cast iron.

Tap size and metal thickness are in inches.

**High-Speed CNC Tapping.**—Tapping speed depends on the type of material being cut, the type of cutting tool, the speed and rigidity of the machine, the rigidity of the part-holding fixture, and the proper use of coolants and cutting fluids. When tapping, each revolution of the tool feeds the tap a distance equal to the thread pitch. Both spindle speed and feed per revolution must be accurately controlled so that changes in spindle speed result in a corresponding change in feed rate. If the feed/rev is not right, a stripped thread or broken tap will result. NC/CNC machines equipped with the *synchronous tapping* feature are able to control the tap feed as a function of spindle speed. These machines can use rigid-type tap holders or automatic tapping attachments and are able to control depth very accurately. Older NC machines that are unable to reliably coordinate spindle speed and feed must use a tension-compression type tapping head that permits some variation of the spindle speed while still letting the tap feed at the required rate.

CNC machines capable of synchronous tapping accurately coordinate feed rate and rotational speed so that the tap advances at the correct rate regardless of the spindle speed. A canned tapping cycle (see *Fixed (Canned) Cycles* on page 1287 in the *NUMERICAL CONTROL* section) usually controls the operation, and feed and speed are set by the machine operator or part programmer. Synchronized tapping requires reversing the tapping spindle twice for each hole tapped, once after finishing the cut and again at the end of the cycle. Because the rotating mass is fairly large (motor, spindle, chuck or tap holder, and tap), the acceleration and deceleration of the tap are rather slow and a lot of time is lost by this process. The frequent changes in cutting speed during the cut also accelerate tap wear and reduce tap life.

A self-reversing tapping attachment has a forward drive that rotates in the same direction as the machine spindle, a reverse drive that rotates in the opposite direction, and a neutral position in between the two. When a hole is tapped, the spindle feeds at a slightly slower rate than the tap to keep the forward drive engaged until the tap reaches the bottom of the hole. Through holes are tapped by feeding to the desired depth and then retracting the spindle, which engages the tapping-head reverse drive and backs the tap out of the hole—the spindle does not need to be reversed. For tapping blind holes, the spindle is fed to a depth equal to the thread depth minus the self-feed of the tapping attachment. When the spindle is retracted (without reversing), the tap continues to feed forward a short distance (the tapping head self-feed distance) before the reverse drive engages and reverse drives the tap out of the hole. The depth can be controlled to within about  $\frac{1}{4}$  revolution of the tap. The tapping cycle normally used for the self-reversing tap attachment is a standard boring cycle with feed return and no dwell. A typical programming cycle is illustrated with a G85 block on page 1289. The inward feed is set to about 95 per cent of the normal tapping feed (i.e.,

95 per cent of the pitch per revolution). Because the tap is lightweight, tap reversal is almost instantaneous and tapping speed is very fast compared with synchronous tapping.

Tapping speeds are usually given in surface feet per minute (sfm) or the equivalent feet per minute (fpm or ft/min), so a conversion is necessary to get the spindle speed in revolutions per minute. The tapping speed in rpm depends on the diameter of the tap, and is given by the following formula:

$$\text{rpm} = \frac{\text{sfm} \times 12}{d \times 3.14159} = \frac{\text{sfm} \times 3.82}{d}$$

where  $d$  is the nominal diameter of the tap in inches. As indicated previously, the feed in in/rev is equal to the thread pitch and is independent of the cutting speed. The feed rate in inches per minute is found by dividing the tapping speed in rpm by the number of threads per inch, or by multiplying the speed in rpm by the pitch or feed per revolution:

$$\text{feed rate (in/min)} = \frac{\text{rpm}}{\text{threads per inch}} = \text{rpm} \times \text{thread pitch} = \text{rpm} \times \text{feed/rev}$$

*Example:* If the recommended tapping speed for 1020 steel is given as 45 to 60 sfm, find the required spindle speed and feed rate for tapping a 1/4–20 UNF thread in 1020 steel.

Assuming that the machine being used is in good condition and rigid, and the tap is sharp, use the higher rate of 60 sfm and calculate the required spindle speed and feed rate as follows:

$$\text{speed} = \frac{60 \times 3.82}{0.25} = 916.8 \approx 920 \text{ rpm} \quad \text{feed rate} = \frac{920}{20} = 46 \text{ in/min}$$

**Coolant for Tapping.**—Proper use of through-the-tap high-pressure coolant/lubricant can result in increased tap life, increased speed and feed, and more accurate threads. In most chip-cutting processes, cutting fluid is used primarily as a coolant, with lubrication being a secondary but important benefit. Tapping, however, requires a cutting fluid with lubricity as the primary property and coolant as a secondary benefit. Consequently, the typical blend of 5 per cent coolant concentrate to 95 per cent water is too low for best results. An increased percentage of concentrate in the blend helps the fluid to cling to the tap, providing better lubrication at the cutting interface. A method of increasing the tap lubrication qualities without changing the concentration of the primary fluid blend is to use a cutting fluid dispenser controlled by an M code different from that used to control the high-pressure flood coolant (for example, use an M08 code in addition to M07). The secondary coolant-delivery system applies a small amount of an edge-type cutting fluid (about a drop at a time) directly onto the tap-cutting surfaces providing the lubrication needed for cutting. The edge-type fluid applied in this way clings to the tap, increasing the lubrication effect and ensuring that the cutting fluid becomes directly involved in the cutting action at the shear zone.

High-pressure coolant fed through the tap is important in many high-volume tapping applications. The coolant is fed directly through the spindle or tool holder to the cutting zone, greatly improving the process of chip evacuation and resulting in better thread quality. High-pressure through-the-tap coolant flushes blind holes before the tap enters and can remove chips from the holes after tapping is finished. The flushing action prevents chip recutting by forcing chips through the flutes and back out of the hole, improving the surface of the thread and increasing tap life. By improving lubrication and reducing heat and friction, the use of high-pressure coolant may result in increased tap life up to five times that of conventional tapping and may permit speed and feed increases that reduce overall cycle time.

**Combined Drilling and Tapping.**—A special tool that drills and taps in one operation can save a lot of time by reducing setup and eliminating a secondary operation in some

applications. A combination drill and tap can be used for through holes if the length of the fluted drill section is greater than the material thickness, but cannot be used for drilling and tapping blind holes because the tip (drill point) must cut completely through the material before the tapping section begins to cut threads. Drilling and tapping depths up to twice the tool diameter are typical. Determine the appropriate speed by starting the tool at the recommended speed for the tap size and material, and adjust the speed higher or lower to suit the application. Feed during tapping is dependent on the thread pitch. NC/CNC programs can use a fast drilling speed and a slower tapping speed to combine both operations into one and minimize cutting time.

**Relief Angles for Single-Point Thread Cutting Tools.**—The surface finish on threads cut with single-point thread cutting tools is influenced by the relief angles on the tools. The leading and trailing cutting edges that form the sides of the thread, and the cutting edge at the nose of the tool must all be provided with an adequate amount of relief. Moreover, it is recommended that the effective relief angle,  $a_e$ , for all of these cutting edges be made equal, although the practice in some shops is to use slightly less relief at the trailing cutting edge. While too much relief may weaken the cutting edge, causing it to chip, an inadequate amount of relief will result in rough threads and in a shortened tool life. Other factors that influence the finish produced on threads include the following: the work material; the cutting speed; the cutting fluid used; the method used to cut the thread; and, the condition of the cutting edge.

Two similar diagrams showing relationships of various relief angles of thread cutting tools

Relief angles on single-point thread cutting tools are often specified on the basis of experience. While this method may give satisfactory results in many instances, better results can usually be obtained by calculating these angles, using the formulas provided further on. When special high helix angle threads are to be cut, the magnitude of the relief angles should always be calculated. These calculations are based on the effective relief angle,  $a_e$ ; this is the angle between the flank of the tool and the sloping sides of the thread, measured in a direction parallel to the axis of the thread. Recommended values of this angle are 8 to 14 degrees for high speed steel tools, and 5 to 10 degrees for cemented carbide tools. The larger values are recommended for cutting threads on soft and gummy materials, and the smaller values are for the harder materials, which inherently take a better surface finish. Harder materials also require more support below the cutting edges, which is provided by using a smaller relief angle. These values are recommended for the relief angle below the cutting edge at the nose without any further modification. The angles below the leading and trailing side cutting edges are modified, using the formulas provided. The angles  $b$  and  $b'$  are the relief angles actually ground on the tool below the leading and trailing side cutting edges respectively; they are measured perpendicular to the side cutting edges. When designing or grinding the thread cutting tool, it is sometimes helpful to know the magnitude of the angle,  $n$ , for which a formula is provided. This angle would occur only in the event that the tool were ground to a sharp point. It is the angle of the edge formed by the intersection of the flank surfaces.

$$\tan \phi = \frac{\text{lead of thread}}{\pi K} \quad \tan \phi' = \frac{\text{lead of thread}}{\pi D}$$

$$a = a_e + \phi$$

$$a' = a_e - \phi'$$

$$\tan b = \tan a \cos \frac{1}{2}\omega$$

$$\tan b' = \tan a' \cos \frac{1}{2}\omega$$

$$\tan n = \frac{\tan a - \tan a'}{2 \tan \frac{1}{2}\omega}$$

where  $\theta$  = helix angle of thread at minor diameter

$\theta'$  = helix angle of thread at major diameter

$K$  = minor diameter of thread

$D$  = major diameter of thread

$a$  = side relief angle parallel to thread axis at leading edge of tool

$a'$  = side relief angle parallel to thread axis at trailing edge of tool

$a_e$  = effective relief angle

$b$  = side relief angle perpendicular to leading edge of tool

$b'$  = side relief angle perpendicular to trailing edge of tool

$\omega$  = included angle of thread cutting tool

$n$  = nose angle resulting from intersection of flank surfaces

*Example:* Calculate the relief angles and the nose angle  $n$  for a single-point thread cutting tool that is to be used to cut a 1-inch diameter, 5-threads-per-inch, double Acme thread. The lead of this thread is  $2 \times 0.200 = 0.400$  inch. The included angle  $\omega$  of this thread is 29 degrees, the minor diameter  $K$  is 0.780 inch, and the effective relief angle  $a_e$  below all cutting edges is to be 10 degrees.

$$\tan \phi = \frac{\text{lead of thread}}{\pi K} = \frac{0.400}{\pi \times 0.780}$$

$$\phi = 9.27^\circ (9^\circ 16')$$

$$\tan \phi' = \frac{\text{lead of thread}}{\pi D} = \frac{0.400}{\pi \times 1.000}$$

$$\phi' = 7.26^\circ (7^\circ 15')$$

$$a = a_e + \phi = 10^\circ + 9.27^\circ = 19.27^\circ$$

$$a' = a_e - \phi' = 10^\circ - 7.26^\circ = 2.74^\circ$$

$$\tan b = \tan a \cos \frac{1}{2}\omega = \tan 19.27 \cos 14.5$$

$$b = 18.70^\circ (18^\circ 42')$$

$$\tan b' = \tan a' \cos \frac{1}{2}\omega = \tan 2.74 \cos 14.5$$

$$b' = 2.65^\circ (2^\circ 39')$$

$$\tan n = \frac{\tan a - \tan a'}{2 \tan \frac{1}{2}\omega} = \frac{\tan 19.27 - \tan 2.74}{2 \tan 14.5}$$

$$n = 30.26^\circ (30^\circ 16')$$

**Lathe Change Gears**

**Change Gears for Thread Cutting.**—To determine the change gears to use for cutting a thread of given pitch, first find what number of threads per inch will be cut when gears of the same size are placed on the lead screw and spindle stud, either by trial or by referring to the index plate; then multiply this number, called the “lathe screw constant,” by some trial number to obtain the number of teeth in the gear for the spindle stud, and multiply the threads per inch to be cut by the *same* trial number to obtain the number of teeth in the gear for the lead screw. Expressing this rule as a formula:

$$\frac{\text{Trial number} \times \text{lathe screw constant}}{\text{Trial number} \times \text{threads per inch to be cut}} = \frac{\text{teeth in gear on spindle stud}}{\text{teeth in gear on lead screw}}$$

For example, suppose the available change gears supplied with the lathe have 24, 28, 32, 36 teeth, etc., the number increasing by 4 up to 100, and that 10 threads per inch are to be cut in a lathe having a lathe screw constant of 6; then, if the screw constant is written as the numerator, the number of threads per inch to be cut as the denominator of a fraction, and both numerator and denominator are multiplied by some trial number, say, 4, it is found that gears having 24 and 40 teeth can be used. Thus:

$$\frac{6}{10} = \frac{6 \times 4}{10 \times 4} = \frac{24}{40}$$

The 24-tooth gear goes on the spindle stud and the 40-tooth gear on the lead screw.

The lathe screw constant is, of course, equal to the number of threads per inch on the lead screw, provided the spindle stud and spindle are geared in the ratio of 1 to 1, which, however, is not always so.

**Compound Gearing.**—To find the change gears used in compound gearing, place the screw constant as the numerator and the number of threads per inch to be cut as the denominator of a fraction; resolve both numerator and denominator into two factors each, and multiply each “pair” of factors by the same number, until values are obtained representing suitable numbers of teeth for the change gears. (One factor in the numerator and one in the denominator make a “pair” of factors.)

*Example:*— $1\frac{3}{4}$  threads per inch are to be cut in a lathe having a screw constant of 8; the available gears have 24, 28, 32, 36, 40 teeth, etc., increasing by 4 up to 100. Following the rule:

$$\frac{8}{1\frac{3}{4}} = \frac{2 \times 4}{1 \times 1\frac{3}{4}} = \frac{(2 \times 36) \times (4 \times 16)}{(1 \times 36) \times (1\frac{3}{4} \times 16)} = \frac{72 \times 64}{36 \times 28}$$

The gears having 72 and 64 teeth are the *driving* gears and those with 36 and 28 teeth are the *driven* gears.

**Fractional Threads.**—Sometimes the lead of a thread is given as a fraction of an inch instead of stating the number of threads per inch. For example, a thread may be required to be cut, having  $\frac{3}{8}$  inch lead. The expression “ $\frac{3}{8}$  inch lead” should first be transformed to “number of threads per inch.” The number of threads per inch (the thread being single) equals:

$$\frac{1}{\frac{3}{8}} = 1 \div \frac{3}{8} = \frac{8}{3} = 2\frac{2}{3}$$

To find the change gears to cut  $2\frac{2}{3}$  threads per inch in a lathe having a screw constant 8 and change gears ranging from 24 to 100 teeth, increasing in increments of 4, proceed as below:

$$\frac{8}{2\frac{2}{3}} = \frac{2 \times 4}{1 \times 2\frac{2}{3}} = \frac{(2 \times 36) \times (4 \times 24)}{(1 \times 36) \times (2\frac{2}{3} \times 24)} = \frac{72 \times 96}{36 \times 64}$$

**Change Gears for Metric Pitches.**—When screws are cut in accordance with the metric system, it is the usual practice to give the lead of the thread in millimeters, instead of the number of threads per unit of measurement. To find the change gears for cutting metric threads, when using a lathe having an inch lead screw, first determine the number of threads per inch corresponding to the given lead in millimeters. Suppose a thread of 3 millimeters lead is to be cut in a lathe having an inch lead screw and a screw constant of 6. As there are 25.4 millimeters per inch, the number of threads per inch will equal  $25.4 \div 3$ . Place the screw constant as the numerator, and the number of threads per inch to be cut as the denominator:

$$\frac{6}{\frac{25.4}{3}} = 6 \div \frac{25.4}{3} = \frac{6 \times 3}{25.4}$$

The numerator and denominator of this fractional expression of the change gear ratio is next multiplied by some trial number to determine the size of the gears. The first whole number by which 25.4 can be multiplied so as to get a whole number as the result is 5. Thus,  $25.4 \times 5 = 127$ . Hence, one gear having 127 teeth is always used when cutting metric threads with an inch lead screw. The other gear required has 90 teeth. Thus:

$$\frac{6 \times 3 \times 5}{25.4 \times 5} = \frac{90}{127}$$

Therefore, the following rule can be used to find the change gears for cutting metric pitches with an inch lead screw:

*Rule:* Place the lathe screw constant multiplied by the lead of the required thread in millimeters multiplied by 5 as the numerator of the fraction and 127 as the denominator. The product of the numbers in the numerator equals the number of teeth for the spindle-stud gear, and 127 is the number of teeth for the lead-screw gear.

If the lathe has a metric pitch lead screw, and a screw having a given number of threads per inch is to be cut, first find the "metric screw constant" of the lathe or the lead of thread in millimeters that would be cut with change gears of equal size on the lead screw and spindle stud; then the method of determining the change gears is simply the reverse of the one already explained for cutting a metric thread with an inch lead screw.

*Rule:* To find the change gears for cutting inch threads with a metric lead screw, place 127 in the numerator and the threads per inch to be cut, multiplied by the metric screw constant multiplied by 5 in the denominator; 127 is the number of teeth on the spindle-stud gear and the product of the numbers in the denominator equals the number of teeth in the lead-screw gear.

**Threads per Inch Obtained with a Given Combination of Gears.**—To determine the number of threads per inch that will be obtained with a given combination of gearing, multiply the lathe screw constant by the number of teeth in the *driven* gear (or by the product of the numbers of teeth in both driven gears of compound gearing), and divide the product thus obtained by the number of teeth in the *driving* gear (or by the product of the two driving gears of a compound train). The quotient equals the number of threads per inch.

**Change Gears for Fractional Ratios.**—When gear ratios cannot be expressed exactly in whole numbers that are within the range of ordinary gearing, the combination of gearing required for the fractional ratio may be determined quite easily, often by the "cancellation method." To illustrate this method, assume that the speeds of two gears are to be in the ratio of 3.423 to 1. The number 3.423 is first changed to  $\frac{3423}{1000}$  to clear it of decimals. Then, in order to secure a fraction that can be reduced, 3423 is changed to 3420;

$$\frac{3420}{1000} = \frac{342}{100} = \frac{3 \times 2 \times 57}{2 \times 50} = \frac{3 \times 57}{1 \times 50}$$

Then, multiplying  $\frac{3}{4}$  by some trial number, say, 24, the following gear combination is obtained:

$$\frac{72}{24} \times \frac{57}{50} = \frac{4104}{1200} = \frac{3.42}{1}$$

As the desired ratio is 3.423 to 1, there is an error of 0.003. When the ratios are comparatively simple, the cancellation method is not difficult and is frequently used; but by the logarithmic method to be described, more accurate results are usually possible.

**Modifying the Quick-Change Gearbox Output.**—On most modern lathes, the gear train connecting the headstock spindle with the lead screw contains a quick-change gearbox. Instead of using different change gears, it is only necessary to position the handles of the gearbox to adjust the speed ratio between the spindle and the lead screw in preparation for cutting a thread. However, a thread sometimes must be cut for which there is no quick-change gearbox setting. It is then necessary to modify the normal, or standard, gear ratio between the spindle and the gearbox by installing modifying change gears to replace the standard gears normally used. Metric and other odd pitch threads can be cut on lathes that have an inch thread lead screw and a quick-change gearbox having only settings for inch threads by using modifying-change gears in the gear train. Likewise, inch threads and other odd pitch threads can be cut on metric lead-screw lathes having a gearbox on which only metric thread settings can be made. Modifying-change gears also can be used for cutting odd pitch threads on lathes having a quick-change gearbox that has both inch and metric thread settings.

The sizes of the modifying-change gears can be calculated by formulas to be given later; they depend on the thread to be cut and on the setting of the quick-change gearbox. Many different sets of gears can be found for each thread to be cut. It is recommended that several calculations be made in order to find the set of gears that is most suitable for installation on the lathe. The modifying-change gear formulas that follow are based on the type of lead screw, i.e., whether the lead screw has inch or metric threads.

*Metric Threads on Inch Lead-Screw Lathes:* A 127-tooth translating gear must be used in the modifying-change gear train in order to be able to cut metric threads on inch lead-screw lathes. The formula for calculating the modifying change gears is:

$$\frac{5 \times \text{gearbox setting in thds/in.} \times \text{pitch in mm to be cut}}{127} = \frac{\text{driving gears}}{\text{driven gears}}$$

The numerator and denominator of this formula are multiplied by equal numbers, called trial numbers, to find the gears. If suitable gears cannot be found with one set, then another set of equal trial numbers is used. (Because these numbers are equal, such as 15/15 or 24/24, they are equal to the number one when thought of as a fraction; their inclusion has the effect of multiplying the formula by one, which does not change its value.) It is necessary to select the gearbox setting in threads per inch that must be used to cut the metric thread when using the gears calculated by the formula. One method is to select a quick-change gearbox setting that is close to the actual number of metric threads in a 1-inch length, called the equivalent threads per inch, which can be calculated by the following formula: Equivalent thds/in. =  $25.4 \div$  pitch in millimeters to be cut.

*Example:* Select the quick-change gearbox setting and calculate the modifying change gears required to set up a lathe having an inch-thread lead screw in order to cut an M12  $\times$  1.75 metric thread.

$$\begin{aligned} \text{Equivalent thds/in.} &= \frac{25.4}{\text{pitch in mm to be cut}} = \frac{25.4}{1.75} = 1.45 \text{ (use 14 thds/in.)} \\ \frac{5 \times \text{gearbox setting in thds/in.} \times \text{pitch in mm to be cut}}{127} &= \frac{5 \times 14 \times 1.75}{127} \\ &= \frac{(24) \times 5 \times 14 \times 1.75}{(24) \times 127} = \frac{(5 \times 14) \times (24 \times 1.75)}{24 \times 127} \\ &= \frac{70 \times 42}{24 \times 127} = \frac{\text{driving gears}}{\text{driven gears}} \end{aligned}$$

*Odd Inch Pitch Threads:* The calculation of the modifying change gears used for cutting odd pitch threads that are specified by their pitch in inches involves the sizes of the standard gears, which can be found by counting their teeth. Standard gears are those used to enable the lathe to cut the thread for which the gearbox setting is made; they are the gears that are normally used. The threads on worms used with worm gears are among the odd pitch threads that can be cut by this method. As before, it is usually advisable to calculate the actual number of threads per inch of the odd pitch thread and to select a gearbox setting that is close to this value. The following formula is used to calculate the modifying-change gears to cut odd inch pitch threads:

$$\begin{aligned} \frac{\text{Standard driving gear} \times \text{pitch to be cut in inches} \times \text{gearbox setting in thds/in.}}{\text{Standard driven gear}} \\ = \frac{\text{driving gears}}{\text{driven gears}} \end{aligned}$$

*Example:* Select the quick-change gearbox setting and calculate the modifying change gears required to cut a thread having a pitch equal to 0.195 inch. The standard driving and driven gears both have 48 teeth. To find equivalent threads per inch:

$$\frac{\text{Thds}}{\text{in.}} = \frac{1}{\text{pitch}} = \frac{1}{0.195} = 5.13 \quad (\text{use 5 thds/in.})$$

$$\begin{aligned} \frac{\text{Standard driving gear} \times \text{pitch to be cut in inches} \times \text{gearbox setting in thds/in.}}{\text{Standard driven gear}} \\ = \frac{48 \times 0.195 \times 5}{48} = \frac{(1000) \times 0.195 \times 5}{(1000)} = \frac{195 \times 5}{500 \times 2} = \frac{39 \times 5}{100 \times 2} = \frac{39 \times 5 \times (8)}{50 \times 2 \times 2 \times (8)} \\ = \frac{39 \times 40}{50 \times 32} = \frac{\text{driving gears}}{\text{driven gears}} \end{aligned}$$

It will be noted that in the second step above, 1000/1000 has been substituted for 48/48. This substitution does not change the ratio. The reason for this substitution is that  $1000 \times 0.195 = 195$ , a whole number. Actually,  $200/200$  might have been substituted because  $200 \times 0.195 = 39$ , also a whole number.

The procedure for calculating the modifying gears using the following formulas is the same as illustrated by the two previous examples.

*Odd Threads per Inch on Inch Lead Screw Lathes:*

$$\frac{\text{Standard driving gear} \times \text{gearbox setting in thds/in.}}{\text{Standard driven gear} \times \text{thds/in. to be cut}} = \frac{\text{driving gears}}{\text{driven gears}}$$

## THREAD CUTTING

*Inch Threads on Metric Lead Screw Lathes:*

$$\frac{127}{5 \times \text{gearbox setting in mm pitch} \times \text{thds/in. to be cut}} = \frac{\text{driving gears}}{\text{driven gears}}$$

*Odd Metric Pitch Threads on Metric Lead Screw Lathes:*

$$\frac{\text{Standard driving gear} \times \text{mm pitch to be cut}}{\text{Standard driven gear} \times \text{gearbox setting in mm pitch}} = \frac{\text{driving gears}}{\text{driven gears}}$$

**Finding Accurate Gear Ratios.**—Tables included in the 23rd and earlier editions of this handbook furnished a series of logarithms of gear ratios as a quick means of finding ratios for all gear combinations having 15 to 120 teeth. The ratios thus determined could be factored into sets of 2, 4, 6, or any other even numbers of gears to provide a desired overall ratio.

Although the method of using logarithms of gear ratios provides results of suitable accuracy for many gear-ratio problems, it does not provide a systematic means of evaluating whether other, more accurate ratios are available. In critical applications, especially in the design of mechanisms using reduction gear trains, it may be desirable to find many or all possible ratios to meet a specified accuracy requirement. The methods best suited to such problems use *Continued Fractions* and *Conjugate Fractions* as explained starting on pages 11 and illustrated in the worked-out example on page 13 for a set of four change gears.

As an example, if an overall reduction of 0.31416 is required, a fraction must be found such that the factors of the numerator and denominator may be used to form a four-gear reduction train in which no gear has more than 120 teeth. By using the method of conjugate fractions discussed on page 12, the ratios listed above, and their factors are found to be successively closer approximations to the required overall gear ratio.

| Ratio      | Numerator Factors     | Denominator               | Error Factors |
|------------|-----------------------|---------------------------|---------------|
| 11/35      | 11                    | 5 × 7                     | +0.00013      |
| 16/51      | 2 × 2 × 2 × 2         | 3 × 17                    | -0.00043      |
| 27/86      | 3 × 3 × 3             | 2 × 43                    | -0.00021      |
| 38/121     | 2 × 19                | 11 × 11                   | -0.00011      |
| 49/156     | 7 × 7                 | 2 × 2 × 3 × 13            | -0.00006      |
| 82/261     | 2 × 41                | 3 × 3 × 29                | +0.00002      |
| 224/713    | 2 × 2 × 2 × 2 × 2 × 7 | 23 × 31                   | +0.000005     |
| 437/1391   | 19 × 23               | 13 × 107                  | +0.000002     |
| 721/2295   | 7 × 103               | 3 × 3 × 3 × 5 × 17        | +0.000001     |
| 1360/4329  | 2 × 2 × 2 × 2395 × 17 | 3 × 3 × 13 × 53           | +0.0000003    |
| 1715/5459  | 5 × 7 × 7 × 7         | 53 × 103                  | +0.0000001    |
| 3927/12500 | 3 × 7 × 11 × 17       | 2 × 2 × 5 × 5 × 5 × 5 × 5 | 0             |

**Lathe Change-gears.**—To calculate the change gears to cut any pitch on a lathe, the “constant” of the machine must be known. For any lathe, the ratio  $C:L = \text{driver}:\text{driven gear}$ , in which  $C = \text{constant of machine}$  and  $L = \text{threads per inch}$ .

For example, to find the change gears required to cut 1.7345 threads per inch on a lathe having a constant of 4, the formula:

$$\frac{C}{L} = \frac{4}{1.7345} = 2.306140$$

may be used. The method of conjugate fractions shown on page 12 will find the ratio,  $113/49 = 2.306122$ , which is closer than any other having suitable factors. This ratio is in error by only  $2.306140 - 2.306122 = 0.000018$ . Therefore, the driver should have 113 teeth and the driven gear 49 teeth.

**Relieving Helical-Fluted Hobs.**—Relieving hobs that have been fluted at right angles to the thread is another example of approximating a required change-gear ratio. The usual method is to change the angle of the helical flutes to agree with previously calculated change-gears. The ratio between the hob and the relieving attachment is expressed in the formula:

$$\frac{N}{(C \times \cos^2 \alpha)} = \frac{\text{driver}}{\text{driven}} \text{ gears}$$

and

$$\tan \alpha = \frac{P}{H_c}$$

in which:  $N$  = number of flutes in hob;  $\alpha$  = helix angle of thread from plane perpendicular to axis;  $C$  = constant of relieving attachment;  $P$  = axial lead of hob; and  $H_c$  = hob pitch circumference, = 3.1416 times pitch diameter.

The constant of the relieving attachment is found on its index plate and is determined by the number of flutes that require equal gears on the change-gear studs. These values will vary with different makes of lathes.

For example, what four change-gears can be used to relieve a helical-fluted worm-gear hob, of 24 diametral pitch, six starts, 13 degrees, 41 minutes helix angle of thread, with eleven helical flutes, assuming a relieving attachment having a constant of 4 is to be used?

$$\frac{N}{(C \times \cos^2 \alpha)} = \frac{11}{(4 \times \cos^2 13^\circ 41')} = \frac{11}{(4 \times 0.944045)} = 2.913136$$

Using the conjugate fractions method discussed on page 12, the following ratios are found to provide factors that are successively closer approximations to the required change-gear ratio 2.913136.

| <i>Numerator/Denominator</i>    | <i>Ratio</i> | <i>Error</i> |
|---------------------------------|--------------|--------------|
| $67 \times 78 / (39 \times 46)$ | 2.913043     | -0.000093    |
| $30 \times 47 / (22 \times 22)$ | 2.913223     | +0.000087    |
| $80 \times 26 / (21 \times 34)$ | 2.913165     | +0.000029    |
| $27 \times 82 / (20 \times 38)$ | 2.913158     | +0.000021    |
| $55 \times 75 / (24 \times 59)$ | 2.913136     | +0.0000004   |
| $74 \times 92 / (57 \times 41)$ | 2.913136     | +0.00000005  |

**THREAD ROLLING**

Screw threads may be formed by rolling either by using some type of thread-rolling machine or by equipping an automatic screw machine or turret lathe with a suitable threading roll. If a thread-rolling machine is used, the unthreaded screw, bolt, or other "blank" is placed (either automatically or by hand) between dies having thread-shaped ridges that sink into the blank, and by displacing the metal, form a thread of the required shape and pitch. The thread-rolling process is applied where bolts, screws, studs, threaded rods, etc., are required in large quantities. Screw threads that are within the range of the rolling process may be produced more rapidly by this method than in any other way. Because of the cold-working action of the dies, the rolled thread is 10 to 20 per cent stronger than a cut or ground thread, and the increase may be much higher for fatigue resistance. Other advantages of the rolling process are that no stock is wasted in forming the thread, and the surface of a rolled thread is harder than that of a cut thread, thus increasing wear resistance.

**Thread-Rolling Machine of Flat-Die Type.**—One type of machine that is used extensively for thread rolling is equipped with a pair of flat or straight dies. One die is stationary and the other has a reciprocating movement when the machine is in use. The ridges on these dies, which form the screw thread, incline at an angle equal to the helix angle of the thread. In making dies for precision thread rolling, the threads may be formed either by milling and grinding after heat treatment, or by grinding "from the solid" after heat treating. A vitrified wheel is used.

In a thread-rolling machine, thread is formed in one passage of the work, which is inserted at one end of the dies, either by hand or automatically, and then rolls between the die faces until it is ejected at the opposite end. The relation between the position of the dies and a screw thread being rolled is such that the top of the thread-shaped ridge of one die, at the point of contact with the screw thread, is directly opposite the bottom of the thread groove in the other die at the point of contact. Some form of mechanism ensures starting the blank at the right time and square with the dies.

**Thread-Rolling Machine of Cylindrical-Die Type.**—With machines of this type, the blank is threaded while being rolled between two or three cylindrical dies (depending upon the type of machine) that are pressed into the blank at a rate of penetration adjusted to the hardness of the material, or wall thickness in threading operations on tubing or hollow parts. The dies have ground, or ground and lapped, threads and a pitch diameter that is a multiple of the pitch diameter of the thread to be rolled. As the dies are much larger in diameter than the work, a multiple thread is required to obtain the same lead angle as that of the work. The thread may be formed in one die revolution or even less, or several revolutions may be required (as in rolling hard materials) to obtain a gradual rate of penetration equivalent to that obtained with flat or straight dies if extended to a length of possibly 15 or 20 feet. Provisions for accurately adjusting or matching the thread rolls to bring them into proper alignment with each other are important features of these machines.

*Two-Roll Type of Machine:* With a two-roll type of machine, the work is rotated between two horizontal power-driven threading rolls and is supported by a hardened rest bar on the lower side. One roll is fed inward by hydraulic pressure to a depth that is governed automatically.

*Three-Roll Type of Machine:* With this machine, the blank to be threaded is held in a "floating position" while being rolled between three cylindrical dies that, through toggle arms, are moved inward at a predetermined rate of penetration until the required pitch diameter is obtained. The die movement is governed by a cam driven through change gears selected to give the required cycle of squeeze, dwell, and release.

**Rate of Production.**—Production rates in thread rolling depend upon the type of machine, the size of both machine and work, and whether the parts to be threaded are inserted by hand or automatically. A reciprocating flat die type of machine, applied to ordinary steels, may thread 30 or 40 parts per minute in diameters ranging from about  $\frac{3}{8}$  to  $1\frac{1}{8}$

inch, and 150 to 175 per minute in machine screw sizes from No. 10 (.190) to No. 6 (.138). In the case of heat-treated alloy steels in the usual hardness range of 26 to 32 Rockwell C, the production may be 30 or 40 per minute or less. With a cylindrical die type of machine, which is designed primarily for precision work and hard metals, 10 to 30 parts per minute are common production rates, the amount depending upon the hardness of material and allowable rate of die penetration per work revolution. These production rates are intended as a general guide only. The diameters of rolled threads usually range from the smallest machine screw sizes up to 1 or 1½ inches, depending upon the type and size of machine.

**Precision Thread Rolling.**—Both flat and cylindrical dies are used in aeronautical and other plants for precision work. With accurate dies and blank diameters held to close limits, it is practicable to produce rolled threads for American Standard Class 3 and Class 4 fits. The blank sizing may be by centerless grinding or by means of a die in conjunction with the heading operations. The blank should be round, and, as a general rule, the diameter tolerance should not exceed ½ to ⅔ the pitch diameter tolerance. The blank diameter should range from the correct size (which is close to the pitch diameter, but should be determined by actual trial), down to the allowable minimum, the tolerance being minus to insure a correct pitch diameter, even though the major diameter may vary slightly. Precision thread rolling has become an important method of threading alloy steel studs and other threaded parts, especially in aeronautical work where precision and high-fatigue resistance are required. Micrometer screws are also an outstanding example of precision thread rolling. This process has also been applied in tap making, although it is the general practice to finish rolled taps by grinding when the Class 3 and Class 4 fits are required.

**Steels for Thread Rolling.**—Steels vary from soft low-carbon types for ordinary screws and bolts, to nickel, nickel-chromium and molybdenum steels for aircraft studs, bolts, etc., or for any work requiring exceptional strength and fatigue resistance. Typical SAE alloy steels are No. 2330, 3135, 3140, 4027, 4042, 4640 and 6160. The hardness of these steels after heat-treatment usually ranges from 26 to 32 Rockwell C, with tensile strengths varying from 130,000 to 150,000 pounds per square inch. While harder materials might be rolled, grinding is more practicable when the hardness exceeds 40 Rockwell C. Thread rolling is applicable not only to a wide range of steels but for non-ferrous materials, especially if there is difficulty in cutting due to "tearing" the threads.

**Diameter of Blank for Thread Rolling.**—The diameter of the screw blank or cylindrical part upon which a thread is to be rolled should be less than the outside screw diameter by an amount that will just compensate for the metal that is displaced and raised above the original surface by the rolling process. The increase in diameter is approximately equal to the depth of one thread. While there are rules and formulas for determining blank diameters, it may be necessary to make slight changes in the calculated size in order to secure a well-formed thread. The blank diameter should be verified by trial, especially when rolling accurate screw threads. Some stock offers greater resistance to displacement than other stock, owing to the greater hardness or tenacity of the metal. The following figures may prove useful in establishing trial sizes. The blank diameters for screws varying from ¼ to ½ are from 0.002 to 0.0025 inch larger than the pitch diameter, and for screws varying from ½ to 1 inch or larger, the blank diameters are from 0.0025 to .003 inch larger than the pitch diameter. Blanks which are slightly less than the pitch diameter are intended for bolts, screws, etc., which are to have a comparatively free fit. Blanks for this class of work may vary from 0.002 to 0.003 inch less than the pitch diameter for screw thread sizes varying from ¼ to ½ inch, and from 0.003 to 0.005 inch less than the pitch diameter for sizes above ½ inch. If the screw threads are smaller than ¼ inch, the blanks are usually from 0.001 to 0.0015 inch less than the pitch diameter for ordinary grades of work.

**Thread Rolling in Automatic Screw Machines.**—Screw threads are sometimes rolled in automatic screw machines and turret lathes when the thread is behind a shoulder so that

it cannot be cut with a die. In such cases, the advantage of rolling the thread is that a second operation is avoided. A circular roll is used for rolling threads in screw machines. The roll may be presented to the work either in a tangential direction or radially, either method producing a satisfactory thread. In the former case, the roll gradually comes into contact with the periphery of the work and completes the thread as it passes across the surface to be threaded. When the roll is held in a radial position, it is simply forced against one side until a complete thread is formed. The method of applying the roll may depend upon the relation between the threading operation and other machining operations. Thread rolling in automatic screw machines is generally applied only to brass and other relatively soft metals, owing to the difficulty of rolling threads in steel. Thread rolls made of chrome-nickel steel containing from 0.15 to 0.20 per cent of carbon have given fairly good results, however, when applied to steel. A 3 per cent nickel steel containing about 0.12 per cent carbon has also proved satisfactory for threading brass.

**Factors Governing the Diameter of Thread Rolling.**—The threading roll used in screw machines may be about the same diameter as the screw thread, but for sizes smaller than, say,  $\frac{3}{4}$  inch, the roll diameter is some multiple of the thread diameter minus a slight amount to obtain a better rolling action. When the diameters of the thread and roll are practically the same, a single-threaded roll is used to form a single thread on the screw. If the diameter of the roll is made double that of the screw, in order to avoid using a small roll, then the roll must have a double thread. If the thread roll is three times the size of the screw thread, a triple thread is used, and so on. These multiple threads are necessary when the roll diameter is some multiple of the work, in order to obtain corresponding helix angles on the roll and work.

**Diameter of Threading Roll.**—The pitch diameter of a threading roll having a single thread is slightly less than the pitch diameter of the screw thread to be rolled, and in the case of multiple-thread rolls, the pitch diameter is not an exact multiple of the screw thread pitch diameter but is also reduced somewhat. The amount of reduction recommended by one screw machine manufacturer is given by the formula shown at the end of this paragraph. A description of the terms used in the formula is given as follows:  $D$  = pitch diameter of threading roll,  $d$  = pitch diameter of screw thread,  $N$  = number of single threads or "starts" on the roll (this number is selected with reference to diameter of roll desired),  $T$  = single depth of thread:

$$D = N\left(d - \frac{T}{2}\right) - T$$

*Example:* Find, by using above formula, the pitch diameter of a double-thread roll for rolling a  $\frac{1}{2}$ -inch American standard screw thread. Pitch diameter  $d = 0.4500$  inch and thread depth  $T = 0.0499$  inch.

$$D = 2\left(0.4500 - \frac{0.0499}{2}\right) - 0.0499 = 0.8001 \text{ inch}$$

**Kind of Thread on Roll and Its Shape.**—The thread (or threads) on the roll should be left hand for rolling a right-hand thread, and *vice versa*. The roll should be wide enough to overlap the part to be threaded, provided there are clearance spaces at the ends, which should be formed if possible. The thread on the roll should be sharp on top for rolling an American (National) standard form of thread, so that less pressure will be required to displace the metal when rolling the thread. The bottom of the thread groove on the roll may also be left sharp or it may have a flat. If the bottom is sharp, the roll is sunk only far enough into the blank to form a thread having a flat top, assuming that the thread is the American form. The number of threads on the roll (whether double, triple, quadruple, etc.) is selected, as a rule, so that the diameter of the thread roll will be somewhere between  $1\frac{1}{4}$  and  $2\frac{1}{4}$  inches. In making a thread roll, the ends are beveled at an angle of 45 degrees, to prevent

the threads on the ends of the roll from chipping. Precautions should be taken in hardening, because, if the sharp edges are burnt, the roll will be useless. Thread rolls are usually lapped after hardening, by holding them on an arbor in the lathe and using emery and oil on a piece of hard wood. To give good results a thread roll should fit closely in the holder. If the roll is made to fit loosely, it will mar the threads.

**Application of Thread Roll.**—The shape of the work and the character of the operations necessary to produce it, govern, to a large extent, the method employed in applying the thread roll. Some of the points to consider are as follows:

- 1) Diameter of the part to be threaded.
- 2) Location of the part to be threaded.
- 3) Length of the part to be threaded.
- 4) Relation that the thread rolling operation bears to the other operations.
- 5) Shape of the part to be threaded, whether straight, tapered or otherwise.
- 6) Method of applying the support.

When the diameter to be rolled is much smaller than the diameter of the shoulder preceding it, a cross-slide knurl-holder should be used. If the part to be threaded is not behind a shoulder, a holder on the swing principle should be used. When the work is long (greater in length than two-and-one-half times its diameter) a swing roll-holder should be employed, carrying a support. When the work can be cut off after the thread is rolled, a cross-slide roll-holder should be used. The method of applying the support to the work also governs to some extent the method of applying the thread roll. When no other tool is working at the same time as the thread roll, and when there is freedom from chips, the roll can be held more rigidly by passing it under instead of over the work. When passing the roll over the work, there is a tendency to raise the cross-slide. Where the part to be threaded is tapered, the roll can best be presented to the work by holding it in a cross-slide roll-holder.

**Speeds and Feeds for Thread Rolling.**—When the thread roll is made from high-carbon steel and used on brass, a surface speed as high as 200 feet per minute can be used. However, better results are obtained by using a lower speed than this. When the roll is held in a holder attached to the cross-slide, and is presented either tangentially or radially to the work, a considerably higher speed can be used than if it is held in a swing tool. This is due to the lack of rigidity in a holder of the swing type. The feeds to be used when a cross-slide roll-holder is used are given in the upper half of the table "Feeds for Thread Rolling;" the lower half of the table gives the feeds for thread rolling with swing tools. These feeds are applicable for rolling threads without a support, when the root diameter of the blank is not less than five times the double depth of the thread. When the root diameter is less than this, a support should be used. A support should also be used when the width of the roll is more than two-and-one-half times the smallest diameter of the piece to be rolled, irrespective of the pitch of the thread. When the smallest diameter of the piece to be rolled is much less than the root diameter of the thread, the smallest diameter should be taken as the deciding factor for the feed to be used.

## Feeds for Thread Rolling

| Root Diam.<br>of Blank | Number of Threads per Inch                          |        |        |        |        |        |        |        |        |        |        |        |        |        |
|------------------------|---|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|--------|
|                        | 72  | 64     | 56     | 48     | 44     | 40     | 36     | 32     | 28     | 24     | 22     | 20     | 18     | 14     |
|                        | Cross-slide Holders — Feed per Revolution in Inches |        |        |        |        |        |        |        |        |        |        |        |        |        |

## THREAD GRINDING

Thread grinding is employed for precision tool and gage work and also in producing certain classes of threaded parts.

Thread grinding may be utilized 1) because of the accuracy and finish obtained; 2) hardness of material to be threaded; and 3) economy in grinding certain classes of screw threads when using modern machines, wheels, and thread-grinding oils.

In some cases pre-cut threads are finished by grinding; but usually, threads are ground "from the solid," being formed entirely by the grinding process. Examples of work include thread gages and taps of steel and tungsten carbide, hobs, worms, lead-screws, adjusting or traversing screws, alloy steel studs, etc. Grinding is applied to external, internal, straight, and tapering threads, and to various thread forms.

**Accuracy Obtainable by Thread Grinding.**—With single-edge or single-ribbed wheels it is possible to grind threads on gages to a degree of accuracy that requires but very little lapping to produce a so-called "master" thread gage. As far as lead is concerned, some thread grinding machine manufacturers guarantee to hold the lead within 0.0001 inch per inch of thread; and while it is not guaranteed that a higher degree of accuracy for lead is obtainable, it is known that threads have been ground to closer tolerances than this on the lead. Pitch diameter accuracies for either Class 3 or Class 4 fits are obtainable according to the grinding method used; with single-edge wheels, the thread angle can be ground to an accuracy of within two or three minutes in half the angle.

**Wheels for Thread Grinding.**—The wheels used for steel have an aluminous abrasive and, ordinarily, either a resinoid bond or a vitrified bond. The general rule is to use resinoid wheels when extreme tolerances are not required, and it is desirable to form the thread with a minimum number of passes, as in grinding threaded machine parts, such as studs, adjusting screws which are not calibrated, and for some classes of taps. *Resinoid wheels*, as a rule, will hold a fine edge longer than a vitrified wheel but they are more flexible and, consequently, less suitable for accurate work, especially when there is lateral grinding pressure that causes wheel deflection. *Vitrified wheels* are utilized for obtaining extreme accuracy in thread form and lead because they are very rigid and not easily deflected by side pressure in grinding. This rigidity is especially important in grinding pre-cut threads on such work as gages, taps and lead-screws. The progressive lead errors in long lead-screws, for example, might cause an increasing lateral pressure that would deflect a resinoid wheel. Vitrified wheels are also recommended for internal grinding.

*Diamond Wheels:* Diamond wheels set in a rubber or plastic bond are also used for thread grinding, especially for grinding threads in carbide materials and in other hardened alloys. Thread grinding is now being done successfully on a commercial basis on both taps and gages made from carbides. Gear hobs made from carbides have also been tested with successful results. Diamond wheels are dressed by means of silicon-carbide grinding wheels which travel past the diamond-wheel thread form at the angle required for the flanks of the thread to be ground. The action of the dressing wheels is, perhaps, best described as a "scrubbing" of the bond which holds the diamond grits. Obviously, the silicon-carbide wheels do not dress the diamonds, but they loosen the bond until the diamonds not wanted drop out.

**Thread Grinding with Single-Edge Wheel.**—With this type of wheel, the edge is trued to the cross-sectional shape of the thread groove. The wheel, when new, may have a diameter of 18 or 20 inches and, when grinding a thread, the wheel is inclined to align it with the thread groove. On some machines, lead variations are obtained by means of change-gears which transmit motion from the work-driving spindle to the lead-screw. Other machines are so designed that a lead-screw is selected to suit the lead of thread to be ground and transmits motion directly to the work-driving spindle.

**Wheels with Edges for Roughing and Finishing.**—The “three-ribbed” type of wheel has a roughing edge or rib which removes about two-thirds of the metal. This is followed by an intermediate rib which leaves about 0.005 inch for the third or finishing rib. The accuracy obtained with this triple-edge type compares with that of a single-edge wheel, which means that it may be used for the greatest accuracy obtainable in thread grinding.

When the accuracy required makes it necessary, this wheel can be inclined to the helix angle of the thread, the same as is the single-edge wheel.

The three-ribbed wheel is recommended not only for precision work but for grinding threads which are too long for the multi-ribbed wheel referred to later. It is also well adapted to tap grinding, because it is possible to dress a portion of the wheel adjacent to the finish rib for the purpose of grinding the outside diameter of the thread, as indicated in Fig. 1. Furthermore, the wheel can be dressed for grinding or relieving both crests and flanks at the same time.

Fig. 1. Wheel with Edges for Roughing and Finishing

Fig. 2. Multi-ribbed Type of Thread-grinding Wheel

Fig. 3. Alternate-ribbed Wheel for Grinding the Finer Pitches

**Multi-ribbed Wheels.**—This type of wheel is employed when rapid production is more important than extreme accuracy, which means that it is intended primarily for the grinding of duplicate parts in manufacturing. A wheel  $1\frac{1}{4}$  to 2 inches wide has formed upon its face a series of annular thread-shaped ridges (see Fig. 2); hence, if the length of the thread is not greater than the wheel width, a thread may be ground in one work revolution plus about one-half revolution for feeding in and withdrawing the wheel. The principle of operation is the same as that of thread milling with a multiple type cutter. This type of wheel is not inclined to the lead angle. To obtain a Class 3 fit, the lead angle should not exceed 4 degrees.

It is not practicable to use this form of wheel on thread pitches where the root is less than 0.007 inch wide, because of difficulties in wheel dressing. When this method can be applied, it is the fastest means known of producing threads in hardened materials. It is not recommended, however, that thread gages, taps, and work of this character be ground with multi-ribbed wheels. The single-ribbed wheel has a definite field for accurate, small-lot production.

It is necessary, in multi-ribbed grinding, to use more horsepower than is required for single-ribbed wheel grinding. Coarse threads, in particular, may require a wheel motor with two or three times more horsepower than would be necessary for grinding with a single-ribbed wheel.

**Alternate-ribbed Wheel for Fine Pitches.**—The spacing of ribs on this type of wheel (Fig. 3) equals twice the pitch, so that during the first revolution every other thread groove section is being ground; consequently, about two and one-half work revolutions are required for grinding a complete thread, but the better distribution of cooling oil and resulting increase in work speeds makes this wheel very efficient. This alternate-type of wheel is adapted for grinding threads of fine pitch. Since these wheels cannot be tipped to the helix angle of the thread, they are not recommended for anything closer than Class 3 fits. The “three-ribbed” wheels referred to in a previous paragraph are also made in the alternate type for the finer pitches.

**Grinding Threads “from the Solid.”**—The process of forming threads entirely by grinding, or without preliminary cutting, is applied both in the manufacture of certain classes of threaded parts and also in the production of precision tools, such as taps and thread gages. For example, in airplane engine manufacture, certain parts are heat-treated and then the threads are ground “from the solid,” thus eliminating distortion. Minute cracks are sometimes found at the roots of threads that were cut and then hardened, or ground from the solid. Steel threads of coarse pitch that are to be surface hardened, may be rough threaded by cutting, then hardened and finally corrected by grinding. Many ground thread taps are produced by grinding from the solid after heat-treatment. Hardening high-speed steel taps before the thread is formed will make sure there are no narrow or delicate crests to interfere with the application of the high temperature required for uniform hardness and the best steel structure.

**Number of Wheel Passes.**—The number of cuts or passes for grinding from the solid depends upon the type of wheel and accuracy required. In general, threads of 12 or 14 per inch and finer may be ground in one pass of a single-edge wheel unless the “unwrapped” thread length is much greater than normal. Unwrapped length = pitch circumference  $\times$  total number of thread turns, approximately. For example, a thread gage  $1\frac{1}{4}$  inches long with 24 threads per inch would have an unwrapped length equal to  $30 \times$  pitch circumference. (If more convenient, outside circumference may be used instead of pitch circumference.) Assume that there are 6 or 7 feet of unwrapped length on a screw thread having 12 threads per inch. In this case, one pass might be sufficient for a Class 3 fit, whereas two passes might be recommended for a Class 4 fit. When two passes are required, too deep a roughing cut may break down the narrow edge of the wheel. To prevent this, try a roughing cut depth equal to about two-thirds the total thread depth, thus leaving one-third for the finishing cut.

**Wheel and Work Rotation.**—When a screw thread, on the side being ground, is moving *upward* or *against* the grinding wheel rotation, less heat is generated and the grinding operation is more efficient than when wheel and work are moving in the same direction on the grinding side; however, to avoid running a machine idle during its return stroke, many screw threads are ground during both the forward and return traversing movements, by reversing the work rotation at the end of the forward stroke. For this reason, thread grinders generally are equipped so that both forward and return work speeds may be changed; they may also be designed to accelerate the return movement when grinding in one direction only.

**Wheel Speeds.**—Wheel speeds should always be limited to the maximum specified on the wheel by the manufacturer. According to the American National Standard Safety Code, resinoid and vitrified wheels are limited to 12,000 surface feet per minute; however, according to Norton Co., the most efficient speeds are from 9,000 to 10,000 for resinoid wheels and 7,500 to 9,500 for vitrified wheels. Only tested wheels recommended by the wheel manufacturer should be used. After a suitable surface speed has been established, it should be maintained by increasing the rpm of the wheel, as the latter is reduced in diameter by wear.

Since thread grinding wheels work close to the limit of their stock-removing capacity, some adjustment of the wheel or work speed may be required to get the best results. If the wheel speed is too slow for a given job and excessive heat is generated, try an increase in speed, assuming that such increase is within the safety limits. If the wheel is too soft and the edge wears excessively, again an increase in wheel speed will give the effect of a harder wheel and result in better form-retaining qualities.

**Work Speeds.**—The work speed usually ranges from 3 to 10 feet per minute. In grinding with a comparatively heavy feed, and a minimum number of passes, the speed may not exceed  $2\frac{1}{2}$  or 3 feet per minute. If very light feeds are employed, as in grinding hardened high-speed steel, the work speed may be much higher than 3 feet per minute and should be determined by test. If excessive heat is generated by removing stock too rapidly, a work speed reduction is one remedy. If a wheel is working below its normal capacity, an increase in work speed would prevent dulling of the grains and reduce the tendency to heat or "burn" the work. An increase in work speed and reduction in feed may also be employed to prevent burning while grinding hardened steel.

**Truing Grinding Wheels.**—Thread grinding wheels are trued both to maintain the required thread form and also an efficient grinding surface. Thread grinders ordinarily are equipped with precision truing devices which function automatically. One type automatically dresses the wheel and also compensates for the slight amount removed in dressing, thus automatically maintaining size control of the work. While truing the wheel, a small amount of grinding oil should be used to reduce diamond wear. Light truing cuts are advisable, especially in truing resinoid wheels which may be deflected by excessive truing pressure. A master former for controlling the path followed by the truing diamond may require a modified profile to prevent distortion of the thread form, especially when the lead angles are comparatively large. Such modification usually is not required for 60-degree threads when the pitches for a given diameter are standard because then the resulting lead angles are less than  $4\frac{1}{2}$  degrees. In grinding Acme threads or 29-degree worm threads having lead angles greater than 4 or 5 degrees, modified formers may be required to prevent a bulge in the thread profile. The highest point of this bulge is approximately at the pitch line. A bulge of about 0.001 inch may be within allowable limits on some commercial worms but precision worms for gear hobbers, etc., require straight flanks in the axial plane.

*Crushing Method:* Thread grinding wheels are also dressed or formed by the crushing method, which is used in connection with some types of thread grinding machines. When this method is used, the annular ridge or ridges on the wheel are formed by a hardened steel cylindrical dresser or crusher. The crusher has a series of smooth annular ridges which are shaped and spaced like the thread that is to be ground. During the wheel dressing operation, the crusher is positively driven instead of the grinding wheel, and the ridges on the wheel face are formed by the rotating crusher being forced inward.

**Wheel Hardness or Grade.**—Wheel hardness or grade selection is based upon a compromise between efficient cutting and durability of the grinding edge. Grade selection depends on the bond and the character of the work. The following general recommendations are based upon Norton grading.

Vitrified wheels usually range from J to M, and resinoid wheels from R to U. For heat-treated screws or studs and the Unified Standard Thread, try the following. For 8 to 12

threads per inch, grade S resinoid wheel; for 14 to 20 threads per inch, grade T resinoid; for 24 threads per inch and finer, grades T or U resinoid. For high-speed steel taps 4 to 12 threads per inch, grade J vitrified or S resinoid; 14 to 20 threads per inch, grade K vitrified or T resinoid; 24 to 36 threads per inch, grade M vitrified or T resinoid.

**Grain Size.**—A thread grinding wheel usually operates close to its maximum stock-removing capacity, and the narrow edge which forms the root of the thread is the most vulnerable part. In grain selection, the general rule is to use the coarsest grained wheel that will hold its form while grinding a reasonable amount of work. Pitch of thread and quality of finish are two governing factors. Thus, to obtain an exceptionally fine finish, the grain size might be smaller than is needed to retain the edge profile. The usual grain sizes range from 120 to 150. For heat-treated screws and studs with Unified Standard Threads, 100 to 180 is the usual range. For precision screw threads of very fine pitch, the grain size may range from 220 to 320. For high-speed steel taps, the usual range is from 150 to 180 for Unified Standard Threads, and from 80 to 150 for pre-cut Acme threads.

**Thread Grinding by Centerless Method.**—Screw threads may be ground from the solid by the centerless method. A centerless thread grinder is similar in its operating principle to a centerless grinder designed for general work, in that it has a grinding wheel, a regulating or feed wheel (with speed adjustments), and a work-rest. Adjustments are provided to accommodate work of different sizes and for varying the rates of feed. The grinding wheel is a multi-ribbed type, being a series of annular ridges across the face. These ridges conform in pitch and profile with the thread to be ground. The grinding wheel is inclined to suit the helix or lead angle of the thread. In grinding threads on such work as socket type set-screws, the blanks are fed automatically and passed between the grinding and regulating wheels in a continuous stream. To illustrate production possibilities, hardened socket set-screws of  $\frac{1}{4}$  20 size may be ground from the solid at the rate of 60 to 70 per minute and with the wheel operating continuously for 8 hours without redressing. The lead errors of centerless ground screw threads may be limited to 0.0005 inch per inch or even less by reducing the production rate. The pitch diameter tolerances are within 0.0002 to 0.0003 inch of the basic size. The grain size for the wheel is selected with reference to the pitch of the thread, the following sizes being recommended: For 11 to 13 threads per inch, 150; for 16 threads per inch, 180; for 18 to 20 threads per inch, 220; for 24 to 28 threads per inch, 320; for 40 threads per inch, 400.

**THREAD MILLING**

**Single-cutter Method.**—Usually, when a single point cutter is used, the axis of the cutter is inclined an amount equal to the lead angle of the screw thread, in order to locate the cutter in line with the thread groove at the point where the cutting action takes place. Tangent of lead angle = lead of screw thread ÷ pitch circumference of screw.

The helical thread groove is generated by making as many turns around the workpiece diameter as there are pitches in the length of thread to be cut. For example, a 16-pitch thread, 1 inch long, would require 16 turns of the cutter around the work. The single cutter process is especially applicable to the milling of large screw threads of coarse pitch, and either single or multiple threads.

The cutter should revolve as fast as possible without dulling the cutting edges excessively, in order to mill a smooth thread and prevent the unevenness that would result with a slow-moving cutter, on account of the tooth spaces. As the cutter rotates, the part on which a thread is to be milled is also revolved, but at a very slow rate (a few inches per minute), since this rotation of the work is practically a feeding movement. The cutter is ordinarily set to the full depth of the thread groove and finishes a single thread in one passage, although deep threads of coarse pitch may require two or even three cuts. For fine pitches and short threads, the multiple-cutter method (described in the next paragraph) usually is preferable, because it is more rapid. The milling of taper screw threads may be done on a single-cutter type of machine by traversing the cutter laterally as it feeds along in a lengthwise direction, the same as when using a taper attachment on a lathe.

**Multiple-cutter Method.**—The multiple cutter for thread milling is practically a series of single cutters, although formed of one solid piece of steel, at least so far as the cutter proper is concerned. The rows of teeth do not lie in a helical path, like the teeth of a hob or tap, but they are annular or without lead. If the cutter had helical teeth the same as a gear hob, it would have to be geared to revolve in a certain fixed ratio with the screw being milled, but a cutter having annular teeth may rotate at any desired cutting speed, while the screw blank is rotated slowly to provide a suitable rate of feed. (The multiple thread milling cutters used are frequently called "hobs," but the term hob should be applied only to cutters having a helical row of teeth like a gear-cutting hob.)

The object in using a multiple cutter instead of a single cutter is to finish a screw thread complete in approximately one revolution of the work, a slight amount of over-travel being allowed to insure milling the thread to the full depth where the end of cut joins the starting point. The cutter which is at least one and one half or two threads or pitches wider than the thread to be milled, is fed in to the full thread depth and then either the cutter or screw blank is moved in a lengthwise direction a distance equal to the lead of the thread during one revolution of the work.

The multiple cutter is used for milling comparatively short threads and coarse, medium or fine pitches. The accompanying illustration shows typical examples of external and internal work for which the multiple-cutter type of thread milling has proved very efficient, although its usefulness is not confined to shoulder work and "blind" holes.

In using multiple cutters either for internal or external thread milling, the axis of the cutter is set parallel with the axis of the work, instead of inclining the cutter to suit the lead angle of the thread, as when using a single cutter. Theoretically, this is not the correct position for a cutter, since each cutting edge is revolving in a plane at right angles to the screw's axis while milling a thread groove of helical form. However, as a general rule, interference between the cutter and the thread, does not result a decided change in the standard thread form.

Usually the deviation is very slight and may be disregarded except when milling threads which incline considerably relative to the axis like a thread of multiple form and large lead angle. Multiple cutters are suitable for external threads having lead angles under  $3\frac{1}{2}$

degrees and for internal threads having lead angles under  $2\frac{1}{2}$  degrees. Threads which have steeper sides or smaller included angles than the American Standard or Whitworth forms have greater limitations on the maximum helix angle and may have to be milled with a single point cutter tilted to the helix angle, assuming that the milling process is preferable to other methods. For instance, in milling an Acme thread which has an included angle between the sides of 29 degrees, there might be considerable interference if a multiple cutter were used, unless the screw thread diameter were large enough in proportion to the pitch to prevent such interference. If an attempt were made to mill a square thread with a multiple cutter, the results would be unsatisfactory owing to the interference.

Examples of External and Internal Thread Milling  
with a Multiple Thread Milling Cutter

Interference between the cutter and work is more pronounced when milling internal threads, because the cutter does not clear itself so well. It is preferable to use as small a cutter as practicable, either for internal or external work, not only to avoid interference, but to reduce the strain on the driving mechanism. Some thread milling cutters, known as "topping cutters," are made for milling the outside diameter of the thread as well as the angular sides and root, but most are made non-tapping.

**Planetary Method.**—The planetary method of thread milling is similar in principle to planetary milling. The part to be threaded is held stationary and the thread milling cutter, while revolving about its own axis, is given a planetary movement around the work in order to mill the thread in one planetary revolution. The machine spindle and the cutter which is held by it is moved longitudinally for thread milling, an amount equal to the thread lead during one planetary revolution. This operation is applicable to both internal and external threads. Other advantages: Thread milling is frequently accompanied by milling operations on other adjoining surfaces, and may be performed with conventional and planetary methods. For example, a machine may be used for milling a screw thread and a concentric cylindrical surface simultaneously. When the milling operation begins, the cutter-spindle feeds the cutter in to the right depth and the planetary movement then begins, thus milling the thread and the cylindrical surface. Thin sharp starting edges are eliminated on threads milled by this method and the thread begins with a smooth gradual approach. One design of machine will mill internal and external threads simultaneously. These threads may be of the same hand or one may be right hand and the other left hand. The threads may also be either of the same pitch or of a different pitch, and either straight or tapered.

**Classes of Work for Thread Milling Machines.**—Thread milling machines are used in preference to lathes or taps and dies for certain threading operations.

There are four general reasons why a thread milling machine may be preferred: 1) Because the pitch of the thread is too coarse for cutting with a die; 2) because the milling process is more efficient than using a single-point tool in a lathe; 3) to secure a smoother and more accurate thread than would be obtained with a tap or die; and 4) because the thread is so located relative to a shoulder or other surface that the milling method is superior, if not the only practicable way.

A thread milling machine having a single cutter is especially adapted for coarse pitches, multiple-threaded screws, or any form or size of thread requiring the removal of a relatively large amount of metal, particularly if the pitch of the thread is large in proportion to the screw diameter, since the torsional strain due to the milling process is relatively small. Thread milling often gives a higher rate of production, and a thread is usually finished by means of a single turn of the multiple thread milling cutter around the thread diameter. The multiple-cutter type of thread milling machine frequently comes into competition with dies and taps, and especially self-opening dies and collapsing taps. The use of a multiple cutter is desirable when a thread must be cut close to a shoulder or to the bottom of a shallow recess, although the usefulness of the multiple cutter is not confined to shoulder work and "blind" holes.

**Maximum Pitches of Die-cut Threads.**—Dies of special design could be constructed for practically any pitch, if the screw blank were strong enough to resist the cutting strains and the size and cost of the die were immaterial; but, as a general rule, when the pitch is coarser than four or five threads per inch, the difficulty of cutting threads with dies increases rapidly, although in a few cases some dies are used successfully on screw threads having two or three threads per inch or less. Much depends upon the design of the die, the finish or smoothness required, and the relation between the pitch of the thread and the diameter of the screw. When the screw diameter is relatively small in proportion to the pitch, there may be considerable distortion due to the twisting strains set up when the thread is being cut. If the number of threads per inch is only one or two less than the standard number for a given diameter, a screw blank ordinarily will be strong enough to permit the use of a die.

**Changing Pitch of Screw Thread Slightly.**—A very slight change in the pitch of a screw thread may be necessary as, for example, when the pitch of a tap is increased a small amount to compensate for shrinkage in hardening. One method of obtaining slight variations in pitch is by means of a taper attachment. This attachment is set at an angle and the work is located at the same angle by adjusting the tailstock center. The result is that the tool follows an angular path relative to the movement of the carriage and, consequently, the pitch of the thread is increased slightly, the amount depending upon the angle to which the work and taper attachment are set. The cosine of this angle, for obtaining a given increase in pitch, equals the standard pitch (which would be obtained with the lathe used in the regular way) divided by the increased pitch necessary to compensate for shrinkage.

*Example:* If the pitch of a  $\frac{3}{4}$ -inch American standard screw is to be increased from 0.100 to 0.1005, the cosine of the angle to which the taper attachment and work should be set is found as follows:

$$\text{Cosine of required angle} = \frac{0.100}{0.1005} = 0.9950$$

which is the cosine of 5 degrees 45 minutes, nearly.

### Change Gears for Helical Milling

**Lead of a Milling Machine.**—If gears with an equal number of teeth are placed on the table feed-screw and the worm-gear stud, then the *lead of the milling machine* is the distance the table will travel while the index spindle makes one complete revolution. This distance is a constant used in figuring the change gears.

The lead of a helix or "spiral" is the distance, measured along the axis of the work, in which the helix makes one full turn around the work. The lead of the milling machine may, therefore, also be expressed as the lead of the helix that will be cut when gears with an equal number of teeth are placed on the feed-screw and the worm-gear stud, and an idler of suitable size is interposed between the gears.

*Rule:* To find the lead of a milling machine, place equal gears on the worm-gear stud and on the feed-screw, and multiply the number of revolutions made by the feed-screw to produce one revolution of the index head spindle, by the lead of the thread on the feed-screw. Expressing the rule given as a formula:

$$\text{lead of milling machine} = \frac{\text{rev. of feed-screw for one revolution of index spindle with equal gears}}{\text{lead of feed-screw}}$$

Assume that it is necessary to make 40 revolutions of the feed-screw to turn the index head spindle one complete revolution, when the gears are equal, and that the lead of the thread on the feed-screw of the milling machine is  $\frac{1}{4}$  inch; then the lead of the machine equals  $40 \times \frac{1}{4}$  inch = 10 inches.

**Change Gears for Helical Milling.**—To find the change gears to be used in the compound train of gears for helical milling, place the lead of the helix to be cut in the numerator and the lead of the milling machine in the denominator of a fraction; divide numerator and denominator into two factors each; and multiply each "pair" of factors by the *same* number until suitable numbers of teeth for the change gears are obtained. (One factor in the numerator and one in the denominator are considered as one "pair" in this calculation.)

*Example:* Assume that the lead of a machine is 10 inches, and that a helix having a 48-inch lead is to be cut. Following the method explained:

$$\frac{48}{10} = \frac{6 \times 8}{2 \times 5} = \frac{(6 \times 12) \times (8 \times 8)}{(2 \times 12) \times (5 \times 8)} = \frac{72 \times 64}{24 \times 40}$$

The gear having 72 teeth is placed on the worm-gear stud and meshes with the 24-tooth gear on the intermediate stud. On the same intermediate stud is then placed the gear having 64 teeth, which is driven by the gear having 40 teeth placed on the feed-screw. This makes the gears having 72 and 64 teeth the driven gears, and the gears having 24 and 40 teeth the driving gears. In general, for compound gearing, the following formula may be used:

$$\frac{\text{lead of helix to be cut}}{\text{lead of machine}} = \frac{\text{product of driven gears}}{\text{product of driving gears}}$$

**Short-lead Milling.**—If the lead to be milled is exceptionally short, the drive may be direct from the table feed-screw to the dividing head spindle to avoid excessive load on feed-screw and change-gears. If the table feed-screw has 4 threads per inch (usual standard), then

$$\text{Change-gear ratio} = \frac{\text{Lead to be milled}}{0.25} = \frac{\text{Driven gears}}{\text{Driving gears}}$$

For indexing, the number of teeth on the spindle change-gear should be some multiple of the number of divisions required, to permit indexing by disengaging and turning the gear.

**Helix.**—A helix is a curve generated by a point moving about a cylindrical surface (real or imaginary) at a constant rate in the direction of the cylinder's axis. The curvature of a screw thread is one common example of a helical curve.

*Lead of Helix:* The lead of a helix is the distance that it advances in an axial direction, in one complete turn about the cylindrical surface. To illustrate, the lead of a screw thread

equals the distance that a thread advances in one turn; it also equals the distance that a nut would advance in one turn.

*Development of Helix:* If one turn of a helical curve were unrolled onto a plane surface (as shown by diagram), the helix would become a straight line forming the hypotenuse of a right angle triangle. The length of one side of this triangle would equal the circumference of the cylinder with which the helix coincides, and the length of the other side of the triangle would equal the lead of the helix.

**Helix Angles.**—The triangular development of a helix has one angle  $A$  subtended by the circumference of the cylinder, and another angle  $B$  subtended by the lead of the helix. The term “helix angle” applies to angle  $A$ . For example, the helix angle of a helical gear, according to the general usage of the term, is always angle  $A$ , because this is the angle used in helical gear-designing formulas. Helix angle  $A$  would also be applied in milling the helical teeth of cutters, reamers, etc. Angle  $A$  of a gear or cutter tooth is a measure of its inclination relative to the axis of the gear or cutter.

*Lead Angle:* Angle  $B$  is applied to screw threads and worm threads and is referred to as the lead angle of the screw thread or worm. This angle  $B$  is a measure of the inclination of a screw thread from a plane that is perpendicular to the screw thread axis. Angle  $B$  is called the “lead angle” because it is subtended by the lead of the thread, and to distinguish it from the term “helix angle” as applied to helical gears.

*Finding Helix Angle of Helical Gear:* A helical gear tooth has an infinite number of helix angles, but the angle at the pitch diameter or mid-working depth is the one required in gear designing and gear cutting. This angle  $A$ , relative to the axis of the gear, is found as follows:

$$\tan \text{ helix angle} = \frac{3.1416 \times \text{pitch diameter of gear}}{\text{Lead of gear tooth}}$$

*Finding Lead Angle of Screw Thread:* The lead or helix angle at the pitch diameter of a screw thread usually is required when, for example, a thread milling cutter must be aligned with the thread. This angle measured from a plane perpendicular to the screw thread axis, is found as follows:

$$\tan \text{ lead angle} = \frac{\text{Lead of screw thread}}{3.1416 \times \text{pitch diameter of screw thread}}$$

## Change Gears for Different Leads—0.670 Inch to 2.658 Inches

| Lead in Inches | Driven       | Driver             | Driven              | Driver        | Lead in Inches | Driven       | Driver             | Driven              | Driver        | Lead in Inches | Driven       | Driver             | Driven              | Driver        |
|----------------|--------------|--------------------|---------------------|---------------|----------------|--------------|--------------------|---------------------|---------------|----------------|--------------|--------------------|---------------------|---------------|
|                | Gear on Worm | First Gear on Stud | Second Gear on Stud | Gear on Screw |                | Gear on Worm | First Gear on Stud | Second Gear on Stud | Gear on Screw |                | Gear on Worm | First Gear on Stud | Second Gear on Stud | Gear on Screw |
| 0.670          | 24           | 86                 | 24                  | 100           | 1.711          | 28           | 72                 | 44                  | 100           | 2.182          | 24           | 44                 | 40                  | 100           |

**Helix Angle for Given Lead and Diameter.**—The table on this and the preceding page gives helix angles (relative to axis) equivalent to a range of leads and diameters. The expression "Diameter of Work" at the top of the table might mean pitch diameter or outside diameter, depending upon the class of work. Assume, for example, that a plain milling cutter 4 inches in diameter is to have helical teeth and a helix angle of about 25 degrees is desired. The table shows that this angle will be obtained approximately by using change-gears that will give a lead of 26.67 inches. As the outside diameter of the cutter is 4 inches,

the helix angle of  $25\frac{1}{4}$  degrees is at the top of the teeth. The angles listed for different diameters are used in setting the table of a milling machine. In milling a right-hand helix (or cutter teeth that turn to the right as seen from the end of the cutter), swivel the right-hand end of the machine table toward the rear, and, inversely, for a left-hand helix, swivel the left-hand end of the table toward the rear. The angles in the table are based upon the following formula:

$$\cot \text{ helix angle relative to axis} = \frac{\text{lead of helix}}{3.1416 \times \text{diameter}}$$

**Lead of Helix for Given Angle.**—The lead of a helix or “spiral” for given angles measured with the axis of the work is given in the table, starting on page 1977, for a diameter of 1. For other diameters, lead equals the value found in the table multiplied by the given diameter. Suppose the angle is 55 degrees, and the diameter 5 inches; what would be the lead? By referring to the table starting on page 1977, it is found that the lead for a diameter of 1 and an angle of 55 degrees 0 minutes equals 2.200. Multiply this value by 5;  $5 \times 2.200 = 11$  inches, which is the required lead. If the lead and diameter are given, and the angle is wanted, divide the given lead by the given diameter, thus obtaining the lead for a diameter equal to 1; then find the angle corresponding to this lead in the table. If the lead and angle are given, and the diameter is wanted, divide the lead by the value in the table for the angle.

**Helix Angle for Given Lead and Pitch Radius.**—To determine the helix angle for a helical gear, knowing the pitch radius and the lead, use the formula:

$$\tan \psi = 2\pi R/L$$

where  $\psi$  = helix angle

$R$  = pitch radius of gear, and

$L$  = lead of tooth

*Example:*

$$R = 3.000, L = 21.000, \tan \psi = (2 \times 3.1416 \times 3.000)/21.000 = 0.89760$$

$$\therefore \psi = 41.911 \text{ degrees}$$

**Helix Angle and Lead, Given Normal DP and Numbers of Teeth.**—When  $N_1$  = number of teeth in pinion,  $N_2$  = number of teeth in gear,  $P_n$  = normal diametral pitch,  $C$  = center distance,  $\psi$  = helix angle,  $L_1$  = lead of pinion, and  $L_2$  = lead of gear, then:

$$\cos \psi = \frac{N_1 + N_2}{2P_n C}, \quad L_1 = \frac{\pi N_1}{P_n \sin \psi}, \quad L_2 = \frac{\pi N_2}{P_n \sin \psi}$$

$$P_n = 6, \quad N_1 = 18, \quad N_2 = 30, \quad C = 4.500$$

$$\cos \psi = \frac{18 + 30}{2 \times 6 \times 4.5} = 0.88889, \therefore \psi = 27.266^\circ, \text{ and } \sin \psi = 0.45812$$

$$L_1 = \frac{3.1416 \times 18}{6 \times 0.45812} = 20.5728, \text{ and } L_2 = \frac{3.1416 \times 30}{6 \times 0.45812} = 34.2880$$

**Lead of Tooth Given Pitch Radius and Helix Angle.**—To determine the lead of the tooth for a helical gear, given the helix angle and the pitch radius, the formula becomes:  
 $L = 2\pi R/\tan \psi$ .

$$\psi = 22.5^\circ, \quad \therefore \tan \psi = 0.41421, \quad R = 2.500.$$

$$L = \frac{2 \times 3.1416 \times 2.500}{0.41421} = 37.9228$$

## SIMPLE, COMPOUND, DIFFERENTIAL, AND BLOCK INDEXING

**Milling Machine Indexing.**—Positioning a workpiece at a precise angle or interval of rotation for a machining operation is called indexing. A dividing head is a milling machine attachment that provides this fine control of rotational positioning through a combination of a crank-operated worm and worm gear, and one or more indexing plates with several circles of evenly spaced holes to measure partial turns of the worm crank. The indexing crank carries a movable indexing pin that can be inserted into and withdrawn from any of the holes in a given circle with an adjustment provided for changing the circle that the indexing pin tracks.

**Hole Circles.**—The Brown & Sharpe dividing head has three standard indexing plates, each with six circles of holes as listed in the table below.

**Numbers of Holes in Brown & Sharpe Standard Indexing Plates**

| Plate Number | Numbers of Holes |    |    |    |    |    |
|--------------|------------------|----|----|----|----|----|
| 1            | 15               | 16 | 17 | 18 | 19 | 20 |
| 2            | 21               | 23 | 27 | 29 | 31 | 33 |
| 3            | 37               | 39 | 41 | 43 | 47 | 49 |

Dividing heads of Cincinnati Milling Machine design have two-sided, standard, and high-number plates with the numbers of holes shown in the following table.

**Numbers of Holes in Cincinnati Milling Machine Standard Indexing Plates**

| Side               | Standard Plate |    |    |    |     |     |     |     |     |     |     |
|--------------------|----------------|----|----|----|-----|-----|-----|-----|-----|-----|-----|
|                    | 1              | 24 | 25 | 28 | 30  | 34  | 37  | 38  | 39  | 41  | 42  |
| 2                  | 46             | 47 | 49 | 51 | 53  | 54  | 57  | 58  | 59  | 62  | 66  |
| High-Number Plates |                |    |    |    |     |     |     |     |     |     |     |
| A                  | 30             | 48 | 69 | 91 | 99  | 117 | 129 | 147 | 171 | 177 | 189 |
| B                  | 36             | 67 | 81 | 97 | 111 | 127 | 141 | 157 | 169 | 183 | 199 |
| C                  | 34             | 46 | 79 | 93 | 109 | 123 | 139 | 153 | 167 | 181 | 197 |
| D                  | 32             | 44 | 77 | 89 | 107 | 121 | 137 | 151 | 163 | 179 | 193 |
| E                  | 26             | 42 | 73 | 87 | 103 | 119 | 133 | 149 | 161 | 175 | 191 |
| F                  | 28             | 38 | 71 | 83 | 101 | 113 | 131 | 143 | 159 | 173 | 187 |

Some dividing heads provide for *Direct Indexing* through the attachment of a special indexing plate directly to the main spindle where a separate indexing pin engages indexing holes in the plate. The worm is disengaged from the worm gear during this quick method of indexing, which is mostly used for common, small-numbered divisions such as six, used in machining hexagonal forms for bolt heads and nuts, for instance.

**Simple Indexing.**—Also called *Plain Indexing* or *Indirect Indexing*, simple indexing is based on the ratio between the worm and the worm gear, which is usually, but not always, 40:1. All the tables in this section are based on a 40:1 gear ratio, except for [Table 8](#) on page 2023 that gives indexing movements for dividing heads utilizing a 60:1 gear ratio.

The number of turns of the indexing crank needed for each indexing movement to produce a specified number of evenly spaced divisions is equal to the number of turns of the crank that produce exactly one full turn of the main spindle, divided by the specified number of divisions required for the workpiece. The accompanying tables in this section provide data for the indexing movements to meet most division requirements, and include the simple indexing movements along with the more complex movements for divisions that are not available through simple indexing. The fractional entries in the tables are deliberately not reduced to lowest terms. Thus, the numerator represents the number of holes to be moved on the circle of holes specified by the denominator.

Setting up for an indexing job includes setting the sector arms to the fractional part of a turn required for each indexing movement to avoid the need to count holes each time. The current location of the indexing pin in the circle of holes to be used is always hole zero when counting the number of holes to be moved. The wormshaft hub carrying the dividing plate may also carry one or two sets of sector arms, each of which can be used to define two arcs of holes. As shown at the right in the drawing of a typical dividing head at the top of the table *Simple and Differential Indexing with Browne & Sharpe Indexing Plates* on page 2011, these sector arms can make up an inner arc, A, and an outer arc, B. The inner arc is used most often, but some indexing movements require the use of the outer arc.

*Example:* With a worm/worm gear ratio of 40:1 making 35 divisions requires each indexing movement to be  $40 \div 35 = 1 \frac{1}{7}$  turns: one full turn of the indexing crank plus one-seventh of a full turn more. A full turn is easily achieved using any circle of holes, but to continue the indexing movement to completion for this example requires a circle in which the number of holes is evenly divisible by 7. The Brown & Sharpe dividing head has a 21-hole circle on plate 2 and a 49-hole circle on plate 3. Either circle could be used because  $3/21$  and  $7/49$  both equal  $1/7$ th. The Cincinnati dividing head standard plate has a 28-hole circle on the first side and a 49-hole circle on the second side and again, either  $4/28$  or  $7/49$  could be used for the fractional part of a turn needed for 35 divisions. In selecting among equivalent indexing solutions, the one with the smallest number of holes in the fractional part of a turn is generally preferred (except that if an indexing plate with an alternate solution is already mounted on the dividing head, the alternate should be used to avoid switching indexing plates).

**Compound Indexing.**—Compound indexing is used to obtain divisions that are not available by simple indexing. Two simple indexing movements are used with different circles of holes on an indexing plate that is not bolted to the dividing head frame so that it is free to rotate on the worm shaft. A second, stationary indexing pin arrangement is clamped or otherwise fixed to the frame of the dividing head to hold the indexing plate in position except during the second portion of the compound indexing movement. If available, a double set of low-profile sector arms would improve the ease and reliability of this method. Sector arms for the innermost circle of an indexing movement should not reach as far as the outermost circle of the movement, and sector arms for the outermost circle should be full length. Positioning the outermost circle sector arms may have to wait until the indexing pin on the innermost circle is withdrawn, and may sometimes coincide with the position of that pin. The indexing pin on the crank is set to track the innermost of the two circles in the compound movement and the stationary indexing pin is set to track the outermost circle. Some divisions are only available using adjacent circles, so the intercircle spacing may become a constraining factor in the design or evaluation of a stationary pin arrangement.

The first part of the indexing movement is performed as in simple indexing by withdrawing the indexing pin on the crank arm from its hole in the indexing plate, rotating the crank to its next position, and reinserting the indexing pin in the new hole. For the second part of the movement, the stationary indexing pin is released from its hole in the indexing plate, and with the crank indexing pin seated in its hole, the crank is used to turn the crank arm and indexing plate together to the next position for reinserting the stationary pin into its new hole.

There are two possibilities for the separate movements in compound indexing: they may both be in the same direction of rotation, referred to as *positive compounding* and indicated in the table by a plus (+) sign between the two indexing movements, or they may be in opposite directions of rotation, referred to as *negative compounding* and indicated in the table by a minus (–) sign between the two indexing movements. In positive compounding, it does not matter whether the rotation is clockwise or counterclockwise, as long as it is the same throughout the job. In negative compounding, there will be one clockwise movement and one counterclockwise movement for each unit of the division. The mathematical difference is in whether the two fractional turns are to be added together or whether one is to

be subtracted from the other. Operationally, this difference is important because of the backlash, or free play, between the worm and the worm gear of the dividing head. In positive compounding, this play is always taken up because the worm is turned continually in the same direction. In negative compounding, however, the direction of each turn is always opposite that of the previous turn, requiring each portion of each division to be started by backing off a few holes to allow the play to be taken up before the movement to the next position begins.

The Tables 1a and 1b, *Simple and Compound Indexing with Brown & Sharpe Plates*, gives indexing movements for all divisions up to and including 250 with plain dividing heads of the Brown & Sharpe design. All the simple indexing movements, and many of the compound indexing movements, are exact for the divisions they provide. There remains a substantial number of divisions for which the indexing movements are approximate. For these divisions, the indexing movements shown come very close to the target number, but the price of getting close is increased length and complexity of the indexing movements. The table shows all divisions that can be obtained through simple indexing and all divisions for which exact compound indexing movements are available. Approximate movements are only used when it is necessary to obtain a division that would otherwise not be available. The approximate indexing movements usually involve multiple revolutions of the workpiece, with successive revolutions filling in spaces left during earlier turns.

**Table 1a. Simple and Compound Indexing with Brown & Sharpe Plates**

| Number of Divisions | Whole Turns | Fractions of a Turn | Number of Divisions | Whole Turns | Fractions of a Turn | Number of Divisions | Whole Turns | Fractions of a Turn |
|---------------------|-------------|---------------------|---------------------|-------------|---------------------|---------------------|-------------|---------------------|
| 2                   | 20          | ...                 | 15                  | 2           | 26/39               | 33                  | 1           | 7/33                |
| 3                   | 13          | 5/15                | 16                  | 2           | 8/16                | 34                  | 1           | 3/17                |
| 3                   | 13          | 7/21                | 17                  | 2           | 6/17                | 35                  | 1           | 3/21                |
| 3                   | 13          | 13/39               | 18                  | 2           | 4/18                | 35                  | 1           | 7/49                |
| 4                   | 10          | ...                 | 18                  | 2           | 6/27                | 36                  | 1           | 2/18                |
| 5                   | 8           | ...                 | 19                  | 2           | 2/19                | 36                  | 1           | 3/27                |
| 6                   | 6           | 10/15               | 20                  | 2           | ...                 | 37                  | 1           | 3/37                |
| 6                   | 6           | 14/21               | 21                  | 1           | 19/21               | 38                  | 1           | 1/19                |
| 6                   | 6           | 26/39               | 22                  | 1           | 27/33               | 39                  | 1           | 1/39                |
| 7                   | 5           | 15/21               | 23                  | 1           | 17/23               | 40                  | 1           | ...                 |
| 8                   | 5           | ...                 | 24                  | 1           | 10/15               | 41                  | ...         | 40/41               |
| 9                   | 4           | 8/18                | 24                  | 1           | 14/21               | 42                  | ...         | 20/21               |
| 9                   | 4           | 12/27               | 24                  | 1           | 26/39               | 43                  | ...         | 40/43               |
| 10                  | 4           | ...                 | 25                  | 1           | 9/15                | 44                  | ...         | 30/33               |
| 11                  | 3           | 21/33               | 26                  | 1           | 21/39               | 45                  | ...         | 16/18               |
| 12                  | 3           | 5/15                | 27                  | 1           | 13/27               | 45                  | ...         | 24/27               |

<sup>a</sup>Requires only the outer most circle of holes on indexing plate.

The greater spacing between successive machining operations may be used to advantage to spread out and reduce the effects of heat generation on the workpiece. The number of workpiece revolutions required by an approximation is shown in the table in the column to the right of the indexing movements. The table gives two or three choices for each division requiring approximate movements.

Two measures of the closeness of each approximation are provided to aid in the trade-off between complexity and precision. The first measure is the precise number of divisions that a set of indexing movements produces, offering a direct comparison of the degree of approximation. However, the difference between the precise number of divisions and the target number of divisions is angular in nature, so the error introduced by an approximation depends on the size of the circle being divided. The second measure of closeness reflects this characteristic by expressing the degree of approximation as the diameter at which the error is equal to 0.001. This second measure is unitless, so that taking the error as 0.001

inch means that the entries in that column are to be taken as diameters in inches, but the measure works as well with 0.001 centimeter and diameters in centimeters. The measure can also be used to calculate the error of approximation at a given diameter. Divide the given diameter by the value of the measure and multiply the result by 0.001 to determine the amount of error that using an approximation will introduce.

*Example:* A gear is to be cut with 127 teeth at 16 diametral pitch using a Brown & Sharpe plain dividing head. The indexing table gives three approximations for 127 divisions. The pitch diameter of a 16 DP gear with 127 teeth is about 7.9 inches, so the calculated error of approximation for the three choices would be about  $(7.9 \div 17.5) \times 0.001 = 0.00045$  inch,  $(7.9 \div 77.5) \times 0.001 = 0.00010$  inch, and  $(7.9 \div 218.98) \times 0.001 = 0.000036$  inch. Considering the increased potential for operator error with longer indexing movements and such other factors as may be appropriate, assume that the first of the three approximations is selected. Plate 3 is mounted on the worm shaft of the dividing head but not bolted to the frame. A double set of sector arms is installed, if available; otherwise, the single pair of sector arms is installed. The indexing pin on the crank arm is set to track the 39-hole circle. The stationary indexing pin is installed and set to track the 47-hole circle. If only one pair of sector arms is used, it is used for the 42/47 movement and is set for 0-42 holes using the outer arc. Six holes should be showing in the inner arc on the 47-hole circle (the zero-hole, the 42-hole, and four extra holes). The second set of sector arms is set for 0-2 holes on the 39-hole circle using the inner arc (three holes showing). If there is no second pair of sector arms, this is a short enough movement to do freehand without adding much risk of error.

**Angular Indexing.**—The plain dividing head with a 40:1 gear ratio will rotate the main spindle and the workpiece 9 degrees for each full turn of the indexing crank, and therefore 1 degree for movements of 2/18 or 3/27 on Brown & Sharpe dividing heads and 6/54 on heads of Cincinnati design. To find the indexing movement for an angle, divide that angle, in degrees, by 9 to get the number of full turns and the remainder, if any. If the remainder, expressed in minutes, is evenly divisible by 36, 33.75, 30, 27, or 20, then the quotient is the number of holes to be moved on the 15-, 16-, 18-, 20-, or 27-hole circles, respectively, to obtain the fractional turn required (or evenly divisible by 22.5, 21.6, 18, 16.875, 15, 11.25, or 10 for the number of holes to be moved on the 24-, 25-, 30-, 32-, 36-, 48-, or 54-hole circles, respectively, for the standard and high number plates of a Cincinnati dividing head). If none of these divisions is even, it is not possible to index the angle (exactly) by this method.

*Example:* An angle of  $61^{\circ} 48'$  is required. Expressed in degrees, this angle is  $61.8^{\circ}$ , which when divided by 9 equals 6 with a remainder of  $7.8^{\circ}$ , or  $468'$ . Division of 468 by 20, 27, 30, 33.75, and 36 reveals an even division by 36, yielding 13. The indexing movement for  $61^{\circ} 48'$  is six full turns plus 13 holes on the 15-hole circle.

**Tables for Angular Indexing.**—Table 2, headed *Angular Values of One-Hole Moves*, provides the angular movement obtained with a move of one hole in each of the indexing circles available on standard Brown & Sharpe and Cincinnati plates, for a selection of angles that can be approximated with simple indexing.

Table 3, titled *Accurate Angular Indexing*, provides the simple and compound indexing movements to obtain the full range of fractional turns with the standard indexing plates of both the Brown & Sharpe and Cincinnati dividing heads. Compound indexing movements depend on the presence of specific indexing circles on the same indexing plate, so some movements may not be available with plates of different configurations. To use the table to index an angle, first convert the angle to seconds and then divide the number of seconds in the angle by 32,400 (the number of seconds in 9 degrees, which is one full turn of the indexing crank). The whole-number portion of the quotient gives the number of full turns of the indexing crank, and the decimal fraction of the quotient gives the fractional turn required.

**Table 2. Angular Values of One-Hole Moves for B&S and Cincinnati Index Plates**

| Holes in Circle | Angle in Minutes | Holes in Circle | Angle in Minutes | Holes in Circle | Angle in Minutes |
|-----------------|------------------|-----------------|------------------|-----------------|------------------|
| 15              | 36.000           | 53              | 10.189           | 129             | 4.186            |
| 16              | 33.750           | 54              | 10.000           | 131             | 4.122            |
| 17              | 31.765           | 57              | 9.474            | 133             | 4.060            |
| 18              | 30.000           | 58              | 9.310            | 137             | 3.942            |
| 19              | 28.421           | 59              | 9.153            | 139             | 3.885            |
| 20              | 27.000           | 62              | 8.710            | 141             | 3.830            |

| 39              | 13.846           | 103             | 5.243            | 181             | 2.983            |
| 41              | 13.171           | 107             | 5.047            | 183             | 2.951            |
| 42              | 12.857           | 109             | 4.954            | 187             | 2.888            |
| 43              | 12.558           | 111             | 4.865            | 189             | 2.857            |
| 44              | 12.273           | 113             | 4.779            | 191             | 2.827            |
| 46              | 11.739           | 117             | 4.615            | 193             | 2.798            |
| 47              | 11.489           | 119             | 4.538            | 197             | 2.741            |
| 48              | 11.250           | 121             | 4.463            | 199             | 2.714            |
| 49              | 11.020           | 123             | 4.390            | ...             | ...              |
| 51              | 10.588           | 127             | 4.252            | ...             | ...              |

Use [Table 3](#) to locate the indexing movement for the decimal fraction nearest to the decimal fraction of the quotient for which there is an entry in the column for the dividing head to be used. If the decimal fraction of the quotient is close to the midpoint between two table entries, calculate the mathematical value of the two indexing movements to more decimal places to make the closeness determination.

*Example:* Movement through an angle of  $31^{\circ} 27' 50''$  is required. Expressed in seconds, this angle  $113270''$ , which, divided by 32,400, equals 3.495987. The indexing movement is three full turns of the crank plus a fractional turn of 0.495987. The nearest [Table 3](#) entry is for 0.4960, which requires a compound indexing movement of 8 holes on the 23-hole circle plus 4 holes on the 27-hole circle in the same direction. Checking the value of these movements shows that  $\frac{8}{23} + \frac{4}{27} = 0.347826 + 0.148148 = 0.495974$ , which, multiplied by 32,400, = 16,069.56, or  $4^{\circ} 27' 49.56''$  from the fractional turn. Adding the  $27^{\circ}$  from three full turns gives a total movement of  $31^{\circ} 27' 49.56''$ .

Table 3. Accurate Angular Indexing

| Part of a Turn | B&S, Becker, Hendey, K&T, & Rockford | Cincinnati and LeBlond | Part of a Turn | B&S, Becker, Hendey, K&T, & Rockford | Cincinnati and LeBlond |

**Approximate Indexing for Small Angles.**—To find *approximate* indexing movements for small angles, such as the remainder from the method discussed in *Angular Indexing* starting on page 1990, on a dividing head with a 40:1 worm-gear ratio, divide 540 by the number of minutes in the angle, and then divide the number of holes in each of the available indexing circles by this quotient. The result that is closest to a whole number is the best approximation of the angle for a simple indexing movement and is the number of holes to

be moved in the corresponding circle of holes. If the angle is greater than 9 degrees, the whole number will be greater than the number of holes in the circle, indicating that one or more full turns of the crank are required. Dividing by the number of holes in the indicated circle of holes will reduce the required indexing movement to the number of full turns, and the remainder will be the number of holes to be moved for the fractional turn. If the angle is less than about 11 minutes, it cannot be indexed by simple indexing with standard B & S plates (the corresponding angle for standard plates on a Cincinnati head is about 8 minutes, and for Cincinnati high number plates, 2.7 minutes. See [Tables 5, 6a, and 6b](#) for indexing movements with Cincinnati standard and high number plates).

*Example:* An angle of  $7^{\circ} 25'$  is to be indexed. Expressed in minutes, it is 445' and 540 divided by 445 equals 1.213483. The indexing circles available on standard B & S plates are 15, 16, 17, 18, 19, 20, 21, 23, 27, 29, 31, 33, 37, 39, 41, 43, 47, and 49. Each of these numbers is divided by 1.213483 and the closest to a whole number is found to be  $17 \div 1.213483 = 14.00926$ . The best approximation for a simple indexing movement to obtain  $7^{\circ} 25'$  is 14 holes on the 17-hole circle.

**Differential Indexing.**—This method is the same, in principle, as compound indexing (see *Compound Indexing* on page 1984), but differs from the latter in that the index plate is rotated by suitable gearing that connects it to the spiral-head spindle. This rotation or differential motion of the index plate takes place when the crank is turned, the plate moving either in the same direction as the crank or opposite to it, as may be required. The result is that the *actual* movement of the crank, at every indexing, is either greater or less than its movement with relation to the index plate. The differential method makes it possible to obtain almost any division by using only one circle of holes for that division and turning the index crank in one direction, as with plain indexing.

The gears to use for turning the index plate the required amount (when gears are required) are shown by [Tables 4a and 4b](#), *Simple and Differential Indexing with Browne & Sharpe Indexing Plates*, which shows what divisions can be obtained by plain indexing, and when it is necessary to use gears and the differential system. For example, if 50 divisions are required, the 20-hole index circle is used and the crank is moved 16 holes, but no gears are required. For 51 divisions, a 24-tooth gear is placed on the wormshaft and a 48-tooth gear on the spindle. These two gears are connected by two idler gears having 24 and 44 teeth, respectively.

To illustrate the principle of differential indexing, suppose a dividing head is to be geared for 271 divisions. [Table 4b](#) calls for a gear on the wormshaft having 56 teeth, a spindle gear with 72 teeth, and a 24-tooth idler to rotate the index plate in the same direction as the crank. The sector arms should be set to give the crank a movement of 3 holes in the 21-hole circle. If the spindle and the index plate were not connected through gearing, 280 divisions would be obtained by successively moving the crank 3 holes in the 21-hole circle, but the gears cause the index plate to turn in the same direction as the crank at such a rate that, when 271 indexings have been made, the work is turned one complete revolution. Therefore, we have 271 divisions instead of 280, the number being reduced because the total movement of the crank, for each indexing, is equal to the movement relative to the index plate, *plus* the movement of the plate itself when, as here, the crank and plate rotate in the same direction.

If they were rotated in opposite directions, the crank would have a total movement equal to the amount it turned relative to the plate, *minus* the plate's movement. Sometimes it is necessary to use compound gearing to move the index plate the required amount for each turn of the crank. The differential method cannot be used in connection with helical or spiral milling because the spiral head is then geared to the leadscrew of the machine.

**Finding Ratio of Gearing for Differential Indexing.**—To find the ratio of gearing for differential indexing, first select some approximate number *A* of divisions either greater or less than the required number *N*. For example, if the required number *N* is 67, the approxi-

mate number  $A$  might be 70. Then, if 40 turns of the index crank are required for 1 revolution of the spindle, the gearing ratio  $R = (A - N) \times 40/A$ . If the approximate number  $A$  is less than  $N$ , the formula is the same as above except that  $A - N$  is replaced by  $N - A$ .

*Example:* Find the gearing ratio and indexing movement for 67 divisions.

$$\text{If } A = 70, \text{ gearing ratio} = (70 - 67) \times \frac{40}{70} = \frac{12}{7} = \frac{\text{gear on spindle (driver)}}{\text{gear on worm (driven)}}$$

The fraction  $12/7$  is raised to obtain a numerator and a denominator to match gears that are available. For example,  $12/7 = 48/28$ .

Various combinations of gearing and index circles are possible for a given number of divisions. The index numbers and gear combinations in the accompanying [Tables 4a](#) and [4b](#) apply to a given series of index circles and gear-tooth numbers. The approximate number  $A$  on which any combination is based may be determined by dividing 40 by the fraction representing the indexing movement. For example, the approximate number used for 109 divisions equals  $40 \div 6/16$ , or  $40 \times 16/6 = 106\frac{2}{3}$ . If this approximate number is inserted in the preceding formula, it will be found that the gear ratio is  $7/8$ , as shown in the table.

*Second Method of Determining Gear Ratio:* In illustrating a somewhat different method of obtaining the gear ratio, 67 divisions will again be used. If 70 is selected as the approximate number, then  $40/70 = 4/7$  or  $12/21$  turn of the index crank will be required. If the crank is indexed four-sevenths of a turn, sixty-seven times, it will make  $4/7 \times 67 = 38\frac{2}{7}$  revolutions. This number is  $1\frac{5}{7}$  turns less than the 40 required for one revolution of the work (indicating that the gearing should be arranged to rotate the index plate in the same direction as the index crank to increase the indexing movement). Hence the gear ratio  $1\frac{5}{7} = 12/7$ .

**To Find the Indexing Movement.**—The indexing movement is represented by the fraction  $40/A$ . For example, if 70 is the approximate number  $A$  used in calculating the gear ratio for 67 divisions, then, to find the required movement of the index crank, reduce  $40/70$  to any fraction of equal value and having as denominator any number equal to the number of holes available in an index circle.

$$\text{To illustrate, } \frac{40}{70} = \frac{4}{7} = \frac{12}{21} = \frac{\text{number of holes indexed}}{\text{number of holes in index circle}}$$

**Use of Idler Gears.**—In differential indexing, idler gears are used to rotate the index plate in the same direction as the index crank, thus *increasing* the resulting indexing movement, or to rotate the index plate in the opposite direction, thus *reducing* the resulting indexing movement.

*Example 1:* If the approximate number  $A$  is *greater* than the required number of divisions  $N$ , simple gearing will require one idler, and compound gearing, no idler. Index plate and crank rotate in the same direction.

*Example 2:* If the approximate number  $A$  is *less* than the required number of divisions  $N$ , simple gearing requires two idlers, and compound gearing, one idler. Index plate and crank rotate in opposite directions.

**When Compound Gearing Is Required.**—It is sometimes necessary, as shown in the table, to use a train of four gears to obtain the required ratio with the gear-tooth numbers that are available.

*Example:* Find the gear combination and indexing movement for 99 divisions, assuming that an approximate number  $A$  of 100 is used.

$$\text{Ratio} = (100 - 99) \times \frac{40}{100} = \frac{4}{10} = \frac{4 \times 1}{5 \times 2} = \frac{32}{40} \times \frac{28}{56}$$

The final numbers here represent available gear sizes. The gears having 32 and 28 teeth are the drivers (gear on spindle and first gear on stud), and gears having 40 and 56 teeth are

driven (second gear on stud and gear on wormshaft). The indexing movement is represented by the fraction  $\frac{40}{100}$ , which is reduced to  $\frac{2}{25}$ , the 20-hole index circle being used here.

*Example:* Determine the gear combination to use for indexing 53 divisions. If 56 is used as an approximate number (possibly after one or more trial solutions to find an approximate number and resulting gear ratio coinciding with available gears):

$$\text{Gearing ratio} = (56 - 53) \times \frac{40}{56} = \frac{15}{7} = \frac{3 \times 5}{1 \times 7} = \frac{72 \times 40}{24 \times 56}$$

The tooth numbers above the line here represent *gear on spindle and first gear on stud*. The tooth numbers below the line represent *second gear on stud and gear on wormshaft*.

$$\text{Indexing movement} = \frac{40}{56} = \frac{5}{7} = \frac{5 \times 7}{7 \times 7} = \frac{35 \text{ holes}}{49\text{-hole circle}}$$

**To Check the Number of Divisions Obtained with a Given Gear Ratio and Index Movement.**—Invert the fraction representing the indexing movement. Let  $C$  = this inverted fraction and  $R$  = gearing ratio.

*Example 1:* If simple gearing with one idler, or compound gearing with no idler, is used: number of divisions  $N = 40C - RC$ .

For instance, if the gear ratio is  $\frac{12}{7}$ , there is simple gearing and one idler, and the indexing movement is  $\frac{12}{21}$ , making the inverted fraction  $C$ ,  $\frac{21}{12}$ ; find the number of divisions  $N$ .

$$N = \left(40 \times \frac{21}{12}\right) - \left(\frac{12}{7} \times \frac{21}{12}\right) = 70 - \frac{21}{7} = 67$$

*Example 2:* If simple gearing with two idlers, or compound gearing with one idler, is used: number of divisions  $N = 40C + RC$ .

For instance, if the gear ratio is  $\frac{7}{8}$ , two idlers are used with simple gearing, and the indexing movement is 6 holes in the 16-hole circle, then number of divisions:

$$N = \left(40 \times \frac{16}{6}\right) + \left(\frac{7}{8} \times \frac{16}{6}\right) = 109$$

Sector Graduations

**Table 4a. Simple and Differential Indexing with Browne & Sharpe Indexing Plates**

| No. of Div. | Index Circle | No. of Turns of Crank | Graduation on Sector | No. of Div. | Index Circle | No. of Turns of Crank | Graduation on Sector | Gear on Worm  | No. 1 Hole         |                     | Gear on Spindle | Idlers     |            |
|-------------|--------------|-----------------------|----------------------|-------------|--------------|-----------------------|----------------------|---|--------------------|---------------------|-----------------|------------|------------|
|             |              |                       |                      |             |              |                       |                      |   | First Gear on Stud | Second Gear on Stud |                 | No. 1 Hole | No. 2 Hole |
| 2           | Any          | 20                    | ...                  | 33          | 33           | 1 7/33                | 41                   | <p><i>Note:</i> The data in columns labeled Graduation on Sector refer to a graduated dial that accompanies the sector arms on some dividing heads, page 2010. The graduated sector ring eliminates the requirement of counting holes and thereby lessens the possibility of error. Graduations in table indicate setting for sector arms when index crank moves through arc A, except figures marked *, when crank moves through arc B.</p> <p><b>Differential Indexing</b><br/>                     Certain divisions such as 51, 53, 57, etc., require the use of differential indexing. In differential indexing, change gears are used to transmit motion from the main spindle of the dividing head to the index plate, which turns (either in the same direction as the index plate or in the opposite direction) whatever amount is required to obtain the correct indexing movement.</p> <p>The numbers in the columns below represent numbers of teeth for the change gears necessary to give the divisions required. Where no numbers are shown simple indexing, which does not require change gears, is used.</p> |                    |                     |                 |            |            |
| 3           | 39           | 13 13/39              | 65                   | 34          | 17           | 1 3/17                | 33                   |   |                    |                     |                 |            |            |

<sup>a</sup> See Note on page 2011.<sup>b</sup> On B & S numbers 1, 1½, and 2 machines, number 2 hole is in the machine table. On numbers 3 and 4 machines, number 2 hole is in the head.

**Table 5. Indexing Movements for Standard Index Plate Cincinnati Milling Machine**

The standard index plate indexes all numbers up to and including 60; all even numbers and those divisible by 5 up to 120; and all divisions listed below up to 400. This plate is drilled on both sides, and has holes as follows:

First side: 24, 25, 28, 30, 34, 37, 38, 39, 41, 42, 43.

Second side: 46, 47, 49, 51, 53, 54, 57, 58, 59, 62, 66.

| No. of Divisions | Index Plate Circle | No. of Turns | No. of Holes | No. of Divisions | Index Plate Circle | No. of Holes | No. of Divisions | Index Plate Circle | No. of Holes | No. of Divisions | Index Plate Circle | No. of Holes |
|------------------|--------------------|--------------|--------------|------------------|--------------------|--------------|------------------|--------------------|--------------|------------------|--------------------|--------------|

**Table 6a. Indexing Movements for High Numbers  
Cincinnati Milling Machine**

| This set of 3 index plates indexes all numbers up to and including 200; all even numbers and those divisible by 5 up to and including 400. The plates are drilled on each side, making six sides <i>A, B, C, D, E</i> and <i>F</i> .                           |          |        |       |       |                  |          |        |       |       |                  |          |        |       |       |
|--|----------|--------|-------|-------|------------------|----------|--------|-------|-------|------------------|----------|--------|-------|-------|
| <i>Example:</i> —It is required to index 35 divisions. The preferred side is <i>F</i> , since this requires the least number of holes; but should one of plates <i>D, A</i> or <i>E</i> be in place, either can be used, thus avoiding the changing of plates. |          |        |       |       |                  |          |        |       |       |                  |          |        |       |       |
| No. of Divisions   | Side     | Circle | Turns | Holes | No. of Divisions | Side     | Circle | Turns | Holes | No. of Divisions | Side     | Circle | Turns | Holes |

**Indexing Tables.**—Indexing tables are usually circular, with a flat, T-slotted table, 12 to 24 in. in diameter, to which workpieces can be clamped. The flat table surface may be horizontal, universal, or angularly adjustable. The table can be turned continuously through 360° about an axis normal to the surface. Rotation is through a worm drive with a graduated scale, and a means of angular readout is provided. Indexed locations to 0.25° with accuracy of ±0.1 second can be obtained from mechanical means, or greater accuracy from an autocollimator or sine-angle attachment built into the base, or under numerical control. Provision is made for locking the table at any angular position while a machining operation is being performed.

Power for rotation of the table during machining can be transmitted, as with a dividing head, for cutting a continuous, spiral scroll, for instance. The indexing table is usually more rigid and can be used with larger workpieces than the dividing head.

**Block or Multiple Indexing for Gear Cutting.**—With the block system of indexing, numbers of teeth are indexed at one time, instead of cutting the teeth consecutively, and the gear is revolved several times before all the teeth are finished. For example, when cutting a gear having 25 teeth, the indexing mechanism is geared to index four teeth at once (see Table 7) and the first time around, six widely separated tooth spaces are cut. The second time around, the cutter is one tooth behind the spaces originally milled. On the third indexing, the cutter has dropped back another tooth, and the gear in question is thus finished by indexing it through four cycles.

The various combinations of change gears to use for block or multiple indexing are given in the accompanying Table 7. The advantage claimed for block indexing is that the heat generated by the cutter (especially when cutting cast iron gears of coarse pitch) is distributed more evenly about the rim and is dissipated to a greater extent, thus avoiding distortion due to local heating and permitting higher speeds and feeds to be used.

Table 7 gives values for use with Brown & Sharpe automatic gear cutting machines, but the gears for any other machine equipped with a similar indexing mechanism can be calculated easily. Assume, for example, that a gear cutter requires the following change gears for indexing a certain number of teeth: driving gears having 20 and 30 teeth, respectively, and driven gears having 50 and 60 teeth.

Then if it is desired to cut, for instance, every fifth tooth, multiply the fractions 20/60 and 30/50 by 5. Then  $20/60 \times 30/50 \times 5/1 = 1/1$ . In this instance, the blank could be divided so that every fifth space was cut, by using gears of equal size. The number of teeth in the gear and the number of teeth indexed in each block must not have a common factor.

**Table 7. Block or Multiple Indexing for Gear Cutting**

| Number of Teeth to be Cut | Number Indexed at Once | 1st Driver | 1st Follower | 2nd Driver | 2nd Follower | Turns of Locking Disk | Number of Teeth to be Cut | Number Indexed at Once | 1st Driver | 1st Follower | 2nd Driver | 2nd Follower | Turns of Locking Disk |

**Linear Indexing for Rack Cutting.**—When racks are cut on a milling machine, two general methods of linear indexing are used. One is by using the graduated dial on the feed-screw and the other is by using an indexing attachment. The accompanying Table 9 shows the indexing movements when the first method is employed. This table applies to milling machines having feed-screws with the usual lead of  $\frac{1}{4}$  inch and 250 dial graduations each equivalent to 0.001 inch of table movement.

$$\text{Actual rotation of feed-screw} = \frac{\text{Linear pitch of rack}}{\text{Lead of feed-screw}}$$

Multiply *decimal* part of turn (obtained by above formula) by 250, to obtain dial reading for fractional part of indexing movement, assuming that dial has 250 graduations.

**Table 9. Linear Indexing Movements for Cutting Rack Teeth on a Milling Machine**

| Pitch of Rack Teeth |                    | Indexing, Movement |                             | Pitch of Rack Teeth |                    | Indexing, Movement |                             |
|---------------------|--------------------|--------------------|-----------------------------|---------------------|--------------------|--------------------|-----------------------------|
| Diametral Pitch     | Linear or Circular | No. of Whole Turns | No. of 0.001 Inch Divisions | Diametral Pitch     | Linear or Circular | No. of Whole Turns | No. of 0.001 Inch Divisions |
| 2                   | 1.5708             | 6                  | 70.8                        | 12                  | 0.2618             | 1                  | 11.8                        |

These movements are for table feed-screws having the usual lead of  $\frac{1}{4}$  inch

*Note:* The linear pitch of the rack equals the circular pitch of gear or pinion which is to mesh with the rack. The table gives both standard diametral pitches and their equivalent linear or circular pitches.

*Example:* Find indexing movement for cutting rack to mesh with a pinion of 10 diametral pitch.

Indexing movement equals 1 whole turn of feed-screw plus 64.2 thousandths or divisions on feed-screw dial. The feed-screw may be turned this fractional amount by setting dial back to its zero position for each indexing (without backward movement of feed-screw), or, if preferred, 64.2 (in this example) may be added to each successive dial position as shown below.

Dial reading for second position =  $64.2 \times 2 = 128.4$  (complete movement = 1 turn  $\times$  64.2 additional divisions by turning feed-screw until dial reading is 128.4).

Third dial position =  $64.2 \times 3 = 192.6$  (complete movement = 1 turn + 64.2 additional divisions by turning until dial reading is 192.6).

Fourth position =  $64.2 \times 4 - 250 = 6.8$  (1 turn + 64.2 additional divisions by turning feed-screw until dial reading is 6.8 divisions past the zero mark); or, to simplify operation, set dial back to zero for fourth indexing (without moving feed-screw) and then repeat settings for the three previous indexings or whatever number can be made before making a complete turn of the dial.

**Counter Milling.**—Changing the direction of a linear milling operation by a specific angle requires a linear offset before changing the angle of cut. This compensates for the radius of the milling cutters, as illustrated in Figs. 1a and 1b.

Fig. 1a. Inside Milling

Fig. 1b. Outside Milling

For inside cuts the offset is subtracted from the point at which the cutting direction changes (Fig. 1a), and for outside cuts the offset is added to the point at which the cutting direction changes (Fig. 1b). The formula for the offset is

$$x = rM$$

where  $x$  = offset distance;  $r$  = radius of the milling cutter; and,  $M$  = the multiplication factor ( $M = \tan \frac{\theta}{2}$ ). The value of  $M$  for certain angles can be found in Table 10.

Table 10. Offset Multiplication Factors

| Deg° | $M$     | Deg° | $M$     | Deg° | $M$     | Deg° | $M$     | Deg° | $M$     |

## GEARS AND GEARING

*External spur gears* are cylindrical gears with straight teeth cut parallel to the axes. Gears transmit drive between parallel shafts. Tooth loads produce no axial thrust. Excellent at moderate speeds but tend to be noisy at high speeds. Shafts rotate in opposite directions.

*Internal spur gears* provide compact drive arrangements for transmitting motion between parallel shafts rotating in the same direction.

*Helical gears* are cylindrical gears with teeth cut at an angle to the axes. Provides drive between shafts rotating in opposite directions, with superior load carrying capacity and quietness than spur gears. Tooth loads produce axial thrust.

*Crossed helical gears* are helical gears that mesh together on non-parallel axes.

*Straight bevel gears* have teeth that are radial toward the apex and are of conical form. Designed to operate on intersecting axes, bevel gears are used to connect two shafts on intersecting axes. The angle between the shafts equals the angle between the two axes of the meshing teeth. End thrust developed under load tends to separate the gears.

*Spiral bevel gears* have curved oblique teeth that contact each other smoothly and gradually from one end of a tooth to the other. Meshing is similar to that of straight bevel gears but is smoother and quieter in use. Left hand spiral teeth incline away from the axis in an anti-clockwise direction looking on small end of pinion or face of gear, right-hand teeth incline away from axis in clockwise direction. The hand of spiral of the pinion is always opposite to that of the gear and is used to identify the hand of the gear pair. Used to connect two shafts on intersecting axes as with straight bevel gears. The spiral angle does not affect the smoothness and quietness of operation or the efficiency but does affect the direction of the thrust loads created. A left-hand spiral pinion driving clockwise when viewed from the large end of the pinion creates an axial thrust that tends to move the pinion out of mesh.

*Zero bevel gears* have curved teeth lying in the same general direction as straight bevel teeth but should be considered to be spiral bevel gears with zero spiral angle.

*Hypoid bevel gears* are a cross between spiral bevel gears and worm gears. The axes of hypoid bevel gears are non-intersecting and non-parallel. The distance between the axes is called the offset. The offset permits higher ratios of reduction than is practicable with other bevel gears. Hypoid bevel gears have curved oblique teeth on which contact begins gradually and continues smoothly from one end of the tooth to the other.

*Worm gears* are used to transmit motion between shafts at right angles, that do not lie in a common plane and sometimes to connect shafts at other angles. Worm gears have line tooth contact and are used for power transmission, but the higher the ratio the lower the efficiency.

**Definitions of Gear Terms.**—The following terms are commonly applied to the various classes of gears:

*Active face width* is the dimension of the tooth face width that makes contact with a mating gear.

*Addendum* is the radial or perpendicular distance between the pitch circle and the top of the tooth.

*Arc of action* is the arc of the pitch circle through which a tooth travels from the first point of contact with the mating tooth to the point where contact ceases.

*Arc of approach* is the arc of the pitch circle through which a tooth travels from the first point of contact with the mating tooth to the pitch point.

*Arc of recession* is the arc of the pitch circle through which a tooth travels from its contact with a mating tooth at the pitch point until contact ceases.

*Axial pitch* is the distance parallel to the axis between corresponding sides of adjacent teeth.

*Axial plane* is the plane that contains the two axes in a pair of gears. In a single gear the axial plane is any plane containing the axis and any given point.

*Axial thickness* is the distance parallel to the axis between two pitch line elements of the same tooth.

*Backlash* is the shortest distance between the non-driving surfaces of adjacent teeth when the working flanks are in contact.

*Base circle* is the circle from which the involute tooth curve is generated or developed.

*Base helix angle* is the angle at the base cylinder of an involute gear that the tooth makes with the gear axis.

*Base pitch* is the circular pitch taken on the circumference of the base circles, or the distance along the line of action between two successive and corresponding involute tooth profiles. The *normal base pitch* is the base pitch in the normal plane and the *axial base pitch* is the base pitch in the axial plane.

*Base tooth thickness* is the distance on the base circle in the plane of rotation between involutes of the same pitch.

*Bottom land* is the surface of the gear between the flanks of adjacent teeth.

*Center distance* is the shortest distance between the non-intersecting axes of mating gears, or between the parallel axes of spur gears and parallel helical gears, or the crossed axes of crossed helical gears or worm gears.

*Central plane* is the plane perpendicular to the gear axis in a worm gear, which contains the common perpendicular of the gear and the worm axes. In the usual arrangement with the axes at right angles, it contains the worm axis.

*Chordal addendum* is the radial distance from the circular thickness chord to the top of the tooth, or the height from the top of the tooth to the chord subtending the circular thickness arc.

*Chordal thickness* is the length of the chord subtended by the circular thickness arc. The dimension obtained when a gear tooth caliper is used to measure the tooth thickness at the pitch circle.

*Circular pitch* is the distance on the circumference of the pitch circle, in the plane of rotation, between corresponding points of adjacent teeth. The length of the arc of the pitch circle between the centers or other corresponding points of adjacent teeth.

*Circular thickness* is the thickness of the tooth on the pitch circle in the plane of rotation, or the length of arc between the two sides of a gear tooth measured on the pitch circle.

*Clearance* is the radial distance between the top of a tooth and the bottom of a mating tooth space, or the amount by which the dedendum in a given gear exceeds the addendum of its mating gear.

*Contact diameter* is the smallest diameter on a gear tooth with which the mating gear makes contact.

*Contact ratio* is the ratio of the arc of action in the plane of rotation to the circular pitch, and is sometimes thought of as the average number of teeth in contact. This ratio is obtained most directly as the ratio of the length of action to the base pitch.

*Contact ratio – face* is the ratio of the face advance to the circular pitch in helical gears.

*Contact ratio – total* is the ratio of the sum of the arc of action and the face advance to the circular pitch.

*Contact stress* is the maximum compressive stress within the contact area between mating gear tooth profiles. Also called the Hertz stress.

*Cycloid* is the curve formed by the path of a point on a circle as it rolls along a straight line. When such a circle rolls along the outside of another circle the curve is called an *epicycloid*, and when it rolls along the inside of another circle it is called a *hypocycloid*. These curves are used in defining the former American Standard composite Tooth Form.

*Dedendum* is the radial or perpendicular distance between the pitch circle and the bottom of the tooth space.

*Diametral pitch* is the ratio of the number of teeth to the number of inches in the pitch diameter in the plane of rotation, or the number of gear teeth to each inch of pitch diameter. Normal diametral pitch is the diametral pitch as calculated in the normal plane, or the diametral pitch divided by the cosine of the helix angle.

*Efficiency* is the torque ratio of a gear set divided by its gear ratio.

*Equivalent pitch radius* is the radius of curvature of the pitch surface at the pitch point in a plane normal to the pitch line element.

*Face advance* is the distance on the pitch circle that a gear tooth travels from the time pitch point contact is made at one end of the tooth until pitch point contact is made at the other end.

*Fillet radius* is the radius of the concave portion of the tooth profile where it joins the bottom of the tooth space.

*Fillet stress* is the maximum tensile stress in the gear tooth fillet.

*Flank of tooth* is the surface between the pitch circle and the bottom land, including the gear tooth fillet.

*Gear ratio* is the ratio between the numbers of teeth in mating gears.

*Helical overlap* is the effective face width of a helical gear divided by the gear axial pitch.

*Helix angle* is the angle that a helical gear tooth makes with the gear axis at the pitch circle, unless specified otherwise.

*Hertz stress*, see *Contact stress*.

*Highest point of single tooth contact (HPSTC)* is the largest diameter on a spur gear at which a single tooth is in contact with the mating gear.

*Interference* is the contact between mating teeth at some point other than along the line of action.

*Internal diameter* is the diameter of a circle that coincides with the tops of the teeth of an internal gear.

*Internal gear* is a gear with teeth on the inner cylindrical surface.

*Involute* is the curve generally used as the profile of gear teeth. The curve is the path of a point on a straight line as it rolls along a convex base curve, usually a circle.

*Land* The top land is the top surface of a gear tooth and the *bottom land* is the surface of the gear between the fillets of adjacent teeth.

*Lead* is the axial advance of the helix in one complete turn, or the distance along its own axis on one revolution if the gear were free to move axially.

*Length of action* is the distance on an involute line of action through which the point of contact moves during the action of the tooth profile.

*Line of action* is the portion of the common tangent to the base cylinders along which contact between mating involute teeth occurs.

*Lowest point of single tooth contact (LPSTC)* is the smallest diameter on a spur gear at which a single tooth is in contact with its mating gear. Gear set contact stress is determined with a load placed on the pinion at this point.

*Module* is the ratio of the pitch diameter to the number of teeth, normally the ratio of pitch diameter in mm to the number of teeth. Module in the inch system is the ratio of the pitch diameter in inches to the number of teeth.

*Normal plane* is a plane normal to the tooth surfaces at a point of contact and perpendicular to the pitch plane.

*Number of teeth* is the number of teeth contained in a gear.

*Outside diameter* is the diameter of the circle that contains the tops of the teeth of external gears.

*Pitch* is the distance between similar, equally-spaced tooth surfaces in a given direction along a given curve or line.

*Pitch circle* is the circle through the pitch point having its center at the gear axis.

*Pitch diameter* is the diameter of the pitch circle. The operating pitch diameter is the pitch diameter at which the gear operates.

*Pitch plane* is the plane parallel to the axial plane and tangent to the pitch surfaces in any pair of gears. In a single gear, the pitch plane may be any plane tangent to the pitch surfaces.

*Pitch point* is the intersection between the axes of the line of centers and the line of action.

*Plane of rotation* is any plane perpendicular to a gear axis.

**Pressure angle** is the angle between a tooth profile and a radial line at its pitch point. In involute teeth, the pressure angle is often described as the angle between the line of action and the line tangent to the pitch circle. *Standard pressure angles* are established in connection with standard tooth proportions. A given pair of involute profiles will transmit smooth motion at the same velocity ratio when the center distance is changed. Changes in center distance in gear design and gear manufacturing operations may cause changes in pitch diameter, pitch and pressure angle in the same gears under different conditions. Unless otherwise specified, the pressure angle is the *standard pressure angle at the standard pitch diameter*. The *operating pressure angle* is determined by the center distance at which a pair of gears operate. In oblique teeth such as helical and spiral designs, the pressure angle is specified in the transverse, normal or axial planes.

**Principle reference planes** are pitch plane, axial plane and transverse plane, all intersecting at a point and mutually perpendicular.

**Rack:** A rack is a gear with teeth spaced along a straight line, suitable for straight line motion. A basic rack is a rack that is adopted as the basis of a system of interchangeable gears. Standard gear tooth dimensions are often illustrated on an outline of a basic rack.

**Roll angle** is the angle subtended at the center of a base circle from the origin of an involute to the point of tangency of a point on a straight line from any point on the same involute. The radian measure of this angle is the tangent of the pressure angle of the point on the involute.

**Root diameter** is the diameter of the circle that contains the roots or bottoms of the tooth spaces.

**Tangent plane** is a plane tangent to the tooth surfaces at a point or line of contact.

**Tip relief** is an arbitrary modification of a tooth profile where a small amount of material is removed from the involute face of the tooth surface near the tip of the gear tooth.

**Tooth face** is the surface between the pitch line element and the tooth tip.

**Tooth surface** is the total tooth area including the flank of the tooth and the tooth face.

**Total face width** is the dimensional width of a gear blank and may exceed the effective face width as with a double-helical gear where the total face width includes any distance separating the right-hand and left-hand helical gear teeth.

**Transverse plane** is a plane that is perpendicular to the axial plane and to the pitch plane. In gears with parallel axes, the transverse plane and the plane of rotation coincide.

**Trochoid** is the curve formed by the path of a point on the extension of a radius of a circle as it rolls along a curve or line. A trochoid is also the curve formed by the path of a point on a perpendicular to a straight line as the straight line rolls along the convex side of a base curve. By the first definition, a trochoid is derived from the *cycloid*, by the second definition it is derived from the *involute*.

**True involute form diameter** is the smallest diameter on the tooth at which the point of tangency of the involute tooth profile exists. Usually this position is the point of tangency of the involute tooth profile and the fillet curve, and is often referred to as the TIF diameter.

**Undercut** is a condition in generated gear teeth when any part of the fillet curve lies inside a line drawn at a tangent to the working profile at its lowest point. Undercut may be introduced deliberately to facilitate shaving operations, as in pre-shaving.

**Whole depth** is the total depth of a tooth space, equal to the addendum plus the dedendum and equal to the working depth plus clearance.

**Working depth** is the depth of engagement of two gears, or the sum of their addendums. The standard working distance is the depth to which a tooth extends into the tooth space of a mating gear when the center distance is standard.

Definitions of gear terms are given in AGMA Standards 112.05, 115.01, and 116.01 entitled "Terms, Definitions, Symbols and Abbreviations," "Reference Information—Basic Gear Geometry," and "Glossary—Terms Used in Gearing," respectively; obtainable from American Gear Manufacturers Assn., 500 Montgomery St., St., Alexandria, VA 22314.

Comparative Sizes and Shape of Gear Teeth

Nomenclature of Gear Teeth

Terms Used in Gear Geometry from Table 1 on page 2035

**Properties of the Involute Curve.**—The involute curve is used almost exclusively for gear-tooth profiles, because of the following important properties.

1) The form or shape of an involute curve depends upon the diameter of the base circle from which it is derived. (If a taut line were unwound from the circumference of a circle—the *base circle* of the involute—the end of that line or any point on the unwound portion, would describe an involute curve.)

2) If a gear tooth of involute curvature acts against the involute tooth of a mating gear while rotating at a uniform rate, the angular motion of the driven gear will also be uniform, even though the center-to-center distance is varied.

3) The relative rate of motion between driving and driven gears having involute tooth curves is established by the diameters of their base circles.

4) Contact between intermeshing involute teeth on a driving and driven gear is along a straight line that is tangent to the two base circles of these gears. This is the *line of action*.

5) The point where the line of action intersects the common center-line of the mating involute gears, establishes the radii of the pitch circles of these gears; hence true pitch circle diameters are affected by a change in the center distance. (Pitch diameters obtained by dividing the number of teeth by the diametral pitch apply when the center distance equals the total number of teeth on both gears divided by twice the diametral pitch.)

6) The pitch diameters of mating involute gears are directly proportional to the diameters of their respective base circles; thus, if the base circle of one mating gear is three times as large as the other, the pitch circle diameters will be in the same ratio.

7) The angle between the line of action and a line perpendicular to the common center-line of mating gears, is the *pressure angle*; hence the pressure angle is affected by any change in the center distance.

8) When an involute curve acts against a straight line (as in the case of an involute pinion acting against straight-sided rack teeth), the straight line is tangent to the involute and perpendicular to its line of action.

9) The pressure angle, in the case of an involute pinion acting against straight-sided rack teeth, is the angle between the line of action and the line of the rack's motion. If the involute pinion rotates at a uniform rate, movement of the rack will also be uniform.

*Nomenclature:*

$\phi$  = Pressure Angle

$a$  = Addendum     $a_G$  = Addendum of Gear     $a_p$  = Addendum of Pinion

$b$  = Dedendum

$c$  = Clearance

$C$  = Center Distance

$D$  = Pitch Diameter     $D_G$  = Pitch Diameter of Gear     $D_p$  = Pitch Diameter of Pinion

$D_B$  = Base Circle Diameter     $D_O$  = Outside Diameter     $D_R$  = Root Diameter

$F$  = Face Width

$h_k$  = Working Depth of Tooth     $h_t$  = Whole Depth of Tooth

$m_G$  = Gear Ratio

$N$  = Number of Teeth     $N_G$  = Number of Teeth in Gear     $N_p$  = Number of Teeth in Pinion

$p$  = Circular Pitch     $P$  = Diametral Pitch

**Diametral and Circular Pitch Systems.**—Gear tooth system standards are established by specifying the tooth proportions of the basic rack. The diametral pitch system is applied to most of the gearing produced in the United States. If gear teeth are larger than about one diametral pitch, it is common practice to use the circular pitch system. The circular pitch system is also applied to cast gearing and it is commonly used in connection with the design and manufacture of worm gearing.

**Pitch Diameters Obtained with Diametral Pitch System.**—The diametral pitch system is arranged to provide a series of standard tooth sizes, the principle being similar to the standardization of screw thread pitches. Inasmuch as there must be a whole number of teeth on each gear, the increase in pitch diameter per tooth varies according to the pitch. For example, the pitch diameter of a gear having, say, 20 teeth of 4 diametral pitch, will be 5 inches; 21 teeth,  $5\frac{1}{4}$  inches; and so on, the increase in diameter for each additional tooth being equal to  $\frac{1}{4}$  inch for 4 diametral pitch. Similarly, for 2 diametral pitch the variations for successive numbers of teeth would equal  $\frac{1}{2}$  inch, and for 10 diametral pitch the varia-

tions would equal  $\frac{1}{10}$  inch, etc. Where a given center distance must be maintained and no standard diametral pitch can be used, gears should be designed with reference to the gear set center distance procedure discussed in *Gears for Given Center Distance and Ratio* starting on page 2043.

**Table 1. Formulas for Dimensions of Standard Spur Gears**

| To Find              | Formula                              | To Find   | Formula                              |

| (Shaved or Ground Teeth)          | $D_R = (N - 2.7) \div P$        | $D_R = 0.3183 \times (N - 2.7)p$ |
| Circular Thickness—Basic          | $t = 1.5708 \div P$             | $t = p \div 2$                   |

<sup>a</sup> When gears are preshaved cut on a gear shaper the dedendum will usually need to be increased to  $1.40/P$  to allow for the higher fillet trochoid produced by the shaper cutter. This is of particular importance on gears of few teeth or if the gear blank configuration requires the use of a small diameter shaper cutter, in which case the dedendum may need to be increased to as much as  $1.45/P$ . This should be avoided on highly loaded gears where the consequently reduced  $J$  factor will increase gear tooth stress excessively.

<sup>b</sup> A minimum clearance of  $0.157/P$  may be used for the basic 20-degree and 25-degree pressure angle rack in the case of shallow root sections and use of existing hobs or cutters. However, whenever less than standard clearance is used, the location of the TIF diameter should be determined by the method shown in *True Involute Form Diameter* starting on page 2061. The TIF diameter must be less than the Contact Diameter determined by the method shown on page 2059.

<sup>c</sup> The fillet radius of the basic rack should not exceed  $0.235/P$  for a 20-degree pressure angle rack or  $0.270/P$  for a 25-degree pressure angle rack for a clearance of  $0.157/P$ . The basic rack fillet radius must be reduced for teeth with a 25-degree pressure angle having a clearance in excess of  $0.250/P$ .

**American National Standard Coarse Pitch Spur Gear Tooth Forms.**—The American National Standard (ANSI B6.1-1968, R1974) provides tooth proportion information on two involute spur gear forms. These two forms are identical except that one has a pressure angle of 20 degrees and a minimum allowable tooth number of 18 while the other has a pressure angle of 25 degrees and a minimum allowable tooth number of 12. (For pinions with fewer teeth, see tooth proportions for long addendum pinions and their mating short addendum gears in Tables 7 through 9d starting on page 2050.) A gear tooth standard is established by specifying the tooth proportions of the basic rack. Gears made to this standard will thus be conjugate with the specified rack and with each other. The basic rack forms for the 20-degree and 25-degree standard are shown on the following page; basic formulas for these proportions as a function of the gear diametral pitch and also of the circular pitch are given in Table 2. Tooth parts data are given in Table 3.

In recent years the established standard of almost universal use is the ANSI 20-degree standard spur gear form. It provides a gear with good strength and without fillet undercut in pinions of as few as eighteen teeth. Some more recent applications have required a tooth form of even greater strength and fewer teeth than eighteen. This requirement has stimulated the establishment of the ANSI 25-degree standard. This 25-degree form will give greater tooth strength than the 20-degree standard, will provide pinions of as few as twelve teeth without fillet undercut and will provide a lower contact compressive stress for greater gear set surface durability.

<sup>a</sup> When using equal addendums on pinion and gear the minimum number of teeth on the pinion is 18 and the minimum total number of teeth in the pair is 36 for 20-degree full depth involute tooth form and 12 and 24, respectively, for 25-degree full depth tooth form.

<sup>b</sup> The dedendum in this column is used when the gear tooth is shaved. It allows for the higher fillet cut by a protuberance hob.

The working depth is equal to twice the addendum.

The whole depth is equal to the addendum plus the dedendum.

**American National Standard Tooth Proportions for Fine-Pitch Involute Spur and Helical Gears.**—The proportions of spur gears in this Standard (ANSI B6.7-1977) follow closely ANSI B6.1-1968, R1974, “Tooth Proportions for Coarse-Pitch Involute Spur Gears.” The main difference between fine-pitch and coarse-pitch gears is the greater clearance specified for fine-pitch gears. The increased clearance provides for any foreign material that may tend to accumulate at the bottoms of the teeth and also the relatively larger fillet radius resulting from proportionately greater wear on the tips of fine-pitch cutting tools.

**Pressure Angle:** The standard pressure angle for fine-pitch gears is 20 degrees and is recommended for most applications. For helical gears this pressure angle applies in the *normal* plane. In certain cases, notably sintered or molded gears, or in gearing where greatest strength and wear resistance are desired, a 25-degree pressure angle may be required.

However, pressure angles greater than 20 degrees tend to require use of generating tools having very narrow point widths, and higher pressure angles require closer control of center distance when backlash requirements are critical.

In those cases where consideration of angular position or backlash is critical and both pinion and gear contain relatively large numbers of teeth, a  $14\frac{1}{2}$ -degree pressure angle may be desirable. In general, pressure angles less than 20 degrees require greater amounts of tooth modification to avoid undercutting problems and are limited to larger total numbers of teeth in pinion and gear when operating at a standard center distance. Information Sheet B in the Standard provides tooth proportions for both  $14\frac{1}{2}$ - and 25-degree pressure angle fine-pitch gears. [Table 4](#) provides tooth proportions for fine-pitch spur and helical gears with  $14\frac{1}{2}$ -, 20-, and 25-degree pressure angles, and [Table 5](#) provides tooth parts.

*Diametral Pitches:* Diametral pitches preferred are: 20, 24, 32, 40, 48, 64, 72, 80, 96, and 120.

| 96              | 0.0327         | 0.0164             | 0.0104           | 0.0145           | 0.0161                       |
| 120             | 0.0262         | 0.0131             | 0.0083           | 0.0120           | 0.0132                       |

<sup>a</sup>Based upon clearance for shaved or ground teeth.

The working depth is equal to twice the addendum. The whole depth is equal to the addendum plus the dedendum. For minimum number of teeth see page [2058](#).

**Other American Spur Gear Standards.**—An appended information sheet in the American National Standard ANSI B6.1-1968, R1974 provides tooth proportion information for three spur gear forms with the notice that they are “not recommended for new designs.” These forms are therefore considered to be obsolescent but the information is given on their proportions because they have been used widely in the past. These forms are the  $14\frac{1}{2}$ -degree full depth form, the 20-degree stub involute form and the  $14\frac{1}{2}$ -degree composite form which were covered in the former American Standard (ASA B6.1-1932). The basic rack for the  $14\frac{1}{2}$ -degree full depth form is shown on page [2036](#); basic formulas for these proportions are given in [Table 6](#).

**Table 6. Formulas for Tooth Parts—Former American Standard Spur Gear Tooth Forms ASA B6.1-1932**

| To Find                              | Diametral Pitch, $P$<br>Known | Circular Pitch, $p$<br>Known |
|--------------------------------------|-------------------------------|------------------------------|
| 14½-Degree Involute Full-depth Teeth |                               |                              |
| Addendum                             | $a = 1.000 \div P$            | $a = 0.3183 \times p$        |
| Minimum Dedendum                     | $b = 1.157 \div P$            | $b = 0.3683 \times p$        |
| Working Depth                        | $h_k = 2.000 \div P$          | $h_k = 0.6366 \times p$      |
| Minimum Whole Depth                  | $h_t = 2.157 \div P$          | $h_t = 0.6866 \times p$      |
| Basic Tooth Thickness on Pitch Line  | $t = 1.5708 \div P$           | $t = 0.500 \times p$         |
| Minimum Clearance                    | $c = 0.157 \div P$            | $c = 0.050 \times p$         |
| 20-Degree Involute Stub Teeth        |                               |                              |
| Addendum                             | $a = 0.800 \div P$            | $a = 0.2546 \times p$        |
| Minimum Dedendum                     | $b = 1.000 \div P$            | $b = 0.3183 \times p$        |
| Working Depth                        | $h_k = 1.600 \div P$          | $h_k = 0.5092 \times p$      |
| Minimum Whole Depth                  | $h_t = 1.800 \div P$          | $h_t = 0.5729 \times p$      |
| Basic Tooth Thickness on Pitch Line  | $t = 1.5708 \div P$           | $t = 0.500 \times p$         |
| Minimum Clearance                    | $c = 0.200 \div P$            | $c = 0.0637 \times p$        |

Note: Radius of fillet equals  $1\frac{1}{3} \times$  clearance for 14½-degree full-depth teeth and  $1\frac{1}{2} \times$  clearance for 20-degree full-depth teeth.

Note: A suitable working tolerance should be considered in connection with all minimum recommendations.

**Fellows Stub Tooth.**—The system of stub gear teeth introduced by the Fellows Gear Shaper Co. is based upon the use of two diametral pitches. One diametral pitch, say, 8, is used as the basis for obtaining the dimensions for the addendum and dedendum, while another diametral pitch, say, 6, is used for obtaining the dimensions of the thickness of the tooth, the number of teeth, and the pitch diameter. Teeth made according to this system are designated as  $\frac{6}{8}$  pitch,  $\frac{12}{14}$  pitch, etc., the numerator in this fraction indicating the pitch determining the thickness of the tooth and the number of teeth, and the denominator, the pitch determining the depth of the tooth. The clearance is made greater than in the ordinary gear-tooth system and equals  $0.25 \div$  denominator of the diametral pitch. The pressure angle is 20 degrees.

This type of stub gear tooth is now used infrequently. For information as to the tooth part dimensions see 18th and earlier editions of Machinery's Handbook.

**Basic Gear Dimensions.**—The basic dimensions for all involute spur gears may be obtained using the formulas shown in Table 1. This table is used in conjunction with Table 3 to obtain dimensions for coarse pitch gears and Table 5 to obtain dimensions for fine pitch standard spur gears. To obtain the dimensions of gears that are specified at a standard circular pitch, the equivalent diametral pitch is first calculated by using the formula in Table 1. If the required number of teeth in the pinion ( $N_p$ ) is less than the minimum specified in either Table 3 or Table 5, whichever is applicable, the gears must be proportioned by the long and short addendum method shown on page 2052.

**Formulas for Outside and Root Diameters of Spur Gears that are  
Finish-hobbed, Shaped, or Pre-shaved**

| Notation   |                                     |
|--|-------------------------------------|
| $D$ = Pitch Diameter   | $a$ = Standard Addendum             |
| $D_O$ = Outside Diameter   | $b$ = Standard Minimum Dedendum     |
| $D_R$ = Root Diameter  | $b_s$ = Standard Dedendum           |
| $P$ = Diametral Pitch  | $b_{ps}$ = Dedendum for Pre-shaving |
| 14½, 20-, And 25-degree Involute Full-depth Teeth (19P and coarser) <sup>a</sup> |                                     |
| $D_O = D + 2a = \frac{N}{P} + \left(2 \times \frac{1}{P}\right)$                 |                                     |
| $D_R = D - 2b = \frac{N}{P} - \left(2 \times \frac{1.157}{P}\right)$             | (Hobbed) <sup>b</sup>               |
| $D_R = D - 2b_s = \frac{N}{P} - \left(2 \times \frac{1.25}{P}\right)$            | (Shaped) <sup>c</sup>               |
| $D_R = D - 2b_{ps} = \frac{N}{P} - \left(2 \times \frac{1.35}{P}\right)$         | (Pre-shaved) <sup>d</sup>           |
| $D_R = D - 2b_{ps} = \frac{N}{P} - \left(2 \times \frac{1.40}{P}\right)$         | (Pre-shaved) <sup>e</sup>           |
| 20-degree Involute Fine-pitch Full-depth Teeth (20P and finer)                   |                                     |
| $D_O = D + 2a = \frac{N}{P} + \left(2 \times \frac{1}{P}\right)$                 |                                     |
| $D_R = D - 2b = \frac{N}{P} - 2\left(\frac{1.2}{P} + 0.002\right)$               | (Hobbed or Shaped) <sup>f</sup>     |
| $D_R = D - 2b_{ps} = \frac{N}{P} - 2\left(\frac{1.35}{P} + 0.002\right)$         | (Pre-shaved) <sup>g</sup>           |
| 20-degree Involute Stub Teeth <sup>a</sup>                                       |                                     |
| $D_O = D + 2a = \frac{N}{P} + \left(2 \times \frac{0.8}{P}\right)$               |                                     |
| $D_R = D - 2b = \frac{N}{P} - \left(2 \times \frac{1}{P}\right)$                 | (Hobbed)                            |
| $D_R = D - 2b_{ps} = \frac{N}{P} - \left(2 \times \frac{1.35}{P}\right)$         | (Pre-shaved)                        |

<sup>a</sup> 14½-degree full-depth and 20-degree stub teeth are not recommended for new designs.

<sup>b</sup> According to ANSI B6.1-1968 a minimum clearance of  $0.157/P$  may be used for the basic 20-degree and 25-degree pressure angle rack in the case of shallow root sections and the use of existing hobs and cutters.

<sup>c</sup> According to ANSI B6.1-1968 the preferred clearance is  $0.250/P$ .

<sup>d</sup> According to ANSI B6.1-1968 the clearance for teeth which are shaved or ground is  $0.350/P$ .

<sup>e</sup> When gears are preshave cut on a gear shaper the dedendum will usually need to be increased to  $1.40/P$  to allow for the higher fillet trochoid produced by the shaper cutter; this is of particular importance on gears of few teeth or if the gear blank configuration requires the use of a small diameter shaper cutter, in which case the dedendum may need to be increased to as much as  $1.45/P$ . This should be avoided on highly loaded gears where the consequently reduced  $J$  factor will increase gear tooth stress excessively.

<sup>f</sup> According to ANSI B6.7-1967 the standard clearance is  $0.200/P + 0.002$  (min.).

<sup>g</sup> According to ANSI B6.7-1967 the clearance for shaved or ground teeth is  $0.350/P + 0.002$  (min.).

**Gears for Given Center Distance and Ratio.**—When it is necessary to use a pair of gears of given ratio at a specified center distance  $C_1$ , it may be found that no gears of standard diametral pitch will satisfy the center distance requirement. Gears of standard diametral pitch  $P$  may need to be redesigned to operate at other than their standard pitch diameter  $D$  and standard pressure angle  $\phi$ . The diametral pitch  $P_1$  at which these gears will operate is

$$P_1 = \frac{N_P + N_G}{2C_1} \quad (1)$$

where  $N_p$  = number of teeth in pinion

$N_G$  = number of teeth in gear

and their operating pressure angle  $\phi_1$  is

$$\phi_1 = \arccos\left(\frac{P_1}{P} \cos \phi\right) \quad (2)$$

Thus although the pair of gears are cut to a diametral pitch  $P$  and a pressure angle  $\phi$ , they operate as standard gears of diametral pitch  $P_1$  and pressure angle  $\phi_1$ . The pitch  $P$  and pressure angle  $\phi$  should be chosen so that  $\phi_1$  lies between about 18 and 25 degrees.

The operating pitch diameters of the pinion  $D_{p1}$  and of the gear  $D_{G1}$  are

$$D_{P1} = \frac{N_P}{P_1} \quad (3a) \quad \text{and} \quad D_{G1} = \frac{N_G}{P_1} \quad (3b)$$

The base diameters of the pinion  $D_{PB1}$  and of the gear  $D_{GB1}$  are

$$D_{PB1} = D_{P1} \cos \phi_1 \quad (4a) \quad \text{and} \quad D_{GB1} = D_{G1} \cos \phi_1 \quad (4b)$$

The basic tooth thickness,  $t_1$ , at the operating pitch diameter for both pinion and gear is

$$t_1 = \frac{1.5708}{P_1} \quad (5)$$

The root diameters of the pinion  $D_{PR1}$  and gear  $D_{GR1}$  and the corresponding outside diameters  $D_{PO1}$  and  $D_{GO1}$  are not standard because each gear is to be cut with a cutter that is not standard for the operating pitch diameters  $D_{P1}$  and  $D_{G1}$ .

The root diameters are

$$D_{PR1} = \frac{N_P}{P} - 2b_{P1} \quad (6a) \quad \text{and} \quad D_{GR1} = \frac{N_G}{P} - 2b_{G1} \quad (6b)$$

where

$$b_{P1} = b_c - \left( \frac{t_{P2} - 1.5708/P}{2 \tan \phi} \right) \quad (7a)$$

and

$$b_{G1} = b_c - \frac{t_{G2} - 1.5708/P}{2 \tan \phi} \quad (7b)$$

where  $b_c$  is the hob or cutter addendum for the pinion and gear.

The tooth thicknesses of the pinion  $t_{P2}$  and the gear  $t_{G2}$  are

$$t_{P2} = \frac{N_P}{P} \left( \frac{1.5708}{N_P} + \text{inv } \phi_1 - \text{inv } \phi \right) \quad (8a)$$

## SPUR GEARING

$$t_{G2} = \frac{N_G}{P} \left( \frac{1.5708}{N_G} + \text{inv } \phi_1 - \text{inv } \phi \right) \quad (8b)$$

The outside diameter of the pinion  $D_{PO}$  and the gear  $D_{GO}$  are

$$D_{PO} = 2 \times C_1 - D_{GR1} - 2(b_c - 1/P) \quad (9a)$$

and 
$$D_{GO} = 2 \times C_1 - D_{PR1} - 2(b_c - 1/P) \quad (9b)$$

 *Example:* Design gears of 8 diametral pitch, 20-degree pressure angle, and 28 and 88 teeth to operate at 7.50-inch center distance. The gears are to be cut with a hob of 0.169-inch addendum.

$$P_1 = \frac{28 + 88}{2 \times 7.50} = 7.7333 \quad (1)$$

$$\phi_1 = \arccos\left(\frac{7.7333}{8} \times 0.93969\right) = 24.719^\circ \quad (2)$$

$$D_{P1} = \frac{28}{7.7333} = 3.6207 \text{ in.} \quad (3a)$$

and 
$$D_{G1} = \frac{88}{7.7333} = 11.3794 \text{ in.} \quad (3b)$$

$$D_{PB1} = 3.6207 \times 0.90837 = 3.2889 \text{ in.} \quad (4a)$$

and 
$$D_{GB1} = 11.3794 \times 0.90837 = 10.3367 \text{ in.} \quad (4b)$$

$$t_1 = \frac{1.5708}{7.7333} = 0.20312 \text{ in.} \quad (5)$$

$$D_{PR1} = \frac{28}{8} - 2 \times 0.1016 = 3.2968 \text{ in.} \quad (6a)$$

and 
$$D_{GR1} = \frac{88}{8} - 2 \times (-0.0428) = 11.0856 \text{ in.} \quad (6b)$$

$$b_{P1} = 0.169 - \left( \frac{0.2454 - 1.5708/8}{2 \times 0.36397} \right) = 0.1016 \text{ in.} \quad (7a)$$

$$b_{G1} = 0.169 - \left( \frac{0.3505 - 1.5708/8}{2 \times 0.36397} \right) = -0.0428 \text{ in.} \quad (7b)$$

$$t_{P2} = \frac{28}{8} \left( \frac{1.5708}{28} + 0.028922 - 0.014904 \right) = 0.2454 \text{ in.} \quad (8a)$$

$$t_{G2} = \frac{88}{8} \left( \frac{1.5708}{88} + 0.028922 - 0.014904 \right) - 0.3505 \text{ in.} \quad (8b)$$

$$D_{PO1} = 2 \times 7.50 - 11.0856 - 2(0.169 - 1/8) = 3.8264 \text{ in.} \quad (9a)$$

$$D_{GO1} = 2 \times 7.50 - 3.2968 - 2(0.169 - 1/8) = 11.6152 \text{ in.} \quad (9b)$$

**Tooth Thickness Allowance for Shaving.**—Proper stock allowance is important for good results in shaving operations. If too much stock is left for shaving, the life of the shaving tool is reduced and, in addition, shaving time is increased. The following figures represent the amount of stock to be left on the teeth for removal by shaving under average conditions: For diametral pitches of 2 to 4, a thickness of 0.003 to 0.004 inch (one-half on each side of the tooth); for 5 to 6 diametral pitch, 0.0025 to 0.0035 inch; for 7 to 10 diametral pitch, 0.002 to 0.003 inch; for 11 to 14 diametral pitch, 0.0015 to 0.0020 inch; for 16 to 18 diametral pitch, 0.001 to 0.002 inch; for 20 to 48 diametral pitch, 0.0005 to 0.0015 inch; and for 52 to 72 diametral pitch, 0.0003 to 0.0007 inch.

The thickness of the gear teeth may be measured in several ways to determine the amount of stock left on the sides of the teeth to be removed by shaving. If it is necessary to measure the tooth thickness during the preshaping operation while the gear is in the gear shaper or hobbing machine, a gear tooth caliper or pins would be employed. Caliper methods of measuring gear teeth are explained in detail on page 2051 for measurements over single teeth, and on page 2140 for measurements over two or more teeth.

When the preshaped gear can be removed from the machine for checking, the center distance method may be employed. In this method, the preshaped gear is meshed without backlash with a gear of standard tooth thickness and the increase in center distance over standard is noted. The amount of total tooth thickness over standard on the preshaped gear can then be determined by the formula:  $t_2 = 2 \tan \phi \times d$ , where  $t_2$  = amount that the total thickness of the tooth exceeds the standard thickness,  $\phi$  = pressure angle, and  $d$  = amount that the center distance between the two gears exceeds the standard center distance.

**Circular Pitch for Given Center Distance and Ratio.**—When it is necessary to use a pair of gears of given ratio at a specified center distance, it may be found that no gears of standard diametral pitch will satisfy the center distance requirement. Hence, circular pitch gears may be selected. To find the required circular pitch  $p$ , when the center distance  $C$  and total number of teeth  $N$  in both gears are known, use the following formula:

$$p = \frac{C \times 6.2832}{N}$$

*Example:* A pair of gears having a ratio of 3 is to be used at a center distance of 10.230 inches. If one gear has 60 teeth and the other 20, what must be their circular pitch?

$$p = \frac{10.230 \times 6.2832}{60 + 20} = 0.8035 \text{ inch}$$

**Circular Thickness of Tooth when Outside Diameter is Standard.**—For a full-depth or stub tooth gear of standard outside diameter, the tooth thickness on the pitch circle (circular thickness or arc thickness) is found by the following formula:

$$t = \frac{1.5708}{P}$$

where  $t$  = circular thickness and  $P$  = diametral pitch. In Fellows stub tooth gears the diametral pitch used is the numerator of the pitch fraction (for example, 6 if the pitch is 6/8).

*Example 1:* Find the tooth thickness on the pitch circle of a 14½-degree full-depth tooth of 12 diametral pitch.

$$t = \frac{1.5708}{12} = 0.1309 \text{ inch}$$

*Example 2:* Find the tooth thickness on the tooth circle of a 20-degree full-depth involute tooth having a diametral pitch of 5.

$$t = \frac{1.5708}{5} = 0.31416, \text{ say } 0.3142 \text{ inch}$$

The tooth thickness on the pitch circle can be determined very accurately by means of measurement over wires which are located in tooth spaces that are diametrically opposite or as nearly diametrically opposite as possible. Where measurement over wires is not feasible, the circular or arc tooth thickness can be used in determining the chordal thickness which is the dimension measured with a gear tooth caliper.
